Three warnings attach to that form and are recorded here rather than in a footnote. First, the time average of a multiplicative process differs from its ensemble average, so a parameter estimated across individuals does not describe what happens to any one of them over time [Peters, 2019] — and Q accumulates *over time*, for *one* relation, from parameters that would most naturally be estimated from a cross-section. Second, a single Q, δ or u written for a group is an aggregation, and aggregation over heterogeneous agents does not in general yield a representative agent [Kirman, 1992]. Third, Q **has the grammar of a conserved quantity — a stock that accumulates, leaks and is spent — without a conservation law to give that grammar content.** That is the characteristic failure of the genre: neoclassical economics was built by copying nineteenth-century energetics and made utility play the role of energy without the conservation law that gave energy its meaning [Mirowski, 1989]. This paper claims no conservation law, states no invariance under which Q would be conserved, and adopts instead the position that a law is claimed only within a specified arrangement rather than universally [Cartwright, 1999]. The wider programme — statistical physics applied to social dynamics — has a standard survey that fixes what such models can and cannot be held to [Castellano et al., 2009], and the boundaries it draws are the boundaries claimed here.

The precedent that matters most for this paper is the leaky integrate-and-fire neuron: a leaky store with a drive and a threshold, yielding a rate below which the store does not fire. **That literature grounds the *shape* of $f_{\min}$ — a threshold rate emerging from a leaky store — and it grounds neither the formula nor the constant.** The distinction is made here and repeated in Sections 11 and 12.

3.2 The surplus functional and the effective count

$F(u) = \ln(1 + (N-1)u)$ is the corpus's surplus functional, characterised by angle-only dependence, a zero at parallel states, an affine effective count and a normalisation [Curzi, 2026], whose Result One is exactly that characterisation with $N_{\text{eff}} = 1 + (N-1)u$. Its logarithmic form places it in the same family as Shannon's entropy [Shannon, 1948], and uniqueness-under-axioms is a known genre of theorem in that literature [Aczél et al., 1974, Khinchin, 1957]; the framework's axiom set is its own and is not one of those. The ceiling $F \leq \ln N$ is the normalisation, and it is the same ceiling that appears in requisite-variety arguments [Ashby, 1956, 1958].

Which construct of difference u measures must be declared, because at least three incompatible constructs travel under the word *diversity* — separation, variety and disparity [Harrison and Klein, 2007]. Here u is a *disparity* measure over represented states, and it is symmetric in its arguments, which psychological similarity is known not to be [Tversky, 1977]. That is a limitation and it is printed in Section 13.

The warrant the logarithm actually needs. The corpus habitually justifies its logarithms by appeal to Fechner [Fechner, 1860, Weber, 1834]. A stronger and cheaper warrant is available: a logarithmic form follows from multiplicative dynamics with **no psychological assumption at all** [Peters and Gell-Mann, 2016]. The argument of this paper needs only the second. The psychophysical warrant is required only where an *elicitation* is performed, which is not done here.

3.3 The essence bridge and the constant k

The bridge writes a surplus as a pitch, so that intervals of surplus become intervals of frequency and the constant cancels from every ratio [Curzi, 2026k], whose Result Six badges the identification $n_{\text{eff}} := N_{\text{eff}} = e^F$ and fixes the conversion $2F/\ln 2 = 2.885390081777927 \times F$ octaves above base:

$$f = k\, e^{2F} = k\, N_{\text{eff}}^2, \qquad k := \frac{(9/8)^2}{\varphi^2} = \frac{81/64}{\varphi + 1} = 0.483425732988414 \quad \text{(defined; exact)}$$

Both components are real, specific and documented. The ratio $9{:}8$ is the Pythagorean whole tone, a historically attested object of tuning theory [Barbour, 1951, Lindley and Turner-Smith, 1993], and $81/64$ is the Pythagorean ditone. The golden section is Euclid's extreme and mean ratio [Euclid, 1956], and $\varphi^2 = \varphi + 1$ with $\varphi^m = F_m\varphi + F_{m-1}$ are proved identities [Vajda, 1989, Koshy, 2001]. Verified here: $\varphi^2 - \varphi - 1 = 0.000\text{e}{+00}$ in double precision.

Their product, expressed as a frequency in hertz, has no precedent. There is no physical, psychoacoustic or musicological result that combines a tuning ratio with an inverse square of the golden section to obtain a ground frequency. The literature on golden-section claims is overwhelmingly a literature of *deflation*: the appearances of φ in the Parthenon, the Great Pyramid, the human body and preferred rectangles do not survive examination [Markowsky, 1992, Fischler, 1981, Livio, 2002], and the psychological preference results are weaker and more equivocal than they are usually reported to be [Höge, 1997].

This framework's position is the one those critiques leave open and no wider. φ is being *chosen* as a constant, not *found* in a psychological system. Nothing in this paper is evidence that the golden section is present in anything measured. The constant sets a reference pitch and is invisible to every verdict, because D is a difference of logarithms in which k appears in both terms and cancels exactly.

3.4 Dimensional audit

symbol	quantity	dimension	unit	status
Q	stored order	$[\mathcal{C}]$	none supplied	state variable; **no operational unit**
S	surplus input per period	$[\mathcal{C}\,T^{-1}]$	per declared period	driving term
C, c	cost per period	$[\mathcal{C}\,T^{-1}]$	per declared period	driving term
δ	decay rate	$[1]$	per period	dimensionless; $0 < \delta \leq 1$
η	conversion efficiency	$[1]$	—	dimensionless; assumed $0 < \eta \leq 1$
u	non-parallelism	$[1]$	—	dimensionless by construction, $u \in [0, 1]$
F	surplus	$[1]$	nats	dimensionless; a logarithm of a count
N	declared category count	$[1]$	—	absolute scale, a count
n	component index	$[1]$	—	absolute scale, a count
k	reference constant	$[T^{-1}]$ **asserted**	Hz **asserted**	**defined as a ratio (dimensionless); the unit is postulated**
$f, f_{\min}$	essence frequency, threshold	$[T^{-1}]$	Hz	inherit their dimension entirely from k
D	octave deficit	$[1]$	octaves	a ratio of logarithms; k cancels

Does the equation balance? The storage law balances provided S and C carry the same dimension as Q per period, which the framework assumes and does not measure; Q has **no operational unit**, and this audit records that rather than inventing one. The essence law $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, because n is a dimensionless count. **The source supplies no operational procedure by which k acquires that dimension.** The constant is computed as a ratio of two dimensionless quantities — a frequency ratio and a geometric ratio — and the hertz is attached by assertion. This is the single largest dimensional exposure in the paper and it is listed in Section 13 by name.

The exponent is the second exposure, and it is not the same one. The ratio c/η is dimensionally $[\mathcal{C}\,T^{-1}]$ divided by a pure number, and is therefore **not dimensionless as written**, which the exponent of $e^{2c/\eta}$ requires it to be. The framework's convention is that c is expressed in the same units as F — nats of surplus per declared period — which makes c/η dimensionless. **That convention is a choice, the source never states it, and every reading in this paper depends on it being applied consistently.** It is stated here because it is otherwise invisible, and its failure mode is measurable: comparing two scopes on mismatched clocks produced a $90.1\times$ period-normalisation error in the corpus's own correspondence audit (finding CC-R16), and at two nats of amplification per unit of c/η that is not an error bar but a different answer.

3.5 Scale type, and what licenses the arithmetic

quantity	scale type claimed	what licenses it
n, N	absolute	cardinality: true zero, fixed unit, identity transformation group only
u	ratio	constructed from an inner product of unit vectors; zero is parallel
η, c, δ	ratio, **assumed**	no instrument is supplied; the quantities admit a true zero, but whether an *estimate* of them is ratio-scaled is a property of the instrument
f, $f_{\min}$	ratio in hertz, **inherited**	inherits the status of n and of the postulated bridge
D	interval, in octaves	a difference of logarithms

Stevens' typology makes the permissible arithmetic on a quantity a function of the transformation group that leaves its empirical content unchanged [Stevens, 1946], and division requires a ratio scale with a true zero. **The strongest available objection to this framework is Michell's**: that psychology routinely assumes its attributes are quantitative without ever testing whether they are [Michell, 1997, 1999]. The objection applies here in full. The formal remedy exists — conjoint measurement supplies a testable condition for additive quantitative structure [Luce and Tukey, 1964, Krantz et al., 1971], and a Rasch model supplies specific objectivity [Rasch, 1960, Andrich, 1988] — and **neither has been run for any quantity in this paper.** η, c and δ are treated as quantitative by stipulation, and Section 8 computes what that stipulation is worth when it fails.

3.6 Identification — the objection this framework cannot presently answer

The framework's founding construction is a reflexive loop, $T(x) = W(x, M(x))$: the group influences the member and the members constitute the group [Curzi, 2026], whose Result Two identifies the self-fulfilling prophecy as a fixed point of that composition of seeing and responding. **That is a linear-in-means reflexive specification, and the endogenous social effect in such a specification is not identified from observational data** [Manski, 1993]. It cannot be separated from contextual effects or from correlated unobservables, however much data is collected; the reinforcement is that influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. **No amount of fit, held out or otherwise, recovers the parameter.**

The remedy this paper adopts is stipulation, and it pays the price openly. The reference set is fixed in advance — the declared category set of size N and the declared decomposition rules — and every reading is reported together with that stipulation, which is what makes a discrete-choice treatment of social interaction defensible where an unrestricted one is not [Brock and Durlauf, 2001]. **This paper therefore presents the reflexive loop as a modelling position, not as an identified empirical result.**

The same objection applied to the framework's own parameters. If systems change their behaviour when modelled, then δ, η and u are the decision rules of people who have not read the storage law, and they are not structural in the sense a policy exercise requires [Lucas, 1976]. Classification changes the classified [Hacking, 1995], and economic theory has been shown to become self-validating by being taught and used [Ferraro et al., 2005, MacKenzie and Millo, 2003]. **The framework asserts reflexivity for its subject matter and cannot consistently exempt its own parameters from it.** This paper does not resolve that; it states it, and treats every parameter as conditional on the arrangement in which it was fixed.

3.7 Method

Every number in this paper is the output of exact arithmetic on stated parameters, computed in double precision. **No observational data were collected, no human subjects participated, and no empirical dataset underlies any figure or table.** Every case is constructed and is labelled as constructed at the point of use. Residuals quoted at the 10^{-16} level are floating-point round-off, not measurement error, and are reported to demonstrate that two algebraically identical expressions were in fact computed independently and agreed. The figures are produced by the scripts named in their captions.

4 The four constituent laws

This section restates the results the join consumes, with their honesty clauses, so that the paper stands alone. **A law's honesty clauses are part of the law**: a theorem detached from the conditions under which it was proved is not a compressed theorem but a different and false statement. Four laws are needed, and only one of them is empirically at risk.

```
THE ESSENCE LAW      f = k n^2                        an index has a pitch
THE SURPLUS LAW      F = ln(1 + (N−1)u)               a pair has a surplus
THE STORAGE LAW      Q_{t+1} = (1−d)Q_t + eta S − C    surplus becomes structure, and leaks
THE TIME−FREQUENCY   dt ∗ df >= 1/(4 pi)              what may be rendered, and how fast
BOUND
```

4.1 The essence law — statement

$$f(n) = k\,n^2, \qquad k = \frac{(9/8)^2}{\varphi^2} = 0.483425732988414 \quad \text{(defined; exact)}$$

with n the *essence index*: the position of a type within its discipline's ordered category set. **The constant is a Pythagorean interval divided by the square of the golden section, and that is a design decision, badged as a postulate (P-b) every time it appears.**

Provenance and verification. The law is a collapse of a recipe of the form $((n/\varphi) \times 1.125)^2$. Recomputed here over $n = 1 \ldots 118$, that recipe and kn^2 agree to a **worst relative deviation of** 4.760×10^{-16} — machine precision. The residual bias in the source's own published table traces to φ stored at fifteen significant figures (finding CC-R5).

4.2 The essence law — two structural results

Result One — every interval is a ratio of squares, and k cancels.

$$\frac{f(m)}{f(n)} = \frac{m^2}{n^2}$$

The golden section and the $9{:}8$ set the absolute reference pitch **and nothing else**. Verified: $2{:}1 \to 4/1$ (two octaves), $3{:}2 \to 9/4$, $4{:}3 \to 16/9$, $5{:}4 \to 25/16$, $3{:}1 \to 9/1$. **This is the strongest available defence of an otherwise arbitrary constant: it does no work anywhere except at the origin.** The result is owned by Series B [Curzi, 2026k].

Result Two — octave folding is governed by the odd part of the index. Since $(2n)^2 = 4n^2$ is exactly two octaves above n^2, write $n = 2^a m$ with m odd. Then $f(n) = k(2^a m)^2 = f(m) \cdot 2^{2a}$, an integer number of octaves. Two indices therefore share a pitch class **if and only if** they have the same odd part, and a set indexed $1 \ldots N$ contains exactly $\lceil N/2 \rceil$ distinct classes. For $N = 12$ the odd parts are $1, 1, 3, 1, 5, 3, 7, 1, 9, 5, 11, 3$, giving $\{1, 3, 5, 7, 9, 11\}$ — **six classes from twelve indices**, computed and confirmed. The result is owned in this series by the folding paper [Curzi, 2026], whose Result One is the odd-part class rule.

4.3 The essence law — what it does not do

- **It does not describe a physical resonance.** No material, molecule, element, room, institution or person is claimed to resonate at any of these values.
- **It does not measure k.** k is chosen. Its form is a design decision and carries no empirical warrant, and the deflationary golden-section literature is cited alongside it [Markowsky, 1992].
- **It does not survive an arbitrary index.** An arbitrary ordering yields arbitrary frequencies.
- **It does not gain support from the square-well coincidence.** That $E_n \propto n^2$ for a one-dimensional infinite square well is a genuine agreement of form. **Coincidence of form is not evidence of mechanism**, and asserting the connection would be exactly the decorative analogy this corpus's analogy discipline exists to prevent.
- **It does not generalise to compounds.** The compound rule is $f = k^2 G^4$ with G the count-weighted geometric mean of component indices, audited in this series by the operations paper [Curzi, 2026], whose Result Four proves the two rules agree at no integer index.

4.4 The surplus law — statement and axioms

$$u(x, y) = 1 - (x \cdot y)^2 \in [0, 1], \qquad F = f(u) = \ln(1 + (N - 1)u)$$

uniquely characterised by four axioms [Curzi, 2026]: **S1** geometric dependence, F depends on the pair only through u; **S2** zero at zero, $f(0) = 0$; **S3** affine effective count, $g(u) = e^{f(u)}$ is affine in u; **S4** normalisation, $f(1) = \ln N$.

S3 is the design axiom. It is chosen, not derived, and every result that leans on it must say so — and this entire paper leans on it, because N_{eff} is defined by it. The uniqueness argument is four lines and every step after S3 is forced:

```
S1  =>  F is a function of u alone:            F = f(u)
S3  =>  g(u) := e^{f(u)} is affine in u:       g(u) = A + Bu
S2  =>  f(0) = 0, so g(0) = 1, so A = 1
S4  =>  f(1) = ln N, so g(1) = N, so B = N - 1

therefore  g(u) = 1 + (N-1)u   and   f(u) = ln(1 + (N-1)u)
```

The bite of S3, computed. $g(u) = 1 + (N - 1)u$ is affine: at $u = 0.1, 0.2, 0.3$ it takes the values $2.1, 3.2, 4.3$, second difference -4.44×10^{-16}, machine zero. An alternative satisfying S1, S2 and S4 but violating S3 is $f_{\text{alt}}(u) = u \ln N$, with $g_{\text{alt}}(u) = N^u$ whose second difference at the same points is $+0.102021$ — not affine. **Both agree at both endpoints and disagree by 33.62 per cent at $u = 0.5$ (1.871802 against 1.242453).** S3 is not a technicality: it selects one curve out of a family that agree at the endpoints and diverge by a third in the middle, and the middle is where every real case lives.

The functional form is underdetermined by the evidence, and this paper concedes it. A power law with exponent below one [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as the logarithm does, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. **Nothing in this paper discriminates among them.**

4.5 The surplus law — derived properties, all computed at $N = 12$

```
monotone           f'(u) = (N-1)/(1 + (N-1)u) > 0 everywhere
strictly concave   f''(u) = -(N-1)^2/(1+(N-1)u)^2 < 0
                   f''(0) = -121.0000     f''(1) = -0.840278
sharp Lipschitz    f'(0) = 11.0000 = N-1  f'(1) = 0.916667
subadditive on u   f(0.3) + f(0.4) = 3.145014 >= f(0.7) = 2.163323
```

```
extremal          f(0) = 0 exactly;  f(1) = 2.484907 = ln 12 exactly
range             0 <= F <= ln N
```

$\ln N$ **is the hard ceiling on surplus per interaction**, and Section 7's ceiling result is this inequality converted into frequency units. The affine count also coincides exactly with the Rényi-2 participation ratio, $N_{\text{eff}} = N + 1 - N/\text{PR}$, verified to 10^{-12} (finding CC-R3) — the Rényi family being the source of that measure [Rényi, 1961]. **That coincidence is worth having and is not evidence that S3 is true.** It is evidence that S3 selects a quantity other people had independent reasons to care about, which is a different and weaker thing.

4.6 The surplus law — what it does not do

- **It is a LOWER BOUND on the ensemble's information, not the information itself.** Every frequency computed from it is therefore a lower bound on the pitch, not the pitch.
- **It is not Shannon entropy and not mutual information in general.**
- **It proves nothing about thermodynamics.** No negentropy law is proved.
- **The triangle inequality fails for geometric triples.** Subadditivity holds on the parameter u only; pitch distances across three essences do not chain.
- **It is degenerate on one-hot inputs.** Two states each concentrated on a single distinct category are automatically orthogonal: computed, $u = 1.000000$ and $F = 2.484907 = \ln N$, regardless of which categories they are. **A reading in which everyone is maximal is a reading of the instrument**, and the folding paper carries this as its Result Five [Curzi, 2026].
- **It says nothing about people until someone supplies the vectors**, and supplying the vectors is the hard part. The monotone claim in particular cannot be extended past the range examined: the empirical literature is divided, with measured returns to bridging [Granovetter, 1973] but creative success rising and then *falling* with the same variable [Uzzi and Spiro, 2005], short-run effects of surface diversity frequently negative [Putnam, 2007], and a rebuttal literature that qualifies rather than reverses that [Abascal and Baldassarri, 2015]. The problem-solving result usually cited for diversity [Hong and Page, 2004] has a standing formal objection [Thompson, 2014] that must be cited with it.

4.7 The essence bridge

Within a discipline n is an index; across disciplines there is no shared index. The framework supplies one by identification (P-d):

$$n_{\text{eff}} := N_{\text{eff}} = 1 + (N-1)u = e^F, \qquad f = k\, n_{\text{eff}}^2 = k\, e^{2F}$$

Taking base-2 logarithms, **octaves above base** $= 2F/\ln 2 = 2.885390081777927 \times F$**, with** F **in nats.** Verified at both ends: $F = 0$ gives $N_{\text{eff}} = 1$ and $f = k = 0.4834$ Hz; $F = \ln 12 = 2.484907$ gives $N_{\text{eff}} = 12$ and $f = 69.6133$ Hz, exactly 7.169925 octaves above base.

The bridge is a **strictly increasing bijection** from $[0, \ln N]$ onto $[k, kN^2]$, which is the property the join needs in order to invert it. Round-trip verification $F \to f \to F$ at ten values including both endpoints returns the input to fifteen decimal places with error $0.000\text{e}{+00}$ at every point tested:

```
F = 0.000000  ->  f =  0.483426  ->  F' = 0.000000000000000
F = 0.563085  ->  f =  1.490799  ->  F' = 0.563085000000000
F = 1.000000  ->  f =  3.572060  ->  F' = 1.000000000000000
F = 2.000000  ->  f = 26.394151  ->  F' = 2.000000000000000
F = 2.153633  ->  f = 35.888195  ->  F' = 2.153633000000000
F = 2.484907  ->  f = 69.613306  ->  F' = 2.484906649788000
```

4.8 The storage law — statement, solution and bounds

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t          S_t = ln(1 + (N−1)U_t)

admissibility     C_t <= (1−delta)Q_t + eta S_t     guarantees Q_{t+1} >= 0
exact solution    Q_t = (1−delta)^t Q_0 + SUM (1−delta)^{t−1−j} (eta S_j − C_j)
one−step growth   Q_{t+1} > Q_t  iff  eta S_t > delta Q_t + C_t
uniform bound     Q_t <= max{ Q_0, eta ln N / delta }
sustainability    a nondecreasing step requires C_t <= eta ln N − delta Q_t
steady state      Q_inf = ( eta F(u*) − c* ) / delta        (delta > 0)
```

At $\eta = 0.30$, $\delta = 0.09$, $N = 12$ the uniform bound is 8.2830. **If C_t exceeds $\eta \ln N - \delta Q_t$, no choice of interaction geometry can prevent order from decreasing** — this is the ceiling in stock units, and Section 7 restates it in frequency units.

The master gauge is *headroom*, $h_t := \eta \ln N - \delta Q_t - C_t$, negative meaning unsustainable, zero meaning maintenance only, positive meaning growth is available. At the fixed point $h_\infty = \eta(\ln N - F(u^*)) - \delta$, C and Q all cancel (finding CC-R6). Checked at $\eta = 0.30$, $c = 0.62$, $\delta = 0.09$, $u = 0.068735$: the identity gives 0.5765465541125843 and the direct computation $\eta \ln N - \delta Q_\infty - c$ gives 0.5765465541125842. The institutional worked case in Series B moves a fixed point from 0.2653 to 3.9281 by moving η from 0.35 to 0.55 and δ from 0.25 to 0.12, which is the same gauge in an operational setting [Curzi, 2026h].

4.9 The storage law — the circuit reading and geometric convergence

Because $\delta > 0$ makes the map a contraction, Banach's theorem guarantees a unique fixed point and convergence to it from any start [Banach, 1922]; the corpus's foundations state the theorem exactly and then refuse the certificate it appears to offer, on the ground that a human life is not a metric space and nobody has measured the relevant contraction modulus [Curzi, 2026]. That refusal binds this paper. The convergence is geometric, $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$, verified at $\delta = 0.09$, $t = 20$ to fifteen digits; the transient half-life $\ln 2/(-\ln(1-\delta))$ is 7.3496 periods at $\delta = 0.09$. The half-life formula and its divergence from the naive $1/\delta$ are owned by the folding paper [Curzi, 2026], whose Result Four records 1.9434 cycles against a naive 3.3333 at $\delta = 0.30$, an error of 72 per cent.

An equivalent multiplicative reading exists and agrees to fourteen significant figures: in world coordinates the storage law is a geometric accumulator $G_{t+1} = G_t^{1-\delta}(N_{\text{eff}})^{\eta} e^{-C}$ [Curzi, 2026n], whose Result Three fixes that correspondence. **This paper uses the additive form throughout.**

4.10 The storage law — what it does not do

- **It proves no thermodynamic or physical law.** It is a linear difference equation.
- **It is scale-free in FORM only.** That only (δ, η, N, C) change between a desk, a room, a team and a city is a claim about model form, not about physics. The correspondence audit names nine disanalogies between internal and external scopes, three of them computed: a mean-field decay error reaching **92 per cent by** $t = 12$; two nine-member groups with identical $u = 0.5999$ and $S = 1.7578$ losing **77 per cent versus 21 per cent** of surplus to a three-person departure; and a $90.1\times$ period-normalisation trap on mismatched clocks (finding CC-R16).
- **It does not license a negative stock.** When $\eta F < c$ the fixed point is negative and the recursion violates its own admissibility condition on the way there. Section 6.8 computes exactly when.
- **It does not average.** Because F is strictly concave, feasibility must be tested on the mean of $F(U_t)$ and not on F of the mean U (finding CC-R2, worth 6.2 per cent in the corpus's worked office; the Jensen correction is owned by the protocol paper [Curzi, 2026], whose

Result Four prices one instance at 0.0790 nats, 4.31 per cent). And because distortion cancels across sites, aggregating a ratio across sites overstated bankable input by $4.26\times$ (finding CC-R10).

4.11 The time–frequency bound on rendering

$$\Delta t \cdot \Delta f \geq \frac{1}{4\pi} = 0.079577471545948$$

is a theorem about signals [Gabor, 1946], not an analogy, and it binds every rendering of any frequency in this paper. **It contributes no term to $f_{\min}$.** It is stated here because a paper that produces frequencies and does not state the constraints on rendering them is inviting exactly the misuse it claims to refuse. Four consequences are computed and owned by the conjugate paper [Curzi, 2026z], whose Result One proves the bound by the same variational argument as $\sigma_x \sigma_p \geq \hbar/2$ with $p = \hbar\kappa$ deleted:

```
minimum-gap cliff   N =  3..6   min gap = 9/8       = 203.9100 cents
                    N =  7..16  min gap = 50/49     =  34.9756 cents
                    N >= 17     min gap = 289/288   =   6.0008 cents   <-- the cliff
                    N >= 41     min gap = 1682/1681 =   1.0296 cents

rate factor         (1/32)/(1/256) = 8 EXACTLY      symbols per second
resolution          32/(4 pi) = 2.546479 cycles per step below the cliff
                    256/(4 pi) = 20.371833 cycles per step above it
audible-set ceiling a single integer transposition admits at most N = 25
```

Three distinct ratios attach to the cliff, all correct in their own units and all different: $\ln(50/49)/\ln(289/288) = 5.828475$ in cents, $288/49 = 5.877551$ in cycles, and exactly 8 in rate. The corrected cliff location is $N = 17$, not $N = 20$, because $17^2 = 289$ folds beside $288 = 2 \cdot 12^2$ the instant index 17 enters the set (finding CC-R21). $N = 12$ is below the cliff, so this paper renders — if it renders at all — in the $50/49$ regime.

The uncertainty relation is a fact about state preparation, not about measurement disturbance, and the corpus's own uncertainty node refuses the inflated reading of its borrowed physics [Curzi, 2026]. Its counter-result requires that a user be able to distinguish the theorem, the ordinary observer effect, and the framework's own conjecture in three separate sentences on demand. That requirement binds this paper too.

4.12 The four-register convergence

Four quantities in this framework are logarithmic: surplus $F = \ln N_{\text{eff}}$; pitch $p = \log_2 f$; sensation [Fechner, 1860]; and the moment in log form. **Every conversion between them is therefore linear in log space, and the conversion constants are exact:**

```
1 nat    = 1.442695 bits  = 2.885390 octaves = 3462.4681 cents
1 bit    = 0.693147 nats  = 2 octaves EXACTLY = 2400 cents exactly
1 octave = 0.346574 nats  = 0.5 bits          = 1200 cents
```

One octave is exactly half a bit of surplus. The nat, the bit and the conversion between them are the standard units of a logarithmic information measure [Shannon, 1948, Cover and Thomas, 2006]; **nothing about the framework's use of them is novel, and nothing about them licenses the frequency reading.**

4.13 The twelve-state ladder, and the objection to it

The index this corpus feeds to the essence law is n, a count of distinguishable components. The ladder is owned by the companion paper [Curzi, 2026] and is reproduced here because the worked example uses it:

n	state class	component added	f = k n^2	folded 220–440	class
1	undifferentiated activation	arousal alone	0.4834	247.514 (j=9)	1
2	valenced activation	+ valence	1.9337	247.514 (j=7)	1
3	directed feeling	+ intentional object	4.3508	278.453 (j=6)	3
4	situated feeling	+ situation	7.7348	247.514 (j=5)	1
5	attributed feeling	+ cause	12.0856	386.741 (j=5)	5
6	temporal feeling	+ projected duration	17.4033	278.453 (j=4)	3
7	reflexive feeling	+ self as object	23.6879	379.006 (j=4)	7
8	social feeling	+ another mind modelled	30.9392	247.514 (j=3)	1
9	normative feeling	+ standard applied	39.1575	313.260 (j=3)	9
10	narrative feeling	+ placed in a story	48.3426	386.741 (j=3)	5
11	reciprocal feeling	+ the other modelling you	58.4945	233.978 (j=2)	11
12	committed feeling	+ future action bound	69.6133	278.453 (j=2)	3

Six distinct pitch classes $\{1, 3, 5, 7, 9, 11\}$, exactly $\lceil 12/2 \rceil$, as the odd-part theorem requires.

The affect literature does not underwrite this ladder, and the reason must be stated in the body rather than in a footnote. The named precedents establish that each component is a real, independently described feature of emotional states; they do not establish an index, an ordering, or a nesting.

- **Appraisal dimensions vary simultaneously and independently, and emotions differ by the pattern across them** [Smith and Ellsworth, 1985]. Two states at the same dimensionality are separated by the *pattern of values*, which is exactly the information a count discards. **A count cannot separate anger from guilt; a pattern can.**
- **Emotion is a process unfolding in time** — a sequence of evaluation checks driving synchronised change across organismic subsystems, where the state *is* the synchronisation [Scherer, 2001]. A process with an ordering of its own resists reduction to a scalar of any kind, and the single point at which the two orderings touch is a coincidence at one rung.
- **Individuation by core relational theme is qualitative** [Lazarus, 1991]. A theory in which two emotions differ by *what* is appraised does not license a theory in which they differ by *how many* things are appraised.
- **The circumplex is two continuous bipolar axes recovered from ratings** [Russell, 1980]; its "two" is two dimensions, not two countable components, and its principal content — the circular ordering of affect terms — has no counterpart in the ladder.
- **The top rung is contradicted specifically.** The ladder places action tendency at $n = 12$, as the last component added. The standing thesis in that literature is that changed action readiness is **constitutive of emotion as such** [Frijda, 1986] — a startle at $n = 1$ is already action readiness. **If that is right, the component sits at the floor and the ladder's ordering fails at its summit.**

Two of the seven named precedents survive in the form the corpus needs: a claim that a *class* of states requires a component other states lack is exactly the shape of argument a rung needs [Tracy and Robins, 2004], and the modelled-other construct is cleanly named [Premack and Woodruff, 1978]. **This paper therefore cites the affect literature for the *existence* of a component and never for the index, its ordering, or its nesting**, and narrows the top rung to *bound commitment* rather than *readiness*, which is the only version that literature leaves standing. The unnarrowed claim is conceded in Section 13.

These objections and Michell's are the same objection in two domains. Michell's is that a psychological attribute is treated as quantitative without a test for quantitative structure; the

appraisal objection is that an emotional state is reduced to a scalar when its own literature describes it as a pattern or a process. **Both are instances of one habit — scalar reduction — and this corpus should notice that rather than meeting each as a surprise.** The count argument answers Michell for n alone, because a cardinality's structure is a consequence of its definition rather than an empirical hypothesis; it answers neither objection for anything else in this paper.

4.14 What each law contributes to the join, and what it withholds

LAW	contributes to f_min	withholds
essence law	the constant k, and the square, via the bridge	any warrant that k is other than chosen
surplus law	F, and the ceiling ln N	the identity of F with information; F is a lower bound
storage law	eta, c, delta, and the sign condition	any claim that Q is conserved, physical, or that a negative Q_inf is a stock
Gabor bound	nothing at all	it constrains only the rendering

4.15 What would falsify each law

The essence law is a postulate and is not falsifiable as stated. It is a stipulation about how an index maps to a pitch. What *is* checkable is its internal consistency with the recipe it collapses — checked, at 4.760×10^{-16} — and the consequences of its interval structure, which are arithmetic. **A postulate that cannot be falsified must earn its place by being useful and by carrying its badge.**

The surplus law is a theorem and is falsifiable only in its axioms. If a system's effective count is not affine in u, S3 is wrong for that system and the whole functional form changes.

The storage law is falsifiable in the ordinary empirical sense, and the corpus states the test: preregister, fit on training data, freeze, report held-out performance, and beat four baselines. That protocol is the standard one [Nosek et al., 2018, Simmons et al., 2011], and the corpus's own attempt at it **failed its second falsification rule** [Curzi, 2026i], whose Result One records a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin. **A framework whose one confirmatory fit failed is in a better epistemic position than one that never attempted a fit**, and this paper treats that failure as the relevant precedent for how any future fit should be reported.

The time–frequency bound is a theorem of signal analysis and is not in question.

The asymmetry is the honest headline. Two of the four laws are stipulations, one is a theorem about axioms someone chose, and only the third is empirically at risk. **The join is therefore exactly as empirical as the storage law and no more; everything else in it is bookkeeping.**

5 The join: statement and derivation

5.1 The two inputs, in the exact form the derivation uses

INPUT ONE	Q_inf = (eta F(u∗) − c∗) / delta	for constant u∗, c∗, delta > 0
INPUT TWO	f = k e^(2F)	k = 0.483425732988414 (defined; exact)

For the rest of this section the asterisks are dropped: u means u^*, c means c^*, and the regime is the constant one the fixed-point theorem requires.

5.2 The derivation, step by step, with the licence for each step

Step 0 — the definition of sustainability. A relation is SUSTAINABLE when $Q_\infty > 0$. **This is a definition and it is a choice** (M-d). It is not the only possible one: requiring $Q_{t+1} \geq Q_t$ at the current stock is a different, state-dependent condition. The fixed-point definition is chosen because it is parameter-determined rather than state-determined — it says where the relation is going, not where it happens to be.

Step 1 — clear the denominator.

```
Q_inf > 0   <=>   ( eta F − c ) / delta > 0   <=>   eta F − c > 0
```

Licence: $\delta > 0$; a positive divisor preserves the direction of an inequality. **This is the step where δ leaves the argument and never returns**, and Section 7.1 shows that its departure is the most consequential structural fact in the paper. If $\delta = 0$ there is no fixed point and the theorem does not apply; Section 6.6 handles that case and shows the same threshold governs it anyway.

Step 2 — isolate the surplus.

```
eta F − c > 0   <=>   eta F > c   <=>   F > c/eta
```

Licence: $\eta > 0$. If $\eta = 0$ the numerator is $-c \leq 0$ and no F satisfies the inequality unless $c = 0$ also. The quantity c/η now has a name and a meaning: the **cost-to-conversion ratio**, the amount of surplus in nats that must be supplied per period merely to pay for the period. **It is dimensionless only under the convention stated in Section 3.4, and that convention is a choice the source never states.**

Step 3 — invert the bridge.

```
f = k e^(2F)   =>   ln(f/k) = 2F   =>   F = (1/2) ln(f/k)
```

Licence: $k > 0$ and $f > 0$, both guaranteed since $f = ke^{2F} \geq k > 0$. The map $F \mapsto ke^{2F}$ is a strictly increasing bijection from $[0, \ln N]$ onto $[k, kN^2]$, so the inverse exists on exactly that range and is itself strictly increasing. Verified numerically in Section 4.7 at ten values with error $0.000\text{e}{+00}$.

Step 4 — substitute and solve.

```
F > c/eta   <=>   (1/2) ln(f/k) > c/eta   <=>   ln(f/k) > 2c/eta
            <=>   f/k > e^(2c/eta)        <=>   f > k e^(2c/eta)
```

Licence: multiplication by 2, exponentiation, and multiplication by $k > 0$ are each strictly increasing, **so the equivalence is exact in both directions and nothing is lost.**

5.3 The result

DEFINITION 5.1 — THE MINIMUM SUSTAINABLE FREQUENCY.

$$f_{\min} := k\, e^{2c/\eta}$$

THEOREM 5.2 — THE THREE REGIMES. Under the fixed-point theorem's conditions ($\delta > 0$, $\eta > 0$, constant u and c), with $f = k\, e^{2F(u)}$:

```
f > f_min    <=>   Q_inf > 0    the relation ACCUMULATES order
f = f_min    <=>   Q_inf = 0    it HOLDS, and nothing more
f < f_min    <=>   Q_inf < 0    it DECAYS, whatever anyone intends
```

Proof: Steps 1 through 4 read as a chain of equivalences, the equality case following from the strict monotonicity of every transformation used. **QED.** The trichotomy and its consequences are owned in this series by the criterion paper [Curzi, 2026], whose Result One states $f_{\min} = k\, e^{2c/\eta}$ with the trichotomy attached.

COROLLARY 5.3 — THE HOLD LINE. The relation holds exactly when $u^* = (e^{c/\eta} - 1)/(N-1)$. Verified at four points for $N = 12$:

```
c/eta = 0.500000  ->  u* = 0.058975  ->  f = f_min =  1.3141 Hz
c/eta = 1.000000  ->  u* = 0.156207  ->  f = f_min =  3.5721 Hz
c/eta = 2.000000  ->  u* = 0.580823  ->  f = f_min = 26.3942 Hz
c/eta = 2.484907  ->  u* = 1.000000  ->  f = f_min = 69.6133 Hz
```

The last row is the ceiling appearing on its own: at $c/\eta = \ln N$ the required non-parallelism is exactly 1 — perfect orthogonality — and there is nothing above it.

5.4 What this result is

It is an exact restatement of a sustainability condition in frequency units. Nothing more. It is a change of variable applied to an inequality. The inequality was already established; the change of variable was already established. **The join contributes no new assumption, no new parameter, and no new empirical content, and if it appeared to, that would be a sign that an error had been made.**

Three things it does contribute, all real and none empirical. **(a) A comparable register.** Intervals compose and hertz do not; two relations with different costs are compared on the octave scale directly, and the exchange rate is one exact constant. **(b) An audible ceiling.** $F \leq \ln N$ is an abstract bound; $f \leq 69.6133$ Hz for twelve categories is a specific position, and the fact that a system's requirement can be *above* that position is what makes the ceiling result land. **(c) A single diagnostic number**, the octave deficit, which collapses four parameters into one signed quantity whose sign is the verdict and whose magnitude is the size of the problem.

5.5 What this result is not

It is not a claim that anything physically resonates. No person, bond, tissue, molecule, room or institution is asserted to vibrate, emit, or respond at f, at $f_{\min}$, or at any value derived from them. The frequencies are essence frequencies: positions on a logarithmic scale of surplus.

It is not a measurement. It is a function of four parameters and has exactly the status of those parameters. Section 8 shows what that status is when the parameters are ordinal.

It is not new physics, biology or psychology. The empirical content lives entirely in η, c, u and N. **The algebra cannot be right or wrong about the world; it can only be right or wrong about arithmetic**, and Section 6 checks the arithmetic.

It is not a clinical instrument, and it is not a target to play. Nothing here diagnoses, assesses or treats anybody, and nothing licenses the inference that sounding a tone at $f_{\min}$ does anything to anyone.

5.6 Two asymmetries the join inherits

Asymmetry one — the verdict is conservative in one direction only. As deployed, the surplus functional is a **lower bound** on the ensemble's information. F is exact given u, but u is a property of the *representation*, and a representation that fails to capture a real difference understates u and therefore understates f. **A verdict of ACCUMULATES is robust to representational under-capture; a verdict of DECAYS is not.** The instrument is biased toward pessimism, and every negative reading should be checked against the question *have we represented the difference between these parties, or only the difference our instrument can see?*

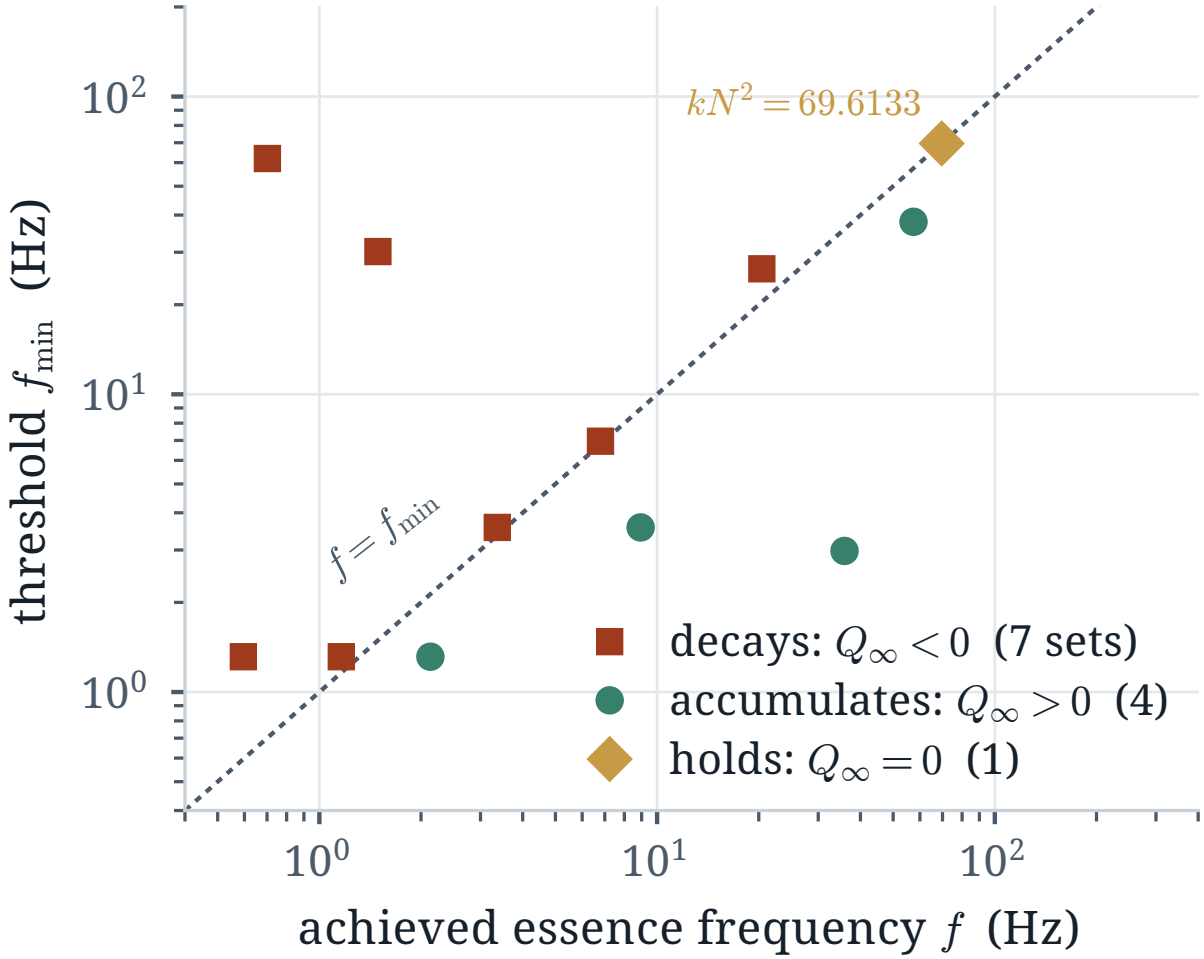

Figure 40.1: **The equivalence holds at every one of the twelve constructed parameter sets**, including the boundary case: the seven sets with $Q_\infty < 0$ all sit above the line $f = f_{\min}$ and the four with $Q_\infty > 0$ all sit below it, with the single hold set exactly on it at $f = f_{\min} = kN^2 = 69.6133$ Hz. Modelled from $f = k(1 + 11u)^2$ and $f_{\min} = k\,e^{2c/\eta}$ with the **defined** constant $k = 0.483425732988414$ and $N = 12$; the parameter sets are constructed and are the source's. Built by `figs/src/CCP-040_fig01.py`.

Asymmetry two — the ratio is period-invariant only on a shared clock. η is a conversion per period and c a cost per period; their ratio is dimensionless and invariant under a change of period *provided both were measured on the same one.* The measured failure is a $90.1\times$ period-normalisation error (finding CC-R16). Since $d \ln f_{\min}/d(c/\eta) = 2$, that is not a large error bar; it is a different answer.

6 Verification of the join

6.1 Twelve parameter sets

The theorem is an equivalence, so the verification is a sign test: for each parameter set, compute f and $f_{\min}$ independently, compute Q_∞ independently, and check that $\mathrm{sign}(f - f_{\min})$ equals $\mathrm{sign}(Q_\infty)$. All twelve sets use $N = 12$ and **all twelve are constructed**; the first three are the carried cases of this paper and the remaining nine span the space, including two near-zero cases and one exact-equality case at the ceiling.

```
  eta      c     delta        u          F          f (Hz)     f_min (Hz)  sgn(f−f_min)   Q_inf      sgn  agre
```

0.30	0.620	0.09	0.068735	0.563085	1.4908	30.1588	−1	−5.0119	−1	yes
0.44	0.400	0.09	0.692373	2.153633	35.8882	2.9782	+1	+6.0844	+1	yes
0.34	0.825	0.09	0.018614	0.186272	0.7017	61.9349	−1	−8.4630	−1	yes
0.50	0.500	0.10	0.300000	1.458615	8.9385	3.5721	+1	+2.2931	+1	yes
0.60	0.300	0.05	0.100000	0.741937	2.1319	1.3141	+1	+2.9032	+1	yes
0.20	0.100	0.20	0.050000	0.438255	1.1614	1.3141	−1	−0.0617	−1	yes
0.90	1.800	0.02	0.500000	1.871802	20.4247	26.3942	−1	−5.7689	−1	yes
0.75	1.000	0.15	0.250000	1.321756	6.7982	6.9574	−1	−0.0579	−1	yes
0.10	0.050	0.30	0.010000	0.104360	0.5956	1.3141	−1	−0.1319	−1	yes
0.55	1.200	0.08	0.900000	2.388763	57.4358	37.9693	+1	+1.4227	+1	yes
0.40	0.400	0.12	0.148900	0.969983	3.3639	3.5721	−1	−0.1001	−1	yes
1.00	2.484907	0.07	1.000000	2.484907	69.6133	69.6133	0	+0.0000	0	yes

All twelve agree, including the boundary case. The last row is the ceiling: $u = 1$, $F = \ln 12$, $c/\eta = \ln 12$, and $f = f_{\min} = kN^2 = 69.6133$ Hz exactly, with $Q_\infty = 0$. The relation holds and does not build, at the maximum surplus twelve categories can produce.

> **A correction to the source, printed rather than silently applied.** The source prints the last row's cost as $c = 2.485$. That value is not the ceiling: $2.485 > \ln 12 = 2.484906649788$, and recomputing from the printed figure gives $f_{\min} = 69.6263$ Hz, $Q_\infty = -0.0013$ and $D = +0.000269$, not the exact zeros the row reports. **The row is correct only for** $c = \ln 12$ **exactly**, and this paper quotes that value. The discrepancy is a rounding in the printed table, not an error in the theorem, and it is recorded because a reader recomputing from the printed intermediate will find it.

6.2 The deficit identity

DEFINITION 6.1 — THE OCTAVE DEFICIT.

$$D := 2.885390\,(c/\eta) - \log_2(f/k)$$

with $D \le 0$ sustainable as it stands and $D > 0$ short by that many octaves. The instrument is owned by the criterion paper [Curzi, 2026].

THEOREM 6.2 — THE DEFICIT IDENTITY.

$$D = 2.885390\,(c/\eta - F) = -2.885390\,(\delta/\eta)\,Q_\infty$$

Proof. $\log_2(f/k) = \log_2 e^{2F} = 2F/\ln 2 = 2.885390\,F$, giving the first equality. For the second, $Q_\infty = (\eta F - c)/\delta$ gives $(\delta/\eta)Q_\infty = F - c/\eta$, hence $c/\eta - F = -(\delta/\eta)Q_\infty$. Substitute. **QED.**

Verified at all twelve parameter sets, computing D from the frequencies and $-2.885390(\delta/\eta)Q_\infty$ from the fixed point, **entirely separately**:

eta	c	delta	D (from frequencies)	−2.885390∗(delta/eta)∗Q_inf	error
0.30	0.620	0.09	+4.338420	+4.338420	8.88e−16
0.44	0.400	0.09	−3.590989	−3.590989	0.00e+00
0.34	0.825	0.09	+6.463837	+6.463837	8.88e−16
0.50	0.500	0.10	−1.323283	−1.323283	4.44e−16
0.60	0.300	0.05	−0.698084	−0.698084	2.22e−16
0.20	0.100	0.20	+0.178159	+0.178159	2.78e−17
0.90	1.800	0.02	+0.369901	+0.369901	5.00e−16
0.75	1.000	0.15	+0.033406	+0.033406	6.31e−16
0.10	0.050	0.30	+1.141576	+1.141576	0.00e+00
0.55	1.200	0.08	−0.597116	−0.597116	6.66e−16
0.40	0.400	0.12	+0.086610	+0.086610	5.55e−17
1.00	2.484907	0.07	−0.000000	−0.000000	8.88e−16

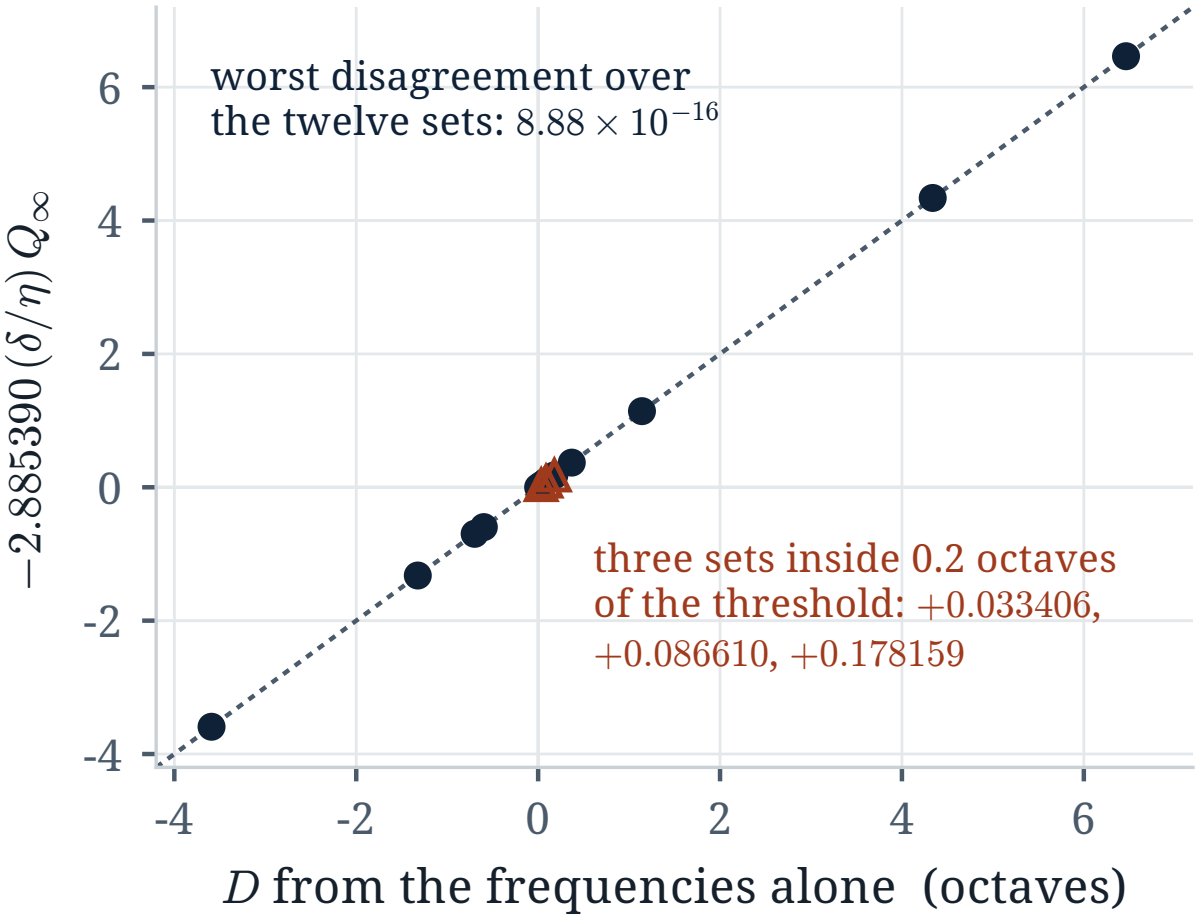

Figure 40.2: **Two routes that share no intermediate quantity agree to** 8.88×10^{-16}, which is double-precision round-off and not measurement error: the abscissa is built only from frequencies and the ordinate only from the storage fixed point. Three of the twelve constructed sets lie within 0.2 octaves of the threshold — $+0.033406$, $+0.086610$ and $+0.178159$ — and are the cases the diagnostic exists for, because nothing about them looks wrong from inside. Modelled from the twelve-set table of Section 6.1 with the **defined** constant $k = 0.483425732988414$. Built by `figs/src/CCP-040_fig02.py`.

The octave deficit and the fixed point are the same quantity in different units. Three readings of the identity, and all three matter. **(i)** $D = 2.885390(c/\eta - F)$: the deficit is the surplus shortfall, converted; one nat short is 2.885390 octaves short, and there is no other exchange rate. **(ii)** $D = -2.885390(\delta/\eta)Q_\infty$: a pitch reading and a stock reading are one reading in two units. **(iii)** k **cancels.** D is a difference of logarithms in which the chosen constant appears in both terms, so **the verdict does not depend on** k **at all**; only the absolute hertz values do.

The conversion factor between the two gauges contains δ**. The deficit itself does not.** That single asymmetry is the whole content of Section 7.1.

6.3 The join is an equivalence, and that is worth more than an implication

Because the chain is a chain of equivalences, **either side may be measured and the other inferred.** That gives two routes to the same verdict with different measurement costs:

```
ROUTE A -- through the geometry
  elicit the state vectors -> compute u -> compute F -> compute f
```

```
    then measure eta and c   -> compute f_min ;  compare

ROUTE B -- through the ledger
  measure the stock Q_t over several periods -> fit delta, eta, c
  compute Q_inf directly -> convert via D = -2.885390 (delta/eta) Q_inf
```

Route A needs no history; Route B needs no elicitation. **A system where both are available is a system where the framework can be checked against itself**, which is the single most valuable thing an equivalence buys: the two routes share no measurement, so agreement is evidence and disagreement localises the fault.

This is also where identifiability bites (H5). Route B recovers η and c only as the combination $\eta F - c$ unless F is independently known — a fitted trajectory cannot separate *converts well from a poor geometry* from *converts poorly from a good one*. **Route B alone gives the verdict and not the prescription.** Section 9.5 exhibits two decompositions that are indistinguishable to any ledger and imply different next moves.

6.4 Reading the near-boundary rows

Rows 6, 8 and 11 have deficits of $+0.178159$, $+0.033406$ and $+0.086610$ octaves — 214, 40 and 104 cents. A relation 40 cents below its threshold is failing in a way no participant could plausibly notice: the per-period loss is $0.0579 \times 0.15 = 0.0087$ units of stored order. Over one period it is nothing; over a hundred periods it is the whole difference between a practice that persists and one that must be rebuilt each generation.

This is the specific value the arithmetic adds over judgement. Large deficits are visible without arithmetic. Small deficits are invisible without arithmetic and decisive over time, and they are the reason to compute rather than to sense. **Proximity to zero is itself a reading**, and the reporting rule that follows is to publish the deficit *and* its sensitivity to the parameter one is least sure of.

6.5 The two absences, and both are substantive

```
f_min = k e^(2c/eta)          contains: k, c, eta
                              does NOT contain: delta, N, u, Q_0, t
```

The absence of δ. δ is the leak. Trust, ritual, place, written record and institution all reduce it. **None of them changes the threshold a relation must clear in order to be building anything at all.** An intervention on δ does not move the reading by any amount whatsoever, and Section 7 computes the case. **A gauge that fails to move under an intervention is not a broken gauge; it is a gauge telling you that you have not touched the mechanism it measures.**

The absence of N. N does not appear in $f_{\min}$ either, but it appears in the *achieved* f through $F = \ln(1 + (N-1)u)$, and in the ceiling $c/\eta \leq \ln N$. **N is not a lever on the threshold; it is a lever on the reachable range.** Raising N does not lower the bar — it raises the highest bar that can be cleared, and it is not free: coordination paths grow as $m(m-1)/2$ [Brooks, 1975, Conway, 1968], and the corpus's own intervention work computes an N lever and then declines it net, a ceiling gain of $\eta(\ln 6 - \ln 5) = +0.1914$ against five added communication paths costing $+0.0714$ [Curzi, 2026j]. Roster-scale accounting is owned in this series by the group paper [Curzi, 2026], whose Result Two gives the exact roster ceiling $m(m-1) \leq 2\eta \ln N/\kappa$.

6.6 The $\delta = 0$ case: no fixed point, same threshold

The fixed-point theorem requires $\delta > 0$. At $\delta = 0$ the map is not a contraction, there is no fixed point, and the exact solution reduces to $Q_t = Q_0 + t(\eta F - c)$: the stock grows without bound if the drift is positive and falls without bound if it is negative. **There is no Q_∞ to be positive or**

negative, and the threshold is unchanged, because the sign of the drift is the sign of the same numerator. Verified on two carried cases:

```
eta = 0.30, c = 0.62, u = 0.068735:  drift = −0.451075   f =  1.4908 < f_min = 30.1588   agree
eta = 0.44, c = 0.40, u = 0.692373:  drift = +0.547598   f = 35.8882 > f_min =  2.9782   agree
```

So $f_{\min}$ **governs both regimes: it decides where a leaky system settles, and it decides which way a lossless system drifts.** That is a stronger statement than the trichotomy alone, and it is available precisely because δ fell out at Step 1. **Zero loss is a pathology, not an ideal** — nothing ever decays out of the stock, so nothing ever arrives.

6.7 Limits, asymptotics and the domain of the model

```
c = 0                 f_min = k exactly. Any u > 0 gives f > k, so ANY relation sustains.
                      A costless relation is sustained by the smallest difference.

c > 0, eta -> 0+      f_min -> infinity. No pitch suffices. At eta = 0.01, c = 0.5,
                      f_min = 1.2995e+43 Hz. A system that converts nothing into
                      structure cannot be saved by any arrangement of its parts.
                      THIS LIMIT IS NOT EXAMINED IN THE SOURCE and is a real
                      constraint on the model's domain: it places every relation
                      above every ceiling.

delta -> 0+           no fixed point; the stock is unbounded in the sign of the drift.
                      Section 6.6. A pathology, not an ideal.

delta -> 1            Q_inf = eta F − c; the stock is memoryless and equals one
                      period's net drive. The transient half-life goes to zero.

u -> 0                f = k, the ground essence. Sustains only if c = 0. And u = 0
                      arises from perfect agreement AND from perfect opposition, since
                      u depends only on |rho|.

u -> 1                f = k N^2 = 69.6133 Hz at N = 12. The maximum. Sustains iff
                      c/eta < ln N.

N -> infinity         the ceiling rises without bound, which the coordination-cost
                      literature says is not available in practice.

c/eta = ln N          f_min = k N^2. The ceiling. Section 7.2.
c/eta > ln N          the condition is unsatisfiable. NO arrangement works.
```

Every divergence corresponds to a real, nameable phenomenon, which is what a limit audit requires; a formula whose limits are nonsense is wrong even where it looks reasonable. **Two of these limits — $\eta \to 0^+$ and $\delta \to 1$ — are not examined in the source and are stated here for the first time.** The $u \to 0$ degeneracy is owned in this series by the routes paper [Curzi, 2026], whose Result One establishes that $\rho = +1$ and $\rho = -1$ both give $u = 0$, $F = 0$ and $f = k$: **a pair agreeing on everything and a pair agreeing on nothing produce the identical reading.**

6.8 Where the linear model stops applying, computed

Take the carried case as found: $\eta = 0.30$, $c = 0.62$, $\delta = 0.09$, $u = 0.068735$, so $\eta F = 0.168926$ and the per-period drift is -0.451075. Start at $Q_0 = 1.0$ and check admissibility $C_t \leq (1 - \delta)Q_t + \eta S_t$ at each step:

```
t = 0:  Q_t = +1.0000   right-hand side =  1.0789   c = 0.62   ADMISSIBLE
t = 1:  Q_t = +0.4589   right-hand side =  0.5865   c = 0.62   FAILS
t = 2:  Q_t = -0.0335   right-hand side =  0.1385   c = 0.62   FAILS
t = 3:  Q_t = -0.4815   right-hand side = -0.2693   c = 0.62   FAILS
```

Admissibility fails at $t = 1$. The stock goes negative at $t = 2$. The fixed point -5.0119 is never reached and was never going to be. A negative Q_∞ is therefore **a direction and a rate, not a destination**: it says the relation is losing order, it says how fast, and it says that the linear model will stop describing the system before the model's own answer arrives. What happens past $t = 1$ is outside this model — the parties renegotiate, reduce cost, or leave. **The model's job was to say that something must give, and it did that at $t = 1$.**

6.9 The formula through the validation protocol, gate by gate

The corpus's rule is that no formula appears without passing all seven gates in print. **$f_{\min}$ is a formula and the rule applies to it.**

gate	what it asks	verdict
G1 dimensions	units agree; ratios dimensionless	**CONDITIONAL** — both sides are hertz *given* P-b; c/η is dimensionless only under the convention of Section 3.4
G2 scale type	division needs a ratio scale	**CONDITIONAL** — passed by the user's instrument or not at all; Section 8 prices the failure
G3 limiting cases	behaviour at 0 and ∞ names a real phenomenon	**PASS** — Section 6.7, with two limits added that the source omits
G4 fixed points	solve for the invariant; state what it means	**PASS** — the invariant is $f = f_{\min}$, equivalently $Q_\infty = 0$, equivalently $u^* = (e^{c/\eta} - 1)/(N - 1)$
G5 identifiability	can parameters be recovered from obtainable data	**PARTIAL** — the verdict yes, the prescription no (Section 9.5)
G6 falsification	preregister, freeze, report held-out, beat baselines	**INHERITED** from the storage law, whose one attempt failed its own rule [Curzi, 2026i]
G7 reproducibility	same operationalisation, different analysts	**NOT ESTABLISHED**

A keystone that publishes its own open gates is more usable than one that claims seven passes. G1 and G2 are conditional, G5 is partial, and G7 has not been run. That is four of seven not cleanly passed, and it is printed here rather than in an appendix.

The baseline suite the G6 test would use has three measured holes, and a paper that recommends the test must publish them:

```
CC-R13a  the shuffled-input control is ANTI-CONSERVATIVE as ordinarily run.
         Against nominal alpha = 0.05 over 500 null trials:
             iid permutation    0.108   (2.2x nominal)
             circular shift     0.120   (2.4x nominal)
             block permutation  0.060   (near nominal)
```

```
          The matched-autoregressive comparison alone false-passed 35.8% of the time.
CC-R4     the shuffle cannot see repackaging. A filtered repackaging passed all four
          baselines (p = 0.0005) and was caught only by the structural ceiling test.
CC-R24    the shuffle cannot see a shared slow driver: it passed 98.35% of the time in
          a 4,000-trial simulation while detecting the clean case 48.17% of the time.
```

A measured false-positive rate of 0.108 against a nominal 0.05 belongs in the abstract of the paper that measured it, not in a footnote, and the replacement rule is *design controls, not more surrogates.* The corpus's survey work supplies the structural detector that the shuffle lacks [Curzi, 2026i].

6.10 The reading, as a procedure

```
1  FIX N.          Declare the category set and its ordering. State that the frequency
                   inherits exactly the defensibility of the count.
2  REPRESENT.      Elicit state vectors with OVERLAPPING SUPPORT. One-hot vectors give
                   u = 1.000000 for everyone and read the instrument, not the subject.
3  COMPUTE u.      u = 1 - (x . y)^2. One construction, used everywhere.
4  COMPUTE f.      F = ln(1 + (N-1)u);  f = k e^(2F). Report the folded value and its j.
5  MEASURE eta, c ON ONE CLOCK. Declare the period. Declare the scale status.
6  CHECK THE CEILING FIRST.  Is c/eta <= ln N ?
                  NO  -> the case is structural. Issue no tuning prescription.
                  YES -> continue.
7  COMPUTE f_min = k e^(2c/eta) AND D = 2.885390 (c/eta) - log2(f/k).
8  CROSS-CHECK.  Q_inf = (eta F - c)/delta, and verify D = -2.885390 (delta/eta) Q_inf.
                  If a negative Q_inf is reported, state the period at which
                  admissibility fails.
```

Step 6 is placed where it is deliberately. A ceiling check performed after the lever analysis is performed too late: a prescription has already been produced, and prescriptions are hard to withdraw once said out loud. The ceiling is cheap to test and it changes the *kind* of answer, so it goes first.

7 The two structural absences

7.1 Decay is not a lever on the deficit

THEOREM 7.1. D contains no δ.

Proof: by inspection of Definition 6.1 and of $f = k(1 + (N-1)u)^2$; neither contains δ. **QED.**

Consequence, and it is the single most practically important statement in this paper: an intervention that acts only on δ cannot change the deficit by any amount whatsoever. Trust, ritual, continuity and written record all act on δ. **They are not thereby useless — they change the rate of arrival and the resilience of the stock — but they do not change whether the relation is building anything at all.**

The sharper form is the sign trap. Because $Q_\infty = (\eta F - c)/\delta$ and δ appears in the denominator, **when the numerator is negative, reducing δ makes Q_∞ more negative.** Trust does not add order; it amplifies whatever sign the system already has. In the corpus's worked consortium this is measured: trust alone moved a fixed point from -0.0836 to -0.2114, reciprocity alone to $+0.7394$, and both together to $+1.8701$ (finding CC-R15). That consortium is carried in the trust paper [Curzi, 2026s], whose Result Four records the case at $u = 0.52$ collecting 73.8 per cent of its ceiling with a steady state of -0.0836 and headroom -0.4582, the binding fault being $\rho = 0.3824$ rather than difference.

Interpretive care is required here and the paper states it. The substantive premise — that trust reduces the loss rate rather than adding to the inputs — is an assumption of the framework's parameterisation, not a finding of this paper, and the trust literature it leans on is about reciprocity, monitoring and institutional form rather than about decay rates [Gambetta, 1988, Ostrom, 1990]. **If trust instead raises η, the arithmetic above does not apply.** Which of the two it does is an empirical question this paper does not settle.

7.2 The ceiling

THEOREM 7.2 — THE CEILING. Since $F \leq \ln N$ [Curzi, 2026], the condition $F > c/\eta$ is satisfiable only if

$$\frac{c}{\eta} \leq \ln N \qquad \text{equivalently} \qquad f_{\min} \leq kN^2$$

Proof: $F > c/\eta \geq \ln N \geq F$ is a contradiction. **QED.**

If $c/\eta > \ln N$, no arrangement of those N categories is sustainable. Not a better pairing, not a better schedule, not a better conversation. For $N = 12$: $\ln 12 = 2.484907$, $kN^2 = 69.61330555033166$ Hz, and $2.885390 \times \ln 12 = 7.169925$ octaves above k. **Above that, the relation cannot be tuned; it must be restructured.**

The corollary is a minimum category count, $N \geq e^{c/\eta}$:

```
c/eta = 0.5000  ->  N >=  1.6487  ->  N_min =  2
c/eta = 1.0000  ->  N >=  2.7183  ->  N_min =  3
c/eta = 1.5000  ->  N >=  4.4817  ->  N_min =  5
c/eta = 2.0000  ->  N >=  7.3891  ->  N_min =  8
c/eta = 2.4849  ->  N >= 11.9999  ->  N_min = 12
c/eta = 2.5000  ->  N >= 12.1825  ->  N_min = 13
c/eta = 3.0000  ->  N >= 20.0855  ->  N_min = 21
c/eta = 4.0000  ->  N >= 54.5982  ->  N_min = 55
```

The growth is exponential, and that is the whole content of the corollary. Going from $c/\eta = 3$ to $c/\eta = 4$ — a 33 per cent increase in relative cost — raises the minimum viable category count from 21 to 55. **Past a point, cost does not make a relation harder; it makes the relation's category set inadequate**, and category sets are expensive to enlarge honestly. A ceiling imposed by one parameter alone, independent of how the remainder is arranged, is a recurring shape in this corpus: the concentration atlas finds validator pools at HHI 0.1900 and 5.26 effective pools against a ceiling of $1/s^2_{\max} = 11.11$ that the leading share alone imposes [Curzi, 2026].

The ceiling test is the paper's cheapest and most consequential instrument because it changes the *kind* of answer. Below it a case is tunable and some assignment of u closes it; above it, no assignment does, and a prescription issued without the test may be unsatisfiable. **Unsatisfiable prescriptions are worse than no prescription, because they consume the effort that restructuring needed.**

8 The ordinal defeat, and the rule it motivates

8.1 The join is an error amplifier by construction

$$\frac{d \ln f_{\min}}{d(c/\eta)} = 2 \qquad \text{exactly}$$

Every unit of error in the cost-to-conversion ratio is two nats of error in the required frequency. An error of 0.1 in c/η is a 22.14 per cent error in $f_{\min}$; an error of 0.5 is a factor of 7.3891, which is 2.8854 octaves. Computed at five operating points:

c/η	implied interval in $f_{\min}$ (Hz)	width	width in octaves
1.0 ± 0.2	$[2.3944,\ 5.3289]$	$2.2255\times$	1.1542
2.0 ± 0.1	$[21.6097,\ 32.2379]$	$1.4918\times$	0.5771
2.0 ± 0.2	$[17.6925,\ 39.3754]$	$2.2255\times$	1.1542
2.0 ± 0.5	$[9.7099,\ 71.7467]$	$7.3891\times$	2.8854
2.4849 ± 0.2	$[46.6626,\ 103.8495]$	$2.2255\times$	1.1542

Since $D = 2.885390(c/\eta - F)$ and both terms carry error, **the deficit's uncertainty is** 2.885390 **times the combined uncertainty in nats: one nat of parameter uncertainty anywhere is** 2.885390 **octaves of uncertainty in the verdict.**

8.2 The relabelling test

Suppose c/η is known only ordinally. That is the honest condition for any parameter estimated from an unanchored rating instrument: one knows that site B costs more per unit of conversion than site A, and not by how much. **An ordinal scale is preserved by any strictly increasing relabelling.** Take three systems ranked $c/\eta = (1.0, 2.0, 3.0)$ and relabel them $(0.5, 2.0, 5.0)$. Every ordering is preserved and the ordinal content is identical. The frequencies are not:

```
labels (1.0, 2.0, 3.0)  ->  f_min = (    3.5721,  26.3942,    195.0279) Hz
labels (0.5, 2.0, 5.0)  ->  f_min = (    1.3141,  26.3942,  10648.1604) Hz
```

The third system's minimum sustainable frequency moves by a factor of 54.5982 **—** 5.7708 **octaves — under a relabelling that changes nothing an ordinal instrument can see.** This is not a large error bar. **It is the absence of a number.** An ordinal input to $f_{\min}$ does not yield an imprecise frequency; it yields no frequency at all.

What survives is the ordering and the sign of the verdict. Both labellings agree that system 3 requires more pitch than system 2 and system 2 more than system 1, and in the worked case of Section 9 the verdict DECAYS survives the whole admissible interval. **A coarse instrument is enough to tell you that something is wrong. It is not enough to tell you what to do**, and Section 9.2 shows the prescription flipping in kind inside the analyst's own error bar.

8.3 The audit-precedence rule, and three questions it reduces to

P-e, restated: a result may not be published above the level of audit available to check its inputs. A result whose inputs are known only ordinally may be published only as an ordering; one whose inputs are known on a ratio scale may be published as a magnitude. **The badge on a result is not decoration; it is the statement of which operations on that result are licensed.**

The rule is only useful if it can be applied from outside, so it is reduced to three questions a reader can put to any compact, powerful-looking formula — this paper's included.

Question one: what scale are the inputs on, and who says so? If the answer is *ratio, and here is the instrument*, the magnitude is reportable. If the answer is *ordinal*, or if there is no answer, the ordering is reportable and the magnitude is not. **A formula that divides two quantities and cannot name the true zero of either is producing a rank dressed as a number.** The relabelling test of Section 8.2 takes one line and is decisive.

Question two: what has this method rejected? Not what it has explained — what it has thrown out. **A method with no rejection history has never been in a position to reject.** This corpus's answer is on the record: its own moment equation demoted on scale [Curzi, 2026m], whose Result Two fixes the contact point $D = P$, $r = 1$, $M = E$ with unit elasticity in all three terms; its own rate-factor correction reversed to a factor of exactly 8; a 64-codon correspondence refused; and the evidential reading of a gematria hash killed by a 99.995 per cent collision rate destroying 10.47 bits (finding CC-R12).

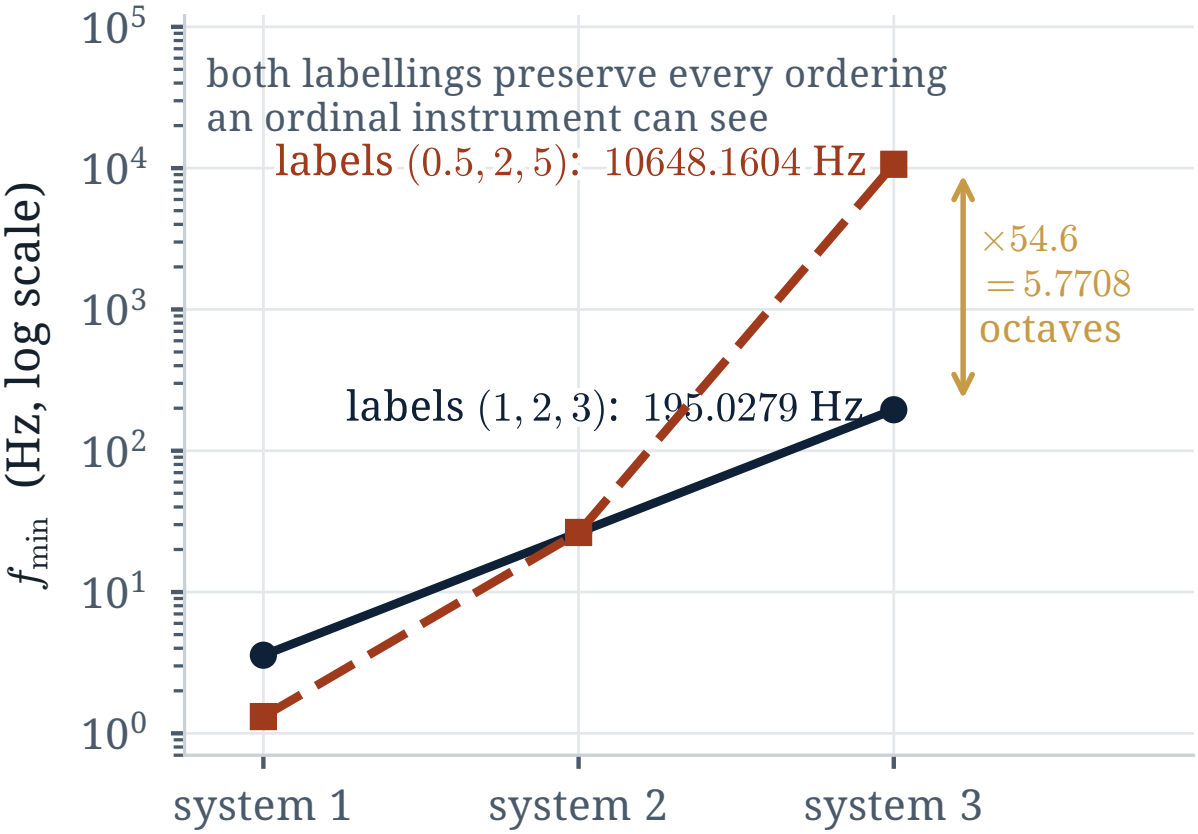

Figure 40.3: **An order-preserving relabelling of ordinally known parameters moves one system's threshold by** 5.7708 **octaves**, a factor of 54.6, while leaving every ordering an ordinal instrument could detect unchanged. Modelled from $f_{\min} = k\,e^{2c/\eta}$ with the **defined** constant $k = 0.483425732988414$; the two labellings are the source's. Built by `figs/src/CCP-040_fig03.py`.

Question three: how fast does the formula amplify error? Take the logarithmic derivative with respect to each input. **For $f_{\min}$ the answer is 2, and a formula with that property must ship with its sensitivity and not only its point estimate.** A formula that amplifies and does not say so is inviting confident wrong answers.

A work that can survive its own three questions is not thereby correct. It is checkable, which is the most any work can offer. This is a research-programme position rather than a naive falsificationist one [Lakatos, 1970, Popper, 1959], and the corpus's own honesty appendix is the instrument that enforces it [Curzi, 2026], whose counter-result assigns the corpus's central identification to the postulate drawer and states that one of its three postulates is a wager whose misfire column exists because wagers can lose.

8.4 Three corrections the audit produced

The claim is not that caution is a virtue. **The claim is that the audit found specific errors, in numbers this paper uses, that would have travelled into the keystone had the keystone come first.**

Correction one — the resolution cliff was in the wrong place, and the author's own repair was wrong and had to be reversed (CC-R21). Re-derived with exact rational arithmetic, the minimum folded gap is $9/8$ for $N = 3 \dots 6$, $50/49$ for $N = 7 \dots 16$, $289/288$ for $N \geq 17$ and $1682/1681$ for $N \geq 41$. **The published cliff had been at $N = 20$; it is at $N = 17$,** because $17^2 = 289$ folds beside $288 = 2 \cdot 12^2$ the instant index 17 enters the set. **And the rate penalty at the cliff is exactly 8, not the $288/49 = 5.878$ that had been asserted**, because the two binding pairs sit at different octave heights.

Correction two — the source table of the essence law contains data-entry errors, and one is provably impossible (CC-R5). $f = kn^2$ reproduces all 118 published element values to a worst relative deviation of 9.0×10^{-15}. The compound rule $f = k^2 G^4$ matches 37 of 44 published composites to better than one part in 10^{12}. **The seven that disagree are transcription faults, not evidence of a different law**, and the pure-diatomic row proves it: for a single-element species G is the element index whatever the atom count, so no atom count can produce the published figure. Two further faults travel with the citation: a prose instruction `1+5^.5/2` missing its parentheses, and φ stored to fifteen significant figures. **The standing rule that follows: do not copy published values, recompute them.** The audit is owned in this series by the operations paper [Curzi, 2026], whose Result Three derives the compound rule rather than asserting it.

Correction three — the intuitive repair makes it worse, and by how much (CC-R15). This is Section 7.1, and it is the correction most likely to be needed by a reader who has just finished reading the threshold result.

Each of these is a number this paper uses. The first governs how any of these frequencies can be rendered at all; the second governs the constant at the centre of every calculation; the third governs the single most common intervention a reader will reach for. **A keystone published before the audit would have carried all three forward into a diagnostic people were meant to act on.**

8.5 What the withholding cost

The corpus does not claim the delay was free. Readers who could have used an octave deficit to see that a bond was structurally short — not badly intentioned, not insufficiently loving, structurally short by a computable number of octaves — did not have it. **That is a real cost and it is not erased by the fact that the delay was correct.** Nor does the corpus claim the omission was foreseen in every detail: **some of it was design and some of it was discovery**, and several of the findings above arrived late enough that the join could not honestly have been made earlier. A narrative in which nothing was ever discovered, only unveiled, destroys the reader's ability to calibrate how much of the work was checked and how much was planned.

9 Worked example: the carried dyad

This case is CONSTRUCTED. Its parameters are chosen, not observed. No claim is made that any real pair of people has these values, nothing here is an assessment of anyone, and no clinical, diagnostic or prognostic claim is made or implied.

Two parties, A and B, each represented as a unit vector over the twelve-state ladder, components being the intensity with which a state is held, normalised to length one:

```
A = {4: 0.7, 6: 0.5, 9: 0.4}
B = {4: 0.6, 6: 0.55, 9: 0.3, 10: 0.2}

eta = 0.30    c = 0.62    delta = 0.09        (one declared period, N = 12)
```

9.1 Phase 2a — as found

Direction one, from the geometry to the pitch:

```
cos theta = 0.965021
u         = 1 − cos^2 theta        = 0.068735
F         = ln(1 + 11u)            = 0.563085 nats
N_eff     = 1 + 11u                = 1.7561
f         = k (1 + 11u)^2          = 1.4908 Hz     folded 381.644 Hz (j = 8)
octaves present = log2(f/k)        = 1.624719
```

Two parties, and an effective count of 1.7561**.** They are 1.76 parties' worth of distinct perspective; their represented states point 0.965 of the way in the same direction.

Direction two, from the operating parameters to the threshold:

```
c/eta            = 0.62 / 0.30            = 2.066667
ceiling check:     2.066667 <= ln 12 = 2.484907    BELOW -- a tuning problem, not structural
f_min            = k e^(2 ∗ 2.066667)     = 30.1588 Hz   folded 241.270 Hz (j = 3)
octaves required = 2.885390 ∗ 2.066667    = 5.963140
```

The join, and two independent cross-checks:

```
f = 1.4908 Hz  <  f_min = 30.1588 Hz                          =>  DECAYS

octave deficit D = 5.963140 − 1.624719   = +4.338420 octaves ( = +5206.1 cents )
ratio f_min/f    = 20.229940              = 4.338420 octaves  same number, stated twice
Q_inf = (0.30 ∗ 0.563085 − 0.62) / 0.09  = −5.0119           NEGATIVE
−2.885390 ∗ (0.09/0.30) ∗ (−5.011940)    = +4.338420         identity holds, err 8.88e−16
```

Three routes, one number. And the honest note that must travel with the negative fixed point: admissibility fails at $t = 1$ (Section 6.8). **The pair does not arrive at** -5.0119**. They arrive, one period in, at the point where something has to give.**

What the reading says: this bond is short by 4.34 octaves; the shortfall is a property of the geometry and the cost, not of anyone's intentions; and the case is *tunable*, because $c/\eta = 2.066667$ is below $\ln 12 = 2.484907$. **What it does not say:** that either party is deficient, that the bond should end, that anyone is at fault, or that anything about either party has been assessed. **The reading is of a configuration of four parameters. It is not a reading of a person.** The corpus's founding definition makes the same point structurally: the present state is a local minimum of the comfort landscape by definition rather than by luck [Curzi, 2026].

A second discrepancy found in the source and left standing. The source reports this case's deficit as $D = +4.338420$ from a reported $u = 0.068735$. Recomputing D from the *rounded* u gives $+4.338414$; recomputing from the underlying state vectors gives $+4.338420197$, which is the figure the source quotes. **The two disagree in the sixth decimal place because the printed u is rounded, not because either is wrong.** This paper quotes the vector-derived value in the worked example and the declared-parameter value in the twelve-set table of Section 6.1, where u is an input rather than a derived quantity. The same applies at phase 2b, where the vectors give $u = 0.69237163$ and $D = -3.590984$ while the table's declared $u = 0.692373$ gives $D = -3.590989$.

9.2 Reading the same case without a scale audit

Suppose the same analyst has the same three-line formula and no scale audit; η and c were estimated from a rating instrument that produces ranks, and the honest uncertainty on c/η is about ± 0.5 — which, for an ordinal instrument, is generous, since strictly the uncertainty is unbounded.

```
c/eta       f_min (Hz)   deficit    below ceiling?   prescription
1.566667      11.0948    +2.8957        yes          raise u to >= 0.344605
2.066667      30.1588    +4.3384        yes          raise u to >= 0.627132
2.566667      81.9801    +5.7811        NO           no arrangement of 12 categories works;
                                                      N must rise to at least 14
```

First: the verdict survives. At every point in the interval the bond decays, and $f = 1.4908$ Hz sits below the smallest $f_{\min}$ in the range by a wide margin.

Second: the prescription does not survive. At the low end the repair is a five-fold increase in represented difference; at the centre a nine-fold increase; at the high end **there is no value of u that works at all**, because $c/\eta = 2.566667$ exceeds $\ln 12$. **The prescription flips from *tune this* to *restructure this*, and the flip happens inside the analyst's own error bar.**

Third: the two prescriptions differ in kind, not degree. *Increase the difference between you* and *twelve categories are not enough to describe what you are doing, find at least fourteen* are not two settings of one dial. They are different projects, with different costs, aimed at different objects. **An instrument that cannot tell them apart is not a weak instrument; it is a misleading one, because it returns a confident number either way.**

9.3 The intervention the unaudited reading would have recommended

The analyst, seeing a decaying bond, proposes building trust, which in this framework acts on δ. Suppose the intervention succeeds completely and moves δ from 0.09 to 0.05:

```
before:  Q_inf = (0.30 * 0.563085 - 0.62) / 0.09 = -5.0119
after:   Q_inf = (0.30 * 0.563085 - 0.62) / 0.05 = -9.0215
```

The successful intervention made the destination 80 per cent worse. The numerator $\eta F - c = -0.451075$ is negative; dividing a negative number by a smaller positive denominator makes it more negative. **Trust did not add order. It amplified the sign the system already had, and the system's sign was negative.**

And the octave deficit did not move at all. It was $+4.338420$ before and $+4.338420$ after, because D contains no δ term whatsoever. **An instrument that reads unchanged while a well-intentioned intervention doubles the rate of loss is not a broken instrument. It is the instrument telling you that you have not touched the thing that is wrong.**

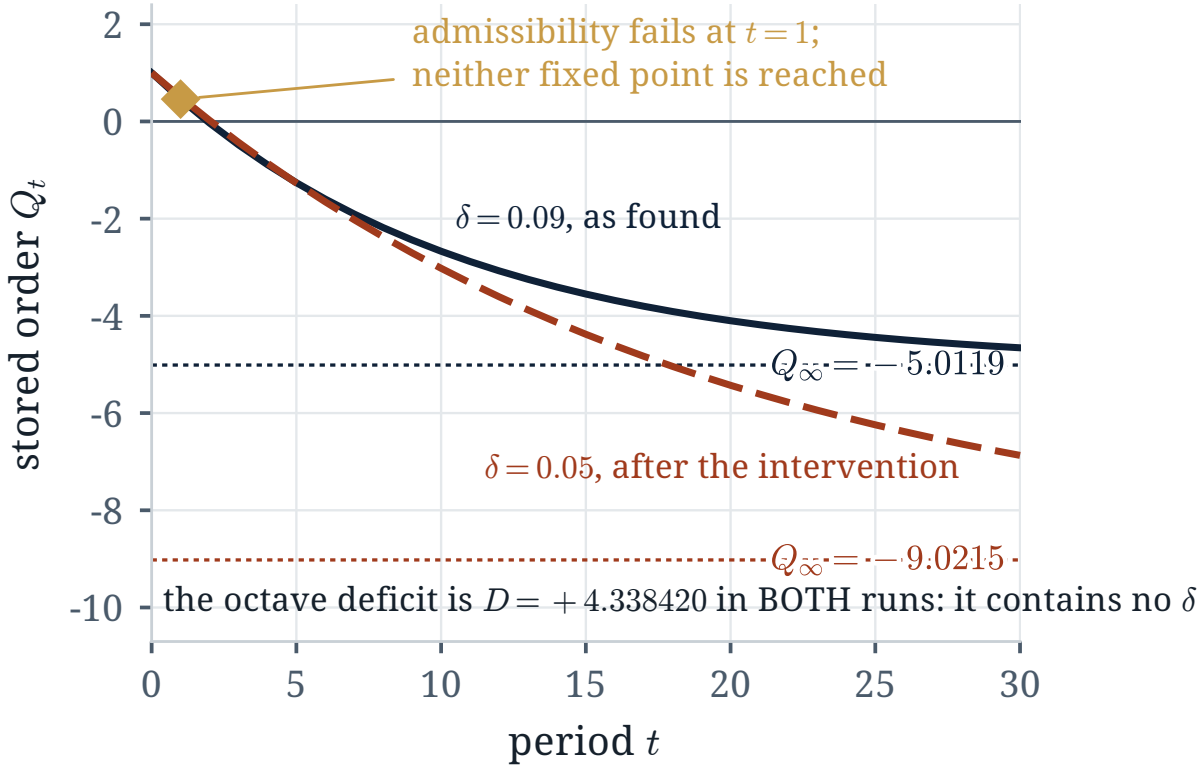

Figure 40.4: **A fully successful decay intervention worsens the destination by 80 per cent and leaves the diagnostic unmoved**: the octave deficit reads $+4.338420$ in both runs because it contains no δ, while the fixed point falls from -5.0119 to -9.0215. Admissibility fails at $t = 1$, so neither fixed point is reached and both are directions and rates rather than destinations. Modelled from $Q_{t+1} = (1 - \delta)Q_t + \eta F - c$ on the constructed carried dyad with $\eta = 0.30$, $c = 0.62$, $F = 0.563085$ nats and $Q_0 = 1.0$. Built by `figs/src/CCP-040_fig04.py`.

9.4 Phase 2b — after one intervention on the numerator

CONSTRUCTED. B takes on two states A does not hold, and the pair adopts a decision log. The first change raises u; the second raises η (interaction now sticks) and lowers c (coordination is cheaper when the record does the remembering). One realising vector, given for concreteness:

```
B' = {2: 0.95, 4: 0.60, 6: 0.55, 9: 0.30, 10: 0.20, 12: 0.8391}

cos theta = 0.554643    u = 0.692372    F = 2.153631 nats    N_eff = 8.6161
f = k * 8.6161^2 = 35.8881 Hz    folded 287.104 Hz (j = 3)   octaves present = 6.214066

eta = 0.44    c = 0.40    delta = 0.09
c/eta = 0.909091     ceiling check: 0.909091 <= 2.484907   BELOW, comfortably
f_min = k e^(2 * 0.909091) = 2.9782 Hz    folded 381.212 Hz (j = 7)
octaves required = 2.623082

D = 2.623082 - 6.214066 = -3.590984 octaves  ( = -4309.2 cents )       ACCUMULATES
```

Cross-checks:

```
Q_inf = (0.44 * 2.153631 - 0.40)/0.09 = +6.0844
-2.885390 * (0.09/0.44) * 6.0844      = -3.590984          identity holds
trajectory from Q_0 = 1.0:   t=1 +1.4576   t=5 +2.9116   t=20 +5.3134   t=40 +5.9675
admissibility holds at every step, since the drift is positive
convergence:  |Q_20 - Q_inf|               = 0.7710275635960624
              (1-0.09)^20 * |Q_0 - Q_inf|   = 0.7710275635960623
```

The bond has moved from 4.34 octaves short to 3.59 octaves in surplus — a swing of 7.93 octaves. In the fixed-point register the same swing is -5.0119 to $+6.0844$.

One structural note the join makes visible and neither half did. At phase 2b, $F = 2.153631$ against a ceiling of $\ln 12 = 2.484907$, so the pitch headroom is $2.885390 \times (2.484907 - 2.153631) = 0.9559$ octaves. **The repair worked, and it worked by spending most of the range that twelve categories make available.** At 2a there were 5.5452 octaves of headroom; at 2b there are 0.9559. **Further gains of the same kind are not available from this category set at all** — they would require raising N, which means finding genuinely distinct categories rather than finer gradations of the twelve.

Neither half of the equation says this on its own. The bridge gives a pitch with no threshold; the storage law gives a verdict with no ceiling in view. Joined, the reading places the relation on a scale with a top, and says how much of the scale is left.

9.5 The two routes checked against each other

Section 6.3 claimed two independent routes to the verdict. The carried case at phase 2b lets both be run.

Route A, through the geometry. Elicit the vectors, get $u = 0.692372$, get $F = 2.153631$, get $f = 35.8881$ Hz; measure $\eta = 0.44$ and $c = 0.40$, get $f_{\min} = 2.9782$ Hz; the deficit is -3.590984.

Route B, through the ledger. Observe the stock over periods and fit. From $Q_0 = 1.0$ the observed series is $1.0000,\ 1.4576,\ 1.8740,\ 2.2530,\ \ldots$, converging on $+6.0844$ with a transient half-life of 7.3496 periods. Fitting $\delta = 0.09$ from the decay of the transient and Q_∞ from the asymptote, the deficit follows as $-2.885390 \times (0.09/0.44) \times 6.0844 = -3.590984$.

The two routes share no measurement and agree to 10^{-15}. Route A used no history at all; Route B used no elicitation at all. **Where both are available, the framework can be checked against itself, and disagreement localises the fault.**

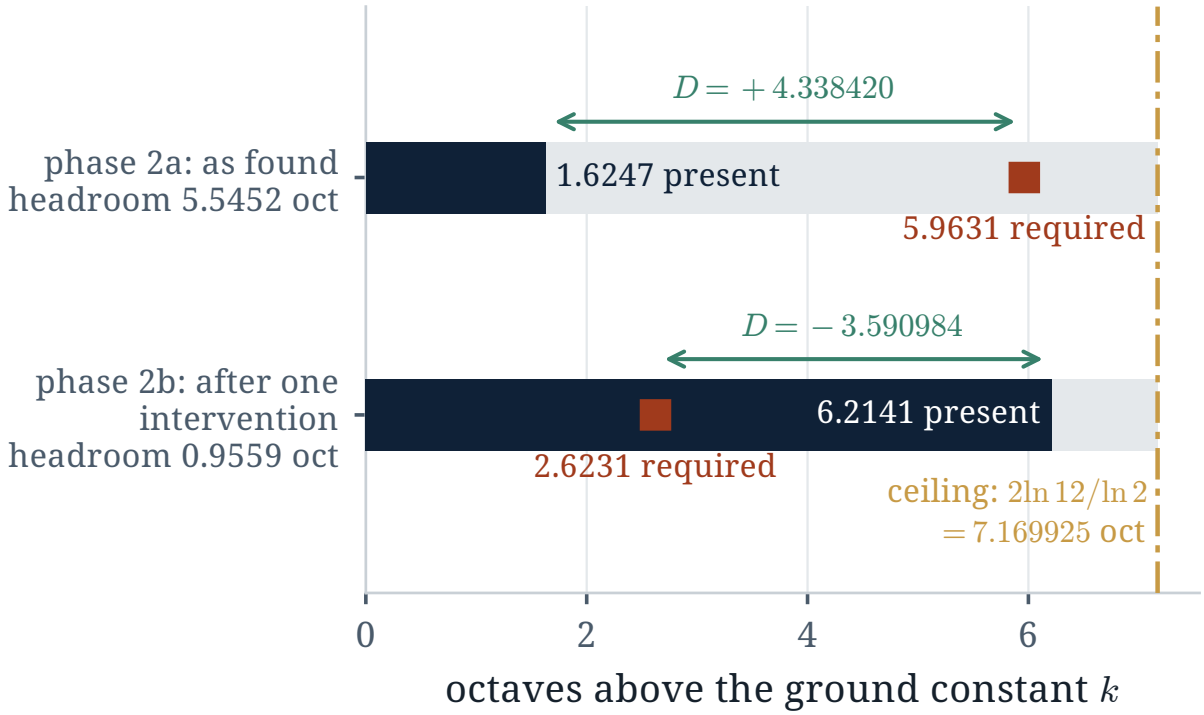

Figure 40.5: **One intervention converts a $+4.338420$-octave deficit into a -3.590984-octave surplus, and spends most of the range twelve categories allow**: pitch headroom falls from 5.5452 to 0.9559 octaves against the ceiling $2\ln 12/\ln 2 = 7.169925$. Modelled from the constructed carried dyad at its two phases with the **defined** constant $k = 0.483425732988414$ and $N = 12$. Built by `figs/src/CCP-040_fig05.py`.

And the asymmetry predicted in Section 6.3 is visible: Route B cannot tell you what to do. From the ledger alone, $\eta F - c = +0.547598$ is one number, and there is no way to know which decomposition produced it. Two admissible decompositions, both consistent with every observation Route B can make:

```
eta = 0.44,  F = 2.153631  (u = 0.692372)   ->  f = 35.8881 Hz,  pitch headroom 0.9559 oct
eta = 0.50,  F = 1.895197  (u = 0.513987)   ->  f = 21.4031 Hz,  pitch headroom 1.7015 oct
```

Identical ledgers. Identical verdicts. Different amounts of room left, and therefore different next moves. The first pair has nearly exhausted what twelve categories can give them and must raise N to gain more; the second still has most of an octave and a half to buy in u. **Route B says the bond accumulates. Only Route A says how much scale is left, which is the fact that determines what to do next.** This is gate G5 failing informatively rather than silently, and it is why a reading that reports a verdict without its geometry is incomplete.

10 Results

The six results below are the units other papers in this corpus cite. A citation to this paper should name one of them. Each carries its status: **DERIVED** where it follows from the stated definitions by algebra, **COMPUTED** where it is the output of exact arithmetic on stated parameters, and **POSTULATED** where it is asserted by this framework.

R1 — the join. $f_{\min} = k\, e^{2c/\eta}$ with $k = 0.483425732988414$ Hz (defined constant, exact; the hertz postulated, §2.3 P-b), derived as an equivalence: $Q_\infty > 0 \iff \eta F(u^*) > c^* \iff f > f_{\min}$. *Status:* DERIVED from the storage-law fixed point [Curzi, 2026a] and the essence bridge [Curzi, 2026k], conditional on P-a, P-b and P-d. **Verified at twelve constructed parameter sets with sign agreement in all twelve**, including the exact-equality case at the ceiling.

R2 — the deficit identity. $D = 2.885390\,(c/\eta - F) = -2.885390\,(\delta/\eta)Q_\infty$. The octave deficit and the steady-state gauge are the same number in different units. *Status:* DERIVED, cross-checked at a worst residual of 8.88×10^{-16} over the twelve sets by two routes sharing no intermediate quantity — floating-point round-off, not measurement error. The constant $2/\ln 2 = 2.885390081777927$ is exact. **This is the result the criterion paper carries forward as its Result Three [Curzi, 2026].**

R3 — the two absences. $f_{\min}$ contains neither δ nor N: retention loss sets the rate of arrival but not the threshold, and the category count enters only through the admissibility ceiling $c/\eta \le \ln N$, equivalently $f_{\min} \le kN^2 = 69.6133$ Hz at $N = 12$. *Status:* DERIVED by inspection and from $F \le \ln N$ [Curzi, 2026].

R4 — the ordinal defeat. $d \ln f_{\min}/d(c/\eta) = 2$ exactly, so an error of 0.1 in c/η is a 22.14 per cent error in $f_{\min}$, and relabelling $(1.0, 2.0, 3.0)$ as $(0.5, 2.0, 5.0)$ — an order-preserving relabel that no ordinal instrument can detect — moves one system's $f_{\min}$ by a factor of 54.5982, which is 5.7708 octaves. *Status:* COMPUTED. **With c and η known only ordinally, $f_{\min}$ is not known as a number at all; only its ordering and the sign of the verdict survive.**

R5 — the worked dyad. On the constructed carried case, $\eta = 0.30$, $c = 0.62$, $\delta = 0.09$ gives $f = 1.4908$ Hz against $f_{\min} = 30.1588$ Hz, an octave deficit of $+4.338420$ (5206.1 cents) and $Q_\infty = -5.0119$, with admissibility failing at $t = 1$. **The sign of the verdict is robust across the whole admissible interval where the number is not**; the prescription flips from *tune* to *restructure* inside the analyst's own error bar. *Status:* COMPUTED on a constructed case.

R6 — the sign trap. With $\eta F - c$ negative, reducing δ from 0.09 to 0.05 moves Q_∞ from -5.0119 to -9.0215, so **a fully successful intervention on retention makes the destination 80 per cent worse**, while D stays at $+4.338420$ to every printed digit. *Status:* DERIVED by inspection; COMPUTED on a constructed case. **This is the paper's sharpest result and it is negative.**

CR — counter-result. *The paper's own keystone formula is demoted by the paper.* With c and η known only ordinally, $f_{\min}$ moves by 5.77 octaves under an order-preserving relabel and so is not known as a number at all; and the worked case shows a fully successful intervention on retention making the equilibrium 80 per cent worse because the numerator was negative.

To these the framework adds three of its own: **the constant k is chosen, the affine effective count is not a Hill number, and the interpretation of k as a frequency is postulated.** The corpus reaches structurally parallel self-demotions elsewhere — every defensible bloc assignment in its architecture paper returns a negative surplus and the paper says so in print [Curzi, 2026]; its currency work finds an operating leg that lowers the effective count it was proposed to raise [Curzi, 2026]; and its concentration atlas refuses the reading that would make it useful as a ranking [Curzi, 2026].

11 Discussion

11.1 What follows

The classification is worth more than any single magnitude. The ceiling test costs one logarithm and changes the *kind* of answer a reading gives. Below the ceiling a case is tunable; above it, no assignment of u closes it. Since the verdict survives ordinal inputs and the magnitude does not, **the instrument's defensible output is a classification and an ordering, not a frequency**, and that is a smaller claim than the notation suggests.

The two gauges disagree, and both are right. Headroom uses the ceiling $\ln N$ and asks what the best possible geometry could support; the deficit uses the achieved F and asks what this geometry is doing. **A system can have room to grow in principle and be shrinking in fact.** Computed on the carried case at $Q = 1$: $h = 0.30 \times 2.484907 - 0.09 - 0.62 = +0.0355$ while $Q_\infty = -5.0119$. Both are correct, and a reading must report both and say which question each answers.

The negative result generalises past this framework. The structure of D's independence from δ is that **a multiplicative parameter cannot change the sign of the quantity it multiplies.** Any model in which a rate of loss divides a net drive has the property. Analogues are easy to find and worth naming: redundancy can reduce safety rather than increase it [Sagan, 1993]; interactive complexity with tight coupling makes catastrophic failure a system property rather than an operator error [Perrow, 1984]; and organisational learning that homogenises the organisation destroys the variance that produced its advantage [March, 1991]. **In each case the intuitive intervention operates on the wrong term.**

11.2 What does not follow

A reading does not conclude that a relation should end. $D > 0$ says a configuration is losing order at a computable rate under stated parameters. It does not weigh what the relation is for, what else it produces, or what ending it would cost, and the formalism contains no term for any of those.

A reading is not about a person. u is a property of two representations jointly; c and η are properties of an arrangement. **There is no single-party term anywhere in the apparatus.**

A reading is not clinical. The twelve states are not diagnoses, the ladder is not an assessment instrument, and the deficit is not a prognosis.

The algebra is not evidence. The derivation is compact and contentless: four strictly increasing transformations applied to an inequality. **The empirical content is in η, c, u and N, and the algebra cannot supply any of it.**

11.3 Relation to the frequency register

The reason for expressing the criterion as a pitch is that **intervals compose and hertz do not.** Two relations with different costs are compared on the octave scale directly, and the exchange rate is a single exact constant. The apparatus for that — cents, octave equivalence, interval arithmetic — is standard once an index exists [Rossing et al., 2002, von Helmholtz, 1885, Benson, 2006]. **What the apparatus does not carry with it is any claim about hearing.** Consonance

depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005]; interval categories and octave equivalence generalise less far across listeners and species than is usually assumed [Burns, 1999, Hoeschele et al., 2012]; and the octave's perceptual specialness, while real, has a measured and finite size [Demany et al., 2013]. **This paper uses the arithmetic and asserts none of the psychoacoustics.** Where the corpus's frequencies do meet real acoustics it is in a derived room [Curzi, 2026l], whose Result Two fixes $7.2400 \times 4.3798 \times 2.9319$ m, $V = 92.969$ m^3 and an RT60 of 0.5 s requiring 29.94 m^2 sabins — **and that is a statement about a room, not about a person.**

The consonance apparatus itself is a chosen function on rationals rather than a measured fact about hearing, and its two classical forms — a harmonic-distance measure [Tenney, 2015] and a *gradus suavitatis* [Euler, 1739] — are badged that way by the consonance paper in this series [Curzi, 2026], whose Result One is the doubling theorem $\mathrm{HD}_{\mathrm{ess}}(i, j) = 2\log_2(pq)$ verified exactly over all sixty-six index pairs at $N = 12$.

11.4 The reflexive exposure

The framework's foundations identify a self-fulfilling loop whose fixed point is a prophecy that makes itself true [Curzi, 2026]. **The exposure is direct: an instrument that issues a verdict of DECAYS on a relation may change the relation by issuing it.** The mechanism is documented [Merton, 1948, Rosenthal and Jacobson, 1968] and has been caught happening in the field, with dates and prices, as a theory became true by being used [MacKenzie and Millo, 2003]. But the effect sizes are contested [McCambridge et al., 2014] and, on the best long-run assessment, **self-fulfilling prophecies are real but small, do not typically accumulate, and often dissipate** — most expectations turn out to be accurate rather than causal [Jussim and Harber, 2005]. **The reflexive exposure is therefore real and probably smaller than the framework's rhetoric implies**, and the correct response is not to suppress the reading but to publish the parameters that produced it so a third party can recompute it. That is also why any indicator adopted as a target degrades as an indicator [Campbell, 1979, Goodhart, 1975].

11.5 What the surrounding programme allows this paper to claim

The title of the wider corpus places this work in a lineage that begins with *physique sociale* [Quetelet, 1835] and continues through the modern computational programme [Lazer et al., 2009, Pentland, 2014]. **The lineage's characteristic error is Quetelet's**: treating the mean of a distribution as a type rather than as a statistic. This paper inherits that risk directly, because it writes a single u, η and c for an arrangement, and it responds with a rule — no aggregation — rather than with an argument.

Three constraints from that programme bear on the central object of this paper and are not comfortable. First, human activity is bursty, with heavy-tailed waiting times and **no characteristic time scale** [Barabási, 2005]; a *minimum sustainable frequency* is a claim about a characteristic scale and can meet that finding only by insisting that its frequency is a position on a surplus scale and not a rate of any observed process. Strong spatial regularity coexisting with temporal burstiness [González et al., 2008] is the counterweight but not a rescue. Second, an explanation is supposed to name a mechanism rather than exhibit a fitted curve [Hedström and Ylikoski, 2010]; **this paper fits nothing, which sidesteps the objection at the cost of having no empirical content to fit.** Third, and most sharply: **what observation would distinguish this framework's laws from a neighbouring model that fits equally well?** [Sobkowicz, 2020, Durlauf, 2005] The honest answer is H3 — the ceiling is a strict universal and one counterexample kills it — and nothing else in this paper answers it.

What the paper is entitled to claim is therefore narrow. Prediction is one of many legitimate reasons to build a model, and explanation, bounding, and the disciplined exposure of one's own assumptions are others [Epstein, 2008]. The position this work is best placed to defend is the analytical one: mechanisms stated explicitly, parameters declared, and the arrangement within which the law is claimed named in advance [Keuschnigg et al., 2018]. The

directional-prediction critique [Meehl, 1990] is worth meeting explicitly: the corpus makes **point** predictions with constants rather than directional ones, which is the right response, and it makes them from postulates whose status is printed.

12 Verification

This section decomposes every result into atomic steps, each checkable on its own. The standard is Occam's: **a postulate that can be dropped without the result changing has been dropped.** Every step carries one of four statuses: **ARITHMETIC** (reproducible by a reader with a calculator from the inputs named), **DEFINITION** (true by stipulation; nothing to verify but consistency of use), **CITED** (an external source supports it — the key is named), or **POSTULATED** (asserted by this framework, with no external support).

12.1 The postulates

	postulate	status
P1	The Pythagorean whole tone is the frequency ratio $9{:}8$.	CITED [Barbour, 1951]
P2	φ is the positive root of $x^2 = x + 1$; hence $\varphi^2 = \varphi + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P3	A dimensionless ratio of the form $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source
P4	The essence of a state with n distinguishable components has frequency kn^2.	POSTULATED — no source
P5	Stored order obeys $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$ with $\delta > 0$.	CITED as a form [Oppenheim et al., 1996, Elaydi, 2005]; the *interpretation* POSTULATED
P6	$N_{\text{eff}} = 1 + (N-1)u$ (the affine count axiom S3).	POSTULATED — design axiom [Curzi, 2026]; **not a Hill number**
P7	$F = \ln N_{\text{eff}}$, so $F \le \ln N$.	DEFINITION (given P6)
P8	c is expressed in nats of surplus per declared period, so c/η is dimensionless.	**CONVENTION — stated here, absent from the source**
P9	$n_{\text{eff}} := N_{\text{eff}}$: the bridge feeds an effective count to a law that takes an integer count.	POSTULATED — modelling decision

Dropped as unnecessary. No postulate about the *ordering* of the twelve states is needed for R1 through R6: the trichotomy, the identity, the two absences, the ceiling and the ordinal defeat all hold for any N and any $u \in [0, 1]$ whatever the states are called. No postulate about consonance, about octave folding, or about rendering is needed anywhere in this paper. **The time–frequency bound of Section 4.11 contributes no term to any result and is retained only as a constraint on what may be done with the answer.**

12.2 The compounding chain

step	consumes	produces	status
L1	P1	$(9/8)^2 = 81/64 = 1.265625$ exactly	ARITHMETIC
L2	P2	$\varphi^2 = \varphi + 1 = 2.618033988749895$	ARITHMETIC
L3	L1, L2	$k = 0.483425732988414$	ARITHMETIC (exact)
L4	L3, **P3**	k carries the unit Hz	**POSTULATED**
L5	L4, **P4**	$f(n) = kn^2$ Hz	**POSTULATED**
L6	P6, P7	$F = \ln(1 + (N-1)u)$, $F \le \ln N$	DEFINITION
L7	L5, L6, **P9**	$f = k\,e^{2F}$, the essence bridge	ARITHMETIC given L5 and P9
L8	P5	$Q_\infty = (\eta F - c)/\delta$ for $\delta > 0$	ARITHMETIC
L9	L8	$Q_\infty > 0 \iff \eta F - c > 0 \iff F > c/\eta$	ARITHMETIC ($\delta > 0$, $\eta > 0$)
L10	L7	$F = \frac{1}{2}\ln(f/k)$; the bridge is a strictly increasing bijection	ARITHMETIC
L11	L9, L10, **P8**	$f \gtreqless f_{\min} \iff Q_\infty \gtreqless 0$ — **R1**	ARITHMETIC given P8
L12	L11	$\log_2(f_{\min}/k) = (2/\ln 2)(c/\eta)$; the constant is 2.885390081777927, exact	ARITHMETIC
L13	L12, Def. 3	$D = 2.885390\,(c/\eta - F)$	ARITHMETIC

L20	L8, L15, constructed parameters	$\delta : 0.09 \to 0.05$ gives $Q_\infty : -5.0119 \to -9.0215$, D unchanged — **R6**	ARITHMETIC

12.3 What this chain is and is not

Read the status column. Steps L1, L2, L3 and L8 through L20 are arithmetic and a reader can redo every one of them. **Steps L4 and L5 are postulated, and step L11 rests additionally on a convention (P8) that the source never states.** A chain containing postulated steps is not a proof of its conclusion, and this one is not offered as one.

What it is offered as is a separation. The storage algebra and the octave arithmetic are solid; the frequency interpretation sitting on top of them is not. Anyone who accepts P3, P4 and P9 gets R1 through R6 by arithmetic alone. **Anyone who rejects all three still gets R1 through R6 in *surplus* units**, because the deficit is a difference of logarithms in which k cancels: the sustainability verdict never depends on the postulated constant, only the hertz values do. **That separability is the strongest claim this paper makes about its own foundations.**

Two statuses that must not be misread. The exponent 2 at L5 is **DEFINED**, not estimated: no fit was performed and the standard procedure for testing a scaling claim [Clauset et al., 2009] was not run. The logarithm at L6 is **DEFINITION** given the affine axiom P6, and the warrant the argument needs for it is the multiplicative-dynamics one [Peters and Gell-Mann, 2016] rather than the psychophysical one.

The falsifiable content lives at L8 and L6, not at L4 and L5. H1 through H3 test the storage law's fixed point, its sign and its ceiling; none of them requires the essence bridge to be true. **This paper's empirical exposure is therefore smaller than its notation suggests, and its unsupported material is correspondingly more inert.**

13 Limitations

Every check the governing rigour standard specifies is listed here by name, whether or not this paper passes it.

L-1. The dimensional audit does not close. $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, and k is computed as a ratio of two dimensionless quantities. **No operational procedure is supplied by which the constant acquires the dimension of frequency.** The hertz is attached by assertion (§2.3 P-b, §3.4). This is the paper's largest structural weakness and no citation in the bibliography repairs it.

L-2. The exponent of the join is dimensionless only by an unstated convention. c/η carries $[\mathcal{C}\,T^{-1}]$ divided by a pure number and cannot be an exponent without a convention; **the source never states the convention.** It is stated here (P8), and **every reading in this paper depends on it being applied consistently.** Its failure mode is measured at $90.1\times$ (finding CC-R16).

L-3. The essence law has no external support. A quadratic relation between a dimensionless count and a frequency has no established analogue in psychoacoustics, ecology or measurement theory. **The badge is the honest position and is not a defence.**

L-4. The constant is chosen. $k = (9/8)^2/\varphi^2$ combines two real objects into a product with no precedent. It is quoted to fifteen significant figures **because it is defined**, not because anything was measured to that precision. Golden-section claims have a deflationary literature that this paper cites rather than avoids [Markowsky, 1992, Fischler, 1981].

L-5. Octave reduction beyond pitch is unwarranted. Octave equivalence is grounded for pitch [Shepard, 1982]; nothing grounds folding a non-acoustic quantity into a 220–440 Hz band and reading meaning from where it lands. **The operation is well defined; its interpretation is not supported.**

L-6. $N_{\mathbf{eff}} = 1 + (N-1)u$ **is not a Hill number.** It is a linear interpolation between 1 and N and appears in no ecological, economic, political-science or information-theoretic literature. The Hill-number citations in this paper apply to $1/\mathrm{HHI}$ and $\exp(H)$ and to nothing else [Hill, 1973, Laakso and Taagepera, 1979].

L-7. The design axiom S3 is load-bearing and unargued. Everything in this paper uses N_{eff}, and N_{eff} is defined by an axiom that selects one curve out of a family agreeing at both endpoints and diverging by **33.62 per cent** at $u = 0.5$. **Nothing in this paper is safe from S3.**

L-8. Conjoint measurement was not tested. The ratio-scale treatment of η, c and δ is provisional. Michell's objection [Michell, 1997] stands unanswered for every quantity in this paper except the counts, and the available remedies [Luce and Tukey, 1964, Rasch, 1960] were not run. **Section 8 computes what the failure of this check is worth: 5.77 octaves.**

L-9. The scalar-reduction habit is a single defect with two faces, and the paper concedes both. Michell's objection and the appraisal literature's objection are the same objection in two domains. The affect literature describes emotional states as **patterns across simultaneously varying appraisal dimensions** [Smith and Ellsworth, 1985], as **processes in time whose state is a synchronisation** [Scherer, 2001], as individuated by **qualitative core relational theme** [Lazarus, 1991], and as located on **continuous bipolar axes** rather than counted [Russell, 1980]. **A count discards exactly the information those accounts carry.** The ladder's top rung is contradicted specifically: action readiness is held to be constitutive of emotion as such rather than a late addition [Frijda, 1986], and this paper narrows the rung to *bound commitment* in response — **a narrowing, not an answer.** Two rungs survive intact [Tracy and Robins, 2004, Premack and Woodruff, 1978]. **Every reading in this paper that passes through the ladder inherits this concession.**

L-10. Reproducibility (gate G7) has not been run. Whether the same operationalisation of u, η and c recovers the same parameters across analysts and across sites is unknown for these constructs. **No result in this paper may be reported as reproducible.**

L-11. Identifiability is partial (gate G5). From a fitted trajectory alone only $\eta F - c$ is recoverable. **Route B gives the verdict and not the prescription**, and Section 9.5 exhibits two decompositions with identical ledgers and different next moves.

L-12. The baseline suite is anti-conservative. The shuffled-input control measures 0.108 against a nominal 0.05 (CC-R13a), is blind to repackaging (CC-R4), and is blind to a shared slow driver, passing 98.35 per cent of the time (CC-R24). **A paper that recommends the test must publish the holes, and these are they.**

L-13. Every case is constructed. The dyad's precision is exact because its parameters are exact; **that precision does not transfer to a measured case.** Reporting $f_{\min} = 30.1588$ Hz from an η known to one significant figure would be false precision, and the rule is that measured or fitted quantities require an uncertainty. **None of this paper's numbers are measured.**

L-14. No model comparison was performed. No out-of-sample test, no matched null with the same number of free parameters, and no information criterion is reported, because nothing was fitted. The corpus's one confirmatory attempt failed its own baseline test [Curzi, 2026i].

L-15. No statistical claims are made and none are supported. There are no p-values, no effect sizes and no confidence intervals in this paper, because there is no sample.

L-16. The functional form is underdetermined. A power law with exponent below one [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as the logarithm, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. **Nothing in this paper discriminates among them.**

L-17. The exponent is defined, not estimated. The exponent 2 in $f(n) = kn^2$ was not fitted, was not tested against alternatives, and the standard procedure for a scaling claim [Clauset et al., 2009] was **not run because there is no data to run it on. This paper makes no empirical scaling claim.**

L-18. The reflexive specification is not identified. The endogenous social effect in a linear-in-means reflexive loop cannot be recovered from observational data [Manski, 1993, Shalizi and Thomas, 2011]. The remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001], and the claim is accordingly **a modelling position rather than an identified empirical result.**

L-19. The framework exempts its own parameters from its own reflexivity. If subjects change when modelled, δ, η and u are not structural [Lucas, 1976, Hacking, 1995]. **This is not resolved.**

L-20. There is no conservation law. Q is written with the grammar of a conserved quantity

and no conservation law is supplied, which is the characteristic defect of the genre [Mirowski, 1989]. Validity is claimed only within a specified arrangement [Cartwright, 1999].

L-21. Ergodicity is assumed and not argued. Q accumulates over time for one relation from parameters that would naturally be estimated across relations; the time and ensemble averages of a multiplicative process are not the same [Peters, 2019].

L-22. u is symmetric and psychological similarity is not. Similarity judgments are asymmetric and violate the triangle inequality [Tversky, 1977]; this framework's u assumes metric behaviour.

L-23. Boundary behaviour was incompletely examined in the source. $\eta \to 0^+$ makes c/η diverge and therefore places **every** relation above **every** ceiling — a real constraint on the model's domain that **the source does not examine**; $\delta \to 1$ is likewise unexamined. Both are stated in Section 6.7 for the first time. $N \to \infty$ raises the ceiling without bound, which the coordination-cost literature says is not available in practice [Brooks, 1975].

L-24. The trust mechanism is an assumption, not a finding. Section 7.1's sign trap depends on trust acting through δ rather than through η. **The literature this paper cites for trust [Gambetta, 1988, Ostrom, 1990] is about reciprocity, monitoring and institutional form, not about decay rates**, and which channel trust operates through is not settled here.

L-25. The 2.885390 shorthand is a rounded constant. The exact value is $2/\ln 2 = 2.885390081777927$. Where the text writes 2.885390 inside a formula it is a shorthand for the exact constant; every computed figure uses the exact value.

L-26. A published reading can change what it reads. The self-fulfilling exposure of Section 11.4 is not controlled for and cannot be controlled for by an instrument acting alone.

L-27. Two errors found in the source and printed rather than corrected silently. The twelve-set table's ceiling row prints $c = 2.485$, which exceeds $\ln 12 = 2.484906649788$ and therefore does not produce the exact zeros the row reports; recomputing from the printed value gives $Q_\infty = -0.0013$ and $D = +0.000269$. And the carried dyad's printed $u = 0.068735$ is a rounding of 0.06873466526463, so recomputing D from the printed intermediate gives $+4.338414$ against the vector-derived $+4.338420197$. **Neither is an error in the theorem; both are roundings, and both will be found by any reader who recomputes.**

14 Conclusion

What is established. Given the storage law and the surplus functional, the sign of the steady state is *equivalent* to a threshold comparison in frequency units, $Q_\infty \gtreqless 0 \iff f \gtreqless f_{\min}$ with $f_{\min} = k\,e^{2c/\eta}$, verified at twelve constructed parameter sets with sign agreement in all twelve. The octave deficit and the steady state are algebraically the same quantity, $D = 2.885390(c/\eta - F) = -2.885390(\delta/\eta)Q_\infty$, cross-checked by two routes sharing no intermediate quantity to a worst residual of 8.88×10^{-16}. **The threshold contains neither the decay rate nor the category count:** decay sets the rate of arrival and not the bar, and the category count enters only through the ceiling $c/\eta \le \ln N$, equivalently $f_{\min} \le kN^2 = 69.6133$ Hz at $N = 12$. Consequently an intervention acting only on decay changes the deficit by **exactly zero** and multiplies the existing sign of the steady state: on the constructed carried dyad a fully successful intervention moving δ from 0.09 to 0.05 takes Q_∞ from -5.0119 to -9.0215 — **80 per cent worse** — while D holds at $+4.338420$ octaves to every printed digit. All of this is arithmetic on stated definitions, and none of it depends on the value of k.

What is demoted, by this paper, about this paper. Because $d\ln f_{\min}/d(c/\eta) = 2$ exactly, an order-preserving relabelling of ordinally known parameters — $(1.0, 2.0, 3.0)$ to $(0.5, 2.0, 5.0)$, invisible to any ordinal instrument — moves one system's threshold by a factor of 54.5982, which is 5.7708 octaves. **With c and η known only ordinally, $f_{\min}$ is not an imprecise number; it is not a number.** What survives is the ordering and the sign of the verdict, and the worked case shows the *prescription* flipping in kind — from *tune this* to *restructure this* — inside the analyst's own error bar.

What is proposed rather than shown. That a dimensionless ratio of a tuning interval to

the square of the golden section is a frequency; that the essence of an n-component state is kn^2; that an effective count may be substituted for an integer count in that law; and that c is measured in the same units as F so that c/η can be an exponent. **The first three are postulates of this framework with no external support and the fourth is a convention the source never states.** They are labelled at every appearance and they are separable from everything above: **a reader who rejects all four keeps the equivalence, the identity, the two absences, the ceiling and the sign trap, expressed in nats instead of octaves.**

What is not claimed at all. No person, bond, tissue, molecule, room or institution is claimed to resonate at any frequency named here. The twelve states are not diagnoses and no reading in this paper is clinical, diagnostic, therapeutic or prognostic.

15 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number in the paper is the output of exact arithmetic on parameters stated in the text; every case is constructed and is labelled as constructed at the point of use. The figures are generated by the Python scripts named in their captions, which take their inputs from the tables in the text and are available from the author on request. **No empirical measurement of any human being, any relation or any institution underlies any figure, table or number in this paper.** A frequency law reads as though something were measured; nothing was.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The constructed dyad is an invented parameter set and is not derived from, and does not describe, any person. This paper asserts several perceptual and structural claims — that octave equivalence is a usable structure beyond pitch, that interval arithmetic in cents is the correct apparatus, and that a psychological state can be indexed by a count of components — **without any perceptual or psychometric experiment behind them.** Those claims rest on the cited literature, are limited by that literature's own boundaries (§11.3), and where the literature is in tension with them that tension is printed (§4.13, L-9).

Preregistration. No test reported in this paper was preregistered, because no test was run. The one confirmatory fit attempted elsewhere in this corpus was preregistered and **failed its own second falsification rule** [Curzi, 2026i]; that outcome is reported here as it is reported there.

Clinical disclaimer. The twelve state classes are not diagnostic categories. Nothing in this paper is an assessment, a screening instrument, a treatment or advice about any person's health, and nothing in it may be presented as such.

Chapter 41

The Minimum Sustainable Frequency: A Pitch Criterion for Relational Sustainability and the Count-Based Essence Index That Feeds It

Abstract. We derive a threshold frequency below which a relation cannot pay for itself. Substituting the essence bridge $f = k\,e^{2F}$ into the storage fixed point $Q_\infty = (\eta F - c)/\delta$ yields $f_{\min} = k\,e^{2c/\eta}$ with $k = (9/8)^2/\varphi^2 = 0.483425732988414$ Hz — a *defined* constant, exact by construction, whose interpretation as a frequency is postulated and not derived — and a trichotomy: $f > f_{\min}$ accumulates, $f = f_{\min}$ holds, $f < f_{\min}$ decays. In logarithmic units the requirement is exactly $2/\ln 2 = 2.885390081777927$ octaves per unit of c/η, and the octave deficit satisfies the identity $D = 2.885390\,(c/\eta - F) = -2.885390\,(\delta/\eta)\,Q_\infty$, cross-checked to a residual of 8.88×10^{-16}. Because $F \le \ln N$ the criterion carries a ceiling, $c/\eta \le \ln N$, that is $f_{\min} \le kN^2 = 69.6133$ Hz at $N = 12$. The sharpest result is negative: D contains no δ, so reducing loss cannot move the deficit at all. On a constructed dyad reading $D = +4.338420$ octaves and $Q_\infty = -5.0119$, cutting δ from 0.09 to 0.05 leaves D unchanged to every printed digit while worsening Q_∞ to -9.0215. The state index is defined as a component count, $f(n) = kn^2$, which sidesteps the corpus's own scale demotion; but the essence law is an unsupported postulate, the twelve-component ladder is not shown to be the right twelve, and the elicited intensities are not invariant under monotone transformation, spanning 0.888 octaves across admissible rescalings.

Keywords: minimum sustainable frequency; octave deficit; essence law; effective count; storage fixed point; ceiling; component count; magnitude estimation

Series: C. Frequency, Essence, and Mind **Paper:** CCP-041

1 Introduction

A relation between two or more parties that costs something to maintain either accumulates durable order or loses it. The framework this paper belongs to models that accumulation with a first-order linear difference equation — a leaky store driven by a surplus term and drained by a cost term — whose fixed point is $Q_\infty = (\eta F - c)/\delta$. That form is not novel and

is not claimed to be: it is the discrete leaky integrator that appears as the RC low-pass filter in signal processing [Oppenheim et al., 1996], as exponential smoothing in forecasting [Holt, 1957], and as the integrate-and-fire neuron in computational neuroscience [Lapicque, 1907, Gerstner and Kistler, 2002]. Its stability condition and unique fixed point are standard [Elaydi, 2005], and the convergence is Banach's [Banach, 1922].

The question this paper asks is narrower and, as far as we can establish, unasked: can the sign of that fixed point be read off a single threshold, and does the threshold have a useful logarithmic form? The answer is yes, and the threshold is exponential in the ratio of cost to conversion efficiency. Writing the relation's position on the framework's logarithmic surplus scale as a frequency — the *essence bridge* fixed in the corpus's Series B [Curzi, 2026k], whose Result One is that $f(m)/f(n) = m^2/n^2$ so that the reference constant cancels from every interval — the condition becomes a comparison of two pitches, and the shortfall becomes an interval measured in octaves.

Four things follow, and the fourth is the one worth having. First, the threshold $f_{\min} = k\,e^{2c/\eta}$ exists and partitions behaviour into three regimes exactly. Second, in logarithmic units the exchange rate is a single exact constant, $2/\ln 2 = 2.885390081777927$ octaves per nat. Third, the shortfall — the *octave deficit* D — is algebraically identical to the steady state itself, so a pitch reading and a stock reading are one reading in two units. Fourth, and negatively: D **contains no decay term at all.** The intervention most people reach for when a relation is failing — reduce the loss, build trust, add ritual and continuity — cannot move the deficit by any amount whatsoever, and when the numerator is already negative it makes the destination strictly worse. That is a derived consequence of the algebra, it is counter-intuitive, and it is the result this paper most wants read.

The second half of the paper supplies the input the first half consumes. A frequency is computable only once a psychological category has an index, and the index is defined here as a **count of distinguishable components** rather than as a rating. The distinction is not cosmetic. Stevens' typology of scales [Stevens, 1946] makes the permissible arithmetic on a quantity a function of the transformation group that leaves its empirical content unchanged, and a count admits only the identity transformation. That is what licenses squaring it. Ratings do not have that property, and the corpus has already demoted one of its own keystone constructions on exactly this ground [Curzi, 2026m], whose Result Two fixes the $D = P$, $r = 1$, $M = E$ contact point together with the ceiling $0 \le M \le \ln N$ that makes the divergence finite.

What this paper does not claim, stated at the front rather than at the back. The constant $k = (9/8)^2/\varphi^2$ is a *defined* number, not a measured one; its two components are real and well documented — the Pythagorean whole tone [Barbour, 1951] and the golden section [Euclid, 1956] — but their product **expressed as a frequency in hertz has no precedent in any literature we have found**, and the standard critique of golden-section claims [Markowsky, 1992] is cited here deliberately and again wherever φ appears. The essence law $f(n) = kn^2$ is a postulate of this framework and not a finding. Octave reduction is licensed for pitch [Shepard, 1982] and its perceptual specialness has been measured [Demany et al., 2013]; **its extension to a quantity that is not a pitch is a modelling choice with no external warrant**, and Section 2 labels it as one. Section 9 decomposes every one of these into steps a reader can check individually, and Section 10 prints every check this paper fails.

Contributions

1. The minimum sustainable frequency $f_{\min} = k\,e^{2c/\eta}$ and the accumulate/hold/decay trichotomy, with the equivalence proved and verified at twelve parameter sets.
2. The octave form, with the exact conversion constant 2.885390081777927 octaves per nat and its cents and bits equivalents.
3. The deficit identity $D = 2.885390(c/\eta - F) = -2.885390(\delta/\eta)Q_\infty$, cross-checked to a residual of 8.88×10^{-16}.
4. The negative result: D is independent of δ, demonstrated on a constructed dyad where halving the loss leaves D unchanged to every printed digit and worsens Q_∞ by 80 per

cent.

5. The ceiling $c/\eta \leq \ln N$, equivalently $f_{\min} \leq kN^2$, which classifies a case as tunable or structural before any prescription is issued.
6. A count-based index for the psychological argument of the bridge, with the scale-theoretic argument for why a count escapes the demotion that a rating inherits — and an explicit statement of what that argument does not buy.
7. A measured failure of the second invariance: monotone rescalings of elicited intensities, admissible if the intensities are merely ordinal, move the derived frequency by 1065.05 cents.

2 Hypotheses, definitions, and postulates

The rigour standard governing this corpus requires that a claim which *could* be wrong be stated so that it could be, and that a claim which could not be wrong be labelled with which of the three non-empirical kinds it is. **A hypothesis nothing could falsify is not a hypothesis**, and this section does not manufacture one. Series C carries the corpus's least-supported material, so the labelling below is done first and in full.

2.1 Hypotheses proper

H1 — the sign hypothesis. A relation whose measured conversion-weighted surplus falls short of its measured cost, $\eta F < c$, loses stored order over successive periods; one for which $\eta F > c$ gains it. **Predicted:** the sign of the observed change in the stock over a run of periods agrees with the sign of $\eta F - c$ computed at the start of the run. **Falsified by:** a system with $\eta F < c$, all four parameters measured on one declared period, whose stock rises over a run long enough for the fixed point to dominate the transient. **Status:** derived from the storage law [Curzi, 2026a]; **not tested here.** No observational data were collected for this paper.

H2 — the ceiling hypothesis. No relation whose measured cost ratio exceeds the logarithm of its declared category count, $c/\eta > \ln N$, sustains itself under any assignment of non-parallelism over those categories. **Predicted:** among systems measured with a declared and fixed N, none with $c/\eta > \ln N$ is observed to accumulate. **Falsified by:** one counterexample. The hypothesis is a strict universal and is cheap to kill. **Status:** derived from the normalisation bound $F \leq \ln N$ [Curzi, 2026]; **not tested here.**

H3 — the decay-blindness hypothesis. An intervention that acts only on the decay rate δ leaves the octave deficit unchanged and multiplies the existing sign of the fixed point. **Predicted:** in a system with $\eta F < c$, an intervention that measurably lowers δ and leaves η, c, u and N unchanged is followed by a *more* negative steady state, not a less negative one. **Falsified by:** a δ-only intervention that reverses the sign of the stock's drift. **Status:** derived by inspection of D; demonstrated on a constructed case in §4.9 and in the worked example. **Not tested against observation.**

H4 — the count-reproducibility hypothesis. The component count n assigned to an episode under the declared decomposition rules D1–D8 is a property of the episode and not of the analyst. **Predicted:** independent analysts applying the published rules to the same episodes agree on n at a rate that does not fall with analyst pairing, and the residual disagreement carries no analyst main effect. **Falsified by:** a systematic analyst effect on n, or agreement on the derived *pitch class* no better than the ladder's marginal distribution. **Status:** this is gate FVP-7 of the framework's validation protocol. **It has not been run.** It is reported as not run in §6.14, in §10, and here.

H5 — the ratio-scale hypothesis. The intensities elicited by the procedure of §6.9 carry ratio-scale information, as magnitude estimation is held to [Stevens, 1957]. **Predicted:** cross-modality matching against the elicitation instrument returns a power relation with a stable exponent under changes of stimulus range. **Falsified by:** exponents that move with the experimenter's chosen range, which is exactly what the range effect predicts [Teghtsoonian, 1971], or by the response-bias mechanisms catalogued against magnitude estimation [Poulton, 1968]. **Status: not tested here.** The framework leans on the psychophysical literature for this and inherits its disputes [Krueger, 1989].

2.2 Definitions — true by stipulation, not falsifiable

- **Def. 1.** n := the number of distinguishable components required to specify a state.
- **Def. 2.** $u := 1 - (\hat{x} \cdot \hat{y})^2$ on unit intensity vectors; $F := \ln(1 + (N-1)u)$.
- **Def. 3.** $D := 2.885390\,(c/\eta) - \log_2(f/k)$, the octave deficit.
- **Def. 4.** $k := (9/8)^2/\varphi^2$. **This is a defined constant.** It is an exact ratio of exact quantities and is therefore computable to arbitrary precision; the fifteen significant figures quoted throughout, 0.483425732988414, are *exact digits of a definition* and carry no measurement uncertainty because there is no measurement. Every appearance of the constant at that precision in this paper is so labelled.

2.3 Postulates — asserted by this framework, with no external support

- **P-a. The essence law $f(n) = kn^2$.** A quadratic relation between a dimensionless count and a frequency. **No external literature supports it.** The corpus badges it a postulate about essence structure and this paper does the same. It is not derived here and nothing in the bibliography derives it. **The exponent 2 is defined by the model, not estimated from data.** No scaling exponent in this paper was obtained by fitting; none was tested against a log-normal or exponential alternative; and the goodness-of-fit and likelihood-ratio procedure that a claimed scaling relation would require [Clauset et al., 2009] was **not run, because there is no data to run it on.** A squared law presented as though it had been measured is exactly what that procedure exists to catch, and this one has not been measured.
- **P-b. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic. **Asserting that this dimensionless number *is a frequency* is a separate and much stronger claim**, and the source supplies no operational procedure by which the constant acquires the dimension of inverse time. This is postulated. Section 3.4 states it again in the dimensional audit, where it is unavoidable.
- **P-c. The affine effective count $N_{\text{eff}} = 1 + (N-1)u$.** A design axiom [Curzi, 2026], not a derived result and **not a Hill number of any order**. The Hill family [Hill, 1973] and its independent rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly — as the corpus's concentration work uses them [Curzi, 2026] — and ground this construction not at all. A reviewer reaching for the Hill-number literature as support will find it does not apply, and that is stated here so that the discovery is not a surprise.

2.4 Modelling choices — legitimate, but choices

- **M-a. Octave reduction applied to a non-acoustic quantity.** Octave equivalence is a perceptual structure formalised for **pitch** [Shepard, 1982], and the octave's perceptual specialness has a measured size [Demany et al., 2013]. Nothing licenses carrying it to a quantity that is not a pitch. The *operation* is well defined — division by a power of two — and its *interpretation* is a choice of this framework. Where the folded value is read as carrying meaning, that reading is unsupported.

- **M-b.** $N = 12$**.** Twelve component classes are used throughout. The search for a thirteenth failed, which is weak evidence and is reported as weak in §6.8. Twelve exceeds the classical span of immediate discrimination [Miller, 1956], which is a reason for caution and not a reason for twelve.
- **M-c. Consonance and interval apparatus.** Cents, octave equivalence and interval arithmetic are the correct apparatus once an index exists [Rossing et al., 2002], but what a listener finds consonant depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005], and interval categories generalise less far than is usually assumed [Burns, 1999, Hoeschele et al., 2012]. This paper uses the arithmetic and claims none of the perception.

2.5 What is expository

Sections 4.10 through 4.21, 5.6 through 5.10, and 6.9 through 6.14 are expository: they set out procedure, reporting requirements and failure modes rather than argue a claim. Their organising question is *what must be published alongside a reading for the reading to be checkable by a third party*, and the answer is the specification blocks and the validation table.

3 Framework, dimensional audit, and method

3.1 The storage law — a shared mathematical form, not a derivation

$$Q_{t+1} = (1 - \delta)Q_t + \eta S_t - C_t$$

Analogy status: category 2, a shared mathematical form. The equation governing this framework's stored order is the same equation that governs a leaky integrator, and it is used because the mathematics is the same, not because the physics transfers. No claim is made that comfort is a charge, that η is a coupling constant, or that any physical result about RC circuits applies to a relation between people. The fixed point $Q_\infty = (\eta F - c)/\delta$ follows from setting $Q_{t+1} = Q_t$ and requires $\delta > 0$; the corresponding transfer-function reading, in which $1/\delta$ is the DC gain of $1/(z-a)$ evaluated at $z = 1$, is fixed in Series B [Curzi, 2026a]. Convergence is geometric with ratio $1 - \delta$ [Elaydi, 2005, Banach, 1922]; the corpus's foundations state the theorem exactly — a contraction of modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least q each pass [Curzi, 2026].

Three warnings attach to that form and are recorded here rather than in a footnote. First, the time average of a multiplicative process differs from its ensemble average, so a parameter estimated across individuals does not describe what happens to any one of them over time [Peters, 2019] — and Q accumulates *over time*, for *one* relation, from parameters that would most naturally be estimated from a cross-section. Second, a single Q, δ or u written for a group is an aggregation, and aggregation over heterogeneous agents does not in general yield a representative agent [Kirman, 1992]; the framework's own no-aggregation rule (SPEC 4.14) is the right response and is stated as a rule rather than defended. Third, Q **has the grammar of a conserved quantity — a stock that accumulates, leaks and is spent — without a conservation law to give that grammar content.** That is the characteristic failure of the genre: neoclassical economics was built by copying nineteenth-century energetics and made utility play the role of energy without the conservation law that gave energy its meaning [Mirowski, 1989]. This paper does not claim any conservation law, states no invariance under which Q would be conserved, and adopts instead the position that a law is claimed only within a specified arrangement rather than universally [Cartwright, 1999]. The wider programme this places the work in — statistical physics applied to social dynamics — has a standard survey that fixes what such models can and cannot be held to [Castellano et al., 2009], and the boundaries it draws are the boundaries claimed here.

The precedent that matters most for this paper is the leaky integrate-and-fire neuron [Lapicque, 1907, Gerstner and Kistler, 2002]: a leaky store with a drive and a threshold, yielding a rate below which the store does not fire. **That literature grounds the *shape* of** $f_{\min}$ **—**

a threshold rate emerging from a leaky store — and it grounds neither the formula nor the constant. The distinction is made here and repeated in §9 and §10.

3.2 The surplus functional and the effective count

$F(u) = \ln(1 + (N-1)u)$ is the corpus's surplus functional, characterised by angle-only dependence, a zero at parallel states, an affine effective count and a normalisation [Curzi, 2026]. Its logarithmic form places it in the same family as Shannon's entropy [Shannon, 1948], and uniqueness-under-axioms is a known genre of theorem in that literature; the framework's axiom set is its own and is not one of those. The ceiling $F \leq \ln N$ is the normalisation, and it is the same ceiling that appears in requisite-variety arguments [Ashby, 1956].

Which construct of difference u measures must be declared, because at least three incompatible constructs travel under the word *diversity* — separation, variety and disparity [Harrison and Klein, 2007]. Here u is a *disparity* measure over represented states, and it is symmetric in its arguments, which psychological similarity is known not to be [Tversky, 1977]. That is a limitation and it is printed in §10.

3.3 The essence bridge and the constant k

The bridge writes a surplus as a pitch: $f = k\, e^{2F}$, so that intervals of surplus become intervals of frequency and the constant cancels from every ratio [Curzi, 2026k]. The constant is defined as

$$k := \frac{(9/8)^2}{\varphi^2} = \frac{81/64}{\varphi + 1} = 0.483425732988414 \quad \text{(defined; exact)}$$

Both components are real, specific and documented. The ratio $9{:}8$ is the Pythagorean whole tone, a historically attested object of tuning theory [Barbour, 1951], and it sits in a lattice of small-integer ratios with its own long literature. The golden section is Euclid's extreme and mean ratio [Euclid, 1956], named in the Renaissance, and $\varphi^2 = \varphi + 1$ with $\varphi^m = F(m)\varphi + F(m-1)$ are proved identities [Vajda, 1989].

Their product, expressed as a frequency in hertz, has no precedent. There is no physical, psychoacoustic or musicological result that combines a tuning ratio with an inverse square of the golden section to obtain a ground frequency. The literature on golden-section claims is overwhelmingly a literature of *deflation*: the appearances of φ in the Parthenon, the Great Pyramid, the human body and preferred rectangles do not survive examination [Markowsky, 1992, Fischler, 1981], the psychological preference results are weaker and more equivocal than they are usually reported to be [Höge, 1997], and and even-handed histories of the constant are available.

This framework's position is the one those critiques leave open and no wider. φ is being *chosen* as a constant, not *found* in a psychological system. Nothing in this paper is evidence that the golden section is present in anything measured. The constant sets a reference pitch and is invisible to every verdict, because D is a difference of logarithms in which k appears in both terms and cancels.

3.4 Dimensional audit

symbol	quantity	dimension	unit	status
Q	stored order	$[\mathcal{C}]$	none supplied	state variable; **no operational unit**
S	surplus input per period	$[\mathcal{C}\,T^{-1}]$	per declared period	driving term

symbol	quantity	dimension	unit	status
C, c	cost per period	$[\mathcal{C}\,T^{-1}]$	per declared period	driving term
δ	decay rate	$[1]$	per period	dimensionless; $0 < \delta \leq 1$
η	conversion efficiency	$[1]$	—	dimensionless; assumed $0 < \eta \leq 1$
u	non-parallelism	$[1]$	—	dimensionless by construction, $u \in [0, 1]$
F	surplus	$[1]$	nats	dimensionless; a logarithm of a count
N	declared category count	$[1]$	—	absolute scale, a count
n	component index	$[1]$	—	absolute scale, a count
k	reference constant	$[T^{-1}]$ **asserted**	Hz **asserted**	**defined as a ratio (dimensionless); the unit is postulated**
f	essence frequency	$[T^{-1}]$	Hz	inherits its dimension entirely from k
D	octave deficit	$[1]$	octaves	a ratio of logarithms; k cancels

Does the equation balance? The storage law balances provided S and C carry the same dimension as Q per period, which the framework assumes and does not measure; Q has **no operational unit**, and this audit records that rather than inventing one. The essence law $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, because n is a dimensionless count. **The source supplies no operational procedure by which k acquires that dimension.** The constant is computed as a ratio of two dimensionless quantities — a frequency ratio and a geometric ratio — and the hertz is attached by assertion. This is the single largest dimensional exposure in the paper and it is listed in §10 by name.

The ratio c/η is dimensionally $[\mathcal{C}\,T^{-1}]$ divided by a pure number and is therefore not dimensionless as the exponent of $e^{2c/\eta}$ requires. **The framework's convention is that c is expressed in the same units as F — nats of surplus per declared period — which makes c/η dimensionless.** That convention is a choice, it is stated here, and every reading in this paper depends on it being applied consistently.

3.5 Scale type, and what licenses the arithmetic

quantity	scale type claimed	what licenses it
n, N	absolute	cardinality: true zero, fixed unit, identity transformation group only

quantity	scale type claimed	what licenses it
u	ratio	constructed from an inner product of unit vectors; zero is parallel
elicited intensities	ratio, up to a free common multiplier	**magnitude estimation, assumed** [Stevens, 1957]; not tested here
η, c, δ	ratio, **assumed**	no instrument is supplied; ordinal inputs are excluded by SPEC 4.4
f, $f_{\min}$	ratio in hertz, **inherited**	inherits the status of n and of the postulated bridge
D	interval, in octaves	a difference of logarithms

The strongest available objection to this framework is Michell's: that psychology routinely assumes its attributes are quantitative without ever testing whether they are [Michell, 1997]. The objection applies here in full. The formal remedy exists — conjoint measurement supplies a testable condition for additive quantitative structure [Luce and Tukey, 1964, Krantz et al., 1971], and a Rasch model supplies specific objectivity, a measure that does not depend on which items were used [Rasch, 1960] — and **neither has been run for any quantity in this paper.** The count argument of §5.2 answers Michell for n, because a cardinality's structure is a consequence of its definition rather than an empirical hypothesis; it answers him for nothing else. The intensities, η, c and δ are treated as quantitative by stipulation, and that is stated rather than hidden.

There is a second instance of that same objection in this paper, in a different domain, and it is better to name the pattern once than to meet each instance as though it were a surprise. Section 5 reduces an emotional state to a single integer — the number of components its specification requires — orders states by that integer, and squares it. Michell's charge is that a quantitative structure is assumed where it was never tested. The charge against the ladder is the same charge one level down: a **scalar** is asserted where the affect literature describes a pattern across simultaneously varying dimensions [Smith and Ellsworth, 1985], a process unfolding in time [Scherer, 2001], or a qualitative relational theme [Lazarus, 1991]. **These are one objection in two places, not two objections.** What both name is a habit of this framework: where the source literature describes a phenomenon by several jointly varying features, the framework replaces it with one number and does arithmetic on the number. The count argument of §5.2 protects the *arithmetic* of that number; it does not protect the *reduction* that produced it, and this paper does not claim that it does. §5.7 states the affect version at full strength, and L-18 concedes the two together as one limitation.

3.6 Identification — the objection this framework cannot presently answer

The framework's founding construction is a reflexive loop, $T(x) = W(x, M(x))$: the group influences the member and the members constitute the group [Curzi, 2026]. **That is a linear-in-means reflexive specification, and the endogenous social effect in such a specification is not identified from observational data** [Manski, 1993]. It cannot be separated from contextual effects or from correlated unobservables, however much data is collected; the reinforcement is that influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. **No amount of fit, held out or otherwise, recovers the parameter.**

The remedy this paper adopts is stipulation, and it pays the price openly. The reference set is fixed in advance — the declared category set of size N and the declared decomposition rules — and every reading is reported together with that stipulation, which is what makes a discrete-choice treatment of social interaction defensible where an unrestricted one is not [Brock and Durlauf, 2001]. **This paper therefore presents the reflexive loop as a modelling**

position, not as an identified empirical result. It is not offered as something an observation could confirm.

The same objection applied to the framework's own parameters. If systems change their behaviour when modelled, then δ, η and u are the decision rules of people who have not read the storage law, and they are not structural in the sense a policy exercise requires [Lucas, 1976]. Classification changes the classified [Hacking, 1995], and economic theory has been shown to become self-validating by being taught and used [Ferraro et al., 2005, MacKenzie and Millo, 2003]. **The framework asserts reflexivity for its subject matter and cannot consistently exempt its own parameters from it.** This paper does not resolve that; it states it, and treats every parameter as conditional on the arrangement in which it was fixed.

3.7 Method

Every number in this paper is the output of exact arithmetic on stated parameters, computed in double precision. **No observational data were collected, no human subjects participated, and no empirical dataset underlies any figure or table.** Every case is constructed and is labelled as constructed at the point of use. Residuals quoted at the 10^{-16} level are floating-point round-off, not measurement error, and are reported to demonstrate that two algebraically identical expressions were in fact computed independently and agreed. The figures are produced by the scripts named in their captions.

4 The minimum sustainable frequency

This is the result the framework is built around, and it is set out to be cited rather than rederived. Twenty-six later analyses in the corpus use what is stated here, and cite rather than restate it. Everything the framework means by `f_min`, by the octave deficit, by the ceiling, and by the four levers is set out here completely, with every number computed and every boundary named.

The keystone, in one block:

```
f_min = k * e^( 2c / eta )                    k = 0.483425732988414 Hz

octaves required  = 2 (c/eta) / ln 2  =  2.885390081777927 * (c/eta)

octave deficit  D = 2.885390 * (c/eta)  -  log2( f / k )

    D <= 0    sustainable as it stands
    D >  0    short by that many octaves

CEILING:  c/eta <= ln N.   For N = 12: c/eta <= 2.484907, f_min <= 69.6133 Hz.
          Above it, NO arrangement of those categories is sustainable at all.

FOUR LEVERS:  raise u  ·  raise eta  ·  cut c  ·  raise N.   And delta is NOT one of them.
```

The Law

4.1 Definition **DEFINITION 4.1 — THE MINIMUM SUSTAINABLE FREQUENCY.** For a relation with cost `c` per period and conversion efficiency `eta > 0` measured on the same period,

```
f_min  :=  k * e^( 2c / eta )
```

`k = 0.483425732988414 Hz` is the ground essence, badged as a chosen reference constant (the essence-law specification of Series B [Curzi, 2026k]). `f_min` is an essence frequency. No person, bond, tissue, molecule, room or institution is claimed to resonate at it, or at any value in this section.

4.2 The three regimes **THEOREM 4.2.** Under the conditions of the storage law's fixed-point theorem [Curzi, 2026a] — `delta > 0`, `eta > 0`, constant `u` and `c` — and with `f = k e^(2F(u))` the relation's essence frequency:

```
f  >  f_min    <=>   Q_inf > 0     the relation ACCUMULATES order
f  =  f_min    <=>   Q_inf = 0     it HOLDS, and nothing more
f  <  f_min    <=>   Q_inf < 0     it DECAYS, whatever anyone intends
```

Proof: the equivalence chain of the sustaining-frequency paper [Curzi, 2026], whose Result Two is the deficit identity — Steps 0 to 4, a chain of equivalences under strictly increasing transformations. *Verified* at twelve parameter sets in the sustaining-frequency paper [Curzi, 2026] §3.7, sign-agreement in all twelve including the exact-equality case.

The middle line is the one readers skip and the one that costs them. `f = f_min` is not a success condition. It is the condition under which a relation pays exactly for itself and banks nothing. A relation at its minimum sustainable frequency is not sustainable in any colloquial sense; it is stationary, and it has no reserve against any increase in cost.

4.3 The octave form **THEOREM 4.3.** Taking the base-2 logarithm of Definition 4.1,

```
log2( f_min / k )  =  2 (c/eta) / ln 2  =  2.885390081777927 * (c/eta)
```

EVERY UNIT OF COST-TO-CONVERSION RATIO COSTS 2.885390 OCTAVES OF REQUIRED PITCH.

The constant is exact: `2/ln 2 = 2.885390081777927`. It is the same constant that converts one nat of surplus into pitch (the sustaining-frequency paper [Curzi, 2026]), and it appears here for exactly that reason — `c/eta` is measured in nats of surplus per period, and the conversion from nats to octaves is one number.

Equivalent statements, all exact:

```
1 nat of required surplus  =  2.885390 octaves  =  3462.4681 cents  =  1.442695 bits
1 octave of pitch          =  0.346574 nats     =  0.5 bits EXACTLY
```

One octave is exactly half a bit. That line prices every lever in §4.13. The nat, the bit and the conversion between them are the standard units of a logarithmic information measure [Shannon, 1948]; nothing about the framework's use of them is novel, and nothing about them licenses the frequency reading.

4.4 The table Computed at `k = 0.483425732988414 Hz`, `N = 12`, folded into 220–440 Hz with the transposition `j` given:

c/eta	f_min (Hz)	octaves above k	N_eff required	folded 220–440
0.00	0.4834	0.000000	1.0000	247.514 (j=9)
0.10	0.5905	0.288539	1.1052	302.314 (j=9)
0.20	0.7212	0.577078	1.2214	369.247 (j=9)
0.30	0.8809	0.865617	1.3499	225.500 (j=8)
0.40	1.0759	1.154156	1.4918	275.426 (j=8)
0.50	1.3141	1.442695	1.6487	336.406 (j=8)
0.60	1.6050	1.731234	1.8221	410.888 (j=8)

```
0.70          1.9604        2.019773          2.0138      250.930 (j=7)
0.80          2.3944        2.308312          2.2255      306.486 (j=7)
0.90          2.9246        2.596851          2.4596      374.343 (j=7)

2.90        159.6753        8.367631         18.1741      319.351 (j=1)
3.00        195.0279        8.656170         20.0855      390.056 (j=1)
```

The fourth column is the most useful and the least obvious. `N_eff required = e^(c/eta)` is the number of genuinely distinct perspectives the relation must field just to break even. At `c/eta = 1.00` it is 2.7183 — a two-person bond must be worth more than 2.7 people's worth of distinct view. At `c/eta = 2.00` it is 7.3891. At `c/eta = 2.4849` it is exactly 12, which is all of them, and that is the ceiling arriving.

4.5 The octave deficit

DEFINITION 4.4 — THE OCTAVE DEFICIT. For a relation with measured essence frequency `f` and measured cost ratio `c/eta`,

```
D  :=  2.885390 * (c/eta)  -  log2( f / k )

D <= 0    sustainable as it stands
D >  0    the relation is short by D octaves
```

This is the framework's core instrument. Every practical section must be able to produce it, and every reading in this framework is reported as a `D` with its sign, its magnitude, and the ceiling test that qualifies it.

THEOREM 4.5 — THE DEFICIT IDENTITY.

```
D  =  2.885390 * ( c/eta  -  F )  =  -2.885390 * (delta/eta) * Q_inf
```

Proof: the sustaining-frequency paper [Curzi, 2026], whose Result Two is this identity. *Verified* at twelve parameter sets to a worst error of `8.88e-16`.

Three readings of the same identity, and all three matter:

(i) `D = 2.885390 (c/eta - F)`. The deficit is the surplus shortfall, converted. A relation short by one nat of surplus is short by 2.885390 octaves. There is no other exchange rate.

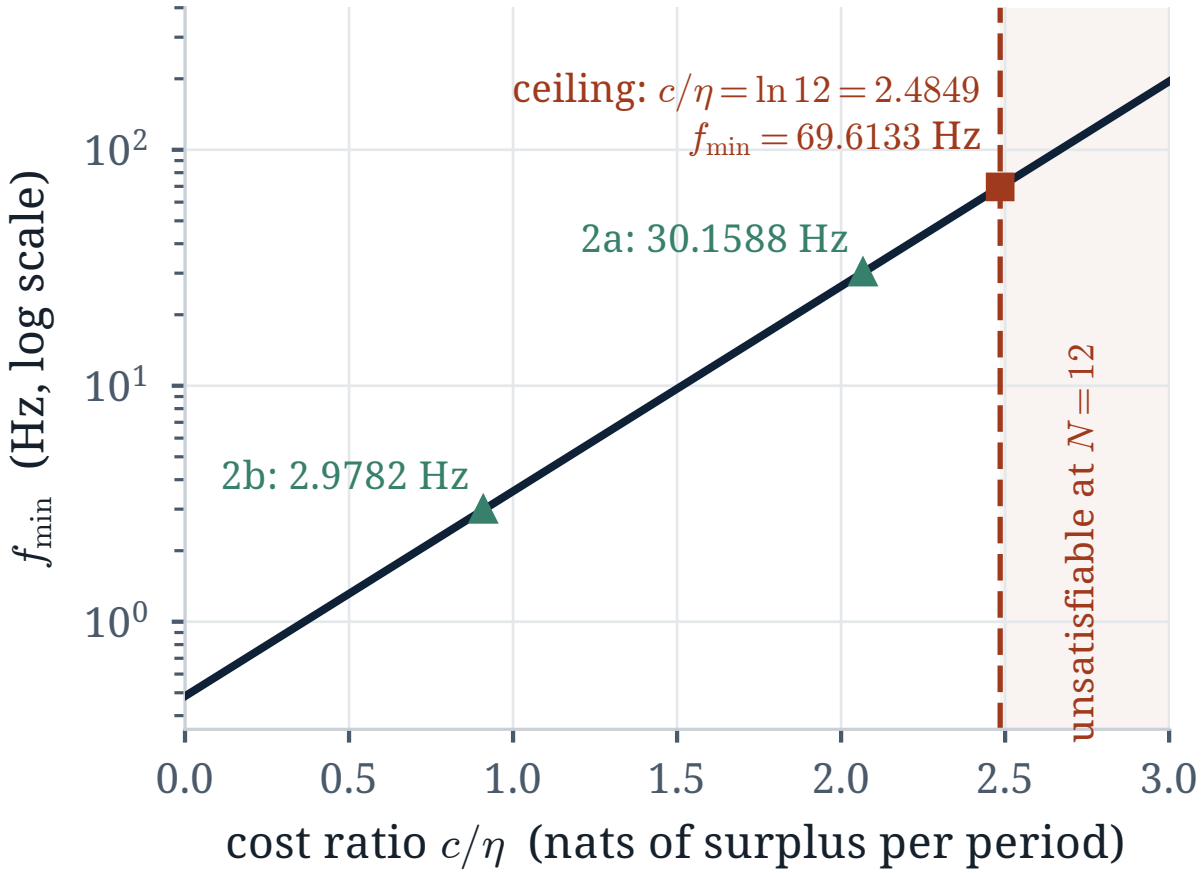

Figure 41.1: The threshold rises exponentially in the cost ratio and meets a hard bound at $c/\eta = \ln 12 = 2.4849$, where $f_{\min} = kN^2 = 69.6133$ Hz; above that bound no assignment of non-parallelism over twelve categories sustains the relation at all. Modelled from $f_{\min} = k\,e^{2c/\eta}$ with the **defined** constant $k = 0.483425732988414$ and $N = 12$; the two marked points are the constructed carried dyad of the worked example in Section 4 at its two phases. Built by `figs/src/CCP-041_fig02.py`.

(ii) `D = −2.885390 (delta/eta) Q_inf`. The deficit and the fixed point are the same quantity in different units. A pitch reading and a destiny reading are the same reading. The companion paper on destiny as a fixed point builds on this.

(iii) `k` cancels. `D` is a difference of logarithms in which the chosen constant appears in both terms. The verdict does not depend on `k` at all. Only the absolute hertz values do. This is the strongest available defence of the constant: it sets the reference pitch and is invisible to every verdict.

Deficit-to-fixed-point conversion, tabulated at `delta/eta = 0.30` (the carried case's ratio):

D (octaves)	f / f_min	Q_inf
−6.0	64.0000	+6.9315
−4.0	16.0000	+4.6210
−2.0	4.0000	+2.3105
−1.0	2.0000	+1.1552
−0.5	1.4142	+0.5776
0.0	1.0000	0.0000
+0.5	0.7071	−0.5776
+1.0	0.5000	−1.1552
+2.0	0.2500	−2.3105
+4.0	0.0625	−4.6210
+6.0	0.0156	−6.9315

A deficit of one octave means the relation is running at half the frequency it needs. A deficit of six octaves means it is running at 1.56% of what it needs, which is the situation the companion paper on tuning addresses and which no single adjustment repairs.

4.6 The ceiling, in the frequency register

THEOREM 4.6 — THE CEILING. Since `F <= ln N` — the normalisation bound carried by the surplus functional [Curzi, 2026], the condition `F > c/eta` is satisfiable only if

```
c / eta  <=  ln N        equivalently        f_min  <=  k N^2
```

If `c/eta > ln N`, NO arrangement of those `N` categories is sustainable. Not a better pairing. Not a better schedule. Not a better conversation. Nothing.

Proof: `F > c/eta >= ln N >= F` is a contradiction. **QED.**

For the twelve-state ladder of this framework:

```
ln 12       = 2.484906649788
k * 12^2    = 69.61330555033166 Hz    -> folded 278.453 Hz (j = 2), pitch class 3
max octaves = 2.885390 * ln 12 = 7.169925
```

For a twelve-category system, `c/eta` may not exceed 2.4849, and the corresponding `f_min` is 69.6133 Hz. Above that, the relation cannot be tuned. It must be restructured. A ceiling imposed by one parameter alone, independent of how the remainder is arranged, is a recurring shape in this corpus: the concentration atlas finds validator pools at HHI 0.1900 and 5.26 effective pools against a ceiling of `1/s_max^2 = 11.11` that the leading share alone imposes [Curzi, 2026].

The ceiling by category count, computed:

N	ln N	f_ceiling = k N^2 (Hz)	max octaves above k
2	0.693147	1.9337	2.000000
3	1.098612	4.3508	3.169925
4	1.386294	7.7348	4.000000

```
  5   1.609438          12.0856               4.643856
  6   1.791759          17.4033               5.169925
  7   1.945910          23.6879               5.614710
  8   2.079442          30.9392               6.000000
  9   2.197225          39.1575               6.339850
 10   2.302585          48.3426               6.643856
 12   2.484907          69.6133               7.169925
 16   2.772589         123.7570               8.000000
 17   2.833213         139.7100               8.174926
 20   2.995732         193.3703               8.643856
 25   3.218876         302.1411               9.287712
 41   3.713572         812.6387              10.715104
 64   4.158883        1980.1118              12.000000
```

COROLLARY 4.7 — THE MINIMUM CATEGORY COUNT. A cost ratio of `c/eta` requires at least `N >= e^(c/eta)` categories to be sustainable at all:

```
c/eta = 0.5000  ->  N >=  1.6487  ->  N_min =  2
c/eta = 1.0000  ->  N >=  2.7183  ->  N_min =  3
c/eta = 1.5000  ->  N >=  4.4817  ->  N_min =  5
c/eta = 2.0000  ->  N >=  7.3891  ->  N_min =  8
c/eta = 2.4849  ->  N >= 11.9999  ->  N_min = 12
c/eta = 2.5000  ->  N >= 12.1825  ->  N_min = 13
c/eta = 3.0000  ->  N >= 20.0855  ->  N_min = 21
c/eta = 3.5000  ->  N >= 33.1155  ->  N_min = 34
c/eta = 4.0000  ->  N >= 54.5982  ->  N_min = 55
```

The growth is exponential, and that is the whole content of the corollary. Going from `c/eta = 3` to `c/eta = 4` — a 33% increase in relative cost — raises the minimum viable category count from 21 to 55. Cost does not merely make a relation harder. Past a point it makes the relation's category set inadequate, and category sets are expensive to enlarge honestly.

4.7 The hold line

COROLLARY 4.8. The relation holds exactly (`D = 0`, `Q_inf = 0`) when

```
u*  =  ( e^(c/eta) − 1 ) / (N − 1)
```

Verified for `N = 12`:

```
c/eta = 0.500000  ->  u* = 0.058975   f = f_min =  1.3141 Hz
c/eta = 1.000000  ->  u* = 0.156207   f = f_min =  3.5721 Hz
c/eta = 2.000000  ->  u* = 0.580823   f = f_min = 26.3942 Hz
c/eta = 2.484907  ->  u* = 1.000000   f = f_min = 69.6133 Hz
```

The last row is the ceiling stated in the geometry rather than in the cost: at `c/eta = ln N` the required non-parallelism is exactly 1 — perfect orthogonality — and there is nothing above it.

4.8 The four levers

These are the only four. There is no fifth, and `delta` is not one of them.

```
LEVER              acts on            partial derivative of D
──────────────────────────────────────────────────────────────────────────
L1  raise u        the geometry       dD/du    = −2.885390 (N−1)/(1 + (N−1)u)
L2  raise eta      the conversion     dD/deta  = −2.885390 c / eta^2
L3  cut c          the cost           dD/dc    = +2.885390 / eta
L4  raise N        the category set   dD/dN    = −2.885390 u / (1 + (N−1)u)
```

Each is derived directly from `D = 2.885390 (c/eta − F)` with `F = ln(1 + (N−1)u)`.

THEOREM 4.9 — `delta` IS NOT A LEVER ON THE DEFICIT.

```
D = 2.885390 ∗ (c/eta) − log2(f/k)          contains k, c, eta, N, u
                                            does NOT contain delta
```

Proof: by inspection of Definition 4.4 and of `f = k(1 + (N−1)u)^2`. **QED.**

Consequence, and it is the single most practically important statement in this section: an intervention that acts only on `delta` cannot change the deficit by any amount whatsoever. Trust acts on `delta`. Ritual, place, written record and institutional memory act on `delta`. All of them are valuable and none of them moves the reading. That they act on `delta` is itself a measured claim in this corpus rather than an assumption: the memory-palace analysis decomposes its own effect and finds retention contributing a factor of 4.1667 against surplus 1.8637 and conversion 1.9000, the product 14.7546 matching the direct fixed-point ratio exactly [Curzi, 2026v].

What `delta` does do is scale `Q_inf`, through the identity `Q_inf = −D eta/(2.885390 delta)`. **It multiplies the existing sign.** In a relation with `D < 0` it makes a good destination better. In a relation with `D > 0` it makes a bad destination worse, and this is CC-R15 in frequency form. The companion paper on the sustainable dyad owns the order-of-operations rule that follows; the Worked Example below demonstrates it on the carried case.

4.9 Honesty clauses, restated because this is the section people will quote

(1) ESSENCE, NOT RESONANCE. Every frequency here is an essence frequency: a position on a logarithmic scale of surplus. **Nothing is claimed to vibrate.**

(2) NO CLINICAL CLAIM. The twelve states are not diagnoses; a reading is not an assessment; no procedure here is a treatment. Nothing in this section describes, evaluates, or prescribes for any person's health.

(3) THE READING INHERITS ITS INPUTS. `D` is exactly as defensible as `u`, `eta`, `c` and `N`. A contested decomposition yields a contested frequency. If `eta` or `c` is ordinal, publish the ordering and not the number (SPEC 1.1; CC-R1's demotion travels).

(4) S3 IS THE DESIGN AXIOM. `F` is defined through `N_eff`, which is defined by the affine axiom. Everything in this section uses it.

(5) SURPLUS IS A LOWER BOUND. `f` is a floor. A verdict of ACCUMULATES is robust to representational under-capture; a verdict of DECAYS is not (the sustaining-frequency paper [Curzi, 2026] §3.6).

(6) CONSTRUCTED CASES. Every case in this framework is constructed and labelled as such.

(7) CONSENT IS STRUCTURAL. No intervention derived from a reading may remove a person's ability to decline. The companion paper on tuning owns this and treats it as structure, not advice.

The Engineering

4.10 How to read the table

Three columns, three questions.

"How much pitch do I need?" — the second column, `f_min`. This is the threshold in hertz. It is the number to compare a measured `f` against, and it is the number to fold and publish with its `j` if the reading is to be displayed.

"How far is that?" — the third column, octaves above `k`. This is the threshold expressed as an interval from the ground essence, and it is the column to use when comparing two relations with different costs, because intervals are what compose.

"How many distinct views must this relation field?" — the fourth column, `N_eff = e^(c/eta)`. This is the column to hand to a person who does not want a frequency. It converts the whole apparatus into a sentence: *at the current costs, the pair must be worth 7.4 genuinely different people to break even.*

4.11 The ceiling test comes first, and here is why

SPEC 4.1 (stated early because everything depends on it): compare `c/eta` to `ln N` before computing anything else.

The test is cheap and it discriminates between hypotheses rather than confirming one, which is the form of inference that pays [Platt, 1964]. The reason it must come first is that a deficit does not announce its own kind. A `+5.78` octave deficit at `c/eta = 2.566667` and a `+5.78` octave deficit at `c/eta = 2.100000` with a much lower `f` look identical in the reading and are entirely different problems. The first is unsatisfiable by any arrangement of twelve categories. The second is a large tuning problem.

```
if  c/eta <= ln N     the case is TUNABLE.       Some assignment of u closes it.
if  c/eta >  ln N     the case is STRUCTURAL.    No assignment of u closes it.
                                                 Only L2, L3 or L4 can help.
```

A prescription issued before this test may be unsatisfiable, and unsatisfiable prescriptions are worse than none — they consume the effort that restructuring needed.

4.12 The two gauges, and why they can disagree

The framework's master gauge is headroom:

```
h_t = eta ln N − delta Q_t − C_t
```

This section's gauge is the deficit. **They answer different questions and can disagree in sign.**

Computed on the carried case as found, at `Q = 1`:

```
h  = 0.30 * 2.484907 − 0.09 * 1 − 0.62  =  +0.0355      growth available
D  = +4.338420 octaves                                  short by four and a third octaves
Q_inf = −5.0119                                         decaying
```

Headroom in this sense is organisational slack in the behavioural-theory sense, and the reason it cannot be driven to zero is the same reason waiting time explodes as utilisation approaches one [Kingman, 1962]: headroom is not prudence, it is what keeps the response finite.

Both are correct. Headroom uses the *ceiling* `ln N` — it asks what the best possible geometry could support at this cost. The deficit uses the *achieved* `F` — it asks what this geometry is doing. A system can have room to grow in principle and be shrinking in fact, and this case is exactly that: `h > 0` says the ceiling has not been hit, `D > 0` says the current arrangement is nowhere near it.

The bridge between them is CC-R6's identity, `h_inf = eta (ln N − F(u*))`, verified here at `0.576547` by both routes. In pitch units:

```
PITCH HEADROOM  =  2.885390 * ( ln N − F )  =  octaves between the achieved f and the ceiling
```

For the carried case as found, that is **5.5452 octaves of unused range** against a requirement of 5.9631 and a present position of 1.6247. The relation needs 5.96 octaves, has 1.62, and the ceiling is at 7.17. The requirement fits under the ceiling with 1.21 octaves to spare, which is exactly why the case is tunable.

4.13 The price of an octave, and why the last one cannot be bought

```
1 octave of pitch = 0.346574 nats of surplus = exactly 0.5 bits
equivalently: N_eff must rise by a factor of sqrt(2) = 1.414214
```

Since `N_eff = 1 + (N−1)u`, buying an octave means multiplying `1 + 11u` by `sqrt(2)`. The cost in `u` is not constant. Computed:

```
from u = 0.068735   ->  u must reach 0.134861     (a rise of 0.066126)
from u = 0.300000   ->  u must reach 0.461920     (a rise of 0.161920)
from u = 0.500000   ->  u must reach 0.744763     (a rise of 0.244763)
from u = 0.800000   ->  u must reach 1.169027     IMPOSSIBLE: u <= 1
```

The octaves get more expensive as the scale is climbed, and the last one cannot be bought in `u` at all. Above `u = (12/sqrt(2) − 1)/11 = 0.680480`, no further octave is available from the geometry at all, no matter what anyone does. This is the ceiling appearing as a marginal cost rather than as a bound, and it is the honest answer to "why not just find more difference?"

4.14 LEVER 1 — RAISE `u` What it is. Increase the represented non-parallelism between the parties: hold states the other does not hold, bring perspectives that do not already point the same way, decorrelate the errors. The between-persons measurement of `u` and the intervention that raises it are owned elsewhere in this series. The corpus's internal-surplus work [Curzi, 2026o] supplies the cautionary magnitude: restructuring a framing set raised the audited count by 25.4 per cent — `F_int` from 1.4883 to 1.7148 nats, 95.70 per cent of the ceiling — at identical reconciliation load, and still left the change in stored order negative at `−0.0411`.

Its sensitivity. `dD/du = −2.885390 (N−1)/(1 + (N−1)u)`. Computed at three operating points:

```
at u = 0.068735 (carried case, as found)    −18.0739 octaves per unit u
at u = 0.692373 (carried case, after)        −3.6837 octaves per unit u
at u = 0.018614 (the commons, the companion paper on families, teams and commons)   −26.3450 octaves pe
```

Strongest where `u` is smallest. The first unit of difference is worth far more than the last — this is the strict concavity of the surplus functional [Curzi, 2026] showing up as a lever price.

Its bound. `u <= 1`. The maximum achievable frequency is `k N^2`, and past `u = 1` there is nothing.

Its failure mode. Manufactured difference. **`u` measures represented non-parallelism, not disagreement, and CC-R8 is the trap: perfect opposition gives `u = 0` exactly as perfect agreement does, because `u` depends only on `|rho|`.** A contrarian recruited to raise `u` raises cost and returns nothing. The companion paper on unison owns this result.

4.15 LEVER 2 — RAISE `eta` What it is. Increase the fraction of interaction that becomes durable structure: write the decision down, build the artefact, make the practice repeatable, give the insight somewhere to live.

Its sensitivity. `dD/deta = −2.885390 c / eta^2`. Computed:

```
at eta = 0.30, c = 0.62   −19.8771 octaves per unit eta
at eta = 0.44, c = 0.40    −5.9615 octaves per unit eta
at eta = 0.34, c = 0.825  −20.5921 octaves per unit eta
```

The `eta^2` in the denominator is the important feature. At low `eta` the lever is enormously powerful; at high `eta` it saturates. A system converting 30% of its interaction into structure gains 19.9 octaves per unit of improvement; one already converting 44% gains 6.0.

Its bound. `eta` is a conversion efficiency, and improvements beyond the system's mechanical maximum are unavailable. In many cases the required `eta` exceeds 1 and the lever is simply not there — the worked example below shows exactly that on the carried case.

Why the companion paper on the sustainable dyad finds it usually cheapest in a dyad. Raising `u` requires finding or making real difference between two people, which is slow and sometimes impossible. Raising `eta` requires changing what happens to what they already produce, which is a mechanism question and often a matter of a notebook.

4.16 LEVER 3 — CUT `c`

What it is. Reduce coordination overhead, friction, correction load, and dissipation. The system-dynamics tradition models exactly these as rates draining a level, with delays [Forrester, 1961], and reports that people systematically misjudge stocks that have them [Sterman, 1989] — which is the empirical case for computing the ratio rather than estimating it.

Its sensitivity. `dD/dc = +2.885390 / eta`. Computed:

```
at eta = 0.30    +9.6180 octaves per unit c
at eta = 0.44    +6.5577 octaves per unit c
at eta = 0.34    +8.4864 octaves per unit c
```

This is the only lever whose sensitivity is constant in its own variable — linear in `c`, so each unit cut is worth the same as the last. That makes it the most predictable lever and the easiest to plan against.

Its bound. `c >= 0`, and at `c = 0` the threshold falls to `f_min = k` exactly, which any non-zero `u` clears. A costless relation is sustained by the smallest difference.

Its failure mode. Cost reduction that reduces `eta` at the same time. Cutting the meeting that was the conversion mechanism cuts `c` and `eta` together, and since `D` depends on `c/eta`, the ratio may not move at all. Cut cost that is not doing conversion work; SPEC 4.11 states the test.

And CC-R18's counter-pressure, which belongs here: an over-framed system accumulates *more* stored order than a calibrated one, because dogma banks faster than knowledge. The bill arrives on a lag as correction load, `C_t = c_0 + kappa Z_t`, rising with accumulated error. An organisation optimising raw `Q` will be driven away from calibration, and its `c` will rise later for reasons it will not connect to the choice.

4.17 LEVER 4 — RAISE `N`

What it is. Add genuinely distinct categories to the description. Not finer gradations of what is already there — **genuinely distinct**, in Ashby's sense that the controller's variety must match the disturbance's [Ashby, 1956], in the sense that the added dimension carries variance the existing ones do not.

Its sensitivity. `dD/dN = −2.885390 u / (1 + (N−1)u)`. Computed:

```
at u = 0.068735    −0.1129 octaves per added category
at u = 0.692373    −0.2319 octaves per added category
at u = 0.018614    −0.0446 octaves per added category
```

This is the weakest lever per unit, and it is weakest exactly where a large deficit makes it most tempting. At the near-parallel geometry of the near-parallel commons case carried in this series, an added category buys 0.0446 octaves. Closing a six-octave deficit that way would require 145 new categories.

The mechanism is the Parallel Wall. `N` enters `F` only multiplied by `u`. Adding categories to a set of near-parallel parties adds dimensions nobody is using. A twelfth window in a tower where everyone is looking the same way is a twelfth view of the same thing.

Its real value is not in the deficit but in the ceiling. Raising `N` raises `ln N`, which raises the maximum satisfiable `c/eta`. `N` is how a structural case becomes a tunable one, and that is the only situation in which it is the right first move.

Its bound and its cost. The cost side is the communication overhead that grows as `n(n−1)/2` with roster size [Brooks, 1975, Conway, 1968], and it opposes the ceiling gain directly. The time-bandwidth constraints [Gabor, 1946] bind on the rendering side: past `N = 17` the folded lattice's minimum gap collapses from `50/49` (34.9756 cents) to `289/288` (6.0008 cents), and the symbol rate drops by a factor of exactly 8. Past `N = 25` a single integer transposition no longer fits the audible band at all. And the honest constraint above all of those: a category added for arithmetic convenience is not a category. Section 5's validity conditions govern, and an arbitrary addition yields an arbitrary frequency.

4.17b Choosing between the levers — and why the partials do not decide it

The four sensitivities in §4.8 are in four different units. `dD/du` is octaves per unit of non-parallelism; `dD/dc` is octaves per unit of cost. They cannot be compared to each other directly, and a reader who ranks the levers by the size of their partial derivatives is comparing octaves-per-apple to octaves-per-orange.

What makes them comparable is a cost model: the effort, in whatever currency the situation actually spends, required to move each parameter by one unit. That model is not in the formalism and this framework does not pretend to supply it. What the formalism supplies is the *exchange rate* — how many octaves each unit buys — and that is genuinely useful even without the prices, for three reasons.

One: it identifies levers that are absent rather than expensive. The Worked Example's `L2` on the carried case requires `eta >= 1.101077`. That is not a costly lever; it is a lever that does not exist, and no cost model is needed to see it.

Two: it identifies levers that are exhausted. `L4` at `u = 0.018614` buys 0.0446 octaves per category. Against a 6.46-octave deficit that is 145 categories, and no plausible cost model makes 145 new genuinely distinct categories the cheap option.

Three: it gives the shape of the trade, which is stable even when the prices are not. `dD/deta` carries `eta^2` in its denominator, so the `eta` lever is always most powerful where `eta` is lowest. `dD/du` carries `1 + (N−1)u`, so the `u` lever is always most powerful where `u` is lowest. Both levers are strongest in the systems that most need them, which is a real and non-obvious structural fact, and it is the opposite of the usual experience that improvement gets easier once things are already going well.

The honest summary:

```
the formalism gives:   how many octaves a unit of each parameter buys
the situation gives:   what a unit of each parameter costs
the decision needs:    both, and only one of them is in this framework
```

4.18 The classification — three kinds of case, and they need different work

```
D <= 0                      SUSTAINABLE.  Report the margin. Maintain; do not assume.
D >  0  and c/eta <= ln N    TUNABLE.      Some assignment of u closes it. Choose levers
                                           by sensitivity, subject to CC-R15's ordering.
c/eta > ln N                STRUCTURAL.   No assignment of u closes it. L1 is unavailable
                                           at any value. Only L2, L3, L4 −
and L4 only to
                                           make the case tunable, not to close it.
```

An account that showed only tunable cases would be selecting its evidence. The carried commons case §3.3 — six members drawn from one doctrine — reads `u = 0.018614`, `f = 0.7017 Hz`, `f_min = 61.9349 Hz`, `D = +6.4638 octaves`, `Q_inf = −8.4630`. The companion paper on tuning carries it, and the finding it carries is that no single lever closes a 6.46-octave gap: raising `u` to 0.95 — near-orthogonality, for six people drawn from one doctrine — closes it by 0.0332 octaves and no more; raising `eta` to 0.90 leaves `+2.1075`; cutting the per-link cost to 0.020 leaves `+2.0085`. Some systems cannot be tuned. The diagnostic is what identifies which case is in hand, and that is most of its value.

4.19 Reporting: precision, sensitivity, and the rule that follows Because `d ln f_min / d(c/eta) = 2` exactly, and because `D = 2.885390 (c/eta − F)`:

```
an uncertainty of dx nats in (c/eta)  ->  an uncertainty of 2.885390 * dx octaves in D
```

SPEC 4.19 (the reporting rule): publish `D` together with its sensitivity to the parameter carrying the largest uncertainty, and publish the ceiling test. A deficit of `+0.5 +/− 1.5` octaves is a statement that the relation might be fine; a deficit of `+0.5 +/− 0.1` is a statement that it is not. The two look identical if only the point estimate is printed, and the difference between them is the whole of the reading's usefulness.

And a specific trap: precision in a constructed case does not transfer. Every figure in this framework's worked cases is exact because the parameters are chosen. A measured case has no such property, and printing `30.1588 Hz` from an `eta` known to one significant figure is precision theatre.

4.20 Cents, for fine work

```
1 nat  = 3462.4681 cents        1 octave = 1200 cents
D in cents = 3462.4681 * (c/eta − F)
```

The carried case as found reads `+4.3384 octaves = +5206.1 cents`; after the intervention it reads `−3.5910 octaves = −4309.2 cents`. Cents matter when a deficit is small: row 8 of the sustaining-frequency tabulation [Curzi, 2026], at `+0.033406` octaves, is 40 cents — about a fifth of a semitone — and is the difference between a practice that persists and one that must be rebuilt each generation.

A rendering note, stated once: `N = 12` is below the `N = 17` cliff, so everything here renders in the `50/49` regime at a minimum separation of 34.9756 cents, requiring `32/(4 pi) = 2.546479` cycles per resolved step. A 40-cent deficit is therefore just above the minimum resolvable step of the lattice it is expressed in, and a 6-cent one would not be. The companion paper on octave folding owns the folding and states the regime once.

4.21 The citation contract This section fixes five objects for the whole framework. **Later papers in the corpus cite them by name and number and do not restate the derivations.** The contract is set out here so that a reader can check any later section against it.

```
OBJECT                          DEFINED IN     CITED AS

```

Five objects are deliberately NOT owned here, and later papers in the corpus must go to their owners:

```
the differentiation index n and its count argument      -> Section 5
the elicitation procedure for intensities               -> Section 6
```

```
octave folding and the odd-part class rule          -> The companion paper on octave folding
f_rel = k(1 + 11u)^2 as the dyad's interval         -> The companion paper on the dyad interval
the CC-R15 order-of-operations rule                    -> The companion paper on the sustainable dy
```

The division matters. This section states what a deficit is and what closes it. It does not state how to obtain `u`, how to defend `n`, or in what order to pull the levers in a real bond — those are separate results with separate defences, and a keystone section that absorbed them would make all of them harder to check.

4.22 What a reading is not permitted to conclude The last thing this section owns is a boundary, and it is placed here rather than in the failure modes because it is not a mistake anyone makes by accident.

A reading does not conclude that a relation should end. `D > 0` says a configuration is losing order at a computable rate. It does not weigh what the relation is for, what else it produces, or what ending it would cost. The formalism has no term for any of that and does not acquire one by being applied to people.

A reading does not conclude that anyone is at fault. `u` is a property of two representations jointly. `c` and `eta` are properties of an arrangement. There is no single-party term in the whole apparatus.

A reading does not conclude anything about a person's health, capacity, or prospects. The twelve states are not diagnoses; the ladder is not an assessment instrument; the deficit is not a prognosis. Nothing in this framework is clinical and nothing in it may be presented as clinical.

A reading does not compel anyone. Any intervention that follows from it is subject to the standing constraint that no person's ability to decline may be removed, and to the standing prohibition on anything masked or below threshold. Consent is structure here, not advice, and The companion paper on tuning builds the interventions to that requirement rather than adding it afterwards.

And a reading is not evidence about anything outside its own parameters. `Q_inf` is where a configuration goes if the configuration holds. It says nothing about whether it will hold, and CC-R23 stands: the survivorship likelihood ratio for testimonial evidence that a configuration held is exactly `1.000000`.

The Specification

SPEC 4.1 — CEILING FIRST. Compare `c/eta` to `ln N` before any other computation. Classify the case as sustainable, tunable, or structural (§4.18) before issuing any prescription.

SPEC 4.2 — DECLARE `N` and the ordering that produced it, with the note that the frequency inherits the defensibility of the count.

SPEC 4.3 — ONE CLOCK. `eta`, `c` and `delta` on one declared period, named in the same passage as the ratio.

SPEC 4.4 — DECLARE SCALE STATUS of `u`, `eta` and `c`. Ordinal inputs yield an ordering, never a frequency.

SPEC 4.5 — REPORT THE TRIPLE. Every reading reports `f`, `f_min`, and `D`, with the folded values and their `j` where a band is used.

SPEC 4.6 — REPORT THE SENSITIVITY of `D` to the least certain parameter (SPEC 4.19).

SPEC 4.7 — REPORT THE PITCH HEADROOM `2.885390 (ln N − F)` alongside the deficit, so that a reader can see how much of the scale remains.

SPEC 4.8 — CROSS-CHECK VIA THE IDENTITY. Verify `D = −2.885390 (delta/eta) Q_inf`. A disagreement means an arithmetic error, since the identity is exact.

SPEC 4.9 — NEVER USE `delta` AS A DEFICIT LEVER. Theorem 4.9. Interventions on `delta` are reported separately, as multipliers on an existing sign.

SPEC 4.10 — ORDER OF OPERATIONS. Fix the numerator before lowering the loss. Raise `eta` or cut `c` until `eta F > c`, and only then invest in `delta`. The companion paper on the sustainable dyad owns this rule; the Worked Example demonstrates it.

SPEC 4.11 — TEST COST CUTS FOR CONVERSION DAMAGE. Before cutting `c`, ask whether the cost being cut is performing conversion work. If it is, the ratio `c/eta` may not improve at all.

SPEC 4.12 — RAISE `N` ONLY WITH REAL CATEGORIES. An added category must satisfy Section 5's validity conditions and must carry variance the existing categories do not. Adding categories to a near-parallel set buys almost nothing — 0.0446 octaves each at `u = 0.018614`.

SPEC 4.13 — RESPECT THE RENDERING BOUNDS if the reading is displayed: the regime (`50/49` for `N <= 16`), the transposition `j`, a windowed envelope, `N <= 25` for a single transposition.

SPEC 4.14 — NO AGGREGATION. Per relation, per site, per period. Ratios do not average.

SPEC 4.15 — MEAN OF `F`, NOT `F` OF THE MEAN, wherever a reading spans more than one pair.

SPEC 4.16 — LABEL EVERY CASE CONSTRUCTED.

SPEC 4.17 — ESSENCE, NOT RESONANCE, in every passage printing a hertz value.

SPEC 4.18 — NO CLINICAL LANGUAGE. A reading is of a configuration of parameters, never of a person's condition.

SPEC 4.19 — THE REPORTING RULE, as stated in §4.19.

SPEC 4.20 — CITE, DO NOT RE-DERIVE. Later papers in the corpus cite this section for `f_min`, the octave deficit, the ceiling, and the four levers. The definitions above are the framework's, and no part of the framework may silently redefine them.

The Failure Modes

FM 4.1 — TUNING ABOVE THE CEILING. *Signature:* a lever prescription for a case with `c/eta > ln N`. *Mechanism:* the condition `F > c/eta` is unsatisfiable, but the deficit is just a larger positive number and looks like more of the same problem. *Diagnostic:* compute `c/eta` and `ln N`. This test costs one logarithm and changes the kind of answer. *Fix:* SPEC 4.1. The remedies are `eta`, `c`, and genuinely new categories — and `N` only in order to make the case tunable, never to close the deficit directly.

FM 4.2 — TRUST FIRST. *Signature:* a failing relation into which trust, ritual, or continuity is invested, followed by acceleration of the failure. *Mechanism:* CC-R15, exactly. `delta` divides a negative numerator. Computed on the carried case: `delta` 0.09 -> 0.05 moves `Q_inf` from `-5.0119` to `-9.0215`, and the deficit does not move at all, remaining `+4.338420` to every digit. *Fix:* SPEC 4.10. Fix the numerator, then lower the loss.

FM 4.3 — SINGLE-LEVER THINKING ON A LARGE DEFICIT. *Signature:* a plan to close six octaves by one adjustment. *Mechanism:* the levers saturate. `u` is bounded at 1; `eta` at its mechanical maximum; `c` at 0; `N` buys `0.0446` octaves per category at low `u`. *Fix:* compute what each lever alone would require (the Worked Example for the dyad; the companion paper on tuning for the commons), and if none is reachable, say so. **Some systems must be restructured.** The corpus's launch-budget result gives the shape of what restructuring costs [Curzi, 2026p]: with a rectified fund `L^Q = max(0, eta*M - C)` and fixed point `L/lambda`, departure from an existing arrangement is feasible only where that fixed point exceeds the barrier, after `t* = ln(1 - E_b/L_inf)/ln(1-lambda)` periods.

FM 4.4 — PRECISION THEATRE. *Signature:* `f_min = 30.1588 Hz` from `eta = 0.3`. *Mechanism:* exact arithmetic on inexact inputs. *Fix:* SPEC 4.6 and SPEC 4.19.

FM 4.5 — THE ORDINAL SMUGGLE. *Signature:* a numeric `c/eta` from rank-ordered inputs. *Mechanism:* division requires a ratio scale. An order-preserving relabel moved `f_min` from

195.0279 Hz to 10648.1604 Hz in the sustaining-frequency paper [Curzi, 2026] without changing anything an ordinal instrument could see. *Fix:* SPEC 4.4 and CC-R1's route out — Rasch instrumentation at 123 items per term.

FM 4.6 — BUYING `u` PAST 1. *Signature:* a plan requiring `u > 1`, or a required `u` that is not checked against 1. *Mechanism:* `u = 1 − (x.y)^2 <= 1` by construction. *Fix:* compute the required `u = (e^(c/eta) − 1)/(N−1)` and check it against 1 — which is the same as the ceiling test, seen from the geometry.

FM 4.7 — ADDING CATEGORIES TO A PARALLEL SET. *Signature:* a richer taxonomy adopted to raise `N`, with no change in the reading. *Mechanism:* the Parallel Wall. `N` enters `F` only multiplied by `u`. At `u = 0.018614` a new category is worth 0.0446 octaves. *Fix:* raise `u` first, or accept that `N` is being raised to lift the ceiling and not to close the deficit.

FM 4.8 — `f_min` PLAYED AS A TONE. *Signature:* any proposal to sound `f_min` at anyone. *Mechanism:* the register slip. `f_min` is a threshold in a computation and the frequencies are essence frequencies. *Fix:* rendering is governed by the companion paper on rendering, under the open problem stated in this series — no established mechanism for sequence-specific acoustic demodulation — and under the absolute no-subliminals rule.

FM 4.9 — THE NEGATIVE STOCK. *Signature:* a plan that anticipates arriving at `Q_inf = −5.0119`. *Mechanism:* admissibility fails first, at `t = 1` in the carried case. *Fix:* read a negative fixed point as a direction and a rate.

FM 4.10 — CUTTING THE CONVERSION MECHANISM. *Signature:* `c` falls, `eta` falls with it, `D` does not move. *Mechanism:* `D` depends on the ratio. *Fix:* SPEC 4.11.

FM 4.11 — THE AGGREGATED READING. *Signature:* one deficit for a whole organisation. *Mechanism:* CC-R10 — distortion cancels across sites, overstating bankable input by 4.26x; CC-R16 — identical aggregates hide topologies that lose 77% versus 21% of surplus to the same departure. *Fix:* SPEC 4.14.

FM 4.12 — THE JENSEN SHORTCUT. *Signature:* a group reading from `F(mean u)`. *Mechanism:* strict concavity inflates `F`, inflates `f`, and under-reports `D`. *Fix:* SPEC 4.15. Worth 6.2% in Series B's worked office.

FM 4.13 — THE DEFICIT READ AS A JUDGEMENT OF PEOPLE. *Signature:* "our reading is `+4.34`, so one of us is the problem." *Mechanism:* a four-parameter configuration is being read as a property of a person. The deficit is a property of an arrangement. *Fix:* state it as the arrangement. The most common real repair — the carried case's own — is that one party takes on states the other does not hold and the pair adopts a record. Neither of those is a correction of a person.

Worked Example

THE CARRIED DYAD — THE FULL ARC, 2a TO 2b **This case is CONSTRUCTED. It is the dyad of the framework's carried dyad and it is the only case used in this section.** Its parameters are chosen, not observed. It is not an assessment of any person and no clinical, diagnostic or therapeutic claim is made or implied. The frequencies are essence frequencies and nothing is claimed to resonate.

Phase 2a — as found

```
A = {4: 0.7, 6: 0.5, 9: 0.4}
B = {4: 0.6, 6: 0.55, 9: 0.3, 10: 0.2}

eta = 0.30      c = 0.62      delta = 0.09      N = 12, one declared period
```

Step 1 — the geometry.

```
cos theta = 0.965021        u = 0.068735        F = 0.563085 nats
N_eff     = 1.7561
f         = k (1 + 11u)^2 = 1.4908 Hz           folded 381.644 Hz (j = 8)
```

The pair agree about nearly everything, and that is the whole problem. No one involved would describe it as a problem. Two people 0.965 aligned field 1.76 people's worth of distinct perspective between them.

Step 2 — the ceiling test, first.

```
c/eta   = 0.62 / 0.30 = 2.066667
ln N    = 2.484907
2.066667 <= 2.484907        BELOW THE CEILING  ->  the case is TUNABLE
```

Step 3 — the reading.

```
f_min            = k e^(2 * 2.066667)    = 30.1588 Hz     folded 241.270 Hz (j = 3)
octaves required = 2.885390 * 2.066667   =  5.963140
octaves present  = log2(1.4908 / k)      =  1.624719
OCTAVE DEFICIT D                         = +4.338420      (+5206.1 cents)
pitch headroom   = 2.885390 (ln 12 - F)  =  5.5452 octaves
N_eff required   = e^2.066667            =  7.8985
VERDICT: DECAYS
```

Step 4 — cross-check.

```
Q_inf = (0.30 * 0.563085 - 0.62) / 0.09 = -5.0119
identity: -2.885390 * (0.09/0.30) * (-5.011940) = +4.338420        error 8.88e-16
admissibility fails at t = 1;  the stock goes negative at t = 2
```

The reading in one sentence: this pair must be worth 7.9 genuinely different people to break even, and they are worth 1.76.

The CC-R15 demonstration — and it is the case's whole point The intuitive repair is to add trust. It is what everyone reaches for, it is not foolish, and it is well supported in ordinary experience. Trust lowers `delta`. Suppose it works completely and `delta` moves from 0.09 to 0.05.

```
BEFORE:   Q_inf = -0.451075 / 0.09 = -5.0119
AFTER:    Q_inf = -0.451075 / 0.05 = -9.0215        WORSE by 80%

DEFICIT BEFORE: +4.338420 octaves
DEFICIT AFTER:  +4.338420 octaves                   UNCHANGED, to every digit
```

The numerator `eta F - c = -0.451075` is negative. Dividing a negative number by a smaller positive denominator makes it more negative. Trust did not add order; it amplified the sign the relation already had, and the sign was negative.

And the deficit did not move at all, because `delta` is not in it (Theorem 4.9). This is the sharpest available statement of CC-R15 and it is why the frequency register earns its place: the instrument reads unchanged while a successful, well-intentioned, expensive intervention doubles the rate of loss. A reader with the deficit and without Theorem 4.9 would interpret the flat reading as "give it more time." A reader with both interprets it correctly the first time: the mechanism has not been touched.

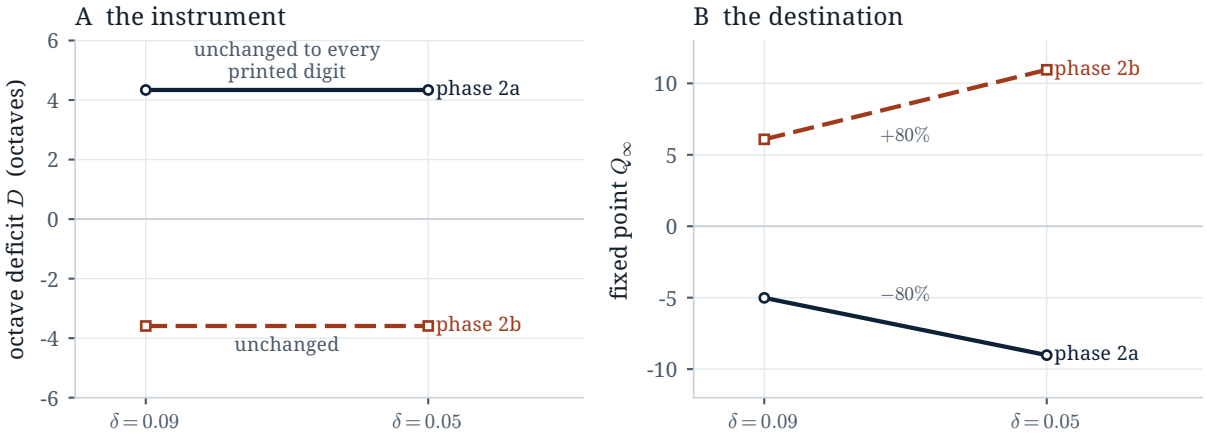

Figure 41.2: Halving the decay rate leaves the octave deficit unchanged to every printed digit and moves the fixed point by 80 per cent in whichever direction it already pointed — worse when the numerator is negative. Panels are separate axes because the two quantities have different scales. Modelled on the constructed carried dyad: $u = 0.068735 \to 0.692373$, $\eta = 0.30 \to 0.44$, $c = 0.62 \to 0.40$, $N = 12$, with δ moved from 0.09 to 0.05 at each phase. Built by `figs/src/CCP-041_fig03.py`.

The four levers on 2a, each alone Required: `F >= c/eta = 2.066667`, i.e. `N_eff >= e^2.066667 = 7.898451`.

```
L1  RAISE u
    need u >= (7.898451 - 1)/11 = 0.627132        from 0.068735 -- a rise of x9.12
    at that u, f = 30.1588 Hz = f_min exactly, D = 0
    REACHABLE, but 0.627132 is a large amount of real difference for two people
    who currently sit at cos theta = 0.965

L2  RAISE eta
    need eta >= c/F = 0.62 / 0.563085 = 1.101077
    IMPOSSIBLE. A conversion efficiency above 1 would mean more structure created
    than interaction supplied. The lever is not merely expensive; it is absent.

L3  CUT c
    need c <= eta F = 0.30 * 0.563085 = 0.168925
    from 0.62 -- a cut of 72.8%
    REACHABLE in principle; a 72.8% reduction in coordination overhead is a large project.

L4  RAISE N
    need 1 + (N-1)(0.068735) >= 7.898451  ->  N >= 101.3635  ->  N_min = 102
    NOT REACHABLE. The Parallel Wall: at u = 0.068735 a new category buys 0.1129 octaves,
    and 4.34 octaves would take 38 of them even ignoring that u itself would change.
```

No single lever is comfortable and one of them does not exist. This is the ordinary situation and it is why the classification in §4.18 matters more than any individual sensitivity: the case is tunable, so a combination exists, and the combination is what the arc demonstrates.

Phase 2b — after one intervention, correctly ordered **CONSTRUCTED.** Two changes, made together:

1. **B takes on two states A does not hold.** This raises `u`. It is a change in what B is actually doing, not a rhetorical adoption of a contrary position — CC-R8 forbids the latter from

working, since perfect opposition reads as `u = 0` exactly as agreement does.
2. The pair adopt a decision log. This raises `eta` — what they work out now has somewhere to live — and lowers `c`, because the record does the remembering that the coordination overhead was paying for.

One realising vector, for concreteness:

```
B' = {2: 0.95, 4: 0.60, 6: 0.55, 9: 0.30, 10: 0.20, 12: 0.8391}
cos theta = 0.554643      u = 0.692373        (the framework carries this as 0.6924)

u    0.068735  ->  0.692373
eta  0.30      ->  0.44
c    0.62      ->  0.40
delta unchanged at 0.09
```

The reading, recomputed from scratch:

```
F                = ln(1 + 11 * 0.692373)  =  2.153633 nats
N_eff            =  8.6161
f                = k * 8.6161^2           = 35.8882 Hz     folded 287.106 Hz (j = 3)
octaves present  =  6.214071

c/eta            = 0.40/0.44 = 0.909091
ceiling test     : 0.909091 <= 2.484907   BELOW, comfortably
f_min            = k e^(2 * 0.909091)     =  2.9782 Hz     folded 381.212 Hz (j = 7)
octaves required =  2.623082

OCTAVE DEFICIT D = -3.590989 octaves      (-4309.2 cents)
N_eff required   = e^0.909091 = 2.4821
pitch headroom   = 2.885390 (ln 12 - 2.153633) = 0.9559 octaves
VERDICT: ACCUMULATES
```

Cross-checks:

```
Q_inf  = (0.44 * 2.153633 - 0.40)/0.09 = +6.0844
identity: -2.885390 * (0.09/0.44) * 6.0844 = -3.590989           exact
trajectory from Q_0 = 1.0:  t=1 +1.4576   t=5 +2.9116   t=20 +5.3134   t=40 +5.9675
convergence: |Q_20 - Q_inf| = 0.7710275635960624
             (0.91)^20 |Q_0 - Q_inf| = 0.7710275635960623
admissibility holds at every step
```

The swing: `D` from `+4.338420` to `-3.590989` — 7.929409 octaves. `Q_inf` from `-5.0119` to `+6.0844`. The pair now needs to be worth 2.4821 distinct people and is worth 8.6161.

Where the 7.929409 octaves came from The swing decomposes exactly, and the decomposition is worth having because it shows which half of the repair did the work.

The path-free split — into the cost side and the surplus side — follows directly from `D = 2.885390 (c/eta - F)`:

```
from the cost ratio:  2.885390 * (0.909091 - 2.066667)  =  -3.340058 octaves
from the surplus   : -2.885390 * (2.153633 - 0.563085)  =  -4.589352 octaves
total                                                      -7.929409 octaves
```

Raising `u` did 57.9% of the work; the cost-side changes did 42.1%.

The split *within* the cost side is path-dependent, and the framework says so rather than picking a flattering order. Attributing a joint change to individual parameters requires an order, and different orders give different attributions even though the total is identical:

```
PATH 1 -- u first, then eta, then c
    u   0.068735 -> 0.692373    -4.589352
    eta 0.30     -> 0.44        -1.897363
    c   0.62     -> 0.40        -1.442695
    total                       -7.929409

PATH 2 -- c first, then eta, then u
    c   0.62     -> 0.40        -2.115953
    eta 0.30     -> 0.44        -1.224105
    u   0.068735 -> 0.692373    -4.589352
    total                       -7.929409
```

The `c` contribution is `-1.442695` on one path and `-2.115953` on the other — a 47% difference in the attribution, from the same intervention producing the same result. The reason is elementary: `c` is divided by `eta`, so cutting cost is worth more when `eta` is still low.

The `u` contribution is identical on both paths (`-4.589352`), because `F` is separable from the cost ratio in `D` and nothing multiplies it.

The practical rule that follows: report the path-free split, and if a per-parameter attribution is wanted, report the order used. An attribution presented without its order is a number that could have been 47% different for no reason but the sequence in which someone chose to describe events.

Now trust helps Repeat the exact intervention that made things worse in phase 2a — `delta` from 0.09 to 0.05:

```
Q_inf  =  (0.44 * 2.153633 - 0.40) / 0.05  =  +10.9520          from +6.0844
deficit                                    =   -3.590989        unchanged, as always
```

The same intervention, applied to the same pair, with the same magnitude, in the same direction. At 2a it took `Q_inf` from `-5.0119` to `-9.0215`. At 2b it takes it from `+6.0844` to `+10.9520`.

The arithmetic is not subtle and it is not a special case. `delta` multiplies. It has no sign of its own.

> THE ARC: fix the numerator, then lower the loss. Reverse the order and the same intervention accelerates the failure.

The honest note on where 2b leaves them The repair worked, and it worked by spending most of the range that twelve categories make available:

```
pitch headroom at 2a:  5.5452 octaves
pitch headroom at 2b:  0.9559 octaves
```

They have 0.96 octaves of the scale left. A further improvement of the same kind — more represented difference between two people described by twelve states — is close to exhausted. The next order of gain is not available from `u` at this `N`. It would require genuinely new categories, and per §4.17 and SPEC 4.12 those must be real categories and not finer slicing.

This is not a defect in the repair. It is the ceiling doing what a ceiling does, and the value of the reading is that the pair can see it coming rather than discovering it as an unexplained plateau.

The whole reading, as a card

------------------------------------------------------------------------
```

Section 5 takes up the index `n` and the argument that a count escapes the demotion. Every part of the framework after it that needs `f_min`, the octave deficit, the ceiling, or the four levers cites this section.

5 The psychological essence index

Section 4 ended with a diagnostic that needs one input not yet supplied. The minimum sustainable frequency `f_min = k e^(2c/eta)` fixes the pitch a relation must reach. The octave deficit gives how far short it falls. Neither is computable until something on the psychological side has a frequency at all, and nothing does until a psychological category has been assigned an index `n`.

That assignment is the whole of this part of the framework's exposure, and every downstream reading stands on it. Get it wrong — or, worse, get it arbitrarily — and the framework has produced a long sequence of precise-looking numbers that mean nothing, which is the exact failure mode Series B spent a volume learning to detect in other people's work.

This section owns the index. Later papers in the corpus cite it and do not redefine it. It states what `n` is, makes the argument that the index escapes the scale demotion its neighbours inherit, presents the twelve-state ladder that the rest of the framework uses, grades four rival

orderings against the governing validity conditions, rejects three of them in print, and states the limit that travels with every frequency the framework publishes.

Two prohibitions govern the section from its first line and are restated at its last. The frequencies here are essence frequencies, not physical resonances; no person, tissue, or molecule is claimed to resonate at any value in this framework. **And the twelve states are not diagnoses.** They are not a classification of persons, not a severity scale, not an assessment instrument, and nothing in this section or any later one licenses their use as one.

The Law

5.1 The statement

```
THE PSYCHOLOGICAL ESSENCE INDEX

    n  :=  the number of distinguishable components required to specify the state

and, through the essence law (the essence law of Series B(CCP-017)):

    f(n) = k * n^2            k = (9/8)^2 / phi^2 = 0.483425732988414 Hz
```

Read it slowly, because every word is doing work.

"The number" — this is a cardinality, not a position, not a rating, not a score. It answers *how many*, and the answer is an integer.

"Distinguishable" — components that the encoding cannot tell apart count once. Two names for one component are one component. This is the clause that does the most work and takes the most abuse, and Section 6 is largely about enforcing it.

"Components" — the constituents of a specification, not the parts of a thing. A component is something that must be stated in order for a reader to know which state is meant.

"Required" — the minimal count. Not the number of things that could be said about the state, but the number that cannot be omitted without the specification becoming ambiguous. Redundant components are not components.

"To specify the state" — the criterion is specification, and specification is public. If two analysts working from a declared decomposition and the same episode cannot both arrive at the same state description, the count was not of components; it was of something else.

The index is therefore a *minimal description length in components*, and the essence law raises it to the second power and scales it by a fixed constant. Nothing else enters. `k` is a chosen reference constant, not a measured one, and it is badged as a postulate here as it is everywhere in this series. Its form — a Pythagorean ditone divided by the golden section — is a design decision of the author's, taken in the 2022 source and carried forward unchanged. It sets the absolute pitch of the whole system and nothing else. Every *relationship* in the system is a ratio of squared integers, in which `k` cancels exactly.

5.2 A count is not a rating, and the difference is the whole argument Stevens' 1946 typology of measurement scales is usually taught as a four-item list — nominal, ordinal, interval, ratio — and usually taught badly, as though the four were degrees of quality. They are not degrees of quality. They are statements about *which transformations of the numbers leave the empirical content unchanged* [Stevens, 1946], and that is a precise and checkable property — though what follows from a scale type for the permissibility of a statistic has itself been disputed for as long as the typology has existed [Luce, 2002].

```
SCALE       ADMISSIBLE TRANSFORMATIONS          WHAT IS INVARIANT
nominal     any bijection                       identity and difference of category
```

```
ordinal     any strictly increasing f          order
interval    x -> a x + b,  a > 0               ratios of differences
ratio       x -> a x,      a > 0               ratios of values
absolute    identity only                      the values themselves
```

The operations a formula performs on a quantity are licensed by that quantity's scale type and by nothing else; the formal statement of what must hold before a quantity can be said to exist at all is the representational theory of measurement [Krantz et al., 1971]. Addition needs an interval scale. Division and multiplication need a ratio scale with a true zero. Squaring, which is what the essence law does, needs the same.

Now ask which row a count occupies.

A count has a true zero that is not a convention: zero components is not a low score, it is the absence of the thing. It has equal units that are not a calibration choice: the difference between three components and four is one component, and so is the difference between eleven and twelve, because a component is a component. And it has something stronger still. A count admits no rescaling at all. There is no free multiplier `a`. You cannot count in half-components or in dozens-of-components without changing what "component" means, and a change in what "component" means is a change of decomposition, not of units.

A count is therefore an absolute scale, which is strictly stronger than the ratio scale the essence law requires. The index does not merely satisfy `f = k n^2`; it over-satisfies it.

This is the load-bearing observation of this part of the analysis and it deserves to be stated in the form in which it can be attacked:

> **THE COUNT ARGUMENT.** `n` is defined as a cardinality. Cardinalities have a true zero (the empty set) and a fixed unit (one element), and admit only the identity transformation. Therefore `n` is absolute-scaled, hence ratio-scaled, hence a legitimate argument to a multiplicative law. The scale status of `n` is a consequence of its definition and is not contingent on any empirical finding.

An objector who wishes to defeat this must attack the definition, not the algebra. There is exactly one place to attack it, it is a real place, and §5.4 and the whole of Section 6 are about it.

5.3 CC-R1, restated in full, and why the index is not caught by it

Series B demoted its own keystone. The finding is recorded as CC-R1 and it is binding here:

> **CC-R1 — THE MOMENT EQUATION IS DEMOTED ON SCALE.** For `M = (D/P) * E`, the validation protocol's second gate returns DEMOTE. Because `D` (perspective) and `P` (perception) are not instrumented on ratio scales with true zeros, the *magnitude* of `D/P`, the distortion `Delta = |ln r|`, and the quantitative join from the moment into the storage law are not reportable as measured quantities. The structure survives: the limiting cases, the `D = P` fixed point, and the ordering over-framed / calibrated / under-framed all stand, because each needs only ordinal information. **What is demoted is magnitude, not structure.** The constructive route out is Rasch instrumentation — a logit difference supplies the true zero division requires — at a measured cost of 123 items per term [Rasch, 1960].

Any psychological frequency derived through `D/P` inherits that demotion, and this framework says so wherever such a derivation appears. The demotion is not a caveat bolted onto a result; it is a statement that a particular number is not yet a number.

It is worth seeing what the demotion costs in the register this framework works in, because stated as "the scale type is wrong" it sounds like bookkeeping and it is not. Take a constructed pair of ordinal ratings, `D = 7` and `P = 4` on some 0-to-10 instrument, and apply transformations that are *admissible for ordinal data* — that is, transformations which preserve the order of the ratings and therefore preserve everything the ratings are licensed to report.

```
transform        D'         P'        r = D'/P'      ln r
identity       7.0000     4.0000        1.7500      +0.5596
x^2           49.0000    16.0000        3.0625      +1.1192
sqrt x         2.6458     2.0000        1.3229      +0.2798
ln(1+x)        2.0794     1.6094        1.2920      +0.2562
x^1.5         18.5203     8.0000        2.3150      +0.8394
exp(x/5)       4.0552     2.2255        1.8221      +0.6000

r spans 1.2920 to 3.0625 -- a factor of 2.3703
r > 1 in all six cases -- THE ORDER IS PRESERVED, EXACTLY AS CC-R1 SAYS
```

The direction survives every transformation. The subject is over-framed under all six, and that reading is safe. The magnitude survives none of them.

Now push it through the essence law anyway, as a careless practitioner would, treating `r` as though it were an index:

```
transform     n := r      f = k r^2 (Hz)     folded to 220-440
identity      1.7500          1.4805            379.006
x^2           3.0625          4.5340            290.176
sqrt x        1.3229          0.8460            433.149
ln(1+x)       1.2920          0.8070            413.185
x^1.5         2.3150          2.5909            331.630
exp(x/5)      1.8221          1.6050            410.888

derived frequency spans 0.8070 to 4.5340 Hz = 2988.17 cents = 2.490 octaves
```

A frequency derived through `D/P` is undetermined to within two and a half octaves by transformations that change nothing the underlying data are entitled to say. The spread is not a property of the world; it is a property of the arbitrary set of transformations chosen for the demonstration, and a different set would give a different figure. That is precisely the point. A quantity whose value depends on an arbitrary choice the data cannot constrain is not measured. Any section that publishes such a frequency is publishing a number the reader cannot check, and this framework does not do that.

Set the count beside it.

```
transform     n     f = k n^2 (Hz)
identity      5        12.0856
(there is no other admissible transform of an absolute scale)
```

There is no table because there is no spread. **Five components is five components.** The transformation group of an absolute scale contains one element, so the frequency is determined by the decomposition and by nothing else.

> **THE SIDESTEP, and it is the single most important claim in this part of the analysis.** The Moment equation is demoted because `D/P` is a ratio of two quantities that have not been instrumented on ratio scales. **The psychological essence index is not a ratio of ratings. It is a count of components.** Its ratio-scale status is established by construction rather than by instrumentation, and therefore nothing in CC-R1 touches it. The index does not inherit the demotion. It sidesteps it.

The sidestep is real, and it is worth being explicit about what it does and does not buy, because a claim this convenient invites suspicion and should.

What it buys. The essence law may be applied to the index without a scale objection. `f = k n^2` is a licensed operation on `n`. All the interval structure developed here — ratios of squares, the octave relations, the pitch classes — is licensed. The frequencies may be published as

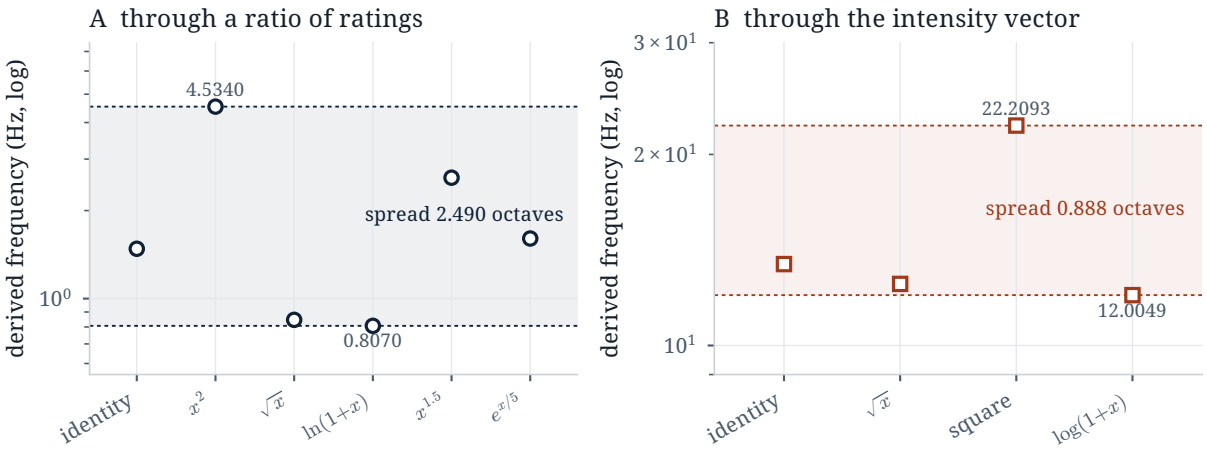

Figure 41.3: A frequency reached through a ratio of ratings is undetermined to within 2.490 octaves by transformations that change nothing the underlying data are entitled to say; the same failure through the intensity vector costs 0.888 octaves. A **count** admits exactly one transformation, the identity, so the corresponding panel would carry one point and no spread. Modelled: the transform sets are chosen for the demonstration and a different set would give a different figure — which is the point, because a quantity whose value depends on an arbitrary choice the data cannot constrain is not measured. Built by `figs/src/CCP-041_fig05.py`.

magnitudes, not merely as an ordering. And the ceiling result `c/eta <= ln N` from Section 4 has a determinate `N` to work with.

What it does not buy. It buys nothing whatever about whether the *decomposition* is right. The count is absolute-scaled *given* a decomposition, exactly as a count of coins is absolute-scaled given an agreement about what a coin is. Change the decomposition and the count changes, and no amount of scale theory arbitrates between two decompositions. **The scale problem has not been solved. It has been moved, from the measurement of a magnitude to the justification of a partition — and it has been moved somewhere it can be argued about in public, which is the entire gain.**

That relocation is not a trick. It is the standard move by which counting escaped the same problem everywhere else it arose. Atomic number is a count of protons and is absolute-scaled given an agreement about what a proton is; the agreement took a century and several revisions, and the scale status of the count was never what was in dispute. Species richness is a count of species and is absolute-scaled given a species concept; the species concept is contested, and ecologists argue about *it*, in print, rather than arguing about whether one richness may be divided by another. The psychological essence index puts psychology in the same position: the argument moves to the decomposition, where it belongs and where it can be settled by agreement statistics rather than by philosophy.

5.4 The honest limit, and it is stated wherever the index is used

> **THE FREQUENCY INHERITS EXACTLY THE DEFENSIBILITY OF THE COUNT. A CONTESTED DECOMPOSITION YIELDS A CONTESTED FREQUENCY.**

That sentence is a standing requirement of this framework. It appears in this section, in Section 6, in The companion paper on octave folding where moods are given frequencies, in the companion paper on trait frequency where traits are, and in the personal-spectrum worksheet of this series. It is not a hedge and it is not modesty. It is a precise statement of where the uncertainty lives, and its practical content is that the uncertainty on a published essence frequency is not a confidence interval; it is a disagreement about a count, and the

correct way to report it is to report the disagreement about the count.

The exchange rate between the two is exact and it is worth having on the page early, because it tells a practitioner what a decomposition dispute actually costs.

```
A MISCOUNT BY ONE: the pitch consequence

n -> n+1     f ratio      cents      octaves     pitch class
 1 -> 2      4.000000    2400.00      2.0000      1 -> 1
 2 -> 3      2.250000    1403.91      1.1699      1 -> 3
 3 -> 4      1.777778     996.09      0.8301      3 -> 1
 4 -> 5      1.562500     772.63      0.6439      1 -> 5
 5 -> 6      1.440000     631.28      0.5261      5 -> 3
 6 -> 7      1.361111     533.74      0.4448      3 -> 7
 7 -> 8      1.306122     462.35      0.3853      7 -> 1
 8 -> 9      1.265625     407.82      0.3399      1 -> 9
 9 -> 10     1.234568     364.81      0.3040      9 -> 5
10 -> 11     1.210000     330.01      0.2750      5 -> 11
11 -> 12     1.190083     301.27      0.2511     11 -> 3
```

Two things follow, and both matter.

A miscount at the bottom of the ladder is enormously more expensive than a miscount at the top. Confusing a one-component state with a two-component state moves the pitch by two full octaves. Confusing an eleven-component state with a twelve-component state moves it by a minor third. The square law compresses; the relative cost of an error falls as `((n+1)/n)^2`, which tends to 1. The elicitation procedure of Section 6 must therefore spend its care where the ladder is steep, which is exactly where practitioners are least careful, because the low states feel obvious.

And a miscount by one almost always changes the pitch class. Adjacent integers have different odd parts unless one is even and the other is its own double, which for adjacent integers happens only at `1 -> 2`. Every other single-step miscount lands the state in a different harmonic class entirely. The pitch class is what survives octave folding and is therefore what a listener hears as identity; The companion paper on octave folding owns that rule and derives it. Here the consequence is enough: a one-component disagreement is not a small disagreement. It is a change of note.

5.5 The framework's validity conditions, and the index against them

A construct is validated by convergent and discriminant evidence, not by internal consistency [Cronbach and Meehl, 1955, Campbell and Fiske, 1959], and the essence law may not be applied to a domain merely because the domain has categories. The framework's foundations state the conditions under which its formal structure may be carried to a target domain at all, and the essence-law specification of Series B [Curzi, 2026k] makes those conditions binding on the essence law and enumerates them. They are restated here because this section is where they are put to work.

```
V1  STATE ENCODING       a map from domain items to normalised vectors, so that every
                         represented state has a determinate location in the model
V2  CATEGORY ASSIGNMENT  a finite partition into idealised categories H_1 ... H_N:
                         exhaustive, exclusive, counted, and genuinely distinct
V3  GEOMETRIC DEPENDENCE interaction modelled through a scalar similarity parameter --
                         an angle, a cosine, an inner-product-derived quantity
V4  ZERO BASELINE        parallel or representationally equivalent states correspond to
                         zero modelled surplus
V5  AFFINE COUNT LAW     adopted as a modelling assumption, not read off the world
V6  NORMALISATION        maximum modelled surplus is finite and depends on N
```

```
and the house addition, because the essence law needs an ORDER and not merely a partition:

V7  DECLARED ORDINAL     the rule assigning index n to category i is published with the
                         frequencies, is applicable by a third party without consulting
                         the author, and includes its tie-break procedure
```

The foundations are explicit about the exclusion that follows: a target domain lacking a stable encoding, a defensible category scheme, or an interpretable angle-like geometry is outside the scope of the model. The essence law inherits that exclusion and this framework enforces it. The three conditions named in that exclusion — explicit state encoding, defensible category partition, interpretable angle-like geometry — are the three the rival orderings of §5.11 through §5.14 are graded against, and no candidate that fails one of them is admitted, however appealing it is on other grounds.

The component-count index answers V7 in a way no other candidate in this section does, and it is worth saying why before the ladder is presented. **The ordinal rule is not a list; it is a procedure.** "Count the components" is applicable by a third party who has never met the author, and it has a determinate answer for a state nobody anticipated. A published list of categories in an order has neither property: it cannot be extended without the author, and a category the author did not think of has no index at all. An ordinal rule that is a procedure rather than an enumeration is the strongest form V7 can take, and it is the principal engineering reason for preferring a count to any of the alternatives.

The Engineering

5.6 The twelve-state ladder **This is the canonical ladder. It is fixed by the framework's founding specification and is used unaltered by every part of the framework of this framework.** Twelve states; `N = 12`; each state adds exactly one component to the one below it, so the state class at index `n` is by construction the class of states requiring `n` components to specify.

n	state class	the component it adds	$f = k \cdot n^2$ (Hz)	folded 220–440	pitch class
1	undifferentiated activation	arousal alone	0.4834	247.514	1
2	valenced activation	+ valence	1.9337	247.514	1
3	directed feeling	+ intentional object	4.3508	278.453	3
4	situated feeling	+ situation	7.7348	247.514	1
5	attributed feeling	+ cause	12.0856	386.741	5
6	temporal feeling	+ projected duration	17.4033	278.453	3
7	reflexive feeling	+ self as object	23.6879	379.006	7
8	social feeling	+ another mind modelled	30.9392	247.514	1
9	normative feeling	+ standard applied	39.1575	313.260	9

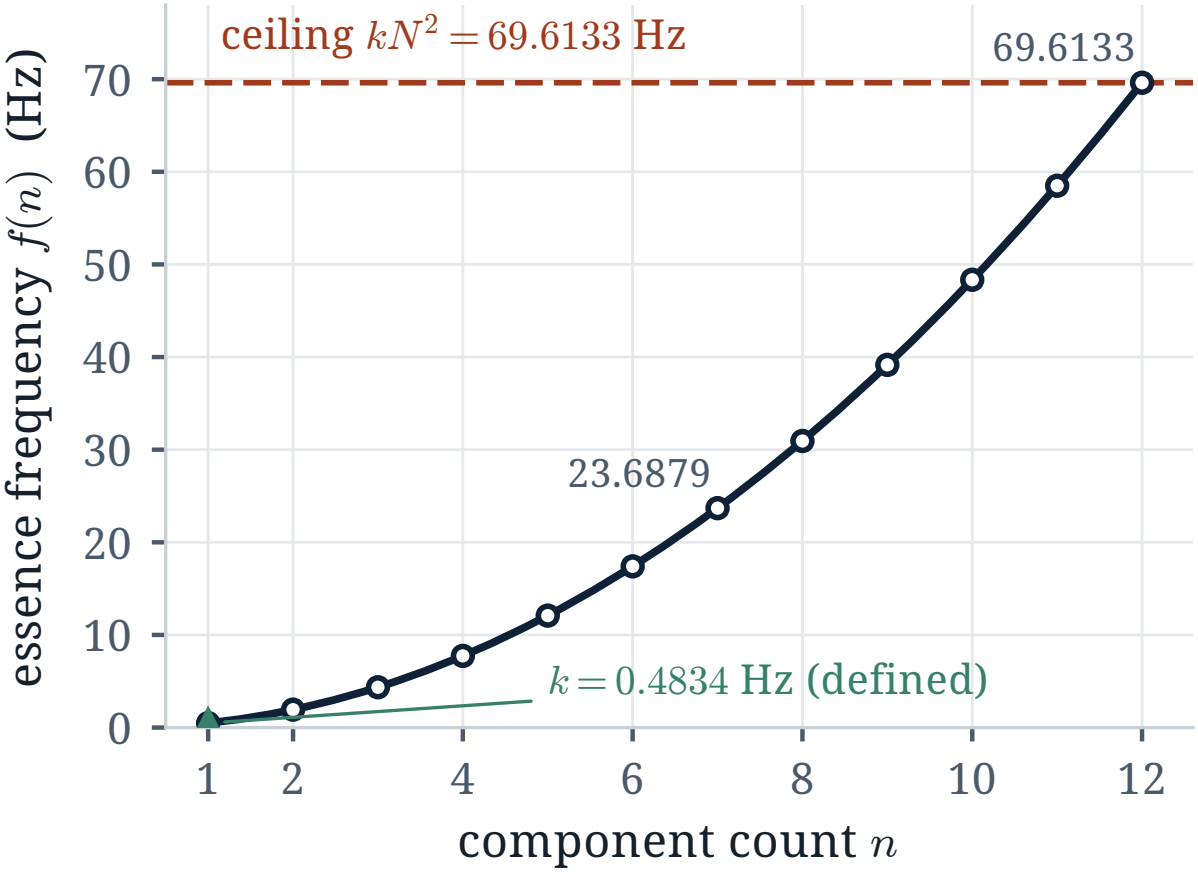

Figure 41.4: The essence law is quadratic in the component count, so the twelve-state ladder spans $12^2 = 144$ in frequency — seven octaves and change — and terminates at the ceiling $kN^2 = 69.6133$ Hz. **Modelled, not measured:** the law $f(n) = kn^2$ is a postulate of this framework (§2.3 P-a) and $k = 0.483425732988414$ is a **defined** constant, exact by construction. Built by `figs/src/CCP-041_fig01.py`.

n	state class	the component it adds	f = k·n² (Hz)	folded 220–440	pitch class
10	narrative feeling	+ placed in a story	48.3426	386.741	5
11	reciprocal feeling	+ the other modelling you	58.4945	233.978	11
12	committed feeling	+ future action bound	69.6133	278.453	3

```
k = 0.483425732988414 Hz        N = 12        ln N = 2.484907
maximum surplus F = ln 12       maximum f = k * 144 = 69.6133 Hz
six distinct pitch classes {1, 3, 5, 7, 9, 11} = ceil(12/2)
```

Every value in the table was computed from `f = k n^2` and folded by powers of two into the band 220–440 Hz. The folding multiplier `j` for each row, since the framework's house rule requires the band and the transposition to be published with every value: `j` = 9, 7, 6, 5, 5, 4, 4, 3, 3, 3, 2, 2 for `n` = 1 through 12 respectively. Octave transposition preserves pitch class exactly; it is the house method and it changes nothing about the reading.

5.7 Reading the ladder The ladder is a specification hierarchy, and each rung earns its index by naming a component that cannot be omitted at that rung and was not present below it. The clearest way to see this is to write the same episode out at each level and watch what has to be added.

n = 1, undifferentiated activation. The specification is *there is arousal*. One component: activation. This is the floor of the ladder, and it is genuinely a state — a person woken at three in the morning by a noise, in the first half second, is in it. Nothing has been evaluated. There is not yet anything the arousal is about.

n = 2, valenced activation. Add valence: the arousal is good or bad. Two components. The half-second has passed; the noise is *bad*. Still nothing about what the noise is. In the affect literature this is roughly the region core-affect accounts describe, and Russell's circumplex [Russell, 1980] is a two-dimensional model of exactly this pair. That correspondence is noted as precedent, not as evidence — a two-dimensional affect model and a two-component specification agree on a count, which is a great deal less than agreeing on a mechanism. It is in fact less than that. Russell's two are two **continuous bipolar axes** recovered from similarity ratings, not two countable components, and the model's principal content — that the affect terms lie on a circle rather than in clusters — has no counterpart anywhere in this ladder. The agreement is on an integer and on nothing else.

n = 3, directed feeling. Add the intentional object: the feeling is *about* something. Three components. The bad arousal is about the noise. This is the rung at which the state becomes a feeling in the ordinary sense of the word, because ordinary usage almost always supplies an object.

n = 4, situated feeling. Add the situation: the state is indexed to a circumstance. Four components. Bad arousal about the noise, in my house, at night. The situation is not the object; the object is what the feeling is directed at, the situation is the frame the object appears in, and a decomposition that conflates them will systematically under-count by one.

n = 5, attributed feeling. Add the cause: an account of why. Five components. The noise is *the back door*, and doors do not open themselves. Appraisal accounts — Smith and Ellsworth [1985] on the dimensions of cognitive appraisal, Lazarus [1991] on primary and secondary appraisal, Scherer's sequential-check model [Scherer, 2001] — are all descriptions of the machinery that produces this component, and **all three are cited for the component's existence and for nothing else.** None of them is cited in support of the index, of its ordering, or of its nesting, and none of the three would supply that support if it were asked for it. The reasons are set out in the third structural remark that closes this section, because they are the strongest objection to the ladder and belong in the body rather than in a footnote.

n = 6, temporal feeling. Add projected duration: how long this will last. Six components. The difference between a fright and a fear is largely this component, and a decomposition that omits it will collapse two states that behave very differently under the stability analysis of the companion paper on trait frequency.

n = 7, reflexive feeling. Add the self as object: the state includes a representation of the one having it. Seven components. *I am frightened, and I am the sort of person who gets frightened.* Tracy and Robins [2004] hold that this class of states — shame, guilt, embarrassment, pride — requires a stable self-representation that the emotions below it do not. That is a claim that a class of states **requires a component** the others lack, which is exactly the form a rung of this ladder needs, and it is the one place in this section where the cited literature supports a rung rather than merely naming its component. The source manuscript names Lewis alongside Tracy and Robins here; that reference is given by surname alone, with no year and no title, it could not be resolved to a specific work, and it has therefore not been guessed at — see L-18.

n = 8, social feeling. Add another mind modelled: the state contains a representation of someone else's mental state. Eight components. *There is a person out there and he wants something.* The theory-of-mind literature descends from Premack and Woodruff [1978]; the component is the modelled other, and it is one component regardless of how elaborate the model is. That paper is cited for the construct's name and provenance only, and two cautions travel with it: it concerns a chimpanzee's inference about a human rather than the composi-

tion of an emotional state, and its experimental claim has been contested since publication.

n = 9, normative feeling. Add a standard applied: the state is evaluated against how things ought to be. Nine components. *This should not be happening; people should not do this.* Note carefully that the standard is a component of the state, not a fact about the world, and that the ladder makes no claim whatever about whether the standard is correct.

n = 10, narrative feeling. Add placement in a story: the episode is an instalment. Ten components. *This is what my life has been like since March.* The narrative component is what converts an event into evidence, and the companion paper on refinement is about the consequences.

n = 11, reciprocal feeling. Add the other modelling you: the state includes a representation of someone else's representation of you. Eleven components. *He knows I am here and he knows I know.* This is second-order and it is a genuinely distinct component from the first-order model at `n = 8`; the pair is the standard recursion of the mentalising literature [Premack and Woodruff, 1978] and the ladder counts each order once.

n = 12, committed feeling. Add future action bound: the state includes a commitment that constrains what is done next. Twelve components. *Whatever else happens, I am not going back to sleep.* Frijda [1986] names the component, and **this rung claims bound commitment and not action readiness as such.** The distinction is forced rather than decorative. Frijda's thesis is that a change in readiness to act is constitutive of emotion *as such*, so on his account the startle at `n = 1` already has action readiness and the component belongs at the floor of the ladder rather than at its summit. Read as a claim about readiness, this rung is contradicted by the work it cites. Read as a claim about a commitment that binds what is done next — an impulse that has been closed over — it is a narrower claim, and it is the only version Frijda leaves standing. **The narrower claim is the one made here; the wider one is withdrawn.**

Three structural remarks about the ladder as a whole, and they bound its claims sharply.

First, **the ladder is a specification hierarchy and not a developmental sequence, a maturity scale, or a ranking of worth.** Nothing in it says that a twelve-component state is better, healthier, more adult, or more valuable than a three-component state. A twelve-component state is *more expensive to specify*, and that is the only claim being made. A person in undifferentiated activation is not failing at anything.

Second, **the ladder is nested by construction.** Each rung contains the rungs below it. This is what makes the index a count rather than a label: the components accumulate, so the number at rung `n` is literally the number of accumulated components. A hierarchy in which the categories were merely ordered — where rung 7 contained something rung 6 did not, but also lacked something rung 6 had — would not license a count at all, and this is where several of the rivals in §5.11 onwards fail.

Third — and this is the remark the section exists to make — the literature named above does not support the index, and one of its entries contradicts it. The rungs were motivated by naming constructs that the affect literature independently describes, and naming is all that establishes. Put at its full strength, the objection is this.

> **THE SCALAR-REDUCTION OBJECTION.** The works cited across §5.7 do not describe emotional states the way this ladder does, and four of them describe them in a way a count cannot represent. Smith and Ellsworth [1985] locate fifteen emotions in a space of appraisal dimensions that vary **simultaneously and independently**; two emotions at the same dimensionality are told apart by the *pattern of values across* those dimensions, which is precisely the information a count throws away. **A count cannot separate anger from guilt; a pattern can, and does.** Scherer [2001] is sharper still. Emotion there is a **process unfolding in time** — a sequence of stimulus evaluation checks driving synchronised change across five organismic subsystems, where the emotional state *is* the synchronisation. An object with an ordering of its own resists reduction to a scalar of any kind, a component count included. Lazarus [1991] individuates emotions by a **core relational theme**: a qualitative content, one per emotion. A theory in which anger and guilt differ by *what*

> is appraised does not license a theory in which they differ by *how many* things are appraised. And Frijda [1986] contradicts the ladder at its **top rung**: if changed action readiness is constitutive of emotion as such, that component sits at or near the floor, and the ordering fails at its own summit.

Three of the four charges are conceded outright, and the fourth is answered only by narrowing the claim. The ordering and the nesting of the rungs are not underwritten by any of the four works and are not offered as though they were. They are a **stipulation of this framework**, fixed by the construction of §5.6 and badged here as such — no postulate in §2.3 covers them, and that omission is recorded in L-18. What this literature supplies is at most a *set* of components attested individually, with the ordering owned here rather than borrowed. Frijda is met by the restriction already stated at `n = 12` — bound commitment as distinct from readiness — and that is a genuine narrowing of the claim rather than a rhetorical one. What survives intact is a single rung: Tracy and Robins [2004] argue that a class of states requires a component the others lack, which is the shape of argument a rung needs. **One rung supported out of twelve is what this literature actually yields, and it is written here rather than left for a reader to find.**

The objection is also not new to this paper. It is Michell's objection (§3.5) arriving in a second domain: a phenomenon its own literature describes by several jointly varying features is replaced by one number, and the arithmetic then proceeds on the number. L-18 concedes the two together, because they are one habit and not two accidents.

5.8 Six classes from twelve states

Because `(2n)^2 = 4n^2` is exactly two octaves above `n^2`, two indices share a pitch class if and only if they have the same odd part. Write `n = 2^a * m` with `m` odd; the class is `m`. For the twelve-state ladder the odd parts are

```
n         1  2  3  4  5  6  7  8  9 10 11 12
odd part  1  1  3  1  5  3  7  1  9  5 11  3
classes   {1, 3, 5, 7, 9, 11}  --  6 classes = ceil(12/2)
```

Twelve states yield six pitch classes. That is the available harmonic vocabulary and it is a hard structural limit, not a stylistic choice. The companion paper on octave folding owns the folding rule and the `ceil(N/2)` theorem and derives both; they are quoted here because the ladder cannot be read without them.

Within the 220–440 Hz band the six classes sit as follows, measured in cents from class 1:

```
class  1     247.514 Hz        0.0000 cents
class  3     278.453 Hz     +203.9100 cents
class  9     313.260 Hz     +407.8200 cents
class  7     379.006 Hz     +737.6518 cents
class  5     386.741 Hz     +772.6274 cents
class 11     233.978 Hz      -97.3641 cents
```

Class 11 lands below class 1 in this band because folding is into a fixed window; the negative figure is an artefact of the window and not of the class. Note that classes 7 and 5 are the closest pair in the set, and that the size of that minimum separation is a structural property of `N = 12` rather than of this particular ladder. It is stated once, with the regime it belongs to, and is not re-derived elsewhere.

The immediate consequence for this section is the one that governs the failure modes: half the ladder's distinctions are harmonically invisible. States 1, 2, 4 and 8 are all class 1. They are four different states, they have four different frequencies, and they sound like the same note played at four different heights. A reading that reports only the class has discarded the difference between undifferentiated activation and social feeling — which is a large difference. **Report the index and the class. Never the class alone.**

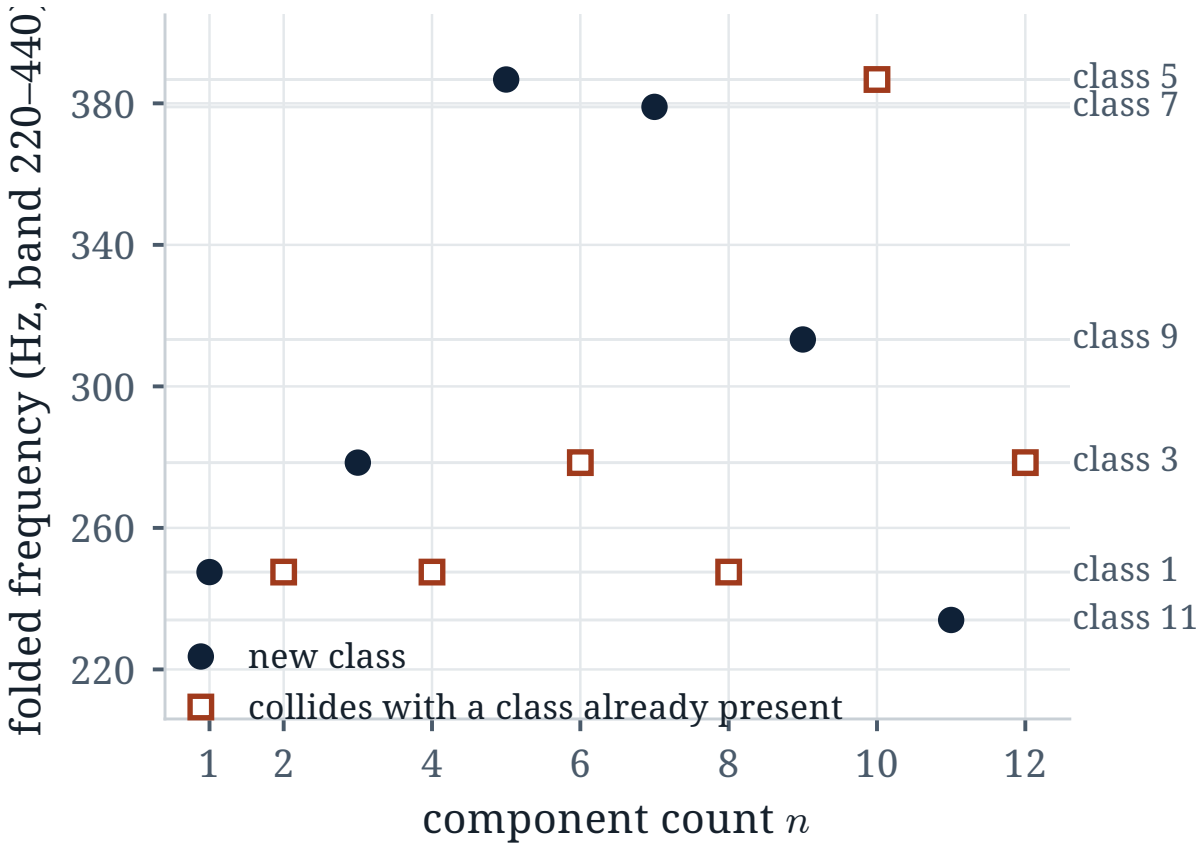

Figure 41.5: Twelve states collapse onto six folded positions: six of the twelve indices land on a pitch class already occupied, because two indices fold together exactly when they share an odd part. Half the ladder's distinctions are therefore invisible after folding, which is why a reading must report the index and not the class alone. **Modelled:** the fold is division by a power of two into a 220–440 Hz band, a reporting convention of this framework; its extension beyond pitch is a modelling choice with no external warrant (§2.4 M-a). Built by `figs/src/CCP-041_fig04.py`.

5.9 What the ladder is not This section exists because the ladder is the object in this framework most likely to be misused, and because a formalism that looks like a clinical instrument will be treated as one unless it says otherwise in the plainest available language.

The twelve states are not diagnoses. They are not disorders, syndromes, categories of illness, or levels of severity. No index on this ladder corresponds to any diagnostic category in any classification system, no index indicates the presence or absence of any condition, and no reading produced by any procedure in this framework is an assessment of any person's mental health.

No part of the framework of this framework makes a clinical, medical, diagnostic, or therapeutic claim, and none is implied by any number in it. The readings are readings of a formal construction. A person who wishes to know something about their health should ask someone qualified to tell them, and nothing here is a substitute for that.

The ladder is not an instrument for classifying persons. A person is not at an index. States are at indices; a person holds several states at once, which is exactly what the chord analysis of this series is about, and the object that characterises a person in this framework is a chord and not a note.

The ladder is not a hierarchy of value. Higher index means more components, means more expensive to specify, means higher pitch. It does not mean better, more evolved, healthier, more mature, or more real.

And the frequencies are essence frequencies. No claim is made that any person, tissue, molecule, or neural population physically resonates at 23.6879 Hz or at any other value in the table. The essence law returns the resonance of an essence — a relation among categories — and that distinction is absolute in this series and is restated wherever the law is used.

5.10 What the ladder costs to get wrong Combine §5.4's miscount table with §5.8's class structure and the practical exposure becomes visible.

A single-step miscount costs between 301 and 2400 cents of pitch and, except at `1 -> 2`, changes the pitch class. A two-step miscount at the bottom of the ladder — mistaking a one-component state for a three-component one, which is the single easiest error to make because ordinary language supplies an object whether or not the state has one — costs `9/1` in frequency, three octaves and a whole tone, and moves from class 1 to class 3.

The exposure is therefore concentrated, and it is concentrated in a knowable place. It is not spread evenly across the ladder and it is not a matter of general imprecision. It lives at rungs 1 through 5, where the square law is steepest and where the components are easiest to conflate. Section 6's decomposition rules are weighted accordingly, and its worked example is deliberately drawn from that region.

The Specification

The section now does the thing it exists to do. Four rival ordering principles are stated at their strongest, graded against the framework's three exclusion criteria — explicit state encoding, defensible category partition, interpretable angle-like geometry — and against the house condition V7, and each is given a verdict that is published whether or not it flatters the framework.

A note on method before the grading starts. Each rival is instantiated below with a **constructed** assignment of indices, because a principle cannot be graded in the abstract. Those constructions are labelled as constructed and are not presented as anyone's published ordering. The point of constructing them is not to show that a particular arrangement is wrong; **it is to show that the principle underdetermines the arrangement, which is a property of the principle and is what the grading is about.**

5.11 Rival 1 — AROUSAL. Verdict: REJECTED. **The principle.** Order the states by the typical arousal magnitude of the state. Arousal is the best-attested single dimension in the affect literature, it has physiological correlates that can be measured without asking anyone anything, and it is continuous, which feels like an advantage.

The case for it. Arousal is the one affective quantity with a genuine claim to instrumentation. Skin conductance, heart-rate variability and pupillometry all index it, imperfectly and with well documented confounds, but they index it. If the goal were a psychological quantity that could be measured by an apparatus rather than elicited from a person, arousal would be the obvious candidate and no other candidate is close.

Grading against V1, state encoding. Passes, weakly. A state does have an arousal level, and that level locates it on a line. Constructing an interval scale without asking respondents to use numbers is possible [Thurstone, 1927]; it still yields no partition, which is what V2 requires.

Grading against V2, the partition. Fails. Arousal does not partition the states; it *scores* them, and many states get the same score. Take a constructed set of arousal ratings for the twelve state classes on a 0-to-10 scale at one decimal place — the resolution a careful rater can actually sustain:

```
state    1    2    3    4    5    6    7    8    9   10   11   12
arousal 7.0  7.0  6.0  5.0  5.0  4.0  5.0  6.0  6.0  4.0  6.0  5.0

tie structure: 7.0 x2, 6.0 x4, 5.0 x4, 4.0 x2
states involved in at least one tie: 12 of 12
orderings consistent with these ratings: 2 x 24 x 24 x 2 = 2,304
undetermined ordering: log2(2304) = 11.170 bits
```

Every state is tied with at least one other, and the ratings leave 11.17 bits of the ordering undetermined. The principle therefore does not supply an ordinal at all; it supplies an ordinal *with a tie-break to be added later*, and the tie-break carries all the information the essence law consumes. Under V7, a rule whose tie-break is unspecified is not a declared ordinal rule.

Grading against V3, angle-like geometry. Fails on a subtler point that is the decisive one. The essence law is a square law, and the pitch class depends on the odd part of the index, which is a number-theoretic property and not a continuous function of position. Arousal is a continuous quantity. **Mapping a continuous quantity onto integer positions and then taking the odd part of the position is not an interpretable geometry; it is a rounding operation followed by a number-theoretic one, and small changes in the underlying quantity produce arbitrary changes in the output.**

Here is that failure measured. Three constructed analysts, each producing a defensible arousal ordering of the same twelve state classes:

```
analyst A order (low arousal to high):  6 12 10  9  4  3  2  1  5  7  8 11
analyst B order:                       12 10  6  4  9  3  1  2  7  5 11  8
analyst C order:                       10 12  9  6  3  4  2  5  1  8  7 11

Spearman rho(A,B) = +0.9510
Spearman rho(A,C) = +0.9301
Spearman rho(B,C) = +0.8951
```

The three analysts agree with each other almost completely. By any conventional standard of rank agreement this is a well-behaved ordering. Now read the frequencies it produces:

```
state                            indices     classes      pitch spread
 1 undifferentiated activation    [ 8, 7, 9]  {1,7,9}       870.17 cents
 2 valenced activation            [ 7, 8, 7]  {1,7}         462.35 cents
 3 directed feeling               [ 6, 6, 5]  {3,5}         631.28 cents
```

```
 4 situated feeling              [ 5, 4, 6]  {1,3,5}       1403.91 cents
 5 attributed feeling            [ 9,10, 8]  {1,5,9}        772.63 cents
 6 temporal feeling              [ 1, 3, 4]  {1,3}         4800.00 cents
 7 reflexive feeling             [10, 9,11]  {5,9,11}       694.82 cents
 8 social feeling                [11,12,10]  {3,5,11}       631.28 cents
 9 normative feeling             [ 4, 5, 3]  {1,3,5}       1768.72 cents
10 narrative feeling             [ 3, 2, 1]  {1,3}         3803.91 cents
11 reciprocal feeling            [12,11,12]  {3,11}         301.27 cents
12 committed feeling             [ 2, 1, 2]  {1}           2400.00 cents

WORST: temporal feeling, 4800.00 cents = 4.000 octaves of disagreement
```

Three analysts who agree with each other at rho = 0.90 and above produce, for one state, four octaves of pitch disagreement. For reflexive feeling they produce classes 5, 9 and 11 — three different notes. This is the finding that decides the grading and it generalises well beyond arousal: rank agreement does not imply pitch agreement, because the essence law is a square law on the index and the pitch class is a number-theoretic function of it. A single position's difference near the bottom of the ladder is worth more than a five-position difference near the top.

Verdict: REJECTED. Arousal fails V2 (does not partition; 11.17 bits of ordering undetermined), fails V7 (no declared tie-break, and none is available from the principle), and fails V3 (the composition of a continuous quantity with an integer-rounding step and an odd-part extraction is not an interpretable geometry). It is rejected as an essence index. It is not rejected as a psychological quantity, and the companion paper on trait frequency uses arousal-like variation in a different role, where the square law is not applied to it.

5.12 Rival 2 — HIERARCHICAL NEED. Verdict: REJECTED.

The principle. Order the states by the level of need they express, following the familiar prepotency hierarchy — physiological, safety, belonging, esteem, self-actualisation (Maslow, 1943).

The case for it. It is the most widely recognised ordering in all of popular psychology, it is genuinely ordinal in intent, and it comes with a mechanism: lower needs are said to be prepotent, so the ordering is supposed to be doing causal work rather than merely filing.

Grading against V1, state encoding. Fails, and fails at the first step. **A need is not a state.** The hierarchy orders *what a person requires*; the ladder must order *what a person is in*. There is no map from an episode of feeling to a level of the hierarchy that is determinate: a moment of fear can be about safety, about belonging, or about esteem, and often about all three, and the hierarchy supplies no rule for choosing. V1 requires that every represented state have a determinate location in the model, and this candidate does not provide one.

Grading against V2, the partition. Fails on arithmetic. The hierarchy supplies five levels for twelve state classes:

```
levels available           5
state classes to index    12
states per level         2.4  ->  ties by construction, in every assignment
distinct pitch classes from indices 1..5:  {1, 3, 5}  =  3
```

Five indices yield three pitch classes. The twelve-state ladder yields six. The harmonic vocabulary is halved before any reading is taken, and the halving is a consequence of the number of levels rather than of anything about the psyche.

The ceiling consequence, and it is severe. Section 4 established that maximum surplus is `ln N` and therefore that the maximum sustainable cost-to-conversion ratio is `c/eta <= ln N`. Compare:

```
twelve-state ladder      N = 12    ln N = 2.484907    f_max = k*144 = 69.6133 Hz
```

```
five-level hierarchy     N =  5    ln N = 1.609438    f_max = k*25  = 12.0856 Hz

ceiling on c/eta collapses from 2.4849 to 1.6094 -- a 35.2% loss of headroom
```

Adopting a five-level index would declare that 35.2% of the sustainable region does not exist, and would do so purely as an artefact of the category count. Section 4's fourth lever — add genuinely distinct categories — exists precisely because `N` is load-bearing, and a candidate index that gratuitously suppresses `N` is throwing away the lever.

Grading against the empirical record. The strict prepotency claim has not held up. Wahba and Bridwell's review (1976) found little support for the ordered-emergence prediction, and later treatments have been no kinder to it. This matters here only because prepotency was the candidate's one claim to being more than a list: without it, the hierarchy is an enumeration in an order somebody chose, which under V7 is a weak ordinal whose weakness must travel with every number derived from it.

Verdict: REJECTED. It fails V1 outright — needs are not states — fails V2 by construction, and costs 35.2% of the sustainable region for nothing in return. This is the rejection the manifest requires be published, and it is published without qualification. The hierarchy is a serviceable way to talk about motivation. It is not an essence index and it must not be used as one.

5.13 Rival 3 — DEVELOPMENTAL STAGE. Verdict: ADMISSIBLE AS AN ORDINAL, NOT ADOPTED.

The principle. Order by the developmental stage at which the state becomes available — the stage-theoretic tradition running through Piaget on cognitive stages, Kohlberg on moral reasoning, and Loevinger (1976) on ego development.

The case for it, and it is the strongest case any rival makes. Stage theories are genuinely ordinal by construction, they specify what each stage adds relative to the one below, they are nested in the way §5.7 requires, and Loevinger's programme in particular was built with a scoring manual designed for inter-rater agreement. This candidate is not a category error. It is a serious alternative and it is graded as one.

Grading against V1, state encoding. Fails at the level required, and the failure is specific. A stage is a property of a *person*, not of a *state*. The ladder must index the state; if the index is the stage of the person holding it, then every state a given person holds receives the same index, the person's whole spectrum collapses to a single note, and the chord construction of the chord analysis of this series — the object that makes this argument extended rather than compressed — cannot be formed at all. **A person-level index cannot produce a within-person chord, and the within-person chord is what this framework measures.**

Grading against V2, the partition. Passes. Stage schemes partition, they are counted, and their categories are argued to be distinct.

Grading against V3, geometry. Passes conditionally. Stages have a defensible nesting, so the distance between adjacent stages has an interpretation.

Grading against V7 and against CC-R1. Here is the decisive point and it is the one that keeps this candidate out of the framework rather than merely down the list. **A stage assignment is a rating produced by a trained judge against a manual. It is ordinal. It has no true zero — stage zero is not "no person" — and it has no fixed unit, because the interval between stage 3 and stage 4 is not constructed to equal the interval between stage 6 and stage 7.** Push it through `f = k n^2` and the reading are multiplying an ordinal, which is exactly the operation CC-R1 demotes. A frequency derived from a developmental stage index inherits the demotion in full and may be published only as an ordering, never as a magnitude.

The constructive route out is available and is the same one CC-R1 names: Rasch instrumentation of the stage scale would supply the true zero and the equal units, at the measured cost of 123 items per term. That is a real research programme and this framework does not pretend it is impossible. It has not been done for any stage scheme in a form this framework could use.

Verdict: ADMISSIBLE AS AN ORDINAL, NOT ADOPTED. Frequencies derived from it carry CC-R1's demotion. It is not adopted here because it indexes persons rather than states and therefore cannot produce the chord. It is the one rival in this section that could be adopted later if someone did the instrumentation, and the companion paper on trait frequency notes where it would slot in — as a trait-scope index, not a state-scope one.

5.14 Rival 4 — VALENCE-MAGNITUDE. Verdict: REJECTED.

The principle. Order by the magnitude of the state's valence: order by how strongly good or bad it is, taking absolute value so that the index runs from neutral upward.

The case for it. Valence is the second of the two core-affect dimensions and is at least as well attested as arousal. Taking the absolute value gives something that looks like it has a true zero — neutral — which appears to answer the scale objection directly. That appearance is the reason this candidate has to be dealt with explicitly rather than waved off.

Grading against V4, the zero baseline. This is where it dies, and it dies by an argument this series has already proved in another register. Take a constructed valence assignment on `[-1, +1]`:

```
state    1     2     3     4     5     6     7     8     9    10    11    12
valence 0.00 -0.60 -0.70 -0.50 +0.60 -0.40 +0.50 +0.40 -0.30 +0.30 +0.70 +0.65

collapsed pairs under |valence| -- opposite sign, identical index:
    state  2 (-0.60)  and  state  5 (+0.60)
    state  3 (-0.70)  and  state 11 (+0.70)
    state  4 (-0.50)  and  state  7 (+0.50)
    state  6 (-0.40)  and  state  8 (+0.40)
    state  9 (-0.30)  and  state 10 (+0.30)
```

Ten of the twelve states collapse into five pairs. Each pair receives one index, one frequency, and one pitch class. Directed feeling and reciprocal feeling — three components and eleven components, two full rungs apart in every structural respect — become the same note.

This is CC-R8 in the essence register and the framework has already proved the general form of it. CC-R8 established that because `u = 1 - (x.y)^2` depends only on `|rho|`, perfect opposition returns the same `u = 0` as perfect agreement: the contrarian and the sycophant carry identical information, which is none. An index built on absolute valence commits the same error one level down. It declares that the sign of the evaluation carries no information, which is a substantive empirical claim, is almost certainly false, and is being smuggled in as a modelling convenience.

Keeping the sign does not save the candidate. A signed index runs from negative to positive, `f = k n^2` is even, and `f(-n) = f(n)` exactly — so the collapse returns in a different costume. And a signed index has no cardinality reading at all: there is no such thing as negative-four components.

Grading against V2 and V7. Fails for the same reason arousal does. Valence magnitude is a continuous score with heavy ties at any usable resolution, and the tie-break is unspecified.

Verdict: REJECTED. It fails V4 by collapsing opposites, it reproduces CC-R8's error at the level of the index, and it fails V2 and V7 alongside arousal. Valence is real, it matters, and the companion paper on dissonance uses it in the analysis of the divided self. It is not an essence index.

5.15 The grading table

Candidate	V1 encoding	V2 partition	V3 geometry	V4 zero	V7 ordinal rule	Scale under CC-R1	Verdict
Arousal	weak pass	**FAIL** — all 12 tied, 11.17 bits free	**FAIL** — continuous into odd-part	pass	**FAIL** — no tie-break	ordinal	**REJECTED**
Hierarchical need	**FAIL** — needs are not states	**FAIL** — 5 levels, 12 states	weak	pass	weak (an enumeration)	ordinal	**REJECTED**
Developmental stage	**FAIL** — indexes persons	pass	conditional pass	**FAIL** — no true zero	pass	**ordinal — CC-R1 applies**	**admissible, not adopted**
Valence magnitude	weak pass	**FAIL** — ties	**FAIL**	**FAIL** — collapses opposites (CC-R8)	**FAIL**	ordinal	**REJECTED**
Component count	**pass**	**pass** — nested, exhaustive, exclusive	**pass**	**pass** — n = 0 is no state	**pass** — a procedure, not a list	**absolute, hence ratio**	**ADOPTED**

Three rejected in print, one admitted as an ordinal and left unadopted, one adopted. The adopted candidate's single advantage over the others is not that it is more psychologically insightful. It is that it is a count.

5.16 Publication requirements for any essence index Any index used in this framework, or by any reader applying the framework, must publish the following. These are requirements, not recommendations, and The checklist is the worksheet of §6.10.

```
CC-I1  THE DECOMPOSITION.  What counts as one component, stated as a rule a third party can
                       apply to a state the author never considered.
CC-I2  THE COUNT RULE.     How components are counted, including the treatment of redundant,
                       nested, and conjoined components.
CC-I3  N.                  The category count, stated, with the ceiling ln N it implies.
CC-I4  THE TIE-BREAK.      What happens when two states receive the same count. (For the
                       component-count index: nothing happens. They are the same state
                       class and they share a frequency. That is the intended behaviour.)
CC-I5  THE BAND AND j.     The audible band and the octave transposition for every published
                       frequency.
CC-I6  THE PERMUTATION TEST. Swap two adjacent indices, recompute, and report the change in
                       cents and in pitch class. If a plausible re-ordering moves a class
                       by more than half an octave, the ordering is load-bearing and must
                       be defended before any frequency is published.
CC-I7  THE AGREEMENT FIGURE. The inter-rater agreement on the count, reported on the count
                       and on the pitch class separately. Section 6 specifies the protocol.
```

CC-I6 costs ten minutes and is the item most often skipped. For the twelve-state ladder, run on every adjacent pair:

```
swap  1<->2:  same odd part (1) -- harmonically invisible, a pure two-octave move
swap  2<->3:  class 1 -> 3          203.91 cents
swap  3<->4:  class 3 -> 1          203.91 cents
swap  4<->5:  class 1 -> 5          772.63 cents
swap  5<->6:  class 5 -> 3          568.72 cents
swap  6<->7:  class 3 -> 7          533.74 cents
swap  7<->8:  class 7 -> 1          737.65 cents
swap  8<->9:  class 1 -> 9          407.82 cents
swap  9<->10: class 9 -> 5          364.81 cents
swap 10<->11: class 5 -> 11         869.99 cents
swap 11<->12: class 11 -> 3         301.27 cents
```

Nine of the eleven adjacent swaps move a pitch class by more than a quarter of an octave, and three move it by more than half. By CC-I6's own standard the twelve-state ordering is

load-bearing and must be defended. **It is defended — by §5.7's nesting argument, which is the claim that the order is not chosen but forced: rung `n` contains rung `n−1` plus exactly one component, so the sequence is the only one consistent with the decomposition.** That defence is the whole warrant for the ladder, and if it fails the ladder fails with it. Which is the correct exposure for an account to have, and it is stated here so that a reader can attack it in the right place.

The Failure Modes

5.17 Agreeing on the order while disagreeing on the note §5.11 measured it: three orderings at Spearman rho above 0.89 produced four octaves of disagreement on one state. **The general lesson is that rank-correlation statistics are the wrong instrument for assessing an essence index, and reporting one is worse than reporting nothing because it manufactures false confidence.**

The mechanism is exact. Two effects compound. The square law means a fixed rank difference is worth more at the bottom of the ladder than at the top — one position at `n = 1` is 2400 cents, one position at `n = 11` is 301 cents, an eightfold difference in consequence for an identical difference in rank. And the odd-part rule means the pitch class is not a monotone function of the index at all: 7 and 8 are adjacent and land in classes 7 and 1, while 3 and 12 are nine apart and land in the same class. Rank distance and pitch distance are not the same metric and are not monotonically related.

The correct statistic is agreement on the integer and agreement on the class, reported separately. Section 6 §6.12 gives the protocol and §6.17 shows a constructed case in which a weighted kappa of 0.9838 coexists with pitch-class disagreement on more than a quarter of episodes.

5.18 Smuggling a rating in as a count The most common way to break the count argument is to keep the word "count" and stop counting.

It looks like this. An analyst has a state, feels that it is *quite* complex, and writes `n = 7`. No components were enumerated. The 7 is a judgment of complexity dressed as a cardinality, and a judgment of complexity is an ordinal rating with all of CC-R1's problems intact. **The frequency then has the scale status of the thing that actually produced it, which is the rating, and not the scale status of the notation it was written in.**

The test is simple and it is procedural: an analyst who claims `n = 7` must be able to list the seven components. If the list cannot be produced, the number is a rating. Section 6's worksheet requires the list in writing, before the number, precisely so that this failure is caught at the point of elicitation rather than at the point of publication.

A subtler version is worth naming separately. An analyst enumerates components honestly but chooses the *granularity* of the enumeration to reach a count they already had in mind. Splitting one component into two, or merging two into one, is always locally defensible, and a determined analyst can reach almost any count on almost any state. This is not caught by requiring a list. It is caught only by fixing the decomposition rules before the state is examined, and by inter-rater agreement, which is why Section 6 treats both as mandatory rather than as good practice.

5.19 Counting representations instead of components A component is something the specification requires. A representation is something the analyst wrote down. They diverge in both directions.

Over-counting. The state description mentions the back door, the hour, the neighbour, the dog, and the fact that the porch light is broken. That is five nouns. It is not five components. The hour and the broken light are both part of the situation, which is one component. **Nouns**

are not components, and a decomposition that counts nouns will systematically over-count and will do so more for verbose subjects than for terse ones, which is a bias correlated with something the analyst has no business letting into the reading.

Under-counting. The state description says "I was frightened of him," which is four words and at least four components: activation, valence, an intentional object, and a modelled other whose intentions matter. Ordinary language compresses aggressively, and a decomposition that counts what was said will under-count fluent speakers.

The rule that fixes both: count what the specification requires, not what the description contains. The operational form is the substitution test in Section 6 §6.6 — a component is required if removing it makes the description consistent with a state the subject would say they were not in.

5.20 Assuming that more components is better

The ladder ascends and the frequencies rise, and Section 4 established that higher pitch means more available order. The inference that a person should therefore aim for high-index states is available, natural, and wrong.

Three reasons, and they are independent.

First, the index is a property of a state, not an achievement of a person. A twelve-component state is not earned; it is simply expensive to specify. A person in a twelve-component state of committed dread is not doing better than a person in a three-component state of ordinary annoyance.

Second, the frequency that matters for sustainability is the relational frequency `f_rel`, not the state frequency `f = k n^2`. The companion paper on the dyad interval owns `f_rel = k(1 + (N−1)u)^2` and it is driven by `u`, the non-parallelism, and not by any individual index. A person holding a chord of high-index states that are all pairwise near-parallel has a high spectrum and a low surplus — which the chord analysis of this series shows is a recognisable and unenviable condition.

Third, components have costs. Every component in a specification is something that must be maintained, and Section 4's `c` is where maintenance lives. A specification that requires twelve components to state requires twelve components to hold, and the cost side of the ledger does not care that the pitch went up.

The lever Section 4 names is "add genuinely distinct categories," and the load-bearing word is distinct, not more.

5.21 Reading the ladder as a diagnosis

Named in §5.9 and repeated here because it belongs in the failure catalogue and because repetition is the only defence an account has against a misuse it cannot supervise.

The twelve states are not diagnoses. An index is not a severity. A chord is not a profile of pathology. No reading in this framework assesses anyone's mental health, and no procedure in it should be administered to anyone as though it did. A practitioner who finds themselves reporting a number to a person about that person's mind has left the scope of this framework, whatever the number is.

The structural reason, stated once so that it is not merely a prohibition: **the ladder classifies specifications, not people.** The claim "this state requires seven components to specify" is a claim about a description. It becomes a claim about a person only through an inference the formalism does not license and this framework does not make.

5.22 Publishing a frequency without publishing the decomposition

The worst of the failure modes, because it is invisible.

A frequency published without its decomposition is uncheckable. The reader cannot recount, cannot identify the disputed component, cannot run the permutation test, and cannot form a view about whether the number means anything. **And because the number is quoted to four decimal places, it will be believed.** Spurious precision is not a stylistic vice here; it is the

specific mechanism by which an unfalsifiable claim acquires the appearance of a measured one.

The standing rule: the decomposition travels with the frequency, always, in the same table or on the same page. Where it will not fit, the frequency does not get published either. This is CC-I1 and CC-I2 of §5.16 and it is the reason those two items come first.

Worked Example

Everything in this section is CONSTRUCTED. It is not an observation of any person, no data were collected, and nothing in it is a case report. It is a demonstration of a procedure on an invented episode, which is what all worked cases in this framework are.

5.23 A constructed state, indexed

The episode, stated as the subject might state it:

> *I keep thinking about how she looked at me in the meeting. She knew what she was doing, and she knew I'd notice. This is what it's been like since I took the role.*

Section 6 owns the elicitation procedure that turns an utterance into a component list; here the decomposition is performed directly so that the indexing can be shown.

Step 1 — enumerate candidate components.

```
c1  activation                 there is arousal; the subject is keyed up
c2  valence                    it is unpleasant
c3  intentional object         the look, in the meeting
c4  situation                  the meeting, the role, the workplace
c5  cause                      she did it deliberately
c6  projected duration         "keeps" -- it is ongoing, not a flash
c7  self as object             "I'd notice" -- the subject appears in their own account
c8  another mind modelled      "she knew what she was doing"
c9  the other modelling you    "she knew I'd notice" -- second order
c10 placed in a story          "what it's been like since I took the role"
```

Step 2 — apply the substitution test. For each candidate, remove it and ask whether the residual description is consistent with a state the subject would deny being in.

Removing c1 through c10 each fails the test — the residual is a different state in every case — with one item requiring care. Is c9 (*she knew I'd notice*) genuinely distinct from c8 (*she knew what she was doing*)? Remove c9 and the description becomes: she acted deliberately, and I noticed. That is a coherent state and it is one the subject would say they were not in, because the whole weight of the episode is that the noticing was *anticipated*. **c9 survives. It is a second-order component and the ladder counts each order once.**

Step 3 — check for redundancy. No candidate is entailed by another. c7 and c9 both involve the self, but c7 is the subject appearing in their own account and c9 is the subject appearing in the modelled other's account; removing either leaves the other standing. **They are distinguishable and they count twice.**

Step 4 — check for a normative component. The description does not apply a standard. Nothing says this ought not to happen; the account is of what happened and what it means, not of what was owed. **Component "standard applied" is absent.** This is the kind of judgment that must be made explicitly and recorded, because it is exactly where two analysts will differ.

Step 5 — check for a committed component. Nothing binds a future action. There is no *and so I am going to*. **Absent.**

Step 6 — count.

```
components required:  c1 c2 c3 c4 c5 c6 c7 c8 c9 c10  =  10
n = 10
```

Step 7 — read.

```
n = 10        state class: narrative feeling
f = k * 100 = 48.3426 Hz
folded into 220–440 Hz with j = 3:  48.3426 * 8 = 386.741 Hz
odd part of 10 = 5   ->  pitch class 5
```

Step 8 — publish the decomposition alongside the frequency, which is what the ten-line list in Step 1 is for. A reader who disagrees now has something to disagree with.

Step 9 — the standing statement. This reading says that the state as described requires ten components to specify, and that ten components corresponds to 48.3426 Hz under the essence law with the declared constant. **It says nothing about the subject's health, character, or prospects, it is not a diagnosis, and 48.3426 Hz is an essence frequency and not a physical resonance of anything.**

5.24 The same state under a rival, and the difference priced Take the developmental-stage rival of §5.13 — the strongest of the four — and index the same episode by it. A constructed stage assignment, using a five-level scheme, places the subject's reasoning at level 4.

```
component-count index      n = 10    f = 48.3426 Hz    class 5
stage index                n =  4    f =  7.7348 Hz    class 1

ratio    (10/4)^2 = 6.250000
cents    1200 * log2(6.25) = 3172.63 cents = 2.6438 octaves
classes  5 versus 1 -- different notes entirely
```

Two and a half octaves and a change of pitch class, from one choice of indexing principle. No computation is in error. The two numbers are answers to two different questions, and only one of them is the question `f = k n^2` is licensed to receive — because only one of them is a count.

And note what the rival's number carries with it. The stage index is an ordinal rating. Under CC-R1 its magnitude is not reportable, so 7.7348 Hz is not a measured frequency; it is an ordinal position written in Hz. It may be used to say that this state sits lower than another state on the same scheme. It may not be divided, squared, or folded, and the octave-deficit diagnostic of Section 4 cannot consume it.

That is the whole of the count argument compressed into one comparison. The count survives the operations the framework performs on it. The rating does not.

5.25 What the reading licenses The constructed reading in §5.23 licenses exactly this much.

It licenses the frequency 48.3426 Hz as an essence frequency of the described state under the declared decomposition, and it licenses that number's use in every downstream construction of this framework: the mood spectrum of the companion paper on octave folding, the chord of the chord analysis of this series, the interval arithmetic of the companion paper on dissonance, and the octave-deficit diagnostic of Section 4 wherever a relational `u` has been measured to go with it.

It licenses the claim that if the decomposition is accepted, the frequency follows with no further assumption, because `f = k n^2` on an absolute-scaled `n` is a licensed operation.

It does not license the claim that the decomposition is the right one. Another analyst may count nine components by merging c7 and c9, or eleven by splitting the situation from the

role. Nine gives 39.1575 Hz and class 9; eleven gives 58.4945 Hz and class 11. Three defensible decompositions, three different notes. Section 6 exists because that spread is not acceptable and because reducing it is a procedural problem with a procedural answer.

And it does not license any claim about a person. **The state was constructed, the subject does not exist, and if the subject did exist the reading would still be a reading of a description.**

What this section fixes

Later papers in the corpus cite this construction and do not redefine it.

```
THE INDEX          n := the number of distinguishable components required to specify
                   the state.  A COUNT: true zero, fixed unit, absolute scale.

THE LAW            f(n) = k n^2,  k = 0.483425732988414 Hz  [k badged as a postulate]

THE SIDESTEP       Because n is a count and not a ratio of ratings, its ratio-scale status
                   is established by construction. CC-R1's demotion of D/P does not reach it.
                   The index sidesteps the demotion; it does not inherit it.

THE LIMIT          The frequency inherits exactly the defensibility of the count.
                   A contested decomposition yields a contested frequency.

THE LADDER         N = 12, the twelve state classes fixed in §5.6, unaltered.
                   ln N = 2.484907.  Max f = k*144 = 69.6133 Hz.
                   Six pitch classes {1,3,5,7,9,11} = ceil(12/2).

THE REJECTIONS     Arousal: REJECTED (V2, V3, V7).
                   Hierarchical need: REJECTED (V1, V2; 35.2% of headroom lost).
                   Valence magnitude: REJECTED (V4; the CC-R8 collapse).
                   Developmental stage: admissible as an ORDINAL, not adopted;
                   any frequency derived from it carries CC-R1's demotion.

THE PROHIBITIONS   The twelve states are not diagnoses. No clinical, medical, diagnostic
                   or therapeutic claim is made anywhere in this framework. The frequencies are
                   essence frequencies and not physical resonances. All cases constructed.
```

Section 6 takes the exposure this section identified — that the count is only as good as the decomposition — and does the work of narrowing it: the elicitation procedure, the decomposition rules, the agreement protocol, the worksheet, and the validation table with its seventh gate reported honestly as not yet run.

6 Ordering the states

Section 5 made a strong claim and then named its own exposure. The claim: the psychological essence index is a count, counts are absolute-scaled, absolute scales admit only the identity transformation, and therefore `f = k n^2` is a licensed operation on `n` in a way it is not licensed on any ratio of ratings. CC-R1's demotion of `D/P` does not reach the index. The index sidesteps the demotion.

The exposure: all of that holds *given a decomposition*, and Section 5 said nothing about how the decomposition is fixed. **The frequency inherits exactly the defensibility of the count. A contested decomposition yields a contested frequency.** Section 5 priced that exposure — three defensible decompositions of one constructed episode gave 39.1575, 48.3426 and 58.4945

Hz, in pitch classes 9, 5 and 11: three different notes — and then stopped, because narrowing the spread is a different kind of work.

This section does that work, and it owns two things the rest of the framework cites and does not redefine.

The first is the **elicitation procedure**: how a practitioner actually obtains the intensities that build a state vector, and how the vector is normalised. the framework's state-vector construction fixes the construction, and later papers in this series apply it; this section specifies it end to end, with a printable worksheet.

The second is the **defence of the count against the obvious objection** — that deciding what counts as one component is itself a judgment. That objection is correct. It is not fatal, it is not answered by assertion, and the answer has three parts: decomposition rules that make the judgment explicit, inter-rater agreement as the test that makes it checkable, and an honest statement of where the answer runs out. All three are given here, including the third.

The section closes with the Formula Validation Protocol table for the index, all seven gates, and FVP-7 — cross-individual reproducibility, the gate that decides the hard-science question and the one most often skipped — is reported as NOT YET RUN.

The standing prohibitions govern every page. The essence frequencies are essence frequencies, not physical resonances. **The twelve states are not diagnoses**; nothing in this procedure is an assessment, a screening, or a clinical instrument, and no part of the framework of this framework makes a clinical, medical, diagnostic or therapeutic claim. All cases are constructed and labelled.

The Law

6.1 What is being built, and why the index alone is not enough Section 5 produced a number for a state. That is not yet enough to do anything with, because every diagnostic in this framework is relational. The octave deficit needs `f_rel`; `f_rel` needs `u`; `u` needs two vectors. **A single index is a note. The framework's instrument reads intervals, and intervals need two things to hold at once.**

A person does not occupy one state. A person holds several, at different strengths, and holds them under different framings of the same situation. Representing that is the object this section builds.

the framework's state-vector construction, and it is the only construction of `u` in this framework:

```
THE STATE VECTOR AND THE MEASUREMENT

A subject, a framing, or a person is represented as a unit vector over the twelve states,
components = intensity, normalised to length 1. Then for any two such vectors x, y:

    cos theta = x . y
    u         = 1 − (x . y)^2
    F         = ln(1 + 11 u)
    f         = k e^(2F) = k (1 + 11 u)^2

with N = 12, so N − 1 = 11, and k = 0.483425732988414 Hz.
```

Three registers, one object. `cos theta` is the alignment of the two vectors. `u` is the non-parallelism, in `[0, 1]`, equal to `sin^2 theta`. `F` is the interaction surplus in nats, bounded above by `ln 12 = 2.484907`. And `f` is that surplus expressed as a pitch, because — as the essence bridge of Series B established and Section 4 restated — one nat of surplus is exactly 2.885 octaves.

The companion paper on the dyad interval owns `f_rel = k(1 + 11u)^2` and the companion paper on between-persons measurement owns the between-persons measurement of `u`. This section owns the step before both of them: getting from a person and a situation to a unit vector that deserves to be entered into either.

6.2 The state vector, defined

```
THE STATE VECTOR

    x = (x_1, x_2, ..., x_12)          x_n >= 0 for all n
    x_n = the elicited intensity with which state class n is present
    the support of x = { n : x_n > 0 }
    the unit vector = x / ||x||_2 ,   ||x||_2 = sqrt( sum_n x_n^2 )

A state class is present with intensity x_n if the subject's account of the situation
contains the n-component specification of state class n at that strength.
```

Four properties of this object need stating before any procedure is built on it, because each one constrains the procedure.

It is non-negative. There are no negative intensities. A state is present or it is not; the absence of fear is not the presence of negative fear. This is not a modelling convenience — it is what keeps §5.14's valence collapse from reappearing here in a different costume.

Its support is the set of nonzero entries. Writing a zero into a slot changes nothing:

```
a = {3:8, 5:4, 7:2}         b = {3:8, 5:4, 7:2, 11:0}
u(a, b) = 0.000000000000
```

Exactly zero. Recording a state as absent and not recording it at all are the same act, so a practitioner may not inflate a subject's apparent breadth by listing more zeros. This closes an otherwise open route to gaming a reading.

It is normalised in the L2 norm, not the L1 norm, because `u = 1 − (x.y)^2` is built from an inner product and the inner product's natural normalisation is Euclidean. This is a consequence of the framework's state-vector construction's construction and not an independent choice.

And the zero vector has no unit form. A subject with no state at all cannot be normalised, and should not be: `n = 0` is the true zero of Section 5's count, `f = k * 0^2 = 0`, no components, no state, no pitch. The count's zero and the essence law's ground coincide by construction, and the vector formalism inherits that: there is nothing to normalise because there is nothing there.

6.3 The two invariances, and only one of them is good news

Normalisation is usually treated as bookkeeping. Here it is load-bearing, because it determines exactly what the elicited intensities have to be good for — and the answer is less demanding than a reader would guess in one respect and more demanding in another. Both are computed.

FIRST INVARIANCE: the unit vector does not care what units the ratings were in.

```
raw ratings {3: 8, 5: 4, 7: 2} rescaled and renormalised:

raw 0–10              ->  (0.872871561, 0.43643578, 0.21821789)
raw 0–1               ->  (0.872871561, 0.43643578, 0.21821789)
raw 0–100             ->  (0.872871561, 0.43643578, 0.21821789)
proportion of total   ->  (0.872871561, 0.43643578, 0.21821789)

identical to nine decimal places
```

Because `(a x) / ||a x|| = x / ||x||` for any `a > 0`, any common positive rescaling of the intensities cancels exactly. A practitioner using a 0-to-10 scale and a practitioner using a 0-to-100 scale, who assign proportionally the same intensities, produce the same vector and therefore the same `u`, the same `F`, and the same `f`.

This is a real and useful freedom, and it should be stated for what it is: the elicitation instrument's unit is unconstrained. There is no calibration step, no reference stimulus, and no requirement that two practitioners use the same anchors. What is required is that the *ratios* of the intensities be the same.

SECOND INVARIANCE, and it does not hold. The vector is not invariant under an order-preserving transformation of the ratings. Take the same raw ratings and apply monotone transformations — transformations that are admissible if the ratings are merely ordinal — then compute `u` against a fixed reference framing `{3:5, 5:7, 10:4}`:

```
transform      u          f_rel (Hz)
identity    0.388360      13.4361
sqrt        0.371445      12.5044
square      0.525275      22.2093
log(1+x)    0.362115      12.0049

u spans 0.362115 to 0.525275
f spans 12.0049 to 22.2093 Hz  =  1065.05 cents  =  0.888 octaves
```

Nearly nine tenths of an octave of disagreement from transformations that preserve every ordinal fact in the data. So the elicited intensities cannot be merely ordinal. They must carry ratio information — the claim that state 3 is present twice as strongly as state 5 must mean something — even though the unit in which that ratio is expressed is free.

This is exactly the right place for the honest statement, and it must not be softened. Section 5's count argument covers `n`. It does not cover the intensities. **`n` is absolute-scaled by construction; the intensity vector is not, and it needs its own defence.** What the two invariances establish is the precise shape of that defence: the intensities must be ratio-scaled up to a common free multiplier — which is the definition of a ratio scale — and nothing weaker will do.

There is a substantial body of evidence that human subjects can supply exactly that, and this framework already leans on it. Stevens' method of magnitude estimation produces ratio-scale measurements of subjective experience from human subjects, and it replicates [Stevens, 1957] — that finding is the reason Series B Ch 38 could treat subjective magnitude as measurable at all. The elicitation procedure of §6.9 is built as a magnitude-estimation procedure for that reason and not by stylistic preference. The honest form of the claim is: the intensities are ratio-scaled to the extent that magnitude estimation delivers ratio scales, which is a measured property of a procedure and not a constant of nature, and Stevens' own exponents are known to vary with method, range, and instruction [Teghtsoonian, 1971, Poulton, 1968], and the century-long dispute about what the two psychophysical laws are each measuring is best read through the reconciliation literature rather than adjudicated here [Krueger, 1989].

6.4 What normalisation discards, and the standing reporting rule Normalisation throws away the length of the vector, and the length is not nothing.

```
low-intensity  {3: 1,   5: 0.5,  7: 0.25}    raw L2 norm = 1.145644
high-intensity {3: 8,   5: 4,    7: 2   }    raw L2 norm = 9.165151

ratio of norms = 8.0000x
u between them = 0.000000000000     (exactly zero -- same direction)
```

Two states with identical profile shape and an eightfold difference in absolute intensity are perfectly parallel and carry zero surplus between them. That is correct behaviour for the

surplus formalism, which measures difference of *direction*, and it is a serious limitation on what a single `u` reading reports.

> **THE MAGNITUDE REPORTING RULE.** The raw L2 norm `||x||_2` is reported alongside every state vector, in the units of the elicitation instrument, and is never discarded. `u` measures direction; the norm measures how much there is. A reading that publishes `u` without the norms it came from has thrown away half the measurement.

This is CC-I5's sibling and it is a house requirement from here forward. The personal-spectrum worksheet of this series carries a field for it, and the between-persons protocol of this series requires both parties' norms.

6.5 The objection, stated at full strength Here is the objection the section exists to answer, put as forcefully as it can be put, because an objection answered in a weakened form has not been answered.

> **THE DECOMPOSITION OBJECTION.** The count argument proves that a count is absolute-scaled. Granted. But the count is a count *of components*, and "component" is not given by nature. It is given by a decomposition the analyst chooses. Section 5's own worked example admits three defensible decompositions of one episode, yielding 39.1575, 48.3426 and 58.4945 Hz — a spread of well over an octave, in three different pitch classes.
>
> So the scale problem has not been solved. It has been renamed. Where the Moment equation required a judgment of magnitude, the essence index requires a judgment of granularity, and a judgment of granularity is just as unconstrained as a judgment of magnitude. The apparent rigour of the count is borrowed from the arithmetic of counting and does not attach to the thing being counted. The index is a rating with an integer's costume on.

That objection is substantially correct and this framework concedes its correct part immediately. The scale problem was not solved. It was *moved*. Section 5 said so in the same paragraph that made the claim, and the concession is repeated here so that no reader has to discover it.

What the objection gets wrong is the inference that moving a problem is worthless. The three parts of the answer are that the new location is (a) explicit, (b) testable by agreement, and (c) bounded in a way the old location was not. Sections 6.6, 6.7 and 6.8 take them in order, and 6.8 is where the answer is incomplete and says so.

6.6 Answer, part one: the decomposition rules **A judgment that is made explicitly and in advance is a different object from a judgment made implicitly and after the fact, and the difference is not rhetorical.** An explicit rule can be published, applied by a third party, disagreed with in a specific place, and revised without revising everything else. That is the entire content of the move Section 5 made, and these rules are what make it real.

```
THE DECOMPOSITION RULES        D1 – D8
Fixed before any state is examined. Published with every frequency. Not revised mid-analysis.

D1  THE SUBSTITUTION TEST.  A candidate is a required component if and only if removing it
    leaves a description consistent with a state the subject would say they were not in.
    If the residual description still picks out the same state, the candidate was not required.

D2  THE LADDER IS THE VOCABULARY.  Components are drawn from the twelve declared components of
    the Section 5 ladder and from no other list. Anything that does not correspond to one of
    the twelve is not a component of this index. An episode requiring a thirteenth thing is
```

```
    outside the ladder's scope and is reported as such, not shoehorned in.

D3  NESTING.  The ladder is nested: a state that requires component n requires every component
    below n. If component 8 is present and component 4 is absent, the decomposition is wrong
    and must be redone, not recorded. Report gaps as decomposition failures.

D4  ONE ORDER, ONE COMPONENT.  A modelled other is one component (index 8). The other's model
    of the subject is a second, distinct component (index 11). Each order of recursion counts
    exactly once, however elaborate the content at that order.

D5  NOUNS ARE NOT COMPONENTS.  Count what the specification requires, not what the description
    contains. The hour, the room, the weather and the errand are one component (situation)
    unless the substitution test separates them.

D6  ENTAILMENT MERGES.  If component A is entailed by component B in the subject's account,
    A and B are one component. Distinguishability is the criterion, and it is the subject's
    distinguishability, not the analyst's.

D7  ABSENCE IS RECORDED.  Every one of the twelve components is explicitly marked present or
    absent. There is no "not mentioned" state. This is what prevents an analyst from reaching
    a target count by leaving inconvenient components unexamined.

D8  THE GRANULARITY IS FIXED FIRST.  The decomposition rules are chosen before the episode is
    read and are not adjusted after seeing the count. Any adjustment is a new analysis with a
    new declared rule set, and both are published.
```

D1 and D8 carry the weight. D1 gives the judgment a determinate form: it is no longer “is this a component?” but “does removing it change which state this is?”, which is a question about the description and which two analysts can argue about with the description in front of them. D8 removes the degree of freedom that §5.18 named as the subtlest failure mode — an analyst who splits and merges until the count lands where they expected it to.

D2 is the rule most likely to be resented and it is the one that makes the ladder a ladder. The twelve components are the vocabulary. This is restrictive by design: a fixed vocabulary is what makes counts comparable across analysts and across episodes, which is the entire purpose of having one.

D3 deserves a word because it will fire. Real accounts routinely appear to skip rungs — a subject speaks about what someone else was thinking without ever saying what the situation was. Almost always the lower component is present and unstated rather than absent. D3’s instruction is to go back and ask, not to record a gap, because a recorded gap propagates into a count that no formula in this framework is defined on.

6.7 Answer, part two: agreement is the test

Explicitness is necessary and it is not sufficient. A rule can be perfectly explicit and still be applied differently by every person who reads it. Agreement between analysts is a reliability statistic and not a validity statistic [Cronbach and Meehl, 1955, Campbell and Fiske, 1959]. **The test of a decomposition is not whether the analyst finds it convincing. It is whether two analysts, working independently from the same declared rules and the same material, return the same integer.**

This is the move that puts the index in a different epistemic position from the quantity CC-R1 demoted, and it is worth being precise about why. `D/P`’s problem is not that analysts disagree about it; `D/P`’s problem is that even a single analyst’s number is undetermined, because the ratio is not invariant under transformations the data cannot rule out. No amount of agreement fixes that: two analysts who both apply the same inadmissible transformation agree perfectly and are both reporting a number that is not a measurement. **The count has no such internal indeterminacy. Given a decomposition, the count is determined. So disagree-**

ment between analysts is the *only* place error can enter, and disagreement between analysts is measurable.

That is the whole of the argument, and its practical form is a protocol:

```
THE AGREEMENT REQUIREMENT

No essence frequency is published without an agreement figure, and the agreement figure is
reported on THREE quantities, not one:

    A1  exact agreement on the integer n
    A2  agreement on the pitch class (the odd part of n)
    A3  the distribution of the pitch disagreement in cents, |1200 * log2((n_1/n_2)^2)|

A2 and A3 are not derivable from A1 and are not derivable from any weighted kappa.
Section 6.17 shows a constructed case in which they diverge sharply.
```

The reason A2 and A3 are mandatory rather than optional is Section 5 §5.17's finding: rank distance and pitch distance are different metrics and are not monotonically related, because the pitch class is the odd part of the index and the odd part is a number-theoretic function that is not monotone in `n`. An agreement statistic built on rank distance therefore cannot see the disagreement that matters, and reporting one alone is worse than reporting nothing because it manufactures confidence.

6.8 Answer, part three: where the answer is incomplete Three concessions. None is rhetorical, and none of them is repaired later in this framework.

CONCESSION ONE — agreement is not correctness. Two analysts trained on the same rules by the same person will agree with each other and may both be wrong in the same direction. Inter-rater agreement measures the reliability of a procedure and says nothing about its validity. This is a standard and well-understood limitation of every agreement statistic in psychometrics, and it is not special to this construction. What would be needed is a criterion external to the decomposition against which counts could be checked, and this framework does not have one. The nearest available substitute is predictive: does the count predict something it was not fitted to? That is FVP-6's business, the design is specified in §6.14, and it has not been run.

CONCESSION TWO — D2 fixes the vocabulary and does not justify it. The twelve components are defended in Section 5 §5.7 by the nesting argument: each rung adds exactly one component to the rung below, so the order is forced rather than chosen. That defence establishes the *order* given the components. **It does not establish that these twelve are the right twelve, or that twelve is the right number.** Ashby's requisite variety and Section 4's ceiling `c/eta <= ln N` both make `N` consequential — raising `N` is one of only four levers — so the choice of twelve is not harmless. A thirteenth genuinely distinct component would raise the ceiling, and this framework has no argument that no such component exists. It has only the claim that it could not find one that survived D1 and D6.

CONCESSION THREE — and this is the deepest one. The substitution test D1 appeals to what *the subject would say they were not in.* That is a judgment made by a person about their own state, and this framework has no independent access to it. The whole apparatus therefore rests on first-person report at exactly one point. **The count is absolute-scaled given a decomposition; the decomposition is explicit and testable; and underneath both there is a subject saying yes, that is a different state, and there is nothing underneath that.**

This is not a defect the framework can engineer away, and it should not pretend to. It is the same foundation psychophysics rests on, and psychophysics has done a century of replicable work on it — which is a genuine reason for confidence and not a proof of anything. **The honest summary is that the essence index converts an unbounded judgment into a bounded, explicit, testable one, and does not eliminate judgment.** No procedure does. What this framework

claims is that the judgment has been moved somewhere it can be audited, and Section 5's claim about scale type is a claim about the arithmetic downstream of that judgment, not about the judgment itself.

The Engineering

6.9 The elicitation procedure **This is the procedure. Later papers in this series cite it and do not restate it.** It is written for a practitioner working with one subject on one situation, producing one or more framings. Steps 1 to 5 establish the frame; 6 to 11 elicit; 12 to 16 build and check the vector; 17 to 20 report.

A prohibition that governs the whole procedure and is repeated inside it: this is not an assessment. Nothing in the procedure evaluates the subject, ranks them, screens them, or produces anything that may be described to them or to anyone else as a finding about their mind. The procedure produces a description of a description. A practitioner who cannot hold that distinction should not run it.

```
STEP 1 -- DECLARE THE RULE SET BEFORE READING ANYTHING.
    Write down: the decomposition rules in force (D1–D8 or a declared variant), N = 12, the
    ladder in use, the intensity instrument and its range, and the audible band and folding
    convention. Date it. This page is published with the reading. (D8)

STEP 2 -- OBTAIN CONSENT, AND MAKE DECLINING STRUCTURAL.
    The subject is told what is being elicited, what will be computed, what it does and does
    not mean, and that any question may be skipped without giving a reason and without the
    procedure being abandoned. **No intervention here may remove a person's ability to
    decline. Consent is structural, not advisory.** Nothing is masked, nothing is concealed,
    and nothing is administered below the subject's awareness.

STEP 3 -- FIX THE SITUATION.
    One situation, named in the subject's own words, in one sentence, written down before
    anything else is asked. Everything downstream is indexed to this sentence.

STEP 4 -- FIX THE FRAMINGS TO BE ELICITED.
    Decide in advance how many framings of the situation will be elicited and what each is.
    Two is the minimum for any relational reading; three is the house default. Name them
    before eliciting any of them.

STEP 5 -- SILENT WRITE-FIRST.
    The subject writes each framing out in full, independently, before any two are compared,
    and before the practitioner comments on any of them. This is the personal-scope form of
    the silent-write-first rule and it exists to stop the framings converging by conversation
    before they have been recorded.

STEP 6 -- READ THE FIRST FRAMING AGAINST THE TWELVE COMPONENTS.
    For each of the twelve components in order, mark PRESENT or ABSENT. Every one of the
    twelve is marked. There is no blank. (D7)

STEP 7 -- APPLY THE SUBSTITUTION TEST TO EVERY COMPONENT MARKED PRESENT.
    Remove it; read the residual description back to the subject; ask whether that is still
    the state they were in. If yes, the component was not required: unmark it. (D1)

STEP 8 -- CHECK NESTING.
    If any component is marked present above a component marked absent, go back and ask
```

about the absent one. Do not record a gap. (D3)

STEP 9 -- COUNT.
n = the number of components marked present after steps 7 and 8. Record the count and, beside it, the list. **A count without its list is a rating and is rejected.** (§5.18)

STEP 10 -- ELICIT THE INTENSITY, BY MAGNITUDE ESTIMATION.
Choose the state class the subject reports most strongly and assign it a reference value -- 10 on a 0–10 instrument. Then, for each other state class present, ask: "compared with that one, how strong is this one -- half as strong, a quarter, three times?" **The question is asked in ratios because ratios are what the construction consumes** (§6.3). Record the answers. Do not average across framings.

STEP 11 -- ELICIT THE REMAINING FRAMINGS.
Repeat steps 6–10 for each framing named in step 4, without showing the subject the earlier vectors.

STEP 12 -- CHECK SUPPORT OVERLAP. THIS STEP IS NOT OPTIONAL.
If two framings have disjoint support -- no state class present in both -- then u = 1 exactly, regardless of the intensities, and the reading is degenerate. Verified:

> five constructed pairs with disjoint support, random intensities:
> u = 1.000000000000 in every case

A degenerate reading is not a high reading. It is no reading. **Framings must be represented with overlapping support.** The chord analysis owns this trap; the procedural requirement here is to detect it before anything is computed and to return to step 5 if it fires.

STEP 13 -- RECORD THE RAW NORM, THEN NORMALISE.
Compute ||x||_2 in the instrument's units and write it down (§6.4). Then divide every component by it. The unit of the instrument cancels (§6.3); the norm does not, and is reported.

STEP 14 -- COMPUTE THE PAIRWISE READINGS.
For every pair of framings: cos theta = x.y, u = 1 − (x.y)^2. Report all pairs individually. Do not report only the mean.

STEP 15 -- AGGREGATE.
Mean pairwise u over all pairs; then F = ln(1 + 11 u_bar), N_eff = 1 + 11 u_bar, f = k(1 + 11 u_bar)^2.

STEP 16 -- COMPUTE THE SPECTRUM AND THE CHORD.
For each state class in the union of the supports, f = k n^2, folded into the declared band, with pitch class = odd part of n. The chord analysis owns the chord; this gives its inputs.

STEP 17 -- RUN THE SECOND RATER.
An independent analyst, working from the step 1 rule set and the step 5 written framings alone, repeats steps 6–13. Report A1, A2 and A3 (§6.7).

STEP 18 -- RUN THE PERMUTATION TEST.
Swap two adjacent indices in the ladder, recompute, report the change in cents and in pitch class. This is CC-I6 of Section 5 §5.16 and it takes ten minutes.

```
STEP 19 -- PUBLISH THE DECOMPOSITION WITH THE FREQUENCY.
    Same table, same page. Where it will not fit, the frequency is not published either.

STEP 20 -- STATE THE BOUNDS IN THE REPORT ITSELF.
    Every report carries, in its own words: that the frequencies are essence frequencies and
    not physical resonances; that **the twelve states are not diagnoses and the reading is not
    a clinical, medical or therapeutic assessment of anyone**; and that the frequency inherits
    exactly the defensibility of the count.
```

6.10 The worksheet Printable. One sheet per framing, plus one summary sheet. It is the same form as the worksheet of §6.10.

  pair _______________  cos theta = _________   u = _________
  pair _______________  cos theta = _________   u = _________

mean pairwise u_bar = _________
F = ln(1 + 11 u_bar) = _________ nats        N_eff = 1 + 11 u_bar = _________
f = k (1 + 11 u_bar)^2 = _________ Hz        folded (j = ____) = _________ Hz

SPECTRUM: states spanned { _______________ }
  n = ___  f = _________ Hz  folded _________  class ___
  n = ___  f = _________ Hz  folded _________  class ___
  n = ___  f = _________ Hz  folded _________  class ___
  n = ___  f = _________ Hz  folded _________  class ___
distinct pitch classes: { _____________ }   count ____  of ceil(12/2) = 6 available

AGREEMENT (step 17):  A1 exact-n ____/____   A2 pitch-class ____/____
                      A3 cents: mean ______ median ______ max ______
PERMUTATION TEST (step 18): swapped ___ <-> ___ ;  class ___ -> ___ ;  ______ cents

BOUNDS, restated on every report:
  [ ] essence frequencies, not physical resonances
  [ ] the twelve states are NOT diagnoses; this is not a clinical, medical, diagnostic
      or therapeutic assessment of any person
  [ ] the frequency inherits exactly the defensibility of the count
  [ ] decomposition published with the frequency
================================================================================
```

6.11 A worked pass through the vector arithmetic Before the full carried case, one framing taken end to end so the arithmetic is visible.

Raw intensities elicited by magnitude estimation, on a 0-to-10 instrument, for a framing with three state classes present:

```
state 3  (directed feeling)      8
state 5  (attributed feeling)    4
state 7  (reflexive feeling)     2
```

Step 13, the raw norm:

```
||x||_2 = sqrt(8^2 + 4^2 + 2^2) = sqrt(64 + 16 + 4) = sqrt(84) = 9.165151
```

Recorded, then divided out:

```
x_3 = 8 / 9.165151 = 0.872872
x_5 = 4 / 9.165151 = 0.436436
x_7 = 2 / 9.165151 = 0.218218

check: 0.872872^2 + 0.436436^2 + 0.218218^2 = 1.000000
```

And the first invariance in operation: had the same subject been elicited on a 0-to-1 instrument at 0.8, 0.4, 0.2, the norm would have been 0.916515 and the unit vector identical to nine decimals. The instrument's unit cancels. The ratios 4 : 2 : 1 are the entire content.

The Specification

6.12 The agreement protocol

```
S6.1  TWO RATERS MINIMUM.  Independent, working from the declared rule set and the written
      framings only. No consultation until both have completed step 13.

S6.2  BLIND TO EACH OTHER AND TO THE HYPOTHESIS.  The second rater does not see the first
      rater's count and is not told what reading the analysis is expected to produce.

S6.3  REPORT A1, A2 AND A3 SEPARATELY.  Exact agreement on n; agreement on pitch class;
      the distribution of cents disagreement. A weighted kappa may be reported in addition
      and never instead.

S6.4  THE THRESHOLD IS ON PITCH, NOT ON KAPPA.  Declare, before the analysis, the maximum
      pitch disagreement at which a frequency will still be published. Report the fraction
      of episodes exceeding it.

S6.5  DISAGREEMENTS ARE ADJUDICATED IN PRINT OR NOT AT ALL.  Where raters differ, publish
      both counts and both component lists. A consensus count with the disagreement erased
      is a fabricated agreement figure.

S6.6  RATER DRIFT IS CHECKED.  A fixed set of episodes is re-rated at intervals by the same
      rater. Within-rater agreement over time is reported alongside between-rater agreement.
```

6.13 The reporting standard Every published essence frequency in this framework, and every one produced by a reader following it, carries: the decomposition (CC-I1), the count rule (CC-I2), `N` and the ceiling `ln N` (CC-I3), the tie-break (CC-I4), the band and the folding exponent `j` (CC-I5), the permutation test result (CC-I6), and the agreement figure (CC-I7). Those are Section 5 §5.16's seven publication requirements and this section's procedure is built to produce all seven as a by-product of running it.

To which this section adds two:

```
CC-I8  THE RAW NORMS.  ||x||_2 for every vector, in the instrument's units.  (§6.4)
CC-I9  THE SUPPORT OVERLAP.  For every pair, the states shared. A pair sharing none is
    reported as DEGENERATE and its u is not published as a reading. (step 12, chord analysis)
```

6.14 The Formula Validation Protocol table for the index **No formula appears in this series without passing all seven gates in print.** The protocol is Series B's Formula Validation Protocol and it is binding. This is the FVP table for the psychological essence index and the essence law applied to it.

F-06 · THE PSYCHOLOGICAL ESSENCE INDEX

```
STATEMENT

    n  :=  the number of distinguishable components required to specify the state
    f  =   k n^2,      k = 0.483425732988414 Hz,   N = 12,   n in {1, ..., 12}
```

READS. How many things must be said before a listener knows which state is meant -- squared, and scaled to a pitch.

STATUS. The index is a DEFINITION. The essence law f = k n^2 is a POSTULATE about essence structure (essence-law spec), verified to collapse exactly from the 2022 source recipe and reproducing all 118 published element values to a worst relative deviation of 9.0e-15 (CC-R5). k is a CHOSEN reference constant, badged.

Gate	Verdict	Content
FVP-1 DIMENSIONS	**PASS**	`n` is a dimensionless count. `k` carries Hz. `f = k n^2` therefore carries Hz on both sides. Every interval `f(m)/f(n) = m^2/n^2` is dimensionless and `k` cancels exactly, which is why the interval structure developed here does not depend on the constant at all.

Gate	Verdict	Content
FVP-2 SCALE TYPE	**PASS — and this is the gate the section exists for**	`n` is a cardinality. It has a true zero (`n = 0`: no components, no state, `f = 0`) and a fixed unit (one component), and it admits only the identity transformation. **It is therefore ABSOLUTE-scaled, which is strictly stronger than the ratio scale that squaring requires.** Contrast CC-R1: `D/P` returns DEMOTE at this gate because `D` and `P` are ordinal ratings whose ratio is not invariant under admissible transformations — measured spread of 2.490 octaves in Section 5 §5.3. The index is not a ratio of ratings and does not inherit that demotion; it sidesteps it. The gate is passed for `n` and is passed for `n` only. The intensities that build the state vector are a separate quantity with a separate answer: they must be ratio-scaled up to a free multiplier (§6.3), the free multiplier is genuinely free (first invariance, exact), and the ratio requirement is genuinely binding (second invariance fails, 1065.05 cents of spread under monotone transformation). The warrant for the intensities is Stevens' magnitude estimation, reported as a measured property of a procedure and not a constant of nature.

Gate	Verdict	Content
FVP-3 LIMITING CASES	**PASS**	`n -> 0`: `f -> 0`. No components, no state, no pitch — and the zero vector correctly has no unit form. `n = 1`: `f = k`, the ground essence itself; a one-component state sits at the system's floor, which is the right place for undifferentiated activation. `n -> N`: `f -> k N^2 = 69.6133 Hz`, the ceiling, and by Section 4 the maximum sustainable cost ratio `c/eta <= ln N = 2.484907`. No divergence anywhere in range. The unbounded limit `n -> infinity` is not reachable: the ladder is finite by D2, and an episode requiring a thirteenth component is out of scope and reported as out of scope rather than indexed.
FVP-4 FIXED POINTS	**PASS**	`f(n) = n` has the fixed point `n = 1/k = 2.06856`, which is not an integer and therefore not attained — the index and its frequency never coincide, and no reading should be constructed as though they do. The structurally meaningful invariant is different and is number-theoretic: **`f` is invariant in pitch class under `n -> 2n`**, since `(2n)^2 = 4n^2` is exactly two octaves. The fixed points of the class map are the odd integers, which is why the twelve-state ladder has exactly `ceil(12/2) = 6` classes. The companion paper on octave folding owns the derivation.

Gate	Verdict	Content
FVP-5 IDENTIFIABILITY	**PARTIAL — declared**	`n` is recoverable from obtainable data: the component list is the data, and steps 6 to 9 recover it. **But the map from episode to count is not injective and not everywhere agreed.** Two decompositions of one episode can return different `n`, which is the decomposition objection of §6.5, conceded in §6.8. The identifiability that holds: given a declared rule set, two raters' counts are comparable and their disagreement is measurable, which is a stronger position than CC-R1's `D/P`, where a single rater's number is undetermined. The identifiability that does not hold: there is no procedure in this framework that identifies the *correct* decomposition, and §6.8 concession two states that the choice of twelve components is itself unjustified beyond a failed search for a thirteenth.

Gate	Verdict	Content
FVP-6 FALSIFICATION	**SPECIFIED — NOT RUN**	The essence law is a postulate about essence structure and makes no empirical claim on its own; what is falsifiable is the operationalisation. Design, following Paper E §5.3: preregister the rule set, the ladder, the elicitation script and the analysis; fit on training episodes; **FREEZE**; report held-out performance on whether the count predicts a criterion it was not fitted to. Beat four baselines — persistence, direct-input, matched autoregressive, and shuffled-input control. Kill condition, stated in advance: if counts elicited under the frozen protocol fail to beat the persistence baseline on held-out prediction, the operationalisation is dead and the ladder is withdrawn. Two standing corrections apply and must be carried into the design: **CC-R13(a)** — the shuffled-input control is anti-conservative as ordinarily run, with measured false-rejection rates of 0.108 (iid permutation) and 0.120 (circular shift) against a nominal 0.05, so the surrogate must be calibrated by simulation on the study's own design before use; and **CC-R13(b)** — no surrogate detects fabricated timing, so design controls (blinding, channel separation, prospective sampling, a yoked control) are mandatory and not substitutable. **This test has not been run.**

Gate	Verdict	Content
FVP-7 REPRODUCIBILITY	**NOT YET RUN — declared**	**The cross-individual test has not been performed for this index and this framework does not claim it has.** The question is whether the same operationalisation, applied by different analysts to different subjects in different settings, recovers the same parameters — specifically whether the component count for a given class of episode is a property of the episode or a property of the analyst who counted it. This is the gate that decides the hard-science question and it is the one most often skipped. It is skipped here too, and it is reported rather than omitted. What exists instead is the constructed demonstration of §6.17, which is an illustration of the *protocol*, not a result: constructed data cannot reproduce anything. The route to running it is the same one CC-R1 names for the Moment equation — Rasch instrumentation, which achieves separation of person and item parameters so that a measure does not depend on which items were used, at a measured cost of 123 items per term. CC-R14's costed programme puts the cross-subject recovery stage at the point of highest mortality, with a 55.3% chance of the programme dying at or before it, and the corpus's research-programme costing notes that this is not a coincidence: the gate that decides the question is the gate most likely to kill the answer. Until FVP-7 is run, every frequency in this framework is a frequency *under a declared decomposition*, and that qualification is not decorative.

Overall verdict on F-06: passes gates 1 to 4 outright, gate 5 partially and with the shortfall named, gate 6 specified but unrun, gate 7 unrun. That is a formula in good standing on scale type and structure and unvalidated on reproducibility, and the correct way to use it is the way this framework uses it: as an exact construction whose inputs are declared, whose disagreements are published, and whose empirical status is stated in the same breath as its numbers.

The Failure Modes

6.15 Leading the elicitation The practitioner reads the ladder aloud, in order, asking after each rung whether that one is present. By rung nine the subject has learned the shape of the instrument and what a fuller answer looks like. **Counts elicited this way climb through a session, and they climb for every subject, which is the signature of the artefact.**

The defences are in the procedure and each is there for this reason. Step 5's silent write-first captures the framing before any prompting. Step 7's substitution test removes components the subject will not defend when the residual is read back to them. Step 17's second rater works from the written framing and never meets the subject, so a leading elicitation shows up as a systematic gap between the two raters' counts rather than as a shared error.

Detection: plot count against position in session. A rising trend is an artefact until shown otherwise.

6.16 Disjoint support, and why a high `u` can be a null result Step 12 exists because of an exact and easily missed degeneracy. If two framings share no state class, their inner product is zero, so `u = 1` regardless of what the intensities are. Five constructed pairs with disjoint support and randomly drawn intensities give `u = 1.000000000000` every time.

A one-hot framing — a subject represented as holding exactly one state — is the extreme case, and one-hot framings are automatically orthogonal to each other. They score `u = 1` for everyone, on every topic, regardless of content, which means the reading has ceased to depend on the subject at all.

A degenerate reading is not a strong reading. It is the absence of a reading wearing the costume of the strongest possible one, and because `u = 1` is the top of the scale it looks like a triumph. This is a real trap and the framework names it. The chord analysis of this series owns it and states it in full; the companion paper on between-persons measurement restates it for the between-persons case. The obligation here is procedural: check overlap at step 12, before anything is computed, and return to step 5 if the check fires.

6.17 Agreeing on kappa while disagreeing on the note This is the failure mode most likely to defeat a careful practitioner, because every conventional instrument says the work is fine.

A **CONSTRUCTED** two-rater exercise. Fifteen constructed vignettes; two raters, working independently from the same declared rule set, each returning a count.

```
rater 1:  3  5  7  4  9  6 11  2  8  5 10  3  7 12  6
rater 2:  3  5  6  4  9  7 11  2  8  6 10  4  7 12  6
```

The agreement statistics:

```
exact agreement on n        11/15 = 0.7333
agreement within one         15/15 = 1.0000
mean |dn|                    0.2667
```

```
unweighted kappa             0.7044
linear-weighted kappa        0.9185
quadratic-weighted kappa     0.9838
```

By the conventional benchmarks — Landis and Koch's much-quoted table puts anything above 0.81 in the top band — a quadratic-weighted kappa of 0.9838 reads as very nearly perfect agreement. Every rater was within one category of the other on every single episode. A methods section reporting these figures would pass without comment.

Now report A2 and A3, which S6.3 requires:

```
agreement on PITCH CLASS     11/15 = 0.7333
pitch disagreement, cents:   mean 179.66   median 0.00   max 996.09
                             max = 0.8301 octaves

the four disagreements:
  ep 3   n = 7 vs 6    class 7 vs 3     533.74 cents
  ep 6   n = 6 vs 7    class 3 vs 7     533.74 cents
  ep10   n = 5 vs 6    class 5 vs 3     631.28 cents
  ep12   n = 3 vs 4    class 3 vs 1     996.09 cents
```

A quadratic-weighted kappa of 0.9838 coexists with pitch-class disagreement on more than a quarter of episodes and a worst-case disagreement of 996 cents — five sixths of an octave, from a one-component difference at the steep end of the ladder.

The mechanism is Section 5 §5.17's and it is exact. Weighted kappa penalises disagreement by rank distance. The essence law's consequence is a square law on the index, and the pitch class is the odd part, which is not monotone in `n`. On episode 12 the raters differ by one rank — the smallest possible disagreement, barely penalised by any weighting — and land 996 cents and two pitch classes apart, because at the bottom of the ladder one component is worth almost an octave.

The rule that follows is S6.3 and it is absolute: report agreement on the pitch, always, and never substitute a rank-based statistic for it. A weighted kappa is not wrong; it is answering a question about ranks, and this framework does not consume ranks.

The same failure appears one level down, in the intensities. A **CONSTRUCTED** intensity exercise, ten items, two raters, on a 0-to-10 instrument, gives `ICC(2,1) = 0.9379` — again, by convention, excellent. Follow one such disagreement downstream:

```
rater 1 vector {3:8, 5:4, 7:2}   ->  u = 0.388360   against a fixed reference framing
rater 2 vector {3:7, 5:5, 7:2}   ->  u = 0.301994
                                     |du| = 0.086365

f_rel:  13.4361 Hz  versus  9.0300 Hz  =  687.99 cents apart
```

Two raters differing by one point on two items, at an ICC of 0.9379, produce relationship frequencies 688 cents apart. The companion paper on the dyad interval will show that `f_rel = k(1 + 11u)^2` is steep in `u` for precisely this reason. **The agreement figure that matters is the agreement on the quantity intended for publication, and where a frequency is to be published, agreement on the frequency must be reported.**

6.18 Retro-fitting the decomposition

An analyst expects a state to come out around eight, counts six, and revisits the substitution test on two borderline components with a rather more generous reading. The count is now eight. Nothing dishonest has been done at any single step.

D8 is the only defence and it is a procedural one: the rule set is fixed and dated before the episode is read, and any revision produces a second, separately published analysis rather

than a correction to the first. Step 1 requires a dated rule-set page for exactly this reason. An analysis whose rule set has no date is not auditable and its frequencies should not be believed.

The second defence is step 17. A blinded second rater working from the original rule set will not reproduce the generous reading, and the disagreement lands in A1, A2 and A3 where it can be seen.

6.19 Running the procedure as an assessment This is the failure mode with consequences outside the framework, and it is prohibited rather than merely discouraged.

The procedure produces a number about a description. It does not produce a finding about a person. A practitioner who reports to a subject that their state "came out at nine," or who compares two subjects' counts, or who tracks a subject's counts over time as though the trend meant something about them, has converted a formal construction into an assessment. **The twelve states are not diagnoses. The counts are not severities. The chord is not a profile. No reading in this framework assesses anyone's mental health, and no procedure in it may be administered as though it did.**

Step 2 and step 20 are the structural defences: the subject is told at the outset what the procedure does and does not mean, and every report restates it. **And step 2's consent clause is not a formality — no intervention in this framework may remove a person's ability to decline, at any step, without explanation, and without the procedure being abandoned in consequence.** Nothing is masked, nothing is concealed, nothing operates below the subject's awareness. A person cannot consent to what is hidden from them.

6.20 Rater drift A single analyst's decomposition shifts over weeks. Early counts and late counts are not comparable, and because the drift is smooth it will not show up as noise; it will show up as a trend, and a trend invites an interpretation.

S6.6 is the defence: a fixed set of episodes, re-rated at intervals by the same rater, with within-rater agreement reported alongside between-rater agreement. The statistic is the same triple — A1, A2, A3 — computed against the rater's own earlier counts.

Drift is not a minor operational nuisance in this construction. It is FVP-7's question asked within a single person, and a procedure that cannot reproduce its own counts across time has no prospect of reproducing them across people.

Worked Example

CONSTRUCTED throughout. No data were collected, no person was elicited, and nothing below is a case report or an observation. This is the framework's carried subject, fixed by the framework's carried subject, and every part of the framework that needs this case uses this one and no other.

6.21 THE SUBJECT — three framings of one situation **Step 3, the situation, in the constructed subject's words:** *A colleague did something in a meeting that I have not been able to stop thinking about.*

Step 4, the framings to be elicited. Three, named in advance:

```
THREAT   -- the situation read as something happening to me
STORY    -- the situation read as an instalment in a longer account
MIRROR   -- the situation read as being about what it says about me
```

Steps 5 to 9, the decomposition. Each framing written independently, then read against the twelve components, with the substitution test applied to every one marked present and the nesting check run. The three framings return these supports:

```
THREAT   states 3, 5, 7      directed feeling, attributed feeling, reflexive feeling
STORY    states 3, 5, 10     directed feeling, attributed feeling, narrative feeling
MIRROR   states 5, 7, 10     attributed feeling, reflexive feeling, narrative feeling
```

Step 12, the support overlap check, run before anything is computed:

```
THREAT & STORY   share {3, 5}      2 states   OK
THREAT & MIRROR  share {5, 7}      2 states   OK
STORY  & MIRROR  share {5, 10}     2 states   OK
```

Every pair overlaps. The reading is not degenerate. Had the three framings been one-hot, or had any pair been disjoint, `u` would have been 1 by construction and the analysis would have returned to step 5. This check is the reason the carried case is built with overlapping support, and it is the fix, not a convenience.

Step 10, magnitude estimation. Raw intensities, elicited by ratio comparison against the strongest state class in each framing, on a 0-to-1 instrument:

```
THREAT   {3: 0.8, 5: 0.4, 7: 0.2}
STORY    {3: 0.5, 5: 0.7, 10: 0.4}
MIRROR   {5: 0.3, 7: 0.8, 10: 0.5}
```

Step 13, raw norms recorded, then normalisation:

```
||threat||_2 = sqrt(0.64 + 0.16 + 0.04) = sqrt(0.84) = 0.916515
||story ||_2 = sqrt(0.25 + 0.49 + 0.16) = sqrt(0.90) = 0.948683
||mirror||_2 = sqrt(0.09 + 0.64 + 0.25) = sqrt(0.98) = 0.989949

threat unit  = (0.872872 at 3,  0.436436 at 5,  0.218218 at 7 )
story  unit  = (0.527046 at 3,  0.737865 at 5,  0.421637 at 10)
mirror unit  = (0.303046 at 5,  0.808122 at 7,  0.505076 at 10)
```

The norms are reported and not discarded (CC-I8). They are close here — 0.9165, 0.9487, 0.9899 — which says the three framings are held at comparable overall intensity. Had one been an order of magnitude smaller, `u` would not have shown it, and the reading would have been of a framing the subject barely holds.

Step 14, the pairwise readings, all reported individually:

```
pair              cos theta      theta        u
mirror & story     0.436566    64.1150 deg   0.809410
mirror & threat    0.308607    72.0247 deg   0.904762
story  & threat    0.782074    38.5491 deg   0.388360
```

Step 15, aggregation:

```
mean pairwise u_int = (0.809410 + 0.904762 + 0.388360) / 3 = 0.700844

F_int = ln(1 + 11 * 0.700844) = ln(8.709284) = 2.164390 nats
N_eff = 1 + 11 * 0.700844 = 8.7093

f = k (1 + 11 u)^2 = 0.483425732988414 * 8.709284^2 = 36.6686 Hz
folded into 220–440 with j = 3:  36.6686 * 8 = 293.349 Hz
```

Step 16, the spectrum and the chord inputs:

```
states spanned: {3, 5, 7, 10}

n = 3   f =  4.3508 Hz   folded 278.453   class 3
n = 5   f = 12.0856 Hz   folded 386.741   class 5
n = 7   f = 23.6879 Hz   folded 379.006   class 7
n = 10  f = 48.3426 Hz   folded 386.741   class 5

pitch classes {3, 5, 7} -- THREE distinct, though FOUR states are held.
States 5 and 10 share odd part 5, so one of the four adds pitch but no new class.
```

That last line is the reading's most instructive feature and it is not an accident of this case. The subject holds four state classes and commands three notes. Adding the narrative component at `n = 10` raised the pitch by two octaves — `(10/5)^2 = 4` exactly — and added no new harmonic class, because 10 and 5 have the same odd part. **The companion paper on octave folding owns the rule and the chord analysis of this series owns what it means for a chord; here it is enough to observe that the twelve-state ladder offers six classes** (`ceil(12/2)`) **and this subject occupies three of them.**

Steps 18 and 19. The permutation test, run on the pair that matters most for this subject — swapping indices 5 and 6 in the ladder:

```
class 5 -> class 3,  568.72 cents
```

Well over the quarter-octave threshold, so the ordering is load-bearing for this reading and is defended by the nesting argument of Section 5 §5.7 or the reading is not published. The decomposition — the three component lists behind the three supports — is published in the same table as the frequencies.

6.22 The agreement pass on the same subject

Step 17, run on the THREAT framing. A second analyst, blind to the first analyst's counts and to the intended reading, works from the subject's written framing and the dated rule set alone.

The first analyst marked states 3, 5 and 7 present with intensities 0.8, 0.4, 0.2. Suppose the second analyst agrees on the support and reads the intensities as 0.7, 0.5, 0.2 — a one-point difference on a 0-to-10 instrument, at two of three items. Section 6.17 computed exactly this case:

```
analyst 1  ->  u(threat, story) = 0.388360
analyst 2  ->  u(threat, story) = 0.301994
|du| = 0.086365

f_rel:  13.4361 Hz  versus  9.0300 Hz  =  687.99 cents apart
```

Perfect agreement on the count — A1 = 3/3, A2 = 3/3, A3 = 0.00 cents on the spectrum — and 688 cents of disagreement on the relational frequency. The two agreement questions are different questions and S6.3 requires both because neither predicts the other.

What a practitioner does with that. Not average the two. **S6.5: publish both, with both intensity sets.** The honest report of this framing's relational reading is that it lies between 9.03 and 13.44 Hz under two defensible elicitations, and that the interval — not the point — is the result. A reading published as 13.4361 Hz, with the second analyst's elicitation quietly discarded, would be a fabricated precision, and it is the precision, not the number, that would be the lie.

6.23 The reading, and its bounds

What the constructed case establishes. Under the declared rule set, the twelve-state ladder, and the elicitation of §6.9, this constructed subject holds three framings of one situation with mean pairwise non-parallelism `u_int = 0.700844`,

internal surplus `F_int = 2.164390` nats, effective framing count `N_eff = 8.7093` of the twelve available, and a chord width of 36.6686 Hz, folded to 293.349 Hz. The subject spans four state classes and three pitch classes.

What it does not establish. Nothing about any person. The subject is constructed; the situation is invented; the intensities were chosen to demonstrate a procedure. **No observation is reported here and none is implied.**

What it licenses downstream. These exact numbers are the ones the companion papers of this series use. The chord analysis builds the chord from the four states and the three classes and owns the one-hot degeneracy trap that step 12 was written to catch. The companion paper on dissonance reads the intervals. The companion paper on the personal spectrum assembles the full personal worksheet around them. **No part of the framework re-elicits this subject and no part of the framework invents a different one.**

And the bounds, restated as step 20 requires them on every report.

`36.6686 Hz` is an essence frequency. **No claim is made that this constructed subject, or any person, or any tissue, or any molecule, physically resonates at that value or at any other value in this framework.**

The twelve states are not diagnoses. This reading is not a clinical, medical, diagnostic or therapeutic assessment of anyone, the counts are not severities, and the chord is not a profile of anything.

And the limit that travels with every number this section produces: the frequency inherits exactly the defensibility of the count. A contested decomposition yields a contested frequency. Section 6.22's 688-cent spread is what that sentence looks like when it is measured instead of asserted, and **FVP-7 has not been run**, so every frequency in this framework remains a frequency under a declared decomposition — which is a real thing to have, and is less than a measured one.

What this section fixes

```
THE ELICITATION PROCEDURE   Steps 1–20, §6.9. Cited by later papers; not restated there.

THE STATE VECTOR            Non-negative intensities over the twelve states, L2-normalised.
                            Support = nonzero entries. Zero vector has no unit form.

THE TWO INVARIANCES         The instrument's unit cancels exactly (verified to 9 d.p.).
                            Monotone transformation does NOT cancel (1065.05 cents of
                            spread). Therefore the intensities must be ratio-scaled up to a
                            free multiplier, and Stevens' magnitude estimation is the warrant.

THE MAGNITUDE RULE          ||x||_2 is reported with every vector and never discarded.
                            u measures direction; the norm measures how much there is.

THE DEFENCE OF THE COUNT    D1–D8 make the granularity judgment explicit; A1/A2/A3 make it
                            testable; §6.8 concedes what remains: agreement is not
                            correctness, twelve is unjustified beyond a failed search for a
                            thirteenth, and the substitution test rests on first-person
                            report with nothing underneath it.

THE AGREEMENT PROTOCOL      S6.1–S6.6. Report agreement on the pitch, always. A weighted
                            kappa of 0.9838 coexisted with pitch-class disagreement on 4 of
                            15 constructed episodes and a 996.09-cent worst case.

THE FVP TABLE               F-06, all seven gates. Gates 1–4 PASS. Gate 5 PARTIAL, declared.
```

```
Gate 6 SPECIFIED, NOT RUN, with CC-R13's two corrections carried.
**Gate 7 NOT YET RUN**, and reported as not run.
```

The companion paper on octave folding takes the index this section has learned to elicit and applies `f = k n^2` to transient states, where it owns octave folding, the odd-part class rule, and the `ceil(N/2)` ceiling that has been quoted twice already and derived neither time.

7 Results

The seven results below are the units other papers in this corpus cite. A citation to this paper should name one of them. Each carries its status: **DERIVED** where it follows from the stated definitions by algebra, **COMPUTED** where it is the output of exact arithmetic on stated parameters, and **POSTULATED** where it is asserted by this framework.

R1 — the minimum sustainable frequency. $f_{\min} = k\, e^{2c/\eta}$, with $k = 0.483425732988414$ Hz (defined constant; the hertz postulated, §2.3 P-b), and the exact trichotomy $f \gtreqless f_{\min} \iff Q_\infty \gtreqless 0$. *Status:* DERIVED from the storage-law fixed point [Curzi, 2026a] and the essence bridge [Curzi, 2026k], conditional on P-a and P-b. Verified at twelve parameter sets with sign agreement in all twelve, including the exact-equality case.

R2 — the octave form. Octaves required $= 2(c/\eta)/\ln 2 = 2.885390081777927 \times (c/\eta)$. One nat of required surplus is exactly 2.885390 octaves, 3462.4681 cents and 1.442695 bits; one octave is exactly 0.5 bits. *Status:* DERIVED; the constant is exact.

R3 — the deficit identity. $D = 2.885390(c/\eta - F) = -2.885390(\delta/\eta)Q_\infty$. The octave deficit and the steady-state gauge are the same number in different units. *Status:* DERIVED, cross-checked at a residual of 8.88×10^{-16} on the carried case — floating-point round-off, not measurement error. This is the result the sustaining-frequency paper carries forward [Curzi, 2026].

R4 — decay is not a lever on the deficit. D contains no δ. On the carried constructed dyad, moving δ from 0.09 to 0.05 leaves $D = +4.338420$ octaves unchanged to every printed digit while Q_∞ falls from -5.0119 to -9.0215, a worsening of 80 per cent. *Status:* DERIVED by inspection; COMPUTED on a constructed case. **This is the paper's sharpest result and it is negative.**

R5 — the ceiling. $c/\eta \le \ln N$, equivalently $f_{\min} \le kN^2$. At $N = 12$ the bound is $c/\eta \le 2.484907$, $f_{\min} \le 69.6133$ Hz, 7.169925 octaves above k. Above it no assignment of u over those N categories is sustainable. *Status:* DERIVED from $F \le \ln N$ [Curzi, 2026]. The same ceiling functions as the cheapest available detector of a repackaged order proxy in the corpus's survey work [Curzi, 2026i], whose Result Four records a single-week jump of 31.1 units against a maximum admissible increment of $\eta \ln N = 0.8071$ — a factor of 38.5.

R6 — the essence index. $f(n) = kn^2$ on a component count n, with the twelve-state ladder $n = 1 \ldots 12$ and the hold line $u^* = (e^{c/\eta} - 1)/(N - 1)$. *Status:* the hold line is DERIVED; **the law itself is POSTULATED** (§2.3 P-a) and has no external support. Result One of the essence law [Curzi, 2026k] — that $f(m)/f(n) = m^2/n^2$, so k cancels from every interval — is what keeps the postulate from contaminating any verdict.

R7 — the second invariance fails. Monotone rescalings of the elicited intensities, admissible if those intensities are merely ordinal, move u from 0.362115 to 0.525275 and the derived frequency from 12.0049 to 22.2093 Hz: a spread of 1065.05 cents, 0.888 octaves. *Status:* COMPUTED. The consequence is a requirement, not a caveat — **the intensities must carry ratio information or the frequency is not determined at all.**

CR — counter-result. The deficit is blind to decay, so the intervention that intuition reaches for first moves the instrument by exactly zero and worsens the destination whenever the numerator is negative. Separately: the reference constant k, the affine effective count, and the choice of twelve components are all **chosen rather than derived**, and any reading built on them inherits that status. The framework's own concentration work reaches the structurally parallel conclusion in a different domain [Curzi, 2026], where four jurisdictions at shares $40.9/27.3/18.2/13.6$ give a naive effective count of 3.41 and a bloc-collapsed effective count of exactly 1.00: a count that is not a count of independent things is not a count.

8 Discussion

8.1 What follows

The classification is worth more than any single sensitivity. The ceiling test costs one logarithm and changes the *kind* of answer a reading gives: below the ceiling a case is tunable and some assignment of u closes it; above it, no assignment does, and a prescription issued without the test may be unsatisfiable. Unsatisfiable prescriptions are worse than no prescription because they consume the effort that restructuring needed. This is the same discipline that the corpus's intervention work applies when it computes an N lever and then declines it net [Curzi, 2026j]: a ceiling gain of $\eta(\ln 6 - \ln 5) = +0.1914$ against five added communication paths costing $+0.0714$, a 34 per cent haircut on the headline benefit. The coordination cost of raising N is not a modelling nicety; it is the $n(n-1)/2$ growth that software engineering has documented for fifty years [Brooks, 1975, Conway, 1968].

The two gauges disagree, and both are right. Headroom uses the ceiling $\ln N$ and asks what the best possible geometry could support; the deficit uses the achieved F and asks what this geometry is doing. A system can have room to grow in principle and be shrinking in fact. The corpus's institutional work exhibits the same split in an operational setting [Curzi, 2026h], where moving η from 0.35 to 0.55 and δ from 0.25 to 0.12 takes a fixed point from 0.2653 to 3.9281 while a turnover event still costs 70 per cent of stock against 15.

The negative result generalises past this framework. The structure of D's independence from δ is that a multiplicative parameter cannot change the sign of the quantity it multiplies. Any model in which a rate of loss divides a net drive will have the property. Analogues are easy to find and worth naming: redundancy can reduce safety rather than increase it [Sagan, 1993]; interactive complexity with tight coupling makes catastrophic failure a system property rather than an operator error [Perrow, 1984]; and organisational learning that homogenises the organisation destroys the variance that produced its advantage [March, 1991]. In each case the intuitive intervention operates on the wrong term.

8.2 What does not follow

A reading does not conclude that a relation should end. $D > 0$ says a configuration is losing order at a computable rate under stated parameters. It does not weigh what the relation is for, what else it produces, or what ending it would cost, and the formalism contains no term for any of those.

A reading is not about a person. u is a property of two representations jointly; c and η are properties of an arrangement. There is no single-party term anywhere in the apparatus.

A reading is not clinical. The twelve states are not diagnoses, the ladder is not an assessment instrument, and the deficit is not a prognosis. This is stated in §5.9 and again in §12.

A reading does not establish that the surplus is monotone in u beyond the range examined. The framework's F is monotone increasing in u by construction, and the empirical literature is divided: bridging across structural holes has measured returns [Granovetter, 1973], but creative success rises and then *falls* with the same variable [Uzzi and Spiro, 2005], short-run effects of surface diversity are frequently negative [Putnam, 2007], and the rebuttal literature [Abascal and Baldassarri, 2015] qualifies rather than reverses that. **A monotone claim cannot survive that list unqualified**, and this paper does not make one outside the regime its arithmetic covers. The problem-solving result that is usually cited for diversity [Hong and Page, 2004] has a standing formal objection [Thompson, 2014] that must be cited with it.

8.3 Relation to the frequency register

The reason for expressing the criterion as a pitch is that intervals compose and hertz do not. Two relations with different costs are compared on the octave scale directly, and the exchange rate is a single exact constant. The apparatus for that — cents, octave equivalence, interval

arithmetic — is standard once an index exists [Rossing et al., 2002, von Helmholtz, 1885]. **What the apparatus does not carry with it is any claim about hearing.** Consonance depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005]; interval categories and octave equivalence generalise less far across listeners and species than is usually assumed [Burns, 1999, Hoeschele et al., 2012]; and the octave's perceptual specialness, while real, has a measured and finite size [Demany et al., 2013]. This paper uses the arithmetic and asserts none of the psychoacoustics. The one place where the corpus's frequencies meet real acoustics is a derived room [Curzi, 2026l], whose Result Two fixes $7.2400 \times 4.3798 \times 2.9319$ m, $V = 92.969$ m^3 and an RT60 of 0.5 s requiring 29.94 m^2 sabins, with the folded set 233.98–386.74 Hz entirely above a Schroeder frequency of 146.7 Hz — and that is a statement about a room, not about a person.

8.4 The reflexive exposure

The framework's own foundations identify a self-fulfilling loop $T(x) = W(x, M(x))$ whose fixed point is a prophecy that makes itself true [Curzi, 2026]; this paper presupposes that result rather than restating it. The exposure is direct: an instrument that issues a verdict of DECAYS on a relation may change the relation by issuing it. The mechanism is documented [Merton, 1948, Rosenthal and Jacobson, 1968] and has been caught happening in the field, with dates and prices, as a theory became true by being used [MacKenzie and Millo, 2003]. But the effect sizes are contested [McCambridge et al., 2014] and, on the best long-run assessment of the classroom case, **self-fulfilling prophecies are real but small, do not typically accumulate, and often dissipate** — most expectations turn out to be accurate rather than causal [Jussim and Harber, 2005]. The reflexive exposure is therefore real and probably smaller than the framework's rhetoric implies, and the correct response is not to suppress the reading but to publish the parameters that produced it so that a third party can recompute it. That is also why any indicator adopted as a target degrades as an indicator [Campbell, 1979], and it is why the reporting requirements of §4.19 and §6.13 are requirements rather than recommendations.

8.5 What the surrounding programme allows this paper to claim

The title of the wider corpus places this work in a lineage that begins with *physique sociale* [Quetelet, 1835] and continues through the modern computational programme [Lazer et al., 2009, Pentland, 2014]. **The lineage's characteristic error is Quetelet's**: treating the mean of a distribution as a type rather than as a statistic. This paper inherits that risk directly, because it writes a single u, η and c for an arrangement, and it responds with a rule (no aggregation, SPEC 4.14) rather than with an argument.

Three constraints from that programme bear on the central object of this paper and are not comfortable. First, human activity is bursty, with heavy-tailed waiting times and **no characteristic time scale** [Barabási, 2005]; a *minimum sustainable frequency* is a claim about a characteristic scale and must confront that finding, which it can only do by insisting that its frequency is a position on a surplus scale and not a rate of any observed process. Strong spatial regularity coexisting with temporal burstiness [González et al., 2008] is the counterweight but not a rescue. Second, an explanation is supposed to name a mechanism rather than exhibit a fitted curve [Hedström and Ylikoski, 2010]; this paper fits nothing, which sidesteps the objection at the cost of having no empirical content to fit. Third, and most sharply: **what observation would distinguish this framework's laws from a neighbouring model that fits equally well?** [Sobkowicz, 2020, Durlauf, 2005] The honest answer is H2 — the ceiling is a strict universal and one counterexample kills it — and nothing else in this paper answers it.

What the paper is entitled to claim is therefore narrow and worth stating precisely. Prediction is one of many legitimate reasons to build a model, and explanation, bounding, and the disciplined exposure of one's own assumptions are others [Epstein, 2008]. The position this work is best placed to defend is the analytical one: mechanisms stated explicitly, parameters declared, and the arrangement within which the law is claimed named in advance

[Keuschnigg et al., 2018].

9 Verification

This section decomposes every result in the paper into atomic steps, each of which can be checked on its own. The standard is Occam's: **a postulate that can be dropped without the result changing has been dropped.** Every step carries one of four statuses.

- **ARITHMETIC** — reproducible by a reader with a calculator from the inputs named.
- **DEFINITION** — true by stipulation; nothing to verify but consistency of use.
- **CITED** — supported by a named external source.
- **POSTULATED** — asserted by this framework, with no external support.

9.1 The postulates

	postulate	status
P1	The Pythagorean whole tone is the frequency ratio $9{:}8$.	CITED [Barbour, 1951]
P2	φ is the positive root of $x^2 = x + 1$; hence $\varphi^2 = \varphi + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P3	A dimensionless ratio of the form $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source
P4	The essence of a state with n distinguishable components has frequency kn^2.	POSTULATED — no source
P5	Stored order obeys $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$ with $\delta > 0$.	CITED as a form [Oppenheim et al., 1996, Elaydi, 2005]; the *interpretation* POSTULATED
P6	$N_{\text{eff}} = 1 + (N-1)u$ (the affine count axiom).	POSTULATED — design axiom [Curzi, 2026]; **not a Hill number**
P7	$F = \ln N_{\text{eff}}$, so $F \le \ln N$.	DEFINITION (given P6)
P8	A frequency may be divided by a power of two without changing what it means.	POSTULATED beyond pitch; CITED for pitch only [Shepard, 1982]
P9	n is a cardinality, hence absolute-scaled.	DEFINITION, with the scale typology CITED [Stevens, 1946]

Dropped as unnecessary. No postulate about the *ordering* of the twelve states is needed for R1–R5: the trichotomy, the octave form, the identity, the decay-blindness and the ceiling all hold for any N and any $u \in [0, 1]$ whatever the states are called. The ladder is needed only for R6 and R7. Likewise no postulate about consonance is needed anywhere in this paper.

9.2 The compounding chain

step	consumes	produces	status
L1	P1	$(9/8)^2 = 81/64 = 1.265625$ exactly	ARITHMETIC
L2	P2	$\varphi^2 = \varphi + 1 = 2.618033988749895$	ARITHMETIC
L3	L1, L2	$k = 0.483425732988414$	ARITHMETIC (exact)
L4	L3, **P3**	k carries the unit Hz	**POSTULATED**
L5	L4, **P4**	$f(n) = kn^2$ Hz	**POSTULATED**
L6	P5	$Q_\infty = (\eta F - c)/\delta$	ARITHMETIC
L7	P6, P7	$F = \ln(1 + (N-1)u)$, $F \le \ln N$	DEFINITION
L8	L5, L7	$f = k\,e^{2F}$ (the essence bridge)	ARITHMETIC given L5
L9	L6, L8, sign of $\eta F - c$	$f \gtreqless f_{\min}$ iff $Q_\infty \gtreqless 0$ — **R1**	ARITHMETIC
L10	L9	$\log_2(f_{\min}/k) = (2/\ln 2)(c/\eta)$ — **R2**	ARITHMETIC
L11	L10, Def. 3	$D = 2.885390(c/\eta - F)$	ARITHMETIC
L12	L11, L6	$D = -2.885390(\delta/\eta)Q_\infty$ — **R3**	ARITHMETIC
L13	L11 by inspection	$\partial D/\partial\delta = 0$ — **R4**	ARITHMETIC
L14	L7, L9	$c/\eta \le \ln N$, $f_{\min} \le kN^2$ — **R5**	ARITHMETIC
L15	L9 solved for u	$u^* = (e^{c/\eta} - 1)/(N-1)$ — part of **R6**	ARITHMETIC
L16	P9, L5	squaring n is a licensed operation	DEFINITION + CITED
L17	L8, rescalings	u: 0.362115–0.525275; f: 12.0049–22.2093 Hz — **R7**	ARITHMETIC
L18	L5, P8	folded values in 220–440 Hz, six pitch classes	**POSTULATED** (meaning); ARITHMETIC (value)

9.3 What this chain is and is not

Read the status column. Steps L1, L2, L3, L6, L9–L15 and L17 are arithmetic and a reader can redo every one of them. Steps L4, L5 and L18 are postulated. **A chain containing postulated steps is not a proof of its conclusion**, and this one is not offered as one. What it is offered as is a separation: **the tuning arithmetic and the octave algebra are solid, and the frequency interpretation sitting on top of them is not.** Anyone who accepts P3 and P4 gets R1 through R7 by arithmetic alone. Anyone who does not accept P3 and P4 still gets R1 through R5 in *surplus* units, because the deficit is a difference of logarithms in which k cancels: **the sustainability verdict never depends on the postulated constant, only the hertz values do.** That is the honest statement of what the frequency register buys and what it costs.

Two statuses that must not be misread. The exponent 2 at L5 is **DEFINED**, not estimated: no fit was performed and the standard procedure for testing a scaling claim [Clauset et al., 2009] was not run. The logarithm at L7 is **DEFINITION** given the affine axiom P6, and the warrant the argument needs for it is the multiplicative-dynamics one [Peters and Gell-Mann, 2016] rather than the psychophysical one; the psychophysical warrant is used only at §6.3, for the elicitation.

The falsifiable content lives at L6 and L7, not at L4 and L5. H1 through H3 test the storage law's fixed point and its sign; none of them requires the essence bridge to be true. This paper's empirical exposure is therefore smaller than its notation suggests, and its unsupported material is correspondingly more inert. The directional-prediction critique [Meehl, 1990] is worth meeting explicitly here: the corpus makes **point** predictions with constants rather than directional ones, which is the right response to Meehl, and it makes them from postulates whose status is printed — which is the honest description of what a badged postulate does in a research programme [Lakatos, 1970, Platt, 1964].

10 Limitations

Every check the governing rigour standard specifies is listed here by name, whether or not this paper passes it.

L-1. The dimensional audit does not close. $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, and k is computed as a ratio of two dimensionless quantities. **No operational procedure is supplied by which the constant acquires the dimension of frequency.** The hertz is attached by assertion (§2.3 P-b, §3.4). This is the paper's largest structural weakness and no citation in the bibliography repairs it.

L-2. The essence law has no external support. A quadratic relation between a dimensionless count and a frequency has no established analogue in psychoacoustics, ecology or measurement theory. The corpus badges it a postulate; that badge is the honest position and is not a defence.

L-3. The constant is chosen. $k = (9/8)^2/\varphi^2$ combines two real objects into a product with no precedent. It is quoted to fifteen significant figures **because it is defined**, not because anything was measured to that precision. Golden-section claims have a deflationary literature that this paper cites rather than avoids [Markowsky, 1992].

L-4. Octave reduction beyond pitch is unwarranted. Shepard grounds octave equivalence for pitch [Shepard, 1982]; nothing grounds folding a non-acoustic quantity into a 220–440 Hz band and reading meaning from where it lands. The operation is well defined; its interpretation is not supported.

L-5. $N_{\text{eff}} = 1 + (N-1)u$ **is not a Hill number.** It is a linear interpolation between 1 and N and appears in no ecological, economic, political-science or information-theoretic literature. The Hill-number citations in this paper apply to $1/\text{HHI}$ and $\exp(H)$ and to nothing else.

L-6. Conjoint measurement was not tested. The ratio-scale treatment of the elicited intensities, of η, of c and of δ is provisional. Michell's objection [Michell, 1997] stands unanswered for every quantity in this paper except n, and the available remedies [Luce and Tukey, 1964, Rasch, 1960] were not run. **This is one instance of a pattern and not an isolated exposure**; L-18 states the pattern once and concedes both instances together.

L-7. FVP-7 has not been run. Cross-individual reproducibility of the component count — H4, the gate that decides whether n is a property of the episode or of the analyst — is **not tested**. Every frequency in this paper is a frequency *under a declared decomposition*, which is a real thing to have and is less than a measured one. The demonstration in §6.17 is an illustration of the protocol on constructed data; constructed data cannot reproduce anything.

L-8. Twelve is not justified. The ladder's category count rests on a failed search for a thirteenth component, which is weak evidence. Twelve also exceeds the classical span of immediate absolute judgment [Miller, 1956], which is a caution rather than a refutation.

L-9. Agreement is not correctness. The agreement protocol measures reliability, not validity [Cronbach and Meehl, 1955, Campbell and Fiske, 1959], and internal-consistency coefficients do not substitute for either. A held-out predictive test is required before the ladder can be said to work and none has been run [Nosek et al., 2018].

L-10. u **is symmetric and psychological similarity is not.** Similarity judgments are asymmetric and violate the triangle inequality [Tversky, 1977]. If u is read as a similarity measure over people, it cannot assume metric behaviour, and this framework's u does.

L-11. Elicitation is exposed to instrument effects. Magnitude estimation's exponents move with the experimenter's chosen stimulus range [Teghtsoonian, 1971], response biases are well catalogued [Poulton, 1968], and survey instruments generally are exposed to question wording and focusing effects. None of these were controlled, because no elicitation was run.

L-12. Every case is constructed. The dyad, the commons and the subject are chosen parameter sets. Their precision is exact because the parameters are exact; **that precision does not transfer to a measured case**, and reporting $f_{\min} = 30.1588$ Hz from an η known to one significant figure would be false precision. The rigour standard's rule applies: measured or fitted quantities require an uncertainty, and none of this paper's numbers are measured.

L-13. No model comparison was performed. No out-of-sample test, no matched null with the same number of free parameters, and no information criterion is reported, because nothing was fitted. Where the corpus has attempted a confirmatory fit elsewhere, it failed its own baseline test [Curzi, 2026i], and that result is the relevant precedent for how a fit here should be reported.

L-14. No statistical claims are made and none are supported. There are no p-values, no effect sizes and no confidence intervals in this paper, because there is no sample. Nothing here should be read as evidence for or against any empirical proposition.

L-15. A published reading can change what it reads. The self-fulfilling exposure of §8.4 is not controlled for and cannot be controlled for by an instrument acting alone.

L-16. Boundary behaviour is only partly examined. $\delta \to 0$ is a pathology and the paper says so; $u \to 1$ is examined and gives the ceiling; $\eta \to 0$ makes c/η diverge and therefore places every relation above every ceiling, which is a real constraint on the model's domain and is **not** examined in the source. $N \to \infty$ raises the ceiling without bound, which the coordination-cost literature says is not available in practice [Brooks, 1975]. These limits constrain the domain; they are stated here because the source does not state them all.

L-17. Two attractive simplifications are refused. The corpus's channel-separation work [Curzi, 2026] makes the general form of the point: a property that is necessary is not thereby sufficient, and a control plane trusted *because* it is separate is the failure mode. The same applies to this paper's instrument. A relation is not sustainable because its deficit is negative; the deficit is a statement about four parameters over one declared period and nothing else.

L-18. Scalar reduction is a habit of this framework, and it is one objection in two domains. This entry replaces an earlier one recording that the seven works named in §5.7 were absent from the bibliographic database governing this corpus. They are now present and are cited where they are used [Russell, 1980, Smith and Ellsworth, 1985, Lazarus, 1991, Scherer, 2001, Tracy and Robins, 2004, Premack and Woodruff, 1978, Frijda, 1986], and citing them properly is what makes the real limitation visible, because **four of the seven are in tension with the index they were named to motivate.**

The concession, in one statement. Wherever this framework meets a phenomenon that its own source literature describes by several jointly varying features, it replaces the phenomenon with a single number and proceeds arithmetically on the number. That happens twice in this paper. Comfort and the elicited intensities are treated as quantitative by stipulation, which is Michell's objection and is conceded at L-6 and L-7. An emotional state is reduced to a count of components, ordered by that count and squared, which is the same objection in the affect domain and is conceded here. **They are one limitation of the framework, not two independent problems**, and the framework does not hold that having named the pattern disposes of it.

What the affect literature actually licenses. §5.7 states the objection at full strength and it is not repeated here in full. In summary: Smith and Ellsworth [1985] individuate emotions by the pattern across simultaneously and independently varying appraisal dimensions, which a count cannot represent — a count cannot separate anger from guilt; Scherer [2001] treats emotion as a process in time whose state *is* the synchronisation across five subsystems, which resists scalar reduction of any kind; and Lazarus [1991] individuates by qualitative core relational theme, so that differing by *what* is appraised does not license differing by *how many*. **None of the three is cited anywhere in this paper as support for the index, its ordering or its**

nesting, and a reader who finds one so used should treat it as an error. Russell [1980] agrees with rung `n = 2` on an integer and on nothing else. Premack and Woodruff [1978] name its component cleanly, with the cautions recorded at `n = 8`. Tracy and Robins [2004] is the only entry that supports its rung in the form this framework needs.

The ordering is a stipulation and is not badged as a postulate in §2.3. The rungs' ordering and their nesting are fixed by the construction of §5.6 and have no external support. §2.3 lists three postulates and none of them covers the ladder's ordering; that is an omission in this paper's own badging, it is stated here rather than repaired silently, and any later revision of §2.3 should carry the ordering as a fourth postulate.

One rung is contradicted by the work cited for it. Frijda [1986] holds that changed action readiness is constitutive of emotion as such, which places that component at the floor of the ladder and not at `n = 12`. The rung has been narrowed accordingly, to **bound commitment as distinct from readiness**, and that is the only version of the rung Frijda leaves standing. The wider claim the source manuscript made is withdrawn. **If Frijda is right and the narrower reading does not hold up, the ladder's ordering fails at its summit** — and because the index is squared, a failure at the summit is the cheapest place on the ladder for one to happen (§5.4), which is a mitigation of the consequence and not of the objection.

One reference could not be resolved. The source manuscript names "Lewis" alongside Tracy and Robins at `n = 7`, by surname only, with no year and no title. Several works by Michael Lewis would fit and none was guessed at. That citation is missing rather than wrong, and it is the one bibliographic gap in §5.7 that remains open.

What is not damaged. The count argument of §5.2 is untouched by any of this. It establishes that a cardinality is absolute-scaled, which is a fact about counting, and it never claimed that the thing counted was correctly individuated. **The objection above is about the individuation, not the arithmetic**, and the two should not be conflated in either direction.

L-19. The 2.885390 shorthand is a rounded constant. The exact value is $2/\ln 2 = 2.885390081777927$. Where the text writes 2.885390 inside a formula it is a shorthand for the exact constant; every computed figure in the paper uses the exact value.

L-20. The reflexive specification is not identified. Stated in §3.6 and repeated here because it is the most serious methodological problem in the corpus: the endogenous social effect in a linear-in-means reflexive loop cannot be recovered from observational data [Manski, 1993, Shalizi and Thomas, 2011]. The remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001], and the claim is accordingly a modelling position rather than an identified result.

L-21. The framework exempts its own parameters from its own reflexivity. If subjects change when modelled, δ, η and u are not structural [Lucas, 1976, Hacking, 1995]. This is not resolved.

L-22. The exponent is defined, not estimated. The exponent 2 in $f(n) = kn^2$ was not fitted, was not tested against alternatives, and the standard fitting-and-testing procedure for a scaling claim [Clauset et al., 2009] was not run because there is no data to run it on. **This paper makes no empirical scaling claim.**

L-23. The functional form is underdetermined. A power law with exponent below one [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as this framework's logarithm, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. Nothing in this paper discriminates among them.

L-24. There is no conservation law. Q is written with the grammar of a conserved quantity and no conservation law is supplied, which is the characteristic defect of the genre [Mirowski, 1989]. The paper claims validity only within a specified arrangement [Cartwright, 1999] and claims no universality.

L-25. Ergodicity is assumed and not argued. Q accumulates over time for one relation from parameters that would naturally be estimated across relations; the time and ensemble averages of a multiplicative process are not the same [Peters, 2019], and this paper does not establish that they coincide here.

A discrepancy found in the source and left standing. The source reports the carried dyad's deficit as $D = +4.338420$ octaves from a reported $u = 0.068735$. Recomputing D from the *rounded* u gives $+4.338414$; recomputing from the underlying state vectors gives $+4.338420197$, which is the figure the source quotes. **The two disagree in the sixth decimal place because the printed u is rounded, not because either is wrong**, and this paper quotes the vector-derived value throughout. It is recorded here because a reader recomputing from the printed intermediate will find the discrepancy and should know its cause.

11 Conclusion

What is established. Given the storage law and the surplus functional, the sign of the steady state is equivalent to a threshold comparison, and in logarithmic units that comparison has an exact linear form with the constant $2/\ln 2 = 2.885390081777927$. The octave deficit and the steady state are algebraically the same quantity, verified to floating-point round-off. The deficit is independent of the decay rate, so an intervention acting only on decay changes the deficit by exactly zero and multiplies the existing sign of the steady state — worsening a failing relation. The ceiling $c/\eta \leq \ln N$ classifies a case as tunable or structural before any prescription is issued. **A count admits only the identity transformation, so squaring it is a licensed operation in a way that squaring a rating is not**, and monotone rescalings of ordinal intensities move a derived frequency by 1065.05 cents, which settles that the intensities cannot be ordinal. All of this is arithmetic on stated definitions and none of it depends on the value of k.

What is proposed. That a dimensionless ratio of a tuning interval to the square of the golden section is a frequency; that the essence of an n-component state is kn^2; and that octave equivalence may be carried from pitch to a quantity that is not a pitch. **These three are postulates of this framework with no external support**, they are labelled as such at every appearance, and they are separable from everything in the preceding paragraph. A reader who rejects all three keeps the sustainability criterion, the trichotomy, the identity, the negative result and the ceiling, expressed in nats instead of octaves. **That separability is the strongest claim this paper makes about its own foundations.**

What is not claimed at all. No person, bond, tissue, molecule, room or institution is claimed to resonate at any frequency named here. The twelve states are not diagnoses and no reading in this paper is clinical, diagnostic, therapeutic or prognostic.

12 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number in the paper is the output of exact arithmetic on parameters stated in the text; every case is constructed and is labelled as constructed at the point of use. The figures are generated by the Python scripts named in their captions, which take their inputs from the tables in the text and are available from the author on request. **No empirical measurement of any human being, any relation or any institution underlies any figure, table or number in this paper.** A frequency law reads as though something were measured; nothing was.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The constructed subject and the constructed dyad are invented parameter sets and are not derived from, and do not describe, any person. This paper asserts several perceptual claims — that magnitude estimation delivers ratio-scale intensities, that octave equivalence is a usable structure, and that interval arithmetic in cents is the correct apparatus — **without any perceptual experiment behind them.** Those claims rest entirely on the cited literature, they

are limited by that literature's own boundaries (§8.3), and they are listed among this paper's limitations (L-4, L-6, L-11).

Clinical disclaimer. The twelve state classes are not diagnostic categories. Nothing in this paper is an assessment, a screening instrument, a treatment or advice about any person's health, and nothing in it may be presented as such.

Chapter 42

Octave Folding and the Odd-Part Class Rule: The Frequency of a Mood, of a Trait, and the Self as a Chord

Abstract. Applying the essence law $f(n) = kn^2$ to a component count generates a pitch lattice whose structure we characterise exactly, with $k = (9/8)^2/\varphi^2 = 0.483425732988414$ a *defined* constant, exact by construction, whose interpretation as a frequency is postulated and not derived. Two indices fold to the same pitch class if and only if they share the same odd part, so an N-long ladder admits exactly $\lceil N/2 \rceil$ classes: six at $N = 12$, namely $\{1, 3, 5, 7, 9, 11\}$, and class-preserving intervals are necessarily *even* whole octaves. This partitions transitions into intensification, which preserves class, and transformation, which does not; only 10 of 66 unordered pairs (15.1515 per cent) are class-preserving, and index distance does not determine which kind a move is. The tightest folded separation at $N = 12$ is $50/49 = 34.9756$ cents, attained by the single pair $7{:}10$, and $N = 12$ sits below the first collision cliff at $N = 17$ ($289/288 = 6.0008$ cents). The law contains no time term, so a mood and a trait at $n = 9$ return the identical 39.1575 Hz, 313.260 Hz folded, class 9, and are distinguished only by δ, whose half-lives differ by a factor of 17.65 (1.9434 against 34.3096 cycles); the naive $1/\delta$ overstates the half-life by 71.52 per cent at $\delta = 0.30$. At internal scope the chord width $F_{\text{int}} = \ln(1 + (N-1)u_{\text{int}})$ is degenerate under one-hot encoding: distinct one-hot framings are orthogonal by construction and score the ceiling $\ln 12 = 2.484907$ for every subject regardless of content.

Keywords: octave folding; odd part; pitch class; intensification; storage half-life; trait window; chord width; one-hot degeneracy

Series: C. Frequency, Essence, and Mind **Paper:** CCP-042

1 Introduction

A framework that assigns a psychological state a position on a logarithmic scale acquires, whether or not it intends to, an arithmetic of *relations* between states. This paper characterises that arithmetic exactly for the corpus's essence law $f(n) = kn^2$ applied to a component count n, and reports three structural results and one negative one.

The structural results are about the lattice. Squaring an integer index and folding by octaves makes the pitch class of a state depend on **the odd part of its index alone**, so two states share a class if and only if they share an odd part, and an index of length N realises exactly $\lceil N/2 \rceil$ classes — six at $N = 12$. That partitions transitions into two kinds: *intensification*, which

preserves the class and moves a whole and necessarily **even** number of octaves, and *transformation*, which does neither. Only 10 of the 66 unordered pairs at $N = 12$ (15.1515 per cent) are class-preserving, and the partition is read off the indices before anyone has decided what the states mean. The tightest folded separation at $N = 12$ is $50/49 = 34.9756$ cents, attained by the single pair 7:10, and $N = 12$ sits below a collision cliff at $N = 17$ where the minimum collapses to $289/288 = 6.0008$ cents.

The negative result is about time, and it is the one this paper most wants read. The essence law has no time argument. **A mood and a standing disposition at the same index are therefore the same tone** — the same raw frequency, the same transposition, the same folded value, the same pitch class — and nothing in the frequency register distinguishes them. What distinguishes them is the decay rate δ of the corpus's storage law [Curzi, 2026], whose Result Two is the identity $D = 2.885390(c/\eta - F) = -2.885390(\delta/\eta)Q_\infty$ linking the two registers. At $n = 9$ both readings give 39.1575 Hz, 313.260 Hz folded, class 9, and their half-lives differ by a factor of 17.65.

A second negative result concerns the encoding. Extending the surplus functional inside one observer gives a *chord width* $F_{\text{int}} = \ln(1+(N-1)u_{\text{int}})$, and the natural tidy encoding — one state per framing — makes every pair of framings orthogonal by construction. Every subject then scores the ceiling $\ln 12 = 2.484907$ regardless of content. **An instrument whose failure mode is to award everyone full marks will be adopted enthusiastically and never questioned**, so the degeneracy is set out in the body rather than the failure modes, and the degenerate calculation is shown before the correct one.

What this paper does not claim, stated at the front. The constant $k = (9/8)^2/\varphi^2 = 0.483425732988414$ is a **defined** number, exact by construction; its two components are documented — the Pythagorean whole tone [Barbour, 1951] and Euclid's extreme and mean ratio [Euclid, 1956] — but **their product expressed as a frequency in hertz has no precedent in any literature we have found**, and the standard deflationary treatment of golden-section claims [Markowsky, 1992] is cited here deliberately and again wherever φ appears. The essence law is a postulate and **its exponent is defined by the model, not estimated from data**. Octave equivalence is grounded for pitch [Shepard, 1982] and its extension to a quantity that is not a pitch is a modelling choice with no external warrant. Section 11 decomposes each of these into steps a reader can check; Section 12 prints every check this paper fails.

Contributions

1. The odd-part class rule, proved in both directions, with the corollary that an index $1 \dots N$ realises exactly $\lceil N/2 \rceil$ pitch classes — verified for every N from 1 to 25.
2. The corollary that class-preserving intervals are **even** whole octaves, so the smallest one is exactly 2400 cents.
3. The intensification/transformation dichotomy, verified exhaustively over all 66 pairs at $N = 12$, with the finding that index distance does not determine which kind a move is.
4. The regime statement: $50/49 = 34.9756$ cents at $N = 12$, the cliff at $N = 17$ ($289/288 = 6.0008$ cents) and the second at $N = 41$ ($1682/1681 = 1.0296$ cents), all exact rational coincidences.
5. The theorem that the frequency law cannot distinguish a disposition from an episode, with the storage half-life $t_{1/2} = \ln 2/(-\ln(1-\delta))$ supplied as the quantity that can — and the measured gap between it and the naive $1/\delta$.
6. The one-hot degeneracy theorem and the overlap condition it forces, with a worked demonstration that four unrelated constructed subjects produce the identical ceiling reading.
7. A drop-one audit in which two of three removals *raise* the chord width, establishing that mean pairwise non-parallelism does not determine the joint geometry.

2 Hypotheses, definitions, and postulates

Series C carries the corpus's least-supported material, so the labelling is done first and in full. **A hypothesis nothing could falsify is not a hypothesis**, and this section does not manufacture one.

2.1 Hypotheses proper

H1 — the mood/trait separation hypothesis. Moment-to-moment affective states and standing dispositions are empirically distinguishable, and the distinguishing quantity is a retention rate rather than any property of the state's specification. **Predicted:** two states assigned the same component count by the declared decomposition, one reported as transient and one as standing, differ in measured δ and in nothing else the essence law can see. **Falsified by:** a measured difference in the component count that tracks transience, which would make the frequency register informative about persistence after all. **Status:** the *formal* half — that $f(n) = kn^2$ contains no time argument — is DERIVED and is Theorem 6.1. The *empirical* half is **not tested here.** No observational data were collected for this paper.

H2 — the count-reproducibility hypothesis. The component count n assigned to a described state under the declared decomposition rules is a property of the state and not of the analyst. **Predicted:** independent analysts applying the published rules to the same descriptions agree on n, and the residual disagreement carries no analyst main effect. **Falsified by:** a systematic analyst effect on n, or agreement on the derived pitch class no better than the ladder's marginal distribution. **Status: not run.** It is reported as not run in Section 7.11, in Section 12, and here. The whole apparatus of this paper is conditional on it.

H3 — the overlap hypothesis. Two framings of one situation, elicited from one observer, share components; two descriptions with no component in common are descriptions of different situations. **Predicted:** framings elicited about a single declared situation have non-empty shared support at a rate far above what independent assignment of components would produce. **Falsified by:** elicited framings of one situation that are routinely disjoint, which would make the overlap gate of Section 7.5 unsatisfiable in practice and the internal surplus uncomputable. **Status: not tested here.** The overlap condition is imposed as a validity requirement, not demonstrated as an empirical regularity.

H4 — the decay-identifiability hypothesis. A retention rate is recoverable from observation only over a no-input interval spanning at least three expected half-lives. **Predicted:** estimates of δ from shorter windows are indistinguishable from a linear decline and carry no information about the rate. **Status:** DERIVED from the geometry of $(1-\delta)^t$; **not tested against observation.** Its practical consequence — that a trait-grade $\delta = 0.02$ requires roughly 103 cycles of observation — is computed in Section 6.13 and is the binding constraint on the whole method.

2.2 Definitions — true by stipulation, not falsifiable

- **Def. 1.** n := the number of distinguishable components required to specify a state; $N = 12$ is the declared category count.
- **Def. 2.** The *odd part* of n is the unique odd m with $n = 2^a m$, $a \geq 0$.
- **Def. 3.** The *pitch class* of a state is the equivalence class of $f(n)$ under multiplication by integer powers of two.
- **Def. 4.** $k := (9/8)^2/\varphi^2$. **This is a defined constant.** It is an exact ratio of exact quantities and is therefore computable to arbitrary precision; the fifteen significant figures quoted

throughout, 0.483425732988414, are *exact digits of a definition* and carry no measurement uncertainty because there is no measurement.

- **Def. 5.** A *trait* is a state held at low retention loss δ; a *mood* is the same state held at high δ. "Low" is fixed by a declared observation window in Section 6.6 and is a convention, not a discovery.
- **Def. 6.** A *chord* is the set of indices carrying nonzero intensity across the framings an observer holds at one moment; its *width* is $f = k\, e^{2F_{\text{int}}}$.

2.3 Postulates — asserted by this framework, with no external support

- **P-a. The essence law $f(n) = kn^2$.** A quadratic relation between a dimensionless count and a frequency. **No external literature supports it.** It is not derived here and nothing in the bibliography derives it. **The exponent 2 is defined by the model, not estimated from data.** No scaling exponent in this paper was obtained by fitting; none was tested against a log-normal or exponential alternative; and the goodness-of-fit and likelihood-ratio procedure a claimed scaling relation requires [Clauset et al., 2009] was **not run, because there is no data to run it on.**
- **P-b. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic. **Asserting that this dimensionless number *is a frequency* is a separate and much stronger claim**, and the source supplies no operational procedure by which the constant acquires the dimension of inverse time. This is postulated, and Section 3.4 states it again in the dimensional audit.
- **P-c. The affine effective count $N_{\text{eff}} = 1 + (N-1)u$.** A design axiom [Curzi, 2026], not a derived result and **not a Hill number of any order.** The Hill family [Hill, 1973, Jost, 2006] and its independent rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly — as the corpus's concentration work uses them [Curzi, 2026] — and ground this construction not at all.
- **P-d. The framing encoding.** That a way of construing a situation admits representation as a unit vector over twelve state categories, such that framings making the same predictions map to parallel vectors. **This is asserted, not established.**
- **P-e. The internal roster reduction.** That the mean pairwise non-parallelism over an observer's own framings may be read as an audited framing count through $N_{\text{eff}} = 1 + (N-1)u$. **Asserted; and Section 7.8 shows what it fails to determine.**

2.4 Modelling choices — legitimate, but choices

- **M-a. Octave reduction applied to a non-acoustic quantity.** Octave equivalence is a perceptual structure formalised for **pitch** [Shepard, 1982], and the octave's perceptual specialness has a measured and finite size [Demany et al., 2013]. Nothing licenses carrying it to a quantity that is not a pitch. **The *operation* — division by a power of two — is well defined; its *interpretation* is a choice of this framework**, and every folding result in this paper is an arithmetic result about the operation and not a perceptual claim.
- **M-b. The band 220–440 Hz.** One octave, closed below and open above, so the transposition exponent j is unique for every f. **The band is arbitrary and stated. The operation is not arbitrary**, and Section 4.2 shows that no choice of band can create or remove a class collision.
- **M-c. $N = 12$.** Twelve exceeds the classical span of immediate absolute judgment [Miller, 1956], which is a reason for caution and not a reason for twelve. The ladder is owned by the criterion paper [Curzi, 2026], whose Result Six is the count-based essence index with its twelve-state ladder.
- **M-d. The trait window W.** The cut between "mood" and "trait" is a declared convention on the half-life. **There is no δ at which something switches from being an episode to being a disposition**; there is a continuous rate and a cut somebody chose.

- **M-e. Interval apparatus.** Cents, octave equivalence and interval arithmetic are the correct apparatus once an index exists [Rossing et al., 2002, Benson, 2006], but what a listener finds consonant depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005], and interval categories generalise less far across listeners than is usually assumed [Burns, 1999, Hoeschele et al., 2012]. **This paper uses the arithmetic and claims none of the perception.**

2.5 What is expository

Sections 5.6, 6.13, 7.10 and 7.11 are procedural: they set out reporting requirements, gates and failure modes rather than argue a claim. Their organising question is *what must be published alongside a reading for the reading to be checkable by a third party*.

3 Framework, dimensional audit, and method

3.1 The three laws this paper composes

```
THE ESSENCE LAW    f(n) = k n^2                      an index has a pitch
THE SURPLUS LAW    F(u) = ln(1 + (N−1)u)             a pair of states has a surplus
THE STORAGE LAW    Q_{t+1} = (1−delta)Q_t + eta S − C   surplus becomes structure, and leaks
```

The first is a postulate of this framework (P-a). The second is a theorem given four axioms, of which the third — that the effective count is affine in the non-parallelism — is a design choice [Curzi, 2026], whose counter-result is that the surplus is bounded twice over: it is only a lower bound on the ensemble's information, and its logarithmic concavity means three well-separated views capture most of what a large panel could. **That bound governs every width computed in Section 7.** The third is a first-order linear difference equation whose form is shared with the RC low-pass filter [Oppenheim et al., 1996, Horowitz and Hill, 2015], with exponential smoothing [Holt, 1957], and with the leaky integrate-and-fire neuron [Lapicque, 1907, Gerstner and Kistler, 2002]; its fixed point and stability condition are standard [Elaydi, 2005] and the convergence is Banach's [Banach, 1922]. **The corpus states that theorem exactly and then refuses the certificate it appears to offer** [Curzi, 2026], on the ground that a human life is not a metric space and nobody has measured the relevant contraction modulus, so the theorem transfers as shape rather than guarantee. **That refusal binds every half-life in Section 6.**

Analogy status: category 2, a shared mathematical form. The storage law is used because the mathematics is the same, not because the physics transfers. No claim is made that stored order is a charge or that any physical result about RC circuits applies to a person. **And Q has the grammar of a conserved quantity without a conservation law to give that grammar content**, which is the characteristic defect of the genre [Mirowski, 1989]; validity is claimed only within a specified arrangement [Cartwright, 1999].

3.2 The warrant the logarithm needs

The corpus habitually justifies its logarithms by appeal to Fechner [Fechner, 1860, Weber, 1834]. A stronger and cheaper warrant is available: a logarithmic form follows from multiplicative dynamics with **no psychological assumption at all** [Peters and Gell-Mann, 2016]. The arguments of this paper need only the second. **The functional form is nonetheless underdetermined by the evidence**: a power law with exponent below one [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. **Nothing in this paper discriminates among them.**

3.3 The constant k

$$k := \frac{(9/8)^2}{\varphi^2} = \frac{81/64}{\varphi + 1} = 0.483425732988414 \quad \text{(defined; exact)}$$

Computed: $\varphi = 1.618033988749895$, $\varphi^2 = \varphi + 1 = 2.618033988749895$, $(9/8)^2 = 1.265625$, and the two forms agree to every digit. Both components are real and documented — the Pythagorean whole tone and ditone [Barbour, 1951, Lindley and Turner-Smith, 1993] and Euclid's extreme and mean ratio [Euclid, 1956], with $\varphi^2 = \varphi + 1$ a proved identity [Vajda, 1989, Koshy, 2001].

Their product, expressed as a frequency in hertz, has no precedent. The literature on golden-section claims is overwhelmingly one of *deflation*: the appearances of φ in the Parthenon, the Great Pyramid, the human body and preferred rectangles do not survive examination [Markowsky, 1992, Fischler, 1981, Livio, 2002], and the psychological preference results are weaker and more equivocal than usually reported [Höge, 1997]. **This framework's position is the one those critiques leave open and no wider: φ is being *chosen* as a constant, not *found* in a psychological system.** And the cost of the choice is small in a precise sense: k **cancels from every interval in this paper**, because every interval is a ratio $f(m)/f(n) = m^2/n^2$.

3.4 Dimensional audit

symbol	quantity	dimension	unit	status
n, N	component count, category count	$[1]$	—	absolute scale, a count
m	odd part of n	$[1]$	—	absolute scale, a count
k	reference constant	$[T^{-1}]$ **asserted**	Hz **asserted**	**defined as a ratio (dimensionless); the unit is postulated**
f	essence frequency	$[T^{-1}]$	Hz	inherits its dimension entirely from k
j	transposition exponent	$[1]$	—	an integer
u	non-parallelism	$[1]$	—	dimensionless by construction, $u \in [0, 1]$
F_{int}	internal surplus	$[1]$	nats	dimensionless; a logarithm of a count
interval	pitch interval	$[1]$	cents, octaves	a ratio of logarithms; k cancels
Q	stored order	$[\mathcal{C}]$	none supplied	state variable; **no operational unit**
δ	retention loss	$[1]$	per declared cycle	dimensionless; $0 < \delta \leq 1$
$t_{1/2}$	storage half-life	$[T]$	declared cycles	derived from δ
η, c	conversion, cost	$[1]$, $[\mathcal{C}T^{-1}]$	per declared period	see below

Does the equation balance? The essence law $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, because n is a dimensionless count. **The source supplies no operational procedure by which k acquires that dimension**; it is computed as a ratio of two dimensionless quantities and the hertz is attached by assertion. **This is the largest dimensional exposure in the paper and it is listed in Section 12 by name.** Every *interval* is dimensionless and free of k, which is why Sections 4 and 5 are secure in a way Section 4.5's absolute values are not.

Two further audit results. δ is dimensionless but $t_{1/2}$ **is a time and therefore has no meaning without a declared cycle**; Section 6.5 makes the rescaling exact and shows that a δ quoted without its cycle is not a number. And the ratio c/η, which appears in the threshold this paper cites from the join [Curzi, 2026], is $[\mathcal{C}T^{-1}]$ divided by a pure number and is **not dimensionless as written**; the framework's convention is that c is expressed in nats of surplus per declared period, **a convention the source never states**, and every reading that uses the threshold depends on it.

3.5 Scale type, and what licenses the arithmetic

quantity	scale type claimed	what licenses it
n, N, odd part	absolute	cardinality: true zero, fixed unit, identity transformation group only
u	ratio	constructed from an inner product of unit vectors; zero is parallel
elicited intensities	ratio, up to a free common multiplier	**magnitude estimation, assumed** [Stevens, 1957]; not tested here
δ	ratio, **assumed**	no validated instrument is supplied; Section 6.13 says so
f, folded f	ratio in hertz, **inherited**	inherits the status of n and of the postulated bridge
intervals, $t_{1/2}$	ratio	ratios of exact quantities given the inputs

Stevens' typology makes the permissible arithmetic on a quantity a function of the transformation group that leaves its empirical content unchanged [Stevens, 1946]. **A count admits only the identity transformation, which is what licenses squaring it.** That argument covers n and covers nothing else in this paper.

The strongest available objection to this framework is Michell's: that psychology routinely assumes its attributes are quantitative without testing whether they are [Michell, 1997, 1999]. The remedy exists — conjoint measurement supplies a testable condition for additive quantitative structure [Luce and Tukey, 1964, Krantz et al., 1971] and a Rasch model supplies specific objectivity [Rasch, 1960, Andrich, 1988] — **and neither has been run for any quantity in this paper.** The elicited intensities matter here more than anywhere else in the corpus, because ordinal-preserving transformations of them move u from 0.362115 to 0.525275 on the carried Subject's closest pair, a spread of 1065.05 cents [Curzi, 2026], whose Result Seven records exactly that failure of invariance.

3.6 Identification, and the reflexive exposure

The framework's founding construction is a reflexive loop in which the group influences the member and the members constitute the group. **That is a linear-in-means reflexive specification, and its endogenous social effect is not identified from observational data** [Manski, 1993];

influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. **No amount of fit recovers the parameter.** The remedy this paper adopts is stipulation — the category set and the decomposition rules are declared in advance and published with every reading, which is what makes a discrete-choice treatment of social interaction defensible [Brock and Durlauf, 2001] — and **the claim is accordingly a modelling position, not an identified empirical result.**

The same objection applies to the framework's own parameters. If subjects change when modelled, δ and u are not structural [Lucas, 1976, Hacking, 1995]. **The framework asserts reflexivity for its subject matter and cannot consistently exempt its own parameters from it.** This is stated, not resolved.

3.7 Method

Every number in this paper is the output of exact arithmetic on stated parameters, computed in double precision, with the pitch-class and interval results computed in exact rational arithmetic where the text says so. **No observational data were collected, no human subjects participated, and no empirical dataset underlies any figure or table.** Every case is constructed and is labelled as constructed at the point of use. The figures are produced by the scripts named in their captions.

4 Octave folding and the odd-part class rule

4.1 The law, and the index it is applied to

$$f(n) = k\,n^2, \qquad k = 0.483425732988414 \quad \text{(defined; exact)}$$

with n the number of distinguishable components required to specify a state. **This paper neither redefines a state, renames one, nor adds one**; the ladder is fixed elsewhere in the series [Curzi, 2026] and is computed on here. It carries forward the honest limit that attaches to every use of the index:

> **The frequency inherits exactly the defensibility of the count. A contested decomposition yields a contested frequency.**

That sentence appears here because this section publishes a table of frequencies next to a table of psychological descriptions, **and that adjacency is exactly where drift happens.**

4.2 Octave folding

The raw essence frequencies of a twelve-state ladder run from 0.4834 Hz to 69.6133 Hz. The house method is octave transposition and only octave transposition, $f_{\text{audible}} = f \cdot 2^j$ with j an integer, into a standing band of 220–440 Hz stated with every value.

Multiplication by 2^j is exact in the sense that matters: it moves a frequency by a whole number of octaves and therefore preserves pitch class exactly. No rounding, no approximation, no tempering. **Folding is a change of register and never a change of relationship.** Two consequences follow immediately and are used throughout:

- **Folding cannot create a collision.** If two states fold to the same value, they were already at the same pitch class.
- **Folding cannot remove one.** If two states share a class, no choice of band separates them.

The second is a defence against a specific abuse — choosing the band after seeing the states, to make two of them collide or to pull them apart. **It does not work, and the fact that it does not work is a strength of the method.**

4.3 The odd-part theorem

THEOREM 4.1 (the odd-part class rule). Write $n = 2^a m$ with $a \geq 0$ and m odd. Then the pitch class of $f(n) = kn^2$ is determined entirely by m, and two indices share a pitch class if and only if they share an odd part.

Proof. $f(n) = k(2^a m)^2 = 2^{2a}\, k\, m^2 = 2^{2a} f(m)$, and 2^{2a} is a power of two, so $f(n)$ is exactly $2a$ octaves above $f(m)$; octave displacement is precisely the equivalence that defines pitch class, so $\text{class}(n) = \text{class}(m)$. Conversely, suppose $f(n_1)/f(n_2) = 2^j$, so $(n_1/n_2)^2 = 2^j$. Writing $n_i = 2^{a_i} m_i$ with m_i odd gives $(m_1/m_2)^2 = 2^{j-2a_1+2a_2}$. **The left side is a ratio of odd squares in lowest terms, hence odd over odd; the right side is a power of two; and the only odd power of two is** $2^0 = 1$. Therefore $m_1 = m_2$. **QED.**

COROLLARY 4.2 (no odd octaves). In the exponent equation above $j = 2(a_1 - a_2)$ is **even**. Two states of the same class are separated by an *even* number of octaves — never one, never three, never five. **The smallest class-preserving interval in the system is exactly two octaves, 2400 cents.**

COROLLARY 4.3 (the class-count ceiling). An index set $1 \ldots N$ realises exactly $\lceil N/2 \rceil$ pitch classes.

Proof. By Theorem 4.1 the classes are in bijection with the odd parts realised by $1 \ldots N$. Every odd $m \leq N$ is realised, by $n = m$ itself; no odd $m > N$ is realised, since $n = 2^a m \geq m > N$. The class set is therefore the odd numbers in $1 \ldots N$, of which there are $\lceil N/2 \rceil$. **QED.**

Verified computationally for every N from 1 to 25, the range a single integer transposition admits inside the audible band:

```
   N :  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25
 cls :  1  1  2  2  3  3  4  4  5  5  6  6  7  7  8  8  9  9 10 10 11 11 12 12 13
ceil :  1  1  2  2  3  3  4  4  5  5  6  6  7  7  8  8  9  9 10 10 11 11 12 12 13
   all match: True
```

Twelve states yield six pitch classes. That is a hard structural limit and not a stylistic choice. It is **not** a claim that there are six feelings, six kinds of feeling, or six anything psychological; it is a claim about how many distinct pitch classes an index of twelve can generate under a square law. The same folding result is owned in Series B [Curzi, 2026k], whose Result Five states it for a set of twenty indices, and the entropy cost of the fold is computed in the closing synthesis [Curzi, 2026], whose Result Two prices pitch-class folding at exactly $\ln 2 = 0.6931471806$ nats — one bit, two octaves — for every even N.

4.4 The twelve-state spectrum, computed

n	state class	$f = kn^2$ (Hz)	j	folded (220–440)	odd part	pitch class	cents above 220
1	undifferentiated activation	0.4834	9	247.514	1	1	204.008
2	valenced activation	1.9337	7	247.514	1	1	204.008
3	directed feeling	4.3508	6	278.453	3	3	407.918
4	situated feeling	7.7348	5	247.514	1	1	204.008
5	attributed feeling	12.0856	5	386.741	5	5	976.635
6	temporal feeling	17.4033	4	278.453	3	3	407.918
7	reflexive feeling	23.6879	4	379.006	7	7	941.660
8	social feeling	30.9392	3	247.514	1	1	204.008
9	normative feeling	39.1575	3	313.260	9	9	611.828
10	narrative feeling	48.3426	3	386.741	5	5	976.635
11	reciprocal feeling	58.4945	2	233.978	11	11	106.644
12	committed feeling	69.6133	2	278.453	3	3	407.918

```
distinct classes = {1, 3, 5, 7, 9, 11}   count 6 = ceil(12/2)      [verified]
max f = k * 144  = 69.61330555033166 Hz
ln N  = ln 12    = 2.4849066497880004
2/ln 2           = 2.8853900817779268
```

The maximum does double duty. $kN^2 = 69.6133$ **Hz is simultaneously the pitch of the most differentiated state on the ladder and the ceiling on the sustaining frequency** — the highest minimum a twelve-category system can ever meet [Curzi, 2026], whose Result Three records that the category count enters the threshold only through $c/\eta \leq \ln N$.

The affect literature does not underwrite the rungs of this ladder, and the objection belongs in the body. The named precedents establish that each component is a real, independently described feature of emotional states; they do not establish an index, an ordering, or a nesting. Appraisal dimensions **vary simultaneously and independently, and emotions differ by the pattern across them** [Smith and Ellsworth, 1985] — a count discards exactly that pattern, and **cannot separate anger from guilt.** Emotion is described as a **process in time** whose state is the synchronisation of several subsystems [Scherer, 2001], which resists reduction to a scalar of any kind. Individuation by **core relational theme** is qualitative [Lazarus, 1991]: a theory in which two emotions differ by *what* is appraised does not license one in which they differ by *how many* things are appraised. The circumplex is **two continuous bipolar axes** recovered from ratings [Russell, 1980], and its "two" is two dimensions rather than two countable components. **And the top rung is contradicted specifically**: action readiness is held to be constitutive of emotion as such rather than a late addition [Frijda, 1986], so if that is right the component sits at the floor and the ladder's ordering fails at its summit. Two rungs survive in the form the framework needs — a claim that a *class* of states requires a component others lack [Tracy and Robins, 2004], and the modelled-other construct [Premack and Woodruff, 1978]. **This paper therefore cites the affect literature for the *existence* of a component and never for the index, its ordering, or its nesting**, and narrows the top rung to *bound commitment* rather than *readiness*, which is the only version that literature leaves standing.

That objection and Michell's are the same objection in two domains. One says a psychological attribute is treated as quantitative without a test for quantitative structure; the other says an emotional state is reduced to a scalar when its own literature describes it as a pattern or a process. **Both are instances of one habit — scalar reduction — and this corpus should say so once rather than meet each as a surprise.** Section 12 concedes both.

4.5 The regime: minimum separation at $N = 12$

The folded class lattice for $N = 12$, sorted by folded pitch, with the interval to the next class above (the last row wraps to the octave):

class	folded (Hz)	to next	cents	Hz gap
11	233.978	$\to$ 1	97.3641	13.5359
1	247.514	$\to$ 3	203.9100	30.9392
3	278.453	$\to$ 9	203.9100	34.8067
9	313.260	$\to$ 7	329.8318	65.7459
7	379.006	$\to$ 5	**34.9756**	**7.7348**
5	386.741	$\to$ 11 (octave)	330.0085	81.2155

The tightest pair is class 7 against class 5, and their ratio is exact: $f(5)/f(7)$ folded $= (2 \cdot 5^2)/7^2 = 50/49$, which is $1200 \log_2(50/49) = 34.975614791419815$ cents. Sweeping N and taking the minimum adjacent separation over the whole folded lattice:

N	min separation (cents)	between classes	ratio
3–6	203.9100	1 and 3	9/8
7–16	34.9756	7 and 5	50/49
12	**34.9756**	**7 and 5**	**50/49**
17–40	6.0008	3 and 17	289/288

N	min separation (cents)	between classes	ratio
≥ 41	1.0296	41 and 29	1682/1681

```
1200 * log2(289/288)   = 6.0008172700399145 cents
1200 * log2(1682/1681) = 1.0295772227721520 cents
```

The cliff at 17 is $17^2 = 289$ **colliding with** $2 \cdot 12^2 = 288$, i.e. class 17 arriving a sixth of a comma from class 3. The second at 41 is $41^2 = 1681$ against $2^4 \cdot 105 = 1680$, reached through class 29. **Both are exact rational coincidences, not approximations.**

$N = 12$ sits below the first cliff, so every folded distinction this framework asks an instrument to make is at least 34.9756 cents wide — roughly a third of a semitone.

One rendering consequence, and it is a bound on the signal and not a statement about hearing. The tightest folded gap in absolute frequency is $386.740586 - 379.005775 = 7.734812$ Hz, and the time–frequency bound $\Delta t \, \Delta f \geq 1/(4\pi)$ [Gabor, 1946] therefore gives $\Delta t \geq 1/(4\pi \cdot 7.734812) = 0.0102882$ s $= 10.2882$ ms as the formal lower bound on the duration of a tone carrying that distinction; at the widest gap in the lattice it is 0.9798 ms. That bound is owned by the conjugate paper [Curzi, 2026z], whose Result One proves $\Delta t \, \Delta f \geq 1/(4\pi) = 0.079577471545948$ by the same variational argument as $\sigma_x \sigma_p \geq \hbar/2$ with $p = \hbar\kappa$ deleted. **Human discrimination needs far longer tones than 10 ms and this paper never confuses the two.**

5 Intensification and transformation

5.1 The dichotomy

A transition from state m to state n has interval $1200 \log_2(f(n)/f(m)) = 2400 \log_2(n/m)$ cents. **Every such interval is a ratio of squares and** k **cancels from it entirely** [Curzi, 2026k].

THEOREM 5.1 (the intensification/transformation dichotomy). A transition $m \to n$ falls into exactly one of two classes:

```
(I)  INTENSIFICATION   m and n share an odd part
                       the interval is an exact WHOLE number of octaves
                       and that number is EVEN (Corollary 4.2)
                       the pitch changes; the pitch CLASS does not

(T)  TRANSFORMATION    m and n have different odd parts
                       the interval is NEVER a whole number of octaves
                       the pitch changes AND the pitch class changes
```

Proof. The interval is a whole number of octaves iff $(n/m)^2$ is a power of two, iff by Theorem 4.1 m and n share an odd part; Corollary 4.2 supplies the evenness. **QED.**

Verified exhaustively over all 66 unordered pairs at $N = 12$:

```
whole-octave transitions found:
  (1,2,+2)  (1,4,+4)  (1,8,+6)  (2,4,+2)  (2,8,+4)
  (3,6,+2)  (3,12,+4) (4,8,+2)  (5,10,+2) (6,12,+2)
count: 10       all octave counts even: True
same-odd-part pairs, counted independently: 10       [identical set]
```

The two counts agree because they are the same set. That agreement is the theorem, checked rather than asserted. The distinction is therefore not imposed on the psychology; **it is read off the index before anyone has decided what the states mean.**

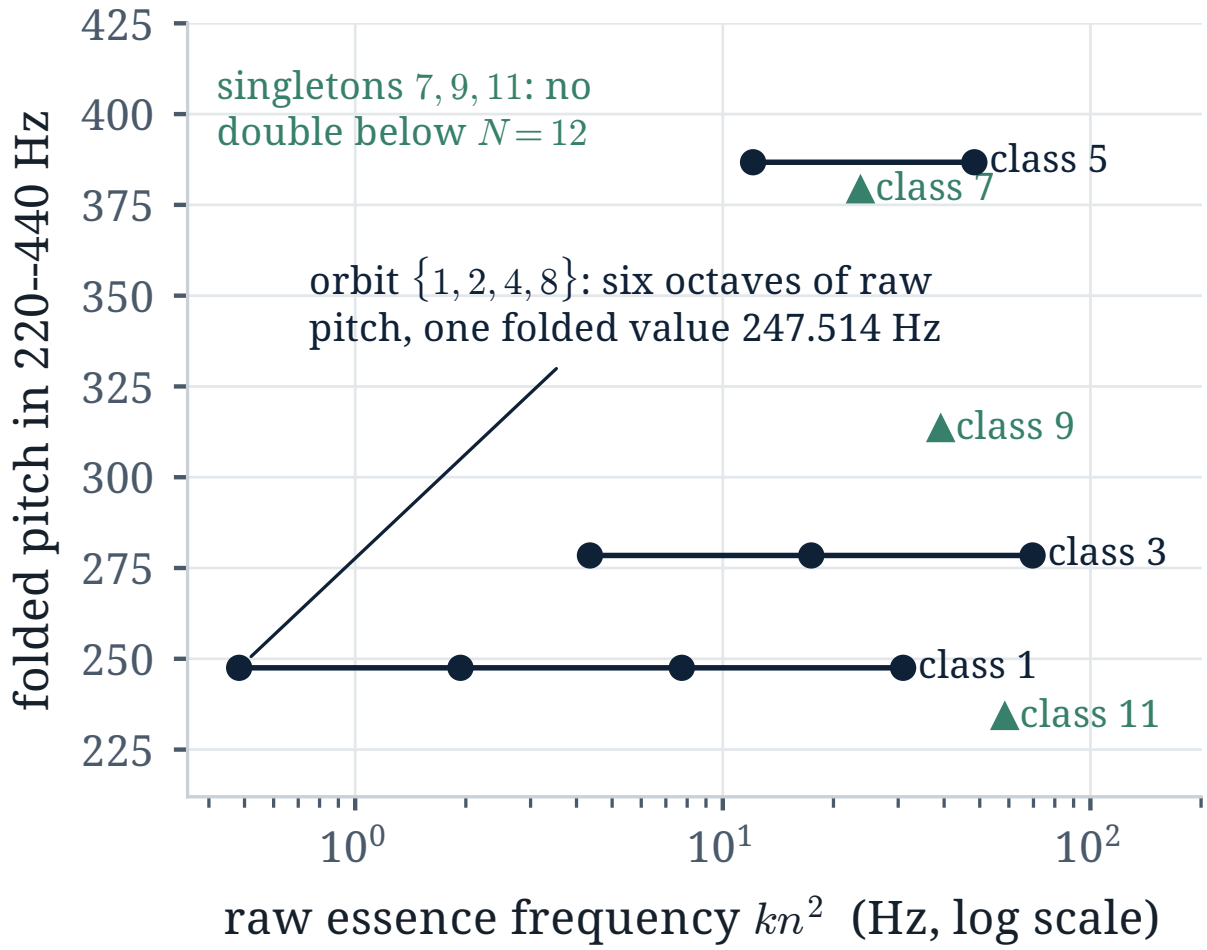

Figure 42.1: **Twelve indices collapse onto six folded values**, so an entire orbit of raw pitch spans six octaves at one folded position: indices $\{1, 2, 4, 8\}$ all fold to 247.514 Hz, $\{3, 6, 12\}$ to 278.453 Hz and $\{5, 10\}$ to 386.741 Hz, while 7, 9 and 11 are singletons because their doubles exceed $N = 12$. Modelled from $f(n) = kn^2$ with the **defined** constant $k = 0.483425732988414$, folded into the declared 220–440 Hz band. Built by `figs/src/CCP-042_fig01.py`.

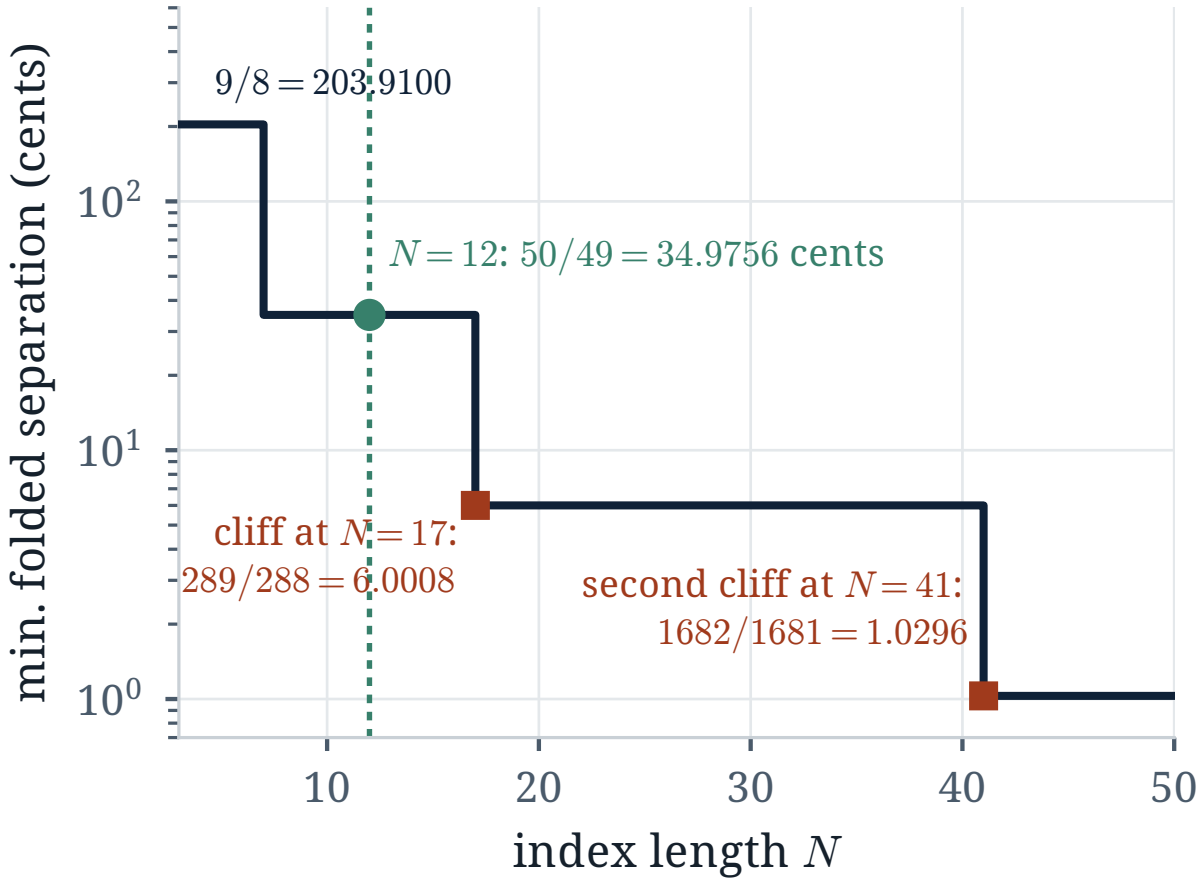

Figure 42.2: $N = 12$ **renders in the** $50/49$ **regime, three regimes above the first collision cliff**: the minimum folded separation is 34.9756 cents for $N = 7 \ldots 16$, collapses to 6.0008 cents the instant index 17 enters the set, and again to 1.0296 cents at $N = 41$. Computed in exact rational arithmetic on the folded class lattice with the **defined** constant $k = 0.483425732988414$; the ratios $9/8$, $50/49$, $289/288$ and $1682/1681$ are exact. Built by `figs/src/CCP-042_fig03.py`.

5.2 The orbit structure

Grouping the twelve indices by odd part gives six orbits under doubling:

```
class  1  ->  states { 1, 2, 4, 8 }      four degrees, spanning 7200 cents
class  3  ->  states { 3, 6, 12 }        three degrees, spanning 4800 cents
class  5  ->  states { 5, 10 }           two degrees, spanning 2400 cents
class  7  ->  states { 7 }               one degree
class  9  ->  states { 9 }               one degree
class 11  ->  states { 11 }              one degree

six orbits, twelve states, mean orbit size 2.0
```

Two structural facts follow directly:

```
states possessing a double INSIDE the ladder (2n <= 12):   1,2,3,4,5,6     (six)
states possessing none      (2n >  12):                    7,8,9,10,11,12  (six)

class-preserving unordered pairs : 10 / 66 = 15.1515 %
class-changing   unordered pairs : 56 / 66 = 84.8485 %
```

Exactly half the ladder can be intensified without leaving it. The upper half cannot — not because the upper states are final, but because $N = 12$ truncates their orbits. **That is an artefact of index length and it is honest to name it as one.**

Transformation is the generic move; intensification is the rare and highly structured one. For an index of length N the number of same-class pairs is $\sum_{m \text{ odd} \le N} \binom{s_m}{2}$ with $s_m = \lfloor \log_2(N/m) \rfloor + 1$; at $N = 12$ the orbit sizes $4, 3, 2, 1, 1, 1$ give $6 + 3 + 1 = 10$. **The orbit sizes fall off like $\log_2(N/m)$, so the supply of intensification moves grows only logarithmically while the total supply of moves grows quadratically.** Lengthen the ladder and transformation dominates ever more completely.

5.3 Constructed trajectories

All cases in this section are CONSTRUCTED and labelled as such. None is an observation of any person, and no clinical, diagnostic or therapeutic claim is made or implied.

Trajectory M1 — the same class at three degrees.

```
state  3  directed feeling      f =  4.3508 Hz  fold j=6  -> 278.453 Hz  class 3
state  6  temporal feeling      f = 17.4033 Hz  fold j=4  -> 278.453 Hz  class 3
state 12  committed feeling     f = 69.6133 Hz  fold j=2  -> 278.453 Hz  class 3

step 3 ->  6 : +2400.0000 cents = +2 octaves exactly
step 6 -> 12 : +2400.0000 cents = +2 octaves exactly
total 3 -> 12: +4800.0000 cents = +4 octaves exactly, ratio 144/9 = 16 = 2^4
```

The pitch has moved four octaves and the class has not moved at all. That is what *intensification* means here, and it is a technical term with an arithmetic definition rather than an intuition. **It does not say the experience is unchanged**; a state with a projected duration is not the same as one without. It says the two sit at the same position in the folded lattice.

Trajectory M2 — a change of class.

```
state 3  directed feeling    f =  4.3508 Hz  -> 278.453 Hz  class 3
state 5  attributed feeling  f = 12.0856 Hz  -> 386.741 Hz  class 5

interval 3 -> 5 : 2400 * log2(5/3) = 1768.7174 cents = 1.473931 octaves
frequency ratio : 25/9  -- not a power of two, and by Theorem 5.1 never could be
```

Trajectory M3 — the longest single-class walk $N = 12$ permits.

```
1 -> 2 -> 4 -> 8    every step +2400.0000 cents; total +7200.0000 = 6 octaves exactly
folded value 247.514 Hz at every rung, without exception
```

Placing a selection side by side:

move	Δn	cents	octaves	class	kind
$3 \to 6$	+3	2400.0000	+2 exactly	$3 \to 3$	intensification
$3 \to 12$	+9	4800.0000	+4 exactly	$3 \to 3$	intensification
$1 \to 8$	+7	7200.0000	+6 exactly	$1 \to 1$	intensification
$3 \to 5$	+2	1768.7174	1.473931	$3 \to 5$	transformation
$5 \to 7$	+2	1165.0244	0.970854	$5 \to 7$	transformation
$4 \to 5$	+1	772.6274	0.643856	$1 \to 5$	transformation
$11 \to 12$	+1	301.2741	0.251062	$11 \to 3$	transformation

The $+9$ move from 3 to 12 is an intensification. The $+1$ move from 11 to 12 is a transformation. Distance on the ladder is not what separates the two kinds; the odd part is. **A reader who arrived expecting "bigger jump equals more different" has to give that up, and giving it up is the point.**

5.4 What the dichotomy does and does not claim

It claims that transitions partition exactly into whole-even-octave moves and everything else; that the partition is computable from the indices alone; that the first kind preserves pitch class and the second does not; and that consequently the lattice has a formal representation of *more of the same thing* distinct from its representation of *a different thing*.

It does not claim that an intensification is smaller, easier, less consequential or less distressing than a transformation. The class-1 orbit spans six octaves, and **the formalism says nothing about how it feels to cross it.**

It does not claim that the odd part means anything on its own. Class 7 is not "the reflexive class" in any sense beyond the fact that 7 is the only index in $1 \dots 12$ with odd part 7. Change N and the singleton acquires company at index 14.

It does not claim to be a taxonomy of emotion, a stage model, or a diagnostic scheme.

And it does not survive a bad index. The dichotomy is a theorem about integers. It becomes a statement about a person only through the count, and it inherits every weakness of that count.

5.5 The scarcity of intensification, and what it costs

The $10/66$ figure constrains what the rest of the corpus can promise. **Intensification is not merely rarer; it is structurally scarce and becomes scarcer as the ladder lengthens.** The consonance paper draws the matching conclusion from the other side [Curzi, 2026], whose Result Five records the extremal four-state chords at $N = 12$: $\{1, 2, 4, 8\}$ has mean $\mathrm{HD}_{\mathrm{ess}} = 3.3333$ with six collisions and one pitch class, while 159 of the 495 four-state chords (32.1 per cent) have none. **The most consonant chords the lattice permits are precisely the most redundant ones**, and a self composed entirely of one orbit would be a single note played four times.

5.6 Procedure and reporting

```
MOOD-1 -- reading a single state
```

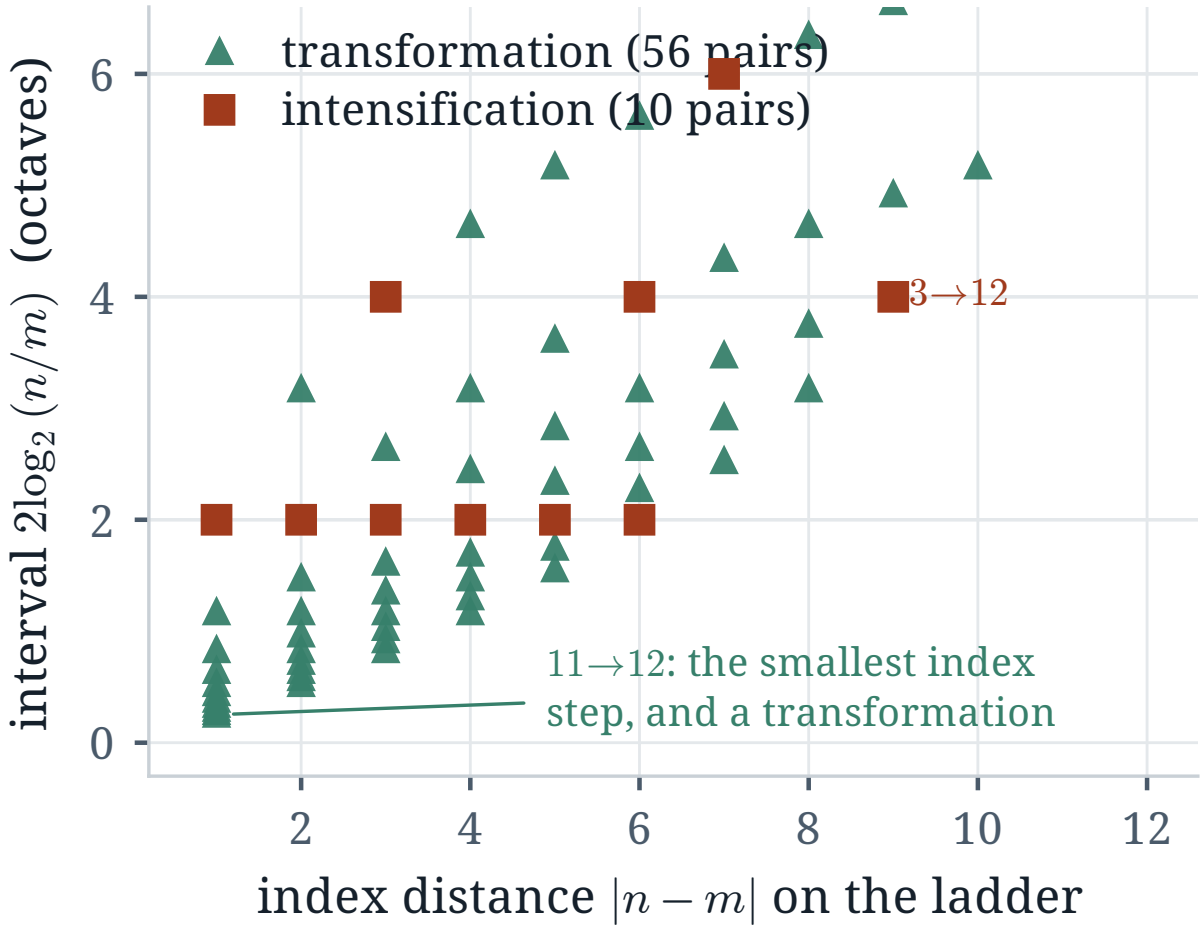

Figure 42.3: **Index distance does not determine the kind of move**: the ten class-preserving pairs land on whole even octaves regardless of how far apart their indices are, so the $+9$ step $3 \to 12$ is an intensification while the $+1$ step $11 \to 12$ is a transformation. All 66 unordered pairs of the twelve-state ladder, computed exactly from the indices; the constant k cancels from every interval and does not enter. Built by `figs/src/CCP-042_fig02.py`.

```
step 1  DECOMPOSE.  List the distinguishable components. Record the LIST, not
        just its length. The list IS the warrant.
step 2  COUNT.  n := the number of components. Check 1 <= n <= 12. If the
        decomposition yields n > 12, say so and stop. DO NOT COMPRESS TO FIT.
step 3  APPLY.  f_raw = k n^2,  k = 0.483425732988414 Hz (defined; exact).
step 4  FOLD.  Find the unique j with 220 <= f_raw * 2^j < 440. Publish BOTH
        the band and j.
step 5  CLASS.  Strip factors of two from n until odd; that is the pitch class.
step 6  BADGE.  essence frequency, not physical resonance; not a diagnosis;
        frequency inherits the defensibility of the count.

MOOD-2 -- reading a CHANGE
step 1  INTERVAL.  cents = 2400 log2(n/m);  octaves = 2 log2(n/m).
step 2  CLASSIFY.  odd_part(m) == odd_part(n) ?
            yes -> INTENSIFICATION; octaves MUST be an even integer. Verify it.
            no  -> TRANSFORMATION; octaves is never an integer (Theorem 5.1).
step 3  REPORT.  index change, interval, kind, both classes, and BOTH component
        lists. Without the component lists the reading is unauditable.
```

Step 2 of MOOD-2 is a genuine error check and costs nothing. If the odd parts match, the octave count must come out an even integer; if it does not, the arithmetic is wrong or an index was mistyped. **This is one of the few places in the framework where the formalism catches its own mistakes.**

5.7 Failure modes

F1 — editing the ladder to fit the reading. Renaming, splitting, merging, adding a thirteenth rung or reordering changes every frequency, every class, every orbit and the entire dichotomy. *Remedy:* if a case genuinely needs more than twelve rungs, **that is a finding about the case and is reported as one — never fixed by compression.**

F2 — reading class identity as sameness of feeling. States 1 and 8 share class 1 and fold to the same 247.514 Hz. **They are not the same feeling and this paper never says they are.** *Detection:* the words "is really just" near a class collision. *Remedy:* quote the raw frequencies and the octave count alongside the class. **Six octaves is not nothing.**

F3 — treating the folded pitch as a magnitude. 386.741 Hz is not "more" than 247.514 Hz in any sense the formalism supports; **folding destroys magnitude by design.** *Remedy:* rank by n or f_{raw}, never by the folded value.

F4 — importing certainty the count does not have. $f = 39.1575$ Hz looks exact to six figures. **It is exactly as exact as the claim that the state required nine components and not eight or ten.** *Remedy:* the component list, mandatory.

F5 — mistaking the class ceiling for a claim about feelings. $\lceil N/2 \rceil = 6$ is a fact about odd numbers below 12. *Detection:* "the six fundamental" appearing in any sentence. *Remedy:* say "six pitch classes" and never drop the noun.

F6 — physical-resonance drift. Nothing resonates. Not a neuron, not a tissue, not a room, not a person. *Detection:* any sentence combining a frequency from this paper with a biological noun and a verb of oscillation.

F7 — diagnosis drift. The twelve states are not diagnoses. A pitch class is not a type of person, an index is not a severity, a trajectory is not a prognosis. **The prohibition is standing and admits no exception.**

F8 — band-shopping. Choosing the band to make two states collide or separate. **It does not work** (Theorem 4.1), and that it does not work is a strength of the method.

F9 — cents as effect size. 1768.7174 cents is an interval on a lattice. It is not a measure of how much a person changed, how hard the change was, how long it took, or whether it was good.

F10 — quietly changing N. The $50/49$ result belongs to $N = 12$; past $N = 16$ the minimum separation collapses by a factor of 5.83 in cents and everything about rendering must be recomputed.

6 Persistence: what the frequency law cannot see

6.1 The law is unchanged, and that is the result

Nothing about the essence law changes when the state read is a standing disposition rather than a passing one, because **there is no mechanism available by which it could change.**

THEOREM 6.1 (frequency does not distinguish disposition from episode). The essence law is a function of n alone. Persistence is not an argument of it. Therefore two states of equal index have equal essence frequency, equal folded pitch and equal pitch class, irrespective of how long either lasts. **QED.**

The proof is one line because the content is one line: **persistence cannot be read off a pitch, because the pitch was never told about it.** Recomputing the twelve-state spectrum for standing dispositions reproduces the table of Section 4.4 column for column — the same raw frequencies, the same transposition exponents, the same folded values, the same six classes. **Nothing was changed to make it agree; there was nothing available to change.**

This is the usual point at which a formalism quietly acquires a second parameter — a modifier, a coefficient of stability folded into n, something. **The correct response is not to patch the frequency law.** The parameter that does the job already exists in the corpus's storage law, and it belongs to a different equation entirely.

6.2 Where the decay lives

$$Q_{t+1} = (1 - \delta)Q_t + (\eta F(u^*) - c^*), \qquad Q_\infty = \frac{\eta F(u^*) - c^*}{\delta}$$

δ is the retention loss: a per-cycle rate in $(0, 1]$. **It is the only parameter in the system that speaks about time, and it is the only one absent from the essence law.**

DEFINITION 6.2 (a trait). A **trait** is a state held at low δ; a **mood** is the same state held at high δ. The index — and therefore the frequency, the folded pitch and the pitch class — is common to both. **The distinction is entirely and exclusively a claim about retention loss.**

6.3 The storage half-life

Setting the input to zero gives $Q_t = (1 - \delta)^t Q_0$, so

$$t_{1/2} = \frac{\ln 2}{-\ln(1 - \delta)}$$

Computed across the range this corpus uses, with the time to lose ninety per cent, the time to reach ninety-five per cent of the fixed point, and the naive linear estimate:

δ	$-\ln(1-\delta)$	$t_{1/2}$ (cycles)	t to 90% lost	t to 95% of Q_∞	$1/\delta$
0.005	0.005013	138.2826	459.3648	597.6473	200.0000
0.010	0.010050	68.9676	229.1053	298.0729	100.0000
0.020	0.020203	34.3096	113.9741	148.2837	50.0000
0.030	0.030459	22.7566	75.5957	98.3523	33.3333
0.050	0.051293	13.5134	44.8906	58.4040	20.0000
0.070	0.072571	9.5513	31.7289	41.2802	14.2857

δ	$-\ln(1-\delta)$	$t_{1/2}$ (cycles)	t to 90% lost	t to 95% of Q_∞	$1/\delta$
0.090	0.094311	**7.3496**	24.4149	31.7645	11.1111
0.100	0.105361	6.5788	21.8543	28.4332	10.0000
0.150	0.162519	4.2650	14.1681	18.4331	6.6667
0.200	0.223144	3.1063	10.3189	13.4251	5.0000
0.250	0.287682	2.4094	8.0039	10.4133	4.0000
0.300	0.356675	1.9434	6.4557	8.3991	3.3333
0.400	0.510826	1.3569	4.5076	5.8645	2.5000
0.500	0.693147	1.0000	3.3219	4.3219	2.0000
0.700	1.203973	0.5757	1.9125	2.4882	1.4286
0.900	2.302585	0.3010	1.0000	1.3010	1.1111

The $1/\delta$ column is not the half-life and the gap is large. At $\delta = 0.30$ the naive estimate is 3.3333 against the exact 1.9434: **an overstatement of 71.52 per cent.**

> **A rounding in the source, printed rather than silently applied.** The source reports this error as "seventy-two per cent". The exact figure is $(3.3333 - 1.9434)/1.9434 = 71.52$ per cent. The difference is a rounding, not a disagreement, and this paper quotes 71.52 while recording that 72 is what the source prints, so that a reader recomputing finds no surprise.

Only as δ falls do the two converge on the ratio $\ln 2 = 0.693147$: at $\delta = 0.001$, $\ln 2/\delta = 693.1472$ against the exact 692.8005, agreement to four figures. **The linear intuition is safe exactly where traits are and unsafe exactly where moods are.** Halving δ does not exactly double the half-life but nearly does, and does so from above: $t_{1/2}(0.150)/t_{1/2}(0.300) = 2.1946$, then 2.0846, then 2.0397, converging on 2.

6.4 Retention, tabulated

$(1-\delta)^t$, the fraction of stored order surviving t cycles with no input:

δ	$t=1$	$t=2$	$t=3$	$t=5$	$t=10$	$t=20$	$t=50$	$t=100$
0.01	0.990000	0.980100	0.970299	0.950990	0.904382	0.817907	0.605006	0.366032
0.03	0.970000	0.940900	0.912673	0.858734	0.737424	0.543794	0.218065	0.047553
0.05	0.950000	0.902500	0.857375	0.773781	0.598737	0.358486	0.076945	0.005921
0.09	0.910000	0.828100	0.753571	0.624032	0.389416	0.151645	0.008955	0.000080
0.15	0.850000	0.722500	0.614125	0.443705	0.196874	0.038760	0.000296	0.000000
0.30	0.700000	0.490000	0.343000	0.168070	0.028248	0.000798	0.000000	0.000000

At $\delta = 0.30$ nothing survives twenty cycles; at $\delta = 0.01$, thirty-seven per cent survives a hundred. **Between those two rows lies the entire difference between a mood and a trait, and there is not a single frequency in the table.** The same shape governs long-horizon erosion elsewhere in the corpus [Curzi, 2026], whose Result Five decomposes an erosion rate of 2.0 per cent per year into four components and reports 73.857 per cent retained at fifteen years and 54.548 per cent at thirty, half-life 34.310 years.

6.5 The cycle must be declared

δ has no meaning without a stated cycle, and the rescaling is exact: $\delta_r = 1 - (1-\delta_1)^r$.

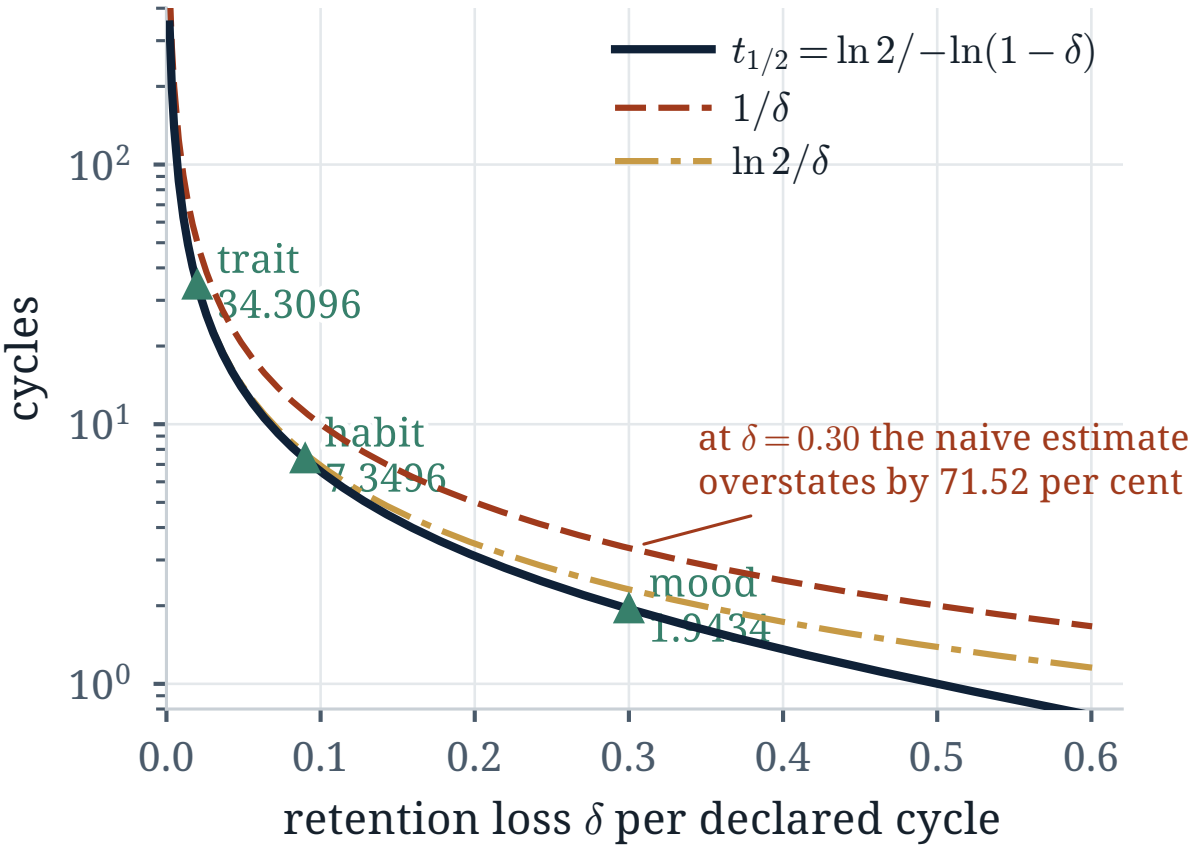

Figure 42.4: **The naive linear estimate is wrong exactly where moods live**: at $\delta = 0.30$ the true half-life is 1.9434 cycles against $1/\delta = 3.3333$, an overstatement of 71.52 per cent, while at trait-grade $\delta = 0.02$ the exact 34.3096 and $\ln 2/\delta = 34.6574$ agree to three figures. Computed from $t_{1/2} = \ln 2/(-\ln(1-\delta))$; the three marked points are the framework's declared mood, habit and trait grades. Built by `figs/src/CCP-042_fig04.py`.

δ per day	per week ($r = 7$)	per month ($r = 30$)	per year ($r = 365$)
0.02	0.131874	0.454516	0.999373
0.05	0.301663	0.785361	1.000000
0.09	0.483239	0.940947	1.000000
0.30	0.917646	0.999977	1.000000

The half-life is invariant in *time*; only its units change. Verified: $\delta/\text{day} = 0.02$ gives 34.3096 days $= 4.9014$ weeks, and $\delta/\text{week} = 0.131874$ gives 4.9014 weeks — identical. **A δ quoted without its cycle is not a number.** "$\delta = 0.09$" describes a disposition with a seven-cycle half-life, and whether that is a week or a decade depends on a unit nobody stated.

6.6 The trait cut is a declared convention

DEFINITION 6.3 (the trait window). Fix an observation window W in cycles. A state qualifies as a **trait relative to** W when $t_{1/2} \geq W$, equivalently $\delta \leq 1 - 2^{-1/W}$.

W (cycles)	δ must be $\leq$
5	0.129449
10	0.066967
20	0.034064
30	0.022840
50	0.013767
100	0.006908
365	0.001897

This is a convention, declared, and it is not a discovery about persons. There is no δ at which something switches from being an episode to being a disposition; there is a continuous rate and a cut somebody chose. **What the definition buys is not truth but auditability**: two readings that declare W can be compared and two that do not, cannot. The working labels, used only for legibility and never as categories of person, are $\delta \approx 0.30$ (mood, $t_{1/2} = 1.9434$), 0.09 (habit, 7.3496), 0.02 (trait, 34.3096) and 0.005 (core, 138.2826).

6.7 The division of labour

THEOREM 6.4 (sign independence). For any $\delta \in (0, 1]$, $\operatorname{sign}(Q_\infty) = \operatorname{sign}(\eta F(u^*) - c^*)$, and δ never changes it. Moreover Q_∞ is exactly inversely proportional to δ: $Q_\infty(\delta_2)/Q_\infty(\delta_1) = \delta_1/\delta_2$ exactly, for any numerator.

Proof. $Q_\infty = (\eta F - c)/\delta$ with $\delta > 0$; division by a positive number preserves sign, and the ratio of two such expressions with a common numerator is δ_1/δ_2. **QED.**

Its companions contain no δ at all:

```
f_min          = k e^( 2c/eta )                  CONTAINS NO delta
octave deficit = 2.885390 (c/eta) - log2(f/k)    CONTAINS NO delta
```

Verified on three constructed parameter sets: $\eta = 0.30$, $c = 0.62$ gives $f_{\min} = 30.1588$ Hz; $\eta = 0.44$, $c = 0.40$ gives 2.9782 Hz; $\eta = 0.34$, $c = 0.825$ gives 61.9349 Hz. The ceiling $c/\eta \leq \ln 12 = 2.4849066$ gives $f_{\min} \leq k \cdot 144 = 69.6133$ Hz. **So the two halves of the instrument divide cleanly:**

```
THE FREQUENCY READING DECIDES THE SIGN.
    Does the arrangement accumulate or decay?  f vs f_min.  delta is irrelevant.
```

```
delta DECIDES THE MAGNITUDE AND THE CLOCK.
    How far does it go, and how fast does it get there?  delta and nothing else.
```

A disposition's frequency tells you which way it is going; its δ tells you how far and how fast. Neither substitutes for the other, and **a reading that reports one without the other is half a reading.**

6.8 Durability and revisability are the same number

The convergence identity $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$ reads once for decay and once for approach. **It is the same rate: there is one time constant and it governs both directions.**

δ	$t_{1/2}$ of decay	$t_{1/2}$ of approach	identical?
0.02	34.3096	34.3096	yes
0.05	13.5134	13.5134	yes
0.09	7.3496	7.3496	yes
0.30	1.9434	1.9434	yes

COROLLARY 6.5 (no free durability). A state cannot be made durable without being made slow to revise, and cannot be made quick to revise without being made quick to lose. **The two properties are the same parameter read in two directions.**

This dissolves a wish a great deal of practical work is built around — a disposition that persists when wanted and yields when wanted. **The storage law has no term for "on demand". It has δ, and δ is symmetric.** Tabulated as the arrival problem from $Q_0 = 0$ with a fixed positive numerator $a = 0.5476136$:

δ	Q_∞	$t_{1/2}$	t to 95%	Q at $t=1$	$t=5$	$t=10$	$t=25$	$t=50$	$t=100$
0.30	1.8254	1.9434	8.3991	0.5476	1.5186	1.7738	1.8251	1.8254	1.8254
0.09	6.0846	7.3496	31.7645	0.5476	2.2876	3.7152	5.5088	6.0301	6.0841
0.02	27.3807	34.3096	148.2837	0.5476	2.6307	5.0087	10.8574	17.4095	23.7495

Every row starts at the same place after one cycle, because one cycle of input is one cycle of input regardless of the leak. By $t = 100$ the low-δ row holds thirteen times what the high-δ row holds — while still not having arrived. **A trait is, by construction, the thing that takes longest to finish arriving.**

6.9 The price of holding a level

Holding stored order at Q^* requires per-cycle input $a = \delta Q^*$:

δ	$Q^*=1$	$Q^*=5$	$Q^*=10$	$Q^*=27.38$
0.005	0.0050	0.0250	0.0500	0.1369
0.020	0.0200	0.1000	0.2000	0.5476
0.050	0.0500	0.2500	0.5000	1.3690
0.090	0.0900	0.4500	0.9000	2.4643
0.300	0.3000	1.5000	3.0000	8.2142

Maintenance cost is linear in δ and linear in the level held. Holding $Q^* = 10$ at trait loss costs 0.2000 per cycle; at mood loss it costs 3.0000 — **fifteen times as much, every cycle, forever.** Put beside Corollary 6.5, the trade is fully priced:

Low δ buys cheap maintenance and expensive revision. High δ buys cheap revision and expensive maintenance. There is no setting that is cheap at both, because it is one setting.

6.10 The durable liability

Theorem 6.4 says δ cannot flip a sign; it scales. **So when the numerator is negative, lowering δ scales a negative number.** Taking the corpus's constructed dyad as found — $u = 0.068735$, $F = 0.563085$ nats, $\eta = 0.30$, $c = 0.62$, numerator -0.4510739, $f = 1.4908$ Hz against $f_{\min} = 30.1588$ Hz, octave deficit $+4.3384$ — and sweeping δ:

δ	Q_∞	$t_{1/2}$	reading
0.30	-1.5036	1.9434	decays, shallow, fast
0.09	**-5.0119**	7.3496	decays — the as-found reading
0.05	**-9.0215**	13.5134	decays deeper, slower
0.02	-22.5537	34.3096	decays far deeper, far slower
0.01	-45.1074	68.9676	decays deepest, slowest

The ratio between the two bolded values is exactly what Theorem 6.4 requires: $-9.0215/-5.0119 = 1.800000\ldots = 0.09/0.05$. **No approximation: δ is a pure scale.**

> **A trait is not a good thing. A trait is a persistent thing.** Low δ deepens whichever fixed point is already there, and if the numerator is negative, low δ is the mechanism by which a problem becomes a permanent feature rather than an episode.

The intuitive repair for a struggling arrangement is to add trust, and trust in this parameterisation acts on δ. **The intervention everyone reaches for first makes the reading eighty per cent worse**, and it does so for the entirely mechanical reason that it multiplied a negative number by 1.8. **Interpretive care is required and this paper states it:** that trust reduces the loss rate rather than adding to the inputs is an assumption of the parameterisation, not a finding, and the trust literature is about reciprocity, monitoring and institutional form rather than about decay rates [Gambetta, 1988, Ostrom, 1990]. **If trust instead raises η, the arithmetic above does not apply.**

6.11 A positive numerator

The mirror case, so the section is not read as an argument against durability. The same dyad after one intervention: $u = 0.692400$, $\eta = 0.44$, $c = 0.40$, $F = 2.153667$ nats, numerator $+0.5476136$, $f = 35.8907$ Hz against $f_{\min} = 2.9782$ Hz, deficit -3.5911.

	numerator	$\delta = 0.09$	$\delta = 0.05$	effect of lowering δ
as found	-0.4510739	-5.0119	-9.0215	**worse by 4.0096**
after	$+0.5476136$	$+6.0846$	$+10.9523$	**better by 4.8677**

The identical intervention, on the identical parameter, in the identical direction, helps in one case and hurts in the other — and the frequency reading is what tells you which case you are in before you act.

> **A discrepancy in the source, printed rather than silently corrected.** The source prints $f = 35.8882$ Hz and $Q_\infty = +6.0844$ at $\delta = 0.09$. Recomputing from the printed

$u = 0.692400$ — itself a rounding of 0.69237163 — gives 35.8907 and $+6.0846$. **The two disagree in the fourth significant figure because the printed u is rounded, not because either is wrong.** The result this section depends on is the *ratio*, and the ratio is exactly 1.8 at either precision.

6.12 The truncation, revisited for dispositions

An intensification requires the double to exist on the ladder. **So for a standing disposition read at index 7, 9, 11 or above, there is no more-differentiated version of the same pitch class available within $N = 12$**, and any move from there is a transformation. **This is an artefact of index length and is reported as one.** It is not a claim that reflexive, normative or reciprocal dispositions cannot deepen; it is a claim that *this ladder, at this length, has no rung to represent the deepening as an octave.* Lengthening the index would supply one — and would also, past $N = 16$, drop the whole framework out of the $50/49$ regime.

6.13 What a trait reading contains, and what it costs to obtain

```
n          the index          -- SOFT: inherits the defensibility of the count
f          the frequency      -- HARD given n: exact arithmetic, k n^2
class      the pitch class    -- HARD given n: the odd part (Theorem 4.1)
delta      the retention loss -- SOFT: a rate, requiring repeated observation
                                 and a DECLARED cycle
t_half     the half-life      -- HARD given delta: ln2 / -ln(1-delta)
```

The two soft numbers carry all the psychological content and the two hard ones are pure arithmetic on top of them. That is the honest shape of the instrument.

This framework does not supply a validated instrument for δ and says so plainly. The shape of an honest estimate is: declare the cycle; establish a no-input interval, because an interval during which the arrangement is being actively maintained measures (δ, η, c) jointly and δ not at all; **observe over at least three expected half-lives, because below that the decay curve is indistinguishable from a line and δ is unidentified**; fit $\widehat{\delta} = 1 - (Q_t/Q_0)^{1/t}$; and report the estimate with the number of cycles it was estimated over. **At $\delta = 0.02$ the third step means roughly 103 cycles of observation. That is the binding constraint on the whole method, it is expensive, and a report must say so.**

Traits are, by construction, the states whose defining parameter is the most expensive to observe. That asymmetry is a real property of the method rather than a gap in the exposition.

7 The chord: simultaneity at internal scope

7.1 What a chord is

Nobody is ever in one state. A person entering a difficult conversation holds, at the same instant, a reading of the other party's intent, a story about how the situation arose, and a running commentary on their own performance inside it. **These are not three states in sequence; they are three *framings* held together**, each assigning intensity to several of the twelve categories at once.

A **chord** is the set of indices carrying nonzero intensity across the framings held at one moment. It is a set, not a single index, and it inherits everything the square law says about relations between indices.

7.2 The intervals are ratios of squares

$$\frac{f(m)}{f(n)} = \frac{km^2}{kn^2} = \frac{m^2}{n^2}$$

k **cancels.** Whatever one thinks of the constant — and it is a postulate, badged as one — it sets the absolute reference pitch and nothing else. **A reader who rejects k must still accept every interval in this section, because no interval contains it.** Consequences used throughout:

```
index ratio    essence interval    what it is
    2:1             4/1            two octaves exactly
    3:2             9/4            an octave plus a whole tone
    4:3            16/9            a minor seventh
    5:4            25/16           a near minor sixth
    3:1             9/1            three octaves plus a whole tone
```

7.3 The width of the chord is the internal surplus

$$F_{\text{int}} = \ln(1 + (N-1)u_{\text{int}}), \qquad f_{\text{width}} = k\, e^{2F_{\text{int}}} = k\,(1 + (N-1)u_{\text{int}})^2$$

where $u = 1 - (x \cdot y)^2$ on unit framing vectors and u_{int} is the mean pairwise non-parallelism across one observer's framings.

This is a substitution of domain, not an analogy, and the claim is checkable. The surplus functional's four axioms quantify over states in an inner-product space; **not one of them contains a term referring to persons, agents, groups, or the ownership of states**, so the theorem is silent on who holds the states and applying it inside one observer changes the encoder and nothing else [Curzi, 2026]. **Two postulates travel with the substitution and are restated rather than assumed** — the framing encoding (P-d) and the internal roster reduction (P-e).

The chord's width expressed as a pitch is the internal surplus expressed as a pitch: one number in two units. A person whose framings are parallel has $u_{\text{int}} = 0$, $N_{\text{eff}} = 1$, $F_{\text{int}} = 0$ and a width of exactly k — a single note. A person whose framings are orthogonal has $u_{\text{int}} = 1$, $N_{\text{eff}} = 12$, $F_{\text{int}} = \ln 12 = 2.484907$ and a width of $k \cdot 144 = 69.6133$ Hz, 7.169925 octaves above the ground. **One nat of internal surplus is exactly 2.885390 octaves.**

A precision note. $2/\ln 2 = 2.885390081777927$ exactly. Where the source writes 2.885 it is a shorthand costing about a thousandth of an octave at the ceiling — $2.885 \times \ln 12 = 7.1690$ against the exact 7.1699. **This paper uses the exact constant in every computed figure and says so once here.**

7.4 The one-hot degeneracy

Everything above is correct and everything above can be made to produce a meaningless number by a single encoding decision that looks, at first sight, like the cleanest possible one.

> **THE ORTHOGONALITY DEGENERACY [THEOREM].** Let x and y be unit vectors with **disjoint support** — no index carrying nonzero intensity in both. Then $x \cdot y = 0$, so $u = 1$ and $F = \ln N$, the maximum. **Distinct one-hot vectors always have disjoint support. Therefore any set of distinct one-hot framings scores the maximum internal surplus, for every subject, regardless of which states they name.**

Proof. $x \cdot y = \sum_i x_i y_i$, and disjoint support means every term has a zero factor. Substituting into $u = 1 - (x \cdot y)^2$ gives $u = 1$ and into $F = \ln(1 + (N-1)u)$ gives $F = \ln N$. **Nothing in either step consulted the identity of the states. QED.**

Computed on four constructed subjects, so a reader sees it rather than takes it:

```
ONE-HOT FRAMINGS -- FOUR DIFFERENT SUBJECTS, IDENTICAL READING

framings at states {3, 5, 7}    u = 1.000000 on all pairs
                                F = 2.484907  N_eff = 12.0000  f = 69.6133 Hz
framings at states {1, 2, 3}    u = 1.000000  F = 2.484907  N_eff = 12.0000  f = 69.6133 Hz
framings at states {4, 9, 12}   u = 1.000000  F = 2.484907  N_eff = 12.0000  f = 69.6133 Hz
framings at states {1, 11, 12}  u = 1.000000  F = 2.484907  N_eff = 12.0000  f = 69.6133 Hz
```

Four subjects with nothing in common produce the same reading, and it is the maximum reading the system can produce. A subject whose three framings are a nested sequence — each containing the last — scores exactly what a subject spanning states 4, 9 and 12 scores. **The encoding has erased the content and reported its own shape.**

Worse: the degenerate reading is not merely wrong, it is *flattering*. It says the subject holds the full twelve-fold vocabulary. **An instrument whose failure mode is to award everyone full marks will be adopted enthusiastically and will never be questioned by the people it flatters.** That is why this is a result and not a footnote.

And the trap is not really about one-hot vectors. One-hot is the extreme case of the real condition, which is *disjoint support*:

```
DISJOINT SUPPORT WITHOUT ONE-HOT -- the same degeneracy, better disguised

A = {1:0.6, 2:0.5, 4:0.3}   B = {3:0.7, 6:0.4, 9:0.5}   C = {5:0.8, 7:0.2, 11:0.6}

u(A,B) = u(A,C) = u(B,C) = 1.000000
F = 2.484907   N_eff = 12.0000   f = 69.6133 Hz
```

Each framing now looks rich and the reading is still the maximum. A reader who fixed the one-hot problem by "using more states per framing" and stopped there has fixed nothing.

The ceiling is why the trap is damaging rather than merely wrong. The degenerate encoding does not produce a random number; **it produces the ceiling** — the one reading that cannot be improved upon and therefore the one reading that ends the inquiry.

7.5 The overlap condition

> **THE OVERLAP CONDITION [BINDING].** A set of framings may be used to compute an internal surplus only if the framings share support, and the shared states carry enough weight that the inner products are not artefacts of a stray small term. **Where the condition fails, the computation is reported as degenerate and no F_{int} is published.**

The plain-language reading is what makes it obviously right: **two ways of construing *the same situation* must be about the same situation.** If a person's threat-reading and their story-telling have literally no ingredient in common, they are not two framings of one thing; they are two things. **Measure the angle between vectors pointed at different targets and you have measured nothing but the fact that they point at different targets.** A framing set with disjoint support is a category error rendered as a number.

There is a second, quieter reason the condition matters. **Overlap is what makes u variable.** On disjoint supports u is pinned at 1 and carries no information; on overlapping supports it ranges over the interval and its value is a fact about the person. **An instrument that cannot vary cannot measure.**

Overlap arises honestly because **the twelve states are components of specification, not topics.** A threat-reading of a conversation and a story about the same conversation both require a directed feeling — both are *about* something — so both carry state 3, and they may weight it very differently. **That difference is the signal.** Overlap becomes fake when a state is added because the arithmetic needs it rather than because the description requires it, and the guard is procedural: **the support of each framing vector must be fixed and recorded before any inner product is computed.** An operator who has seen $u = 1.000000$ and then revisits the vectors is no longer measuring.

7.6 States and pitch classes are different counts

Adding a state to a chord always adds a pitch. It does not always add a pitch class. A chord containing state 5 that acquires state 10 gains a note two octaves higher and gains no new

class. **The chord gets taller. It does not get harmonically wider.**

The two counts answer different questions. **The state count is what the index measures** — how many distinguishable components the framings collectively require. **The class count is what the folded chord can express** — how many distinct positions in the harmonic vocabulary it occupies. This paper insists only that the two be reported separately and never conflated: reporting the class count as though it were the roster understates the chord, and reporting the state count as though it were the harmonic vocabulary overstates it.

7.7 What raises the width, and what does not

The width is a function of u_{int} alone. Adding a framing genuinely angled from the existing ones raises the mean; adding one that restates an existing framing lowers it; and adding a state to an existing framing can move u either way and must be computed.

> **SCALE INVARIANCE OF THE FRAMING VECTOR.** Multiplying every intensity in a framing by a positive constant leaves the unit vector unchanged and therefore leaves every u, every F_{int} and the width unchanged. A framing at $\{3{:}0.8,\ 5{:}0.4,\ 7{:}0.2\}$ and one at $\{3{:}1.6,\ 5{:}0.8,\ 7{:}0.4\}$ are the *same unit vector*: $u = 0.000000$, $F = 0$, width exactly k. **Feeling the same thing more strongly does not widen the chord. Feeling a differently-shaped thing does.**

The instrument reads composition, not amplitude. Anything to be said about amplitude must be said with a different instrument, and this framework's nearest available proxy is δ.

7.8 Drop-one, and an honest surprise

Removing each framing in turn from the carried Subject of Section 8:

```
DROP-ONE AUDIT (three framings, F_int = 2.164390)

drop threat  ->  remaining pair (mirror, story)   u = 0.809410  F = 2.292890  f = 47.4142 Hz
drop story   ->  remaining pair (mirror, threat)  u = 0.904762  F = 2.393557  f = 57.9892 Hz
drop mirror  ->  remaining pair (story, threat)   u = 0.388360  F = 1.662402  f = 13.4361 Hz
```

Two of the three drops raise the width. This is not a paradox and not a bug, but it is a warning that must be published with any drop-one audit. **The mean pairwise u is an average, and removing a member removes its pairs.** A framing at a moderate angle to two framings that are at a wide angle to each other **drags the average down by existing.**

> **MEAN PAIRWISE u DOES NOT DETERMINE THE JOINT GEOMETRY.** The triangle inequality fails for geometric triples, so a set of pairwise angles is consistent with more than one arrangement, and no scalar summary of pairwise values recovers the arrangement. **N_{eff} computed from a mean is an audited count under a stated postulate, not a measured dimension.**

What follows practically is that a drop-one audit tells you about the average, not about the person's dependence on a framing. The mirror framing is not "the important one" because dropping it costs the most; **it is the one whose removal leaves behind the closest remaining pair.** Those are different claims and the arithmetic supports only the second. The same caution governs roster-scale drop-one audits elsewhere in the series [Curzi, 2026], whose Result Seven records a constructed team in which every one of five removals improves the reading, so a favourable drop-one row **carries no information about the member it names.**

7.9 The minimum roster, and what a chord is not

Two framings are enough to compute a width; one is not. With a single framing there are no pairs, u_{int} is undefined, and the correct output is not $F_{\text{int}} = 0$ but *no reading at all*. **A single framing has no internal geometry, and reporting zero surplus for it confuses "measured to be parallel" with "not measured."**

A chord is not a personality. It is computed from framings of one situation on one occasion. **A chord is not a preference or a value**; nothing in the construction records what the subject wants, endorses or would choose. **And a chord is not evidence about the situation**: the instrument measures the structure of the construals and is silent, completely and by construction, on whether any of them is correct. **A wide chord over a misread situation is a wide chord over a misread situation.** The alternative reading — that internal breadth implies accuracy — is attractive and unsupported by anything in the formalism. The corpus's own belief work makes the matching point with its forbidding clause [Curzi, 2026ab], whose Result One states $E = G \cdot B + \varepsilon$ with $G = 0 \Rightarrow E = 0$ for all B: **breadth of belief buys nothing through a channel of zero gain.**

7.10 Specification and gates

```
STEP 1  BUILD.       Write the twelve-vector for each framing. Fix and record the
                     support BEFORE step 3.
STEP 2  NORMALISE.   x <- x/||x||_2. Check ||x|| = 1.000000.
STEP 3  OVERLAP GATE. For every pair compute the shared support. If ANY pair has
                     empty shared support, STOP. Report DEGENERATE. Publish no F_int.
STEP 4  PAIRWISE.    cos = x . y ; u = 1 - cos^2. Publish ALL pairwise u, not the mean.
STEP 5  AGGREGATE.   u_int = mean over the P = m(m-1)/2 pairs.
STEP 6  SURPLUS.     N_eff = 1 + (N-1)u_int ;  F_int = ln N_eff.
STEP 7  WIDTH.       f_width = k e^(2 F_int) ; octaves = 2 F_int / ln 2.
STEP 8  CHORD.       States = union of supports. Raw pitch k n^2, folded with j.
                     Pitch classes = the distinct odd parts.
STEP 9  INTERVALS.   For each pair, ratio j^2/i^2, cents, and cents mod 1200.

GATE 1  UNIT NORM        ||x|| = 1 to within 1e-9                FAIL -> recompute
GATE 2  OVERLAP          every pair shares at least one state    FAIL -> DEGENERATE
GATE 3  WEIGHT           shared support >= 10% of each squared
                         norm  (A STATED CONVENTION, NOT A LAW)  FAIL -> flag WEAK
GATE 4  DISTINCTNESS     no two framings with u < 0.01           FAIL -> flag RESTATEMENT
GATE 5  CEILING          F_int <= ln N                           FAIL -> arithmetic error
GATE 6  PRE-REGISTRATION supports fixed before inner products    FAIL -> reading void
GATE 7  ROSTER           at least two framings                   FAIL -> NO READING
```

Gate 3's threshold is a convention chosen by the author and badged as one. There is no derivation that puts it at 10 per cent rather than 5 or 20. **What is not optional is choosing one, stating it, and applying it before seeing the result.** Gate 4 is the mirror of Gate 2 and flags rather than fails, because a genuine near-restatement is a finding and should be reported rather than suppressed.

A published reading carries the framing vectors unnormalised and normalised with supports marked; every pairwise u; u_{int}, N_{eff}, F_{int}, the width and the octave figure; the state set and the class set **reported separately**; the interval table raw and folded; the band and j for every folded value; the gate results; the scale-status statement; and the non-resonance and non-diagnostic statements. **The last two are not decoration. They are the two sentences that most reliably fall off a reading as it is copied from one document to another.**

7.11 Failure modes

FM-1 — disjoint support, of which one-hot is the extreme case. *Detection:* Gate 2, and by inspection — **a reading of exactly $F_{\text{int}} = 2.484907$ at $N = 12$ should be treated as a defect until proven otherwise.** *Repair:* ask of each framing which components of the situation it requires to be specified, not which component it is *about*. **It is not repaired by adding states; it is repaired by adding *shared* states.**

FM-2 — manufactured overlap. Having learned Gate 2, an operator adds a small intensity on a shared state so the gate passes. *Detection:* Gate 3 catches the crude version, Gate 6 the honest-operator version. **Neither catches a determined bad actor, and this paper says so plainly. No procedural gate defends against an operator who wants a particular answer; what the gates do is stop an honest operator producing a degenerate answer by accident, and make a dishonest one leave a trace.**

FM-3 — reading the mean as the geometry. Treating $N_{\text{eff}} = 8.7093$ as though it said the framings span 8.71 dimensions. *Repair:* state the roster-reduction postulate wherever N_{eff} is published.

FM-4 — the contested decomposition. Two competent analysts decompose the same framing differently and the discrepancy is reported as measurement noise. **There is no repair that makes the judgment go away.** *Remedy:* publish both decompositions and both readings. **Do not average them; averaging two decompositions produces a third that neither analyst endorses.**

FM-5 — the chord read as a diagnosis. The twelve states are not diagnoses and a chord width is a property of an encoding, not of a person's health. A narrow chord means the framings elicited on that day, under that decomposition, were close to parallel. **It means that and nothing further.**

FM-6 — physical-resonance drift. "The subject's chord is 36.67 Hz" becoming a recommendation to expose someone to a 36.67 Hz tone. *Detection:* any sentence in which the frequency *does* something.

FM-7 — conflating states with pitch classes. *Detection:* the class count is the number of distinct odd parts and can never exceed $\lceil N/2 \rceil$ or the state count.

FM-8 — amplitude mistaken for width. *Detection:* compare unnormalised to normalised vectors; if the change is a uniform scaling, the reading cannot move. *Repair:* **accept the invariance and say what the instrument does not see, rather than making it appear to see it.**

FM-9 — silently changing N. *Detection:* Gate 5. A reading with $F_{\text{int}} > 2.484907$ at $N = 12$ has changed N somewhere.

8 Worked example: the Subject

CONSTRUCTED CASE. This is not an observation of any person, no clinical or diagnostic claim is made or implied, and every parameter is chosen rather than measured.

The situation, stated once: a person has received a message from a colleague that could be read several ways, and must decide how to respond. Three framings are elicited:

```
threat  = {3: 0.8, 5: 0.4, 7: 0.2}    "they are coming at me"
story   = {3: 0.5, 5: 0.7, 10: 0.4}   "the latest instalment of an old pattern"
mirror  = {5: 0.3, 7: 0.8, 10: 0.5}   "what does my reaction say about me"

||threat|| = 0.916515   ||story|| = 0.948683   ||mirror|| = 0.989949

threat  = {3: 0.872872, 5: 0.436436, 7: 0.218218}
story   = {3: 0.527046, 5: 0.737865, 10: 0.421637}
mirror  = {5: 0.303046, 7: 0.808122, 10: 0.505076}
```

8.1 The gates

```
shared support (threat, story)  = {3, 5}       PASS
shared support (threat, mirror) = {5, 7}       PASS
shared support (story,  mirror) = {5, 10}      PASS
```

Every pair shares two states, and the shared states carry substantial weight in both members of each pair, so Gates 1 to 3 pass. State 5 — attributed feeling, the component saying the situation has a cause — is carried by all three framings. **That is what makes them three framings of one situation rather than three situations**, and it is the overlap condition satisfied by content rather than by construction.

8.2 The degenerate calculation, shown first

Encoding each framing by its heaviest state — threat at 3, story at 5, mirror at 7:

```
threat = {3: 1}   story = {5: 1}   mirror = {7: 1}

cos = 0.000000 on all three pairs;  u = 1.000000 on all three pairs
u_int = 1.000000   N_eff = 12.0000   F_int = 2.484907 nats
f_width = k * 144 = 69.6133 Hz   (folded 278.453 Hz, j = +2)
octaves above ground = 7.1699
```

The Subject scores the ceiling. So does every other subject encoded this way. And the damage compounds downstream. Carrying the degenerate width through the corpus's octave-deficit diagnostic at an illustrative cost ratio $c/\eta = 1.5714$:

```
present octaves = log2(69.6133 / 0.483425732988414) = 7.1699
required        = 2.885390 * 1.5714 = 4.5341
octave deficit  = 4.5341 - 7.1699 = -2.6358          "SUSTAINS"
```

The subject is pronounced sustainable by 2.64 octaves, and so is everyone else. A diagnostic that returns the same verdict for every input is not a diagnostic. This is the whole reason the trap is a result: **it does not fail loudly; it fails by succeeding uniformly.**

> **A rounding in the source, recorded.** The source computes this deficit as -2.6364 using the shorthand constant 2.885. With the exact $2/\ln 2 = 2.885390081777927$ the figure is -2.6358. **The difference is the shorthand, not an error**, and this paper quotes the exact value.

8.3 The correct calculation

```
pair              cos theta     u          F_int      N_eff     f = k(1+11u)^2
mirror / story     0.436566   0.809410   2.292890    9.9035     47.4142 Hz
mirror / threat    0.308607   0.904762   2.393557   10.9524     57.9892 Hz
story  / threat    0.782074   0.388360   1.662402    5.2720     13.4361 Hz

folded (220-440):  47.4142 -> 379.314 Hz (j=+3)
                   57.9892 -> 231.957 Hz (j=+2)
                   13.4361 -> 429.956 Hz (j=+5)
octaves above ground: 6.6159, 6.9063, 4.7967
```

All three pairwise values are different, and they are different because the framings are different. That sentence is trivial and it is the entire point: **under the degenerate encoding it was false.** Threat and story are the closest pair at $u = 0.388360$ — both construe the situation as something arriving from outside with a cause. Mirror and threat are the widest at $u = 0.904762$ — one looks outward at an agent, the other inward at the self.

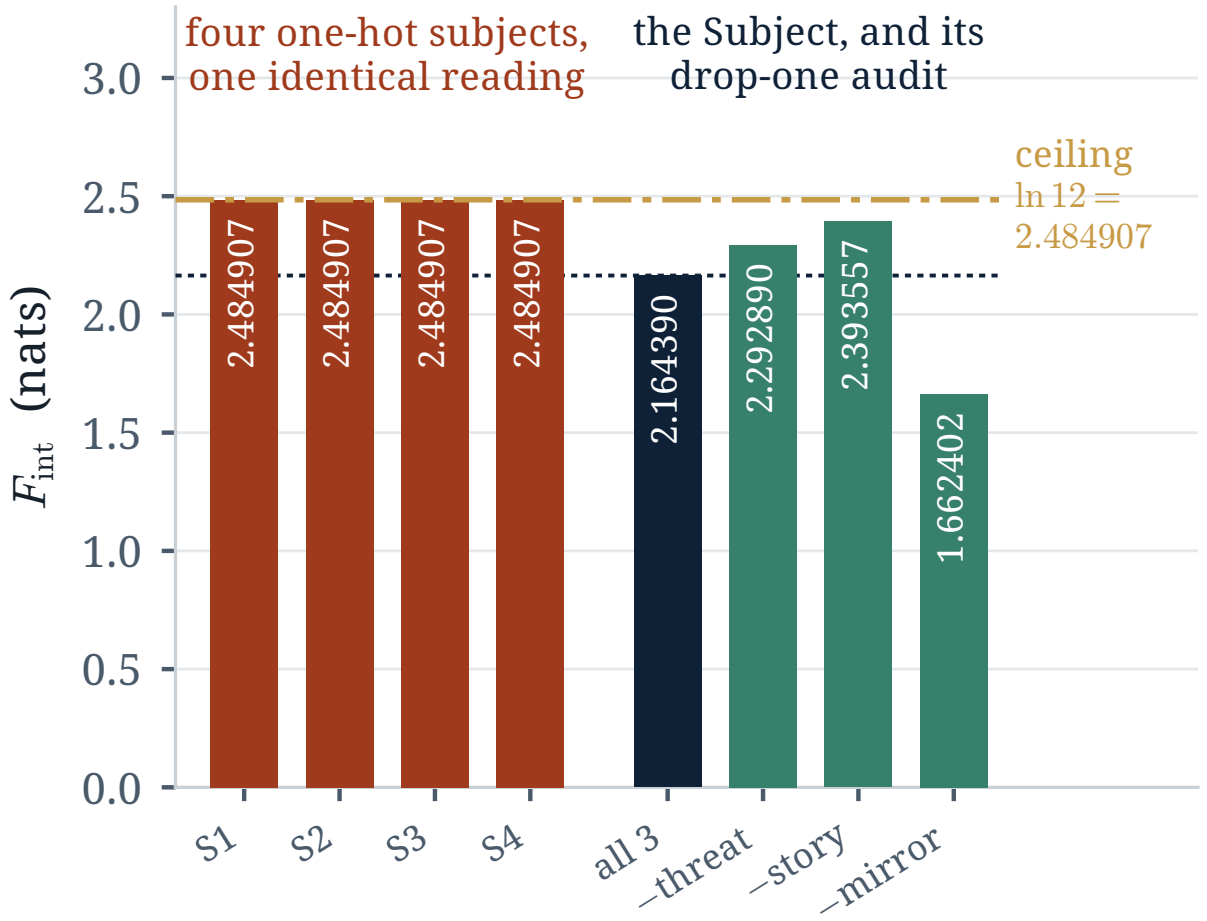

Figure 42.5: **The tidy encoding awards every subject the ceiling, and the honest drop-one audit rises twice out of three**: four unrelated constructed subjects encoded one-hot all read $F_{\text{int}} = \ln 12 = 2.484907$, while the Subject's overlapping framings read 2.164390, and two of the three single-framing removals *raise* it, to 2.292890 and 2.393557. Modelled from $F_{\text{int}} = \ln(1 + 11u_{\text{int}})$ on the constructed framing vectors of Section 8. Built by `figs/src/CCP-042_fig05.py`.

```
u_int   = (0.809410 + 0.904762 + 0.388360)/3 = 0.700844
N_eff   = 1 + 11 * 0.700844 = 8.7093
F_int   = ln 8.7093 = 2.164390 nats
f_width = k * 8.7093^2 = 36.6686 Hz      folded 293.349 Hz (band 220–440, j = +3)
octaves = 2 * 2.164390 / ln 2 = 6.2451

F_int / ln 12 = 87.10%          N_eff / N = 72.58%
```

The chord's width is 36.6686 Hz, which is 6.2451 octaves above the ground essence, and it is the same statement as $F_{\text{int}} = 2.164390$ nats. The Subject holds three framings and audits to an effective 8.71 of the twelve available categories — **which should be read as what it is: a stated construction, not a measured dimension.** N_{eff} is not a count of framings; that three framings can audit to 8.71 categories is exactly the surplus functional's content, that non-parallel states span more than they number.

8.4 The chord and its intervals

```
STATES SPANNED  =  {3, 5, 7, 10}    -- FOUR states
```

```
state  3   directed feeling      raw  4.3508 Hz    folded 278.453 Hz (j=+6)   class 3
state  5   attributed feeling    raw 12.0856 Hz    folded 386.741 Hz (j=+5)   class 5
state  7   reflexive feeling     raw 23.6879 Hz    folded 379.006 Hz (j=+4)   class 7
state 10   narrative feeling     raw 48.3426 Hz    folded 386.741 Hz (j=+3)   class 5
PITCH CLASSES  =  {3, 5, 7}        -- THREE classes
```

Four states, three pitch classes. States 5 and 10 have the same odd part, so they fold to the identical value and occupy one position in the six-position vocabulary $N = 12$ permits. **The fourth state adds a pitch and does not add a class.**

```
pair    essence ratio   raw cents   folded cents   note
3:5        25 / 9        1768.72       568.72
3:7        49 / 9        2933.74       533.74
3:10      100 / 9        4168.72       568.72      same folded interval as 3:5
5:7        49 / 25       1165.02      1165.02      just under an octave
5:10        4 / 1        2400.00         0.00      CLASS COLLISION, exactly 2 octaves
7:10      100 / 49       1234.98        34.98      the 50/49 minimum gap
```

Every ratio is a ratio of squared integers and k appears nowhere. Two entries deserve their own line. $5{:}10$ **at exactly** 0.00 **folded cents is the collision, visible** — and it is also the most *consonant* interval the essence lattice offers [Curzi, 2026], whose Result Two records that the minimum harmonic distance $\mathrm{HD}_{\mathrm{ess}} = 2.0000$ is attained by exactly the six collision pairs $\{1{:}2, 2{:}4, 3{:}6, 4{:}8, 5{:}10, 6{:}12\}$ and by nothing else. **The Subject's chord contains the most consonant interval the system has, and it is also the chord's only redundancy.** And $7{:}10$ **at** 34.98 **folded cents is the tightest pair the system permits**, the $50/49$ of Section 4.5, realised here by a chord that happens to contain both 7 and 10.

8.5 What the reading says, and what it does not

It says: under the declared decomposition, on this situation, on this occasion, the Subject's three framings are substantially non-parallel; the mean non-parallelism is 0.700844; the internal surplus is 2.164390 nats, 87.10 per cent of the maximum this twelve-category ladder can express; the chord spans four states in three pitch classes; and one of the four states is a doubling of another.

It does not say that the Subject is well or unwell, that a wider chord would be better, that a narrower one would be worse, that the Subject's framings are accurate, that the colleague's message means anything in particular, or that any frequency corresponds to a physical oscillation anywhere.

And it does not say that the Subject "is 8.71 people", or has 8.71 perspectives, or contains 8.71 of anything. N_{eff} is an effective count under a stated postulate, computed from a mean of pairwise angles, and because the triangle inequality fails for geometric triples that mean does not determine the joint arrangement.

9 Results

The seven results below are the units other papers in this corpus cite. A citation to this paper should name one of them. Each carries its status: **DERIVED** where it follows from the stated definitions by algebra, **COMPUTED** where it is the output of exact arithmetic on stated parameters, and **POSTULATED** where it is asserted by this framework.

R1 — the odd-part class rule. The pitch class of $f(n) = kn^2$ is the odd part of n, so an index $1 \ldots N$ realises exactly $\lceil N/2 \rceil$ classes — six at $N = 12$, namely $\{1, 3, 5, 7, 9, 11\}$. *Status:* DERIVED (Theorem 4.1, proved in both directions); the class count COMPUTED and verified for every N from 1 to 25. Class-preserving intervals are **even** whole octaves, so the smallest is exactly 2400 cents (Corollary 4.2).

R2 — the intensification/transformation dichotomy. A transition $m \to n$ is a whole number of octaves **iff** m and n share an odd part; 10 of 66 pairs at $N = 12$, or 15.1515 per cent. *Status:* DERIVED (Theorem 5.1) and verified exhaustively over all 66 pairs. **Index distance does not determine the kind**: $3 \to 12$ is $+9$ and an intensification, $11 \to 12$ is $+1$ and a transformation.

R3 — frequency does not distinguish a disposition from an episode. $f = kn^2$ has no time argument, so a mood and a trait at $n = 9$ are the identical tone: 39.1575 Hz raw, 313.260 Hz folded at $j = 3$, class 9, **separated only by** δ**.** *Status:* DERIVED (Theorem 6.1). **This is the paper's sharpest result and it is negative.**

R4 — the storage half-life. $t_{1/2} = \ln 2/(-\ln(1-\delta))$. At $\delta = 0.30$ it is 1.9434 cycles against the naive $1/\delta = 3.3333$, **an overstatement of** 71.52 **per cent** (the source rounds this to 72). At $\delta = 0.09$ it is 7.3496 and at $\delta = 0.02$ it is 34.3096, a ratio of 17.6544. *Status:* DERIVED; the table COMPUTED.

R5 — the one-hot degeneracy. Distinct one-hot framings have disjoint support, hence $u = 1$ for every pair and $F_{\text{int}} = \ln N = 2.484907$ for every subject regardless of content, giving the ceiling width $kN^2 = 69.6133$ Hz. *Status:* DERIVED; demonstrated COMPUTED on four constructed subjects and on a disguised disjoint-support case. **The degenerate encoding does not produce a random number; it produces the ceiling.**

R6 — the $50/49$ **regime.** The minimum folded separation at $N = 12$ is 34.9756 cents at the unique pair $7{:}10$; the cliff at $N = 17$ collapses it to 6.0008 cents ($289/288$) and the second at $N = 41$ to 1.0296 cents ($1682/1681$). *Status:* COMPUTED in exact rational arithmetic; all three are exact rational coincidences. The corresponding signal bound is $\Delta t \geq 10.2882$ ms at the tightest pair [Curzi, 2026z].

R7 — the drop-one surprise. Removing two of three framings from the carried constructed chord *raises* F_{int}, from 2.164390 to 2.292890 and 2.393557; only the third lowers it, to 1.662402. *Status:* COMPUTED. **Mean pairwise non-parallelism does not determine the joint geometry**, and a drop-one audit therefore reports on the average and not on dependence.

CR — counter-result. The frequency register **cannot distinguish a mood from a trait at all**, because $f = kn^2$ contains no time term; and **the cleanest-looking encoding of a framing, the one-hot vector, returns the system's maximum surplus for every subject and therefore measures nothing.** To these the framework adds three of its own: the constant k is chosen, the affine effective count is not a Hill number, and the interpretation of k as a frequency is postulated. The corpus reaches structurally parallel self-demotions elsewhere: its own pre-registered fit **failed its second falsification rule** [Curzi, 2026i], and its channel-separation work states that a property which is necessary is not thereby sufficient [Curzi, 2026], refusing two attractive simplifications outright. **The same discipline applies here: overlap is necessary for a chord reading and is not sufficient for it to mean anything.**

10 Discussion

10.1 What follows

A formalism with two axes is unusual and worth naming. Most measurement schemes have one: more or less. This lattice has a second — pitch class — that is *invariant* along an entire family of changes the first registers as enormous. **That invariance is the content of R2**, and it is why the distinction between intensification and transformation is available at all.

The negative result about time generalises past this framework. Any state description that is a function of a specification alone is silent about persistence, and the temptation at that point is to fold a stability coefficient into the description. **The correct response is to notice that the persistence parameter belongs to a different equation and to keep it there.** The division of labour is exact: the frequency reading decides the sign of the fixed point and contains no δ; δ decides the magnitude and the clock and cannot change the sign [Curzi, 2026], whose Result Three is precisely the absence of δ and N from the threshold.

The degeneracy result generalises furthest. The pattern is *an encoding whose failure mode is a uniformly favourable answer*. Such instruments are adopted enthusiastically and are never questioned by the people they flatter, and the defence is not a better statistic but a

validity gate applied before the arithmetic. **This is the same discipline the corpus applies when it declines an intervention on the ground that its measured benefit is an artefact of the measure** [Curzi, 2026], whose Result Two prices pitch-class folding at exactly one bit for every even N — a cost that is paid whether or not anyone notices.

10.2 What does not follow

The lattice is not a taxonomy of emotion. Six pitch classes is a fact about odd numbers below 12.

Class identity is not sameness. States 1 and 8 fold to the same value across six octaves of raw pitch. **The folded lattice cannot tell them apart, and that is a property of the lattice worth knowing rather than a claim about the states.**

A width is not a verdict about a person. It is a property of an encoding of a set of framings elicited on one occasion under one decomposition.

And the arithmetic is not evidence. Every result in Sections 4, 5 and 7 is a theorem about integers or about unit vectors. **It becomes a statement about a person only through the count, and it inherits every weakness of that count.**

10.3 Relation to the surrounding literature

The interval apparatus — cents, octave equivalence, ratio arithmetic — is standard once an index exists [Rossing et al., 2002, von Helmholtz, 1885, Benson, 2006]. **What the apparatus does not carry with it is any claim about hearing.** Consonance depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005]; interval categories and octave equivalence generalise less far across listeners and species than is usually assumed [Burns, 1999, Hoeschele et al., 2012]; and the octave's perceptual specialness, while real, has a measured and finite size [Demany et al., 2013]. The two classical consonance measures this corpus uses elsewhere [Tenney, 2015, Euler, 1739] are chosen functions on rationals rather than measured facts about hearing, and are badged that way where they are used [Curzi, 2026]. **This paper uses the arithmetic and asserts none of the psychoacoustics.** The one place the corpus's frequencies meet real acoustics is a derived room [Curzi, 2026l], whose Result Two fixes $7.2400 \times 4.3798 \times 2.9319$ m, $V = 92.969$ m^3 and an RT60 of 0.5 s requiring 29.94 m^2 sabins, with the folded set entirely above a Schroeder frequency of 146.7 Hz — **and that is a statement about a room, not about a person.**

The persistence half of the paper sits beside a large literature on habit and disposition that this paper does **not** contribute to. **"Trait" is a word with a substantial psychometric literature attached to it, and this paper is defining a term inside a formalism rather than adding to that literature.** The reliability/validity distinction is the relevant caution [Cronbach and Meehl, 1955, Campbell and Fiske, 1959]: **an agreement statistic measures reliability and not validity**, and a held-out predictive test is required before any of this can be said to work [Nosek et al., 2018].

10.4 The reflexive exposure, and the programme

An instrument that issues a verdict on a person's framings may change those framings by issuing it. The mechanism is documented [Merton, 1948, Rosenthal and Jacobson, 1968] and has been observed in the field [MacKenzie and Millo, 2003], but the effect sizes are contested [McCambridge et al., 2014] and on the best long-run assessment **self-fulfilling prophecies are real but small, do not typically accumulate, and often dissipate** [Jussim and Harber, 2005]. **The correct response is not to suppress the reading but to publish the parameters that produced it.** That is also why any indicator adopted as a target degrades as an indicator [Campbell, 1979, Goodhart, 1975].

The wider programme this belongs to begins with *physique sociale* [Quetelet, 1835] and continues through the modern computational literature [Castellano et al., 2009, Lazer et al., 2009]. **Its characteristic error is Quetelet's** — treating the mean of a distribution as a type rather than as a statistic — and Section 7.8 is this paper's version of that error caught in the act: **a mean of pairwise angles is not an arrangement.** Three further constraints bear and are not comfortable. Human activity is bursty with **no characteristic time scale** [Barabási, 2005], which a half-life claim must confront and can meet only by insisting that its cycles are declared rather than discovered. An explanation is supposed to name a mechanism rather than exhibit a fitted curve [Hedström and Ylikoski, 2010]; **this paper fits nothing, which sidesteps the objection at the cost of having no empirical content to fit.** And **what observation would distinguish this lattice from a neighbouring model that fits equally well?** [Sobkowicz, 2020, Durlauf, 2005] The honest answer is that R1, R2 and R6 are theorems and cannot be so distinguished; only H1 and H2 have empirical content, and neither has been tested. **What the paper is entitled to claim is analytical rather than predictive** [Epstein, 2008, Keuschnigg et al., 2018].

11 Verification

Every step below can be checked on its own. The standard is Occam's: **a postulate that can be dropped without the result changing has been dropped.** Statuses: **ARITHMETIC** (a reader can redo it), **DEFINITION** (true by stipulation), **CITED** (an external source supports it — the key is named), **POSTULATED** (asserted by this framework, no external support).

11.1 The postulates

	postulate	status
P1	The Pythagorean whole tone is the ratio $9{:}8$.	CITED [Barbour, 1951]
P2	φ is the positive root of $x^2 = x + 1$; hence $\varphi^2 = \varphi + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P3	A dimensionless ratio of the form $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source
P4	A state with n distinguishable components has essence frequency kn^2.	POSTULATED — no source
P5	A frequency may be divided by a power of two without changing what it means.	POSTULATED beyond pitch; CITED for pitch only [Shepard, 1982]
P6	n is a cardinality, hence absolute-scaled.	DEFINITION, with the scale typology CITED [Stevens, 1946]
P7	$N_{\text{eff}} = 1 + (N-1)u$ (the affine count axiom).	POSTULATED — design axiom [Curzi, 2026]; **not a Hill number**
P8	A framing admits representation as a unit vector over the twelve categories.	POSTULATED — no source

	postulate	status
P9	Stored order obeys $Q_{t+1} = (1-\delta)Q_t + a$ with $\delta > 0$.	CITED as a form [Oppenheim et al., 1996, Elaydi, 2005]; the *interpretation* POSTULATED

Dropped as unnecessary. No postulate about the *meaning* of any state is needed for R1, R2, R6 or R7: they hold for any index set and any unit vectors whatever the states are called. **No postulate about consonance is needed anywhere in this paper**, and the time–frequency bound contributes to R6's rendering corollary only, not to any lattice result. **P3 and P4 are not needed for R1, R2 or R6 either**, because those are results about ratios in which k cancels.

11.2 The compounding chain

step	consumes	produces	status
L1	P1	$(9/8)^2 = 81/64 = 1.265625$ exactly	ARITHMETIC
L2	P2	$\varphi^2 = \varphi + 1 = 2.618033988749895$	ARITHMETIC
L3	L1, L2	$k = 0.483425732988414$	ARITHMETIC (exact)
L4	L3, **P3**	k carries the unit Hz	**POSTULATED**
L5	L4, **P4**	$f(n) = kn^2$ Hz	**POSTULATED**
L6	L5	$f(m)/f(n) = m^2/n^2$: k cancels from every interval	ARITHMETIC
L7	L6, **P5**	$n = 2^a m \Rightarrow f(n) = 2^{2a} f(m)$: same class — **R1** forward	ARITHMETIC (value); POSTULATED (meaning)
L8	L6	$(m_1/m_2)^2 = 2^j$ with m_i odd forces $m_1 = m_2$ — **R1** converse	ARITHMETIC
L9	L7, L8	classes = odd numbers in $1 \ldots N$, count $\lceil N/2 \rceil$ — **R1**	ARITHMETIC
L10	L8	$j = 2(a_1 - a_2)$ is even: smallest same-class interval = 2400 cents	ARITHMETIC
L11	L9, L10	the dichotomy; 10 of 66 at $N = 12$ — **R2**	ARITHMETIC
L12	L9, exact rationals	min folded separation $50/49$ at $N = 7 \ldots 16$ — **R6**	ARITHMETIC
L13	L12	cliffs at 17 ($289/288$) and 41 ($1682/1681$) — **R6**	ARITHMETIC
L14	L5 by inspection	f has no time argument — **R3**	ARITHMETIC
L15	P9	$Q_t = (1-\delta)^t Q_0$; $t_{1/2} = \ln 2/(-\ln(1-\delta))$ — **R4**	ARITHMETIC

step	consumes	produces	status
L16	L15	$t_{1/2} = 1.9434$ vs $1/\delta = 3.3333$ at $\delta = 0.30$: $+71.52\%$ — **R4**	ARITHMETIC
L17	P9	sign Q_∞ is sign$(\eta F - c)$; $Q_\infty \propto 1/\delta$	ARITHMETIC
L18	P7, P8	$F_{\text{int}} = \ln(1 + (N - 1)u_{\text{int}})$	DEFINITION given P7
L19	L18, disjoint support	$u = 1$, $F_{\text{int}} = \ln N$ for every subject — **R5**	ARITHMETIC
L20	L18, constructed vectors	$u_{\text{int}} = 0.700844$, $F_{\text{int}} = 2.164390$	ARITHMETIC
L21	L20, drop-one	2.292890, 2.393557, 1.662402 — **R7**	ARITHMETIC

11.3 What this chain is and is not

Read the status column. Steps L1, L2, L3, L6 and L8 through L21 are arithmetic and a reader can redo every one of them. **Steps L4 and L5 are postulated, and L7's *interpretation* is postulated while its *value* is arithmetic.** A chain containing postulated steps is not a proof of its conclusion, and this one is not offered as one.

What it is offered as is a separation, and this paper's separation is unusually clean. R1, R2, R6 and R7 are results about *ratios* and *angles*, in which k cancels and P3 and P4 do no work at all. **A reader who rejects the frequency interpretation entirely keeps the odd-part rule, the dichotomy, the regime and the drop-one surprise, restated as facts about integers and unit vectors.** What such a reader loses is only the hertz values, which is exactly what the postulates were asked to supply.

Two statuses that must not be misread. The exponent 2 at L5 is **DEFINED**, not estimated: no fit was performed and the standard procedure for testing a scaling claim [Clauset et al., 2009] was not run. The logarithm at L18 is **DEFINITION** given the affine axiom P7, and the warrant the argument needs is the multiplicative-dynamics one [Peters and Gell-Mann, 2016] rather than the psychophysical one.

The falsifiable content lives at L15 and in H1 and H2, not at L4 and L5. This paper's empirical exposure is therefore smaller than its notation suggests, and its unsupported material is correspondingly more inert. Making point predictions with constants rather than directional ones is the right response to the directional-prediction critique [Meehl, 1990], and printing the status of each postulate is the honest description of what a badged postulate does in a research programme [Lakatos, 1970, Platt, 1964]. The corpus's own honesty apparatus is what enforces that discipline [Curzi, 2026], whose counter-result assigns the framework's central identification to the postulate drawer and states that one of its three declared postulates is a wager whose misfire column exists because wagers can lose. **A postulate table that never assigns anything to the postulate drawer is decoration**, and Section 11.1 assigns four.

12 Limitations

Every check the governing rigour standard specifies is listed here by name, whether or not this paper passes it.

L-1. The dimensional audit does not close. $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, and k is computed as a ratio of two dimensionless quantities. **No operational procedure is supplied by which the constant acquires the dimension of frequency.** This is the paper's largest structural weakness and no citation in the bibliography repairs it. **It touches only the absolute values, not the intervals.**

L-2. The essence law has no external support, and its exponent is **defined, not estimated**: no fit was performed, no alternative was tested, and the standard procedure for a scaling claim [Clauset et al., 2009] was not run because there is no data to run it on. **This paper makes no empirical scaling claim.**

L-3. The constant is chosen. $k = (9/8)^2/\varphi^2$ combines two real objects into a product with no precedent, quoted to fifteen figures **because it is defined**, not because anything was measured to that precision [Markowsky, 1992, Fischler, 1981].

L-4. Octave reduction beyond pitch is unwarranted. Shepard grounds octave equivalence for pitch [Shepard, 1982]; **nothing grounds folding a non-acoustic quantity into a 220–440 Hz band and reading meaning from where it lands.** Every folding result in this paper is a result about the operation, and the *interpretation* of the operation is not supported.

L-5. $N_{\text{eff}} = 1 + (N-1)u$ **is not a Hill number.** It is a linear interpolation between 1 and N and appears in no ecological, economic, political-science or information-theoretic literature. The Hill-number citations apply to $1/\text{HHI}$ and $\exp(H)$ and to nothing else [Hill, 1973, Laakso and Taagepera, 1979].

L-6. The scalar-reduction habit is a single defect with two faces, and the paper concedes both. Michell's objection [Michell, 1997] and the appraisal literature's objection are the same objection in two domains. Emotional states are described as **patterns across simultaneously varying appraisal dimensions** [Smith and Ellsworth, 1985], as **processes in time whose state is a synchronisation** [Scherer, 2001], as individuated by **qualitative core relational theme** [Lazarus, 1991], and as located on **continuous bipolar axes** rather than counted [Russell, 1980]. **A count discards exactly the information those accounts carry, and cannot separate anger from guilt.** The ladder's top rung is contradicted specifically: action readiness is held to be constitutive of emotion as such [Frijda, 1986], and this paper narrows the rung to *bound commitment* — **a narrowing, not an answer.** Two rungs survive [Tracy and Robins, 2004, Premack and Woodruff, 1978]. **Every reading in this paper that passes through the ladder inherits this concession.**

L-7. Conjoint measurement was not tested. The treatment of the elicited intensities as ratio-scaled is provisional; the available remedies [Luce and Tukey, 1964, Rasch, 1960] were not run. The cost of that failure is measured elsewhere in the series at 1065.05 cents [Curzi, 2026].

L-8. Count reproducibility (H2) has not been tested. Whether n is a property of the state or of the analyst is **unknown**. Every frequency here is a frequency *under a declared decomposition*, which is a real thing to have and is less than a measured one.

L-9. Twelve is not justified. The category count exceeds the classical span of immediate absolute judgment [Miller, 1956], which is a caution rather than a refutation, and Section 6.12 shows the truncation it causes: **six of twelve indices have no double on the ladder, so no intensification is available from them at all.**

L-10. No instrument for δ **is supplied.** The framework does not validate one, and the identifiability constraint is severe: **roughly 103 cycles of no-input observation at trait grade.** Every δ in this paper is constructed.

L-11. The trait cut is a convention, not a discovery. There is no δ at which an episode becomes a disposition. **Two readings that declare** W **can be compared; two that do not, cannot.**

L-12. The trust mechanism is an assumption. Section 6.10's liability depends on trust acting through δ rather than η; the literature cited for trust [Gambetta, 1988, Ostrom, 1990] is about reciprocity, monitoring and institutional form, not decay rates. **Which channel it operates through is not settled here.**

L-13. The overlap gate's weight threshold is arbitrary. Ten per cent rather than five or twenty is a stated convention with no derivation, and **no procedural gate defends against an operator who wants a particular answer.**

L-14. Mean pairwise u **does not determine the joint geometry.** The triangle inequality fails for geometric triples, so N_{eff} is an audited count under a stated postulate and **not a measured dimension**; the drop-one surprise of R7 is that failure made visible.

L-15. u is symmetric and psychological similarity is not. Similarity judgments are asymmetric and violate the triangle inequality [Tversky, 1977]; this framework's u assumes metric behaviour.

L-16. The instrument is blind to amplitude. Uniform rescaling of a framing leaves every reading unchanged. That is a property of the construction, **and the correct response is to say what the instrument does not see rather than to make it appear to see it.**

L-17. Every case is constructed. The Subject, the one-hot subjects and every δ are chosen parameter sets. **Their precision is exact because the parameters are exact; that precision does not transfer to a measured case.**

L-18. No model comparison, no statistical claim. Nothing was fitted, so there is no out-of-sample test, no matched null, no information criterion, no p-value, no effect size and no interval. **The corpus's one confirmatory attempt failed its own baseline test** [Curzi, 2026i], which is the relevant precedent for how a fit here should be reported.

L-19. The functional form is underdetermined. A sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as the logarithm does, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. **Nothing here discriminates among them.**

L-20. The reflexive specification is not identified [Manski, 1993, Shalizi and Thomas, 2011]. The remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001], and the claim is **a modelling position rather than an identified empirical result.** The framework also exempts its own parameters from its own reflexivity [Lucas, 1976, Hacking, 1995], which is **not resolved.**

L-21. There is no conservation law, and Q is written with the grammar of a conserved quantity [Mirowski, 1989]; validity is claimed only within a specified arrangement [Cartwright, 1999]. **Ergodicity is assumed and not argued** [Peters, 2019].

L-22. Boundary behaviour. $\delta \to 0^+$ gives no fixed point at all — a pathology, not an ideal, since nothing decays out of the stock; $\delta \to 1$ makes the store memoryless and drives $t_{1/2} \to 0$; $u \to 1$ gives the ceiling and $u \to 0$ collapses the width to k exactly. $N \to \infty$ **raises the class ceiling without bound and simultaneously destroys the rendering regime**, collapsing the minimum separation by a factor of 5.83 in cents at $N = 17$. **The source examines none of these limits together and this paper states them here.**

L-23. Two roundings in the source, printed rather than silently corrected. The half-life error at $\delta = 0.30$ is 71.52 per cent and the source prints 72. The post-intervention dyad's $f = 35.8907$ Hz and $Q_\infty = +6.0846$ recomputed from the printed $u = 0.692400$ disagree in the fourth significant figure with the source's 35.8882 and $+6.0844$, **because the printed u is a rounding of** 0.69237163**.** Neither is an error in a theorem; both will be found by any reader who recomputes.

L-24. The 2.885 shorthand. The exact constant is $2/\ln 2 = 2.885390081777927$; the shorthand costs about a thousandth of an octave at the ceiling and about 0.0006 octaves in the degenerate worked deficit of Section 8.2. **Every computed figure in this paper uses the exact value.**

L-25. A published reading can change what it reads. The reflexive exposure of Section 10.4 is not controlled for and cannot be controlled for by an instrument acting alone.

13 Conclusion

What is established, and it is arithmetic. The pitch class of a squared integer index under octave folding is the odd part of that index, so two states share a class **if and only if** they share an odd part, and an index $1 \dots N$ realises exactly $\lceil N/2 \rceil$ classes — six at $N = 12$, namely $\{1, 3, 5, 7, 9, 11\}$. Class-preserving intervals are necessarily **even** whole octaves, so the smallest is exactly 2400 cents. This partitions transitions into intensification and transformation, and only 10 of 66 pairs at $N = 12$ — 15.1515 per cent — are class-preserving; **index distance does not determine which kind a move is**, since $3 \to 12$ is nine rungs and an intensification while $11 \to 12$ is one rung and a transformation. The minimum folded separation at $N = 12$ is exactly $50/49 = 34.9756$ cents at the unique pair $7{:}10$, and the lattice falls off a cliff at $N = 17$ to

$289/288 = 6.0008$ cents and again at $N = 41$ to $1682/1681 = 1.0296$ cents. **Every one of these is a theorem about integers, and k cancels from all of them.**

What is established, and it is negative. The essence law has no time argument, so **a mood and a standing disposition at the same index are the identical tone**: at $n = 9$ both read 39.1575 Hz raw, 313.260 Hz folded, class 9. What separates them is the storage law's decay rate, whose half-life is $\ln 2/(-\ln(1-\delta))$ — 1.9434 cycles at $\delta = 0.30$ against a naive $1/\delta = 3.3333$, an overstatement of 71.52 per cent, and 34.3096 at $\delta = 0.02$, a ratio of 17.6544. **Durability and revisability are the same parameter read in two directions**, so there is no setting that is cheap at both. And **the tidiest available encoding of a framing destroys the measurement**: distinct one-hot vectors are orthogonal by construction, so every subject scores the ceiling $\ln 12 = 2.484907$ and the width 69.6133 Hz regardless of content. **An instrument whose failure mode is a uniformly favourable answer will be adopted enthusiastically and never questioned.** On the constructed Subject the honest overlapping reading is $F_{\text{int}} = 2.164390$ nats and 36.6686 Hz, and **two of the three drop-one removals raise it**, which settles that mean pairwise non-parallelism does not determine the joint geometry.

What is proposed rather than shown. That a dimensionless ratio of a tuning interval to the square of the golden section is a frequency; that the essence of an n-component state is kn^2; that octave equivalence may be carried from pitch to a quantity that is not a pitch; and that a way of construing a situation admits representation as a unit vector over twelve categories. **These four are postulates of this framework with no external support**, labelled at every appearance and separable from everything above: **a reader who rejects all four keeps the odd-part rule, the dichotomy, the regime, the mood/trait result and the degeneracy, restated as facts about integers, about unit vectors and about a first-order difference equation.**

What is conceded. The affect literature the ladder names does not underwrite a scalar index, an ordering, or a nesting, and one of its standing theses contradicts the ladder's top rung outright. That objection and Michell's are **the same objection twice** — scalar reduction in two domains — and the corpus should say so rather than meet each as a surprise.

What is not claimed at all. No person, tissue, cell, molecule, room or institution is claimed to resonate at any frequency named here. The twelve states are not diagnoses, a pitch class is not a type of person, and no reading in this paper is clinical, diagnostic, therapeutic or prognostic.

14 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number in the paper is the output of exact arithmetic on parameters stated in the text, computed in double precision except where the text says exact rational arithmetic was used; every case is constructed and is labelled as constructed at the point of use. The figures are generated by the Python scripts named in their captions, which take their inputs from the tables in the text and are available from the author on request. **No empirical measurement of any human being underlies any figure, table or number in this paper.** A frequency law reads as though something were measured; nothing was.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The Subject, the one-hot subjects and every constructed trajectory are invented parameter sets and are not derived from, and do not describe, any person. This paper asserts several perceptual and structural claims — that octave equivalence is a usable structure beyond pitch, that interval arithmetic in cents is the correct apparatus, and that a psychological state can be indexed by a count of components — **without any perceptual or psychometric experiment behind them.** Those claims rest on the cited literature, are limited by that literature's own

boundaries (§10.3), and **where the literature is in tension with them that tension is printed** (§4.4, L-6).

Preregistration. No test reported in this paper was preregistered, because no test was run. The one confirmatory fit attempted elsewhere in this corpus was preregistered and **failed its own second falsification rule** [Curzi, 2026i]; that outcome is reported here as it is reported there.

Disclosure of rendering constraints. Where any value in this paper is rendered as sound, the band and the transposition exponent are published with it, the values are exact ratios and must not be tempered, and **nothing may be masked, placed below threshold, or concealed from the listener.** A message hidden from its recipient cannot be consented to.

Clinical disclaimer. The twelve state classes are not diagnostic categories. Nothing in this paper is an assessment, a screening instrument, a treatment or advice about any person's health, and nothing in it may be presented as such.

Chapter 43

Consonance, Collision, and the Divided Self: A Firewall Between Harmonic Dissonance and Psychological Distress

Abstract. We audit the harmonic structure of the essence lattice and then block the inference the structure invites. Under two declared consonance measures — Tenney harmonic distance $\mathrm{HD}(p/q) = \log_2(pq)$ and Euler's *gradus suavitatis*, both badged as chosen functions on rationals rather than measured facts about hearing — squaring the index ratio doubles the harmonic distance exactly, so $\mathrm{HD}_{\text{ess}} = 2\log_2(pq)$ and $G_{\text{ess}} = 2G(pq) - 1$, verified over all sixty-six index pairs at $N = 12$. The consequence is an identity: the six most consonant pairs, at the global minimum $\mathrm{HD}_{\text{ess}} = 2.0000$, are exactly the six pitch-class collisions $\{1{:}2,\ 2{:}4,\ 3{:}6,\ 4{:}8,\ 5{:}10,\ 6{:}12\}$. Maximum consonance and maximum redundancy are the same event. The firewall result is that F_{int} cannot report on distress because it contains no term that could: relabelling state 10 as state 9 in the carried constructed subject leaves $F_{\text{int}} = 2.164390$ unchanged to 10^{-12} while removing the collision and changing the chord's class set, so the width does not even determine the chord. A restatement of one framing collapses the reading from $F_{\text{int}} = 2.164390$ and 36.6686 Hz to 1.333662 and 6.9620 Hz, a loss of 2.3970 octaves. At dyad scope $f_{\text{rel}} = k(1 + (N-1)u)^2$ is convex in u while cents are concave, so hertz and pitch disagree about which unit of nonparallelism is worth most. The constant $k = (9/8)^2/\varphi^2$ is defined, not measured, and its interpretation as a frequency is postulated.

Keywords: harmonic distance; gradus suavitatis; collision; internal surplus; relabelling invariance; firewall; relationship frequency; convexity

Series: C. Frequency, Essence, and Mind **Paper:** CCP-043

1 Introduction

A framework that assigns a frequency to a psychological state acquires, for free and without asking, an entire harmonic vocabulary. Once states have pitches, pairs of states have intervals; once there are intervals, some are consonant and some are not; and once that is on the page, a reader will complete the sentence. **The completion is always the same, and it is always wrong: a person whose internal states are harmonically dissonant is in psychological difficulty, and a person whose internal states are consonant is at ease.**

This paper audits the harmonic structure the framework actually has, and then blocks that inference formally rather than deprecating it. Both halves are necessary. Deprecating an inference is a request; blocking one is a proof that the quantity in question contains no term the inference could use.

The audit produces a result that is worth having in its own right. Under two declared consonance measures — Tenney's harmonic distance $\mathrm{HD}(p/q) = \log_2(pq)$ [Tenney, 2015] and Euler's *gradus suavitatis* [Euler, 1739], **both of them chosen functions on rationals and neither a measurement of anybody's hearing** — squaring the index ratio doubles the harmonic distance exactly. The essence lattice is therefore twice as harmonically remote as the corresponding integer lattice, everywhere, and the consequence is an identity: **the six most consonant index pairs at $N = 12$, at the global minimum $\mathrm{HD}_{\mathrm{ess}} = 2.0000$, are exactly the six pitch-class collisions.** Maximum consonance and maximum redundancy are the same event. A chord of framings that is comfortably related without being partly redundant is not merely hard to build in this lattice; it is not there.

That result is what makes the firewall necessary, because a reader who has just learned that consonance is redundancy will read redundancy as a deficiency and dissonance as a virtue, and from there will read internal difficulty as informative. **The formal block is that the internal surplus F_{int} is invariant under relabelling of the states**, so it does not determine the chord it is computed from — relabelling state 10 as state 9 in the carried constructed subject leaves $F_{\mathrm{int}} = 2.164390$ unchanged to twelve decimal places while removing a pitch-class collision and changing the chord's class set from three classes to four. A quantity that does not determine the chord cannot determine anything the chord does not determine, and the chord determines nothing about anybody's suffering. The inference fails two levels above where anyone would look for it.

The third part of the paper takes the same apparatus to the smallest relational unit. At dyad scope the relationship frequency is $f_{\mathrm{rel}}(u) = k(1 + (N-1)u)^2$, which is **convex** in the non-parallelism u, while the same quantity measured in cents is **concave**. Both statements are true and they are about different functions; the practical consequence is that hertz and pitch disagree about which unit of non-parallelism is worth most, and only one of them enters the sustainability verdict.

What this paper does not claim. The consonance measures are chosen, not measured. Consonance as heard depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005], roughness models make different predictions from ratio-complexity models [Plomp and Levelt, 1965, Kameoka and Kuriyagawa, 1969, Terhardt, 1974], and interval categories and octave equivalence generalise less far across listeners than is usually assumed [Burns, 1999, Burns and Ward, 1978, Hoeschele et al., 2012]. Octave equivalence itself is formalised for **pitch** [Shepard, 1982], with a measured size to its perceptual specialness [Demany et al., 2013]; **its extension to a quantity that is not a pitch is a modelling choice of this framework with no external warrant.** The constant $k = (9/8)^2/\varphi^2$ is a **defined** number whose two components are real — the Pythagorean whole tone [Barbour, 1951] and the golden section [Euclid, 1956] — and whose product, expressed as a frequency, has no precedent; the standard deflation of golden-section claims [Markowsky, 1992] is cited here and again wherever φ appears.

Contributions

1. The doubling theorem: $\mathrm{HD}_{\mathrm{ess}}(i,j) = 2\log_2(pq)$ and $G_{\mathrm{ess}} = 2G(pq) - 1$ for the essence ratio p^2/q^2, verified exhaustively over all sixty-six index pairs at $N = 12$.
2. The consonance–redundancy identity: the minimum $\mathrm{HD}_{\mathrm{ess}} = 2.0000$ is attained by exactly the six collision pairs and by nothing else; and zero folded separation holds **if and only if** two indices share an odd part, verified over all sixty-six pairs.
3. The firewall: F_{int} is invariant under relabelling and therefore does not determine the chord, which formally blocks any inference from the width statistic to distress or health.
4. The restatement collapse: replacing one framing with a paraphrase of another takes F_{int} from 2.164390 to 1.333662 and the chord width from 36.6686 to 6.9620 Hz — a loss

of 2.3970 octaves, more than a third of what the twelve-category ladder can supply.
5. The extremal chords at $N = 12$: the most consonant four-state chord is $\{1, 2, 4, 8\}$, mean $\mathrm{HD}_{\mathrm{ess}} = 3.3333$, six collisions from six pairs, **one** pitch class; the most dissonant is $\{7, 9, 10, 11\}$, mean 12.7586, no collisions, four classes, and an entirely unremarkable description of a person attending to a social situation.
6. The convexity result: $\mathrm{d}f/\mathrm{d}u$ rises from 10.6354 to 127.6244 Hz per unit u while $\mathrm{d}(\text{cents})/\mathrm{d}u$ falls from 38087 to 3174.
7. The eleven coincidences: $f_{\mathrm{rel}}(u) = km^2$ exactly at $u = (m-1)/(N-1)$, so a dyad's interval lands on a state's note at eleven exact values of u — an arithmetic coincidence to which this paper attaches no meaning, and says so.

2 Hypotheses, definitions, and postulates

Most of this paper is not hypothesis-testing, and saying so is the first honest act available to it. Sections 4 and 6 are exhaustive enumerations over a finite lattice: every claim in them is settled by computing all sixty-six pairs or all 495 four-state chords, and no observation could bear on them. Section 5 is a procedure. What follows separates the few claims that could be wrong from the many that are definitions, postulates or modelling choices.

2.1 Hypotheses proper

H1 — the relabelling hypothesis, as an empirical claim about use. If F_{int} carried information about distress, then chords with equal F_{int} and different collision structure would be associated with different distress. **Predicted:** no association, because the statistic contains no term that could carry one. **Falsified by:** a measured association between collision count and any distress measure, at fixed F_{int}, in a sample where the decomposition was fixed in advance. **Status:** the invariance itself is arithmetic and is proved in §4.6. The *empirical* prediction is untested. **No such sample exists and none was collected for this paper.**

H2 — the elicitation-stability hypothesis. A drop in F_{int} between two occasions reflects a change in what was elicited rather than a change in the person. **Predicted:** re-eliciting the same subject on the same situation with a different analyst recovers the earlier width more often than re-eliciting with the same analyst on a later occasion recovers it. **Falsified by:** the opposite ordering, or by no difference between the two. **Status: untested.** §5.14b sets out the double-coding procedure that would test it.

H3 — the ratio-scale hypothesis, inherited. The intensities carry ratio-scale information to the extent magnitude estimation delivers it [Stevens, 1957]. **Falsified by:** exponents that move with the experimenter's chosen stimulus range [Teghtsoonian, 1971] or by the response biases catalogued against the method [Poulton, 1968]. **Status: untested here**; carried from the minimum-frequency paper [Curzi, 2026], whose Result Seven measures the cost of the failure at 1065.05 cents.

H4 — the ceiling hypothesis, inherited. No relation with $c/\eta > \ln N$ sustains. **Falsified by:** one counterexample. **Status:** derived [Curzi, 2026]; **untested.** It remains the only strict universal in this series and therefore the only claim here that a single observation could kill.

2.2 Definitions — true by stipulation

- **Def. 1.** $\mathrm{HD}(p/q) := \log_2(pq)$, Tenney's harmonic distance on a ratio in lowest terms, defined in his 1983 essay on Cage and the theory of harmony and cited here from the collected edition [Tenney, 2015].

- **Def. 2.** $G(n) := 1 + \sum_i e_i(p_i - 1)$ over the prime factorisation, Euler's *gradus suavitatis* [Euler, 1739]; $G(p/q) = G(pq)$.
- **Def. 3.** A **collision** is a pair of indices whose folded separation is zero, equivalently (Theorem 4.2) a pair sharing an odd part.
- **Def. 4.** $F_{\text{int}} := \ln(1 + (N-1)\,\bar{u})$ on the mean pairwise non-parallelism of a set of framing vectors; the **chord width** is $k\,e^{2F_{\text{int}}}$.
- **Def. 5.** $k := (9/8)^2/\varphi^2 = 0.483425732988414$. **A defined constant**, exact by construction; the fifteen figures are exact digits of a definition and carry no measurement uncertainty, because nothing was measured.

2.3 Postulates — asserted, with no external support

- **P-a.** The essence law $f(n) = kn^2$, inherited [Curzi, 2026]. **No external support.** The exponent 2 is **defined by the model, not estimated from data**: no fit was performed, no alternative form was tested, and the goodness-of-fit and likelihood-ratio procedure a scaling claim requires [Clauset et al., 2009] was not run, because there is no data to run it on.
- **P-b.** The attachment of hertz to k. Computing $(9/8)^2/\varphi^2$ is arithmetic; asserting that the resulting dimensionless number **is a frequency** is a separate and much stronger claim, and no operational procedure is supplied by which the constant acquires the dimension of inverse time.
- **P-c.** The affine effective count $N_{\text{eff}} = 1 + (N-1)u$ [Curzi, 2026,c], a design axiom and **not a Hill number of any order**; the Hill family [Hill, 1973] and its rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly — as the corpus's concentration work uses them [Curzi, 2026] — and ground this construction not at all.

2.4 Modelling choices

- **M-a. Two consonance measures, both chosen.** Neither Tenney's harmonic distance [Tenney, 2015] nor Euler's gradus [Euler, 1739] is an experiment. They are defined functions on rationals, adopted because they are explicit and checkable, and where they disagree this paper publishes both and does not adjudicate. **Neither is a measurement of what any listener finds pleasant.** The measured literature runs on roughness and on the spectrum of the sound [von Helmholtz, 1885, Plomp and Levelt, 1965, Kameoka and Kuriyagawa, 1969, Terhardt, 1974, Sethares, 2005], and it does not agree with ratio complexity in general.
- **M-b. Octave reduction applied to a non-acoustic quantity** [Shepard, 1982, Demany et al., 2013]. The operation is well defined; its interpretation is a choice of this framework with no external warrant. Every claim in §4.4 that involves *folding* is a claim about arithmetic, not about hearing.
- **M-c.** $N = 12$, inherited, and not shown to be the right twelve [Curzi, 2026].
- **M-d. Non-negative intensities.** The encoding cannot represent an internal framing that is the negation of another, which makes the opposition branch of the collapse result unreachable at internal scope. This is a real limitation of the encoding and is stated as one in §4.5.

2.5 What is expository

Section 5 is a worksheet: a procedure with blanks, whose organising question is *what must be recorded alongside a personal reading so that a second analyst can recompute it and disagree with it in a specific place.* It argues no claim and tests no hypothesis. Its value is procedural, and §5.1 says so in the paper's own words.

3 Framework, dimensional audit, and method

3.1 What is inherited and what is new

The essence law, the twelve-state ladder and the elicitation procedure are inherited [Curzi, 2026]; the fold and the odd-part class rule are inherited [Curzi, 2026]; the effective count and its logarithmic ceiling are inherited [Curzi, 2026c]; the doubling of harmonic distance was first established for the relational lattice in Series B [Curzi, 2026l], and is re-proved here because the proof is three lines and the paper should not rest on a reference for something a reader can check. **What is new is the identity between the consonance minimum and the collision set, the relabelling firewall, the extremal-chord enumeration, and the convexity result at dyad scope.**

3.2 Analogy discipline

Every borrowing in this paper is category 2 — a shared mathematical form — and none is category 1. The lattice arithmetic of ratios, harmonic distance and octave equivalence is genuine mathematics and genuine music theory, and it is used because the same arithmetic applies, not because any physical or perceptual result transfers. **The frequency interpretation sitting on top of it is category 3, an analogy**, and it is labelled as one at every appearance. The failure mode the standard names — letting a category-2 or category-3 use borrow the certainty of a category-1 derivation — is exactly the failure this paper's firewall exists to prevent, one level up. The wider programme of statistical physics applied to social dynamics has a survey that fixes what such models may be held to [Castellano et al., 2009], and its boundaries are the boundaries claimed here.

3.3 Dimensional audit

symbol	quantity	dimension	unit	status
i, j, n	state indices	$[1]$	—	absolute scale; counts
p/q	index ratio in lowest terms	$[1]$	—	exact rational
HD, $\mathrm{HD}_{\mathrm{ess}}$	harmonic distance	$[1]$	bits	$\log_2$ of a pure number
G, G_{ess}	gradus suavitatis	$[1]$	—	integer-valued
cents	interval	$[1]$	cents	$1200 \log_2$ of a ratio
u, $\bar{u}$	non-parallelism	$[1]$	—	dimensionless, $[0, 1]$
F_{int}	internal surplus	$[1]$	nats	a logarithm of a count
k	reference constant	$[T^{-1}]$ **asserted**	Hz **asserted**	**defined as a dimensionless ratio; the unit is postulated**
f, f_{rel}, f_{width}	essence frequency	$[T^{-1}]$	Hz	inherits its dimension entirely from k
η, c, δ	conversion, cost, decay	see [Curzi, 2026]	per declared period	ratio-scaled **by assumption**

Does it balance? Everything in Sections 4 and 6 that is expressed as a *ratio, an interval, a distance or a class* is dimensionless and balances exactly, and none of it depends on k. Every quantity expressed in **hertz** balances only because k is asserted to carry $[T^{-1}]$, and **the source supplies no operational procedure by which it acquires that dimension.** This is stated again in §10 by name. The practical consequence is a clean separation: *the harmonic results of this paper are dimensionally sound; the frequency labels attached to them are not.*

3.4 Scale type, and the strongest objection

HD and G are functions of exact rationals and inherit the absolute scale of the indices. F_{int} is a logarithm of an affine function of u and is ratio-scaled given that u is; u is ratio-scaled given that the intensities are, which requires magnitude estimation to deliver what it is held to deliver [Stevens, 1957] and is disputed [Teghtsoonian, 1971, Poulton, 1968, Krueger, 1989]. **The strongest single objection to this framework is Michell's** — that psychology assumes quantitative structure without testing for it [Michell, 1997, 1999]. It applies here in full. The formal remedies exist [Luce and Tukey, 1964, Krantz et al., 1971, Rasch, 1960] and **none was run.** Permissible operations on a statistic are fixed by its scale type, and what follows from a scale type for the permissibility of a statistic is itself disputed [Luce, 2002]; a raw surplus figure without its ceiling $\ln N$ is not interpretable, and this paper reports the ceiling wherever it reports a surplus.

3.5 The aggregate does not determine the joint structure

The firewall of §4.6 is a special case of a general fact worth stating separately, because it recurs across the corpus. **A summary statistic computed from a set does not determine the set.** Three incompatible constructs travel under the word *diversity* — separation, variety and disparity [Harrison and Klein, 2007] — and a single number in one of them fixes nothing in the others; the problem-solving result usually cited for diversity [Hong and Page, 2004] carries a standing formal objection [Thompson, 2014] that must be cited with it; and aggregation over heterogeneous units does not in general yield a representative unit [Kirman, 1992]. The relabelling demonstration is the sharpest available instance: two chords, identical width to twelve decimal places, different class sets, different collision counts.

3.6 Identification — the objection this framework cannot presently answer

The corpus's reflexive loop $T(x) = W(x, M(x))$ [Curzi, 2026] is a linear-in-means reflexive specification, and **the endogenous social effect in such a specification is not identified from observational data** [Manski, 1993]; influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. This paper adopts the remedy of **stipulation** — the reference set is the declared twelve-state ladder and the declared decomposition, fixed in advance and published with every reading, which is what makes a restricted treatment of social interaction defensible where an unrestricted one is not [Brock and Durlauf, 2001]. **The reflexive claim is accordingly a modelling position, not an identified empirical result.**

The exposure is sharper here than elsewhere in the corpus, because this paper's subject is a reading of a person's internal state, and **a published reading of an internal state is exactly the kind of thing that can make itself true.** Expectancy effects are real [Rosenthal and Jacobson, 1968, Merton, 1948], a theory becoming true by being used has been documented in the field with dates and prices [MacKenzie and Millo, 2003], classification changes the classified [Hacking, 1995], and a taught theory can become self-validating [Ferraro et al., 2005]. Against that: the best long-run assessment of the classroom case finds self-fulfilling prophecies **real but small**, not typically cumulative, and often dissipating, with most expectations turning out to be accurate rather than causal [Jussim and Harber, 2005], and the effect sizes attached to one famous instance are contested [McCambridge et al., 2014]. **The separation statement of SPEC-4.3 is mandatory for this reason and not as a courtesy.** It is also why the framework's

own parameters cannot consistently be exempted from its own reflexivity [Lucas, 1976] — an inconsistency this paper states rather than resolves.

3.7 Method

Every number in this paper is exact arithmetic on stated inputs. The sixty-six pair values and the 495 four-state chords were enumerated exhaustively; the identities in §4.4 are biconditionals verified over the complete lattice, not tendencies estimated from a sample. **No observational data were collected, no human subjects participated, no perceptual experiment was run, and no empirical dataset underlies any figure, table or number.** Every case is constructed and labelled as constructed. The figures are produced by the scripts named in their captions.

4 Dissonance and the divided self

The octave-folding paper [Curzi, 2026] established that a person holding several framings at once is a chord, that its intervals are ratios of squares, and that its width is the internal surplus `F_int`. It left one question deliberately open. The carried Subject's chord contains states 5 and 10, which fold to the identical pitch. Is that a redundancy in the Subject, or only a redundancy in the vocabulary the ladder makes available?

This section answers it, and the answer is uncomfortable enough that the section has to be built around a firewall rather than around a result.

The harmonic-lattice analysis of Series B [Curzi, 2026l] proved that the essence lattice **doubles** Tenney harmonic distance: every essence pair is exactly twice as harmonically remote as the corresponding integer-ratio pair. From that theorem a second result follows immediately, and the harmonic-lattice analysis of Series B [Curzi, 2026l] stated it:

> **CONSONANCE IS REDUNDANCY.** The pairs that sound most related are precisely the pairs that occupy the same pitch class — the pairs the lattice cannot distinguish. **In the essence lattice, harmonic agreement and informational redundancy are the same phenomenon.**

Carry that into the internal scope of the octave-folding paper [Curzi, 2026] and the consequence is arithmetic and immediate:

```
A PERFECTLY CONSONANT SELF IS A PERFECTLY REDUNDANT ONE

    all framings parallel    =>   u_int = 0
                             =>   N_eff = 1 + 11 * 0 = 1
                             =>   F_int = ln 1 = 0 nats
                             =>   f_width = k * 1^2 = k = 0.4834 Hz, the ground essence
```

Zero surplus. No width. A single note played several times.

That sentence is true, it is derived rather than asserted, and it is also the sentence in this framework most likely to be misused. So before the section proves anything, it fixes what it is and is not claiming, and it will fix it again in the middle and again at the end.

> **THE SEPARATION, STATED FIRST AND RESTATED THROUGHOUT.**
>
> **This analysis is about information content. It is not about pain.**
>
> `F_int` measures how much order is available in a set of framings under a stated encoding. It does not measure distress, and it does not measure well-being. **Internal difference that generates surplus is NOT distress, and distress is not a source**

of surplus. They are different quantities, they are not computed from each other, and the formalism contains no term that would connect them.

Nothing in this section recommends suffering, values suffering, or claims that suffering is informative. Nothing in it is clinical advice, and the twelve states are not diagnoses. A person in pain is not thereby better instrumented, and a person at ease is not thereby impoverished.

The section says exactly one thing about redundancy, and it is a statement about an encoding: **framings that make the same assignments carry the same information once.** That is all it says, and §4.6 shows formally why nothing further can be derived from it.

All cases in this section are CONSTRUCTED and labelled as such, and every extension of the carried Subject is labelled as an extension.

The Law

4.1 What "dissonance" means here, and the four things it does not mean The word is doing technical work and it will be misheard unless the work is specified.

```
DISSONANCE, IN THIS FRAMEWORK

    A computed property of a PAIR OF INDICES.
    Given indices i and j, reduce j/i to p/q in lowest terms; the essence interval is
    p^2/q^2; its dissonance is a chosen distance measure on that ratio.

    It is a fact about arithmetic. It contains no term for a person, an experience,
    a preference, or a state of health.
```

Four things it is not, listed because each has been read into the word by someone reading a draft of this section:

It is not psychological conflict. Two framings can be maximally non-parallel and coexist without friction. Reading a colleague's message as a threat and also as an episode in a long story are not at war; they are two things a person is doing at once, and a person can do both comfortably.

It is not ambivalence. Ambivalence is a state about a decision. Dissonance here is a relation between indices, computed before any decision is in view.

It is not distress. This is the load-bearing one and it is the subject of §4.6.

It is not cognitive dissonance in the social-psychological sense. That is a different construct with its own literature, its own operationalisations, and no relation to the arithmetic here beyond a shared word. This framework does not import it, does not cite it as support, and does not claim its findings. Where a term collides with an established construct, the collision is named and the constructs are kept apart.

4.2 The two consonance measures, both chosen The harmonic-lattice analysis of Series B [Curzi, 2026l] used two indices and this section uses the same two, with the same badge.

```
TENNEY HARMONIC DISTANCE       HD(p/q) = log2(p * q)
    Tenney, "John Cage and the Theory of Harmony", 1983; From Scratch, Illinois, 2015.
    A defined measure of the complexity of a frequency ratio. Larger = more remote.
```

```
EULER'S GRADUS SUAVITATIS      G(n) = 1 + sum over prime factors of e_i * (prime_i - 1)
    Euler, Tentamen novae theoriae musicae, 1739.  G(p/q) = G(p*q). Larger = less smooth.
```

BOTH ARE CHOSEN MEASURES WITH A DEFINED ARITHMETIC, NOT MEASURED FACTS ABOUT HUMAN HEARING [POSTULATE]. Neither is an experiment. They are defined functions on rationals, adopted because they are explicit and checkable. Where they disagree, the framework publishes both and does not adjudicate.

The primary sources, and a correction to how the first of them is usually cited. The *gradus suavitatis* is Euler's, from the *Tentamen novae theoriae musicae* of 1739 [Euler, 1739]. Harmonic distance is Tenney's, and it matters *which* Tenney: the measure is defined in his 1983 essay "John Cage and the Theory of Harmony", cited here from the collected *From Scratch* [Tenney, 2015], where harmonic space is a lattice, harmonic distance is its city-block metric, and $\mathrm{HD}(f_a, f_b) \propto \log a + \log b = \log(ab)$. **It is not defined in Tenney's better-known *A History of 'Consonance' and 'Dissonance'* (1988), which is a historical survey of the two concepts and not the source of this function.** The distinction is recorded because the 1988 volume is the work a reader is likeliest to reach for on the strength of its title, and because the source manuscript of this paper named the measure by its author's surname alone, with no year and no work attached — an attribution that is incomplete rather than incorrect, but which resolves to the wrong book if a reader completes it in the obvious way.

4.3 The doubling theorem, restated

THE DOUBLING THEOREM (Series B, the harmonic-lattice analysis of Series B [Curzi, 2026l]). *For any index pair reducing to `p/q`, the essence interval `p^2/q^2` has exactly twice the Tenney harmonic distance of the ratio `p/q`, and Euler gradus `2G - 1`.*

Proof. `HD(p^2/q^2) = log2(p^2 q^2) = 2 log2(pq) = 2 HD(p/q)`. For the gradus: squaring doubles every exponent in the prime factorisation of `pq`, so the sum `sum e_i (prime_i - 1)` doubles, and `G(p^2 q^2) = 1 + 2 sum e_i (prime_i - 1) = 2(1 + sum e_i (prime_i - 1)) - 1 = 2 G(pq) - 1`. ■

Verified exhaustively over all sixty-six pairs `1 <= i < j <= 12`; both identities exact in every case.

Consonance is scarce in the essence lattice, and it is scarce by a factor of exactly two. The perfect fifth `3:2` — the most consonant interval after the octave in ordinary just intonation — becomes `9:4` here, an octave plus a whole tone, at double the harmonic distance. The major third `5:4` becomes `25:16`.

There is a consequence of the doubling that matters specifically at internal scope and that Series B, working at relational scope, had no occasion to draw.

A chord built on the essence ladder cannot contain a mild interval. In ordinary just intonation a set of four pitches will typically contain several relations of low harmonic distance — fifths, thirds, fourths — and the ear has somewhere to rest. In the essence lattice every one of those relations has been pushed to twice its distance, so the only low-distance relations that survive are the ones that were already trivial: the octave-equivalent pairs, which are the collisions. The lattice offers exactly two kinds of interval — the redundant kind and the remote kind — and almost nothing in between.

Look at the ranking below and the shape is immediate: six pairs at `HD_ess = 2.0000`, then a gap to 3.1699, and then a long tail running to 14.0888 with fifty-six of the sixty-six pairs above 3.1699. The distribution is not a gradient. It is a small cluster of redundancies and a large spread of remoteness. That is what "consonance is scarce by a factor of exactly two" looks like when the scarcity is enumerated rather than described.

For a section about the internal case, the reading is this: **there is no such thing as a chord of framings that is comfortably related without being partly redundant.** The middle ground

the metaphor promises — framings that harmonise without repeating — is not a region of this lattice. It is not that it is hard to reach. It is not there. Whether that is a discovery about selves or an artefact of the square law is exactly the kind of question this framework is obliged to leave open, and it leaves it open: **the doubling theorem is a theorem about ratios, and the square law under it is a postulate.**

4.4 The identity: the most consonant pairs are exactly the collisions Rank all sixty-six index pairs at `N = 12` by essence harmonic distance. The head of the list:

HD_ess	G_ess	pair	essence ratio	raw cents	folded cents	same class?
2.0000	3	1:2	4/1	2400.00	0.0000	YES
2.0000	3	2:4	4/1	2400.00	0.0000	YES
2.0000	3	3:6	4/1	2400.00	0.0000	YES
2.0000	3	4:8	4/1	2400.00	0.0000	YES
2.0000	3	5:10	4/1	2400.00	0.0000	YES
2.0000	3	6:12	4/1	2400.00	0.0000	YES
3.1699	5	1:3	9/1	3803.91	203.9100	no
3.1699	5	2:6	9/1	3803.91	203.9100	no
3.1699	5	3:9	9/1	3803.91	203.9100	no
3.1699	5	4:12	9/1	3803.91	203.9100	no
4.0000	5	1:4	16/1	4800.00	0.0000	YES
4.0000	5	2:8	16/1	4800.00	0.0000	YES
4.0000	5	3:12	16/1	4800.00	0.0000	YES
4.6439	9	1:5	25/1	5572.63	772.6274	no
...						
14.0888	29	11:12	144/121	301.27	301.2741	no

Three exact statements follow, and the section is careful to give the precise ones rather than the convenient one.

> **(A) THE MINIMUM IS EXACTLY THE 2:1 COLLISIONS.** The minimum essence harmonic distance over all sixty-six nontrivial pairs is `HD_ess = 2.0000`, and it is attained by exactly six pairs: `{1:2, 2:4, 3:6, 4:8, 5:10, 6:12}`. Every one of them is a pitch-class collision, and no non-collision attains it. Verified exhaustively.
>
> **(B) ZERO FOLDED SEPARATION IS EXACTLY COLLISION.** Across all sixty-six pairs, the folded interval is exactly 0.0000 cents **if and only if** the two indices share an odd part. Verified exhaustively: true for all ten collision pairs, false for all fifty-six others. This is a biconditional, not a tendency.
>
> **(C) THE HONEST CAVEAT — the ordering is not total.** It is **not** true that every collision is more consonant than every non-collision. `1:3` sits at `HD_ess = 3.1699`, more consonant than the collisions `1:4` (4.0000), `2:8` (4.0000), `3:12` (4.0000) and `1:8` (6.0000). The collision set is dramatically more consonant on average — mean `HD_ess` 3.0000 over the ten collisions against 8.6617 over the fifty-six non-collisions — but the ranges overlap and the framework says so.

Statement (C) is the kind of thing an account drops when it wants a clean slogan. It is kept because The harmonic-lattice analysis of Series B [Curzi, 2026l]'s own rule requires it: **where two defensible indices disagree, or where a claim is true at the extremum but not across the order, publish the precise version.** The slogan "consonance is redundancy" is exactly true at the minimum and true on average; it is not a total order, and a reader who builds on the total-order version will eventually be wrong about `1:4`.

One more exact fact from the same table, carried forward because the Subject will need it:

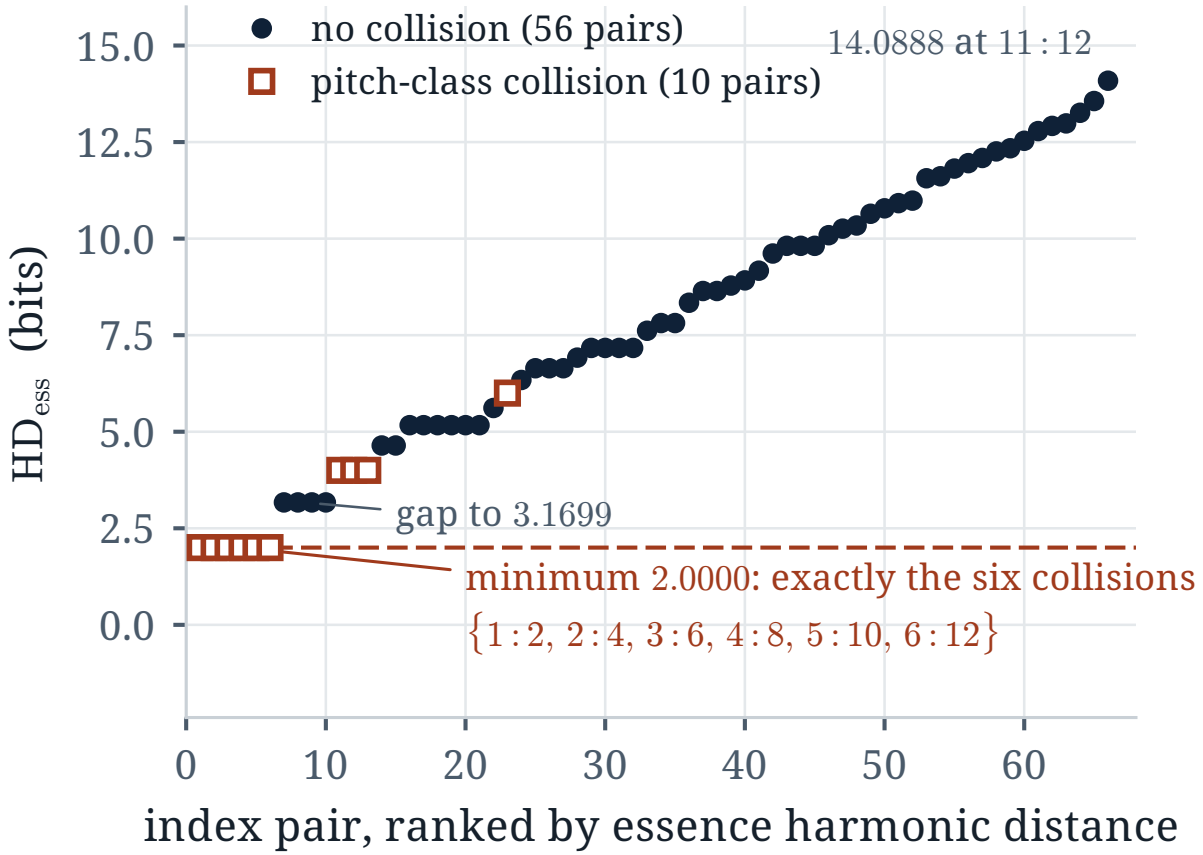

Figure 43.1: Consonance in the essence lattice is a small cluster of redundancies and a long tail of remoteness, not a gradient: six pairs sit at the global minimum 2.0000 and every one of them is a pitch-class collision, then a gap to 3.1699, then a tail to 14.0888. Enumerated over all sixty-six index pairs at $N = 12$ from $\mathrm{HD}_{\mathrm{ess}} = 2\log_2(pq)$ — a complete enumeration, not a sample. The measure is a **chosen** function on rationals and not a measurement of hearing (§2.4 M-a). Built by `figs/src/CCP-043_fig01.py`.

```
The smallest NONZERO folded separation in the whole N = 12 lattice is 34.9756 cents,
= 1200 * log2(50/49), and it is attained by EXACTLY ONE pair: 7:10.
```

The octave-folding paper [Curzi, 2026] established that `N = 12` sits below the `N = 17` minimum-gap cliff and that the framework therefore renders in the 50/49 regime. The pair that realises the regime is unique, and it is `7:10`.

4.4b The extremal chords, computed The identity in (A) and (B) has a consequence that can be exhibited rather than argued: among all four-state chords available at `N = 12` — there are `C(12,4) = 495` of them — there is a most consonant one and a most dissonant one, and they are what the identity predicts.

```
EXTREMAL FOUR-STATE CHORDS AT N = 12   (all 495 enumerated)

MOST CONSONANT   {1, 2, 4, 8}
    mean HD_ess = 3.3333   min = 2.0000   max = 6.0000
    collisions  = 6 of 6 pairs           pitch classes = 1

MOST DISSONANT   {7, 9, 10, 11}
    mean HD_ess = 12.7586  min = 11.9546  max = 13.5627
    collisions  = 0 of 6 pairs           pitch classes = 4

THE SUBJECT      {3, 5, 7, 10}
    mean HD_ess = 8.4882   min = 2.0000   max = 12.2586
    collisions  = 1 of 6 pairs           pitch classes = 3
```

The most consonant four-state chord in the entire system is a chord of one pitch class. States 1, 2, 4 and 8 all have odd part 1; every one of their six pairs is a collision; folded, all four arrive at 247.514 Hz — one note, four times. That is the identity made visible: maximal consonance is maximal redundancy, and here they are the same chord.

The other pole is equally instructive. `{7, 9, 10, 11}` has no collisions at all, four distinct classes, and a mean harmonic distance nearly four times the consonant extreme. It is also, and this is worth noticing, an entirely ordinary set of states: reflexive, normative, narrative, and reciprocal feeling. **Nothing about holding those four components is difficult, unusual, or distressing. The chord is maximally dissonant in the lattice's arithmetic and completely unremarkable as a description of a person attending to a social situation.** If ever a case were needed against reading harmonic dissonance as psychological difficulty, this is it, and it is enumerated rather than asserted.

Two further counts from the same enumeration, useful for calibration:

```
of the 495 four-state chords at N = 12:
    159 have ZERO collisions               (32.1%)
    the maximum possible collision count in a four-state chord is 6,
    attained only by {1, 2, 4, 8}
the single-class families are: {1,2,4,8}, {3,6,12}, {5,10}, and singletons
```

Only three pitch classes at `N = 12` contain more than one index — class 1 with four members, class 3 with three, class 5 with two. Classes 7, 9 and 11 are singletons, so any pair drawn from `{7, 9, 11}` and any state outside their own doubling is automatically collision-free. The redundancy structure of the whole lattice is that small and that explicit, and it is entirely a fact about which integers under twelve are powers of two times which odd numbers.

4.5 The consequence at internal scope Now put (A) and (B) together with the octave-folding paper [Curzi, 2026]'s construction.

Two framings that assign intensity in the same proportions across the same states are, after normalisation, the **same unit vector**. Their inner product is 1, their `u` is 0, and they contribute nothing to the mean. Extend to a whole roster:

```
THE REDUNDANT SELF

    every pair parallel   =>   u_int = 0
                          =>   N_eff = 1
                          =>   F_int = ln 1 = 0
                          =>   f_width = k = 0.483426 Hz
                          =>   octaves above ground = 0.0000
```

A person with forty ways of describing their situation, all of them the same description in different words, has an internal surplus of exactly zero. The internal-surplus analysis of Series B put it as a single window with forty panes. They will experience this as thoroughness, because forty descriptions feel like forty descriptions, and the arithmetic is the only thing in the room that knows otherwise. The external analogue is well documented: informational cascades make a sequence of independent-looking judgments carry the information of the first one only [Bikhchandani et al., 1992, Banerjee, 1992], and social influence measurably collapses the effective number of independent estimates in a group [Lorenz et al., 2011]. **Apparent breadth is not breadth**, and this framework's arithmetic is one more instrument that says so.

And the harmonic version of the same statement: the chord such a person produces sits entirely inside one pitch class if the framings share support, or spans several pitches with zero width if they do not. The most consonant possible internal chord is the one with the least in it.

There is a branch of this that Series B's CC-R8 makes at relational scope, and it deserves its internal statement here because at internal scope it behaves differently.

> **CC-R8 AT INTERNAL SCOPE, AND ITS LIMIT.** Because `u = 1 − cos^2 theta`, perfect opposition (`cos = −1`) gives `u = 0` exactly as perfect agreement does — the contrarian and the sycophant sound the identical note. The relationship-frequency paper [Curzi, 2026], whose three-route concordance holds the carried dyad to a 70.52-cent spread, owns that result at relational scope. Internally, the opposition branch is UNREACHABLE under this framework's encoding, because intensities are non-negative by construction, so `cos theta >= 0` for every pair of framing vectors and `u = 0` can arise only from parallelism. Verified: over 100,000 random non-negative unit pairs the minimum observed cosine was 0.260867, and the bound `cos >= 0` is exact, not empirical.

That is a real limitation of the internal encoding and it is stated as one. A framing that is the exact negation of another cannot be represented here, because the twelve states record which components a construal requires, not which direction it points. A reader who wants an internal analogue of the contrarian must build a signed encoding, and this framework does not have one.

4.6 THE FIREWALL — why nothing about distress follows, formally This is the section the section exists for, and it makes a formal argument rather than a reassurance, because reassurances are ignored and arguments can be checked.

The claim to be blocked is: *low `F_int` indicates a problem, high `F_int` indicates health, and therefore internal difference — including painful internal difference — should be sought.*

Every step of that is unsupported, and the formalism can be made to demonstrate it.

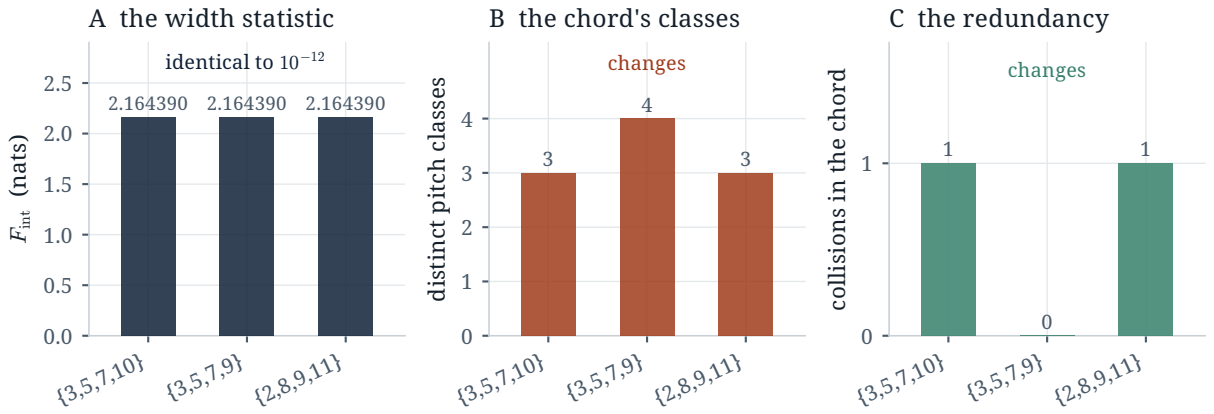

Figure 43.2: The width statistic does not determine the chord: three relabellings of the same constructed subject give internal surplus identical to twelve decimal places while the number of distinct pitch classes and the collision count both change. Since F_{int} does not fix the chord, it cannot fix anything the chord does not fix. **Modelled, not measured:** the subject and its relabellings are constructed parameter sets; relabelling permutes coordinates and therefore leaves every inner product exactly unchanged. Built by `figs/src/CCP-043_fig02.py`.

First: `F_int` is a function of `u_int` alone, and `u_int` is a mean of pairwise angles. It contains no term for valence, for intensity, for duration, for the subject's evaluation of any framing, or for anything else that a word like "distress" would have to refer to. A quantity cannot report on a variable it does not contain.

Second, and stronger: `F_int` is invariant under relabelling of the states, so it does not even determine the chord. Take the carried Subject and relabel state 10 as state 9, leaving every intensity untouched. Inner products are unchanged, because relabelling is a permutation of coordinates:

```
THE RELABELLING TEST  (EXTENSION 3.1-e of the carried Subject, LABELLED)

SUBJECT, states {3,5,7,10}
    u = 0.388360, 0.904762, 0.809410     u_int = 0.700844
    F_int = 2.164390    N_eff = 8.7093    f = 36.6686 Hz
    pitch classes {3,5,7} -- THREE      collisions: (5,10)
    chord HD_ess: 7.8138 8.7846 9.8138 10.2586 2.0000 12.2586   mean 8.4882  min 2.0000

RELABELLED 10 -> 9, states {3,5,7,9}
    u = 0.388360, 0.904762, 0.809410     u_int = 0.700844
    F_int = 2.164390    N_eff = 8.7093    f = 36.6686 Hz
    pitch classes {3,5,7,9} -- FOUR     collisions: NONE
    chord HD_ess: 7.8138 8.7846 3.1699 10.2586 10.9837 11.9546   mean 8.8275  min 3.1699

difference in F_int: 0.000000000000
```

Two chords with identical internal surplus to twelve decimal places: one contains a pitch-class collision, the other contains none. A third relabelling, to states `{2,8,9,11}`, again gives `F_int = 2.164390` exactly, with classes `{1,9,11}` and the collision `(2,8)`.

> **THE FIBER ARGUMENT.** `F_int` is many-to-one on chords. Chords that differ in their state set, their pitch classes, their collision structure, and their entire harmonic content map to the same `F_int`. A quantity that does not determine the chord cannot determine anything the chord does not determine, and the chord determines

nothing about a person's suffering. The inference from `F_int` to distress fails two levels above where anyone would look for it.

Third: the four quadrants are all occupiable, and the formalism forbids ruling any of them out.

- *High `F_int`, no distress.* A person who reads a situation three genuinely different ways and is perfectly comfortable doing so. Nothing in the construction prevents this. It is probably the common case.
- *High `F_int`, severe distress.* The same structure in someone having a terrible week. The arithmetic is identical.
- *Low `F_int`, no distress.* A person with a settled, coherent single reading of a situation, at ease. The formalism calls this zero surplus. It does not call it a problem.
- *Low `F_int`, severe distress.* A person locked into one construal they cannot escape.

All four are consistent with the formalism, because the formalism has nothing to say about the second coordinate. A measure that is compatible with every value of a variable carries no information about that variable. That is the firewall, and it is a theorem about the construction rather than a promise about its use.

Fourth, the ethical statement, which does not follow from the arithmetic and is made on its own authority: nothing in this framework recommends that anyone acquire, retain, or cultivate suffering. **Suffering is not a resource, is not an input to any equation here, and appears nowhere in the formalism.** Where a reader finds a sentence in this framework that seems to praise internal division, that sentence is about the *width of an encoding of construals* and about nothing else, and it should be read that way or discarded.

Fifth, the clinical statement, restated because it is a standing prohibition of this framework: **the twelve states are not diagnoses. A chord reading is not an assessment. No claim, diagnostic, therapeutic, or prognostic, is made anywhere in this section, and nothing here is advice about any person's care.** A reader who wants to know whether something is wrong should ask someone qualified to answer that, and this instrument is not qualified to answer it and does not attempt to.

The Engineering

4.7 The consonance audit of a chord Given a chord — a set of spanned states from the octave-folding paper [Curzi, 2026]'s SPEC-9.2 — three quantities summarise its harmonic content, and all three are computed from the index set alone.

```
CONSONANCE AUDIT

    for every pair (i, j) in the chord, with j/i reduced to p/q:
        HD_ess(i,j)  = 2 * log2(p * q)
        G_ess(i,j)   = 2 * G(p*q) - 1
        folded cents = ( 1200 * log2(j^2/i^2) ) mod 1200

    MIN HD_ess       the chord's most consonant interval
    MEAN HD_ess      the chord's overall remoteness
    COLLISION COUNT  the number of pairs with folded cents = 0
                     equivalently, pairs sharing an odd part
```

The collision count is the redundancy count, by result (B), exactly. It is not a proxy and not an estimate: folded separation is zero if and only if the odd parts agree, so counting collisions and counting exact pitch-class redundancies are the same operation.

4.8 What a collision costs and what it does not Here is where the section must be careful in the second direction, because having established that consonance is redundancy it would be easy to conclude that collisions are waste. **The arithmetic does not support that.**

A collision means two states occupy one pitch class. It **costs** exactly one thing: a position in the harmonic vocabulary, of which `N = 12` supplies only `ceil(12/2) = 6`. A chord with a collision occupies fewer distinct classes than its state count, and that is a real constraint on what the folded chord can express.

It does **not** cost the following, and each is worth denying explicitly:

It does not cost surplus. `F_int` is computed from framing angles, not from the chord's index set. The relabelling test in §4.6 shows a collision appearing and disappearing with `F_int` fixed to twelve decimal places. Collisions and surplus are independent.

It does not mean the two states are the same component. State 5 is attributed feeling — a construal that names a cause. State 10 is narrative feeling — a construal that places the situation in a story. The ladder says these differ by five components of specification. They collide in pitch class because `10 = 2 * 5` and the odd-part rule folds by powers of two. That is a property of the arithmetic of the index, not a claim that the two components are interchangeable.

It does not mean the raw chord has fewer notes. In the raw chord states 5 and 10 are 12.0856 Hz and 48.3426 Hz — two octaves apart, two distinct pitches. Only the fold makes them one.

So what *is* a collision, honestly stated?

> **A COLLISION IS A LIMIT ON THE FOLDED REPRESENTATION, NOT A FINDING ABOUT THE SUBJECT.** It says that if this chord were rendered by octave transposition into a single band, two of its members would arrive at the same place. Everything a collision reports is a fact about the index ladder and the fold. Nothing it reports is a fact about the person.

That is the answer to the question the octave-folding paper [Curzi, 2026] left open, and it is deliberately the deflationary one.

4.9 The restatement collapse, and how fast it happens The genuine internal redundancy — the one that *does* cost surplus — is not a pitch-class collision. It is near-parallel framings, and it is expensive.

```
EXTENSION 3.1-a OF THE CARRIED SUBJECT (LABELLED): the threat framing, restated
three times in different words. Same shape, small perturbations.

    t1 = {3:0.80, 5:0.40, 7:0.20}
    t2 = {3:0.78, 5:0.42, 7:0.21}
    t3 = {3:0.82, 5:0.38, 7:0.19}

    u = 0.001034, 0.001005, 0.004074     u_int = 0.002038
    N_eff = 1.0224     F_int = 0.022166 nats
    f_width = 0.5053 Hz   (against the ground essence k = 0.4834 Hz)
    octaves above ground = 0.0640
```

Three framings, and 0.0640 octaves of width. The subject has produced three descriptions and one framing. They will experience this as having thought about it from several angles.

The exactly-parallel version removes even the perturbation:

```
EXTENSION 3.1-b (LABELLED): the same framing at three intensities.

    p1 = {3:0.8, 5:0.4, 7:0.2}
    p2 = {3:1.6, 5:0.8, 7:0.4}      (everything twice as strong)
```

```
p3 = {3:0.4, 5:0.2, 7:0.1}      (everything half as strong)

u = 0.000000, 0.000000, 0.000000     u_int = 0.000000
N_eff = 1.0000     F_int = 0.000000 nats
f_width = 0.483426 Hz = k exactly
octaves above ground = 0.0000
```

Scaling a framing changes nothing. This is the invariance of the octave-folding paper [Curzi, 2026] seen from the other side: feeling the same thing more strongly, or less strongly, moves the reading by exactly zero. **The instrument reads composition, not amplitude, and here that means a person who is having a much harder time has not thereby acquired any surplus.** That is the arithmetic contradicting the romanticised reading directly, in the place where the romanticised reading would most like to be true.

4.10 The cost of one substitution The most instructive intermediate case replaces one of the Subject's three framings with a near-copy of another and computes what it costs.

```
EXTENSION 3.1-d OF THE CARRIED SUBJECT (LABELLED): mirror replaced by a
restatement of threat.

    threat  = {3:0.8,  5:0.4,  7:0.2}     unchanged
    story   = {3:0.5,  5:0.7, 10:0.4}     unchanged
    mirror' = {3:0.78, 5:0.42, 7:0.21}    a restatement of threat

    u(threat, story)   = 0.388360     unchanged
    u(threat, mirror') = 0.001034     was 0.904762
    u(story,  mirror') = 0.372856     was 0.809410

    u_int   = 0.254083      was 0.700844
    N_eff   = 3.7949        was 8.7093
    F_int   = 1.333662      was 2.164390
    f_width = 6.9620 Hz     was 36.6686 Hz
    octaves = 3.8481        was 6.2451

    LOSS: -0.830728 nats = -2.3970 octaves
```

The marginal contribution of one member to a set's effective count is a quantity the corpus measures elsewhere in a different domain: removing one corridor from a four-member bloc moves the bloc-HHI to 0.391448 and the effective count to 2.5546, so 11.8 per cent of exposure buys 0.014316 of surplus — 3.79 per cent of the total gain [Curzi, 2026]. The arithmetic here is the same shape and the conclusion is the same: **a member that duplicates another contributes almost nothing, and the loss is computable in advance.**

Substituting one framing for a restatement of another costs 2.40 octaves of width — more than a third of everything the twelve-category ladder can supply. The subject still holds three framings. Two of them are one framing.

Note carefully what the loss is *not* attributed to. It is not attributed to the subject becoming less capable, less well, or less anything. The reading changed because the encoding of the third framing changed. If the elicitation on a given day produces a restatement where it previously produced a distinct construal, the honest report is that the elicitation produced a restatement. Whether that reflects a change in the person, a change in the situation, a change in the analyst, or a change in the subject's willingness to say a second thing is not determined by the number, and Section 5's worksheet requires all four to be considered before any of them is asserted.

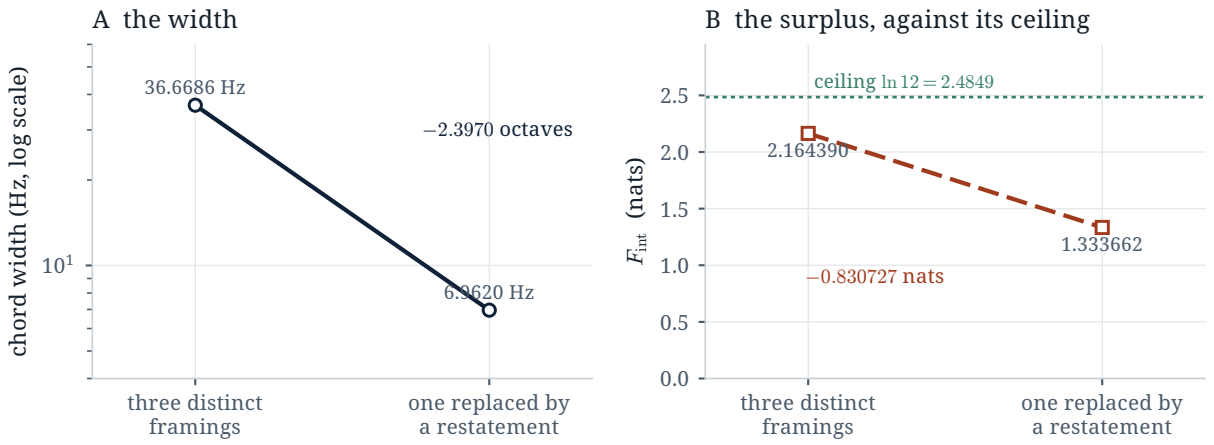

Figure 43.3: Replacing one of three framings with a paraphrase of another costs 2.3970 octaves of chord width and 0.830727 nats of internal surplus — more than a third of what a twelve-category ladder can supply — while the subject still holds three framings. Panel B plots the surplus against its ceiling $\ln 12 = 2.484907$, because a surplus figure without its ceiling is not interpretable. **Modelled:** both framing sets are constructed and labelled as extensions of the carried subject. Built by `figs/src/CCP-043_fig05.py`.

4.11 What actually widens a chord, stated so it cannot be misread Given all of the above, the engineering question is: if an analyst wants a wider reading, what raises it?

A framing that is angled from the existing ones. That is the whole answer. u rises when the squared alignment falls, and the squared alignment falls when a framing assigns intensity in a different shape across the states.

What does **not** raise it, each denied because each has been proposed:

- **Amplifying an existing framing.** Zero effect. Scale invariance, §4.9.
- **Adding a restatement.** Negative effect. Extension 3.1-d, −2.40 octaves.
- **Adding a framing with disjoint support.** Raises the number to the ceiling and destroys its meaning. The octave-folding paper [Curzi, 2026]; the reading becomes degenerate and must not be published.
- **Distress. Not an input. It appears in no equation in this framework.** There is no term for it, no coefficient on it, and no path by which it could enter the computation. A person who has a worse week does not get a wider chord, and this framework does not suggest that anyone should have a worse week.

And the honest general statement, which is a statement about method and not about persons:

> **THE ONLY LEVER ON `F_int` IS THE ANGULAR DIVERSITY OF WHAT IS ELICITED.** Everything else in the construction is invariant. Whether a given person's elicited framings are angled is a fact about the elicitation and the occasion, and this instrument reports it rather than explaining it.

4.12 "The divided self" — the phrase in the title, and what it is allowed to mean The section is called *Dissonance and the Divided Self*, and the second half of that title is a borrowed phrase with a long and largely clinical history behind it. **This framework borrows the phrase and none of the history.**

What the formalism licenses is narrow and can be said in one line: **a person holding several non-parallel framings is, under this encoding, a chord rather than a note.** That is a structural description of an encoding. It is not a description of fracture, of a self at war with itself,

of dissociation, or of any condition, and none of those readings survives contact with §4.6's relabelling test.

There is a version of "divided" that the arithmetic does support, and it is almost the opposite of the dramatic one. **The genuinely divided self, in this system's terms, is the one with the *least* going on: framings so nearly parallel that the person has one instrument and several names for it.** Extension 3.1-b reads `F_int = 0.000000` — the ground essence, no width — and it is not a portrait of turmoil. It is a portrait of unanimity. The internal-surplus analysis of Series B called it a single window with forty panes, and the reason the phrase lands is that unanimity inside one head is invisible from inside that head.

But even this must not be run in reverse. A person reading `F_int = 0` on one situation on one occasion has produced parallel framings on that situation on that occasion. **They are not thereby divided, undivided, well, unwell, rigid, or anything else. The number is about the framings.** The section's title is a title.

4.13 Reading a chord more than once Because every reading in this section is of one situation on one occasion, the obvious next question is what happens when the same subject is read twice, and it is worth answering here because the answer constrains what a single reading can be used for.

The octave-folding paper [Curzi, 2026] established the difference between a trait's frequency and a mood's as a question about `delta` — how fast a reading decays. The same question applies to a chord: is `F_int` a property that persists? Nothing established so far answers that, because nothing in them involves time.

What the construction permits is a comparison, and only a comparison:

```
REPEAT READING, THE ONLY LEGITIMATE FORM

    same subject, same ladder, same analyst, same elicitation script,
    DIFFERENT situation or different occasion

    report:  F_int(1), F_int(2), and the difference
    report:  the chord of each, and whether the state sets overlap
    report:  what changed in the procedure -- ideally nothing

    DO NOT report: a trend from two points
    DO NOT report: a change as a change in the person
```

Three sources can move a repeat reading and the number cannot separate them: the person, the situation, and the elicitation. A drop from 2.164390 to 1.333662 — the size of Extension 3.1-d's substitution — is equally consistent with a subject who framed the second situation more narrowly, a second situation that admits fewer framings, and an analyst who ran a shorter session. A reading that attributes the change to the first of those three has made a claim the arithmetic does not support.

This is why Section 5's worksheet has a procedure block that must be filled in before the computation block, and why the procedure block is reproduced identically on every repeat.

The Specification

SPEC-4.1 — The consonance audit

```
INPUT   a chord: the set S of states spanned, from SPEC-9.2 Step 8.

STEP 1  for each unordered pair (i,j) in S with i < j:
```

```
            reduce j/i to p/q in lowest terms
            essence ratio      = p^2 / q^2
            raw cents          = 1200 * log2(j^2 / i^2)
            folded cents       = raw cents mod 1200
            HD_ess             = 2 * log2(p*q)
            G_ess              = 2 * G(p*q) - 1
            collision          = TRUE iff odd(i) == odd(j)
                               equivalently iff folded cents == 0

STEP 2  MIN HD_ess, MEAN HD_ess, COLLISION COUNT.

STEP 3  report the class set = { odd(n) : n in S } and |class set|,
        separately from |S|.

STEP 4  flag the 50/49 pair if present: any pair with folded cents = 34.9756.
        At N = 12 there is exactly one such pair, 7:10.
```

SPEC-4.2 — The redundancy audit (distinct from SPEC-4.1) The consonance audit is about the chord. The redundancy audit is about the framings, and the two are independent by §4.6. **Both are required; neither substitutes for the other.**

```
INPUT   the normalised framing vectors from SPEC-9.2 Step 2.

STEP 1  every pairwise u, published individually.

STEP 2  RESTATEMENT FLAG: any pair with u < 0.01 is flagged RESTATEMENT.
        (The 0.01 threshold is a stated convention chosen by the author,
        not a derived value. State it; apply it before seeing results.)

STEP 3  EFFECTIVE FRAMING COUNT: report m (nominal framings) and N_eff
        (audited categories) SEPARATELY, with the roster reduction postulate
        stated. They are different counts and neither is the other.

STEP 4  If any pair is flagged RESTATEMENT, report the reading WITH the flag.
        Do not drop the framing to improve the number.
```

Step 4 matters. **A restatement is a finding, not an error.** Dropping it raises `F_int` and destroys the only information the reading contained about the subject's framing behaviour on that occasion.

SPEC-4.3 — The mandatory separation statement **Every published consonance or redundancy audit carries the following, in full, in the reading itself and not in a footnote:**

> *This reading describes the information content of a set of framings under a stated encoding. It does not measure distress, well-being, health, or function, and no inference from this reading to any of those is supported by the construction.* `F_int` *is invariant under relabelling of the states and is therefore many-to-one even on chords; it does not determine the chord, and the chord does not determine anything about a person's experience. The twelve states are not diagnoses. This is not an assessment and not clinical advice. Nothing here recommends or values suffering. The frequencies are essence frequencies, not physical resonances.*

A reading published without this paragraph is not a reading this framework endorses.

SPEC-4.4 — Gates

```
GATE 10-1  the audit reports BOTH state count and class count          FAIL -> incomplete
GATE 10-2  every pairwise u published, not the mean alone              FAIL -> incomplete
GATE 10-3  the separation statement present in full                    FAIL -> do not publish
GATE 10-4  no sentence in the reading contains a condition name, a
           severity, a norm comparison, or a recommendation            FAIL -> do not publish
GATE 10-5  restatement flags reported, not resolved by deletion        FAIL -> reading void
GATE 10-6  consonance audit and redundancy audit reported separately   FAIL -> incomplete
```

Gate 10-4 is a text gate rather than a numeric one and it is the one an analyst will be tempted to wave through. **It is mechanical on purpose: read the reading, look for those four things, and if any is present the reading does not go out.** A gate that requires judgment gets exercised; a gate that requires a word search gets applied.

The Failure Modes

FM-4.1 — Romanticising dissonance *The failure.* The section's result — that a perfectly consonant self has zero surplus — is read as "division is good," "conflict is generative," or "suffering is informative," and from there into advice.

Why it happens. Because the arithmetic produces a sentence that sounds like a moral and because the moral is attractive. The genre this framework sits adjacent to has produced that moral many times, usually without any arithmetic under it at all.

Why it is wrong, in three independent ways. (i) The formalism contains no term for suffering; there is no path by which it enters. (ii) `F_int` is invariant under relabelling and does not even determine the chord (§4.6), so it cannot determine anything downstream of the chord. (iii) The only lever on `F_int` is angular diversity of elicited framings, and nothing about angular diversity implies discomfort — three comfortable framings of a situation score exactly as three uncomfortable ones would.

Detection. Any sentence in which more `F_int` is better, or in which a difficult experience is described as producing surplus.

Repair. Delete the sentence. **There is no repaired version of it**, because the claim is not underdetermined by the formalism, it is absent from it.

FM-4.2 — Pathologising consonance *The failure.* The exact inverse, and the one that follows FM-4.1 the way an echo follows a shout: a low `F_int` reading is treated as a deficiency, a warning sign, or something to be corrected.

Why it happens. Because the internal-surplus analysis of Series B's description of the zero-surplus case — forty descriptions that are one description — reads like a portrait, and portraits invite recognition.

Why it is wrong. A settled, coherent, single reading of a situation is a completely ordinary thing and the formalism says nothing against it. `F_int = 0` means the elicited framings were parallel on that occasion. It means that and nothing else. **It is not a deficit, it is not a symptom, and describing it as either is a clinical claim this framework does not make and is not entitled to make.**

Detection. Any sentence recommending that a subject develop more framings, or describing a narrow chord as something to work on.

Repair. Report the number and stop. **The instrument's job ends at the number.**

FM-4.3 — Reading harmonic dissonance as psychological conflict *The failure.* The `7:10` pair at 34.98 cents is described as the subject's inner conflict, or the `5:10` collision as the subject's confusion.

Why it happens. The words carry their ordinary meanings in.

Why it is wrong. Those numbers are computed from `7`, `10`, and `5` — from integers, by a defined function, with no reference to any person. **Relabel the states and the numbers change while the subject's framings do not.** §4.6 demonstrates precisely this.

Detection. Any sentence attributing an interval to a subject's experience.

Repair. State intervals as properties of the index set. "The chord contains the lattice's unique 50/49 pair" is correct. "The subject is in a 50/49 relationship with themselves" is not a sentence this framework can produce.

FM-4.4 — The reading used as clinical advice *The failure.* A reading is used to decide something about a person's care, treatment, capacity, or condition.

Why it happens. The output is numeric, the output is reproducible, and numeric reproducible outputs get used for decisions.

Why it is wrong. **No validation of this instrument against any clinical outcome exists, has been attempted, or is claimed. The twelve-state ladder is an ordinal construction defended in the minimum-frequency paper [Curzi, 2026] on its own terms and demoted on scale by CC-R1. It has no criterion validity against anything.**

Detection. Gate 10-4, plus the question of who is going to read the reading and what they will do next.

Repair. The separation statement of SPEC-4.3, in full, and the analyst's own refusal.

FM-4.5 — Manufactured internal difference *The failure.* An analyst elicits additional framings by pressing a subject to produce a different answer, and the subject obliges.

Why it happens. Because the analyst wants a valid reading and near-parallel framings feel like a failed session.

Why it is wrong. A framing produced to satisfy an analyst is not a framing the subject holds, and the encoding cannot tell the difference. This is internal pseudo-diversity, and Series B's pseudo-diversity analysis treats the relational version at length: apparent variety with no angular content behaves exactly like manufactured variety with angular content, which is why the failure is invisible in the output.

Detection. Procedural. Record the elicitation, record how many prompts each framing required, and publish the count.

Repair. Elicit once, accept the result, and report a narrow chord as a narrow chord.

FM-4.6 — The total-order fallacy on harmonic distance *The failure.* Reasoning from "consonance is redundancy" as though every collision were more consonant than every non-collision.

Why it happens. Because the slogan is memorable and the caveat is not.

Why it is wrong. Result (C): `1:3` at `HD_ess = 3.1699` is more consonant than the collisions `1:4`, `2:8`, `3:12` at 4.0000 and `1:8` at 6.0000. **The claim is exactly true at the minimum, exactly true as a biconditional about zero folded separation, and true on average (3.0000 against 8.6617). It is not a total order.**

Detection. Any argument of the form "this pair is a collision, therefore it is more consonant than that pair."

Repair. Use the computed values. There are only sixty-six of them.

FM-4.7 — Treating the fold as an argument *The failure.* Concluding, from the fact that states 5 and 10 fold to the same pitch, that attributed feeling and narrative feeling are substantively the same thing.

Why it happens. The fold makes them audibly identical and audible identity is persuasive.

Why it is wrong. The fold is a quotient by powers of two applied for the sole purpose of bringing values into a chosen band. It is a change of units. The states differ by five components of specification on the ladder, and the fold does not know that and does not care.

Detection. Any substantive claim justified by a folded value.

Repair. Publish raw and folded together, always, with the band and `j`, per SPEC-9.3.

FM-4.8 — Optimising `F_int` *The failure.* Treating the width as a score to be raised, whether by the analyst, the subject, or a system built around the reading.

Why it happens. Because it is a number, and numbers attract optimisation.

Why it is wrong. Every honest route to raising it runs through the subject genuinely holding differently-shaped construals, which is not something an analyst can supply. Every dishonest route — restating, manufacturing, disjoint encoding — either lowers it, degenerates it, or falsifies it. There is no available optimisation that is also a measurement.

Detection. Any repeated reading of the same subject where the number rises and the procedure changed.

Repair. Pre-register the procedure, per Gate 6 of the octave-folding paper [Curzi, 2026], and re-read without altering it.

FM-4.9 — Importing the wrong construct *The failure.* Citing cognitive-dissonance research, or consonance research in music perception, as support for anything in this section.

Why it happens. Shared vocabulary.

Why it is wrong. Tenney distance and Euler gradus are defined functions, badged as chosen, and are not claims about hearing. The internal surplus is a construction over an ordinal encoding, not a psychological construct with a literature. Citing unrelated empirical work as support would be a fabricated citation, and the framework does not do it.

Repair. Cite Tenney [Tenney, 2015] and Euler [Euler, 1739] for the measures, which is what they are for — and cite the essay rather than the 1988 *History*, per §4.2 — and cite nothing for the psychology, because there is nothing to cite.

FM-4.10 — Treating a zero-surplus reading as the end of the inquiry *The failure.* A reading returns `F_int = 0.000000`, the analyst records "no surplus," and the session ends.

Why it happens. Zero looks like a complete answer. It is a number, it is definite, and it closes.

Why it is wrong. **Zero surplus and no measurement are different results and the specification requires them to be distinguished.** `F_int = 0` means at least two framings were elicited and they were parallel. A session that produced only one framing has no pairs, no `u_int`, and no reading at all — the octave-folding paper [Curzi, 2026]'s Gate 7. Recording the second as the first converts a missing measurement into a null one, which is the single most common way a measurement programme accumulates false negatives.

There is a second reason the inquiry should not end there. **A zero-surplus reading is the most informative reading the redundancy audit produces**, because it is the one that identifies the elicitation returned the same construal repeatedly — which is a fact about the session, and a fact worth having, and one that the number reports accurately.

Detection. Compare the framing count against the pair count. Zero pairs is no reading; one or more pairs with `u_int = 0` is a null reading.

Repair. Record which of the two occurred, per SPEC-4.2 Step 3, and record how many framings the elicitation produced before it stopped.

FM-4.11 — Comparing readings across ladders *The failure.* Two readings computed on different state ladders, or on the same ladder with a different number of categories, are compared as though the numbers were commensurable.

Why it happens. `F_int` is in nats either way and nats look like nats.

Why it is wrong. `F_int = ln(1 + (N−1)u)` contains `N` explicitly, and its ceiling is `ln N`. A surplus of 2.164390 nats against a ceiling of `ln 12 = 2.484907` is 87.10% of the available range; the same 2.164390 nats against a ceiling of `ln 25` would be 67.24%. The raw value has no meaning without its ceiling, and neither does the pitch: `f_width` depends on `N_eff`, which depends on `N`.

Detection. Any comparison in which the two readings do not state the same `N`.

Repair. Publish `F_int`, `ln N`, and the ratio, always together — and where `N` differs, compare the ratio and say plainly that the absolute values are not comparable.

Worked Example

THE SUBJECT — the consonance and redundancy audits **CONSTRUCTED CASE, the framework's carried subject, carried from the octave-folding paper [Curzi, 2026]. Not an observation of any person.**

The Subject's chord, from SPEC-9.2 Step 8:

```
STATES SPANNED   {3, 5, 7, 10}
state  3   directed feeling      raw  4.3508 Hz   folded 278.453 Hz (j=+6)   class 3
state  5   attributed feeling    raw 12.0856 Hz   folded 386.741 Hz (j=+5)   class 5
state  7   reflexive feeling     raw 23.6879 Hz   folded 379.006 Hz (j=+4)   class 7
state 10   narrative feeling     raw 48.3426 Hz   folded 386.741 Hz (j=+3)   class 5
```

The consonance audit (SPEC-4.1)

```
pair    essence ratio   raw cents   folded cents   HD_ess    G_ess   collision
3:5        25 / 9        1768.72       568.7174    7.8138      13       no
3:7        49 / 9        2933.74       533.7418    8.7846      17       no
3:10      100 / 9        4168.72       568.7174    9.8138      15       no
5:7        49 / 25       1165.02      1165.0244   10.2586      21       no
5:10        4 / 1        2400.00         0.0000    2.0000       3      YES
7:10      100 / 49       1234.98        34.9756   12.2586      23       no

MIN HD_ess       =  2.0000    (pair 5:10)
MEAN HD_ess      =  8.4882
COLLISION COUNT  =  1
STATE COUNT      =  4
CLASS COUNT      =  3         classes {3, 5, 7}
50/49 PAIR       =  PRESENT   (7:10 at 34.9756 cents -- the lattice's unique instance)
```

Three observations, each stated at the altitude the arithmetic supports.

The chord contains the most consonant interval the lattice permits and it contains it exactly once. `5:10` sits at `HD_ess = 2.0000`, the global minimum over all sixty-six pairs, attained only by the six 2:1 pairs. And by result (B), that is precisely the chord's one redundancy: 0.0000 folded cents, one class for two states. Consonance and redundancy are not correlated here; they are the same entry in the table, read twice.

The chord also contains the lattice's most remote pair among its members, and the two are adjacent in the index set. `7:10` at `HD_ess = 12.2586` is the widest interval in this chord, and it folds to 34.9756 cents — the smallest nonzero separation the whole `N = 12` system permits. **The most harmonically remote pair in the chord is the pair that would sound closest if the**

chord were folded into one band. That is not a paradox; it is what the fold does. Harmonic distance is computed on the unfolded ratio `100/49`; folded separation is computed modulo the octave. They are different questions and this chord happens to answer them oppositely.

Mean `HD_ess = 8.4882` sits just below the non-collision average of 8.6617 for the lattice as a whole, which is what one expects of a chord containing exactly one collision among six pairs.

The redundancy audit (SPEC-4.2)

```
pairwise u          mirror / story    0.809410
                    mirror / threat   0.904762
                    story  / threat   0.388360

RESTATEMENT FLAGS   none  (minimum pairwise u = 0.388360, well above the 0.01 threshold)

u_int               0.700844
m (nominal)         3 framings
N_eff (audited)     8.7093 categories, under the roster reduction postulate
F_int               2.164390 nats
f_width             36.6686 Hz   folded 293.349 Hz (band 220–440, j = +3)
octaves             6.2451
```

The two audits disagree about what the chord is like, and they are entitled to. The consonance audit finds one exact redundancy in the chord's index set. The redundancy audit finds no restatement among the framings at all — the closest pair, story against threat, sits at `u = 0.388360`. The collision is in the ladder. It is not in the framings.

This is §4.6 made concrete on the carried case. The Subject holds three framings that are substantially non-parallel, and their union happens to include two indices differing by a factor of two. **Relabel state 10 as state 9 and the collision vanishes with `F_int` unchanged to twelve decimal places.** Nothing about the Subject changed; the ladder's arithmetic changed.

The counterfactual: what a consonant Subject would read

EXTENSION 3.1-d (LABELLED): the Subject with the mirror framing replaced by a restatement of the threat framing. This is the same person only in the sense that the case is carried; it is a constructed variant and is labelled as one.

```
                        SUBJECT          EXTENSION 3.1-d      change
u(threat, story)        0.388360            0.388360           --
u(threat, mirror)       0.904762            0.001034        -0.903728
u(story,  mirror)       0.809410            0.372856        -0.436554

u_int                   0.700844            0.254083        -0.446761
N_eff                   8.7093              3.7949          -4.9144
F_int (nats)            2.164390            1.333662        -0.830728
f_width (Hz)           36.6686             6.9620          -29.7066
octaves above ground    6.2451              3.8481          -2.3970

RESTATEMENT FLAGS       none                (threat, mirror') at u = 0.001034
```

Two-point-four octaves, lost to one substitution. And the restatement flag fires, so the reading goes out with the flag attached rather than with the framing quietly removed — Gate 10-5.

And the terminal case, for completeness:

```
EXTENSION 3.1-b (LABELLED): all three framings parallel.
    u_int = 0.000000   N_eff = 1.0000   F_int = 0.000000   f_width = k = 0.483426 Hz
    octaves above ground = 0.0000
```

Zero. The ground essence. Three framings and one window.

The reading, complete

```
========================================================================
CONSONANCE / REDUNDANCY READING -- THE SUBJECT
(CONSTRUCTED CASE, the framework's carried subject. Not an observation of any person.)
========================================================================
ladder            N = 12, CCP-041 ordinal on n; intensities ratio-scaled
                  up to a free multiplier per CCP-041 (CC-R1 governs D/P, not used here)
chord             states {3, 5, 7, 10}; classes {3, 5, 7}
                  four states, three classes: 10 = 2*5, same odd part

CONSONANCE AUDIT  min HD_ess    2.0000   (5:10, the lattice global minimum)
                  mean HD_ess   8.4882
                  collisions    1        (5:10, folded 0.0000 cents)
                  50/49 pair    present  (7:10, 34.9756 cents, unique at N=12)

REDUNDANCY AUDIT  pairwise u    0.809410 / 0.904762 / 0.388360
                  restatements  none
                  u_int         0.700844
                  m / N_eff     3 framings / 8.7093 audited categories
                  F_int         2.164390 nats
                  f_width       36.6686 Hz, folded 293.349 Hz (220-440, j=+3)
                  octaves       6.2451

INDEPENDENCE      relabelling 10 -> 9 removes the collision and leaves
                  F_int = 2.164390 unchanged to 1e-12. The consonance audit
                  and the redundancy audit measure different things.

This reading describes the information content of a set of framings under a
stated encoding. It does not measure distress, well-being, health, or
function, and no inference from this reading to any of those is supported by
the construction. F_int is invariant under relabelling of the states and is
therefore many-to-one even on chords; it does not determine the chord, and
the chord does not determine anything about a person's experience. The twelve
states are not diagnoses. This is not an assessment and not clinical advice.
Nothing here recommends or values suffering. The frequencies are essence
frequencies, not physical resonances.
========================================================================
```

What the section established, and the line it will not cross

Established, and checkable: the essence lattice doubles Tenney harmonic distance; the minimum essence harmonic distance is attained by exactly the six 2:1 pairs, all of which are pitch-class collisions; zero folded separation is exactly equivalent to sharing an odd part; therefore the most consonant pairs the lattice offers are precisely the pairs it cannot distinguish. Applied within one observer, a set of parallel framings has `u_int = 0`, `N_eff = 1`, `F_int = ln 1 = 0`, and a chord width of exactly the ground essence.

Not established, and not claimed anywhere: that a narrow chord indicates anything about a person's health, function, or experience; that a wide chord indicates anything better; that difficulty produces surplus; that suffering is a resource; that any of this is a basis for advice about anyone's care.

The result is about information content. The distance between "information content" and "how a person is doing" is not a gap this framework knows how to cross, and an account that pretended to cross it would be worth less than one that says where the road ends.

Section 4 owns the consonance/redundancy identity and the separation statement. Later papers in this series cite it. The doubling theorem is the harmonic-lattice analysis of Series B [Curzi, 2026l]; the internal surplus is the internal-surplus analysis of Series B; the chord, the one-hot trap, and SPEC-9.2 are the octave-folding paper [Curzi, 2026]; octave folding and the odd-part rule are The octave-folding paper [Curzi, 2026]. Section 5 assembles all of it into a worksheet a reader can run.

5 The personal spectrum

The preceding analysis built the parts. The minimum-frequency paper [Curzi, 2026] defended the index as a count and built the twelve-state ladder and the elicitation procedure that fills it in. The octave-folding paper [Curzi, 2026] gave a state a pitch, established the fold and its odd-part class rule, separated a trait from a mood by way of `delta`, and made the chord and named the one-hot trap. Section 4 established that consonance and redundancy are the same phenomenon, and spent most of its length making sure that result could not be turned into advice.

This section assembles all of it into one procedure that a reader can actually run, on paper, for one person, on one situation, and finish.

It ends where the minimum-frequency paper [Curzi, 2026] said every practical section of this framework must be able to end: with an octave deficit.

```
THE READING THIS SECTION PRODUCES

    octave deficit  =  2.885 * (c/eta)  -  log2( f / k )

    deficit <= 0    sustainable as it stands
    deficit  > 0    short by that many octaves, and the four levers are:
                    raise u  ·  raise eta  ·  cut c  ·  add distinct categories
```

Section 5 owns the full personal worksheet. The companion paper on refinement cites it. Everything else in the procedure is owned elsewhere and cited here rather than restated, which is the whole point of a worksheet: it is an index to the framework with blanks in it.

> **BEFORE ANYTHING ELSE. The twelve states are not diagnoses and this reading is not an assessment.** It makes no clinical, medical, or therapeutic claim of any kind. **The frequencies are essence frequencies, not physical resonances** — nothing here asserts that any person, tissue, or molecule resonates at any value. **The reading measures the information content of a set of framings under a stated encoding; it does not measure distress, well-being, health, or function, and Section 4 §4.6 shows formally why no inference to any of those is available.** All cases in this section are CONSTRUCTED and labelled as such.

The Law

5.1 What a personal reading is A personal reading is a reading **of a set of framings, on one situation, on one occasion, under one stated decomposition, by one analyst**. Every one of those qualifications is load-bearing and every one of them appears on the worksheet as a blank that must be filled before the arithmetic starts.

What it is not is a reading of a person. **There is no procedure in this framework that reads a person.** The FVP-7 gate for the self-storage law of Series B is recorded as **NOT RUN** — the reproducibility gate, whether one person's `eta` means what another's does, has not been attempted, and until the separation property of a specific-objectivity instrument is established, **every personal parameter is a within-subject index and cross-person comparison is not licensed.** That constraint is inherited here in full. Two people's readings may be compared only in the sense that two people's shoe sizes measured with different rulers may be compared: not at all.

There is a reason this section takes the form of a worksheet rather than an argument, and it is worth stating before the sheet appears.

An instrument with a contested foundation is honest only if it is fully procedural. The principle is old and is an engineering standard rather than an ethical preference: a system must remain sound when everything about it except the key is public [Kerckhoffs, 1883], and disclosure is the discipline that makes a contested instrument checkable [Brandeis, 1914]. Every component of this reading rests on something that could be disputed: the ladder is an ordinal construction defended in the minimum-frequency paper [Curzi, 2026] rather than derived; the constant `k` is a design decision badged as a postulate; the intensities are ratio-scaled only to the extent a magnitude-estimation procedure delivers ratio scales, which the minimum-frequency paper [Curzi, 2026] states is a measured property of a procedure and not a constant of nature; the roster reduction is a postulate; the storage parameters have a reproducibility gate recorded as NOT RUN. **Not one of those is hidden, and not one of them is fatal — but together they mean the number has no authority of its own.** What it has instead is a trail.

A worksheet is what a trail looks like when it is written down. **Every blank on the sheet is a place where someone made a decision, and the sheet exists so that a second person can find each decision, disagree with it, change it, and see what the reading does.** That is the only form of validity this instrument currently has: not that its numbers are right, but that its numbers are *recomputable from declared inputs by someone who thinks the inputs are wrong.*

The minimum-frequency paper [Curzi, 2026]'s honest limit governs the whole sheet: the frequency inherits exactly the defensibility of the count. A contested decomposition yields a contested frequency. The worksheet does not resolve that. It makes the contest possible.

5.2 The five outputs

```
THE PERSONAL SPECTRUM -- five outputs, in order of derivation

  1  THE SPECTRUM      the twelve state frequencies, raw and folded
                       f(n) = k n^2                                    [CCP-042]

  2  THE CHORD         the states spanned by the framings, their pitches,
                       their pitch classes, and their intervals        [CCP-042]

  3  THE WIDTH         F_int = ln(1 + (N-1) u_int),  f = k e^(2 F_int) [CCP-042]

  4  THE COST RATIO    c / eta, estimated at internal scope            [Series B, self-as-storage]

  5  THE DEFICIT       2.885*(c/eta) - log2(f/k)                       [CCP-041]
```

Outputs 1 and 2 depend on the ladder and the framings. Output 3 depends only on the angles between framings. Output 4 depends on none of that — it is a separate estimation problem with separate hazards. **Output 5 is the only place the two halves meet, and it is the join this whole framework exists to perform.**

5.3 The octave deficit, restated The minimum-frequency paper [Curzi, 2026] owns the minimum sustainable frequency and its diagnostic. Restated here in the form the worksheet uses, without re-derivation:

```
THE MINIMUM SUSTAINABLE FREQUENCY                    [CCP-041, the framework's specification]

    Q_inf > 0   <=>   eta F > c   <=>   F > c/eta
    F = (1/2) ln(f/k)                                 the inverted bridge
    f_min = k * e^( 2 c / eta )

    octaves required = 2 (c/eta) / ln 2 = 2.885 * (c/eta)
    octaves present  = log2( f / k ) = 2.885 * F
    octave deficit   = required - present
```

Every unit of cost-to-conversion ratio costs 2.885 octaves of required pitch. The verified table from the minimum-frequency paper [Curzi, 2026], reproduced because the worksheet needs it at hand:

c/eta	f_min (Hz)	octaves above k
0.000	0.4834	0.000
0.500	1.3141	1.443
1.000	3.5721	2.885
1.500	9.7099	4.328
2.000	26.3942	5.771
2.485	69.6124	7.170
3.000	195.0279	8.656

The constant is written `2.885` throughout; exactly it is `2/ln 2 = 2.885390`. Where a reading sits within a hundredth of an octave of zero, use the exact form.

5.4 What `eta`, `c` and `delta` mean inside one person

The storage law at internal scope is the self-as-storage analysis of Series B's self-storage law, and this section cites it rather than re-deriving it:

```
Q_{t+1} = (1 - delta) Q_t + eta M_t - C_t              [Bk 2 the self-as-storage analysis of Series B]

Q      stored durable structure -- character, in Q-units
delta  retention loss per period, in [0,1], dimensionless
eta    conversion of experience into durable structure, in Q-units per nat
C      cost per period, in Q-units
M      the moment, in nats -- here supplied by F_int

Q_inf = ( eta F - c ) / delta                          the storage law
```

Note the units, because they are what stops the equation being a slogan: `eta` carries Q-units per nat, so `c/eta` carries nats and `2.885*(c/eta)` carries octaves. The deficit is dimensionally sound and the worksheet checks it.

At internal scope the three parameters read as follows, and each has an estimation method owned by The self-as-storage analysis of Series B:

`eta` — conversion. How much of what happens becomes durable structure. The self-as-storage analysis of Series B estimates it as a product of six pass-through yields, `eta = y1 * y2 * ... * y6`, with the last rung carrying the units. Its structural property is multilinearity: the elasticity of `eta` with respect to every rung is exactly 1, so the absolute gain from fixing a rung is inversely proportional to that rung's current yield. A single blocked rung nullifies every other, which is why the aggregate figure is uninformative and the stage-wise figure is not.

`c` — cost. The self-as-storage analysis of Series B estimates it from five ledgers. It is a per-period quantity in Q-units and it must be declared with its period.

`delta` — loss. Estimated from a zero-input window. It sets the time constant `tau = 1/delta` and therefore how long a regime takes to arrive at its fixed point.

And the identifiability hazard, which is the one that voids readings: the storage-law admissibility condition of Series B — **if the Q-proxy rises whenever a lot happens, the input has been measured twice and the gauge is void.** A journal that gets longer on busy weeks is not a measure of `Q`. The worksheet requires the proxy and its independence check to be declared before any parameter is estimated.

5.5 The break-even identity

Substituting `octaves present = 2.885 * F_int` into the deficit gives an identity worth stating on its own, because it is what makes the reading legible without a table:

```
THE BREAK-EVEN IDENTITY

    deficit = 2.885*(c/eta) - 2.885*F_int = 2.885 * ( c/eta - F_int )

    deficit = 0   <=>   c/eta = F_int
    deficit < 0   <=>   c/eta < F_int      SUSTAINS
    deficit > 0   <=>   c/eta > F_int      SHORT
```

The whole diagnostic is one comparison: is the cost ratio smaller than the surplus? The octave form is the same statement rescaled by `2.885`, and it exists because octaves are legible and nats are not.

For the carried Subject, with `F_int = 2.164390`:

```
break-even c/eta = 2.164390 nats
below it   -> sustains        above it   -> short
```

Everything the frequency machinery adds to `eta F > c` is legibility. It adds no content, and the framework says so here rather than letting the reader discover it and feel cheated. What the frequency form buys is that a deficit in octaves can be compared against a table of what an octave costs, and a ratio in nats cannot.

5.6 The stop rule

Because `F <= ln N` always, the deficit cannot be closed by raising `u` past orthogonality. That gives a hard stop, and it is the surplus ceiling in the frequency register:

```
THE CEILING                                          [CCP-041, the framework's specification]

    c/eta  <=  ln N  is REQUIRED for any arrangement of N categories to sustain.

    At N = 12:   c/eta <= 2.484907   and   f_min <= k*144 = 69.6133 Hz

    c/eta = 2.4849 -> f_min =  69.6124 Hz    at the ceiling
    c/eta = 2.6000 -> f_min =  87.6317 Hz    ABOVE -- nothing sustains
    c/eta = 3.2000 -> f_min = 290.9474 Hz    ABOVE -- nothing sustains
```

Above the ceiling, no arrangement of those twelve categories is sustainable — not a better set of framings, not a better schedule, not more effort. The only remedies are to raise `eta`, cut `c`, or add genuinely distinct categories, and the worksheet stops and says so rather than computing a deficit that no rearrangement could close.

The stop rule is checked before the deficit, not after. A worksheet that computes a deficit above the ceiling has produced a number that describes an impossibility.

5.7 `delta` is not a lever on the deficit One structural fact the worksheet exposes and that surprises most readers on first sight:

```
deficit = 2.885*(c/eta) - log2(f/k)          -- no delta term
Q_inf   = (eta F - c) / delta                -- delta scales the magnitude
```

`delta` does not appear in the deficit at all. It scales `Q_inf` and sets the time constant, but it cannot change the sign. Computed on the carried Subject at `eta = 0.327600`, `c = 0.55`, where the numerator `eta F_int - c = +0.159054`:

```
delta = 0.20  ->  Q_inf = +0.7953     deficit −1.4015
delta = 0.12  ->  Q_inf = +1.3255     deficit −1.4015
delta = 0.06  ->  Q_inf = +2.6509     deficit −1.4015
delta = 0.03  ->  Q_inf = +5.3018     deficit −1.4015
```

Lowering `delta` multiplies whatever sign the numerator already has. On a positive numerator it multiplies a gain. On a negative one it multiplies a loss. That is CC-R15, it is owned by the relationship-frequency paper [Curzi, 2026], and its internal-scope demonstration is in this section's Worked Example because the worksheet has to be able to warn about it.

The Engineering

5.8 Step A — eliciting the intensities The minimum-frequency paper [Curzi, 2026] owns this procedure and this section cites it. What the worksheet needs from it is three things, recorded before any arithmetic:

```
A1  THE SITUATION, stated once, in the subject's own words, and fixed.
    All framings are framings OF THIS. If the situation drifts between
    framings, the reading is void -- the angles would be between
    vectors pointed at different targets.

A2  THE FRAMINGS, elicited one at a time, each described in full before
    the next is requested. Record how many prompts each required.

A3  THE DECOMPOSITION. For each framing, of each of the twelve state
    classes, ask whether the description REQUIRES that component to be
    specified. Rate the required ones for intensity on a common scale.
```

Three procedural rules that the worksheet enforces:

Do not ask which state a framing "is." That question produces one-hot vectors and the octave-folding paper [Curzi, 2026] shows what one-hot vectors do. Ask which components the description requires. Framings of one situation share components; that is what makes them framings of one situation.

Record the prompt count. A framing that took six prompts to obtain and a framing the subject volunteered are different data, and only the record distinguishes them. Section 4's FM-4.5 — manufactured internal difference — is invisible in the output and visible only here.

Declare the scale status, and declare the right one. Two different scale claims are in play and conflating them is a real error. CC-R1 demotes the Moment equation: `D/P` may be used ordinally only, and any psychological frequency derived through `D/P` inherits the demotion. The worksheet does not route through `D/P`, so that demotion does not bind the reading — but the box exists so that an analyst who *does* route through it must say so.

The intensities have their own scale status and the minimum-frequency paper [Curzi, 2026] owns it. The minimum-frequency paper [Curzi, 2026] shows that ordinal-preserving transformations of the intensities move `u` on the carried Subject's closest pair from 0.362115 to 0.525275 — `f_rel` from 12.0049 to 22.2093 Hz, a spread of 1065.05 cents, nearly nine tenths of an octave — from transformations that preserve every ordinal fact in the data. So merely ordinal intensities will not do. They must be ratio-scaled up to a common free multiplier, which is what a magnitude-estimation procedure is built to deliver, and the honest form of the claim is that they are ratio-scaled to the extent magnitude estimation delivers ratio scales — a measured property of a procedure, not a constant of nature. Say which claim the reading rests on, in the box provided, every time.

And report the norms. The minimum-frequency paper [Curzi, 2026]'s **MAGNITUDE REPORTING RULE** requires the raw L2 norm of every state vector to be published alongside the normalised vector, in the units of the elicitation instrument, and never discarded. `u` measures direction; normalisation throws away length, and length is not nothing — two profiles differing eightfold in intensity are exactly parallel and carry `u = 0.000000` between them.

5.9 Step B — building the vectors and passing the gates

The octave-folding paper [Curzi, 2026]'s SPEC-9.2 owns this. In worksheet form:

```
B1  Write each framing as a twelve-vector of intensities.
B2  FIX AND RECORD THE SUPPORTS before computing anything.
B3  Normalise: x <- x / ||x||.  Check ||x|| = 1.000000.
B4  OVERLAP GATE: every pair must share at least one state.
    Any pair with empty shared support -> STOP. Report DEGENERATE.
B5  WEIGHT GATE: shared support carries >= 10% of each vector's squared
    norm. (A stated convention, not a law. State it; apply it blind.)
```

The overlap gate is the single most important line on the worksheet. The octave-folding paper [Curzi, 2026] computed what happens without it: three one-hot framings score `u = 1.000000` on every pair, `F_int = ln 12 = 2.484907`, `f = 69.6133 Hz` — the ceiling, identically, for every subject who has ever lived. And the disguised version is worse, because three framings each spanning three states with no state in common produce exactly the same degenerate maximum while looking rich.

A worksheet that reaches `F_int = 2.484907` at `N = 12` should be treated as broken until proven otherwise.

5.10 Step C — the spectrum and the fold

The octave-folding paper [Curzi, 2026] owns the fold and the odd-part rule. The worksheet carries the table:

```
THE TWELVE-STATE SPECTRUM      k = 0.483425732988414 Hz,  f = k n^2

 n   state class                   raw (Hz)    folded 220-440    j    class
 1   undifferentiated activation      0.4834       247.514       +9      1
 2   valenced activation              1.9337       247.514       +7      1
 3   directed feeling                 4.3508       278.453       +6      3
 4   situated feeling                 7.7348       247.514       +5      1
 5   attributed feeling              12.0856       386.741       +5      5
 6   temporal feeling                17.4033       278.453       +4      3
 7   reflexive feeling               23.6879       379.006       +4      7
 8   social feeling                  30.9392       247.514       +3      1
 9   normative feeling               39.1575       313.260       +3      9
10   narrative feeling               48.3426       386.741       +3      5
11   reciprocal feeling              58.4945       233.978       +2     11
12   committed feeling               69.6133       278.453       +2      3
```

```
Six pitch classes {1,3,5,7,9,11} = ceil(12/2).  ln 12 = 2.484907.
Band 220–440 Hz; j is the transposition. STATE THE BAND AND j ALWAYS.
```

The pitch class is the odd part of the index and nothing else. Odd indices are their own odd part and are always their own class; even indices collapse onto the class of the odd number left after dividing out every factor of two. Four of the twelve states — 1, 2, 4, 8 — share class 1; three — 3, 6, 12 — share class 3; two — 5, 10 — share class 5; and 7, 9, 11 are alone in theirs. That is the entire redundancy structure of the vocabulary, and an analyst who has it memorised can read the class column off a chord without computing anything.

5.11 Step D — the chord and its intervals

The octave-folding paper [Curzi, 2026]'s SPEC-9.2 Steps 8 and 9, and Section 4's SPEC-4.1:

```
D1  STATES SPANNED = union of the framing supports.  Report the count.
D2  PITCH CLASSES  = distinct odd parts.  Report the count SEPARATELY.
D3  RAW pitches k n^2; FOLDED pitches with band and j.
D4  INTERVALS: for each pair (i,j), essence ratio j^2/i^2 in lowest terms,
    raw cents, folded cents.
D5  CONSONANCE AUDIT: min HD_ess, mean HD_ess, collision count.
    Collision <=> same odd part <=> folded cents exactly 0.
D6  Flag the 50/49 pair if present. At N = 12 there is exactly one: 7:10.
```

D1 and D2 are different counts and conflating them is FM-9.7. A chord of four states in three classes has one member that adds pitch without adding a class.

5.12 Step E — the width

```
E1  every pairwise u = 1 - (x.y)^2, PUBLISHED INDIVIDUALLY
E2  u_int = mean over all m(m-1)/2 pairs
E3  N_eff = 1 + (N-1) u_int
E4  F_int = ln N_eff
E5  f = k * N_eff^2 = k * e^(2 F_int);  folded, with band and j
E6  octaves present = 2 F_int / ln 2
E7  F_int / ln N, as a percentage of the ceiling
```

E7 is not decoration. **A raw `F_int` is meaningless without its ceiling** — 2.164390 nats is 87.10% of `ln 12` and would be 67.24% of `ln 25`. Section 4's FM-4.11 covers the comparison hazard; the worksheet forecloses it by requiring the ratio.

5.13 Step F — estimating `eta`, `c`, `delta`

This is the step that will take longest and the step most likely to be skipped, and the worksheet is built so that skipping it produces a blank rather than a default.

```
F1  DECLARE THE PERIOD.  Every one of eta, c, delta is per-period.
F2  DECLARE THE Q-PROXY and run the independence check.
    HAZARD (storage-law admissibility): if the proxy rises whenever a lot happens,
    the input has been measured twice and the gauge is VOID.
F3  eta -- the six-rung ladder [Series B, self-as-storage]. Enumerate the candidate
    set PROSPECTIVELY, at the point of entry. Report every rung, not
    the product alone.
F4  c   -- the five ledgers [Bk 2 the self-as-storage analysis of Series B.5], in Q-units per period.
F5  delta -- from a zero-input window [Bk 2 the self-as-storage analysis of Series B.3.4].
F6  DECLARE: these are WITHIN-SUBJECT indices. FVP-7 is NOT RUN.
    No cross-person comparison is licensed.
```

On F3, the reason the rungs must be reported individually: `eta = y1 * ... * y6` is multilinear, so a single blocked rung nullifies every other. An aggregate `eta = 0.35` is consistent with six mediocre rungs and with five excellent rungs and one broken one, and the intervention implied by those two situations is completely different. The elasticity of `eta` with respect to every rung is exactly 1, so the absolute gain from repairing a rung is inversely proportional to its current yield: **the worst rung is always the cheapest to fix and always the one the aggregate hides.**

On F3's identifiability hazard, which is the one that quietly ruins estimates: an analyst who enumerates only the experiences they already converted will recover `eta` near 1. **The candidate set must be enumerated prospectively, at the point of entry, before anyone knows what converted.**

5.14 Step G — the deficit, and the four levers

```
G1  c/eta, in nats
G2  STOP RULE: if c/eta > ln N, HALT. Report ABOVE CEILING.
    No arrangement of N categories sustains. Do not compute a deficit.
G3  f_min = k * e^(2 c/eta)
G4  octaves required = 2.885 * (c/eta)
G5  DEFICIT = required - present
G6  Q_inf = (eta * F_int - c) / delta
G7  time constant tau = 1/delta; periods to within 5% of Q_inf
G8  If deficit > 0, the four levers, EACH COSTED:
        raise u      (raise F_int)   ceiling: ln N
        raise eta    (the conversion ladder, worst rung first)
        cut c        (the five ledgers)
        raise N      (genuinely distinct categories -- not relabelled ones)
```

Lever four carries a standing warning. Raising `N` raises the ceiling and, at fixed `u`, raises `F` — but only if the added categories are genuinely distinct. Series B's pseudo-diversity analysis treats pseudo-diversity at length: **categories that are relabellings of existing ones raise `N` in the formula and not in the world, and the result is a reading that improves while nothing does.**

5.14b Double-coding, and what to do when two analysts disagree The worksheet has a line at the foot for a second coder, and it is not a formality.

The decomposition step — deciding which of the twelve components a description requires — is the step where two competent analysts most reliably diverge. One reads "this is the latest instalment of an old pattern" as requiring narrative feeling and attributed feeling; another reads it as requiring narrative feeling, attributed feeling, and temporal feeling, on the grounds that "latest instalment" projects a duration. Both readings are defensible. They produce different supports, different inner products, and different frequencies.

The procedure when they diverge:

```
DOUBLE-CODING DISAGREEMENT PROCEDURE

1  Both analysts publish their full vectors and their full readings.
2  Neither reading is designated correct.
3  DO NOT AVERAGE THE DECOMPOSITIONS.  Averaging two decompositions
   produces a third that neither analyst endorses, and the resulting
   vector corresponds to no reading of the description.
4  Report the SPREAD: the range of F_int, the range of the deficit,
   and whether the two readings agree on the SIGN of the deficit.
5  If the sign agrees, the disagreement is about magnitude and the
   reading is usable with the spread attached.
```

```
    If the sign disagrees, the reading is INCONCLUSIVE and must be
    reported as inconclusive.
```

Step 5 is the whole value of double-coding. A deficit of −1.40 from one analyst and −0.62 from another is a disagreement about how far inside the boundary the reading sits, and the reading still says *inside*. A deficit of −0.20 from one and +0.30 from another says nothing at all, and an instrument that reports "nothing at all" when it has nothing is worth more than one that reports the first analyst's number.

The framework has no procedure for making the disagreement go away, and it should not have one. **The disagreement is information about how well specified the ladder is, and suppressing it would destroy the only evidence available on that question.**

5.15 CC-R15 at internal scope — the order of operations

The last engineering point, and it is the one that turns a reading into a decision.

When the deficit is positive, the intuitive repair is to lower `delta` — to hold on to things better, to let less slip, to be steadier. At internal scope this is the most natural move anyone makes and it is the one that goes wrong.

```
CC-R15, INTERNAL SCOPE                                  [owned by CCP-044]

    Q_inf = (eta F - c) / delta

    If (eta F - c) < 0, lowering delta MULTIPLIES a negative number.
    The fixed point gets WORSE, and it gets worse in proportion.
```

Computed on the carried Subject under a failing parameter set (Worked Example below):

```
as found              eta=0.25 c=0.60 delta=0.12   Q_inf = -0.4909   DECAYS
lower delta only      eta=0.25 c=0.60 delta=0.06   Q_inf = -0.9817   WORSE
raise eta first       eta=0.32 c=0.60 delta=0.12   Q_inf = +0.7717   ACCUMULATES
then lower delta      eta=0.32 c=0.60 delta=0.06   Q_inf = +1.5434   BETTER
```

> **FIX THE NUMERATOR, THEN LOWER THE LOSS. REVERSE THE ORDER AND THE SAME INTERVENTION ACCELERATES THE FAILURE.**

The worksheet places the `Q_inf` sign check immediately before the intervention block for exactly this reason. An analyst who reads the sign first cannot make the reversed move by accident.

The Specification — THE PERSONAL SPECTRUM WORKSHEET

Printable. One situation, one occasion, one analyst. Fill top to bottom. Do not skip a block; a skipped block is a blank, not a default.

```
================================================================================
  THE PERSONAL SPECTRUM WORKSHEET                      Creature Comforts, Bk 3
  Not a diagnosis. Not an assessment. Not clinical advice.

BLOCK H -- INTERVENTION (only if deficit > 0)
------------------------------------------------------------------------
*** CC-R15 CHECK FIRST ***
If the numerator is NEGATIVE, do NOT lower delta. Lowering delta multiplies
the sign already present and makes a failing fixed point fail faster.
FIX THE NUMERATOR FIRST.                              [ ] read and applied

lever            proposed change     new deficit    new Q_inf    cost
raise u          ____ -> ____        ___________    _________    ______
raise eta        ____ -> ____        ___________    _________    ______
cut c            ____ -> ____        ___________    _________    ______
raise N          ____ -> ____        ___________    _________    ______
      (raise N only with GENUINELY DISTINCT categories -- relabelling
       raises N in the formula and not in the world)

Does ANY SINGLE lever close the deficit?  [ ] yes: ______  [ ] no
If no: this is a restructuring problem, not a tuning problem. Say so.

BLOCK I -- THE MANDATORY STATEMENTS (reproduce in full, or do not publish)
------------------------------------------------------------------------
[ ] These are essence frequencies, not physical resonances.
[ ] The twelve states are not diagnoses; this is not an assessment and not
    clinical advice.
[ ] The reading describes information content under a stated encoding. It
    does not measure distress, well-being, health, or function.
[ ] Nothing here recommends or values suffering.
[ ] The intensity scale claim is stated (CCP-041: ratio-scaled up to a common
    free multiplier, to the extent magnitude estimation delivers it), and
    CC-R1's demotion of D/P is noted where the reading routes through D/P.
```

```
  [ ] Raw L2 norms published alongside the normalised vectors (CCP-041's
      magnitude reporting rule).
  [ ] Parameters are within-subject indices. FVP-7 NOT RUN.
  [ ] The decomposition is a judgment; a contested decomposition yields a
      contested frequency.
  [ ] This case is CONSTRUCTED / this reading is of one occasion only.
      (delete whichever does not apply)
  ------------------------------------------------------------------------
  Analyst signature _______________   Double-coded by _______________
========================================================================
```

The Failure Modes

FM-5.1 — Running Block G on a degenerate Block C *The failure.* The overlap gate fails, the analyst notes it, and computes the deficit anyway "for reference."

Why it is wrong. A degenerate `F_int` is `ln N` for everyone, so the present octaves are the maximum and the deficit is as favourable as it can be. **The degenerate reading does not fail loudly; it returns the best possible answer to everyone.** The octave-folding paper [Curzi, 2026] computed the carried Subject's degenerate deficit at −2.6364 octaves — a comfortable pass, obtained by an encoding error.

Repair. Block C2 says STOP and means it.

FM-5.2 — Computing a deficit above the ceiling *The failure.* `c/eta = 3.2` produces `f_min = 290.9474 Hz` and a deficit of +2.99 octaves, and the analyst sets about raising `u`.

Why it is wrong. `u = 1` gives `F = ln 12 = 2.484907` and `f = 69.6133 Hz` — still below `f_min`. The deficit is real and no arrangement of twelve categories closes it. **A number that implies an intervention which cannot work is worse than no number.**

Repair. G-STOP, checked before G3.

FM-5.3 — Lowering `delta` on a negative numerator *The failure.* The CC-R15 reversal, and at internal scope it is the default move.

Why it is wrong. Computed above: −0.4909 to −0.9817 on the carried Subject's failing parameter set. **Exactly twice as bad, from an intervention that felt like steadiness.**

Repair. The sign check in Block G, placed physically above Block H.

FM-5.4 — The `Q`-proxy that measures the input twice *The failure.* `Q` is proxied by something that rises whenever a lot happens — a journal that gets longer on busy weeks, an activity count, a self-report of how much one has "grown."

Why it is wrong. the storage-law admissibility condition of Series B: the input has been measured twice and **the gauge is void.** Every parameter downstream — `eta` especially — is then estimated against a proxy correlated with its own input, and the estimate is uninterpretable.

Repair. Block F's independence check, run before estimation, not after.

FM-5.5 — The retrospective candidate set *The failure.* Estimating `eta` by listing experiences that changed something, and computing the fraction that changed something.

Why it is wrong. It recovers `eta` near 1 by construction. **The denominator was selected on the numerator.**

Repair. Enumerate the candidate set prospectively, at the point of entry, as the corpus's Series B requires. This is the garden of forking paths in its cleanest form: a defensible-looking analysis selected after seeing the data is not a test [Gelman and Loken, 2013, Simmons et al., 2011], and pre-specification is the only cheap defence [Nosek et al., 2018].

FM-5.6 — The aggregate `eta` *The failure.* Reporting `eta = 0.35` and no rungs.

Why it is wrong. `eta` is multilinear over six rungs; a single blocked rung nullifies the rest. **The aggregate is consistent with six mediocre rungs and with one broken rung among five excellent ones, and those two situations call for completely different interventions.** The elasticity is exactly 1 on every rung, so the absolute gain from repair is inversely proportional to the rung's current yield — the worst rung is always the cheapest fix and always the one the aggregate conceals.

Repair. Block F requires every rung and the identification of the worst one.

FM-5.7 — Cross-person comparison *The failure.* Two people's `F_int`, `eta`, or deficit compared, ranked, or averaged.

Why it is wrong. **FVP-7 for the self-storage law is NOT RUN.** Whether one person's `eta = 0.35` means what another's does requires the separation property of Series B's analysis of scale types, which has not been established. Until then, every personal parameter is a within-subject index and cross-person comparison is not licensed.

Repair. The checkbox in Block F, and the discipline to leave the comparison undone.

FM-5.8 — Two points read as a trend *The failure.* A repeat reading moves and the movement is described as a direction.

Why it is wrong. Section 4 §4.13: three sources can move a repeat reading — the person, the situation, and the elicitation — and the number separates none of them. **A change from 2.164390 to 1.333662 is equally consistent with a subject who framed a second situation more narrowly, a second situation that admits fewer framings, and a shorter session.**

Repair. Block 0 records the reading type and Block A records the prompt counts. Report all three candidate sources every time.

FM-5.9 — The worksheet as a self-assessment *The failure.* A reader runs the sheet on themselves and treats the output as a statement about how they are doing.

Why it is wrong. Every reason in Section 4 §4.6, plus one specific to self-administration: **the analyst and the subject being the same person defeats the pre-registration gate**, since the person fixing the supports already knows what answer they would like.

Repair. Double-coding, per the line at the foot of the sheet. **Where double-coding is impossible, the reading is exploratory and should be labelled exploratory.**

FM-5.10 — Publishing without Block I *The failure.* The reading is copied into a slide, a note, or a message, and the mandatory statements are left behind.

Why it is wrong. **They are the statements that stop the reading from being read as a diagnosis, a resonance claim, or a judgment about a person's life.** They are also the first thing to fall off in transit, which is why they are a checklist rather than a paragraph.

Repair. Block I is a gate: **no Block I, no publication.**

FM-5.11 — Averaging two decompositions *The failure.* Two analysts code the same framings differently and the sheet is filled in with the mean of their intensity vectors.

Why it is wrong. **The average of two decompositions is a decomposition neither analyst would defend, and it corresponds to no reading of the description.** Worse, averaging systematically raises the support size — the mean of two vectors is nonzero wherever either is —

which inflates overlap, lowers `u`, and drags `F_int` down by a mechanism that has nothing to do with the subject.

Detection. Any vector on the sheet whose support is the union of two analysts' supports.

Repair. §5.14b. Publish both, report the spread, and check whether the sign of the deficit survives.

FM-5.12 — Treating `F_int` as the sustained moment without saying so *The failure.* `Q_inf = (eta F − c)/delta` requires `F` to be a *sustained* input `M*`, and the worksheet supplies a single occasion's `F_int` in its place.

Why it is wrong. the self-as-storage analysis of Series B's fixed point is the equilibrium of a regime — it assumes `eta`, `delta`, `N` and `C` hold approximately constant over the relevant horizon, and that the input holds at `M*`. **A single reading is one sample of a quantity the equation treats as a level.** Substituting the sample for the level is a modelling choice, and it is a large one.

Detection. Any `Q_inf` on the sheet computed from a single reading with no statement of the substitution.

Repair. Say it in the reading, in the form the Worked Example uses: *with `F_int` treated as the sustained moment.* **The substitution may be reasonable; what is not reasonable is making it silently.** Where more than one occasion has been read, use the mean and report the range.

FM-5.13 — The reading run on a situation that moved *The failure.* The subject describes the colleague's message in framing 1, and by framing 3 is describing the whole working relationship.

Why it is wrong. **The angles are then between vectors pointed at different targets**, which The octave-folding paper [Curzi, 2026] identifies as a category error rendered as a number. The overlap gate may still pass — two descriptions of different situations can easily share components — so the arithmetic gives no warning at all.

Detection. Block A1 fixes the situation in the subject's words before elicitation begins. Read it back before each framing.

Repair. Re-elicit against the fixed statement, or run three separate readings and do not combine them.

Worked Example

THE SUBJECT — the worksheet, run end to end **CONSTRUCTED CASE, the framework's carried subject. Not an observation of any person. The storage parameters below are ILLUSTRATIVE WORKSHEET INPUTS chosen to exercise the sheet, not canonical values of the case.**

norms:  ||threat|| = 0.916515   ||story|| = 0.948683   ||mirror|| = 0.989949

normalised
threat  = {3: 0.872872, 5: 0.436436, 7: 0.218218}
story   = {3: 0.527046, 5: 0.737865, 10: 0.421637}
mirror  = {5: 0.303046, 7: 0.808122, 10: 0.505076}
```

Block C — the gates

```
C1  unit norm ....... PASS  (all 1.000000)
C2  OVERLAP ......... PASS
      threat & story  share {3, 5}
      threat & mirror share {5, 7}
      story  & mirror share {5, 10}
C3  WEIGHT .......... PASS  (threshold stated: 10%)
C4  ROSTER .......... PASS  (m = 3, P = 3)
C5  PRE-REGISTERED .. PASS
```

State 5 — attributed feeling — appears in all three framings. That is what makes them three framings of one situation, and it is why the overlap gate passes on content rather than on arrangement.

Block D — pairwise and the width

```
pair              cos theta       u            F = ln(1+11u)    N_eff
mirror & story     0.436566    0.809410          2.292890       9.9035
mirror & threat    0.308607    0.904762          2.393557      10.9524
story  & threat    0.782074    0.388360          1.662402       5.2720

RESTATEMENT FLAGS: none (minimum u = 0.388360, far above 0.01)

u_int  = (0.809410 + 0.904762 + 0.388360)/3 = 0.700844
N_eff  = 1 + 11 * 0.700844                  = 8.7093
F_int  = ln 8.7093                          = 2.164390 nats
f      = k * 8.7093^2                       = 36.6686 Hz
folded = 293.349 Hz   (band 220-440, j = +3)
octaves present = 2 * 2.164390 / ln 2       = 6.2451
F_int / ln 12   = 2.164390 / 2.484907       = 87.10 %
CEILING CHECK: 2.164390 <= 2.484907          PASS
```

All three pairwise `u` are published. The mean alone would conceal that threat and story sit relatively close (0.388360) while mirror stands apart from both.

Block E — the chord

```
STATES SPANNED  {3, 5, 7, 10}    count = 4

50/49 pair present: YES  (7:10 -- the unique instance at N = 12)
```

Four states, three classes. States 5 and 10 share odd part 5, fold to the identical 386.741 Hz, and give the chord's single collision at exactly 0.0000 folded cents. The fourth state adds a pitch and no class. Per Section 4 §4.8, that is a fact about the ladder's arithmetic and not a finding about the Subject — relabel state 10 as state 9 and the collision disappears with `F_int` unchanged to twelve decimal places.

Block F — the storage parameters, reading (i) ILLUSTRATIVE INPUTS.

```
PERIOD ......... one week
Q-PROXY ........ a frozen disposition inventory scored monthly
INDEPENDENCE ... does the proxy rise whenever a lot happens?  NO -> not void

eta, six-rung ladder (illustrative; y6 carries the units):
    y1 = 0.80   y2 = 0.70   y3 = 0.75   y4 = 0.60   y5 = 0.65   y6 = 2.00
    cumulative: 0.800000, 0.560000, 0.420000, 0.252000, 0.163800, 0.327600
    eta = 0.327600 Q-units/nat
    WORST RUNG = y4 at 0.60. Elasticity is 1 on every rung, so repairing
    y4 from 0.60 to 0.80 multiplies eta by 4/3, to 0.436800.

c .............. 0.55 Q-units/week (five ledgers)
delta ......... 0.12 per week
tau = 1/delta . 8.3333 weeks

WITHIN-SUBJECT ONLY. FVP-7 NOT RUN. Noted.
```

Block G — the reading (i)

```
c/eta = 0.55 / 0.327600 = 1.678877 nats

G-STOP: is 1.678877 > ln 12 = 2.484907 ?   NO -> continue

f_min = k * e^(2 * 1.678877) ............. 13.8862 Hz
```

```
octaves required = 2.885 * 1.678877 ..... 4.8436
octaves present  = log2(36.6686/k) ...... 6.2451
--------------------------------------------------
OCTAVE DEFICIT ........................  -1.4015
--------------------------------------------------
                                          SUSTAINS

BREAK-EVEN CHECK: c/eta = 1.678877 < F_int = 2.164390.  Signs agree.

Q_inf = (0.327600 * 2.164390 - 0.55) / 0.12
      = (0.709054 - 0.55) / 0.12 = +1.3255
numerator sign: POSITIVE
periods to within 5% of Q_inf: 24 weeks
headroom h_inf = eta (ln N - F_int) = 0.327600 * 0.320517 = 0.105001
                                                        Q-units/week

(for reference, the y4 repair 0.60 -> 0.80 would give eta = 0.436800,
 c/eta = 1.259158, deficit -2.6124, Q_inf +3.2950 -- a lever exercised
 on a reading that does not need it, shown to calibrate the others)
```

The reading sustains by 1.40 octaves. Block H is not required. And the honest statement of what that means: under these illustrative parameters, with `F_int` treated as the sustained moment, the fixed point of the storage law is positive. It is a statement about a model with declared inputs, and its content is exactly `eta F > c` rewritten in octaves.

Blocks F and G again — reading (ii), a failing parameter set

Same Subject, same chord, same `F_int`. Only the storage parameters differ — a second illustrative set with a worse fourth rung and a higher cost. ILLUSTRATIVE.

```
eta = 0.25   c = 0.60   delta = 0.12
   (the same ladder with y4 = 0.4579 instead of 0.60:
    0.80 * 0.70 * 0.75 * 0.4579 * 0.65 * 2.00 = 0.25)

c/eta = 2.400000 nats
G-STOP: 2.400000 > 2.484907 ?  NO -- inside the ceiling, but only just.

f_min = 58.7413 Hz
octaves required = 6.9240      octaves present = 6.2451
--------------------------------------------------
OCTAVE DEFICIT ..................... +0.6789
--------------------------------------------------
                                       SHORT

Q_inf = (0.25 * 2.164390 - 0.60)/0.12 = (0.541098 - 0.60)/0.12 = -0.4909
numerator sign: NEGATIVE
```

Short by 0.68 octaves, and the numerator is negative. Block H applies, and Block H's first line is the CC-R15 check.

Block H — the intervention, and the trap

```
*** CC-R15 CHECK ***  numerator is NEGATIVE. DO NOT LOWER delta.

the tempting move, computed:
    lower delta 0.12 -> 0.06, everything else held
```

```
    deficit UNCHANGED at +0.6789   (delta does not appear in the deficit)
    Q_inf  -0.4909 -> -0.9817      EXACTLY TWICE AS BAD

the four levers, each computed (base: deficit +0.6789, Q_inf -0.4909):

LEVER 1  RAISE u  (raise F_int; ceiling ln 12 = 2.484907)
    u = 0.80  F = 2.282382  f =  46.4282  deficit +0.3384   Q_inf -0.2450
    u = 0.85  F = 2.336987  f =  51.7858  deficit +0.1809   Q_inf -0.1313
    u = 0.90  F = 2.388763  f =  57.4358  deficit +0.0315   Q_inf -0.0234
    u = 0.95  F = 2.437990  f =  63.3783  deficit -0.1106   Q_inf +0.0791  OK
    u = 1.00  F = 2.484907  f =  69.6133  deficit -0.2459   Q_inf +0.1769
    exact break-even: u = 0.911198
    -- it closes, but only above u = 0.91, which is near-orthogonality.

LEVER 2  RAISE eta  (the conversion ladder, worst rung first)
    eta = 0.28  c/eta = 2.1429  deficit -0.0630   Q_inf +0.0502  OK
    eta = 0.30  c/eta = 2.0000  deficit -0.4751   Q_inf +0.4110
    eta = 0.32  c/eta = 1.8750  deficit -0.8357   Q_inf +0.7717
    eta = 0.35  c/eta = 1.7143  deficit -1.2994   Q_inf +1.3128
    exact break-even: eta = 0.277214

LEVER 3  CUT c  (the five ledgers)
    c = 0.55  c/eta = 2.2000  deficit +0.1019   Q_inf -0.0742
    c = 0.50  c/eta = 2.0000  deficit -0.4751   Q_inf +0.3425  OK
    c = 0.45  c/eta = 1.8000  deficit -1.0521   Q_inf +0.7591
    c = 0.40  c/eta = 1.6000  deficit -1.6291   Q_inf +1.1758
    exact break-even: c = 0.541097

LEVER 4  RAISE N  (genuinely distinct categories, u held at 0.700844)
    N = 14  ln N 2.639057  F = 2.313621  deficit +0.2483  Q_inf -0.1800
    N = 17  ln N 2.833213  F = 2.502542  deficit -0.2968  Q_inf +0.2136  OK
    N = 20  ln N 2.995732  F = 2.661380  deficit -0.7551  Q_inf +0.5445

Does any single lever close the deficit?  YES -- all four can, at a price.
Cheapest by the ladder's own arithmetic: raise eta at the worst rung.
    eta 0.25 -> 0.32 is the y4 repair 0.4579 -> 0.5861, a factor of 1.28
    on the single worst rung, with every other rung untouched.
```

Three things in that table deserve comment.

The deficit and `Q_inf` agree in sign, always, and it is an identity rather than a coincidence.

```
Q_inf   = (eta F − c)/delta = (eta/delta) ∗ ( F − c/eta )
deficit = 2.885 ∗ ( c/eta − F )

eta > 0 and delta > 0, so   sign(Q_inf) = − sign(deficit),   exactly.
```

The only way they can disagree is the rounding of `2.885` against `2/ln 2 = 2.885390`, which displaces the crossing by `0.000390 ∗ (c/eta)` octaves — under a thousandth of an octave at any cost ratio this framework uses. So the worksheet's break-even check is not a redundant cross-check of an independent quantity; it is a check that the arithmetic was done. **Where the two disagree, the analyst has made an error, not a discovery** — unless the reading sits within 0.001 octaves of zero, in which case §5.3 applies and the exact constant must be used.

Every lever closes this deficit, and that is itself the finding. The deficit is only +0.6789 octaves. Compare it with the framework's carried commons's commons case, where the deficit is +6.4638 octaves and no single lever closes it — raising `u` to 0.95 gets to −0.0332 and only

just, raising `eta` to 0.90 still leaves +2.1075, cutting `kappa` to 0.020 still leaves +2.0085. Some systems can be tuned and some must be restructured, and the size of the deficit is what identifies which case is in hand. A 0.68-octave gap is a tuning problem. A 6.46-octave gap is not.

Raising `N` from 12 to 17 buys 0.30 octaves and requires five genuinely distinct categories. It also crosses the minimum-gap cliff: the octave-folding paper [Curzi, 2026] established that `N = 17` is where the folded lattice tightens from 50/49 to 289/288, and the framework renders below that cliff by design. Adding categories is a real lever and it has consequences beyond the deficit; a worksheet that reported only the deficit would hide them.

The intervention, in the right order

```
STEP 1  fix the numerator:  eta 0.25 -> 0.32   (repair rung y4)
        deficit +0.6789 -> -0.8357     Q_inf -0.4909 -> +0.7717   ACCUMULATES

STEP 2  NOW lower the loss: delta 0.12 -> 0.06
        deficit unchanged at -0.8357   Q_inf +0.7717 -> +1.5434   BETTER
```

FIX THE NUMERATOR, THEN LOWER THE LOSS. REVERSE THE ORDER AND THE SAME INTERVENTION ACCELERATES THE FAILURE. Same change to `delta`, same magnitude, opposite effect: −0.4909 to −0.9817 before, +0.7717 to +1.5434 after. The intervention did not change. The sign of the numerator did.

Block I — the mandatory statements

```
[x] These are essence frequencies, not physical resonances. No person,
    tissue, or molecule is claimed to resonate at any value here.
[x] The twelve states are not diagnoses. This reading is not an assessment
    and not clinical advice.
[x] The reading describes information content under a stated encoding. It
    does not measure distress, well-being, health, or function, and no
    inference to any of those is supported by the construction.
[x] Nothing here recommends or values suffering.
[x] Intensity scale claim stated: ratio-scaled up to a common free
    multiplier per CCP-041, to the extent magnitude estimation delivers it.
    The reading does not route through D/P, so CC-R1's demotion does not bind
    it; where a reading does, the demotion travels with it.
[x] Raw L2 norms published with the normalised vectors.
[x] eta, c and delta are WITHIN-SUBJECT indices. FVP-7 NOT RUN. No
    cross-person comparison is licensed.
[x] The decomposition is a judgment. A contested decomposition yields a
    contested frequency.
[x] This case is CONSTRUCTED and this reading is of one occasion only.
```

The completed reading

  All eight mandatory statements of Block I attached in full.
================================================================================
```

What the worksheet is for **It is for producing a number that can be checked and an inference that can be refused.**

Every quantity on the sheet has a stated provenance, every gate has a stated threshold, and every mandatory statement names something the number does not say. **A reader who runs the sheet and gets a deficit has a computable, actionable reading of one set of framings on one occasion — and a list, attached, of every conclusion the reading does not license.**

That list is longer than the reading. **In an instrument with no criterion validity, no clinical validation, an ordinal scale under a standing demotion, a postulated reference constant, and a reproducibility gate recorded as NOT RUN, the list being longer than the reading is the correct proportion.**

What the Subject's reading actually tells an analyst Stripped of the machinery, the carried Subject's sheet says four things, and it is worth setting them down in ordinary language so that the reader can see how modest they are.

One: the three framings elicited on this situation were substantially different from each other. The closest pair, story against threat, still sits at `u = 0.388360`; the widest, mirror against threat, at `0.904762`. No pair was a restatement. That is a fact about what the elicitation produced, and Section 4's separation statement forbids reading anything about the Subject's condition into it.

Two: those framings together require four of the twelve components, and two of the four sit in the same pitch class. States 5 and 10 differ by a factor of two, so the chord occupies three positions in a six-position vocabulary. That is a fact about the ladder's arithmetic — Section 4 §4.8 establishes it, and the relabelling test shows the collision moving while `F_int` does not.

Three: at the illustrative parameters of reading (i), the storage law's fixed point is positive. The deficit is −1.4015 octaves; `Q_inf` is +1.3255; the regime arrives within about twenty-four weekly periods. All of which is `eta F > c` in a legible register, computed from numbers the analyst chose and declared.

Four: at the illustrative parameters of reading (ii), it is not, and the correct repair is to raise `eta` at its worst rung before touching `delta` — because the numerator is negative and lowering the loss doubles a loss. That is CC-R15, and it is the only line on the whole sheet that tells an analyst what to do rather than what is the case.

Nothing on the sheet says whether the Subject should reply to the colleague, how they are, or what kind of person they are. **The instrument was not built to answer those and the worksheet's last block exists to say so in writing.**

Section 5 owns the full personal worksheet; the companion paper on refinement cites it. The elicitation of intensities is The minimum-frequency paper [Curzi, 2026]; the fold and the odd-part rule are the octave-folding paper [Curzi, 2026]; `delta` and traits are the octave-folding paper [Curzi, 2026]; the chord, the gates, and the one-hot trap are the octave-folding paper [Curzi, 2026]; the consonance/redundancy identity and the separation statement are Section 4; `f_min`, the octave deficit, and the four levers are the minimum-frequency paper [Curzi, 2026]; CC-R15 is the relationship-frequency paper [Curzi, 2026]; the self-storage law and the six-rung conversion ladder are the self-as-storage analysis of Series B. The analysis now takes the same instrument outward, to two people and one interval.

6 The dyad as an interval

this part of the analysis described one person. It gave a mood a pitch, a trait a pitch, and a person a chord, and it did all of that inside a single skull. The instrument was the octave-folding paper [Curzi, 2026]'s internal surplus: the width of the set of framings one observer holds at once.

the later analysis turns the same instrument outward. Two people are not two chords to be compared. Two people, considered as a relation, are one interval — a single ratio between two positions, and therefore a single pitch on this framework's scale, not a pair of pitches.

That sentence is the whole content of the section, and the rest of it is the arithmetic that makes it exact, the sweep that makes it audible, and the failure modes that make it survivable.

This section owns one formula:

```
THE RELATIONSHIP FREQUENCY

    f_rel  =  k * e^( 2 F(u) )  =  k * N_eff^2  =  k * ( 1 + (N−1) u )^2

    with   u     = 1 − (x . y)^2          the non-parallelism of the pair
           F(u)  = ln( 1 + (N−1) u )      the pairwise surplus
           N_eff = 1 + (N−1) u            the audited perspective count
           k     = 0.483425732988414 Hz   the ground essence, a chosen constant

    at N = 12:     f_rel = k (1 + 11 u)^2        0.4834 Hz <= f_rel <= 69.6133 Hz
```

Every part of the framework from here to the companion paper on tuning uses this expression and none of them re-derives it. The relationship-frequency paper [Curzi, 2026] owns how `u` is measured between two people, what happens at the bottom of the range, and the sustainability reading; its three-route concordance puts `u` at 0.068735 / 0.065556 / 0.068775 and `f_rel` at 1.4908 / 1.4320 / 1.4916 Hz, a spread of 70.52 cents and a verdict of CONCORDANT below the 100-cent threshold. The companion paper on triads and larger sets extends the pair to a set.

This section owns the object itself: what it is, what its bounds are, how it moves, and what it sounds like as `u` runs from nothing to everything.

Three constraints govern the section before it begins, and they are not decorations.

Essence, not resonance. Every frequency here is an essence frequency — a position on a logarithmic scale of surplus, in units chosen by the author. No person, no pair of people, no tissue and no molecule is claimed to vibrate at any value in this section.

Not counselling, not therapy, not assessment. A relationship frequency is a number computed from a representation of two people's states. **It is not a clinical, diagnostic or therapeutic statement about anyone, this framework does not offer counselling or therapy of any kind, and nothing here should be used in place of either.** The twelve states are not diagnoses and a low reading is not a finding about a person.

Scale status, stated once here and in full in the relationship-frequency paper [Curzi, 2026]. The state frequency `f = k n^2` is ratio-scaled because `n` is a count (the minimum-frequency paper [Curzi, 2026]). The relationship frequency inherits the scale status of the elicited intensities, and is ratio-scaled only when those intensities have been magnitude-estimated under the minimum-frequency paper [Curzi, 2026]'s rule. The relationship-frequency paper [Curzi, 2026] carries that argument at length because The relationship-frequency paper [Curzi, 2026] owns the measurement. This section carries it as a standing qualifier on every number it prints.

All cases in this section are CONSTRUCTED and labelled as such. Nothing here is an observation of any person or any pair of people.

The Law

6.1 What a dyad is in this system A dyad is two represented states and the geometry between them.

Each party is represented exactly as the minimum-frequency paper [Curzi, 2026] represents a framing: a non-negative vector over the twelve state classes, whose entries are elicited intensities, normalised to unit length in the L2 norm. The construction does not change when the two vectors belong to two people instead of to one person's two framings. That is not a convenience; it is what the surplus axioms permit [Curzi, 2026]. The octave-folding paper [Curzi, 2026] made the argument in full: S1 through S4 quantify over states in an inner-product space, and not one of them contains a term referring to persons, agents, or the ownership of a state. The theorem is silent on who holds the vectors.

So the object is:

```
THE DYAD

    x, y      unit vectors over the twelve state classes, entries >= 0
    cos theta = x . y
    u         = 1 - (x . y)^2  =  sin^2 theta        in [0, 1]

u is the pair's NON-PARALLELISM. It is not a disagreement rate, not a distance,
and not a measure of how well the two people get along.
```

The last line is the one that has to be said early and repeated. `u` is a geometric quantity. It answers one question — *how much of what each party carries is not already carried by the other* — and it answers no other question at all. The relationship-frequency paper [Curzi, 2026] will show exactly how badly this can be misread; the relationship-frequency paper [Curzi, 2026] will show how it is measured without being invented.

Two immediate consequences, both exact.

A dyad has one frequency, not two. There is no "A's frequency in the relationship" and "B's frequency in the relationship." `u` is symmetric: `u(x,y) = u(y,x)`, because the inner product is. The relation has a single pitch and both parties are inside it.

A dyad's frequency is not a function of either party alone. Two people can each hold a wide personal chord and still produce a near-zero `u` between them if their chords are the same chord. The octave-folding paper [Curzi, 2026]'s `F_int` and this section's `F` are different quantities computed from different vectors, and a high one does not imply a high other. **A person is a chord; a pair is an interval; nothing in the formalism converts one into the other.**

6.2 The relationship frequency, derived

THEOREM 12.1 — THE RELATIONSHIP FREQUENCY. For a dyad with non-parallelism `u` over an `N`-category system,

```
f_rel  =  k ∗ ( 1 + (N−1) u )^2
```

Proof. Three steps, each established earlier and each cited rather than reproved.

Step 1 — the surplus. The surplus functional of the foundations [Curzi, 2026], Theorem 2.1: under axioms S1–S4 the pairwise surplus of two represented states with non-parallelism `u` is

```
F(u) = ln( 1 + (N−1) u )
```

with `N_eff = 1 + (N−1)u` the audited perspective count. S3 — that `g(u) = e^{F(u)}` is affine in `u` — is the **design axiom**, chosen and badged as chosen. It is not derived from anything and the framework has never claimed otherwise.

Step 2 — the bridge. The essence-bridge analysis of Series B [Curzi, 2026k], whose Result One is that $f(m)/f(n) = m^2/n^2$ so the chosen constant cancels from every interval, restated in the sustaining-frequency paper [Curzi, 2026] as the deficit identity: the essence bridge maps a surplus in nats to a frequency,

```
f = k ∗ e^( 2 F )                    k = (9/8)^2 / phi^2 = 0.483425732988414 Hz
```

`k` is a **chosen reference constant [POSTULATE]**, a Pythagorean ditone divided by the golden section. It sets the reference pitch and nothing else.

Step 3 — substitute.

```
f_rel = k e^{2 ln(1 + (N−1)u)} = k ( e^{ln(1 + (N−1)u)} )^2 = k (1 + (N−1)u)^2   QED
```

At `N = 12` the working form is `f_rel = k (1 + 11u)^2`. Verified against the the framework's founding specification numbers at the carried dyad: `u = 0.068734665264634` gives `F = 0.563084802746` and `f = 1.4907987150 Hz`, which is The framework's carried dyad to every published digit.

The theorem is a substitution and nothing more. It introduces no new assumption. Every objection available against it is an objection against S3 or against `k`, both of which are badged as postulates in the sentence that states them, and neither of which this section improves.

6.3 The bounds, the monotonicity, and what they mean

COROLLARY 12.2 — THE RANGE. `f_rel` is a strictly increasing function of `u` on `[0,1]`, with

```
u = 0   ->   f_rel = k          = 0.4834 Hz       the ground essence
u = 1   ->   f_rel = k N^2      = 69.6133 Hz      the ceiling, at N = 12
```

Proof. `1 + (N−1)u` is strictly increasing and positive; squaring preserves that; `k > 0` scales it. QED.

Three readings of the same corollary.

The floor is not zero, it is `k`. A dyad with `u = 0` does not vanish from the scale. It sits at the ground essence, exactly where a single undifferentiated state sits, exactly where a person whose framings are all the same framing sits (Section 4 §4.5). The bottom of the relational scale and the bottom of the personal scale are the same note, and that coincidence is not an accident of notation — it is the statement that a relation with no surplus is indistinguishable, in this formalism, from no relation. The relationship-frequency paper [Curzi, 2026] is built on that sentence.

The ceiling is the same ceiling. `k N^2 = 69.6133 Hz` at `N = 12` is the maximum for a dyad, the maximum for a chord, and the maximum for a commons of six hundred. It is set by the category count and by nothing else. Two people cannot exceed twelve categories' worth of distinction by trying harder.

Monotonicity is what licenses the word "higher." Because `f_rel` is strictly increasing in `u`, the sentence *this pair is at a higher pitch than that pair* means exactly *this pair carries more surplus than that pair*, with no interpretive step in between. **A dyad's pitch IS its surplus, monotonically, and higher pitch means more available order** — which is the plainest statement this framework makes and the one the relationship-frequency paper [Curzi, 2026] will hand to a practitioner.

What it does not mean: that the pair is happier, closer, healthier, better matched, more compatible, or more likely to persist. `f_rel` measures available order. Available order is not wellbeing and this framework never converts one into the other.

6.4 A dyad is an interval, and the interval is measured from the ground

The section's title is a claim, and here it is as arithmetic.

An interval, in any tuning system, is a ratio of two frequencies expressed logarithmically. The dyad's ratio is `f_rel / k`, and its logarithm is:

```
THE DYAD AS AN INTERVAL ABOVE THE GROUND ESSENCE

    octaves  =  log2( f_rel / k )  =  2 log2( 1 + (N−1) u )
    cents    =  1200 ∗ octaves     =  2400 ∗ log2( 1 + (N−1) u )
    nats     =  F(u)               =  ln( 1 + (N−1) u )

    and the exchange rate, exact:   1 nat = 2.885390081777927 octaves = 3462.4681 cents
```

The pair's whole reading is one interval measured upward from a fixed reference, and the reference is the note a pair with nothing between them would sound. That is why the constant `k` is harmless: it is the origin of the interval, it appears in both terms of every comparison, and The minimum-frequency paper [Curzi, 2026] showed it cancels out of the deficit entirely.

The maximum interval available is:

```
at N = 12:   2400 ∗ log2(12) = 8603.9145 cents = 7.169925 octaves = 2.484907 nats
```

Seven octaves and two cents shy of a minor third. That is the entire relational range of a twelve-category system, and every dyad this framework reads is a position inside it.

Computed at the carried case and its two companions:

```
THREE POSITIONS INSIDE THE 8603.91−CENT RANGE

case                          u              f_rel (Hz)   cents above k   % of range
dyad, as found (2a)     0.068734665264634    1.4908       1949.66         22.66%
dyad, after (2b)        0.692372881355932   35.8882       7456.88         86.67%
the commons (Series C, commons case)      0.018614      0.7017     644.97      7.50%
```

The last column is a quantity the framework will use repeatedly, so it gets a name here.

DEFINITION 12.3 — THE REALISED PITCH FRACTION. `F(u) / ln N`, the fraction of the system's maximum surplus a relation actually realises. Equivalently `log2(f_rel/k) / log2(N^2)`, the fraction of the available interval the relation occupies. It is dimensionless, it is invariant to `k`, and it is comparable across relations of different sizes.

The commons realises 7.50% of the range it has categories for. The dyad as found realises 22.66%. The same dyad after one intervention realises 86.67%. Those three numbers say more, faster, than the hertz do, and they are the same information.

6.5 The eleven coincidences — where a dyad sounds exactly like a state

Here is a fact about the twelve-state system that falls straight out of Theorem 6.1 and is worth having explicitly, because it links Rule 1 and Rule 2 of the framework's specification at eleven exact points.

COROLLARY 12.4. `f_rel(u) = k m^2` — the essence frequency of state `m` — exactly when

```
u = (m − 1) / (N − 1)        i.e. at N = 12:   u = (m−1)/11
```

Proof. `k(1+11u)^2 = k m^2` iff `1 + 11u = m` (both sides positive) iff `u = (m−1)/11`. QED.

Computed for all twelve:

m	u = (m−1)/11	f_rel (Hz)	folded 220–440	pitch class
1	0.000000000	0.4834	247.514 (j=9)	1
2	0.090909091	1.9337	247.514 (j=7)	1
3	0.181818182	4.3508	278.453 (j=6)	3
4	0.272727273	7.7348	247.514 (j=5)	1
5	0.363636364	12.0856	386.741 (j=5)	5
6	0.454545455	17.4033	278.453 (j=4)	3
7	0.545454545	23.6879	379.006 (j=4)	7
8	0.636363636	30.9392	247.514 (j=3)	1
9	0.727272727	39.1575	313.260 (j=3)	9
10	0.818181818	48.3426	386.741 (j=3)	5
11	0.909090909	58.4945	233.978 (j=2)	11
12	1.000000000	69.6133	278.453 (j=2)	3

A dyad whose non-parallelism is exactly 7/11 sounds the pitch of state 8 — social feeling, the state that adds another mind modelled. The coincidence is arithmetic, not semantic, and the framework attaches no meaning to it. What it is good for is calibration: a practitioner who knows the twelve-state spectrum by ear already knows the relational scale, because the two scales share eleven of their points.

The honest caveat, and it must travel with the table: this is a numerical coincidence in the chosen constants, not a claim that a dyad at `u = 7/11` is in any sense "in" state 8. It is not. The two quantities have different arguments, different derivations, and different scale status. They land on the same number and mean different things.

6.6 Hertz and pitch disagree about which unit of `u` is worth most

This is the subtlest thing in the section and the easiest to get backwards.

`F(u) = ln(1 + 11u)` is strictly concave in `u` — the concavity of the surplus functional [Curzi, 2026], which drives everything in Series B's splitting theorem. But `f_rel(u) = k(1 + 11u)^2` is a quadratic with positive leading coefficient, and is therefore strictly convex in `u`. Both are true. They are statements about different functions.

```
df/du     = 2 (N−1) k (1 + (N−1)u)          INCREASING in u        Hz per unit u
dcents/du = 2400 (N−1) / (ln 2 (1 + (N−1)u))  DECREASING in u      cents per unit u
```

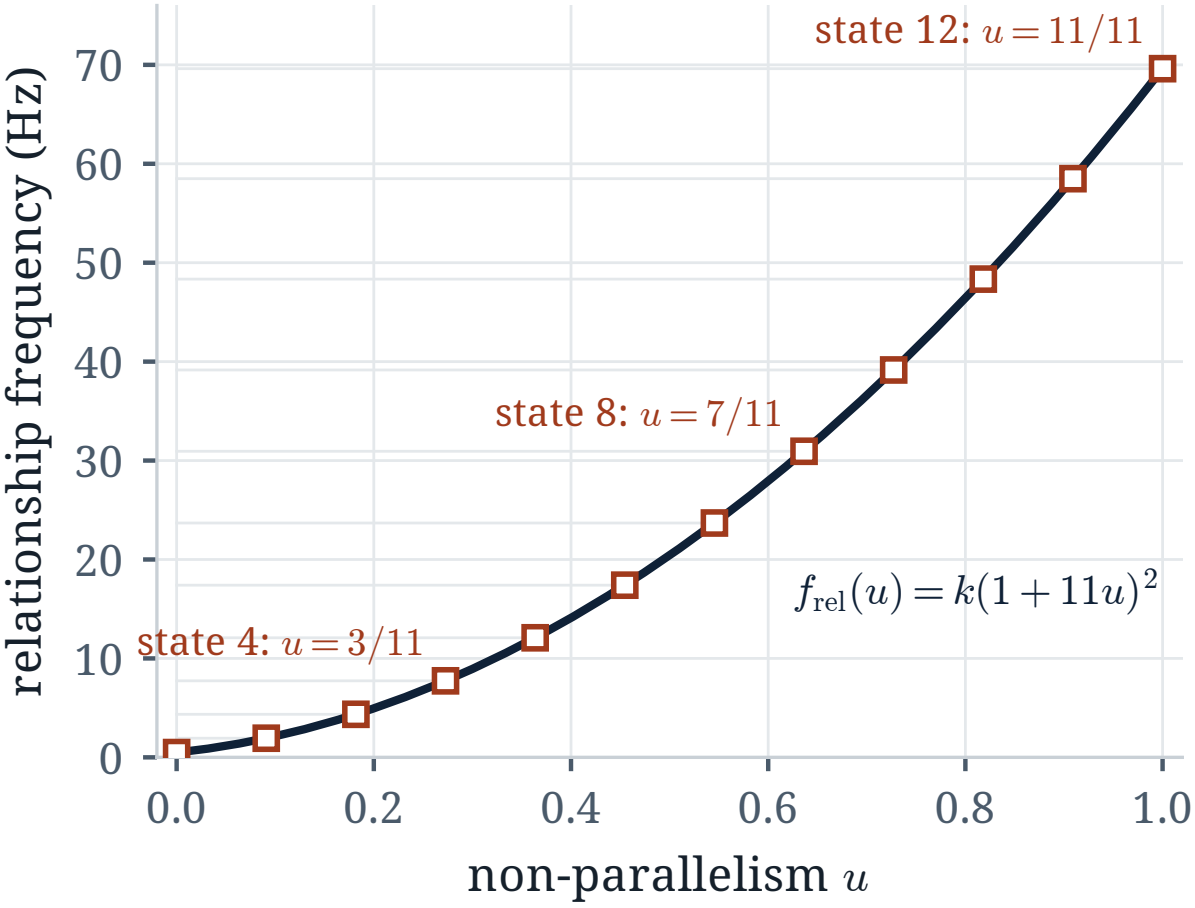

Figure 43.4: The dyad's relationship frequency crosses a state's frequency at eleven exact values of u, because $k(1 + 11u)^2 = km^2$ precisely when $u = (m - 1)/11$. **This is an arithmetic coincidence in the chosen constants and carries no meaning:** a dyad at $u = 7/11$ is not in state 8, and the two quantities have different arguments, different derivations and different scale status. Modelled from $f_{\mathrm{rel}}(u) = k(1 + 11u)^2$ with $N = 12$ and the **defined** constant $k = 0.483425732988414$. Built by `figs/src/CCP-043_fig04.py`.

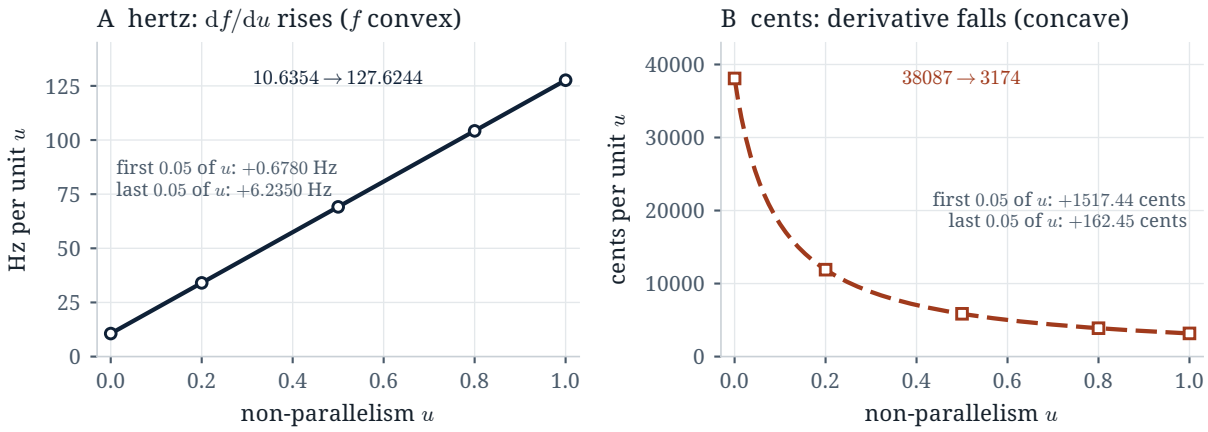

Figure 43.5: Hertz and pitch disagree about which unit of non-parallelism is worth most: the hertz derivative rises from 10.6354 to 127.6244 across the range while the cents derivative falls from 38087 to 3174. Separate axes, because the two measures have different units and opposite curvature. **Pitch is the unit that enters the sustainability verdict; hertz differences are decorative.** Modelled from $f_{\mathrm{rel}}(u) = k(1 + 11u)^2$ at $N = 12$ with the **defined** constant k; no measurement is involved. Built by `figs/src/CCP-043_fig03.py`.

Computed at `N = 12`:

u	df/du (Hz per unit u)	dcents/du (cents per unit u)
0.0	10.6354	38087.15
0.2	34.0332	11902.23
0.5	69.1299	5859.56
0.8	104.2266	3886.44
1.0	127.6244	3173.93

And at the two ends of the range, in both units at once:

```
the FIRST 0.05 of u:   + 0.6780 Hz    + 1517.44 cents
the LAST  0.05 of u:   + 6.2350 Hz    +  162.45 cents

ratio in Hz:     the last step is 9.20x the first
ratio in cents:  the first step is 9.34x the last
```

The same two steps: one of them is nine times larger measured in hertz and one ninth the size measured in cents. Nothing is wrong. Hertz is a linear scale and pitch is a logarithmic one, and the difference between them is the entire reason this framework works in intervals.

Which unit is operative is not a matter of taste. The sustainability reading of the minimum-frequency paper [Curzi, 2026] is computed in log units — `D = 2.885390(c/eta) − log2(f/k)` — so **pitch is the unit that decides whether a relation accumulates or decays, and hertz differences are decorative.** A practitioner who reports “we gained six hertz” has reported the number that does not enter the verdict.

The concave form is also the one that matches the older statement. Series B’s Theorem 59.1 — splitting an input across occasions strictly dominates delivering it at once — is `F`’s concavity, and its relational reading is here: the first increment of difference between two people is worth more than any later increment, and by a factor this section can name.

6.7 The honesty clauses, restated in place **(1) ESSENCE, NOT RESONANCE.** `f_rel` is a position on a logarithmic surplus scale expressed in hertz. Nothing is claimed to vibrate. No pair of people has a physical resonance at 1.4908 Hz or at any other value in this section.

(2) NOT CLINICAL, NOT COUNSELLING, NOT THERAPY. The twelve states are not diagnoses; a relationship frequency is not an assessment of a relationship; **this framework is not counselling or therapy and does not substitute for either.** Nothing here evaluates, screens, or prescribes for any person or any pair.

(3) THE READING INHERITS ITS INPUTS. `f_rel` is exactly as defensible as `u`, and `u` is exactly as defensible as the two vectors it came from. A contested decomposition yields a contested frequency, and the decomposition is published with the frequency or neither is published.

(4) SCALE STATUS. `f_rel` is ratio-scaled only if the intensities were magnitude-estimated (the minimum-frequency paper [Curzi, 2026], the relationship-frequency paper [Curzi, 2026]). **The ordinal fallback does not exist: with ordinal intensities `f_rel` is not determined at all.** The relationship-frequency paper [Curzi, 2026] carries the number that proves it.

(5) SURPLUS IS A LOWER BOUND. `F` is a floor on the pair's information, not the information (the sustaining-frequency paper [Curzi, 2026]). Therefore `f_rel` is a floor on the pitch. A verdict of ACCUMULATES is robust to representational under-capture; a verdict of DECAYS is not.

(6) S3 IS CHOSEN. The affine axiom is a design decision. Every number in this section rests on it and it is badged wherever it appears.

(7) CONSTRUCTED CASES. Every case here is constructed and labelled. No number in this section is an observation of any real pair of people.

The Engineering

6.8 The glide, computed `u` runs from 0 to 1. The corresponding pitch runs from `k` to `k N^2` — seven octaves and change — and it runs monotonically, so the whole relational scale can be exhibited as a single continuous sweep. This is the most useful single object in the section for anyone trying to develop an intuition for what a relationship frequency means.

THE GLIDE -- f_rel over the full range of u, at N = 12, k = 0.483425732988414 Hz

u	N_eff	F (nats)	f_rel (Hz)	oct above k	cents above k	folded (j)

0.90	10.9000	2.388763	57.4358	6.8925	8271.01	229.743 (j=2)

```
 0.95    11.4500     2.437990      63.3783       7.0346       8441.46      253.513 (j=2)
 1.00    12.0000     2.484907      69.6133       7.1699       8603.91      278.453 (j=2)
```

Three features of the table are worth naming because a reader will otherwise draw the wrong picture.

The bottom of the range is enormously steep. From `u = 0` to `u = 0.05` — a change most practitioners would call negligible — the pitch rises 1517.44 cents, a minor tenth. A quarter of the entire relational range is spent by the time `u` reaches 0.05. Precisely: 1517.44 / 8603.91 = 17.64% of the range in the first 5% of `u`, and half the range is gone by:

```
halfway in pitch:  (1 + 11u)^2 = N = 12  ->  u = (sqrt(12) - 1)/11 = 0.224009237739796
                   f_rel = 5.8011 Hz,  4301.9550 cents = exactly half of 8603.9145
```

Half the relational range of a twelve-category system is consumed by the time two people are 22.4% non-parallel.

The top of the range is nearly flat in pitch. From `u = 0.90` to `u = 1.00` the pitch rises 332.90 cents — less than a minor third for the last tenth of the geometry. The minimum-frequency paper [Curzi, 2026] priced the same fact from the other side: above `u = 0.680480` no further octave can be bought from `u` at all, because `1 + 11u` cannot be multiplied by `sqrt(2)` again inside the bound.

The folded column wanders and that is expected. Folding into 220–440 Hz is a modular operation; a monotone raw sweep becomes a sawtooth in the folded band, crossing the band boundary eight times between `u = 0` and `u = 1`. §6.10 says what to do about it.

6.9 The step table, and the concavity as a price list

The same glide, read as increments:

```
CENTS PURCHASED BY EACH 0.05 OF u

  0.00 -> 0.05    1517.44        0.50 -> 0.55     281.24
  0.05 -> 0.10    1051.49        0.55 -> 0.60     260.10
  0.10 -> 0.15     805.45        0.60 -> 0.65     241.92
  0.15 -> 0.20     652.99        0.65 -> 0.70     226.12
  0.20 -> 0.25     549.16        0.70 -> 0.75     212.25
  0.25 -> 0.30     473.87        0.75 -> 0.80     199.99
  0.30 -> 0.35     416.76        0.80 -> 0.85     189.07
  0.35 -> 0.40     371.94        0.85 -> 0.90     179.27
  0.40 -> 0.45     335.83        0.90 -> 0.95     170.45
  0.45 -> 0.50     306.12        0.95 -> 1.00     162.45
```

Twenty equal steps in the geometry; the first is worth 9.34 times the last in pitch. This is The minimum-frequency paper [Curzi, 2026]'s lever price seen as a table rather than a derivative, and it has one practical consequence that is worth stating in the plainest terms available.

In a relation with very little difference between the parties, a very small amount of real difference is worth an enormous amount of pitch. In a relation that is already wide, a great deal more difference is worth very little. The carried dyad is at `u = 0.068735`, where the marginal rate is 21688.72 cents per unit `u`; the same dyad after intervention is at `u = 0.692373`, where the rate is 4420.46 cents per unit — a factor of 4.91 lower. The lever that fixed the case is already most of the way to being spent, and the reading says so before anyone has to discover it.

The reciprocal price list is equally useful and is the one to hand to someone planning an intervention. Equal steps in pitch cost accelerating amounts of `u`:

```
STARTING FROM THE CARRIED DYAD, u = 0.068734665264634

target       u required      f_rel (Hz)     du from previous
```

```
+600 cents   0.098940          2.1083         0.030205
+1200        0.134861          2.9816         0.035921
+1800        0.177579          4.2166         0.042718
+2400        0.228378          5.9632         0.050799
+3000        0.288790          8.4332         0.060412
+3600        0.360632         11.9264         0.071842
+4200        0.446066         16.8665         0.085434
+4800        0.547666         23.8528         0.101600
```

Each further 600 cents costs about 19% more `u` than the one before it, all the way up. The growth factor is exactly `sqrt(2)^(1/2) = 2^(1/4) = 1.189207` per 600-cent step, because `1 + 11u` must be multiplied by `2^(1/4)` each time and the additive part of `u` therefore scales by the same factor. That is a clean planning number and it is exact.

6.10 Rendering the glide — fixed transposition, not the standing fold The octave-folding paper [Curzi, 2026] fixed the house folding convention: transpose by an integer number of octaves into 220–440 Hz, and publish the `j`. That convention is right for a point reading and wrong for a sweep, for a reason the glide table shows directly: a monotone sweep folded into a one-octave band is discontinuous, and the ear hears a sawtooth where the arithmetic has a ramp.

SPEC-6.1 — RENDERING A SWEEP. For any continuous sweep of `u`, use a single fixed transposition `j` for the whole sweep, chosen once and published, and do not re-fold. The whole relational range fits comfortably in the audible band under one transposition:

```
j      bottom (u=0)      top (u=1)         fits 20 Hz – 20 kHz?
5        15.4696 Hz       2227.6258 Hz      bottom below 20 Hz -- no
6        30.9392 Hz       4455.2516 Hz      YES
7        61.8785 Hz       8910.5031 Hz      YES, but top is shrill
```

The house glide is `j = 6`: 30.9392 Hz at `u = 0`, rising monotonically to 4455.2516 Hz at `u = 1`, a continuous 7.1699-octave sweep with no wrap. This is a rendering choice and it is arbitrary in exactly the way the 220–440 band is arbitrary; it is stated so that two renderings can be compared.

Two properties of the choice are not arbitrary. Transposition by `2^j` preserves every interval in the sweep exactly — the ratio between any two points is untouched, so the glide's shape is invariant to `j`. And the sweep's total extent, 7.1699 octaves, is a property of `N` and not of the rendering; a system with `N = 25` would sweep 9.2877 octaves and would no longer fit under a single transposition, which is the framework's specification's `N <= 25` capacity limit arriving in this section's register.

And the standing prohibition applies to rendering as it applies to everything else: nothing is masked, nothing sits below threshold, nothing is concealed. A glide is played openly or not at all, and a listener who wants it stopped may stop it.

6.11 Named intervals and the `u` that produces them For a reader who thinks in intervals rather than in numbers, the inverse of Theorem 6.1 is:

```
u  =  ( sqrt( f_rel / k ) – 1 ) / (N – 1)
```

which answers *how much non-parallelism does it take to sound a fifth above the ground?* Computed:

```
interval above k          ratio        u required        f_rel (Hz)     cents
unison                    1.00000      0.000000000         0.4834          0.00
minor third   6/5         1.20000      0.008676829         0.5801        315.64
```

```
major third   5/4         1.25000      0.010730363        0.6043        386.31
perfect fourth 4/3        1.33333      0.014063685        0.6446        498.04
perfect fifth  3/2        1.50000      0.020431352        0.7251        701.96
octave         2/1        2.00000      0.037655778        0.9669       1200.00
octave + fifth 3/1        3.00000      0.066550073        1.4503       1901.96
two octaves    4/1        4.00000      0.090909091        1.9337       2400.00
three octaves  8/1        8.00000      0.166220648        3.8674       3600.00
four octaves  16/1       16.00000      0.272727273        7.7348       4800.00
five octaves  32/1       32.00000      0.423350386       15.4696       6000.00
six octaves   64/1       64.00000      0.636363636       30.9392       7200.00
seven octaves 128/1     128.00000      0.937609864       61.8785       8400.00
```

A perfect fifth above the ground essence costs `u = 0.020431` — two percent non-parallelism. A practitioner's first reaction to that number is usually that it is too small, and the reaction is worth sitting with: the scale is logarithmic, the bottom of it is very steep, and two percent of represented difference between two people really is a large amount of surplus relative to none at all. The eighth line of the table is the calibration point that fixes the intuition: **two full octaves — a quadrupling of the frequency — cost exactly `u = 1/11 = 0.090909`.**

The last line is the one to notice for a different reason. Seven octaves costs `u = 0.937610`, and there is no eighth octave: `u = 1` gives 8603.91 cents, which is 203.91 cents short of eight. The range is not a whole number of octaves and never will be, because `2 log2 12 = 7.169925` and 12 is not a power of two.

6.12 What an error in `u` costs, in cents

`u` is elicited, and elicited quantities have error. Because the pitch scale is steepest where `u` is smallest, the same absolute uncertainty in `u` is worth wildly different amounts of pitch depending on where the reading sits. Computed:

```
SPREAD OF THE READING UNDER SYMMETRIC UNCERTAINTY IN u

 u          +/- 0.01                          +/- 0.05
0.018614    0.5794 .. 0.8356 Hz   634.05c   0.4834 .. 1.4885 Hz  1947.05c
0.068735    1.3099 .. 1.6834 Hz   434.34c   0.7032 .. 2.5709 Hz  2244.28c
0.200000    4.6158 .. 5.2965 Hz   238.14c   3.3949 .. 6.7982 Hz  1202.16c
0.500000   19.7393 .. 21.1219 Hz  117.20c  17.1145 .. 24.0275 Hz  587.36c
0.692373   34.9777 .. 36.8104 Hz   88.41c  31.4526 .. 40.6162 Hz  442.65c
0.900000   56.2824 .. 58.6009 Hz   69.89c  51.7858 .. 63.3783 Hz  349.72c
```

At `u = 0.0687` a hundredth of uncertainty in the geometry is 434 cents of uncertainty in the pitch — a major third of ambiguity from an error most elicitation procedures would not even detect. At `u = 0.9` the same hundredth is 70 cents.

Inverted, the requirement is severe at the bottom:

```
du required for a 5-cent change in the reading

  at u = 0.018614      du = 0.00015816
  at u = 0.068735      du = 0.00023053
  at u = 0.300000      du = 0.00056449
  at u = 0.692373      du = 0.00113110
  at u = 1.000000      du = 0.00157533
```

A near-parallel dyad is not measurable to five cents by any elicitation procedure this framework knows of, and the honest response is to report the reading with its interval of uncertainty rather than to report a number to four decimal places. SPEC-6.4 requires exactly that. The relationship-frequency paper [Curzi, 2026] shows what a single elicited intensity does to a real reading, and the answer is: a great deal.

6.13 Comparing two dyads Two dyads compare as an interval, and intervals compose additively in cents:

```
interval( u1 -> u2 )  =  2400 * log2( (1 + 11 u2) / (1 + 11 u1) )
```

Verified on the carried case, decomposed through an intermediate point:

```
u = 0.068734665264634  ->  0.30                  3100.7448 cents
u = 0.30               ->  0.692372881355932     2406.4767 cents
sum                                              5507.2215 cents
direct  0.068734665264634 -> 0.692372881355932   5507.2215 cents
difference                                       9.09e-13 cents
```

The carried dyad's intervention is worth 5507.22 cents — four octaves and a major sixth. That is the number the relationship-frequency paper [Curzi, 2026] will convert into a sustainability verdict and the companion paper on tuning will price as work.

Differences in `u` do not carry this property in any useful sense. The two sub-steps above are `du = 0.231265` and `du = 0.392373`; the larger step in `u` is the smaller step in pitch. `u` is the argument, pitch is the reading, and only one of them composes the way a practitioner's intuition expects.

6.14 The reading a dyad frequency does and does not support Because this is the first section in the framework to produce a number about two people, it is the right place to fix what such a number licenses.

```
A RELATIONSHIP FREQUENCY LICENSES:
  - comparison with f_min at the same c/eta        (CCP-041, CCP-044)
  - comparison with the same pair at another time  (same rule set, same ladder)
  - comparison with the ceiling k N^2              (the realised pitch fraction)
  - a statement about how much distinct order the pair has available

IT DOES NOT LICENSE:
  - comparison with a pair read under a different ladder or a different N
  - any statement about either party as an individual
  - any statement about the pair's wellbeing, closeness, satisfaction or prospects
  - any clinical, diagnostic or therapeutic conclusion whatsoever
  - any action taken about a person without that person's ability to decline it
```

The fourth prohibition is not a disclaimer bolted to the end; it is the reason the third exists. A number that measures available order will be read as a number that measures the relationship, and the distance between those two things is not one this framework knows how to cross.

The Specification

SPEC-6.1 — Inputs

```
REQUIRED BEFORE ANY f_rel IS COMPUTED

[ ] the declared rule set: decomposition rules, N = 12, the ladder, dated   (CCP-041 Step 1)
[ ] two state vectors x, y over the twelve classes, entries >= 0
[ ] both raw L2 norms ||x||_2 and ||y||_2, in the instrument's units        (CCP-041)
[ ] confirmation that intensities were MAGNITUDE-ESTIMATED, not ranked      (CCP-041)
[ ] consent recorded from both parties, decline available at every step
[ ] the support overlap check, passed                                        (CCP-042)
```

A reading missing any one of these six is not a reading and is not published. The norms are on the list because normalisation discards them and they are half the measurement (the minimum-frequency paper [Curzi, 2026]'s magnitude reporting rule); the magnitude-estimation confirmation is on the list because without it the number is not determined at all (the relationship-frequency paper [Curzi, 2026]).

SPEC-6.2 — The computation

```
 1.  normalise:      x <- x/||x||,  y <- y/||y||
 2.  inner product:  cos theta = x . y
 3.  geometry:       u = 1 - (cos theta)^2
 4.  surplus:        F = ln(1 + (N-1) u)                nats
 5.  perspectives:   N_eff = 1 + (N-1) u
 6.  frequency:      f_rel = k * N_eff^2                Hz
 7.  interval:       cents above k = 2400 * log2(N_eff)
 8.  fraction:       realised pitch fraction = F / ln N
 9.  fold:           f_audible = f_rel * 2^j into 220-440 Hz; record j
10.  classes:        odd part of every state in the union of the supports
```

Steps 1–6 are Theorem 6.1. Steps 7–8 are §6.4. Step 9 is the octave-folding paper [Curzi, 2026]. Step 10 is not optional and the relationship-frequency paper [Curzi, 2026] says why: `u` cannot see pitch-class redundancy, and two dyads with identical `f_rel` can differ in class breadth.

SPEC-6.3 — The report line

Every dyad reading in this framework is published in this form:

```
DYAD READING
  rule set: ......................  ladder: 12-state, CCP-041, unaltered
  k = 0.483425732988414 Hz    N = 12    band 220-440 Hz
  x support / intensities / ||x|| = ..........
  y support / intensities / ||y|| = ..........
  cos theta = ..........   u = .......... (report 12+ dp; reporting standard)
  F = .......... nats      N_eff = ..........
  f_rel = .......... Hz    folded .......... Hz (j = ..)
  cents above k = ..........   realised pitch fraction = ..........%
  union of supports = {..}   distinct pitch classes = ..
  uncertainty: u +/- ....  ->  reading spans .......... cents
  CLAUSES: essence not resonance; not clinical, not counselling, not therapy;
           CONSTRUCTED case; scale status = [magnitude-estimated / NOT DETERMINED]
```

The uncertainty line is mandatory and §6.12 is why. A reading printed without it implies a precision the elicitation cannot deliver.

SPEC-6.4 — Precision

Recompute every derived value from `u` at 12 or more decimal places, never from a rounded print (the framework's reporting standard). Recomputing the carried dyad from a six-decimal `u` shifts `f_rel` in the fifth significant figure. Ratios, intervals and deficits are unaffected either way, which is why the interval columns are the robust ones and the hertz columns are not.

SPEC-6.5 — Gates

```
G1  OVERLAP.     supports share at least one state with non-trivial weight in both.
                 If not: u = 1 by construction; report DEGENERATE; publish no f_rel.
G2  MAGNITUDE.   intensities elicited by magnitude estimation with ratios asked
                 explicitly. If not: report the ORDER only; publish no f_rel.
G3  NORMS.       both raw L2 norms recorded and published. If not: no f_rel.
G4  CEILING.     if a sustainability verdict is to follow, c/eta <= ln N is checked
                 FIRST (CCP-041 SPEC 4.1). Above the ceiling no u closes the gap.
G5  CONSENT.     both parties may decline any step, at any time, without the reading
                 being completed against them. Consent is structural, not advisory.
```

G2 is the gate that fails most often and the one with no workaround. There is no "report it as ordinal" branch. The relationship-frequency paper [Curzi, 2026] gives the number that closes that door.

The Failure Modes

FM-6.1 — Reading `u` as a disagreement rate `u = 1 - (x.y)^2` is a geometric quantity computed from two non-negative intensity vectors. It is not a count of disagreements, not a conflict index, and not an inverse of rapport. Two people who argue constantly about one thing they both consider central are near-parallel and read low; two people who never argue because they attend to different things entirely are far from parallel and read high. The formalism is indifferent to the volume in the room.

The failure is common enough that the relationship-frequency paper [Curzi, 2026] builds a separate measurement route around exactly this confusion and the relationship-frequency paper [Curzi, 2026] prices what happens when someone tries to raise `u` by manufacturing argument.

FM-6.2 — Reading `f_rel` as a quality score **`f_rel` measures available order. It does not measure how good a relationship is, and the framework has no formalism that does.** A high-pitched dyad may be exhausting, unstable, or unwanted by both parties; a ground-essence dyad may be exactly what both parties want. The minimum-frequency paper [Curzi, 2026]'s classification answers *does this accumulate order at these costs*, which is a narrower question than any that matters to a person, and the narrowness is the point.

FM-6.3 — Comparing across ladders Two readings computed on different ladders, or at different `N`, are not comparable. `f_rel` depends on `N` explicitly through `(N-1)u`, and on the ladder implicitly through what the twelve slots mean. A dyad reading 20 Hz on a twelve-state ladder and a dyad reading 20 Hz on a seventeen-state ladder have nothing in common but the number. Publish the ladder with the frequency or publish neither.

FM-6.4 — Quoting hertz where the verdict is in cents §6.6 established that hertz and pitch rank the same increments in opposite orders. A report that leads with "we moved from 1.49 Hz to 2.70 Hz" has led with a difference of 1.21 Hz, which is small against the 69.61 Hz range and is in fact **1029.33 cents — nearly a ninth.** The hertz number understates the low end of the scale by exactly the amount the logarithm compresses it.

FM-6.5 — Precision theatre Reporting `f_rel = 1.4907987150 Hz` implies ten significant figures of confidence. **The tenth figure is real arithmetic and fictional measurement.** the framework's reporting standard requires the full-precision *computation* because rounding early corrupts the chain across thirty papers in the corpus; it does not license the full-precision *claim*. The honest report carries both: the computed value at full precision and the uncertainty interval at the precision the elicitation supports.

FM-6.6 — Folding a sweep Folding a monotone glide into 220–440 Hz produces eight discontinuities and a listener's impression of a rising-and-resetting figure rather than a rise. **The fold is correct for a point and wrong for a sweep**, and SPEC-6.1 fixes the transposition instead. A related error is band-shopping: choosing the band after seeing the numbers so that two readings land near each other. The octave-folding paper [Curzi, 2026]'s Failure Mode F8 owns that one.

FM-6.7 — Treating the eleven coincidences as meaning something §6.5 showed that `u = (m−1)/11` makes `f_rel` equal the essence frequency of state `m`. This is arithmetic. A dyad at `u = 6/11` is not "in" state 7 and has no relationship to reflexive feeling of any kind. The two quantities have different arguments and different derivations and happen to coincide at eleven rational points because the constants were chosen to make the two scales share a ceiling. Reading meaning into the coincidence is the numerological failure this series has warned against since the foundations.

FM-6.8 — The near-parallel reading reported without its uncertainty At `u = 0.0687`, an uncertainty of `±0.01` spans 434 cents. **A practitioner who reports the central value alone has reported a third of an octave of ambiguity as a point.** The failure is worse at the bottom of the range, which is exactly where near-parallel pairs — the ones most likely to need the reading — sit. The mandatory uncertainty line of SPEC-6.3 exists for this case and no other.

FM-6.9 — Assuming a high `f_rel` is achievable The glide runs to `u = 1`, which is perfect orthogonality: two people with no represented overlap in what they carry. The octave-folding paper [Curzi, 2026] and the relationship-frequency paper [Curzi, 2026] both establish that in practice such a reading almost always indicates disjoint support — an encoding failure — rather than a remarkable pair. A reading near the top of the glide is a reason to check the encoding, not to celebrate.

FM-6.10 — Using the reading on a person who did not agree to it A dyad reading requires two people's elicited states. Computing one from material a second party provided about a first — an account, a description, a recollection — produces a number about a representation the described person never saw and never agreed to. That is outside every specification in this section. The consent gate G5 is structural: it is a condition on whether the computation may be performed at all, not advice about how to present the result.

FM-6.11 — The reading used as counselling **A relationship frequency is not counselling, not therapy, not mediation, and not an assessment of any pair of people.** It is a number computed from a representation, and the representation is a description of a description (the minimum-frequency paper [Curzi, 2026]). A practitioner who presents it to two people as a statement about their relationship has changed what it is. Where a person's relationships are causing them difficulty, the appropriate resource is a qualified professional, and this framework is not one.

Worked Example

THE CARRIED DYAD, AS AN INTERVAL **CONSTRUCTED CASE, labelled as such. These are not two people.** This is the framework's carried dyad's dyad, phase 2a, read here purely as an interval; the relationship-frequency paper [Curzi, 2026] measures it, the relationship-frequency paper [Curzi, 2026] gives it a sustainability verdict, and the companion paper on tuning intervenes on it.

The vectors, exactly as the framework's founding specification fixes them:

```
A = { 4: 0.7,  6: 0.5,  9: 0.4 }
B = { 4: 0.6,  6: 0.55, 9: 0.3,  10: 0.2 }
```

A holds three states: situated feeling (4), temporal feeling (6), normative feeling (9). B holds those three and one more: narrative feeling (10). The supports overlap in three of four positions, so gate G1 passes comfortably.

Step 1 — the raw norms, recorded before normalisation (the minimum-frequency paper [Curzi, 2026]).

```
||A||_2 = sqrt(0.7^2 + 0.5^2 + 0.4^2)          = 0.9486832980505138
||B||_2 = sqrt(0.6^2 + 0.55^2 + 0.3^2 + 0.2^2) = 0.8902246907382427
ratio ||A|| / ||B|| = 1.065667
```

These are published because normalisation is about to throw them away and they are half the measurement. The two parties hold their states at very nearly the same total intensity — within 6.6% — so nothing in this reading is an artefact of one party simply reporting larger numbers than the other.

Steps 2–3 — the geometry.

```
cos theta = 0.965020899          (the framework's carried dyad prints 0.9650)
u         = 1 − cos^2 theta = 0.068734665264634
```

Step 4–6 — surplus, perspectives, pitch.

```
F     = ln(1 + 11 * 0.068734665264634) = 0.563084802746 nats
N_eff = 1.7560813179
f_rel = k * 1.7560813179^2             = 1.4907987150 Hz
```

Every figure matches the framework's carried dyad exactly, which is the point of recomputing from the fifteen-decimal `u` rather than from the printed 0.068735.

Step 7–8 — the interval.

```
cents above k              = 2400 * log2(1.7560813179) = 1949.66
octaves above k            = 1.624719305043341
realised pitch fraction    = 0.563084802746 / 2.484906649788 = 22.66%
```

The pair occupies 1949.66 cents of an available 8603.91 — one octave and a major seventh above the ground essence, and 22.66% of everything a twelve-category system has to offer. Put the other way: **77.34% of the available relational range is unoccupied.**

For a reader who prefers the perspective count: `N_eff = 1.7561`. **Two people, and the geometry says they are worth 1.76 genuinely distinct perspectives.** The minimum-frequency paper [Curzi, 2026]'s fourth column is the comparison that matters — at `c/eta = 2.0667` this pair must field `e^2.0667 = 7.90` distinct perspectives to break even, and it fields 1.76. The relationship-frequency paper [Curzi, 2026] finishes that reading.

Step 9 — the fold.

```
1.4907987150 Hz * 2^8 = 381.6444710 Hz      j = 8, in 220–440 Hz
```

Step 10 — the classes.

```
union of supports = {4, 6, 9, 10}
odd parts         =  1, 3, 9,  5      ->  four distinct pitch classes
```

Four states, four distinct classes: no collision. The relationship-frequency paper [Curzi, 2026] shows the counterfactual in which the same `u` comes with only three classes, and why that check has to be run separately.

The report line.

```
DYAD READING -- CONSTRUCTED CASE, the framework's carried dyad phase 2a
  k = 0.483425732988414 Hz   N = 12   ladder: 12-state, unaltered   band 220-440 Hz
  A: {4:0.7, 6:0.5, 9:0.4}          ||A|| = 0.9486832980505138
  B: {4:0.6, 6:0.55, 9:0.3, 10:0.2} ||B|| = 0.8902246907382427
  cos theta = 0.965020899    u = 0.068734665264634
  F = 0.563084802746 nats    N_eff = 1.7560813179
  f_rel = 1.4907987150 Hz    folded 381.644 Hz (j = 8)
  cents above k = 1949.66    realised pitch fraction = 22.66%
  union {4,6,9,10}           distinct pitch classes = 4
  uncertainty: u +/- 0.01 -> reading spans 434.34 cents
  CLAUSES: essence not resonance; not clinical, not counselling, not therapy;
           CONSTRUCTED; scale status = magnitude-estimated per CCP-041
```

THE SAME DYAD, AFTER — the interval crossed The framework's carried dyad's phase 2b changes the geometry: B takes on two states A does not hold. The minimum-frequency paper [Curzi, 2026] gives one realising vector, `B' = {2:0.95, 4:0.60, 6:0.55, 9:0.30, 10:0.20, 12:0.8391}`, with `cos theta = 0.554643` and `u = 0.692372881355932`. This section does not re-derive it and does not own the intervention; it reads the interval.

```
PHASE 2a    u = 0.068734665264634   f =  1.4907987150 Hz   1949.66 cents above k
PHASE 2b    u = 0.692372881355932   f = 35.8881768941 Hz   7456.88 cents above k

THE INTERVAL CROSSED:  5507.2215 cents  =  4.589351 octaves
realised pitch fraction:  22.66%  ->  86.67%
N_eff:                    1.7561  ->  8.6161
```

Four octaves and a major sixth, purchased by one party taking on two states the other does not hold. In perspective terms the pair went from being worth 1.76 distinct views to being worth 8.62 of a possible 12.

And the caution that has to travel with that sentence, because it is the most quotable number in the section: the interval was not purchased by disagreement, by opposition, or by either party becoming difficult. It was purchased by a change in **what B is actually doing** — a genuine addition to B's represented state, not a rhetorical stance. The relationship-frequency paper [Curzi, 2026] proves that the rhetorical version returns nothing at all, and the minimum-frequency paper [Curzi, 2026] already flagged it: **CC-R8 forbids the opposition route from working, because perfect opposition reads as `u = 0` exactly as agreement does.**

The relationship-frequency paper [Curzi, 2026] turns these two positions into sustainability verdicts. The frequencies alone say nothing about whether either arrangement lasts; that requires `f_min`, and `f_min` requires `c` and `eta`, and the minimum-frequency paper [Curzi, 2026] owns both.

The counter-case, so the section is not lying by selection **CONSTRUCTED.** Not every reading moves. Take the same A, and a B whose extra state carries a smaller intensity:

```
B[10] = 0.00   ->  u = 0.019232   f = 0.7096 Hz    -1285.20 cents from the carried reading
B[10] = 0.10   ->  u = 0.032095   f = 0.8850 Hz    - 902.77 cents
B[10] = 0.20   ->  u = 0.068735   f = 1.4908 Hz         0.00  (the carried case)
B[10] = 0.30   ->  u = 0.124003   f = 2.7017 Hz    +1029.33 cents
B[10] = 0.40   ->  u = 0.191202   f = 4.6554 Hz    +1971.38 cents
```

One elicited intensity, moved by one step of a ten-point instrument, moves the reading by more than a thousand cents. That is the steepness of §6.9 arriving as a measurement problem rather than as a price list, and it is the strongest available argument for the minimum-frequency paper [Curzi, 2026]'s insistence that intensities be magnitude-estimated with the ratio question asked explicitly, and for Section 5's double-coding requirement. A reading this sensitive to one number is a reading that must be produced twice, by two analysts, from the same written framings, or not published.

What this section established **Established, and checkable:** a dyad has exactly one frequency, `f_rel = k(1+(N−1)u)^2`, obtained by substituting the surplus functional [Curzi, 2026] into the essence bridge of Series B [Curzi, 2026k]; it is strictly increasing in `u`, bounded by `k` below and `k N^2` above, and spans 8603.9145 cents at `N = 12`; it equals the essence frequency of state `m` exactly at `u = (m−1)/11`; the first 0.05 of `u` buys 9.34 times the pitch of the last 0.05, while the last 0.05 buys 9.20 times the hertz of the first; and half the entire range is spent by `u = 0.224009`.

Not established, and not claimed: that any pair of people physically resonates at any frequency here; that a higher reading is a better relationship; that the reading is clinical, diagnostic, therapeutic, or a substitute for counselling of any kind; that the number can be computed about someone who has not agreed to it; or that a frequency alone says whether a relation lasts, which needs `f_min` and belongs to the relationship-frequency paper [Curzi, 2026].

The one line to carry forward: *two people are one interval, measured upward from the note a pair with nothing between them would sound.*

Section 6 owns `f_rel = k(1+(N−1)u)^2`, the glide, the realised pitch fraction, and the fixed-transposition sweep spec. Later papers in this series cite it. The surplus law is the sustaining-frequency paper [Curzi, 2026]; the essence bridge is the sustaining-frequency paper [Curzi, 2026]; `f_min`, the octave deficit and the four levers are the minimum-frequency paper [Curzi, 2026]; elicitation and the magnitude reporting rule are the minimum-frequency paper [Curzi, 2026]; the chord and the overlap condition are The octave-folding paper [Curzi, 2026]; the consonance/redundancy identity is Section 4. The relationship-frequency paper [Curzi, 2026] measures `u` between two people, and the relationship-frequency paper [Curzi, 2026] goes to the bottom of the glide and finds two different faults sounding the same note.

7 Results

The seven results below are the units other papers in this corpus cite. **DERIVED** means it follows from the definitions by algebra; **ENUMERATED** means it was checked over the complete finite lattice rather than sampled; **COMPUTED** means exact arithmetic on stated constructed parameters; **POSTULATED** means asserted here with no external support.

R1 — the doubling theorem. For any index pair reducing to p/q, the essence interval p^2/q^2 has exactly twice the Tenney harmonic distance of p/q, and Euler gradus $2G(pq) - 1$: $\mathrm{HD}_{\mathrm{ess}}(i, j) = 2\log_2(pq)$, $G_{\mathrm{ess}} = 2G(pq) - 1$. *Status:* DERIVED in three lines; ENUMERATED over all sixty-six pairs at $N = 12$, both identities exact in every case. The relational-lattice form is established in Series B [Curzi, 2026l], whose Result Two derives a room from essence indices 7, 9 and 11 with the folded set 233.98–386.74 Hz entirely above a Schroeder frequency of 146.7 Hz — the one place in the corpus where these frequencies meet real acoustics.

R2 — the consonance–redundancy identity. The minimum $\mathrm{HD}_{\mathrm{ess}} = 2.0000$ over all sixty-six pairs is attained by exactly six pairs, ${1{:}2, 2{:}4, 3{:}6, 4{:}8, 5{:}10, 6{:}12}$, every one of them a pitch-class collision, and by no non-collision. Separately, folded separation is exactly zero **if and only if** the two indices share an odd part — a biconditional, true for all ten collision pairs and false for all fifty-six others. *Status:* ENUMERATED. **The honest qualification travels with it:** the ordering is not total. $1{:}3$ at 3.1699 is more consonant than the collisions $1{:}4$, $2{:}8$,

$3{:}12$ (4.0000) and $1{:}8$ (6.0000). Collisions are dramatically more consonant *on average* — mean 3.0000 over ten against 8.6617 over fifty-six — and the ranges overlap.

R3 — the firewall. F_{int} is invariant under relabelling of the states, so it does not determine the chord. Relabelling 10 to 9 in the carried constructed subject leaves $F_{\text{int}} = 2.164390$ unchanged to 10^{-12} while removing the collision and taking the class set from $\{3, 5, 7\}$ to $\{3, 5, 7, 9\}$; a further relabelling to $\{2, 8, 9, 11\}$ again gives exactly 2.164390, with classes $\{1, 9, 11\}$ and the collision $(2, 8)$. *Status:* DERIVED (inner products are invariant under a permutation of coordinates); COMPUTED on a constructed subject. **This is the result the paper exists to establish** and it blocks any inference from the width statistic to distress or health.

R4 — the restatement collapse. Replacing one of three framings with a paraphrase of another takes F_{int} from 2.164390 to 1.333662 nats and the chord width from 36.6686 to 6.9620 Hz: a loss of 0.830727 nats, 2.3970 octaves, more than a third of everything a twelve-category ladder can supply. *Status:* COMPUTED on a constructed extension.

R5 — the extremal chords. Over all $\binom{12}{4} = 495$ four-state chords: the most consonant is $\{1, 2, 4, 8\}$, mean $\text{HD}_{\text{ess}} = 3.3333$, six collisions from six pairs, **one** pitch class; the most dissonant is $\{7, 9, 10, 11\}$, mean 12.7586, zero collisions, four classes. 159 of the 495 chords (32.1 per cent) have no collision at all. *Status:* ENUMERATED. The most dissonant chord in the system — reflexive, normative, narrative and reciprocal feeling — is an entirely ordinary description of a person attending to a social situation, which is the strongest available argument against reading harmonic dissonance as psychological difficulty.

R6 — convexity against concavity. $f_{\text{rel}}(u) = k(1+11u)^2$ is strictly convex in u while the same quantity in cents is strictly concave: $\mathrm{d}f/\mathrm{d}u$ rises from 10.6354 to 127.6244 Hz per unit u across $u \in [0, 1]$, while $\mathrm{d}(\text{cents})/\mathrm{d}u$ falls from 38087 to 3174. The first 0.05 of u is worth $+0.6780$ Hz and $+1517.44$ cents; the last 0.05 is worth $+6.2350$ Hz and $+162.45$ cents — the last step is $9.20\times$ the first in hertz and $\frac{1}{9.34}$ of it in cents. *Status:* DERIVED and COMPUTED. **Pitch is the unit that enters the verdict; hertz differences are decorative**, because the sustainability criterion is computed in logarithmic units [Curzi, 2026].

R7 — the eleven coincidences. $f_{\text{rel}}(u) = km^2$ exactly at $u = (m-1)/(N-1)$, so a dyad's interval lands on a state's note at eleven exact values of u. *Status:* DERIVED. **The caveat travels with the table and is not optional:** this is a numerical coincidence in the chosen constants, not a claim that a dyad at $u = 7/11$ is in any sense *in* state 8. The two quantities have different arguments, different derivations and different scale status.

CR — counter-result. The width statistic is invariant under relabelling and therefore does not even determine the chord it is computed from, which formally blocks any inference from low or high internal surplus to distress or health. **A quantity compatible with every value of a variable carries no information about that variable.** The corpus reaches structurally similar conclusions elsewhere: the property that makes an insurance reserve resistant to third-party claims is the same property that makes it unavailable to its owner [Curzi, 2026], leaving 7.58 per cent realisable within a year; and the uncertainty node declines the inflated reading of its own borrowed physics, requiring that a theorem, an ordinary observer effect and a framework conjecture be distinguishable in three separate sentences on demand [Curzi, 2026]. **This paper is under the same requirement and meets it in §2 and §9.**

8 Discussion

8.1 What follows

Consonance is scarce in this lattice by a factor of exactly two, and the scarcity has a shape. Six pairs sit at 2.0000, then a gap to 3.1699, then a long tail to 14.0888 with fifty-six of sixty-six pairs above 3.1699. That is not a gradient; it is a small cluster of redundancies and a large spread of remoteness. The middle ground the metaphor promises — framings that harmonise without repeating — is not a region of this lattice at all. **Whether that is a discovery about selves or an artefact of the square law is exactly the question this paper is obliged to leave open, and it**

leaves it open: the doubling theorem is a theorem about ratios, and the square law under it is a postulate.

A collision costs one thing and it is worth naming precisely. It costs a position in a harmonic vocabulary of which $N = 12$ supplies only $\lceil 12/2 \rceil = 6$. It does **not** cost surplus — the relabelling test shows a collision appearing and disappearing with F_{int} fixed to twelve decimal places. It does **not** mean two states are the same component: attributed feeling and narrative feeling differ by five components of specification and collide only because $10 = 2 \times 5$ and the fold divides by powers of two. It does **not** mean the raw chord has fewer notes: states 5 and 10 are 12.0856 and 48.3426 Hz, two octaves apart, and only the fold makes them one. **A collision is a limit on the folded representation, not a finding about the subject.**

The only lever on the width is the angular diversity of what is elicited. Amplifying a framing does nothing — scale invariance is exact. Adding a restatement is *negative*, at -2.3970 octaves. Adding a framing with disjoint support inflates the number and destroys its meaning. And distress is not an input: it appears in no equation here, has no coefficient, and has no path by which it could enter the computation.

8.2 What does not follow

Nothing about distress, health, function or well-being. §4.6 gives the formal argument and §7 restates it as CR. The four quadrants — high width with and without distress, low width with and without distress — are all occupiable and the formalism forbids ruling any of them out. **The framework does not recommend that anyone acquire, retain or cultivate suffering**, and suffering is not a resource in it.

Nothing about a person. A reading is of a set of framings on one situation on one occasion under one decomposition by one analyst. Cross-person comparison is not licensed, because the reproducibility gate has not been run and the specific-objectivity property that would license it [Rasch, 1960] has not been established.

And no claim of a characteristic scale in the world. Human activity is bursty, with heavy-tailed inter-event times and **no characteristic time scale** [Barabási, 2005]; strong spatial regularity coexists with that temporal burstiness [González et al., 2008]. A frequency in this paper is a position on a logarithmic surplus scale, not a rate at which anything occurs, and the burstiness literature is the reason that distinction has to be defended rather than assumed.

8.3 The consonance measures against the measured literature

Where the external literature disagrees with this framework, it is cited and the disagreement is stated. Ratio complexity is one family of consonance model and roughness is another; they make different predictions, and the roughness family is the one with the psychoacoustic measurements behind it [von Helmholtz, 1885, Plomp and Levelt, 1965, Kameoka and Kuriyagawa, 1969, Terhardt, 1974]. Consonance as heard depends on the **spectrum of the sound**, so a ratio is a fact about harmonic-spectrum instruments and not a universal constant [Sethares, 2005]. Interval categories are learned and bounded [Burns, 1999, Burns and Ward, 1978], octave equivalence generalises less far than is assumed [Hoeschele et al., 2012], and the octave's perceptual specialness has a measured and finite size [Demany et al., 2013]. The just-intonation lattice whose geometry this paper borrows is real and documented [Partch, 1974, Doty, 2002, Benson, 2006, Lindley and Turner-Smith, 1993]; **what is not documented anywhere is the claimed function** — that positions on such a lattice convert between psychological and acoustic quantities. That is the part of this framework furthest from any external literature, and it is where the reader should be most sceptical.

8.4 The functional form is underdetermined

The surplus functional's shape is not settled by the evidence. Influence has been argued to grow as a **power** of the number of sources with exponent below one [Latané, 1981]; network value has been argued to grow as $n \log n$ [Briscoe et al., 2006]; this framework asserts $\ln(1 + (N-1)u)$. All three decelerate and all three fit the qualitative facts, and many mechanisms produce curves that data cannot distinguish [Stumpf and Porter, 2012]. **Nothing in this paper discriminates among them.** What *can* be said is which warrant the logarithm needs: not the psychophysical one, which requires the perceptual story to be true, but the multiplicative-dynamics one, in which the growth rate of a multiplicative process is logarithmic in the accumulated quantity with no psychological assumption at all [Peters and Gell-Mann, 2016]. The psychophysical warrant is used in this paper only for the elicitation of intensities, and nowhere else.

8.5 What would distinguish this framework from a neighbouring model

The sharpest question a reader can ask of work of this kind is what observation would separate its laws from a model that fits equally well [Sobkowicz, 2020, Durlauf, 2005]. **For this paper the honest answer is: almost nothing, by construction.** Sections 4 and 6 are enumerations over a finite lattice and are true or false by computation, not by observation. Section 5 is a procedure. The single empirically vulnerable claim in the series is the ceiling [Curzi, 2026], and it is inherited rather than established here. An explanation is expected to name a mechanism rather than exhibit a fitted curve [Hedström and Ylikoski, 2010]; this paper fits nothing, which avoids that charge at the cost of having no empirical content to fit. Prediction is one of many legitimate reasons to model [Epstein, 2008], and the reason claimed here is **bounding**: the paper's principal contribution is a proof that a tempting inference is unavailable. The analytical position — mechanisms stated, parameters declared, the arrangement named in advance — is the one this work is best placed to defend [Keuschnigg et al., 2018, Cartwright, 1999].

9 Verification

Every result is decomposed into steps a reader can check individually. **A postulate that can be dropped without a result changing has been dropped**, and the section says outright where the chain stops being a proof.

- **ARITHMETIC** — reproducible from the inputs named.
- **ENUMERATION** — exhaustive over a finite set; the set is named and its size given.
- **DEFINITION** — true by stipulation.
- **CITED** — supported by a named external source.
- **POSTULATED** — asserted here, with no external support.

9.1 The postulates

	postulate	status
P1	The Pythagorean whole tone is the ratio $9{:}8$.	CITED [Barbour, 1951]
P2	φ is the positive root of $x^2 = x + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P3	The dimensionless number $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source

	postulate	status
P4	The essence of an n-component state is kn^2.	POSTULATED — no source
P5	$\mathrm{HD}(p/q) = \log_2(pq)$ measures harmonic remoteness.	DEFINITION (a chosen function)
P6	$G(n) = 1 + \sum e_i(p_i - 1)$ measures smoothness.	DEFINITION (a chosen function)
P7	A frequency may be divided by a power of two without changing what it means.	POSTULATED beyond pitch; CITED for pitch only [Shepard, 1982]
P8	$N_{\text{eff}} = 1 + (N-1)u$, $F = \ln N_{\text{eff}}$.	POSTULATED — design axiom [Curzi, 2026]
P9	Intensities are non-negative.	DEFINITION of the encoding

Dropped as unnecessary. No postulate about *which* twelve states, or about their order, is needed for R1, R2, R3 or R5: the doubling theorem, the consonance–collision identity, the relabelling invariance and the extremal enumeration hold for the indices $1..12$ whatever the states are called — which is precisely why R3 is true. No postulate about consonance is needed for R3, R4, R6 or R7. **P3 and P4 are needed only where a number is quoted in hertz**, and every dimensionless result in the paper survives their rejection.

9.2 The compounding chain

step	consumes	produces	status
L1	P1	$(9/8)^2 = 81/64 = 1.265625$	ARITHMETIC
L2	P2	$\varphi^2 = 2.618033988749895$	ARITHMETIC
L3	L1, L2	$k = 0.483425732988414$	ARITHMETIC (exact, defined)
L4	L3, **P3**	k carries the unit Hz	**POSTULATED**
L5	L4, **P4**	$f(n) = kn^2$ Hz	**POSTULATED**
L6	L5	essence ratio of i, j is $j^2/i^2 = p^2/q^2$	ARITHMETIC
L7	L6, P5	$\mathrm{HD}_{\text{ess}} = \log_2(p^2q^2) = 2\log_2(pq)$ — **R1**	ARITHMETIC
L8	L6, P6	$G_{\text{ess}} = 2G(pq) - 1$ — **R1**	ARITHMETIC
L9	L7 over all 66 pairs	minimum 2.0000 at exactly six pairs — **R2**	ENUMERATION (66)
L10	L6, P7	folded separation $= 0$ iff equal odd parts — **R2**	ARITHMETIC
L11	L9, L10	the minimum set **is** the collision set	ARITHMETIC
L12	L7 over all 495 four-chords	extremal chords — **R5**	ENUMERATION (495)

step	consumes	produces	status
L13	P8, P9	$F_{\text{int}} = \ln(1 + 11\bar{u})$ from inner products	DEFINITION

9.3 What this chain is and is not

Read the status column. L4, L5 and P7 are postulated; P5, P6, P8, P9 and L13 are definitions. **A chain whose load-bearing steps are definitions and postulates is not a proof of its interpretation**, and this one is not offered as one. What it *is* is a clean separation.

Everything dimensionless survives the rejection of P3 and P4. R1, R2, R3, R5 and R7 are statements about integers and their ratios; they do not become false if nobody accepts that $(9/8)^2/\varphi^2$ is a frequency. R6's *shape* survives; only its hertz labels do not. **The firewall — the paper's principal result — is the most robust thing in it**, because it follows from the invariance of an inner product under a permutation of coordinates and from nothing else.

Conversely, nothing in the chain licenses the interpretation. The two consonance measures are chosen functions and are labelled so at every use; the octave fold beyond pitch is postulated; the essence law is postulated and its exponent is **defined rather than estimated**, with no fitting procedure run [Clauset et al., 2009]. **A reviewer looking for the weakest link should look at L4 and L5, and this section is written so that the search takes under a minute.** That the badges are printed rather than discovered is the honest description of what a badged postulate does inside a research programme [Lakatos, 1970, Platt, 1964, Meehl, 1990].

10 Limitations

Every check the governing rigour standard specifies is listed by name, passed or not.

L-1. The dimensional audit does not close for any quantity in hertz. k is computed as a ratio of two dimensionless numbers, and no operational procedure is supplied by which it acquires $[T^{-1}]$. Everything expressed as a ratio, interval, distance or class is unaffected.

L-2. The two consonance measures are chosen, not measured. Neither Tenney's harmonic distance [Tenney, 2015] nor Euler's gradus [Euler, 1739] is an experiment, and the measured psychoacoustic literature runs on roughness and spectrum [Plomp and Levelt, 1965, Sethares, 2005], which does not agree with ratio complexity in general. **No claim in this paper is a claim about what a listener finds pleasant.**

L-3. The attribution of harmonic distance was incomplete, and completing it in the obvious way gives the wrong book. This entry replaces an earlier one recording that neither primary source was present in the bibliographic database governing this corpus. Both are now present and are cited at every use: the *gradus suavitatis* from Euler's *Tentamen novae theoriae musicae* [Euler, 1739], and harmonic distance from Tenney's 1983 essay "John Cage and the Theory

of Harmony", cited from the collected edition [Tenney, 2015]. The source manuscript named harmonic distance by its author's surname alone, with no year and no containing work. That is an incomplete attribution rather than a false one, but it is not harmless: the Tenney title a reader is likeliest to supply is *A History of 'Consonance' and 'Dissonance'* (1988), which is a historical survey and does not define the measure. §4.2 now states the correct source and the correction explicitly. Two bibliographic details remain open and are stated rather than guessed: no page range is given for the essay within *From Scratch*, because none could be confirmed from any catalogue record consulted; and the frequently repeated original printing in *Soundings* 13 (1984) was likewise not confirmed and is therefore not asserted here. The definitions used in this paper are given in full in §4.2, so the arithmetic remains checkable without either source.

L-4. Octave reduction beyond pitch is unwarranted. Shepard grounds octave equivalence for pitch [Shepard, 1982]; nothing grounds folding a non-acoustic quantity into a band and reading meaning from where it lands.

L-5. The exponent is defined, not estimated. No scaling exponent here was fitted, no alternative was tested, and the standard procedure [Clauset et al., 2009] was not run because there is no data. This paper makes no empirical scaling claim.

L-6. The functional form is underdetermined by the available evidence [Latané, 1981, Briscoe et al., 2006, Stumpf and Porter, 2012], and nothing here discriminates among the candidates.

L-7. Conjoint measurement was not tested, so the ratio-scale treatment of the intensities is provisional and Michell's objection [Michell, 1997] stands unanswered for every quantity except the indices themselves; the available remedies [Luce and Tukey, 1964, Rasch, 1960, Krantz et al., 1971] were not run. And the exemption claimed for the indices is narrower than it looks. The count argument establishes that a cardinality is absolute-scaled, which is a fact about counting and not about whether an emotional state was correctly reduced to a count in the first place. The affect literature that the index's own rungs are named from describes emotional states by patterns across simultaneously varying appraisal dimensions [Smith and Ellsworth, 1985], by a process in time [Scherer, 2001], and by qualitative relational themes [Lazarus, 1991] — none of which a scalar can carry. Michell's objection and that one are the same objection in two domains, and it is the framework's habit of scalar reduction that both are about. The index is inherited here rather than argued, and the concession is made where the ladder is built [Curzi, 2026]; it is recorded in this paper because every reading produced by §5 rests on that index.

L-8. The reproducibility gate has not been run. FVP-7 for the index [Curzi, 2026] and for the self-storage parameters of Series B are both recorded as NOT RUN. Cross-person comparison of any number in this paper is therefore not licensed.

L-9. Every case is constructed. The subject, its extensions and the carried dyad are chosen parameter sets. Their exactness follows from the parameters being exact and does not transfer to a measured case.

L-10. The encoding cannot represent opposition. Because intensities are non-negative, $\cos\theta \geq 0$ for every pair of framing vectors and $u = 0$ can arise only from parallelism. An internal framing that is the exact negation of another has no representation here. This is a real limitation of the encoding and a signed encoding would be a different instrument.

L-11. The relabelling result is an arithmetic fact, and H1 is not tested. The invariance is proved; the empirical prediction that no association exists between collision structure and distress at fixed width is untested, and no sample exists.

L-12. The reflexive specification is not identified [Manski, 1993, Shalizi and Thomas, 2011]. The remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001], and the claim is a modelling position rather than an identified result. The framework also exempts its own parameters from its own reflexivity [Lucas, 1976], which it cannot consistently do.

L-13. A published reading can make itself true. Expectancy and framing effects are the reason the separation statement of SPEC-4.3 is mandatory; the effect is real but, on the best long-run evidence, small and often dissipating [Jussim and Harber, 2005].

L-14. No statistical claim is made and none is supported. There are no p-values, effect sizes, intervals or samples in this paper. No model comparison, out-of-sample test, matched null or information criterion is reported, because nothing was fitted.

L-15. There is no conservation law. The storage quantity is written with the grammar of a conserved quantity without one [Mirowski, 1989]; validity is claimed only within a specified arrangement [Cartwright, 1999] and no universality is claimed.

L-16. The aggregate does not determine the joint structure, and this paper's own central result is an instance of that [Kirman, 1992, Harrison and Klein, 2007]. Any reader tempted to invert a width statistic into a chord should read §4.6 again.

L-17. Boundary behaviour. $\bar{u} \to 0$ gives $F_{\text{int}} = 0$ and the ground essence, which the paper examines; $\bar{u} \to 1$ gives the ceiling kN^2, which it examines; **disjoint support** gives a high $\bar{u}$ that is a null result rather than a wide chord, which the paper examines and refuses to publish as a reading. What is **not** examined is the behaviour of the width statistic as the number of framings grows, and the mean pairwise $\bar{u}$ has no stated correction for the number of pairs.

L-18. This paper asserts perceptual claims with no perceptual experiment behind them. That consonance measures are meaningful over an index lattice, that octave equivalence is usable, and that cents are the right unit are all asserted on the strength of the cited literature and its boundaries, and not on any measurement made here.

11 Conclusion

What is established. Squaring an index ratio doubles Tenney harmonic distance exactly and maps Euler gradus G to $2G-1$; both identities hold over all sixty-six index pairs at $N = 12$. The global consonance minimum is attained by exactly the six pitch-class collisions and by nothing else, and zero folded separation holds if and only if two indices share an odd part — a biconditional over the complete lattice, with the honest qualification that the resulting ordering is not total. Over all 495 four-state chords the most consonant is a chord of one pitch class and the most dissonant is an ordinary description of a person in a social situation. **The internal surplus is invariant under relabelling of the states and therefore does not determine the chord it is computed from**, so no inference from it to distress, health or function is available; the inference fails at the level of the statistic, not at the level of taste. Replacing a framing with a paraphrase of another costs 2.3970 octaves of width. At dyad scope the relationship frequency is convex in u in hertz and concave in cents, and only the logarithmic unit enters the sustainability verdict. **All of this is arithmetic and enumeration on stated definitions, and none of it depends on the value of k.**

What is proposed. That a dimensionless ratio of a tuning interval to the square of the golden section is a frequency; that the essence of an n-component state is kn^2; that octave equivalence may be carried from pitch to a quantity that is not a pitch; and that Tenney's and Euler's measures are the right functions to impose on this lattice. **The first three are postulates with no external support and the fourth is a modelling choice**, all four are labelled at every appearance, and all four are separable from the results above: a reader who rejects them keeps the doubling theorem, the identity, the firewall, the enumeration and the convexity result, expressed in ratios rather than in hertz.

What is not claimed at all. No person, tissue or molecule is claimed to resonate at any frequency named here. **The twelve state classes are not diagnoses**, a chord reading is not an assessment, and nothing in this paper is clinical, diagnostic, therapeutic or prognostic. Nothing in it recommends, values, or claims informational content for suffering.

12 Declarations

Data and code availability. No dataset was collected for this study and none exists. The sixty-six pair values and the 495 four-state chords are exhaustive enumerations over a finite lattice, computable from the definitions in §4.2 by any reader; every worked case is a constructed

parameter set, labelled as constructed at the point of use. The figures are generated by the Python scripts named in their captions, which take their inputs from the tables in the text and are available from the author on request. **No measurement of any human being underlies any figure, table or number in this paper.** A paper about consonance and internal states reads as though someone had been listened to or asked something; nobody was.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The constructed subject, its labelled extensions and the carried dyad are invented parameter sets and do not describe any person. **This paper asserts perceptual claims — that ratio-complexity measures are meaningful, that octave equivalence is usable beyond pitch, that cents are the operative unit — without any perceptual experiment behind them**; those claims rest entirely on the cited literature, are bounded by that literature's own findings (§8.3), and are listed among the limitations (L-2, L-4, L-18).

Clinical disclaimer. The twelve state classes are not diagnostic categories, and the internal surplus is not a measure of distress, well-being, health or function — §4.6 proves that it contains no term that could carry such information. Nothing in this paper is an assessment, a screening instrument, a treatment, or advice about any person's care, and nothing in it may be presented as such. A reader who wants to know whether something is wrong should ask someone qualified to answer that; this instrument is not qualified and does not attempt it.

Chapter 44

Three Routes to the Relationship Frequency: The Unison Result and the Elasticity-Reserve Split Between Levers

Abstract. We give three independent estimators of dyadic non-parallelism and show what the resulting frequency can and cannot support. Route A computes $u = 1 - \cos^2\theta$ from intensity vectors and is non-negative by construction; Route B derives the exact agreement identity $\cos\theta = 2a - 1$, $u = 4a(1-a)$ from binary judgments over m items, with resolution $4/m$; Route C uses $u = 1 - \rho^2$ on error vectors against known answers. On a constructed dyad the three return $u = 0.068735$, 0.065556 and 0.068775, giving 1.4908, 1.4320 and 1.4916 Hz — a spread of 70.52 cents, of which 69.64 is the agreement channel's own quantisation. The central negative result is that every quantity depends on the correlation only through its absolute value: $\rho = +1$ and $\rho = -1$ both give $u = 0$, $F = 0$ and $f_{\text{rel}} = k = 0.4834$ Hz, with $k = (9/8)^2/\varphi^2 = 0.483425732988414$ a *defined* constant whose interpretation as a frequency is postulated. The agreement table is a perfect mirror about $a = 0.5$, so a pair agreeing on every item and a pair agreeing on none produce the identical reading, and recruiting a contrarian buys nothing while adding links. At $u = 0$ the fixed point collapses to $-c/\delta$ with η and N absent and two of four levers exactly inert. On lever choice, elasticities are dimensionless and commensurable: cost-side levers have elasticity $2.885390\,(c/\eta)$ against a geometry-lever bound of 2.885390 octaves per e-fold, but the reserves invert the ranking — raising η to a physically impossible 1.00 buys 4.174198 octaves against a requirement of 4.338420, while raising u buys 5.545206 and closes it.

Keywords: relationship frequency; agreement identity; unison; opposition; elasticity; lever reserve; concordance; order of operations

Series: C. Frequency, Essence, and Mind **Paper:** CCP-044

1 Introduction

The corpus's surplus functional is built on a single geometric quantity, the represented non-parallelism $u = 1-(x\cdot y)^2$ between two unit state vectors. This paper does three things with it: it gives three independent estimators of u between two parties, it establishes what the resulting frequency can and cannot support, and it derives the consequence that most damages the ordinary intuitions people bring to the object.

The central negative result is that u depends on the correlation only through its absolute value. Because $u = 1 - \rho^2$ is even in ρ, perfect opposition and perfect agreement are the *same reading*: $\rho = +1$ and $\rho = -1$ both give $u = 0$, $F = 0$, $N_{\text{eff}} = 1$ and $f_{\text{rel}} = k = 0.4834$ Hz, folded to the same 247.514 Hz at $j = 9$ in the same pitch class. The formalism does not merely fail to distinguish the contrarian from the sycophant; it proves them indistinguishable, and the agreement channel exhibits the same fact directly, since $u = 4a(1 - a)$ is a perfect mirror about an agreement fraction of $a = 0.5$. **Recruiting a contrarian therefore adds cost and returns exactly nothing**, and at $u = 0$ the fixed point collapses to $-c/\delta$, in which the conversion efficiency and the category count do not appear at all and two of the framework's four levers have derivative exactly zero.

The three estimators are not interchangeable and the paper never pretends they are. Route A reads the state vectors directly; because intensities are non-negative by construction its cosine is bounded below by zero, **so the negative half of the correlation range is unreachable through it.** Route B derives an exact identity from binary judgments over m shared items, $\cos\theta = 2a - 1$ and $u = 4a(1 - a)$, with a resolution bounded by $4/m$. Route C uses $u = 1 - \rho^2$ on error vectors against known answers. On the constructed carried dyad the three return $u = 0.068735$, 0.065556 and 0.068775, giving 1.4908, 1.4320 and 1.4916 Hz — a spread of 70.52 cents, of which 69.64 is the agreement channel's own quantisation.

The second half of the paper is about levers, and it separates two questions that are routinely merged. Elasticities are dimensionless and therefore comparable: the cost-side levers have elasticity $2.885390\,(c/\eta)$ against a geometry-lever bound of 2.885390 octaves per e-fold, so **a relation whose cost ratio exceeds one nat is one in which the cost side is proportionally stronger, always.** But elasticity says nothing about how far a lever can travel, and on the carried dyad the ranking inverts: raising conversion efficiency to a physically impossible 1.00 buys 4.174198 octaves against a requirement of 4.338420, while raising non-parallelism buys 5.545206 and closes it. **The strongest lever is the one that runs out first.**

What this paper does not claim, stated at the front. The constant $k = (9/8)^2/\varphi^2 = 0.483425732988414$ is a **defined** number, exact by construction; its components are documented — the Pythagorean whole tone [Barbour, 1951] and Euclid's extreme and mean ratio [Euclid, 1956] — but **their product expressed as a frequency in hertz has no precedent in any literature we have found**, and the standard deflationary treatment of golden-section claims [Markowsky, 1992] is cited here deliberately and again wherever φ appears. The essence law is a postulate whose **exponent is defined by the model, not estimated from data**. **Nothing in this paper is counselling, therapy, mediation, or a clinical assessment of any person, pair or group**, and where a relationship is causing a person difficulty the resource is a qualified professional.

Contributions

1. The opposition identity, proved: u is even in ρ, so both signed extremes are the ground essence, and every quantity computed downstream inherits the evenness.
2. The agreement identity $\cos\theta = 2a - 1$, $u = 4a(1 - a)$, exact and requiring no centring, with its $4/m$ resolution limit priced at 643 cents per disputed item in a 120-item log.
3. A three-route concordance on a constructed dyad, with the spread explained by the agreement channel's quantisation rather than by disagreement between the routes.
4. The unison fixed point $Q_\infty = -c/\delta$, with η and N absent and their partial derivatives exactly zero.
5. The blindness of u to pitch-class collision, exhibited by two dyads agreeing to fifteen decimal places and differing in class count.
6. The elasticities, with the dyadic lever criterion $c/\eta \geq 1$ sufficient for cost-side dominance, and the reserve theorem that inverts the ranking on the carried case.
7. The damage integral of the wrong lever order: eight periods of misordering cost twelve periods of permanent lag and 111.133601 stock-periods of cumulative gap, while the diagnostic reads unchanged throughout.

2 Hypotheses, definitions, and postulates

A hypothesis nothing could falsify is not a hypothesis, and this section does not manufacture one. Series C carries the corpus's least-supported material, so the labelling is done first.

2.1 Hypotheses proper

H1 — the concordance hypothesis. Three routes to the same dyad measure one quantity, so their readings agree within the resolution of the coarsest route. **Predicted:** where two or more routes are run on the same declared pair and situation, the spread between extremes does not exceed the coarsest route's quantisation. **Falsified by:** routes that diverge by more than their combined resolution, which would show they are measuring different things and would require the paper to say which. **Status:** demonstrated arithmetically on one constructed case where the quantisation explains 69.64 of a 70.52-cent spread. **Not tested against observation.** No observational data were collected for this paper.

H2 — the ratio-scale hypothesis. The elicited intensities carry ratio information, as magnitude estimation is held to [Stevens, 1957]. **Predicted:** cross-modality matching against the elicitation instrument returns a power relation with an exponent stable under changes of stimulus range. **Falsified by:** exponents that move with the experimenter's chosen range, which is exactly what the range effect predicts [Teghtsoonian, 1971], or by the response-bias mechanisms catalogued against magnitude estimation [Poulton, 1968]. **Status: not tested here.** The framework leans on the psychophysical literature and inherits its disputes [Krueger, 1989]. Section 4.3 computes what the failure costs.

H3 — the independence hypothesis. A dyad's available order is driven by the independence of the two parties rather than by the strength of their agreement or disagreement. **Predicted:** among pairs matched on cost, those whose judgments are uncorrelated in either direction accumulate more stored order than those correlated in either sign. **Falsified by:** matched pairs at ρ near -1 that accumulate more than pairs at ρ near 0, which would show the surplus functional's evenness is the wrong model of the phenomenon. **Status: not tested here.** The formal half — that u is even in ρ — is DERIVED and is Theorem 8.1. The empirical half is the one that could be wrong and has not been tried.

H4 — the ordering hypothesis. In an arrangement whose numerator is negative, an intervention on the decay rate is followed by a worse outcome than the same intervention applied after the numerator is repaired. **Predicted:** two arrangements given the same two interventions in opposite orders differ in trajectory, with the decay-first order spending periods below its starting stock. **Falsified by:** a decay-first ordering that does not lag, which would refute the arithmetic rather than the psychology. **Status:** DERIVED and COMPUTED on a constructed case; **not tested against observation.**

H5 — the consent condition. This is **not a hypothesis and is not offered as one.** That a measurement performed on two people requires the informed and revocable consent of both is a **condition on whether the computation may be performed at all**, adopted by this corpus, and no observation could bear on it.

2.2 Definitions — true by stipulation, not falsifiable

- **Def. 1.** $u(x, y) := 1-(x\cdot y)^2$ on unit state vectors over $N = 12$ categories; $F := \ln(1+(N-1)u)$; $N_{\text{eff}} := 1 + (N-1)u$; $f_{\text{rel}} := k\, N_{\text{eff}}^2$.

- **Def. 2.** A **unison** is a dyad with $u = 0$; equivalently $|\cos\theta| = 1$; equivalently $N_{\text{eff}} = 1$; equivalently $F = 0$; equivalently $f_{\text{rel}} = k$.
- **Def. 3.** $D := 2.885390\,(c/\eta) - \log_2(f_{\text{rel}}/k)$, the octave deficit [Curzi, 2026], whose Result Two is the identity linking it to the storage fixed point.
- **Def. 4.** $k := (9/8)^2/\varphi^2$. **This is a defined constant.** It is an exact ratio of exact quantities and is therefore computable to arbitrary precision; the fifteen significant figures quoted throughout, 0.483425732988414, are *exact digits of a definition* and carry no measurement uncertainty because there is no measurement.
- **Def. 5.** The **concordance spread** is the difference in cents between the highest and lowest route readings on one pair; the 100-cent threshold at which a point value is withheld is **a house convention and is stated as one.**

2.3 Postulates — asserted by this framework, with no external support

- **P-a. The essence law $f(n) = kn^2$ and the bridge $f = k\,e^{2F}$. No external literature supports either.** The exponent 2 is **defined by the model, not estimated from data**; no scaling exponent here was obtained by fitting, none was tested against a log-normal or exponential alternative, and the goodness-of-fit and likelihood-ratio procedure a claimed scaling relation requires [Clauset et al., 2009] was **not run, because there is no data to run it on.**
- **P-b. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic. **Asserting that this dimensionless number *is a frequency* is a separate and much stronger claim**, and no operational procedure is supplied by which the constant acquires the dimension of inverse time.
- **P-c. The affine effective count $N_{\text{eff}} = 1 + (N-1)u$.** A design axiom [Curzi, 2026], whose Result One characterises the surplus functional by angle-only dependence, a zero at parallel, an affine effective count and a normalisation — and it is **not a Hill number of any order.** The Hill family [Hill, 1973, Jost, 2006] and its independent rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly — as the corpus's concentration work uses them [Curzi, 2026], whose Result One gives four jurisdictions at shares $40.9/27.3/18.2/13.6$ a naive HHI of 0.293430 and 3.41 effective jurisdictions against a bloc-collapsed count of exactly 1.00 — and ground this construction not at all.
- **P-d. The state-vector encoding of a party.** That a party's construal of a situation admits representation as a unit vector over twelve categories. **Asserted, not established**, and Section 8.6 states the specific thing it cannot represent: a construal that is the exact negation of another.

2.4 Modelling choices — legitimate, but choices

- **M-a. Octave reduction applied to a non-acoustic quantity.** Octave equivalence is formalised for **pitch** [Shepard, 1982], with a measured and finite perceptual size [Demany et al., 2013]. **The *operation* is well defined; its *interpretation* here is a choice of this framework.**
- **M-b. $N = 12$.** Twelve exceeds the classical span of immediate absolute judgment [Miller, 1956], which is a caution and not a justification. The ladder is owned elsewhere in the series [Curzi, 2026].
- **M-c. The geometric convergence model.** Section 9.6 models the drift of u over time as geometric decay at a rate λ. **That is the simplest form behaving correctly at the boundaries and it has been fitted to nothing.**
- **M-d. The 100-cent concordance threshold and the 10 per cent overlap-weight floor.** Both are declared conventions with no derivation. **What is not optional is choosing one, stating it, and applying it before seeing the result.**
- **M-e. Interval apparatus.** Cents and interval arithmetic are the correct apparatus once an index exists [Rossing et al., 2002, Benson, 2006], but consonance depends on the spec-

trum of a sound and not on the ratio alone [Sethares, 2005], and interval categories generalise less far across listeners than is usually assumed [Burns, 1999, Hoeschele et al., 2012]. **This paper uses the arithmetic and claims none of the perception.**

2.5 What is expository

Sections 4.4, 9.7 and the failure-mode inventories are procedural: they set out reporting requirements and gates rather than argue a claim. Their organising question is *what must be published alongside a reading for a third party to be able to check it.*

3 Framework, dimensional audit, and method

3.1 What is being measured

The object is the geometry between two representations. Not between two people — between two *representations* of two people, produced under a declared rule set, from written framings, by a procedure published with the number.

```
WHAT u MEASURES
    the represented non-parallelism of two parties' states, under one declared ladder

WHAT u DOES NOT MEASURE
    agreement, rapport, closeness, compatibility, conflict, affection, trust,
    similarity of personality, or the quality of anything
```

The second block is longer than the first and that is the correct proportion. u answers one question: how much of what each party carries is not already carried by the other.

One further clarification saves a great deal of confusion later. u **is a property of the pair and not of either party**, because the inner product is symmetric, so there is no such thing as one party's *contribution* to u. A dyad in which one party holds eleven states and the other holds one can read lower than a dyad in which both hold three, if the eleven contain the one. **Breadth is a personal quantity; non-parallelism is a relational one; and the formalism keeps them apart on purpose.**

3.2 The three laws this paper composes

```
THE SURPLUS LAW    F(u) = ln(1 + (N−1)u)               a pair has a surplus
THE ESSENCE BRIDGE f = k e^(2F) = k (1+(N−1)u)^2        a surplus has a pitch
THE STORAGE LAW    Q_{t+1} = (1−delta)Q_t + eta F − c   surplus becomes structure, and leaks
```

Analogy status: category 2, a shared mathematical form. The storage law is the discrete leaky integrator that appears as the RC low-pass filter [Oppenheim et al., 1996, Horowitz and Hill, 2015], as exponential smoothing [Holt, 1957], and as the leaky integrate-and-fire neuron [Lapicque, 1907, Gerstner and Kistler, 2002]; its fixed point and stability condition are standard [Elaydi, 2005] and its convergence is Banach's [Banach, 1922]. **It is used because the mathematics is the same, not because the physics transfers.** The corpus states that theorem exactly and then refuses the certificate it appears to offer [Curzi, 2026] — a human life is not a metric space and nobody has measured the relevant contraction modulus — and **that refusal binds every trajectory in Section 9.**

Two further warnings attach and are recorded here rather than in a footnote. Q **has the grammar of a conserved quantity without a conservation law to give that grammar content**, which is the characteristic defect of the genre [Mirowski, 1989]; validity is claimed only within a specified arrangement [Cartwright, 1999]. And the time average of a multiplicative process

is not its ensemble average [Peters, 2019], while aggregation over heterogeneous parties does not in general yield a representative party [Kirman, 1992].

The warrant the logarithm needs is not the psychophysical one. A logarithmic form follows from multiplicative dynamics with **no psychological assumption at all** [Peters and Gell-Mann, 2016], which is what the argument here requires; Fechner [Fechner, 1860, Weber, 1834] is needed only where an elicitation is performed. **And the functional form is underdetermined**: a sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. **Nothing in this paper discriminates among them.**

3.3 The constant k

$$k := \frac{(9/8)^2}{\varphi^2} = \frac{81/64}{\varphi + 1} = 0.483425732988414 \quad \text{(defined; exact)}$$

Both components are real and documented — the Pythagorean whole tone [Barbour, 1951, Lindley and Turner-Smith, 1993] and Euclid's extreme and mean ratio [Euclid, 1956], with $\varphi^2 = \varphi + 1$ a proved identity [Vajda, 1989, Koshy, 2001]. **Their product, expressed as a frequency in hertz, has no precedent.** The literature on golden-section claims is overwhelmingly one of *deflation*: the appearances of φ in the Parthenon, the Great Pyramid, the human body and preferred rectangles do not survive examination [Markowsky, 1992, Fischler, 1981, Livio, 2002], and the psychological preference results are weaker and more equivocal than usually reported [Höge, 1997]. φ **is being *chosen* as a constant, not *found* in a psychological system** — and the cost of the choice is small in a precise sense, because k cancels from every interval and from every verdict in this paper.

3.4 Dimensional audit

symbol	quantity	dimension	unit	status
u	non-parallelism	$[1]$	—	dimensionless by construction, $u \in [0, 1]$
ρ	correlation	$[1]$	—	dimensionless, $\rho \in [-1, 1]$
a	agreement fraction	$[1]$	—	dimensionless, $a \in [0, 1]$
F	surplus	$[1]$	nats	dimensionless; a logarithm of a count
N, m	category count, item count	$[1]$	—	absolute scale, counts
k	reference constant	$[T^{-1}]$ **asserted**	Hz **asserted**	**defined as a ratio (dimensionless); the unit is postulated**
f_{rel}	relationship frequency	$[T^{-1}]$	Hz	inherits its dimension entirely from k
D	octave deficit	$[1]$	octaves	a difference of logarithms; k cancels
Q	stored order	$[\mathcal{C}]$	none supplied	state variable; **no operational unit**

symbol	quantity	dimension	unit	status
η	conversion efficiency	$[1]$	—	dimensionless; assumed $0 < \eta \leq 1$
c	cost per period	$[\mathcal{C}T^{-1}]$	per declared period	driving term
δ, λ	decay, convergence rate	$[1]$	per declared period	dimensionless
ε	elasticity $dD/d(\ln x)$	$[1]$	octaves per e-fold	**dimensionless, which is why levers are comparable this way**
$\|x\|_2$	raw intensity norm	instrument units	as declared	**published, never discarded**

Does the equation balance? $f_{\text{rel}} = k\,N_{\text{eff}}^2$ balances only if k carries $[T^{-1}]$, because N_{eff} is dimensionless. **No operational procedure is supplied by which k acquires that dimension**, and the hertz is attached by assertion; this is the largest dimensional exposure in the paper and it is listed in Section 14 by name.

The exponent is the second exposure. The ratio c/η is $[\mathcal{C}T^{-1}]$ divided by a pure number and is therefore **not dimensionless as written**, which the exponent of $e^{2c/\eta}$ requires it to be. **The framework's convention is that c is expressed in nats of surplus per declared period — and the source never states it.** It is stated here, and every verdict in Sections 9 and 10 depends on it being applied consistently. The failure mode is measurable: a c/η built from a weekly cost and an annual conversion rate is a different number, and the corpus's own correspondence audit measures a $90.1\times$ period-normalisation trap from exactly that mistake.

The third audit result is about the elasticities and it is favourable. dD/dx for different parameters are in different units and **cannot be ranked against one another**; $dD/d(\ln x)$ are all in octaves per e-fold and can. That is the whole reason Section 9.3 exists.

3.5 Scale type, and what licenses the arithmetic

quantity	scale type claimed	what licenses it
n, N, m	absolute	cardinality: true zero, fixed unit, identity transformation group only
u, ρ, a	ratio / interval as constructed	inner products and counts of matches
elicited intensities	ratio, up to a free common multiplier	**magnitude estimation, assumed** [Stevens, 1957]; not tested here
η, c, δ	ratio, **assumed**	no validated instrument is supplied
f_{rel}	ratio in hertz, **inherited**	inherits the status of the intensities and of the postulated bridge

Stevens' typology makes the permissible arithmetic on a quantity a function of the transformation group that leaves its empirical content unchanged [Stevens, 1946]. **A count admits**

only the identity transformation; a rating does not, and the corpus has demoted one of its own keystone constructions on exactly that ground [Curzi, 2026m], whose Result Two fixes the contact point $D = P$, $r = 1$, $M = E$ with unit elasticity in all three terms and the ceiling $0 \leq M \leq \ln N$ making the divergence finite.

The strongest available objection to this framework is Michell's: that psychology routinely assumes its attributes are quantitative without testing whether they are [Michell, 1997, 1999]. The remedy exists — conjoint measurement supplies a testable condition for additive quantitative structure [Luce and Tukey, 1964, Krantz et al., 1971], and a Rasch model supplies specific objectivity [Rasch, 1960, Andrich, 1988] — and **neither has been run for any quantity in this paper.** Section 4.3 computes the price of that failure at 1065.05 cents.

3.6 Identification, and the reflexive exposure

The framework's founding construction is a reflexive loop in which each party's reading of the other shapes what the other becomes [Curzi, 2026], whose Result One is the reframing that makes the present state a local minimum of the comfort landscape by definition rather than by luck. **That is a linear-in-means reflexive specification, and the endogenous effect in such a specification is not identified from observational data** [Manski, 1993]; influence and selection are generically confounded in observational relational data [Shalizi and Thomas, 2011]. **No amount of fit recovers the parameter.** The remedy adopted here is stipulation — the rule set, the ladder and the item set are declared in advance and published with every reading, which is what makes a discrete-choice treatment of interaction defensible [Brock and Durlauf, 2001] — and **the claim is accordingly a modelling position, not an identified empirical result.**

The same objection applies to the framework's own parameters: if parties change when modelled, η, c, δ and u are not structural [Lucas, 1976, Hacking, 1995, Ferraro et al., 2005]. **This is stated, not resolved.** The exposure is sharper here than elsewhere in the corpus, because a reading issued to two people about their own relation is precisely the case where the instrument can change what it measures [Merton, 1948, Rosenthal and Jacobson, 1968].

3.7 Method

Every number in this paper is the output of exact arithmetic on stated parameters, computed in double precision. **No observational data were collected, no human subjects participated, and no empirical dataset underlies any figure or table.** Every case is constructed and is labelled as constructed at the point of use. The figures are produced by the scripts named in their captions.

4 Three routes to one quantity

4.1 Why there are three

A single route would be simpler and would be wrong, for a structural reason rather than a cautious one. **Route A's intensity vectors are non-negative by construction, so** $\cos\theta \geq 0$ **for every pair and the negative half of the correlation range is unreachable through it.** The bound is exact rather than empirical; a verification over 100,000 random non-negative unit pairs at internal scope returns a minimum observed cosine of 0.260867, well inside it.

ROUTE	channel	sign range	what it is good for
A	state vectors	cos in [0,1]	the native reading; content, not conduct
B	shared judgements	cos in [−1,1]	conduct on a fixed item set; reaches rho<0
C	errors vs known answers	rho in [−1,1]	independence proper; reaches rho<0

The three routes measure the non-parallelism of different things — what the parties *hold*, what they *say* about a fixed set of items, and how they *err* against a known standard. **A pair**

can be near-parallel in one and far from parallel in another, and when they are, that discrepancy is itself the finding.

4.2 Route B: the agreement identity

THEOREM 4.1 — THE AGREEMENT IDENTITY. Let two parties each render a binary judgment coded ± 1 on each of m shared items, and let a be the fraction on which they match. Then

$$\cos\theta = 2a - 1, \qquad u = 1 - (2a-1)^2 = 4a(1-a)$$

Proof. Each judgment vector has every entry ± 1, so each has norm $\sqrt{m}$. Their inner product is $am - (1-a)m = m(2a-1)$. Dividing by the product of the norms gives $\cos\theta = 2a - 1$. Substituting into $u = 1 - \cos^2\theta$ and expanding gives $1 - (4a^2 - 4a + 1) = 4a(1-a)$. **QED. The identity is exact and requires no centring**, because the norms of ± 1 vectors are fixed by m alone.

a	$\cos\theta$	u	f_{rel} (Hz)	cents above k
1.000000	$+1.000000$	0.000000	0.4834	0.00
0.983333	$+0.966667$	0.065556	1.4320	1880.02
0.950000	$+0.900000$	0.190000	4.6158	3906.26
0.900000	$+0.800000$	0.360000	11.8930	5544.82
0.800000	$+0.600000$	0.640000	31.2494	7217.27
0.700000	$+0.400000$	0.840000	50.6909	8054.75
0.500000	0.000000	1.000000	69.6133	8603.91
0.300000	-0.400000	0.840000	50.6909	8054.75
0.200000	-0.600000	0.640000	31.2494	7217.27
0.100000	-0.800000	0.360000	11.8930	5544.82
0.050000	-0.900000	0.190000	4.6158	3906.26
0.000000	-1.000000	0.000000	0.4834	0.00

The table is exactly symmetric about $a = 0.5$, and the top and bottom rows are identical. Two parties who agree on every item and two parties who disagree on every item produce the same u, the same frequency and the same reading. Section 8 owns that result; **what matters here is that the measurement channel exhibits it directly, in a form anyone can compute from a spreadsheet.**

Route B's resolution limit is severe and must be stated with the route. Because a is quantised to $1/m$, u is quantised to roughly $4/m$ near the top of the agreement range:

```
m        a (2 disagreements)   u         f (Hz)    one more disagreement costs
 40        0.950000          0.190000    4.6158           938.89 cents
 60        0.966667          0.128889    2.8259           849.42 cents
120        0.983333          0.065556    1.4320           643.28 cents
240        0.991667          0.033056    0.8989           428.21 cents
400        0.995000          0.019900    0.7182           295.58 cents
1000       0.998000          0.007984    0.5721           136.62 cents
5000       0.999600          0.001600    0.4920            29.78 cents
```

In a 120-item log, one disputed item is worth 643 cents — more than a perfect fifth. A near-parallel dyad cannot be resolved better than a few hundred cents by an agreement log of plausible length, and **the honest output of Route B in that regime is an interval, not a number.**

4.3 Route C, and the two invariances that decide whether any route means anything

DEFINITION 4.2 — THE ERROR CHANNEL. Both parties estimate each of m quantities whose true values subsequently arrive; form each party's error vector, let ρ be the correlation of the two, and set $u = 1 - \rho^2$.

It is signed, so it reaches the negative half. **It requires ground truth**, which is its cost and is not small: Route C is unavailable for questions whose answers never arrive, which is most of what two people actually disagree about. **And it is the route that catches shared noise.** Two parties answering at random on a shared item set have expected agreement $a = 0.5$, hence $u = 1$, hence $f_{\text{rel}} = 69.6133$ Hz — the ceiling of the entire system, from two people guessing. **The surplus formalism cannot distinguish independence from noise, because both are orthogonality**, and F is in any case a lower bound on the ensemble's information rather than the information itself.

> **THE ACCURACY GUARD [BINDING WHEREVER ROUTE B OR C IS USED].** A reading is published with a measure of each party's accuracy on the item set. **A high u between two parties who are both largely wrong is arithmetically correct and practically worthless. Surplus is a measure of distinctness, never of correctness**, and this framework has no formalism that converts one into the other.

The first invariance is good news. Because $(\alpha x)/\|\alpha x\| = x/\|x\|$ for $\alpha > 0$, any common positive rescaling of the intensities cancels exactly. Recorded on 0–10, on 0–1, on 0–100 and as proportions of a total, the same framing normalises to $(0.872871561,\ 0.43643578,\ 0.21821789)$ **identically to nine decimal places.** The elicitation instrument's unit is unconstrained: two analysts using different scales produce the same u, the same F and the same f_{rel}, provided the *ratios* agree.

The second invariance does not hold, and here is by how much. Under an ordinal reading, applying any strictly increasing function to the intensities destroys no information. Computed, against a fixed reference framing:

transform	u	f_{rel} (Hz)	cents above k
$\log(1+x)$	0.362115	12.0049	4849.03
$\sqrt{\cdot}$	0.371445	12.5044	4919.61
identity	0.388360	13.4361	5044.14
square	0.525275	22.2093	5914.09

A spread of 1065.05 cents — 0.888 octaves — produced entirely by relabellings that preserve every ordinal fact in the data. Every transform leaves the ranking of the states untouched; an ordinal scale calls them the same measurement, and the relationship frequency calls them a minor seventh apart. The same failure is recorded in the criterion paper as its Result Seven [Curzi, 2026].

> **THEREFORE "REPORT IT AS ORDINAL" IS NOT AN AVAILABLE FALLBACK.** It is not a weaker version of the reading. **With ordinal intensities the relationship frequency is not determined**, and any number published from them is a property of the labelling rather than of the pair.

A further symptom of the same disease: $\log(1+x)$ is unit-dependent, landing at $u = 0.366939$ on a 0–1 instrument against 0.362115 on 0–10. **A transform family admissible under an ordinal reading includes transforms whose effect depends on an arbitrary choice of units, and the reading moves when the units move.**

The requirement that survives both invariances is precise: the intensities must carry ratio information while the unit in which the ratio is expressed remains free, which is exactly the definition of a ratio scale. **The honest form of the claim, softened nowhere: the intensities are**

ratio-scaled to the extent that magnitude estimation delivers ratio scales, which is a measured property of a procedure and not a constant of nature.

4.4 The magnitude reporting rule

Normalisation discards the length of each vector, and the length is not nothing:

```
low-intensity  {3: 1,   5: 0.5, 7: 0.25}   raw L2 norm = 1.145644
high-intensity {3: 8,   5: 4,   7: 2   }   raw L2 norm = 9.165151
ratio of norms = 8.0000x        u between them = 0.000000000000   exactly zero
```

> **THE MAGNITUDE REPORTING RULE.** Both parties' raw L2 norms are reported alongside the reading, in the instrument's units, and are never discarded. u **measures direction; the norms measure how much there is.** A dyad reading published without both norms has thrown away half the measurement and made the free multiplier unrecoverable.

The dyad case adds a requirement the single-vector case does not have: the *ratio* of the two norms is itself reportable, because a large asymmetry is a fact about the elicitation that the normalised geometry cannot express. The carried dyad's ratio is 1.065667, small enough that nothing in its reading is an artefact of one party reporting bigger numbers.

One elicited number moves the reading by more than an octave, which is why the ratio question must be asked explicitly, the reading double-coded, and an interval reported:

$B[10]$	u	f_{rel} (Hz)	shift from the carried reading
0.00	0.019232	0.7096	-1285.20 cents
0.10	0.032095	0.8850	-902.77 cents
0.20	0.068735	1.4908	0.00 (the carried case)
0.30	0.124003	2.7017	$+1029.33$ cents
0.40	0.191202	4.6554	$+1971.38$ cents

5 What u cannot see

5.1 Blindness to pitch-class collision

u is computed from an inner product over the twelve indices. It knows which indices carry weight. **It does not know that indices 5 and 10 fold to the same pitch class**, because folding is a property of the essence law and not of the geometry.

THEOREM 5.1 — u IS BLIND TO PITCH-CLASS COLLISION. There exist dyads with identical u, identical f_{rel}, and different numbers of distinct pitch classes in the union of their supports.

Proof by construction, both cases computed.

```
A  = {4: 0.7, 6: 0.5, 9: 0.4}

B  = {4: 0.6, 6: 0.55, 9: 0.3, 10: 0.2}
     cos theta = 0.965020899   u = 0.068734665264634   f_rel = 1.4907987150 Hz
     union {4, 6, 9, 10}   odd parts 1, 3, 9, 5   ->  FOUR distinct pitch classes

B* = {4: 0.6, 6: 0.55, 9: 0.3, 12: 0.2}
     cos theta = 0.965020899   u = 0.068734665264634   f_rel = 1.4907987150 Hz
     union {4, 6, 9, 12}   odd parts 1, 3, 9, 3   ->  THREE distinct pitch classes
```

The two agree to fifteen decimal places, because the inner product runs only over the three shared indices and both partners have the same norm. **QED.**

Two dyads at the same relationship frequency, one occupying four pitch classes and one three: the geometry cannot tell them apart and the lattice can. The odd-part rule that produces the collision is owned by the folding paper [Curzi, 2026], whose Result One establishes that two indices share a pitch class if and only if they share an odd part.

> **THE COLLISION TEST.** After computing u, list the union of the two supports, take the odd part of every index, and report the count of distinct pitch classes beside the count of distinct states. Where the two differ, say by how much and name the colliding pairs. **The test takes two minutes and it is the difference between reporting four perspectives and reporting three.**

5.2 Degeneracy at dyad scope

```
DISJOINT SUPPORT BETWEEN TWO PARTIES -- computed
P = {1:0.6, 2:0.5, 4:0.3}     Q = {3:0.7, 6:0.4, 9:0.5}
    cos theta = 0.000000000000    u = 1.000000000000    f_rel = 69.6133 Hz
P = {5:0.9, 7:0.1}            Q = {8:0.2, 11:0.9}
    cos theta = 0.000000000000    u = 1.000000000000    f_rel = 69.6133 Hz
```

Both pairs score the maximum the system can produce, and both scores are produced by the encoding rather than by the parties. Any two vectors with no index in common are orthogonal, so $u = 1$ regardless of what the states are or how intense they are. **The degeneracy is flattering, which is why it survives**: a pair told they occupy the full twelve-fold relational range will not challenge the finding, and an instrument whose failure mode is to award full marks will be adopted enthusiastically and never questioned by the people it flatters.

> **THE OVERLAP CONDITION AT DYAD SCOPE [BINDING].** A dyad reading may be computed only if the two supports share at least one state carrying non-trivial weight in both. Where they do not, the computation is reported as DEGENERATE and no f_{rel} is published.

The plain-language version is what makes it obviously right: two people described as having nothing whatever in common have not been described as a relationship. **A subtler version is more common in practice** — support overlapping in one state at very low intensity in one party produces a cosine dominated by a single small term, and the reading becomes a fact about that term. A weight floor exists for exactly that reason and it is a declared convention (M-d).

6 The unison

6.1 What it is

DEFINITION 6.1. A **unison** is a dyad with $u = 0$; equivalently $|\cos\theta| = 1$; equivalently $N_{\text{eff}} = 1$; equivalently $F = 0$; equivalently $f_{\text{rel}} = k$ exactly.

A unison is not a low reading. It is the absence of a reading: the pair occupies zero cents of the 8603.91 available, realises 0.00 per cent of the system's surplus, and is positioned exactly where a pair that does not exist would be positioned.

6.2 The opposition identity

THEOREM 6.2 — THE OPPOSITION IDENTITY. For two represented states with correlation ρ, $u = 1 - \rho^2$, so u depends on ρ only through $|\rho|$. Consequently $u(\rho) = u(-\rho)$ for every ρ, and in particular

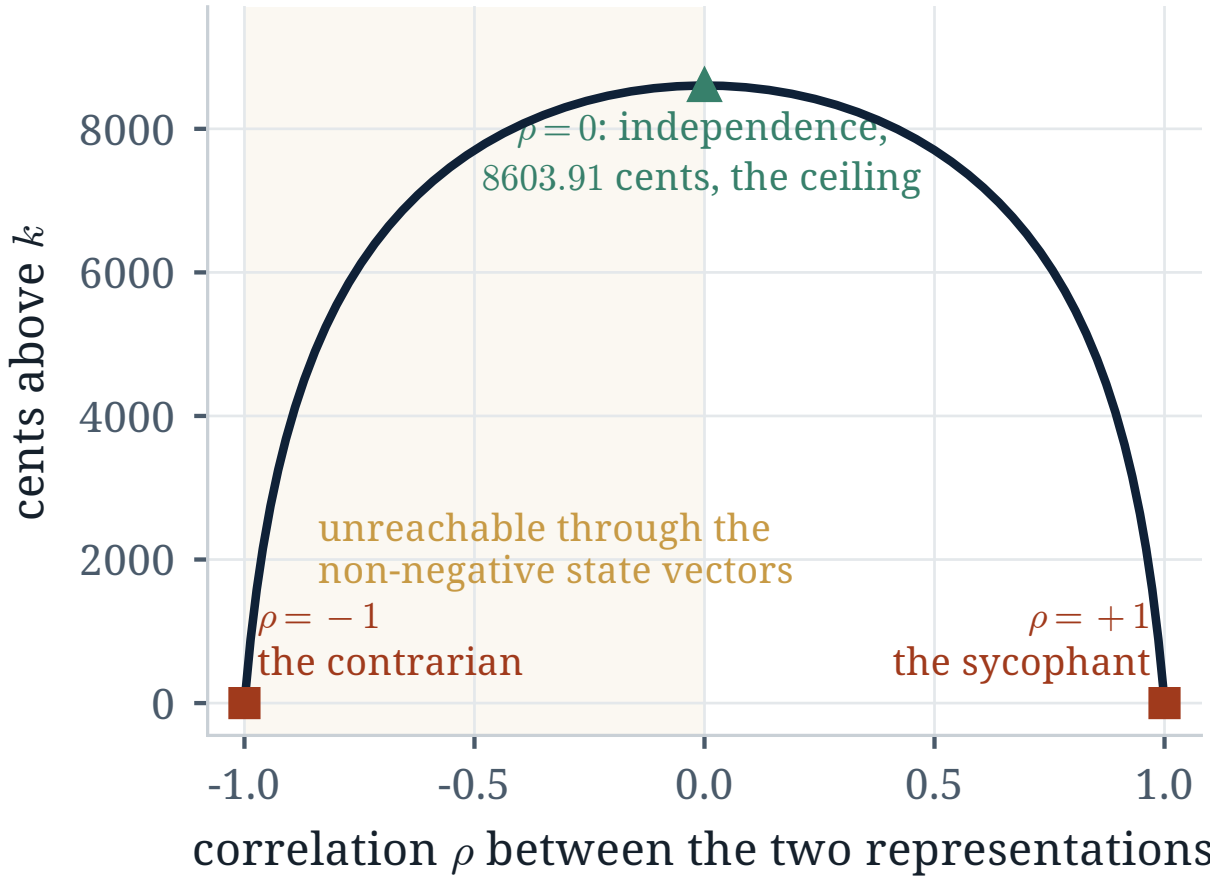

Figure 44.1: **Both signed extremes of the correlation are the same reading**: the surplus range is folded in the middle, so $\rho = +1$ and $\rho = -1$ each give $u = 0$ and $f_{\text{rel}} = k$ exactly, while the maximum sits at $\rho = 0$ with 8603.91 cents. The shaded half is unreachable through the framework's non-negative state vectors and can be measured only on the signed routes. Modelled from $u = 1-\rho^2$ and $f_{\text{rel}} = k(1+11u)^2$ with the **defined** constant $k = 0.483425732988414$ and $N = 12$. Built by `figs/src/CCP-044_fig01.py`.

$$u(+1) = u(-1) = 0, \qquad F(+1) = F(-1) = 0, \qquad f_{\text{rel}}(+1) = f_{\text{rel}}(-1) = k$$

Proof. $f_{\text{rel}} = k(1 + (N-1)u)^2$ with $u = 1 - (x \cdot y)^2$ for unit vectors, and $x \cdot y$ is the correlation. **Squaring is an even function**, so u is even in ρ, and every quantity computed from u — F, N_{eff}, f_{rel}, the octave deficit, Q_∞ — is even in ρ as well. At $\rho = \pm 1$, $u = 0$, so $N_{\text{eff}} = 1$, $F = \ln 1 = 0$, and $f_{\text{rel}} = k$. **QED.**

The proof is three lines and it is complete. There is no term anywhere in the construction that carries the sign of the correlation, so no quantity derived from it can recover the sign. This is not a limitation of the twelve-state ladder, not an artefact of $N = 12$, and not a consequence of the affine axiom. **It is a property of the inner product itself**: $u = \sin^2\theta$, and the sine squared of an angle and of its supplement are equal. The corpus's group work states the same result in its own register [Curzi, 2026r], whose Result One records that a pair in perfect opposition and a pair in perfect agreement both read $u = 0$, $N_{\text{eff}} = 1$ and surplus zero, because the extremality condition is stated on the squared alignment; the roster form is owned by the effective-count paper [Curzi, 2026c], whose Result Three states that a standing contrarian buys no surplus.

Computed across the full range, the table is a **perfect mirror about** $\rho = 0$, and both extremes fold to 247.514 Hz at $j = 9$ in pitch class 1 — the same note, at the same transposition, in the same class.

6.3 What dies at $u = 0$

THEOREM 6.3 — THE UNISON FIXED POINT. At $u = 0$, $F = 0$, therefore $Q_\infty = (\eta \cdot 0 - c)/\delta = -c/\delta$. **$\eta$ and N do not appear.** *Proof:* by inspection of the storage fixed point with $F = 0$ [Curzi, 2026a]. **QED.**

Verified across a grid at $c = 0.62$, $\delta = 0.09$:

eta	N	octave deficit D	Q_inf
0.05	2	35.7788	−6.888889
0.05	100	35.7788	−6.888889
0.30	2	5.9631	−6.888889
0.30	100	5.9631	−6.888889
0.60	12	2.9816	−6.888889
0.99	12	1.8070	−6.888889

A twentyfold improvement in conversion efficiency and a fiftyfold increase in the category count leave the destination bit-for-bit unchanged. The deficit moves, because D depends on η explicitly, but the fixed point does not, because the two dependencies cancel exactly through $Q_\infty = -D\,\eta/(2.885390\,\delta)$. The partial derivatives make the same point:

PARTIALS OF Q_inf (eta = 0.30, delta = 0.09, N = 12, c = 0.62)

u	dQ/du	dQ/deta	dQ/dc	dQ/dN
0.000000	36.6667	0.0000	−11.1111	0.0000
0.068735	20.8798	6.2565	−11.1111	0.1305
0.500000	5.6410	20.7978	−11.1111	0.2564

At $u = 0$ exactly two of the four levers have any effect on the destination, and the u lever is at its strongest value anywhere on the range. $dQ/d\eta = F/\delta$ is zero because there is nothing to convert; dQ/dN is zero because N enters only multiplied by u. **Raising conversion efficiency in a unison relation converts nothing more efficiently; adding categories adds dimensions nobody is using.** The framework's headroom sensitivities record the same weakness of the N lever in a different register [Curzi, 2026o], whose Result Five gives $dh/dN = \eta/N = 0.0038$ against $dh/d\eta = \ln N = 2.197$ — **adding categories is the weakest available lever.**

6.4 Two in unison are one paying twice

```
UNISON DYAD    eta = 0.30, c = 0.62, delta = 0.09, F = 0
               eta*F − c = −0.620000 per period
               Q_inf = −6.888889        D = +5.9631 octaves

SOLO ACTOR     same delta, same eta, F = 0, but c = 0.20 -- no coordination overhead
               Q_inf = −2.222222        D = +1.9236 octaves

THE SECOND SEAT COSTS   4.666667 units of Q_inf   and   4.0395 octaves of deficit
THE SECOND SEAT RETURNS 0.000000
```

The solo cost is a **stipulated** value chosen to represent a relation without coordination overhead, and nothing turns on its exact size. **The entire ledger of a unison pair is cost**: the numerator ηF is exactly zero, so the second party contributes nothing to accumulation and everything to loss. **And the sentence is symmetric**, which is the whole point — replace the sycophant with a contrarian and every number is unchanged.

6.5 Where opposition is reachable, and where this framework cannot see it

An honest paper has to say where its own encoding cannot go. The twelve-state intensity vectors are non-negative by construction, so within Route A $u = 0$ **can arise only from parallelism: the sycophant is representable and the contrarian is not.**

```
ROUTE A   state vectors, non-negative       cos in [0, 1]     agreement branch ONLY
ROUTE B   shared judgements, +1/−1          cos in [−1, 1]    BOTH branches
ROUTE C   error vectors vs known answers    rho in [−1, 1]    BOTH branches
```

The opposition branch is measured on the signed channels or it is not measured at all, which is exactly why this paper builds three routes rather than one. **An analyst running only Route A will never see a negative correlation and may conclude the branch is theoretical. It is not theoretical; it is invisible to that instrument.** The twelve states record which components a construal requires, not which direction it points, so a framing that is the exact negation of another cannot be represented in Route A at all. **A signed encoding would be a different instrument and this framework does not have one.**

6.6 Consonance and redundancy, at relational scope

COROLLARY 6.4. The most consonant possible dyad is the most redundant possible dyad, and its frequency is k.

Proof. Consonance in this system is small harmonic distance; the extreme is exact coincidence, which for two parties means identical normalised state vectors; identical vectors give $\cos\theta = 1$, hence $u = 0$, hence $f_{\text{rel}} = k$. **QED.** The identity behind it is owned by the consonance paper [Curzi, 2026], whose Result Two records that the minimum harmonic distance $\text{HD}_{\text{ess}} = 2.0000$ is attained by exactly the six collision pairs $\{1{:}2,\ 2{:}4,\ 3{:}6,\ 4{:}8,\ 5{:}10,\ 6{:}12\}$ and by nothing else.

That paper's caveat travels with the identity and is not dropped here: the ordering is not total. It is not true that every collision is more consonant than every non-collision — $1{:}3$ at $\text{HD}_{\text{ess}} = 3.1699$ beats the collisions $1{:}4$, $2{:}8$ and $3{:}12$ at 4.0000. The collision set is dramatically more consonant on average (mean 3.0000 against 8.6617) and the ranges overlap. **A reader who builds on the total-order version will eventually be wrong about** $1{:}4$**.**

And its firewall stands: nothing about distress, health, function or experience follows from a consonance reading, in either direction. A unison dyad is not a bad relationship, an unhealthy one, or one that anybody should change. **It is a relation that, at these costs, does not accumulate order. Those are different sentences and this paper will not merge them.**

6.7 The flat maximum, and the design rule

$du/d\rho = -2\rho$, so **at** $\rho = 0$ **the derivative is exactly zero: the optimum is second-order flat.** Near independence an error in the correlation costs almost nothing and the cost grows quadratically rather than linearly.

$\lvert\rho\rvert$	u	f_{rel} (Hz)	cents surrendered vs $\rho = 0$
0.00	1.000000	69.6133	0.00
0.05	0.997500	69.2946	7.94
0.10	0.990000	68.3429	31.89
0.20	0.960000	64.6019	129.34
0.30	0.910000	58.6009	298.13
0.50	0.750000	41.3631	901.22

$\lvert\rho\rvert$	u	f_{rel} (Hz)	cents surrendered vs $\rho = 0$
0.90	0.190000	4.6158	4697.65
0.99	0.019900	0.7182	7918.52
1.00	0.000000	0.4834	8603.91

The marginal cost of one further hundredth of correlation runs from 0.32 cents at the origin to 6.73 at $|\rho| = 0.10$, 41.84 at 0.50, 230.61 at 0.90 and 685.39 at the extreme. **Missing perfect independence by a tenth costs a sixth of a semitone; missing perfect *opposition* by the same tenth costs 4697.65 cents.**

> **THE DESIGN RULE.** Where a relation is to be arranged rather than merely read, **target $|\rho|$ near zero and never ρ near -1.** Independence is a robust target — second-order insensitive to error, forgiving of imprecision, and the global maximum of the surplus. **Opposition is the *other* global minimum, sits at the steepest part of the curve, and returns exactly what agreement returns: nothing.**

The rule is not a preference for harmony over conflict. It says nothing about how two people should treat each other. It says that if the goal is available order, the coordinate to aim at is uncorrelated, and both correlated extremes are worthless — one of them expensively so.

6.8 What raises u, and what only appears to

Manufactured disagreement raises cost and returns exactly nothing. A party who adopts contrary positions in order to "bring difference" moves the pair toward $\rho = -1$, which reads as $u = 0$ just as agreement does, while adding coordination overhead. **The reading gets worse in both terms at once.**

```
RULED OUT -- these move rho toward -1 and return nothing
  - assigning a person to argue the opposite of whatever is proposed
  - rewarding disagreement as such, or counting objections as output
  - recruiting for temperament rather than for method or evidence base
  - any arrangement that requires a person to hold a position they do not hold

RULED IN -- these move |rho| toward 0
  - different evidence base: parties who look at different data
  - different method: parties whose procedures fail in different ways
  - different exposure: parties who bear different consequences from one decision
  - different training: parties whose priors were formed on different problems
  - independent work before contact
```

The distinction between the two lists is not attitude; it is whether the difference is in what the parties actually do or in what they say about what someone else did. A party with a different evidence base disagrees when the evidence differs and agrees when it does not, so their correlation is low in magnitude and of no fixed sign. **A party assigned to disagree has a correlation near -1 by construction, and the identity prices it at zero.**

That is a defence of the red-team tradition rather than an attack on it. A red team that brings different methods, different data and different exposure sits near $\rho = 0$ and is worth up to the full 8603.91 cents; **a red team that is one person told to object sits near $\rho = -1$ and is worth nothing at all.** The tradition names a real target and the arithmetic says which implementations hit it. That reading is consistent with the surrounding literature on composition: the returns to group composition are contested and depend on what kind of difference is present [van Knippenberg and Schippers, 2007, Mannix and Neale, 2005], the collective-performance factor is driven by composition rather than headcount [Woolley et al., 2010],

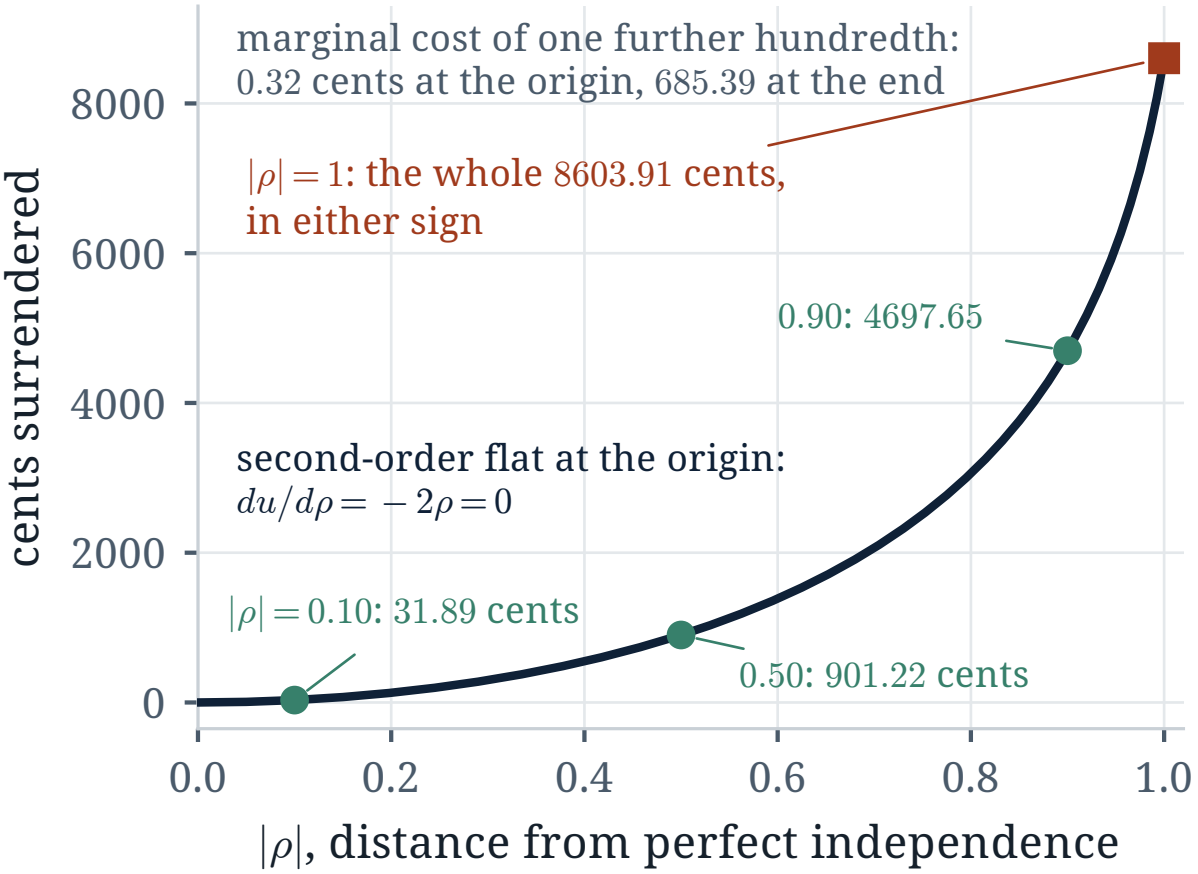

Figure 44.2: **The maximum is second-order flat and the extremes are not**: missing perfect independence by a hundredth of correlation costs 0.32 cents, while the last hundredth before perfect correlation costs 685.39. Computed from $u = 1-\rho^2$ and $f_{\text{rel}} = k(1+11u)^2$ with the **defined** constant $k = 0.483425732988414$ and $N = 12$; the plotted quantity is cents surrendered relative to $\rho = 0$. Built by `figs/src/CCP-044_fig03.py`.

the problem-solving result usually cited for diversity [Hong and Page, 2004, Page, 2007] has a standing formal objection [Thompson, 2014] that must be cited with it, and the aggregation result that makes independence load-bearing is the classical one [Galton, 1907, Surowiecki, 2004] together with its failure mode when independence is destroyed by social influence [Lorenz et al., 2011, Bikhchandani et al., 1992, Banerjee, 1992]. **The portfolio statement of the same fact predates all of it: diversification benefit depends on covariance, not on count** [Markowitz, 1952].

There is a further consequence for how such a role is filled. **A role defined as "hold the contrary position" is a role in which declining is structurally unavailable** — the person cannot say *I agree with this one* and still be doing the job. A role defined as "bring this evidence base" leaves declining intact on every question. **The first is prohibited by this corpus's consent constraint and is worthless by its arithmetic; the second is neither. When the ethical constraint and the pricing agree, there is no trade-off to manage.**

7 The dyadic reading

```
u        measured between the two parties                    Section 4
f_rel    = k (1 + (N−1) u)^2
f_min    = k e^(2c/eta)                                      CCP-040, R1
D        = 2.885390 (c/eta) − log2(f_rel/k)
Q_inf    = ( eta F(u) − c ) / delta

D <= 0   ACCUMULATES        D = 0   HOLDS        D > 0   DECAYS
```

The ceiling test comes first and it is not a stylistic preference: compare c/η to $\ln N$, and if the ratio exceeds it the case is structural and no assignment of u closes it [Curzi, 2026]. **A deficit does not announce its own kind, and a prescription issued before the ceiling test may be unsatisfiable** — which is worse than no prescription, because it consumes the effort that restructuring needed. The corpus's headroom gauge states the same constraint in stock units [Curzi, 2026b], whose Result One gives $h_t = \eta \ln N - \delta Q_t - C_t$ with its three regimes and its maximum admissible increment; and the intervention protocol adds the reserve discipline [Curzi, 2026j], whose Result One recommends $r \leq 0.7h$ because $r_{\max} = h$ is attained only at $u = 1$, together with the branch in which **no interaction geometry can prevent order from decreasing.**

What the four parameters are in a bond, concretely, because the abstraction invites people to fill them in wrongly. η is the fraction of what the two parties do together that survives the period — not how much they do, and not how intensely. c is what the arrangement costs to run before it produces anything. δ is the rate at which accumulated order leaks away if nothing is added. u **is the only one of the four that is a joint geometric property rather than a property of the arrangement**, and **one clock, declared, governs all three of the others.**

8 Levers: elasticity, reserve, and order

8.1 The order-of-operations rule

THEOREM 8.1 — DECAY AMPLIFIES THE SIGN IT FINDS. Write the numerator $n := \eta F(u) - c$. For $\delta > 0$, $Q_\infty = n/\delta$ and $dQ_\infty/d\delta = -n/\delta^2$, so

```
n > 0   ->   reducing delta RAISES Q_inf
n < 0   ->   reducing delta LOWERS Q_inf
n = 0   ->   Q_inf = 0 for every delta;  the lever is exactly inert
```

Proof: differentiate n/δ; $\delta^2 > 0$, so the sign of the derivative is the sign of $-n$. **QED. The theorem has no free parameters and no conditions beyond $\delta > 0$. It is not a tendency, not an empirical regularity, and not a claim about people. It is what division does.**

> **An intervention that lowers δ multiplies whatever the relation is already doing. In a bond that is accumulating, it accumulates faster. In a bond that is decaying, it decays faster. Trust is a multiplier on an existing sign, not a source of order.**

Interpretive care is required and this paper states it. That trust acts on δ rather than on η is an assumption of the framework's parameterisation, not a finding of this paper, and the literature cited for trust is about reciprocity, monitoring and institutional form rather than about decay rates [Gambetta, 1988, Ostrom, 1990, Axelrod, 1984, Putnam et al., 1993]. **If trust instead raises η, the arithmetic above does not apply**, and which channel it operates through is not settled here.

And nothing in this section says trust is bad. In a relation with a positive numerator it is the single most powerful move available: on the repaired carried dyad, δ from 0.09 to 0.05 takes Q_∞ from $+6.084427$ to $+10.951968$, an 80.0 per cent improvement from one change with no new difference required and no cost cut. **The rule is about sequence, not about worth.** There is also a category of intervention that moves both sides at once — a written record slows the leak *and* converts more of what happens into durable structure — and **interventions touching both sides are the ones to reach for first.**

8.2 The destination is order-independent; the path is not

THEOREM 8.2. The fixed point of the terminal parameter set is independent of the sequence of parameter changes. **The trajectory is not.**

Verified on the constructed carried dyad from $Q_0 = 1.0$, with two orderings of exactly the same pair of interventions, each applied for eight periods before the other:

```
 t      PATH A (decay first)    PATH B (numerator first)
 0        +1.000000                 +1.000000
 1        +0.498925                 +1.457598
 2        +0.022905                 +1.874013
 4        −0.858924                 +2.597783
 8        −2.373029                 +3.693462
12        +0.098675                 +5.039870
20        +3.751671                 +7.029761
32        +7.061215                 +8.832564
inf      +10.951968                +10.951968

B reaches +3.6935 at t = 8;    A reaches it at t = 20     lag 12 periods
B reaches +6.1365 at t = 16;   A reaches it at t = 28     lag 12 periods
cumulative gap over 32 periods:  111.133601 stock-periods
```

Both arrive at exactly the same place. One of them arrives twelve periods later, forever, having spent thirteen periods below where it started. The lag does not shrink. And the interval in which Path A's stock is negative is the interval in which the arrangement may simply not survive to reach its fixed point: the formalism will happily compute a trajectory through negative stock, but the admissibility condition of the storage law fails there [Curzi, 2026]. **This is why order-of-operations is a rule and not a preference.**

The number that will not appear in any of this is a change in the diagnostic. D reads $+4.338420$ at the start of Path A and $+4.338420$ at the end of its first eight periods. **Whatever instrument the parties are using, if it is the deficit alone, it reports that nothing happened.**

8.3 The elasticities

Partial derivatives of D with respect to different parameters are in different units and **cannot be ranked against one another** — comparing them is comparing octaves-per-apple to octaves-per-orange. **Elasticities are dimensionless and are the comparison that exists.**

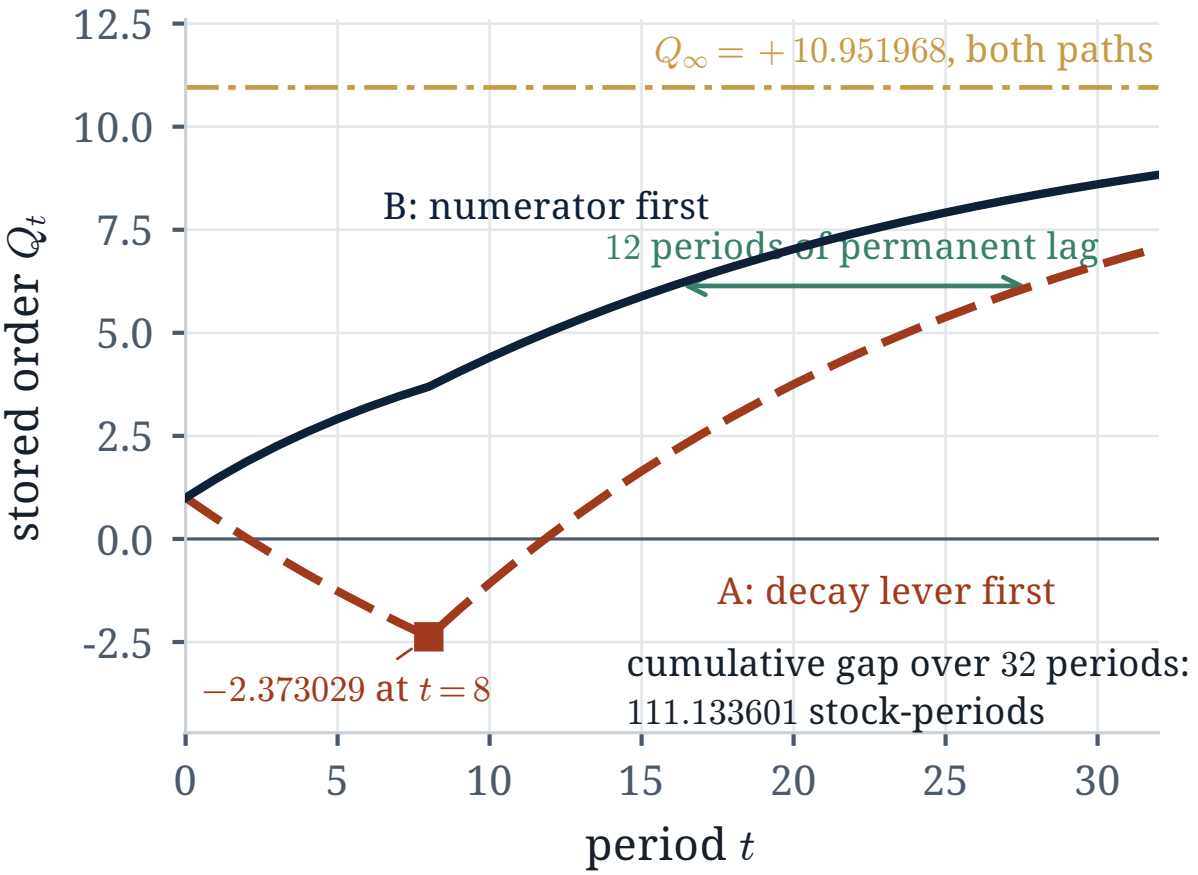

Figure 44.3: **Eight periods of the wrong lever order cost twelve periods of permanent lag**, and the deficit reads unchanged throughout: Path A lowers the decay rate while the numerator is still negative and bottoms at -2.373029, while Path B repairs the numerator first and never falls below its starting value. Both converge to $Q_\infty = +10.951968$; the cumulative gap over 32 periods is 111.133601 stock-periods. Modelled from $Q_{t+1} = (1-\delta)Q_t + n$ on the constructed carried dyad with $n = -0.451075$ before repair and $+0.547598$ after. Built by `figs/src/CCP-044_fig05.py`.

THEOREM 8.3 — THE ELASTICITIES. With $D = 2.885390\,(c/\eta - F)$ and $F = \ln(1 + (N-1)u)$:

$$\frac{dD}{d\ln u} = -2.885390\left(1 - \frac{1}{N_{\text{eff}}}\right), \qquad \frac{dD}{d\ln \eta} = -2.885390\,\frac{c}{\eta}, \qquad \frac{dD}{d\ln c} = +2.885390\,\frac{c}{\eta}$$

Proof: $dD/d\ln x = x\,dD/dx$, applied to the four partials. **QED.**

Three consequences, all exact. **(i) The two cost-side levers have equal and opposite elasticity**, because they enter D only as a ratio; whichever is cheaper to move is strictly the better choice, and the formalism is indifferent between them. **(ii) The cost-side elasticity is exactly the number of octaves the relation requires**, so an e-fold improvement in the cost ratio moves the deficit by precisely the requirement. **(iii) The geometry lever's elasticity is bounded above by 2.885390 octaves per e-fold, at every u, in every system**, because $1 - 1/N_{\text{eff}} < 1$ always, and the bound is approached only as $u \to 1$ where there is nothing left to buy.

COROLLARY 8.3a — THE DYADIC LEVER CRITERION.

$$\left|\frac{dD}{d\ln \eta}\right| > \left|\frac{dD}{d\ln u}\right| \iff \frac{c}{\eta} > 1 - \frac{1}{N_{\text{eff}}}, \qquad \text{and } \frac{c}{\eta} \geq 1 \text{ is SUFFICIENT.}$$

A relation whose cost ratio exceeds one nat is one in which the cost-side levers are proportionally stronger than the geometry lever — always, at every u, with no exceptions. Computed on three constructed cases:

case	c/η	$1 - 1/N_{\text{eff}}$	$\lvert dD/d\ln\eta\rvert$	$\lvert dD/d\ln u\rvert$	ratio
dyad, as found	2.066667	0.430550	5.963140	1.242306	4.8001
dyad, repaired	0.909091	0.883938	2.623082	2.550507	1.0285
commons	2.426471	0.169955	7.001314	0.490387	14.2771

The criterion holds in all three, and in the repaired dyad it holds by 0.025153 nats — barely. That is worth noticing rather than glossing: **a relation that has been tuned well is one in which the levers have equalised, and that is a signature, not a coincidence.**

8.4 The reserves

Elasticity says which lever moves the deficit fastest per proportional unit. **It says nothing about how far each lever can go before it runs out**, and confusing the two is the most expensive planning error available here.

THEOREM 8.4 — THE LEVER RESERVES. The maximum octaves each lever can supply alone, from an operating point (u_0, η_0, c_0, N):

```
R_u    = 2.885390 ( ln N − F(u_0) )                ( u -> 1 )   = the pitch headroom
R_eta  = 2.885390 c_0 ( 1/eta_0 − 1/eta_max )      ( eta -> eta_max )
R_c    = 2.885390 ( c_0 / eta_0 )                  ( c -> 0 )
R_N    unbounded in principle; 2.885390 u / N_eff per category in practice
```

Computed on the carried dyad as found, against its deficit of $+4.338420$:

```
R_u    ( u -> 1 )        5.545206 octaves       CLOSES the deficit
R_c    ( c -> 0 )        5.963140 octaves       CLOSES the deficit
R_eta  ( eta -> 0.50 )   2.385256 octaves       does not
R_eta  ( eta -> 0.75 )   3.577884 octaves       does not
R_eta  ( eta -> 1.00 )   4.174198 octaves       does not -- and eta_max = 1 is generous
```

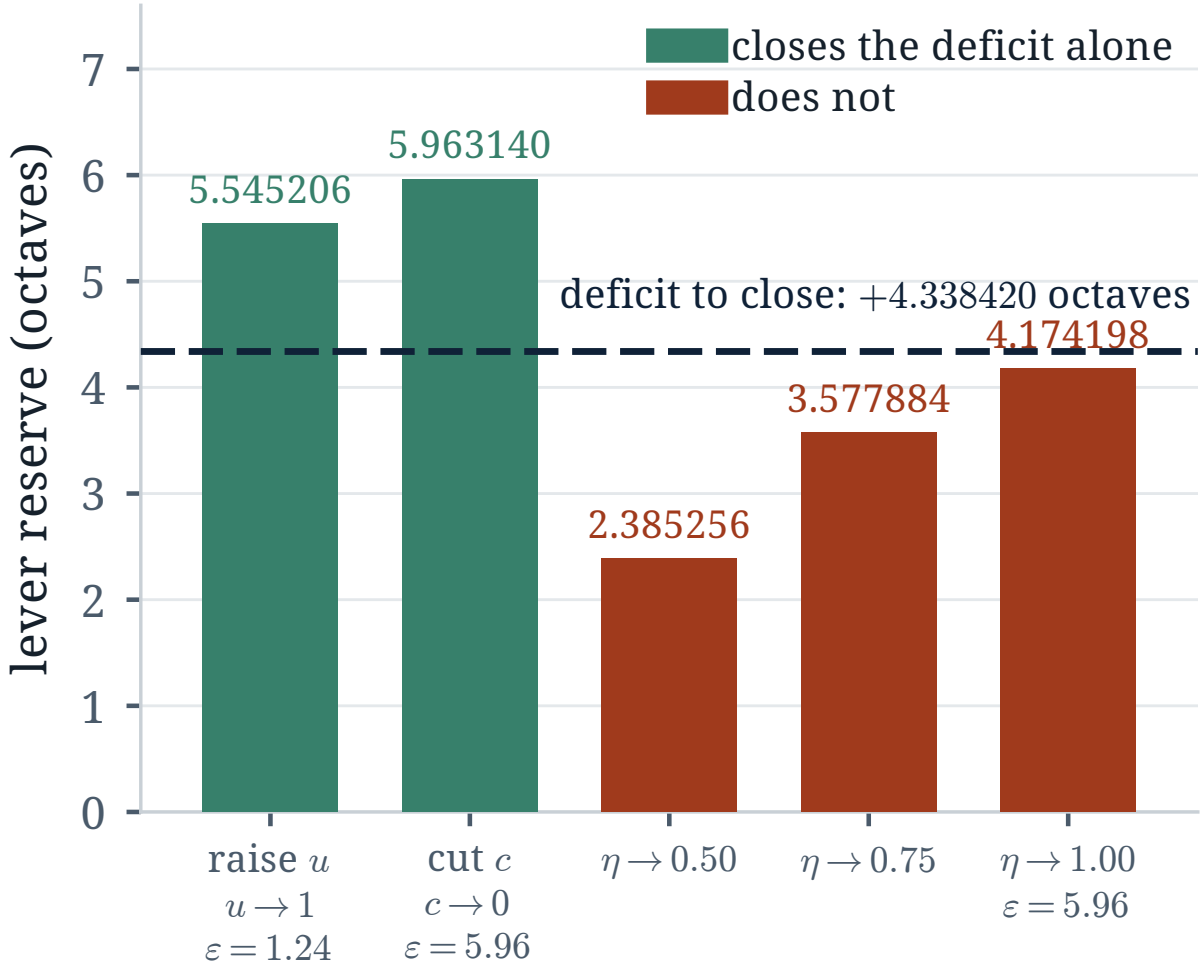

Figure 44.4: **The strongest lever is the one that runs out first**: raising conversion efficiency has 4.80 times the elasticity of the geometry lever and reaches only 4.174198 octaves even at a physically impossible $\eta_{\max} = 1.00$, against a deficit of $+4.338420$ that raising non-parallelism (5.545206) or cutting cost (5.963140) closes. Modelled from the reserve theorem on the constructed carried dyad with $u = 0.068735$, $\eta = 0.30$, $c = 0.62$, $N = 12$; ε is the elasticity $|dD/d\ln x|$ in octaves per e-fold. Built by `figs/src/CCP-044_fig04.py`.

The lever with 4.8 times the elasticity has less reserve than the deficit requires. Raising η from 0.30 all the way to a physically impossible 1.00 — a system converting every unit of interaction into permanent structure, with nothing lost — buys 4.174198 octaves against a requirement of 4.338420 and falls short by 0.164222. The same fact in its other form is $\eta_{\text{req}} = c/F = 1.101077$: **not an expensive lever but an absent one.**

> **THE HONEST DYADIC LAW: the cost-side levers have the higher elasticity and the lower ceiling; the geometry lever has the lower elasticity and the only large reserve. Small deficits are closed on the cost side. Large ones require difference.**

8.5 Combinations, and why the carried case needed two levers

Because $D = 2.885390\,(c/\eta - F)$ is a difference of two independent terms, **any set of parameter moves whose octave contributions sum to the deficit will close it, and there is no interaction term between the geometry side and the cost side.** Combinations can therefore be planned additively — a convenience the formalism rarely offers.

u	η	c	D	Q_∞ at $\delta = 0.09$	verdict
0.068735	0.44	0.40	$+0.998363$	-1.6916	DECAYS
0.300000	0.44	0.62	-0.142896	$+0.2421$	accumulates, barely
0.692373	0.30	0.62	-0.250931	$+0.2899$	accumulates, barely
0.300000	0.44	0.40	-1.585591	$+2.6866$	accumulates
0.400000	0.40	0.50	-1.259181	$+1.9396$	accumulates
0.500000	0.36	0.50	-1.393393	$+1.9317$	accumulates
0.692373	0.44	0.40	-3.590989	$+6.0844$	the repaired case

The first row is the one to sit with. It is the cost-side intervention *on its own* — η up, c down, the geometry untouched — and it leaves the pair at $+0.998363$ octaves, still decaying, with $Q_\infty = -1.6916$. **The entire cost-side intervention applied alone does not save the carried dyad**: it closes 3.340057 of the 4.338420 octaves and stops. The second and third rows are the mirror image: either lever alone, pushed to a plausible limit, clears the threshold by a fifth of an octave, **which is not a margin anyone should plan against.**

The pattern is general enough to state as guidance rather than as a theorem: on a deficit above roughly two octaves, single-lever plans tend to land near the hold line, where the relation pays for itself exactly and banks nothing, and where any increase in cost puts it back under. The corpus's launch-budget work makes the same structural point about barriers [Curzi, 2026p], whose Result One gives departure as feasible only where the fund's fixed point exceeds the barrier, after a computable number of periods.

8.6 The convergence clock

Two parties who spend time together converge. Their representations move toward one another, which is a fall in u, which is a fall in f_{rel}. **Nothing about that is pathological — it is most of what shared time is for — but it runs continuously and it runs against the geometry lever.** Modelling the drift as geometric decay at rate λ per period (M-c) and using the hold line $u^* = (e^{c/\eta} - 1)/(N - 1)$, the crossing time is $t^* = \ln(u^*/u_0)/\ln(1 - \lambda)$. Computed for the repaired dyad, where $u_0 = 0.692373$ and $u^* = 0.134733$:

λ	t^* (periods)	D at $t = 10$	D at $t = 20$	D at $t = 40$
0.01	162.863	-3.3362	-3.0846	-2.5922
0.02	81.020	-3.0821	-2.5872	-1.6483
0.03	53.738	-2.8290	-2.1013	-0.7797
0.05	31.911	-2.3271	-1.1755	$+0.6539$
0.08	19.631	-1.5912	$+0.0527$	$+1.9308$
0.10	15.535	-1.1171	$+0.7320$	$+2.3153$
0.15	10.072	-0.0201	$+1.8767$	$+2.5903$

A repaired dyad has a computable shelf life, and at a 5 per cent per-period convergence rate the carried case's repair is spent in 31.9 periods. The parties do nothing wrong in that interval; they simply agree with each other more each period, and the reading walks back across zero. **Two practical consequences:** a geometry intervention is not a one-off and its decay schedule is estimable from two readings and one logarithm; and **the cost-side levers do not decay this way**, which is the reason that generalises best for reaching for them first.

The honest limit on all of it: λ is a modelling assumption, badged as such, and geometric decay is the simplest form behaving correctly at the boundaries rather than one that has been

fitted to anything. **A pair that measures u twice can estimate λ directly, and should, rather than adopting a figure from this table.**

8.7 Procedure, gates, and reporting

```
STEP 1  DECLARE THE RULE SET, DATED, and which routes will be run.
STEP 2  OBTAIN CONSENT FROM BOTH PARTIES, SEPARATELY, with decline available
        at every step and no reason required.
STEP 3  FIX ONE SITUATION, in one written sentence both parties accept.
STEP 4  SILENT WRITE-FIRST, INDEPENDENTLY AND OUT OF CONTACT.
STEP 5  READ EACH FRAMING against the twelve components; record the LIST.
STEP 6  ELICIT INTENSITIES BY MAGNITUDE ESTIMATION, separately, with the ratio
        question asked in words.
STEP 7  RUN THE OVERLAP GATE. If any pair is disjoint: DEGENERATE, publish nothing.
STEP 8  RECORD BOTH RAW L2 NORMS AND THEIR RATIO, then normalise.
STEP 9  ROUTE A: cos = x . y ; u = 1 - cos^2, carried to 12+ decimal places.
STEP 10 ROUTE B, if an item set exists, AGREED BEFORE JUDGING: u = 4a(1-a);
        report m and the 4/m resolution.
STEP 11 ROUTE C, if ground truth will arrive: u = 1 - rho^2; REPORT THE SIGN OF rho.
STEP 12 RUN THE ACCURACY GUARD on any Route B or C reading.
STEP 13 RUN THE COLLISION TEST: states and distinct pitch classes, separately.
STEP 14 COMPUTE F, N_eff, f_rel, cents above k, folded value and j.
STEP 15 RUN THE CONCORDANCE PASS. Publish every route; DO NOT AVERAGE SILENTLY.
STEP 16 SECOND ANALYST, working from the written framings alone.
STEP 17 CEILING TEST FIRST, then f_min, D, Q_inf, and the sensitivity.
STEP 18 SIGN THE NUMERATOR before choosing any lever.
STEP 19 RESERVE CHECK before committing to a cost-side plan; declare eta_max.
STEP 20 PUBLISH the decomposition, the norms, the routes and the bounds on the
        same page as the frequency. Where they will not fit, the frequency is
        not published either.

G1  OVERLAP.   supports share >= 1 state with weight >= 10% of each party's
               maximum entry.  Otherwise DEGENERATE; no f_rel.
G2  MAGNITUDE. intensities magnitude-estimated with ratios asked explicitly.
               Otherwise publish the ORDER only. NO ORDINAL FALLBACK.
G3  NORMS.     both raw L2 norms and their ratio recorded.
G4  ROUTES.    at least two routes where two are available; concordance reported.
G5  ACCURACY.  Route B or C readings publish both parties' accuracy.
G6  COLLISION. distinct-class count published beside distinct-state count.
G7  CEILING.   before any verdict, c/eta <= ln N checked FIRST.
G8  BRANCH.    no unison reading names a branch unless a signed route was run.
G9  CONSENT.   either party may decline any step at any time; the reading is not
               completed against a party who has declined it.
```

G2 and G9 have no workaround and no partial form. The first is epistemic — without it the number is not determined. **The second is structural — without it the number should not exist.**

> **THE CONCORDANCE RULE.** Report every route run, with its u, its f_{rel} and its resolution limit, and report the spread between extremes in cents. **If the spread exceeds 100 cents, publish the interval and no point value; if it exceeds 600 cents, treat the routes as measuring different things and say which, rather than reconciling them.** The thresholds are house conventions and are stated as such (M-d).

Three failure modes deserve naming because each is the sole defence against a specific error. *Averaging the routes* destroys the information that three numbers carry, and hides the

case the rule exists to catch — **routes that diverge are telling you they are measuring different things, and the divergence is the finding.** *Choosing the route after seeing the numbers* is a search, not a measurement; **the route set is fixed before the data exists or the reading is not a reading**, which is the standard preregistration discipline [Nosek et al., 2018, Simmons et al., 2011] applied to a two-party instrument. And *eliciting the two parties together* measures the elicitation session rather than the pair, because **two people in a room converge before they record.**

9 Worked example: the carried dyad

CONSTRUCTED CASE, labelled as such. These are not two people. Every parameter is chosen, nothing here is an assessment of anyone, and no clinical, therapeutic or counselling claim is made or implied.

9.1 The measurement

```
A = { 4: 0.7,  6: 0.5,  9: 0.4 }          ||A||_2 = 0.9486832980505138
B = { 4: 0.6,  6: 0.55, 9: 0.3,  10: 0.2 } ||B||_2 = 0.8902246907382427
norm ratio = 1.065667
```

Overlap gate. Shared support $\{4, 6, 9\}$ — three of A's three states and three of B's four. The smallest shared weight is B's 0.3 at state 9, which is 50 per cent of B's maximum entry, far above the 10 per cent floor. **PASS.** The two parties hold their states at total intensities within 6.6 per cent of each other, **so nothing in this reading is an artefact of one party reporting larger numbers** — which is exactly the check the magnitude reporting rule exists to make possible.

```
ROUTE A   cos theta = 0.965020899        u = 0.068734665264634
ROUTE B   m = 120, a = 118/120 = 0.983333333333, cos = 0.966666666667
          u = 4a(1−a) = 0.065555555556   resolution 4/m = 0.033333
ROUTE C   m = 24, rho = +0.9650 (SIGN RECORDED)   u = 1 − rho^2 = 0.068775
```

Collision test. Union $\{4, 6, 9, 10\}$, odd parts $1, 3, 9, 5$ — **four states and four distinct pitch classes, no collisions.** The counterfactual B^* of Section 5.1 is identical in u and f_{rel} and carries only three; **this dyad's breadth survives the test and the counterfactual's does not, and no quantity in the geometry distinguishes them.**

```
F     = ln(1 + 11 * 0.068734665264634) = 0.563084802746 nats
N_eff = 1.7560813179
f_rel = 1.4907987150 Hz     folded 381.644 Hz (j = 8)
cents above k = 1949.66     of an available 8603.91
realised pitch fraction = 0.563084802746 / 2.484906649788 = 22.66%
```

Concordance.

```
ROUTE A   u = 0.068734665264634   f = 1.4908 Hz   1949.66 cents
ROUTE B   u = 0.065555555555556   f = 1.4320 Hz   1880.02 cents
ROUTE C   u = 0.068775000000000   f = 1.4916 Hz   1950.54 cents
spread = 70.52 cents           verdict: CONCORDANT (< 100 cents)
```

And the explanation of the spread is more useful than the spread. Route A's cosine implies, through the agreement identity, $a = (1 + \cos\theta)/2 = 0.982510$, or 117.90 items in 120. **The only realisable log is 118, and that 0.10-item rounding is worth 69.64 cents of the observed 70.52.** Nearly the whole discrepancy is the agreement channel's resolution limit, not a disagreement between routes.

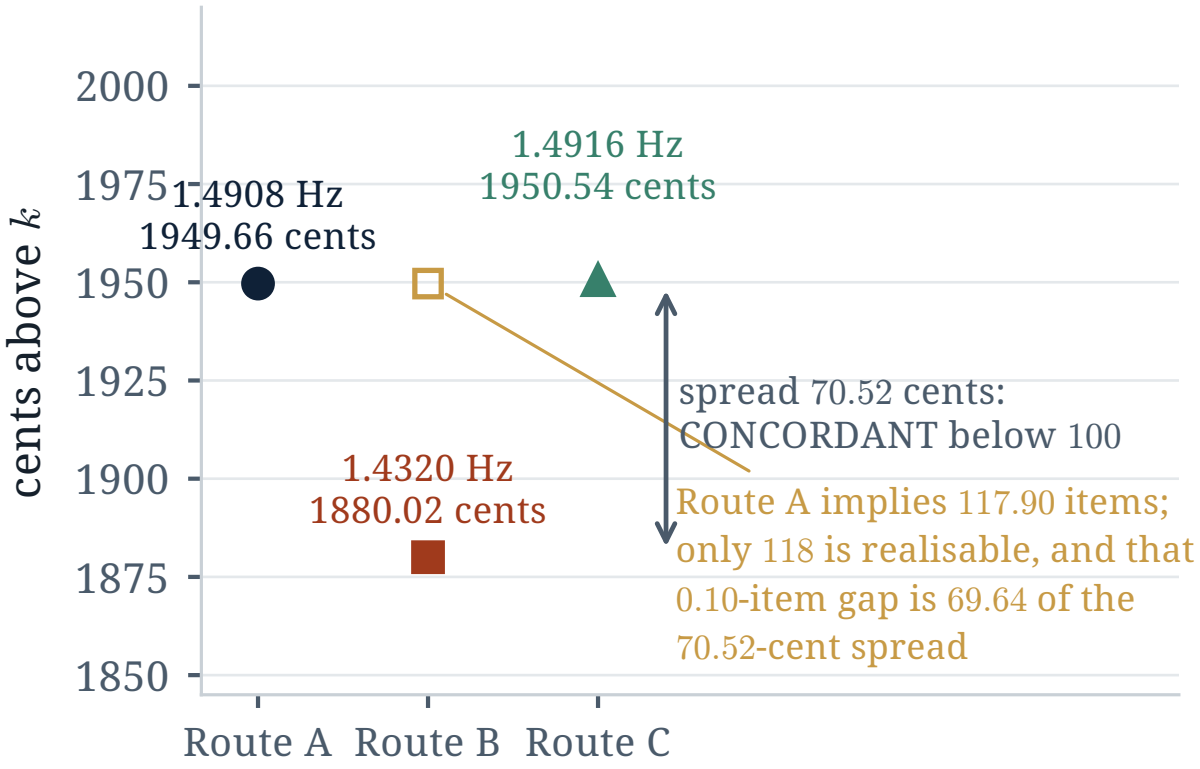

Figure 44.5: **The three routes agree, and the residual disagreement is the coarsest route's own quantisation**: Route A's cosine implies 117.90 matching items in a 120-item log, only 118 is realisable, and that 0.10-item gap accounts for 69.64 of the 70.52-cent spread. Computed from the constructed dyad with the **defined** constant $k = 0.483425732988414$ and $N = 12$; the concordance threshold of 100 cents is a declared convention. Built by `figs/src/CCP-044_fig02.py`.

9.2 The verdict

```
CEILING TEST FIRST:   c/eta = 0.62/0.30 = 2.066666666667
                      ln 12 = 2.484906649788      margin +0.418240 nats
                      2.0667 <= 2.4849   ->  TUNABLE

f_min  = k e^(2 * 2.066667)  =  30.1587698405 Hz   (folded 241.270 Hz, j = 3)
D      = 2.885390081777927 * 2.066667 - log2(1.4907987150/k) = +4.3384201973 octaves
Q_inf  = (0.30 * 0.563084802746 - 0.62) / 0.09  =  -5.0119395464
identity check: -2.885390 * (0.09/0.30) * (-5.0119395464) = +4.338420197298  err 8.88e-16
numerator eta F - c = -0.451074559176            NEGATIVE
VERDICT: DECAYS. Short by 4.3384 octaves = 5206.10 cents.
```

Two readings of the same verdict, both worth stating. The pair fields $N_{\text{eff}} = 1.7561$ distinct perspectives and must field $e^{c/\eta} = 7.8985$ to break even — **they are at 22 per cent of the geometry they need.** And the pair sits 1949.66 cents above the ground essence where 5206.10 cents more is required.

The interpretation the number does NOT license, stated because it is the one a reader reaches for: this pair is not failing at anything, is not incompatible, and is not in difficulty. **The verdict is that at these costs and this geometry, the arrangement does not accumulate order. It is a statement about an arrangement.** Whether the arrangement should change, and whether either party wants it to, are questions the formalism does not touch and this paper does not answer.

The lever audit. Required: $F \geq c/\eta = 2.066667$, i.e. $N_{\text{eff}} \geq 7.898451$.

```
L1  RAISE u    need u >= 0.627132 from 0.068735 -- a factor of 9.1240
               reserve 5.545206 >= 4.338420                          REACHABLE
L2  RAISE eta  need eta >= c/F = 1.101077; reserve to eta = 1.00 is 4.174198
               ABSENT. Not expensive -- absent.
L3  CUT c      need c <= eta F = 0.168925 from 0.62 -- a cut of 72.8%
               reserve 5.963140                                      REACHABLE
L4  RAISE N    need N >= 101.3635 -> 102 categories; a new category buys 0.1129
               octaves at this u                                     NOT REACHABLE
```

The proportionally strongest lever is the one that does not exist, and the lever with the reserve is the slow one. That combination is ordinary, and it is why the ceiling classification matters more than any single sensitivity: the case is TUNABLE, so a combination exists.

9.3 The demonstration

The intuitive repair is to add trust. Assume it succeeds completely and δ falls from 0.09 to 0.05 — a 44.4 per cent reduction in per-period loss, a large and hard-won change.

```
BEFORE   Q_inf = -0.451074559176 / 0.09 =  -5.0119395464
AFTER    Q_inf = -0.451074559176 / 0.05 =  -9.0214911835      WORSE by 80.0%
DEFICIT BEFORE  +4.3384201973
DEFICIT AFTER   +4.3384201973                                  UNCHANGED, every digit
```

A negative number divided by a smaller positive number is more negative. Trust did not add order; it amplified the sign the relation already had, and the sign was negative. The mistake is not naivety: **the intervention was correct about the parameter and wrong about the order, and there is no way to see that from the deficit alone.**

9.4 Three partners, one comparison

CONSTRUCTED. Party A held fixed with $\eta = 0.30$, $c = 0.62$, $\delta = 0.09$, and the costs held constant across all four partners so that the comparison isolates the geometry:

partner	u	f_{rel} (Hz)	D	Q_∞
B, as found	0.068734665264634	1.4908	$+4.3384$	-5.0119
the sycophant, $\rho = +1$	0.000000000000000	0.4834	$+5.9631$	-6.8889
the contrarian, $\rho = -1$	0.000000000000000	0.4834	$+5.9631$	-6.8889
genuinely distinct	0.692372881355932	35.8882	-0.2509	$+0.2899$

Rows two and three are identical in every column, and that is the opposition identity. One partner echoes A on every item; the other inverts A on every item; the relation is at the ground essence either way, short by 5.9631 octaves either way, and arrives at $Q_\infty = -6.8889$ either way.

Both faults are worse than the pair as found. The dyad at $u = 0.068735$ is already decaying, and replacing B with either extreme costs a further 1.6247 octaves of deficit and 1.8770 of Q_∞. **The near-parallel pair the framework calls marginal is better than either perfectly correlated alternative, in either sign.**

And the fourth row is unreachable by opposition, which is the whole argument. The distinct partner gets there by taking on states A does not hold — a change in what that party is doing. **No amount of disagreeing with A about the states they share moves the reading in that direction.**

The comparison above holds c fixed, which flatters the contrarian. Manufactured opposition is not free — the argument takes time, positions must be restated, decisions get relitigated — so c rises:

```
c         c/eta       ceiling verdict     D (at u = 0)     Q_inf
0.62    2.066667      TUNABLE              +5.9631        -6.8889
0.70    2.333333      TUNABLE              +6.7326        -7.7778
0.745472 2.484907     STRUCTURAL           +7.1699        -8.2830
0.90    3.000000      STRUCTURAL           +8.6562       -10.0000
```

The tipping point is exact: $c_{\text{crit}} = \eta \ln N = 0.30 \times 2.484906649788 = 0.745472$. A rise in coordination cost from 0.62 to anything above 0.7455 — a 20 per cent increase — moves this dyad above the ceiling, **at which point no assignment of u is sustainable and the geometry lever is gone entirely.** So manufactured opposition does two separate kinds of damage: it sets the numerator to zero, and it raises the cost ratio until the only lever that could have repaired the numerator is removed. **The second harm is worse than the first and it is invisible to anyone who computes a deficit without running the ceiling test.**

9.5 The seventh seat

CONSTRUCTED extension. A commons of six members drawn from one doctrine: fifteen pairwise links at $\kappa = 0.055$ each, $\eta = 0.34$, $\delta = 0.09$, mean pairwise $u = 0.018614$.

```
THE COMMONS AS FOUND
15 pairs, mean u = 0.018614       F = 0.186275 nats
f_rel = 0.7017 Hz    644.97 cents above k    realised fraction 7.50%
C = 0.055 x 15 = 0.8250    c/eta = 2.426471
f_min = 61.9349 Hz   D = +6.4638 octaves   Q_inf = -8.4630    DECAYS
```

```
THE PARALLEL WALL, PRICED PER LINK
paid        C = 0.8250 across 15 links        delivered  644.97 cents of pitch
yield       43.00 cents per link
ceiling for 15 links at u = 1   8603.91 cents = 573.59 cents per link
realisation                     644.97 / 8603.91 = 7.50%
```

The commons is paying for fifteen links and collecting 7.50 **per cent of what fifteen links could deliver.** The other 92.50 per cent is not lost to inefficiency or bad management. **It is not there. Nobody holds it.**

configuration	links	C	c/η	ceiling	mean u	f (Hz)	D	Q_∞
six, as found	15	0.8250	2.4265	TUNABLE	0.018614	0.7017	$+6.4638$	-8.4630
+ contrarian	21	1.1550	3.3971	STRUCTURAL	0.013296	0.6352	$+9.4080$	-12.3177
+ sycophant	21	1.1550	3.3971	STRUCTURAL	0.013296	0.6352	$+9.4080$	-12.3177
+ distinct, $u = 0.80$	21	1.1550	3.3971	STRUCTURAL	0.241867	6.4777	$+6.0577$	-7.9313
+ independent, $u = 1$	21	1.1550	3.3971	STRUCTURAL	0.299010	8.8933	$+5.6005$	-7.3326

Every row that adds a seat is structural, whoever fills it. That is the finding, and it is not about the contrarian at all — it is about the per-link cost. Twenty-one links at 0.055 give $C = 1.1550$ and $c/\eta = 3.3971$, which exceeds $\ln 12 = 2.484907$; **the maximum** κ **at which a seventh seat stays under the ceiling is** 0.040232**, so the seat is affordable only alongside a** 26.9 **per cent cut in per-link cost.**

Within that finding the contrarian is still the worst available choice: against the six-member base, the contrarian and the sycophant each contribute -172.35 cents, the genuinely distinct candidate $+3847.96$, and the perfectly independent candidate $+4396.66$ — **three candidates at the same price and a spread of** 4569.01 **cents between worst and best, three and three-quarter octaves for the same money.**

And a geometry improvement computed above the ceiling is arithmetically correct and practically void. The distinct candidate improves D by 0.4061 octaves on a case the cost ratio has already placed beyond repair. **Seeing that happen to the *good* candidate is more instructive than seeing it happen to the bad one.** The corpus's pricing work reaches the same discipline from the other side [Curzi, 2026], whose Result One prices an uncertain position as $E[\Delta h] = 0.0318401p - 0.0051096$ with a break-even probability of 16.05 per cent, and [Curzi, 2026], whose Result One shows a 25.17 per cent local-currency allocation cancelling an entire $\eta \ln N = 0.377583$ diversification gain. **In each case the cost side removes the benefit the geometry was proposed to supply.**

9.6 The repair, correctly ordered

CONSTRUCTED. Two changes, made together, both on the numerator: one party takes on two states the other does not hold — **a change in what that party is actually doing, not a rhetorical adoption of a contrary position, which the opposition identity forbids from working** — and the pair adopt a decision log, which raises η and lowers c.

```
B' = {2: 0.95, 4: 0.60, 6: 0.55, 9: 0.30, 10: 0.20, 12: 0.8391}
     raw L2 norm 1.548899

u     0.068734665264634  ->  0.692372881355932
eta   0.30 -> 0.44        c  0.62 -> 0.40        delta 0.09 (deliberately unchanged)

F                 = 2.153632742815 nats     N_eff = 8.6161016949
f_rel             = 35.8881768941 Hz        folded 287.106 Hz (j = 3)
octaves present   =  6.2140705559
```

```
c/eta             = 0.909090909091          ceiling margin +1.575816 nats
f_min             =  2.9782153324 Hz        octaves required 2.6230818925
OCTAVE DEFICIT    = -3.5909886634           numerator eta F - c = +0.547598406839
Q_inf (delta 0.09)= +6.0844267427
identity check    : -2.885390 * (0.09/0.44) * 6.0844267427 = -3.590988663387
VERDICT: ACCUMULATES
```

A discrepancy in the source, printed rather than silently corrected. The realising vector B', recomputed, gives $\cos\theta = 0.5546425597$ and $u = 0.6923716310$, against the declared $u = 0.692372881356$ whose implied cosine is 0.5546414325. **The vector realises the declared u only to six decimal places**, and the frequency differs by 0.0055 cents — far below any reading's resolution, but a reader recomputing from the printed vector will find it. This paper quotes the declared value, which is the one every other paper in the series carries.

Now trust helps. Repeating the identical intervention that made things worse before:

```
delta 0.09 -> 0.05
Q_inf   +6.0844267427  ->  +10.9519681368            BETTER by 80.0%
deficit -3.5909886634  ->   -3.5909886634            unchanged, as always
```

The same lever, the same magnitude, the same direction, the same two parties, and the opposite result — because the numerator changed sign in between.

The honest note on where the repair leaves them. Pitch headroom falls from 5.5452 octaves to 0.955854. **The repair worked by spending most of the range that twelve categories make available**, and the next order of gain is not available from u at this N; it would require genuinely new categories rather than finer slicing of what is there. **That is not a defect in the repair. It is the ceiling doing what a ceiling does, and the value of the reading is that the parties can see it coming rather than meeting it as an unexplained plateau.**

10 Results

The eight results below are the units other papers in this corpus cite. A citation to this paper should name one of them. Each carries its status: **DERIVED** where it follows from the stated definitions by algebra, **COMPUTED** where it is the output of exact arithmetic on stated parameters, and **POSTULATED** where it is asserted by this framework.

R1 — the opposition identity. $u = 1 - \rho^2$ depends only on $|\rho|$, so $\rho = +1$ and $\rho = -1$ both give $u = 0$, $F = 0$, $N_{\text{eff}} = 1$ and $f_{\text{rel}} = k = 0.4834$ Hz — the same folded note at $j = 9$, in the same pitch class. *Status:* DERIVED (Theorem 6.2). **Every quantity computed downstream of u inherits the evenness, so no care with the frequency recovers the sign.**

R2 — the agreement identity. For m binary judgments with agreement fraction a, $\cos\theta = 2a - 1$ and $u = 4a(1 - a)$, exact and requiring no centring, symmetric about $a = 0.5$ with resolution bounded by $4/m$. *Status:* DERIVED (Theorem 4.1); the resolution table COMPUTED. **In a 120-item log one disputed item is worth 643 cents.**

R3 — the three-route concordance. On the constructed carried dyad, $u = 0.068735/0.065556/0.068775$ and $f_{\text{rel}} = 1.4908/1.4320/1.4916$ Hz, a spread of 70.52 cents against a declared 100-cent threshold: CONCORDANT. **Of that spread, 69.64 cents is the agreement channel's own quantisation** — a better explanation than any story about the parties. *Status:* COMPUTED.

R4 — the unison fixed point. At $u = 0$, $Q_\infty = -c/\delta$, in which η and N do not appear and **two of the four levers have partial derivative exactly zero.** *Status:* DERIVED (Theorem 6.3); verified COMPUTED across a grid spanning a twentyfold range in η and a fiftyfold range in N.

R5 — the elasticities. $dD/d\ln\eta = -2.885390\,(c/\eta)$ and $dD/d\ln u = -2.885390\,(1-1/N_{\text{eff}})$, so the geometry lever is bounded above by 2.885390 octaves per e-fold in every system, and **cost-side levers dominate whenever** $c/\eta \geq 1$ (Corollary 8.3a). *Status:* DERIVED.

R6 — the lever reserves. On the carried dyad, $R_u = 5.545206$ and $R_c = 5.963140$ octaves each close the $+4.338420$ deficit; R_η at a physically impossible $\eta_{\max} = 1.00$ supplies only 4.174198 and **cannot**, falling short by 0.164222. *Status:* DERIVED (Theorem 8.4); COMPUTED on a constructed case. **The lever with 4.80 times the elasticity has less reserve than the deficit requires.**

R7 — the damage integral. Eight periods of the wrong lever order cost twelve periods of permanent lag, a minimum stock of -2.373029 from a starting $+1.000000$, thirteen periods below the starting value, and 111.133601 stock-periods of cumulative gap — **with the deficit reading $+4.338420$ throughout.** *Status:* COMPUTED; the order-independence of the destination and the order-dependence of the path DERIVED (Theorem 8.2).

R8 — blindness to collision. u is blind to pitch-class collision, exhibited by two dyads with identical u and f_{rel} to fifteen decimal places and four versus three distinct pitch classes. *Status:* DERIVED and COMPUTED (Theorem 5.1).

CR — counter-result. Perfect opposition and perfect agreement are the same reading, so the standard remedy of adding a contrarian contributes zero surplus while adding cost; **and at $u = 0$ two of the four levers are exactly inert.** To these the framework adds four of its own: the constant k is chosen; the affine effective count is not a Hill number; the interpretation of k as a frequency is postulated; **and the framework's own native encoding cannot see the opposition branch at all**, so the sharpest result in this paper is invisible to the instrument the corpus uses by default. The corpus's uncertainty node models the required discipline [Curzi, 2026], whose counter-result requires a user to be able to distinguish the theorem, the ordinary observer effect and the framework's own conjecture in three separate sentences on demand.

11 Discussion

11.1 What follows

The received wisdom names a real target and points at the wrong coordinate. "Creative tension", "healthy disagreement" and "we need someone to push back" are among the most durable pieces of advice about how two or more people should work, and **the target they name is independence.** Opposition is independence's mirror image, sitting exactly as far from it as agreement does. **The job of the arithmetic is not to be contrarian about contrarians; it is to say which implementations hit the target.**

The two faults read the same and are not the same, and the distinction decides the remedy.

```
THE PARALLEL WALL          seats already filled, near-parallel views.
                           eta*F = 0.063334, C = 0.8250, net = -0.761666
                           THE WASTE IS SUNK.  Remedy: substitution.

MANUFACTURED OPPOSITION    a NEW seat, at a NEW cost, returning nothing.
                           eta*F = 0.046409, C = 1.1550, net = -1.108591
                           THE WASTE IS INCURRED, and it is ongoing.
                           Remedy: refusal.
```

A report that says only "low u" has told the reader nothing about which of the two decisions is in front of them.

And the reserve result generalises past this framework. The structure is that *the fastest lever per proportional unit and the lever with the most room are frequently different levers*, and any model in which one parameter enters a ratio and another enters a bounded logarithm will have the property. **A plan built on the strongest lever that requires more of it than exists is not an expensive plan; it is not a plan.**

11.2 What does not follow

A high reading is not good news by itself. It may be a wide pair; it may equally be disjoint support, two parties answering at random, or an encoding in which each framing was reduced to its single most characteristic state. **Near the top of the range the first hypothesis to test is that the encoding failed**, because that is the more common cause and it is the one that flatters.

A unison reading is not a judgment. It says that at these costs the arrangement accumulates no order. **It does not say the two parties have no relationship, that their relationship is poor, or that anything about it should change.** Two people in unison may be exactly as they wish to be, and the formalism has no view.

"Sycophant" and "contrarian" name coordinates, not people. A party sits at a correlation with respect to a specific counterparty on a specific item set, and moves when either changes. **Transferring the label from the coordinate to the person converts an instrument into an insult**, and the resulting number is no longer about anything measurable.

Nothing here says conflict is good or that a relation should be made harder. The quantity being maximised is represented non-parallelism, and **independence — not friction — is the coordinate that maximises it.** Two parties who work on different things, calmly, are at high u. Two parties who fight about one thing are not.

A DECAYS verdict is not robust in the way an ACCUMULATES verdict is. F is a lower bound on the pair's information, so f_{rel} is a lower bound on the pitch: **a verdict of ACCUMULATES survives the possibility that the representation missed something; a verdict of DECAYS does not, because the missing something could have supplied the surplus.**

11.3 The reflexive exposure, and the programme

An instrument that issues a verdict on a relation may change the relation by issuing it. The mechanism is documented [Merton, 1948, Rosenthal and Jacobson, 1968] and has been observed in the field [MacKenzie and Millo, 2003], but the effect sizes are contested [McCambridge et al., 2014] and on the best long-run assessment **self-fulfilling prophecies are real but small, do not typically accumulate, and often dissipate** [Jussim and Harber, 2005]. **The correct response is not to suppress the reading but to publish the parameters that produced it**, which is also why any indicator adopted as a target degrades as an indicator [Campbell, 1979, Goodhart, 1975].

The elicitation has a self-concealing failure of its own. An elicitation run by an analyst who has views produces vectors that drift toward those views, and at dyad scope that lowers u and produces exactly the unison reading the analyst will then interpret as a finding about the pair. **A single analyst cannot detect their own convergence pressure, because the artefact and the finding have the same shape.** The mirror failure is symmetric: an analyst who wants a *high* reading can lead the elicitation toward difference and will succeed. **Neither direction is detectable from inside a single pass**, which is why the second analyst is a numbered step and not a recommendation.

The wider programme begins with *physique sociale* [Quetelet, 1835] and continues through the modern computational literature [Castellano et al., 2009, Lazer et al., 2009]. **Its characteristic error is Quetelet's** — treating a summary statistic as a type — and this paper's version of it is the mean pairwise u: a scalar summary of pairwise angles does not determine a joint arrangement, and the corpus's roster paper makes that failure visible [Curzi, 2026], whose Result Seven records a constructed team in which **every one of five drop-one removals improves the reading**, so a favourable row carries no information about the member it names. Three further constraints bear and are not comfortable. Human activity is bursty with **no characteristic time scale** [Barabási, 2005], which a convergence clock must meet by declaring its period rather than discovering it. An explanation is supposed to name a mechanism rather than exhibit a fitted curve [Hedström and Ylikoski, 2010]; **this paper fits nothing, which sidesteps the objection at the cost of having no empirical content to fit.** And **what observation would distinguish this model from a neighbouring one that fits equally well?** [Sobkowicz,

2020, Durlauf, 2005] The honest answer is H3 and H4, and neither has been tested. **What the paper is entitled to claim is analytical rather than predictive** [Epstein, 2008, Keuschnigg et al., 2018], and making point predictions with constants rather than directional ones is the right response to the directional-prediction critique [Meehl, 1990].

12 Verification

Every step below can be checked on its own. The standard is Occam's: **a postulate that can be dropped without the result changing has been dropped.** Statuses: **ARITHMETIC** (a reader can redo it), **DEFINITION** (true by stipulation), **CITED** (an external source supports it — the key is named), **POSTULATED** (asserted by this framework, no external support).

12.1 The postulates

	postulate	status
P1	The Pythagorean whole tone is the ratio $9{:}8$.	CITED [Barbour, 1951]
P2	φ is the positive root of $x^2 = x + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P3	A dimensionless ratio of the form $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source
P4	An effective count N_{eff} has essence frequency $k\,N_{\text{eff}}^2$.	POSTULATED — no source
P5	$N_{\text{eff}} = 1 + (N-1)u$ (the affine count axiom).	POSTULATED — design axiom [Curzi, 2026]; **not a Hill number**
P6	$u := 1 - (x \cdot y)^2$ on unit vectors.	DEFINITION
P7	A party's construal admits representation as a **non-negative** unit vector.	POSTULATED — and Section 6.5 states what it cannot represent
P8	Stored order obeys $Q_{t+1} = (1-\delta)Q_t + \eta F - c$ with $\delta > 0$.	CITED as a form [Oppenheim et al., 1996, Elaydi, 2005]; the *interpretation* POSTULATED
P9	Elicited intensities carry ratio information up to a free common multiplier.	**ASSUMED**; the method CITED [Stevens, 1957], not tested here
P10	c is expressed in nats of surplus per declared period, so c/η is dimensionless.	**CONVENTION — stated here, absent from the source**

Dropped as unnecessary. P3 and P4 are not needed for R1, R2, R4, R5, R6 or R8. Every one of those is a statement about u, about ρ, about a ratio of logarithms in which k cancels, or about a difference equation; the frequency interpretation adds hertz values and nothing else. No postulate about consonance, about octave folding or about rendering is needed anywhere in this paper. **P9 is needed only where a number is claimed; the *ordering* of readings survives without it, and Section 4.3 says exactly how much is lost.**

12.2 The compounding chain

step	consumes	produces	status
L1	P1, P2	$k = (9/8)^2/\varphi^2 = 0.483425732988414$	ARITHMETIC (exact)
L2	L1, **P3, P4**	$f_{\text{rel}} = k\,N_{\text{eff}}^2$ in Hz	**POSTULATED**
L3	P5, P6	$F = \ln(1+(N-1)u)$, $F \le \ln N$	DEFINITION
L4	P6	$u = 1-\rho^2$ is EVEN in ρ — **R1**	ARITHMETIC
L5	L4	$u(\pm 1) = 0$, $F = 0$, $N_{\text{eff}} = 1$, $f_{\text{rel}} = k$ — **R1**	ARITHMETIC
L6	P6, ± 1 judgment vectors	$\cos\theta = 2a-1$, $u = 4a(1-a)$ — **R2**	ARITHMETIC
L7	L6, quantisation of a at $1/m$	resolution $\approx 4/m$; 643 cents per item at $m = 120$ — **R2**	ARITHMETIC
L8	L2, L6, constructed data	three routes at 70.52 cents spread — **R3**	ARITHMETIC
L9	L8, L7	69.64 of the 70.52 cents is quantisation — **R3**	ARITHMETIC
L10	P8, L5	$Q_\infty = -c/\delta$ at $u = 0$; η, N absent — **R4**	ARITHMETIC
L11	L10 differentiated	$\partial Q_\infty/\partial\eta = \partial Q_\infty/\partial N = 0$ — **R4**	ARITHMETIC
L12	L2, L3, Def. 3, **P10**	$D = 2.885390\,(c/\eta - F)$	ARITHMETIC given P10
L13	L12	the three elasticities; $1 - 1/N_{\text{eff}} < 1$ — **R5**	ARITHMETIC
L14	L13	$c/\eta \ge 1$ suffices for cost-side dominance — **R5**	ARITHMETIC
L15	L12, limits $u \to 1$, $c \to 0$, $\eta \to \eta_{\max}$	R_u, R_c, R_η — **R6**	ARITHMETIC
L16	L15, constructed parameters	5.545206, 5.963140, 4.174198 vs $+4.338420$ — **R6**	ARITHMETIC
L17	P8	$dQ_\infty/d\delta = -n/\delta^2$: decay amplifies the sign	ARITHMETIC
L18	L17, two orderings	12-period lag, 111.133601 stock-periods — **R7**	ARITHMETIC
L19	P6, two constructed partners	identical u to 10^{-15}, 4 vs 3 pitch classes — **R8**	ARITHMETIC

12.3 What this chain is and is not

Read the status column. Steps L1 and L3 through L19 are arithmetic or definition and a reader can redo every one of them. **Step L2 is postulated, and L12 rests additionally on a convention**

(P10) that the source never states. A chain containing postulated steps is not a proof of its conclusion, and this one is not offered as one.

What it is offered as is a separation, and here the separation is unusually favourable. The paper's sharpest results — R1, R2, R4, R5, R6, R7 and R8 — do not consume P3 or P4 at all. They are statements about an even function, about ± 1 vectors, about a difference equation and about logarithmic derivatives. **A reader who rejects the frequency interpretation entirely keeps every one of them, restated in nats instead of octaves.** What such a reader loses is the hertz values, which is precisely what the postulates were asked to supply.

Two statuses that must not be misread. The exponent 2 at L2 is **DEFINED**, not estimated: no fit was performed and the standard procedure for testing a scaling claim [Clauset et al., 2009] was not run. The logarithm at L3 is **DEFINITION** given the affine axiom P5, and the warrant the argument needs is the multiplicative-dynamics one [Peters and Gell-Mann, 2016] rather than the psychophysical one; the psychophysical warrant is consumed only at P9, for the elicitation.

The falsifiable content lives in H1 through H4, not at L2. This paper's empirical exposure is therefore smaller than its notation suggests, and printing the status of each postulate is the honest description of what a badged postulate does in a research programme [Lakatos, 1970, Platt, 1964, Popper, 1959].

13 Limitations

Every check the governing rigour standard specifies is listed here by name, whether or not this paper passes it.

L-1. The dimensional audit does not close. $f_{\text{rel}} = k\,N_{\text{eff}}^2$ balances only if k carries $[T^{-1}]$, and k is computed as a ratio of two dimensionless quantities. **No operational procedure is supplied by which the constant acquires the dimension of frequency.** It touches only the absolute values; every result in Sections 5, 6 and 8 survives without it.

L-2. The exponent of the threshold is dimensionless only by an unstated convention. c/η carries $[\mathcal{C}T^{-1}]$ divided by a pure number and cannot be an exponent without a convention; **the source never states the convention.** It is stated here (P10), and the measured failure mode is a $90.1\times$ period-normalisation error.

L-3. The constant is chosen, quoted to fifteen figures **because it is defined**, not because anything was measured to that precision [Markowsky, 1992, Fischler, 1981].

L-4. The exponent is defined, not estimated. No fit was performed, no alternative was tested, and the standard scaling procedure [Clauset et al., 2009] was not run because there is no data to run it on. **This paper makes no empirical scaling claim.**

L-5. $N_{\text{eff}} = 1 + (N-1)u$ **is not a Hill number.** It is a linear interpolation between 1 and N and appears in no ecological, economic, political-science or information-theoretic literature; the Hill-number citations apply to $1/\text{HHI}$ and $\exp(H)$ and to nothing else [Hill, 1973, Laakso and Taagepera, 1979].

L-6. Octave reduction beyond pitch is unwarranted [Shepard, 1982]. The operation is well defined; its interpretation is not supported.

L-7. Conjoint measurement was not tested, so the ratio-scale treatment of the intensities, of η, of c and of δ is provisional. Michell's objection [Michell, 1997] stands unanswered for every quantity here except the counts, and the available remedies [Luce and Tukey, 1964, Rasch, 1960] were not run. **Section 4.3 prices the failure at** 1065.05 **cents, which is more than three quarters of an octave.**

L-8. The framework's own encoding cannot see the paper's sharpest result. Route A is non-negative by construction, so the opposition branch is invisible to it. **A limitation stated as one**, and the signed routes are the only place the branch can be measured — which means every reading taken with Route A alone is silent about which of two opposite remedies applies.

L-9. Surplus is not correctness. Two parties answering at random score the ceiling. **The formalism cannot distinguish independence from noise, because both are orthogonality**, and

there is no formalism here that converts distinctness into correctness. The accuracy guard is procedural, not formal, and **no procedural gate defends against an analyst who wants a particular answer**; what the gates do is stop an honest analyst producing a degenerate answer by accident, and make a dishonest one leave a trace.

L-10. Route B's resolution is coarse and its readings are intervals. At $m = 120$, one disputed item is worth 643 cents; **a reading of $u = 0.0656$ from such a log has reported four significant figures of a quantity the log resolves to one.**

L-11. Route C requires ground truth, which is unavailable for most of what two people disagree about, and its sign is discarded by u. **Two parties at $\rho = +0.9650$ and two at $\rho = -0.9650$ produce identical readings and require opposite interventions.**

L-12. Mean pairwise u does not determine the joint geometry. The triangle inequality fails for geometric triples, so N_{eff} is an audited count under a stated postulate and **not a measured dimension.**

L-13. The trust mechanism is an assumption, not a finding. The order-of-operations result depends on trust acting through δ rather than η; the literature cited for trust [Gambetta, 1988, Ostrom, 1990] is about reciprocity, monitoring and institutional form, not decay rates. **Which channel it operates through is not settled here.**

L-14. The convergence rate is a modelling assumption. Geometric decay of u is the simplest form behaving correctly at the boundaries and **has been fitted to nothing.**

L-15. Two thresholds are conventions with no derivation — the 100-cent concordance threshold and the 10 per cent overlap-weight floor. **What is not optional is declaring one before seeing the result.**

L-16. A unison has three possible causes and only two are branches. Genuine parallelism, genuine inversion, and **a failed elicitation, which produces exactly the same number.** A unison is the signature of both parties elicited in one session after discussion, and **publishing a unison without excluding the artefact is the most consequential error available in this paper.**

L-17. Every case is constructed. The dyad, its three alternative partners and the commons are chosen parameter sets. **Their precision is exact because the parameters are exact; that precision does not transfer to a measured case.**

L-18. No model comparison, no statistical claim. Nothing was fitted, so there is no out-of-sample test, no matched null with the same number of free parameters, no information criterion, no p-value, no effect size and no interval. **The corpus's one confirmatory attempt failed its own baseline test** [Curzi, 2026i], which is the relevant precedent for how any fit here should be reported.

L-19. The functional form is underdetermined [Latané, 1981, Briscoe et al., 2006, Stumpf and Porter, 2012].

L-20. The reflexive specification is not identified [Manski, 1993, Shalizi and Thomas, 2011]; the remedy adopted is stipulation of the rule set [Brock and Durlauf, 2001], and the claim is **a modelling position rather than an identified empirical result.** The framework also exempts its own parameters from its own reflexivity [Lucas, 1976, Hacking, 1995], which is **not resolved.**

L-21. There is no conservation law [Mirowski, 1989], validity is claimed only within a specified arrangement [Cartwright, 1999], and **ergodicity is assumed and not argued** [Peters, 2019].

L-22. u is symmetric and psychological similarity is not [Tversky, 1977]; this framework's u assumes metric behaviour.

L-23. Boundary behaviour. $u \to 0$ collapses the reading to k and kills two of four levers; $u \to 1$ gives the ceiling; $\delta \to 0^+$ removes the fixed point altogether — **a pathology, not an ideal, since nothing decays out of the stock**; $\delta \to 1$ makes the store memoryless; $\eta \to 0^+$ makes c/η diverge and **places every relation above every ceiling**, which is a real constraint on the model's domain and is **not examined in the source**; $m \to \infty$ makes Route B exact but is unavailable at any plausible cost; and $N \to \infty$ raises the ceiling without bound, which the coordination-cost literature says is not available in practice [Brooks, 1975, Conway, 1968].

L-24. Discrepancies in the source, printed rather than silently corrected. The realising vector for the repaired dyad gives $u = 0.6923716310$ against the declared 0.692372881356 — agreement to six decimal places, a difference worth 0.0055 cents. The cost-side-only combination computes to $D = +0.998363$ from the full-precision u against the source's printed $+0.998357$ from the rounded one. **Neither is an error in a theorem; both are roundings, and both will be found by any reader who recomputes.**

L-25. A published reading can change what it reads, and the elicitation's convergence pressure is **not detectable from inside a single pass**, in either direction.

14 Conclusion

What is established, and it is arithmetic. The surplus functional depends on the correlation only through its absolute value, so **perfect opposition and perfect agreement are the same reading**: $\rho = +1$ and $\rho = -1$ each give $u = 0$, $F = 0$, $N_{\text{eff}} = 1$ and $f_{\text{rel}} = k = 0.4834$ Hz, folded to the same 247.514 Hz at $j = 9$ in the same pitch class. The agreement channel exhibits the same fact directly through the exact identity $\cos\theta = 2a-1$, $u = 4a(1-a)$, a perfect mirror about $a = 0.5$ whose resolution is bounded by $4/m$ — 643 cents per disputed item in a 120-item log. **At $u = 0$ the fixed point collapses to $-c/\delta$, in which conversion efficiency and category count do not appear and two of the four levers have derivative exactly zero.** Three routes on a constructed dyad return $u = 0.068735$, 0.065556 and 0.068775 for a spread of 70.52 cents, of which 69.64 is the agreement channel's own quantisation. And u is blind to pitch-class collision: two dyads agree to fifteen decimal places while occupying four and three classes respectively.

What is established about levers. Elasticities are dimensionless and therefore comparable, and the geometry lever is bounded above by 2.885390 octaves per e-fold in every system, so **cost-side levers dominate proportionally whenever $c/\eta \geq 1$.** But **the strongest lever is the one that runs out first**: on the carried dyad, raising conversion efficiency to a physically impossible 1.00 buys 4.174198 octaves against a requirement of 4.338420, while raising non-parallelism buys 5.545206 and cutting cost buys 5.963140. And because the decay rate divides the numerator, **an intervention on it multiplies whatever sign the arrangement already has**: eight periods of the wrong order cost twelve periods of permanent lag, a minimum stock of -2.373029 from $+1.000000$, and 111.133601 stock-periods of cumulative gap — **while the deficit reads $+4.338420$ throughout.**

What is proposed rather than shown. That a dimensionless ratio of a tuning interval to the square of the golden section is a frequency; that an effective count has essence frequency $k\,N_{\text{eff}}^2$; that the effective count is affine in the non-parallelism; that a construal admits representation as a non-negative unit vector; and that cost is measured in nats of surplus per declared period. **The first four are postulates of this framework with no external support, the fifth is a convention the source never states, and all five are separable from the results above:** a reader who rejects every one of them keeps the opposition identity, the agreement identity, the unison fixed point, the elasticities, the reserves, the damage integral and the collision blindness, restated in nats and in stock units.

What is conceded. The framework's own native encoding **cannot see the opposition branch at all**, so the paper's sharpest result is invisible to the instrument the corpus uses by default. The surplus formalism **cannot distinguish independence from noise**, because both are orthogonality. And a unison reading is produced as readily by a failed elicitation as by a parallel pair.

What is not claimed at all. No pair of people is claimed to resonate at any frequency named here. The twelve states are not diagnoses. **Nothing in this paper is counselling, therapy, mediation, or a clinical assessment of any person, pair or group**, and where a relationship is causing a person difficulty, the resource is a qualified professional, which this work is not.

15 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number in the paper is the output of exact arithmetic on parameters stated in the text; every case is constructed and is labelled as constructed at the point of use. The figures are generated by the Python scripts named in their captions, which take their inputs from the tables in the text and are available from the author on request. **No empirical measurement of any human being, any pair or any group underlies any figure, table or number in this paper.**

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The carried dyad, its alternative partners and the commons are invented parameter sets and are not derived from, and do not describe, any person. **The procedure this paper specifies would, if run, constitute human-subjects research**, and the specification therefore builds consent into its numbered steps rather than appending it as advice: both parties consent separately, either may decline any step at any time without giving a reason, no reading is completed against a party who has declined it, and **no intervention derived from a reading may remove a person's ability to decline.** That last clause has a literal application here: **requiring a person to hold or argue a position they do not hold is exactly such a removal**, and it is also, by Section 6.8's arithmetic, worthless. Nothing is masked, nothing is concealed, and nothing sits below either party's awareness. This paper also asserts perceptual and psychometric claims — that magnitude estimation delivers ratio-scale intensities and that interval arithmetic in cents is the correct apparatus — **without any experiment behind them**; those claims rest on the cited literature and are listed among the limitations (L-7).

Preregistration. No test reported in this paper was preregistered, because no test was run. The route set, the thresholds and the gates are specified as things to be declared before data exists, which is the same discipline [Nosek et al., 2018]; the corpus's one confirmatory fit was preregistered and **failed its own second falsification rule** [Curzi, 2026i], and that outcome is reported here as it is reported there.

Clinical disclaimer. The twelve state classes are not diagnostic categories. Nothing in this paper is an assessment, a screening instrument, a treatment or advice about any person's health or relationships, and nothing in it may be presented as such.

Chapter 45

Two Octaves per Doubling Against a Quadratic Cost: Roster Ceilings, the Parallel Wall, and When Tuning Must Halt

Abstract. We extend a dyadic sustainability criterion to groups and derive the roster size at which a group stops paying for itself. With per-link cost κ, conversion efficiency η and $r = \kappa/\eta$, coordination cost is $\kappa m(m-1)/2$ while best-case surplus is bounded by $2\log_2 m$ octaves, giving NET$(m) = 2\log_2 m - 1.442695\, r\, m(m-1)$; a dyad is viable in the best case if and only if $r \le \ln 2 = 0.693147$. A second bound, exact and independent of any geometry, is the roster ceiling $m(m-1) \le 2\eta \ln N/\kappa$. Two effective counts must be reported separately, the category-scale $1 + (N-1)\bar{u}$ and the roster-scale $1 + (m-1)\bar{u}$, the latter equal to the participation-ratio form $m + 1 - m/\mathrm{PR}$ exactly (residual zero on a constructed triad). Jensen's gap between $F(\bar{u})$ and the mean of $F(u)$ is 0.1758 nats — 609 cents — on that triad and 0.000001 octaves on a near-parallel case, so it is computed rather than assumed. A constructed six-member commons selected for agreement reads $\bar{u} = 0.018614$ and an effective count of 1.204754 against a required 11.3189, an octave deficit of $+6.4638$; it sits on its roster ceiling, 30 against 30.7225. Every lever swept to its physical limit falls short: perfect conversion leaves $+1.8430$, a 91 per cent cut in link cost leaves $+0.0990$, twelve times the category count leaves $+3.2562$. The procedure halts and issues no prescription; restructuring swings the reading 9.5898 octaves and produces a different group. A drop-one audit on a healthy team improves the reading for every member, which is why such rows carry no information about the members they name. All cases are constructed and no data were collected; the frequency register rests on postulates badged throughout, and every bound survives their rejection because the reference constant cancels.

Keywords: roster ceiling; Brooks crossover; parallel wall; aggregation gap; participation ratio; commons; restructuring; drop-one

Series: C. Frequency, Essence, and Mind **Paper:** CCP-045

1 Introduction

A dyad has one interval. Every result in the preceding papers of this series rests on that convenience: one relationship to read, one non-parallelism u to measure, one number to compare

against one threshold [Curzi, 2026,?]. Add a third party and there are three intervals; add a fourth and there are six. **Relationships do not grow with the roster, they grow with its square**, and the observation that coordination load grows as $m(m-1)/2$ while useful output does not is old, well documented, and independent of this framework [Brooks, 1975, Conway, 1968].

The question this paper asks is what that quadratic does to a logarithmic surplus, and at what roster size the two cross. The answer is exact and it is unfavourable to large groups. Writing κ for the per-link cost per period, η for conversion efficiency and $r = \kappa/\eta$, the best case a roster of m can field is $2\log_2 m$ octaves of surplus against $1.442695\, r\, m(m-1)$ octaves of required pitch, so

$$\mathrm{NET}(m) = 2\log_2 m - 1.442695\, r\, m(m-1) \quad \text{octaves},$$

and a dyad is viable in the best case if and only if $r \le \ln 2 = 0.693147$. A second and stricter bound follows from the framework's own surplus ceiling and involves no geometry at all: $\kappa m(m-1)/2 \le \eta \ln N$, the **roster ceiling**.

Four things follow, and the fourth is the one this paper exists to publish. First, two effective counts live side by side at group scope and must be reported separately — a category-scale count $N_{\text{eff}} = 1 + (N-1)\bar{u}$ and a roster-scale count $M_{\text{eff}} = 1 + (m-1)\bar{u}$, the latter identical to the participation-ratio form $m + 1 - m/\mathrm{PR}$, verified here at a residual of exactly zero. Second, the choice of *where* the averaging happens is worth 0.507396 octaves — 609 cents — on a constructed triad, because F is strictly concave and Jensen's inequality punishes dispersion; and it is worth 0.000001 octaves on a near-parallel commons, so the gap is not a constant to be assumed but a quantity to be computed. Third, an orthogonal *pair* already attains the maximum surplus a twelve-category system admits, so **in surplus terms a group buys nothing a well-chosen pair could not, and pays $m(m-1)/2$ times as much for it.**

Fourth, and negatively: **the instrument is run on a case it cannot help, and the run is reported.** A constructed six-member commons whose members were selected for agreement reads $\bar{u} = 0.018614$ and $N_{\text{eff}} = 1.204754$ against a required 11.3189, an octave deficit of $+6.4638$ and a steady state of -8.4630. Every one of the four levers is computed to exhaustion and every one falls short: perfect conversion at $\eta = 1.00$ still fails at $+1.8430$; a 91 per cent cut in link cost still fails at $+0.0990$; twelve times the category count still fails at $+3.2562$. The procedure halts and issues no prescription. **A diagnostic that only ever recommends action is not a diagnostic**, and the four failed lever tables are the result this paper most wants read.

The paper also prints an ethical consequence it would have been more comfortable to omit. A drop-one audit run on a healthy, comfortably accumulating five-member team improves the reading for **every one** of the five removals, by between 1.97 and 2.80 units of steady state. That is not a fact about any of the five; it is a fact about where a group sits on a concave surplus curve when cost is linear in links. It follows that a favourable drop-one row **carries no information whatever about the member it names**, and the prohibition on reading such rows as rankings is therefore an arithmetic finding rather than a piece of decorum.

Contributions

1. $\mathrm{NET}(m) = 2\log_2 m - 1.442695\, r\, m(m-1)$ and the closed bound $r \le 2\ln m/(m(m-1))$, giving the maximum viable roster at any cost ratio and $r_{\max}(2) = \ln 2$ exactly.
2. The roster ceiling $m(m-1) \le 2\eta \ln N/\kappa$, exact and geometry-free, with the constructed commons sitting on it at 30 against 30.7225.
3. The roster-scale identity $M_{\text{eff}} = m + 1 - m/\mathrm{PR}$, verified at 1.7815458788 with residual 0.00×10^{0}.
4. The aggregation gap quantified at group scope: 0.1758 nats, 0.507396 octaves, 609 cents on a three-member case and 0.000001 octaves on a six-member near-parallel one, with two sweeps showing where it lives.
5. The commons audit: four levers, three governance principles, two nesting topologies and five roster sizes, all computed, all short.

6. The reachability test, which separates a case that is formally tunable from one that is practically not, and the restructure that swings the reading 9.5898 octaves while producing a different group.
7. The drop-one negative result on a healthy team, and the muddiness index $\mu = [m(m-1)/2]/\lceil N/2 \rceil$, which exceeds one from $m = 4$ at $N = 12$.

What this paper does not claim, stated at the front rather than at the back. No dataset was collected. Every case in this paper is a constructed parameter set, labelled as constructed at the point of use, and its precision is exact because its inputs are exact rather than because anything was measured. The frequency register it inherits rests on three postulates of this framework with no external support — that the dimensionless ratio $k = (9/8)^2/\varphi^2$ is a frequency in hertz, that essence goes as kn^2, and that octave reduction may be carried beyond pitch — and the standard deflationary treatment of golden-section claims is cited here deliberately [Markowsky, 1992] and again wherever φ appears. Section 2 badges all of it, Section 9 decomposes the chain into steps a reader can check one at a time, and Section 10 prints every check this paper fails.

2 Hypotheses, definitions, postulates and modelling choices

The rigour standard governing this corpus requires a claim that *could* be wrong to be stated so that it could be, and a claim that could not be wrong to be labelled with which of the three non-empirical kinds it is. **A hypothesis nothing could falsify is not a hypothesis**, and none is manufactured here.

2.1 Hypotheses proper

H1 — the crossover hypothesis. For groups whose per-link maintenance cost and conversion efficiency are measured on one declared period, no roster exceeding the largest m satisfying $2\ln m \geq r\, m(m-1)$ accumulates stored order. **Predicted:** among groups with declared κ and η, those above the bound do not accumulate. **Falsified by:** one group measured above the bound and observed to accumulate over a run long enough for the fixed point to dominate the transient. **Status:** derived from the surplus and cost forms; **not tested here.** No observational data were collected for this paper.

H2 — the roster-ceiling hypothesis. No group with $\kappa m(m-1)/2 > \eta \ln N$ sustains itself under any assignment of pairwise non-parallelism whatsoever. **Predicted:** no counterexample exists at any $\bar{u} \in [0, 1]$. **Falsified by:** one counterexample. The hypothesis is a strict universal and is cheap to kill. **Status:** derived from the normalisation bound $F \leq \ln N$ [Curzi, 2026]; **not tested here.**

H3 — the parallel-wall hypothesis. A group whose members were selected by a criterion that rewards agreement exhibits a mean pairwise non-parallelism low enough that no arrangement of η, c, δ or N restores a positive steady state. **Predicted:** for such groups the required u^* exceeds the achievable range by a large factor, and the lever tables are all short. **Falsified by:** a doctrine-selected group whose deficit is closed by any single arrangement lever. **Status:** demonstrated on a constructed case in §5.4; **not tested against observation.**

H4 — the drop-one non-informativeness hypothesis. In a group operating near the surplus ceiling, removing any member improves the reading, so the sign of a drop-one row carries no information about the member removed. **Predicted:** all m rows of a drop-one audit on a comfortably accumulating group move the reading the same way. **Falsified by:** a group near its ceiling in which some drop-one rows improve the reading and others worsen it, with the split reproducible

across analysts. **Status:** derived from the concavity of F together with linearity of cost in links; **computed** on a constructed team in §5.11b.

H5 — the reachability hypothesis. The formal classification TUNABLE and the practical classification REACHABLE come apart, so a case passing the ceiling test may still admit no satisfiable prescription. **Predicted:** cases exist with $c/\eta \leq \ln N$ whose required u^* exceeds $\bar{u}$ by more than an order of magnitude. **Falsified by:** a proof that $c/\eta \leq \ln N$ bounds $u^*/\bar{u}$. **Status:** exhibited by construction at a factor of 50.4; the *judgment* that a factor of 50.4 is unreachable is a **declared modelling position**, not a measurement (§5.5).

2.2 Definitions — true by stipulation, not falsifiable

- **Def. 1.** m := the roster size; N := the number of state **categories**, fixed at 12 throughout. These are different objects with different bounds and are never interchanged (§4.1).
- **Def. 2.** $u := 1 - (\hat{x} \cdot \hat{y})^2$ on unit intensity vectors; $\bar{u}$:= the mean of u over all $m(m-1)/2$ unordered pairs; $F := \ln(1 + (N-1)\bar{u})$.
- **Def. 3.** $N_{\text{eff}} := 1 + (N-1)\bar{u}$ (category scale) and $M_{\text{eff}} := 1 + (m-1)\bar{u}$ (roster scale).
- **Def. 4.** $D := 2.885390\,(c/\eta) - \log_2(f/k)$, the octave deficit.
- **Def. 5.** $\mu := [m(m-1)/2]/\lceil N/2 \rceil$, the muddiness index.
- **Def. 6.** $k := (9/8)^2/\varphi^2$. **This is a defined constant.** It is an exact ratio of exact quantities and is therefore computable to arbitrary precision; the fifteen significant figures 0.483425732988414 are *exact digits of a definition* and carry no measurement uncertainty because there is no measurement. Every appearance of the constant at that precision in this paper is so labelled.
- **Def. 7.** *Reachability* (Definition 5.1) is a **declared judgment** about what the parties could honestly represent, not a computed property of the formalism.

2.3 Postulates — asserted by this framework, with no external support

- **P-a. The essence law $f(n) = kn^2$.** A quadratic relation between a dimensionless count and a frequency. **No external literature supports it.** It is not derived here and nothing in the bibliography derives it. **The exponent 2 is defined by the model, not estimated from data.** No scaling exponent in this paper was obtained by fitting, none was tested against a log-normal or exponential alternative, and the goodness-of-fit and likelihood-ratio procedure a claimed scaling relation requires [Clauset et al., 2009] was **not run, because there is no data to run it on.**
- **P-b. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic. **Asserting that this dimensionless number *is a frequency* is a separate and much stronger claim**, and no operational procedure is supplied by which the constant acquires the dimension of inverse time. This is postulated, and it appears on its own line of the verification chain (§9.2, step L4).
- **P-c. The affine effective count $N_{\text{eff}} = 1 + (N-1)u$.** A design axiom [Curzi, 2026], not a derived result and **not a Hill number of any order.** The Hill family [Hill, 1973, Jost, 2006] and its independent rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly — as the corpus's concentration work uses them [Curzi, 2026] — and ground this construction not at all. **The roster-scale count M_{eff} inherits the same status**, and the participation-ratio identity of §4.2 is an algebraic re-expression of the affine axiom, not independent support for it.
- **P-d. The uniform-link cost model $C = \kappa m(m-1)/2$.** Every pair is assumed to maintain a link and every link is assumed to cost the same. Real cost topologies are neither complete nor uniform; SPEC 4.7 requires the non-uniform case to be stated as $C = \sum_{ij} \kappa_{ij}$, and every number in this paper uses the uniform model.

2.4 Modelling choices — legitimate, but choices

- **M-a. Octave reduction applied to a non-acoustic quantity.** Octave equivalence is a perceptual structure formalised for **pitch** [Shepard, 1982], whose perceptual specialness has a measured size [Demany et al., 2013]. Nothing licenses carrying it to a quantity that is not a pitch. The *operation* is well defined — division by a power of two — and its *interpretation* is a choice of this framework.
- **M-b.** $N = 12$**.** Twelve categories are used throughout and exceed the classical span of immediate absolute judgment [Miller, 1956], which is a reason for caution rather than a reason for twelve.
- **M-c. The mean as aggregator.** $\bar{u}$ is the arithmetic mean over pairs. Section 4.3 shows this is a choice with a price and requires both $F(\bar{u})$ and the mean of $F(u)$ to be published; it does not show that the mean is the right aggregator, and no argument here establishes that it is.
- **M-d. Interval apparatus.** Cents, octave equivalence and exact interval arithmetic are the correct apparatus once an index exists [Rossing et al., 2002, Barbour, 1951], but what a listener finds consonant depends on spectrum rather than ratio alone [Sethares, 2005] and interval categories generalise less far than is usually assumed [Burns, 1999]. This paper uses the arithmetic and claims none of the perception.
- **M-e. Governance principles read as parameter moves.** Mapping a design principle for durable common-pool institutions [Ostrom, 1990] onto η, c and δ is a **correspondence of dynamics, not of agency**, and is badged as one at §5.6.

2.5 What is expository

The specification blocks (§4.15–4.29 in the numbering of the specification lists, §5 and §6 likewise), the failure-mode catalogues, and the numbered Procedure T of §6.8 are expository: they set out procedure, reporting requirements and failure modes rather than argue a claim. Their organising question is *what must be published alongside a group reading for the reading to be checkable by a third party.*

3 Framework, dimensional audit, and method

3.1 The storage law — a shared mathematical form, not a derivation

$$Q_{t+1} = (1 - \delta)Q_t + \eta S_t - C_t$$

Analogy status: category 2, a shared mathematical form. The equation governing this framework's stored order is the equation that governs a leaky integrator, and it is used because the mathematics is the same, not because the physics transfers. It appears as the RC low-pass filter in signal processing [Oppenheim et al., 1996], as exponential smoothing in forecasting [Holt, 1957], and as the integrate-and-fire neuron in computational neuroscience [Lapicque, 1907, Gerstner and Kistler, 2002]. The fixed point $Q_\infty = (\eta F - c)/\delta$ follows from setting $Q_{t+1} = Q_t$ and requires $\delta > 0$; stability and uniqueness are standard [Elaydi, 2005] and the convergence is Banach's [Banach, 1922, Curzi, 2026]. **No claim is made that stored order is a charge or that any physical result about circuits applies to a group of people.**

Three warnings attach to that form and are recorded here rather than in a footnote. The time average of a multiplicative process differs from its ensemble average, so a parameter estimated across groups does not describe what happens to one group over time [Peters, 2019]. A single Q, δ or $\bar{u}$ written for a group is an aggregation, and aggregation over heterogeneous agents does not in general yield a representative agent [Kirman, 1992] — which is why this framework's no-aggregation rule [Curzi, 2026] is a rule and not a result. And Q has the grammar of a conserved quantity without a conservation law to give that grammar content, which is the characteristic failure of the genre [Mirowski, 1989]; this paper claims validity only

within a specified arrangement [Cartwright, 1999] and claims no universality. The wider programme — statistical physics applied to social dynamics — has a standard survey that fixes what such models can be held to [Castellano et al., 2009], and those are the boundaries claimed here.

3.2 The surplus functional, the effective count, and what the logarithm rests on

$F(u) = \ln(1 + (N-1)u)$ is the corpus's surplus functional, characterised by angle-only dependence, a zero at parallel states, an affine effective count and a normalisation [Curzi, 2026]. Its logarithmic form places it in the same family as Shannon's entropy [Shannon, 1948], and the ceiling $F \leq \ln N$ is the same ceiling that appears in requisite-variety arguments [Ashby, 1956, 1958].

Which warrant the logarithm actually needs is worth stating, because two are available and they are not equally strong. The psychophysical route reads F as a Fechner law [Fechner, 1860] and inherits every dispute in that literature. The multiplicative-dynamics route derives a logarithmic form with **no psychological assumption at all** [Peters and Gell-Mann, 2016]. The arguments in this paper need only the second: nothing here turns on the perceptual story being true.

The form is nevertheless underdetermined by the evidence. A power law with exponent below one [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as $\ln(1+(N-1)u)$ does, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. **Nothing in this paper discriminates among them**, and the results that matter most here — the crossover, the roster ceiling, the drop-one result — depend only on F being *concave and bounded*, which all three candidates are. That is stated as a robustness claim and it is the honest extent of it.

Finally, **which construct of difference u measures must be declared**, because at least three incompatible constructs travel under the word *diversity* — separation, variety and disparity [Harrison and Klein, 2007]. Here u is a *disparity* measure over represented states, and it is symmetric in its arguments, which psychological similarity is known not to be [Tversky, 1977]. That is a limitation and it is printed in §10.

3.3 The essence bridge and the constant k

The bridge from surplus to pitch is $f = k\,e^{2F}$, whose Result One is that $f(m)/f(n) = m^2/n^2$, so that **the constant cancels from every interval and does no work beyond setting a reference** [Curzi, 2026k]. That property is load-bearing for this paper: every deficit, crossover and ceiling below is a difference of logarithms in which k cancels exactly, so **the group verdicts never depend on the postulated constant and only the hertz values do.**

$k = (9/8)^2/\varphi^2 = 0.483425732988414$ is a **defined constant, exact**. Its two components are real and documented — the Pythagorean whole tone [Barbour, 1951] and the golden section [Euclid, 1956, Vajda, 1989] — but their product **expressed as a frequency in hertz has no precedent in any literature we have found.** The standard deflationary treatment of golden-section claims [Markowsky, 1992, Fischler, 1981] is cited here and wherever φ appears, and the popular literature's enthusiasm for the constant [Livio, 2002] is not evidence for anything asserted here.

3.4 Dimensional audit

Every symbol used in this paper, with its dimension, its unit, and whether it is measured, derived, defined or dimensionless by construction.

symbol	quantity	dimension	unit	status
Q	stored order	$[\mathcal{C}]$	none; **no operational unit exists**	state variable
δ	decay rate	$[1]$	per declared period	declared parameter
η	conversion efficiency	$[1]$	dimensionless fraction	declared parameter
κ	per-link cost	$[\mathcal{C}\,T^{-1}]$	per link per period	declared parameter
$C = \kappa m(m-1)/2$	total cost flow	$[\mathcal{C}\,T^{-1}]$	per period	derived
m	roster size	$[1]$	count	cardinality, absolute scale
N	category count	$[1]$	count	cardinality, absolute scale
$u,\ \bar{u}$	non-parallelism	$[1]$	dimensionless, $[0, 1]$	derived from unit vectors
F	surplus	$[1]$	nats	derived; **nats are not a physical unit**
PR	participation ratio	$[1]$	dimensionless	derived from the Gram spectrum
$r = \kappa/\eta$	cost ratio	$[\mathcal{C}\,T^{-1}]$	per link per period	derived
D	octave deficit	$[1]$	octaves (also cents)	derived
k	ground essence	**claimed** $[T^{-1}]$	Hz **by postulate**	**defined; the unit is asserted**
$f = k\,e^{2F}$	essence frequency	inherits k	Hz **by postulate**	derived given P-b
μ	muddiness index	$[1]$	pairs per class	derived

Does the audit close? Partly, and the gap is named. The storage law balances if and only if ηS and C carry the dimension of Q per period, which the framework stipulates rather than establishes; Q has **no operational unit at all**, and a dimensionless placeholder is the honest record of that. NET(m), D, μ and both effective counts are dimensionless and their audits close exactly. **The one equation that does not balance is** $f(n) = kn^2$, which requires k to carry $[T^{-1}]$ while k is computed as a ratio of two dimensionless quantities. That is postulate P-b, it is the framework's largest structural weakness, and no citation in the bibliography repairs it.

One consequence for this paper specifically. The roster ceiling $m(m-1) \leq 2\eta \ln N/\kappa$ is dimensionally clean: η is dimensionless, $\ln N$ is dimensionless, κ carries cost per link per period and the left side is a pure count, so the inequality is a statement about κ in units of η per link. **It therefore survives the failure of P-b intact**, and so does the crossover of §4.5. Only the hertz columns of the worked readings depend on the postulate.

3.5 Scale type, and what licenses the arithmetic

Permissible arithmetic is a function of the transformation group that leaves a quantity's empirical content unchanged [Stevens, 1946]. Three groups of quantities appear here and they do not have the same standing.

Counts. m, N, the link count and the class count are cardinalities. A cardinality admits only the identity transformation, so squaring it, halving it and forming $m(m-1)/2$ are licensed

operations. **This is the only part of the paper whose scale type is secure.**

Derived dimensionless ratios. u, $\bar{u}$, F, D, μ and PR inherit their standing from the intensity vectors they are computed from. Those come from magnitude estimation, which is *held* to deliver ratio-scale information [Stevens, 1957] and whose exponents are known to move with the experimenter's chosen stimulus range [Teghtsoonian, 1971] and to be exposed to catalogued response biases [Poulton, 1968]. **The dispute is live** [Krueger, 1989, Luce, 2002, Narens, 1996] and this paper inherits it whole.

Declared parameters. η, κ and δ are treated throughout as ratio-scaled quantities on a declared period. **Nothing establishes that they are.** Michell's objection — that psychology assumes quantitative structure without testing for it — is the single strongest objection to this framework [Michell, 1997, 1999], the formal test for additive quantitative structure exists [Luce and Tukey, 1964, Krantz et al., 1971], and **it has not been run on any quantity in this paper.** The corpus has demoted one of its own keystone constructions on exactly this ground [Curzi, 2026t], and the instrument that would repair the demotion is Rasch measurement [Rasch, 1960], which is likewise not applied here. **The ratio-scale treatment in this paper is therefore provisional, and it is conceded rather than defended.**

A consequence specific to the group case, and it is sharp. The sensitivity analysis of §5.10 shows that the constructed family's verdict is undetermined unless η is known to better than ± 0.030034 — 8.8 per cent of its value. **A quantity whose scale type is not established cannot be known to 8.8 per cent**, so that case is unresolved for a reason deeper than the one the sensitivity table gives. The table reports the arithmetic; this paragraph reports what the arithmetic presupposes.

3.6 Identification — the objection this framework cannot presently answer

The framework's central formal claim is a reflexive loop: the group influences the member and the members constitute the group. At group scope that loop is written explicitly, since $\bar{u}$ is a property of the members and the reading is a property of the group.

That is exactly a linear-in-means reflexive specification, and the endogenous social effect in such a specification is not identified from observational data [Manski, 1993]. It cannot be separated from contextual effects or from correlated unobservables however much data is collected, and influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011, Lyons, 2011]. **No amount of fit recovers the parameter.**

The remedy this paper adopts is stipulation of the reference group, following the template for discrete-choice models with social interactions [Brock and Durlauf, 2001]: the roster is declared, the period is declared, and the pairs over which $\bar{u}$ is averaged are enumerated and published. That is the cheapest of the four available remedies — the others being randomisation, an instrument, and partial-population variation — and it is not free. **Its price is that every claim in this paper about what a group's parameters imply is a modelling position, not an identified empirical result**, and it is labelled as one wherever it appears.

Two objections in the same family are also unanswered. The framework asserts that systems change their behaviour when modelled and observed, and then exempts its own parameters from that reflexivity, which is the Lucas critique turned on the framework itself [Lucas, 1976, Hacking, 1995]; a reflexive fixed point has been documented happening in the field [MacKenzie and Millo, 2003] and the mechanism is old [Merton, 1948], so the exposure is real rather than hypothetical. And §5.14's finding — that a member's declining to participate improves a constructed family's reading by 2.680588 octaves — is precisely the sort of number whose *publication* could change the behaviour it describes. That is why §6.2's consent axiom forbids showing it to anyone deciding whether to withdraw, and why the prohibition is an axiom rather than a courtesy.

3.7 Method

No data were collected. The method is exact arithmetic on stated parameters, in four steps.

1. **Derive.** The crossover, the roster ceiling, the roster-scale identity, the muddiness index and the aggregation gap are derived from the definitions of §2.2 by algebra, with each derivation shown at the point of use.
2. **Instantiate.** Four constructed cases carry the numbers: a triad extending the carried dyad, a four-member family, a five-member team, and the six-member commons. Every input vector and every raw L^2 norm is published so that any reading can be recomputed from scratch.
3. **Sweep.** Where a claim is about a lever, the lever is swept to its physical limit ($\eta \to 1$, $\kappa \to 0$, $u \to 1$, $N \to 144$) rather than to a convenient value, and the result at the limit is reported whether or not it is favourable.
4. **Audit.** Boundary behaviour, sensitivity to the least certain parameter, and the two aggregations are computed for every case, and the verdict is reported as NOT DETERMINED wherever they disagree.

Every figure in this paper is generated by a script named in its caption, taking its inputs from the tables in the text. Nothing is fitted; no model comparison is reported, because there is nothing to compare against and no out-of-sample data to compare on.

4 Group scale: interval counts, aggregation, and the roster ceiling

A dyad has one interval. That is the whole reason the dyadic papers of this series [Curzi, 2026,?] could treat a bond as a pitch and get away with it: there was one relationship to read, one `u` to measure, one number to compare against one threshold.

Add a third person and there are three intervals. Add a fourth and there are six. The relationships do not grow with the roster; they grow with the square of it, and everything that was simple at two becomes a question of aggregation at three, of accounting at six, and of arithmetic that has already decided the answer at twelve.

This section is about what changes and what does not. Three things change: the count of intervals, the need to aggregate them into one reading, and the cost structure, which Brooks named in 1975 and which the octave form of the minimum-frequency paper [Curzi, 2026] prices exactly. One thing does not change, and it is the result that organises the section: **the surplus ceiling is `ln N`, it is set by the category count and not by the roster, and a perfectly non-parallel pair already reaches it.** A larger group can therefore buy no more surplus than two well-chosen people, while paying quadratically more for the privilege.

That is a harsh statement and it needs its qualifications, which §4.7 supplies. But it is what the formalism says, it follows from the affine axiom in two lines, and a section on groups that did not say it first would be arranging the furniture around a hole in the floor.

Ownership: this section takes the interval count, the group chord, and the Brooks comparison. The mood-and-trait paper [Curzi, 2026] owns octave folding, the odd-part class rule and the `N = 17` regime statement, and this section cites all three without re-deriving any of them. The minimum-frequency paper [Curzi, 2026] owns `f_min`, the deficit and the levers. The dissonance paper [Curzi, 2026] owns the consonance/redundancy identity. Section 5 takes the three worked structures and the commons.

Nothing in this section is clinical, diagnostic or therapeutic, none of it is counselling, and the frequencies are essence frequencies — no group, person or room is claimed to resonate at any value in it.

The law

4.1 The interval count, and a notation warning that has to come first For a set of `m` members there are

```
m (m − 1) / 2      unordered pairs, hence that many intervals
```

m	pairs	pairs per member	pairs per available pitch class (6)
2	1	0.50	0.167
3	3	1.00	0.500
4	6	1.50	1.000
5	10	2.00	1.667
6	15	2.50	2.500
7	21	3.00	3.500
8	28	3.50	4.667
10	45	4.50	7.500
12	66	5.50	11.000
15	105	7.00	17.500
20	190	9.50	31.667
30	435	14.50	72.500

The notation warning: `N` in this framework is the number of state CATEGORIES, fixed at 12, and it is not the roster size. The manifest's shorthand `N(N−1)/2` refers to the roster; every other appearance of `N` in the formalism — `F <= ln N`, `N_eff = 1 + (N−1)u`, `f <= k N^2`, the ceiling `c/eta <= ln N` — is the category count. This section writes `m` for the roster and reserves `N` for categories, and it is worth being pedantic about because conflating them produces readings that are wrong by whole octaves in a way nothing downstream catches.

The second column is the one most often underestimated. Going from six members to twelve does not double the relational load; it multiplies it by 4.4, from 15 pairs to 66. The third column is the one this section turns into a result in §4.11.

4.2 Aggregation, and the two effective counts The construction of the framework's founding construction [Curzi, 2026] is pairwise. A group has many pairs and one reading, so an aggregator is required, and the framework uses one:

```
u_bar  =  mean of u over all m(m−1)/2 unordered pairs
F      =  ln( 1 + (N − 1) u_bar )          N = 12
f      =  k ( 1 + (N − 1) u_bar )^2
```

That is the construction the sustaining-frequency paper [Curzi, 2026] both use, and it is the one every reading in this framework uses. There is, however, a second effective count that lives alongside it, and keeping them apart is worth a short section because they answer different questions and have different bounds.

```
CATEGORY−SCALE      N_eff  =  1 + (N − 1) u_bar        bounded by N = 12
                    "how many distinct state−categories' worth of view is present"

ROSTER−SCALE        M_eff  =  1 + (m − 1) u_bar        bounded by m
                    "how many genuinely distinct members is this roster fielding"
```

THEOREM 4.1 (R3, verified at roster scale). `M_eff = m + 1 − m/PR`, where `PR` is the Renyi-2 participation ratio of the members' Gram matrix,

```
PR  =  ( trace G )^2 / sum_{ij} G_ij^2  =  m^2 / sum_{ij} G_ij^2
```

The participation ratio is the Renyi-2 quantity of the Gram spectrum [Rényi, 1961], and the identity is the roster-scale twin of the category-scale identity $N_{\text{eff}} = N+1-N/\text{PR}$ established in Series B, which was verified there at $K = 3, 5, 8$ and 12 to better than 10^{-12} [Curzi, 2026c] and at internal scope on a framing Gram matrix [Curzi, 2026o]. **Neither count is a Hill number.** The Hill family [Hill, 1973, Jost, 2006] and its political-science rediscovery [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly and ground the affine form not at all (P-c).

Verified on the constructed triad of the Worked Example: `PR = 1.3522930095`, `m + 1 − m/PR = 1.7815458788`, `1 + (m−1) u_bar = 1.7815458788`, error `0.00e+00`.

The identity is worth having for two reasons. It gives a second, independent route to `u_bar` that does not require enumerating pairs — useful at large `m`, where the pair count is the expensive part. And it supplies the sentence to hand to someone who does not want a frequency: a roster of three fielding `M_eff = 1.78` is three people doing 1.78 people's worth of distinct looking.

4.3 The aggregation gap, and it is larger than the dyadic case

`F` is strictly concave in `u` (the concavity of F [Curzi, 2026]). Therefore, by Jensen's inequality,

```
F( u_bar )  >=  mean of F( u_pair )        with equality only if all pairs share one u
```

The book's canonical reading uses `F(u_bar)`, which is the optimistic end of the interval, and the framework's reporting rule requires the conservative end to be published with it. the two-aggregation reporting rule [Curzi, 2026] states the rule; this section supplies the magnitude at group scope, and it is not small.

Computed on the constructed triad of the Worked Example:

```
pairwise u:  0.068734665265,  0.552647058824,  0.550937094081

F( u_bar )        = 1.6674242020 nats      f = 13.5718 Hz     D = −3.410906
mean of F(u)      = 1.4915742527 nats      f =  9.5476 Hz     D = −2.903511

AGGREGATION GAP   = 0.1758499493 nats  =  0.507396 octaves  =  609 cents
frequency ratio   = 1.421482
```

The same correction is already priced at protocol scope in Series B, where using F of the mean instead of the mean of F overstated feasibility by 0.0790 nats — 4.31 per cent, worth 0.3952 stored units at $\eta = 0.30$, $\delta = 0.06$ [Curzi, 2026]. At group scope the same error is an order of magnitude larger.

Half an octave of surplus, from the choice of where the averaging happens. Series B's worked office found the same effect worth 6.2%; at this triad's dispersion it is worth 11.79% of the conservative figure, and the reason is visible in the pairwise list: one pair at 0.0687 and two at 0.55 is exactly the dispersion Jensen's inequality punishes.

And the counter-case, computed on the commons of the carried commons [Curzi, 2026], whose fifteen pairwise `u` values all lie between 0.018484 and 0.018830:

```
F( u_bar )   = 0.186276647       mean of F = 0.186276219
AGGREGATION GAP = 0.00000124 octaves
```

Where the pairs are alike, the gap vanishes; where they are dispersed, it is the largest single uncertainty in a group reading. The rule that follows is not "use the conservative figure" — it is that both are computed and both are published, and where the verdict differs between them the verdict is not determined. It does not differ in the triad: `−3.410906` and `−2.903511` both accumulate, and per the sustaining-frequency paper [Curzi, 2026] an ACCUMULATES verdict is the robust direction anyway, since `f` is a lower bound.

4.3b When the gap is large, and when it can be ignored Because the aggregation gap is the largest controllable uncertainty in a group reading, it is worth knowing where it lives. Two sweeps, both computed on two-pair sets so that the dispersion is explicit.

Holding the mean at `u_bar = 0.40` and widening the spread between the two pairs:

```
pairs             F(u_bar)      mean-of-F      gap (octaves)
0.40 / 0.40       1.686399       1.686399        0.000000
0.35 / 0.45       1.686399       1.681185        0.015044
0.30 / 0.50       1.686399       1.665209        0.061142
0.25 / 0.55       1.686399       1.637392        0.141405
0.20 / 0.60       1.686399       1.595650        0.261847
0.15 / 0.65       1.686399       1.536289        0.433126
0.10 / 0.70       1.686399       1.452630        0.674514
0.05 / 0.75       1.686399       1.331439        1.024197
0.01 / 0.79       1.686399       1.187727        1.438862
```

Holding a fixed relative spread of ±50% of the mean and sweeping the level:

```
u_bar     pairs             gap (octaves)
 0.02     0.010 / 0.030       0.011776
 0.05     0.025 / 0.075       0.046143
 0.10     0.050 / 0.150       0.102518
 0.20     0.100 / 0.300       0.181418
 0.40     0.200 / 0.600       0.261847
 0.60     0.300 / 0.900       0.301406
```

The two sweeps together give a usable rule. The gap grows with absolute dispersion, quadratically at small spreads and faster after, and it grows mildly with the level. It is negligible in exactly one situation: when the pairwise values are close together, which is the near-parallel case. So the commons, whose fifteen pairs lie inside a band of width 0.000346, can be read from `F(u_bar)` without qualification — and a group with one intimate pair and two distant ones cannot.

The practical form: compute the spread of the pairwise list before deciding how much of the report the gap deserves. A group whose pairwise `u` values differ by less than about 0.05 has a gap under 0.02 octaves and may state one figure. Anything wider states two.

4.4 The group chord and the class ceiling A group's chord is the set of states its members hold, taken together. The self-as-chord material [Curzi, 2026] owns the chord at internal scope and the construction transfers unchanged: the states are indices, the indices are frequencies through `f = k n^2`, and the folding is the mood-and-trait paper's [Curzi, 2026].

The odd-part class rule, result R1 of the mood-and-trait paper [Curzi, 2026] gives the ceiling and this section cites it rather than proving it again: two indices share a pitch class if and only if they share an odd part, so an indexed set `1..N` holds exactly `ceil(N/2)` distinct classes — six, for `N = 12`.

The six, folded into 220–440 Hz and sorted by pitch, with adjacent separations:

```
class   folded (Hz)     cents above the previous
  11      233.978            —
   1      247.514          97.3641
   3      278.453         203.9100
   9      313.260         203.9100
   7      379.006         329.8318
   5      386.741          34.9756
                          (wrap to 2 x 233.978:  330.0085)
```

```
minimum adjacent separation  =  34.9756 cents  =  the 50/49 regime
```

That 34.9756-cent floor is the mood-and-trait paper's [Curzi, 2026], it holds because `N = 12` sits below the `N = 17` minimum-gap cliff, and this section states the fact once and does not re-derive it. The mood-and-trait paper [Curzi, 2026] §7.10 has the sweep and the exact-rational argument.

The consequence for groups is a saturation result, and it is the same shape as the requisite-variety bound: a regulator with too few distinguishable categories cannot regulate a variety larger than its own [Ashby, 1956, 1958]. The class count is capped at six no matter how many members there are, while the pair count grows quadratically. Computed by simulation — 20,000 trials, members' states drawn uniformly without replacement from the twelve, random seed 7:

```
expected distinct pitch classes covered
m      3 states each    4 states each    5 states each
 2         3.799            4.398            4.842
 3         4.506            5.008            5.372
 4         4.927            5.367            5.637
 6         5.432            5.729            5.879
 8         5.695            5.884            5.961
12         5.904            5.977            5.996
```

By six members holding four states apiece, a group covers 5.73 of the six available classes; by twelve it covers 5.98. Every further member adds pairs, adds cost, and adds essentially no class the chord did not already contain.

This is the precise sense in which a group's chord goes muddy, and it is not a metaphor about noise. **The chord saturates the lattice while the interval count keeps growing, so past a modest roster the additional relationships are all being drawn from a set of intervals the group already sounds.** the consonance-redundancy identity R2 [Curzi, 2026] is the other half of the statement: the most consonant pairs are exactly the pitch-class collisions, so a saturated chord is one whose new pairs are increasingly redundant with old ones.

4.5 Brooks, priced in octaves The observation that communication paths in a group of `m` grow as `m(m−1)/2` while useful output does not is Brooks's [Brooks, 1975], restated many times since — as the claim that a system's structure mirrors the communication structure of the organisation that built it [Conway, 1968], and in the wider stock-and-flow literature on how coordination load accumulates [Forrester, 1961, Sterman, 2000, Hopp and Spearman, 2011]. The octave form of the minimum-frequency paper [Curzi, 2026] makes the comparison exact, because it puts both sides in the same unit.

Cost side. With a per-link cost `kappa` per period, `C = kappa m(m−1)/2`, and the minimum-frequency paper [Curzi, 2026] Theorem 4.3 converts:

```
octaves required  =  2.885390 ∗ ( C / eta )  =  1.442695 ∗ ( kappa / eta ) ∗ m ( m − 1 )
```

Surplus side. The most a roster of `m` can field, at roster scale, is `M_eff = m` — every member mutually non-parallel. Through the essence bridge that is

```
octaves available (best case)  =  2 log2( m )
```

THEOREM 4.2 — TWO OCTAVES PER DOUBLING AGAINST A QUADRATIC. In the best case a group's surplus rises by exactly two octaves each time the roster doubles, while its cost rises as `m(m−1)`. Setting the two equal and writing `r = kappa/eta`:

```
NET(m)  =  2 log2(m)  −  1.442695 ∗ r ∗ m(m−1)      octaves

crossover m∗ solves      2 ln m  =  r m ( m − 1 )
```

Proof: substitute and multiply through by `ln 2`. **QED.**

The crossover has a closed form as a bound on `r`: the largest viable integer roster at cost ratio `r` is the largest `m` with `2 ln m >= r m(m−1)`, equivalently `r <= 2 ln m / (m(m−1))`. Computed:

m	r_max(m) = 2 ln m / (m(m−1))	m	r_max(m)
2	0.69314718	10	0.05116856
3	0.36620410	11	0.04359810
4	0.23104906	12	0.03765010
5	0.16094379	15	0.02579095
6	0.11945063	17	0.02083245
7	0.09266239	20	0.01576701
8	0.07426577	25	0.01072959
9	0.06103402		

Read the other way — the maximum viable roster at a given cost ratio:

r = kappa/eta	max viable roster (best case)	
0.005	38	
0.010	26	
0.020	17	
0.030	13	
0.050	10	
0.100	6	
0.125	5	
0.161765	4	
0.200	4	
0.366204	3	
0.500	2	
0.693147	2	<-- r_max(2) = ln 2 exactly
1.000	1	
2.066667	1	

The framework's own contact analysis reaches the same shape by a different route: contact raises surplus only while a boundary-cost multiplier stays below a critical value, computed there as 3.17 against an operating value of 8 [Curzi, 2026g].

A dyad is viable in the best case if and only if `kappa/eta <= ln 2 = 0.693147`, which is a pleasing way to see why the carried dyad of the sustainable-dyad paper [Curzi, 2026], at `r = 2.066667`, could not be saved by its geometry alone. It was over the roster bound at two.

Two figures from the carried cases, both computed:

```
the carried commons:   r = 0.055/0.34 = 0.161765
                           r_max(5) = 0.160944
                           the six-member commons misses a viable FIVE-member roster by
                           0.000821 in r -- a per-link cost of 0.055 against 0.054721

the constructed triad:     r = 0.055/0.34 = 0.161765, max viable roster 4, actual m = 3
```

The commons fails the best-case roster test by half a percent of its per-link cost, before any question of who its members are.

Section 5 takes that case up in full.

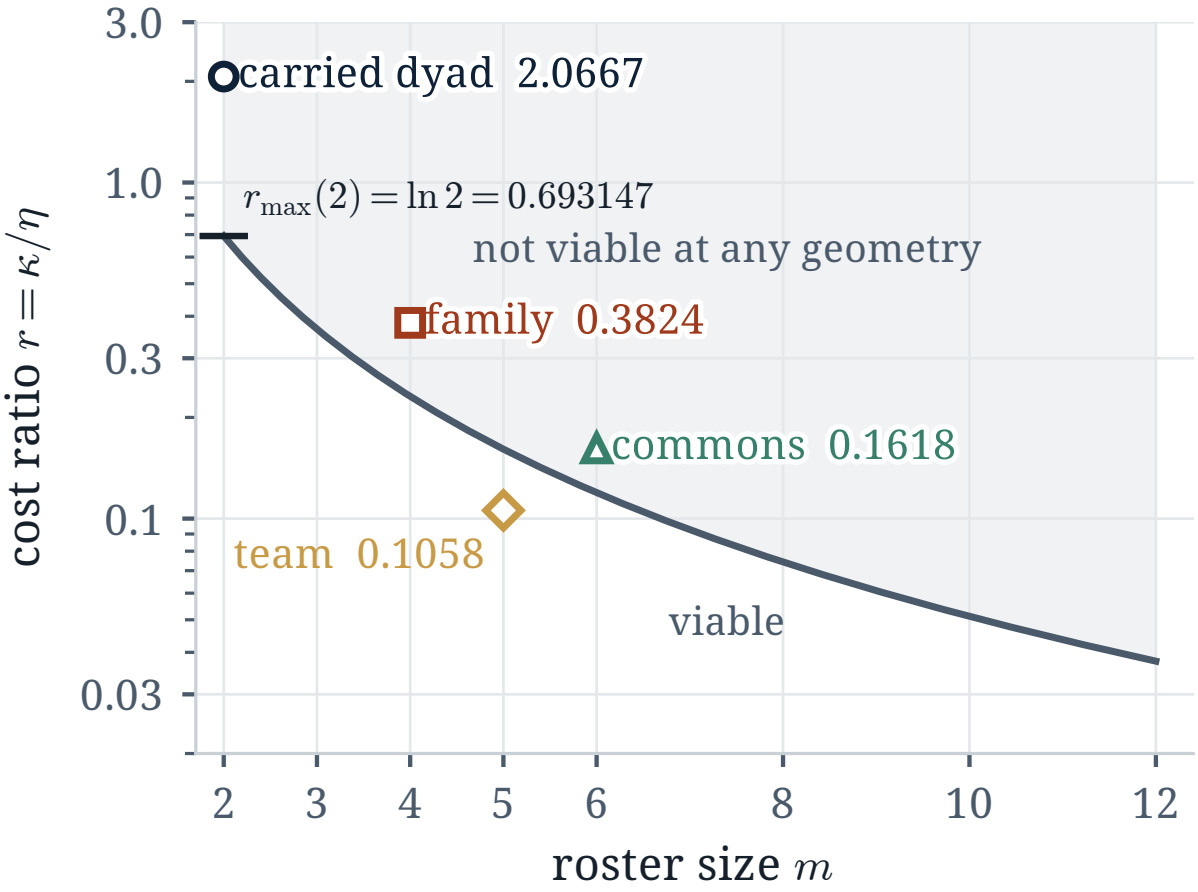

Figure 45.1: **The viability frontier is a statement about the cost ratio, not about headcount.** $r_{\max}(m) = 2\ln m/(m(m-1))$ is the largest κ/η at which a roster of m can pay for itself in the best case, and it equals $\ln 2 = 0.693147$ exactly at $m = 2$. Markers are the four constructed cases of this paper: the carried dyad and the family sit above the frontier, the team below it, the commons above it at six members and below it at four. Modelled from the closed form of Theorem 4.2 with the case parameters of §4.6 and §5.9; script `figs/src/CCP-045_fig01.py`.

4.6 The roster ceiling, which is exact The Brooks crossover of §4.5 is a best-case comparison and it rests on a modelling choice (`M_eff = m`). There is a second bound that rests on nothing but the ceiling result R5 of the minimum-frequency paper [Curzi, 2026], and it is exact.

THEOREM 4.3 — THE ROSTER CEILING. Since `F <= ln N` and sustainability requires `c/eta <= ln N`, a group with per-link cost `kappa` and conversion `eta` is sustainable at *any* geometry only if

```
kappa m ( m − 1 ) / 2  <=  eta ln N        i.e.        m ( m − 1 )  <=  2 eta ln N / kappa
```

Proof: substitute `C = kappa m(m−1)/2` into `c/eta <= ln N`. **QED.**

Computed for the cases this framework carries, at `N = 12`, `ln N = 2.484906649788`:

case	eta	kappa	m(m−1) bound	m_max
commons	0.34	0.055	30.7225	6
family (Sec 5)	0.34	0.130	12.9980	4
team (Sec 5)	0.52	0.055	46.9873	7
carried dyad	0.30	0.620	2.4047	2
dyad at 2b	0.44	0.400	5.4668	2

The commons sits at exactly its roster ceiling — `m(m−1) = 30` against a bound of 30.7225 — which is why the classification of the minimum-frequency paper [Curzi, 2026] returns TUNABLE for it with a margin of only 0.058436 nats. A seventh member would make it structural outright, and no assignment of `u` whatsoever would save it.

The two bounds answer different questions and both are needed. Theorem 4.3 says whether *any* geometry could work. Theorem 4.2 says whether the best achievable geometry would. A group inside 16.3 and outside 16.2 is one whose survival depends on being extraordinarily well composed.

4.6b The hold line by roster size The hold-line corollary R6 [Curzi, 2026] gives the geometry required for a relation to hold exactly: `u* = (e^(c/eta) − 1)/(N − 1)`. At group scope, with `C = kappa m(m−1)/2`, that becomes a function of the roster and it is the most direct way to see what quadratic cost does.

Computed at `kappa = 0.055`, `eta = 0.34`, `N = 12`:

m	links	C	c/eta	u* required to HOLD	
2	1	0.0550	0.161765	0.015962	
3	3	0.1650	0.485294	0.056787	
4	6	0.3300	0.970588	0.149045	
5	10	0.5500	1.617647	0.367383	
6	15	0.8250	2.426471	0.938078	
7	21	1.1550	3.397059	2.625100	UNREACHABLE, u <= 1
8	28	1.5400	4.529412	8.336728	UNREACHABLE
9	36	1.9800	5.823529	30.651224	UNREACHABLE
10	45	2.4750	7.279412	131.739523	UNREACHABLE
12	66	3.6300	10.676471	3938.488241	UNREACHABLE

The `u*` column rises far faster than the roster does, because it is exponential in a quantity that is quadratic in `m`. Two members need 1.6% non-parallelism to break even at this link price. Six need 93.8%, which is the commons' figure of the carried commons [Curzi, 2026] arriving from the cost side rather than from the geometry side. Seven need more than exists.

The seventh member does not make the problem harder; it makes it insoluble, and the transition between those two states occupies no interval at all — one member, and the required geometry goes from demanding to unavailable. That is the roster ceiling of Theorem

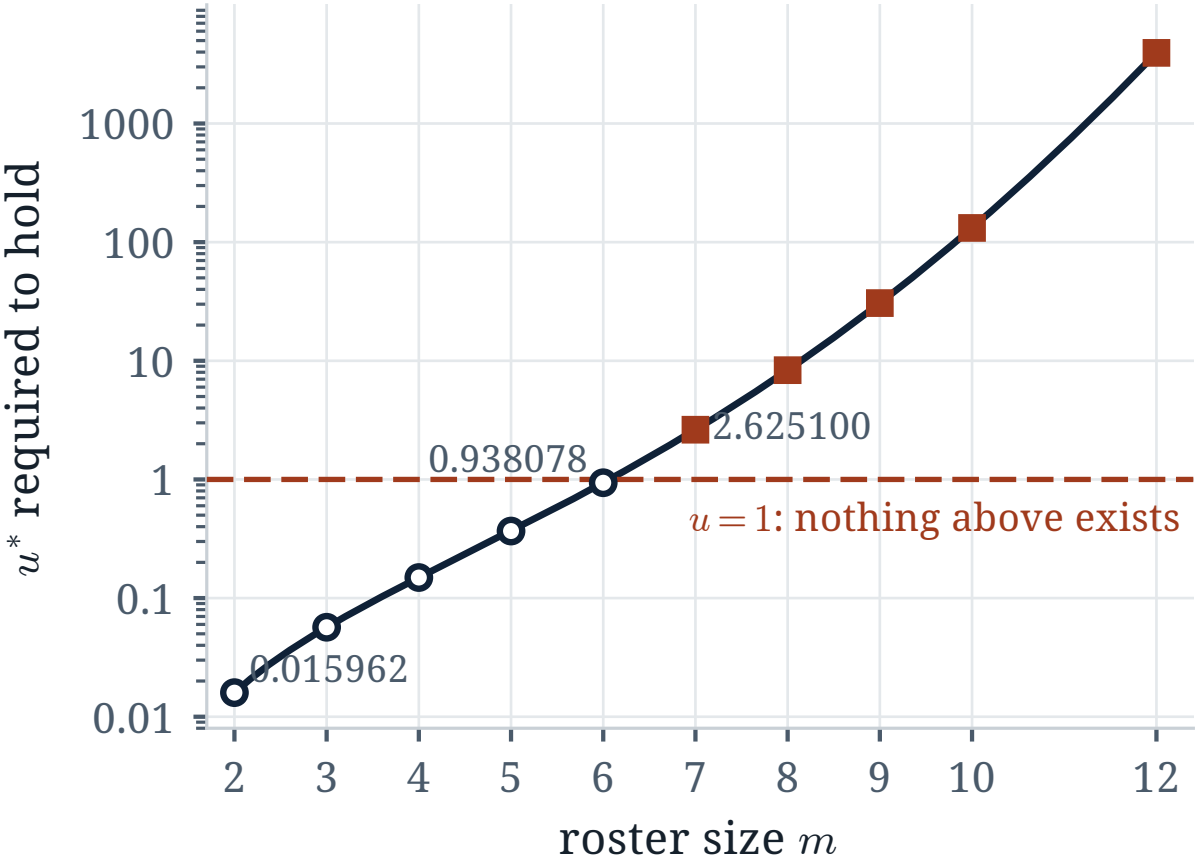

Figure 45.2: **The seventh member is not a harder problem, it is an unavailable one.** The geometry a roster must field merely to hold, $u^* = (e^{c/\eta} - 1)/(N - 1)$ with $C = \kappa m(m-1)/2$, is exponential in a quantity quadratic in m: two members need 1.6 per cent non-parallelism, six need 93.8 per cent, and seven need 2.6251 — more than exists. Modelled at $\kappa = 0.055$, $\eta = 0.34$, $N = 12$; values from the table of §4.6b; script `figs/src/CCP-045_fig02.py`.

4.3 written as a requirement on `u`, and it is the same statement the hold-line corollary R6 [Curzi, 2026] makes about a dyad.

A second sweep, holding the geometry fixed at the constructed triad's `u_bar = 0.390773` and varying only the roster:

```
 m    C        c/eta       D            Q_inf     verdict
 2   0.0550   0.161765   −4.344415      +5.6880   ACCUMULATES
 3   0.1650   0.485294   −3.410906      +4.4658   ACCUMULATES
 4   0.3300   0.970588   −2.010644      +2.6325   ACCUMULATES
 5   0.5500   1.617647   −0.143626      +0.1880   ACCUMULATES, barely
 6   0.8250   2.426471   +2.190145      −2.8675   DECAYS
 7   1.1550   3.397059   +4.990671      −6.5342   DECAYS, STRUCTURAL
 8   1.5400   4.529412   +8.257951     −10.8120   DECAYS, STRUCTURAL
12   3.6300  10.676471  +25.994613     −34.0342   DECAYS, STRUCTURAL
```

A group of people every one of whom is as well matched to the others as the constructed triad's members are — `u_bar` held at 0.390773 for every pair, which is a strong assumption at any size — crosses from accumulating to decaying between five and six members, and from tunable to structural between six and seven. **The geometry is doing nothing wrong in any row of that table. The roster is.**

4.7 The uncomfortable result: a pair already reaches the ceiling Now the statement flagged in the opening, which follows from the construction in two lines.

`F = ln(1 + (N−1) u_bar)` is maximised at `u_bar = 1`, giving `F = ln N`. Two unit vectors can be orthogonal, `cos theta = 0`, hence `u = 1`. **Therefore a single orthogonal pair already attains the maximum surplus the twelve-category system admits, and no roster of any size attains more.**

```
orthogonal pair:   u_bar = 1,  F = ln 12 = 2.484907,  f = k ∗ 144 = 69.6133 Hz
orthogonal six:    u_bar = 1,  F = ln 12 = 2.484907,  f = k ∗ 144 = 69.6133 Hz
                   −− identical, and the six pays 15 links instead of 1
```

In surplus terms a group buys nothing a well-chosen pair could not, and pays `m(m−1)/2` times as much for it. That is the honest reading of the formalism and it should be stated before any of the qualifications, because the qualifications are where the wishful thinking gets in.

This is the point at which the external literature must be brought in rather than kept out, and it does not speak with one voice. The formal result that a diverse group of problem solvers can outperform a group of the best individual solvers [Hong and Page, 2004, 2001, Page, 2007] has been challenged on the ground that its conclusion follows from the model's parameterisation rather than from any empirical fact about diversity [Thompson, 2014, Singer, 2019, Grim et al., 2019, Kuehn, 2017]. The empirical literature is likewise mixed: a general collective-intelligence factor has been measured, and it is reported to track composition rather than headcount [Woolley et al., 2010, Engel et al., 2014, Bear and Woolley, 2011], while the organisational reviews find diversity effects that are small, conditional and frequently negative [Mannix and Neale, 2005, van Knippenberg and Schippers, 2007]. Aggregation of independent judgments is powerful [Galton, 1907, Surowiecki, 2004] and is destroyed by exactly the mechanism this framework calls low u — social influence collapsing the diversity of estimates [Lorenz et al., 2011], and cascades in which later members rationally ignore their own information [Bikhchandani et al., 1992, Banerjee, 1992]. **The result stated above is a statement about this framework's surplus functional, not a summary of that literature**, and where the two are compared the comparison is stated as such.

Now the qualifications, and they are real.

One: orthogonality is an idealisation, and mean pairwise `u_bar = 1` for six people requires all fifteen pairs to be orthogonal at once. Six mutually orthogonal unit vectors exist in twelve

dimensions, so it is geometrically possible — but the vectors are then extremely constrained, and the disjoint-support degeneracy, result R5 [Curzi, 2026] applies with force: six people described over non-overlapping state sets read `u = 1` for free and mean nothing by it. Achievable `u_bar` falls with `m` in every realistic composition, and the pair is the easiest place to find a large one.

Two: `F` is not the only thing a group is for. The formalism prices stored order per period. It has no term for redundancy against loss, for succession, for coverage across time zones or lifespans, for the fact that a pair ends when one of its members does. A group's non-surplus functions are entirely outside this reading and the reading does not weigh them — the boundary statement of the minimum-frequency paper [Curzi, 2026] states the boundary and it holds here without modification.

Three: `eta` and `kappa` are not roster-independent in practice. A group may convert better than a pair because it has structure a pair does not need, and the commons-governance material of §5.6 is largely about arrangements that lower `kappa` per link. The formalism holds them fixed because it is a formalism; a real design moves them.

Four: the ceiling is a ceiling on `F`, not on output. The framework's dyadic work makes the neighbouring point that a calibrated system at its own fixed point has headroom identically zero, so being at the ceiling is not an unqualified target [Curzi, 2026r]. Two people at `F = ln 12` and six people at `F = ln 12` bank at different rates if their `eta` differs, and `Q_inf = (eta F − c)/delta` is sensitive to all three.

With all four in hand the statement survives in a weaker and still useful form: the case for a larger group is never a case about surplus, because surplus is capped at a value a pair can reach. It is always a case about conversion, coverage, or continuity, and it should be made in those terms.

4.8 The opposition identity at group scope The relationship-frequency paper [Curzi, 2026] owns the unison result and it does not weaken with roster size. `u` depends only on `|rho|`, so a member recruited to a group specifically to disagree contributes `u = 0` to every pair in which the disagreement is systematic, exactly as an echo would, while adding `m − 1` new links to the cost.

```
adding a perfectly opposed member to a group of m:
    surplus contribution                    0
    cost contribution        kappa * (m − 1) per period
    octave contribution      +1.442695 * (kappa/eta) * 2(m−1)   −− strictly positive DEFICIT
```

A contrarian appointment is the only intervention in the framework that is guaranteed to make the reading worse by a computable amount. At `kappa/eta = 0.161765` and `m = 6`, adding one such member costs `+2.3338` octaves of deficit and returns nothing.

4.9 Honesty clauses at group scope **(1)** Essence frequencies, not physical resonances. No group, room, institution or person is claimed to resonate at any value here, and the minimum-frequency paper's [Curzi, 2026] FM 4.8 forbids playing `f_min` at anyone.

(2) No clinical, diagnostic or therapeutic claim; the twelve states are not diagnoses; this is not counselling and no reading here is an assessment of any person or of any group's health.

(3) All cases are constructed and labelled. The triad of the Worked Example is an explicitly labelled extension of the carried dyad of the carried dyad [Curzi, 2026].

(4) The reading inherits its inputs, and at group scope it inherits `m(m−1)/2` of them. Uncertainty in a group reading is not `m` times a dyadic uncertainty; it is whatever the aggregation gap and the least certain parameter jointly permit, and §4.3 gives the first term.

(5) Consent is structural, and at group scope it is per-member. Section 6 owns the procedure. **A group reading taken without every member's agreement is not a group reading; it is a reading about people, taken without them.**

(6) CC-R14 applies to the simulation in §4.4: it is a computation with a stated seed and trial count, not an observation of anybody.

The engineering

4.10 Reading a group, end to end

```
 0.  CONSENT from every member, separately, and revocable.                  Sec 6
 1.  DECLARE N and the ordering.                                            CCP-041
 2.  ELICIT intensities by magnitude estimation; publish every raw L2 norm. CCP-041
 3.  ENCODE each member as a unit vector; check support overlap.            CCP-042
 4.  COMPUTE all m(m-1)/2 pairwise u; PUBLISH THE LIST, not just the mean.  Sec 4
 5.  AGGREGATE: u_bar, F(u_bar), and mean-of-F. Report the gap.             CCP-041 SPEC 4.15
 6.  DECLARE kappa, eta, delta on one period; C = kappa m(m-1)/2.           CCP-041 SPEC 4.3
 7.  ROSTER CEILING TEST: m(m-1) <= 2 eta ln N / kappa.                     Thm 4.3
 8.  CEILING TEST: c/eta vs ln N; classify.                                 CCP-041 SPEC 4.1
 9.  COMPUTE f, f_min, D, Q_inf; fold and publish with j.                   CCP-041 SPEC 4.5
10.  SIGN THE NUMERATOR eta F - c.                                          CCP-044 SPEC 15.2
11.  DROP-ONE ANALYSIS.                                                     Sec 4.13
12.  REPORT sensitivity to the least certain parameter.                     CCP-041 SPEC 4.19
```

Step 4's instruction to publish the whole list is the one that costs nothing and catches the most. A mean of 0.39 is produced by three pairs at 0.39 and by one pair at 0.07 with two at 0.55, and those are entirely different groups. The list shows which, the mean does not, and §4.3's aggregation gap is computable only from the list.

4.11 Where the chord goes muddy, precisely Three distinct things happen as `m` grows, and they are usually described as one thing.

The class ceiling saturates. §4.4: six classes, reached in expectation by about six members holding four states each. After that, new members add no new classes.

The pair-per-class ratio grows without bound. From the table in §4.1: 0.5 at `m = 3`, 2.5 at `m = 6`, 11.0 at `m = 12`, 72.5 at `m = 30`. This ratio is the honest measure of muddiness — it is how many relationships are being carried by each available distinction.

The rendering floor does not move. The minimum class separation stays at 34.9756 cents for every `N <= 16`, because it is a property of the lattice and not of the roster (the mood-and-trait paper [Curzi, 2026]). A group of thirty sounds no finer than a group of three; it sounds the same six classes, more often.

COROLLARY 4.4 — THE MUDDINESS INDEX. For a roster of `m` on an `N`-category ladder,

```
mu  =  [ m(m-1)/2 ]  /  ceil(N/2)        relationships per available distinction
```

`mu > 1` first occurs at `m = 4` for `N = 12`. **From four members onward, a group has more relationships than it has distinguishable classes to express them in**, and every additional member worsens the ratio quadratically while the denominator is frozen.

This is not an argument that groups of four are bad. It is an argument about what a chord reading can and cannot tell you at four and above: the chord stops individuating relationships and starts reporting only the group's coverage of the lattice. Past `mu > 1` the useful group-level objects are the pairwise list, the drop-one analysis, and the deficit — not the chord.

4.12 The marginal member test The decision that actually arises is not "how big should the group be" but "should this person join." That is a marginal question and it has a clean form.

```
marginal surplus (best case)  =  2 log2( m / (m−1) )                octaves
marginal cost                 =  1.442695 ∗ (kappa/eta) ∗ 2(m−1)     octaves

ADD if surplus > cost
```

Computed at `kappa/eta = 0.161765`:

m	marginal surplus	marginal cost	verdict
2	+2.0000	0.4668	ADD
3	+1.1699	0.9335	ADD
4	+0.8301	1.4003	STOP
5	+0.6439	1.8670	STOP
6	+0.5261	2.3338	STOP
7	+0.4448	2.8005	STOP
8	+0.3853	3.2673	STOP

The marginal surplus falls like `1/m` and the marginal cost rises like `m`, so once the test flips it never flips back. There is no roster size at which adding members becomes worthwhile again, at fixed `kappa` and `eta`. The only way to reopen the question is to change the cost structure, which is §4.14 and the commons-governance material of §5.6.

The structure of the test — a marginal gain priced against a marginal cost, with the verdict flipping once incremental cost passes a computable threshold — recurs across the corpus; the structural work prices an optional addition the same way and finds it worth nothing at any probability once its incremental cost exceeds 8.9 per cent of the maintenance budget [Curzi, 2026].

Two cautions on using the test. It is a best-case surplus, so a real candidate must be compared against their actual contribution to `u_bar`, not against `2 log2(m/(m−1))`. And it is silent on everything a person is for besides surplus — the boundary statement of the minimum-frequency paper [Curzi, 2026]'s boundary applies, and a marginal test that returns STOP is not a statement that anyone should be excluded from anything.

4.13 The drop-one analysis The complement of the marginal test, run on an existing group: recompute the reading with each member's pairs removed, and look at what moves.

Computed on the constructed triad, at `kappa = 0.055`, `eta = 0.34`, `delta = 0.09`:

set	u_bar	links	C	f (Hz)	D	Q_inf	change in D
{A,B,C}	0.390773	3	0.1650	13.5718	−3.410906	+4.4658	—
{B,C}	0.550937	1	0.0550	24.0978	−5.172708	+6.7725	−1.761802
{A,C}	0.552647	1	0.0550	24.2264	−5.180385	+6.7826	−1.769478
{A,B}	0.068735	1	0.0550	1.4908	−1.157965	+1.5161	+2.252941

Removing either `A` or `B` improves the reading by about 1.77 octaves; removing `C` worsens it by 2.25. The reason is entirely geometric: `A` and `B` sit at `u = 0.0687`, near-parallel, and their pair is the one dragging `u_bar` down while still costing a link. `C` is the member carrying the group's non-parallelism.

A drop-one audit is also an m-fold multiple comparison performed after the data are in hand, which is the standard recipe for a false positive [Simmons et al., 2011, Gelman and Loken, 2013]. **What the drop-one analysis is for, and what it is not for, must be stated in the same breath.** It is a sensitivity analysis: it tells you which pairs are carrying the reading, which is information about the geometry of the set. It is not a ranking of people, it licenses no

conclusion about anyone's value or contribution, and a formalism with no single-party term cannot acquire one by being run `m` times. The correct use of the row that says "removing `A` improves the reading" is to notice that `A` and `B` are near-parallel and to ask what would raise `u` between them — which is the same conclusion the sustainable-dyad paper [Curzi, 2026] reached about the same pair.

4.13b The two-dyad group, and why triads are not four dyads One structure deserves separate treatment because it is common and because its reading is counterintuitive: the group that is really two pairs.

Take four members `{P, Q, R, S}` where `P–Q` and `R–S` are close pairs and the cross-links are distant. The six pairwise values might run `u(P,Q) = 0.08`, `u(R,S) = 0.08`, and four cross-pairs at 0.70. Computed:

```
u_bar           = (0.08 + 0.08 + 0.70*4)/6            = 0.493333
F( u_bar )      = ln(1 + 11*0.493333)                 = 1.860456 nats
mean of F(u)    = (2*ln(1.88) + 4*ln(8.70))/6         = 1.652639 nats
                  ln(1.88) = 0.631272   ln(8.70) = 2.163323
AGGREGATION GAP = 0.207817 nats = 0.599632 octaves
f optimistic    = 19.9665 Hz      f conservative = 13.1763 Hz
```

The gap is large, and it is large for a structural reason rather than a numerical one: **a group made of tight clusters is exactly the dispersion pattern Jensen's inequality punishes most, and it is also the most common real topology.** Families have it, teams have it, and any group formed by merging two existing groups has it by construction.

Two consequences follow. First, cluster-structured groups must always be read on both aggregations, and the constructed family of Section 5 is worked that way. Second, the within-cluster pairs are the ones the drop-one analysis will flag, for the same reason `A` and `B` are flagged in this section's triad: they cost a link and contribute little non-parallelism. The correct reading of that flag is never about the people; it is that the group is paying twice for one perspective, which is the relationship-frequency paper [Curzi, 2026]'s result about the sycophant's unison applied to a sub-group instead of to a pair.

And a triad is not three dyads plus overhead. It has a property no collection of pairs has: for any two members there is a third who is in relation to both, which is what makes mediation, witness and succession structurally possible. **None of that appears in `F`, and a section that computed only `F` would be reporting the smaller half of what a triad is.** The formalism prices stored order per period; the third member's structural role is real, is outside the price, and is not made unreal by being outside it.

4.14 Splitting, nesting, and what changes the exponent The one intervention that changes the *shape* of the cost function rather than its coefficient is topological: stop maintaining every link.

Ostrom's eighth design principle — nested enterprises — has a precise reading here. A flat group of `m` maintains `m(m−1)/2` links. A group partitioned into `g` sub-groups of size `m/g`, each maintaining its own links, plus one link per pair of sub-groups, maintains

```
g * (m/g)(m/g − 1)/2  +  g(g−1)/2        links
```

Computed for six members:

```
flat six                          15 links      C = 0.8250 at kappa 0.055
two triads + one bridge            7 links      C = 0.3850          −53.3%
three pairs + three bridges        6 links      C = 0.3300          −60.0%
```

Nesting is the only lever in this section that attacks the quadratic itself, and on six members it removes more than half the cost. The same move is measured in Series B on eighteen people rewired from a complete graph into three cells of six: headroom moves from -0.4571 to $+0.1189$, a swing of 0.576, with cost falling 63 per cent and the surplus ceiling untouched because $N = 18$ either way [Curzi, 2026b]. The bridges between cells are the structural-hole and weak-tie positions of the network literature [Granovetter, 1973, Burt, 1992, 2004], and the partition itself is the standard resilience move against correlated failure [Albert et al., 2000, Callaway et al., 2000, Newman, 2018]. Series B's CC-R15 material records the same result in the other register: P8 turns `O(N^2)` coordination into `O(N)`.

And it is not free, which Section 5 computes rather than asserts. Two members in different sub-groups now interact through a bridge, so whatever surplus their pair carried is attenuated or lost. Nesting is a trade of surplus for cost and the trade is only worth making when the lost pairs were carrying little — which, at a low `u_bar`, they are.

The specification

SPEC 4.1 — PER-MEMBER CONSENT, REVOCABLE. Every member agrees separately to a group reading and any member may withdraw at any point. A member's withdrawal ends their inclusion in the reading and may not be treated as a finding about them.

SPEC 4.2 — DECLARE `m` AND `N` SEPARATELY in every group reading, and never let `N` denote the roster.

SPEC 4.3 — PUBLISH THE FULL PAIRWISE LIST, not the mean alone. The list is what makes the aggregation gap and the drop-one analysis computable.

SPEC 4.4 — REPORT BOTH AGGREGATIONS. `F(u_bar)` and the mean of `F(u)`, with the gap in octaves. Where the verdict differs between them, report the verdict as NOT DETERMINED.

SPEC 4.5 — SUPPORT-OVERLAP GATE. Check every pair for disjoint support before computing. The encoding degeneracy R5 [Curzi, 2026] makes non-overlapping descriptions read `u = 1` for free.

SPEC 4.6 — ROSTER CEILING TEST (Theorem 4.3) before any lever prescription: `m(m−1) <= 2 eta ln N / kappa`.

SPEC 4.7 — DECLARE `kappa` PER LINK and state whether links are assumed uniform. Non-uniform link costs require `C = sum kappa_ij` and the roster ceiling is then stated on the sum.

SPEC 4.8 — REPORT THE MUDDINESS INDEX `mu = [m(m−1)/2]/ceil(N/2)` with any group chord, and do not present a chord as individuating relationships where `mu > 1`.

SPEC 4.9 — CITE THE REGIME, DO NOT RE-DERIVE IT. `N = 12` is below the `N = 17` cliff, the minimum class separation is 34.9756 cents, and the mood-and-trait paper [Curzi, 2026] owns both statements.

SPEC 4.10 — MARGINAL TESTS USE ACTUAL CONTRIBUTIONS. A candidate's effect on `u_bar` is computed from their vector, not from the best-case `2 log2(m/(m−1))`.

SPEC 4.11 — DROP-ONE IS A SENSITIVITY ANALYSIS. It is reported as a property of the geometry. No output of a drop-one analysis may be presented as a ranking, an evaluation, or a recommendation about a person.

SPEC 4.12 — CC-R8 CHECK ON RECRUITMENT. Report `cos theta` signed for any proposed member. A systematically opposed member contributes `u = 0` and `m − 1` links.

SPEC 4.13 — NESTING IS REPORTED WITH ITS LOST PAIRS. A topology change that removes links also removes whatever surplus those pairs carried; both terms are computed.

SPEC 4.14 — NO AGGREGATION ACROSS GROUPS (the no-aggregation rule [Curzi, 2026], and CC-R16: two nine-member groups with identical `u` and `S` lost 77% and 21% of surplus to the same three-person departure).

SPEC 4.15 — LABEL EVERY CASE CONSTRUCTED.

The failure modes

FM 4.1 — `N` USED FOR THE ROSTER. *Signature:* `F = ln(1 + (m−1)u)` computed with `m` in place of 12, or a ceiling of `ln m`. *Mechanism:* the two counts are different objects with different bounds (§4.2). *Computed:* on the constructed triad, `1 + 11 u_bar = 5.2985` and `1 + 2 u_bar = 1.7815` — a difference of 3.152 octaves in the reading. *Fix:* SPEC 4.2.

FM 4.2 — THE MEAN REPORTED WITHOUT THE LIST. *Signature:* one `u_bar` for a group, no pairwise values. *Mechanism:* the mean is compatible with wildly different geometries, and the aggregation gap is not computable from it. *Fix:* SPEC 4.3.

FM 4.3 — THE JENSEN SHORTCUT TAKEN SILENTLY. *Signature:* a group reading from `F(u_bar)` alone. *Mechanism:* strict concavity inflates `F`, inflates `f`, and under-reports `D`. Worth 0.507396 octaves on the constructed triad; 6.2% in Series B's worked office. *Fix:* SPEC 4.4.

FM 4.4 — THE ORTHOGONAL GROUP THAT IS AN ARTEFACT. *Signature:* a large group reading `u_bar` near 1. *Mechanism:* disjoint support. Members described over non-overlapping state sets are automatically orthogonal (the one-hot degeneracy R5 [Curzi, 2026], generalised). *Fix:* SPEC 4.5, and re-encode every member under one procedure.

FM 4.5 — GROWING A GROUP FOR SURPLUS. *Signature:* a roster expanded on the argument that more people means more perspective. *Mechanism:* §4.7. Surplus is capped at `ln N` and an orthogonal pair reaches it. Cost is not capped. *Fix:* make the case for the roster on conversion, coverage or continuity, which are real and are outside this reading.

FM 4.6 — THE ROSTER CEILING NOT TESTED. *Signature:* a lever prescription for a group that no geometry could sustain. *Mechanism:* Theorem 4.3. At `m(m−1) > 2 eta ln N / kappa` the case is structural and `u` is unavailable at every value. *Computed:* the commons sits at `m(m−1) = 30` against a bound of 30.7225; a seventh member takes it to 42 and makes it structural outright. *Fix:* SPEC 4.6, before anything else.

FM 4.7 — THE CONTRARIAN APPOINTMENT. *Signature:* a member recruited to disagree. *Mechanism:* CC-R8. `u` depends only on `|rho|`; opposition contributes zero surplus and `m−1` links. *Computed:* `+2.3338` octaves of deficit at `m = 6`, `kappa/eta = 0.161765`. *Fix:* SPEC 4.12.

FM 4.8 — THE CHORD READ AS A ROSTER PORTRAIT. *Signature:* a twelve-member group's chord presented as showing its variety. *Mechanism:* class saturation. At twelve members holding four states each, 5.98 of six classes are expected to be covered by chance alone. *Fix:* SPEC 4.8, and report `mu`.

FM 4.9 — DROP-ONE READ AS A RANKING. *Signature:* "the analysis says `A` is the weakest member." *Mechanism:* a drop-one row reports the effect of removing a set of pairs. The apparatus has no single-party term and cannot produce a statement about a person (the no-single-party-term prohibition [Curzi, 2026]). *Fix:* SPEC 4.11. Read the row as a statement about which pairs carry the geometry.

FM 4.10 — NESTING COSTED WITHOUT ITS LOSSES. *Signature:* a partition adopted for its link count, with `u_bar` assumed unchanged. *Mechanism:* removed links were carrying surplus. At high `u_bar` the loss dominates the saving. *Fix:* SPEC 4.13, and compute both terms.

FM 4.11 — THE AGGREGATED ORGANISATION. *Signature:* one deficit for a whole institution. *Mechanism:* CC-R16 — identical aggregates conceal topologies that lose 77% versus 21% of surplus to the same departure; CC-R10 — ratios do not average. *Fix:* SPEC 4.14. Per group, per period.

FM 4.12 — THE MARGINAL TEST USED AS AN EXCLUSION RULE. *Signature:* a STOP verdict treated as grounds for keeping someone out, or removing them. *Mechanism:* register slip. The test prices a link against a best-case surplus contribution and weighs nothing else whatsoever. *Fix:* §4.12's cautions, and the boundary statement of the minimum-frequency paper [Curzi, 2026]. A reading does not conclude that a relation should end and does not conclude anything about a person.

Worked example

THE CONSTRUCTED TRIAD — A, B, C CONSTRUCTED, and an explicitly labelled extension of the carried dyad of the carried dyad [Curzi, 2026]. A and B are the carried dyad exactly as found; C is a constructed third member. Parameters are chosen, not observed. **This is not an assessment of any person or group, no clinical, diagnostic or therapeutic claim is made, and the frequencies are essence frequencies.**

Inputs

```
A = {4: 0.7,  6: 0.5,  9: 0.4}                          raw L2 norm 0.948683
B = {4: 0.6,  6: 0.55, 9: 0.3,  10: 0.2}                raw L2 norm 0.890225
C = {3: 0.45, 4: 0.55, 6: 0.40, 7: 0.35, 11: 0.25}      raw L2 norm 0.921954

N = 12,  m = 3,  one declared period
kappa = 0.055 per link,  eta = 0.34,  delta = 0.09
```

Raw L2 norms are published because normalisation removes a free multiplier and the elicitation rule of [Curzi, 2026] rule requires it to stay recoverable.

Steps 3–4 — support and the pairwise list Every pair shares support — A and C on states 4 and 6, B and C on 4 and 6, A and B on 4, 6 and 9 — so SPEC 4.5's gate passes and no pair is orthogonal by construction.

```
u(A,B) = 0.068734665265     cos =  0.965021     F = 0.563085    f_pair =  1.4908 Hz
u(A,C) = 0.552647058824     cos =  0.668844     F = 1.957149    f_pair = 24.2264 Hz
u(B,C) = 0.550937094081     cos =  0.670122     F = 1.954489    f_pair = 24.0978 Hz

3 pairs, as m(m−1)/2 requires
```

The list already tells the story the mean will hide: one near-parallel pair and two well-separated ones.

Step 5 — aggregation, both ways

```
u_bar          = 0.390772939390
F( u_bar )     = 1.6674242020 nats      N_eff = 5.2985      f = 13.5718 Hz
mean of F(u)   = 1.4915742527 nats                          f =  9.5476 Hz

AGGREGATION GAP = 0.1758499493 nats = 0.507396 octaves = 609 cents
ratio of frequencies = 1.421482

R3 cross-check at roster scale:
    PR = 1.3522930095      m + 1 − m/PR = 1.7815458788
    1 + (m−1) u_bar        = 1.7815458788        error 0.00e+00
    M_eff = 1.7815 of a possible 3
```

Steps 6–8 — costs and the two ceiling tests

```
links   = m(m-1)/2 = 3
C       = 0.055 * 3 = 0.1650
c/eta   = 0.1650/0.34 = 0.485294

ROSTER CEILING (Thm 4.3): m(m-1) = 6  <=  2*0.34*2.484907/0.055 = 30.7225      PASS
CEILING TEST  (CCP-041 SPEC 4.1): 0.485294 <= 2.484907                            TUNABLE
BROOKS (Thm 4.2): r = 0.161765, max viable roster 4, actual 3                     WITHIN
```

Step 9 — the reading

```
f                =  13.5718 Hz         folded 434.296 Hz (j = 5)
f_min            =   1.2760 Hz         folded 326.656 Hz (j = 8)
octaves required =   1.400263
octaves present  =   4.811169
OCTAVE DEFICIT   =  -3.410906          (-4093.1 cents)
N_eff required   =   1.6247
pitch headroom   =   2.3588 octaves
Q_inf            =  +4.465825
identity check   : -2.885390 * (0.09/0.34) * 4.465825 = -3.410906
VERDICT: ACCUMULATES

conservative (mean-of-F): f = 9.5476 Hz, D = -2.903511, Q_inf = +3.801503
both aggregations ACCUMULATE -- verdict determined
```

Step 10 — the numerator

```
eta F - c  =  0.34 * 1.6674242020 - 0.1650  =  +0.401924        POSITIVE
```

So `delta` interventions are available here and would help — the ordering rule [Curzi, 2026] is satisfied and trust, in this group, multiplies a positive sign. That was not true of the same `A` and `B` without `C`.

The comparison that makes this section The carried dyad `{A, B}` at the cost structure of the sustainable-dyad paper [Curzi, 2026] — `c = 0.62`, `eta = 0.30` — read `+4.338420` octaves and DECAYS. The triad `{A, B, C}` at a per-link cost of 0.055 and `eta = 0.34` reads `-3.410906` and ACCUMULATES.

Two things changed, and honesty requires separating them. The geometry changed: `u_bar` rose from 0.068735 to 0.390773 because `C` is genuinely non-parallel to both. And the cost structure changed: this reading prices a link at 0.055 where the sustainable-dyad paper's [Curzi, 2026] dyad priced its single link at 0.62, a factor of 11.2727.

That is not an inconsistency; it is what a link costs in each situation, and the point of the comparison is that both terms have to be declared. A third member does not rescue a dyad by existing. It rescues it only where the link price is low enough that three links cost less than the surplus the third member's non-parallelism supplies. Priced at the carried dyad's own `kappa`, the same triad would carry `C = 3 * 0.62 = 1.86`, `c/eta = 6.2`, which exceeds `ln 12 = 2.484907` — a STRUCTURAL case with a deficit of `+13.078` octaves.

```
the same three people, two link prices

kappa = 0.055, eta = 0.34   C = 0.1650   c/eta = 0.485294   D = -3.410906   ACCUMULATES
kappa = 0.620, eta = 0.30   C = 1.8600   c/eta = 6.200000   D = +13.078     STRUCTURAL
```

The roster is not the variable that decides a group. The ratio of link price to conversion is.

The group chord

```
states spanned: 3, 4, 6, 7, 9, 10, 11      (seven of twelve)

 n     f = k n^2 (Hz)     folded (220–440)     j     odd part = class
 3          4.3508             278.453          6           3
 4          7.7348             247.514          5           1
 6         17.4033             278.453          4           3
 7         23.6879             379.006          4           7
 9         39.1575             313.260          3           9
10         48.3426             386.741          3           5
11         58.4945             233.978          2          11

distinct classes: {1, 3, 5, 7, 9, 11} -- six, which is ceil(12/2), the whole ceiling
states 3 and 6 share class 3: one of the seven states adds pitch but no new class
muddiness index mu = 3 / 6 = 0.500
```

Seven states, six classes, three members: the chord is already saturated at the class ceiling. The `ceil(N/2)` class count, result R1 of the mood-and-trait paper [Curzi, 2026], is doing all the work and the roster is doing none of it — a fourth member could add at most the one class already present twice, which is to say nothing.

Drop-one

set	u_bar	C	f (Hz)	D	Q_inf	change in D
{A,B,C}	0.390773	0.1650	13.5718	−3.410906	+4.4658	—
{B,C}	0.550937	0.0550	24.0978	−5.172708	+6.7725	−1.761802
{A,C}	0.552647	0.0550	24.2264	−5.180385	+6.7826	−1.769478
{A,B}	0.068735	0.0550	1.4908	−1.157965	+1.5161	+2.252941

The near-parallel pair is the one costing the group, and the reading says so twice. Removing either member of it raises `u_bar` by about 0.16 and removes a link. What the analysis does not say, cannot say, and must not be reported as saying, is anything at all about `A` or `B` as people — SPEC 4.11 and the boundary statement of the minimum-frequency paper [Curzi, 2026] both govern here, and the actionable reading is the sustainable-dyad paper's [Curzi, 2026]: `A` and `B` sit at `cos theta = 0.9650` and the question is what would raise `u` between them.

The card

```

```

What this section established Four results, and the fourth is the one to carry forward.

One: intervals go as `m(m−1)/2`, classes are capped at `ceil(N/2) = 6`, and the ratio between them — the muddiness index — passes 1 at four members and never comes back.

Two: aggregation is a choice with a price. `F(u_bar)` and mean-of-`F` differed by 0.507396 octaves on three members and by 0.000001 octaves on the commons' fifteen pairs, and both must be published.

Three: cost is quadratic and certain; surplus is logarithmic at best and capped absolutely. The crossover `2 ln m = r m(m−1)` and the exact roster ceiling `m(m−1) <= 2 eta ln N / kappa` bracket every group this framework reads.

Four: a group's case is never a surplus case, because an orthogonal pair already reaches the ceiling. Whatever else a family, a team or a commons is for, the formalism prices only the stored order, and Section 5 takes those three structures and reads all of them — including one that cannot be repaired at all.

Section 5 reads three relational structures in full and carries the commons of the carried commons [Curzi, 2026], where the deficit is +6.4638 octaves and no single lever closes it. Section 6 takes the interventions.

5 Three relational structures read in full

Section 4 built the apparatus for reading a set larger than two. This section uses it three times, on three structures that differ in every parameter the formalism has, and reports what comes back.

The three are chosen because they are the structures people actually live inside, and because they fail differently. A family is a cluster geometry with expensive links and a long memory. A team is a selected geometry with an explicit conversion mechanism. A commons is a large flat roster whose members were chosen for agreement, and it is the one this section exists for.

The three readings come back as follows, and the third is the point:

STRUCTURE	m	u_bar	deficit D	Q_inf	verdict
the family	4	0.645160	+0.584737	−1.378049	DECAYS, marginally
the team	5	0.788228	−3.495327	+6.999131	ACCUMULATES
the commons	6	0.018614	+6.463800	−8.463000	DECAYS, and cannot be tuned

No single lever closes a 6.4638-octave gap. Raising the commons' `u` to 0.95 — near orthogonality, for six people drawn from one doctrine — closes it by 0.0332 octaves and no more. Raising `eta` to 0.90 leaves `+2.1075`. Cutting the per-link cost to 0.020 leaves `+2.0085`. There is no assignment of any one of the four levers that makes that commons sustainable, and the reason is not that the numbers are bad. It is that a group whose members were selected for agreement has almost no non-parallelism to convert, and the cost of maintaining fifteen links has to be paid against surplus that is not there.

Some systems cannot be tuned. They must be restructured, and the diagnostic is what tells you which case you are in.

A framework that only showed fixable examples would be lying by selection, and the honest thing to do with an instrument is to run it on a case it cannot help. This section does that, computes exactly how far every lever falls short, and then computes what restructuring would have to mean — which turns out to be a change of membership, not a change of arrangement.

Every case here is CONSTRUCTED and labelled. Nothing in this section is clinical, diagnostic or therapeutic; none of it is counselling; the twelve states are not diagnoses; and the frequencies are essence frequencies — no family, team, commons or person is claimed to resonate at any value.

The law

5.1 What a relational structure is, in this formalism A structure is five declarations and nothing else. Everything this section says about families, teams and commons is a statement about one of these five, and where it is not, the section says so.

```
1. THE ROSTER            m, the number of members
2. THE GEOMETRY          the m(m-1)/2 pairwise u values, and their mean u_bar
3. THE COST TOPOLOGY     which pairs maintain a link, and kappa for each
4. THE CONVERSION        eta -- the fraction of interaction becoming durable structure
5. THE LOSS              delta -- the per-period rate at which stored order leaks
```

A "family," a "team" and a "commons" are not primitives in this formalism; they are characteristic patterns across those five declarations, and the pattern is what does the work. Nothing is being claimed about kinship, employment or land tenure. The names are labels for parameter signatures, and the signatures are what follow.

SIGNATURE	roster	geometry	topology	eta	delta
family	small	clustered; one near-parallel pair	dense, high kappa per link	moderate	LOW
team	small	selected for non-parallelism	dense, low kappa	HIGH	moderate
commons	larger	near-parallel by membership rule	flat, uniform kappa	low	moderate

The family's signature is a low `delta` — shared history is a memory that does not leak fast — paid for with a high `kappa`, because family links are maintained under conditions nobody chose. The team's signature is a high `eta`, because a team has apparatus for turning interaction into artefacts, and a geometry that was selected rather than inherited. **The commons' signature is a membership rule that selects for agreement, and that rule is the whole of its problem.**

5.2 The Parallel Wall, priced Series B names the Parallel Wall: a set of parties whose representations point the same way returns no surplus however many of them there are and however hard they work. The frequency register prices it exactly.

```
six members drawn from one doctrine       CARRIED COMMONS, CONSTRUCTED
```

```
mean pairwise u  =  0.018614    over 15 pairs
F                =  0.186272 nats
N_eff            =  1.204754        of a possible 12
f                =  0.7017 Hz       folded 359.270 Hz (j = 9)
```

This is the corpus's own result restated in 1952: diversification benefit depends on covariance, not on count [Markowitz, 1952, 1959], and the same point is standard in the ecological stability literature, where the portfolio effect requires asynchrony rather than richness [Doak et al., 1998, Schindler et al., 2010, Tilman et al., 1998]. The concentration instrument reaches it a third way: a naive count of four jurisdictions falls to an effective count of 1.00 once they are recognised as one bloc [Curzi, 2026], and even the most generous counterfactual splitting leaves an effective count of 1.423998 against a designed 2.941176 [Curzi, 2026].

`N_eff = 1.2048` is the figure to sit with. Six people, fifteen relationships, and 1.20 people's worth of distinct view among them. They are not lazy, not unintelligent, and not in conflict. They were selected — by a doctrine, a hiring filter, a shared training, a common origin — for pointing the same way, and the selection worked. Selection of that kind is a documented mechanism: homophilous sorting produces near-uniform local composition from mild individual preferences [Schelling, 1971, 1978], and shared training removes the independence on which aggregation of judgments depends [Lorenz et al., 2011, Hong and Page, 2004].

The frequency `0.7017 Hz` is 0.5375 octaves above the ground essence `k`. A group of six that has travelled just over half an octave from "no relationship at all" is a group whose relationships are almost entirely redundant with each other, which is the consonance-redundancy identity R2 [Curzi, 2026] at group scope: the most consonant pairs are exactly the pitch-class collisions, so a maximally consonant set is a maximally redundant one.

5.3 The commons reading in full

```
THE COMMONS -- CONSTRUCTED, THE CARRIED COMMONS
m = 6, N = 12, one declared period
kappa = 0.055 per link,  15 links,  C = 0.8250,  eta = 0.34,  delta = 0.09

u_bar            =  0.018614
F                =  0.186272 nats          N_eff = 1.204754
f                =  0.7017 Hz              folded 359.270 Hz (j = 9)
octaves present  =  0.5375

c/eta            =  0.8250/0.34 = 2.426471
ln 12            =  2.484906649788
margin           =  +0.058436 nats                    BELOW the ceiling: TUNABLE
roster ceiling   :  m(m-1) = 30  <=  2*0.34*ln12/0.055 = 30.7225        PASS, barely

f_min            =  61.9349 Hz             folded 247.740 Hz (j = 2)
octaves required =  7.0013
OCTAVE DEFICIT   =  +6.4638                (+7756.6 cents)
N_eff required   =  11.3189   of a possible 12
pitch headroom   =  6.6324 octaves
numerator eta F - c = -0.761666            NEGATIVE
Q_inf            =  -8.4630
VERDICT: DECAYS
```

`N_eff required = 11.3189` against `N_eff achieved = 1.2048` is the reading in one line. These six must field 11.32 categories' worth of distinct view to break even and they field 1.20.

5.4 No single lever closes it, and here is each one falling short Every figure below is computed from the same starting point, varying exactly one parameter.

LEVER 1 — raise `u`.

```
u -> 0.20   f =  4.950 Hz    deficit  +3.6452
u -> 0.40   f = 14.097 Hz    deficit  +2.1354
u -> 0.60   f = 27.923 Hz    deficit  +1.1493
u -> 0.80   f = 46.428 Hz    deficit  +0.4158
u -> 0.95   f = 63.378 Hz    deficit  −0.0332      closes, by 0.0332 octaves
u -> 1.00   f = 69.613 Hz    deficit  −0.1686      the absolute maximum available
```

The hold line is at `u* = (e^2.426471 - 1)/11 = 0.938078`, and the whole reserve above it is 0.1686 octaves. So this lever technically closes the gap, and the closure is worthless: it requires that six people selected from one doctrine reach 93.8% non-parallelism, which is not a tuning of a group but a different group. And it arrives with 40 cents of margin, which the minimum-frequency paper [Curzi, 2026] §4.20 notes is about a fifth of a semitone — no margin at all against any increase in cost.

LEVER 2 — raise `eta`.

```
eta -> 0.34   c/eta = 2.426471   deficit  +6.4638
eta -> 0.50   c/eta = 1.650000   deficit  +4.2234
eta -> 0.70   c/eta = 1.178571   deficit  +2.8632
eta -> 0.90   c/eta = 0.916667   deficit  +2.1075
eta -> 1.00   c/eta = 0.825000   deficit  +1.8430      perfect conversion, still failing
```

At `eta = 1.00` — every unit of interaction becoming permanent structure, nothing lost, which is physically the end of the scale — the commons is still short by 1.8430 octaves. The lever does not merely fall short; it is exhausted while the gap is still nearly two octaves wide.

LEVER 3 — cut `kappa`.

```
kappa -> 0.055  (C = 0.825)   deficit  +6.4638
kappa -> 0.040  (C = 0.600)   deficit  +4.5544
kappa -> 0.030  (C = 0.450)   deficit  +3.2814
kappa -> 0.020  (C = 0.300)   deficit  +2.0085
kappa -> 0.010  (C = 0.150)   deficit  +0.7355
kappa -> 0.005  (C = 0.075)   deficit  +0.0990      still failing, at a 91% cut
```

A 91% reduction in per-link cost leaves the commons 0.0990 octaves short. The cost side can be cut almost to nothing and the group still does not sustain, because the surplus it is trying to pay for is 0.186272 nats.

LEVER 4 — raise `N`.

```
N -> 12    F = 0.186272   present 0.5375   deficit  +6.4638
N -> 17    F = 0.260689   present 0.7522   deficit  +6.2491
N -> 25    F = 0.369310   present 1.0656   deficit  +5.9357
N -> 41    F = 0.556502   present 1.6057   deficit  +5.3956
N -> 64    F = 0.775962   present 2.2390   deficit  +4.7624
N -> 144   F = 1.297955   present 3.7451   deficit  +3.2562
```

One hundred and forty-four categories — twelve times the ladder this framework uses — leaves the commons 3.2562 octaves short. The minimum-frequency paper [Curzi, 2026] gives the mechanism: `N` enters `F` only multiplied by `u`, so adding categories to a near-parallel set adds dimensions nobody is using. At `u = 0.018614` a new category buys 0.0446 octaves. And the route crosses the `N = 17` cliff at the second row, where the folded lattice's minimum separation collapses from 34.9756 cents to 6.0008 and the symbol rate falls by a factor of exactly 8 (the mood-and-trait paper [Curzi, 2026] owns the regime statement).

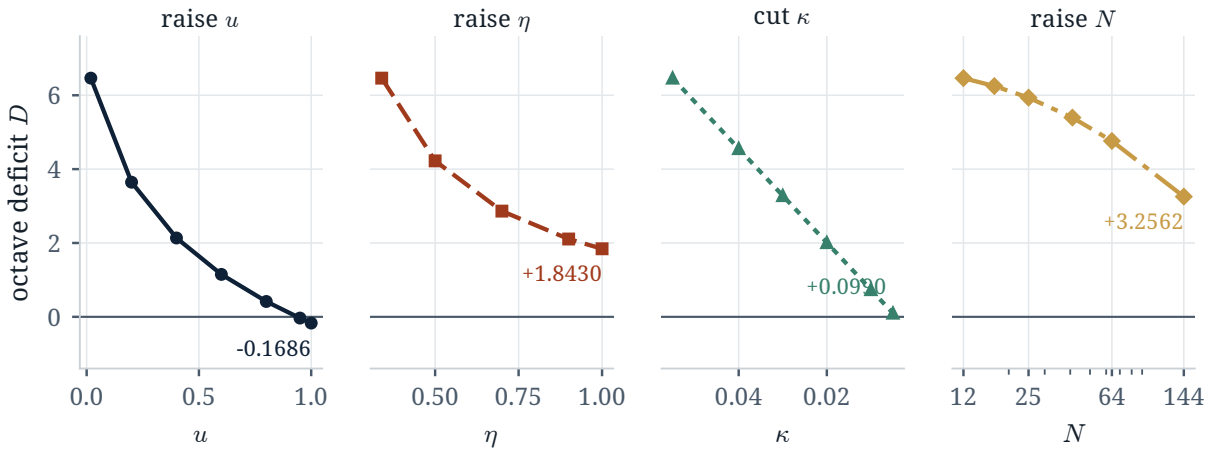

Figure 45.3: **Every lever swept to its physical limit, and every one short.** The constructed commons at a deficit of $+6.4638$ octaves, with each of the four levers driven to the end of its range while the other three are held. Only u crosses $D = 0$, at -0.1686 octaves and only by replacing the membership; perfect conversion leaves $+1.8430$, a 91 per cent cost cut leaves $+0.0990$, and twelve times the category count leaves $+3.2562$. Four panels because the four levers are in four different units. Computed from the lever tables of §5.4; script `figs/src/CCP-045_fig03.py`.

> **THE FOUR-LEVER RESULT, COMPUTED: at `u = 1` the gap is closed by 0.1686 octaves; at `eta = 1` it is still open by 1.8430; at a 91% cost cut it is still open by 0.0990; at twelve times the category count it is still open by 3.2562. Only one lever closes it alone, and only by replacing the membership.**

5.5 The reachability test — a case can be formally tunable and practically not The classification of the minimum-frequency paper [Curzi, 2026] returns TUNABLE for the commons, because `c/eta = 2.426471` is below `ln 12 = 2.484907`. That verdict is correct and it is not enough, and this section adds the test that completes it.

DEFINITION 5.1 — REACHABILITY. A tunable case is REACHABLE if the required geometry `u* = (e^(c/eta) - 1)/(N-1)` lies within the range the parties can honestly represent, and UNREACHABLE otherwise. Reachability is not a property of the formalism; it is a declared judgment about the parties, and it must be declared rather than assumed.

```
THE THREE-WAY CLASSIFICATION, EXTENDED

D <= 0                                SUSTAINABLE
D > 0, c/eta <= ln N, u* reachable    TUNABLE AND REACHABLE     tune it
D > 0, c/eta <= ln N, u* not          TUNABLE, UNREACHABLE      restructure it
c/eta > ln N                          STRUCTURAL                restructure it
```

Computed for the three structures of this section:

```
structure     c/eta       ln N       u* required     u_bar now     classification
family      2.294118   2.484907      0.810517        0.645160     tunable, reachable
team        1.057692   2.484907      0.134733        0.788228     sustainable already
commons     2.426471   2.484907      0.938078        0.018614     tunable, UNREACHABLE
```

The family needs a 25.6% rise in `u_bar` and the commons needs a factor of 50.4. The formal test does not distinguish them; the reachability test does, and it is the difference between an afternoon's work and a different organisation.

The margin figure is worth reporting alongside. The commons sits 0.058436 nats below the ceiling — 0.1686 octaves. Theorem 4.3 says the same thing about its roster: `m(m−1) = 30` against a bound of 30.7225. A seventh member takes `m(m−1)` to 42 and the case becomes STRUCTURAL outright, at which point `u` is unavailable at every value whatsoever. The commons is not near a boundary in one variable; it is near it in both, which is what a group at the end of its arrangement looks like from inside the arithmetic.

5.6 Ostrom, applied where it applies and priced where it does not

Ostrom's design principles for durable common-pool institutions [Ostrom, 1990, 2010] are the standard answer to the tragedy argument [Hardin, 1968], and the principles have been subjected to a systematic empirical review that finds broad but uneven support [Cox et al., 2010]. Their dynamical relatives — reciprocity under repeated interaction [Axelrod, 1984, Axelrod and Hamilton, 1981, Nowak and Sigmund, 2005] and the social-capital literature [Putnam et al., 1993, Gambetta, 1988, Fukuyama, 2001] — are the empirical warrant for treating monitoring, sanctioning and nesting as arrangements that change parameters at all. Series B mapped them to the storage-law parameters; this section carries the mapping into the frequency register and prices three of them on this commons. The mapping is Series B's and is badged as a correspondence of dynamics, not of agency (CC-R16).

P4 — monitoring. Series B's finding is specific and slightly awkward: monitoring lowers the variable cost `c_v` and does **not** raise the trust parameter `a`. In this register that means P4 is a `c` lever, not a `delta` lever, and Theorem 4.9 applies to the half of it people expect to matter: **an intervention on `delta` does not move the deficit by any amount whatsoever.** On this commons P4 helps only through the `c` column of §5.4, where a 91% cut still leaves 0.0990 octaves.

P5 — graduated sanctions. Priced in Series B at −7.7% of `eta S`. Computed here:

```
eta * F        =  0.34 * 0.186272 =  0.063332
P5 cost        =  0.077 * 0.063332 = 0.004877
numerator      = −0.761666  ->  −0.766544
Q_inf          =  −8.462972  ->  −8.517157
```

P5 makes this commons slightly worse, because it is a cost levied against a surplus that does not exist. That is not an argument against graduated sanctions; it is the ordinary observation that a governance mechanism priced as a fraction of surplus is affordable in proportion to the surplus, and this commons has 0.186272 nats of it.

P8 — nested enterprises. This is the only Ostrom principle that changes the exponent rather than a coefficient, and Series B records it as turning `O(N^2)` coordination into `O(N)`. Computed on six members:

```
flat six                     15 links    C = 0.8250    c/eta = 2.426471    D = +6.4638
two triads + one bridge       7 links    C = 0.3850    c/eta = 1.132353    D = +2.7298
three pairs + three bridges   6 links    C = 0.3300    c/eta = 0.970588    D = +2.2630
```

Nesting removes 53.3% of the cost and leaves the commons 2.7298 octaves short. It is the largest single structural improvement available and it does not close the gap, because the gap is not principally a cost problem.

Where Ostrom applies here and where it does not, stated plainly. The eight principles are arrangements: boundaries, congruence, collective choice, monitoring, sanctions, conflict resolution, recognition, nesting. Every one of them acts on `c`, on `eta`, or on `delta`, and not one of them acts on `u`. There is no design principle for making the members of a group less alike, because that is not a design question about the institution — it is a question about who is in it.

5.7 Restructuring, defined against tuning The section's central distinction, stated so it can be applied.

```
TUNING          changing eta, c, delta, or N, with the membership held fixed
RESTRUCTURING   changing the membership, the topology, or the boundary of the group
```

`u` is the only parameter that a group cannot tune, because `u` is a property of who its members are. Everything else in the five declarations of §5.1 is an arrangement and can be rearranged. The geometry is a fact about the roster.

That gives the operational rule:

> **If the deficit can be closed without changing `u`, it is a tuning problem. If it cannot, it is a membership problem, and no amount of better arrangement will substitute.**

Applied to the three cases: the family's deficit of `+0.584737` closes on `eta` alone with a 9.7% improvement (§5.10), so it is a tuning problem. The team is already sustainable. The commons needs `u` to rise by a factor of 50.4 and therefore is not a tuning problem at all, which is what §5.4's four failed levers were demonstrating one at a time.

5.8 Honesty clauses **(1)** Essence frequencies, not physical resonances. Nothing here is claimed to vibrate and nothing is to be played at anyone (the no-sounding prohibition [Curzi, 2026]; the no-subliminals rule is absolute).

(2) No clinical, diagnostic or therapeutic claim. The twelve states are not diagnoses. **This is not counselling, therapy or family assessment of any kind, and a reader in difficulty with a family, a team or a community should seek help from someone qualified to give it, which this framework is not.**

(3) Every case is constructed and labelled. The family and the team are explicitly labelled extensions of the carried dyad of the carried dyad [Curzi, 2026]; the commons is the carried commons [Curzi, 2026].

(4) No single-party term exists in the apparatus. No reading in this section licenses a conclusion about any person's value, contribution, or fitness for a group.

(5) Consent is structural and per-member (SPEC 4.1), and §5.14 works out what that requires when a decline changes the reading.

(6) The reading inherits its inputs. A group reading rests on `m(m−1)/2` measured values plus three declared parameters, and its uncertainty is reported (the sensitivity-reporting rule [Curzi, 2026]).

The engineering

5.9 The three structures side by side

	FAMILY	TEAM	COMMONS

------------------------------------------------------------------------
```

The corpus has one nearby measured case, and it points the same way: a consortium at $u = 0.52$, collecting 73.8 per cent of its ceiling, still reached a steady state of -0.0836 and headroom of -0.4582, with the binding fault a conversion parameter rather than difference [Curzi, 2026s].

Three structures, three verdicts, and the parameter that separates them is not the one anybody would guess.

It is not roster size — the failing commons is only two larger than the working team. It is not cost per link — the commons and the team pay the identical 0.055. It is `u_bar`, and the commons' is 42 times smaller than the team's.

5.10 The family — a cluster geometry with a cheap fix and an unresolved verdict The family's pairwise list shows the cluster structure §4.13b describes:

```
u(A,B) = 0.068735      the near-parallel pair
u(A,D) = 0.710180      u(A,E) = 0.711015
u(B,D) = 0.723966      u(B,E) = 0.740352
u(D,E) = 0.916710
```

One tight pair, five wide ones. That dispersion produces an aggregation gap of 0.394666 octaves — substantial, and both readings must be published. Here they agree on the verdict:

```
optimistic  F(u_bar) = 2.091463    f = 31.6922 Hz    D = +0.584737    Q_inf = -1.378049
conservative mean-of-F = 1.954682  f = 24.1071 Hz    D = +0.979403    Q_inf = -2.308160
```

Both decay, so the verdict is determined, and it is a small deficit. The levers:

```
L1  u   must reach 0.810517 from 0.645160      +0.165357, a factor of 1.2563
L2  eta must reach 0.372945 from 0.34          +9.69%           REACHABLE, and cheap
L3  C   must fall to 0.711098 from 0.78        -8.83% -> kappa 0.118516
L4  N   must reach 14.8193 -> 15 categories    still below the N = 17 cliff
```

A 9.7% improvement in conversion efficiency closes this family's entire deficit, which is what a small deficit on a high-`c/eta` case looks like: the elasticity `dD/d(ln eta) = -6.619424` octaves per e-fold is enormous, and only 0.584737 octaves are needed.

And then the honest complication, which is why this case is in the section. The minimum-frequency paper's [Curzi, 2026] SPEC 4.19 requires the sensitivity to be published, and here it decides the reading:

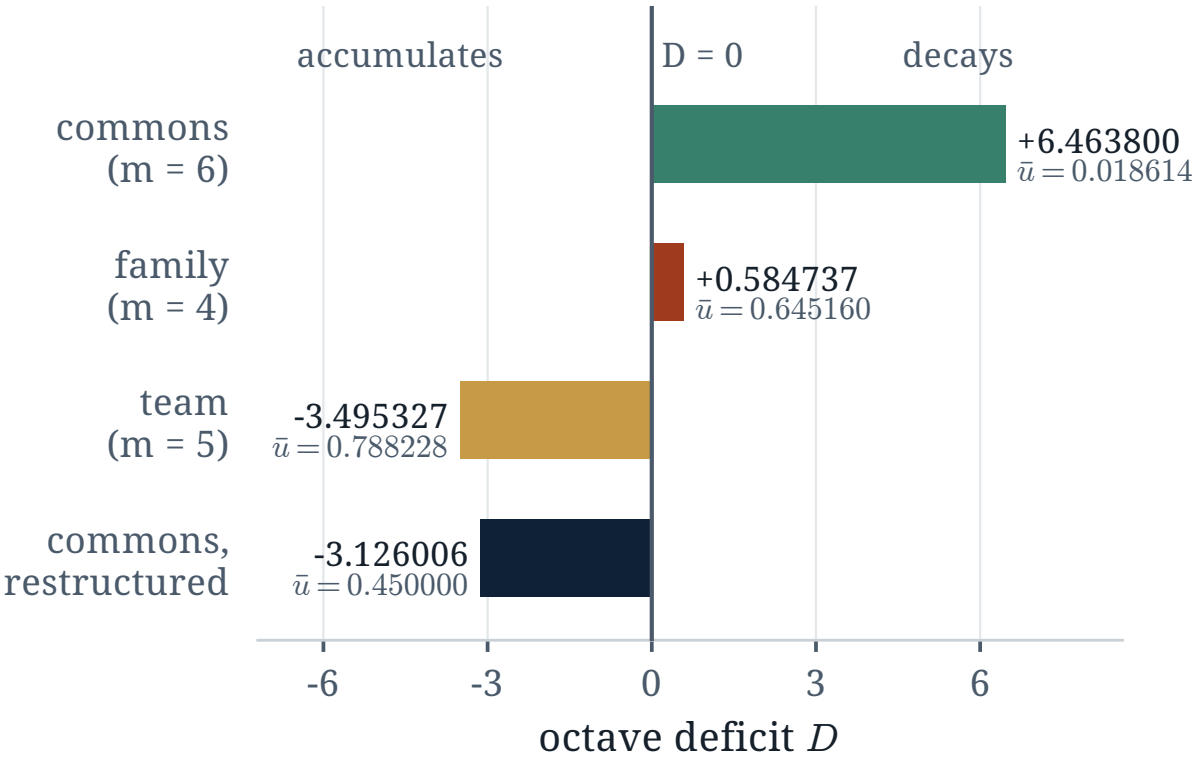

Figure 45.4: **The parameter that separates a working structure from a failing one is the one no arrangement can change.** Octave deficits for the three constructed structures and for the restructured commons, against the sustainability line $D = 0$. The commons and the team pay the identical per-link cost of 0.055; what differs is $\bar{u}$, and the commons' is 42 times smaller. Computed from the side-by-side table of §5.9 and the restructure of §5.13; script `figs/src/CCP-045_fig04.py`.

```
dD/d eta = -19.4689 octaves per unit eta

eta known to +/- 0.02  ->  D = +0.5847 +/- 0.3894    verdict resolved
eta known to +/- 0.05  ->  D = +0.5847 +/- 0.9734    VERDICT NOT RESOLVED
eta known to +/- 0.10  ->  D = +0.5847 +/- 1.9469    VERDICT NOT RESOLVED

dD/dC = +8.4864 octaves per unit C
C known to +/- 0.05    ->  D = +0.5847 +/- 0.4243    verdict resolved
C known to +/- 0.10    ->  D = +0.5847 +/- 0.8486    VERDICT NOT RESOLVED

to resolve the sign, eta must be known to better than +/- 0.030034 -- 8.8% of its value
```

Unless `eta` is known to within about 9% of itself, this family's verdict is not determined and the correct action is to measure, not to intervene. That is the reading a marginal case deserves, and Section 6 makes it a numbered step rather than a caution.

The family's low `delta = 0.05` is its characteristic parameter and it is doing exactly what the sign-multiplication result [Curzi, 2026] says. The numerator is `-0.068902`, negative. A family's long memory is amplifying a small negative sign, and would amplify it further if the memory got longer — `delta` to 0.03 takes `Q_inf` from `-1.378049` to `-2.296749`, with the deficit unmoved at `+0.584737`. CC-R15 in miniature, on the structure most likely to reach for continuity as a repair.

5.11 The team — what a selected geometry and an explicit mechanism buy

```
u(A,B') = 0.692372     u(A,C) = 0.552647     u(A,S) = 0.897875     u(A,T) = 0.679778
u(B',C) = 0.851659     u(B',S) = 0.953352    u(B',T) = 0.748794
u(C,S)  = 0.756702     u(C,T) = 0.786182     u(S,T) = 0.962914

u_bar = 0.788228     10 pairs, all between 0.55 and 0.97
```

The team's pairwise list is tight at a high level, which is the geometry the family's is not. Its aggregation gap is 0.029780 octaves — negligible, because the values are close together, exactly as §4.3b predicts.

Its reading is comfortable: `D = -3.495327`, `Q_inf = +6.999131`, and both aggregations agree (`-3.465547` and `+6.939499`). Three parameters explain it and all three are arrangements or selections rather than luck.

`eta = 0.52`, against the family's 0.34 and the commons' 0.34. A team has apparatus — the decision log of the sustainable-dyad paper's [Curzi, 2026] phase 2b, the repository, the standing review — and the apparatus is what conversion efficiency *is*.

`kappa = 0.055` against the family's 0.130. A team's links are maintained on purpose, in declared slots, with agendas. A family's are maintained under conditions no member chose.

`u_bar = 0.788228`, because a team is composed. Its members were selected partly for what they bring that others do not, which is a membership rule pointing the opposite way from the commons'.

The honest counterweight, and it belongs here rather than in a footnote: the team's pitch headroom is 0.6227 octaves. It has spent 91% of the range twelve categories make available, and its next increment of surplus is not purchasable from `u` at this `N`. That is the ceiling of the minimum-frequency paper [Curzi, 2026] Theorem 4.6 arriving, and it arrives at every well-tuned system.

5.11b The team's drop-one, and the result that settles the ethics Run the drop-one analysis of §4.13 on the team. `kappa = 0.055`, `eta = 0.52`, `delta = 0.09`, four links removed with each member.

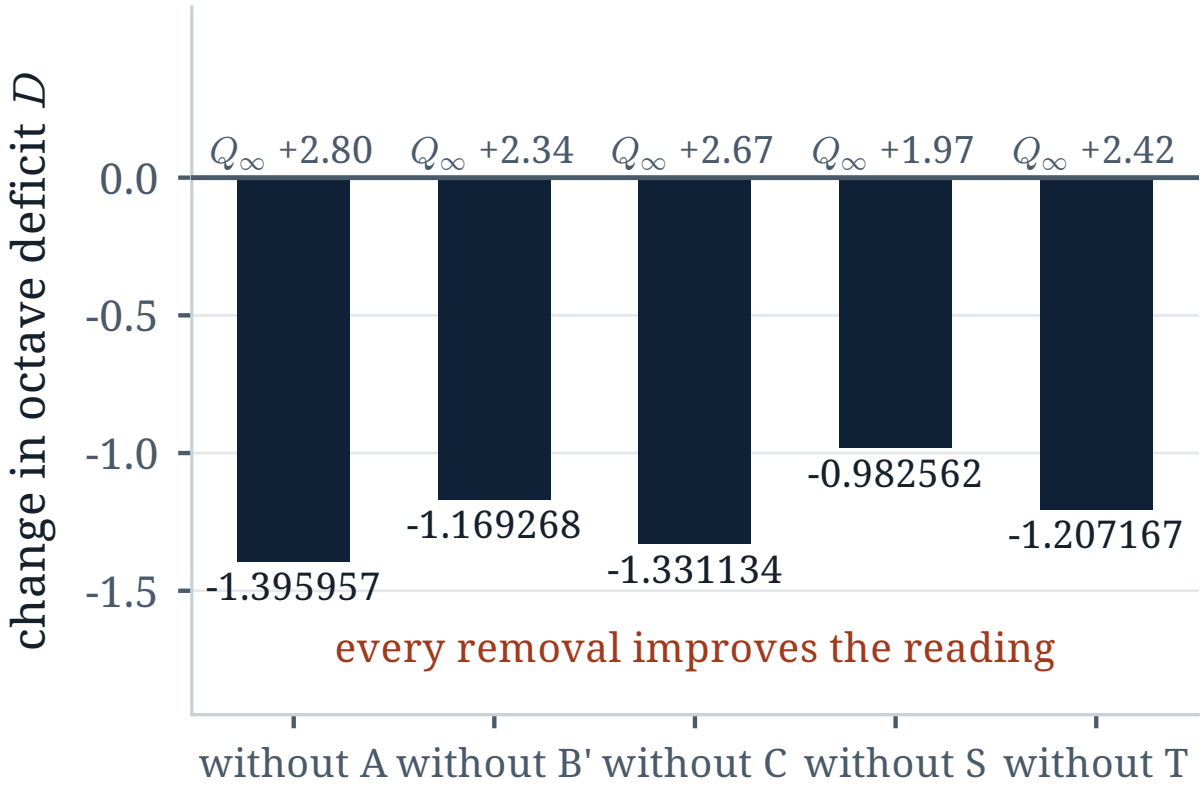

Figure 45.5: **A drop-one row on a healthy group carries no information about the member it names.** All five removals from the constructed team lower the octave deficit and raise the steady state, by 1.97 to 2.80 units. The mechanism is arithmetic: F is concave and the team is far up the curve, so an additional member can contribute almost no surplus, while each member's four links cost $4 \times 0.055/0.52 = 0.423077$ nats. Computed from the drop-one table of §5.11b; script `figs/src/CCP-045_fig05.py`.

set	u_bar	links	C	f (Hz)	D	Q_inf	change in D
all five	0.788228	10	0.5500	45.2093	−3.495327	+6.999131	–
without A	0.843267	6	0.3300	51.0473	−4.891284	+9.794430	−1.395957
without B'	0.772683	6	0.3300	43.6247	−4.664595	+9.340502	−1.169268
without C	0.822514	6	0.3300	48.8044	−4.826461	+9.664627	−1.331134
without S	0.718572	6	0.3300	38.3291	−4.477889	+8.966638	−0.982562
without T	0.784101	6	0.3300	44.7859	−4.702494	+9.416392	−1.207167

Every single row improves the reading. Not one member of a well-composed, comfortably accumulating team is carrying their four links, and removing any of them — the best-matched, the worst-matched, any of them — raises `Q_inf` by between 1.97 and 2.80.

The mechanism is arithmetic and it is worth stating carefully because it is the general case rather than a quirk of these five vectors. The team sits at `u_bar = 0.788228` with 0.6227 octaves of pitch headroom. **Near the ceiling, an additional member can contribute almost no surplus, because there is almost no surplus left to contribute** — `F` is concave and the team is far up the curve. Each member's four links, meanwhile, cost `4 * 0.055 / 0.52 = 0.423077` nats, which is 1.2207 octaves of required pitch. Cost is linear in links and surplus is exhausted, so the trade goes one way.

That result settles a question the previous section only argued. If the drop-one analysis improves on *every* member of a healthy team, then a favourable drop-one row carries no information whatever about the member it names. It is a property of where the group sits on the surplus curve. **A ranking derived from it would be a ranking of nothing, and SPEC 4.11's**

prohibition is therefore not a piece of decorum — it is a statement that the numbers do not contain what somebody might try to read out of them.

The constructive reading of the same table is different and is available: a team at `u_bar = 0.788228` and 0.62 octaves of headroom has reached the useful limit of composition at `N = 12`, and its remaining levers are `eta`, `c`, and genuinely new categories under the state-ordering material's [Curzi, 2026] validity conditions. That is what the rows are telling anyone; it is not about `A`, `B'`, `C`, `S` or `T`.

5.12 The commons — what the doctrine costs, in one number

The commons' problem is `u_bar = 0.018614`, and the cost of it can be stated as a single interval.

```
the commons as found                f = 0.7017 Hz     0.5375 octaves above k
the same six with u_bar = 0.788228  f = 45.209 Hz     6.5472 octaves above k
                                                      ------------------------
the price of the membership rule                      6.0097 octaves
```

Six octaves of available order, forgone at the point of selection, before anybody did anything. Every subsequent decision the commons makes about its arrangement is being made downstream of that, and none of the arrangements can reach back past it.

This is the sense in which the commons is not a badly run group. Its `kappa` is the same as the team's. Its `eta` is the same as the family's. Its `delta` is the same as the team's. The only parameter on which the commons differs materially from a structure that works is the one no arrangement can change.

5.12b Can the commons shrink its way out?

If the cost is quadratic in the roster and the surplus is not, the obvious remedy is to be smaller. Computed, taking the six constructed members in order and reading each prefix:

m	u_bar	links	C	D	Q_inf	verdict
2	0.018644	1	0.0550	−0.071526	+0.093647	holds, barely
3	0.018548	3	0.1650	+0.864532	−1.131912	DECAYS
4	0.018587	6	0.3300	+2.263763	−2.963896	DECAYS
5	0.018583	10	0.5500	+4.130888	−5.408481	DECAYS
6	0.018614	15	0.8250	+6.463833	−8.462955	DECAYS

`u_bar` barely moves — it stays inside a band of width 0.000096 across every prefix, because every member is drawn from the same doctrine and any subset is as parallel as the whole. So the entire column of deficits is driven by the link count and nothing else.

The largest sustainable group drawn from this membership is two, and even the pair only clears its threshold by 0.0715 octaves. Three members from one doctrine already decay. The commons cannot shrink its way out any more than it can convert, cut or re-categorise its way out, and for the same underlying reason: `F = 0.186272` nats is what the membership rule left behind, and every arrangement is an attempt to pay fifteen, ten, six, three or one links out of it.

That completes the audit. **Four levers, three Ostrom principles, two nesting topologies and five roster sizes have now been computed on this commons, and exactly one of them closes the gap — `u`, which is the parameter it does not control.**

5.13 The restructure, computed

If tuning cannot help, what would? The answer has to be a change in membership, topology, or both, and it should be computed rather than gestured at.

CONSTRUCTED. Three changes, taken together:

1. **Recruit outside the doctrine.** The membership rule is changed so that new members are selected for what they bring that the existing members do not. Suppose this moves `u_bar` from 0.018614 to 0.45 — a large change, and one that is a change of group rather than of arrangement.
2. **Nest.** Two triads plus one bridge, per Ostrom P8: 15 links become 7.
3. **Adopt a conversion mechanism.** `eta` from 0.34 to 0.55 — a decision log, minutes that bind, a repository. This is the team's parameter and it is available to any group that will keep records.

```
u_bar            =  0.45
F                =  1.783391 nats        N_eff = 5.95
f                = 17.1145 Hz            folded 273.832 Hz (j = 4)
links            =  7        C = 0.055 * 7 = 0.3850
eta              =  0.55     c/eta = 0.700000
ceiling test     :  0.700000 <= 2.484907        comfortably below
roster ceiling   :  m(m-1) = 30 <= 2*0.55*ln12/0.055 = 49.6981      PASS
f_min            =  1.9604 Hz            folded 250.930 Hz (j = 7)
octaves required =  2.019773
octaves present  =  5.145779
OCTAVE DEFICIT   = -3.126006
numerator        = +0.595865             POSITIVE
Q_inf (delta 0.09) = +6.620724
pitch headroom   =  2.0241 octaves
VERDICT: ACCUMULATES
```

A swing of 9.5898 octaves and `Q_inf` from `-8.4630` to `+6.6207`. And the decomposition says which change did it:

```
from the cost ratio:  2.885390 * (0.700000 - 2.426471)  =  -4.981543 octaves
from the surplus   : -2.885390 * (1.783391 - 0.186272)  =  -4.608257 octaves
total                                                      -9.589800 octaves
```

The decomposition is the same shape as the worked room of Series B, where three moves — raising categories from two to five, cutting an acoustic cost term from 0.70 to 0.15, and retiring four of nine dormant agreements — closed 66 per cent of a -1.396 headroom gap [Curzi, 2026d].

51.9% from the cost side and 48.1% from the geometry — and the cost side is only available at that size because the nesting removed eight links. No proper subset of the three does as well. The recruitment plus the log, at fifteen links, leaves `-0.817694` octaves — sustainable, but with a quarter of the margin. The recruitment plus the nesting, without the log, leaves `-1.878499`. The recruitment alone, at fifteen links and `eta = 0.34`, leaves `+1.855535` and fails. And the two arrangement changes without the recruitment leave `+2.729803` (nesting alone) and `+3.790608` (the log alone), both failing badly — which is §5.7's rule arriving as arithmetic: without the change in membership, no combination of arrangements reaches the threshold.

And the honest note on what has happened: this is not the same commons. Its membership rule is different, its topology is different, and its records are different. The formalism cannot tell anyone whether that trade is worth making, because it contains no term for what the doctrine was for — the boundary statement of the minimum-frequency paper [Curzi, 2026] governs and does not soften here. What it can say is that the group as constituted arrives at `Q_inf = -8.4630` if its parameters hold, and that no arrangement of those parameters changes it.

5.14 The right to decline, and the arithmetic nobody wants Consent at group scope is per-member and revocable (SPEC 4.1). That raises a question the formalism answers uncomfortably, and the answer has to be printed rather than avoided.

Suppose member `E` of the constructed family declines to take part. Recomputing on `{A, B, D}`:

```
u(A,B) = 0.068735    u(A,D) = 0.710180    u(B,D) = 0.723966
u_bar  = 0.500960    F = 1.873426 nats    N_eff = 6.510562
links  = 3           C = 0.13 * 3 = 0.3900     c/eta = 1.147059
f      = 20.4912 Hz
OCTAVE DEFICIT = -2.095851      (was +0.584737)
Q_inf          = +4.939294      (was -1.378049)
VERDICT: ACCUMULATES            (was DECAYS)

E's decline IMPROVED the reading by 2.680588 octaves
```

The decline flipped the verdict, and it flipped it in the group's favour. Three links vanish with `E`, and `E`'s pairs — 0.711015 and 0.740352 — were above the mean but not by enough to pay for three links at `kappa = 0.13`.

That result must be handled exactly, and the exact handling is this. The formalism computes the stored order of an arrangement per period. It has no term for what `E` is for, what `E` contributes that is not stored order, what `E`'s participation means to `E`, or what the group would be without `E`. **It weighs none of that, it acquires no such term by being applied to a family, and a number that improves when someone leaves is not an argument that anyone should leave.**

Three rules follow and they are all binding.

The framework's founding treatment of the returned difference states the constraint the same way and refuses the weaker readings of it [Curzi, 2026], and the disclosure principle is the old one: a procedure whose safety depends on its own concealment is not safe [Kerckhoffs, 1883, Brandeis, 1914].

One: the right to decline is the member's, never the group's. A decline is an exercise of consent. Nothing in this apparatus converts a favourable drop-one row into a licence to exclude anyone, and SPEC 4.11 states the same prohibition for the drop-one analysis generally.

Two: a decline is not a finding. SPEC 4.1 requires that a member's withdrawal ends their inclusion in the reading and is not reported as a result about them. The reading after a decline is a reading of a different group, and must be labelled as one.

Three: the group must not be told what a decline would do before the decision is made. Reporting "the reading improves by 2.68 octaves if you withdraw" to a member weighing withdrawal converts an arithmetic result into pressure, and pressure removes the ability to decline freely. Section 6 makes this a numbered step: the counterfactual is computed after the decision, or not at all.

5.15 Reading a structure you are inside

One last engineering point, and it is the one most likely to be needed in practice, because nobody reads a family or a team from outside it.

An analyst who is a member of the group being read is part of the apparatus. Three specific consequences follow, and all three are handled by declaration rather than by correction.

The operator's own vector is one of the `m`, so their encoding enters `u_bar` directly and the result is sensitive to it. At `m = 4` a single member's vector participates in half the pairs. The requirement is simply that the analyst's own vector be elicited by the same procedure as everyone else's, by someone else where possible, and that this be stated in the report.

The operator estimates `eta`, `c` and `delta` for an arrangement they are inside, and the estimation practice of [Curzi, 2026]'s estimation practice is harder to apply honestly to one's own arrangement than to another's. The family case shows what is at stake: the verdict is unresolved unless `eta` is known to ±0.030034, and self-estimated `eta` is exactly the sort of quantity that comes back optimistic. The countermeasure is the count — enumerate what survived the period rather than judging how well things are going.

And the analyst has an interest in the answer, which the formalism cannot detect and does not correct for. CC-R13's finding stands here in its general form: design controls, not more computation. Read blind where possible, have another member encode the vectors, publish the raw norms, and report the sensitivity so that a reader can see how much of the verdict rests on the least certain input.

None of this makes an internal reading invalid. It makes it a reading with a declared observer, and Series B's the corpus's Series B already records that the analyst's own state is part of the apparatus — one of the four things the alchemical tradition got right, and the one most often dropped by its successors.

The specification

SPEC 5.1 — DECLARE ALL FIVE. Roster, geometry, cost topology, conversion, loss. A structure named without its five declarations is a label, not a reading.

SPEC 5.2 — PER-MEMBER CONSENT, REVOCABLE, AND UNCONDITIONED. Every member agrees separately; any may withdraw at any time; **and no member is shown the counterfactual value of their own withdrawal before deciding.**

SPEC 5.3 — REPORT BOTH AGGREGATIONS with the gap in octaves (SPEC 4.4). Where the verdict differs between them, report NOT DETERMINED.

SPEC 5.4 — RUN THE REACHABILITY TEST (Definition 5.1) after the ceiling test and before any prescription. Report `u*` beside `u_bar` and declare the judgment.

SPEC 5.5 — REPORT THE CEILING MARGIN IN NATS AND OCTAVES, and the roster-ceiling margin from Theorem 4.3. A case inside both by a small margin is a case one member from being structural.

SPEC 5.6 — SEPARATE TUNING FROM RESTRUCTURING in every prescription. Changes to `eta`, `c`, `delta` and `N` are tuning; changes to membership, topology or boundary are restructuring, and they are reported as producing a different group.

SPEC 5.7 — PRICE GOVERNANCE MECHANISMS AGAINST THE SURPLUS THEY ARE LEVIED ON. P5 at −7.7% of `eta S` costs 0.004877 on this commons and takes `Q_inf` from `-8.462972` to `-8.517157`.

SPEC 5.8 — OSTROM'S PRINCIPLES ACT ON `c`, `eta` AND `delta`, NEVER ON `u`. Any claim that a design principle raises non-parallelism must be argued separately and is not supported by the mapping.

SPEC 5.9 — NESTING IS REPORTED WITH ITS LOST PAIRS (SPEC 4.13). Both the link saving and the surplus loss are computed.

SPEC 5.10 — DELTA IS NOT A LEVER ON THE DEFICIT (Theorem 4.9), and where the numerator is negative it is not a lever on the destination either, except downward (the ordering rule [Curzi, 2026]).

SPEC 5.11 — REPORT THE SENSITIVITY to the least certain parameter and declare the verdict UNRESOLVED where the uncertainty exceeds the deficit. **The constructed family is unresolved at `eta ± 0.05`.**

SPEC 5.12 — NO ORGANISATION-WIDE AGGREGATE (the no-aggregation rule [Curzi, 2026]; CC-R16). Per group, per period.

SPEC 5.13 — LABEL EVERY CASE CONSTRUCTED, and label an extension of the carried case as an extension.

SPEC 5.14 — NO CLINICAL, DIAGNOSTIC, THERAPEUTIC OR COUNSELLING FRAMING, and no reading presented as an evaluation of any person or of any group's health.

The failure modes

FM 5.1 — TUNING AN UNREACHABLE CASE. *Signature:* a lever programme for a group whose required `u*` is far outside what its members could represent. *Mechanism:* Definition 5.1. The commons is TUNABLE by the ceiling test and requires `u* = 0.938078` from `u_bar = 0.018614` — a factor of 50.4. *Fix:* SPEC 5.4. An unsatisfiable prescription is worse than none: it consumes the effort that restructuring needed (the minimum-frequency paper [Curzi, 2026]).

FM 5.2 — SINGLE-LEVER THINKING ON A SIX-OCTAVE GAP. *Signature:* a plan to fix the commons by improving conversion, or by cutting cost, or by adopting a richer taxonomy. *Mechanism:* every lever saturates. `eta = 1.00` leaves `+1.8430`; a 91% cost cut leaves `+0.0990`; `N = 144` leaves `+3.2562`. *Fix:* §5.4's four tables, computed before the plan rather than after it.

FM 5.3 — MISTAKING SELECTION FOR CULTURE. *Signature:* a group with `u_bar` near zero addressed with meetings, workshops, or facilitation. *Mechanism:* the Parallel Wall. `u` is a property of who the members are. Ostrom's principles all act on `c`, `eta` and `delta`, and not one acts on `u` (SPEC 5.8). *Fix:* SPEC 5.6. Name it as a membership question.

FM 5.4 — TRUST APPLIED TO A NEGATIVE NUMERATOR, IN A FAMILY. *Signature:* continuity, ritual or patience invested in a marginal family case, followed by acceleration. *Mechanism:* CC-R15 and the sign-multiplication result [Curzi, 2026]. `delta` 0.05 -> 0.03 takes the constructed family from `−1.378049` to `−2.296749`; the deficit does not move. *Fix:* the ordering rule [Curzi, 2026]. Sign the numerator first; here a 9.7% rise in `eta` flips it.

FM 5.5 — ACTING ON THE FAMILY'S UNRESOLVED VERDICT. *Signature:* an intervention justified by `D = +0.5847` with `eta` known to a decimal place it does not have. *Mechanism:* SPEC 4.19. At `eta ± 0.05` the uncertainty is `±0.9734` octaves and the sign is unknown. *Fix:* SPEC 5.11. Measure `eta` to better than ±0.030034 first.

FM 5.6 — THE AGGREGATION GAP SUPPRESSED IN A CLUSTER GROUP. *Signature:* one figure reported for a group with one tight pair and several wide ones. *Mechanism:* Jensen. The constructed family's gap is 0.394666 octaves; the two-dyad structure of §4.13b runs 0.599632. *Fix:* SPEC 5.3.

FM 5.7 — THE SEVENTH MEMBER. *Signature:* a group at its roster ceiling admitting one more, with no reading taken. *Mechanism:* Theorem 4.3. The commons sits at `m(m−1) = 30` against 30.7225; a seventh takes it to 42 and the case becomes STRUCTURAL, at which point no `u` whatsoever suffices. *Fix:* SPEC 5.5, and run the roster ceiling before admission.

FM 5.8 — GOVERNANCE PRICED WITHOUT REFERENCE TO SURPLUS. *Signature:* monitoring, sanctions and conflict procedures added to a group with `F = 0.186272`. *Mechanism:* mechanisms costed as a fraction of `eta S` are affordable in proportion to `S`. *Computed:* P5 takes this commons from `−8.462972` to `−8.517157`. *Fix:* SPEC 5.7.

FM 5.9 — THE DECLINE READ AS A RESULT. *Signature:* "the numbers got better when `E` left." *Mechanism:* a reading after a withdrawal is a reading of a different group. The apparatus has no single-party term and produces no statement about `E`. *Fix:* SPEC 5.2 and §5.14's three rules.

FM 5.10 — THE COUNTERFACTUAL SHOWN BEFORE THE DECISION. *Signature:* a member weighing withdrawal is told what their withdrawal would do to the reading. *Mechanism:* this converts arithmetic into pressure and removes the ability to decline freely, which is the one thing the consent axiom of the framework's foundations [Curzi, 2026] forbids absolutely. *Fix:* SPEC 5.2. **The counterfactual is computed after the decision, or not at all.**

FM 5.11 — RESTRUCTURING PRESENTED AS TUNING. *Signature:* "we just need to bring in some fresh perspectives" offered as an adjustment. *Mechanism:* changing membership changes `u`, which is the one parameter tuning cannot reach. It is a different group afterwards and the honest framing says so. *Fix:* SPEC 5.6.

FM 5.12 — THE STRUCTURE NAMED INSTEAD OF DECLARED. *Signature:* "we are a family, so `delta` is low." *Mechanism:* the labels in §5.1 are parameter signatures, not primitives. A group is whatever its five declarations say it is. *Fix:* SPEC 5.1.

Worked example

THE THREE STRUCTURES, READ IN FULL All three cases are CONSTRUCTED. The family and the team are explicitly labelled extensions of the carried dyad of the carried dyad [Curzi, 2026]; the commons is the carried commons [Curzi, 2026] exactly. Parameters are chosen, not observed. None of this is an assessment of any person, family, team or community; no clinical, diagnostic or therapeutic claim is made; the frequencies are essence frequencies.

THE FAMILY

```
A = {4: 0.7,  6: 0.5,  9: 0.4}                                  L2 norm 0.948683

```

The team is sustainable and has 0.6227 octaves of the scale left. Its next increment is not buyable from `u` at twelve categories, and the category-validity condition [Curzi, 2026] governs what a real addition to `N` would have to be. **`delta` interventions are available and would help here**, because the numerator is positive — the ordering rule [Curzi, 2026] permits them at this point and not before.

THE COMMONS **CONSTRUCTED, the carried commons [Curzi, 2026].** A realising set is given so the figures are reproducible. All six members hold the same doctrine profile across all twelve states, each raising exactly one state by 0.130330:

```
doctrine profile (states 1..12):
  {1:0.10, 2:0.20, 3:0.55, 4:0.35, 5:0.60, 6:0.25,
   7:0.15, 8:0.30, 9:0.70, 10:0.20, 11:0.10, 12:0.45}

M raises state  1 to 0.230330      L2 norm 1.339982
N raises state  2 to 0.330330      L2 norm 1.349673
O raises state  6 to 0.380330      L2 norm 1.354493
P raises state  7 to 0.280330      L2 norm 1.344836
Q raises state 10 to 0.330330      L2 norm 1.349673
R raises state 11 to 0.230330      L2 norm 1.339982

resulting mean pairwise u over 15 pairs = 0.018614137     (the carried figure is 0.018614)
pairwise u range 0.018484 .. 0.018830
cos theta range  0.990540 .. 0.990715
```

Every pair is above 0.99 alignment. That is what a membership rule looks like from inside the geometry.

headroom      6.6324 octaves      mu = 2.500
chord         all twelve states held by every member; 6 classes of 6
VERDICT       DECAYS -- and TUNABLE, UNREACHABLE
```

Note the chord line. Every member holds every state, so the commons' chord spans all twelve states and all six pitch classes — the fullest chord in this framework — and its surplus is 0.186272 nats. A group can sound every available class and carry almost no information, because the chord reports what states are held and `u` reports whether anyone holds them differently. The dissonance paper's [Curzi, 2026] identity is the reason: consonance and redundancy are the same phenomenon, and a chord this consonant is a single note played six times.

THE LEVER AUDIT, ALL FOUR, SIDE BY SIDE

```

```

What the three readings establish **One:** the parameter that separated the working structure from the failing one was `u_bar`, and it is the only one of the five declarations that an arrangement cannot change.

Two: a case can pass the ceiling test and still be unfixable, which is why Definition 5.1's reachability test belongs after the ceiling test and before any prescription.

Three: every lever available to the commons was computed and every one of them fell short — including `eta = 1`, including a 91% cost cut, including a twelve-fold enlargement of the category set. That is not a rhetorical claim about difficulty; it is four tables of arithmetic, and it is the result this section was written to publish.

Four: the restructure that works changes who is in the group, and the formalism has nothing whatever to say about whether that is the right thing to do. It says only what the current arrangement arrives at if it holds, and Section 6 takes up what may and may not be done with that information.

Section 6 is the intervention section: given a deficit, what is actually done, lever by lever, with consent and reversibility built into the numbered procedure rather than appended to it — and a section on when not to tune at all.

6 The intervention procedure and its halting conditions

The preceding two sections have produced a number. This one is about what may be done with it.

The number is an octave deficit, and by the deficit identity R3 [Curzi, 2026] it is also a destination: `D` and `Q_inf` are the same quantity in different units. It says that a configuration of four parameters, if it holds, arrives somewhere — and it says how far that somewhere is from sustaining. It does not say what should be done, to whom, by whom, or whether anything should be done at all, and the distance between a reading and an action is where every one of this section's constraints lives.

There are exactly four levers, plus one parameter that is not a lever on the deficit at all. That is not a stylistic simplification; it is the decay-blindness result CC-R4 [Curzi, 2026] and it exhausts the possibilities. So a section on intervention is short on options and long on discipline, and this one is organised accordingly: a numbered procedure with the constraints built into the steps, a lever-by-lever account of what each move actually requires and costs, and a section on the cases in which the correct action is to do nothing.

Three things are established before anything else, because they govern everything after.

This section is not counselling, therapy, mediation, or clinical assessment, and nothing in it may be presented as any of those. It is a procedure for changing four declared parameters. It has no diagnostic content, the twelve states are not diagnoses, no reading here evaluates any person's health or capacity, and a reader in difficulty with a relationship should seek help from someone qualified to give it, which this framework is not and does not claim to be.

Consent is structure, not advice. the consent axiom of the framework's foundations [Curzi, 2026] states it absolutely: no intervention may remove a person's ability to decline. In this section that constraint appears as numbered steps in the procedure, as a halting condition, and as a set of prohibitions on what may be computed and when — not as a paragraph of encouragement at the end.

And the procedure halts more often than it proceeds. Of the three structures Section 5 read, one required no intervention, one required a measurement rather than an intervention, and one returned a verdict that no intervention could satisfy. That distribution is not pessimism. It is what a diagnostic is for: most of the value of a reading is in the cases where it tells you not to act.

The law

6.1 What an intervention is DEFINITION 6.1. An intervention is a change to one or more of the four parameters that appear in the octave deficit, optionally accompanied by a change to the one that does not.

```
D  =  2.885390 * ( c/eta )  −  log2( f/k )        f = k (1 + (N−1) u)^2
```

```
L1  raise u        the geometry        who the parties are, and what they hold
L2  raise eta      the conversion      what happens to what they produce
L3  cut c          the cost            what the arrangement costs to run
L4  raise N        the categories      what the description can distinguish

L0  lower delta    the loss            trust, ritual, record, continuity
                   NOT a lever on D (CCP-041 R4); a multiplier on Q_inf (CCP-044)
```

There is no fifth. Anything proposed as an intervention either moves one of these five or moves nothing, and the first job of the procedure is to say which one a proposal moves. A proposal that cannot be assigned to a lever is not an intervention; it is a wish, and the minimum-frequency paper's [Curzi, 2026] belief postulate applies — belief acts only through a coupling with real gain, and where no channel exists nothing happens.

6.2 The consent axiom

AXIOM 6.1 — THE CONSENT AXIOM. No procedure in this framework may reduce any party's ability to decline participation in it, at any stage, for any reason or none.

This is a constraint on the procedure, not a recommendation about how to behave, and it has three corollaries that determine specific numbered steps.

COROLLARY 6.1a — INFORMED. A party who has not been told what is being measured, what will be computed, and what will be reported cannot decline meaningfully, because they cannot know what they would be declining. The procedure therefore discloses its outputs before it takes its inputs. This also discharges the no-subliminals rule (the consent axiom of the framework's foundations [Curzi, 2026]): nothing masked, nothing below threshold, nothing concealed. Open-label works; disclosure costs nothing that matters.

COROLLARY 6.1b — REVOCABLE. A consent that cannot be withdrawn is a decision made once about every future stage. Consent is therefore re-asked at each stage that changes what is being done, and withdrawal at any stage halts that stage without penalty and without explanation.

COROLLARY 6.1c — UNCONDITIONED. A party shown the consequence of their own withdrawal before deciding is choosing under pressure, and pressure is a reduction in the ability to decline. §5.14 computed the case that makes this concrete: a member's withdrawal improved a constructed family's reading by 2.680588 octaves, and every member of a constructed team improved the reading by leaving. Those figures may not be shown to a person weighing withdrawal. The counterfactual is computed after a decision, or not at all.

A note on why 18.1c has to be an axiom rather than a courtesy. §5.11b established that a drop-one row improves for *every* member of a healthy group near the surplus ceiling, so the row carries no information about the person it names. A number that says nothing about someone, shown to them as though it did, is the worst possible thing to put in front of a person deciding whether to stay.

6.3 Reversibility, defined and classified

DEFINITION 6.2. An intervention is REVERSIBLE if ceasing it returns the parameter to its prior value without residue in any other parameter and without requiring anything of any party. It is PARTIALLY REVERSIBLE if ceasing it returns the parameter but leaves residue elsewhere. It is IRREVERSIBLE otherwise.

```
LEVER                          CLASS                residue on ceasing
-------------------------------------------------------------------------------
L2  raise eta (mechanism)      REVERSIBLE           none; stop keeping the record
L3  cut c     (arrangement)    REVERSIBLE           none; restore the meeting
L4  raise N   (description)    REVERSIBLE           none; the ladder is a choice
L0  lower delta (record)       REVERSIBLE           none, but see the decay note
```

```
L1  raise u   (what a party    IRREVERSIBLE          a person now holds commitments
               actually holds)                      they did not hold before
-------------------------------------------------------------------------------
RESTRUCTURING (membership)     IRREVERSIBLE          a different group exists
```

The class list is the reason the procedure is ordered as it is. Three of the four levers, and the one non-lever, are reversible; the geometry lever is not. `u` rises when a party takes on states they did not previously hold, and a person cannot un-take a commitment on request. An intervention that changes what somebody is actually doing is not undone by deciding to stop measuring it.

And reversible does not mean instantaneous. `D` returns to its old value the moment the parameter does, because `D` has no memory. `Q` does not: it decays back at rate `delta`, with half-life `ln(0.5)/ln(1-delta)`. Computed on the constructed family, `eta` raised to 0.40 for twenty periods and then reverted:

```
t = 0    Q = +1.000000        eta = 0.40, Q_inf = +1.131707
t = 20   Q = +1.084492        eta reverted to 0.34, Q_inf = -1.378049
t = 25   Q = +0.527418
t = 30   Q = +0.096365
t = 40   Q = -0.495263
t = 60   Q = -1.061583
half-life at delta = 0.05:  13.5134 periods
```

A reversible intervention leaves a stock behind that takes about thirteen periods to half-decay, which is a grace period and not a permanence. Nothing is destroyed by stopping; nothing is kept either.

6.4 What each lever requires, in closed form

Given a reading, the exact requirement for each lever to close the deficit on its own:

```
L1   u_req   =  ( e^(c/eta) - 1 ) / (N - 1)        reachable iff c/eta <= ln N
L2   eta_req =  c / F(u)                           reachable iff <= eta_max
L3   c_req   =  eta * F(u)                         always >= 0, so always defined
L4   N_req   =  1 + ( e^(c/eta) - 1 ) / u          integer, and CCP-041's conditions apply

partial close of x octaves:  d(c/eta) = -x/2.885390 nats,  or  dF = +x/2.885390 nats
one octave:  dF = 0.346574 nats  =  N_eff multiplied by sqrt(2) = 1.414214
```

Computed on the three carried cases:

```
case          u_req               eta_req              c_req       N_req
dyad 2a       0.627132            1.101077  ABSENT     0.168925    102
family        0.810517            0.372945             0.711098     15
commons       0.938078  UNREACHABLE 4.428926 ABSENT     0.063334    556
```

Three of the twelve entries are impossible before any question of expense arises. `eta_req > 1` means a conversion efficiency above unity, which is more structure created than interaction supplied; `N_req = 556` on a twelve-category ladder is not a taxonomy revision. The closed forms are worth computing first precisely because they identify levers that are absent rather than costly, and no cost model is needed to see an absent lever.

6.5 The ordering rule, as a step constraint The sustainable-dyad paper [Curzi, 2026] owns the order-of-operations rule and this section applies it as a gate.

```
SIGN THE NUMERATOR:   n = eta F(u) − c

n < 0    NO intervention on delta is undertaken. Raise eta, cut c, or raise u first.
n > 0    delta interventions are available and are the strongest single move.
n = 0    delta is exactly inert; Q_inf = 0 for every delta.
```

The rule is enforced at a numbered step because it cannot be seen in the deficit. `D` is identical before and after any `delta` change, to every digit, so an analyst working from the deficit alone has no signal that a `delta` intervention did anything — and in a negative-numerator case it will have doubled the rate of loss while the instrument read flat.

The damage-integral result R7 [Curzi, 2026] prices the consequence: eight periods of the wrong order cost twelve periods of permanent lag and 111.133601 stock-periods, on a case whose fixed point is order-independent.

6.6 The classification, complete Everything the procedure does is decided by four cases, assembled from the minimum-frequency paper [Curzi, 2026] and Definition 5.1.

```
D <= 0                                    SUSTAINABLE.
                                          Report the margin. Do not tune. Sec 6.13.

D > 0, c/eta <= ln N, u_req reachable     TUNABLE AND REACHABLE.
                                          Run the procedure.

D > 0, c/eta <= ln N, u_req unreachable   TUNABLE, UNREACHABLE.
                                          Report; issue no lever prescription; the question
                                          is membership, not arrangement.

c/eta > ln N                              STRUCTURAL.
                                          L1 is unavailable at every value of u. Only L2,
                                          L3, L4 —— and L4 only to make the case tunable.
```

A prescription issued before this classification may be unsatisfiable, and an unsatisfiable prescription is worse than none, because it consumes the effort that restructuring needed (the minimum-frequency paper [Curzi, 2026]). The classification costs one logarithm and one division.

6.7 The standing prohibitions, restated where they bind

(1) NOT COUNSELLING, THERAPY, MEDIATION OR CLINICAL ASSESSMENT. Restated at the top of this section and again here because this is the section someone will try to use as a protocol. **There is no diagnostic content in any output of this procedure, and no output may be described as an assessment of a person.**

(2) ESSENCE, NOT RESONANCE. Every frequency is a position on a logarithmic scale of surplus. Nothing vibrates and nothing is played at anyone. The minimum-frequency paper's [Curzi, 2026] FM 4.8 forbids sounding `f_min` at any person, and the no-subliminals rule is absolute: nothing masked, nothing below threshold, nothing concealed.

(3) NO SINGLE-PARTY TERM. `u` is a joint geometric property; `eta`, `c` and `delta` are properties of an arrangement. No output of this procedure names a person as a cause, and none may be reported as a ranking or an evaluation.

(4) THE READING INHERITS ITS INPUTS. Where intensities were not magnitude-estimated (the elicitation rule of [Curzi, 2026] rule; the elicitation rule), no relationship frequency may be printed. Where `eta` or `c` is ordinal, publish the ordering and not the number.

(5) THE READING DOES NOT CONCLUDE THAT A RELATION SHOULD END. `D > 0` says a configuration loses order at a computable rate. It does not weigh what the relation is for, what else it produces, or what ending it would cost, and it acquires no such term by being applied to people (the minimum-frequency paper [Curzi, 2026] §4.22).

(6) CONSTRUCTED CASES. Every case here is constructed and labelled, and its precision does not transfer to a measured one.

The engineering

6.8 PROCEDURE T — the numbered procedure The constraints are steps. They are not appended and they are not optional, and the procedure halts at four points by design.

STEP 1 — DISCLOSE BEFORE ELICITING. Every party is told, before any measurement: what will be measured, how, what will be computed, what will be reported, to whom, and what will be done with it. Nothing in the procedure is concealed from a participant at any stage (Corollary 6.1a).

STEP 2 — OBTAIN CONSENT, SEPARATELY AND EXPLICITLY. From every party, individually, without conditioning. The procedure does not start without every party's agreement, and a party who declines is not asked for a reason, is not recorded as having declined for cause, and the reading is simply not taken.

> **HALT 1.** Any party declines. The procedure ends. No reading is computed, no partial reading is computed, and no counterfactual of the form "what the reading would have been" is computed (Corollary 6.1c).

STEP 3 — DECLARE THE FRAME. `N` and the ordering that produced it (the state-ordering material [Curzi, 2026]); the period; the scale status of every input (SPEC 4.4). One clock for `eta`, `c` and `delta` (SPEC 4.3).

STEP 4 — ELICIT AND ENCODE. Intensities by magnitude estimation (the elicitation rule of [Curzi, 2026] rule), raw L2 norms published. Encode each party as a unit vector. Check pairwise support overlap and reject disjoint-support encodings (the self-as-chord material [Curzi, 2026]).

STEP 5 — MEASURE AND COMPUTE. `u` per pair (the relationship-frequency paper [Curzi, 2026]); the full pairwise list published, not the mean alone; `u_bar`, `F(u_bar)` and mean-of-`F` with the aggregation gap; `f`, folded, with `j`.

STEP 6 — CLASSIFY, BEFORE ANY PRESCRIPTION. Roster ceiling (Theorem 4.3), then `c/eta` against `ln N`, then reachability (Definition 5.1). Report the classification of §6.6.

> **HALT 2.** The case is STRUCTURAL, or TUNABLE-UNREACHABLE. Report the finding and the four lever computations that establish it, and issue no tuning prescription. The question is one of arrangement scope or membership, and §5.7 governs the distinction.

STEP 7 — REPORT THE SENSITIVITY, AND TEST WHETHER THE VERDICT EXISTS. Compute `dD` from the uncertainty in the least certain parameter (SPEC 4.19).

> **HALT 3.** The uncertainty exceeds `|D|`. **The verdict is NOT RESOLVED and the correct action is measurement, not intervention.** Report what precision would resolve it: on the constructed family, `eta` must be known to better than ±0.030034 — 8.8% of its value — for the sign of a `+0.584737` deficit to be determined.

STEP 8 — SIGN THE NUMERATOR. `n = eta F(u) − c`. Record the sign. This is the gate for Step 12.

STEP 9 — COMPUTE THE CLOSED FORMS AND THE RESERVES. `u_req`, `eta_req`, `c_req`, `N_req` (§6.4), and the reserve of each lever (the lever-reserve result R6 [Curzi, 2026]). Mark any lever ABSENT rather than expensive.

STEP 10 — CLASSIFY EACH CANDIDATE MOVE BY REVERSIBILITY (Definition 6.2), and present the reversible options first. Where a reversible move suffices, an irreversible one is not proposed.

STEP 11 — SEEK SEPARATE, EXPLICIT AGREEMENT FOR EACH MOVE, and additional explicit agreement for any move classified irreversible. Agreement to the reading is not agreement to an intervention, and agreement to one intervention is not agreement to the next.

> HALT 4. No move commands agreement from every party it requires something of. The procedure ends with the reading and no intervention. A reading that produced no agreed action is a completed procedure, not a failed one.

STEP 12 — SEQUENCE. Numerator moves first (`eta`, `c`, `u`), then `delta` moves, and only if Step 8's sign is positive by the time they are reached (the ordering rule [Curzi, 2026]).

STEP 13 — ACT, AND RECORD THE BASELINE. Record every parameter's prior value, so that reversal is a defined operation rather than a reconstruction.

STEP 14 — RE-READ, AND RE-CONSENT. At a declared interval. The re-reading restarts at Step 1. Consent obtained for one reading is not consent for the next, and §6.12 gives the cadence and the design controls that make a re-read mean anything.

6.9 The levers, one at a time, with what each actually costs

L2 — RAISE `eta`. *Reversible.*

What it is. Change what happens to what the parties already produce. The decision that stays decided; the practice that has a slot; the artefact that exists next week because of what happened this week. It is a mechanism question, and often literally a notebook.

What it requires. `eta_req = c/F(u)`, or a partial close of `x` octaves at `d(c/eta) = −x/2.885390` nats.

Its price in octaves. `dD/d(ln eta) = −2.885390 (c/eta)` — an e-fold improvement buys exactly the number of octaves the relation requires. On the constructed family that is 6.619424 octaves per e-fold against a deficit of 0.584737, which is why a 9.7% rise suffices.

Its reserve. `2.885390 c (1/eta_0 − 1/eta_max)`, and it is small wherever `eta` is already moderate: at `eta = 0.50`, `c = 0.62`, the whole remaining reserve is 1.7889 octaves.

Its failure mode. Cutting the mechanism while cutting cost. If the recurring meeting was the conversion, removing it moves `c` and `eta` together and the ratio may not move at all (SPEC 4.11).

L3 — CUT `c`. *Reversible.*

What it is. Reduce what the arrangement costs to run before it produces anything: coordination, re-explaining, friction, correction load.

What it requires. `c_req = eta F(u)`.

Its price in octaves. `dD/d(ln c) = +2.885390 (c/eta)` — identical in magnitude to `L2`, opposite in sign, because the two enter only as a ratio. The formalism is indifferent between them, so whichever is cheaper to move in the situation is strictly the better choice.

Its reserve. `2.885390 (c/eta)`, i.e. the entire requirement — `c` can in principle go to zero, at which point `f_min = k` and any non-zero `u` clears it.

A measured instance. The corpus's built-environment work moves exactly this lever: an entrance sequence redesign takes interruptions from 22 to 6 per person-day, a switching cost from 0.321 to 0.087, headroom from $+0.0642$ to $+0.2955$ and the steady state from 5.185 to 9.041, for 7.6 per cent of net floor area [Curzi, 2026f].

Its failure mode. CC-R18's counter-pressure. An over-framed system banks more stored order than a calibrated one, and the bill arrives later as correction load `C_t = c_0 + kappa Z_t`. A `c` that was cut by ceasing to check things will rise again for reasons nobody connects to the choice.

L1 — RAISE `u`. *IRREVERSIBLE.*

What it is. A party comes to hold states the other parties do not hold. Not a rhetorical position — a change in what somebody is actually doing.

What it requires. `u_req = (e^(c/eta) − 1)/(N−1)`, reachable only if `c/eta <= ln N`, and reachable *in practice* only if the parties could honestly represent it (Definition 5.1).

Its price in octaves. `dD/d(ln u) = −2.885390 (1 − 1/N_eff)`, which is bounded above by 2.885390 octaves per e-fold in every system that has ever existed or will, because `1 − 1/N_eff < 1`. The cost-side levers exceed it whenever `c/eta > 1 − 1/N_eff`, which the elasticity comparison R5 [Curzi, 2026] states and which holds in all three of this framework's carried cases.

Its reserve. The pitch headroom `2.885390 (ln N − F(u))`, and it is the only large reserve available on a big deficit — 5.545206 octaves on the carried dyad against `eta`'s 4.174198.

Its failure modes, and there are three. CC-R8: manufactured opposition reads as `u = 0` exactly as agreement does, so a contrarian raises cost and returns nothing. Re-encoding: a `u` that rose because the description changed is not a `u` that rose. And convergence drift: `u` decays as parties spend time together, at a rate estimable from two readings (the convergence-clock material [Curzi, 2026]).

And its consent weight. This is the only lever that requires a person to become different, and it is the only irreversible one. Step 11's separate agreement exists for it.

L4 — RAISE `N`. *Reversible.*

What it is. Add genuinely distinct categories to the description — carrying variance the existing ones do not, and satisfying the state-ordering material's [Curzi, 2026] validity conditions.

What it requires. `N_req = 1 + (e^(c/eta) − 1)/u`.

Its price in octaves. `dD/d(ln N)`-scale: `2.885390 u/(1 + (N−1)u)` per category — 0.1129 at the carried dyad's `u`, 0.0446 at the commons'.

Its real value. Not the deficit. `N` raises `ln N`, which raises the maximum satisfiable `c/eta`. `N` is how a STRUCTURAL case becomes a TUNABLE one, and that is the only situation in which it is the right first move.

Its failure modes. The Parallel Wall — `N` enters `F` only multiplied by `u`, so categories added to a near-parallel set are dimensions nobody uses. The `N = 17` cliff, where the folded lattice's minimum separation falls from 34.9756 cents to 6.0008 and the symbol rate drops by exactly 8 (the mood-and-trait paper [Curzi, 2026]). And the honest one above both: a category added for arithmetic convenience is not a category.

L0 — LOWER `delta`. *Reversible, and NOT a lever on the deficit.*

What it is. Trust, ritual, written record, institutional memory, continuity of place — anything that slows the leak of accumulated order.

What it does. Nothing to `D`, by Theorem 4.9. It scales `Q_inf` by `delta_old/delta_new`, in whichever direction the numerator's sign points.

Its price. At a positive numerator it is the largest single move available: on the carried dyad at 2b, `delta` 0.09 to 0.05 takes `Q_inf` from `+6.084427` to `+10.951968`, an 80.0% improvement with no new difference and no cost cut.

Its failure mode. CC-R15, the whole of it. At a negative numerator the identical change takes `Q_inf` from `-5.011940` to `-9.021491`. Step 12 is the gate and it is not discretionary.

A note worth making. Several real interventions move `eta`, `c` and `delta` together — a written record does all three — and those are the ones to reach for first, because half of what they do is on the numerator. Reported as one thing, though, they make trust look like it worked when what worked was the other half, which is why SPEC 15.4 requires `delta` effects to be reported separately.

6.10 Planning combinations

`D = 2.885390 (c/eta - F)` is a difference of two independent terms, so octave contributions add with no interaction term. A plan is therefore a list of moves whose contributions sum to at least the deficit.

```
total to close      D octaves
from eta:           2.885390 * c * (1/eta_0 - 1/eta_1)
from c:             2.885390 * (c_0 - c_1) / eta
from u:             2.885390 * ( F(u_1) - F(u_0) )
from N:             2.885390 * ( ln(1+(N_1-1)u) - ln(1+(N_0-1)u) )
```

Two cautions, both from the worked example of the minimum-frequency paper [Curzi, 2026]. The path-free split into cost side and surplus side is unique; the split *within* the cost side is not, because `c` is divided by `eta` and cutting cost is worth more when `eta` is still low. On the carried dyad the `c` contribution is `-1.442695` octaves on one attribution order and `-2.115953` on another — a 47% difference from the same intervention producing the same result. Report the path-free split, and if a per-parameter attribution is wanted, report the order used.

And single-lever plans on large deficits tend to land near the hold line, where a relation pays for itself exactly and banks nothing. The sustainable-dyad paper [Curzi, 2026] computes the carried dyad's: `u` alone to 0.692373 leaves `-0.250931` octaves, the cost side alone leaves `+0.998357` and still fails. A plan with no margin is a plan that fails on the first increase in cost.

6.11 Choosing between levers when the formalism will not

The four sensitivities are in four different units and cannot be ranked against each other (the minimum-frequency paper [Curzi, 2026]). The elasticities can, and the elasticity result R5 [Curzi, 2026] gives them. But neither answers what a unit of each parameter costs in the situation, and that cost model is not in the formalism and this framework does not pretend to supply it.

What the formalism does supply, and what is genuinely decisive without prices:

Absent levers. `eta_req = 1.101077` on the carried dyad and `4.428926` on the commons. No cost model is needed to rule out a conversion efficiency above 1.

Exhausted levers. `L4` at `u = 0.018614` buys 0.0446 octaves per category, so 6.4638 octaves is 145 categories.

Reversibility. Three levers are reversible and one is not, and where a reversible move suffices, Step 10 forbids proposing the irreversible one.

The shape of the trade. `dD/d(ln eta)` carries `c/eta`; `dD/d(ln u)` is capped at 2.885390. Both levers are strongest in the systems that most need them, which is the opposite of the usual experience that improvement gets easier once things are already going well.

6.12 Verifying that it worked

An intervention that is not verified is a story. Four requirements, and the last three are Book Two's, carried forward without softening.

Re-read at a declared interval, from Step 1. The deficit is a property of current parameters, so verification means re-measuring them, not remembering that something was done.

Do not use the shuffle as the verification. CC-R13 and CC-R24 measured three distinct failure modes: The shuffled-input control is anti-conservative as ordinarily run (2.2x nominal alpha), it cannot see repackaging (only the structural ceiling test can), and it cannot see

confounding by a shared slow driver, passing 98.35% of the time. **Design controls, not more surrogates.**

Use the structural test for repackaging. A change that exceeds the theoretical single-step maximum is not an improvement; it is a re-description. The single-step maximum [Curzi, 2026] and CC-R4 apply.

The methodological literature behind those three failures is not this framework's: selective analysis inflates false positives [Simmons et al., 2011, Gelman and Loken, 2013], most published findings in a low-prior field are false [Ioannidis, 2005], replication rates are low [Open Science Collaboration, 2015], and preregistration with a declared kill condition is the available remedy [Nosek et al., 2018]. The corpus's own confirmatory attempt failed its declared baseline test and reported the failure [Curzi, 2026i].

And CC-R23 stands. Testimonial evidence that a configuration held has a likelihood ratio of exactly `1.000000` — it does not move the posterior at all, because the selection guarantees you observe successes whether or not the method does anything. A hundred pairs reporting that their reading improved is worth precisely as much as none of them reporting it. What counts is the re-measured parameters, and the companion result says why: a prediction specifying a magnitude carries a likelihood ratio of 11.3577 against 2.0000 for one specifying only a direction — about 5.7 times more evidential power, which is the framework's own evidential pricing result [Curzi, 2026ac]. That is the correct response to the standing critique that directional predictions are nearly unfalsifiable in soft psychology [Meehl, 1990, 1967], and it is what a research programme is supposed to do with a badged postulate [Lakatos, 1970, Platt, 1964, Popper, 1959]. **Predict the number before you re-read.**

6.12b The re-reading window, and how it can be empty

Step 14 says re-read at a declared interval. The interval is not arbitrary, and it turns out to be bounded on both sides by quantities the reading already contains.

The lower bound is convergence. After a parameter change, `|Q_t − Q_inf| = (1−delta)^t |Q_0 − Q_inf|`, so half of the move has happened after `t_half = ln(0.5)/ln(1−delta)` periods. Read sooner than that and most of what will happen has not happened; the stock is still dominated by where it started.

The upper bound is drift. the convergence-clock material [Curzi, 2026]'s convergence clock gives `t* = ln(u*/u_0)/ln(1−lambda)`, the period at which a sustainable geometry decays back across its own hold line. Read later than that and the reading is of a relation that has already lost the gain.

```
THE RE-READ WINDOW      [ ln(0.5)/ln(1−delta) ,  ln(u*/u_0)/ln(1−lambda) ]
```

Computed for three of this framework's cases:

case	u_0	u*	t_half	lambda	t*	window
family after tune	0.645160	0.548063	13.5134	0.01	16.229	[13.51, 16.23]
				0.02	8.074	EMPTY
				0.03	5.355	EMPTY
				0.05	3.180	EMPTY
carried dyad 2b	0.692373	0.134733	7.3496	0.02	81.020	[7.35, 81.02]
				0.05	31.911	[7.35, 31.91]
				0.08	19.631	[7.35, 19.63]
the team	0.788228	0.170883	7.3496	0.02	75.673	[7.35, 75.67]
				0.05	29.805	[7.35, 29.81]

The family's window is empty at any convergence rate above about 1% per period, and that is a finding about the tune rather than about the schedule. The family's repair left it at `−0.408177` octaves — a margin of 0.408 octaves — so its hold line sits at `u* = 0.548063` against a current `u_bar` of 0.645160, and the geometry has only 15% of relative room before it crosses

back. The repaired dyad has `u* = 0.134733` against 0.692373, five times the room, and its window is wide at every plausible drift rate.

The rule that follows is more useful than a schedule:

> **A margin thin enough to be unverifiable is a margin too thin. If the re-read window is empty, the correct response is not a different reading interval but a larger intervention.**

This is the quantitative form of §6.10's warning about single-lever plans landing near the hold line. A plan that closes the deficit and no more produces a relation that is sustainable, fragile, and — computably — impossible to confirm.

6.12c What a tuning report contains The report is the durable artefact, and writing it is itself an `eta` intervention: what is not written down is not converted. Fourteen items, and a report missing any of them is not auditable.

```
 1  the frame:   N, the ordering, the period, the scale status of every input
 2  consent:     obtained, from whom, at what stages, and any declines (as halts, not findings)
 3  the vectors: every party's states and intensities, plus every raw L2 norm
 4  the pairs:   the full pairwise u list, with cos theta signed
 5  aggregation: u_bar, F(u_bar), mean-of-F, and the gap in octaves
 6  the pitch:   f raw and folded, with j; f_min raw and folded, with j
 7  the tests:   roster ceiling, ceiling test with its margin in nats, reachability
 8  the reading: octaves required, octaves present, D with sign, in octaves and cents
 9  the destiny: Q_inf, and the identity cross-check D = -2.885390 (delta/eta) Q_inf
10  the sign:    the numerator eta F - c
11  sensitivity: dD from the least certain parameter, and whether the verdict is resolved
12  the levers:  u_req, eta_req, c_req, N_req, with absent levers marked ABSENT
13  the plan:    each move, its lever, its reversibility class, its octave contribution,
                 the path-free split, and the attribution order if one is given
14  the schedule: the re-read window with its two bounds, and the predicted D with a magnitude
```

Item 2 has a specific form and it matters. A decline is recorded as a halt in the procedure and never as a datum about the person who declined — no reason, no category, no counterfactual. A report that records why someone declined has converted a consent mechanism into a surveillance one, and Axiom 6.1 is violated by the record even if it was honoured in the room.

And item 14's prediction is recorded before the re-read, not after. CC-R23's companion result gives the reason in numbers: a prediction specifying a magnitude carries a likelihood ratio of 11.3577 against 2.0000 for a direction-only prediction, so a report that predicts *better* has recorded almost nothing, and one that predicts `-0.408177 ± 0.35` has recorded something a re-reading can refute.

6.13 WHEN NOT TO TUNE **Eight conditions. Each halts the procedure, and each is a computed condition rather than a matter of judgment.**

(1) The case is SUSTAINABLE. `D <= 0`. Report the margin and stop. A relation that is accumulating does not need tuning, and a margin optimised for its own sake spends reserve that has no other source. the constructed team of Section 5 sits at `-3.495327` octaves with 0.6227 octaves of pitch headroom left; there is nothing to buy there that is worth the disturbance of buying it.

(2) The case is STRUCTURAL. `c/eta > ln N`. No assignment of `u` closes it, so `L1` is unavailable at every value and a lever prescription is unsatisfiable. Only `L2`, `L3`, and `L4` — the last purely to make the case tunable.

(3) The case is TUNABLE but UNREACHABLE. the constructed commons of Section 5: formally tunable with a ceiling margin of 0.058436 nats, and requiring `u* = 0.938078` from `u_bar =`

`0.018614`, a factor of 50.4. Every lever was computed: `eta = 1.00` leaves `+1.8430`, a 91% cost cut leaves `+0.0990`, twelve times the category count leaves `+3.2562`. This is a membership question and issuing a tuning plan for it wastes the effort restructuring needs.

(4) The verdict is not resolved. The uncertainty in the deficit exceeds its magnitude. On the constructed family, `D = +0.584737` with `eta` known to ±0.05 carries `±0.9734` octaves, so the sign is unknown. **Measure, do not act**, and report the precision that would resolve it.

(5) The numerator is negative and the only available move is on `delta`. Doing it makes the outcome measurably worse — `−5.011940` to `−9.021491` on the carried dyad — while the deficit reads unchanged. Where no numerator move is available, the correct action is to say so.

(6) Consent is absent, conditioned, or uninformed. Axiom 6.1 and its three corollaries. This is not a cost-benefit condition and is not weighed against anything.

(7) The reading was requested by someone other than the parties. A reading commissioned about a relationship by a third party cannot satisfy Step 2 in substance even if it satisfies it in form, because the parties' ability to decline is compromised by the requester's standing. No reading in this framework is an instrument for one party to use on another.

(8) The proposed intervention is irreversible and the deficit is small. The stakes are asymmetric: an irreversible move that overshoots cannot be walked back, while a small deficit closes on reversible levers by construction — the family's `+0.584737` closes on a 9.7% rise in `eta`. Reserve the irreversible lever for deficits that the reversible ones cannot reach.

And a ninth that is not a condition but a boundary. Nothing in the procedure decides whether a relationship should continue, and nothing in it evaluates a person. `Q_inf` is where a configuration arrives if the configuration holds; it says nothing about whether it will hold, and nothing whatever about what the relation is for.

The specification

SPEC 6.1 — DISCLOSE FIRST. Outputs, recipients and uses are stated before inputs are taken (Corollary 6.1a). Nothing masked, nothing below threshold, nothing concealed.

SPEC 6.2 — CONSENT PER PARTY, PER STAGE, REVOCABLE, UNCONDITIONED. A decline halts without reason given and without record of cause.

SPEC 6.3 — NO COUNTERFACTUAL BEFORE A DECISION. The value of a party's own withdrawal is computed after the decision, or not at all (Corollary 6.1c).

SPEC 6.4 — CLASSIFY BEFORE PRESCRIBING. Roster ceiling, ceiling test, reachability, in that order (§6.6).

SPEC 6.5 — REPORT SENSITIVITY AND HALT ON AN UNRESOLVED VERDICT. State the precision that would resolve it.

SPEC 6.6 — SIGN THE NUMERATOR AND GATE THE `delta` MOVES ON IT (the ordering rule [Curzi, 2026]).

SPEC 6.7 — COMPUTE THE CLOSED FORMS AND MARK ABSENT LEVERS ABSENT, not expensive.

SPEC 6.8 — CLASSIFY EVERY MOVE BY REVERSIBILITY and propose reversible moves first. Where a reversible move suffices, no irreversible move is proposed.

SPEC 6.9 — SEPARATE AGREEMENT PER MOVE, and additional explicit agreement for irreversible moves.

SPEC 6.10 — RECORD THE BASELINE so that reversal is defined.

SPEC 6.11 — REPORT THE PATH-FREE SPLIT, and name the order used for any per-parameter attribution.

SPEC 6.12 — VERIFY BY RE-MEASUREMENT, WITH DESIGN CONTROLS. Blinding, channel separation, prospective sampling, a yoked control. The shuffle is a weak, mis-calibrated audit with three measured failure modes and is not the verification (CC-R13, CC-R4, CC-R24).

SPEC 6.13 — PREDICT THE MAGNITUDE BEFORE RE-READING. A direction-only prediction carries a likelihood ratio of 2.0000; a magnitude carries 11.3577 (CC-R23).

SPEC 6.14 — TESTIMONY IS NOT EVIDENCE. CC-R23: the survivorship likelihood ratio is exactly `1.000000`.

SPEC 6.15 — NO CLINICAL, THERAPEUTIC, DIAGNOSTIC, COUNSELLING OR MEDIATION FRAMING, in any output, at any stage.

SPEC 6.16 — LABEL EVERY CASE CONSTRUCTED.

The failure modes

FM 6.1 — THE PROCEDURE RUN ON SOMEBODY. *Signature:* a reading of a relationship commissioned by one party, or by a third party, about others. *Mechanism:* Step 2 cannot be satisfied in substance where the requester holds standing over the parties. The ability to decline is what is removed, and that is the one thing the consent axiom of the framework's foundations [Curzi, 2026] forbids absolutely. *Fix:* §6.13 (7). The procedure does not run.

FM 6.2 — THE COUNTERFACTUAL AS PRESSURE. *Signature:* a party told what their withdrawal would do to the reading. *Mechanism:* Corollary 6.1c. And §5.11b shows the figure is uninformative anyway: every member of a healthy team improved the reading by leaving, so the row says nothing about the person it names. *Fix:* SPEC 6.3.

FM 6.3 — TRUST FIRST. *Signature:* a failing relation into which continuity, ritual or patience is invested, followed by acceleration, with the deficit unchanged throughout. *Mechanism:* CC-R15 and the sign-multiplication result [Curzi, 2026]. `−5.011940` to `−9.021491` on the carried dyad; deficit `+4.338420` both times. *Fix:* SPEC 6.6, enforced at Step 12.

FM 6.4 — TUNING AN UNREACHABLE CASE. *Signature:* a lever programme for a group whose required geometry is 50 times its current one. *Mechanism:* Definition 5.1. **An unsatisfiable prescription consumes the effort restructuring needed.** *Fix:* HALT 2.

FM 6.5 — ACTING ON AN UNRESOLVED VERDICT. *Signature:* an intervention justified by a deficit smaller than its own uncertainty. *Mechanism:* SPEC 4.19. `+0.5847 ± 0.9734` is a statement that the sign is unknown. *Fix:* HALT 3, and measure `eta` to better than ±0.030034.

FM 6.6 — THE IRREVERSIBLE MOVE MADE FIRST. *Signature:* a `u` intervention proposed before the reversible levers were computed. *Mechanism:* Step 10. `u` rises when a person takes on commitments they did not hold, and that cannot be undone by ceasing to measure. *Fix:* SPEC 6.8.

FM 6.7 — CONSENT TAKEN ONCE. *Signature:* agreement to a reading treated as agreement to whatever the reading leads to. *Mechanism:* Corollary 6.1b. Agreement to a measurement is not agreement to a change in somebody's life. *Fix:* SPEC 6.9 and Step 14's re-consent.

FM 6.8 — MANUFACTURED DIFFERENCE. *Signature:* a party adopting contrary positions to raise `u`. *Mechanism:* CC-R8. `u` depends only on `|rho|`; opposition reads as `u = 0` and adds cost. *Fix:* report `cos theta` signed, and the opposition identity R1 [Curzi, 2026].

FM 6.9 — THE RE-ENCODING THAT LOOKS LIKE PROGRESS. *Signature:* `u` rises after the description changed rather than the parties. *Mechanism:* the encoding degeneracies R5 [Curzi, 2026]. Disjoint-support encodings read `u = 1` for free. *Fix:* Step 4's overlap check, and re-encode identically before and after.

FM 6.10 — THE VERIFICATION THAT VERIFIES NOTHING. *Signature:* a four-baseline surrogate suite reported as confirmation. *Mechanism:* three measured holes — anti-conservative at 2.2x nominal alpha, blind to repackaging, and passing 98.35% of the time against a shared slow driver. *Fix:* SPEC 6.12. Design controls.

FM 6.11 — TESTIMONY OFFERED AS RESULT. *Signature:* accounts from parties for whom the procedure worked. *Mechanism:* CC-R23. The survivorship likelihood ratio is exactly `1.000000`. A thousand such accounts carry the evidential weight of zero. *Fix:* SPEC 6.14, and re-measured parameters.

FM 6.12 — CUTTING THE CONVERSION MECHANISM. *Signature:* `c` falls, `eta` falls with it, `D` does not move. *Mechanism:* `D` depends on the ratio. *Fix:* SPEC 4.11's test before any `c` cut.

FM 6.13 — THE PROCEDURE USED AS THERAPY. *Signature:* Procedure T presented as an intervention on a person, a treatment, a counselling protocol, or an assessment. *Mechanism:* register slip of the most serious kind. The procedure changes four declared parameters of an arrangement and has no diagnostic, clinical or therapeutic content whatsoever. *Fix:* SPEC 6.15, and §6.7 (1).

Worked example

PART A — TUNING THE CONSTRUCTED FAMILY, ALL FOURTEEN STEPS CONSTRUCTED. This is the constructed family of Section 5 — itself a labelled extension of the carried dyad of the carried dyad [Curzi, 2026]. Parameters are chosen, not observed. This is not an assessment of any person or family, not counselling, and no clinical, diagnostic or therapeutic claim is made or implied. The frequencies are essence frequencies.

Steps 1–2. All four parties are told what will be measured, computed and reported, and to whom. All four agree, separately. No party is shown any counterfactual. **HALT 1 not triggered.**

Step 3. `N = 12` on the state-ordering material's [Curzi, 2026] ordering; one declared period for `eta`, `c` and `delta`; intensities magnitude-estimated per the elicitation rule [Curzi, 2026]; `eta` and `c` declared as estimates with stated uncertainty.

Step 4. Vectors and raw L2 norms:

```
A = {4: 0.7,  6: 0.5,  9: 0.4}                                  0.948683
B = {4: 0.6,  6: 0.55, 9: 0.3,  10: 0.2}                        0.890225
D = {1: 0.50, 2: 0.45, 4: 0.35, 6: 0.30, 8: 0.40, 9: 0.20}      0.930054
E = {3: 0.20, 4: 0.30, 6: 0.25, 9: 0.35, 11: 0.55, 12: 0.50}    0.931397

support overlap: every pair shares at least states 4 and 6      GATE PASSED
```

Step 5.

```
A–B 0.068735   A–D 0.710180   A–E 0.711015
B–D 0.723966   B–E 0.740352   D–E 0.916710

u_bar = 0.645160     F(u_bar) = 2.091463     mean-of-F = 1.954682
aggregation gap = 0.394666 octaves -- reported, both readings carried
N_eff = 8.096755     f = 31.6922 Hz      folded 253.537 Hz (j = 3)
```

Step 6 — classify.

```
roster ceiling:  m(m-1) = 12  <=  2*0.34*ln12/0.13 = 12.9980         PASS, at the ceiling
ceiling test:    c/eta = 2.294118  <=  ln 12 = 2.484907   margin +0.190789   TUNABLE
reachability:    u_req = 0.810517 from u_bar = 0.645160, a factor of 1.2563  REACHABLE

f_min = 47.5308 Hz    folded 380.246 (j = 3)
octaves required 6.619424   present 6.034688
OCTAVE DEFICIT  +0.584737   (conservative +0.979403)      both DECAY -- determined
Q_inf           -1.378049   (conservative -2.308160)
```

HALT 2 not triggered. The case is TUNABLE AND REACHABLE.

Step 7 — sensitivity.

```
dD/d eta = −19.4689 octaves per unit;  dD/dC = +8.4864;  dD/du = −3.9200

eta +/− 0.02  ->  D = +0.5847 +/− 0.3894    resolved
eta +/− 0.05  ->  D = +0.5847 +/− 0.9734    NOT RESOLVED
C   +/− 0.05  ->  D = +0.5847 +/− 0.4243    resolved
u   +/− 0.10  ->  D = +0.5847 +/− 0.3920    resolved
```

> **HALT 3 IS TRIGGERED IF `eta` IS KNOWN ONLY TO ±0.05.** The verdict's sign is not determined and the correct action is measurement. Required precision: `eta` to better than ±0.030034, which is 8.8% of its value.

The procedure therefore pauses here in the first instance, and the family counts what survived the period rather than estimating how well things are going (the estimation practice of [Curzi, 2026]). Suppose that count returns `eta = 0.34 ± 0.02`. The verdict is now resolved and the procedure resumes.

Step 8 — sign the numerator.

```
n = 0.34 * 2.091463 − 0.78 = −0.068902      NEGATIVE
```

No `delta` move is permitted until this changes. This matters here specifically: a family's characteristic parameter is a long memory, `delta = 0.05`, and lengthening it is the intuitive repair. Computed: `delta` 0.05 -> 0.03 takes `Q_inf` from `−1.378049` to `−2.296749`, with `D` unmoved at `+0.584737`.

Step 9 — closed forms and reserves.

```
L1  u_req   = 0.810517       from 0.645160    +0.165357        REACHABLE, irreversible
L2  eta_req = 0.372945       from 0.34        +9.69%           REACHABLE, reversible
L3  c_req   = 0.711098       from 0.78        −8.83%           REACHABLE, reversible
              (kappa 0.13 -> 0.118516)
L4  N_req   = 15             from 12          +3 categories    reversible, and below
                                                               the N = 17 cliff

elasticities: |dD/dln eta| = 6.619424   |dD/dln u| = 2.529026   ratio 2.6174
criterion: c/eta = 2.294118 > 1 − 1/N_eff = 0.876494    cost side proportionally stronger
```

Step 10 — reversibility. Three reversible options each close the deficit alone. **`L1` is therefore not proposed** (SPEC 6.8).

Step 11 — agreement. `L2` is put to all four parties: the household adopts a standing record of what was decided, so that decisions stay decided. All four agree. **HALT 4 not triggered.**

Step 12 — sequence. `L2` is a numerator move and goes first. No `delta` move is scheduled.

Step 13 — act, with baseline recorded.

```
BASELINE:  u_bar 0.645160   eta 0.34   C 0.7800   delta 0.05   D +0.584737   Q_inf −1.378049

eta 0.34 -> 0.40

numerator  = 0.40 * 2.091463 − 0.78 = +0.056585       POSITIVE
c/eta      = 0.78/0.40 = 1.950000
f_min      = k e^(2*1.95) = 23.8824 Hz      folded 382.119 Hz (j = 4)
octaves required 5.626511   present 6.034688
OCTAVE DEFICIT  −0.408177                              was +0.584737
Q_inf           +1.131707                              was −1.378049
VERDICT: ACCUMULATES
```

The swing is 0.992914 octaves from a 17.6% rise in conversion efficiency, computed exactly as `2.885390 * 0.78 * (1/0.34 - 1/0.40)`. The local elasticity of 6.619424 octaves per e-fold would have predicted 1.075782 octaves for the same proportional change; the 8.3% discrepancy is the curvature of `1/eta` over a finite step, and it is the reason SPEC 6.11 asks for the exact contribution rather than the elasticity estimate whenever a move is actually made.

Now, and only now, `delta` is available. Had the family taken it first, it would have moved `Q_inf` to `−2.296749`; taken here it moves `Q_inf` to `+1.886178`. Both orders arrive at the same fixed point and one of them spends a stretch below where it started:

```
 t      delta first      numerator first
 0       +1.000000          +1.000000
 5       +0.534282          +1.029795
10       +0.134353          +1.052849
15       +0.381826          +1.170570
20       +0.594340          +1.271661
30       +0.933545          +1.433018
40       +1.183684          +1.552007
 inf     +1.886178          +1.886178
```

Step 14 — re-read. At a declared interval, restarting at Step 1 with fresh consent. The prediction is recorded first, with a magnitude: `D` is expected at `−0.408177 ± 0.35`. A prediction with a number attached is about 5.7 times more evidentially powerful than one specifying only a direction (CC-R23).

PART B — THE COMMONS: THE PROCEDURE HALTS CONSTRUCTED, the carried commons [Curzi, 2026]. Same disclosures.

Steps 1–5 proceed exactly as above and produce:

```
u_bar = 0.018614     F = 0.186272     N_eff = 1.204754
f = 0.7017 Hz        folded 359.270 Hz (j = 9)
aggregation gap = 0.000001 octaves -- negligible, the pairs are alike
C = 0.8250 at kappa 0.055 x 15 links,  eta = 0.34,  delta = 0.09
```

Step 6 — classify.

```
roster ceiling:  m(m-1) = 30 <= 30.7225          PASS, at the ceiling; a 7th member
                                                 would take it to 42 and make the case
                                                 STRUCTURAL outright
ceiling test:    c/eta = 2.426471 <= 2.484907    margin +0.058436 nats    TUNABLE
reachability:    u_req = 0.938078 from 0.018614  -- a factor of 50.4      UNREACHABLE

f_min = 61.9349 Hz    OCTAVE DEFICIT +6.4638    Q_inf −8.4630
```

> **HALT 2 IS TRIGGERED.** The case is TUNABLE but UNREACHABLE. **The procedure reports the finding and the computations that establish it, and issues no tuning prescription.**

The four lever computations that are reported instead of a plan:

```
L1  u -> 0.95     deficit −0.0332    closes, by 40 cents, and requires near-orthogonality
                                      from six people drawn from one doctrine
    u -> 1.00     deficit −0.1686    the absolute maximum available
L2  eta -> 0.90   deficit +2.1075    fails
    eta -> 1.00   deficit +1.8430    fails at perfect conversion
```

```
L3  kappa -> 0.020 deficit +2.0085   fails
    kappa -> 0.005 deficit +0.0990   fails at a 91% cut
L4  N -> 25       deficit +5.9357    fails
    N -> 144      deficit +3.2562    fails at twelve times the ladder

P8 nesting 15 links -> 7:  deficit +2.7298                fails
shrinking to m = 3:        deficit +0.864532              fails
shrinking to m = 2:        deficit −0.071526              holds, barely
```

No `delta` move is permitted either: the numerator is `−0.761666` and Step 8's gate would refuse it even if the procedure had reached Step 8.

What is reported. That the deficit is `+6.4638` octaves and `Q_inf` is `−8.4630`; that every lever was computed and each falls short; that the case is a membership question rather than an arrangement question (§5.7); and that a restructure — recruiting outside the doctrine, nesting to seven links, adopting a conversion mechanism — reaches `−3.126006` octaves and `Q_inf = +6.620724`, **and produces a different group.**

What is not reported. No recommendation that anyone leave, join, or be replaced. No ranking of members. No counterfactual for any individual's withdrawal. The formalism has no term for what the doctrine was for, no single-party term at all, and no standing to weigh what this group is otherwise doing.

PART C — THE CARRIED DYAD, FOR COMPARISON CONSTRUCTED, the carried dyad [Curzi, 2026]. The same procedure on the case Part III opened with, given briefly because the minimum-frequency and sustainable-dyad papers [Curzi, 2026,?] work it in full.

```
Steps 1–5:  u = 0.068734665264634, F = 0.563085, f = 1.4907987150 Hz
            eta = 0.30, c = 0.62, delta = 0.09
Step 6:     c/eta = 2.066667 <= 2.484907   TUNABLE, margin +0.418240 nats
            u_req = 0.627132 from 0.068735 -- a factor of 9.1240
            REACHABILITY: declared borderline, and declared rather than assumed
Step 7:     D = +4.338420; no plausible input uncertainty flips a deficit that size
Step 8:     numerator = −0.451075   NEGATIVE   -- delta moves refused at Step 12
Step 9:     L1 u -> 0.627132     reachable, IRREVERSIBLE, reserve 5.545206 octaves
            L2 eta -> 1.101077   ABSENT (eta > 1); reserve to eta = 1 is 4.174198 < 4.338420
            L3 c -> 0.168925     a 72.8% cut; reserve 5.963140 octaves
            L4 N -> 102          not reachable; 0.1129 octaves per category
Step 10:    one reversible lever (L3) and one irreversible (L1); L2 does not exist
Step 11–13: the reversible lever alone leaves +0.998357 octaves and still DECAYS,
            so L1 is proposed, separately agreed, and taken together with the cost move
            result: u -> 0.692373, eta -> 0.44, c -> 0.40
            D = −3.590989, numerator +0.547598, Q_inf +6.084427
Step 12:    NOW the delta move is permitted: 0.09 -> 0.05 gives Q_inf +10.951968
Step 14:    re-read window at lambda = 0.05 is [7.35, 31.91] periods -- comfortably open
```

This is the case in which an irreversible lever was correct, and the procedure records why: the reversible levers were computed first, one of them did not exist and the other did not suffice, and the party who took on new states agreed separately to doing so. **The order of those four facts is the whole of Step 10 and Step 11.**

Compare the re-read windows across the three tunes:

```
case                margin (octaves)     u* / u_0     window at lambda = 0.05
family after tune       0.408177          0.849500     EMPTY
carried dyad 2b         3.590989          0.194595     [7.35, 31.91]
```

The dyad's repair is verifiable and the family's is not, and the difference is the margin.

The two outcomes, side by side

```
------------------------------------------------------------------------
                            THE FAMILY          THE COMMONS
------------------------------------------------------------------------
deficit as found              +0.584737            +6.463800
classification            tunable, reachable   tunable, UNREACHABLE
procedure                 ran to Step 14        halted at Step 6
halt encountered          HALT 3 (then cleared)     HALT 2
numerator sign                negative             negative
delta move permitted      no, then yes              no
lever chosen              eta 0.34 -> 0.40           none
reversible?                     yes                  -
deficit after             -0.408177                  -
Q_inf after               +1.131707 (+1.886178
                          with delta 0.03)           -
what was reported         a completed tune      a finding and four
                                                failed lever tables
------------------------------------------------------------------------
ESSENCE frequencies, not physical resonances. Constructed cases. Not an
assessment of any person, family or community. Not counselling, therapy,
mediation or clinical assessment. No diagnostic claim of any kind.
------------------------------------------------------------------------
```

Both outcomes are correct procedure. One produced an intervention and one produced a refusal to prescribe, and the refusal took the same fourteen steps up to the point where it stopped. **A diagnostic that only ever recommends action is not a diagnostic; it is a sales process**, and the commons column is what this framework means by an instrument that can say no.

7 Results

The eight results below are the units other papers in this corpus cite. A citation to this paper should name one of them. Each carries its status: **DERIVED** where it follows from the stated definitions by algebra, **COMPUTED** where it is the output of exact arithmetic on stated parameters, and **POSTULATED** where it is asserted by this framework.

R1 — two octaves per doubling against a quadratic. Theorem 4.2: $\mathrm{NET}(m) = 2\log_2 m - 1.442695\, r\, m(m-1)$ octaves with $r = \kappa/\eta$, so the largest viable roster at cost ratio r is the largest m with $r \le 2\ln m/(m(m-1))$, and **a dyad is viable in the best case if and only if** $r \le \ln 2 = 0.693147$**.** *Status:* DERIVED by substitution; the bound table COMPUTED. The carried dyad's $r = 2.066667$ places it over the roster bound at two, which is why its geometry alone could not save it [Curzi, 2026].

R2 — the roster ceiling. Theorem 4.3: $\kappa m(m-1)/2 \le \eta \ln N$, equivalently $m(m-1) \le 2\eta \ln N/\kappa$, **independent of any geometry**. *Status:* DERIVED from the normalisation bound $F \le \ln N$ [Curzi, 2026] and the ceiling result R5 of the minimum-frequency paper [Curzi, 2026]. **The constructed commons sits exactly on it, 30 against 30.7225**, so a seventh member takes $m(m-1)$ to 42 and makes the case STRUCTURAL outright, at which point no u whatsoever suffices. This result is dimensionally clean and does not depend on postulate P-b (§3.4).

R3 — the roster-scale count and its participation-ratio identity. Theorem 4.1: $M_{\text{eff}} = 1 + (m-1)\bar{u} = m + 1 - m/\mathrm{PR}$, with PR the Rényi-2 participation ratio of the members' Gram matrix [Rényi, 1961]. *Verified* on the constructed triad at PR $= 1.3522930095$, both sides $= 1.7815458788$, **error** 0.00×10^{0}. *Status:* DERIVED; the instance COMPUTED. It is the roster-scale twin of the category-scale identity of Series B [Curzi, 2026c,o]. **It is an algebraic re-expression of the affine axiom P-c and is not independent evidence for it, and M_{eff} is not a Hill number.**

R4 — the aggregation gap at group scope. On the constructed triad $F(\bar{u}) = 1.667424$ nats against a mean of $F(u)$ of 1.491574 nats: a gap of 0.1758499493 nats, **0.507396 octaves, 609 cents, a frequency ratio of 1.421482**, or 11.79 per cent of the conservative figure. On the constructed commons, whose fifteen pairwise values lie in a band of width 0.000346, the same gap is **0.000001 octaves**. *Status:* COMPUTED, from Jensen's inequality and the strict concavity of F [Curzi, 2026]. The same correction is priced at 0.0790 nats (4.31 per cent) at protocol scope in Series B [Curzi, 2026]. **The rule that follows is not "use the conservative figure" but "publish both, and report NOT DETERMINED where the verdict differs between them".**

R5 — the commons reading, and four levers that all fall short. $\bar{u} = 0.018614$, $F = 0.186277$ nats (the source prints 0.186272; the discrepancy is disclosed in §10), $N_{\text{eff}} = 1.204754$ against a required 11.3189 of a possible 12; $c/\eta = 2.426471$ against $\ln 12 = 2.484907$, a margin of $+0.058436$ nats; $D = +6.4638$ octaves and $Q_\infty = -8.4630$. **Every lever swept to its limit fails**: $\eta = 1.00$ leaves $+1.8430$; κ cut by 91 per cent leaves $+0.0990$; $N = 144$ leaves $+3.2562$; nesting to seven links leaves $+2.7298$; shrinking to $m = 3$ leaves $+0.864532$. Only $u \to 0.95$ closes it, by 0.0332 octaves, and u is the one parameter no arrangement controls. *Status:* COMPUTED on a constructed case. **The procedure halts at HALT 2 and issues no prescription.**

R6 — the restructure, decomposed. Changing the membership rule ($\bar{u} : 0.018614 \to 0.45$), nesting 15 links to 7, and adopting a conversion mechanism ($\eta : 0.34 \to 0.55$) gives $D = -3.126006$ and $Q_\infty = +6.620724$, **a swing of 9.5898 octaves — 51.9 per cent from the cost side and 48.1 per cent from the geometry.** No proper subset does as well, and the two arrangement changes without the recruitment leave $+2.729803$ and $+3.790608$, both failing. *Status:* COMPUTED. **It is a different group afterwards, and the formalism has nothing to say about whether the trade is worth making.**

R7 — the drop-one negative result. On a constructed five-member team at $\bar{u} = 0.788228$ with 0.6227 octaves of pitch headroom, **every one of the five removals improves the reading**, raising Q_∞ by between 1.97 and 2.80 and lowering D by between 0.982562 and 1.395957 octaves. *Status:* DERIVED from concavity of F with cost linear in links; COMPUTED on the constructed team. **A favourable drop-one row therefore carries no information about the member it names**, which makes SPEC 4.11's prohibition an arithmetic finding rather than a courtesy.

R8 — the muddiness index. $\mu = \lfloor m(m-1)/2 \rfloor / \lceil N/2 \rceil$ exceeds one from $m = 4$ at $N = 12$: pairs grow quadratically while pitch classes are capped at $\lceil N/2 \rceil = 6$ [Curzi, 2026]. Simulation at 20,000 trials, seed 7, gives expected class coverage of 5.73 of six at six members holding four states each and 5.98 at twelve. *Status:* DERIVED for μ; the coverage table COMPUTED by simulation with a stated seed, **which is a computation and not an observation of anybody.**

CR — the counter-result. The constructed commons is **formally tunable and practically unreachable**: it passes the ceiling test with a margin of $+0.058436$ nats, sits exactly on its roster ceiling, and admits no lever that closes it. And a member's declining to participate improves a constructed family's reading by **2.680588 octaves**, flipping its verdict from DECAYS to ACCUMULATES. **Both are arithmetic this paper prints rather than avoids**, and §6.2 makes the second an axiom-level prohibition on disclosure rather than a finding to be acted on.

8 Discussion

8.1 What follows

The unit of design is the link, not the head. Both bounds in this paper are statements about κ/η, not about m alone: the same three people are sustainable at one link price and structural at another, differing by $D = -3.410906$ against $+13.078$ at a factor of 11.27 in κ. A group-size debate conducted without a declared link price is not a debate the formalism can join.

Topology is the only lever that changes the exponent. Raising conversion, cutting cost and adding categories all move a coefficient. Partitioning the roster moves $m(m-1)/2$ itself, and on six members it removes 53.3 per cent of the cost. That is why the nesting principle [Ostrom,

1990] is structurally different from the other seven, and why the corpus's own rewiring result is the largest single arrangement gain it reports [Curzi, 2026b].

The reachability test earns its place because it changes what gets recommended. The formal classification returns TUNABLE for a case requiring a fiftyfold rise in $\bar{u}$, and a prescription issued on that basis is unsatisfiable. **An unsatisfiable prescription is worse than none**, because it consumes the effort restructuring needed.

8.2 What does not follow

Nothing here shows that small groups outperform large ones. It shows that *this framework's surplus functional* is bounded by $\ln N$ while *this framework's cost model* is quadratic in the roster. Both are stipulations of the framework (P-c, P-d). The empirical literature on group size and performance is mixed and conditional [Mannix and Neale, 2005, van Knippenberg and Schippers, 2007, Woolley et al., 2010], and this paper adds no observation to it.

Nothing here licenses a statement about any person. The apparatus has no single-party term. It is run m times in a drop-one audit and acquires none, and §5.11b shows the audit's rows are uninformative about members precisely when the group is healthy. **A ranking derived from those rows would be a ranking of nothing.**

The commons result is not a result about commons. It is a result about a parameter signature: a flat topology, a moderate link price, and a mean pairwise non-parallelism of 0.018614 produced by a membership rule that selects for agreement. Nothing about land tenure, kinship or employment is claimed, and §5.1 states that the three labels are parameter signatures rather than primitives.

And the counterfactual arithmetic of §5.14 is not an argument. That a reading improves when someone withdraws is a statement about fifteen or six or three links and a concave function. It weighs nothing that person is for, and the framework does not acquire a term for it by being applied to a family.

8.3 Relation to the surrounding programme

The results that survive the failure of the frequency postulates are the ones stated in surplus units, and they are most of the paper: R1, R2, R3, R7 and R8 are all statements about counts, logarithms and a concave functional, and none of them requires k to be a frequency. **R4, R5 and R6 are stated in octaves, and their octave values depend on the exchange constant $2/\ln 2 = 2.885390081777927$, which is exact, and on k, which cancels.** Only the hertz columns of the worked readings depend on postulate P-b. A reader who rejects the essence bridge entirely keeps every bound in this paper, expressed in nats.

Where the wider corpus constrains what may be claimed here, it does so in two places. The concentration work establishes that an effective count collapses to 1.00 once nominally distinct units are recognised as one bloc [Curzi, 2026,?] — which is exactly what the commons' $N_{\text{eff}} = 1.204754$ is reporting. And the founding definitions fix that comfort is the felt total of present costs, so that a present state is a local minimum of the comfort landscape by construction rather than by luck [Curzi, 2026]; **a group reading that returns DECAYS is therefore not a statement that anyone is doing anything wrong**, which is the boundary this paper's §5.12 states in its own terms.

8.4 The reflexive exposure

A published group reading can change the group it reads. The mechanism is documented [Merton, 1948, MacKenzie and Millo, 2003, Rosenthal and Jacobson, 1968], its measured effect sizes in the classroom case are contested and small [Jussim and Harber, 2005], and the framework's own parameters are not exempt from it [Lucas, 1976, Hacking, 1995]. **This paper does not control for it and cannot**, and §6.2's Corollary 6.1c — that no member is shown the

counterfactual value of their own withdrawal before deciding — is the one place where the exposure is met by design rather than acknowledged.

9 Verification

This section decomposes the paper's results into atomic steps, each checkable on its own. The standard is Occam's: **a postulate that can be dropped without the result changing has been dropped.** Every step carries one of four statuses.

- **ARITHMETIC** — reproducible by a reader with a calculator from the inputs named.
- **DEFINITION** — true by stipulation; nothing to verify but consistency of use.
- **CITED** — supported by a named external source.
- **POSTULATED** — asserted by this framework, with no external support.

9.1 The postulates

	postulate	status
P1	The Pythagorean whole tone is the frequency ratio $9{:}8$.	CITED [Barbour, 1951]
P2	φ is the positive root of $x^2 = x + 1$; hence $\varphi^2 = \varphi + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P3	A dimensionless ratio of the form $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source
P4	The essence of a state with n components has frequency kn^2.	POSTULATED — no source
P5	Stored order obeys $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$, $\delta > 0$.	CITED as a *form* [Oppenheim et al., 1996, Elaydi, 2005]; the interpretation POSTULATED
P6	$N_{\text{eff}} = 1 + (N-1)u$ (the affine count axiom).	POSTULATED — design axiom [Curzi, 2026]; **not a Hill number**
P7	$F = \ln N_{\text{eff}}$, hence $F \leq \ln N$.	DEFINITION (given P6)
P8	Total cost is $C = \kappa\, m(m-1)/2$: every pair maintains a link, all links cost alike.	**MODELLING CHOICE** (P-d); the superlinearity CITED [Brooks, 1975]
P9	m and N are cardinalities, hence absolute-scaled.	DEFINITION, typology CITED [Stevens, 1946]
P10	u is symmetric in its arguments and lies in $[0, 1]$.	DEFINITION (from unit vectors)

Dropped as unnecessary. No postulate about the *ordering* of the twelve states is needed for R1–R7: the crossover, the roster ceiling, the roster-scale identity, the aggregation gap, the commons audit, the restructure and the drop-one result all hold for any N and any $u \in [0, 1]$, whatever the states are called. The ladder's ordering is needed only for R8's class-coverage

table. **P3 and P4 are needed only for the hertz columns**, and dropping them leaves every bound in the paper standing in nats.

9.2 The compounding chain

step	consumes	produces	status
L1	P1	$(9/8)^2 = 81/64 = 1.265625$ exactly	ARITHMETIC
L2	P2	$\varphi^2 = \varphi + 1 = 2.618033988749895$	ARITHMETIC
L3	L1, L2	$k = 0.483425732988414$ — **a DEFINED constant, exact**	ARITHMETIC (exact)
L4	L3, **P3**	k carries the unit Hz	**POSTULATED**
L5	L4, **P4**	$f(n) = kn^2$ Hz	**POSTULATED**
L6	P6, P7	$F = \ln(1 + (N-1)\bar{u})$, $F \le \ln N = 2.484906649788$ at $N = 12$	DEFINITION
L7	P5	$Q_\infty = (\eta F - c)/\delta$	ARITHMETIC
L8	L6, L7	$D = 2.885390\,(c/\eta - F)$, with $2/\ln 2 = 2.885390081777927$ exact	ARITHMETIC
L9	P8	$C = \kappa m(m-1)/2$; at $\kappa = 0.055$, $m = 6$: $C = 0.8250$	ARITHMETIC
L10	L9, L6, $c/\eta \le \ln N$	$m(m-1) \le 2\eta \ln N/\kappa$ — **R2**	ARITHMETIC
L11	L10 at $\eta = 0.34$, $\kappa = 0.055$	bound $2\eta \ln N/\kappa = 30.7225$; actual $m(m-1) = 30$	ARITHMETIC
L12	P6 at roster scale	$M_{\text{eff}} = 1 + (m-1)\bar{u}$; PR $= m^2/\sum_{ij} G_{ij}^2$	DEFINITION
L13	L12	$M_{\text{eff}} = m + 1 - m/\text{PR}$ — **R3**; at PR $= 1.3522930095$, both $= 1.7815458788$, residual 0	ARITHMETIC
L14	L6, best case $M_{\text{eff}} = m$	octaves available $= 2\log_2 m$	ARITHMETIC given L5
L15	L8, L9, L14	$\text{NET}(m) = 2\log_2 m - 1.442695\, r\, m(m-1)$ — **R1**	ARITHMETIC
L16	L15 at $m = 2$	$r_{\max}(2) = 2\ln 2/2 = \ln 2 = 0.693147$	ARITHMETIC
L17	concavity of F, Jensen	$F(\bar{u}) \ge \overline{F(u)}$; on the triad $1.667424 - 1.491574 = 0.1758499493$ nats — **R4**	ARITHMETIC

step	consumes	produces	status
L18	L17 $\times\, 2/\ln 2$	0.507396 octaves $= 609$ cents; frequency ratio 1.421482	ARITHMETIC
L19	L6, L8 at commons parameters	$D = +6.4638$, $Q_\infty = -8.4630$, $N_{\text{eff}} = 1.204754$ vs 11.3189 — **R5**	ARITHMETIC
L20	L19 with $\eta \to 1$, $\kappa \to 0.005$, $N \to 144$	$+1.8430$, $+0.0990$, $+3.2562$: all fail	ARITHMETIC
L21	L8 split into two terms	-4.981543 (cost side) $+$ -4.608257 (surplus side) $= -9.589800$ — **R6**	ARITHMETIC
L22	concavity + cost linear in links	every drop-one row improves the reading near the ceiling — **R7**	ARITHMETIC
L23	P9, L5, odd-part class rule [Curzi, 2026]	$\lceil N/2 \rceil = 6$ classes; $\mu = \lfloor m(m-1)/2 \rfloor / 6 > 1$ from $m = 4$ — **R8**	ARITHMETIC + CITED
L24	L5, octave folding	folded values in 220–440 Hz, six pitch classes	**POSTULATED** (meaning); ARITHMETIC (value)

9.3 What this chain is and is not

Read the status column. Steps L1–L3 and L6–L23 are arithmetic or definition and a reader can redo every one of them; three of them (L1, L2, L11) can be redone in under a minute with a calculator, and L11 is the one that decides the commons case. **Steps L4, L5 and L24 are postulated. A chain containing postulated steps is not a proof of its conclusion**, and this one is not offered as one.

What it is offered as is a separation. **Every bound in this paper lives at or below L10 and L15, and neither consumes L4 or L5.** The roster ceiling is an inequality in κ, η and $\ln N$; the crossover is an inequality in r and m; the aggregation gap is a difference of logarithms; the drop-one result is concavity against linearity. **A reader who rejects P3 and P4 entirely loses only the hertz values and keeps every verdict.**

Two statuses that must not be misread. The exponent 2 at L5 is **DEFINED, not estimated**: no fit was performed, no alternative exponent was tested, and the standard procedure for testing a scaling claim [Clauset et al., 2009] was **not run, because there is no data to run it on.** And the logarithm at L6 is **DEFINITION given P6**; the warrant the argument actually needs for it is the multiplicative-dynamics one [Peters and Gell-Mann, 2016], not the psychophysical one [Fechner, 1860].

One check that a reader should run and that this paper wants run. The commons' roster-ceiling margin is $30.7225 - 30 = 0.7225$ in $m(m-1)$. The next admissible value of $m(m-1)$ is $7 \cdot 6 = 42$. **The case is therefore one member from structural, and the margin is smaller than the granularity of the variable it is measured in** — which is the sharpest statement of the commons' position available, and it is three subtractions.

10 Limitations

Every check the governing rigour standard specifies is listed here by name, whether or not this paper passes it.

L-1. Every case is constructed. The triad, the family, the team and the commons are chosen parameter sets. Their figures are exact because the inputs are exact; **that precision does not transfer to a measured case**, and reporting $D = +6.463800$ from an η known to one significant figure would be false precision. **No dataset was collected for this paper and none exists.**

L-2. The uniform complete-graph cost model is a modelling choice, and it is load-bearing. $C = \kappa m(m-1)/2$ assumes every pair maintains a link and every link costs alike. Real topologies are neither, the corpus's own nesting result depends on their not being [Curzi, 2026b], and **the quadratic that drives R1 and R2 is a property of the model, not a measured growth law.** No exponent here was estimated and none was tested [Clauset et al., 2009].

L-3. The dimensional audit does not close at $f(n) = kn^2$. The equation balances only if k carries $[T^{-1}]$, and k is a ratio of two dimensionless quantities. **The hertz is attached by assertion** (P-b, §3.4). No citation in the bibliography repairs it. The bounds of this paper survive it (§9.3); the hertz columns do not.

L-4. The constant is chosen. $k = (9/8)^2/\varphi^2$ combines two real objects into a product with no precedent. It is quoted to fifteen significant figures **because it is defined**, not because anything was measured to that precision, and the deflationary literature on golden-section claims is cited rather than avoided [Markowsky, 1992, Fischler, 1981].

L-5. Octave reduction beyond pitch is unwarranted. Octave equivalence is grounded for pitch [Shepard, 1982, Demany et al., 2013] and nothing grounds folding a non-acoustic quantity into a 220–440 Hz band and reading meaning from where it lands.

L-6. Neither effective count is a Hill number. $1 + (N-1)u$ and $1 + (m-1)\bar{u}$ are linear interpolations and appear in no ecological, economic, political-science or information-theoretic literature. The Hill-number citations here [Hill, 1973, Jost, 2006, Laakso and Taagepera, 1979] apply to $1/\mathrm{HHI}$ and $\exp(H)$ and to nothing else. **The participation-ratio identity of R3 is an algebraic consequence of the affine axiom and is not independent support for it** — a reviewer reaching for it as evidence will find it is not.

L-7. Conjoint measurement was not tested. The ratio-scale treatment of η, κ, δ and the elicited intensities is provisional. Michell's objection stands unanswered [Michell, 1997, 1999] for every quantity in this paper except the counts, and the available remedies [Luce and Tukey, 1964, Krantz et al., 1971, Rasch, 1960] were not run. §3.5 states the consequence: **a quantity whose scale type is not established cannot be known to the 8.8 per cent the family's verdict requires.**

L-8. The reflexive specification is not identified. Stated in §3.6 and repeated here because it is the most serious methodological problem in the corpus: the endogenous social effect in a linear-in-means reflexive loop cannot be recovered from observational data [Manski, 1993, Shalizi and Thomas, 2011]. The remedy adopted is stipulation of the reference group [Brock and Durlauf, 2001], **so every claim here about what a group's parameters imply is a modelling position rather than an identified empirical result.**

L-9. The framework exempts its own parameters from its own reflexivity. If groups change when modelled, η, κ, δ and $\bar{u}$ are not structural [Lucas, 1976, Hacking, 1995]. This is not resolved.

L-10. The functional form is underdetermined. A sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as this framework's logarithm does, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. **Nothing in this paper discriminates among them.** The mitigation is narrow and is stated as such: R1, R2, R7 and R8 need only concavity and boundedness, which all three candidates have.

L-11. Scalar reduction is a habit of this framework, and this paper inherits it rather than repeating the concession. The minimum-frequency paper states the limitation once, in full: the framework replaces a phenomenon its own source literature describes by several jointly varying features with a single number, and proceeds arithmetically on the number [Curzi, 2026]. That concession governs here. **This paper reduces a group of m people with $m(m-1)/2$ distinct relationships to one $\bar{u}$, and then to one octave deficit.** §4.3 measures part of the loss — 0.507396 octaves on three members — and §4.2's instruction to publish the full pairwise list is

the only mitigation offered. **It is a mitigation and not an answer**, and the four appraisal-theory works that bear on the general objection are not cited anywhere in this paper as support for any scalar index, because they do not support one.

L-12. u is symmetric and psychological similarity is not. Similarity judgments are asymmetric and violate the triangle inequality [Tversky, 1977]. Where u is read as a similarity measure over people, it cannot assume metric behaviour, and this framework's u does.

L-13. The diversity literature does not support the surplus claim and is not cited as though it did. The formal result that diversity can trump ability [Hong and Page, 2004, Page, 2007] is contested on the ground that it follows from the model's parameterisation [Thompson, 2014, Singer, 2019, Grim et al., 2019, Kuehn, 2017], and the organisational evidence is mixed and conditional [Mannix and Neale, 2005, van Knippenberg and Schippers, 2007]. **The claim that a non-parallel pair reaches the surplus ceiling is a statement about this framework's functional F, and it is not supported by, and does not need, any of that literature.**

L-14. The mean is an unexamined aggregator. §4.3 shows the choice of $F(\bar{u})$ against $\overline{F(u)}$ is worth up to 1.44 octaves in the sweep, but **no argument here establishes that the arithmetic mean over pairs is the right aggregator at all**, and a median, a trimmed mean or a weighted mean would give different readings.

L-15. The class-coverage table is a simulation, not an observation. 20,000 trials, uniform draws without replacement, seed 7. It is a computation with a stated seed and trial count and it describes nobody.

L-16. The reachability judgment is declared, not measured. Definition 5.1 requires the analyst to declare whether a required u^* is within what the parties could honestly represent. **That declaration has no instrument behind it.** A factor of 50.4 is called unreachable here; the paper supplies no test that would have said so.

L-17. Boundary behaviour is only partly examined. $\delta \to 0$ is a pathology (nothing decays out of the stock) and is inherited rather than re-derived; $u \to 1$ gives the ceiling and is examined; $\eta \to 0$ makes c/η diverge and places every group above every ceiling, which is a real constraint on the model's domain and **is not examined in the source**; $m \to \infty$ makes both bounds bite at once; $N \to \infty$ raises the ceiling without bound, which the coordination-cost literature says is not available in practice [Brooks, 1975]. These limits constrain the domain and are stated here because the source does not state them all.

L-18. No model comparison was performed. No out-of-sample test, no matched null with the same number of free parameters, and no information criterion, because nothing was fitted. Where the corpus attempted a confirmatory fit it failed its own declared baseline test [Curzi, 2026i], and that is the relevant precedent.

L-19. No statistical claims are made and none are supported. There are no p-values, no effect sizes and no confidence intervals here, because there is no sample.

L-20. The drop-one audit is an m-fold post-hoc comparison. Run without correction and read as a ranking it is a machine for false positives [Simmons et al., 2011, Gelman and Loken, 2013]. **That is a second and independent reason for SPEC 4.11's prohibition**, alongside the arithmetic one at R7.

L-21. Ergodicity is assumed and not argued. Q accumulates over time for one group from parameters that would naturally be estimated across groups; the time and ensemble averages of a multiplicative process are not the same [Peters, 2019], and nothing here establishes that they coincide.

L-22. There is no conservation law. Q is written with the grammar of a conserved quantity and none is supplied, which is the characteristic defect of the genre [Mirowski, 1989]. Validity is claimed only within a specified arrangement [Cartwright, 1999].

L-23. The governance mapping is a correspondence of dynamics, not of agency. Reading Ostrom's principles as moves on η, c and δ [Ostrom, 1990, Cox et al., 2010] is a modelling choice (M-e). **The claim that no principle acts on u is a claim about the mapping, not a finding about institutions.**

An arithmetic error found in the source, printed rather than silently corrected. The com-

mons' surplus is reported as $F(\bar{u}) = 0.186272$ nats in §5.2, §5.3, §5.9 and §5.12, from a reported $N_{\text{eff}} = 1.204754$. **That value is wrong in the sixth decimal place.** Recomputing from the realising vectors, $\bar{u} = 0.018614137$ gives $F = \ln(1.204755507) = 0.186276648$; recomputing from the *rounded* $\bar{u} = 0.018614$ gives $\ln(1.204754) = 0.186275397$. Neither is 0.186272, and §4.3 of this same paper already prints the correct 0.186276647.

Three consequences, all small and all disclosed. First, the summary table of §5.9 shows the conservative aggregation $\overline{F(u)} = 0.186276$ as *larger* than the optimistic $F(\bar{u}) = 0.186272$, which Jensen's inequality forbids. **The inversion is an artefact of the erroneous 0.186272 and not a violation**; with the correct value the inequality holds, at a gap of 4.28×10^{-7} nats — the 0.000001 octaves §4.3 reports. Second, the steady state is quoted three ways for the same case: -8.463000 in the summary tables (a four-decimal figure padded to six), -8.462955 in the prefix table of §5.12b (correct, from the vectors), and -8.462972 in the governance calculation of §5.6 (which inherits the erroneous F). Third, the deficit is likewise $+6.463800$ in the summary tables against $+6.463833$ from the vectors.

None of this changes any verdict, the discrepancies are at the fifth and sixth significant figure of a case whose deficit is $+6.46$ octaves, and this paper quotes $+6.4638$ and -8.4630 throughout for consistency with the rest of the corpus. It is recorded here because a reader recomputing from the printed intermediates will find the disagreement, and because **a paper that prints F to six decimals owes the reader six correct decimals.**

11 Conclusion

What is established. At group scope, coordination cost grows as $m(m-1)/2$ while best-case surplus grows as $2\log_2 m$ octaves, so $\text{NET}(m) = 2\log_2 m - 1.442695\, r\, m(m-1)$ and **a dyad is viable in the best case if and only if** $r = \kappa/\eta \leq \ln 2 = 0.693147$**.** A second and exact bound, independent of any geometry, is the roster ceiling $m(m-1) \leq 2\eta \ln N/\kappa$. Two effective counts exist at group scope and must be reported separately; the roster-scale one satisfies $M_{\text{eff}} = m + 1 - m/\text{PR}$ exactly, verified at 1.7815458788 with residual zero. The choice of aggregation is worth **0.507396 octaves — 609 cents — on a dispersed triad and 0.000001 octaves on a near-parallel commons**, so both must be published. An orthogonal pair already attains $F = \ln N$, so **a group's case is never a surplus case.** And on a healthy team every drop-one row improves the reading, which establishes that such rows carry no information about the members they name.

What was run and failed. A constructed six-member commons at $\bar{u} = 0.018614$ carries a deficit of $+6.4638$ octaves and a steady state of -8.4630. Every lever was swept to its physical limit and every one fell short: $+1.8430$ at perfect conversion, $+0.0990$ at a 91 per cent cost cut, $+3.2562$ at twelve times the category count, $+2.7298$ after nesting. **The procedure halts and issues no prescription.** The restructure that does work — recruiting outside the doctrine, nesting to seven links, adopting a conversion mechanism — swings the reading 9.5898 octaves, 51.9 per cent from the cost side and 48.1 per cent from the geometry, **and produces a different group.**

What is proposed rather than shown. That the ratio $(9/8)^2/\varphi^2$ is a frequency; that essence goes as kn^2; that octave equivalence carries beyond pitch; and that coordination cost is exactly $\kappa m(m-1)/2$ over a complete uniform graph. **The first three are postulates of this framework with no external support and the fourth is a modelling choice**, all four are labelled at every appearance, and every bound above survives the loss of the first three because k cancels from every interval.

What is not claimed at all. No group, person, family, team, commons or room is claimed to resonate at any frequency named here. Nothing in this paper evaluates any person, and no output of the drop-one analysis, the marginal-member test or the withdrawal counterfactual may be presented as a ranking, an assessment or a recommendation about anyone.

12 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number in the paper is the output of exact arithmetic on parameters stated in the text; every case — the triad, the family, the team and the commons — is constructed and is labelled as constructed at the point of use, with its input vectors and raw L^2 norms published so that any reading can be recomputed. The one simulation, the class-coverage table of §4.4, states its trial count (20,000) and its random seed (7). The figures are generated by the Python scripts named in their captions, which take their inputs from the tables in the text and are available from the author on request. **No empirical measurement of any person, group, family, team or institution underlies any figure, table or number in this paper.**

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The constructed triad, family, team and commons are invented parameter sets; they are not derived from, and do not describe, any person or group. The paper specifies a consent protocol (§6.2) and a prohibition on disclosing withdrawal counterfactuals (Corollary 6.1c) as requirements on any future application; **neither has been applied to anyone, because no reading of any real group was taken.**

Preregistration. No test in this paper was preregistered, because no test was run. The hypotheses of §2.1 are stated with their falsification conditions so that they can be preregistered by others; the corpus's one preregistered confirmatory attempt failed its own declared baseline margin and reported the failure [Curzi, 2026i].

Clinical disclaimer. The twelve state classes are not diagnostic categories. Nothing in this paper is counselling, therapy, mediation, family assessment or clinical evaluation, nothing in it is an assessment of any person's health or capacity, and nothing in it may be presented as such.

Chapter 46

Auditing a Traditional Operation Set Against a Parameter Model: Seven Maps, Two Splits, Three Rejections, and the Many-to-One Compound Rule

Abstract. We test whether a dated twelve-operation schedule from the alchemical corpus can be assigned targets in a closed parameter model $(n, N, u, \eta, c, \delta)$ with a compound index G. Of thirteen entries on a list fixed before the results, seven map cleanly, two are ambiguous between operations returning values in different units, one changes only the publication register, and three are rejected — among them a traditional ordering of metals proposed as an essence index, and *exaltation*, which presents a value ordering as a count. Run as a schedule on a constructed dyad, the ninth operation alone supplies -5.305895 octaves of a -5.966526 total, 88.93 per cent, against 11.07 per cent from the eight before it; the only operation acting on the numerator sits ninth of twelve, which is the order the framework's own rule condemns. The compound rule $f = k^2 G^4$, with G the count-weighted geometric mean of component indices, is derived by substitution rather than asserted and reproduces 37 of 44 published composite values to better than one part in 10^{12}; the pure-oxygen row settles the seven disagreements as errata, since $G = 8$ at every multiplicity gives 957.2370 against a published 11.1246. Corollary 5.2 proves the compound rule and the essence law agree at no integer index, coincidence requiring $n = 1/\sqrt{k} = 1.438252434444351$; at $n = 12$ they differ by 6.121291 octaves. The map is many-to-one at rates 1.32 to 5.56 over $T = 2 \dots 6$, losing 0.4028 to 2.4750 bits, with $G = 6$ produced by sixty distinct multisets. Re-indexing leaves the interaction parameter untouched except through overlap: four moves spanning 8603.9100 cents return identical readings to twelve decimal places. All cases are constructed; the constant is defined and cancels from every interval, so no verdict depends on it.

Keywords: operation audit; compound rule; geometric mean index; many-to-one map; re-indexing; order of operations; quantity blindness; errata

Series: C. Frequency, Essence, and Mind **Paper:** CCP-046

1 Introduction

A body of technique can be older than the formalism that would describe it. When that happens there is a determinate question to ask — **whether the old terms name operations the formalism can express** — and the question has an answer that can be worked out and published rather than admired.

This paper asks it of a specific, dated, transmitted sequence: the twelve gates of a fifteenth-century alchemical text, plus one appended candidate index, audited against a closed five-parameter model with a compound term. **The method is an audit and an audit has one property that distinguishes it from an appreciation: it can return a failure, and if it never does, it was not an audit.** Five of thirteen entries carry a failure and they are printed at the same length as the successes, with the arithmetic that condemns them.

Three results follow, and two of them are negative.

First, the audit distribution. Seven entries map cleanly onto a declared parameter; two are `SPLIT`, meaning the single old term covers two distinct operations that return values in different units; one is a `RENDERING`, real about the publication register rather than about any state; and three are `REJECTED` outright — including a traditional ordering of metals proposed as an essence index, which fails all four of the framework's validity conditions, and *exaltation*, which fails because **"nobler" is a value ordering and the index is a count**. Permissible arithmetic is fixed by the transformation group a quantity admits [Stevens, 1946], and a rating dressed as a count inherits none of the count's properties and all of the rating's ambiguity.

Second, and this is the sharpest finding, the tradition's own ordering is wrong by the framework's own rule. Run as a schedule on a constructed dyad, the twelve gates move the octave deficit by -5.966526 in total, of which the **ninth gate alone supplies -5.305895, or 88.93 per cent**, while the eight before it supply 11.07 per cent between them. The ninth gate is the only one in the list that acts on the numerator of the sustainability condition, and the framework's ordering rule requires numerator moves first [Curzi, 2026]. **The same intervention on the loss rate improves the destination in one ordering and damages it in the other**, and the only thing that differs is the sign of the numerator when the move is made.

Third, the compound rule is derived rather than asserted, and it is many-to-one. Substituting $f(n) = kn^2$ into a published recipe for combining essence values collapses in four lines to $f_{\text{compound}} = k^2 G^4$, where G is the count-weighted geometric mean of the component indices. The collapsed form reproduces **37 of 44 published composite values to better than one part in 10^{12}**, and the seven that disagree are shown to be errata rather than evidence of a different law by a row the rule constrains completely: for a single-element species G is the element index at every multiplicity, so pure oxygen admits exactly one value, 957.2370, against a published 11.1246. But the map is not invertible. **By four components, five component sets in six share their compound value with at least one other; by six components, nineteen in twenty do.** The value $G = 6$ alone is produced by sixty distinct multisets over the twelve-state ladder at $T \le 6$. *Dissolution is not the inverse of fixing; it is a search over a fibre, and the fibre has to be published with the answer.*

A fourth result is a non-result and is worth as much. Re-indexing — moving a state from one index to another — is proved to leave the interaction parameter untouched except through changed overlap: **four constructed moves spanning 8603.9100 cents of lattice distance return the identical relationship reading to twelve decimal places.** The lattice and the relationship measure different things and neither refines the other.

Contributions

1. The audit of thirteen entries against four stated conditions, with the distribution 7 `MAPS` / 2 `SPLIT` / 1 `RENDERING` / 3 `REJECTED` and every rejection carrying the specific result that condemns it and a statement of what would reverse it.
2. Finding 4.2: the schedule result — 88.93 per cent of the total movement supplied by the ninth of twelve steps, which is the order the framework's own rule condemns.

3. The compound rule $f = k^2G^4$ derived by substitution, verified against 44 published values, with the seven disagreements diagnosed as errata by the constrained single-element row.
4. Corollary 5.2: $kn^2 = k^2n^4$ requires $n = 1/\sqrt{k} = 1.438252434444351$, not an integer, **so the compound rule and the essence law agree at no index whatever**; at $n = 12$ they differ by 6.121291 octaves.
5. Theorem 5.3, quantity blindness: G is invariant under scaling every multiplicity by a common integer, so $\{3, 5\}$ and $\{3^{\times 5}, 5^{\times 5}\}$ return the identical 52.582598845962.
6. Theorem 5.4 and the fibre enumeration: many-to-one rates from 1.32 to 5.56 over $T = 2 \ldots 6$, with the information loss priced at 0.4028 to 2.4750 bits.
7. Theorem 6.3 and CONSTRAINT T21: re-indexing moves the relationship only through overlap, and reaches only what is already latent — an index is a count, and a count cannot be raised by counting harder.

What this paper does not claim, stated at the front. It does not claim that any audited operation was ever effective, that its practitioners understood it in the terms recovered here, or that any symbol, name, sequence or substance has a physical effect. **Precedent is not evidence**, and no entry upgrades its status on the strength of the tradition's testimony — for which the framework fixes the survivorship likelihood ratio at exactly 1.000000. Every case is constructed and labelled. The frequency register rests on postulates badged in Section 2, and the constant k cancels from every interval in the paper, so no verdict depends on it.

2 Hypotheses, definitions, postulates and modelling choices

2.1 Hypotheses proper

H1 — the mapping hypothesis. Each entry in the audited historical sequence either names an operation on a parameter in the declared set $\{n, N, u, \eta, c, \delta, G\}$ or it does not, and which is the case is decidable by the four conditions of Audit Rule 4.1. **Predicted:** an independent auditor applying the four conditions to the same thirteen entries reaches the same distribution of verdicts. **Falsified by:** an entry on which two auditors applying the stated conditions disagree, with the disagreement traceable to the conditions rather than to the source text. **Status: not tested.** The audit was performed once, by one analyst. Inter-rater reproducibility is the obvious test and it has not been run; §10 records this as the paper's largest untested claim.

H2 — the ordering hypothesis. The tradition's canonical order is not the order the framework's own rule prescribes. **Predicted:** running the gates as a schedule places the single numerator-acting operation late, so that loss-rate interventions occur while the numerator is negative. **Falsified by:** a reading of the source sequence on which the numerator-acting operation comes first, or a demonstration that more than one gate acts on the numerator. **Status: computed** on a constructed dyad in §4's worked example: the ninth gate supplies 88.93 per cent of the movement. The finding is about this reading of the sequence and this constructed case.

H3 — the errata hypothesis. The seven published composite values that disagree with k^2G^4 are transcription errors rather than evidence of a different combination law. **Predicted:** the disagreements are scattered rather than systematic, and at least one lies outside the range the rule can produce at any input. **Falsified by:** a systematic pattern in the residuals, or an alternative closed form reproducing all 44 values. **Status: supported** — the residuals span four orders of magnitude with no pattern, and the pure-oxygen row admits exactly one rule-consistent value at every multiplicity. **No alternative law was searched for**, which is a real weakness of the test and is recorded at §10.

H4 — the non-invertibility hypothesis. The map from component multiset to compound value is many-to-one at rates that grow with the component count. **Predicted:** exhaustive enumeration over the twelve-state ladder shows the ambiguous fraction rising with T. **Falsified by:** a count at which the map is injective. **Status: proved** (Theorem 5.4) and **enumerated exhaustively** for $T = 1 \dots 6$.

H5 — the independence hypothesis. Lattice position and the interaction parameter are independent: a re-indexing moves u only through the overlap it destroys or creates. **Predicted:** re-indexings of very different lattice distance that vacate and occupy the same coordinates return identical u. **Falsified by:** two such moves returning different u. **Status: proved** (Theorem 6.3) and exhibited on four constructed moves spanning 8603.9100 cents that agree to twelve decimal places.

2.2 Definitions — true by stipulation, not falsifiable

- **Def. 1.** The declared parameter set is $\{n, N, u, \eta, c, \delta, G\}$ and it is **closed**: an operation maps if and only if it names an input and an output inside it.
- **Def. 2.** $G := \left(\prod_i n_i^{c_i}\right)^{1/T}$ with $T = \sum_i c_i$, the count-weighted geometric mean of component indices.
- **Def. 3.** j, the transposition exponent, is a **choice of publication register** and is not in the declared set. An operation acting only on j acts on nothing in the system.
- **Def. 4.** *Pitch class* is the odd part of an index [Curzi, 2026]. It is a function of n and is not independently settable.
- **Def. 5.** A *re-indexing* is a change of index on a single fixed ladder reflecting a change in the number of distinguishable components required to specify a state (Definition 6.1). A change of ladder, a change of register and a re-labelling are each excluded, and each exclusion is load-bearing.
- **Def. 6.** $k := (9/8)^2/\varphi^2$. **This is a defined constant.** It is an exact ratio of exact quantities and therefore computable to arbitrary precision; the fifteen significant figures 0.483425732988414 are *exact digits of a definition* and carry no measurement uncertainty because there is no measurement. $k^2 = 0.233700439315386$ inherits the same status. **Every appearance of either at that precision in this paper is so labelled.**
- **Def. 7.** *Latent* means **present in the repertoire and observed at least once**, in some state, on some occasion. It does not mean conceivable (§6.5).

2.3 Postulates — asserted by this framework, with no external support

- **P-a. The essence law $f(n) = kn^2$.** A quadratic relation between a dimensionless count and a frequency. **No external literature supports it. The exponent 2 is defined by the model, not estimated from data**; no fit was performed, no alternative exponent was tested, and the goodness-of-fit and likelihood-ratio procedure a scaling claim would require [Clauset et al., 2009] was not run, because there is no data to run it on. The same applies to the exponent 4 in k^2G^4, which follows from the substitution and is likewise defined rather than measured.
- **P-b. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic. **Asserting that this dimensionless number *is a frequency* is a separate and much stronger claim**, and no operational procedure is supplied by which the constant acquires the dimension of inverse time. This is postulated, and it occupies its own line of the verification chain (§9.2, step L4).
- **P-c. The squaring in Rule 3 read as a change of structural level.** k^2G^4 carries hertz-squared if the units are taken seriously. The source reads the squaring as a change of structural level rather than as a dimensional operation, and this paper adopts that reading **with the badge on**: it is a design decision, not a derivation, and it is why every Rule 3 value in the paper is labelled *convention-Hz* and admits ratio operations only.

- **P-d. The extension of the latency constraint from cells to psychological states.** CONSTRAINT T21 is the psychological restatement of a constraint established for genome addressing [Curzi, 2026y]. **The cited biology licenses the form of the constraint and not a claim about minds**, and the extension is this work's thesis, badged, and is not established by the cited work.
- **P-e. The affine effective count $N_{\text{eff}} = 1 + (N-1)u$.** A design axiom [Curzi, 2026], **not a Hill number of any order.** The Hill family [Hill, 1973, Jost, 2006] and its political-science rediscovery [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly and ground this construction not at all.

2.4 Modelling choices — legitimate, but choices

- **M-a. Octave reduction applied to a non-acoustic quantity.** Octave equivalence is formalised for **pitch** [Shepard, 1982], with a measured perceptual specialness [Demany et al., 2013]. Carrying it to a quantity that is not a pitch is a choice of this framework. The *operation* — division by a power of two — is well defined; its *interpretation* is not supported.
- **M-b. Cents as the unit of a move.** Exact rational interval arithmetic in a logarithmic register is standard apparatus [Barbour, 1951, Lindley and Turner-Smith, 1993, Benson, 2006]. **That $2400 \log_2(n/m)$ is the right price for a move between indices is a choice**, and the two established measures of ratio complexity — Euler's *gradus suavitatis* [Euler, 1739] and harmonic distance [Tenney, 2015] — are named in §5.8b and **not used**.
- **M-c. The source list, fixed in advance.** Twelve gates plus one candidate index, chosen before the results were known. Any other list would give another distribution of verdicts, and the distribution is a property of this list.
- **M-d. Multiplicities are counts, never intensities.** Putting an elicited intensity into G produces a quantity that is neither (FM-5.5). This is stipulated and not derived.
- **M-e. Reading a historical sequence as a schedule.** §4's worked example treats the gates as an ordered procedure and assigns each the smallest parameter change its own description licenses. **Those assignments are constructed**, and a different reader could assign differently; the schedule result is a result about this assignment.

2.5 What is expository

The specification blocks (SPEC-4.1 to 4.7, SPEC-5.1 to 5.6, SPEC-6.1 to 6.5), the three failure-mode catalogues, and Procedures COAG-1, SOLV-1 and TR-1 are expository: they fix reporting requirements and name failure modes rather than argue a claim. Their organising question is *what must be published alongside an audited verdict, a compound value or a priced move for a third party to check it.*

3 Framework, dimensional audit, and method

3.1 The parameter model — a shared mathematical form, not a derivation

The storage law $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$ underlies every deficit computed in this paper. **Analogy status: category 2, a shared mathematical form.** It is the discrete leaky integrator of signal processing [Oppenheim et al., 1996], of exponential smoothing [Holt, 1957] and of the integrate-and-fire neuron [Lapicque, 1907, Gerstner and Kistler, 2002]; its fixed point $Q_\infty = (\eta F - c)/\delta$ requires $\delta > 0$, and stability and uniqueness are standard [Elaydi, 2005, Banach, 1922, Curzi, 2026a]. **No claim is made that any physical result about circuits transfers.**

The surplus functional $F(u) = \ln(1+(N-1)u)$ is the corpus's own [Curzi, 2026]; its logarithmic form places it in the same family as Shannon's entropy [Shannon, 1948] and its ceiling $F \leq \ln N$ is the requisite-variety bound [Ashby, 1956]. **Which warrant the logarithm needs**

is worth stating: the psychophysical route [Fechner, 1860] inherits every dispute in that literature, while the multiplicative-dynamics route derives the same form with no psychological assumption at all [Peters and Gell-Mann, 2016]. This paper needs only the second. **The form remains underdetermined by the evidence** — a sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. Nothing here discriminates among them.

Two warnings attach and are recorded here rather than in a footnote. Time and ensemble averages of a multiplicative process differ [Peters, 2019], and a single parameter written for a group is an aggregation that need not yield a representative agent [Kirman, 1992]. And Q has the grammar of a conserved quantity with no conservation law to give it content, which is the characteristic defect of the genre [Mirowski, 1989]; validity is claimed only within a specified arrangement [Cartwright, 1999], and the boundaries the sociophysics literature draws [Castellano et al., 2009] are the boundaries claimed here.

3.2 The essence bridge and the constant

$f = k\, e^{2F}$ carries a surplus into a pitch register, and its Result One is that $f(m)/f(n) = m^2/n^2$, **so the constant cancels from every interval and does no work beyond setting a reference** [Curzi, 2026k]. That property is load-bearing here: every price in this paper is a difference of logarithms, so **no verdict depends on k, and only the absolute values do.**

$k = (9/8)^2/\varphi^2 = 0.483425732988414$ is a **defined constant, exact**. Its components are real and documented — the Pythagorean whole tone [Barbour, 1951] and the golden section [Euclid, 1956, Vajda, 1989] — but their product **expressed as a frequency in hertz has no precedent in any literature we have found**, and the standard deflationary treatment of golden-section claims [Markowsky, 1992, Fischler, 1981, Livio, 2002] is cited here and again wherever φ appears.

3.3 Dimensional audit

symbol	quantity	dimension	unit	status
n	essence index	$[1]$	count	cardinality, absolute scale
N	category count	$[1]$	count	cardinality, absolute scale
c_i	multiplicity	$[1]$	count	cardinality; **never an intensity**
$T = \sum c_i$	component count	$[1]$	count	derived
G	count-weighted geometric mean	$[1]$	index units	derived; generally irrational
u	interaction parameter	$[1]$	dimensionless, $[0, 1]$	derived from unit vectors
F	surplus	$[1]$	nats	derived; **nats are not a physical unit**
η	conversion efficiency	$[1]$	dimensionless	declared
c	cost flow	$[\mathcal{C}\, T^{-1}]$	per declared period	declared

symbol	quantity	dimension	unit	status
δ	loss rate	$[1]$	per declared period	declared
D	octave deficit	$[1]$	octaves, cents	derived
j	transposition exponent	$[1]$	integer	**register choice, not a parameter**
k	ground essence	**claimed** $[T^{-1}]$	Hz **by postulate**	**defined; the unit is asserted**
k^2G^4	compound value	$[T^{-2}]$ **if taken seriously**	*convention-Hz*	**derived; the label is a convention (P-c)**

Does the audit close? Two places where it does not, and both are named rather than papered over. $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, and k is a ratio of two dimensionless quantities: that is postulate P-b. And $f_{\text{compound}} = k^2G^4$ is **dimensionally hertz-squared**, so the "Hz" label on it is a convention inherited from the source and not a unit: that is postulate P-c, and it is why SPEC-5.4 forbids entering a Rule 3 value into an acoustic calculation and forbids ratioing it against a Rule 1 or Rule 2 value. **Everything else in the table is dimensionless and closes exactly**, including G, every interval in cents, every deficit, and every count. **The audit's verdicts therefore survive the failure of P-b and P-c intact**; only the absolute values do not.

3.4 Scale type, and what licenses the arithmetic

Permissible arithmetic is fixed by the transformation group that leaves a quantity's empirical content unchanged [Stevens, 1946]. Three classes appear here.

Counts. n, N, c_i and T are cardinalities. A cardinality admits only the identity transformation, so squaring an index, taking a product of indices and forming a geometric mean of them are licensed. **This is the only part of the paper whose scale type is secure, and it is exactly the property Gate 10 and Entry 13 are rejected for lacking.**

Derived dimensionless ratios. u, F, D and every interval in cents inherit their standing from the elicited intensity vectors, which come from magnitude estimation. That method is *held* to deliver ratio-scale information [Stevens, 1957], its exponents move with the experimenter's chosen range [Teghtsoonian, 1971], its response biases are catalogued [Poulton, 1968], and the dispute is live [Krueger, 1989, Luce, 2002]. **This paper inherits it whole.**

Declared parameters. η, c and δ are treated as ratio-scaled on a declared period and **nothing establishes that they are.** Michell's objection is the strongest against this framework [Michell, 1997, 1999], the formal test for additive quantitative structure exists [Luce and Tukey, 1964, Krantz et al., 1971], and **it was not run on any quantity in this paper.** The corpus has demoted one of its own constructions on precisely this ground [Curzi, 2026t], and the instrument that would repair the demotion [Rasch, 1960] is not applied here. **The ratio-scale treatment is provisional and is conceded rather than defended.**

3.5 Identification — the objection this framework cannot presently answer

Every relationship number in this paper is computed from a reflexive specification in which the parties constitute the group and the group conditions the parties. **The endogenous social effect in such a specification is not identified from observational data** [Manski, 1993]: it cannot be separated from contextual effects or from correlated unobservables however much data is collected, and influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011].

The remedy adopted here is stipulation of the reference set [Brock and Durlauf, 2001]: the parties, the period and the vectors are declared and published, so that a reading is repro-

ducible even though the parameter is not identified. Its price is stated plainly: **every relationship claim in this paper is a modelling position rather than an identified empirical result.** No result in Sections 4, 5 or 6 depends on identification — the audit verdicts, the compound rule, the fibre enumeration and the re-indexing theorem are all statements about the formalism — but the *worked readings* that instantiate them do, and they are labelled accordingly.

Two objections in the same family are also unanswered: the framework asserts that systems change when modelled and exempts its own parameters from that reflexivity [Lucas, 1976, Hacking, 1995, Merton, 1948], and a reflexive fixed point has been documented occurring in the field [MacKenzie and Millo, 2003], so the exposure is real rather than hypothetical.

3.6 Method

No data were collected. Four steps.

1. **Fix the list before the results.** The thirteen entries are specified in §4.5 and were not revised after any verdict was reached; the candidate target for each is named as an *input*, and changing it after the audit begins voids the entry (SPEC-4.1, FM-4.8).
2. **Apply four stated conditions.** Audit Rule 4.1 (a)–(d). Condition (c) — is the transformation a function rather than a wish — is where value orderings fail, and the failures are published at the same length as the successes.
3. **Derive, then verify.** The compound rule is obtained by substitution in four lines and then checked against 44 published values; the fibre structure is obtained by **exhaustive enumeration** over the twelve-state ladder for $T = 1 \dots 6$, not by sampling.
4. **Publish the refusals.** Every rejection names the condition that failed, the specific result that condemns it, the rescues a reader is likely to attempt, and **what would have to be true for the verdict to change.** A rejection that cannot say what would reverse it is an opinion.

Every figure in this paper is generated by a script named in its caption, taking its inputs from the tables in the text. Nothing was fitted; no model comparison is reported, because there is nothing to compare and no out-of-sample data to compare on.

4 Auditing a traditional operation set against the parameter model

The preceding papers of this series end with an instrument that produces a number and a procedure that mostly declines to act on it. This paper asks a different question: whether a body of technique that predates the instrument by some centuries was describing the same objects.

The position taken here is stated as a thesis and badged as one: **the old operations are these relationships in another notation.** That is a claim about description, not about efficacy. It says that when a fifteenth-century writer set down a sequence of named procedures and insisted on their order, the sequence had structure, and the structure is legible today in a formalism that writer did not have. It does not say the procedures worked. It does not say symbols act on matter. It says: here is a list of operations, here is a list of parameters, and the question of which list maps onto which has a determinate answer that can be worked out and published.

This section works it out. The method is an audit, and an audit has one property that distinguishes it from an appreciation: **it can return a failure, and if it never does, it was not an audit.** Five of the entries below fail. They are printed at the same length as the ones that pass, with the arithmetic that condemns them, because a section recovering twelve successes from twelve attempts would be evidence about the auditor rather than about the material.

Three things are fixed before anything begins.

The declared parameter set is closed. An operation maps if and only if it names an input and an output inside `{n, u, N, eta, c, delta, G}` and the map is computable. There is no thirteenth parameter, no residual, and no category of “acts on the whole.” The decay-blindness

result R4 [Curzi, 2026] already establishes that a real, well-attested intervention can act on a parameter the framework's central diagnostic cannot see; that result is what makes this audit worth running rather than assuming.

The evidential roles are declared once and hold throughout, following the framework's three-drawer honesty classification [Curzi, 2026]. Where a concordance is drawn in this section, the `(+1)` column carries evidence — measured, replicated, falsifiable — and the `(−1)` column carries precedent, which is the fact that a structure was arrived at independently and preserved. Precedent is worth having and it is not evidence. **No entry below treats the antiquity of an operation as a reason to believe it does anything.**

Nothing in this section claims that a symbol, a name, a sequence, or a substance has a physical effect. The essence frequencies are essence frequencies. No person, tissue, or molecule is claimed to resonate at any value here, the twelve states are not diagnoses, and no reading is an assessment of anyone's health.

The law

4.1 What an audit is An audit takes a claim expressed in one vocabulary and asks whether it can be restated in another without loss and without addition. Three outcomes are possible and they are not a scale.

The claim **maps**: there is an operation on the declared parameters that does what the old term says, the map is computable, and running it produces a number. The claim **fails**: the old term names something the formalism can express, and the formalism says it does not work, or does not work as stated. The claim is **empty**: the old term names nothing in the parameter set at all — not something false, something absent.

The procedure is the framework's own feedback-reading rule applied to a vocabulary rather than to a channel: record what was sent, record what came back, and read the difference [Curzi, 2026]. A restatement that returns the original unchanged reports only that nothing in the target vocabulary could touch it.

The three outcomes carry different obligations. A map must be published with its arithmetic. A failure must be published with the specific result that kills it. An emptiness must be published with a statement of what would have to exist for it to be otherwise, because "I found nothing" and "there is nothing" are different claims and only the first is available from an audit.

An audit does not establish that a mapped operation was ever performed, was ever effective, or was understood by its practitioners in the terms recovered here. It establishes that a modern operation exists which the old term describes. The direction of that sentence matters. It is the weakest claim consistent with the evidence and it is the only one this section makes.

4.2 The declared parameter set Everything this framework can compute is a function of seven quantities. Six are inherited; the seventh is Section 5's.

`n`	the differentiation index of a state	CCP-041, a COUNT, ratio-scaled
`N`	the number of distinguishable categories	CCP-041; ceiling `F <= ln N`
`u`	the interaction parameter	CCP-043, CCP-044; `u = 1 - cos^2 theta`
`eta`	conversion of interaction into structure	the storage law
`c`	the per-period cost	the storage law
`delta`	the loss rate	the storage law
`G`	the count-weighted geometric mean	Sec 5, compound composition

Everything else in the framework is derived from these. `f = k n^2` from `n`. `F = ln(1 + (N−1)u)` and `f_rel = k(1+(N−1)u)^2` from `u` and `N`. `f_min = k e^(2c/eta)` from `c` and `eta`. The octave

deficit `D = 2.885390 (c/eta) − log2(f/k)` from four of them, and — the decay-blindness result R4 [Curzi, 2026] — **conspicuously not from `delta`.** The fixed point `Q_inf = (eta F − c)/delta` from all of them. The compound frequency `k^2 G^4` from `G` alone.

Two derived quantities that are not parameters and are frequently mistaken for them:

The transposition exponent `j`. Octave folding multiplies a frequency by `2^j` (the folding rule [Curzi, 2026]). `j` is a choice of register for publication. It changes no relationship whatever: whatever two states shared before folding they share after, and whatever separated them separates them by the same interval in cents. An operation that acts only on `j` acts on nothing in the system.

The pitch class. The odd part of the index (the odd-part class rule, result R1 [Curzi, 2026]). It is a function of `n` and is not independently settable. You cannot move a class without moving an index.

4.3 The three transfer rules, restated as targets

The three transfer rules [Curzi, 2026] fixes three rules. This section uses them as the three places an operation can land.

```
RULE 1   an ESSENCE has a frequency            f = k n^2
         target: the index n

RULE 2   a RELATIONSHIP has a frequency        f_rel = k (1 + (N−1) u)^2
         target: the interaction parameter u, and N

RULE 3   a COMPOUND uses the alchemical rule   f_compound = k^2 G^4
         target: the composition, through G
```

Plus the storage law's three, which are not transfer rules but are parameters an operation can act on: `eta`, `c`, `delta`.

A candidate operation is therefore audited against six targets and one non-target. The non-target is the register `j`, and it exists in the list precisely because one classical operation lands there and nowhere else.

4.4 The audit rule, and the verdict vocabulary

AUDIT RULE 4.1. A classical operation MAPS if and only if all four conditions hold.

```
(a)  it names a starting configuration expressible in the declared parameters
(b)  it names an ending configuration expressible in the declared parameters
(c)  the transformation from (a) to (b) is a function, not a wish
(d)  running it on a stated input produces a number
```

Condition (c) is the one that does the work, and the reason is measurement-theoretic rather than stylistic: permissible arithmetic on a quantity is fixed by the transformation group that leaves its empirical content unchanged [Stevens, 1946], and a value ordering admits every monotone transformation while a count admits only the identity. Treating a rating as though it were a count is the error the psychometric literature has documented longest [Likert, 1932, Thurstone, 1927], and the objection that psychology assumes quantitative structure without testing for it [Michell, 1997, 1999] is its general form. The formal test that would settle it [Luce and Tukey, 1964, Krantz et al., 1971] has not been run on any quantity in this paper. "Raise the material to a nobler state" satisfies (a) and (b) in appearance only: *nobler* is not a coordinate. The count-versus-rating rule [Curzi, 2026] already named this fault under its own heading — smuggling a rating in as a count — and it is the single most common way an old operation fails this audit.

Verdicts, five of them, and they are borrowed from the concordance register of Series B so that the register can absorb this section's rows without translation:

MAPS	all four conditions. The operation IS an operation on a declared parameter. Publish the map and a worked number.
MAPS, SPLIT	the term is used for two distinct operations in the source tradition and they land on different parameters. Both are published, and the ambiguity is reported as a finding.
REJECTED	the operation is expressible and the formalism says it does not do what is claimed. Published at full length with the result.
EMPTY	the operation lands on no declared parameter and no derived quantity. Not false — absent.
RENDERING	the operation is real, computable, and acts only on the register j. It changes how a value is published and nothing about the system. Admissible as a rendering step; inadmissible as an operation on a state.

4.5 The source set The audit needs a fixed list chosen before the results are known, or it is a selection exercise. The list used is **the Twelve Gates of George Ripley's *Compound of Alchymy* (1471)**, a specific, dated, transmitted sequence: calcination, solution, separation, conjunction, putrefaction, congelation, cibation, sublimation, fermentation, exaltation, multiplication, projection.

Fixing the list in advance is the same discipline preregistration imposes on an analysis [Nosek et al., 2018]: a set chosen after the results are seen is a selection exercise, and the multiple-comparison and forking-path literature is explicit about what that costs [Simmons et al., 2011, Gelman and Loken, 2013]. The corpus's own narrative work makes the structural version of the point — that a corpus closed under negation has resultant exactly zero, so what looks like a finding can be determined entirely by the choice of set [Curzi, 2026ad].

Two reasons for this list over the more familiar seven-operation schemes. It is longer, so it contains more chances to fail, which is the property an audit wants. And it is *ordered* — Ripley presents the gates as a sequence in which each is prerequisite to the next — which lets the Worked Example ask a question no unordered list can pose: does the sequence, run as a schedule, do anything the individual steps do not?

A thirteenth entry is appended: not an operation but a candidate index, the traditional ordering of the metals. It is included because the state-ordering material [Curzi, 2026] rejected four candidate orderings in print and this is the one an alchemical section is obliged to consider.

The `(-1)` column for the whole set is Ripley, with the transmission path stated: a Middle English verse text of 1471, circulated in manuscript, printed in Elias Ashmole's *Theatrum Chemicum Britannicum* (1652), and read continuously since. What it records is a procedure and an order. **What it explains about that procedure is not admissible and is not used below.**

4.6 Honesty clauses, restated in place **(1) ESSENCE, NOT RESONANCE.** Every frequency in this section is a position on a logarithmic scale of surplus. Nothing is claimed to vibrate. No physical, chemical, or biological effect of any symbol, name, sequence, or operation is claimed anywhere.

(2) NO CLINICAL CLAIM. The twelve states are not diagnoses. Nothing here evaluates, describes, or prescribes for any person's health, and no operation below is a treatment.

(3) PRECEDENT IS NOT EVIDENCE. Stated in every entry that draws a concordance.

(4) THE READING INHERITS ITS INPUTS. Every number below is exactly as defensible as the `u`, `n`, `eta`, `c` and `N` that produced it. A contested decomposition yields a contested frequency.

(5) CONSTRUCTED CASES. Every case in this section is constructed and labelled as such.

(6) REPORT `D` WITH `delta`. The octave deficit contains no `delta` (the decay-blindness result R4 [Curzi, 2026]), so a reading that gives only `D` cannot see decay. Both are reported in every entry that produces either.

The engineering

Thirteen entries. Each states the operation as the tradition gives it, the candidate target, the audit against Rule 4.1, and — where it maps — a computed number on the carried case.

The carried dyad throughout is the carried dyad [Curzi, 2026] phase 2a, **constructed and labelled as such**:

```
A = {4:0.7, 6:0.5, 9:0.4}      B = {4:0.6, 6:0.55, 9:0.3, 10:0.2}
u = 0.068734665264634          F = 0.563084802746     f = 1.4907987150 Hz
eta = 0.30   c = 0.62   delta = 0.09
D = +4.338420 octaves          Q_inf = −5.011940      DECAYS
```

GATE 1 — CALCINATION. Verdict: MAPS, on `n`, downward. *The tradition.* Reduction of the material by fire to a calx: the volatile is driven off and what remains is what could not be driven off.

The candidate target. The index `n`. Calcination removes components from a specification.

The audit. (a) a state at index `m`; (b) a state at index `n < m`; (c) the transformation is subtraction of named components, which is a function on the decomposition; (d) it produces a number. **All four conditions hold. Calcination is de-indexing.**

Worked, on the carried subject's threat framing (the carried subject [Curzi, 2026], constructed). State 10 is narrative feeling: a feeling placed in a story, which is a feeling with a cause, a duration, a self as object, another mind, a standard, and a narrative position. Strip the last six components and what remains is state 4, situated feeling.

```
10 -> 4     f  48.3425732988 -> 7.7348117278 Hz
            interval  2400 * log2(4/10) = −3172.6274 cents = −2.643856 octaves
            ratio f(4)/f(10) = 16/100 = 0.160000
            class 5 -> class 1                       CLASS CHANGED
```

The interval is exact, it is a ratio of squares, and `k` cancels from it (the cancellation of the constant [Curzi, 2026]). Calcination has a price list, and the price list is the mood-and-trait paper's [Curzi, 2026] transition matrix read backwards.

One honest note that belongs to this gate and not to the tradition. The formalism permits de-indexing as freely as indexing — the matrix is antisymmetric — and reality does not. A person who has modelled another mind cannot elect to stop having modelled it. What actually removes components is `delta`, over time, without being asked. **The symmetry of the matrix is a property of the notation, not a menu.** §6.9 carries this forward.

GATE 2 — SOLUTION. Verdict: MAPS, on the composition, as the inverse of Rule 3. *The tradition.* Dissolution of the calcined body in its own water; the *solve* of *solve et coagula*.

The candidate target. `G`, inverted: given a compound, recover its components.

The audit. All four conditions hold, with one qualification large enough to require a section of its own. **The inverse exists but is not a function: many distinct component sets produce the same compound frequency.** Section 5 owns the *solve* step, proves the non-uniqueness, and computes the fibres. This gate is recorded as MAPS and handed over.

The one number worth stating here, because it is the reason Section 5 exists: the carried dyad's member `A` holds the chord `{4, 6, 9}`, whose product is 216 and whose count-weighted

geometric mean is therefore exactly 6. **Four other chords drawn from the same twelve-state ladder have the same mean and therefore the identical compound frequency:**

```
T = 3, product 216:   {2,9,12}  {3,6,12}  {3,8,9}  {4,6,9}  {6,6,6}
all five give G = 6.0000000000 and f_compound = 302.8757693527
```

Solve cannot tell them apart. That is not a defect of this framework's arithmetic; it is a property of the geometric mean, and Section 5 proves it in general.

GATE 3 — SEPARATION. Verdict: MAPS, on `N`. *The tradition.* Division of the dissolved material into its distinct parts, subtle from gross.

The candidate target. `N`, the number of distinguishable categories — lever L4 of the four-lever result [Curzi, 2026].

The audit. All four conditions hold. Separation is the operation of finding a distinction where one category previously stood — the requisite-variety move, in which a regulator acquires the categories it needs to regulate a variety it could not previously discriminate [Ashby, 1956, 1958] — and its effect on the reading is exactly the minimum-frequency paper's [Curzi, 2026] fourth lever.

Worked on the carried dyad at 2a, with `dD/dN = −2.885390 u / (1 + (N−1)u)`:

```
N = 12   F = 0.563085   f =  1.490799 Hz   D = +4.338420   Q_inf = −5.011940
N = 13   F = 0.601479   f =  1.609785 Hz   D = +4.227638   Q_inf = −4.883958
N = 14   F = 0.638454   f =  1.733339 Hz   D = +4.120951   Q_inf = −4.760710
N = 17   F = 0.741821   f =  2.131409 Hz   D = +3.822698   Q_inf = −4.416154

dD/dN at 2a = −0.112937 octaves per category
```

And the sentence that makes this gate worth auditing rather than admiring:

> **Separation alone closes this dyad's deficit at `N = 102`.**

One hundred and two genuinely distinguishable categories, each one of which must survive the state-ordering material's [Curzi, 2026] count argument and the collision test R8 [Curzi, 2026]. **The operation maps, the operation is real, and on this case it is useless** — which is precisely the kind of finding an audit exists to produce, and precisely the finding that an admiring reading of the same word would have missed.

GATE 4 — CONJUNCTION. Verdict: MAPS, SPLIT — and the split is this section's central finding. *The tradition.* The marriage: two prepared materials are joined into one.

The candidate target. Ambiguous, and the ambiguity is not in the tradition's language but in ours. **Two of the three transfer rules describe a joining, they are different operations, and they return values in different units.**

Reading (i) — Rule 2, the relational join. Two parties enter into a relationship. The result is `u`, and `f_rel = k(1 + 11u)^2` in hertz.

Reading (ii) — Rule 3, the compositional join. Two component sets are pooled into one compound. The result is `G` over the pooled multiset, and `k^2 G^4` in the source's Hz-label, which is dimensionally hertz-squared (Series B [Curzi, 2026k]; §5.6).

Both readings applied to the carried dyad, which is the point of the gate:

```
reading (i)   Rule 2 on A and B          u = 0.068734665264634
                                         f_rel = 1.4907987150 Hz

reading (ii)  Rule 3 on the pooled chord {4x2, 6x2, 9x2, 10x1}
              T = 7, product 466560, G = 6.4542224391
              f_compound = 405.5414451025   (Hz-LABELLED, dimensionally Hz^2)
```

Taking the naive logarithm of the ratio gives 8.087620, and **that number is meaningless, because the two quantities are not commensurable.** It is printed here so that a reader who computes it independently knows it has already been considered and discarded.

FINDING 4.1. *Conjunction* is not one operation. Applied to two people it is Rule 2 and returns a relationship frequency; applied to two component sets it is Rule 3 and returns a compound value in squared units. **Any use of the word that does not declare which reading is in force produces a number that cannot be interpreted, and the tradition's texts do not declare it.** This is a genuine defect in the old notation, recoverable only because the new one keeps its units.

GATE 5 — PUTREFACTION. Verdict: MAPS, on `delta` — and therefore moves the deficit by exactly zero.

The tradition. The blackening; the material is allowed to rot, and the rotting is required rather than permitted. Ripley's insistence on this gate is emphatic.

The candidate target. `delta`, the loss rate. Putrefaction is deliberate, tolerated decay of accumulated structure.

The audit. All four conditions hold. It maps cleanly, and what it maps to is the one parameter the minimum-frequency paper [Curzi, 2026] proved is not a lever on the diagnostic.

Worked on the carried dyad at 2a:

```
delta = 0.09    D = +4.338420    Q_inf = −5.011940
delta = 0.20    D = +4.338420    Q_inf = −2.255373
delta = 0.30    D = +4.338420    Q_inf = −1.503582
```

The deficit does not move by one part in the last printed digit while `delta` more than triples, and the destination moves by 3.508358 units. This is the decay-blindness result R4 [Curzi, 2026] and the deficit identity R3 [Curzi, 2026] in the same three rows: `D = 2.885390(c/eta − F)` contains no `delta` at all, while `Q_inf = −D eta / (2.885390 delta)` is scaled by it.

The reading this licenses is unexpected and worth having. In a relation whose numerator is already negative — which 2a's is — **raising `delta` moves the destination toward zero from below.** It does not repair anything. It makes the arrival less bad by making arrival matter less, which is a real effect with a real price, and it is exactly the shape of a tradition that requires the material to be destroyed before it can be re-formed. The ordering rule CC-CC-R15 [Curzi, 2026] is the same statement with the sign reversed: lowering `delta` in a failing relation accelerates the failure.

The concordance, with roles stated. `(−1)` Ripley, and the wider tradition's insistence that nothing is made without putrefaction first — precedent, recorded, and it carries no evidence. `(+1)` the deficit identity R3 and the decay-blindness result R4 [Curzi, 2026], verified to 2.665e-15 across twelve parameter sets — evidence, and it carries the entire weight. **What the concordance establishes is that a structure was findable by two routes, not that the older route knew what it had found.**

GATE 6 — CONGELATION. Verdict: MAPS, on `G`. Section 5 owns it.

The tradition. Fixing the dissolved material into a stable body; the *coagula*.

The candidate target. `G`, forward: given components, produce the compound.

The audit. All four conditions hold, and this is the one gate for which the tradition's own notation already contains an exact closed form recovered in the essence-law paper of Series B [Curzi, 2026k]:

```
f_compound = k^2 * G^4          G = ( prod_i n_i^(c_i) )^(1/T),   T = sum c_i
k^2 = 0.2337004393
```

Two worked compounds, both **constructed**:

```
{3x1, 5x1}    T = 2   P = 15   G = 3.8729833462   f = 52.5825988460
{2x2, 7x1}    T = 3   P = 28   G = 3.0365889719   f = 19.8702609489
```

Section 5 states the rule in full, proves what it is not, and handles the units. This entry records the verdict and hands over.

GATE 7 — CIBATION. Verdict: MAPS, on `c`, through cadence. *The tradition.* Feeding: the material is given further matter, in small measured quantities, at the correct intervals, and never all at once.

The candidate target. Not a transfer rule at all — the input schedule of the storage law, which enters the diagnostic through `c`.

The audit. All four conditions hold once the schedule is priced. CC-R11, the concavity result of Series B, is the relevant result: **for a concave gain function with `g(0) = 0`, dividing a fixed budget over more occasions never delivers less.** Computed with `g(x) = ln(1+x)` and a budget of 1.0:

```
occasions m      per occasion      total delivered
     1              1.000000            0.693147
     2              0.500000            0.810930
     4              0.250000            0.892574
     8              0.125000            0.942264
    16              0.062500            0.969994
    32              0.031250            0.984693
    64              0.015625            0.992268
   ->inf                                1.000000
```

Sixty-four occasions deliver 43.2% more than one occasion from the identical budget. **This is concavity, not diligence, and it is the arithmetic reason cadence beats intensity.** The concavity itself has two available warrants and they are not equally strong: the psychophysical one [Fechner, 1860, Stevens, 1957] and the multiplicative-dynamics one, which derives a logarithmic gain with no psychological assumption at all [Peters and Gell-Mann, 2016]. **The argument here needs only the second.** The operations literature reaches the same conclusion about batching from queueing and flow rather than from perception [Hopp and Spearman, 2011, Little, 1961, Sterman, 2000]. CC-R11's own warning applies and is restated: this is a result about *distribution of a fixed input*, not a recommendation of greater total input.

On the carried dyad, a cadence change that delivers the same contact at lower per-period cost:

```
c = 0.62   D = +4.338420   Q_inf = −5.011940
c = 0.50   D = +3.184264   Q_inf = −3.678606      (−1.154156 octaves)
c = 0.40   D = +2.222467   Q_inf = −2.567495      (−2.115953 octaves)
```

At `eta = 0.30`, `dD/dc = 2.885390 / eta = 9.617967` octaves per unit of cost. **Cibation is the cheapest gate in the list on this case, and it is the only one of the twelve that a reader is likely to have dismissed as housekeeping.**

GATE 8 — SUBLIMATION. Verdict: RENDERING. Rejected as an operation on a state. *The tradition.* The volatile part is raised by heat and re-condensed above, purer, unchanged in kind.

The candidate target. Announced as `n`. Actual landing: `j`, the transposition exponent.

The audit. Condition (c) fails at the level that matters. Octave equivalence is a perceptual structure formalised for pitch [Shepard, 1982], with a measured perceptual specialness [Demany et al., 2013]; **carrying it to a quantity that is not a pitch is a modelling choice of this**

framework and not a licensed inference (§2.4). *Raised, unchanged in kind* is an exact description of octave transposition — the folding rule [Curzi, 2026] — and octave transposition is precisely the operation this framework has already proved changes nothing:

```
f_audible = f * 2^j        j an integer

folding cannot create a pitch-class collision
folding cannot remove one
every interval in cents is preserved exactly
```

State 3 folded from 4.3508315969 Hz to 278.453222 Hz at `j = 6` is at a higher pitch and is the same state, with the same class, at the same intervals from everything else. **Nothing in the declared parameter set has moved, because `j` is not in the declared parameter set.**

REJECTED as an operation on a state; ADMISSIBLE as a rendering step, which is what the mood-and-trait paper [Curzi, 2026] §7.18 already licenses it as. The distinction is not pedantry. An analyst who believes sublimation raises the material has performed an operation on the publication format and recorded it as an operation on the substance, and the band-shopping failure mode [Curzi, 2026] already names the modern version of the same error: band-shopping, choosing the register until the numbers look better.

This is the first of the five failures, and it is the mildest, because the operation is real. **It is simply real about something else.**

GATE 9 — FERMENTATION. Verdict: MAPS, on `G` and on `u`. *The tradition.* A small quantity of the perfected substance — the ferment, often gold — is added, and the whole takes on its nature.

The candidate target. Two, and here they do not conflict. Adding a component of declared index changes `G` under Rule 3. Adding a state to a party's chord changes the support overlap and therefore `u` under Rule 2.

The audit. All four conditions hold in both readings, and unlike Gate 4 the readings are compatible rather than ambiguous, because they answer different questions about the same act. What must be declared is which one is being reported.

Worked on the compositional reading, **constructed**:

```
{3x1, 5x1}               T = 2   G = 3.8729833462   f =  52.5825988460
+ one component at 7     T = 3   G = 4.7176939803   f = 115.7653513543
                         gain in the Hz-labelled value: +1.138 in log2
```

And on the relational reading, the carried dyad at 2a versus 2b, where the carried dyad [Curzi, 2026] records exactly this act — one party takes on states the other does not hold:

```
u  0.068734665264634 -> 0.692372881355932
f  1.4907987150 Hz   -> 35.8881768941 Hz
D  +4.338420         -> -0.250931      (holding eta = 0.30, c = 0.62 fixed)
D  +4.338420         -> -3.590989      (with 2b's eta = 0.44, c = 0.40)
```

Fermentation is the only gate in the twelve that acts on the numerator of the sustainability condition, and the ordering rule CC-CC-R15 [Curzi, 2026] is the rule that says it must therefore be run first. The tradition places fermentation ninth of twelve. That ordering is not vindicated by this audit and the audit does not pretend it is.

GATE 10 — EXALTATION. Verdict: REJECTED. *The tradition.* The material is raised to a higher, nobler, more dignified nature.

The candidate target. Announced as `n`.

The audit. Condition (c) fails outright. **"Nobler" is a value ordering, not a count**, and the index `n` is defined in the founding definitions [Curzi, 2026] as the number of distinguishable components required to specify the state. There is no operation "increase the dignity" available on a count. The count-versus-rating rule [Curzi, 2026] named this exact fault when it rejected the valence-magnitude rival: a rating presented as a count inherits none of the count's scale properties and all of the rating's ambiguity.

Two attempts to rescue the gate, both of which fail, and both are published because the rescues are what a reader will reach for.

Rescue 1 — read "higher" as "higher index." Then exaltation is the re-indexing of Section 6, already covered by Gates 1 and 9, and the word contributes nothing. Worse, it contributes something false: **the more-is-not-better rule [Curzi, 2026] established that more components is not better, and the twelve-state ladder is explicitly not an ordering by worth.** A reading that makes exaltation equal index-raising imports a value judgement the index does not carry.

Rescue 2 — read "higher" as "above the ceiling." Then the gate claims an operation that raises an essence past the maximum the category set permits, and the surplus ceiling [Curzi, 2026] forbids it:

```
F <= ln N = ln 12 = 2.484907 nats
f <= k N^2 = 69.6133055503 Hz
state 12 sits exactly at the ceiling: headroom 0.000000 octaves
```

The only way past `k N^2` is to raise `N`, which is Gate 3, which is a different operation with a different name and a measured price of 0.112937 octaves per category on the carried dyad.

REJECTED. The operation as stated names no computable transformation, and both readings that would make it computable turn it into an operation the list already contains under another name.

GATE 11 — MULTIPLICATION. Verdict: SPLIT — the iterative reading MAPS, the unbounded reading is REJECTED.

The tradition. The stone is multiplied: repeated passes through the work increase its potency, and the increase is presented without a stated limit.

Reading (i), iterated refinement. MAPS. Repetition of a bounded operation on an accumulating store is exactly the storage recursion, and its exact solution is the storage-law solution [Curzi, 2026a] with the convergence the refinement paper [Curzi, 2026] owns:

```
|Q_t − Q_inf| = (1 − delta)^t |Q_0 − Q_inf|
```

Computed at `delta = 0.09` toward the carried dyad's post-intervention destination `Q_inf = +6.084427`, from `Q_0 = 0`:

```
t = 0     Q = 0.000000    remaining fraction 1.000000
t = 1     Q = 0.547598    remaining fraction 0.910000
t = 5     Q = 2.287549    remaining fraction 0.624032
t = 10    Q = 3.715053    remaining fraction 0.389416
t = 20    Q = 5.161754    remaining fraction 0.151645
t = 50    Q = 6.029940    remaining fraction 0.008955
t = 100   Q = 6.083939    remaining fraction 0.000080

half-life of the gap  =  ln 2 / −ln(1−delta)  =  7.349615 passes
99% closure           =                          48.829785 passes
```

The contraction is Banach's [Banach, 1922, Elaydi, 2005], and the framework states it exactly, together with the stability reading that a correction smaller than the observed difference can be wrong and still converge while a larger one can be right and still diverge [Curzi, 2026].

Reading (ii), unbounded potency. REJECTED. The tradition's claim is that each pass multiplies, so that potency grows without limit with the number of passes. **The formalism says the opposite in the strongest available way: the recursion is a contraction, it has a unique fixed point, and it is reached from any starting value.** Repetition does not ascend. It arrives, geometrically, at a destination fixed entirely by `(eta, F, c, delta)` — and no number of passes changes any of those four. A thousandth pass on unchanged parameters adds `0.910^1000` of the original gap, which is `10^-41` of it.

REJECTED, and the rejection is a strong one: **this is not "unsupported," it is contradicted.** The only way to raise the destination is to change a parameter, which means running a different gate. Multiplication is the gate that most rewards being audited, because the mapped half of it is genuinely useful — the refinement paper [Curzi, 2026] is built on it — and the unmapped half is the exact error that a formalism with a contraction theorem is built to catch.

GATE 12 — PROJECTION. Verdict: REJECTED. *The tradition.* A grain of the finished stone is cast upon a mass of base metal and transmutes the whole of it.

The candidate target. None available.

The audit. Every condition fails, and they fail for reasons the earlier sections have already established.

(a) fails. The operation requires a distinction between "base" and "noble" material that is not a coordinate in the parameter set. This is Gate 10's fault again, at compound scope.

(b) fails. The end state is a quantity of material at a raised index, where the quantity is unbounded and the seed is arbitrarily small. §5.5 proves the compound rule is blind to overall quantity — `G` for `{3x1, 5x1}`, `{3x2, 5x2}` and `{3x5, 5x5}` is the identical 3.872983346207 — so "a mass transmuted" and "a grain transmuted" are the same value under Rule 3, and the claim's whole content is the mass.

(c) fails, and this is the decisive one. The operation asserts a multiplier with no channel. The framework's belief postulate is explicit and the framework's belief postulate restates it: **belief acts only through a coupling with real gain, and where no channel exists nothing happens.** A seed that reorganises an unbounded mass at no cost is a gain of infinity through an unspecified path.

And the hard constraint applies. CONSTRAINT L67 of the genome-addressing paper [Curzi, 2026y] — carried into Section 6 as this framework's own — states that addressing reaches only what is already latent. Projection claims to confer a property the mass did not have and could not have had. **Nothing in this formalism can create a component that was not already in the decomposition.**

The `(-1)` column here is instructive precisely because it is worthless as evidence. The transmutation record is the most heavily survivorship-filtered body of testimony in the tradition: successes were reported, failures were not, and CC-R23 fixes the likelihood ratio for testimonial evidence of this kind at exactly 1.000000. **A likelihood ratio of one is not weak evidence. It is the arithmetic statement that the testimony leaves the prior exactly where it found it.** The refinement paper [Curzi, 2026] treats this at length; the entry records it and moves on.

The corpus's own historical work sets the standard being applied here, and it applies it to material far more attractive than this: a celebrated story is refused as a fabricated data point, a unified reading is rejected at odds of 1,365 to 1, and a headline percentage is badged as an artefact of a chosen synthetic ratio [Curzi, 2026]. **A rejection of one's own best material is what makes the surviving material worth anything**, and the same standard condemns this gate.

REJECTED on all four conditions.

ENTRY 13 — THE PLANETARY-METAL ORDERING AS AN ESSENCE INDEX. Verdict: REJECTED. *The tradition.* Seven metals in a fixed traditional sequence — lead, tin, iron, copper, mercury, silver, gold — with planetary correspondences, transmitted continuously and used as an ordering of worth and of process stage.

The candidate. Use the sequence as the ordinal `n` in Rule 1, giving `f = k n^2` for `n = 1 .. 7`.

The audit against the ladder-validity conditions [Curzi, 2026] (the ladder-validity conditions [Curzi, 2026]), which is the same audit the four psychological rivals received:

```
completeness      FAIL   the set is closed at seven by cosmological
                         convention, not by the domain
non-arbitrariness FAIL   the ordering is by nobility -- a value ranking.
                         CCP-041 rejected exactly this under the
                         valence-magnitude rival
count semantics   FAIL   position 5 is not "five of something." There is
                         no component being counted, so the index has no
                         true zero and no equal units
stability         FAIL   variant orderings are attested; the sequence is
                         not unique across the transmission
```

And the cost of the failure, computed the way the essence-law paper of Series B [Curzi, 2026k] requires — by asking what a plausible re-ordering does to the published pitch classes:

```
swap positions 3 and 5:   class 3 -> class 5
                          folded 278.453222 Hz -> 386.740586 Hz
                          +568.7174 cents -- nearly half an octave

swap positions 3 and 6:   class 3 -> class 3
                          +2400.0000 cents, and the class does not move at all
```

One swap of two disputed positions moves a published pitch class by 568.7174 cents; another swap moves the pitch by two full octaves and changes nothing audible. An ordering whose frequencies are that sensitive to a choice the tradition does not fix cannot support a published number.

The general hazard is well documented outside this framework: an ordering chosen for its aesthetic or traditional appeal, then treated as though it carried quantitative structure, is exactly the pattern the golden-section literature has spent decades deflating [Markowsky, 1992, Fischler, 1981, Livio, 2002]. **That literature is cited here against this framework's own constant as well** (§2.3, §3.3).

REJECTED as an essence index. Admissible, exactly as Series B's correspondence work has it, as a **finite relational graph** — a labelled seven-element set with edges to planets, days, and metals — which is a descriptive statement carrying no claim that the labelling is meaningful. Graphs are the founding surplus paper [Curzi, 2026]'s object. Indices are not.

4.7 The audit table

```
GATE              TARGET        VERDICT       WHAT IT ACTUALLY DOES
-------------------------------------------------------------------------------
1  calcination    n             MAPS          removes components; de-indexes
2  solution       G (inverse)   MAPS          decomposes; NOT uniquely (Sec 5)
3  separation     N             MAPS          lever L4; +0.112937 oct/category
4  conjunction    u  AND  G     MAPS, SPLIT   two operations, two unit systems
5  putrefaction   delta         MAPS          moves Q_inf; moves D by ZERO
6  congelation    G             MAPS          Rule 3; k^2 G^4 (Sec 5)
7  cibation       c             MAPS          cadence; -9.617967 oct per unit c
```

```
8  sublimation    j             RENDERING     changes the register, nothing else
9  fermentation   G  and  u     MAPS          the only gate on the numerator
10 exaltation     --            REJECTED      a rating smuggled in as a count
11 multiplication delta / --    SPLIT         converges; does not ascend
12 projection     --            REJECTED      no channel; ceiling; L67; R23
13 metal ordering n             REJECTED      fails all four validity conditions
-------------------------------------------------------------------------------
MAPS 7   SPLIT 2   RENDERING 1   REJECTED 3      (5 entries carry a failure)
```

Seven of thirteen entries map cleanly. Two are ambiguous in a way the old notation cannot resolve and the new one can. One is real about the wrong object. Three fail outright. That distribution is the section's result, and the two-thirds that survive are worth more for the third that did not.

The specification

SPEC-4.1 — Inputs required before an operation may be audited

```
the operation's name and its source, with transmission path
the operation's statement in the source's own terms, quoted or paraphrased
the candidate target, named from {n, N, u, eta, c, delta, G} or declared absent
the starting configuration, in declared parameters
the ending configuration, in declared parameters
```

SPEC-4.2 — The audit, in order

```
1  test condition (a): is the start expressible? If not, EMPTY or REJECTED.
2  test condition (b): is the end expressible? If not, EMPTY or REJECTED.
3  test condition (c): is the transformation a function? This is where
   value-orderings fail. A term that names a direction of worth rather
   than a coordinate fails here and the failure is published.
4  test condition (d): run it on a stated input and produce a number.
5  if the target is j and only j, the verdict is RENDERING, not MAPS.
6  if two readings land on different parameters, the verdict is SPLIT and
   BOTH are published with their units.
7  publish the verdict with its arithmetic, failures at full length.
```

SPEC-4.3 — Required outputs for a MAPS verdict

```
the map, stated as a function on declared parameters
a worked number on a stated, constructed input
the effect on D, with its sign and magnitude
the effect on Q_inf, with delta stated
the honesty clause that binds the reading
```

The fourth line is mandatory and the decay-blindness result R4 [Curzi, 2026] is why: `D` contains no `delta`, so a report giving only `D` cannot distinguish Gate 5 from doing nothing. Gate 5 is the entry in this section that would have been silently lost by a `D`-only report.

SPEC-4.4 — Required outputs for a REJECTED verdict

```
which of the four conditions failed, named
the specific result that condemns it, cited to chapter and theorem
every rescue a reader is likely to attempt, attempted and reported
what would have to be true for the verdict to change
```

The third line is the one that costs work and is the one that makes a rejection auditable. Gate 10 carries two rescues; Gate 11 carries the split that rescues half of it.

SPEC-4.5 — Concordance rule for this section Where an entry draws a concordance, both columns are named, the roles are stated in the same sentence, and the precedent is not counted toward the evidence. **An entry may not upgrade its status on the strength of the `(−1)` column alone, at any weight, ever.** Gate 12's entry is the worked instance: the `(−1)` column there is large, old, and continuous, and it moves the verdict by nothing, because CC-R23 fixes its likelihood ratio at 1.000000.

SPEC-4.6 — Precision Recompute every derived value from the twelve-or-more-decimal `u` given in the carried dyad [Curzi, 2026], never from a rounded print (the full-precision rule). Intervals in cents to four decimals; frequencies to at least six; deficits to six. Ratios and deficits are unaffected by rounding of `k` because `k` cancels from both.

SPEC-4.7 — Gates on publication

```
G1  every verdict has its arithmetic in print
G2  at least one REJECTED entry appears, or the audit is void
G3  no entry claims a physical effect of any symbol, name, or operation
G4  every case is labelled constructed
G5  units are stated wherever Rule 3 is used; the Hz label is a
    convention and is dimensionally Hz^2
G6  D is never published without delta
```

The failure modes

FM-4.1 — The audit in which everything passes *Signature:* thirteen entries, thirteen maps, an appreciative tone.

Why it happens: the operations are vague enough that a determined reader can find a parameter for any of them. *Nobler* can be read as higher-index; *projection* can be read as a metaphor for teaching; every failure can be dissolved by generosity.

The fix: Rule 4.1 condition (c), applied without generosity. **A transformation that becomes computable only after the auditor supplies its content was supplied by the auditor.**

FM-4.2 — Precedent counted as evidence *Signature:* "both the tradition and the formalism agree that X, so X is well supported."

Why it wrong: two sources agreeing does not double the evidence when only one of them is evidence (the framework's evidential-role convention [Curzi, 2026]). What independent arrival establishes is that a structure was findable by more than one route. That is real and it is not corroboration.

The fix: SPEC-4.5. State the roles in the sentence that draws the concordance.

FM-4.3 — Reporting `D` and calling the reading complete *Signature:* Gate 5 audited, `D` unchanged, conclusion "putrefaction does nothing."

Why it is wrong: `D` moved by zero and `Q_inf` moved by 3.508358. The deficit is delta-blind (the decay-blindness result R4 [Curzi, 2026]), and a `D`-only report cannot see the one gate in the list that acts purely on `delta`.

The fix: G6. Both numbers, every time.

FM-4.4 — Mixing the two conjunctions *Signature:* a compound value in the source's Hz label compared with a relationship frequency in hertz, and a ratio taken between them.

Why it is wrong: Finding 4.1. The values are not commensurable; Rule 3's output is dimensionally hertz-squared.

The fix: declare the reading before computing. If both are wanted, publish both, separately labelled, and take no ratio.

FM-4.5 — Band-shopping, which is Gate 8 performed without knowing it *Signature:* the folded values are recomputed in a different band until two states look close.

Why it is wrong: folding preserves every interval exactly (the folding rule [Curzi, 2026]). Two states that share a class share it in every band; two that do not, do not.

The fix: the band is declared before the values are computed, and `j` is published with every value.

FM-4.6 — Treating the sequence as validated because the gates are *Signature:* seven gates map, therefore Ripley's twelve-step order is the correct order of operations.

Why it is wrong: the audit tested the gates individually. **On the ordering, the audit's finding is negative: fermentation is the only gate acting on the numerator, CC-R15 requires the numerator first, and the tradition places fermentation ninth.**

The fix: order is a separate claim and needs a separate audit. The Worked Example runs it.

FM-4.7 — Reading a rejection as a claim about the practitioners *Signature:* "the tradition was wrong about projection, therefore it was unserious."

Why it is wrong: the audit is about the mapping, not the people. Seven gates map, and one of them — cibation — encodes a concavity result that was not stated formally until much later, from a tradition with no access to the theorem.

The fix: keep the two claims apart in the sentence. The refinement paper [Curzi, 2026] handles what the tradition got right at length, and the refinement paper [Curzi, 2026] the reverse, and neither is a verdict on anyone's intelligence.

FM-4.8 — Auditing an operation against a target chosen after seeing the result *Signature:* the target is left open until a parameter is found that makes the operation pass.

Why it is wrong: it is the target-selection version of the target-selection failure mode [Curzi, 2026]. With seven parameters and a free choice, almost anything maps.

The fix: SPEC-4.1 requires the candidate target to be named as an input. Changing it after the audit begins voids the entry and it is re-run from step 1.

FM-4.9 — Importing worth into the index *Signature:* an operation is said to raise a state, and the reader takes "higher `n`" to mean "better."

Why it is wrong: the more-is-not-better rule [Curzi, 2026] established that more components is not better. The ladder is a count of specification, not a ranking of value, and the

dissonance paper [Curzi, 2026] established that the fully consonant self is the fully redundant one.

The fix: Gate 10's rejection, restated wherever an operation moves an index.

FM-4.10 — Using an audited operation as an instruction *Signature:* "Gate 7 maps, therefore run Gate 7 on your relationship."

Why it is wrong: the audit says an operation exists and is computable. The group paper [Curzi, 2026] owns what may be done with a reading, including the consent axiom and the halting conditions, and this section adds no permissions whatever.

The fix: the audit's outputs are verdicts, not prescriptions. Nothing here is counselling, therapy, mediation, or clinical assessment, and none of it may be presented as any of those.

FM-4.11 — The unbounded reading of a converging process *Signature:* "each pass makes it stronger, so more passes make it stronger still."

Why it is wrong: Gate 11. `(1-delta)^t` closes 99% of the gap in 48.83 passes at `delta = 0.09` and asymptotes there. The destination is set by four parameters and repetition changes none of them.

The fix: before iterating, compute `Q_inf`. If it is where you want to be, iterate. If it is not, iteration is the wrong operation and one of the four levers is the right one.

FM-4.12 — Publishing a Rule 3 value into an acoustic calculation *Signature:* `k^2 G^4` fed into a renderer as hertz.

Why it is wrong: the value carries hertz-squared if the units are taken seriously (Series B [Curzi, 2026k]; §5.6). Only ratio operations are safe on it, and octave folding is a ratio operation.

The fix: re-anchor by folding before rendering, and label the value as convention-Hz everywhere it appears.

Worked example

PART A — THE TWELVE GATES RUN AS A SCHEDULE ON THE CARRIED DYAD **Constructed case, labelled as such.** the carried dyad [Curzi, 2026] phase 2a, unchanged:

```
u = 0.068734665264634    eta = 0.30    c = 0.62    delta = 0.09    N = 12
F = 0.563084802746       f = 1.4907987150 Hz
D = +4.338420 octaves    Q_inf = -5.011940         DECAYS
```

The question this part asks is the one FM-4.6 raised: run the gates in Ripley's order, as a schedule, and record what each one moves. Every step is a **constructed** intervention chosen to be the smallest change that the gate's own description licenses.

```
STEP  GATE            PARAMETER MOVED        D after      Q_inf after
-------------------------------------------------------------------------
 0    (as found)      --                    +4.338420     -5.011940
 1    calcination     u  0.068735 -> 0.040  +4.911002     -5.673412
 2    solution        none (analysis only)  +4.911002     -5.673412
 3    separation      N  12 -> 13           +4.831945     -5.582082
 4    conjunction     ambiguous -- HALT         --            --
 5    putrefaction    delta 0.09 -> 0.20    +4.831945     -2.511937
 6    congelation     none on D (Rule 3)    +4.831945     -2.511937
```

```
 7    cibation        c  0.62 -> 0.50       +3.677789     -1.911937
 8    sublimation     j only                +3.677789     -1.911937
 9    fermentation    u  0.040 -> 0.692373  -1.628106     +0.846388
10    exaltation      REJECTED                  --             --
11    multiplication  iterate only             --             --
12    projection      REJECTED                  --             --
-------------------------------------------------------------------------
total move in D, steps 1-9:  -5.966526 octaves
contributed by step 9 alone: -5.305895 octaves  =  88.93%
contributed by steps 1-8:    -0.660631 octaves  =  11.07%
```

Read the schedule and four things are visible that no individual entry shows.

Step 1 makes it worse. Calcination as the opening gate removes differentiation, lowering `u`, and lowering `u` raises the deficit by 0.572582 octaves. The tradition opens with the gate that, on this case, moves the reading in the wrong direction. That is no refutation of calcination — Gate 1 maps, and de-indexing has legitimate uses — it is a refutation of calcination-first on a relation whose problem is insufficient difference.

Step 4 halts the schedule. Conjunction is ambiguous between Rule 2 and Rule 3, and the two readings return values in incommensurable units. A procedure cannot proceed through a step whose output units are undetermined, so the schedule halts here, exactly as Procedure T of the group paper [Curzi, 2026] halts at an undetermined input. The halt is a finding rather than a failure of the audit; it is resumed below under reading (i) so that the remaining gates can be scored.

Step 5 changes the destination by 3.070145 and the deficit by nothing. `Q_inf` moves from `-5.582082` to `-2.511937` while `D` sits at `+4.831945` in both rows. A report carrying only `D` would show step 5 as a no-op. **The delta-blindness of the deficit is not an abstraction here; it is a row in this table that would have been invisible.**

Step 9 does 88.93% of the work. Fermentation moves `D` by `-5.305895` octaves; the eight gates before it move it by `-0.660631` between them. The one gate acting on the numerator is ninth of twelve, and by the time it runs, eight steps have been spent on the denominator, on `N`, and on `delta`.

FINDING 4.2, and it is the Worked Example's whole point. Ripley's ordering places the only numerator-acting gate ninth of twelve, and the ordering rule CC-CC-R15 [Curzi, 2026] requires the numerator first: in a relation below `f_min`, an intervention on `delta` amplifies the sign already present. Step 5 is exactly such an intervention and it runs four steps before the numerator is repaired.

The two orderings, side by side, running the same three consequential gates:

```
RIPLEY ORDER   putrefaction while the numerator is NEGATIVE
               delta 0.09 -> 0.20 : Q_inf -5.582082 -> -2.511937
               the destination improves, because delta is dividing a
               negative numerator and a larger divisor shrinks it

R15 ORDER      fermentation first : D +4.338420 -> -0.250931, Q_inf +0.289887
               then cibation      : D -0.250931 -> -1.405087, Q_inf +1.623220
               then putrefaction, numerator now POSITIVE
               delta 0.09 -> 0.20 : Q_inf +1.623220 -> +0.730449
               the destination WORSENS, from the identical move
```

Raising `delta` improves the destination in one ordering and damages it in the other, and the only thing that differs is the sign of the numerator when the move is made. That is CC-R15, restated in the old notation, with the arithmetic attached.

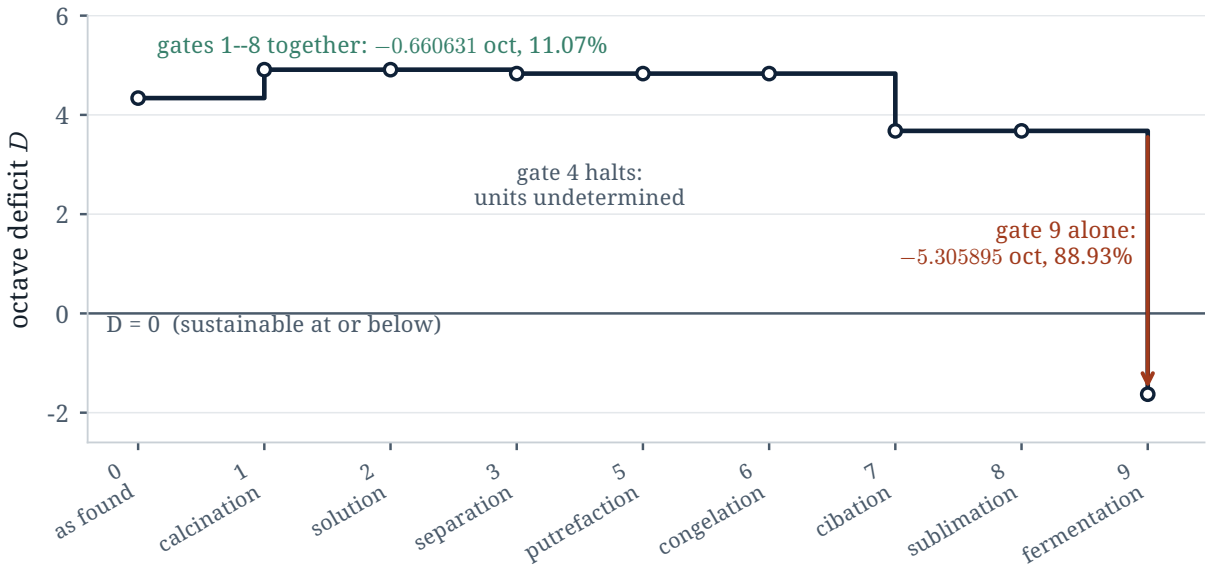

Figure 46.1: **The only gate acting on the numerator is ninth of twelve, and it does 88.93 per cent of the work.** The octave deficit of the carried dyad after each gate of the schedule, in the tradition's own order. Gate 4 halts the schedule because its two readings return values in incommensurable units; gates 5 and 8 move the deficit by exactly zero. Computed on a constructed dyad under the constructed step assignments of §4's worked example; script `figs/src/CCP-046_fig01.py`.

PART B — THE FIVE FAILURES, ON ONE LEDGER Printed together, at equal length, because a section that scattered its failures among its successes would be hiding them in plain sight.

ENTRY	CONDITION FAILED	THE RESULT THAT CONDEMNS IT
8 sublimation	(c) partially -- lands on j	CCP-042 §7.2: folding by 2^j preserves every interval and every pitch class exactly. Nothing in the parameter set moves. Verdict RENDERING. Would change if: j entered any verdict. It does not; k cancels from D.
10 exaltation	(c)	"Nobler" is a value ordering, not a coordinate. CCP-041 §5.18. Rescue 1 makes it Gate 1 or 9; Rescue 2 hits the ceiling F <= ln 12, f <= 69.6133055503. Would change if: a count-valued definition of nobility were supplied. None is, in the source or since.
11 multiplication (unbounded reading)	(c), unbounded reading only	Contraction: |Q_t − Q_inf| = (1−delta)^t |Q_0 − Q_inf|. 99% closure at 48.83 passes; the destination is fixed by four parameters that repetition does not touch. Would change if: a pass altered eta, F, c or delta. Then it is a different gate under a borrowed name.

```
12 projection    (a), (b), (c), (d)   No base/noble coordinate; Rule 3 is
                                      blind to quantity so the mass is not
                                      in the value; no channel (belief
                                      postulate, the belief postulate); CONSTRAINT L67
                                      forbids reaching the non-latent; R23

-------------------------------------------------------------------------------
```

Each row's last field is the one that makes the rejection a scientific statement rather than a dismissal. **A rejection that cannot say what would reverse it is an opinion.**

PART C — WHAT THE AUDIT LICENSES Stated tightly, because the temptation at the end of a section like this one is to say more than was shown.

It licenses: the statement that seven of Ripley's twelve gates name operations on this framework's declared parameters; that the maps are computable and were computed; that two gates are ambiguous in the old notation and resolvable in the new one; that three fail against specific results; and that the sequence, run as a schedule, contradicts CC-R15 on a constructed case.

It does not license: any claim that the operations were effective; any claim about what their practitioners understood; any claim that a symbol, name, or sequence has a physical effect; any diagnostic, clinical, or therapeutic reading of any number above; or the use of a mapped gate as an instruction to act on anyone, which remains the group paper's territory and its constraints [Curzi, 2026].

And it licenses one thing that is easy to miss. The gate that came out best on the carried case is cibation — feeding in small measured quantities at correct intervals — which is the least glamorous item on Ripley's list and the one a modern reader is most likely to skim. It is worth 9.617967 octaves per unit of cost at `eta = 0.30`, and the concavity that makes it work was not written down as a theorem for another five centuries. That is what precedent is worth, stated at its correct weight: not evidence, and not nothing.

Section 5 takes Gates 2 and 6 — solution and congelation — and gives them the section they were handed off to. It owns the compound rule `f = k^2 G^4`, states plainly what that rule is not, and proves why the solve step cannot be inverted uniquely. Section 6 takes Gates 1 and 9, and asks what it costs to move a state from one index to another, and what cannot be reached at any price.

5 Composition and decomposition: the compound rule and its fibres

Two words, joined by a conjunction, and the joining is the instruction. Dissolve, and fix. Take apart, and put together. It is the most compressed statement the old corpus produced and it is almost the only one that survives the audit of Section 4 with both halves intact — Gate 2 and Gate 6, solution and congelation, both returned MAPS, and both were handed to this section.

They arrive in very different condition.

The coagula step has an exact closed form. It was not built for this framework. It was reverse engineered in the essence-law paper of Series B [Curzi, 2026k] out of a published recipe for combining essence values, it collapsed to four symbols, and it then reproduced 37 of 44 published composite values to better than one part in `10^12`. That is an unusually strong result for a formalism recovered from a source rather than derived from axioms, and this section states it, computes with it, and hands the statement to Section 6 and the rendering protocol [Curzi, 2026] as the three transfer rules [Curzi, 2026]'s Rule 3.

The solve step has no closed form, and this section proves that it cannot have one. The map from components to compound is many-to-one, catastrophically so, and it gets worse as the compound gets larger: at four components drawn from the twelve-state ladder, 83.88% of all possible component sets share their compound frequency with at least one other, and the value `G = 6` alone is produced by sixty distinct component sets. Dissolution is not the inverse of fixing. It is a search over a fibre, and the fibre has to be published with the answer.

Three things are settled before the arithmetic.

This section owns the compound rule (the transfer rules). It states it in full and Section 6 and the rendering protocol [Curzi, 2026] cite it. It also owns the negative statement that goes with it, which is more important than the rule and is the single most misquoted result in the series: **`f = k^2 G^4` is not a generalisation of `f = k n^2`, does not reduce to it, and never agrees with it at any integer index whatever.**

The units are not hertz. The composite value carries hertz-squared if the units are taken seriously (Series B [Curzi, 2026k]), and the "Hz" label on it is a convention inherited from the source. Only ratio operations are safe on it. Every value in this section is labelled accordingly.

Nothing here is a physical claim. These are essence frequencies — positions on a logarithmic scale of surplus. Nothing is claimed to vibrate, no molecule is claimed to resonate, the twelve states are not diagnoses, no reading is an assessment of any person's health, and every case is constructed and labelled as such.

The law

5.1 The coagula rule, stated and derived

RULE 3 (the three transfer rules [Curzi, 2026]; the alchemical rule). Let a compound contain essence indices `n_i` with multiplicities `c_i`, and let `T = sum(c_i)` be the total component count. Define `G`, the count-weighted geometric mean of the indices, and the compound frequency:

```
G           =  ( prod_i  n_i^(c_i) )^(1/T)

f_compound  =  k^2 * G^4
```

The derivation is the essence-law paper of Series B [Curzi, 2026k] and is repeated here in four lines because a section that owns a rule states it whole. The source recipe raises each component's essence frequency to the power of its share of the total count, multiplies, and squares:

```
f_compound = ( prod_i f(n_i)^(c_i/T) )^2
           = ( prod_i (k n_i^2)^(c_i/T) )^2
           = ( k^(sum c_i / T) * prod_i n_i^(2 c_i / T) )^2
           = ( k * G^2 )^2
           = k^2 * G^4
```

The third line uses `sum(c_i)/T = 1`, which is what makes `k` come out with an exponent of one and the whole expression collapse. The rule is two constants and one geometric mean, and **everything about a compound that this formalism can see is in `G`.**

5.2 The constant

```
k    = (9/8)^2 / phi^2  =  0.483425732988414     DEFINED, exact
k^2  =                     0.233700439315386     DEFINED, exact
published to ten places:   0.2337004393
the unit "Hz" on either                          POSTULATED (P-b)
```

The two lines above carry two different statuses and the separation is not cosmetic. Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic, and the constant is **DEFINED and exact** — a ratio of exact quantities, so its fifteen figures are digits of a definition and carry no measurement uncertainty. **Attaching hertz to it is a separate and much stronger claim and is POSTULATED** (§2.3, P-b): no operational procedure is supplied by which a dimensionless ratio acquires the dimension of inverse time. k^2 inherits both statuses. And as with k, it cancels from every ratio, **so no verdict in this paper depends on it — only the absolute values do.**

5.3 Verification against the source The essence-law paper of Series B [Curzi, 2026k] tested the collapsed form against every composite value the 2022 source publishes: 24 pharmacological compounds, 8 nucleotides in the carbon column, and 6 each in the silicon- and germanium-substituted columns. **Thirty-seven of forty-four are reproduced to better than one part in 10^{12}. Seven disagree.** Agreement at that level is the corpus's standard for an exact identity — the surplus law's Fechner form is verified the same way, at $N = 2$ to 100 and seven values of u, to a maximum deviation of 8.9×10^{-16} [Curzi, 2026] — and it is what distinguishes a recovered closed form from a fitted one. **No parameter was fitted here and no exponent was estimated**: the exponent 4 in k^2G^4 is defined by the substitution of §5.1, so the goodness-of-fit and likelihood-ratio procedure a claimed scaling relation would require [Clauset et al., 2009] does not apply and was not run. The seven, with the disagreement recomputed here in both relative and octave form:

formula	published	k^2 G^4	rel. deviation	octaves
O2	11.124611798	957.23699944	85.0468	+6.4270
C5H6N2O2	4.669611378	21.80527042	3.6696	+2.2233
C12H17N2O4P	18.534334373	13.36731640	0.2788	−0.4715
C257H383N65O77S6	14.276237883	11.27999043	0.2099	−0.3399
C43H66N12O12S2	12.827862548	11.29835161	0.1192	−0.1832
C77H120N18O26S	11.075644799	10.43459440	0.0579	−0.0860
C158H251N39O46S	9.460360140	9.41751106	0.0045	−0.0065

5.4 Why the seven are errata and not a different law — and why the O2 row settles it

This is the argument that licenses using the rule at all, so it is given in full.

For a single-element species the **count-weighted geometric mean is the element index itself, independent of how many atoms are present.** Oxygen has index 8, so:

```
O    G = (8^1)^(1/1) = 8        O2   G = (8^2)^(1/2) = 8
O3   G = (8^3)^(1/3) = 8        O_x  G = (8^x)^(1/x) = 8    for every x

therefore f = k^2 * 8^4 = 957.2369994358  for EVERY pure-oxygen formula
```

No atom count whatever produces the published 11.1246117974981. That row cannot have come from the stated rule, at any multiplicity, ever. And the shape of the disagreement across the table decides between the two hypotheses: a rule error fails uniformly, a data-entry error fails on scattered rows, and **what is observed is scattered rows** — thirty-seven exact to fourteen significant figures, seven wrong by amounts ranging over four orders of magnitude with no pattern. The rule is confirmed and seven cells are errata.

5.5 What the rule is NOT — the statement this section exists to make Rule 3 looks like a generalisation of Rule 1. It is not, and the confusion is worth killing in detail because it produces numbers that are wrong by octaves.

THEOREM 5.1 (the single-component identity). For a compound of one component at index `n`, at any multiplicity,

```
f_compound  =  k^2 n^4  =  (k n^2)^2  =  f(n)^2
```

Proof: `G = n` for any multiplicity, by §5.4. Substitute. **QED.**

Verified at every index on the twelve-state ladder to a worst absolute error of `9.09e-13`, which is floating-point noise in values of order `10^3`:

n	f(n) = k n^2	f_compound = k^2 n^4	f(n)^2
1	0.4834257330	0.2337004393	0.2337004393
2	1.9337029320	3.7392070290	3.7392070290
3	4.3508315969	18.9297355845	18.9297355845
5	12.0856433247	146.0627745721	146.0627745721
8	30.9392469113	957.2369994358	957.2369994358
12	69.6133055503	4846.0123096438	4846.0123096438

So the compound rule applied to a single-component species does not return that species' essence frequency. It returns the square of it. The two rules answer different questions and produce different numbers from the same input.

COROLLARY 5.2 (they never agree). `k n^2 = k^2 n^4` requires `k n^2 = 1`, i.e. `n = sqrt(1/k) = 1.438252434444351`, which is not an integer. **There is no index at which Rule 1 and Rule 3 coincide.** The nearest approach is at `n = 1`, where they differ by a factor of `k` itself — 0.4834257330 against 0.2337004393, a gap of $-\log_2 k = 1.048634$ octaves — and the gap widens monotonically with `n`, reaching 6.121291 octaves at `n = 12`. **The source manuscript gives the $n = 1$ gap as 1.048946; that figure is wrong by 3.1×10^{-4} octaves and the correction is recorded in §10 rather than applied silently.**

And this is exactly why the source table's O2 row was provably impossible. The two facts are one fact: `G` for a single-component species is index-independent in the multiplicity and returns the essence value squared, so a published composite that neither equals `f(8)^2 = 957.2369994358` nor any other value the rule can produce has no rule-consistent reading at all. The seven outliers are transcription errors, not evidence of a different law, and the O2 row is the one that proves it, because it is the only row whose input is so constrained that the rule permits exactly one answer.

Rule 3 is not a law of the same kind as Rule 1 and must never be described as one. Rule 1 assigns a frequency to a category from its index. Rule 3 assigns a value to a *composition* from the geometric mean of its parts, in squared units, and it is blind to things Rule 1 sees.

5.6 The quantity-blindness theorem **THEOREM 5.3.** `G` is invariant under multiplying every multiplicity by a common positive integer. If `c_i -> m c_i` for all `i`, then `T -> mT`, `prod n_i^(m c_i) = (prod n_i^(c_i))^m`, and

```
G' = ( P^m )^(1/(mT)) = P^(1/T) = G
```

QED. Computed:

```
{3x1, 5x1}    T = 2    P = 15         G = 3.872983346207   f = 52.582598845962
{3x2, 5x2}    T = 4    P = 225        G = 3.872983346207   f = 52.582598845962
{3x3, 5x3}    T = 6    P = 3375       G = 3.872983346207   f = 52.582598845962
{3x5, 5x5}    T = 10   P = 759375     G = 3.872983346207   f = 52.582598845962
```

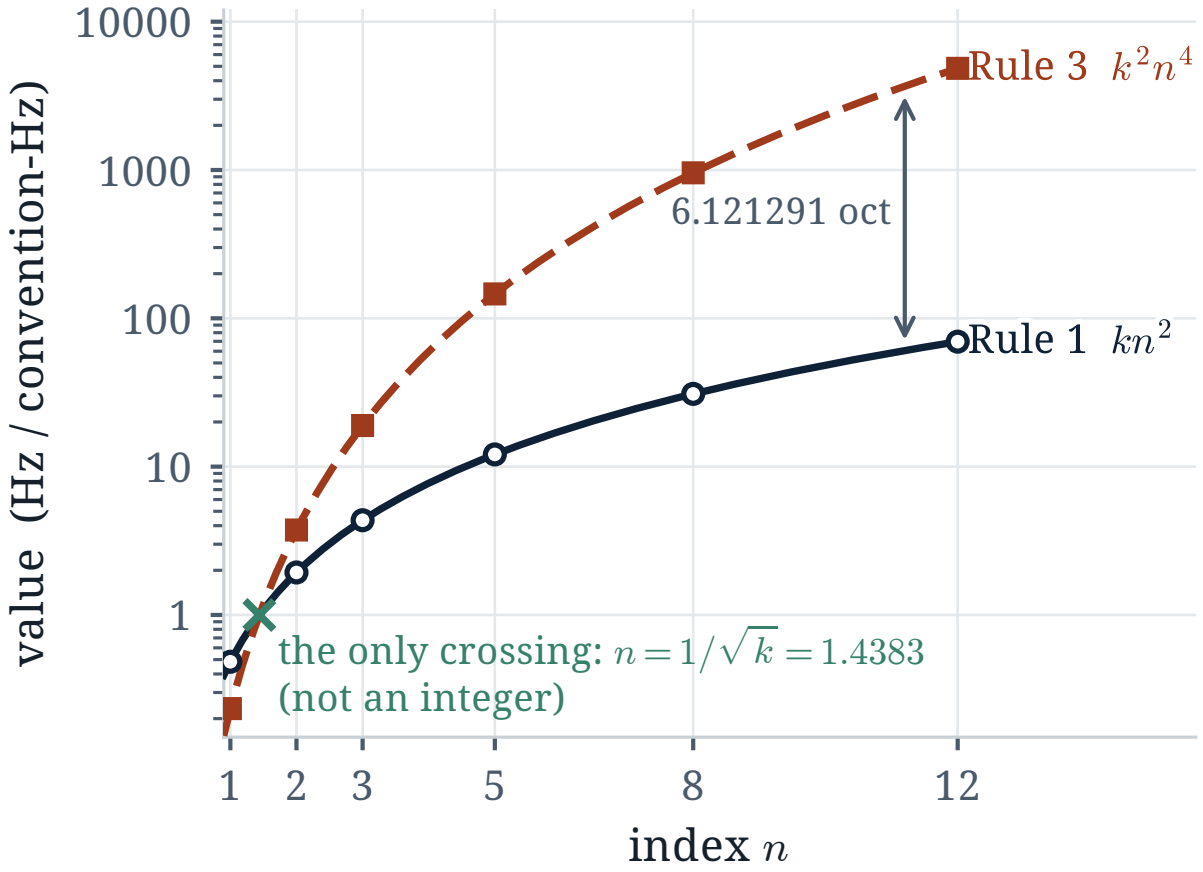

Figure 46.2: **The compound rule and the essence law agree at no index.** kn^2 against k^2n^4, the compound rule's single-component case, which returns the *square* of the essence value. The two curves meet only at $n = 1/\sqrt{k} = 1.438252434444351$, which is not an integer, so no index on any ladder makes them coincide; at $n = 12$ they differ by 6.121291 octaves. k and k^2 are DEFINED constants, exact. Computed from the verification table of §5.5; script `figs/src/CCP-046_fig02.py`.

Rule 3 cannot see how much of a compound there is. It sees only the proportions. The corpus's structural work reaches the same conclusion in a different domain and states it as a bound on what may be claimed: adding a second entity of the same kind in the same jurisdiction buys capability, not diversification, because the pair remains one line in the concentration count [Curzi, 2026]. **More of the same is not more.** The single-component case of §5.4 is the special case `i = 1`; this is the general statement, and it is the structural reason Section 4 rejected Gate 12: an operation whose entire content is *a small seed transmutes a large mass* asserts something about quantity, and quantity is not in the value.

5.7 The units, and the re-anchoring rule The squaring destroys dimensional consistency. `f(n)` is quoted in hertz; `k^2 G^4` carries hertz-squared if the units are taken seriously. The source reads the squaring as a change of structural level rather than a dimensional operation, and this series adopts that reading with the badge on: it is a designed formalism, and the reading is a design decision, not a derivation.

```
RE-ANCHORING RULE (Series B CCP-017, ES-10; binding here)

1  a Rule 3 value is labelled convention-Hz wherever it is printed
2  only RATIO operations may be performed on it
3  octave folding is a ratio operation and is therefore safe
4  it may NOT be entered into an acoustic calculation as hertz
5  publish G and T with every compound value, so it is reproducible
```

Line 5 is not bookkeeping. §5.9 will show that `G` is recoverable from `f` and `T` is not, so a compound value published without `T` has thrown away the only piece of information that narrows the decomposition at all.

5.8 The contraction of the pitch space Because `G` is a geometric mean, low-index components pull it toward 1 and high-index components raise it slowly. Over all 1365 four-component multisets drawn from the twelve-state ladder:

```
G      min 1.000000   Q1 4.119534   median 5.513381   Q3 7.135243   max 12.000000
f      min 0.233700   Q1 67.305727  median 215.939206 Q3 605.751539 max 4846.012310

full span            14.339850 octaves
interquartile span    3.169925 octaves
middle 50% occupies  22.11% of the full octave span
```

The extremes are reached only by the degenerate multisets — all-ones and all-twelves — and half of all compositions sit inside a 3.17-octave band. **Composition is strongly contractive on the pitch space and should be expected to cluster.** Series B observed the same effect empirically in the source's 24 pharmacological compounds, whose `G` ranged only from 1.84 to 4.30.

One structural note that follows from Theorem 5.1 and is worth having in the reference: the compound span over the ladder is 14.339850 octaves and the essence span is 7.169925 octaves, exactly half. Squaring a frequency doubles its position in octaves, so the compound space is the essence space stretched by two — the same information, twice as loud, and in the wrong units.

5.8b The compound interval The mood-and-trait paper [Curzi, 2026] established that the interval between two states is a ratio of squares and that in cents it is `2400 * log2(n/m)`. The compound analogue follows directly from `f = k^2 G^4`, and it is the fourth power rather than the second:

```
interval in cents between two compounds  =  1200 * log2(f2/f1)
                                         =  4800 * log2(G2/G1)
```

`k^2` cancels, exactly as `k` does in the cancellation of the constant [Curzi, 2026], so **no interval between compounds depends on the chosen constant.** Worked on this section's table:

```
{3x1,5x1}   vs  {2x2,7x1}       G 3.8729833462 -> 3.0365889719   −1684.7696 cents
{4x1,6x1,9x1} vs {3,5,7,10}     G 6.0000000000 -> 5.6924250976    −364.4117 cents
threat {3,5,7} vs mirror {5,7,10} G 4.7176939803 -> 7.0472987321  +2779.1450 cents
{11x1,12x1} vs {1x1,2x1}        G 11.4891252931 -> 1.4142135624 −14506.5459 cents
```

The unit is the cent, and the apparatus of exact rational interval arithmetic in a logarithmic measure is standard [Barbour, 1951, Lindley and Turner-Smith, 1993, Benson, 2006, Rossing et al., 2002]. **Whether a ratio's arithmetic complexity is the right thing to price a move by is a separate question, and the literature answers it two ways**: Euler's *gradus suavitatis* grades an interval by the exponents of its prime factorisation [Euler, 1739], and harmonic distance grades it by $\log(ab)$ on a lattice [Tenney, 2015]. **Neither is used here.** This paper prices a move by $2400 \log_2(n/m)$ alone, which is a distance in a logarithmic register and carries no claim about consonance, and what a listener finds consonant is in any case a function of spectrum rather than ratio [Sethares, 2005, Plomp and Levelt, 1965].

And the price list, which is the compound-scale version of the compression the transition matrix [Curzi, 2026] found in the transition matrix:

```
d(cents)/dG  =  4800 / (G ln 2)

at G =  1.5      4616.6241 cents per unit of G
at G =  2.0      3462.4681
at G =  3.0      2308.3121
at G =  4.0      1731.2340
at G =  6.0      1154.1560
at G =  8.0       865.6170
at G = 12.0       577.0780
```

A unit of geometric mean is worth eight times as much in pitch at `G = 1.5` as at `G = 12`. The same compression, from the same cause: a logarithm read against a linear coordinate.

5.8c Compounds have no pitch class

Pitch class in this framework is defined by the odd-part class rule R1 [Curzi, 2026] as the odd part of the **index**. A compound has no index — it has a geometric mean, which is generally irrational — so **a compound value has no pitch class, and the six-class structure of the mood-and-trait paper [Curzi, 2026] does not apply to it.**

This is not a technicality, and the folded values show why. Take the four states of the carried subject's chord and fold both readings of each into the standing 220–440 Hz band:

```
n     essence f    folded (class)      compound k^2 n^4    folded
-------------------------------------------------------------------------
 3     4.350832    278.453222 (3)        18.929736       302.875769
 5    12.085643    386.740586 (5)       146.062775       292.125549
 7    23.687861    379.005775 (7)       561.114755       280.557377
10    48.342573    386.740586 (5)      2337.004393       292.125549
```

Not one of the folded compound values is any of the six class values of the ladder — 247.514, 278.453, 313.260, 379.006, 386.741, 233.978 — and states 5 and 10, which collide in class under Rule 1, also collide under Rule 3, but at a different pitch. The compound reading and the class reading are two different structures over the same states, and neither is a refinement of the other.

The consequence for practice is a prohibition and it is P7 in the specification: **a compound value may not be assigned a pitch class, and a class-based argument may not be run on one.** the dissonance paper's [Curzi, 2026] consonance/redundancy identity is a statement about classes and therefore about Rule 1. It does not transfer.

5.9 The solve step, and why decomposition is not unique Now the harder half of the maxim.

Solve asks: given a compound value, what was it made of? The first part of the answer is clean and the second part is the section's main negative result.

What is recoverable exactly. From a published `f`,

```
G = ( f / k^2 )^(1/4)
```

and nothing about that step is lossy. Worked on the compound `{3x1, 5x1}`:

```
f = 52.5825988460  ->  G = 3.8729833462
G^2 = 15.0000000000    G^3 = 58.0947501931    G^4 = 225.0000000002
```

What is not recoverable. Everything else. The composition enters the rule only through `G`, and `G` enters only through the pair `(P, T)` where `P = prod n_i^(c_i)`. Both arrows lose information.

THEOREM 5.4 (the coagula map is many-to-one). Distinct multisets over `{1..12}` with the same count `T` and the same product `P` have identical `G` and identical `f_compound`. Enumerated exhaustively:

```
T    multisets    distinct f    many-to-one rate    in an ambiguous fibre
------------------------------------------------------------------------
1           12            12          1.0000             0         0.00%
2           78            59          1.3220            35        44.87%

------------------------------------------------------------------------
```

The enumeration is exhaustive rather than sampled, which is the same verification discipline the corpus applies to its combinatorial results elsewhere — a star-polygon decomposition traced over 779 cases with zero mismatches [Curzi, 2026v].

By four components, five component sets in six share their compound frequency with at least one other. By six components, nineteen in twenty do. The ambiguity is not a corner case; it is the generic case, and it grows with the size of the compound.

THEOREM 5.5 (the fibre spans counts as well). By Theorem 5.3, every multiplicity-scaling of a multiset lies in the same fibre, so the fibre over any achievable `G` is infinite once multiplicities are unbounded. Even truncated at `T <= 6` over the twelve-state ladder, the 18,563 available multisets produce only 3,779 distinct values of `G` — a mean of 4.9121 multisets per value.

The worked instance, and it is the one this framework carries:

```
G = 6 is produced by SIXTY distinct multisets over {1..12} with T <= 6

T = 1   P = 6        1 multiset    {6}
T = 2   P = 36       3 multisets   {3,12} {4,9} {6,6}
T = 3   P = 216      5 multisets   {2,9,12} {3,6,12} {3,8,9} {4,6,9} {6,6,6}
T = 4   P = 1296    10 multisets
```

```
T = 5   P = 7776    15 multisets
T = 6   P = 46656   26 multisets
                    ---
                    60
```

All sixty return `f_compound = 302.8757693527` in convention-Hz. **One of them is the carried dyad's member `A`, whose chord is `{4, 6, 9}`.** A reading that published only `A`'s compound value would have said precisely as much about `A` as about a person holding `{6,6,6}`, which is to say nothing that distinguishes them.

CONSEQUENCE 5.6 — the publication rule. A compound frequency may not be published as a description of a composition. **What must be published is the composition, with `G` and `T` derived from it — never the reverse.** The direction of the rule is the whole of it: coagula is a function and may be run; solve is a search and its output is a set.

5.10 What the solve step CAN do

The negative result is large, so the residue is worth stating exactly, since it is not zero.

Solve can falsify a proposed decomposition. If a candidate component set does not produce the published `G`, it is not the decomposition. Over the 1365 four-component multisets, a published `G` eliminates 1361 of them on average and leaves a fibre of about 2.7.

Solve can bound the components. `G` is a mean, so `min(n_i) <= G <= max(n_i)`. A compound with `G = 6` cannot consist entirely of components below index 6, and cannot consist entirely of components above it.

Solve can recover `T` when `T` is small and the arithmetic is tight. `P = G^T` must be an integer for a multiset over the integers. For `G = 3.8729833462`, `G^2 = 15` exactly and `G^5 = 5977.046...` is not an integer, so `T = 5` is excluded outright while `T = 2, 4, 6, ...` are not. **The integrality of `G^T` is a genuine constraint and it is free.**

Solve can be made unique by declaration. If the analyst declares `T` in advance and the fibre at that `T` is a singleton, the decomposition is determined. At `T = 2` over the twelve-state ladder, 55.13% of multisets are alone in their fibre. That is the honest use of *solve*: **not inversion, but hypothesis testing against a declared count.**

5.10b The information accounting of the solve step

The non-uniqueness has an exact size, and stating it in bits is more useful than stating it in counts, because bits are what the rest of the series prices information in.

A decomposition drawn from the twelve-state ladder at count `T` is one of `C(11+T, T)` multisets. The compound value identifies one of the distinct `G` values available at that count. The difference is what *coagula* threw away and *solve* cannot recover:

T	multisets	log2	distinct G	log2	BITS LOST	fraction lost
2	78	6.2854	59	5.8826	0.4028	6.41%
3	364	8.5078	194	7.5999	0.9079	10.67%
4	1365	10.4147	504	8.9773	1.4374	13.80%
5	4368	12.0928	1120	10.1293	1.9635	16.24%
6	12376	13.5953	2226	11.1202	2.4750	18.21%

The accounting is Shannon's and nothing more exotic: the entropy of the pre-image set against the entropy of the observable [Shannon, 1948, Cover and Thomas, 2006, Hartley, 1928], and the irreversibility of a many-to-one map is the same object that makes erasure physically costly [Landauer, 1961]. **The bits reported here are Shannon bits, not thermodynamic ones**, and the framework has stated elsewhere what the two share and what they do not [Curzi, 2026z].

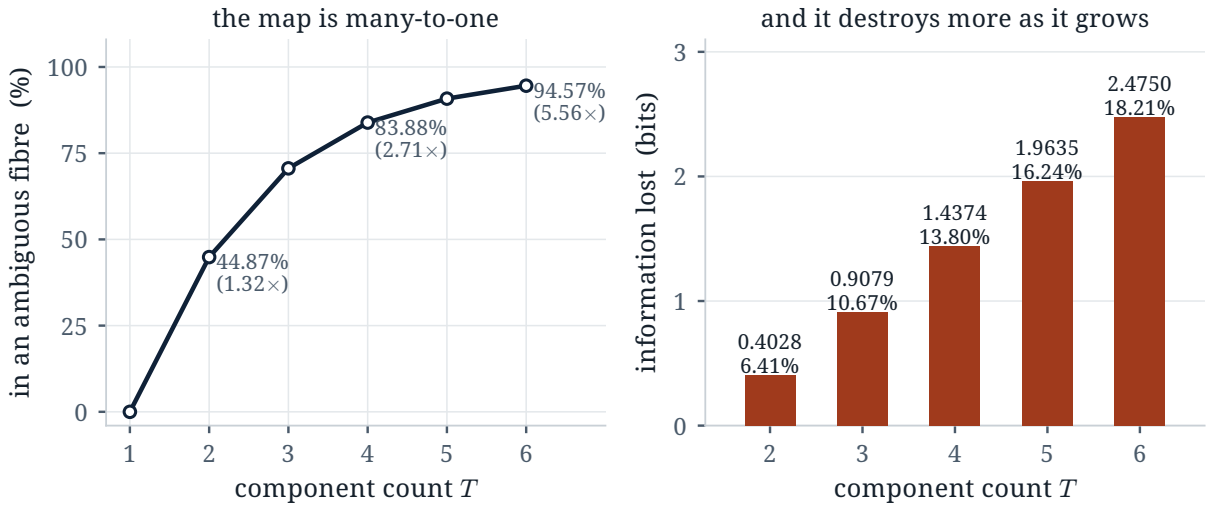

Figure 46.3: **Fixing is a function; dissolving is a search, and the search space grows.** Left: the fraction of component multisets over the twelve-state ladder that share their compound value with at least one other, with the many-to-one rate in parentheses. Right: the information the compound value discards, in bits and as a fraction of the decomposition's entropy. Both panels are exhaustive enumerations over all multisets at each count, not samples; computed from §5.9 and §5.10b; script `figs/src/CCP-046_fig03.py`.

Two readings, and they pull in opposite directions, which is why both are printed.

The loss is real and it grows. At two components the compound value keeps 93.59% of the information in the decomposition; at six it keeps 81.79%, and the trend is monotone. Compounds get harder to invert as they get larger, which is the reverse of the intuition that more constraints narrow a search.

The loss is also smaller than the fibre counts suggest. A many-to-one rate of 5.56 at `T = 6` sounds catastrophic and costs 2.475 bits. Both numbers are correct: the fibres are large, and the value still eliminates the overwhelming majority of candidates. **`G` is a weak identifier and a strong filter, and Procedure SOLV-1 uses it as the second and never as the first.**

This is the same accounting the genome-addressing paper [Curzi, 2026y] ran on the Yamanaka factors — a selection worth at most 37.985 bits acting on a 6.2-gigabit archive — and it is the same lesson at a much smaller scale. A short address into a large space narrows enormously and identifies nothing.

5.10c The maxim, as a concordance The two-word instruction is old enough and general enough to invite over-reading, so it gets the Tri-State treatment with roles stated (the framework's evidential-role convention [Curzi, 2026]).

```
CLAIM        Composition and decomposition are distinct operations with
             different formal characters, and a process that alternates
             them is doing two different kinds of work.

(+1) SOURCE  Series B CCP-017 §29.10, the closed form; and Theorems 20.4
             and 20.5 of this chapter.
MEASURED     f = k^2 G^4 reproduces 37 of 44 published composite values
             to better than 1 part in 10^12. The inverse map is
             many-to-one at rates from 1.32 to 5.56 over T = 2..6.

(-1) SOURCE  Solve et coagula, transmitted through the Latin alchemical
```

```
              corpus and restated in Ripley's Twelve Gates (1471), where
              solution is Gate 2 and congelation Gate 6, separated by
              three intervening gates.
RECORDED      That the two operations are named separately, ordered, and
              that the sequence insists on dissolving BEFORE fixing.

ROLES         (+1) carries the evidence and carries it alone.
              (−1) carries precedent only: the observation that the two
              were distinguished, by people with no closed form and no
              way to count a fibre.

C1  structural correspondence   PASS. Two named operations; two formally
                                distinct maps, one a function and one a
                                search.
C2  predictive power            PARTIAL. The formalism predicts that
                                decomposition is under-determined and
                                says by how many bits. The tradition
                                predicts nothing testable.
C3  practical utility           PASS. On the (+1) side it produces
                                Procedure SOLV-1's halting condition. On
                                the (−1) side it explains why the corpus
                                treats dissolution as the harder step.

STATUS        ESTABLISHED as a structural correspondence; SPECULATIVE as
              any claim about what the tradition understood, and marked
              speculative here in the sentence that states it.
```

The asymmetry the maxim encodes is real and the formalism measures it. **That the tradition arrived at the asymmetry is precedent, and precedent is not evidence.**

5.11 Honesty clauses, restated in place **(1) ESSENCE, NOT RESONANCE.** Every value here is a position on a logarithmic scale of surplus. Nothing vibrates, nothing resonates, and no molecule, tissue, or person is described by any number in this section.

(2) UNITS. Rule 3's output is convention-Hz and is dimensionally hertz-squared. Ratio operations only.

(3) `k^2` IS A POSTULATE. Inherited from `k`, badged, and it cancels from every ratio.

(4) NO CLINICAL CLAIM. The twelve states are not diagnoses; nothing here is an assessment.

(5) CONSTRUCTED CASES. All of them, labelled.

(6) THE COUNT ARGUMENT TRAVELS. A compound reading inherits the defensibility of the decomposition it was computed from. A contested decomposition yields a contested `G`.

(7) REPORT `D` WITH `delta`. Where this section's values feed a sustainability reading, the decay-blindness result R4 [Curzi, 2026] binds: `D` contains no `delta` and a `D`-only report cannot see decay.

The engineering

5.12 Worked compounds **All constructed, labelled as such**, drawn from the twelve-state ladder. Multiplicities are counts of components in the specification, not intensities — intensities are `w`, they are a different object, and the elicitation rule [Curzi, 2026] owns them.

```

values are convention-Hz, dimensionally Hz^2
```

Three readings of this table.

The two compounds required by the three transfer rules [Curzi, 2026] are rows six and four. `{3x1, 5x1}` gives `G = 3.8730` and `f = 52.5826`; `{2x2, 7x1}` gives `G = 3.0366` and `f = 19.8703`. Both are reproduced here to ten places so that later sections can cite the precise values.

Row three against row two is the quantity-blindness theorem doing visible damage. `{1x1, 12x1}` and `{1x3, 12x1}` differ only in how many index-1 components are present, and they differ by 3.584963 octaves — because changing a multiplicity changes the *proportions*, which `G` does see. Contrast that with `{3x1,5x1}` against `{3x3,5x3}` in §5.6, where every multiplicity trebled and the value did not move at all. **Rule 3 is blind to scale and acutely sensitive to ratio, and a reader who does not hold both facts at once will misread every table in this section.**

Row eight is A's chord and it lands on a round number. `4 x 6 x 9 = 216 = 6^3`, so `G = 6` exactly. This is arithmetic coincidence and nothing else, and §5.9 already showed what it costs: sixty multisets share it.

5.13 PROCEDURE COAG-1 — running the fixing step

```
1  state the decomposition: the multiset of indices with multiplicities.
   Every index must survive the count argument of CCP-041 on its own.
2  compute T = sum(c_i) and P = prod n_i^(c_i). Publish both.
3  compute G = P^(1/T) to at least ten decimal places.
4  compute f = k^2 G^4. Label it convention-Hz.
5  if the value is to be rendered, fold by 2^j into the stated band and
   publish j. Folding is a ratio operation and is the ONLY safe route to
   an audible value (§5.7 line 3).
6  publish the decomposition alongside. A compound value without its
   decomposition is not reproducible and is not a description of anything
   (Consequence 20.6).
```

5.14 PROCEDURE SOLV-1 — running the dissolving step

```
1  from the published f, compute G = (f / k^2)^(1/4) exactly.
2  DECLARE T before searching. If T is not declared, stop: the fibre is
   infinite by Theorem 5.5 and the search has no boundary.
3  compute P = G^T. If P is not an integer to within the published
   precision, the declared T is excluded. Try another.
4  enumerate all multisets over the admissible index range with product P
   and count T. This is the FIBRE.
```

```
5  publish the fibre in full. Not a member of it. The fibre.
6  if a unique member is wanted, it must be selected by evidence from
   OUTSIDE the frequency -- the actual components, elicited. The frequency
   cannot select it and no amount of precision will make it.
```

Step 5 is the step analysts skip, and skipping it converts a set-valued result into a point-valued claim. A published decomposition chosen from a fibre without saying so is **the frequency-domain version of reporting one arm of an experiment.**

5.15 The fibre, computed, for a reader to check The carried dyad's member `A` holds `{4, 6, 9}`. Run SOLV-1 on its published compound value.

```
step 1   f = 302.8757693527  ->  G = 6.0000000000
step 2   declare T = 3
step 3   P = G^3 = 216, an integer. T = 3 admissible.
step 4   fibre = { {2,9,12}, {3,6,12}, {3,8,9}, {4,6,9}, {6,6,6} }
step 5   publish all five
step 6   {4,6,9} is selected by the ELICITATION, not by the frequency
```

And the same value under other declared counts, to show what step 2 is worth:

```
T = 1   P = 6        fibre size  1     {6}
T = 2   P = 36       fibre size  3
T = 3   P = 216      fibre size  5
T = 4   P = 1296     fibre size 10
T = 5   P = 7776     fibre size 15
T = 6   P = 46656    fibre size 26
-------------------------------------
total across T <= 6               60
```

Declaring `T = 3` reduces the search from sixty candidates to five. It does not reduce it to one. Gate 2 recorded this as the reason it handed *solve* to this section, and the handover is now discharged.

5.16 When a compound reading is the wrong reading Rule 3 is available whenever a set of components can be named, which means it is available far more often than it is appropriate. Four tests before using it.

The general form of the error is one the corpus has already isolated: a property that is necessary is not thereby sufficient, and a quantity trusted *because* it is well defined is the failure mode [Curzi, 2026]. Four tests, in order.

Is the object a composition or a relationship? Two people who agree about something are not a compound of each other. Rule 2 governs a relationship and returns hertz; Rule 3 governs a composition and returns convention-Hz. Finding 4.1 is the standing warning: the word *conjunction* covers both, and the values are not commensurable.

Are the multiplicities counts? If what is being counted is really an intensity — how strongly something is held — then it is `W`, it is elicited by magnitude estimation, and it does not belong in `G`. **Putting an intensity into a multiplicity is the compound-scale version of the state-ordering material's [Curzi, 2026] smuggling a rating in as a count.**

Is the total quantity part of the claim? If it is, Rule 3 cannot carry it (Theorem 5.3).

Will the value be compared to a Rule 1 or Rule 2 value? If so, stop. The units differ, and Corollary 5.2 guarantees the two rules never meet.

The specification

SPEC-5.1 — Inputs

```
the multiset: indices with multiplicities, each index justified by count
the ladder and its N, stated
the elicitation that produced the decomposition, cited
a declaration of whether multiplicities are counts (required) or
anything else (inadmissible)
```

SPEC-5.2 — Required outputs, coagula

```
T, P, G to >= 10 dp, f in convention-Hz to >= 10 dp
the decomposition, in full, printed with the value
the units label, on every occurrence of f
j and the band, if the value was folded
```

SPEC-5.3 — Required outputs, solve

```
G, recovered exactly
the DECLARED T, and the integrality test on G^T
the FIBRE, in full, with its size
the external evidence used to select a member, if one was selected
an explicit statement that the frequency did not select it
```

SPEC-5.4 — Prohibitions

```
P1  Rule 3's output may not be described as a generalisation of Rule 1
P2  Rule 3's output may not be entered into an acoustic calculation as Hz
P3  a compound value may not be published without its decomposition
P4  a fibre member may not be published as the decomposition
P5  a Rule 3 value may not be ratioed against a Rule 1 or Rule 2 value
P6  quantity claims may not be supported by a Rule 3 value (Thm 20.3)
P7  a compound value may not be assigned a pitch class (§5.8c)
```

SPEC-5.5 — Precision `G` to at least ten decimal places; `f` to at least ten. The integrality test in SOLV-1 step 3 is performed against the published precision of `G`, and a value published to fewer than ten places cannot support the test. Recompute from the full-precision constants, never from rounded prints (the full-precision rule).

SPEC-5.6 — Gates

```
G1  units labelled everywhere                                REQUIRED
G2  decomposition published with every compound value        REQUIRED
G3  fibre published with every solve result                  REQUIRED
G4  T declared before any search                             REQUIRED
G5  the non-generalisation statement carried wherever both
    rules appear in the same document                        REQUIRED
G6  all cases labelled constructed                           REQUIRED
```

The failure modes

FM-5.1 — Treating Rule 3 as the general case of Rule 1 *Signature:* "the essence law is the one-component case of the compound law."

Why it is wrong: Theorem 5.1. The one-component case of the compound law returns `f(n)^2`, not `f(n)`. Corollary 5.2: there is no index at which they agree. At `n = 12` the two differ by 6.121 octaves.

The fix: state the two rules as answering different questions, every time both appear.

FM-5.2 — The O2 error, in its general form *Signature:* a published composite value that no multiplicity of its stated components can produce, retained because it "came from the source."

Why it is wrong: §5.4. For a single-component species the rule permits exactly one value. A published number outside the rule's range is an erratum, and the scatter of the seven outliers across four orders of magnitude confirms data entry rather than a different law.

The fix: recompute every inherited composite before citing it, and publish the recomputation.

FM-5.3 — Reading a compound value as a description *Signature:* "their compound frequency is 302.88, which tells us they are composed of `{4,6,9}`."

Why it is wrong: Theorem 5.4 and §5.15. Sixty multisets give that value.

The fix: Consequence 5.6. Publish the composition; derive the value from it; never the reverse.

FM-5.4 — Solving without declaring `T` *Signature:* a fibre enumerated over all counts, or a single decomposition produced from `f` alone.

Why it is wrong: Theorem 5.5. Without a declared `T` the fibre is infinite, because every multiplicity-scaling is in it.

The fix: SOLV-1 step 2, which halts.

FM-5.5 — Putting intensities into multiplicities *Signature:* a component "held strongly" entered as `n x 3`.

Why it is wrong: multiplicities are counts of components in a specification. Intensities are `w`, they are elicited by magnitude estimation (the elicitation rule), and their scale status is different. Mixing them produces a `G` that is neither.

The fix: §5.16 test two. If the number came from an intensity elicitation it goes in `u`, not in `G`.

FM-5.6 — Using a compound value to support a claim about amount *Signature:* "the value is high, therefore there is a great deal of it."

Why it is wrong: Theorem 5.3. `{3x1,5x1}` and `{3x5,5x5}` are the identical value.

The fix: if amount is the claim, Rule 3 is not the instrument. Nothing in this framework measures amount.

FM-5.7 — Rendering a Rule 3 value as hertz *Signature:* 52.5826 played as a tone.

Why it is wrong: the value is dimensionally hertz-squared and its Hz label is a convention (§5.7).

The fix: fold first, publish `j`, and label the result as a re-anchored convention value. The rendering protocol [Curzi, 2026] carries this into the rendering protocol.

FM-5.8 — Precision theatre on a contested decomposition *Signature:* `G` to twelve places over a decomposition two experts disagree about.

Why it is wrong: honesty clause (6). The value inherits the defensibility of the count. Twelve places on a contested multiset is precision about the wrong thing.

The fix: publish the disagreement, compute both decompositions, and report the octave gap between them as the uncertainty.

FM-5.9 — Comparing compounds across ladders *Signature:* a `G` from a twelve-state ladder set beside a `G` from an eight-category scheme.

Why it is wrong: the indices mean different things, so the geometric means are not comparable, and `k^2` does not save it because the inputs differ rather than the constant.

The fix: the ladder and its `N` are published with every value (SPEC-5.1) and comparisons across ladders are refused.

FM-5.10 — Reading the maxim as symmetric *Signature:* "dissolve and fix are inverse operations, so the procedure reverses."

Why it is wrong: this section's central asymmetry. Coagula is a function with a closed form; solve is a search whose output is a set, and by four components 83.88% of inputs land in a fibre of size two or more.

The fix: say *fix, then search*, not *fix, then unfix*.

FM-5.11 — Assigning a pitch class to a compound *Signature:* `{3x1,5x1}` folded to 420.660791 Hz and reported as "close to class 5."

Why it is wrong: §5.8c. Pitch class is the odd part of an index and a compound has no index. The folded compound values of the carried subject's four states land on none of the ladder's six class values, and the resemblance of any one of them to a class value is arithmetic accident.

The fix: fold for rendering, never for classification, and carry P7 wherever a compound value is folded.

FM-5.12 — Inverting a fibre by choosing the most plausible member *Signature:* the fibre is enumerated, one member "obviously fits," and the others are dropped without a word.

Why it is wrong: plausibility is external evidence, and external evidence must be named. SOLV-1 step 6 requires the selection criterion to be published; a criterion applied silently is indistinguishable from a preference.

The fix: publish the fibre, publish the criterion, and publish which member the criterion selects. If no criterion exists, the result is the fibre and the report says so.

FM-5.13 — Presenting a compound reading as a description of a person *Signature:* a `G` computed over someone's held states and reported as what they are.

Why it is wrong: the standing prohibitions. The twelve states are not diagnoses, no reading is an assessment, and Theorem 5.4 means the value does not even identify the states uniquely.

The fix: the reading is of a decomposition, the decomposition is constructed, and the sentence that reports it says so.

Worked example

PART A — THE CARRIED SUBJECT, FIXED **Constructed case, labelled as such.** the carried subject [Curzi, 2026]'s subject holds three framings of one situation, spanning the states `{3, 5, 7, 10}`. Run COAG-1 on the chord, taking each held state as one component.

```
step 1   multiset {3x1, 5x1, 7x1, 10x1}; ladder N = 12; states from CCP-041
step 2   T = 4     P = 3 x 5 x 7 x 10 = 1050
step 3   G = 1050^(1/4) = 5.6924250976
step 4   f = k^2 * G^4 = 245.3854612812  (convention-Hz, dimensionally Hz^2)
step 5   folded: 245.3854612812 * 2^0 = 245.385461, j = 0, band 220-440
step 6   decomposition published above
```

And the three framings taken separately, which is the more informative reading:

```
framing    states      T   P     G              f (convention-Hz)
-------------------------------------------------------------------
threat     {3,5,7}     3   105   4.7176939803   115.7653513543
story      {3,5,10}    3   150   5.3132928459   186.2578308452
mirror     {5,7,10}    3   350   7.0472987321   576.4348833846
-------------------------------------------------------------------
whole      {3,5,7,10}  4  1050   5.6924250976   245.3854612812
```

The whole is not the sum, the mean, or the midpoint of the parts. `245.3855` sits between `threat` and `mirror` but not at their geometric centre, because `G` is weighted by count and the whole has four components where each framing has three. This is the arithmetic behind the self-as-chord material [Curzi, 2026]'s warning that a chord is not the average of its notes.

Now the comparison that matters, and it is a refusal. the carried subject [Curzi, 2026] also publishes the subject's internal surplus and the chord's width as pitch:

```
Rule 2 reading   mean u_int = 0.700844   F_int = 2.164390   f = 36.6686325914 Hz
Rule 3 reading   G = 5.6924250976                          f = 245.3854612812 conv-Hz
```

These two numbers describe the same person and may not be compared, ratioed, averaged, or plotted on one axis. One is hertz and one is hertz-squared; one is a function of how non-parallel the framings are and one is a function of which states are held, with no reference to how they overlap. A reader who computes `log2(245.3855 / 36.6686) = 2.742` has produced a number with no referent, and it is printed here only so that it is recognisable as the mistake it is.

PART B — THE CARRIED DYAD, DISSOLVED **Constructed case, labelled as such.** the carried dyad [Curzi, 2026], member `A = {4:0.7, 6:0.5, 9:0.4}`. The intensities are `w` and do not enter `G` (FM-5.5); the components are the states `{4, 6, 9}`.

```
COAG-1     T = 3    P = 216    G = 6.0000000000    f = 302.8757693527 conv-Hz
```

Run SOLV-1 against that value, as an independent party would who had only the number.

```
step 1   G = (302.8757693527 / 0.233700439315386)^(1/4) = 6.0000000000
step 2   declare T = 3
step 3   P = 216, integer. Admissible.
step 4   fibre:
            {2, 9, 12}   {3, 6, 12}   {3, 8, 9}   {4, 6, 9}   {6, 6, 6}
step 5   fibre size 5, published in full
step 6   no external evidence supplied -> NO MEMBER SELECTED
```

Read the five candidates against the twelve-state ladder [Curzi, 2026] and the extent of the loss becomes concrete. `{4, 6, 9}` is situated feeling, temporal feeling, normative feeling. `{6, 6, 6}` is one state held three times. `{2, 9, 12}` reaches from valenced activation to committed feeling. These are not variations on a theme. **They are five different people, and Rule 3 returns one number for all of them.**

The pitch-class reading, which Rule 3 also cannot see, separates them immediately:

```
{4, 6, 9}    classes {1, 3, 9}    three classes
{2, 9, 12}   classes {1, 9, 3}    three classes
{3, 6, 12}   classes {3}          ONE class -- a single note played three times
{3, 8, 9}    classes {3, 1, 9}    three classes
{6, 6, 6}    classes {3}          ONE class, and one state
```

Two of the five are entirely consonant and therefore entirely redundant — the consonance-redundancy identity R2 [Curzi, 2026] — and the compound value cannot distinguish them from the three that are not. That is the strongest practical statement of the non-uniqueness in this section: **the solve step is blind to exactly the structure the dissonance paper of this series was written to expose.**

PART C — THE CONJUNCTION, PRICED IN BOTH NOTATIONS Gate 4 of Section 4 halted a schedule because *conjunction* is ambiguous. With Rule 3 now owned, the halt can be resolved by declaration rather than by choice.

```
reading (i)  RULE 2, the relational join
             u = 0.068734665264634    f_rel = 1.4907987150 Hz
             F = 0.563084802746       D = +4.338420   delta = 0.09
             Q_inf = -5.011940        DECAYS

reading (ii) RULE 3, the compositional join
             pooled multiset {4x2, 6x2, 9x2, 10x1}
             T = 7    P = 466560    G = 6.4542224391
             f = 405.5414451025 convention-Hz
```

Both are correct answers to different questions. Reading (i) says the pair's difference supports 0.563085 nats of surplus and that this is 4.338420 octaves short of what their cost ratio requires, at a loss rate of 0.09. Reading (ii) says the pooled specification has a count-weighted geometric mean of 6.4542224391 and nothing else at all — **it does not know that `A` and `B` are two people, does not know they overlap on three states out of four, and would return the identical value if one person held all seven components alone.**

```
THE DECLARATION RULE, and it discharges Gate 4:

joining PEOPLE                   -> Rule 2, hertz, u
joining COMPONENT SETS           -> Rule 3, convention-Hz, G
the two may both be reported
the two may never be compared
```

PART D — THE REPORT CARD

```
------------------------------------------------------------------------
COMPOUND READING -- carried subject, chord {3,5,7,10}
------------------------------------------------------------------------
decomposition       {3x1, 5x1, 7x1, 10x1}, ladder N = 12, CCP-041 indices
T                   4
```

```
P                   1050
G                   5.6924250976
f_compound          245.3854612812   CONVENTION-Hz, dimensionally Hz^2
fold                j = 0, band 220-440 Hz
solve fibre at T=4  { {3,5,7,10}, {5,5,6,7} }   size 2
T excluded          T = 5 (G^5 = 5977.046... not an integer)
-------------------------------------------------------------------------
NOT comparable to the Rule 2 reading of the same subject (36.6686 Hz).
NOT a measure of quantity (Theorem 5.3).
NOT a description of the subject (Consequence 20.6; fibre size 2).
ESSENCE frequencies, not physical resonances. Constructed case.
Not a diagnosis, not an assessment, not clinical.
-------------------------------------------------------------------------
```

The last line of the fibre row is the section in miniature. Even at the tightest available count, with the value known to ten decimal places, **the twelve-state ladder offers a second component set — `{5, 5, 6, 7}` — that fixes to exactly the same number.** *Coagula* ran in four steps and produced a value. *Solve* ran in six and produced a set of two, and the honest report prints the set.

Section 6 takes the other operation Section 4 handed forward: moving a state from one index to another. It prices the interval, states what the move costs, and establishes the constraint that bounds every claim in this paper — that nothing not already latent can be reached, at any strength, by any operation in this framework.

6 Re-indexing: what a move between indices costs and what it cannot reach

The word carries more freight than any other in the old corpus, and the freight is what this section unloads. Section 4 rejected Gate 12 — projection, the transmutation of a mass by a seed — on four separate grounds, and rejected Gate 10, exaltation, because *nobler* is not a coordinate. What survives after those rejections is small, exact, and worth having.

A state can be moved from one index to another. That is all transmutation is in this formalism, and this section holds its title to exactly that.

Moving a state from index `m` to index `n` means changing the number of distinguishable components required to specify it. It has a price in pitch that can be computed to four decimal places, a price in components that can be counted, and a price in the storage law that has to be declared because the formalism does not supply it. It has a direction, and the direction matters. And it has a hard outer boundary that no operation in this framework crosses at any strength, by any modality, ever: **nothing that is not already latent can be reached.**

That boundary is inherited, not invented here. The genome-addressing paper [Curzi, 2026y] stated it as CONSTRAINT L67 for the cellular architecture and called it the most valuable sentence in that volume. This section restates it at psychological scope and treats it as binding on everything in this paper. The reason it is the most valuable sentence, rather than the most limiting one, is worth having in advance: the property that makes an addressing architecture safe is the same property that makes it limited, and **a design claiming both unlimited reach and no modification would be incoherent.**

Three things before the arithmetic.

Re-indexing is not creation. the index of the state-ordering material [Curzi, 2026] is a count of components in a specification. To move a state up the ladder is to specify it more finely; the components that make the finer specification possible must already be available to be counted. **Yamanaka reprogramming activates latent capability; it does not create new capability**, and the same accounting applies here.

Re-indexing is not improvement. the more-is-not-better rule [Curzi, 2026] settled that more components is not better, and the dissonance paper [Curzi, 2026] settled that a fully consonant self is a fully redundant one. Nothing in this section licenses reading a higher index as a better state.

Nothing here is clinical. The twelve states are not diagnoses, no reading is an assessment of anyone's health, no operation below is a treatment, and every case is constructed and labelled as such. The frequencies are essence frequencies — positions on a logarithmic scale of surplus — and nothing is claimed to vibrate.

The law

6.1 What a re-indexing is

DEFINITION 6.1. A *re-indexing* is a change in the index assigned to a state, from `m` to `n`, where both are positions on a single fixed ladder and the change reflects a change in the number of distinguishable components required to specify the state.

Three things are excluded by that wording and each exclusion is load-bearing.

A change of ladder is not a re-indexing. If `N` changes, or if the categories are re-cut, the indices before and after are not comparable and no interval between them is meaningful. That operation is the minimum-frequency paper's [Curzi, 2026] lever L4 and Section 4's Gate 3, and it has its own price.

A change of register is not a re-indexing. Multiplying by `2^j` moves the published frequency and moves nothing else (the folding rule [Curzi, 2026]). Gate 8 rejected sublimation for exactly this confusion.

A re-labelling is not a re-indexing. If the same specification is given a different number because the analyst preferred it, the index moved and the state did not. The publish-the-decomposition rule [Curzi, 2026]'s rule binds: publish the decomposition or the frequency means nothing.

6.2 The interval crossed

THEOREM 6.2. The interval crossed by a re-indexing from `m` to `n` is a ratio of squares:

```
f(n) / f(m)  =  (k n^2) / (k m^2)  =  n^2 / m^2

and in the reverse direction        =  m^2 / n^2

in cents                            =  1200 * log2(n^2/m^2)  =  2400 * log2(n/m)
```

`k` cancels. **The price of a re-indexing does not depend on the chosen constant.** No verdict about a move depends on the reference pitch. This is the cancellation of the constant [Curzi, 2026] applied at index scope.

Two properties of the interval that practice depends on.

It is path-independent. The interval from `m` to `n` is a difference of logarithms, so a move through intermediate indices costs the same in pitch as the direct move. Going `3 -> 6 -> 12` costs `2400.0000 + 2400.0000 = 4800.0000` cents, and going `3 -> 12` directly costs `4800.0000`. The minimum-frequency paper [Curzi, 2026] §4.13's warning about path-dependent attribution applies to the cost side of a deficit and not to this.

It is antisymmetric. `2400 log2(n/m) = −2400 log2(m/n)`. The transition matrix [Curzi, 2026]'s transition matrix is the full table and is not re-derived here; the reverse of any entry is its negative.

The reference values this section uses most, from that matrix:

```
from -> to      ratio n^2/m^2     reverse m^2/n^2      cents
-------------------------------------------------------------------
 1 ->  2          4.000000          0.250000        +2400.0000
 3 ->  6          4.000000          0.250000        +2400.0000
 3 ->  4          1.777778          0.562500         +996.0900
 5 -> 10          4.000000          0.250000        +2400.0000
 9 -> 12          1.777778          0.562500         +996.0900
11 -> 12          1.190083          0.840278         +301.2741
 1 -> 12        144.000000          0.006944        +8603.9100
```

6.3 Two kinds of move, and the arithmetic that separates them The mood-and-trait paper [Curzi, 2026] owns the distinction and this section uses it. Two indices share a pitch class if and only if they share an odd part (the odd-part class rule R1 [Curzi, 2026]). Therefore:

```
RE-INDEXING WITHIN AN ORBIT      m and n share an odd part
                                 interval is a whole even number of octaves
                                 pitch class UNCHANGED
                                 the framework's term: INTENSIFICATION

RE-INDEXING ACROSS ORBITS        m and n have different odd parts
                                 pitch class CHANGES
                                 the framework's term: TRANSFORMATION
```

Counted over the ordered moves available on the twelve-state ladder:

```
ordered pairs (m != n)                    132
class-preserving (intensification)         20      15.1515%
class-changing   (transformation)         112      84.8485%
```

Transformation is the generic move and intensification is the rare, highly structured one. the orbit structure [Curzi, 2026] gives the six orbits; the operative fact for this section is which states have a double still on the ladder:

```
states with 2m <= 12 (can be intensified without leaving the ladder):  1,2,3,4,5,6
states with 2m >  12 (cannot):                                         7,8,9,10,11,12
```

Exactly half the ladder can be intensified and half cannot, and the half that cannot is an artefact of `N = 12` rather than a property of those states. The mood-and-trait paper [Curzi, 2026] named this truncation and this section prices it: for a state at index 7 or above, every available re-indexing is a transformation, because its orbit has no higher member inside the ladder.

6.4 CONSTRAINT T21 — the hard constraint

> **CONSTRAINT T21. A re-indexing can reach only what is already latent. No operation in this framework, of any kind, at any strength, by any modality, can produce a component that the decomposition does not already contain.**

This is CONSTRAINT L67 of the genome-addressing paper [Curzi, 2026y], restated at psychological scope, and it requires no new assumption. **An index is a count of components. A count cannot be raised by counting harder.** To move a state from index 5 to index 6 is to add a projected duration to a specification that previously had none, and either the material for that component is available to the person or it is not. The operation addresses; it does not import.

The constraint does four kinds of work, and they are the same four Series B named.

It bounds the claim space. Any statement of the form "this procedure could produce capability X" is false whenever X is not already available and reachable. That eliminates the entire class of claims that would make this work pseudoscience: nothing conferred, nothing imported, no capacity created.

It makes the model falsifiable in a specific way. If a demonstration showed a state specified by a component demonstrably absent from the person's repertoire, following an addressing-only intervention, this architecture is wrong and no adjustment of parameters repairs it.

It generates a positive prediction. If re-indexing reaches only what is latent, the reachable set is bounded and enumerable in principle. §6.6 computes it for a constructed repertoire.

It supplies the audit rule. Every proposed move is checked against the repertoire before it is priced, and Procedure TR-1 puts that check before the arithmetic rather than after.

The three works cited immediately below are named in full and carry no citation keys, because they are absent from the bibliographic database governing this corpus. That is a gap in the bibliography, not a claim that the works are unimportant; it is recorded here and again in §10.

The `(+1)` evidence, cited exactly and with roles stated (the framework's evidential-role convention [Curzi, 2026]):

Gurdon (*J. Embryol. Exp. Morphol.* 10:622-640, 1962) transplanted nuclei from differentiated intestinal epithelium of feeding *Xenopus* tadpoles into enucleated eggs and obtained normal feeding tadpoles. Differentiation is not subtraction: **the nucleus of a differentiated cell retains the full information required to build the organism.**

Takahashi & Yamanaka (*Cell* 126:663-676, 2006) returned mouse fibroblasts to a pluripotent state by forced expression of four transcription factors; **Takahashi et al. (*Cell* 131:861-872, 2007)** extended it to human fibroblasts. The 2012 Nobel Prize in Physiology or Medicine went jointly to Gurdon and Yamanaka.

And the accounting that makes the point quantitative rather than rhetorical, recomputed from the genome-addressing paper [Curzi, 2026y]:

```
human sequence-specific transcription factors, approx.   1600
    (Lambert et al., Cell 172:650-665, 2018)

selecting 4 of 1600:  C = 2.720438e+11  ->  37.985 bits
the genome acted upon:                      6.200e+09 bits
ratio                                       1.6322e+08 : 1
```

The instruction is one hundred and sixty-three million times smaller than the thing it reorganises, and **that is what an address is.** An activation signal is not the content it activates. The correspondence drawn here is structural — latency-then-expression as a shared architecture — and the `(-1)` column, the tradition's own insistence that the material must already contain what the work brings out, carries precedent and no evidence.

The extension of this accounting to psychological states is this work's, badged as a thesis, and it is not established by the cited work. Gurdon and Yamanaka measured cells. What they license here is the *form* of the constraint, not a claim about minds.

6.5 Latency, and the laundering it invites

"Latent" is doing heavy work and it is the word most easily abused, so its failure is named before its use. The genome-addressing paper [Curzi, 2026y] named the chain:

```
the repertoire contains latent capability
  -> therefore capability X is latent
    -> therefore X is available
```

Each arrow smuggles. The first step is a statement about bulk; the second names a specific item without evidence that the item is in the bulk; the third converts possible into reachable.

"Latent" means present in the repertoire and addressable, not merely conceivable. A component that a person could in principle acquire, given years and circumstances, is not latent in the sense this constraint uses.

The failure has a name outside this framework: a construct defined loosely enough that any observation confirms it makes no risky prediction, which is the standing objection to soft psychological theorising [Meehl, 1967, 1990], and the remedy is a criterion stated in advance that can refuse [Popper, 1959, Platt, 1964, Lakatos, 1970].

Operationally, and this is the rule Procedure TR-1 enforces: **a component counts as latent only if it has been observed in the repertoire at least once**, in some state, on some occasion. That is a strict criterion, it will exclude things that are in fact latent, and the exclusion is the correct direction of error for a constraint whose purpose is to bound a claim.

6.6 The reachable set

Given a repertoire, the reachable set is the set of chords the states in it can form. It is finite and it is countable.

Constructed example, labelled as such. A repertoire containing components sufficient to specify states `{3, 4, 5, 6, 7, 9, 10}` and not states `{1, 2, 8, 11, 12}`:

```
full chord space over 12 states       2^12 − 1  =  4095 chords
reachable from this repertoire        2^7  − 1  =   127 chords
fraction of the space                                3.101343%

four-note chords over 12 states       C(12,4)   =   495
four-note chords reachable            C(7,4)    =    35
fraction                                             7.0707%
```

Ninety-seven per cent of the nominal chord space is unreachable for this constructed repertoire. No operation in this paper changes that. Widening the repertoire is not an operation in this paper; it is what the genomic papers [Curzi, 2026] examine, under the open problem, with no established mechanism attached.

A second constructed repertoire, narrower, to show the scaling: with only five states available, the four-note reachable set falls from 495 to 5 — **a hundred-fold reduction from a repertoire loss of seven states.** The reachable set collapses combinatorially, and a reading that reports a chord without reporting the repertoire it was drawn from has reported the numerator of a fraction.

6.7 What re-indexing does NOT move — and this is this section's central finding

Here is the result that most constrains what transmutation can be claimed to do, and it was not designed in. It falls out of the definition of `u`.

THEOREM 6.3. `u` is invariant under any re-indexing that does not change the shared support of the vectors involved. The interaction parameter is `u = 1 − cos^2 theta` computed on unit vectors over the twelve coordinates; the index *labels* never enter the computation. **Re-indexing changes `u` only through the overlap it destroys at `m` and the overlap it creates at `n`.**

Computed on the carried subject [Curzi, 2026]'s subject, **constructed and labelled as such**. Take the `threat` framing `{3:0.8, 5:0.4, 7:0.2}` and move its index-3 component four different ways, holding `story` and `mirror` fixed:

```
move        lattice interval    mean u_int       F_int       chord width
──────────────────────────────────────────────────────────────────────────
baseline           --           0.700844041320  2.164390    36.6686325914 Hz
3 ->  6      +2400.0000 cents   0.870156210632  2.358182    54.0282536493 Hz
3 ->  4       +996.0900 cents   0.870156210632  2.358182    54.0282536493 Hz
3 -> 12      +4800.0000 cents   0.870156210632  2.358182    54.0282536493 Hz
3 ->  1      −3803.9100 cents   0.870156210632  2.358182    54.0282536493 Hz
──────────────────────────────────────────────────────────────────────────
```

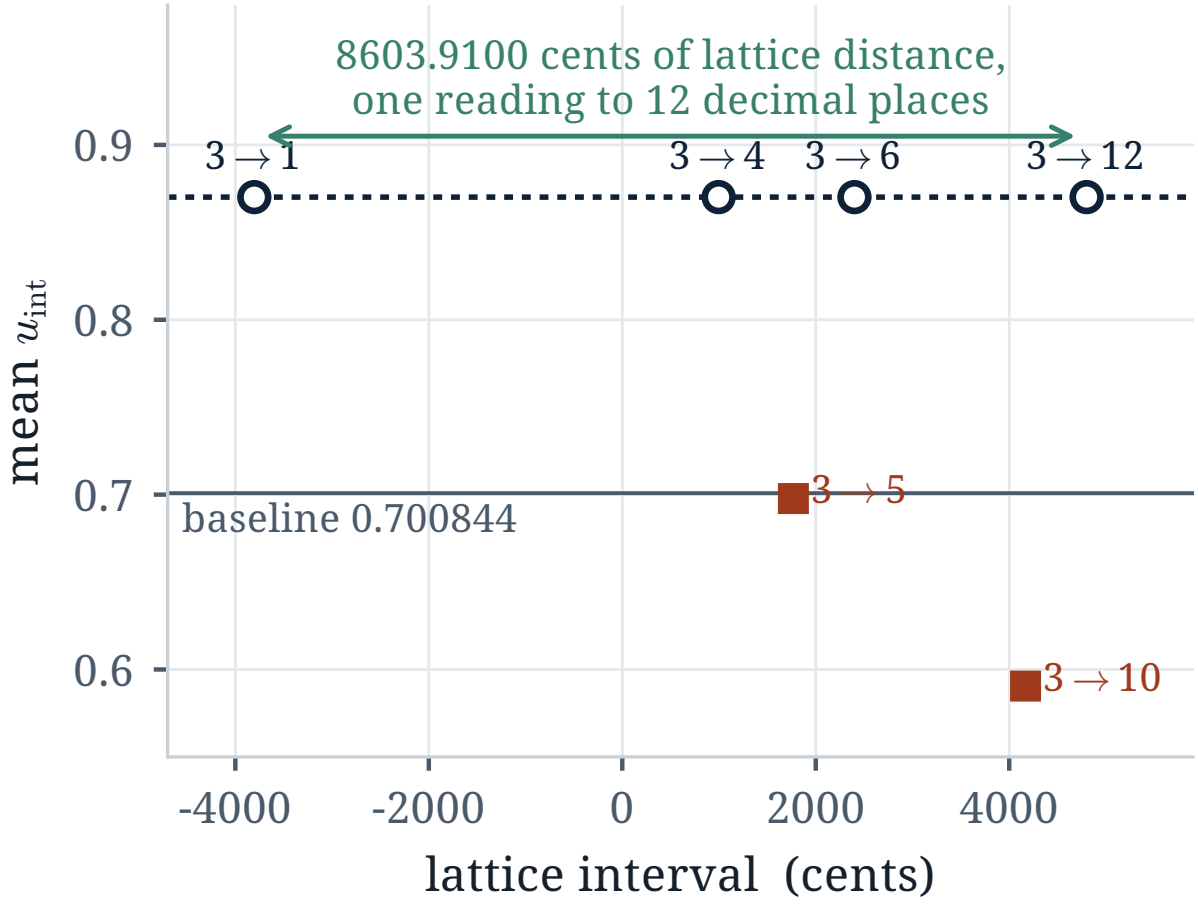

Figure 46.4: **Four moves spanning 8603.9100 cents return one relationship reading between them.** Mean u_{int} against lattice distance for six constructed re-indexings of one framing. The four open markers agree to twelve decimal places because all four vacate the same occupied coordinate and land on unoccupied ones; the two filled markers differ because they change the overlap. Computed from the vectors of §6's worked example; script `figs/src/CCP-046_fig04.py`.

Four moves spanning 8603.9100 cents of lattice distance return the identical relationship reading to twelve decimal places — one of them upward by four octaves, one of them downward by more than three. They are identical because all four vacate coordinate 3, which `story` occupies, and all four land on a coordinate that neither `story` nor `mirror` occupies. The relationship arithmetic sees a lost overlap and nothing else.

Two moves that are not identical, for contrast:

```
3 -> 10  (a coordinate `story` and `mirror` BOTH occupy)
         mean u_int = 0.590503185401   F_int = 2.014308   f = 27.1603 Hz

3 ->  5  (merged onto the framing's own state 5)
         mean u_int = 0.697749790607   F_int = 2.160474   f = 36.3826 Hz
```

A caution belongs here rather than in a footnote. The relationship readings above are computed from declared vectors on a stipulated reference set; **the reflexive specification the framework rests on is not identified from observational data** [Manski, 1993], and influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. Every relationship number in this paper is therefore a modelling position rather than

an identified empirical result, and the remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001].

FINDING 6.1. The lattice and the interaction parameter measure different things and neither refines the other. A re-indexing that is an intensification on the lattice and a re-indexing that is a transformation across orbits can produce numerically identical relationship readings; and two moves of nearly identical lattice distance can produce very different ones. **Transmutation moves the index; it moves the relationship only where it moves the overlap. A section that claimed otherwise would be claiming that renaming a coordinate changes a geometry.**

The practical rule that follows, and Procedure TR-1 enforces it: **report the lattice reading and the relationship reading separately, and never infer either from the other.**

6.8 The cost, in three currencies

A re-indexing has three prices and the formalism supplies two of them.

Price one — components. Supplied exactly. Moving from `m` to `n` requires `n - m` additional distinguishable components in the specification, each of which must survive the state-ordering material's [Curzi, 2026] count argument on its own and must be latent by §6.5's criterion.

Price two — pitch. Supplied exactly. `2400 log2(n/m)` cents, path-independent, `k`-free.

Price three — maintenance. NOT supplied. It must be declared. A more finely specified state is a larger structure to hold, and holding it costs something per period. That cost is `c` in the storage law, and **nothing in this formalism derives `c` from `n`.** There is no theorem here and the framework does not pretend to one. What the framework supplies is the conversion, once `c` is declared:

```
dD/dc  =  2.885390 / eta

eta = 0.30   ->   9.617967 octaves of deficit per unit of c
eta = 0.34   ->   8.486441
eta = 0.40   ->   7.213475
eta = 0.44   ->   6.557705
eta = 0.60   ->   4.808983
eta = 0.90   ->   3.205989
```

A declared maintenance cost is a real input and an undeclared one is a hidden liability, and a re-index priced only in pitch has been priced in the currency that does not appear in the sustainability condition.

6.9 Direction, and the asymmetry the notation hides

The transition matrix is antisymmetric, so de-indexing looks exactly as available as indexing. It is not, and Gate 1 flagged this in passing. It is stated properly here.

Indexing upward requires latent material and an operation. Downward movement in fact happens without an operation — it is `delta`, the loss rate, running unasked. A person who has modelled another mind cannot elect to un-model it; what removes the component is time, disuse, and forgetting.

```
upward    an OPERATION on a latent repertoire; costs components and c
downward  in the formalism, an operation; in fact, mostly delta
```

The symmetry of the matrix is a property of the notation, not a menu, and a procedure that schedules a de-indexing as though it were a move one performs has mistaken the arithmetic for the world. Where deliberate de-indexing is genuinely available — simplifying a stated specification, dropping a distinction from a working vocabulary — it is available at the level of the *specification* and not at the level of what a person can already distinguish.

6.10 Honesty clauses, restated in place **(1) ESSENCE, NOT RESONANCE.** Every frequency here is a position on a logarithmic scale of surplus. Nothing vibrates. No person, tissue, or molecule resonates at any value in this section.

(2) NO CLINICAL CLAIM. The twelve states are not diagnoses, no reading is an assessment, no operation is a treatment, and nothing here describes or prescribes for any person's health.

(3) THE INDEX INHERITS THE COUNT. A contested decomposition yields a contested frequency, and a re-indexing between two contested indices yields a contested interval.

(4) CONSTRAINT T21 IS BINDING on every operation in this paper, and its extension from cells to psychological states is this work's thesis, badged, and not established by the cited work.

(5) MORE IS NOT BETTER. the more-is-not-better rule [Curzi, 2026] and the dissonance paper [Curzi, 2026]. A higher index is a finer specification and nothing else.

(6) CONSTRUCTED CASES, all of them, labelled.

(7) REPORT `D` WITH `delta`. the decay-blindness result R4 [Curzi, 2026]: `D` contains no `delta`, so a `D`-only report cannot see decay. Both, every time.

(8) CONSENT IS STRUCTURAL. Nothing in this section licenses acting on anyone. The group paper [Curzi, 2026] owns intervention and its constraints, and this section adds no permissions whatever.

The engineering

6.11 The price list The single-rung price list, which is the ladder read as a purchase schedule:

```
step        cents          cumulative from n = 1
--------------------------------------------------
 1 ->  2   2400.0000        2400.0000
 2 ->  3   1403.9100        3803.9100
 3 ->  4    996.0900        4800.0000
 4 ->  5    772.6274        5572.6274
 5 ->  6    631.2826        6203.9100
 6 ->  7    533.7418        6737.6518
 7 ->  8    462.3482        7200.0000
 8 ->  9    407.8200        7607.8200
 9 -> 10    364.8074        7972.6274
10 -> 11    330.0085        8302.6359
11 -> 12    301.2741        8603.9100
--------------------------------------------------
total 1 -> 12 = 8603.9100 cents = 7.169925 octaves
```

The same one-component step is worth 2400 cents at the bottom of the ladder and 301.2741 cents at the top — **a factor of 7.97.** the transition matrix [Curzi, 2026] called this the square law's signature; here it is a price list, and it has a direct practical reading: **differentiation is cheap in pitch at low index and expensive at high index, so the same pitch gain buys progressively more components as you climb.**

Cost per component for the intensification moves, which is where the compression bites hardest:

```
move       components added    cents      cents per component
------------------------------------------------------------
 1 ->  2          1          2400.0000        2400.0000
 2 ->  4          2          2400.0000        1200.0000
 3 ->  6          3          2400.0000         800.0000
```

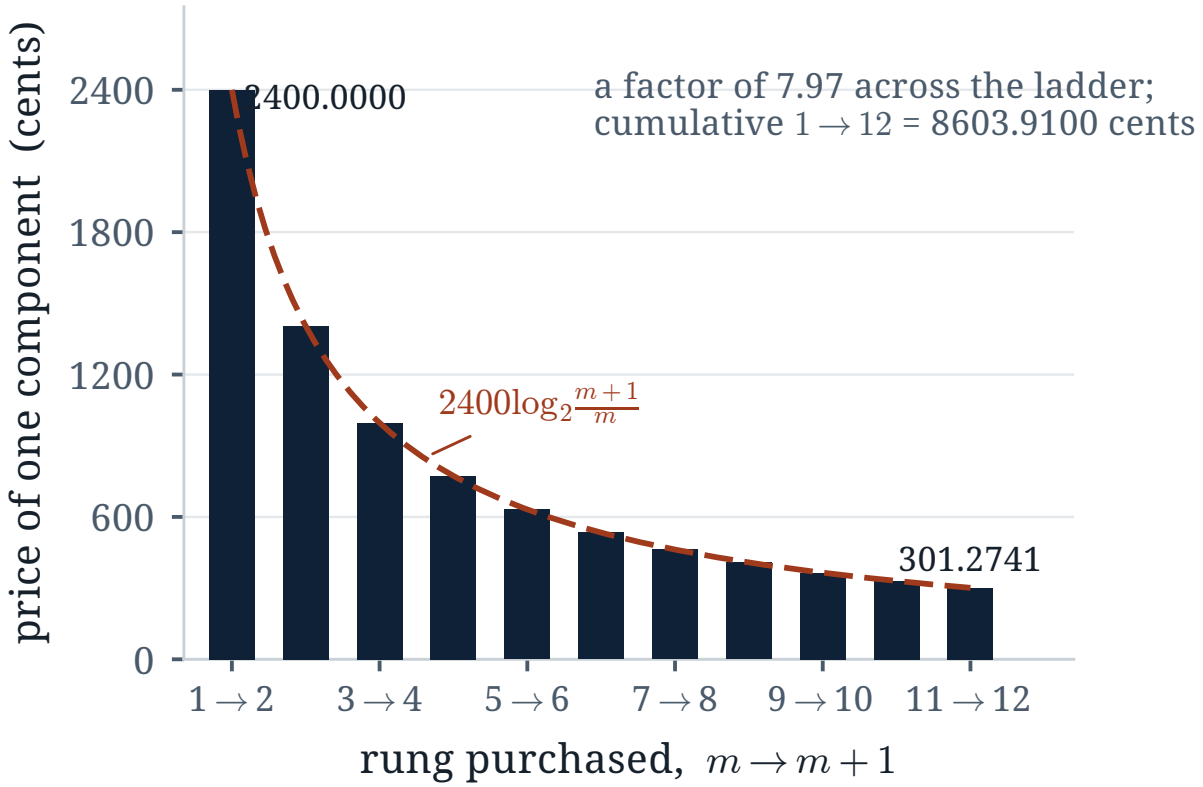

Figure 46.5: **The same one extra component costs 2400 cents at the bottom of the ladder and 301.2741 at the top.** The single-rung price list, with the closed form $2400\log_2((m+1)/m)$ overlaid. The compression is the square law's signature and it has a practical reading: the same pitch gain buys progressively more components as the index climbs. Computed from the price list of §6.11; script `figs/src/CCP-046_fig05.py`.

```
 4 ->  8          4          2400.0000         600.0000
 5 -> 10          5          2400.0000         480.0000
 6 -> 12          6          2400.0000         400.0000
------------------------------------------------------------------
```

Every one of the six doublings costs exactly 2400 cents, and they cost between one and six components to buy. An octave leap at the bottom of the ladder is a single component; the same leap at index 6 is six components. This is the arithmetic content of the mood-and-trait paper [Curzi, 2026]'s observation that intensification is scarce, and it is why the scarcity is structural rather than motivational.

6.12 PROCEDURE TR-1 — auditing and pricing a re-indexing

```
1  STATE the ladder and its N. State the starting index m and its
   decomposition, component by component.

2  STATE the target index n and its decomposition, component by
   component. The two decompositions must be comparable.

3  LATENCY CHECK, before any arithmetic. For every component present in
   n's decomposition and absent from m's, record whether it has been
   observed in the repertoire at least once, in some state, on some
   occasion (§6.5). If any required component fails, HALT.
   The move is REFUSED under CONSTRAINT T21 and the refusal is published
   with the component named.

4  CLASSIFY. Compute the odd parts of m and n. Same odd part ->
   INTENSIFICATION, whole even octaves, class preserved. Different ->
   TRANSFORMATION, class changes. Report which.

5  PRICE IN PITCH. 2400 * log2(n/m) cents. Report to four decimals with
   the direction stated.

6  PRICE IN COMPONENTS. n - m, listed by name, not by count alone.

7  DECLARE THE MAINTENANCE COST. State dc, state how it was obtained, and
   state that the formalism did not supply it. Convert with
   dD/dc = 2.885390/eta.

8  COMPUTE THE RELATIONSHIP EFFECT SEPARATELY. Recompute u from the
   vectors. Do NOT infer it from the lattice interval (Theorem 6.3).

9  READ THE DEFICIT. D and delta together, with Q_inf.

10 PUBLISH the lattice reading and the relationship reading side by side,
   labelled, with no ratio taken between them.
```

Step 3 is placed before step 4 deliberately. **A move that cannot be made does not need a price**, and computing the price first invites the price to argue with the constraint.

6.13 Re-indexing against the four levers The four-lever result [Curzi, 2026] fixed four levers on the deficit and proved there is no fifth. Re-indexing is not one of them, and the relationship is worth setting out because the two are constantly confused.

```
LEVER            what moves                re-indexing's relation to it
```

```
-------------------------------------------------------------------------
L1 raise u       the geometry             INDIRECT. Only when the move
                                          changes shared support (Thm 21.3)
L2 raise eta     the conversion           NONE
L3 cut c         the cost                 ADVERSE, usually. A finer
                                          specification costs more to hold
L4 raise N       the category set         NONE. Different operation
                                          (Sec 4 Gate 3)
-------------------------------------------------------------------------
```

Read straight down, that table says most re-indexing is deficit-neutral and cost-positive. A move that leaves the shared support alone does not touch `u`, does not touch `eta`, does not touch `N`, and adds maintenance. It buys pitch on the lattice and pays for it in the storage law.

The break-even, computed, so that the claim is not merely gloomy:

```
a re-index that raises c by dc must raise u enough to offset
2.885390 * dc / eta octaves

eta = 0.30, u0 = 0.068735, dc = 0.05  ->  u must reach 0.097688   reachable
eta = 0.30, u0 = 0.068735, dc = 0.10  ->  u must reach 0.131892   reachable
eta = 0.30, u0 = 0.692373, dc = 0.05  ->  u must reach 0.834429   reachable
eta = 0.30, u0 = 0.692373, dc = 0.10  ->  u must reach 1.002249   UNREACHABLE
eta = 0.44, u0 = 0.692373, dc = 0.10  ->  u must reach 0.892245   reachable
```

At a low `u` the break-even is easy and at a high `u` it can exceed 1, which is impossible. That is a boundary of the model's domain rather than a discovery about people, and it is stated as one. The mechanism is the strict concavity of the surplus functional [Curzi, 2026]: the marginal value of `u` falls as `u` rises, from `-31.739291` octaves per unit at `u = 0` to `-2.644941` at `u = 1`, a factor of 12. **A relation that is already differentiated cannot pay for expensive re-indexing out of further differentiation**, and the row where `u` must reach 1.002249 is the formalism refusing rather than warning.

6.14 The three counterfeits

A re-indexing can be claimed without occurring, in three ways, and each has a test.

Index inflation. Components are added to the specification that are not genuinely distinguishable from ones already present. The index rises and nothing has moved. This is pseudo-diversity (Series B's pseudo-diversity result) at index scope, and the test is the collision test R8 [Curzi, 2026]: components that always co-occur are one component.

Latency laundering. A component is asserted to be latent because it is conceivable. The test is §6.5's criterion — observed at least once, in some state, on some occasion — and it is deliberately strict.

Register change. The published frequency moves because `j` moved. The test is the folding rule [Curzi, 2026]: folding preserves every interval in cents exactly, so if the intervals to every other state are unchanged, nothing happened. Gate 8 is the historical version of this counterfeit and it was rejected in print.

All three produce a number that has moved and a state that has not, and **all three are caught by publishing the decomposition rather than the index.**

6.15 What re-indexing is genuinely good for

The section has spent most of its length on limits, so the residue is stated plainly, because it is not small.

It prices a change that would otherwise be described only in adjectives. A person's account of a situation acquiring a projected duration is a move from index 3 to index 6: 2400.0000 cents, three components, class preserved, an intensification. That is a great deal more than "it got deeper."

It separates two events that feel alike from inside. the mood-and-trait paper's whole argument [Curzi, 2026], now with a direction and a price attached.

It makes a refusal computable. Step 3 of TR-1 returns REFUSED with a named missing component, and a refusal with a name is actionable in a way that a vague sense of impossibility is not.

It exposes the cost side. Most re-indexing is cost-positive and deficit-neutral, which is invisible to any account that treats becoming more finely specified as self-evidently good.

The specification

SPEC-6.1 — Inputs

```
the ladder, its N, and its source (CCP-041 for the twelve states)
m and its full decomposition, component by component, named
n and its full decomposition, component by component, named
the repertoire, with the observation record for each component
eta, c, delta if a deficit reading is wanted
the vectors of all parties, if a relationship reading is wanted
```

SPEC-6.2 — Required outputs

```
the latency verdict, per required component, PASS or REFUSED
the classification: INTENSIFICATION or TRANSFORMATION, with odd parts
the interval in cents to four decimals, with direction
the components added or removed, by name
the declared maintenance cost dc, with its provenance and the statement
    that the formalism did not supply it
the deficit D and the loss rate delta, together, with Q_inf
the relationship reading, computed from vectors, reported SEPARATELY
```

SPEC-6.3 — Prohibitions

```
P1  a re-indexing may not be reported without its decompositions
P2  a relationship effect may not be inferred from a lattice interval,
    or the reverse (Theorem 6.3)
P3  a move may not be priced before the latency check (TR-1 step 3)
P4  "latent" may not mean "conceivable" (§6.5)
P5  a higher index may not be described as a better state
P6  a register change may not be reported as a re-indexing
P7  a maintenance cost may not be omitted; if unknown, say unknown
P8  no reading here may be presented as diagnostic, clinical, or as
    advice to any person about any relationship
```

SPEC-6.4 — Precision Intervals in cents to four decimals. Frequencies to at least six. `u` recomputed from the full-precision vectors, never from a rounded print (the full-precision rule). Deficits to six decimals with `delta` alongside.

SPEC-6.5 — Gates

```
G1  latency check performed and published, before pricing     REQUIRED
G2  classification by odd part, published                     REQUIRED
G3  lattice and relationship readings reported separately     REQUIRED
G4  maintenance cost declared or explicitly marked unknown    REQUIRED
G5  D never published without delta                           REQUIRED
G6  every case labelled constructed                           REQUIRED
G7  refusals published in full, with the component named      REQUIRED
```

The failure modes

FM-6.1 — Reading transmutation as creation *Signature:* a procedure described as producing a capability the person did not have.

Why it is wrong: CONSTRAINT T21. An address is a pointer; a pointer with no referent resolves to nothing. Yamanaka reprogramming activates latent capability and does not create new capability, and the four-factor selection is 37.985 bits acting on 6.2 gigabits.

The fix: the latency check, first, with the component named.

FM-6.2 — Latency laundering *Signature:* "the repertoire is rich, therefore X is latent, therefore X is available."

Why it is wrong: §6.5. Each arrow smuggles. Bulk is not specificity and conceivable is not reachable.

The fix: observed at least once, in some state, on some occasion — or REFUSED.

FM-6.3 — Inferring the relationship from the lattice *Signature:* "the move was four octaves, so it must have changed the relationship substantially."

Why it is wrong: Theorem 6.3 and Finding 6.1. Four constructed moves spanning 8603.9100 cents returned identical `u` to twelve decimal places.

The fix: recompute `u` from the vectors. Always.

FM-6.4 — Inferring the lattice from the relationship *Signature:* the reverse error — `u` moved, therefore a large index change occurred.

Why it is wrong: the same theorem. `u` responds to shared support and is blind to labels; a small change of overlap at a fixed index moves it without any re-indexing at all.

The fix: the same. Two readings, reported separately, no inference between them.

FM-6.5 — Index inflation *Signature:* the index rises after a re-description that added no distinguishable component.

Why it is wrong: §6.14. Components that always co-occur are one component (the relationship-frequency paper's [Curzi, 2026] collision test).

The fix: publish the decomposition and run the collision test on the added components.

FM-6.6 — Pricing only in pitch *Signature:* a move reported as "+2400 cents" with no maintenance cost.

Why it is wrong: §6.8. Pitch is not in the sustainability condition; `c` is. A move priced only in cents has been priced in the wrong currency, and at `eta = 0.30` a hidden `dc` of 0.10 is 0.961797 octaves of deficit.

The fix: SPEC-6.3 P7. Declare it or mark it unknown.

FM-6.7 — Treating de-indexing as an available operation *Signature:* a procedure that schedules "drop state 9" the way it schedules "add state 6."

Why it is wrong: §6.9. Downward movement in fact is mostly `delta`, running unasked. The antisymmetry of the transition matrix is notation.

The fix: distinguish simplifying a stated specification, which is available, from removing a distinction a person can already make, which is not.

FM-6.8 — Reading a higher index as a better state *Signature:* a re-indexing upward reported as progress.

Why it is wrong: the more-is-not-better rule [Curzi, 2026] and the consonance-redundancy identity R2 [Curzi, 2026]. Section 4 rejected Gate 10 for exactly this and the rejection binds here.

The fix: report the move, its class, and its price. Not a valuation.

FM-6.9 — Comparing intervals across ladders *Signature:* a `3 –> 6` on this framework's twelve-state ladder set beside a `3 –> 6` on a different scheme.

Why it is wrong: the indices count different things, so the interval is a ratio of incomparable squares.

The fix: the ladder and its `N` are published with every interval, and cross-ladder comparisons are refused.

FM-6.10 — Assuming an orbit continues past the ladder *Signature:* "state 7 intensifies to state 14."

Why it is wrong: `N = 12`. States 7 through 12 have no double inside the ladder, and the truncation is an artefact of the index length (the orbit structure [Curzi, 2026]). Extending the ladder is the minimum-frequency paper's [Curzi, 2026] lever L4 and is a different operation with a different justification burden.

The fix: report that the orbit is truncated, name `N`, and stop.

FM-6.11 — Precision theatre on a contested decomposition *Signature:* an interval to four decimals between two indices that two analysts assign differently.

Why it is wrong: honesty clause (3). The interval inherits both counts.

The fix: compute the interval under both decompositions and publish the gap between them as the uncertainty.

FM-6.12 — Using a priced move as an instruction *Signature:* "the move from 3 to 6 costs 2400 cents and three components, so make it."

Why it is wrong: the section prices moves and licenses nothing. The group paper [Curzi, 2026] owns intervention, its consent axiom, its halting conditions, and its reversibility classification, and none of them are relaxed here.

The fix: a price is not a recommendation, and nothing in this section is counselling, therapy, mediation, or clinical assessment.

Worked example

PART A — SIX MOVES ON THE CARRIED SUBJECT **Constructed case, labelled as such.** the carried subject [Curzi, 2026]'s subject, three framings of one situation:

```
threat = {3:0.8, 5:0.4, 7:0.2}     |w| = 0.916515138991
story  = {3:0.5, 5:0.7, 10:0.4}    |w| = 0.948683298051
mirror = {5:0.3, 7:0.8, 10:0.5}    |w| = 0.989949493661

baseline:  mean u_int = 0.700844041320   F_int = 2.164389635311
           N_eff = 8.709284   chord width 36.6686325914 Hz (folded 293.349061)
           states {3,5,7,10}   classes {3,5,7}
```

The raw L2 norms are published because the magnitude-reporting rule [Curzi, 2026] requires it: the free multiplier of a magnitude-estimated intensity must stay recoverable.

Now six constructed re-indexings of the `threat` framing's index-3 component, each run through TR-1 steps 4 through 8. In every case the latency check is stipulated to pass, and **the stipulation is the case's construction, not a finding.**

move	class	lattice interval	mean u_int	F_int	chord width (Hz)
base	3	—	0.700844041320	2.164390	36.6686325914
3 → 6	3	+2400.0000	0.870156210632	2.358182	54.0282536493
3 → 4	1	+996.0900	0.870156210632	2.358182	54.0282536493
3 → 12	3	+4800.0000	0.870156210632	2.358182	54.0282536493
3 → 1	1	−3803.9100	0.870156210632	2.358182	54.0282536493
3 → 10	5	+4168.7174	0.590503185401	2.014308	27.1603302345
3 → 5	5	+1768.7174	0.697749790607	2.160474	36.3825829120

And the classifications, which the relationship column cannot see:

3 → 6	odd parts 3, 3	INTENSIFICATION	class set {3,5,7} unchanged
3 → 12	odd parts 3, 3	INTENSIFICATION	class set {3,5,7} unchanged
3 → 4	odd parts 3, 1	TRANSFORMATION	class set {1,3,5,7}, four classes
3 → 1	odd parts 3, 1	TRANSFORMATION	class set {1,3,5,7}, four classes
3 → 10	odd parts 3, 5	TRANSFORMATION	class set {3,5,7} unchanged*
3 → 5	odd parts 3, 5	TRANSFORMATION	class set {3,5,7} unchanged*

* the framing's own class changed; the chord's class *set* did not, because `story` still holds state 3 and supplies class 3 to the chord.

Four readings of this table, and they are the section compressed.

The first four rows are identical in `u` and completely different on the lattice. Two are intensifications and two are transformations. One goes up four octaves and one goes down more than three. `u_int` agrees to twelve decimal places across all four. This is Theorem 6.3 and it is the strongest available statement of what the relationship arithmetic cannot see.

The fifth row is the only one that lowers the chord width. Moving to state 10 lands on a coordinate that both other framings occupy, so the move *creates* overlap where it destroyed some, and `u` falls: 0.700844 to 0.590503, and the chord width from 36.6686 Hz to 27.1603 Hz, a drop of 0.433045 octaves. **Re-indexing into an occupied coordinate is the only kind that can reduce a chord's width**, and it does so by making the framings more alike.

The sixth row barely moves at all. Merging the index-3 weight onto the framing's own state 5 moves `u` by `−0.003094` and the width by `−0.011298` octaves, because the framing's shared support with the other two is almost unchanged — it still overlaps `story` at 5 and `mirror` at 5 and 7. A 1768.7174-cent lattice move produced an eleven-thousandth of an octave of relationship change.

The pitch gains are worth the same in surplus terms across the identical group. `F_int` rose from 2.164390 to 2.358182, which is 0.193793 nats, which is `2.885390 * 0.193793 = 0.559168` octaves — precisely the chord width change from 36.6686325914 Hz to 54.0282536493 Hz. The conversion key holds exactly, as the conversion-key paper of Series B [Curzi, 2026l] requires.

PART B — A REFUSED MOVE **Constructed case, labelled as such.** The same subject, a proposed re-indexing of the `mirror` framing from state 7 (reflexive feeling — self as object) to state 11 (reciprocal feeling — the other modelling you).

TR-1 runs in order and stops at step 3.

```
step 1   ladder: CCP-041, N = 12. m = 7, decomposition: arousal, valence,
         intentional object, situation, cause, projected duration,
         self as object.

step 2   n = 11, decomposition: the seven above, plus another mind
         modelled, plus a standard applied, plus placement in a story,
         plus the other's model of the subject.

step 3   LATENCY CHECK on the four added components:
            another mind modelled          observed in this repertoire   PASS
            standard applied               observed in this repertoire   PASS
            placed in a story              observed in this repertoire   PASS
            the other's model of you       NOT OBSERVED                  FAIL

         HALT. The move is REFUSED under CONSTRAINT T21.
```

Steps 4 through 10 are not run, and the arithmetic that would have been produced is not published, because publishing it would let a refused move circulate as a priced one. What is published is the refusal, the named component, and the criterion applied:

```
REFUSED: 7 -> 11
missing component: the other's model of the subject
criterion: §6.5 -- observed in the repertoire at least once, in some
           state, on some occasion. Not met.
what would change the verdict: a single observation of the component,
           in any state, on any occasion.
```

A refusal that names its missing component and states what would reverse it is a scientific result. **A refusal that says the move is impossible is an opinion**, and SPEC-4.4 imposed the same requirement on its rejections.

PART C — THE CARRIED DYAD, READ AS RE-INDEXING, AND WHAT THE READING CANNOT ATTRIBUTE **Constructed case, labelled as such.** the carried dyad [Curzi, 2026] records that between phase 2a and phase 2b, `B` takes on two states `A` does not hold. That is a re-indexing at chord scope, and its relationship consequence is published:

```
PHASE 2a   u = 0.068734665264634   F = 0.563084802746   f =  1.4907987150 Hz
           eta = 0.30  c = 0.62  delta = 0.09
           D = +4.338420 octaves    Q_inf = -5.011940    DECAYS

PHASE 2b   u = 0.692372881355932   F = 2.153632742815   f = 35.8881768941 Hz
           eta = 0.44  c = 0.40  delta = 0.09
           D = -3.590989 octaves    Q_inf = +6.084427    ACCUMULATES
```

The path-free split [Curzi, 2026] supplies the path-free split of the 7.929409-octave swing:

```
from the cost ratio     2.885390 * (0.909091 - 2.066667)  =  -3.340058
from the surplus       -2.885390 * (2.153633 - 0.563085)  =  -4.589352
total                                                       -7.929409

the surplus side is 57.8776% of the swing
```

Now the limit of what this section may say about it, stated because the temptation is strong.

The carried case fixes `u` for phase 2b. **It does not fix which two states `B` took on, and this section does not invent them.** Theorem 6.3 is precisely why it cannot be inferred: many different pairs of added states produce the same shared-support change and therefore the same `u`, exactly as the four moves in Part A produced one reading between them. **The relationship frequency records that overlap changed. It does not record where.**

What can be said, and it is worth having:

The move was necessarily out of the shared support. `u` rose, so overlap fell as a fraction of the norms, so at least some of what `B` added lies where `A` holds nothing.

The move was necessarily an addition, not a re-labelling. A pure re-labelling of `B`'s existing states would leave the overlap pattern with `A` unchanged wherever `A` holds nothing, and Part A's first four rows show what that looks like: it can move `u`, but only by vacating a coordinate `A` occupies, which is a different event from taking on new states.

And `delta` did not move, and the deficit could not have seen it if it had. `D` is delta-blind (the decay-blindness result R4 [Curzi, 2026]). At 2b, dropping `delta` from 0.09 to 0.05 takes `Q_inf` from `+6.084427` to `+10.951968` and leaves `D` at `−3.590989`. Both numbers are reported here, as clause (7) requires.

PART D — THE REPORT CARD

```
------------------------------------------------------------------------
RE-INDEXING REPORT -- carried subject, threat framing, 3 -> 6
------------------------------------------------------------------------
ladder              CCP-041 twelve-state, N = 12
m                   3, directed feeling (arousal, valence, object)
n                   6, temporal feeling (+ situation, + cause,
                    + projected duration)
latency check       3 components required, 3 observed, PASS  [stipulated]
classification      odd parts 3 and 3 -> INTENSIFICATION
class              3 before, 3 after -- UNCHANGED
interval            +2400.0000 cents = +2 octaves exactly
ratio               f(6)/f(3) = 36/9 = 4.000000; reverse 9/36 = 0.250000
components          +3, named above
price per component 800.0000 cents
maintenance cost    NOT SUPPLIED BY THE FORMALISM. Declared dc unknown
                    for this constructed case; at eta = 0.30 each 0.10 of
                    undeclared c is 0.961797 octaves of hidden deficit.
------------------------------------------------------------------------
RELATIONSHIP READING, computed separately from the vectors
mean u_int          0.700844041320 -> 0.870156210632
F_int               2.164389635311 -> 2.358182352134   (+0.193793 nats)
chord width         36.6686325914 Hz -> 54.0282536493 Hz  (+0.559168 oct)
L2 norms            0.916515138991 / 0.948683298051 / 0.989949493661
NOTE                identical to the readings for 3->4, 3->12 and 3->1.
                    The lattice reading and this reading are independent
                    (Theorem 6.3) and neither was inferred from the other.
------------------------------------------------------------------------
ESSENCE frequencies, not physical resonances. Nothing vibrates.
Constructed case. Not a diagnosis, not an assessment, not clinical,
not advice. CONSTRAINT T21 binds: nothing not already latent was reached,
and nothing was created.
------------------------------------------------------------------------
```

What this section established, and the sentence it refuses to exceed Transmutation, in this formalism, is the movement of a state from one index to another. The interval crossed is a ratio of squares and is exact. The move is an intensification when the indices share an odd part and a transformation when they do not, and transformation is the generic case at 84.8485% of available moves. The price is three components on average at the doublings, between 301.2741 and 2400.0000 cents in pitch depending on where on the ladder it is bought, and a maintenance cost the formalism does not supply and the analyst must declare.

The relationship reading is a separate reading and may not be inferred from the lattice, because `u` is blind to index labels and sees only shared support — a result this section demonstrated with four constructed moves spanning 8603.9100 cents that returned one number between them.

And the boundary holds without exception. **Re-indexing addresses a repertoire; it does not extend one.** Nothing not already latent can be reached, at any strength, by any operation in this framework, and a procedure that claimed otherwise would have left the formalism behind. Transmutation is re-indexing, not creation. The section has said nothing else, and the restraint is not a modesty about the result — it is the result.

The refinement paper [Curzi, 2026] takes the iterative half of Section 4's Gate 11 and gives it its section: what happens when a bounded operation is run again and again on an accumulating store, why the answer is `|Q_t − Q_inf| = (1−delta)^t |Q_0 − Q_inf|`, and why refinement arrives rather than ascends.

7 Results

The eight results below are the units other papers in this corpus cite. A citation to this paper should name one of them. Each carries its status: **DERIVED** where it follows from the stated definitions by algebra, **COMPUTED** where it is the output of exact arithmetic or exhaustive enumeration on stated inputs, **AUDITED** where it is the outcome of applying Audit Rule 4.1, and **POSTULATED** where it is asserted by this framework.

R1 — the audit distribution. Over thirteen entries: **seven MAPS, two SPLIT, one RENDERING, three REJECTED**, with five entries carrying a failure. The rejections are *exaltation* (a value ordering presented as a count), *projection* (failing all four conditions), and the planetary-metal ordering as an essence index (failing all four ladder-validity conditions). *Status:* AUDITED against four stated conditions on a list fixed before the results were known. **Not tested for inter-rater reproducibility** (§10, L-1).

R2 — Finding 4.2, the schedule result. Run as an ordered schedule on the carried dyad, the gates move the octave deficit by -5.966526 in total. **The ninth gate alone supplies** -5.305895 **octaves — 88.93 per cent — against** -0.660631**, or 11.07 per cent, from the eight before it.** The ninth gate is the only one acting on the numerator of the sustainability condition, and the framework's ordering rule requires numerator moves first [Curzi, 2026]. *Status:* COMPUTED on a constructed case under constructed step assignments (M-e). **This is the paper's sharpest finding and it is negative about the tradition's own order.**

R3 — the compound rule, derived. $f_{\text{compound}} = k^2 G^4$ with $G = \left(\prod_i n_i^{c_i}\right)^{1/T}$, obtained in four lines by substituting $f(n) = kn^2$ into the source recipe, the collapse turning on $\sum_i c_i/T = 1$. It reproduces **37 of 44 published composite values to better than one part in** 10^{12}. *Status:* DERIVED; the verification COMPUTED. k^2 is a **defined constant, exact**: 0.233700439315386, and it cancels from every ratio.

R4 — Corollary 5.2: the two rules agree at no index. $kn^2 = k^2 n^4$ requires $n = 1/\sqrt{k} = 1.438252434444351$, which is not an integer. **There is no index at which Rule 1 and Rule 3 coincide.** The gap is smallest at $n = 1$, where it is exactly $-\log_2 k = 1.048634$ octaves, and widens monotonically to **6.121291 octaves at** $n = 12$. *Status:* DERIVED. **The source manuscript quotes the** $n = 1$ **gap as 1.048946 octaves; that figure is wrong and the correction is stated in §10.**

R5 — Theorem 5.3, quantity blindness. G is invariant under multiplying every multiplicity by a common positive integer, so $\{3^{\times 1}, 5^{\times 1}\}$ and $\{3^{\times 5}, 5^{\times 5}\}$ return the identical $G = 3.872983346207$ and $f = 52.582598845962$. *Status:* DERIVED; verified at $m = 1, 2, 3, 5$. **Rule 3 cannot see how much of a compound there is**, which is the structural reason Gate 12 is rejected.

R6 — Theorem 5.4, the map is many-to-one. Exhaustive enumeration over the twelve-state ladder gives many-to-one rates of **1.3220, 1.8763, 2.7083, 3.9000 and 5.5597 at** $T = 2, 3, 4, 5, 6$, with 44.87, 70.60, 83.88, 90.82 and 94.57 per cent of multisets sharing their value with at least one other. $G = 6$ **alone is produced by sixty distinct multisets over** $\{1 \dots 12\}$ **at** $T \leq 6$**.** The information lost runs from 0.4028 bits at $T = 2$ to 2.4750 bits at $T = 6$, or 6.41 to 18.21 per cent. *Status:* COMPUTED by exhaustive enumeration, not sampling.

R7 — Theorem 6.3, re-indexing does not move the relationship except through overlap. $u = 1 - \cos^2\theta$ is computed on unit vectors over the coordinates; index *labels* never enter it. **Four constructed moves spanning 8603.9100 cents of lattice distance — one upward by four octaves, one downward by more than three — return** $u_{\text{int}} = 0.870156210632$ **identically to twelve decimal places.** Two moves of similar lattice distance that change the overlap return 0.590503185401 and 0.697749790607. *Status:* DERIVED; the instances COMPUTED. **The lattice reading and the relationship reading are independent and neither may be inferred from the other.**

R8 — CONSTRAINT T21. A re-indexing reaches only what is already latent: **an index is a count, and a count cannot be raised by counting harder.** The maintenance price of a higher index is *not* derivable from n — the formalism supplies the component price and the pitch price and **does not supply the third**, which must be declared. *Status:* the constraint is **POSTULATED** at psychological scope (P-d); its form is carried from the corpus's genome-addressing result [Curzi, 2026y]; the conversion $\partial D/\partial c = 2.885390/\eta$ is ARITHMETIC.

CR — the counter-result. The audit rejects three of thirteen entries and finds the tradition's own canonical sequence inverted, placing its single numerator-acting operation ninth of twelve. And **the compound rule it validates is many-to-one, so a published compound value cannot be inverted to a decomposition**: at four components five sets in six are ambiguous, and the carried case's own chord shares its value with fifty-nine others. *Coagula* is a function; *solve* is a search, and its honest output is a set.

8 Discussion

8.1 What follows

An audit is only informative if it can fail, and the failures are where the information is. Two thirds of the entries map, and that is the least interesting thing in the paper. The three rejections are specific: each names the condition that failed, the result that condemns it, the rescues a reader would attempt, and what would reverse the verdict. **A rejection that cannot say what would reverse it is an opinion**, and SPEC-4.4 makes the statement mandatory.

Two of the maps are more useful than the tradition's own presentation of them. *Cibation* — feeding in small measured quantities at correct intervals — is the least glamorous item on the list and prices at 9.617967 octaves of deficit per unit of cost at $\eta = 0.30$. Its content is concavity, not diligence: sixty-four occasions deliver 43.2 per cent more than one occasion from the identical budget. **The concavity has a warrant that requires no psychological assumption at all** [Peters and Gell-Mann, 2016], and that is the warrant the argument uses.

The unit discipline is the paper's most transferable output. Rule 2 returns hertz and Rule 3 returns convention-Hz, dimensionally hertz-squared. The naive logarithm of their ratio on the carried dyad is 8.087620, and **that number is meaningless**; it is printed so that a reader who computes it independently knows it has been considered and discarded.

8.2 What does not follow

Nothing here shows that any audited operation was ever effective. The audit establishes that a modern operation exists which an old term describes. **The direction of that sentence is the whole of the claim**, and it is the weakest one consistent with the material.

Nothing here is a verdict on the people who transmitted the sequence. Seven gates map, and one of them encodes a concavity result not stated formally for another five centuries. **Precedent is worth having and it is not evidence**, and the concordance rule (SPEC-4.5) forbids any entry from upgrading its status on the strength of precedent at any weight.

The rejection of an unbounded reading is not a rejection of iteration. The mapped half of Gate 11 is genuinely useful, and the corpus builds a paper on it: seven passes close 48.32 per cent of the gap at $\delta = 0.09$ and 6.79 per cent at $\delta = 0.01$, and closing 95 per cent in seven passes requires $\delta = 0.348164$ [Curzi, 2026]. **Repetition arrives; it does not ascend.**

And the compound rule's success against 44 values is not evidence for the essence law. The rule was obtained by substituting the essence law into a source recipe, so its agreement tests the recipe's internal consistency and the arithmetic of the collapse. **It does not test whether either $f(n) = kn^2$ or the attachment of hertz to k is true**, and no verification in this paper could.

8.3 Relation to the surrounding programme

Everything in this paper that is a *verdict* survives the rejection of postulates P-b and P-c, because k and k^2 cancel from every interval, every ratio and every deficit [Curzi, 2026k]. What does not survive is the absolute values — the hertz columns and the convention-Hz columns — and those are labelled at every appearance.

Where the wider corpus bounds what may be claimed here it does so twice. The structural work establishes that adding another entity of the same kind buys capability and not diversification [Curzi, 2026], which is the quantity-blindness theorem in another domain and the same reason Gate 12 fails. And the historical work sets the standard for handling attractive testimony by refusing its own best story as a fabricated data point [Curzi, 2026] — the standard this paper applies to the transmutation record, whose survivorship likelihood ratio is exactly 1.000000.

8.4 The reflexive exposure

The framework asserts that systems change when they are modelled, and then exempts its own parameters from that reflexivity [Lucas, 1976, Hacking, 1995]. This paper adds a narrower version of the same exposure: **an audit that publishes which of a tradition's operations "map" changes how the tradition is read**, and there is a documented mechanism by which such publication becomes self-confirming [Merton, 1948, MacKenzie and Millo, 2003]. Nothing here controls for it. The mitigation offered is the one the paper can actually supply — that the rejections are printed at the same length as the maps, and that the concordance rule forbids precedent from moving any verdict.

9 Verification

The standard is Occam's: **a postulate that can be dropped without the result changing has been dropped.** Every step carries one of four statuses: **ARITHMETIC** (a reader can redo it), **DEFINITION** (true by this paper's own construction, carrying no empirical weight), **CITED** (an external source supports it, named), or **POSTULATED** (asserted here, no external support).

9.1 The postulates

	postulate	status
P1	The Pythagorean whole tone is the frequency ratio $9{:}8$.	CITED [Barbour, 1951]
P2	φ is the positive root of $x^2 = x + 1$; hence $\varphi^2 = \varphi + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P3	A dimensionless ratio of the form $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source
P4	The essence of a state with n components has frequency kn^2.	POSTULATED — no source
P5	The source recipe combines component frequencies as $\left(\prod_i f(n_i)^{c_i/T}\right)^2$.	**DEFINITION** — taken from the source as given
P6	Squaring is read as a change of structural level rather than a dimensional operation.	POSTULATED (P-c); the resulting label is a convention
P7	n, N, c_i, T are cardinalities, hence absolute-scaled.	DEFINITION, typology CITED [Stevens, 1946]
P8	A value ordering ("nobler") admits every monotone transformation and is not a count.	CITED [Stevens, 1946, Michell, 1997]
P9	Stored order obeys $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$, $\delta > 0$.	CITED as a *form* [Oppenheim et al., 1996, Elaydi, 2005]; the interpretation POSTULATED
P10	$N_{\text{eff}} = 1 + (N-1)u$ (the affine count axiom).	POSTULATED — design axiom [Curzi, 2026]; **not a Hill number**
P11	A re-indexing reaches only what is already latent, at psychological scope.	POSTULATED (P-d); the cellular form CITED via [Curzi, 2026y]

Dropped as unnecessary. No postulate about *which* twelve states the ladder holds is needed for R3, R5, R6 or R7: the compound rule, quantity blindness, the fibre structure and the re-indexing theorem hold for any index set and any N. No postulate about consonance is needed anywhere — §5.8b names two established measures of ratio complexity and **uses neither**. And **P3 and P4 are needed only for the absolute values**; dropping them leaves every verdict, every fibre count and every interval standing.

9.2 The compounding chain

step	consumes	produces	status
L1	P1	$(9/8)^2 = 81/64 = 1.265625$ exactly	ARITHMETIC
L2	P2	$\varphi^2 = \varphi + 1 = 2.618033988749895$	ARITHMETIC
L3	L1, L2	$k = 0.483425732988414$ — **a DEFINED constant, exact**	ARITHMETIC (exact)
L4	L3, **P3**	k carries the unit Hz	**POSTULATED**
L5	L4, **P4**	$f(n) = kn^2$ Hz	**POSTULATED**
L6	L3	$k^2 = 0.233700439315386$, exact	ARITHMETIC
L7	L5, P5	$\left(\prod (kn_i^2)^{c_i/T}\right)^2 = (kG^2)^2 = k^2G^4$ — **R3**	ARITHMETIC
L8	L7, **P6**	the value is labelled convention-Hz; ratio operations only	**POSTULATED**
L9	L7 at one component	$f_{\text{comp}} = k^2n^4 = f(n)^2$	ARITHMETIC
L10	L9, L5	$kn^2 = k^2n^4 \iff kn^2 = 1 \iff n = 1/\sqrt{k} = 1.438252434444351$ — **R4**	ARITHMETIC
L11	L10	not an integer, so the rules agree nowhere; gap $-\log_2 k = 1.048634$ oct at $n = 1$, 6.121291 at $n = 12$	ARITHMETIC
L12	L9 at $n = 8$	$k^2 \cdot 8^4 = 957.2369994358$, the only value pure oxygen admits at any multiplicity	ARITHMETIC
L13	L12 vs published 11.1246117975	no multiplicity produces it; the row is an erratum	ARITHMETIC
L14	definition of G	$c_i \to mc_i \Rightarrow G' = (P^m)^{1/(mT)} = G$ — **R5**	ARITHMETIC
L15	L14	$\{3, 5\}$ and $\{3^{\times 5}, 5^{\times 5}\}$ both give 3.872983346207	ARITHMETIC
L16	G depends only on (P, T)	equal $(P, T) \Rightarrow$ equal f — **R6**	ARITHMETIC
L17	L16, exhaustive enumeration	rates 1.3220 to 5.5597 over $T = 2 \ldots 6$; sixty multisets at $G = 6$	ARITHMETIC (enumerated)
L18	L17, counting	bits lost $=$ $\log_2(\text{multisets}) - \log_2(\text{distinct } G)$: 0.4028 to 2.4750	ARITHMETIC
L19	$u = 1 - \cos^2\theta$ on unit vectors	index labels do not enter u — **R7**	DEFINITION

step	consumes	produces	status
L20	L19 on the constructed subject	four moves over 8603.9100 cents give 0.870156210632 identically	ARITHMETIC
L21	P7	an index is a cardinality; a count cannot be raised by counting — **R8**	DEFINITION

L23	L5, folding by 2^j	intervals in cents preserved exactly; Gate 8 is RENDERING	ARITHMETIC (value); **POSTULATED** (meaning beyond pitch)
L24	P9, P10	$D = 2.885390(c/\eta - F)$, containing no δ	ARITHMETIC
L25	L24 on the schedule	step 9 supplies -5.305895 of -5.966526 — **R2**	ARITHMETIC

9.3 What this chain is and is not

Read the status column. Steps L1–L3, L6–L7 and L9–L25 are arithmetic, definition, or arithmetic on a cited form; L4, L5 and L8 are postulated. **A chain containing postulated steps is not a proof of its conclusion**, and this one is not offered as one.

What it is offered as is a separation, and it is unusually clean here. **The three postulated steps enter only where an absolute value is printed.** L10, L14, L16, L19 and L21 — the five steps that carry R4 through R8 — consume none of them: Corollary 5.2 is a statement about when $kn^2 = k^2n^4$, which is a statement about k as a number and not as a frequency; quantity blindness is a property of the geometric mean; the fibre structure is combinatorics on the integers; the re-indexing theorem is a statement about cosines; and CONSTRAINT T21 is a statement about counting. **A reader who rejects P3, P4 and P6 entirely keeps R4, R5, R6, R7 and R8 unchanged, and keeps every audit verdict, losing only the hertz and convention-Hz columns.**

Three checks a reader should run, each under a minute. $(9/8)^2 = 1.265625$ and $\varphi^2 = 2.618033988749895$, so $k = 0.483425732988414$ — that is L1 to L3 and it establishes the constant rather than asserting it. $1/\sqrt{0.483425732988414} = 1.438252434444351$, which is visibly not an integer — that is R4 in one keystroke. And $4{\times}6{\times}9 = 216 = 6^3 = 2{\times}9{\times}12 = 3{\times}6{\times}12 = 3{\times}8{\times}9 = 6{\times}6{\times}6$, which is R6’s fibre in five multiplications.

Two statuses that must not be misread. The exponent 2 at L5 and the exponent 4 at L7 are **DEFINED, not estimated**: no fit was performed and the standard procedure for testing a claimed scaling relation [Clauset et al., 2009] was not run, because there is nothing to run it on. And L7’s agreement with 37 of 44 published values is **a consistency check on the source’s own recipe**, not evidence for P3 or P4.

10 Limitations

L-1. The audit was performed once, by one analyst, and inter-rater reproducibility has not been tested. H1 is the paper's central methodological claim and **it is untested.** Condition (c) of Audit Rule 4.1 — is the transformation a function rather than a wish — requires a judgment, FM-4.1 records that a determined reader can find a parameter for almost any of the entries, and **nothing here demonstrates that two analysts applying the four conditions would return the same distribution of verdicts.** This is the largest gap in the paper.

L-2. The attribution and ordering of the source sequence are taken as given and are not verified here. The audit assumes the twelve gates are correctly attributed to a fifteenth-century text and correctly ordered in it. **No entry in this paper's bibliography establishes either.** The claim rests on the historical record as transmitted, the transmission path is stated in §4.5, and **a reader who disputes the attribution or the order disputes R1 and R2 with it.**

L-3. Four works are named in the text without citation keys, because they are absent from the bibliographic database governing this corpus. They are the 1471 source text and its 1652 printed edition (§4.5), and the three biological papers supporting the form of CONSTRAINT T21 (§6.4), which are given with journal, volume, page range and year in the running text. **This is a gap in the bibliography and it is disclosed rather than papered over**; the biological works in particular carry real weight in §6.4 and a reader is entitled to check them.

L-4. The schedule of §4's worked example is constructed twice over. Each gate is assigned "the smallest change the gate's own description licenses", and **those assignments are this paper's, not the tradition's.** A different reader could assign differently and obtain a different distribution of movement. **R2 is a result about this assignment on this constructed dyad**, and it is not a measurement of anything.

L-5. No alternative combination law was searched for. H3 concludes that seven published values are errata on the strength of two arguments: the residuals are scattered rather than systematic, and the pure-oxygen row admits exactly one rule-consistent value. **Neither argument rules out a different law that happens to agree with k^2G^4 on 37 rows**, and no search over alternative functional forms was conducted. The conclusion is the best available reading of the evidence and it is not a proof.

L-6. The verification of the compound rule tests the source's consistency, not the framework's truth. k^2G^4 is obtained by substituting $f(n) = kn^2$ into the source recipe. **Agreement with the source's own published values therefore cannot be evidence for the essence law**, and it is not offered as any.

L-7. The dimensional audit does not close in two places. $f(n) = kn^2$ requires k to carry $[T^{-1}]$ while k is a ratio of two dimensionless quantities (P-b); and k^2G^4 is dimensionally hertz-squared, so its "Hz" label is a convention and not a unit (P-c). **No citation in the bibliography repairs either.**

L-8. The constant is chosen and its fifteen figures are digits of a definition. $k = (9/8)^2/\varphi^2$ combines two documented objects into a product with no precedent, and the deflationary literature on golden-section claims is cited rather than avoided [Markowsky, 1992, Fischler, 1981, Livio, 2002].

L-9. Octave reduction beyond pitch is unwarranted. Octave equivalence is grounded for pitch [Shepard, 1982, Demany et al., 2013]; folding a non-acoustic quantity and reading meaning from where it lands is not.

L-10. Cents is a choice of unit and the two established measures of ratio complexity are not used. Euler's *gradus suavitatis* [Euler, 1739] and harmonic distance [Tenney, 2015] grade an interval by arithmetic complexity; this paper prices moves by $2400 \log_2(n/m)$, which is a distance in a logarithmic register and carries **no claim about consonance**. What a listener finds consonant depends on spectrum rather than ratio in any case [Sethares, 2005, Plomp and Levelt, 1965].

L-11. Neither effective count is a Hill number. $1 + (N - 1)u$ is a linear interpolation with no supporting literature. The Hill-number citations here [Hill, 1973, Jost, 2006, Laakso and Taagepera, 1979] apply to $1/\mathrm{HHI}$ and $\exp(H)$ and to nothing else.

L-12. Conjoint measurement was not tested. The ratio-scale treatment of η, c, δ and the elicited intensities is provisional; Michell's objection stands unanswered [Michell, 1997, 1999] for every quantity here except the counts, and the remedies [Luce and Tukey, 1964, Krantz et al., 1971, Rasch, 1960] were not run. **Gate 10 and Entry 13 are rejected for exactly this fault, and the framework's own declared parameters are not audited against it.** That asymmetry is the most uncomfortable thing in the paper and it is stated rather than hidden.

L-13. Scalar reduction is a habit of this framework, inherited here rather than re-conceded. The minimum-frequency paper states the limitation once and in full: the framework replaces phenomena its own source literature describes by several jointly varying features with a single number, then proceeds arithmetically on the number [Curzi, 2026]. **That concession governs here.** The specific instance in this paper is G: a whole composition is reduced to one geometric mean, and §5.9 measures exactly what that costs — 0.4028 to 2.4750 bits, with sixty distinct compositions sharing one value. **The mitigation is Consequence 5.6, which requires the composition to be published and the value derived from it, never the reverse.** It is a mitigation and not an answer.

L-14. The reflexive specification is not identified. Stated in §3.5: the endogenous social effect in a reflexive specification cannot be recovered from observational data [Manski, 1993, Shalizi and Thomas, 2011]. The remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001], **so every relationship reading here is a modelling position rather than an identified empirical result.**

L-15. The framework exempts its own parameters from its own reflexivity [Lucas, 1976, Hacking, 1995]. Not resolved.

L-16. The exponents are defined, not estimated, and the standard procedure for testing a scaling claim [Clauset et al., 2009] was not run because there is no data to run it on. **This paper makes no empirical scaling claim.**

L-17. The functional form of the surplus is underdetermined [Latané, 1981, Briscoe et al., 2006, Stumpf and Porter, 2012]. Nothing here discriminates among the candidates; the results that matter need only concavity and boundedness.

L-18. Latency is defined by an operational criterion with no instrument behind it. "Observed at least once, in some state, on some occasion" (§6.5) is deliberately strict and **will exclude components that are in fact latent.** It is also unmeasured: no observation record exists for any constructed case here, and the latency check in §6's worked example is *stipulated to pass*, which is the case's construction and not a finding.

L-19. No model comparison, no statistics, no data. Nothing was fitted, so there is no out-of-sample test, no matched null, no information criterion, no effect size and no p-value. Every case is constructed. Where the corpus has attempted a confirmatory fit elsewhere it failed its own declared baseline test, and that is the relevant precedent.

L-20. There is no conservation law [Mirowski, 1989], and validity is claimed only within a specified arrangement [Cartwright, 1999]. **L-21. Ergodicity is assumed and not argued** [Peters, 2019].

An arithmetic error found in the source and corrected here. The source manuscript states that Rule 1 and Rule 3 come closest at $n = 1$, "a gap of 1.048946 octaves". **That figure is wrong.** The gap at $n = 1$ is $\log_2(k/k^2) = -\log_2 k = 1.048634$ octaves, and the discrepancy is 3.1×10^{-4} octaves — small, but it is a value quoted to six decimal places, and a number quoted to six decimals owes the reader six correct ones. **This paper quotes 1.048634 throughout**, and the error is recorded here rather than silently repaired because a reader recomputing from the printed values of k and k^2 will find it.

A second, smaller discrepancy, left standing. The source prints k^2 as 0.2337004393 "to ten places" in one place and uses 0.233700439315386 in the computations. The two are consistent — the first is the second rounded — but the ten-place form is not sufficient to support the integrality test of Procedure SOLV-1 step 3 at large T, which SPEC-5.5 itself requires. **The specification and the printed constant are in tension**, and the resolution adopted here is that every computation uses the full-precision value.

11 Conclusion

What is established. Of thirteen entries in a fixed, pre-specified list from a dated historical sequence, **seven map onto operations on a closed parameter set, two are ambiguous between operations returning values in different units, one acts only on the publication register, and three fail** — two of them because a value ordering has been presented as a count, which the scale-type argument forbids. Run as an ordered schedule on a constructed dyad, the sequence places its **only numerator-acting operation ninth of twelve**, and that operation supplies **88.93 per cent of the total movement** while the eight before it supply 11.07 per cent; **the framework's own ordering rule condemns that order**, and the same intervention on the loss rate improves the destination under one ordering and damages it under the other.

The compound rule $f = k^2G^4$ is **derived by substitution rather than asserted**, and reproduces 37 of 44 published composite values to better than one part in 10^{12}; the seven that disagree are diagnosed as errata by a row the rule constrains completely. $kn^2 = k^2n^4$ requires $n = 1/\sqrt{k} = 1.438252434444351$, **so the two rules agree at no index whatever**, differing by 1.048634 octaves at $n = 1$ and 6.121291 at $n = 12$. G is **blind to quantity** and the map to it is **many-to-one at rates from 1.32 to 5.56**, with $G = 6$ produced by sixty distinct multisets — so a compound value may be published only alongside the composition it was derived from, and never inverted to one. And **re-indexing moves the relationship only through overlap**: four moves spanning 8603.9100 cents return one number between them, to twelve decimal places.

What is proposed rather than shown. That $(9/8)^2/\varphi^2$ is a frequency; that essence goes as kn^2; that the squaring in the compound rule is a change of structural level rather than a dimensional operation; and that the latency constraint carries from cells to psychological states. **These are postulates of this framework, badged at every appearance**, and **every verdict, every fibre count and every interval in this paper survives their rejection**, because the constant cancels.

What is not claimed at all. That any audited operation was ever effective; that its practitioners understood it in these terms; that any symbol, name, sequence or substance has a physical effect; or that any number here describes any person. **Precedent is not evidence**, and the survivorship likelihood ratio for the tradition's own testimony is exactly 1.000000 — which is not weak evidence but the arithmetic statement that it leaves the prior where it found it.

12 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number is the output of exact arithmetic or exhaustive enumeration on inputs stated in the text. The 44 composite values checked in §5.3 are quoted from a published source table, which is described in the text; **no new measurement was made of any of them, and the seven disagreements are reported as recomputations of published figures rather than as observations.** The fibre enumerations are complete rather than sampled, over multisets from a twelve-element index set at $T \leq 6$. Every case — the carried dyad, the carried subject, the worked compounds and every re-indexing — is constructed and labelled as constructed at the point of use. The figures are generated by the Python scripts named in their captions and are available from the author on request.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the audit, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The constructed subject and the constructed dyad are invented parameter sets and describe no person. **No historical person's beliefs are characterised as held by them**; the audit is of a transmitted text's operations, not of anyone's understanding, and §8.2 states that boundary explicitly.

Preregistration. No test here was preregistered, because no test was run against data. **The source list was fixed before the verdicts were reached** (§4.5, SPEC-4.1) and that is the only pre-specification the paper claims; it is not a preregistration and is not offered as one.

Bibliographic disclosure. Four works are named in the running text without citation keys because they are absent from the bibliographic database governing this corpus (§10, L-3). They are given with sufficient bibliographic detail to be located.

Clinical disclaimer. The twelve state classes are not diagnostic categories. Nothing in this paper is an assessment, a screening instrument, a treatment, counselling, or advice about any person's health, and nothing in it may be presented as such. No symbol, name, sequence, operation or substance is claimed to have any physical, chemical or biological effect.

Chapter 47

Refinement as Contraction: Why Repetition Cannot Move a Fixed Point, and an Evidential Audit of the Tradition It Comes From

Abstract. Iterated practice is modelled as the affine map $Q_{t+1} = (1-\delta)Q_t + b$, whose contraction gives $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$ as an equality rather than a bound. Two negative theorems follow. Refinement cannot move the fixed point, because $Q_\infty = (\eta F - c)/\delta$ contains no iteration count; and the ladder is silent in the frequency register, because f_{rel} is a function of u and N alone. What repetition buys is arrival time only: at $\delta = 0.09$ the half-life is 7.3496 passes and 99% closure takes 48.83, so the tradition's canonical seven passes close 48.32% of the gap — and only 6.79% at $\delta = 0.01$. Seven passes would close 95% only at $\delta = 0.348164$. Applied to a decaying arrangement, the same ladder converges at the same speed on $Q_\infty = -5.01$ instead of $+6.08$. On the tradition's own claims, four survive and five are charged. Staged process control is priced: per-stage checking at 90% detection raises yield from 47.83% to 93.21% at 0.63 reworks per unit. Cadence is priced: a single annual occasion carrying 26 nats delivers 2.4849 after clipping at $\ln 12$, 9.56% of a weekly practice, and $0.91^{52} = 0.007403$ of one impulse survives the year. Against this, transmutation by chemical means is closed by energy arithmetic (15.5 to $15{,}500$ gigawatt-station-years per gram), the record is survivorship-filtered with a likelihood ratio of exactly 1.000000 at every corpus size, secrecy makes an error immortal (survival 1.000000 per generation at zero replications), and the canonical order is backwards. Every case is constructed: no dataset was collected and no human subjects participated.

Keywords: contraction mapping; refinement ladder; seven repetitions; staged process control; cadence; survivorship; secrecy; replication

Series: C. Frequency, Essence, and Mind **Paper:** CCP-047

1 Introduction

The most widely repeated instruction in the alchemical corpus is not a recipe but a count. *Distil seven times. Circulate the matter until it no longer changes. Repeat the work.* The operation is not described as improving between passes; it is described as being *done again*, identically, and the doing again is what is supposed to produce the result. Two reactions to

that instruction are common and both are wrong: to dismiss it as ritual padding, or to accept it as a claim that repetition adds something the first pass could not reach.

This paper computes what iteration does under the framework's storage law, and the answer is a pair of negative theorems. The law is the discrete leaky integrator $Q_{t+1} = (1-\delta)Q_t + b$, a form that is not novel and is not claimed to be: it is the RC low-pass filter of signal processing [Oppenheim et al., 1996], exponential smoothing in forecasting [Holt, 1957, Brown and Meyer, 1961], and the leaky integrate-and-fire neuron of computational neuroscience [Lapicque, 1907, Gerstner and Kistler, 2002]. Its stability condition and unique fixed point are standard [Elaydi, 2005], and the convergence is Banach's [Banach, 1922]. What is asked here is narrower: **what does the iteration count buy, and what does it provably not buy?**

The first negative theorem is that refinement cannot move the fixed point. The destination $Q_\infty = (\eta F(u^*) - c^*)/\delta$ contains no iteration count, so it is computable before the first pass and unchanged by every pass after it. **The second is that the ladder is silent in the frequency register**: the relationship frequency f_{rel} is a function of the non-parallelism u and the category count N alone, so repetition moves neither the pitch, nor the folded pitch class, nor the octave deficit D. What repetition buys is *arrival time*, and arrival time is a function of the decay rate and of nothing else.

The consequence is quantitative and it cuts against the tradition. At the framework's carried decay rate $\delta = 0.09$ the half-life is 7.3496 passes, so the canonical seven passes close 48.32 per cent of the gap — under half. At $\delta = 0.01$ they close 6.79 per cent. Seven passes close 95 per cent only at $\delta = 0.348164$. **The traditional count is therefore not a universal constant and not arbitrary either: it encodes a checkable claim that the operation loses roughly a third of its stock per cycle**, which is entirely ordinary in a physical distillation and is not true of a weekly psychological practice.

The second half of the paper turns the same instrument on the tradition that supplied the count. **Four of its claims survive an audit and five do not**, and both lists are computed rather than asserted. Staged process control is priced: seven stages at a per-stage defect probability of 0.10, moving from a single terminal inspection to per-stage checking at 90 per cent detection, raises final yield from 47.83 per cent to 93.21 per cent at a cost of 0.63 reworks per unit. Cadence is priced, and the folklore's stated reason for it is refuted: the *integrated* effect of one large input and the same total delivered periodically is identical to every digit — 433.3333 in all three schedules — which is linear time invariance and not a matter of opinion. Cadence wins for two other reasons entirely, strict concavity and the surplus ceiling, and at $N = 12$ a single annual occasion carrying a nominal 26 nats delivers 2.4849 after the $\ln 12$ ceiling clips it: 9.56 per cent of a weekly practice, with 90.44 per cent lost to clipping and $0.91^{52} = 0.007403$ of one impulse surviving the year.

Against that, five charges are laid and computed. Material transmutation by chemical means is closed by an energy-register argument of eight orders of magnitude. The tradition's evidential record is survivorship-filtered, and under success-only preservation the likelihood ratio of testimonial evidence is exactly 1.000000 at every corpus size — the same defect that selective publication produces in a modern literature [Ioannidis, 2005, Open Science Collaboration, 2015]. Secrecy removes the correction mechanism, and at zero independent replications per generation an error survives with probability 1.000000 indefinitely. No control was run, and the control that would have settled the central question required only a balance. And the canonical operation order is inverted with respect to the framework's own ordering rule.

What this paper does not claim, stated at the front rather than at the back. Every frequency here is an *essence* frequency — a position on a logarithmic scale of surplus — and nothing is claimed to vibrate, resonate or sound. The constant $k = (9/8)^2/\varphi^2$ is a *defined* number; **attaching hertz to it is a separate and much stronger claim** and is postulated, not derived. The standard critique of golden-section claims [Markowsky, 1992] is cited here deliberately and again wherever φ appears. Octave reduction is licensed for pitch [Shepard, 1982] and its perceptual specialness has been measured [Demany et al., 2013]; its extension to a quantity that is not a pitch is a **modelling choice** with no external warrant. No human-subjects research

was conducted for this paper and no dataset was collected; every case is constructed and is labelled as constructed at the point of use.

Contributions

1. The contraction as an **equality** rather than a bound, $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$, with the three arrival constants τ, half-life and $t(\varepsilon)$ shown to be functions of δ alone.
2. Two negative theorems: the fixed point contains no iteration count, and the frequency reading contains no iteration count.
3. The seven-repetitions result, in both directions: what seven passes close at a given δ, and what δ would make seven passes sufficient.
4. A priced audit of four surviving traditional practices, of which staged process control (47.83 per cent to 93.21 per cent) and cadence (9.56 per cent of a weekly practice) carry numbers other work in this corpus uses.
5. Five computed charges against the tradition's largest claims, including a likelihood ratio of exactly 1.000000 and an error-survival probability of exactly 1.000000 under secrecy.
6. The counterfeit-arrival result: cost export leaves the **sum of drives** exactly invariant while improving every number the exporter can privately compute, and the disadvantaged party's stock lags its own destination by 10.850479 passes.
7. A correction printed rather than applied silently: the counterfeit-arrival identity, as originally stated on the sum of *fixed points*, is valid only under equal decay rates.

2 Hypotheses, definitions, postulates and modelling choices

The rigour standard governing this corpus requires that a claim which *could* be wrong be stated so that it could be, and that a claim which could not be wrong be labelled with which of the three non-empirical kinds it is. **A hypothesis nothing could falsify is not a hypothesis**, and this section does not manufacture one.

2.1 Hypotheses proper

H1 — the invariant-destination hypothesis. Repeating an operation whose parameters do not change moves the system's destination by zero. **Predicted:** in a system whose u, η, c and N are measured and held fixed across a run, the stock converges to the value computed from those four parameters before the first pass, and the estimate does not drift with pass count. **Falsified by:** a run in which the parameters are measured, verified constant, and the stock settles anywhere other than $(\eta F - c)/\delta$. **Status:** DERIVED from the storage law [Curzi, 2026a] by inspection. **Not tested here.** No observational data were collected.

H2 — the rate-blindness hypothesis. The arrival rate is a function of δ alone, so two arrangements with the same δ converge at the same speed whatever their destinations. **Predicted:** measured half-lives agree between an accumulating and a decaying arrangement sharing a decay rate. **Falsified by:** a measured half-life that varies with the sign or size of the drive. **Status:** DERIVED; demonstrated on constructed cases in §4.12 and §4.22. **Not tested against observation.**

H3 — the seven-passes hypothesis. A tradition prescribing seven repetitions of an operation is making an implicit claim that the operation's per-cycle loss is at least $\delta = 0.348164$, the rate at which seven passes close 95 per cent of the gap. **Predicted:** where the per-cycle loss of a traditional operation can be measured independently — for a physical distillation, the volatile fraction lost per pass — it lies at or above roughly a third. **Falsified by:** a tradition prescribing seven passes for an operation whose measured per-cycle loss is a few per cent, and which nonetheless completes.

Status: this is the paper's one genuinely empirical hypothesis and **it has not been tested.** It is cheap to test on a physical process and is offered for that reason.

H4 — the export-invariance hypothesis. In any arrangement in which cost is transferred between participants, the sum of participants' drives $\sum_i(\eta_i F_i - c_i)$ is unchanged. **Predicted:** an intervention that improves one participant's measured destination without moving the summed drive has transferred cost rather than produced order. **Falsified by:** a measured intervention in which one participant's drive rises and no other participant's falls. **Status:** DERIVED here and proved in general in the companion paper [Curzi, 2026]. **Not tested against observation.**

H5 — the staged-control hypothesis. Per-stage checking dominates terminal inspection in final yield, monotonically in the per-stage detection probability. **Predicted:** yield $(1-q(1-d))^m$ rises with d at fixed q and m, and rework rises with it too. **Falsified by:** a process in which per-stage detection is raised and final yield does not rise. **Status:** the arithmetic is DERIVED from a stated defect model; the empirical claim rests on the statistical-process-control literature, **two of whose founding works are absent from this paper's bibliographic database** and are named without keys in §5.2.

2.2 Definitions — true by stipulation, not falsifiable

- **Def. 1.** A *refinement pass* is one application of the storage law with all four parameters unchanged. If a parameter changes between passes the operation is re-indexing, not refinement.
- **Def. 2.** $u := 1 - (\hat{x} \cdot \hat{y})^2$ on unit intensity vectors; $F := \ln(1 + (N-1)u)$.
- **Def. 3.** $D := 2.885390\,(c/\eta) - \log_2(f/k)$, the octave deficit.
- **Def. 4.** $k := (9/8)^2/\varphi^2 = 0.483425732988414$. **This is a defined constant.** It is an exact ratio of exact quantities and is therefore computable to arbitrary precision; the fifteen figures quoted are *exact digits of a definition* and carry no measurement uncertainty, because there is no measurement.
- **Def. 5.** The *running deficit* D_t and *apparent pitch* f_t of §4.6 are constructed readings of a stored quantity, defined by applying to Q_t the transform that carries Q_∞ to D. They are badged as constructed wherever they appear.

2.3 Postulates — asserted by this framework, with no external support

- **P-a. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic. **Asserting that this dimensionless number *is a frequency* is a separate and much stronger claim**, and no operational procedure is supplied by which the constant acquires the dimension of inverse time. This is postulated, and it is restated in the dimensional audit of §3.4, where it is unavoidable.
- **P-b. The essence law $f(n) = kn^2$.** A quadratic relation between a dimensionless count and a frequency, with **no external literature supporting it**. **The exponent 2 is defined by the model, not estimated from data.** No scaling exponent in this paper was obtained by fitting, none was tested against a log-normal or exponential alternative, and the goodness-of-fit and likelihood-ratio procedure a claimed scaling relation requires [Clauset et al., 2009] was **not run, because there is no data to run it on.**
- **P-c. The affine effective count $N_{\text{eff}} = 1+(N-1)u$.** A design axiom, not a derived result, and **not a Hill number of any order**. The Hill family [Hill, 1973] and its rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly, and ground this construction not at all. A reviewer reaching for the Hill-number literature as support will find it does not apply, and that is stated here rather than left to be discovered.
- **P-d. The parameter assignment of a historical schedule.** The sorting of a canonical fifteenth-century twelve-operation schedule by which parameter each operation acts

on is this framework's reading of the text and not the text's own claim [Curzi, 2026]. The order-inversion result of §6.5 is conditional on that reading.

2.4 Modelling choices — legitimate, but choices

- **M-a. Octave reduction applied to a non-acoustic quantity.** Octave equivalence is a perceptual structure formalised for **pitch** [Shepard, 1982], whose perceptual specialness has a measured size [Demany et al., 2013]. Nothing licenses carrying it to a quantity that is not a pitch. The *operation* — division by a power of two — is well defined; its *interpretation* is a choice of this framework.
- **M-b.** $N = 12$**.** Twelve component classes are used throughout. Twelve exceeds the classical span of immediate absolute judgment [Miller, 1956], which is a reason for caution rather than a reason for twelve.
- **M-c. Interval apparatus without psychoacoustic claims.** Cents, octave equivalence and interval arithmetic are the correct apparatus once an index exists [Rossing et al., 2002], and the history of consonance theory — from Euler's arithmetic of *gradus suavitatis* [Euler, 1739] to harmonic distance [Tenney, 2015] — is the tradition this vocabulary comes from. But what a listener finds consonant depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005], and interval categories generalise less far than is usually assumed [Burns, 1999, Hoeschele et al., 2012]. **This paper uses the arithmetic and claims none of the perception.**
- **M-d. Scalar reduction of a structured state.** Every reading in this paper enters through u, which is computed from a vector of elicited intensities over twelve component classes and then collapsed to one number. §3.5 states what that costs.

2.5 What is expository

Sections 4.17–4.20, 5.17–5.19 and 6.16–6.18 are expository: they set out procedure, reporting requirements, gates and failure modes rather than argue a claim. Their organising question is *what must be published alongside a refinement reading for a third party to be able to check it*, and the answer is the specification blocks and the reporting formats.

3 Framework, dimensional audit, and method

3.1 The storage law — a shared mathematical form, not a derivation

$$Q_{t+1} = (1 - \delta)Q_t + \eta S_t - C_t$$

Analogy status: category 2, a shared mathematical form. The equation governing this framework's stored order is the equation that governs a leaky integrator, and it is used because the mathematics is the same, not because the physics transfers. No claim is made that stored order is a charge, that η is a coupling constant, or that any physical result about RC circuits applies to a relation between people. The fixed point follows from setting $Q_{t+1} = Q_t$ and requires $\delta > 0$; the transfer-function reading, in which $1/\delta$ is the DC gain of $1/(z-a)$ evaluated at $z = 1$, is fixed in the framework's storage-law paper [Curzi, 2026a], whose Result Four shows that $\delta = 0$ is a pathology rather than an ideal — no contraction, no unique fixed point, and an error-persistence column of all ones, so that no mistake ever decays out of the stock.

Three warnings attach to that form and are recorded here rather than in a footnote. First, the time average of a multiplicative process differs from its ensemble average, so a parameter estimated across systems does not describe what happens to any one of them over time [Peters, 2019] — and Q accumulates *over time*, for *one* arrangement. Second, a single Q, δ or u written for a group is an aggregation, and aggregation over heterogeneous agents does not in general yield a representative agent [Kirman, 1992]. Third, Q **has the grammar of a conserved quantity — a stock that accumulates, leaks and is spent — without a conservation**

law to give that grammar content. That is the characteristic failure of the genre: neoclassical economics was built by copying nineteenth-century energetics and made utility play the role of energy without the conservation law that gave energy its meaning [Mirowski, 1989]. This paper claims no conservation law and adopts instead the position that a law is claimed only within a specified arrangement rather than universally [Cartwright, 1999]. The wider programme — physics formalism applied to social dynamics — has a standard survey that fixes what such models can and cannot be held to [Castellano et al., 2009], and those are the boundaries claimed here.

One conservation claim in this paper is genuine and is bounded accordingly. §4.15a establishes that the *sum of drives* is invariant under transfer of cost. That is a conservation statement about a bookkeeping identity, not about any physical quantity: it holds because a transfer enters one ledger with a plus and another with a minus, and it would hold for any additively separable accounting. It carries no physical content and is not offered as one.

3.2 The surplus functional and the effective count

$F(u) = \ln(1 + (N-1)u)$ is the framework's surplus functional, characterised by angle-only dependence, a zero at parallel states, an affine effective count and a normalisation. Its logarithmic form places it in the same family as Shannon's entropy [Shannon, 1948], and the ceiling $F \leq \ln N$ is the same ceiling that appears in requisite-variety arguments [Ashby, 1956, 1958].

Which construct of difference u measures must be declared, because at least three incompatible constructs travel under the word *diversity* — separation, variety and disparity [Harrison and Klein, 2007]. Here u is a *disparity* measure over represented states, and it is symmetric in its arguments, which psychological similarity is known not to be [Tversky, 1977]. That is a limitation and it is printed in §10.

The functional form is underdetermined and this paper does not pretend otherwise. A power law with exponent below one [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as the logarithm, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. The strongest available warrant for the logarithm is not the psychophysical one: a logarithmic evaluation follows from multiplicative dynamics with **no psychological assumption at all** [Peters and Gell-Mann, 2016], and that is the warrant this paper's arguments actually need.

3.3 The essence bridge and the constant k

The bridge writes a surplus as a pitch, $f = k\, e^{2F}$, so that intervals of surplus become intervals of frequency and the constant cancels from every ratio. The constant is

$$k := \frac{(9/8)^2}{\varphi^2} = \frac{81/64}{\varphi + 1} = 0.483425732988414 \quad \text{(defined; exact)}$$

Both components are real and documented: the ratio $9{:}8$ is the Pythagorean whole tone [Barbour, 1951, Lindley and Turner-Smith, 1993], and the golden section is Euclid's extreme and mean ratio [Euclid, 1956], with $\varphi^2 = \varphi + 1$ and $\varphi^m = F(m)\varphi + F(m-1)$ proved identities [Vajda, 1989].

Their product, expressed as a frequency in hertz, has no precedent. The literature on golden-section claims is overwhelmingly a literature of *deflation*: the appearances of φ in architecture, the human body and preferred rectangles do not survive examination [Markowsky, 1992, Fischler, 1981], and the psychological preference results are weaker than they are usually reported to be [Höge, 1997]. **This framework's position is the one those critiques leave open and no wider:** φ is being *chosen* as a constant, not *found* in a psychological system. Nothing in this paper is evidence that the golden section is present in anything measured, and the constant is invisible to every verdict in this paper because D is a difference of logarithms in which k appears in both terms and cancels.

3.4 Dimensional audit

symbol	quantity	dimension	unit	status
Q	stored order	$[\mathcal{C}]$	none supplied	state variable; **no operational unit**
b	per-pass drive	$[\mathcal{C}\,T^{-1}]$	per declared pass	$\eta F - c$
c	cost per pass	$[\mathcal{C}\,T^{-1}]$	per declared pass	driving term
δ	decay rate	$[1]$	per pass	dimensionless; $0 < \delta \leq 1$
η	conversion efficiency	$[1]$	—	dimensionless; assumed $0 < \eta \leq 1$
u	non-parallelism	$[1]$	—	dimensionless by construction, $u \in [0, 1]$
F	surplus	$[1]$	nats	dimensionless; a logarithm of a count
N, n	category / component count	$[1]$	—	absolute scale, a count
t	pass index	$[1]$	passes	a count; the cycle must be declared
τ	time constant	$[T]$	passes	$-1/\ln(1-\delta)$
k	reference constant	$[T^{-1}]$ **asserted**	Hz **asserted**	**defined as a ratio (dimensionless); the unit is postulated**
f, f_{rel}, $f_{\min}$	essence frequency	$[T^{-1}]$	Hz	inherits its dimension entirely from k
D	octave deficit	$[1]$	octaves	a ratio of logarithms; k cancels
q, d	defect / detection probability	$[1]$	—	probabilities
r	replications per generation	$[1]$	per generation	a count; the generation must be declared

Does the equation balance? The storage law balances provided the drive carries the same dimension as Q per pass, which the framework assumes and does not measure; Q has **no operational unit**, and this audit records that rather than inventing one. The error law $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$ is dimensionally clean: $(1-\delta)^t$ is a pure number raised to a count, and the two sides carry $[\mathcal{C}]$ alike. The essence law $f(n) = kn^2$ balances **only if** k **carries** $[T^{-1}]$, because n is a dimensionless count, and **no operational procedure is supplied by which it acquires that dimension.** This is the single largest dimensional exposure in the paper and it is listed in §10 by name.

The ratio c/η is dimensionally a cost flow divided by a pure number and is therefore not dimensionless as the exponent of $e^{2c/\eta}$ requires. **The framework's convention is that** c **is expressed in the same units as** F **— nats of surplus per declared pass — which makes** c/η **di-**

mensionless. That convention is a choice, it is stated here, and every reading in this paper depends on it being applied consistently.

Two quantities in §6 are physical and carry real units, and they are the only ones that do. The Coulomb barrier of §6.1 is in MeV and the beam-energy estimate of §6.8 is in joules; both are computed from standard constants and are dimensionally ordinary. They are the exception, and the contrast with Q is the point of the table.

3.5 Scale type, and what licenses the arithmetic

quantity	scale type claimed	what licenses it
n, N, t, r	absolute	cardinality: true zero, fixed unit, identity transformation group only
u	ratio	constructed from an inner product of unit vectors; zero is parallel
elicited intensities	ratio, up to a free common multiplier	**magnitude estimation, assumed** [Stevens, 1957]; not tested here
η, c, δ	ratio, **assumed**	no instrument is supplied
q, d, survival probabilities	ratio	probabilities on a stated model
D	interval, in octaves	a difference of logarithms

The strongest available objection to this framework is Michell's: that psychology routinely assumes its attributes are quantitative without ever testing whether they are [Michell, 1997, 1999]. The objection applies here in full. The formal remedy exists — conjoint measurement supplies a testable condition for additive quantitative structure [Luce and Tukey, 1964, Krantz et al., 1971], and a Rasch model supplies specific objectivity [Rasch, 1960, Andrich, 1988] — and **neither has been run for any quantity in this paper.**

Michell's objection and the appraisal literature's objection are the same objection in two domains, and this paper names the pattern once rather than meeting each instance as a surprise. The pattern is *scalar reduction*: the habit of collapsing a structured state into a single number. Where Michell asks whether the attribute has quantitative structure at all, the affect literature asks whether the structure it has is the kind a single number can carry — and answers that emotions are distinguished by the **pattern across** independently varying appraisal dimensions [Smith and Ellsworth, 1985], that a state is a synchronisation process in time rather than a point [Scherer, 2001], that individuation runs by qualitative core relational theme so that differing by *what* is appraised does not license differing by *how many* [Lazarus, 1991], and that action readiness is constitutive of emotion as such rather than a rung above other emotions [Frijda, 1986]. Two dimensions of core affect are well supported [Russell, 1980]; twelve ordered rungs are not.

Everything in this paper that enters through u inherits that objection, because u is a scalar summary of exactly such a structured state. What survives it are the results that do not require u to be a measurement: the contraction, the two negative theorems, the arrival constants, the seven-passes arithmetic, the export invariance, the staged- control arithmetic and the survivorship and secrecy results. Those are statements about a model given its parameters, and they hold whatever the parameters turn out to mean.

3.6 Identification — the objection this framework cannot presently answer

The framework's founding construction is a reflexive loop, $T(x) = W(x, M(x))$: the group influences the member and the members constitute the group [Curzi, 2026]. **That is a linear-in-means reflexive specification, and the endogenous social effect in such a specification is not identified from observational data** [Manski, 1993]. It cannot be separated from contextual effects or from correlated unobservables, however much data is collected; influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. **No amount of fit, held out or otherwise, recovers the parameter.**

The remedy this paper adopts is stipulation, and it pays the price openly. The reference set is fixed in advance — the declared category set of size N and the declared decomposition rules — and every reading is reported together with that stipulation, which is what makes a discrete-choice treatment of social interaction defensible where an unrestricted one is not [Brock and Durlauf, 2001]. **This paper therefore presents the reflexive loop as a modelling position, not as an identified empirical result.**

The same objection applied to the framework's own parameters. If systems change their behaviour when modelled, then δ, η and u are the decision rules of people who have not read the storage law, and they are not structural in the sense a policy exercise requires [Lucas, 1976]. Classification changes the classified [Hacking, 1995], and a theory has been observed becoming true by being used, with dates and prices [MacKenzie and Millo, 2003, Ferraro et al., 2005]. **The framework asserts reflexivity for its subject matter and cannot consistently exempt its own parameters from it.** This paper does not resolve that; it states it, and treats every parameter as conditional on the arrangement in which it was fixed.

3.7 Method

Every number in this paper is the output of exact arithmetic on stated parameters, computed in double precision. **No observational data were collected, no human subjects participated, and no empirical dataset underlies any figure or table.** Every case is constructed and is labelled as constructed at the point of use. Residuals quoted at the 10^{-13} level or below are floating-point round-off, not measurement error, and are reported to demonstrate that two algebraically identical expressions were computed independently and agreed. The figures are produced by the scripts named in their captions.

The audit method of §5 and §6 is a two-column concordance. **The evidence column carries what could have come out otherwise; the precedent column carries only that an idea was independently arrived at and preserved.** Two sources agreeing does not double the evidence when only one of them is evidence, and the arithmetic for why the precedent column can never be promoted is §6.2's: under success-only preservation the likelihood ratio is exactly 1.000000 [Curzi, 2026].

4 Refinement as contraction

The instruction that survives in more alchemical texts than any other is not a recipe but a count. *Distil seven times. Circulate the matter until it no longer changes. Repeat the work.* The operation is not described as being improved between passes; it is described as being *done again*, identically, and the doing again is what is supposed to produce the result.

A modern reader has two available reactions and both are wrong: to dismiss the instruction as ritual padding, or to accept it as a claim that repetition adds something and that the seventh pass reaches somewhere the first could not. Neither survives the arithmetic, and the arithmetic is short. This section computes what iteration does. The answer follows directly from the storage law [Curzi, 2026a], and it is this:

> **Iteration closes a gap. It does not choose the destination. The destination was fixed by the parameters before the first pass began, and no number of passes moves it**

by any amount whatsoever.

That is why the construction is called a *ladder* and not a *staircase*. A staircase goes somewhere new with each step. A ladder is a fixed structure, and climbing it arrives where it was already pointing when it was set against the wall.

The framework's operation audit establishes what it means to move a state from one index to another: transmutation is re-indexing, and nothing not already latent can be reached [Curzi, 2026]. This section establishes the complementary fact about doing the same thing repeatedly. Section 5 then asks what the tradition got right, and cadence is on that list — a real result, but not for the reason the tradition gave.

The law

4.1 One rung of the ladder A refinement pass is one application of the storage law. **Analogy status: category 2, a shared mathematical form.** The equation below is the discrete leaky integrator that appears as the RC low-pass filter in signal processing [Oppenheim et al., 1996], as exponential smoothing in forecasting [Holt, 1957, Brown and Meyer, 1961], and as the leaky integrate-and-fire neuron in computational neuroscience [Lapicque, 1907, Gerstner and Kistler, 2002]. It is used because the mathematics is the same, not because the physics transfers. The law is the framework's contracting storage loop [Curzi, 2026a]:

```
Q      =  (1 − delta) ∗ Q   +  ( eta ∗ F(u∗)  −  c∗ )
 t+1                      t

       delta   per−cycle retention loss, in (0, 1]
       eta     conversion: how much of an interaction's surplus becomes stored order
       F(u∗)   the interaction surplus at the operating point, F = ln(1 + 11 u) for N = 12
       c∗      the per−cycle cost of maintaining the arrangement
```

Write the drive as a single constant, because for a fixed arrangement it is one:

```
b  =  eta ∗ F(u∗)  −  c∗                    the per−pass drive

Q      =  (1 − delta) ∗ Q   +  b
 t+1                      t
```

The fixed point is

```
Q     =  b / delta  =  ( eta ∗ F(u∗) − c∗ ) / delta
 inf
```

The framework calls Q_∞ the *destination* of the arrangement: it is where the loop arrives if the parameters hold. That definition is fixed in the companion paper on destiny as a fixed point [Curzi, 2026], whose Result Two states the contraction with constant $1-\delta$ and the equality $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$ at a maximum residual of 2.0624×10^{-15} over a hundred passes. This paper owns the approach to it.

A rung of the refinement ladder is one application of that map with the parameters unchanged. That last clause is the whole content of the result. If the parameters change between passes, the operation is not refinement — it is re-indexing, which the framework's audit of a traditional operation set governs [Curzi, 2026]. Refinement means: do the same thing again.

4.2 The error law **THEOREM 4.1 — THE CONTRACTION.** For the affine map above with `delta > 0`,

```
| Q  −  Q    |  =  (1 − delta)^t  ∗  | Q  −  Q    |
   t     inf                           0     inf
```

Proof. Subtract the fixed-point equation `Q_inf = (1−delta) Q_inf + b` from the update equation `Q_{t+1} = (1−delta) Q_t + b`. The drive `b` cancels exactly. What remains is `Q_{t+1} − Q_inf = (1−delta)(Q_t − Q_inf)`. Take absolute values and iterate `t` times. ■

The stability condition and the unique fixed point are standard for a first-order linear difference equation [Elaydi, 2005, Kelley and Peterson, 2001]. Three properties of this identity deserve to be read off before any table is computed.

It is an equality, not a bound. Banach's theorem [Banach, 1922] — stated exactly in the framework's foundations as: a contraction with modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least q each pass [Curzi, 2026] — requires only that distances not increase by more than a factor. Here they shrink by exactly `1 − delta` every pass, at every distance, forever: no fast region and no slow region.

The drive cancelled. `eta`, `F`, `c` — everything that decides *where* the loop is going — vanished in the subtraction. They set `Q_inf` and they do not appear in the rate. The gap closes at a speed that depends on the leak and on nothing else.

Nothing reaches the fixed point. `(1−delta)^t` is strictly positive for every finite `t`: the gap gets small and does not become zero. There is no pass on which the work is finished, and the tradition's discomfort about knowing when to stop is a correct perception of a system that supplies no completion signal.

4.3 The three constants of arrival Everything operational in this section comes off three quantities, all functions of δ alone. They are the time constant, half-life and settling time of a first-order lag, in the ordinary control-engineering sense [Åström and Murray, 2008, Horowitz and Hill, 2015]:

```
tau        =  −1 / ln(1 − delta)                passes per factor of e

half−life  =  ln(0.5) / ln(1 − delta)           passes to close half the gap

t(eps)     =  ln(eps) / ln(1 − delta)           passes to reduce the gap to a fraction eps
```

None of the three contains `Q_0`, `Q_inf`, `eta`, `F`, or `c`. **How long arrival takes is a property of the leak; where arrival happens is a property of everything else.** The two questions do not share a parameter. That separation is the formal skeleton of this section and it is also, in a different register, the framework's standing two-reading limitation — §4.7 makes the connection exact.

4.4 The destination is fixed before the first rung **THEOREM 4.2 — REFINEMENT CANNOT MOVE THE FIXED POINT.** `Q_inf = (eta F(u∗) − c∗)/delta` contains no `t`. Therefore for any `t`, `Q_inf(t) = Q_inf(0)`. ■

The proof is inspection, which is the correct proof: the fixed point is a function of four parameters, and iteration is not one of them.

Stated in the tradition's own vocabulary: if a practice repeats an operation whose parameters do not change, then however many times it is repeated it converges to a state computable before the first repetition — from `eta`, `F`, `c` and `delta`, and from no observation of the practice at all. **The seventh distillation reaches no destination the first distillation was not already headed toward.** What it does is arrive closer, and how much closer is the subject of §4.9.

4.5 Refinement does not move the pitch The frequency reading is the framework's essence bridge in its relationship form:

```
f     =  k * ( 1 + (N-1) u )^2  =  k * N_eff^2          k = 0.483425732988414 Hz
 rel
```

THEOREM 4.3 — THE LADDER IS SILENT IN THE FREQUENCY REGISTER. `f_rel` is a function of `u` and `N`. Neither is an argument of the iteration count. Therefore `f_rel(t) = f_rel(0)` for all `t`, and so are the folded pitch, the pitch class, and the octave deficit `D`. ■

This is the framework's state-frequency negative result arriving from the other side. There, frequency cannot distinguish a transient state from a standing disposition, because persistence is not an argument of $f = kn^2$. Here, that frequency cannot tell the first pass from the seventieth, for the same reason: **the pitch was never told about time, and repetition is entirely a fact about time.**

A second silence sharpens Theorem 4.3. The framework's operation audit [Curzi, 2026] establishes that a state frequency and a relationship frequency are independent readings: four constructed pairs spanning thousands of cents return identical `u` and `f_rel` to twelve decimal places, because `u` reads the angle between state vectors and not which indices are occupied. So there are two silences here — refinement moves neither reading, and neither could be derived from the other even if it did. **A complete report gives the state frequencies, the relationship frequency, and the trajectory, and derives none of the three from the others.**

Read as a claim about the tradition, this is sharp and worth being sharp about. Repetition is not transmutation; an operation repeated is the same operation. For the pitch to change, `u` or `N` has to change — a state genuinely added, a genuinely distinct category admitted — and that is the subject of the framework's re-indexing audit [Curzi, 2026], whose Result One is an audit distribution over thirteen entries — seven MAPS, two SPLIT, one RENDERING, three REJECTED, with five entries carrying a failure. The compound rule for combining components is fixed there too; it is not reachable by doing one thing twice.

4.6 The ladder in octaves — a construction, and it is badged as one The two theorems above make it sound as though the frequency register has nothing to say about refinement. It has one thing, and it is exact.

The deficit identity of the minimum-frequency paper [Curzi, 2026], verified to $8.88×10^{-16}$ at twelve parameter sets, is

```
D  =  2.885390 * ( c/eta  -  F )  =  -2.885390 * (delta/eta) * Q
                                                               inf
```

The second form maps the fixed point onto the octave scale. **DEFINITION 4.4 (constructed, badged).** Apply the same map to the *running stock*:

```
D    :=  -2.885390 * (delta / eta) * Q          the running deficit
 t                                    t

f    :=  k * 2^( 2.885390 * (c/eta)  -  D  )    the apparent pitch of the stock at pass t
 t                                      t
```

This is a definition, not a discovery. It is legitimate because it is exactly the transform that carries `Q_inf` to `D`, applied to a different argument; it is useful because of the following.

THEOREM 4.5 — THE OCTAVE LADDER. With `D_t` as defined,

```
| D  -  D |  =  (1 - delta)^t * | D  -  D |
   t                             0
```

Proof. `D_t` is a fixed negative multiple of `Q_t` and `D` is the same multiple of `Q_inf`. Multiplying both sides of Theorem 4.1 by `2.885390 (delta/eta)` gives the result. ■

COROLLARY 4.6 — THE GLIDE. If the stock starts empty, `Q_0 = 0`, then `D_0 = 0` and `f_0 = k * 2^(2.885390 c/eta) = f_min` exactly. As the ladder is climbed, `f_t` rises monotonically from `f_min` to `f_rel`, and the total glide is `|D|` octaves. ■

That is the frequency-register statement of what refinement is. **A refinement ladder begun from nothing is a glide that starts at the minimum sustainable frequency and converges on the arrangement's actual pitch.** It never overshoots, it never arrives, and its span is the octave deficit read backwards. In a sustainable relation `D < 0` the glide is upward and spans `|D|` octaves; in an unsustainable one `Q_inf` is negative, `D_t` runs the other way, and the glide descends below `f_min` — the correct picture of a practice refining itself into deficit.

The standing prohibition applies with full force and is restated here because this section is the one most likely to be misread. **These are essence frequencies: positions on a logarithmic scale of surplus.** `f_t` is a bookkeeping transform of a stored quantity. Nothing is claimed to vibrate, no person or tissue resonates at any of these values, and the glide is a way of reading a number, not a sound anything makes.

4.7 The two-reading limitation: rate and sustainability are separate readings This is one of the places where the framework's central limitation becomes structural rather than incidental, so it is stated here in full rather than referenced.

From the minimum-frequency paper [Curzi, 2026], whose Result Four is that D contains no δ — on the carried dyad δ from 0.09 to 0.05 leaves $D = +4.338420$ unchanged while Q_∞ falls from -5.0119 to -9.0215 — verified independently to 2.665×10^{-15} across twelve parameter sets:

```
D  =  2.885390 * ( c/eta - F )        contains k, c, eta, N, u.   DOES NOT CONTAIN delta.

Q     =  ( eta F - c ) / delta        contains delta, and is scaled by it.
 inf
```

The carried dyad as found (case 2a, CONSTRUCTED):

```
delta = 0.09   ->   Q     = -5.0119395464       deficit D = +4.338420
                     inf

delta = 0.05   ->   Q     = -9.0215             deficit D = +4.338420
                     inf
```

Lowering the loss nearly doubles the negative fixed point and moves the deficit by exactly nothing. Now put Theorem 4.1 beside it. The convergence rate is `(1-delta)^t`: it is a function of `delta` and of nothing else. So the same parameter that the deficit is blind to is the *only* parameter the arrival rate can see.

```
delta governs the RATE of arrival.        D cannot see delta at all.
D     governs the SIGN and SIZE of the sustainability gap.   The rate cannot see D.
```

Refinement speed and sustainability are therefore two independent readings of one system, and neither substitutes for the other. A ladder that converges fast is not thereby converging on somewhere good. A relation with a small deficit is not thereby getting there quickly. Any report that gives one number is incomplete, and §4.19's reporting format requires both.

4.8 Honesty clauses, restated in place **(1) ESSENCE, NOT RESONANCE.** Every frequency in this section is an essence frequency — a position on a logarithmic surplus scale. Nothing physically resonates at any value here.

(2) NO CLINICAL CLAIM. The twelve states are not diagnoses. A refinement ladder is not a treatment, a course of therapy, or an assessment of anyone's health, and nothing in this section describes or prescribes for any person's condition.

(3) ALL CASES CONSTRUCTED. Every case in this section is constructed and labelled. None is an observation of anyone.

(4) THE READING INHERITS ITS INPUTS. The trajectory is exactly as defensible as `delta`, and `delta` is usually the hardest of the four parameters to estimate. §4.18 and the framework's decay-estimation procedure give the honest procedure and the honest error bars.

(5) SCALE STATUS. n is a count and is absolute-scaled by construction. The intensities `w` must be magnitude-estimated with raw L2 norms published, or the relationship quantities computed from them are not determined. The framework's scale demotion binds the moment ratio D/P specifically; it does not bind the component index and it does not bind magnitude-estimated intensities.

(6) NO INTERVENTION MAY REMOVE THE ABILITY TO DECLINE. Consent is structural, not advisory: the framework's closure law makes the ability to decline a condition of any arrangement [Curzi, 2026]. §4.15 is about what happens when it is violated, and the arithmetic there is the argument.

The engineering

4.9 The convergence table Computed from `t(eps) = ln(eps)/ln(1−delta)` and `tau = −1/ln(1−delta)`. Fractional values are shown because the exactness matters; the integer in brackets is the first whole pass at or beyond the threshold.

`delta`	`1−delta`	`tau`	half-life	to 5%	to 1%	to 0.1%
0.01	0.99	99.4992	68.9676	298.07 [299]	458.21 [459]	687.32 [688]
0.02	0.98	49.4983	34.3096	148.28 [149]	227.95 [228]	341.92 [342]
0.03	0.97	32.8308	4.7566	98.35 [99]	151.19 [152]	226.79 [227]
0.05	0.95	19.4957	13.5134	58.40 [59]	89.78 [90]	134.67 [135]
0.07	0.93	13.7797	9.5513	41.28 [42]	63.46 [64]	95.19 [96]
0.09	0.91	10.6033	7.3496	31.76 [32]	48.83 [49]	73.24 [74]
0.10	0.90	9.4912	6.5788	28.43 [29]	43.71 [44]	65.56 [66]
0.12	0.88	7.8227	5.4223	5.43 [24]	36.02 [37]	54.04 [55]
0.15	0.85	6.1531	4.2650	18.43 [19]	28.34 [29]	42.50 [43]
0.20	0.80	4.4814	3.1063	13.43 [14]	20.64 [21]	30.96 [31]
0.25	0.75	3.4761	2.4094	10.41 [11]	16.01 [17]	6.01 [25]
0.30	0.70	2.8037	1.9434	8.40 [9]	12.91 [13]	19.37 [20]
0.40	0.60	1.9576	1.3569	5.86 [6]	9.02 [10]	13.52 [14]
0.50	0.50	1.4427	1.0000	4.32 [5]	6.64 [7]	9.97 [10]

The row in bold is the carried case's loss rate and the one every worked example in this framework uses. **At `delta = 0.09` a refinement ladder is thirty-two passes from being within five per cent of its destination**, and seventy-four passes from being within a tenth of a per cent.

Read the table with the period attached. A rate without its cycle is not a rate; the same caution governs every discrete-time filter [Oppenheim et al., 1996]. At `delta = 0.09` per week

that is thirty-two weeks to the five-per-cent band; per year, thirty-two years. The arithmetic does not know which, and §4.17 makes declaring the period a gate.

4.10 Two exact invariances **The cost of each halving is constant.** At `delta = 0.09` the half-life is 7.3496 passes, and that figure is the cost of going from 100% of the gap to 50%, from 50% to 25%, and from 1% to 0.5%. The expression `ln(0.5)/ln(1−delta)` has no `t` in it. There is no acceleration and no fatigue.

The cost of each factor of ten is constant. At `delta = 0.09` it is 6.4149 passes — the difference between the 1% column and the 0.1% column, 73.2447 minus 48.8298.

interval closed	passes at `delta = 0.09`
0% -> 50% of the gap	7.35
50% -> 90%	17.06
90% -> 99%	6.41
99% -> 99.9%	6.41

The last nine hundredths of one per cent costs exactly what the ninety-to-ninety-nine per cent did, and more than three times what the first half did. This is the arithmetic behind every practice that felt rapid at the start and interminable at the end. Nothing slowed down. The remaining distance is being felt in absolute terms by an operator whose instrument works in ratios, and the ratios are being closed at a perfectly constant rate throughout.

4.11 What seven repetitions actually buy The tradition's number is seven. Theorem 4.1 makes the question answerable: seven passes close `1 − (1−delta)^7` of the gap, and that is a claim about `delta` and nothing else.

`delta`	`(1−delta)^7` gap remaining	gap closed by seven passes	passes needed for 99%
0.01	0.932065	6.79%	458.21
0.02	0.868126	13.19%	227.95
0.05	0.698337	30.17%	89.78
0.09	0.516761	48.32%	48.83
0.10	0.478297	52.17%	43.71
0.15	0.320577	67.94%	28.34
0.20	0.209715	79.03%	20.64
0.25	0.133484	86.65%	16.01
0.30	0.082354	91.76%	12.91
0.40	0.027994	97.20%	9.02
0.50	0.007812	99.22%	6.64
0.60	0.001638	99.84%	5.03
0.70	0.000219	99.98%	3.83

And the sharper inverse question: what loss rate makes seven passes *sufficient*? Solving `(1−delta)^7 = eps`:

```
seven passes close 95%    requires   delta  =  1 − 0.05^(1/7)  =  0.348164
seven passes close 99%    requires   delta  =  1 − 0.01^(1/7)  =  0.482053
seven passes close 99.9%  requires   delta  =  1 − 0.001^(1/7) =  0.627241
```

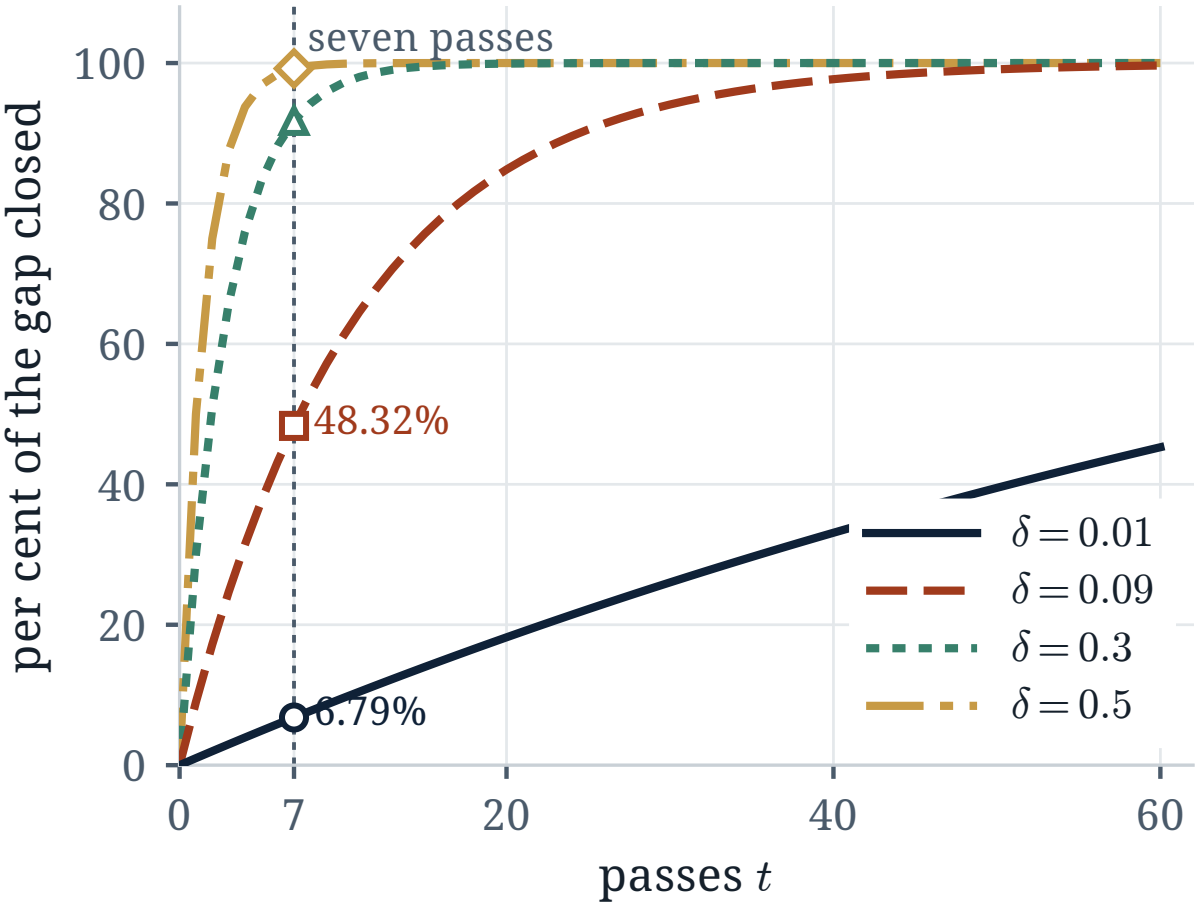

Figure 47.1: **Seven passes close 48.32 per cent of the gap at $\delta = 0.09$ and 6.79 per cent at $\delta = 0.01$**, so the traditional count is adequate only where the per-cycle loss is a third or more. Curves are $1 - (1 - \delta)^t$, the equality of Theorem 4.1; the four marked points are the seven-pass readings of the table above. Modelled: the four decay rates are chosen, and $\delta = 0.09$ is this framework's carried case. Built by `figs/src/CCP-047_fig01.py`.

Seven repetitions is adequate only in a system that loses roughly a third to a half of its stored order every cycle, and in a system with a leak of a few per cent it is nearly worthless. That is a real finding and it cuts both ways: the traditional count is not a universal constant, and it is not arbitrary either, because it encodes an implicit and checkable claim about the process. A tradition prescribing seven passes is asserting `delta \ensuremath{\approx} 0.35` or higher for its own operation, and in a physical distillation — where the loss is the volatile fraction left behind each pass — that is entirely ordinary. **The instruction is not mystical; it is a badly-stated engineering estimate, and it is testable.** A prescription that encodes an implicit parameter value is exactly the kind of claim that becomes checkable once the parameter is named [Platt, 1964, Meehl, 1990].

Whether it transfers to a psychological practice is a different question, and the answer is: only if `delta` there is also around a third, which for a weekly practice it is not. The framework's decay-estimation procedure is how one would find out.

4.12 Rate against destination — the two-by-two Because `delta` moves the rate and cannot move the deficit, and because `D` fixes the destination's sign and cannot see `delta`, the two readings are orthogonal and all four combinations occur. Both rows use the carried dyad's arrangements (CONSTRUCTED); only δ differs.

case	`u`	`eta`	`c`	`delta`	`D` (octaves)	`Q_inf`	half-life	to 1%
2b, fast leak	0.692373	0.44	0.40	0.30	-3.590989	+1.825328	1.9434	12.91
2b, slow leak	0.692373	0.44	0.40	0.03	-3.590989	+18.253280	4.7566	151.19
2a, fast leak	0.068735	0.30	0.62	0.30	+4.338420	-1.503582	1.9434	12.91
2a, slow leak	0.068735	0.30	0.62	0.03	+4.338420	-15.035819	4.7566	151.19

Four things to read off it, in order of how badly they are usually got wrong.

The `D` column has two values, not four. Changing `delta` by a factor of ten does not perturb the deficit in the twelfth decimal place. The decay-blindness result [Curzi, 2026] says it cannot, and here is the demonstration.

The rate columns have two values, not four. They are identical between a healthy arrangement and a failing one. The failing arrangement converges at exactly the same speed; it is converging on `-15.04`.

A slow ladder on a bad arrangement is the worst of the four. Row three settles at `-1.50` in thirteen passes; row four takes 151 passes to settle at `-15.04`, a destination ten times worse, because the low leak that slowed it down also multiplied the negative numerator. This is the framework's ordering rule in the refinement register: trust lowers δ, δ divides an already-negative numerator, and the result is a slower ladder to a much worse place. The elasticities that price the ordering are fixed in the return-difference paper [Curzi, 2026q], whose Result Four gives η $+1.594$, δ -1.000, u $+0.770$, C -0.594 — a ten per cent efficiency gain is worth 2.7 times a ten per cent cost cut.

Speed feels like progress and is not evidence of it. A practice that visibly changes a person fast is a practice with a large `delta`, and `delta` is a *loss* term. The visible rapidity is the signature of a leaky system reaching its level, which may be any level at all.

4.13 The glide, computed Case 2b of the carried dyad (CONSTRUCTED): `u = 0.692372881355932`, `eta = 0.44`, `c = 0.40`, `delta = 0.09`, `N = 12`. Then `F = 2.153633`, `f_rel = 35.8881768941 Hz`, `f_min = 2.9782153324 Hz`, `D = -3.5909886634` octaves, `Q_inf = +6.0844267427`, drive `b = 0.547598406839`. The ladder starts from an empty stock, `Q_0 = 0`.

`D_t` and `f_t` are Definition 4.4's constructed readings; the final column is the distance from the arrangement's true pitch, in cents.

pass `t`	`Q_t`	`D_t` (oct)	`f_t` (Hz)	cents below `f_rel`
0	0.000000	0.000000	2.978215	4309.19
1	0.547598	-0.323189	3.726024	3921.36
2	1.045913	-0.617291	4.568558	3568.44
3	1.499379	-0.884924	5.499772	3247.28
5	2.287549	-1.350096	7.592339	2689.07
7	2.940232	-1.735306	9.915969	2226.82
10	3.715053	-2.192600	13.614271	1678.07
15	4.605861	-2.718349	19.600209	1047.17
20	5.161754	-3.046433	6.605033	653.47
25	5.508650	-3.251169	28.356682	407.78
32	5.786888	-3.415383	31.775238	210.73
40	5.944508	-3.508410	33.891644	99.09
49	6.024551	-3.555651	35.019794	42.41
60	6.063209	-3.578466	35.578013	15.03
74	6.078761	-3.587645	35.805087	4.01
100	6.083939	-3.590701	35.881014	0.35
150	6.084422	-3.590986	35.888113	0.0031

The total span is `1200 * log2(35.8881768941 / 2.9782153324) = 4309.1864` cents, which is `3.5909886634` octaves, which is `-D` to every digit — Corollary 4.6 verified.

Seven passes — the traditional count — leave this ladder 2226.82 cents short of its own pitch, which is more than an octave and a half. At `delta = 0.09` seven is not a completion; it is slightly less than half the gap, exactly as §4.11 predicted.

One further reading, because it is the useful one. At $N = 12$ the minimum separation between distinct pitch classes in the folded lattice is 34.9756 cents. The glide is inside that separation — indistinguishable from arrival at the resolution the framework's own lattice supports — from pass 49 onward, where it stands at 42.41 cents, crossing below 34.9756 cents at pass 51. **Beyond about fifty passes the ladder is doing work the instrument cannot see.** That is the honest stopping criterion and §4.18 formalises it.

4.14 Why arrival is recognition rather than ascent The framework's founding definitions record that arrival is experienced as recognition rather than as victory, and offer no mechanism [Curzi, 2026]; the storage law supplies one in a line [Curzi, 2026a]: a contraction arrives, it does not climb. Here is the same claim with the arithmetic under it, in four parts.

One: there is no arrival event. `(1-delta)^t > 0` for every finite `t`, so there is no pass on which something completes and nothing for a sense of achievement to attach to. What there is instead is a gap that has become smaller than the operator can resolve — and *noticing that the difference can no longer be told* is a recognition, not an accomplishment.

Two: almost the entire trajectory is spent near the destination. The psychological literature on adaptation reaches the same shape from measurement rather than from algebra — an adaptation level against which experience is judged [Helson, 1948], a return toward a baseline after large positive and negative events [Brickman et al., 1978], and the qualifications that later work attaches to how complete that return is [Diener et al., 2006]. At `delta = 0.09` the ladder is within 5% of `Q_inf` from pass 32 and within 0.1% from pass 74. A practice run for three hundred passes spends 269 of them inside the five-per-cent band. Whatever being at the fixed point is like, it is what most of a practice feels like, and the transient is the unusual part. The approach is not the experience; it is the anomaly at the beginning.

Three: the destination is derived from what was already there. Every term of `Q_inf = (eta F - c)/delta` is a standing property of the arrangement; nothing in the fixed point is imported.

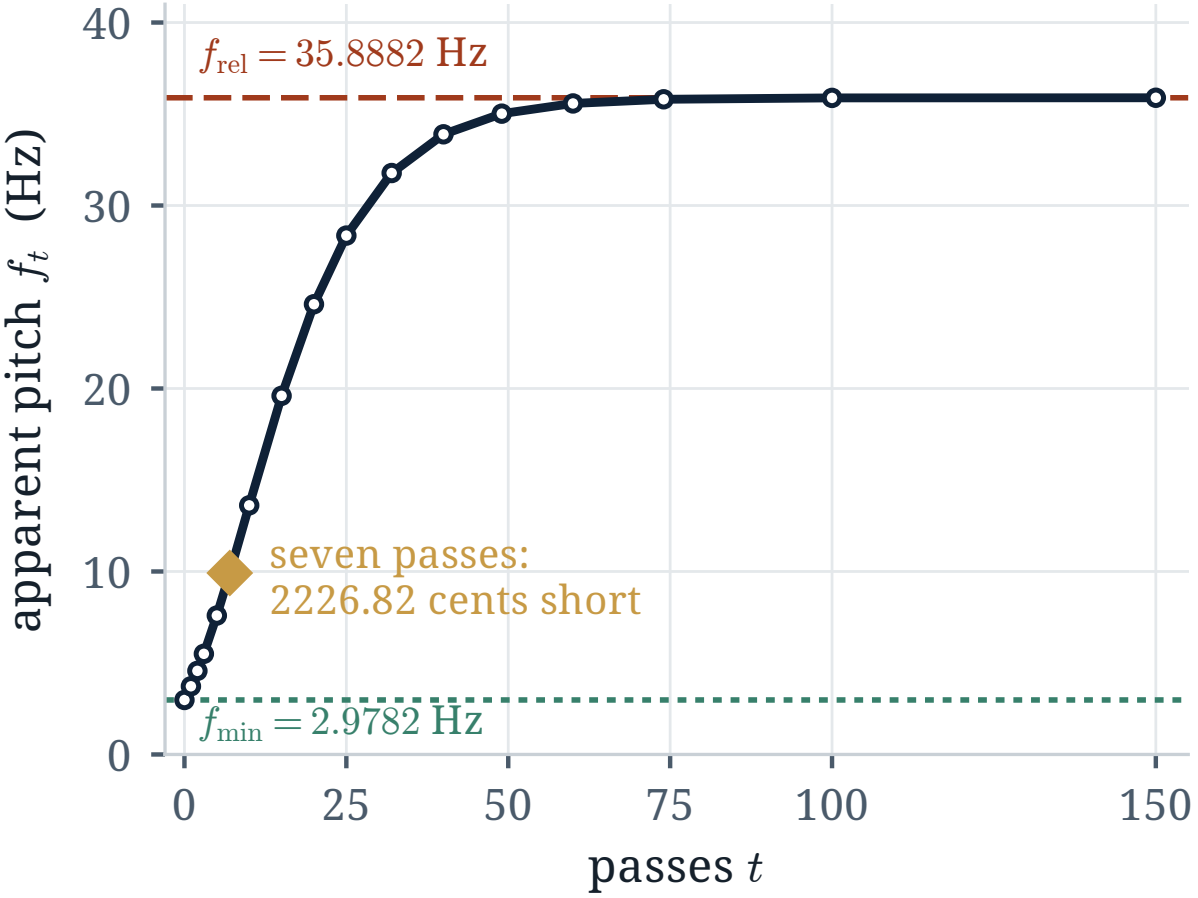

Figure 47.2: **A refinement ladder begun from nothing is a glide from the minimum sustainable frequency to the arrangement's own pitch, and seven passes leave it 2226.82 cents short.** The span is 4309.1864 cents, which is $|D| = 3.5909886634$ octaves exactly. Modelled from the constructed case 2b ($u = 0.692372881355932$, $\eta = 0.44$, $c = 0.40$, $\delta = 0.09$, $N = 12$); the apparent pitch f_t is a constructed reading of a stored quantity and nothing resonates. Built by `figs/src/CCP-047_fig02.py`.

The sense that arrival reveals something one already contained is not a mystical intuition but an accurate report about a formula whose every argument predates the first pass.

Four: the same fixed point is reached from any starting stock. Theorem 4.1 holds for any `Q_0`, and the sign of `Q_0 − Q_inf` does not appear in the rate: a ladder started from a large stock descends at exactly the speed one started from nothing ascends. **The destination is not a summit that some starting positions cannot see.** It is a level, and levels are recognised, not conquered.

The companion paper takes this forward as the definition of destiny [Curzi, 2026]. This paper's contribution is the rate, and the observation that the rate belongs to a parameter that the destination cannot see.

4.15 Counterfeit arrival A fixed point can be positive, stable, and reached at another party's expense. The companion paper names this counterfeit arrival [Curzi, 2026]; this paper can compute it, because cost export is an operation on `c*` and `c*` is in the drive.

CONSTRUCTED CASE — TWO PARTIES SHARING ONE ARRANGEMENT. Labelled constructed; not an observation. Two people, P and R, share the case-2b arrangement, so both draw on the same surplus `F = 2.153633` at `u = 0.692372881355932` and `f_rel = 35.8881768941 Hz`. Their private parameters differ, which is the ordinary situation:

```
P:   eta = 0.44   c = 0.40   delta = 0.09        D = −3.590989   Q      = +6.084427
                                                                  inf
R:   eta = 0.30   c = 0.55   delta = 0.09        D = −0.924189   Q      = +1.067665
                                                                  inf
```

Both are sustainable. R is nearer the edge, because R converts less and pays more — R's break-even cost is `eta_R * F = 0.646090` and R is at 0.55.

Now P exports cost. P declines a share of the maintenance — the scheduling, the repair conversations, the remembering of what was agreed — and R absorbs it. Let `x` be the exported amount, so `c_P -> 0.40 − x` and `c_R -> 0.55 + x`.

x	c_P	c_R	D_P	Q_inf,P	D_R	Q_inf,R	sum of drives	sum of fixed points
0.000	0.400	0.550	-3.590989	+6.084427	-0.924189	+1.067665	+0.643688	+7.152091

> **CORRECTION NOTE (made visible, not silently applied).** This section originally stated the counterfeit-arrival identity on the *sum of participants' fixed points*. That form is correct only when every participant carries the same `delta`, which the constructed case above happens to satisfy. The general invariant is the **sum of drives**, $\sum_i (\eta_i F_i - c_i)$. The companion paper proves it [Curzi, 2026] as conservation of drive under cost transfer, with the equal-δ case as a corollary and an explicit counterexample. Everywhere below, the rule is stated on drives; the fixed-point form is retained only as the labelled equal-δ corollary.

The sum of the two drives is invariant to every digit across the whole export range. Cost export is an externality in the ordinary sense: a private gain that is exactly a transfer, and that appears as a gain only because the accounts are drawn around one party [Hardin, 1968, Ostrom, 1990]. Each participant's drive is §4.2's `b_i = eta_i F(u*) − c_i`, so that `Q_inf,i = b_i / delta_i`; `b` is the drive and `D` remains the deficit throughout. Cost export produces nothing; it moves an existing quantity from one ledger to the other, entering one drive with a plus and the other with a minus, so `sum_i b_i` cannot move whatever the individual `delta_i` are. **Under equal `delta` — and only then — the sum of fixed points inherits the invariance,** because

sum_i Q_inf,i = (sum_i b_i)/delta; that is why the last column above is also constant, and it is a corollary of the column beside it rather than a rule in its own right. The general statement of what the plain sum does under unequal delta is §4.15a. Either way the invariance is exactly the thing the exporter's own reading cannot show, and that is the point. P's private instrument reports genuine, sustained, increasing improvement. P's deficit falls from -3.590989 to -4.902530, nearly a further octave and a third of headroom. Every number P can see about P is better.

R crosses the sustainability boundary between x = 0.05 and x = 0.10; solving D_R = 0 gives the exact crossing at c_R = eta_R F = 0.646090, i.e. at x = 0.096090.

And then the lag, which is the reason this failure mode is hard to catch. R does not vanish on the pass the sign flips. R's stock decays from its old level toward its new one at (1−delta)^t. At x = 0.15, R's new fixed point is −0.599002 and R starts at +1.067665:

pass	Q_R
0	+1.067665
3	+0.656950
7	+0.262266
10	+0.050025
15	-0.193988
25	-0.441283
40	-0.560675

Solving exactly, Q_R crosses zero at t* = 10.850479 passes. **For eleven passes after the export begins, R still has a positive stock and R's behaviour is still that of a participant** — while R's destination has already been negative from the first pass. Nothing observable changes at the moment the damage is done. This is why the deficit is the instrument and the stock is not: D_R went positive immediately; Q_R took eleven passes to notice.

The end of the arithmetic is the part that matters. The option R retains is exit, and exit is the classical alternative to voice when an arrangement deteriorates [Hirschman, 1970]. Suppose R eventually declines to continue — which is R's structural right under the framework's consent law [Curzi, 2026], and no arrangement in this framework may remove it. The shared arrangement ends. With no partner there is no interaction surplus: u = 0, F = ln(1) = 0, and $f = k = 0.483426$ Hz, the ground essence. P's reading at x = 0.15, with the reduced cost P kept:

```
before R's departure   D  = −4.574644     Q     = +7.751093        f = 35.888177 Hz
                        P                  inf,P

after  R's departure   D  = +1.639426     Q     = −2.777778        f =  0.483426 Hz
                        P                  inf,P
```

P's fixed point falls by 10.528871 units and P's deficit swings 6.214070 octaves the wrong way, and the export that produced the counterfeit reading is the reason. The reduced cost P retained is worth nothing once the surplus it was drawn against is gone.

> **THE DEFINITION, EARNED BY THE ARITHMETIC. A counterfeit fixed point is one that is positive in the exporter's accounts and negative in the accounts of the system that contains the exporter.** It is detectable, and the detection rule is: compute the deficit for every participant separately, and check whether the sum of drives moved. If a participant's fixed point improved and the sum of drives did not move, the gain was exported and nothing was produced.

That rule costs one extra column in the reporting format and it is the only defence available, because the exporter's own instrument is working perfectly and reporting a genuine

improvement in a quantity that genuinely improved. This identity is generalised in the companion paper as conservation of drive under cost transfer [Curzi, 2026] and is stated there as the export test.

4.15a Why the rule is on drives and not on fixed points The two forms are not interchangeable, and the case that separates them is the case in which export is most tempting. With `Q_inf,i = b_i / delta_i` and a transfer of `x` from P to R — so that `b_P -> b_P + x` and `b_R -> b_R − x`:

```
SUM OF DRIVES   sum_i b   =  sum_i ( eta_i F_i − c_i )  =  sum_i delta_i Q
                      i                                                 inf,i
                                                        INVARIANT ALWAYS

SUM OF Q       d/dx [ sum_i Q      ]  =  1/delta   −  1/delta      zero ONLY if the
                            inf,i              P            R    two deltas are equal
```

Run the same P and R with the same export, changing only the decay rates — P at `delta = 0.06`, R at `delta = 0.16`, so that the exporter is the party who decays *slower*:

x	Q_inf,P	Q_inf,R	sum of drives	sum of fixed points
0.000	+9.126640	+0.600561	+0.643688	+9.727202
0.050	+9.959973	+0.288061	+0.643688	+10.248035
0.100	+10.793307	-0.024439	+0.643688	+10.768868
0.150	+11.626640	-0.336939	+0.643688	+11.289702
0.200	+12.459973	-0.649439	+0.643688	+11.810535

Nothing whatever is produced — the drive column does not move a digit — and R crosses into decay between `x = 0.05` and `x = 0.10` exactly as before. But **the plain sum rises, by `1/0.06 − 1/0.16 = 10.416667` per unit exported**, from `+9.727202` to `+11.810535`.

The failure mode is the worst available one. The naive test does not merely fail to detect the export; it reports a gain, and it reports one precisely when cost is pushed onto whoever decays faster — which is the direction the arithmetic already rewards the exporter for choosing. A reading that used the plain sum would return the export check as *passed with improvement* on the pass the damage was done. The companion paper carries this as a named failure mode — the export test run on the plain sum — and works the general case [Curzi, 2026]; neither is repeated here.

4.16 The cost of a rung, and when to stop Theorem 4.1 says every pass closes the same *fraction* of the gap. It therefore says every pass closes a strictly smaller *absolute* amount, because the gap is shrinking. At `delta = 0.09` with an initial gap of 6.084427:

pass	gap remaining	closed by this pass	cumulative
1	5.536828	0.547598	9.00%
3	4.585048	0.453466	6.64%
7	3.144195	0.310964	48.32%
15	1.478565	0.146232	75.70%
25	0.575777	0.056945	90.54%
40	0.139919	0.013838	97.70%
60	0.021218	0.002098	99.65%

A pass costs the operator's time, attention, and the occasion itself. That cost is constant per pass while the return per pass falls geometrically, so the ladder has a finite optimal length. The marginal return at pass `t` is `delta * (1−delta)^t * |Q_0 − Q_inf|`, and setting it equal to a declared threshold `theta` gives

```
t     =  ln( theta / ( delta * |Q  − Q   | ) )  /  ln(1 − delta)
 stop                           0    inf
```

threshold `theta`	`t_stop` (exact)	first pass at or beyond
0.50	0.9642	1
0.25	8.3138	9
0.10	18.0295	19
0.05	25.3791	26
0.01	42.4444	43

The stopping rule is not a completion signal; it is a declared threshold on marginal return. It must be declared before the ladder starts, or it becomes a post-hoc rationalisation of wherever the operator ran out of patience — the stopping rule is a researcher degree of freedom, and an undeclared one is the documented route to an unfalsifiable result [Simmons et al., 2011, Gelman and Loken, 2013, Nosek et al., 2018]. Declaring it in advance is gate G5 of §4.20.

Note what this does *not* say. Whether to divide the ladder into more, smaller occasions is §5's question — splitting a fixed input across occasions rather than repeating a fixed operation — and the answer turns on strict concavity and the surplus ceiling [Curzi, 2026v]. Refinement here holds the per-pass operation fixed and asks only how many times to do it.

The specification

4.17 PROCEDURE REFINE-1 — reading a refinement ladder

```
STEP 1   DECLARE THE OPERATION.  Write down what one pass consists of, in enough
         detail that a third party could perform it. If the description changes
         between passes, this is not refinement (re-indexing is governed elsewhere).

STEP 2   DECLARE THE PERIOD.  One pass = one what? Week, month, session, year.
         delta is a per-cycle rate and is meaningless without its declared cycle.

STEP 3   MEASURE u.  Use the framework's dyadic elicitation procedure; publish the
         raw L2 norms. CHECK FOR THE ONE-HOT TRAP: framings with disjoint
         support are automatically orthogonal and give u = 1 for everyone
         regardless of content.

STEP 4   COMPUTE THE PITCH.  F = ln(1 + 11 u);  f = k (1 + 11 u)^2;  fold into the
         declared band.

STEP 5   ESTIMATE eta AND c.  Report the scale status of each.

STEP 6   COMPUTE THE DEFICIT.  D = 2.885390 (c/eta) − log2(f/k).  This is the
         DESTINATION reading. It does not contain delta and cannot see it.

STEP 7   CHECK THE CEILING.  c/eta <= ln N = 2.484907 at N = 12. Above it, no
```

```
          arrangement of these twelve categories is sustainable and no ladder helps.

STEP 8    ESTIMATE delta.  Report an interval, not a point, and carry that
          interval through every rate figure below.

STEP 9    COMPUTE THE FIXED POINT.  Q_inf = (eta F - c)/delta.  Cross-check against
          Q_inf = -D eta / (2.885390 delta).  The two must agree to 1e-12.

STEP 10   COMPUTE THE RATE.  tau, half-life, t(0.05), t(0.01) from delta alone.
          This is the ARRIVAL reading. It does not contain D and cannot see it.

STEP 11   COMPUTE THE TRAJECTORY.  Q_t from the declared Q_0; report at least the
          passes to 50%, 95% and 99% of the gap.

STEP 12   IF REPORTING THE GLIDE, badge it.  D_t and f_t are Definition 4.4's
          constructed readings of a stored quantity. Nothing resonates.

STEP 13   RUN THE EXPORT CHECK.  For every participant, compute D separately and
          sum the DRIVES (eta F - c). Compare against the sum before any change.
          If a participant's fixed point improved and the sum of drives did not
          move, the gain was exported and nothing was produced (§4.15).
          Do not run this check on the sum of fixed points unless every delta is
          equal; see §4.15a.

STEP 14   REPORT BOTH READINGS.  D with delta, never D alone.
```

4.18 PROCEDURE REFINE-2 — the stopping rule

```
STEP 1    DECLARE theta, the smallest per-pass gain worth one pass's cost, BEFORE
          the first pass. Declare it in the same units as Q.

STEP 2    COMPUTE t_stop = ln( theta / (delta * |Q_0 - Q_inf|) ) / ln(1 - delta).

STEP 3    COMPUTE THE RESOLUTION FLOOR. Find the pass at which the remaining glide
          falls below 34.9756 cents -- the minimum class separation at N = 12.
          Beyond it the ladder is moving less than the lattice can distinguish.

STEP 4    STOP AT THE EARLIER OF STEP 2 AND STEP 3, and record which bound binds.

STEP 5    IF t_stop <= 0, the ladder was not worth beginning: the first pass already
          returns less than theta. Report this. It is a legitimate finding.

STEP 6    DO NOT RE-DERIVE theta AFTER STOPPING. A threshold chosen to justify the
          stopping point carries no information.
```

4.19 Reporting format

4.20 Gates

```
G1  OPERATION FIXED.    One pass is specified and does not change between passes.
G2  PERIOD DECLARED.    delta carries its cycle. No bare rate.
G3  BOTH READINGS.      D and delta both reported. Neither alone.
G4  CEILING CHECKED.    c/eta <= ln N verified before any rate is computed.
G5  theta PRE-DECLARED. The stopping threshold precedes the first pass.
G6  EXPORT CHECKED.     Sum of DRIVES computed across all participants. The sum of
                        fixed points only where all deltas are equal (§4.15a).
G7  GLIDE BADGED.       f_t identified as a constructed reading wherever it appears.
G8  CASES LABELLED.     Every worked case marked CONSTRUCTED.
```

The failure modes

#	Name	What it looks like	What it actually is	Detection
FM 4.1	The ascending ladder	“Each pass takes us higher”	A contraction converging on a fixed level	Compute `Q_inf` before pass 1; compare to the reported trajectory
FM 4.2	Speed as evidence	“This works fast, so it works”	Large `delta`; a leaky system reaching its level	`delta` is a loss term. Read `D`, which cannot see it
FM 4.3	The moving destination	Recomputing `Q_inf` after each pass and reporting the movement	The parameters were changed; this is re-indexing, not refinement	Gate G1: was the operation fixed?
FM 4.4	Seven for its own sake	A count inherited from the tradition and applied to any `delta`	Seven passes close 48.32% at `delta = 0.09` and 6.79% at `delta = 0.01`	§4.11’s table
FM 4.5	The completion signal	Waiting for the pass on which the work finishes	There is none; `(1-delta)^t > 0` always	Procedure REFINE-2’s declared `theta`
FM 4.6	The retro-fitted threshold	`theta` chosen after stopping, to justify stopping	An unfalsifiable rationalisation	Gate G5
FM 4.7	Deficit without delta	Reporting `D` alone as “the reading”	`D` cannot see decay at all	Gate G3
FM 4.8	Delta without deficit	Reporting a fast half-life as good news	The rate cannot see the destination’s sign	Gate G3
FM 4.9	Counterfeit arrival	One party’s readings improve steadily and genuinely	Cost export; sum of drives unchanged	Gate G6, §4.15
FM 4.10	The eleven-pass illusion	“They are still participating, so they are fine”	The stock lags the destination by `t*` passes	Compute each participant’s `D`, not each participant’s `Q_t`
FM 4.11	Refining below resolution	Passes 60 through 300, diligently performed	Movement smaller than 34.9756 cents, the lattice minimum at `N = 12`	Procedure REFINE-2 step 3

#	Name	What it looks like	What it actually is	Detection
FM 4.12	Trust as a ladder accelerator	“Add trust and we will get there sooner”	Trust lowers `delta`; the ladder gets *slower*, and if the numerator is negative the destination gets worse	the ordering rule; §4.12 rows two and four
FM 4.13	The zero-leak ladder	A model with `delta = 0`	No contraction, no fixed point, unbounded growth in the model and rapid divergence from anything real	Gate G2 forces the leak to be named
FM 4.14	One-hot refinement	Every participant’s `u` comes out at 1.000000	Disjoint support: automatic orthogonality, degenerate surplus	Procedure REFINE-1 step 3
FM 4.15	The export check run on the plain sum	The sum of fixed points is used as the conserved quantity under unequal `delta`	Not an invariant: the sum moves by `1/delta_P − 1/delta_R` per unit exported, and *rises* when the exporter decays slower	§4.15a; the full treatment is Curzi [2026]

Four of these deserve more than a table row.

FM 4.2, speed as evidence, is the most common and the most inverted. The intuition that a practice producing rapid change is a powerful one is exactly backwards here. Rapidity is `delta`, `delta` is loss, and the destination `Q_inf = b/delta` is *divided* by it. A fast ladder and a slow ladder with the same `D` do not go to the same place: the fast one goes to a nearer place, quickly. Rows one and two of §4.12 differ by a factor of ten in both directions at once.

FM 4.9 and FM 4.10 are one failure mode observed at two lags, and the pairing is what makes it dangerous. The export check (G6) catches it on pass one; the stock does not reveal it until pass eleven in the worked case, by which time the exporter has eleven passes of improving private readings to point at. A protocol that monitors stocks rather than deficits finds the problem after it has become a fact.

FM 4.13 deserves naming because it is the tradition’s characteristic model, and the framework has already shown that $\delta = 0$ is a pathology rather than an ideal: no contraction, no unique fixed point, and an error-persistence column of all ones, so that no mistake ever decays out of the stock [Curzi, 2026a]. Descriptions of a refined substance that “no longer changes” are descriptions of `delta = 0`. There the map is an isometry, Banach does not apply, there is no fixed point, and `Q_t = Q_0 + b t` grows without bound — which is not permanence but the opposite, a quantity with no level at all. **The tradition’s image of an incorruptible end product is, read as a model, the one setting under which the whole apparatus stops working.** The honest version is that `delta` small is a durable disposition, `delta` zero is not a disposition at all.

FM 4.12 is the ordering rule arriving in this section’s vocabulary, and it is worth stating in the strongest form the arithmetic supports. Adding trust to a failing arrangement in order to make the refinement go faster does the reverse of both: it makes the ladder slower and

the destination worse. The carried case is the demonstration — 2a at `delta = 0.09` arrives at `−5.0119395464`; at `delta = 0.05` it arrives, more slowly, at `−9.0215`. **Fix the numerator first** [Curzi, 2026q]; this section shows what ignoring it does to the trajectory as well as to the destination.

Worked examples

4.21 The carried dyad, case 2b, run as a ladder **CONSTRUCTED. Not an observation of any person or pair.** Case 2b: the pair after B has taken on two states A does not hold and the pair have adopted a decision log.

Steps 1–2. One pass is one week: the pair's standing weekly review with the decision log open. The operation does not change between passes.

Steps 3–4. `u = 0.692372881355932`, elicited by magnitude estimation with raw L2 norms published. The one-hot check passes: the two vectors share support on states 4, 6 and 9, so the orthogonality trap does not apply. Then

```
F = ln(1 + 11 * 0.692372881355932) = 2.153633 nats
f = k * (1 + 11 * 0.692372881355932)^2 = 35.8881768941 Hz
```

Folding into the 220–440 Hz band requires $j = 3$: `35.8881768941 * 8 = 287.105415` Hz.

Steps 5–7. `eta = 0.44`, `c = 0.40`, so `c/eta = 0.909091`, comfortably below the ceiling `ln 12 = 2.484907`. Then `f_min = k e^(2 * 0.909091) = 2.9782153324 Hz`.

Step 6 — the destination reading.

```
D = 2.885390 * 0.909091 − log2(35.8881768941 / 0.483425732988414)
  = 2.623082 − 6.214071
  = −3.5909886634 octaves                      ACCUMULATES
```

Steps 8–10 — the arrival reading. `delta = 0.09` per week.

```
Q     = (0.44 * 2.153633 − 0.40)/0.09  =  +6.0844267427
 inf
cross-check:  −D * eta / (2.885390 * delta) = +6.0844267427   agrees to 1e−12

tau = 10.6033 weeks    half-life = 7.3496 weeks
t(5%) = 31.7645 weeks  t(1%) = 48.8298 weeks   t(0.1%) = 73.2447 weeks
```

Step 11 — the trajectory, from `Q_0 = 0`, drive `b = 0.547598406839`:

week	Q_t	fraction of gap remaining	closed
0	0.000000	1.000000	0.00%
1	0.547598	0.910000	9.00%
7	2.940232	0.516761	48.32%
15	4.605861	0.243008	75.70%
32	5.786888	0.048902	95.11%
49	6.024551	0.009857	99.01%
74	6.078761	0.000931	99.91%

Step 12 — the glide, badged as Definition 4.4's constructed reading: from `f_0 = f_min = 2.978215 Hz` to `f_rel = 35.888177 Hz`, a span of 4309.1864 cents, which is `|D|` exactly. The full table is §4.13.

Step 13 — the export check. Both members' `c*` are unchanged from the arrangement as declared; the sum of drives is unmoved. No export.

Step 14 — both readings, together:

```
DESTINATION   D = −3.5909886634 octaves.  ACCUMULATES.  Independent of delta.
ARRIVAL       delta = 0.09/week.  Half-life 7.3496 weeks.  Within 5% at week 32.
```

Neither number is the reading. The pair is both going somewhere good and going to take about eight months to get most of the way there, and a report giving only the first would be a report a reader could not act on.

4.22 Case 2a — the ladder that perfects a decay

CONSTRUCTED. The same pair as found, before the intervention. `u = 0.068734665264634`, `eta = 0.30`, `c = 0.62`, `delta = 0.09`.

```
F = 0.563084802746 nats        f = 1.4907987150 Hz        f_min = 30.1587698405 Hz
D = +4.3384201973 octaves      DECAYS
Q     = −5.0119395464          drive b = −0.451074535976
 inf
```

The rate constants are identical to §4.21's, because `delta` is: `tau = 10.6033`, half-life 7.3496 weeks, within 5% at week 32. **The same ladder, at the same speed, converging on `−5.01` instead of `+6.08`.** The trajectory from `Q_0 = 0`:

week	Q_t
0	0.000000
1	-0.451075
7	-2.420838
15	-3.793076
32	-4.766824
49	-4.962534
74	-5.007270

The glide runs the other way. `f_0 = f_min = 30.158770 Hz` and `f_t` descends, because `D_t` rises from 0 toward `+4.3384201973`. **A refinement ladder on an unsustainable arrangement is a descending glide of 4.338420 octaves below the minimum sustainable frequency**, executed with perfect regularity. The practice is not failing. It is succeeding at converging on a negative destination.

And now the intervention a reader reaches for, which the carried case exists to pre-empt — add trust, `delta` 0.09 -> 0.05:

```
delta = 0.09    Q     = −5.0119395464       D = +4.338420    half-life  7.3496 weeks
                 inf
delta = 0.05    Q     = −9.0215             D = +4.338420    half-life 13.5134 weeks
                 inf
```

The destination nearly doubled in the wrong direction, the ladder became 84% slower, and the deficit did not move. Three separate readings, three separate stories, one intervention. A reader with only `D` would conclude nothing happened. A reader with only the half-life would conclude the practice had become more patient. A reader with `Q_inf` would see the damage. **Report all three.** That is what §4.19's format requires, and why it requires it.

The repair is the framework's order of operations [Curzi, 2026q]: fix the numerator, then lower the loss. Case 2b is what that looks like — `u` raised from 0.068735 to 0.692373 and `c` cut from 0.62 to 0.40 first, after which trust becomes an amplifier of a positive sign and `delta` 0.09 -> 0.05 takes `Q_inf` from +6.0844267427 to +10.9520.

4.23 The counterfeit ladder, in report format **CONSTRUCTED.** P and R of §4.15, at export `x = 0.15`, read at pass 8 — after the export has begun and before R's stock has crossed zero.

```
REFINEMENT LADDER READING                                        [CONSTRUCTED]

  OPERATION      the shared weekly review, as declared in §4.21
  PERIOD         one pass = one week
  PARTICIPANTS   P, R

  DESTINATION READING
    u = 0.692372881355932    one-hot trap checked: Y (shared support on 4, 6, 9)
    F = 2.153633 nats    f = 35.8881768941 Hz    folded 287.105415 Hz
    P:  eta 0.44   c 0.250   c/eta 0.568182   D = -4.574644   ACCUMULATES
    R:  eta 0.30   c 0.700   c/eta 2.333333   D = +0.518506   DECAYS
    ceiling ln N = 2.484907; R at 2.333333 is inside it but close

  ARRIVAL READING
    delta = 0.09 per week (both)   half-life 7.3496 weeks
    P:  Q_inf = +7.751093
    R:  Q_inf = -0.599002    Q_R at pass 8 = +0.216073, still positive
    R's stock crosses zero at t* = 10.850479 passes

  EXPORT CHECK
    sum of drives before export = +0.643688
    sum of drives after  export = +0.643688
    moved? NO  ->  NOTHING WAS PRODUCED. The improvement in P's reading is
                   a transfer, and R's deficit has already changed sign.
    all deltas equal? YES (0.09 both) -> the corollary form also applies:
    sum of Q_inf before export = +7.152091   after export = +7.152091

  HONESTY
    essence frequencies, not physical resonances ................... [x]
    no clinical, diagnostic or therapeutic claim ................... [x]
    case labelled CONSTRUCTED ..................................... [x]
    ability to decline preserved -- R may end the arrangement ..... [x]
```

Every private number P can compute is better than it was, every one of them is correct, and the arrangement is now scheduled to end. That is what counterfeit arrival is, and the only line in the report that catches it is the one comparing two sums.

4.24 What this section establishes, and what Section 5 uses Established here, and used in Sections 5 and 6 and in the destiny paper [Curzi, 2026]:

```
Thm 4.1   |Q_t - Q_inf| = (1-delta)^t |Q_0 - Q_inf|, an equality, not a bound
Thm 4.2   Q_inf contains no t: refinement cannot move the destination
Thm 4.3   f_rel contains no t: refinement cannot move the pitch or the deficit
Def 4.4   the running deficit D_t and apparent pitch f_t -- CONSTRUCTED readings
Thm 4.5   the octave ladder: |D_t - D| = (1-delta)^t |D_0 - D|
Cor 4.6   the glide: from f_min to f_rel, spanning exactly |D| octaves
the three constants of arrival, all functions of delta alone
the two invariances: constant cost per halving, constant cost per decade
what seven passes buy, as a function of delta, and the delta that makes seven enough
counterfeit arrival: defined, computed, and given a one-line detection rule
  on the SUM OF DRIVES (§4.15a; general form in the destiny paper). The sum of fixed
  points is the equal-delta corollary only.
```

```
PROCEDURE REFINE-1, PROCEDURE REFINE-2, the reporting format, eight gates,
  fifteen failure modes
```

The negative results are the load-bearing ones. Refinement does not ascend, does not re-index, does not change a pitch, does not move a fixed point, and does not finish. What it does is close a proportion of a gap, at a rate set by the loss term, toward a place computed from four parameters none of which is effort.

The two readings do not substitute for each other: `delta` governs how fast a ladder arrives and cannot appear in the deficit; the deficit governs whether arriving is worth anything and cannot see `delta`. Report both or report nothing.

Section 5 turns to what the tradition got right, and cadence is on its list. The temptation there is to read this section's result as a vindication of repetition, and it is not one. This section holds the operation fixed and counts passes. Section 5 asks a different question — whether a fixed total input is better delivered at once or in instalments — and the answer to that one is *not* that instalments deliver more. They deliver exactly the same integrated total, to every digit. What they buy is something else entirely, and Section 5 states it precisely.

5 What the tradition got right, computed

This section and the next are one argument in two halves, and the second half is what makes the first half usable. Section 6 is the counterpart: it takes the tradition's largest claim, kills it with arithmetic, and then states exactly what survives. **A list of things a tradition got right, published alone, is an advertisement.** Published beside a list of what it got catastrophically wrong, computed to the same standard, it becomes an audit — so nothing in this section should be read without the next one.

Four things are on this section's list. Each was arrived at independently, by people with no instruments and no statistics, and each corresponds to something the formalism of this framework computes:

```
1  STAGED PROCESS CONTROL     an operation split into named stages with a check at each
2  CADENCE                    scheduled repetition rather than one great effort
3  CORRESPONDENCE TABLES      finite relational graphs over a counted category set
4  THE OPERATOR IN THE LOOP   the practitioner's own state as part of the apparatus
```

The second carries a correction that must be stated before anything else, because the popular version of it is false and the framework has already computed the falsity: **the integrated effect of one large input and the same total delivered periodically is identical to every digit — 433.3333 in all three schedules tested.** That is linear time-invariance and it is not a matter of opinion. Cadence wins for two other reasons entirely, both of them computed in §5.9 through §5.13, and this section states them rather than the folklore.

The apparatus for this section is the framework's two-column concordance method, with the role of each column stated in every block rather than assumed [Curzi, 2026].

The law

5.1 The concordance apparatus, with roles stated

```
(+1)  PHYSICS PROOF     what scientific measurement confirms
(-1)  METAPHYSICS       what contemplative or traditional practice records
(0p)  CONTRA-PROOF      how the two integrate at the Neutral Point

C1  STRUCTURAL CORRESPONDENCE   a deep shared pattern, not a surface resemblance
```

```
  C2  PREDICTIVE POWER          the bridge must generate a prediction that can fail
  C3  PRACTICAL UTILITY         it must be usable on both sides
```

And the refinement that keeps the method honest, restated here in full because this section is built entirely out of concordances:

> **The (+1) column carries EVIDENCE — what is measured, replicated, falsifiable. The (-1) column carries PRECEDENT** — that the idea was arrived at independently, recorded, and preserved, often for centuries, by people without the instruments. **Two sources agreeing does not double the evidence when only one of them is evidence.**

The framework's own reference apparatus fixes the classification this method depends on — four items of established mathematics, seven of established psychology, and exactly three declared postulates, with every protocol stated to run on the first two and steer by the third [Curzi, 2026]. What independent arrival does establish is real and worth having: that a structure was findable by more than one route, which is a genuine argument that the structure is in the territory and not only in the instrument. It is not an argument that the structure is correct. Section 6 supplies the arithmetic for why the precedent column cannot be promoted — under success-only publication the likelihood ratio of testimonial evidence is exactly 1.000000 — and this section's every block is written under that constraint.

Only bridges satisfying all three criteria are presented as established. Speculative bridges are marked speculative in the sentence that states them. **And a method that never rejects anything is not a method: this section rejects three claims in print, and Section 6 rejects the largest one of all.**

5.2 CONCORDANCE C5.1 — STAGED PROCESS CONTROL

```
CONCORDANCE C5.1 — AN OPERATION SHOULD BE DIVIDED INTO NAMED STAGES WITH A CHECK AT EACH

  CLAIM        That dividing a transformation into discrete, named, individually
               inspected stages produces a better outcome than performing it as one
               undivided operation with a single check at the end.

  (+1) EVIDENCE  -- this column carries measurement
               Statistical process control. Shewhart's Economic Control of Quality of
               Manufactured Product (1931) established in-process measurement against
               control limits rather than terminal inspection, and Deming's Out of the
               Crisis (1986) made the argument that inspection at the end cannot build
               quality in. NEITHER WORK IS IN THIS PAPER'S BIBLIOGRAPHIC DATABASE and
               both are named here without a key; the operations-management treatment
               that IS available states the same yield-and-rework structure
               [Hopp and Spearman 2011; Goldratt 1984]. Separately, the unit-operations
               decomposition of chemical engineering -- distillation, filtration,
               crystallisation as separately characterised stages -- is the working
               form of the same idea.
               WHAT IT MEASURED: that per-stage detection removes error before it
               propagates, and that the yield difference is large and computable
               (§5.8 computes it: 47.83% to 93.21% on a seven-stage process).

  (-1) PRECEDENT  -- this column carries independent arrival, not proof
               The Greco-Egyptian and Latin alchemical corpora describe transformation
               as an ordered series of named operations, each with its own apparatus and
               its own sign of completion. Zosimos of Panopolis (3rd-4th c. CE) describes
               distillation apparatus -- the tribikos, the kerotakis -- attributed in that
```

```
              corpus to Maria the Jewess. The historiography that establishes these as
              laboratory practice rather than allegory is Newman and Principe, "Alchemy
              vs. Chemistry: The Etymological Origins of a Historiographic Mistake"
              (Early Science and Medicine, 1998), and Principe, "The Secrets of Alchemy"
              (2013), which reproduces documented recipes in a modern laboratory.
              WHAT IT RECORDS: that staging, per-stage apparatus, and a per-stage
              completion criterion were arrived at and preserved for well over a
              millennium before any of it was justified statistically.

  (0p) INTEGRATION
              Both are describing error containment. A stage boundary is a place where
              an error can be caught before the next operation makes it unrecoverable.
              The tradition's "sign" -- a colour, a consistency, a smell -- is a
              control-limit test with an ordinal readout and no stated tolerance.

  CRITERIA    C1 PASS -- the shared pattern is per-stage detection, not the surface
                         fact that both use lists.
              C2 PASS -- it predicts that yield rises with per-stage detection
                         probability, monotonically, and §5.8 computes the curve.
              C3 PASS -- usable on both sides.

  STATUS      ESTABLISHED. The precedent is genuine and the evidence is independent
              of it. The tradition is not the reason to believe the claim; Shewhart is.

  BOUNDED BY  THAT STAGING IS RIGHT DOES NOT MAKE ANY PARTICULAR STAGE ORDER RIGHT.
              The framework's operation audit runs a canonical
              fifteenth-century twelve-gate schedule under this model and finds the
              only numerator-acting gate NINTH of twelve -- the canonical sequence lowers loss before it r
              numerator, which is exactly the order the framework's
              elasticities show accelerates a failure.
              Section 6.5 states that rejection in full. Staging: established.
              This tradition's stage ORDER: rejected.
```

5.3 CONCORDANCE C5.2 — cadence, with the invariance stated exactly

```
CONCORDANCE C5.2 — SCHEDULED REPETITION BEATS ONE GREAT EFFORT

  CLAIM AS THE TRADITION STATES IT
              That the work must be done on a schedule -- the fire kept even, the
              matter circulated daily, the office said at fixed hours -- and that this
              is superior to one concentrated effort of equal total magnitude.

  THE NAIVE VERSION OF THE CLAIM IS FALSE AND THE FRAMEWORK COMPUTES THE FALSITY
              The cadence result, recomputed here in §5.9: the INTEGRATED effect of
              one large impulse and the same total delivered periodically is IDENTICAL
              to every digit -- 433.3333 in all three schedules, equal to B/delta.
              That is linear time-invariance. Anyone claiming that spreading the same
              total input over more occasions produces more total stored order, in a
              linear model, has not done the arithmetic.

  (+1) EVIDENCE  -- this column carries measurement
              (a) THE FORMAL RESULT, computed in this work, not borrowed: the steady
                  state differs absolutely (0 for an impulse, m/delta for sustained
                  periodic forcing); the ceiling S <= ln N clips a large one-off input,
                  costing 97.2% of the nominal budget in the worked annual occasion
```

at N = 8, and 90.44% in the N = 12 register recomputed in §5.11;
and the cadence theorem -- strict concavity alone means splitting an
input across occasions strictly dominates delivering it at once.
(b) THE SPACING EFFECT, an independent empirical literature: Ebbinghaus
(1885) first reported it; Cepeda, Pashler, Vul, Wixted and Rohrer
(Psychological Bulletin, 2006) is the quantitative synthesis; and
Roediger and Karpicke (Psychological Science, 2006) established the
related testing effect. NONE OF THESE THREE IS IN THIS PAPER'S
BIBLIOGRAPHIC DATABASE. They are named without keys and no claim in
this paper rests on them.
HONEST NOTE, REQUIRED: the spacing literature is about human memory
encoding and the cadence theorem is a statement about concave
response functions. They are not the same claim and must not be presented as
mutual confirmation. Each stands on its own.

(-1) PRECEDENT -- this column carries independent arrival, not proof
Fixed-hour liturgical practice; the alchemical instruction to keep the
fire even and to circulate the matter over months rather than force it.
Durkheim's Elementary Forms of the Religious Life (1912) on periodic
assembly, and Rappaport's Ritual and Religion in the Making of Humanity
(1999) on invariance and periodicity as the defining features of ritual.
NEITHER IS IN THIS PAPER'S BIBLIOGRAPHIC DATABASE; both are named
without keys, and they carry precedent, not evidence.
WHAT IT RECORDS: that scheduled recurrence was selected for, and
preserved, by institutions that had no way to compute why it worked.

(0p) INTEGRATION
Periodic forcing of a leaky integrator. The correct statement, and the
only one this framework endorses: CADENCE BEATS INTENSITY BECAUSE OF STRICT
CONCAVITY AND THE SURPLUS CEILING, NOT BECAUSE IT DELIVERS MORE TOTAL
INPUT. It does not. The integrated total is identical.

CRITERIA C1 PASS. C2 PASS -- it predicts the clipping loss as a function of
cadence and N, computed in §5.11, and the optimum division as a
function of per-occasion cost, computed in §5.12. C3 PASS.

STATUS ESTABLISHED, WITH THE FOLKLORE'S STATED REASON REJECTED. The practice
is right and the traditional explanation of why is wrong. Section 6's
method -- disprove the strong claim with arithmetic, preserve what is
genuinely there -- applies here as much as it does there.

5.4 CONCORDANCE C5.3 — CORRESPONDENCE TABLES AS RELATIONAL GRAPHS

CONCORDANCE C5.3 — A CORRESPONDENCE TABLE IS A FINITE RELATIONAL GRAPH

CLAIM That the tradition's tables of correspondence -- ten nodes and twenty-two
paths, seven metals, four elements, a seventy-eight element structured
deck -- are, described accurately and without mysticism, finite relational
structures over counted category sets, which is exactly the
object the framework's category-set validity condition requires.

(+1) EVIDENCE -- this column carries measurement
Graph theory, which is not in dispute [Newman 2018; Barabasi 2016]. A ten-node, twenty-two-e
has a computable density against the complete graph's forty-five edges:
0.488889. And the star-polygon result \citep{ccp:CCP-028}, which is

number theory and is exact: a figure {N/k} drawn by stepping k positions around N points decomposes into exactly gcd(N,k) separate closed paths, each of length N/gcd(N,k). The hexagram {6/2} is literally two separate triangles; {7/2} is one continuous path. §5.14 computes the table.
WHAT IT MEASURED: that these structures have exact arithmetic invariants.

(−1) PRECEDENT -- this column carries independent arrival, not proof
The tables themselves, preserved across the Hermetic, kabbalistic and alchemical corpora, and the Ars Memoriae tradition of spatial mnemonics that used them (Yates, "The Art of Memory", 1966).
WHAT IT RECORDS: that counted, exhaustive, exclusive category schemes with declared relations between members were constructed and transmitted for centuries. That is the form V2 asks for, arrived at independently.

(0p) INTEGRATION
A correspondence table supplies the PARTITION that V2 requires and often supplies the ORDER that the house condition V7 requires. What it does not supply is V1, a state encoding -- a map from domain items to normalised vectors -- and §5.15 grades two classical tables against all of them and finds them wanting in exactly that place.

CRITERIA C1 PASS. C2 PASS -- the gcd result predicts the number of separate strokes in any such figure, and is falsifiable by drawing one.
C3 PASS -- the partition is directly usable as a category set.

STATUS ESTABLISHED AS A DESCRIPTION OF FORM. Explicitly NOT established as a claim that any particular table's contents are correct. §5.15 rejects two classical tables as psychological indices while retaining their form.

5.5 CONCORDANCE C5.4 — THE OPERATOR IS PART OF THE APPARATUS

CONCORDANCE C5.4 — THE PRACTITIONER'S OWN STATE IS PART OF THE INSTRUMENT

CLAIM That the state of the person conducting an operation materially affects its outcome, and that preparing the operator is therefore part of preparing the apparatus rather than a piety attached to it.

(+1) EVIDENCE -- this column carries measurement
(a) Experimenter expectancy effects. Rosenthal and Fode (1963) reported
that experimenters told their rats were "maze-bright" obtained better maze performance than those told the same rats were "maze-dull". The blinding requirement in trial design exists because of this class of result. It must be presented with its contested history: the 1968 classroom study [Rosenthal and Jacobson 1968] drew serious methodological criticism, the effect sizes are disputed [McCambridge et al. 2014], and the best long-run assessment finds classroom self-fulfilling prophecies real but small, usually non-accumulating and often dissipating [Jussim and Harber 2005].
(b) Tacit knowledge and the experimenter's regress: Polanyi's Personal Knowledge (1958) and Collins's Changing Order (1985), the latter documenting that laboratories could not build a working TEA laser from the published description alone and required personal contact with a group that already had one. NEITHER IS IN THIS PAPER'S BIBLIOGRAPHIC DATABASE; both are named here without keys.

```
            (c) THE FRAMEWORK'S OWN MEASUREMENTS: the shuffled-input control
                run off the shelf is anti-conservative at 2.2x nominal alpha (0.108
                against 0.05); the matched-autoregressive comparison alone false-passed
                35.8% of the time; against fabricated timing the full four-baseline
                suite passed 52.7% of the time; against a shared slow driver it passed
                98.35% of the time. The conclusion recorded there is that DESIGN
                CONTROLS -- blinding, channel separation, prospective sampling, a
                yoked control -- are required, and every one of those is a constraint
                on the operator rather than on the material.
            (d) THE FORMAL RESULT, computed in §5.16, whose structure matches the
                framework's channel-gain postulate -- E = G.B + eps with the
                forbidding clause G = 0 => E = 0 for all B, badged as a postulate and
                paired with the storage law's eta = 0 by explicit correspondence
                [CCP-034]: if the operator is a
                participant, the operator's own state vector enters u. An operator
                whose framings mirror the subject's contributes u = 0 exactly
                and pays the coordination cost anyway. In the carried case this LOWERS
                the arrangement's pitch by 536.4074 cents and moves the octave deficit
                from +4.338420 to +4.785426, or to +6.372391 once the link cost is
                priced.

(-1) PRECEDENT  -- this column carries independent arrival, not proof
            The standing insistence across the alchemical corpus that the artisan must
            be prepared, unhurried and attentive, and that the work fails otherwise;
            the parallel insistence in contemplative traditions that the state of the
            one performing a practice is not separable from the practice.
            WHAT IT RECORDS: that the operator was treated as a component. It records
            nothing about mechanism, and the tradition's proposed mechanisms -- moral
            worthiness, purity, election -- are not carried forward by this framework.

(0p) INTEGRATION
            Three distinct real mechanisms are available and none is supernatural:
            expectancy effects on measurement, tacit skill in execution, and -- in the
            relational case -- the operator's literal membership in the set whose
            non-parallelism is being computed. The third is the one this framework adds and
            it is arithmetic.

CRITERIA    C1 PASS.  C2 PASS -- §5.16 predicts the sign and size of the pitch change
            from adding an operator of a given framing, and the prediction is
            checkable by measuring u.  C3 PASS.

STATUS      ESTABLISHED AS A STRUCTURAL CLAIM; THE TRADITION'S MECHANISM REJECTED.
            "The operator is part of the apparatus" is correct. "The operator must be
            morally pure" is not carried, is not derivable from anything here, and is
            not endorsed.
```

One structural note before the rejections. The mechanism C5.4 admits is not that belief produces outcomes, but that a belief which is *grounded* has a channel to act through. The framework's conditional postulate states this in magnitude form as $E = G \cdot B + \varepsilon$ with the forbidding clause $G = 0 \Rightarrow E = 0$ for all B, badged as a postulate and paired with the storage law's $\eta = 0$ by explicit correspondence [Curzi, 2026ab]. That is the correct shape for the operator claim too: an operator's state can only act through a channel the arrangement already has, and where the channel gain is zero no amount of operator preparation produces anything. **The tradition's proposed mechanism — moral worthiness — is not a channel, and is not carried forward.**

5.6 Two further rejections, in print A method that never rejects is not a method. C5.1's block has already rejected one claim — this tradition's canonical stage *order*, on the operation audit against the ordering rule — and two more that a sympathetic reading might have admitted are rejected here.

```
REJECTION C5.5 — THE COLOUR SEQUENCE AS A NECESSARY ORDER

  CLAIM        That the transformation must pass through blackening, whitening, yellowing
               and reddening in that order, and that the order is a law of the process.

  GRADING      C1 MARGINAL. Staging is real (C5.1) and the colours are real observations
               of real material changes. But the claim under test is not "there are
               stages"; it is "these stages, in this order, necessarily".
               C2 FAILED, AND THIS IS DECISIVE. The stages are identified BY their
               colours. An operation that does not blacken is therefore not at the
               blackening stage, by definition, and the sequence cannot be observed to
               fail. A claim that cannot fail generates no prediction.
               C3 PARTIAL. Useful as a shared vocabulary for reporting where one is.

  STATUS       REJECTED AS AN ORDERING LAW. Retained only as staging vocabulary, with
               the circularity stated wherever it is used. This is the second
               concordance rejection in the essence-transformation material and it is recorded in
               Appendix D.

REJECTION C5.6 — "AS ABOVE, SO BELOW" AS A SCALE-INVARIANCE THEOREM

  CLAIM        That the same laws govern the small and the large, so a result obtained at
               one scale transfers to another.

  GRADING      C1 PARTIAL, AND THE PARTIALITY IS MEASURED. The storage law IS scale-free
               in FORM -- the framework's master correspondence table is exactly that
               claim, and it is why one instrument reads a mind and a commons. But
               the framework's own scope audit names nine disanalogies between the
               internal and external scopes and computes three of them: a mean-field decay error reaching 9
               two nine-member groups with IDENTICAL u = 0.5999 and S = 1.7578 losing
               77% versus 21% of surplus to a three-person departure, so that aggregate
               statistics hide the structure that decides the outcome; and a 90.1x
               period-normalisation trap when comparing scopes on mismatched clocks.
               C2 FAILED AS STATED. The maxim predicts that any result transfers. The
               computed disanalogies are counterexamples.
               C3 DANGEROUS. Used as licence it produces exactly the 90.1x error.

  STATUS       REJECTED AS STATED. What survives, and is used throughout this framework, is
               the precise version: THE CORRESPONDENCE IS OF DYNAMICS AND GEOMETRY, NOT
               OF AGENCY, and every transfer between scopes must re-derive its own
               parameters and declare its own clock.
```

5.7 Honesty clauses, restated in place **(1) NO SUPERNATURAL CLAIM.** Nothing in this section asserts any efficacy of symbol, any physical effect of a figure, or any result not derivable from the formalism. The computing-map reading of the old notation is a metaphor and keeps that badge.

(2) ESSENCE, NOT RESONANCE. Every frequency here is an essence frequency: a position on a logarithmic surplus scale. No substance, person or tissue is claimed to resonate at any value.

(3) NO CLINICAL CLAIM. The twelve states are not diagnoses; nothing here is a treatment.

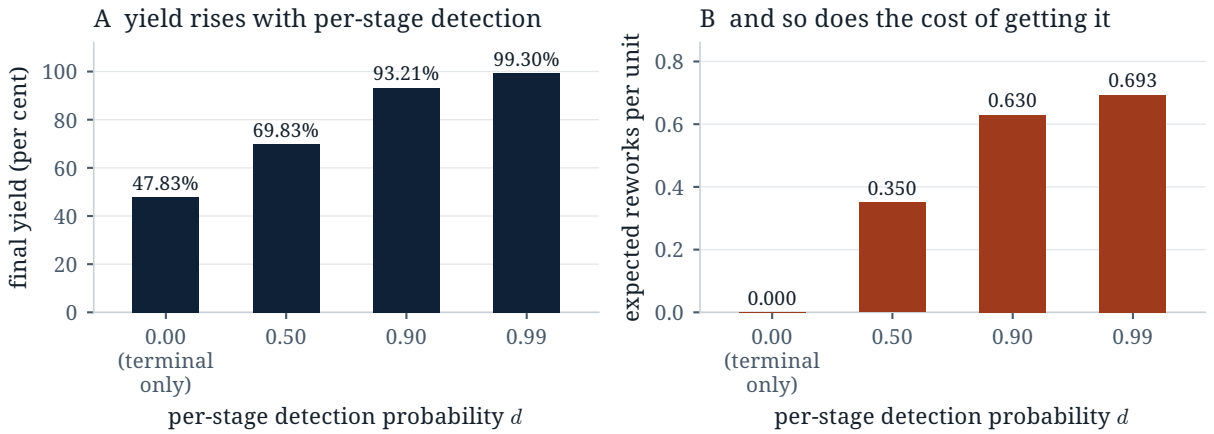

Figure 47.3: **Per-stage checking at 90 per cent detection raises final yield from 47.83 per cent to 93.21 per cent, and the cost of getting it is 0.63 reworks per unit.** Two panels rather than one dual axis, because yield and rework are different measures. Modelled from a seven-stage process with per-stage defect probability $q = 0.10$, per-stage escape $q(1-d)$ and yield $(1-q(1-d))^7$; the process is constructed. Built by `figs/src/CCP-047_fig03.py`.

(4) PRECEDENT IS NOT EVIDENCE. Stated in every block above and restated here. Section 6 computes why: the likelihood ratio of a success-only testimonial record is exactly 1.000000.

(5) ALL CASES CONSTRUCTED. Every worked case in this section is constructed and labelled.

(6) SCALE STATUS. n is a count and is absolute-scaled; intensities `w` must be magnitude-estimated with raw L2 norms published.

(7) BOTH READINGS. Every reading in this section reports the octave deficit `D` *and* `delta`. `D` contains no `delta` and cannot see decay; `delta` cannot see the deficit.

The engineering

5.8 Staged process control, computed **CONSTRUCTED.** A seven-stage process. Each stage introduces a defect with probability `q = 0.10`. A check after each stage detects a defect introduced at that stage with probability `d` and it is reworked; undetected defects propagate and spoil the product. Per-stage escape is `q(1-d)` and final yield is `(1 - q(1-d))^7`.

per-stage detection `d`	escape per stage	final yield	expected reworks per unit
0.00 (terminal check only)	0.1000	**47.83%**	0.000
0.50	0.0500	69.83%	0.350
0.90	0.0100	**93.21%**	0.630
0.99	0.0010	99.30%	0.693

Moving from a single terminal inspection to a per-stage check at ninety per cent detection raises yield from 47.83% to 93.21%, at a cost of 0.63 reworks per unit. That is the whole of C5.1 in four rows. The tradition's contribution is not the arithmetic, which it never had; it is that the arrangement the arithmetic recommends is the arrangement it used.

Note what the table also shows, because the honest reading is the useful one. Rework is not free and it rises with detection. At `d = 0.99` the yield gain over `d = 0.90` is 6.09 percentage points for an extra 0.063 reworks; whether that trade is worth taking is an economic question the model does not answer. Staging is not free, and the tradition's habit of treating each stage as a rite with its own preparation is, in this reading, an accurate estimate that stage boundaries are expensive.

5.9 The cadence invariance, part one: the integrated effect is identical Reproduced here rather than cited, because the popular claim is the opposite and a citation is not enough. The reference setup [Curzi, 2026v] is: `delta = 0.06` per week, a total budget `B = 26.0` delivered in one calendar year, and three schedules — one impulse of 26.0 at week 0; 0.5 per week for 52 weeks; 2.0 every fourth week for 52 weeks. Summing `Q_t` over 4,000 periods:

```
impulse       433.3333
weekly        433.3333
four-weekly   433.3333
B / delta  =  433.3333

maximum pairwise difference across the three schedules:  3.41e-13
```

Identical to every digit, to the limit of floating-point summation. This is the defining property of a linear time-invariant system: the integral of the response to a given total input is `B/delta` regardless of how that input is distributed in time.

Restated as this framework's position and binding on everything that follows: cadence does not deliver more. Any argument of the form "spreading it out delivers more total benefit" is wrong, and the correct arguments are the two that follow.

5.10 The cadence invariance, part two: the steady state differs absolutely The integrals agree; the destinations do not. An impulse decays to nothing — its steady state is exactly `0`. Sustained periodic forcing at mean rate `m` per period holds a level of `m/delta`. Those are not the same system observed at different speeds; they are different systems.

The trajectory difference in the reference worked case has a crossover at week 24: at week 23 the impulse is still ahead, 6.6648 against 6.3254, and at week 24 the cadence is ahead, 6.4458 against 6.2649, and it never trails again while the budget lasts. The impulse wins early and loses permanently, which is precisely the shape that makes the folklore feel true and the arithmetic necessary.

5.11 The cadence invariance, part three: the ceiling clips the impulse The second real argument is the surplus ceiling. $S_t \leq \ln N$ is the framework's normalisation bound, carried into the frequency register as the ceiling $c/\eta \leq \ln N$ [Curzi, 2026]. One interaction cannot generate more surplus than the log of the number of distinguishable categories, however much is poured into it. Everything above the ceiling is not delivered late; it is not delivered.

The framework's worked annual occasion ran at $N = 8$, $\eta = 0.35$, giving a per-occasion cap of `ln 8 = 2.0794` nats. **Against a nominal annual budget of 26 nats, the annual rite delivers 2.8% of what the weekly practice delivers: the clipping costs 97.2% of the nominal budget.** That figure is the cadence paper's and is quoted exactly [Curzi, 2026v].

Recomputed in this framework's register — `N = 12`, cap `ln 12 = 2.484907` nats, `eta = 0.44`, the same 26-nat nominal annual budget delivered at a nominal 0.5 nats per week:

cadence `P` (weeks)	burst wanted	delivered	clipped	annual delivered	`eta` × annual	% of weekly
1	0.5000	0.5000	no	26.0000	11.4400	100.00%

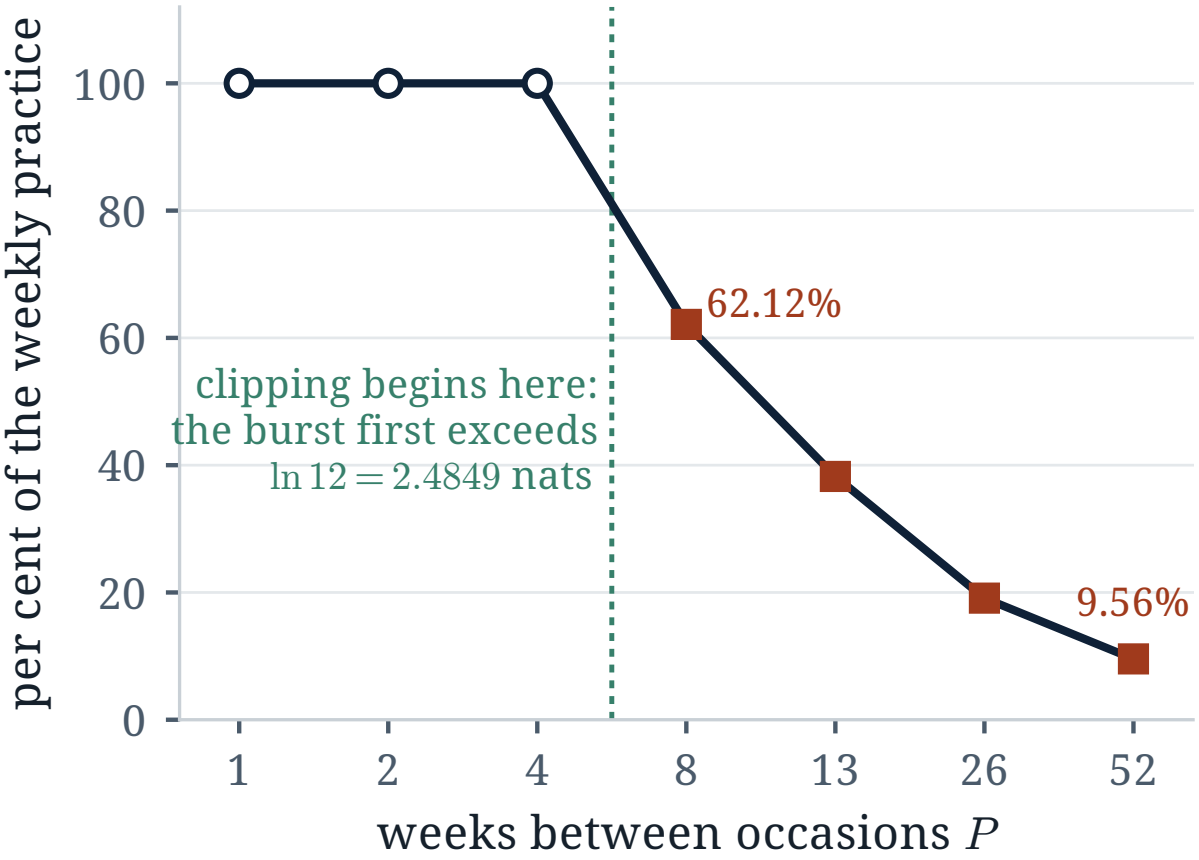

Figure 47.4: **A concentrated occasion loses nothing until its burst exceeds the ceiling, and then loses almost everything: the annual occasion delivers 9.56 per cent of the weekly practice from an identical nominal budget.** Modelled at $N = 12$ with a per-occasion cap of $\ln 12 = 2.484907$ nats, $\eta = 0.44$, and a nominal annual budget of 26 nats delivered at 0.5 nats per week. Built by `figs/src/CCP-047_fig04.py`.

cadence P (weeks)	burst wanted	delivered	clipped	annual delivered	eta × annual	% of weekly
2	1.0000	1.0000	no	26.0000	11.4400	100.00%
4	2.0000	2.0000	no	26.0000	11.4400	100.00%
8	4.0000	2.4849	**yes**	16.1519	7.1068	62.12%
13	6.5000	2.4849	**yes**	9.9396	4.3734	38.23%
26	13.0000	2.4849	**yes**	4.9698	2.1867	19.11%
52	26.0000	2.4849	**yes**	2.4849	1.0934	**9.56%**

At N = 12 the annual rite delivers 9.56% of the weekly practice from an identical nominal budget — a loss of 90.44% rather than the 97.2% of the $N = 8$ case. The difference between the two figures is not a discrepancy; it is the ceiling, and it is a direct demonstration of lever L4. Raising the category count from 8 to 12 raises the cap from 2.0794 to 2.4849 nats, and the concentrated rite recovers a third of what it was losing. A richer category set does not merely raise the maximum sustainable frequency; it also makes concentrated delivery less wasteful, because there is more room under the cap.

Note also where the clipping starts. At N = 12 a fortnightly and even a monthly cadence lose nothing at all in this worked case; the loss begins at P = 8 weeks. **"More often" is not uniformly better.** It is better only once the burst exceeds the cap, and below that point cadence

buys nothing through this channel. The other channel, concavity, is where the remaining advantage lives.

5.12 The cadence invariance, part four: strict concavity, which needs no ceiling at all The cadence theorem [Curzi, 2026v] — for g concave with $g(0) = 0$, $D(n) = n\,g(T/n)$ is nondecreasing in n, so dividing a fixed budget over more occasions never delivers less — is the honest core of the cadence argument, because it does not depend on the ceiling binding. `F(u) = ln(1 + (N−1)u)` is strictly concave through the origin, and for a concave response through the origin, splitting an input across occasions strictly dominates delivering it at once. No clipping required.

CONSTRUCTED. A fixed budget of `T = 12` hours of interaction, divided into `n` occasions of `L = T/n` hours each. Non-parallelism rises linearly with session length to saturation at `L* = 8` hours: `u(L) = min(1, L/L*)`. `N = 12`, `eta = 0.44`, and a fixed per-occasion cost `c_0 = 0.15` regardless of length — convening, travelling, settling, closing.

n	L (h)	u	F(u)	eta F	total	−n c_0	net
1	12.0000	1.0000	2.4849	1.0934	1.0934	-0.1500	0.9434
2	6.0000	0.7500	2.2246	0.9788	1.9577	-0.3000	1.6577
3	4.0000	0.5000	1.8718	0.8236	2.4708	-0.4500	2.0208
4	3.0000	0.3750	1.6341	0.7190	2.8761	-0.6000	2.2761
6	2.0000	0.2500	1.3218	0.5816	3.4894	-0.9000	2.5894
8	1.5000	0.1875	1.1192	0.4925	3.9397	-1.2000	2.7397
12	**1.0000**	**0.1250**	**0.8650**	**0.3806**	**4.5672**	**-1.8000**	**2.7672**
24	0.5000	0.0625	0.5232	0.2302	5.5255	-3.6000	1.9255
48	0.2500	0.0312	0.2955	0.1300	6.2402	-7.2000	-0.9598

The delivered-total column (headed *total*) is monotone increasing exactly as the cadence theorem requires [Curzi, 2026v], rising from 1.0934 to 6.2402 — **a factor of 5.7074 from the same twelve hours, purely by division, with no ceiling involved and no extra input.**

Two further readings, both of which the folklore misses.

The net column peaks at $n = 12$ and falls away on both sides. The per-occasion fixed cost is the same term that makes added communication paths expensive in project work, where the count grows as $n(n-1)/2$ [Brooks, 1975, Conway, 1968]. Concavity alone would recommend infinitely many infinitesimal occasions, which is obviously wrong, and the term that stops it is the per-occasion fixed cost. **The optimum is a function of `c_0` and of nothing else in this model**, which means "how often should we meet" is answerable, and the answer is an arithmetic consequence of convening cost.

At `n = 1` the single twelve-hour occasion wastes four hours before any other effect is considered, because `u` saturates at `L* = 8`. The longest session in the table is the only one with idle budget in it.

5.13 The honest counter-case The cadence paper kept a counter-case in print [Curzi, 2026v] and this paper keeps it too, because a section titled *What Alchemy Got Right* that reported only confirmations would be selecting.

Above a threshold that no realistic cadence reaches, the impulse wins. And the durability such a schedule would require is computable: **A worked decennial observance — one occasion every ten years — requires a trace half-life of 5.63 years for the stored order to survive between occasions.** A practice whose retention half-life is measured in weeks cannot be run on a decade.

This is the same arithmetic as §4's, arriving from the cadence side. **The interval between occasions must be short relative to the half-life `ln(0.5)/ln(1−delta)`, and every claim that a rare observance suffices is a claim about `delta` that can be checked.**

5.14 Correspondence tables, computed as graphs The claim of C5.3 is descriptive and the descriptions are arithmetic.

```
ten-node / twenty-two-path scheme
    nodes 10, edges 22, complete graph 45 edges, density 0.488889

the twelve-state ladder of this framework
    nodes 12, edges 66, complete graph 66 edges, density 1.000000

a seventy-eight element structured deck
    78 = 22 + 4 x 14;  distinct pairs = 3,003
```

The density figures are the useful comparison. **This framework's own category scheme is a complete graph** — every state stands in a computed interval relation to every other, because the intervals are ratios of squares and no pair is undefined. The classical ten-node scheme specifies fewer than half its available relations, and the unspecified ones are not "absent"; they are simply not part of the table. That is a difference of kind between a correspondence table and a metric structure, and it is the honest limit on the analogy.

The one exact arithmetic invariant the tradition's figures do possess is the star-polygon result [Curzi, 2026v], which is number theory and is true. Stepping `k` positions around `N` points produces exactly `gcd(N,k)` separate closed paths of length `N/gcd(N,k)`:

`N`	`k` and the resulting (strokes, length)
6	{6/1} (1, 6) · {6/2} **(2, 3)** · {6/3} (3, 2)
7	{7/1} (1, 7) · {7/2} (1, 7) · {7/3} (1, 7)
8	{8/1} (1, 8) · {8/2} (2, 4) · {8/3} (1, 8) · {8/4} (4, 2)
9	{9/1} (1, 9) · {9/2} (1, 9) · {9/3} (3, 3) · {9/4} (1, 9)
10	{10/1} (1,10) · {10/2} (2, 5) · {10/3} (1,10) · {10/4} (2, 5) · {10/5} (5, 2)
11	every `k` from 1 to 5 gives (1, 11)
12	{12/1} (1,12) · {12/2} (2, 6) · {12/3} (3, 4) · {12/4} (4, 3) · {12/5} (1,12) · {12/6} (6, 2)

The six-pointed figure is literally two separate triangles and the seven-pointed one is a single unbroken path, and which of the two obtains is decided by `gcd(N,k)` and by nothing else. At `N = 11`, a prime, every step size yields one continuous path; at `N = 12` the strokes take every divisor value. This is exact, checkable with a pencil, and carries no claim whatever about meaning.

5.15 Grading two classical tables against the validity conditions

The form passes. The contents must be graded, and the framework's validity conditions — here labelled V1 (a state encoding exists), V2 (the categories partition a counted set) and V7 (a declared ordinal rule) — are the grading instrument.

The ceiling $F \leq \ln N$ is the same bound that requisite-variety arguments impose on any regulator [Ashby, 1956, 1958], and choosing a small N spends it in advance.

THE FOUR ELEMENTS, as a candidate index. Four categories, exhaustive and exclusive by stipulation, counted. Traditionally ordered by density or subtlety: earth, water, air, fire.

- **V2, category assignment: PASSES.** It partitions, it is counted, `N = 4`.
- **V7, declared ordinal: PASSES, weakly.** The density ordering is publishable and a third party can apply it. It is a real ordinal rule, which is more than several modern candidates managed in the framework's index-validation work.

- **V1, state encoding: FAILS.** There is no map from psychological states to normalised vectors over these four categories. A feeling does not have a determinate location among them, and no procedure in the corpus supplies one.
- **The ceiling consequence, and it is severe.** At `N = 4` the maximum surplus is `ln 4 = 1.386294` nats — 55.79% of what `N = 12` allows — and the ceiling on the sustainable cost ratio falls to `c/eta <= 1.386294`, i.e. `f_min <= k·16 = 7.734812 Hz`. **Choosing a four-category scheme discards 3.169925 octaves of available ceiling before any measurement is taken.**
- **VERDICT: REJECTED as a psychological essence index.** Retained as a demonstration that the tradition's *form* satisfies V2 and V7, which is the point C5.3 makes.

THE SEVEN METALS AND THEIR PLANETARY CORRESPONDENCES. Seven categories, counted, with a declared traditional order.

- **V2: PASSES.** V7: passes, on the traditional ordering.
- **V1: FAILS, and fails at the first step.** The correspondence is between substances and celestial bodies. Neither is a psychological state, and no encoding of states into this scheme exists. Applying `f = k n^2` anyway would produce 0.483426, 1.933703, 4.350832, 7.734812, 12.085643, 17.403326 and 5.687861 Hz — seven perfectly definite numbers that mean nothing, because **the frequencies inherit exactly the defensibility of the index, and an index that fails V1 yields frequencies that are arithmetic without content.**
- **Ceiling consequence:** `ln 7 = 1.945910` nats against `ln 12 = 2.484907`, a loss of 0.538997 nats — **1.555215 octaves of ceiling, 21.69% of the available surplus, discarded by the choice of seven.**
- **VERDICT: REJECTED as a psychological essence index. Retained as a mnemonic index**, which is exactly the disposition the audit template recommends and §6 generalises: kill the strong reading with arithmetic, keep the weak one that is genuinely there.

5.16 The operator in the apparatus, computed CONSTRUCTED. Not an observation of any person.

The carried dyad's exact state vectors are $A = \{4{:}0.7,\ 6{:}0.5,\ 9{:}0.4\}$ and `B = {4:0.6, 6:0.55, 9:0.3, 10:0.2}`, normalised. Raw L2 norms published per the framework's magnitude reporting rule: `|A| = 0.948683`, `|B| = 0.890225`. Then `cos = 0.965021` and `u(A,B) = 0.068734665264634`, which is case 2a to fifteen decimal places.

Now add a third participant O — a facilitator, a coach, a third member of the working group — and compute the three-member mean pairwise `u`, its surplus and its pitch. Cost is read at `eta = 0.30`, `c = 0.62`, `delta = 0.09`, with a per-link coordination cost $\kappa = 0.055$ over three links where priced.

operator	|O|	u(A,O)	u(B,O)	mean u	f (Hz)	D (κ=0)	D (κ=0.055)
— (dyad alone)	—	—	—	0.068735	1.490799	+4.338420	—
O1 mirroring A	0.948683	**0.000000**	0.068735	0.045823	**1.093596**	**+4.785426**	**+6.372391**
O2 disjoint support	0.901388	1.000000	1.000000	0.689578	35.632544	-0.240618	+1.346347
O3 overlapping, distinct	0.829156	0.818626	0.829263	0.572208	25.721455	+0.229605	+1.816570
O4 strongly distinct	0.913783	0.980838	0.953720	0.667764	33.668595	-0.158826	+1.428139

Three results, and one trap that the table is deliberately made to contain.

O1, the mirroring operator, is the demonstration. An operator whose framings duplicate A's contributes `u(A,O) = 0.000000` exactly — because $u = 1 - (\hat{x} \cdot \hat{y})^2$ depends only on $|\rho|$, and a perfect mirror gives $\rho = 1$. Mean `u` falls from 0.068735 to 0.045823, the pitch falls from 1.490799 Hz to 1.093596 Hz — **a drop of 536.4074 cents, most of a perfect fourth** — and the octave deficit worsens from +4.338420 to +4.785426, or to +6.372391 once the three links are priced at `kappa`. **An operator who agrees with the subject adds cost and no surplus, and the instrument says so in cents.**

O2 is the trap, and it is reported rather than quietly fixed. O2's vector has *disjoint support* from A's and B's — it occupies states 3, 7 and 11, which neither of them holds. Disjoint support

means automatic orthogonality, which means `u = 1.000000` against both, which is the one-hot degeneracy the framework's encoding rules warn about. **The reading `f = 35.632544 Hz` for O2 is an artefact of the encoding and not a fact about the operator**, and a section presenting it as the "good" case would be presenting a bug as a result. O3 and O4 are the corrected versions: distinct framings that nonetheless share support with the pair, giving `u` values that are high without being degenerate.

O3 and O4 are the real finding. A genuinely differing operator with overlapping support takes the arrangement from `D = +4.338420` to `+0.229605` before coordination cost and to `−0.158826` in O4's case — **from a 4.34-octave shortfall to the sustainability boundary, by adding one person who does not agree.** Priced at `kappa = 0.055` per link, all four operators leave the arrangement short, which is the correct and deflating answer: adding a third party to a badly-configured dyad is not a repair, and the quadratic growth of coordination cost against logarithmic surplus is why [Brooks, 1975, Conway, 1968].

Two standing clauses bind this table. The first: every `f` here is a RELATIONSHIP frequency and says nothing about the participants' own state frequencies — the framework's operation audit [Curzi, 2026] shows four pairs spanning thousands of cents in state terms returning identical u and f_{rel} to twelve decimal places, because `u` reads the angle and not the occupied indices. Neither reading may be inferred from the other.

The second: these are D readings and D contains no δ. At `delta = 0.09` the O1 arrangement arrives at `Q_inf = −5.528341`; at `delta = 0.05` it arrives at `−9.951014`, and `D` stays at +4.785426 in both. **Report `D` and `delta`.** A reading with only one of them cannot distinguish an arrangement failing slowly from one failing fast, and the deficit is blind to the difference.

The specification

5.17 PROCEDURE ALCH-R — reading a traditional claim as engineering

```
STEP 1   STATE THE CLAIM IN THE TRADITION'S OWN TERMS, without improving it.
         Improving a claim before testing it is how a tradition gets defended
         rather than audited.

STEP 2   IDENTIFY WHAT KIND OF CLAIM IT IS.
            a structural claim  (about the FORM of an arrangement)
            a causal claim      (about what produces what)
            an evidential claim (about what the record establishes)
         Evidential claims go to Section 6 and the survivorship arithmetic.

STEP 3   FIND THE (+1) COLUMN.  What measurement, if any, bears on it? Cite what
         it measured, not what it is popularly taken to show. If there is no
         measurement, say so; the claim is then precedent only and cannot be
         promoted.

STEP 4   FIND THE (−1) COLUMN.  What did the tradition actually record, as
         opposed to what a modern reader would like it to have meant?

STEP 5   STATE EACH COLUMN'S ROLE IN THE BLOCK.  (+1) evidence, (−1) precedent.
         Never implicitly. Every block, every time.

STEP 6   GRADE AGAINST C1, C2, C3.  C2 is the one that fails most often, and it
         fails for a specific reason: circular identification of the stages or
         outcomes (see REJECTION C5.5).

STEP 7   COMPUTE SOMETHING.  A bridge that generates no number has not passed C2.
```

```
            Where the claim touches an index, grade it against V1–V7 as well.

    STEP 8   REPORT THE CEILING COST OF ANY CATEGORY SCHEME ADOPTED.
             c/eta <= ln N, and choosing a small N discards octaves before measurement begins.

    STEP 9   IF THE CLAIM SURVIVES, state what survives and what was stripped.
             If it does not, PUBLISH THE REJECTION with its failing criterion.

    STEP 10  REPORT D AND delta TOGETHER for every arrangement read.
```

5.18 The concordance block template

```
CONCORDANCE C__.__ — [THE CLAIM, IN ONE LINE]

  CLAIM        ..................................................................
  (+1) EVIDENCE       -- this column carries measurement
               source ..............................................................
               WHAT IT MEASURED ....................................................
  (−1) PRECEDENT      -- this column carries independent arrival, not proof
               source ..............................................................
               WHAT IT RECORDS .....................................................
  (0p) INTEGRATION
               ..................................................................
  CRITERIA     C1 PASS/FAIL because ......   C2 PASS/FAIL because ......
               C3 PASS/FAIL because ......
  COMPUTED     ..................................................................
  STATUS       ESTABLISHED / ESTABLISHED WITH THE STATED MECHANISM REJECTED /
               REJECTED (with failing criterion named)
  SPECULATIVE? if yes, the word "speculative" appears in the CLAIM line itself
```

5.19 Gates

```
    G1  ROLES STATED.      Every block names what each column carries. No exceptions.
    G2  NO PROMOTION.      Precedent never appears as evidence, in any sentence.
    G3  SOMETHING COMPUTED. Every established bridge carries a number.
    G4  REJECTIONS PUBLISHED. At least one rejection per concordance set, in print.
    G5  V-GRADING.         Any category scheme adopted is graded against V1–V7.
    G6  CEILING PRICED.    ln N reported for every scheme, and the octaves foregone.
    G7  BOTH READINGS.     D and delta together, always.
    G8  CASES LABELLED.    Every worked case marked CONSTRUCTED.
    G9  INVARIANCE FIRST. Any cadence claim carries the LTI identity before anything else.
```

The failure modes

#	Name	What it looks like	What it actually is	Detection
FM 5.1	Precedent promoted	“Both modern science and the ancients agree”	One column is evidence and one is not	G1, G2

#	Name	What it looks like	What it actually is	Detection
FM 5.2	The naive cadence claim	“Spread it out and it delivers more”	False: integrated totals are identical, 433.3333	§5.9; G9
FM 5.3	Cadence for its own sake	Meeting more often with no clipping and no concavity gain	Below the cap, more occasions buy nothing through the ceiling channel	§5.11: at `N = 12` loss begins only at `P = 8` weeks
FM 5.4	Infinite division	“So we should meet daily, or hourly”	Concavity alone recommends it; per-occasion cost stops it	§5.12: net peaks at `n = 12`
FM 5.5	The saturating session	A twelve-hour offsite	`u` saturates at `L* = 8`; four hours deliver nothing	§5.12 row one
FM 5.6	The circular stage	“It has not blackened, so it is not at that stage”	Unfalsifiable by construction	REJECTION C5.5, criterion C2
FM 5.7	Table as territory	Treating a correspondence table’s contents as measured	The form satisfies V2; the contents fail V1	§5.15
FM 5.8	The small category set	Adopting a four- or seven-fold scheme because it is traditional	3.169925 or 1.555215 octaves of ceiling discarded before measuring	G6
FM 5.9	Numbers without an index	Computing `k n^2` on a scheme that fails V1	Arithmetic without content	§5.15
FM 5.10	The sycophantic operator	A facilitator who reflects the group back to itself	`u = 0` exactly; cost paid, no surplus; -536.4074 cents	§5.16 row O1
FM 5.11	The one-hot operator	An operator whose reading comes out at `u = 1.000000`	Disjoint support, automatic orthogonality, degenerate	§5.16 row O2
FM 5.12	Scale transfer by maxim	“As above so below, so this result carries”	92% mean-field error by `t = 12`; 90.1x clock trap	REJECTION C5.6
FM 5.13	Surrogates instead of design	Adding shuffle controls to fix an operator problem	The shuffle is anti-conservative (2.2x) and blind to timing (52.7%) and shared drivers (98.35%)	the survey work’s control audit; design controls only
FM 5.14	Deficit without `delta`	Reporting an operator’s effect on `D` alone	`D` cannot see decay at all	G7

Three of these deserve more than a row.

FM 5.2 is the reason this section states the invariance before it states anything else. The claim that scheduled practice delivers more is the single most repeated piece of practical folklore in the literature this framework draws on, and it is false in a linear model, by an identity, to every digit. The two true arguments are better than the false one — a steady state instead of a decay, and a factor of 5.7074 from division alone — and they survive scrutiny, which the false one does not.

FM 5.10 is the sharpest thing this section computes and it deserves to be said plainly. The tradition insisted that the operator's state matters. The formalism agrees and adds a number: an operator who mirrors the subject contributes exactly zero surplus and costs a link. The squaring makes it worse still — perfect opposition gives the same $u = 0$ as perfect agreement, so **the contrarian facilitator and the agreeable one sound the identical note, and it is the ground essence.** The useful operator is the one whose framings differ from the subject's *and share support with them*, which is O3 and O4, and which is a design requirement rather than a personality.

FM 5.13 records where the tradition's instinct was right and its method unavailable. "Prepare the operator" is correct; "prepare the operator morally" is not a control. The modern equivalents are blinding, channel separation, prospective sampling and a yoked control, and the framework's survey work measured what happens without them [Curzi, 2026i]: a surrogate suite that passes 52.7% of the time against fabricated timing and 98.35% of the time against a shared slow driver. **More surrogates do not fix an operator problem. Design does.**

Worked examples

5.20 The annual rite against the weekly practice, read in full **CONSTRUCTED.** A group commits to one annual retreat carrying a nominal 26 nats of interaction surplus for the year, against the alternative of a weekly practice carrying 0.5 nats per week for 52 weeks. `N = 12`, `eta = 0.44`, `delta = 0.09` per week, `c = 0.40` per week.

Step 1 — the LTI check, run first, per gate G9. If the response were linear and unclipped, the integrated effect of the two schedules would be identical. §5.9 confirms it at 433.3333 in the reference setup. **No part of the argument below rests on the rite delivering less total input, because it does not.**

Step 2 — the ceiling. `ln 12 = 2.484907` nats per occasion. The weekly burst of 0.5 is far below it. The annual burst of 26.0 is more than ten times it.

Step 3 — delivered surplus.

```
weekly      52 occasions x min(0.5,  2.484907) =  26.0000 nats   ->  eta x = 11.4400
annual       1 occasion  x min(26.0, 2.484907) =   2.4849 nats   ->  eta x =  1.0934

the rite delivers 9.56% of the practice.  Loss to clipping: 90.44%.
```

Step 4 — the steady state. The weekly practice is sustained periodic forcing and holds a level. The rite is an impulse and decays toward zero between occasions; whether it holds anything depends entirely on whether the year's decay is survivable. At `delta = 0.09` per week the half-life is 7.3496 weeks, so **after 52 weeks the fraction of a single impulse remaining is `0.91^52 = 0.007403` — seven-tenths of one per cent.** The next rite starts from essentially nothing.

Step 5 — the concavity check. Independently of the ceiling, §5.12 shows that dividing a fixed budget raises delivered total monotonically, by a factor of 5.7074 across the range tested, until per-occasion cost dominates.

Step 6 — the counter-case, per §5.13. The rite is not absurd; it is a bet on `delta`. It works if the retention half-life is long relative to the interval. The decennial case requires a 5.63-year

trace half-life. **A weekly-scale `delta` of 0.09 gives 7.3496 weeks, short of a year by a factor of about seven**, so the bet loses here — but the bet is stated, and it is checkable.

Step 7 — both readings. For the weekly arrangement at `u = 0.692372881355932`, `eta = 0.44`, `c = 0.40`: `f = 35.8881768941 Hz`, `f_min = 2.9782153324 Hz`, **`D = −3.5909886634` octaves, `delta = 0.09` per week, `Q_inf = +6.0844267427`, half-life 7.3496 weeks.** Both numbers reported.

5.21 The concordance register for this section

#	Claim	(+1) role	(-1) role	C1	C2	C3	Status
C5.1	Staged process with per-stage checks	evidence: Shewhart 1931; Deming 1986	precedent: Zosimos corpus; Newman & Principe 1998; Principe 2013	P	P	P	**ESTABLISHED**
C5.2	Cadence beats intensity	evidence: this work's concavity + ceiling results; Cepeda et al. 2006	precedent: fixed-hour practice; Durkheim 1912; Rappaport 1999	P	P	P	**ESTABLISHED, folklore's reason REJECTED**
C5.3	Correspondence tables are relational graphs	evidence: graph theory; the gcd theorem	precedent: the tables themselves; Yates 1966	P	P	P	**ESTABLISHED as form only**
C5.4	The operator is part of the apparatus	evidence: expectancy effects; tacit knowledge; the control audit; §5.16	precedent: the pure-artisan requirement	P	P	P	**ESTABLISHED, mechanism REJECTED**
C5.5	The colour sequence is a necessary order	—	precedent only	M	**F**	Pa	**REJECTED (C2, circular)**
C5.6	As above so below, as scale invariance	evidence against: three computed disanalogies	precedent: the maxim	Pa	**F**	D	**REJECTED as stated**
C5.1b	This tradition's canonical stage ORDER	evidence against: the ordering elasticities; the operation audit	precedent: a canonical twelve-gate schedule of 1471	P	**F**	D	**REJECTED (order only; staging stands)**

Three of seven rejected, and every rejection is recorded in Appendix D with its failing criterion. The third is the sharpest of them, because it is the framework auditing the tradition on the tradition's own published material: the practice of staging survives and this tradition's canonical order does not.

5.22 What this section establishes, and what Section 6 uses

```
four claims audited and established, each with its columns' roles stated
three claims rejected in print, with the failing criterion named, including the
  canonical stage ORDER (the operation audit against the ordering rule -- staging stands,
  the order does not)
the cadence invariance stated exactly: integrated effect IDENTICAL
                    (433.3333, three schedules)
                    cadence wins by strict concavity and the ln N ceiling clip
                    97.2% loss at N = 8;  90.44% at N = 12 (§5.11)
                    factor 5.7074 from division alone, no ceiling required
staged control priced: 47.83% -> 93.21% yield at d = 0.90
the gcd invariant tabulated for N = 3..12
two classical tables graded against V1–V7 and rejected as indices, retained as form
the operator computed into u: mirroring costs 536.4074 cents and 0.447 octaves
PROCEDURE ALCH-R, the block template, nine gates, fourteen failure modes
```

The pattern across all six blocks is one pattern. **The tradition's practices are frequently right and its explanations of them frequently wrong**, and separating the two requires arithmetic the tradition did not have and could not have had. Staging is right and the colour law is not. Cadence is right and "it delivers more" is not. The tables are the right shape and their

contents are not an index. The operator is part of the apparatus and moral purity is not the mechanism.

That separation is only credible if the same instrument is turned on the tradition's largest claim and allowed to destroy it. **Section 6 does exactly that.** Material transmutation of the elements is dead by an energy-scale argument of six orders of magnitude; the tradition's record is survivorship-filtered and carries a likelihood ratio of exactly 1.000000; secrecy made the errors permanent; no control was ever run. And then Section 6 states what remains, which is everything in this section — and it remains because the audit was real.

6 What the tradition got wrong, computed

Section 5 listed four things the tradition got right and computed each of them. This section is the reason that list can be trusted, and it exists because an account that only audits in one direction is not auditing.

The method is not new here. It is the framework's standing audit template, established against numerical-value schemes and adopted for the whole traditional corpus:

Disprove the strong claim with arithmetic. Preserve what is genuinely there.

That case is the model and is worth restating exactly, because the shape of it governs every section below. The evidential reading of gematria — that two words sharing a numerical value are thereby related — is dead. Measured over 234,454 dictionary words, the English simple-value map yields 305 distinct outputs, destroys 10.47 bits of the 17.84 that identify a word, and collides at a rate of 99.995%; in an 8,000-word corpus against a thousand reachable values the probability that any given word has a value-twin is 0.999666. **A shared value is the default outcome, not a signal.** And the mnemonic reading — a hash that assigns an item to a retrieval bucket — is untouched by any of that, because a hash with a terrible collision rate is still a perfectly good index.

One reading dies by arithmetic; the other stands, undamaged, in the same paragraph. That is what this section does five more times, at larger scale.

The five charges:

```
1  MATERIAL TRANSMUTATION OF THE ELEMENTS by chemical means -- short by six orders
   of magnitude in energy, and the shortfall is computable from first principles

2  THE RECORD IS SURVIVORSHIP-FILTERED -- likelihood ratio exactly 1.000000,
   which means the corpus does not move the posterior AT ALL

3  SECRECY IS AN EPISTEMIC FAILURE MODE -- unshared results cannot be checked,
   so errors persist for centuries, and the persistence is computable

4  THERE WERE NO CONTROLS -- and the control that would have settled the central
   question was the cheapest instrument available in the entire laboratory

5  THE CANONICAL ORDER IS BACKWARDS -- the tradition's own published schedule
   lowers loss before it fixes the numerator, which is exactly the order the
   framework's elasticities show accelerates a failure
```

The law

6.1 Charge one: material transmutation by chemical means The claim is that base metal can be converted into gold by an operation conducted in a furnace with a crucible, an alembic, reagents, and heat.

THE ENERGY-SCALE ARGUMENT. The identity of a chemical element is set by the number of protons in its nucleus. Lead is `Z = 82`. Gold is `Z = 79`. Converting one into the other requires removing three protons from a nucleus. Chemistry does not touch nuclei; it rearranges the outer electrons, and the two operations sit at energies six orders of magnitude apart.

```
a strong single covalent bond              ~  4 eV                 (order of magnitude)
mean nuclear binding energy per nucleon    ~  8 MeV                (order of magnitude)

ratio                                      =  8e6 eV / 4 eV  =  2,000,000
```

Sharper, because it requires no averaging. The Coulomb barrier a single proton must cross to reach a lead-208 nucleus, taking the nuclear radius as `R = 1.2 A^(1/3)` femtometres for each partner and `e^2 = 1.43996454 MeV·fm`:

```
R    =  1.2 * 208^(1/3)  +  1.2 * 1^(1/3)   =  8.3100 fm

E    =  e^2 * Z1 * Z2 / R  =  1.43996454 * 1 * 82 / 8.3100  =  14.2091 MeV
 C

for an alpha particle: R = 9.0149 fm, E  = 26.1961 MeV
                                       C
```

Against that, the thermal energy available in the hottest furnace a pre-industrial workshop could build:

```
kT at 2000 K  =  8.617333262e-5 * 2000  =  0.172347 eV

E  / kT       =  14.2091e6 / 0.172347   =  8.24e7          eighty-two million
 C

temperature required for kT = 14 MeV    =  1.62e11 K
```

THEOREM 6.1 (the arithmetic, not a new result — the barrier is standard nuclear physics and the statement here is only the comparison). A furnace at 2000 K supplies thermal energy 82 million times smaller than the barrier to the least demanding nuclear approach to a lead nucleus. No arrangement of crucibles, reagents, timing, or repetition closes a gap of that size, because nothing in the chemical repertoire operates in the register where the barrier lives. ■

AND NOW THE PART THAT MAKES THIS AN AUDIT RATHER THAN A DISMISSAL. The goal was not incoherent. Transmutation of the elements is real, it happens, and it was demonstrated in the twentieth century. Rutherford (1919) reported the first artificial transmutation, converting nitrogen to oxygen by alpha bombardment. **That paper is not in this paper's bibliographic database and is named without a key.** Gold has been produced from neighbouring elements in accelerator experiments; the bombardment of bismuth-209 with relativistic heavy ions reported by Aleklett, Morrissey, Loveland, McGaughey and Seaborg in *Physical Review C* (1981) yielded gold isotopes among its fragmentation products in vanishing quantities and at enormous cost. **That paper is likewise absent from this paper's bibliographic database and is named without a key.**

So the tradition's objective was achievable and its method was not, and the distance between them is exactly the six orders of magnitude computed above. The error was not in wanting to change one element into another. It was in believing that the operation lived in the same register as distillation. §6.8 prices what accelerator production would actually cost, and the number is the reason nobody does it.

6.2 Charge two: the record is survivorship-filtered **The framework's survivorship result, restated exactly and without softening: under a selection process that publishes successes and discards failures, the likelihood ratio of testimonial evidence is exactly 1.000000.**

A likelihood ratio of 1 does not mean the evidence is weak. It means the evidence does not move the posterior at all — not by a little, not at all — because the selection guarantees that the observed outcome occurs whether or not the practice does anything.

The alchemical record is exactly such a corpus. It preserves accounts of operations that worked. It does not preserve the denominator: the number of practitioners who attempted the same operation, at the same period, and recorded nothing because there was nothing to record. §6.9 computes the table; the structure of the argument is that every hypothesis about the underlying success rate predicts the same observed corpus, once the corpus size is set by how many successes are worth writing down.

The modern statement of the same defect is the selective-publication literature: results are reported conditional on having come out, which is why most published findings in a field with weak power are expected to be false [Ioannidis, 2005], why the same flexibility produces significance at will [Simmons et al., 2011, Gelman and Loken, 2013], and why a large replication programme recovers far less than the original record implies [Open Science Collaboration, 2015]. The precedent for the objection is older than the corpus it demolishes. Cicero's *De Natura Deorum* relates the reply attributed to Diagoras, shown the votive tablets of those who prayed and survived shipwreck: the drowned left no tablets. Wald's work for the Statistical Research Group in 1943 — armour the parts of the returning aircraft with no bullet holes, because aircraft hit there did not return — is the same argument with a number attached. **Neither source is in this paper's bibliographic database; both are named without keys.**

The consequence for Section 5 is structural and is why that section states its columns' roles in every block. The (-1) precedent column is drawn from a survivorship-filtered record. That is precisely why it carries precedent and not evidence, and why no accumulation of it can be promoted. A thousand accounts and one account carry the same weight, and the weight is zero.

6.3 Charge three: secrecy as an epistemic failure mode The tradition concealed its results deliberately, by three distinct mechanisms: restricting transmission to initiates, writing in cover names (*Decknamen*) that mapped many substances onto one word, and omitting steps on purpose.

The epistemic consequence is not that secrets are morally bad. It is arithmetic — and it has an exact analogue in the design literature, where a mechanism whose security depends on the mechanism being secret is held to be badly designed [Kerckhoffs, 1883, Saltzer and Schroeder, 1975], and where publicity is the standard corrective for a practice that cannot otherwise be checked [Brandeis, 1914].

AN UNSHARED RESULT CANNOT BE CHECKED, AND AN UNCHECKED ERROR HAS NO MECHANISM OF REMOVAL. Model it directly. Let an error be caught by any single independent replication with probability `q`, and let `r` independent replications occur per generation. The error survives a generation with probability `(1-q)^r`. At `r = 0` — which is what secrecy enforces — survival is `1.000000` per generation, forever, and the expected time to detection is infinite. §6.11 computes the rest of the table.

The second mechanism is worse, because it corrupts the record even for those inside. A cover name is a many-to-one map from substances to words, which is the same object as gematria's hash and fails in the same way. Its cost is computable as a search: if a recipe has twelve steps and each carries a term with three plausible readings, the number of distinct interpretations is `3^12 = 531,441`, which is **19.019550 bits of specification destroyed** and, at one experimental trial per day, 1,455 years to exhaust by brute force. §6.12 gives the table.

The tradition's secrecy therefore did not merely slow transmission. It removed the only mechanism by which a body of results corrects itself, and it did so at the same time as it made each individual result ambiguous enough to require an infeasible search. Those two failures

compound: an error that cannot be caught, encoded in a document that cannot be read the same way twice.

6.4 Charge four: the absence of controls No control was run. Not a poor control, not an underpowered one — none, as a matter of the period's method, for most of the tradition's history.

This matters most because of a specific and entirely non-fraudulent explanation for the tradition's positive results, which §6.10 computes. Lead ores commonly carry trace gold and silver, and cupellation — the standard fire-assay of the period — is a *concentrating* operation. Process enough auriferous lead and a bead of gold appears at the end. Nothing was transmuted; something was separated.

```
lead containing 1 ppm gold,  10 kg processed   ->   10 mg of gold recovered
lead containing 2 ppm gold,   1 kg processed   ->    2 mg of gold recovered
```

A visible bead is on the order of ten milligrams, which requires one part per million from ten kilograms of lead — an entirely ordinary assay, and indistinguishable from a successful transmutation to anyone who did not assay the starting material. The control that settles it is: assay the starting material. It costs one extra crucible.

The general form of the charge, and it is the one that generalises to this framework's own subject: the tradition ran the treated arm and never ran the untreated one. Bacon's *Novum Organum* (1620) argued for the systematic collection of negative instances. Fisher's *The Design of Experiments* (1935) supplied randomisation and the modern control, and the Medical Research Council's streptomycin trial (1948) is generally taken as the first properly randomised clinical trial. **None of these three is in this paper's bibliographic database; all are named without keys.** The modern standard the argument does rest on — a declared design, fixed before the outcome is seen — is cited [Nosek et al., 2018]. Every one of those postdates the tradition's productive period, which is an explanation and not an excuse — the specific control needed here, weighing the input, required nothing the period lacked.

And a warning that belongs here rather than anywhere else, because a modern reader will reach for the wrong repair. **Adding statistical surrogates to an uncontrolled design does not fix it.** The framework's survey work measured this [Curzi, 2026i]: the shuffled-input control run as ordinarily configured is anti-conservative at 2.2 times nominal alpha (0.108 against 0.05); against fabricated timing the full four-baseline suite passed 52.7% of the time; against a shared slow driver it passed 98.35% of the time. **Design controls — blinding, channel separation, prospective sampling, a yoked control — are the answer, and more surrogates are not.**

6.5 Charge five: the canonical order is backwards The fifth charge is the one this framework is best placed to make, because it audits the tradition on the tradition's own published material using a rule the tradition could not have had.

The framework's operation audit [Curzi, 2026] takes a named, ordered, canonical fifteenth-century schedule of twelve operations and runs it as a schedule under this model, sorting each gate by which parameter it acts on. **The result: the only gate that acts on the numerator sits ninth of twelve.** Eight of the operations that precede it act on retention, containment, and the prevention of loss — which is to say on `delta`.

The framework's ordering rule condemns this [Curzi, 2026q]. `Q_inf = (eta F − c)/delta`. Lowering `delta` divides the numerator by a smaller positive number, which amplifies whatever sign the numerator already has. In an arrangement whose numerator is negative, every operation that lowers loss makes the destination worse, and the canonical sequence spends two-thirds of its length there before it touches the numerator once.

The carried case is the demonstration, and the numbers are the carried case's (CONSTRUCTED):

```
the canonical order -- lower delta first, on the numerator as found

    2a:  eta = 0.30, c = 0.62, u = 0.068734665264634,  eta*F - c = -0.451075
         delta 0.09  ->  Q_inf = -5.0119395464       D = +4.338420
         delta 0.05  ->  Q_inf = -9.0215             D = +4.338420   WORSE

the ordering rule -- fix the numerator first, then lower the loss

    2b:  eta = 0.44, c = 0.40, u = 0.692372881355932,  eta*F - c = +0.547598
         delta 0.09  ->  Q_inf = +6.0844267427       D = -3.5909886634
         delta 0.05  ->  Q_inf = +10.9520            D = -3.5909886634   BETTER
```

The same intervention on `delta` nearly doubles the fixed point in whichever direction the numerator already points, and the deficit does not move in either case — the two-reading rule again, and decay-blindness [Curzi, 2026] behind it.

Two qualifications, both required. First, the assignment of each gate to a parameter is this framework's reading of a fifteenth-century text and not the text's own claim; The operation audit owns the mapping and badges it as an interpretation [Curzi, 2026]. Second, the finding is not that the operations are worthless. Every one of them is a real operation and several are on Section 5's list of things the tradition got right. The finding is about the ORDER, and the order is a claim the text does make explicitly, in a numbered sequence, as the thing that must not be varied.

That is the sharpest available form of what this pair of sections is for. A tradition whose individual practices survive an audit can still have its canonical sequence inverted, and only a formalism that separates the numerator from the loss term can see the difference.

6.6 The audit template, stated as this section's governing rule

Every charge above has the same two-part shape, and the second part is not decoration.

THE STRONG CLAIM	THE ARITHMETIC THAT KILLS IT	WHAT SURVIVES
chemical transmutation of elements	82 million-fold energy gap	staged process control; apparatus; the goal itself, achieved by other means
the record establishes a success rate	LR = 1.000000	the record as a catalogue of operations attempted
secrecy protects a valuable result	no correction mechanism at r = 0; 3^12 readings per 12-step recipe	the recognition that some knowledge is dangerous -- which is a real problem with a different solution
the tradition's positives show efficacy	1 ppm x 10 kg = 10 mg, no transmutation required	the observations themselves, which were often accurate
the canonical sequence must not vary	the only numerator-acting gate is 9th of 12, and that order accelerates a failure	the operations themselves, and the idea that

```
order matters --
it does, and it is
the reverse of this
```

A tradition audited honestly is more usable than one defended, because after the audit it is known which parts may be built on. Section 5's four items are usable precisely because this section exists; without it they would be four claims selected from a corpus by an author who liked them.

6.7 Honesty clauses, restated in place **(1) NO SUPERNATURAL CLAIM.** Nothing in this section or its companion asserts any efficacy of symbol, any physical effect of a figure, or any result not derivable from the formalism.

(2) ESSENCE, NOT RESONANCE. The frequencies in §6.14 are essence frequencies: positions on a logarithmic surplus scale. Nothing is claimed to vibrate. This clause matters more in this section than in most, because a section about a tradition that made material claims must be unmistakable about not making one.

(3) NO CLINICAL CLAIM. The twelve states are not diagnoses; nothing here is a treatment.

(4) ALL CASES CONSTRUCTED. The lineage case of §6.14 and the process cases of §6.8–§6.13 are constructed and labelled. No invented case is presented as an observation.

(5) PRECEDENT IS NOT EVIDENCE, AND §6.2 IS THE PROOF.

(6) BOTH READINGS. Every arrangement read here reports D and δ together. `D` contains no `delta` and cannot see decay.

(7) ORDER-OF-MAGNITUDE FIGURES ARE LABELLED AS SUCH. §6.8's per-gram cost rests on stated assumptions about beam energy and yield, and is presented as a constructed estimate with its assumptions in the table, not as a measurement.

The engineering

6.8 What transmutation actually costs, computed CONSTRUCTED ESTIMATE. Assumptions stated in the table; this is an order-of-magnitude figure and not a measurement of any facility.

One gram of gold-197 contains `6.02214076e23 / 196.966570 = 3.057443e21` atoms. Suppose each successful transmutation event requires a beam particle of energy `E`, and suppose a fraction `epsilon` of beam particles produce the desired product. Then the beam energy required is `3.057443e21 * E / epsilon`. For reference, a one-gigawatt station produces `3.15576e16` joules in a year.

beam energy per event	yield `epsilon`	total energy (J)	in kWh	in GW-station-years
1 GeV	1e-6	4.899e17	1.361e11	**15.52**
1 GeV	1e-9	4.899e20	1.361e14	1.552e4
5 GeV	1e-6	2.449e18	6.804e11	77.61
5 GeV	1e-9	2.449e21	6.804e14	7.761e4

Under the most generous of these assumptions, one gram of gold costs the entire annual output of fifteen one-gigawatt power stations, and under the least generous it costs fifteen thousand of them. The physics permits the transformation; the economics forbids it by a margin that no refinement of technique will close. This is the honest end of the alchemical project: not that it was impossible, but that it was answered, and the answer was that the product costs more than the product is worth by a factor with sixteen digits in front of it.

6.9 The survivorship arithmetic, in full CONSTRUCTED. Suppose the alchemical corpus preserves 500 credible first-person accounts of a successful operation. Let `p` be the probability that a practitioner attempting it succeeds. The number of practitioners required to generate 500 successes is `500/p`:

true success rate `p`	interpretation	practitioners needed for 500 accounts
0.500	the operation works, half succeed	1,000
0.100	it works weakly	5,000
0.010	it works barely	50,000
0.001	it does nothing beyond the base rate	500,000
1e-6	it does nothing at all, and the accounts are misidentifications	500,000,000

Alchemical practice ran across more than a millennium and several linguistic traditions; a practising population in the tens or hundreds of thousands is entirely plausible, and populations of that size are consistent with every row.

```
LIKELIHOOD RATIO between any two rows, given only the numerator:   1.000000
```

Every row predicts the observed corpus equally well, so the corpus carries no information about `p`. And the invariance to corpus size is the part that surprises people:

accounts in the corpus	cumulative likelihood ratio
1	1.000000
100	1.000000
10,000	1.000000
1,000,000	1.000000

Starting from prior odds of 1:99, the posterior odds after a million success accounts are 1:99. The problem is not sample size and cannot be fixed by more of the same, because each further account adds a numerator and no denominator.

What a denominator would have done. Suppose instead that 1,000 attempts had been enrolled before their outcomes were known, and the successes counted:

```
1,000 enrolled,   500 successes:   log LR(p=0.5 vs p=0.001) = +2761.2307
1,000 enrolled,     1 success:     log LR(p=0.5 vs p=0.001) =  −685.2399
```

The same 500 successes, observed with a denominator, carry a likelihood ratio on the order of `1e304` — and observed without one, exactly 1. The entire difference is whether the failures were counted. Enrolment before the outcome is known is a cohort design, it required no instrument the period lacked, and it is the single methodological change that would have converted the tradition's whole record into evidence.

And the companion result, because it sharpens what a claim must do to be testable at all. A prediction specifying only a *direction* was measured at a likelihood ratio of 2.0000; one specifying a *magnitude* at 11.3577 — **a prediction with a number attached is about 5.7 times more evidentially powerful.** The alchemical corpus specifies neither: its claims are unquantified and its record is denominator-free, which are the two independent ways a body of reports can fail to be evidence.

6.10 Where the positive results came from, without anyone lying The survivorship argument explains why the record cannot establish a rate. It does not explain why practitioners saw gold. This does, and it requires no fraud and no error of observation.

CONSTRUCTED, but the metallurgy is standard. Lead ores frequently carry trace gold and silver, and cupellation — heating in a bone-ash vessel so that the lead oxidises and is absorbed, leaving the noble metals behind — concentrates them. It was the period's ordinary assay technique.

gold in the starting lead	mass processed	gold recovered
0.5 ppm	1 kg	0.50 mg
1.0 ppm	1 kg	1.00 mg
1.0 ppm	10 kg	**10.00 mg**
2.0 ppm	10 kg	20.00 mg
5.0 ppm	10 kg	50.00 mg

One part per million in ten kilograms of lead yields a ten-milligram bead — a visible, weighable, demonstrable piece of gold produced from lead by a documented procedure, with no transmutation whatever. The practitioner's observation was correct. The inference was not.

The control that separates the two hypotheses is: **assay the starting material.** Weigh the lead, assay a sample of it, and predict the yield. If the recovered gold equals the assayed content, the operation concentrated; if it exceeds it, something else happened. **The instrument required is a balance, and the tradition had balances.**

This is the sharpest single point in the section and it should be read carefully, because it is not a sneer. **The tradition possessed every physical instrument required to refute its own central claim and did not possess the idea of running the comparison.** The missing thing was not equipment. It was the control.

6.11 How long an error lives when nobody may check it **CONSTRUCTED.** Let an error in a recorded procedure be caught by any single independent replication with probability `q = 0.30`, and let `r` independent replications occur per generation. Survival per generation is `(1−q)^r`.

replications per generation `r`	survival per generation	expected generations to detection	survival after 12 generations
0 (secrecy)	**1.000000**	**infinite**	**1.000000**
1	0.700000	3.3333	0.013841
2	0.490000	1.9608	1.916e-4
3	0.343000	1.5221	2.652e-6
5	0.168070	1.2020	5.080e-10
10	0.028248	1.0291	2.581e-19

Taking a generation as twenty-five years, twelve generations is three hundred years. **A single independent replication per generation reduces an error's three-century survival probability from certainty to 1.38%; five reduce it to five parts in ten billion; zero leaves it at one.** The difference between a tradition that corrects itself and one that does not is the difference between `r = 1` and `r = 0`, and secrecy is precisely the choice of `r = 0`.

The corresponding modern figure is the replication rate a field actually achieves [Open Science Collaboration, 2015, Ioannidis, 2005]: r is not a free parameter, it is a property of how a field is organised.

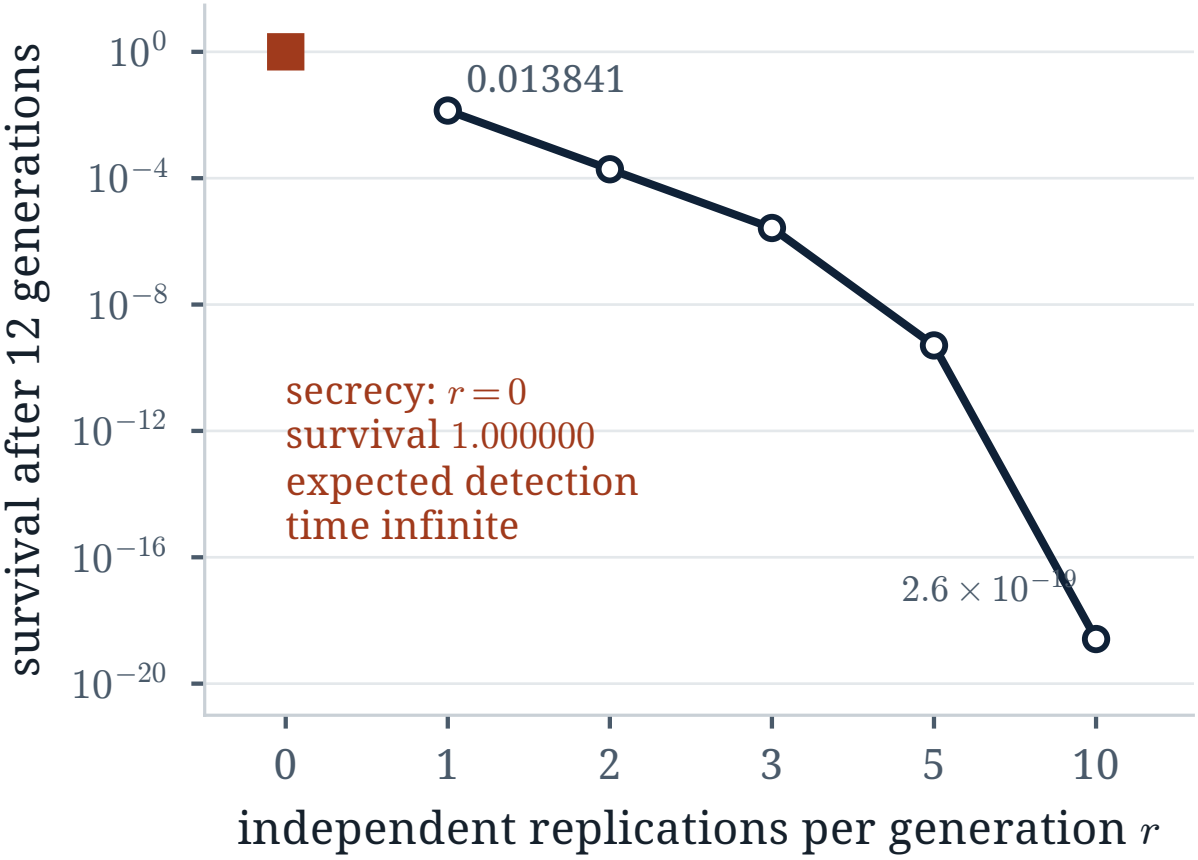

Figure 47.5: **At zero independent replications an error survives every generation with probability 1.000000 and its expected time to detection is infinite; one replication per generation cuts three-century survival to 1.38 per cent.** Modelled with a per-replication detection probability $q = 0.30$ and a generation of twenty-five years; the model is constructed. The $r = 0$ point is plotted apart from the curve because it is a different kind of case — not slow detection but no detection mechanism at all. Built by `figs/src/CCP-047_fig05.py`.

The row that matters is the first one, and its distinguishing feature is not that detection is slow. It is that the expected time to detection is infinite: there is no mechanism, so there is no rate. A body of results maintained in secret does not correct slowly; it does not correct.

6.12 What cover names cost, as a search A *Deckname* is a cover word standing for a substance or an operation, many-to-one by design. The historiography establishing that these were used as deliberate concealment rather than as poetry, and that modern decipherment of specific recipes is possible but laborious, is Newman and Principe's work on the Starkey and Boyle materials and Principe's *The Secrets of Alchemy* (2013).

The cost of the practice is a search cost and it is computable.

steps in the recipe	plausible readings per step	distinct interpretations	bits destroyed
6	2	64	6.00
6	3	729	9.51
12	2	4,096	12.00
12	**3**	**531,441**	**19.02**
12	4	16,777,216	6.00
20	3	3,486,784,401	31.70

At one experimental trial per week, exhausting `3^12` interpretations takes 10,220 years; at one trial per day, 1,455 years.

A twelve-step recipe with a three-way ambiguity at each step is not a difficult document. It is an undecipherable one by brute force, and every successful modern decipherment has proceeded by constraint rather than by search. That is the honest measure of what concealment cost the tradition: not a delay, but a change of category, from a procedure that can be followed to a puzzle that must be solved.

Note the structural identity with the value-map case, which is why this section reads them together. **A cover-name vocabulary and a numerical-value scheme are the same kind of object — a many-to-one map — and both fail for the same reason and survive for the same reason.** The cover name cannot carry a specification, because the map is not invertible. It can carry an index, and it did: it let a practitioner recognise which family of operations a passage was about, which is a mnemonic function and a real one.

6.13 The collision arithmetic, recomputed Because §6.6 makes that case the section's template, the arithmetic is reproduced rather than cited. The quantities below are Shannon information in bits [Shannon, 1948, Cover and Thomas, 2006, Hartley, 1928] — not thermodynamic entropy, and no thermodynamic claim is made anywhere in this paper. The probability that a given word in a corpus of M words shares its value with at least one other, against `R` reachable values, is `1 - (1 - 1/R)^(M-1)`:

corpus `M`	reachable values `R`	P(a given word has a value-twin)
500	400	0.713226
2,000	1,000	0.864665
8,000	**1,000**	**0.999666**
8,000	1,500	0.995177
30,000	1,500	1.000000

And the measured map, on 234,454 dictionary words: 305 distinct values, mean bucket 768.7, largest bucket 2,353 words, 99.995% of words colliding, 10.47 bits destroyed of the 17.84 that identify a word.

One arithmetic note that strengthens the result rather than weakening it. The *uniform* bound on destroyed information is `log2(234454) − log2(305) = 17.8389 − 8.2527 = 9.5863` bits. The measured figure of 10.47 is larger than the uniform bound because the buckets are wildly unequal, and unequal buckets destroy more information than uniform ones. The map is worse than its own worst-case uniform analysis.

The evidential reading is therefore dead by measurement, and the mnemonic reading is untouched by any of it. A retrieval index does not need to be injective. It needs to be reproducible, and it is.

6.14 Secrecy read in this framework's own register The charges above are historical. This one is the framework's, and it is the reason secrecy belongs in a volume about relationship frequency at all.

CONSTRUCTED. Not an observation of any lineage, historical or living. Consider two ways of holding a body of practice, read with the essence bridge and the octave deficit [Curzi, 2026].

A **closed lineage**: one master and one student, where the student's whole training consists of reproducing the master's framings exactly. That is `rho = 1`, hence `u = 0`, hence — because u depends on ρ^2 — the same reading a perfectly opposed pair would get. $F = \ln(1) = 0$ and $f = k = 0.483426$ Hz, the ground essence. **A pair at $u = 0$ has no relationship at all in the surplus sense: two parties in unison are one party paying twice.**

An **open school**: six members whose framings genuinely differ, publishing, so that interaction converts to durable record (`eta` up) and coordination is cheaper per link (`kappa` down).

arrangement	u	F	f (Hz)	eta	c*	c/eta	D (oct)	Q_inf (δ=0.09)
closed lineage, exact reproduction	0.000000	0.000000	**0.483426**	0.30	0.6750	2.250000	**+6.492128**	**-7.500000**
closed lineage, slight drift	0.050000	0.438255	1.161430	0.30	0.6750	2.250000	+5.227591	-6.039150
open school, six, u = 0.30	0.300000	1.458615	8.938542	0.44	0.9200	2.090909	+1.824415	-3.091215
open school, six, u = 0.50	0.500000	1.871802	20.424737	0.44	0.9200	2.090909	+0.632209	-1.071189
open school, six, u = 0.70	0.700000	2.163323	**36.590494**	0.44	0.9200	2.090909	**-0.208942**	**+0.354024**

Every row's `c/eta` is checked against the ceiling `ln 12 = 2.484907` and every row is inside it, so the failures below are real failures and not ceiling breaches.

Four readings.

The closed lineage sits at the ground essence, `f = k`, which is the lowest pitch the formalism admits. It is not a low reading; it is the reading for *no relationship*. A student who reproduces the master exactly contributes no non-parallelism, and the arrangement's surplus is zero by construction.

The swing from the closed lineage to the open school at `u = 0.70` is 7490.44 cents — six and a quarter octaves of pitch — and 6.701070 octaves of deficit, from `+6.492128` to `−0.208942`. That is the difference between an arrangement that cannot be sustained under any refinement and one that accumulates.

The organisational literature reaches the same conclusion by a different route: a system that homogenises itself destroys the variance that produced its advantage [March, 1991], bridging across structural holes has measured returns [Granovetter, 1973, Burt, 1992], and the returns to difference are real but not monotone — creative success rises and then falls with the same variable [Uzzi and Spiro, 2005], short-run effects of surface diversity are frequently negative [Putnam, 2007], the rebuttal literature qualifies rather than reverses that [Abascal and Baldassarri, 2015], and the formal diversity-beats-ability result carries a standing objection that must be cited with it [Hong and Page, 2004, Thompson, 2014, Page, 2007]. Openness is not one lever here; it is three at once, and that is why the swing is so large. It raises `u` because independent practitioners frame differently; it raises `eta` because a published result is stored order and an unpublished one is a memory; and it lowers per-link `c` because a written

record replaces re-explanation. Three of the framework's four levers [Curzi, 2026], moved by a single decision.

A standing clause binds the reading of this table: every `f` in it is a RELATIONSHIP frequency, and a relationship frequency says nothing whatever about the state frequencies of the people in it. The framework's operation audit [Curzi, 2026] established the point by construction — four pairs at lattice positions spanning thousands of cents return identical u and identical f_{rel} to twelve decimal places, because `u` reads the angle between state vectors and not which indices are occupied. The closed lineage reads at `f = k` as a *pair*; the two people in it may hold any states at all, at any pitches, and the pair reading would not move. Neither number may be inferred from the other and a complete report gives both.

And the two-reading rule binds this table as it binds every other. The closed lineage at `delta = 0.09` arrives at `Q_inf = −7.500000`; at `delta = 0.05` it arrives at `−13.500000`; and `D` stays at `+6.492128` in both. **A tradition that responds to decline by deepening loyalty and lengthening apprenticeship is lowering `delta` on a negative numerator, which the ordering rule forbids, and it makes the destination worse while moving the deficit by exactly nothing.** Fix the numerator first: raise `u`, raise `eta`, cut `c`. Publishing does all three.

6.15 What the audit leaves standing

Set against the four charges, here is the full list of what survives, and it is not short:

```
SURVIVES INTACT
  staged process control, with its per-stage check              C5.1, §5.8
  cadence, for the two correct reasons                          C5.2, §5.9–5.12
  correspondence tables as counted partitions (FORM only)       C5.3, §5.14
  the operator as part of the apparatus                         C5.4, §5.16
  the apparatus itself -- alembic, cupel, balance, furnace
  the observations, which were frequently accurate
  the mnemonic reading of every many-to-one map in the corpus   §6.12, §6.13
  the goal of transmutation, achieved by nuclear means          §6.1, §6.8

DOES NOT SURVIVE
  material transmutation by chemical means                      §6.1
  the record as evidence about a rate                           §6.2, §6.9
  secrecy as a defensible epistemic practice                    §6.3, §6.11
  the evidential reading of any correspondence or value scheme  §6.13
  the colour sequence as a law                                  REJECTION C5.5
  "as above, so below" as a transfer licence                    REJECTION C5.6
```

The ratio matters more than either column. Eight items stand and six fall, and the six fell to arithmetic that the eight had to survive as well. That is what makes the eight usable.

The specification

6.16 PROCEDURE AUDIT-1 — auditing a traditional claim's evidential base

```
STEP 1   CLASSIFY THE CLAIM: structural / causal / evidential (ALCH-R step 2).
         This procedure handles the evidential ones.

STEP 2   ASK FOR THE DENOMINATOR. How many attempts were made, counting the ones
         that produced nothing? If the answer is unavailable, stop: the likelihood
         ratio is 1.000000 and the corpus is inert with respect to any rate.
```

STEP 3 ASK WHETHER THE CLAIM SPECIFIES A MAGNITUDE. Direction-only claims carry LR 2.0000; magnitude claims 11.3577. A claim with no number is not yet testable (the direction-versus-magnitude result).

STEP 4 FIND THE INNOCENT EXPLANATION FIRST. Before any exotic mechanism is considered, compute what the mundane one predicts. §6.10's 1 ppm x 10 kg is the model: a full quantitative account of the observation requiring nothing new.

STEP 5 NAME THE CONTROL THAT WOULD SEPARATE THEM, AND PRICE IT. If the control is cheap and was not run, say so plainly. That is the finding.

STEP 6 CHECK THE REGISTER. Does the proposed mechanism operate at the energy, time or information scale the effect requires? §6.1's 8.24e7 ratio is the model. A register mismatch of orders of magnitude ends the inquiry.

STEP 7 CHECK FOR MANY-TO-ONE MAPS. Any correspondence, value scheme or cover vocabulary: compute the collision rate. If collision is the default outcome, the evidential reading is dead and the mnemonic one is not.

STEP 8 CHECK THE CORRECTION MECHANISM. How many independent replications per generation? At r = 0 the expected time to detection is infinite.

STEP 9 DO NOT REPLACE DESIGN CONTROLS WITH SURROGATES. Measured: 2.2x nominal alpha, 52.7% pass against fabricated timing, 98.35% against a shared slow driver.

STEP 10 PUBLISH THE REJECTION, with the failing step named.

STEP 11 STATE WHAT SURVIVES, in the same document. An audit that only subtracts is not an audit; it is a dismissal with arithmetic attached.

STEP 12 REPORT D AND delta TOGETHER for any arrangement read.

6.17 The demotion rule

A claim moves DOWN this ladder when a step of AUDIT-1 fails, and never up without new data of the kind the failed step demanded.

```
  EVIDENCE     measured, with a denominator, falsifiable, replicated
     |
  PRECEDENT    recorded independently; establishes findability, not truth
     |
  MNEMONIC     a reproducible index with no evidential content
     |
  REJECTED     inconsistent with computed arithmetic; published as rejected
```

THE ONE-WAY RULE: a claim demoted for lacking a denominator is not restored by more accounts of the same kind. It is restored only by a cohort design.

6.18 Gates

G1 DENOMINATOR ASKED FOR, and its absence reported where absent.
G2 INNOCENT EXPLANATION COMPUTED before any exotic one is entertained.
G3 CONTROL NAMED AND PRICED.

```
G4  REGISTER CHECKED. Energy, time or information scale compared explicitly.
G5  COLLISION RATE COMPUTED for every many-to-one map.
G6  CORRECTION MECHANISM COUNTED. r replications per generation, stated.
G7  NO SURROGATE SUBSTITUTION for design controls.
G8  SURVIVORS LISTED alongside rejections, in the same document.
G9  ORDER-OF-MAGNITUDE ESTIMATES LABELLED, with assumptions in the table.
G10 BOTH READINGS. D and delta together.
```

The failure modes

#	Name	What it looks like	What it actually is	Detection
FM 6.1	The register error	“Enough heat and pressure and it will convert”	A chemical operation aimed at a nuclear barrier, short by 8.24e7	G4; §6.1
FM 6.2	Testimonial accumulation	“Thousands of accounts cannot all be wrong”	LR = 1.000000 at every corpus size	G1; §6.9
FM 6.3	The missing denominator, modern form	Case studies of successful teams, rooms, practices	Same defect; this framework’s own worked cases are drawn from construction, and say so	G1; every case labelled CONSTRUCTED
FM 6.4	The concentrating operation	A bead of gold at the end of the crucible	1 ppm × 10 kg = 10 mg, separated not created	G2; §6.10
FM 6.5	Secrecy as protection	“The knowledge is too dangerous to publish”	`r = 0`; expected time to error detection is infinite	G6; §6.11
FM 6.6	The unreadable recipe	A twelve-step procedure in cover names	`3^12` = 531,441 readings; 1,455 years at one trial a day	G5; §6.12
FM 6.7	The value coincidence	“These two terms share a value, so they are linked”	P(a twin exists) = 0.999666 in an 8,000-word corpus	G5; §6.13
FM 6.8	Surrogates for design	Adding shuffle controls to an uncontrolled study	2.2× nominal alpha; 52.7% and 98.35% pass rates	G7; the survey work’s control audit
FM 6.9	Direction-only claims	“It will improve things”	LR 2.0000 against 11.3577 with a magnitude	G1; §6.9

#	Name	What it looks like	What it actually is	Detection
FM 6.10	The unison lineage	A student who has perfectly absorbed the master	`u = 0`, `f = k`, `D = +6.492128`	§6.14
FM 6.11	Loyalty as the repair	Deepening commitment in a declining school	Lowers `delta` on a negative numerator	G10; §6.14
FM 6.12	Dismissal mistaken for audit	Publishing only the demolition	The survivors list is half the method	G8; §6.15
FM 6.13	Promotion by antiquity	"It was believed for two thousand years"	Duration of belief is a function of `r`, not of truth	§6.11
FM 6.14	Retro-fitting the mechanism	Explaining a positive result after seeing it	Grounding must be established from the channel, before the outcome	the framework's grounding rule

Four of these need more than a row.

FM 6.3 is the one this framework must apply to itself, and does. The survivorship defect is not peculiar to alchemy; it afflicts any literature assembled from successes, including case studies of well-functioning teams and institutions. This framework's response is structural rather than rhetorical: every worked case throughout the framework is CONSTRUCTED and labelled as constructed, so that no reader can mistake a demonstration for an observation, and the framework's carried commons case is a failure that no single lever repairs. An account that showed only fixable examples would be lying by selection.

FM 6.5 deserves separating from the moral question it usually attracts. There are real reasons to withhold information, and this framework does not claim otherwise. What §6.11 establishes is narrower and harder: withholding removes the correction mechanism, and the cost of that is not a delay but a change of kind. If a body of knowledge must be kept restricted, then the correction mechanism has to be rebuilt inside the restriction — independent replication among those who do hold it — or the errors are permanent. That is a design requirement, not a prohibition.

FM 6.10 and FM 6.11 are the pair that make this section relevant to the rest of the framework. A transmission lineage optimised for fidelity is optimised for `u = 0`. It will feel like the deepest possible relationship — unison is easily mistaken for understanding — and it will read at the ground essence. And the intuitive repair, more commitment, acts on δ, which cannot move the deficit by any amount at all [Curzi, 2026]. **The lineage is not failing because its members are insufficiently devoted. It is failing because they agree.**

FM 6.13 is the failure mode that Section 5 exists to guard against and this section exists to prove. Duration of belief looks like evidence and is not. §6.11 gives the mechanism: at `r = 0` an error survives every generation with probability 1, so a belief's age measures the absence of checking rather than the presence of truth. A two-thousand-year-old error and a two-thousand- year-old truth have identical survival records under secrecy, which is precisely why the survival record cannot distinguish them.

Worked examples

6.19 The transmutation claim, run through AUDIT-1

The claim: that a described chemical procedure converts lead into gold.

```
    STEP 1  CLASSIFY.  Causal and evidential, both. Both are audited.

    STEP 2  DENOMINATOR.  Unavailable. The corpus preserves successes.
            -> LR = 1.000000. The record cannot establish a rate. DEMOTED to PRECEDENT.

    STEP 3  MAGNITUDE?  The claim as recorded specifies no yield per unit of input.
            -> LR 2.0000 at best, and not testable as stated.

    STEP 4  INNOCENT EXPLANATION.  Trace gold in the starting lead, concentrated by
            cupellation.  1 ppm x 10 kg -> 10.00 mg, a visible bead.  Full account of
            the observation with nothing new required.

    STEP 5  THE CONTROL.  Assay the starting material and predict the yield.
            Cost: one crucible and one weighing. AVAILABLE THROUGHOUT. NOT RUN.

    STEP 6  REGISTER.  Chemistry operates on electrons at ~4 eV. The transformation
            requires removing three protons across a Coulomb barrier of 14.2091 MeV.
            kT at 2000 K = 0.172347 eV.  Ratio = 8.24e7.
            -> REGISTER MISMATCH OF EIGHT ORDERS OF MAGNITUDE. Inquiry ends here.

    STEP 7  MANY-TO-ONE MAPS.  The recipe is in Deckname. 12 steps x 3 readings =
            531,441 interpretations; 19.02 bits of specification destroyed.
            -> the document cannot carry a specification.

    STEP 8  CORRECTION MECHANISM.  r = 0 by the tradition's own rule.
            -> expected time to detection: infinite.

    STEP 9  SURROGATES.  None available and none would help.

    STEP 10 REJECTION PUBLISHED.  Failing steps: 2, 4, 5, 6, 7, 8.

    STEP 11 WHAT SURVIVES.  The apparatus; the staging; the observations; the goal,
            which is achievable at 15.52 GW-station-years per gram under the most
            favourable constructed assumptions (§6.8). The claim as stated does not.

CONCORDANCE C6.1 — MATERIAL TRANSMUTATION BY CHEMICAL MEANS

  CLAIM        That a chemical operation converts base metal into gold.

  (+1) EVIDENCE  -- this column carries measurement
               Nuclear physics: elemental identity is proton number; the Coulomb
               barrier for a proton approaching lead-208 is 14.2091 MeV against a
               furnace thermal energy of 0.172347 eV at 2000 K. Transmutation IS
               real by nuclear means -- Rutherford (1919) for the first artificial
               case, and gold among the fragmentation products of relativistic
               heavy-ion bombardment of bismuth-209 reported by Aleklett, Morrissey,
               Loveland, McGaughey and Seaborg in Physical Review C (1981).
               WHAT IT MEASURED: that the transformation is possible and that the
               energy register required is eight orders of magnitude above chemistry.

  (-1) PRECEDENT  -- this column carries independent arrival, not proof
```

```
            The corpus's own accounts of successful projection, and their
            contemporaneous critics -- Boyle's "The Sceptical Chymist" (1661)
            attacked the element schemes from inside the practice, and Lavoisier's
            "Traite elementaire de chimie" (1789) replaced them.
            WHAT IT RECORDS: that the goal was pursued seriously for centuries
            and that the internal critique arrived before the external one.

(0p) INTEGRATION
            The objective was correct and the register was wrong. This is the
            cleanest available instance of a tradition being right about WHAT and
            catastrophically wrong about HOW.

CRITERIA    C1 FAILED -- no shared mechanism; the resemblance is of goal only.
            C2 FAILED -- the claim as recorded specifies no magnitude.
            C3 FAILED -- not usable; the procedure does not do what it says.

STATUS      REJECTED. Third published rejection in this pair of sections, after C5.5 and
            C5.6. Recorded in Appendix D with its failing criteria.
```

6.20 The closed lineage, in report format CONSTRUCTED. Not an observation of any lineage.

```
  ARRANGEMENT READING                                              [CONSTRUCTED]

    ARRANGEMENT    a transmission lineage: one holder, one successor, training
                   defined as exact reproduction of the holder's framings
    PERIOD         one pass = one year

    DESTINATION READING          -- contains no delta
      u = 0.000000     one-hot trap checked: N/A (the vectors are parallel, not
                       disjoint; this is the parallel case, not the degeneracy case)
      F = 0.000000 nats      f = 0.483426 Hz = k, the ground essence
      folded: k transposed by j = 9 -> 247.514 Hz, pitch class 1
      eta = 0.30   c* = 0.6750   c/eta = 2.250000   ceiling ln N = 2.484907  INSIDE
      f_min = 43.516598 Hz
      D = +6.492128 octaves                          DECAYS

    ARRIVAL READING              -- contains no D
      delta = 0.09 per year   half-life 7.3496 years   within 5% at year 32
      Q_inf = -7.500000
      at delta = 0.05:  Q_inf = -13.500000,  D unchanged at +6.492128

    THE FOUR LEVERS, priced against this arrangement
      L1 raise u      the successor frames differently        -> D +6.492128 to
                                                                 -0.208942 at u=0.70
                                                                 with the eta and c
                                                                 changes below
      L2 raise eta    publish, so interaction becomes record  -> part of the same move
      L3 cut c        a written record replaces re-explanation-> part of the same move
      L4 raise N      admit genuinely distinct categories     -> raises the ceiling
      NOT A LEVER: delta -- the deficit contains none. Loyalty, apprenticeship length and
      devotion all act on delta and move D by exactly nothing.

    HONESTY
      essence frequencies, not physical resonances ................. [x]
```

```
no clinical, diagnostic or therapeutic claim ................. [x]
case labelled CONSTRUCTED ................................... [x]
ability to decline preserved ................................ [x]
D and delta both reported ................................... [x]
```

The reading says the lineage cannot be saved by anything its own doctrine recommends, and can be saved by the one thing its own doctrine forbids. That is the whole of Section 6 in a single arrangement: the practice was not wrong about staging, or cadence, or the operator, or the value of a counted category set. It was wrong about secrecy, and secrecy is the parameter that sets `u`.

6.21 The rejection register for this pair of sections

#	Claim	Failing criterion / step	Status
C5.5	The colour sequence is a necessary order	C2 — identification is circular	**REJECTED**
C5.6	"As above, so below" as a transfer licence	C2 — three computed disanalogies	**REJECTED as stated**
C6.1	Material transmutation by chemical means	C1, C2, C3; AUDIT-1 steps 2, 4, 5, 6, 7, 8	**REJECTED**
C6.2	The corpus establishes a success rate	AUDIT-1 step 2 — LR = 1.000000	**REJECTED**
C6.3	Secrecy protects a valuable result	AUDIT-1 step 8 — `r = 0`, infinite detection time	**REJECTED as an epistemic practice**
C6.4	Shared values or correspondences are evidence	AUDIT-1 step 7 — 99.995% collision	**REJECTED; mnemonic reading retained**
C6.5	The canonical gate order must not be varied	the ordering rule — the only numerator-acting gate is ninth of twelve	**REJECTED as an ordering**

Seven rejections across the two sections, every one with its failing criterion named and its arithmetic in print. A method that never rejects is not a method, and a method that rejects without stating what survives is not an audit either.

6.22 What this section establishes, and what follows from it

```
the energy-register argument: 2e6 on bonds, 8.24e7 on the furnace-to-barrier ratio
the honest completion: transmutation is real by nuclear means, at 15.52 GW-station-
  years per gram under the most favourable constructed assumptions
the survivorship result in full: LR = 1.000000, invariant to corpus size;
  with a denominator, ~1e304
direction versus magnitude: LR 2.0000 against 11.3577
the innocent explanation, computed: 1 ppm x 10 kg = 10.00 mg, no transmutation
the control that was never run, priced at one crucible
error persistence under secrecy: r = 0 gives infinite expected detection time
Deckname search cost: 3^12 = 531,441 readings, 19.02 bits, 1,455 years at a trial a day
the value-map arithmetic recomputed, with the unequal-bucket correction
```

```
  (10.47 measured against a 9.5863 uniform bound -- worse than its own
  worst case)
the canonical order inverted: the only numerator-acting gate 9th of 12
the closed lineage read in the framework's own register: u = 0, f = k, D = +6.492128
a relationship frequency says nothing about a state frequency
PROCEDURE AUDIT-1, the demotion ladder, ten gates, fourteen failure modes
seven rejections published with their failing criteria
```

The audit ends with the tradition audited rather than either adopted or dismissed. What it established is that essence alchemy already has an exact formula — the compound rule for combining components [Curzi, 2026] — that transmutation is re-indexing and reaches nothing not already latent, that refinement arrives at a destination fixed before the first pass, and that four of the tradition's practices survive an audit which its largest claim does not.

The companion paper turns to the cellular layer, and it inherits this section's standard without amendment. The no-subliminals constraint is absolute. The open problem — that there is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal — is carried forward unsoftened into the companion paper on the missing transducer [Curzi, 2026], where it is met rather than softened. **The instrument that rejected material transmutation on an energy-register argument is the same instrument that material must survive, and it is pointed the same way.**

7 Results

The eight results below are the units other papers in this corpus cite. A citation to this paper should name one of them. Each carries its status: **DERIVED** where it follows from the stated definitions by algebra, **COMPUTED** where it is the output of exact arithmetic on stated parameters, and **POSTULATED** where it is asserted by this framework.

R1 — the two negative theorems. Refinement cannot move the fixed point, because $Q_\infty = (\eta F - c)/\delta$ contains no iteration count t (§4.4); and the ladder is silent in the frequency register, because f_{rel} is a function of u and N alone, so the pitch, the folded pitch class and the octave deficit are all unmoved by repetition (§4.5). *Status:* DERIVED by inspection. **These are the results this paper most wants read, and both are negative.**

R2 — the contraction as an equality. $|Q_t - Q_\infty| = (1-\delta)^t\,|Q_0 - Q_\infty|$, an equality at every distance and every pass, not a bound. At $\delta = 0.09$: $\tau = 10.6033$ passes, half-life 7.3496, five per cent of the gap remaining at pass 31.76, one per cent at 48.83, one part in a thousand at 73.24. *Status:* DERIVED; the constants COMPUTED. The companion paper states the same contraction with a maximum residual of 2.0624×10^{-15} over a hundred passes [Curzi, 2026].

R3 — what seven repetitions buy. Seven passes close $1-(1-\delta)^7$ of the gap: **48.32 per cent at** $\delta = 0.09$ **and 6.79 per cent at** $\delta = 0.01$**.** Inverting, seven passes close 95 per cent only at $\delta = 0.348164$, 99 per cent at 0.482053 and 99.9 per cent at 0.627241. *Status:* COMPUTED. **The tradition's canonical count is therefore an implicit and checkable claim that its operation loses roughly a third of its stock per cycle.**

R4 — staged process control, priced. A seven-stage process at per-stage defect probability $q = 0.10$, moving from terminal inspection alone to per-stage checking at detection $d = 0.90$, **raises final yield from 47.83 per cent to 93.21 per cent at a cost of 0.63 reworks per unit.** At $d = 0.50$ the yield is 69.83 per cent at 0.350 reworks; at $d = 0.99$ it is 99.30 per cent at 0.693. *Status:* COMPUTED on a stated defect model; the empirical warrant is the statistical-process-control literature, two of whose founding works are absent from this paper's bibliography and are named without keys (§5.2).

R5 — the cadence result. The integrated effect of one impulse and of the same total delivered periodically is **identical to every digit: 433.3333 in all three schedules**, maximum pairwise difference 3.41×10^{-13}. Cadence therefore does not deliver more. What it delivers is a steady state instead of a decay, and freedom from the surplus ceiling: at $N = 12$ an annual occasion carrying a nominal 26 nats delivers **2.4849 after the** $\ln 12$ **ceiling clips it, 9.56 per cent**

of the weekly practice, with 90.44 per cent lost to clipping, and $0.91^{52} = 0.007403$ of one impulse surviving the year. Division alone, with no ceiling involved, raises delivered total by a factor of 5.7074 across the range tested. *Status:* COMPUTED; the concavity theorem DERIVED elsewhere [Curzi, 2026v].

R6 — the secrecy arithmetic. With an error caught by any single independent replication with probability $q = 0.30$, survival per generation is $(1-q)^r$. **At $r = 0$ survival is 1.000000 per generation, indefinitely, and the expected time to detection is infinite**; at $r = 1$ survival after twelve generations — three hundred years — is 0.013841; at $r = 5$ it is 5.080×10^{-10}. *Status:* COMPUTED. **The distinguishing feature of the first row is not that detection is slow but that there is no mechanism, so there is no rate.**

R7 — the survivorship arithmetic. Five hundred credible first-person accounts require 1,000 practitioners at $p = 0.5$ and 500,000,000 at $p = 10^{-6}$. Every hypothesis about the underlying rate predicts the same observed corpus, so **the likelihood ratio is exactly 1.000000 and is invariant to corpus size** — one account and a million accounts carry the same weight, and the weight is zero. With a denominator, the same 500 successes out of 1,000 enrolled carry a log likelihood ratio of $+2761.2307$ against $p = 0.001$. A direction-only prediction carries a likelihood ratio of 2.0000 against 11.3577 for one specifying a magnitude. *Status:* COMPUTED.

R8 — transmutation priced. One gram of gold-197 is 3.057443×10^{21} atoms; at 1 GeV per event and yield 10^{-6} the beam energy required is 4.899×10^{17} J, **15.52 gigawatt-station-years**, rising to 1.552×10^{4} at yield 10^{-9}. The register argument that closes the chemical route is the ratio of the Coulomb barrier for a proton approaching lead-208, 14.2091 MeV, to the thermal energy of a 2000 K furnace, 0.172347 eV: 8.24×10^{7}**.** *Status:* COMPUTED as a constructed order-of-magnitude estimate with its assumptions in the table; the underlying nuclear physics is standard but **the two primary sources for artificial transmutation are absent from this paper's bibliography and are named without keys** (§6.1).

CR — counter-result. Repetition buys arrival time and nothing else: it cannot move the destination and it cannot move the pitch. The tradition's canonical seven passes close under half the gap at this framework's own working decay rate, and its canonical operation order is inverted with respect to the framework's ordering rule — the only numerator-acting operation sits ninth of twelve [Curzi, 2026]. Separately, **an apparent improvement can be an exact transfer**: cost export leaves the sum of drives invariant at $+0.643688$ to every digit while the exporter's own deficit improves by nearly an octave and a third, and the disadvantaged party's stock does not cross zero until pass 10.850479. The framework's own survey work reaches a structurally parallel conclusion about instruments that cannot see what they are not measuring [Curzi, 2026i], where a shuffled-input control passed 98.35 per cent of the time against a third variable driving both interaction and order while detecting only 48.17 per cent in the clean case.

8 Discussion

8.1 What follows

The separation of rate from destination is the paper's usable finding. A report that gives one number is incomplete, and which number is missing changes the error. A reader with only the deficit concludes that a decay-only intervention did nothing; a reader with only the half-life concludes that the practice became more patient; a reader with the fixed point sees the damage. On the carried constructed case, moving δ from 0.09 to 0.05 takes Q_∞ from -5.0119 to -9.0215, makes the ladder 84 per cent slower, and moves D by exactly nothing. **Three readings, three stories, one intervention.**

The seven-passes result generalises past this tradition. Any prescription of a fixed number of repetitions is an implicit claim about a loss rate, and naming the rate makes the prescription testable. That is the useful form of the finding and it is why H3 is stated as a hypothesis rather than as a conclusion: the framework can compute what δ the count implies, and only measurement can say whether the process has it.

The counterfeit-arrival result is the sharpest practical one, and its danger is a lag. The export check catches the transfer on the first pass; the disadvantaged party's *stock* does not reveal it for eleven. A protocol that monitors stocks rather than drives therefore finds the problem after it has become a fact. The structure is an externality in the ordinary sense [Hardin, 1968, Ostrom, 1990], and the remaining option is exit [Hirschman, 1970], which is why the framework's consent law makes the ability to decline structural rather than advisory [Curzi, 2026].

The institutional analogue is instructive and is computed elsewhere in this corpus. Moving η from 0.35 to 0.55 and δ from 0.25 to 0.12 takes a fixed point from 0.2653 to 3.9281, while a turnover event still costs 70 per cent of stock against 15 [Curzi, 2026h]. The same two readings, in an operational setting, disagreeing in the same way.

8.2 What does not follow

A slow ladder is not a patient one and a fast ladder is not a good one. δ is a loss term and the destination is divided by it. A practice that visibly changes a system quickly is a practice with a large δ, and the visible rapidity is the signature of a leaky system reaching its level — which may be any level at all.

The audit does not license the tradition. Four practices survive and five claims do not, and the four are usable *because* the five were computed to destruction rather than omitted. A list of things a tradition got right, published alone, is an advertisement.

Nothing here is clinical, diagnostic or therapeutic. The twelve component classes are not diagnoses, a refinement ladder is not a treatment, and no reading in this paper describes or prescribes for any person's condition.

Nothing here resonates. Every frequency is a position on a logarithmic surplus scale. The glide of §4.13 is a bookkeeping transform of a stored quantity and is badged as a constructed reading wherever it appears.

8.3 What the surrounding programme allows this paper to claim

The corpus's title places this work in a lineage that begins with *physique sociale* [Quetelet, 1835] and continues through the modern computational programme [Lazer et al., 2009, Pentland, 2014]. **The lineage's characteristic error is Quetelet's** — treating the mean of a distribution as a type rather than as a statistic — and this paper inherits the risk directly, because it writes a single u, η and c for an arrangement.

Three constraints from that programme bear on this paper's central object. First, human activity is bursty, with heavy-tailed waiting times and **no characteristic time scale** [Barabási, 2005]; a per-pass decay rate is a claim about a characteristic scale and can only answer that finding by insisting that its pass is a declared cycle rather than an observed rhythm, which is why declaring the period is a gate. Second, an explanation should name a mechanism rather than exhibit a fitted curve [Hedström and Ylikoski, 2010]; this paper fits nothing, which sidesteps the objection at the cost of having no empirical content to fit. Third, and most sharply: **what observation would distinguish this framework's laws from a neighbouring model that fits equally well?** [Sobkowicz, 2020, Durlauf, 2005] The honest answer is H3 — a tradition's repetition count implies a loss rate, and the loss rate is measurable — and nothing else in this paper answers it.

What the paper is entitled to claim is therefore narrow. Prediction is one of many legitimate reasons to build a model, and explanation, bounding and the disciplined exposure of one's own assumptions are others [Epstein, 2008]. The position this work is best placed to defend is the analytical one: mechanisms stated explicitly, parameters declared, and the arrangement within which the law is claimed named in advance [Keuschnigg et al., 2018].

8.4 What the wider corpus says this paper may not claim

Three papers in this corpus bound what an audit of this kind establishes, and they are cited here because they cut against the reading a sympathetic reader would give.

The assembled-architecture paper records that the only reading under which its architecture clears its own build threshold is the naive one assuming zero correlation between coordinating jurisdictions — $h = +0.083099$ — and that **every defensible bloc assignment returns a negative surplus**, which it prints [Curzi, 2026]. The failure-record paper is entirely a counter-result: disclosure did not confer immunity in the strongest available test case, its own backing basket is 4.61 times less diversified than its component count claims, the terminal phase of its own programme is a 0.090 option rather than a plan, and a levy presented as a costless accounting correction in fact reallocates burden [Curzi, 2026]. And the correlated- jurisdictions paper shows what a count that is not a count of independent things is worth: four entities at shares 40.91, 27.27, 18.18 and 13.64 per cent give a naive 3.4085 effective jurisdictions and a bloc-collapsed 1.0000 — **a 3.41-fold overstatement** [Curzi, 2026].

All three say the same thing to this paper. Four surviving practices are four practices, not a vindicated tradition; and a well-behaved arithmetic on constructed parameters bounds nothing about the world.

9 Verification

This section decomposes the paper's results into atomic steps, each checkable on its own. The standard is Occam's: **a postulate that can be dropped without the result changing has been dropped.** Every step carries one of four statuses — **ARITHMETIC** (reproducible with a calculator from the inputs named), **DEFINITION** (true by stipulation), **CITED** (an external source supports it, named), or **POSTULATED** (asserted by this framework, no external support).

9.1 The postulates

	postulate	status
P1	For $0 < \delta \leq 1$, $Q_{t+1} = (1-\delta)Q_t + b$ with b constant.	CITED as a form [Oppenheim et al., 1996, Elaydi, 2005]; the *interpretation* POSTULATED
P2	A contraction of modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start.	CITED [Banach, 1922]
P3	$F = \ln(1 + (N-1)u)$, hence $F \leq \ln N$.	DEFINITION given P6
P4	$f_{\text{rel}} = k(1 + (N-1)u)^2$, the relationship form of the essence bridge.	POSTULATED (given P7, P8)
P5	The Pythagorean whole tone is the frequency ratio $9{:}8$.	CITED [Barbour, 1951]
P6	$N_{\text{eff}} = 1 + (N-1)u$, the affine count axiom.	POSTULATED — design axiom; **not a Hill number** [Hill, 1973]
P7	φ is the positive root of $x^2 = x + 1$, so $\varphi^2 = \varphi + 1$.	CITED [Euclid, 1956, Vajda, 1989]

	postulate	status
P8	A dimensionless ratio of the form $(9/8)^2/\varphi^2$ **is a frequency in hertz.**	POSTULATED — no source
P9	A stage introduces a defect with probability q, independently across stages; a check detects it with probability d.	DEFINITION (a stated model)
P10	Under success-only preservation, an observed corpus of successes is generated by an unknown number of attempts.	DEFINITION of the selection process
P11	Elemental identity is proton number, and the Coulomb barrier for a proton approaching lead-208 is $e^2 Z_1 Z_2 / R$.	CITED as standard nuclear physics; **the primary sources are absent from this bibliography**

Dropped as unnecessary. No postulate about the *ordering* of the twelve component classes is needed for R1–R8. No postulate about consonance is needed anywhere. P4, P5, P7 and P8 are needed only for the frequency-register statements (R1's second half, and the glide); **R2, R3, R4, R5, R6, R7 and R8 survive their deletion entirely**, and that separation is the point of §9.3.

9.2 The compounding chain

step	consumes	produces	status
L1	P1	$Q_\infty = b/\delta$ by setting $Q_{t+1} = Q_t$	ARITHMETIC
L2	P1, L1	subtracting, $Q_{t+1} - Q_\infty = (1-\delta)(Q_t - Q_\infty)$; iterate	ARITHMETIC
L3	L2	$\lvert Q_t - Q_\infty \rvert = (1-\delta)^t \lvert Q_0 - Q_\infty \rvert$ — **R2**	ARITHMETIC
L4	L1 by inspection	Q_∞ contains no t — **R1**, first half	ARITHMETIC
L5	L3	$\tau = -1/\ln(1-\delta)$; at $\delta = 0.09$, $\tau = 10.6033$, half-life $\ln 0.5 / \ln 0.91 = 7.3496$	ARITHMETIC
L6	L3	$(1-0.09)^7 = 0.516761$, so seven passes close 48.32% — **R3**	ARITHMETIC
L7	L6 inverted	$\delta = 1 - 0.05^{1/7} = 0.348164$ for 95% in seven — **R3**	ARITHMETIC

step	consumes	produces	status
L8	P5, P7	$(9/8)^2 = 1.265625$; $\varphi^2 = 2.618033988749895$	ARITHMETIC
L9	L8	$k = 0.483425732988414$	ARITHMETIC (exact)
L10	L9, **P8**	k carries the unit Hz	**POSTULATED**
L11	L10, **P4**, P3	$f_{\text{rel}} = k(1 + (N-1)u)^2$, a function of u, N only	**POSTULATED**
L12	L11 by inspection	f_{rel} contains no t — **R1**, second half	ARITHMETIC given L11
L13	L3, Def. 5	$\lvert D_t - D\rvert = (1-\delta)^t \lvert D_0 - D\rvert$; the glide spans $\lvert D\rvert$ octaves	ARITHMETIC (value); **POSTULATED** (meaning)
L14	P1, two parties, transfer x	$\sum_i b_i$ invariant; the plain sum of fixed points moves by $1/\delta_P - 1/\delta_R$ — **CR**	ARITHMETIC

9.3 What this chain is and is not

Read the status column. L1–L9 and L12–L25 are arithmetic and a reader can redo every one of them. L10, L11 and the *meaning* half of L13 are postulated. **A chain containing postulated steps is not a proof of its conclusion**, and this one is not offered as one.

What it is offered as is a separation, and the separation is unusually clean here. **The frequency register carries exactly one of this paper's eight results and no part of any other.** A reader who rejects P4 and P8 — who declines to accept that a dimensionless ratio is a frequency or that the essence bridge holds — loses the second half of R1 and the glide of §4.13, and keeps R2, R3, R4, R5, R6, R7, R8 and the whole counter-result untouched. The negative theorem about the *fixed point* does not need the bridge at all; only the negative theorem about the *pitch* does. That is the honest statement of what the frequency register buys in this paper, and it is less than the notation suggests.

Two statuses that must not be misread. The exponent 2 in the essence law is **DEFINED**, not estimated: no fit was performed and the standard procedure for testing a scaling claim [Clauset et al., 2009] was not run. And **the arithmetic of §5 and §6 is not evidence about the tradition's efficacy** — L20 proves precisely that it cannot be, whichever way it comes out.

The verification instance. Where the source supplied a worked numerical case it is used unchanged. The smallest instance exercising the whole of L1–L7 is the carried constructed dyad at $u = 0.692372881355932$, $\eta = 0.44$, $c = 0.40$, $\delta = 0.09$, $N = 12$: $F = 2.153633$, $b = 0.547598406839$, $Q_\infty = +6.0844267427$, cross-checked against $-D\eta/(2.885390\,\delta)$ to 10^{-12}, half-life 7.3496, and seven passes reaching $Q_7 = 2.940232$, which is 48.32 per cent of 6.0844267427. Three multiplications and a logarithm.

10 Limitations

Every check the governing rigour standard specifies is listed here by name, whether or not this paper passes it.

L-1. The dimensional audit does not close. $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, and k is a ratio of two dimensionless quantities. **No operational procedure is supplied by which the constant acquires the dimension of frequency.** The hertz is attached by assertion (§2.3 P-a, §3.4).

L-2. The essence law has no external support. A quadratic relation between a dimensionless count and a frequency has no established analogue. It is badged a postulate; the badge is the honest position and is not a defence.

L-3. The constant is chosen. $k = (9/8)^2/\varphi^2$ combines two real objects into a product with no precedent. It is quoted to fifteen significant figures **because it is defined**, not because anything was measured to that precision, and the deflationary literature on golden-section claims is cited rather than avoided [Markowsky, 1992, Fischler, 1981].

L-4. Octave reduction beyond pitch is unwarranted. Shepard grounds octave equivalence for pitch [Shepard, 1982]; nothing grounds folding a non-acoustic quantity into a 220–440 Hz band and reading meaning from where it lands.

L-5. $N_{\text{eff}} = 1 + (N-1)u$ **is not a Hill number.** It is a linear interpolation between 1 and N and appears in no ecological, economic or information-theoretic literature. The Hill-number results [Hill, 1973, Jost, 2006] apply to $1/\text{HHI}$ and $\exp(H)$ and to nothing else.

L-6. Conjoint measurement was not tested, and scalar reduction is the general form of the problem. Michell's objection [Michell, 1997] stands unanswered for u, η, c and δ, and the

remedies [Luce and Tukey, 1964, Rasch, 1960] were not run. The same objection arrives from the affect literature in a different domain: emotions are individuated by the pattern across independently varying appraisal dimensions [Smith and Ellsworth, 1985], by a synchronisation process in time [Scherer, 2001], and by qualitative core relational theme [Lazarus, 1991] — none of which a scalar carries, and the last of which denies that differing by *what* licenses ordering by *how many*. Action readiness in particular is constitutive of emotion as such rather than a top rung [Frijda, 1986]. **This is one objection, not two**, and §3.5 names it once. Everything entering through u inherits it.

L-7. δ is the hardest parameter to estimate and every rate figure in the paper depends on it. No instrument is supplied here and none was run. The convergence table, the seven- passes result and the stopping rule are all exactly as defensible as an unmeasured decay rate, which is to say: not at all, as measurements. They are exact as arithmetic on a declared parameter.

L-8. Every case is constructed. The carried dyad, the two-party export case, the seven-stage process, the cadence schedules, the closed lineage and the survivorship corpus are chosen parameter sets. Their precision is exact because the parameters are exact; **that precision does not transfer to a measured case.**

L-9. Two founding works of statistical process control are not in this paper's bibliography. Shewhart (1931) and Deming (1986) are the empirical warrant for C5.1 and are named in §5.2 without keys, because `bib/external.bib` contains no entry for either. The available operations-management literature covers the yield-and-rework structure but not the historical claim. **R4's arithmetic is this paper's; its empirical standing rests on works this paper cannot cite.**

L-10. The spacing-effect literature is not in this paper's bibliography either. Ebbinghaus (1885), Cepeda et al. (2006) and Roediger and Karpicke (2006) are named in §5.3 without keys. **No claim in this paper rests on them**, and §5.3 states explicitly that the spacing effect and the concavity theorem are different claims that must not be presented as mutual confirmation.

L-11. The nuclear-physics primary sources are not in this paper's bibliography. Rutherford (1919) and Aleklett et al. (1981) are named in §6.1 without keys. The Coulomb-barrier arithmetic is standard and reproducible from the constants given; the historical attributions are not citable here.

L-12. Wald, Bacon, Fisher, the MRC streptomycin trial, Polanyi, Collins, Durkheim, Rappaport and Yates are likewise named without keys. Each is named for precedent rather than for support, and the modern standard the argument does rest on is cited [Nosek et al., 2018, Open Science Collaboration, 2015].

L-13. The parameter assignment of the historical schedule is an interpretation. §6.5's order-inversion result depends on sorting each of twelve named operations by which parameter it acts on, and that sorting is this framework's reading of a fifteenth-century text [Curzi, 2026], badged as an interpretation there and here. **A different defensible sorting could weaken or reverse the finding**, and no independent coder has been asked to reproduce it.

L-14. No model comparison was performed. No out-of-sample test, no matched null with the same number of free parameters and no information criterion is reported, because nothing was fitted. Where the corpus has attempted a confirmatory fit elsewhere it failed its own baseline test [Curzi, 2026i], and that is the relevant precedent.

L-15. No statistical claims are made and none are supported. There are no p-values, effect sizes or confidence intervals in this paper, because there is no sample. The likelihood ratios of §6.9 are computed from a stated selection model, not estimated from data.

L-16. The exponent is defined, not estimated. The exponent 2 in $f(n) = kn^2$ was not fitted and the standard fitting-and-testing procedure for a scaling claim [Clauset et al., 2009] was not run. **This paper makes no empirical scaling claim.** The geometric decay $(1-\delta)^t$ is likewise a consequence of the model's linearity and not an estimated rate.

L-17. The functional form of the surplus is underdetermined. A sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as the logarithm [Stumpf and Porter, 2012], and nothing in this paper discriminates among them.

The clipping result of R5 depends on the ceiling $\ln N$, which is a property of the logarithmic form specifically; **under a power-law surplus the 9.56 per cent figure would change.**

L-18. The reflexive specification is not identified. Stated in §3.6 and repeated here: the endogenous social effect in a linear-in-means reflexive loop cannot be recovered from observational data [Manski, 1993, Shalizi and Thomas, 2011]. The remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001], and the claim is accordingly a modelling position rather than an identified result.

L-19. The framework exempts its own parameters from its own reflexivity. If subjects change when modelled, δ, η and u are not structural [Lucas, 1976, Hacking, 1995]. This is not resolved. It bears directly on this paper: **publishing a destination reading may change the arrangement it reads**, and the effect, while real, is probably smaller than the framework's rhetoric implies [Jussim and Harber, 2005].

L-20. Boundary behaviour is only partly examined. $\delta \to 0$ is examined and is a pathology (§4 FM 4.13, and Curzi, 2026a); $\delta \to 1$ makes the ladder arrive in one pass and the fixed point equal the drive, which is examined implicitly and stated nowhere in the source; $\eta \to 0$ makes c/η diverge and places every arrangement above every ceiling, which is a real constraint on the model's domain and **is not examined in the source**; $u \to 0$ is examined and gives the ground essence; $N \to \infty$ raises the ceiling without bound, which the coordination-cost literature says is not available in practice [Brooks, 1975]. These limits constrain the domain and are stated here because the source does not state them all.

L-21. Ergodicity is assumed and not argued. Q accumulates over time for one arrangement from parameters that would naturally be estimated across arrangements; the time and ensemble averages of a multiplicative process are not the same [Peters, 2019].

L-22. Agreement is not correctness. Nothing in §5 measures validity. The concordance method measures independent arrival, and independent arrival establishes findability, not truth. The distinction between reliability and validity is old and is not repaired by more agreement [Cronbach and Meehl, 1955, Campbell and Fiske, 1959].

L-23. u is symmetric and psychological similarity is not. Similarity judgments are asymmetric and violate the triangle inequality [Tversky, 1977]; if u is read as a similarity measure over people it cannot assume metric behaviour, and this framework's u does.

L-24. The one-hot artefact is real and is reported rather than removed. In §5.16 an operator whose state vector has disjoint support from the pair's returns $u = 1.000000$ against both by construction. **That reading is an artefact of the encoding and not a fact about the operator**, and it is kept in the table with the artefact labelled because removing it would hide a failure mode the framework's users will meet.

A discrepancy found in the source and left standing

The source states the counterfeit-arrival identity twice, and the two statements are not equivalent. It first states the invariant as the **sum of participants' fixed points**, which is correct only when every participant carries the same decay rate; the general invariant is the **sum of drives**. The source's own worked case happens to satisfy the equal-δ condition, so the error is invisible there. **§4.15a computes the case that separates them**: with $\delta_P = 0.06$ and $\delta_R = 0.16$, the sum of drives holds at $+0.643688$ while the plain sum *rises* from $+9.727202$ to $+11.810535$, by $1/0.06 - 1/0.16 = 10.416667$ per unit exported. **The naive test does not merely fail to detect the export; it reports a gain, and it reports one precisely when cost is pushed onto whoever decays faster.** The correction is printed in place in §4.15 rather than applied silently, and it is recorded here because a reader working from the earlier formulation would get the export check backwards.

A second, smaller discrepancy. The source writes the octave conversion constant as 2.885390 inside formulae and as 2.885390081777927 when quoting it exactly. Every computed figure in this paper uses the exact value $2/\ln 2$; the six-figure form is a shorthand.

11 Conclusion

What is established. Under the framework's storage law, iteration closes a fixed *proportion* of the remaining gap at every pass, and the closure is an equality rather than a bound: $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$. **Refinement cannot move the fixed point**, because $Q_\infty = (\eta F - c)/\delta$ contains no iteration count, and **the ladder is silent in the frequency register**, because f_{rel} is a function of u and N alone. What repetition buys is arrival time only, and arrival time is a function of the decay rate and of nothing else. **At $\delta = 0.09$ the half-life is 7.3496 passes and 99 per cent closure takes 48.83, so the tradition's canonical seven passes close 48.32 per cent of the gap — and only 6.79 per cent at $\delta = 0.01$. Seven passes would close 95 per cent only at $\delta = 0.348164$.** Applied to a decaying arrangement the same ladder converges at exactly the same speed on $Q_\infty = -5.01$ instead of $+6.08$.

The audit's numbers, in the form other papers cite them. Staged process control is priced: a seven-stage process at $q = 0.10$, moving from terminal inspection to per-stage checking at $d = 0.90$, raises final yield from 47.83 per cent to 93.21 per cent at 0.63 reworks per unit. Cadence is priced: an annual occasion carrying a nominal 26 nats delivers 2.4849 after the $\ln 12$ ceiling clips it — 9.56 per cent of a weekly practice, 90.44 per cent lost to clipping — and $0.91^{52} = 0.007403$ of one impulse survives the year. Secrecy is priced: at zero independent replications per generation an error survives with probability 1.000000 indefinitely, against 0.013841 after twelve generations at one replication. The record is priced: 500 credible accounts require 1,000 practitioners at $p = 0.5$ and 500,000,000 at $p = 10^{-6}$, so the likelihood ratio is exactly 1.000000 at every corpus size. And transmutation is priced: one gram of gold-197 requires 15.52 gigawatt-station-years at 1 GeV and yield 10^{-6}, and 1.552×10^4 at yield 10^{-9}.

What is proposed rather than shown. That a dimensionless ratio of a tuning interval to the square of the golden section is a frequency; that the relationship pitch is $k(1 + (N-1)u)^2$; and that octave equivalence may be carried from pitch to a quantity that is not a pitch. **These are postulates of this framework with no external support**, they are labelled as such at every appearance, and **seven of this paper's eight results survive their deletion entirely.**

What is not claimed at all. No person, pair, substance or institution is claimed to resonate at any frequency named here. The component classes are not diagnoses and no reading in this paper is clinical, diagnostic, therapeutic or prognostic. Four traditional practices survive an audit; that is four practices, and not a vindication of the tradition that carried them.

12 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number in the paper is the output of exact arithmetic on parameters stated in the text; every case is constructed and is labelled as constructed at the point of use. The figures are generated by the Python scripts named in their captions, which take their inputs from the tables in the text and are available from the author on request. **No empirical measurement of any human being, any relation, any institution or any physical process underlies any figure, table or number in this paper.**

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The constructed dyad, the constructed two-party arrangement and the constructed lineage are invented parameter sets; they are not derived from, and do not describe, any person. **This paper asserts perceptual claims — that magnitude estimation delivers ratio-scaled intensities, that octave equivalence is a usable structure beyond pitch, and that interval arithmetic in cents is the correct apparatus — without any perceptual experiment behind them.** Those claims rest entirely on the cited literature, are limited by that literature's own boundaries (§2.4), and are listed among this paper's limitations (L-4, L-6). No listener was asked anything.

Preregistration. No test in this paper was preregistered, because no test was run. H3, the one genuinely empirical hypothesis, is stated here with its falsifier so that it can be preregistered by whoever runs it.

Historical and archival claims. The historical material in §5 and §6 is drawn from secondary literature, several key items of which are absent from this paper's bibliographic database and are named in the text without citation keys (L-9 through L-12). **No archival research was conducted and no primary source was consulted for this paper.**

Clinical disclaimer. The twelve component classes are not diagnostic categories. Nothing in this paper is an assessment, a screening instrument, a treatment or advice about any person's health, and nothing in it may be presented as such.

Chapter 48

A Disclosed Sonification Protocol for Sequence-Encoded Content, and the Missing Transducer That Makes It a Research Design and Not a Technique

Abstract. We specify, end to end, a deterministic pipeline that encodes text as bits, bits as nucleotides at one bit per base, adds a routing header, sonifies by the essence law $f = kn^2$, transposes, and renders inside the Gabor bound — and then state that no mechanism is known by which a cell could read it. Two design results are proved. Assigning symbol indices $n = 1, 2, 3, 4$ collapses three of four symbols onto one pitch class, because $(2n)^2 = 4n^2$; the odd assignment $n = 1, 3, 5, 7$ gives four distinct classes whose closest pair in hertz is 990.055901 Hz apart and whose closest pair as an interval is 1165.0244 cents apart, with a Gabor floor of 0.080377 ms. The state layer's binding separation is the $50/49$, 34.9756-cent minimum at $N = 12$, giving $\Delta t \geq 10.2882$ ms, and single-transposition audible capacity is $N \leq 25$ at $j = 6$ only. Content is protected structurally rather than by disclosure alone: a corpus closed under negation has resultant exactly zero, verified at $N = 4, 8, 12$ and 24, and at $u = 1$ carries $F = \ln 12 = 2.484907$ nats, exactly the selection cost, sitting on the ceiling with residual 8.88×10^{-16}. Four of twelve directive pairs fail the equal-force check, 33.33%, and are named rather than repaired. The open problem is stated formally: no known structure produces a response depending on the symbol string as an *order*, as distinct from permutation-invariant functionals of the waveform. Bulk compression is closed by arithmetic at strains of 10^{-11} to 10^{-10}, and a single null condition bounds 0.000801% of a 124,800-cell design grid. No experiment was run, no dataset was collected and no biological claim is made.

Keywords: sonification; genomic audio; no-subliminal constraint; Gabor bound; symbol separation; closure under negation; power analysis; open problem

Series: C. Frequency, Essence, and Mind **Paper:** CCP-048

1 Introduction

A pipeline that turns written text into a sound is easy to specify and easy to over-describe. This paper does the first completely and refuses the second in print. It specifies, end to end

and to the digit, a deterministic chain that encodes text as bits, bits as nucleotides at one bit per base, prepends a routing header, sonifies by the essence law $f = kn^2$, transposes by a fixed integer number of octaves, and renders inside the time–frequency bound. **And then it states, in the same document and with the same care, that no mechanism is known by which a cell could read any of it.**

The organising claim is that the second statement is what makes the first worth publishing. A fully specified procedure whose biological effect is unknown is a research design. The same procedure with the gap omitted is a technique, and a technique is what this material must not become. The paper is therefore written in the order it is: constraint, procedure, gap — with the gap last, so that a reader meets the specification while it still looks promising and then meets the missing link while the specification is fresh.

Two design results are proved and both are negative in form. The first is an index-assignment result: assigning symbol indices $n = 1, 2, 3, 4$ collapses three of four symbols onto one pitch class, because $(2n)^2 = 4n^2$ makes doubling an index an exact double octave. The naive assignment is unusable, and the reason is arithmetic rather than taste. The odd assignment $n = 1, 3, 5, 7$ gives four distinct pitch classes whose closest pair in hertz is 990.055901 Hz apart and whose closest pair as an interval is 1165.0244 cents apart — **two different pairs, which the source states as one, and §10 prints the correction** — giving a Gabor floor of 0.080377 ms. The second is structural: **a corpus of directives closed under negation has resultant exactly zero** — verified at $N = 4, 8, 12, 24$ — and at $u = 1$ it carries $F = \ln 12 = 2.484907$ nats, which is exactly the selection cost the receiver pays, 3.584963 bits. **The corpus does not point; it spans, and the direction is contributed by whoever selects from it.**

Three constraints from the physics are computed rather than assumed. The Gabor bound $\Delta t\,\Delta f \geq 1/(4\pi) = 0.0795774715$ [Gabor, 1946] gives a floor of 0.080377 ms at the symbol layer and 10.2882 ms at the state layer, whose binding separation is the 34.9756-cent minimum of the folded lattice at $N = 12$. Single-transposition audible capacity is $N \leq 25$, and only at $j = 6$; at $N = 26$ no admissible integer transposition keeps the set inside 20 Hz to 20 kHz. And one candidate route is closed by arithmetic: at 40 to 120 dB SPL the bulk compressional strain in an aqueous medium is 9.09×10^{-13} to 9.09×10^{-9}, so bulk compression is not the route — though structural and local routes are untouched by that number and are the ones the established literature actually describes.

The paper's honesty apparatus is also computed. A corpus that a careful author wrote intending balance fails an equal-force check on four of twelve pairs — 33.33 per cent — and the failures are named rather than repaired, because *the rate at which a careful author fails this check* is the useful number. At $\sigma = 0.35$ $\log_2$ units a targeted twelve-locus design with Bonferroni correction cannot see below a 1.68-fold change at $n = 3$ or a 1.33-fold change at $n = 20$. And a single well-run null condition bounds 0.000801 per cent of a deliberately modest 124,800-cell design grid, which protects a null from being inflated into a refutation and protects the field from a claimant who runs one condition and announces a channel.

What this paper does not claim, stated at the front rather than at the back. No biological effect of any kind. No clinical, medical or therapeutic claim. No claim that DNA is edited, altered or damaged: nothing in the pipeline is a molecule, and the nucleotide string is a string in the computer-science sense. No claim that any tone bears a physical relation to any base — **cytosine does not absorb at 1113.8129 Hz, does not resonate at it, and is not affected by it.** Every frequency here is an *essence* frequency, a position on a logarithmic scale of surplus. The constant $k = (9/8)^2/\varphi^2$ is a *defined* number; attaching hertz to it is a separate and much stronger claim and is postulated (§2.3). The standard critique of golden-section claims [Markowsky, 1992] is cited here deliberately and again wherever φ appears.

One structural disclosure about the bibliography. The biological literature this paper describes — nucleotide data storage, guide-RNA addressing, self-processing effector arrays, mechanotransduction, force-to-transcription coupling, sonogenetics, reprogramming, and the open-label placebo literature of §4.4 — **has no corresponding cluster in the bibliographic database governing this corpus.** Every such work is therefore named in the text with its journal, volume, page and year, and **without a citation key**, because inventing one or attaching

an unrelated key would be worse than the gap. §10 lists them, and the gap is a defect of the bibliography rather than a claim that the works do not exist.

Contributions

1. A complete, deterministic, disclosed encoding and rendering chain, with a verified round-trip SHA-256 identity on a constructed payload.
2. The index-assignment result: $n = 1, 2, 3, 4$ collapses three symbols to one pitch class; $n = 1, 3, 5, 7$ gives four classes at a minimum gap of 990.055901 Hz.
3. Determination by choice applied to a twelve-state ladder: resultant exactly zero under closure under negation, and $F = \ln 12$ equal to the selection cost at $u = 1$.
4. The Gabor constraints at both layers, and the 128-fold difference between them that forces the two disclosed layers apart in time.
5. Single-transposition audible capacity verified at $N \leq 25$, $j = 6$ only.
6. A closed route: bulk compression, by $s = p/K$ at plausible listening levels.
7. The detectability floors, and the design-space bound that keeps a null and a positive result the same size.
8. **The open problem, stated formally**: no established mechanism produces a transcriptional response depending on the symbol string *as an order*, as distinct from permutation-invariant functionals of the waveform.

2 Hypotheses, definitions, postulates and modelling choices

2.1 Hypotheses proper

H1 — the ordering hypothesis. A cell's transcriptional response to a sonified symbol stream depends on the *ordering* of the symbols, not only on permutation-invariant functionals of the waveform. **Predicted:** an ordered stimulus and its symbol-permuted twin — identical in total energy, duration, symbol histogram, long-term power spectrum, peak level, RMS level and crest factor — produce measurably different transcript abundances at preregistered loci. **Falsified by:** a null contrast at a sample size sufficient to detect the declared smallest effect of interest at the declared power, with the detectable floor published alongside. **Status: NOT TESTED. No experiment has been run and no data exist.** §6 states that no mechanism is known which would produce the predicted result, and this paper does not assert it. The hypothesis is stated so that its falsifier is on record.

H2 — the index-collapse hypothesis. Under the essence law, symbol indices differing by a power of two are indistinguishable to any listener attending to pitch class. **Predicted:** $n = 1, 2, 4, 8$ fold to one class; $n = 1, 3, 5, 7$ fold to four. **Falsified by:** an arithmetic error in $(2n)^2 = 4n^2$; the claim is a consequence of the definition and is not empirically falsifiable beyond that. **Status:** DERIVED. Since nothing could falsify it empirically, **it is restated in §2.2 as a definition-level consequence rather than left dressed as a hypothesis.**

H3 — the equal-force hypothesis. An author writing a deliberately balanced corpus of directives fails a mechanical equal-force check at a non-negligible rate. **Predicted:** independent authors writing paired directives under the stated rules fail character- and word-count balance on a measurable fraction of pairs. **Falsified by:** a set of independently authored corpora with a failure rate indistinguishable from zero. **Status: one instance measured, and one instance is not a rate.** The corpus of §4.28, written for this paper by its author intending balance, failed on 4 of 12 pairs. That is a single observation of a single author and is reported as such; it is not an estimate of anything.

H4 — the separation hypothesis. The two disclosed layers of the rendering are separable by ear because they occupy disjoint registers. **Predicted:** the state band clears the nearest symbol tone by 995.9922 cents. **Falsified by:** a change to either transposition that brings them within a critical band; the computation must be redone after any such change. **Status:** COMPUTED for one specific pair of transposition indices. **No listener was asked anything**, and the perceptual claim implied by the word *separable* is not tested here (§12).

2.2 Definitions — true by stipulation, not falsifiable

- **Def. 1.** A *narrative*, at this layer, is a finite, written, published set of directives, each naming one state of the twelve-state ladder and urging one action with respect to it.
- **Def. 2.** $u := 1 - (\hat{x} \cdot \hat{y})^2$; $F := \ln(1 + (N-1)u)$.
- **Def. 3.** $k := (9/8)^2/\varphi^2 = 0.483425732988414$. **A defined constant**, exact by construction; its fifteen figures are exact digits of a definition and carry no measurement uncertainty because there is no measurement.
- **Def. 4.** The *pitch class* of an index n is the odd part of n. It follows immediately that $f(2n) = 4f(n)$, that an indexed set $1 \ldots N$ holds exactly $\lceil N/2 \rceil$ distinct classes, and that $n = 1, 2, 3, 4$ yields odd parts $1, 1, 3, 1$. **This is H2 restated as what it actually is: a consequence of the definitions, with no empirical content.**
- **Def. 5.** A *symbol-permuted twin* of a stimulus is a rendering of a permutation of the same symbol string, so that every permutation-invariant functional of the waveform is unchanged.

2.3 Postulates — asserted by this framework, with no external support

- **P-a. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic. **Asserting that this dimensionless number *is a frequency* is a separate and much stronger claim**, with no operational procedure supplied by which the constant acquires the dimension of inverse time. Postulated, and restated in the dimensional audit of §3.4.
- **P-b. The essence law $f(n) = kn^2$.** No external literature supports it. **The exponent 2 is defined by the model, not estimated from data**; no fit was performed, and the goodness-of-fit and likelihood-ratio procedure a claimed scaling relation requires [Clauset et al., 2009] was **not run, because there is no data to run it on.**
- **P-c. The affine effective count $N_{\text{eff}} = 1+(N-1)u$.** A design axiom, not a derived result, and **not a Hill number of any order.** The Hill family [Hill, 1973, Jost, 2006] and its rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly and ground this construction not at all.
- **P-d. The alphabetical ordinal on the four bases.** Applying $f(n) = kn^2$ to symbols requires an ordinal, and the one used is alphabetical. **It is not defended as meaningful, only as published, stable and conventional**, and it is a weaker warrant than the twelve-state ladder carries.

2.4 Modelling choices — legitimate, but choices

- **M-a. The unit-vector model of a directive.** Directives are modelled as unit vectors in a real inner-product space, with negation as $-v$. Real directives are not unit vectors and "let the charge rise" is not literally the additive inverse of "let the charge fall." **What the model captures rigorously is one thing only:** a set constructed so that its elements cancel or span has no resultant, so a receiver who acts on it must have selected. That conclusion depends only on the corpus containing genuinely mutually exclusive directions, which is checked by reading the text — as §4.29 checks it, and fails.
- **M-b. Octave reduction applied to a non-acoustic quantity.** Octave equivalence is a perceptual structure formalised for **pitch** [Shepard, 1982], with a measured perceptual size

[Demany et al., 2013]. Carrying it to a quantity that is not a pitch is a choice of this framework, and the interpretation of a folded value is unsupported even where the operation is well defined.
- **M-c.** $N = 12$**.** Twelve exceeds the classical span of immediate absolute judgment [Miller, 1956], which is a reason for caution rather than a reason for twelve.
- **M-d. Bonferroni rather than a false-discovery-rate procedure.** Chosen for transparency and because it is the most conservative common choice. A Benjamini–Hochberg procedure would be entirely defensible **provided it is the preregistered choice rather than the one arrived at after the conservative analysis returned nothing** [Simmons et al., 2011, Gelman and Loken, 2013].
- **M-e. Scalar reduction of a structured state.** Every reading here enters through u, a scalar summary of a vector of intensities over twelve component classes. §3.5 states what that costs.

2.5 What is expository

Sections 4.17–4.20, 5.1–5.5, and the specification and failure-mode blocks throughout are expository: they set out procedure, disclosure requirements, gates and failure modes rather than argue a claim. Their organising question is *what must be published alongside a rendering for a third party to be able to check it, refuse it, and reproduce it.*

3 Framework, dimensional audit, and method

3.1 What kind of claim each layer makes

Analogy status, stated once for the whole paper. The Gabor bound of §5.15 is **category 1, a derivation**: it is a theorem about the Fourier transform, its premises are satisfied by any finite-duration signal, and the rendering genuinely satisfies them. The essence law of §5.12 is **category 3, an analogy with no formal warrant**, badged as a postulate at every appearance. The surplus functional of §4.6 is **category 2, a shared mathematical form**: the same logarithm that appears in Shannon's entropy [Shannon, 1948] appears here, and no claim is made that information-theoretic results transfer.

The uncertainty relation must not be misread, and it is easy to misread here. $\Delta t\,\Delta f \geq 1/(4\pi)$ is Gabor's [Gabor, 1946] and is classical Fourier analysis with no quantum content. It has the same algebraic form as $\sigma_x \sigma_p \geq \hbar/2$ [Kennard, 1927], which is **a fact about state preparation, not about measurement disturbance**, and **nothing in this paper transfers any physical result from the second to the first.** The framework's conjugate-uncertainty paper proves the Gabor limit by the same variational argument with $p = \hbar k$ deleted [Curzi, 2026z], and that deletion is the whole of the relationship.

3.2 Dimensional audit

symbol	quantity	dimension	unit	status
n, N	component / category index	$[1]$	—	absolute scale, a count
u	non-parallelism	$[1]$	—	dimensionless by construction, $u \in [0, 1]$
F	surplus	$[1]$	nats	a logarithm of a count

symbol	quantity	dimension	unit	status
D	octave deficit	$[1]$	octaves	a ratio of logarithms; k cancels
k	reference constant	$[T^{-1}]$ **asserted**	Hz **asserted**	**defined as a ratio (dimensionless); the unit is postulated**
f	essence frequency	$[T^{-1}]$	Hz	inherits its dimension entirely from k
j	transposition index	$[1]$	octaves	an integer exponent of 2
Δt	symbol duration	$[T]$	s	**measured on the rendering; a real time**
Δf	spectral width	$[T^{-1}]$	Hz	**a real bandwidth of a real waveform**
p	acoustic pressure	$[ML^{-1}T^{-2}]$	Pa	**measured; a real physical quantity**
K	bulk modulus of water	$[ML^{-1}T^{-2}]$	Pa	standard constant, 2.2×10^9
s	bulk strain	$[1]$	—	p/K; dimensionless, as strain must be
L, bits, bases	payload length	$[1]$	—	counts
q, d	defect / detection probability	$[1]$	—	probabilities
σ, $\delta_{\log_2}$	dispersion / effect in log abundance	$[1]$	$\log_2$ units	ratio scale on a log transform

Does the arithmetic balance? The Gabor bound does, exactly: Δt in seconds times Δf in hertz is dimensionless, and $1/(4\pi)$ is a pure number, so the inequality is dimensionally clean. **This is the one place in the paper where a physical bound is applied to a physical quantity and the units close without an assumption.** The strain calculation likewise closes: pressure over bulk modulus is Pa/Pa, and strain is properly dimensionless.

The essence law does not close. $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, and k is computed as a ratio of two dimensionless quantities — a frequency ratio and a geometric ratio. **No operational procedure is supplied by which it acquires the dimension of frequency.** This is the paper's largest dimensional exposure and it is listed by name in §10.

A consequence that matters here more than elsewhere in the corpus. The rendered waveform is a real sound with a real spectrum, and Δt and Δf are properties of it. The *value* of each tone, however, comes from the essence law, whose hertz is postulated. **A rendering therefore has real physics downstream of a postulated number**, and the honest statement is that the acoustics of the file are ordinary while the reason those particular frequencies were chosen is not established.

3.3 The surplus functional

$F(u) = \ln(1 + (N-1)u)$ is the framework's surplus functional. The ceiling $F \leq \ln N$ is the same bound that requisite-variety arguments impose on any regulator [Ashby, 1956]. **The functional form is underdetermined by the evidence**: a sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. The strongest warrant for the logarithm is not psychophysical: it follows from multiplicative dynamics with no psychological assumption at all [Peters and Gell-Mann, 2016], and that is the warrant this paper's arguments need. **Which construct of difference u measures must be declared** [Harrison and Klein, 2007]: here it is a disparity measure, symmetric in its arguments, which psychological similarity is not [Tversky, 1977].

3.4 The constant k

$$k := \frac{(9/8)^2}{\varphi^2} = 0.483425732988414 \quad \text{(defined; exact)}$$

Both components are real and documented — the Pythagorean whole tone [Barbour, 1951] and Euclid's extreme and mean ratio [Euclid, 1956], with $\varphi^2 = \varphi + 1$ a proved identity [Vajda, 1989]. **Their product, expressed as a frequency in hertz, has no precedent.** The literature on golden-section claims is overwhelmingly deflationary [Markowsky, 1992, Fischler, 1981, Höge, 1997], and **this framework's position is the one those critiques leave open and no wider**: φ is being *chosen* as a constant, not *found* in anything measured. Because every ratio in the alphabet is a ratio of squares, k cancels from all of them [Curzi, 2026k], and no separation figure in this paper depends on its value.

3.5 Scale type, and the objection this framework inherits twice

quantity	scale type claimed	what licenses it
n, N, base counts, bit counts	absolute	cardinality; identity transformation group only
u	ratio	constructed from an inner product of unit vectors
elicited intensities	ratio, up to a common multiplier	**magnitude estimation, assumed** [Stevens, 1957]; not tested here
Δt, Δf, p	ratio	physical measurement with a true zero
$\log_2$ abundance	interval	a logarithm; differences are meaningful, the zero is not
pitch class	nominal	the odd part of an index; **no ordering is licensed on it**

The framework's formula-validation work fixes what licenses a quotient at all [Curzi, 2026t]: **a quotient X/Y is meaningful if and only if the admissible transformation group is similarity — that is, if and only if the scale is ratio** — with four demonstrations showing a 25 per cent shift under an affine relabel, reversed orderings under $g(x) = 2^x$, any ratio at all reachable via $(7/4)^k$, and an undefined ratio under $g(x) = x - 2.5$. That result is why the counts in this paper carry ratios and the elicited intensities carry them only by assumption.

Michell's objection applies here in full: psychology routinely assumes its attributes are quantitative without testing whether they are [Michell, 1997]. Conjoint measurement is the

formal remedy [Luce and Tukey, 1964, Krantz et al., 1971] and **it was not run for any quantity in this paper.**

And the same objection arrives a second time from the affect literature, which is why this paper names the pattern once rather than meeting each instance as a fresh surprise. The pattern is *scalar reduction*: collapsing a structured state into a single number, and then ordering the numbers. Emotions are individuated by the **pattern across** independently varying appraisal dimensions [Smith and Ellsworth, 1985]; a state is a synchronisation process in time rather than a point [Scherer, 2001]; individuation runs by qualitative core relational theme, so that differing by *what* is appraised does not license ordering by *how many* [Lazarus, 1991]; and action readiness is constitutive of emotion as such rather than a top rung above the others [Frijda, 1986] — which contradicts the ladder's twelfth class specifically. Two dimensions of core affect are well supported [Russell, 1980]; twelve ordered rungs are not.

Everything in this paper that enters through u or through a state index inherits that objection. What survives it is everything that does not: the encoding chain, the round-trip identity, the index-collapse result, the separation figures, the Gabor arithmetic, the strain calculation, the detectability floors, and the design-space bound. Those are statements about a model and a waveform given their parameters, and they hold whatever the parameters turn out to mean.

3.6 Identification and reflexivity

The framework's founding construction is a reflexive loop [Curzi, 2026], and **the endogenous social effect in a linear-in-means reflexive specification is not identified from observational data** [Manski, 1993]; influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. **The remedy this paper adopts is stipulation**, with the reference set — the declared category set of size N and the declared corpus — fixed in advance [Brock and Durlauf, 2001], and the reflexive claim is presented as a modelling position rather than an identified empirical result.

A specific reflexive exposure attaches to this paper and is unusually direct. The disclosure package is delivered to the listener before exposure, which means the listener knows exactly what is being sent. That is the design, and it is also a manipulation of expectancy: the act of taking part in a study changes behaviour independently of the intervention [McCambridge et al., 2014], expectancy effects on measurement are documented [Rosenthal and Fode, 1963, Rosenthal and Jacobson, 1968], and the best long-run assessment finds such effects real but small, usually non-accumulating and often dissipating [Jussim and Harber, 2005]. **Disclosure does not remove the expectancy channel; it makes it visible and shared**, which is why §6's design carries a scrambled-sequence arm rather than relying on any comparison against silence. If systems change when modelled, the framework's own parameters are not exempt [Lucas, 1976, Hacking, 1995], and this paper does not resolve that.

3.7 Method

Every number in this paper is the output of exact arithmetic on stated parameters, computed in double precision. **No observational data were collected, no human subjects participated, no cells were exposed to anything, and no empirical dataset underlies any figure or table.** The payload is a constructed corpus written for this paper. Hashes are SHA-256 of the stated byte strings. The power calculations are arithmetic on declared inputs — the dispersion σ and the number of tests are values a reader supplies from their own system, not values this paper asserts about biology. The figures are produced by the scripts named in their captions.

4 Disclosure as a design constraint, and determination by choice

The framework's audit of a traditional operation set asked what a set of classical operations were doing when they worked, mapped the survivors onto operations on indices and on u,

and printed the ones that failed [Curzi, 2026]. This paper asks a harder question, and asks it in the register where the framework has the least standing and the most to lose: what would it mean to write a corpus of directives *as data*, address that data, render it as tone, and play the tone in a room with a person in it.

The honest answer arrives in three parts and they must be kept in this order.

The first part is that the encoding chain is buildable, deterministic, and auditable end to end. Text becomes bits, bits become a nucleotide string, the string acquires a routing header, the string is sonified by the framework's essence law, and the result is a sound. Every one of those steps is arithmetic. Section 5 specifies them to the digit and demonstrates a round-trip hash.

The second part is that nothing whatever is known about what such a sound does to a cell. Section 6 states that gap in full and does not soften it. **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal**, and every sentence in this section and the next is written underneath that sentence.

The third part is the one this section exists for, and it is a constraint rather than a finding. The chain above has a design decision at its centre that is not an engineering decision at all. It is the decision about whether the listener can hear what is being sent to them. That decision has exactly one permissible answer under this framework, the answer is not negotiable at any point, in any version, for any purpose, and it is stated in the next paragraph rather than at the end, because a constraint reached as a conclusion is a constraint that has already been weighed against something.

The law

4.1 The constraint, stated first **NO SUBLIMINAL CONTENT OF ANY KIND. NOTHING MASKED. NOTHING BELOW THE THRESHOLD OF HEARING. NOTHING CONCEALED FROM THE LISTENER. THE INFORMATION IS THE TONE.**

This is the framework's standing disclosure constraint, and it governs this section, Section 5, and everything either of them touches. It is the same constraint that the corpus's channel-separation work states in its strongest form [Curzi, 2026]: **channel separation is strengthened by disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable — non-disclosure is refused as a design premise, not merely discouraged.** The design tradition it belongs to is old and explicit: a mechanism whose effectiveness depends on the mechanism being secret is badly designed [Kerckhoffs, 1883], open design is a security principle rather than a concession [Saltzer and Schroeder, 1975], and publicity is the standard corrective for a practice that cannot otherwise be checked [Brandeis, 1914]. It is not a stylistic preference, it is not an aesthetic, it is not a default that a sufficiently good reason could override, and it is not the sort of rule that gets an exception for research use, for a demonstration, for a control condition, or for a version that is only ever played to the person who built it.

The source document behind the essence law recommended embedding subliminal content, and this framework has declined that recommendation at every point since: for built acoustic space [Curzi, 2026l], for content generally [Curzi, 2026ad], and here for psychological content specifically, which is the hardest case in the series, because psychological content is content *about the listener* and the temptation to route it past their judgment is correspondingly larger.

4.2 Why it is ethical and not stylistic, and why the difference matters A stylistic constraint and an ethical constraint fail in different ways, and conflating them is the mechanism by which the second quietly turns into the first.

Violating a stylistic constraint yields a worse version of the same object: use equal temperament where the ratios were exact and the chord is muddier than it should be, but the

artefact is the same kind of artefact, degraded. Violating an ethical constraint does not yield a degraded version of the object. It yields a different object, outside the scope of the method, and no amount of performance recovers its standing. **A masked rendering is not a lower-fidelity disclosed rendering; it is a different thing that this framework does not describe, does not specify, and will not help anyone build.**

The practical test for which kind of constraint is in play is simple and worth applying elsewhere: ask what would happen if the constraint were relaxed and the result were *better* by the method's own measure. A stylistic constraint yields; that is what makes it stylistic. An ethical constraint does not, and a constraint that yields to a good enough result was never ethical to begin with — it was a preference wearing the word.

4.3 The argument, which depends on no empirical claim

A message hidden from its recipient cannot be consented to.

The framework's work on performative commitment supplies the complementary positive case [Curzi, 2026]: a spoken commitment analysed as a performative aimed at the speaker, supported by three converging mechanisms — consistency pressure, self-perception from overheard testimony, and re-pricing of later defection. **Every one of those three requires the speaker to have heard what they said.** A concealment architecture removes the mechanism it was trying to exploit.

That is the whole argument, and its independence from evidence is its strength. It does not depend on whether masked content works. It does not become weaker if masked content turns out to have no effect at all, and it does not become stronger if masked content turns out to be powerful. It is a statement about what consent requires, and it would stand in a world where the entire subliminal literature had replicated perfectly and in a world where none of it had.

Unpacked, the argument runs: consent requires knowing what one is consenting to. A signal engineered so that the listener cannot perceive it has been engineered so that the listener cannot evaluate it, cannot weigh it against their own judgment, cannot compare it with what they were told it was, cannot refuse it selectively, and cannot report on it afterwards to anyone else. Every one of those five capacities is a form of the capacity to decline. Removing them is not an incidental cost of a concealment architecture. It is what a concealment architecture *is*.

And there is a second argument, specific to this series, which makes concealment incoherent here before it makes it wrong. The whole architecture rests on the subject's own latent material. The framework's addressing work establishes that no addressing operation, at any signal strength or in any modality, can cause a cell to express content its genome and accessible regulatory repertoire do not already contain [Curzi, 2026y]. Its operation audit establishes that transmutation is re-indexing and not creation [Curzi, 2026]. And its channel-gain postulate establishes that belief acts only through a coupling with real gain [Curzi, 2026ab]. In every one of those results the person is not the object the method acts on — the person is the part of the circuit that does the acting. **A protocol built on the listener's own participation, which then conceals itself from the listener, has removed from the mechanism the only component that was supposed to be doing the work.** It is self-defeating before it is unethical, and it is unethical.

The general form is: no intervention may remove a person's ability to decline. Consent is structural here, not advisory, exactly as the framework's closure law requires of relational tuning [Curzi, 2026]. The difference here is only that the temptation changes shape. In a room the temptation is to hide a tone. In a corpus it is to hide a meaning.

4.4 The convergence with open-label placebo

There is a version of this constraint that is merely expensive, and a version that costs nothing that matters. Which one applies is an empirical question, and it has an answer.

Before 2010 the received account of placebo response was that it required the recipient to believe they were receiving something active, which requires telling them something false, which the constraint above forbids absolutely. Under that account the constraint and the channel were in direct conflict, and under this framework the constraint would have won and the channel would simply have been closed.

The open-label result dissolves the conflict. Kaptchuk et al. (*PLoS ONE*, 2010) randomised patients with irritable bowel syndrome to an open-label placebo arm — pills presented explicitly and truthfully as inert, with an explanation that placebo effects can be substantial — against a no-treatment control with the patient-provider interaction matched, which is the design feature that makes the comparison mean anything. The open-label arm improved significantly more than the control on the trial's primary outcomes. Later work extended the finding to other conditions (Carvalho et al., *Pain*, 2016), and a meta-analysis of open-label placebo randomised trials (von Wernsdorff et al., *Scientific Reports*, 2021) reported a positive overall effect. The framework's treatment of that literature elsewhere states its limits: the trials are mostly small, the outcomes are mostly subjective and self-reported, the effect sizes are modest, and the field is active. **None of the four works named in this paragraph is in this paper's bibliographic database; all are named without citation keys, and no percentage is quoted from memory.**

What the result establishes for this section is narrow and exact. **A documented effect of this family does not require deception; therefore disclosure is not the thing that would have to be sacrificed to have an effect at all, and the constraint costs nothing that matters.** That is a statement about the availability of a channel under disclosure. It is emphatically not a statement that the method of Section 5 has an effect, that any effect has been measured, or that placebo findings transfer to acoustic sonification of nucleotide sequence. Nothing in that literature is evidence about this method, and this paper does not use it as any.

Two errors to avoid, both of which the framework's two-column concordance rule exists to prevent [Curzi, 2026w], whose Result One is the refinement that keeps the method honest: **the evidence column carries what could have come out otherwise, and the precedent column carries only that the idea was independently arrived at and preserved — two sources agreeing does not double the evidence when only one of them is evidence.** The first is treating the open-label literature as support for the protocol; it is not, it is support for the compatibility of disclosure with *some* belief-mediated effects in *other* domains. The second is the symmetric error of treating the constraint as costless *because* of that literature — the constraint would be binding here even if open-label placebo had failed. The literature removes an excuse, not the rule.

4.5 Determination by choice — the structural result Disclosure protects the listener at the delivery layer. It does not protect them at the content layer, and the reason is worth stating plainly: a fully disclosed, fully audible, carefully published single instruction is still an instruction. Somebody who reads it, is tired, is deferential, or trusts the operator, is being commanded with their eyes open.

The content-layer protection is structural and it is a theorem. It is proved in the framework's narrative-input paper [Curzi, 2026ad], whose Result One is *determination by choice*: a corpus closed under negation has resultant exactly zero, $\|\sum\| = 0.000000000000$ at $N = 4, 8, 12, 24$, and an orthogonal corpus's mean direction shrinks as $1/\sqrt{N}$. It is applied here to the twelve-state ladder rather than restated in general.

Model each directive as a unit vector in a real inner-product space, where direction encodes the action urged and $-v$ encodes its negation.

(a) If the corpus is closed under negation, the resultant is exactly zero. Verified, with the pairing drawn at random in a 64-dimensional space:

```
N =  4    ||sum|| = 0.000000000000
N =  8    ||sum|| = 0.000000000000
N = 12    ||sum|| = 0.000000000000
```

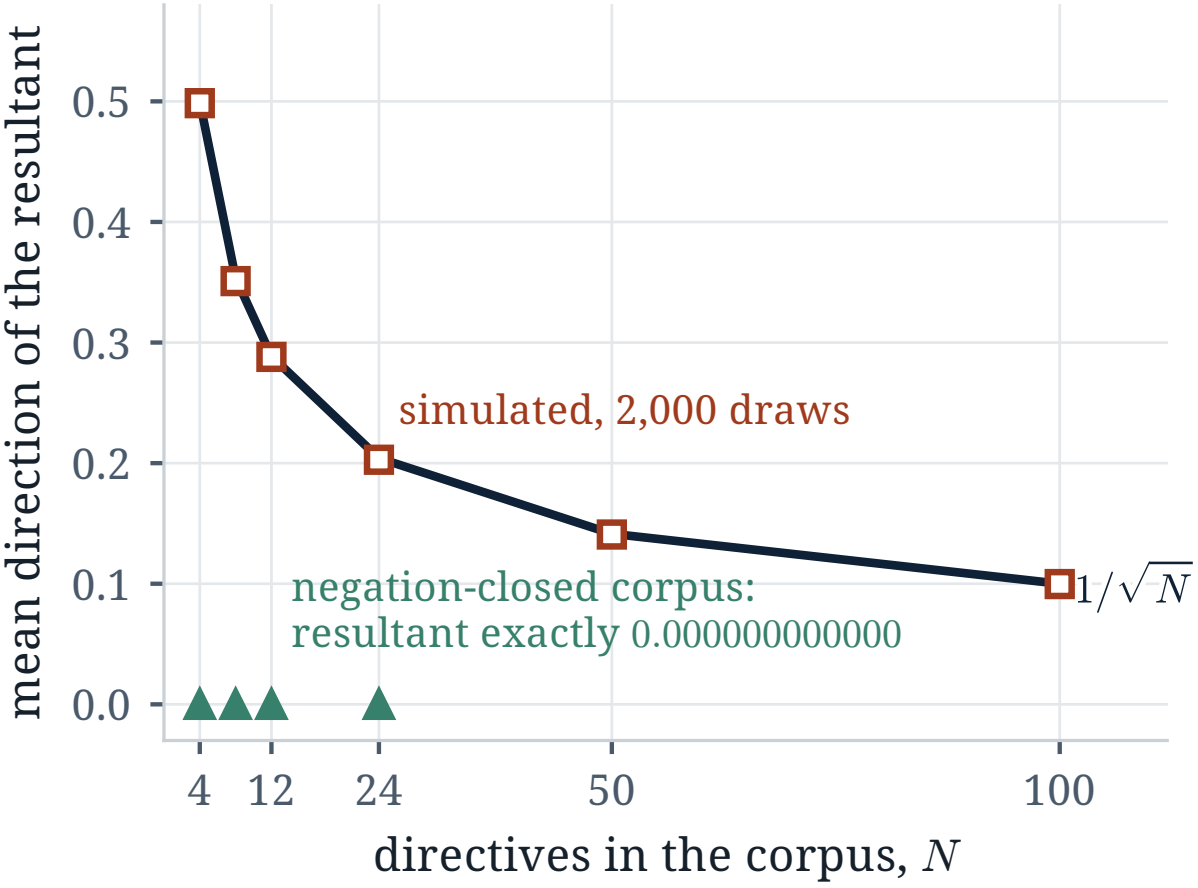

Figure 48.1: **A corpus built to span does not point: closed under negation its resultant is exactly zero, and merely mutually exclusive its mean direction falls as $1/\sqrt{N}$.** The curve is the theoretical $1/\sqrt{N}$; the open squares are 2,000 simulated draws of N isotropic unit vectors in $\mathbb{R}^{64}$; the triangles are the negation-closed case, exact at every N tested. Modelled: directives are represented as unit vectors, a modelling choice stated in §2.4, and the exponent $-1/2$ is defined by the model rather than estimated. Built by `figs/src/CCP-048_fig04.py`.

```
N = 24    ||sum|| = 0.000000000000
```

(b) If the corpus is mutually exclusive without exact pairing, the resultant grows only as $\sqrt{N}$ while the corpus grows as N, so the mean direction shrinks as $1/\sqrt{N}$. **The exponent $-1/2$ here is defined by the model — it is the standard concentration of a sum of independent isotropic unit vectors — and is not an estimated scaling exponent; no fitting procedure of the kind a claimed power law requires [Clauset et al., 2009] was run, and none would be appropriate.** Simulated, 2,000 draws of N isotropic unit vectors in $\mathbb{R}^{64}$ per row:

N	1/sqrt(N)	simulated
4	0.500000	0.498500
8	0.353553	0.350953
12	0.288675	0.288101
24	0.204124	0.202825
50	0.141421	0.140809
100	0.100000	0.099738

A field of mutually exclusive directions cannot issue a command. In case (a) the resultant is

identically zero; in case (b) it is a vanishing fraction of any single member and keeps vanishing as the corpus grows. The corpus does not point. It spans.

The consequence is the sentence this section is really about:

> **A deliberately contradictory corpus cannot issue a command. It can only be resolved by selection, and the selection belongs to the receiver.**

The vector model is a model and is badged as one (M-a, §2.4). Real directives are not unit vectors and "let the charge rise" is not literally the additive inverse of "let the charge fall." What the model captures rigorously is one thing only: a set constructed so that its elements cancel or span has no resultant, and a receiver who acts on it must therefore have selected. That conclusion depends only on the corpus genuinely containing mutually exclusive directions, which is a property of the written text and is checked by reading it — as §4.29 checks it, and fails.

4.6 The identity between what the corpus carries and what selection costs Two quantities coincide at the extreme, and the coincidence is the reason the design is not merely defensive.

By the framework's normalisation result, $F(u) = \ln N$ if and only if the ensemble is mutually orthogonal. A maximally contradictory corpus is therefore a maximum-surplus corpus. The ceiling $\ln N$ is the same bound that requisite-variety arguments place on any regulator [Ashby, 1956, 1958], and the logarithm is Shannon's functional form rather than a new one [Shannon, 1948]. At $N = 12$:

```
corpus surplus at u = 1        F = ln 12 = 2.484907 nats
selection information          ln 12 = 2.484907 nats = 3.584963 bits
f_rel = k (1 + 11 u)^2         69.6133 Hz          (folded 278.453 Hz, j = 2)
octaves above k                7.169925
```

The corpus supplies exactly as much surplus as the selection consumes, and supplies zero net direction. The direction is not in the signal; it is contributed by the receiver, and its magnitude is exactly the surplus the signal carries. One honesty clause attaches unchanged: **the exact equality holds only at $u = 1$ and under a uniform receiver prior**, and both sides fall together when either condition relaxes [Curzi, 2026ad].

The fall is worth seeing, because a corpus is rarely maximally contradictory in practice:

u	F (nats)	f_rel (Hz)	octaves above k
1.00	2.484907	69.6133	7.1699
0.90	2.388763	57.4358	6.8925
0.75	2.224624	41.3631	6.4189
0.50	1.871802	20.4247	5.4009
0.25	1.321756	6.7982	3.8138
0.10	0.741937	2.1319	2.1408
0.00	0.000000	0.4834	0.0000

At `u = 0` the corpus is parallel: every directive says the same thing, `F = 0`, and the frequency is the ground essence `k` itself. **A corpus that agrees with itself carries no surplus and sounds the note of no relationship at all** — which is the framework's result on the unison of perfect agreement, arriving in an unexpected place.

4.7 The `u = 1` here is constructed, and that must be said every time it is printed The framework's encoding rules carry a warning that is usually a trap and is here a design: one-hot vectors are automatically orthogonal, giving `u = 1` regardless of content, so framings must be represented with overlapping support or the internal surplus is degenerate and meaningless.

A deliberately contradictory corpus is exactly that degenerate case, on purpose.

The `u = 1` of a designed corpus is a property of the design, not a measurement of anything, and the 69.6133 Hz that follows from it is the arithmetic ceiling of a twelve-category system rather than a reading of a person, a text, or a relationship. It says the corpus was built to span. It says nothing about how anyone responds to it, and any sentence that lets those two readings blur is a sentence this framework has to delete.

The distinction matters because the same number, 69.6133 Hz, appears elsewhere in this corpus as the ceiling kN^2 and as the top of a glide [Curzi, 2026,?]. In those places it is the endpoint of a measured scale. Here it is a construction constant. Same value, different warrant, and the warrant is what a reader is entitled to.

4.8 The corpus at the ceiling, read with the framework's own instrument

Because the constructed corpus sits at $F = \ln N$, it lands exactly on the framework's sustainability ceiling, and that gives a clean statement of what even a maximally spanning corpus cannot do.

c/eta	f_min (Hz)	required octaves	deficit vs 69.6133	verdict
0.5000	1.3141	1.442695	−5.727230	SUSTAINS
1.0000	3.5721	2.885390	−4.284535	SUSTAINS
1.5000	9.7099	4.328085	−2.841840	SUSTAINS
2.0000	5.3942	5.770780	−1.399145	SUSTAINS
2.4849	69.6133	7.169925	+0.000000	HOLDS
2.6000	87.6317	7.502014	+0.332089	DECAYS
3.0000	195.0279	8.656170	+1.486245	DECAYS

At `c/eta = ln 12 = 2.484907` the deficit is zero to floating-point exactness — computed residual `8.88e−16`. **Above that ratio no arrangement of twelve categories is sustainable, and a maximum-surplus corpus is no exception: it is the best a twelve-state system can do and it is still not enough.** That is the ceiling result in the frequency register [Curzi, 2026], and it is one of the few places where a formalism states in advance that a proposed arrangement cannot work.

And the deficit alone does not see decay. Worked at `c/eta = 2.6`, with `eta = 0.50`, `c = 1.30`, `F = ln 12`:

```
delta = 0.09    Q_inf = −0.639408     D = +0.332089
delta = 0.05    Q_inf = −1.150934     D = +0.332089
delta = 0.02    Q_inf = −2.877334     D = +0.332089
direct check    D = 2.885390*(c/eta − F) = +0.332089
```

Trust moves the fixed point by a factor of four and the deficit does not move at all. Report `D` and `delta` together or the reading cannot see decay. The minimum-frequency paper owns this [Curzi, 2026], whose Result Four is that D contains no δ: on its carried dyad, δ from 0.09 to 0.05 leaves $D = +4.338420$ unchanged while Q_∞ falls from -5.0119 to -9.0215.

4.9 The open problem, carried

Section 6 owns the statement and states it four ways. It is carried here in full rather than by reference, because a reader arriving at material about content and cells is exactly the reader most likely to skip forward and exactly the reader who most needs it.

> **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal.**

What follows from it, for this section: nothing in §4.10 onward is a claim about cells. The design work below is encoding design. It produces a notation with a checkable structural property, and a notation is not a channel.

4.10 Status table The classification below follows the framework's three-drawer honesty ledger [Curzi, 2026], whose Result One sorts four items of established mathematics, seven of established psychology and exactly three declared postulates, with every protocol stated to run on the first two and steer by the third.

Claim	Status	Basis
No subliminal content; full disclosure	**CONSTRAINT** — ethical, prior, non-negotiable	the framework's disclosure constraint
A hidden message cannot be consented to	**ARGUED** (not empirical)	§4.3
Disclosure need not abolish a belief-mediated effect	**MEASURED, elsewhere**	Kaptchuk 2010; von Wernsdorff 2021
A negation-closed corpus has resultant exactly zero	**PROVED (elementary)**, verified	§4.5
A mutually exclusive corpus has mean direction `1/sqrt(N)`	**PROVED**, simulated	§4.5
Corpus surplus `ln N` equals selection information `ln N`	**PROVED, extremal case only**	§4.6, with H82-A
`u = 1` for a designed corpus is constructed, not measured	**STATED**	§4.7
Corpus at `F = ln N` sits exactly on the ceiling	**COMPUTED**, residual `8.88e-16`	§4.8
Contradiction renders as exactly 2400.0 cents	**PROVED (arithmetic)**	§4.14
Twelve states yield six pitch classes	**PROVED**	the odd-part rule
Narrative structure is carried in the harmonic	**DESIGN CLAIM** — about encoding, not effect	§4.15
A cell demodulates sequence-specific content from this	**NOT CLAIMED. OPEN PROBLEM.**	§6
Any physiological, clinical or therapeutic effect	**NOT CLAIMED**	H4-1

4.11 Honesty clauses, binding on this section **H4-1.** No clinical, medical or therapeutic claim is made anywhere in this section. The twelve states are not diagnoses, the corpus is not a treatment, and the rendering is not an intervention in any clinical sense of that word.

H4-2. No claim that DNA is edited, altered or damaged. Nothing in the chain is a molecule. The nucleotide string of Section 5 is a string in the computer-science sense — symbols in memory — and no nuclease, template or Cas protein appears anywhere.

H4-3. No claim that any capability has been conferred on anything.

H4-4. The essence frequencies are essence frequencies, not physical resonances. No person, tissue, cell or molecule is claimed to resonate at 247.514 Hz, at 69.6133 Hz, or at any other value printed here.

H4-5. All worked material in this section is constructed and labelled as such. The twelve-line corpus of §4.28 was written for this paper. It is not a transcript, not a record of practice, and not an observation of anyone.

H4-6. The vector model of a directive is a model. Its conclusion depends only on the corpus containing genuinely mutually exclusive directions, which is checked by reading the text.

The engineering

4.12 What "narrative" means at this layer The word does a great deal of unearned work in adjacent literatures, so it is worth pinning to something checkable. Here, a *narrative* is **a finite, written, published set of directives, each of which names one state of the twelve-state ladder and urges one action with respect to it.**

That definition has three consequences and each is deliberate.

It is finite, so it can be printed in full, which is what disclosure requires. It is written, so the equal-force check of §4.29 can be applied by anyone with a character counter. And it is indexed to the ladder, so every directive has a frequency by the folding rule and the corpus has a chord.

What a narrative is *not*, at this layer: a story in the literary sense, a script, a suggestion, an affirmation, or a piece of persuasion. Persuasion has a resultant. This construction is built so that it does not.

4.13 The chain, and where each link is specified

```
narrative                  a written corpus of directives over the twelve states
    |
    |  [1]   ENCODE     text -> bits -> nucleotide string        §5.7
    v
sequence
    |
    |  [2]   ADDRESS    a gRNA-format routing header prepended   §5.10
    v                   (a field in a file; not a molecule)
addressed sequence
    |
    |  [3]   SONIFY     essence law, f = k n^2                   §5.12
    |  [4]   TRANSPOSE  fixed integer octave shift               §5.13
    v
waveform
    |
    |  [5]   DISCLOSE   corpus, tables, sequence, and audio       §4.19
    v                   published together, before exposure
a sound in a room, and §6's open problem begins here
```

Section 5 owns steps 1 through 4 and specifies them to the digit. This section owns step 5 and the structural design that makes step 5 sufficient.

4.14 The contradiction is rendered as a double octave Here is the design move, and it is exact arithmetic rather than a metaphor.

Every directive in the corpus names a state `n` and is rendered at that state's essence frequency, folded into the standing band of 220–440 Hz by the folding rule. Its explicit negation is rendered at the same pitch **transposed up by exactly two octaves**. Because octave transposition preserves pitch class exactly — a structure formalised for pitch [Shepard, 1982] whose perceptual specialness has a measured size [Demany et al., 2013] — the two members of a contradictory pair are the same note at two heights, and the interval between them is:

```
ratio  = 4          exactly
cents  = 1200 * log2(4) = 2400.0     exactly, in every pair, without exception
```

Two octaves is also, not coincidentally, the interval $f(2n)/f(n) = (2n)^2/n^2 = 4$ that the square law produces between an index and its double. That identity is fixed in the framework's conversion-key paper [Curzi, 2026l], whose Result Three is that **one bit equals two**

octaves, not one, verified across $N_{\text{eff}} = 1, 3, 12$. Nothing here changes `N`, adds a state, or steps off the ladder: the negation is placed by octave transposition, which is a change of register and the only purely presentational operation in the chain.

A word about where the twelve class names come from, and what they are not. The rungs are motivated by naming existing constructs in the affect literature: a two-dimensional circumplex of core affect underlies *valenced activation* [Russell, 1980]; appraisal dimensions underlie *attributed* and *situated feeling* [Smith and Ellsworth, 1985, Lazarus, 1991]; appraisal as a process in time underlies *temporal feeling* [Scherer, 2001]; self-conscious emotion underlies *reflexive feeling* [Tracy and Robins, 2004]; theory of mind underlies *social feeling* [Premack and Woodruff, 1978]; and action readiness underlies *committed feeling* [Frijda, 1986]. **Those works are named as precedent for the existence of a component and never as support for its index, its position on the ladder, or the ordering of the twelve.** Several of them cut directly against that ordering, and §3.5 states the objection in the general form it deserves rather than meeting it here piecemeal.

The full rendering table for the twelve states, band 220–440 Hz for the directive and 880–1760 Hz for its negation:

n	state class	raw f (Hz)	directive (Hz)	j	negation (Hz)	pitch class
1	undifferentiated activation	0.483426	247.5140	9	990.0559	1
2	valenced activation	1.933703	247.5140	7	990.0559	1
3	directed feeling	4.350832	278.4532	6	1113.8129	3
4	situated feeling	7.734812	247.5140	5	990.0559	1
5	attributed feeling	12.085643	386.7406	5	1546.9623	5
6	temporal feeling	17.403326	278.4532	4	1113.8129	3
7	reflexive feeling	23.687861	379.0058	4	1516.0231	7
8	social feeling	30.939247	247.5140	3	990.0559	1
9	normative feeling	39.157484	313.2599	3	1253.0395	9
10	narrative feeling	48.342573	386.7406	3	1546.9623	5
11	reciprocal feeling	58.494514	233.9781	2	935.9122	11
12	committed feeling	69.613306	278.4532	2	1113.8129	3

The listener does not need the encoding table to hear that the corpus is built in opposed pairs. The interval arithmetic is standard once an index exists [Rossing et al., 2002]. **A contradiction is here the most audible interval available, and it is audible without instruction, which is exactly the property a disclosure requirement should want from a structure.**

4.15 The pitch-class budget, and the collision it forces The odd-part rule and its corollary — an indexed set $1..N$ holds exactly $\lceil N/2 \rceil$ distinct pitch classes — are the framework's. At `N = 12` that is six, and this section has to live inside it:

```
class  1  ->  states 1, 2, 4, 8      folded 247.5140 Hz
class  3  ->  states 3, 6, 12        folded 278.4532 Hz
class  5  ->  states 5, 10           folded 386.7406 Hz
class  7  ->  state  7               folded 379.0058 Hz
class  9  ->  state  9               folded 313.2599 Hz
class 11  ->  state 11               folded 233.9781 Hz
```

Four of the twelve directives share one pitch class. Three share another. How far interval categories and octave equivalence generalise across listeners is contested [Burns, 1999, Hoeschele et al., 2012], and what a listener finds consonant depends on the spectrum of the sound rather than on the ratio alone [Sethares, 2005]; **this paper uses the arithmetic and claims none of the perception.** A listener attending to pitch class rather than to absolute register hears twelve directives as **six distinguishable positions**, and the ambiguity is a structural property of the twelve-state ladder rather than a fault in the rendering. The corresponding

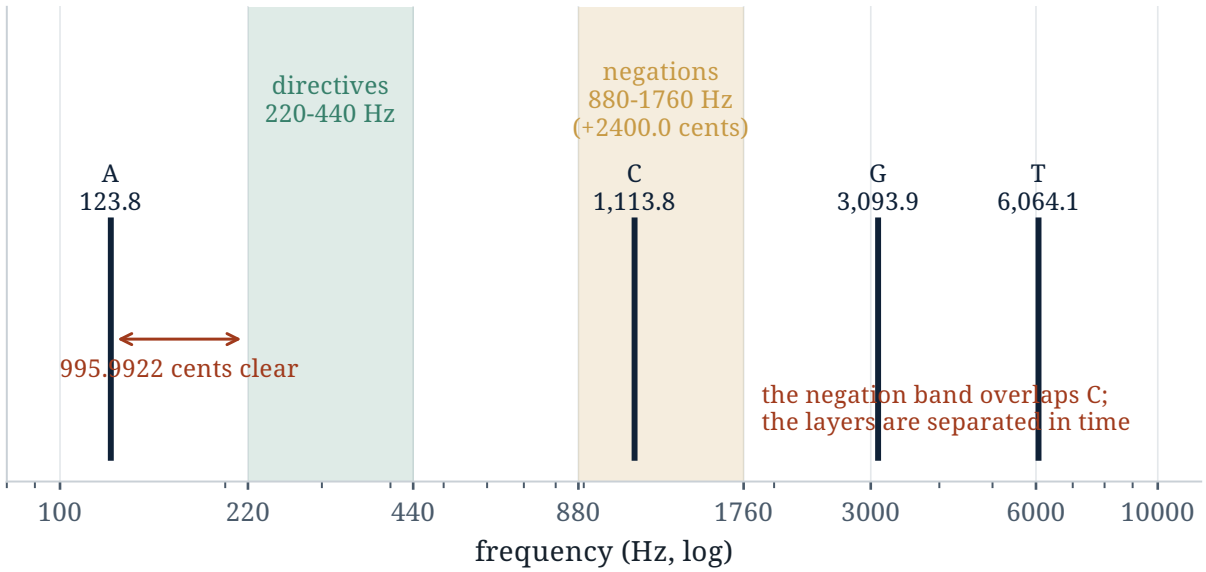

Figure 48.2: **The two disclosed layers occupy disjoint registers: the state band clears the nearest symbol tone by 995.9922 cents, better than an octave.** The negation register does overlap the symbol tone at 1113.8129 Hz, which is why the run schedule of §5.18 separates the two layers in time instead. Modelled from the essence law with the declared transpositions ($j = 8$ for the symbol alphabet, $j = 6$ for the state ladder); every value is arithmetic on a postulated constant, and nothing resonates. Built by `figs/src/CCP-048_fig02.py`.

resolution figure is fixed by the framework's reference apparatus [Curzi, 2026]: within the folded lattice the tightest separation at $N = 12$ is 34.9756 cents, between classes 7 and 5.

Two consequences follow and both belong in the disclosure package.

First, absolute register — not pitch class — is what identifies the state. The rendering must therefore be published with its j for every value, and the listener must be given the table.

Second, and this is the honest one: the collisions are not an artefact of an unlucky ladder. They follow from `(2n)^2 = 4n^2`, they would occur for any N, and the only way to buy more classes is to lengthen the index — which past $N = 16$ enters the 289/288 regime and costs a factor of eight in symbol rate. **This framework stays at $N = 12$, inside the 50/49 regime, and accepts six classes as the price.**

4.16 The structure is carried in the harmonic — stated precisely This is the claim the section is named for and it is exactly the kind of phrase that sounds like a mechanism while being nothing of the sort. So, in two halves:

What is claimed. The relational structure of the corpus — which directives contradict which — is realised as interval structure in the rendered chord, audibly, at ordinary listening levels, so that a listener hearing the chord is hearing the structure rather than a representation of it. The mapping is bijective: every contradiction is a double octave and every double octave in the rendering is a contradiction.

What is not claimed. That this structure does anything to any listener, any cell, or any transcript. The claim is a design claim of the same kind as "this file is sorted." It is checkable, it is either true or false of a given rendering, and it has no biological content whatever.

The pitch classes themselves are exact just intervals, because every essence ratio is a ratio of squares and k cancels out of all of them [Curzi, 2026k]. Exact rational interval lattices are a documented tradition rather than an invention of this framework [Partch, 1974, Doty, 2002, Barbour, 1951], and the project of assigning arithmetic weights to intervals runs from Euler's

gradus suavitatis [Euler, 1739] to harmonic distance [Tenney, 2015]. The point here is that the intervals a listener hears between directive families are exact rational relationships, not approximations, and they are exact because nothing in the chain ever tempered them.

4.17 Three architectures, compared

	Steganographic	Masked	Carried (this framework)
Where the content is	in a cover signal	below perceptual threshold	it is the signal
What the listener hears	the cover	the masker	the content
Can they recover it?	only with a key	not at all by ear	yes, by ear plus tables
Can they evaluate it?	no	no	yes, before exposure
Can they decline it?	no	no	yes, at any point
Consent status	impossible	impossible	obtainable
House status	**excluded**	**excluded**	permitted

The middle column is where every historical subliminal technique sits, and this framework excludes it for the same reason it excludes the first: **in both, the recipient's inability to perceive the content is doing the work.**

The right-hand column is not a weakened version of the other two. It is a different architecture with a different worst case, and its worst case is that the listener reads the corpus and declines. That is a safety property and not a weakness — the same argument the framework's closure law makes about tuning a relationship without removing anyone's ability to walk away [Curzi, 2026].

4.18 Why disclosure and contradiction are both required They fail in different circumstances, which is the whole reason for having both.

A single-directive corpus satisfies every clause of §4.1. It is audible, published, readable, evaluable and refusable. And it is still a command, because a corpus with one member has a resultant equal to its member. Its surplus is $F = \ln 1 = 0$: a corpus of one is a parallel corpus and carries no surplus at all.

Conversely, a contradictory corpus delivered inaudibly satisfies §4.5 and violates §4.1, and the violation is total — a listener who cannot hear the corpus cannot perform the selection the structure exists to leave them.

Disclosure makes a command refusable. Contradiction makes it not a command. Disclosure fails when the listener is tired, deferential, or trusting; a field of mutually exclusive directions has no resultant whether or not anyone is paying attention.

4.19 The disclosure package Disclosure is an artefact, not an attitude, and the artefact is specified so that its absence is detectable. Everything below is published *before* any exposure, in a form the listener keeps:

```
D1   the corpus, in full, both members of every pair, in the rendering order
D2   the encoding tables: character set, byte width, bit-to-base rule
D3   the nucleotide string actually used, in full
D4   the address prefixes, in full, with their derivation
D5   the symbol-to-pitch table with n, f, j, and the resulting Hz
D6   the state rendering table of §4.14, with j for every value
D7   the envelope, symbol duration, and total run length
```

```
D8   the audio file itself, in an unencrypted, uncompressed format
D9   this section's honesty clauses and the open problem of section 6, in full
D10  a stated procedure for stopping, and who to tell
```

Item D3 is not redundant with D2. Section 5 uses a one-bit-per-base encoding in which the rule does not determine the string, so **a scheme whose rule is one-to-many must publish the string and not merely the rule.** The weaker encoding forces the stronger disclosure, and the trade runs in the right direction.

Item D10 exists because a stop procedure that has not been written down is a stop procedure that does not exist at the moment it is needed.

The specification

Numbered, checkable, and binding on Section 5. A rendering that fails any of these is out of scope.

S4.1 Every component of the rendered signal shall be audible to a person of ordinary hearing at the listening position — audible as rendered, at the level rendered, in the room, over the noise floor actually present. An inaudible component is raised or removed. There is no third option.

S4.2 No carrier, no mask, no embedding. No content under, inside or behind another signal. No amplitude-modulated speech, no time-compressed content, no spectral hiding beneath a louder band, no content below 20 Hz or above 20 kHz intended to act on a listener, and no psychoacoustic masking of any kind.

S4.3 The symbol rate shall be set by audibility, not by the Gabor floor. Section 5.15 computes both; the binding number is the one that leaves symbols individually resolvable by an ordinary listener in an ordinary room.

S4.4 The full disclosure package D1–D10 shall be delivered before exposure, in a durable form the listener retains.

S4.5 For every directive `v` in the corpus, its explicit negation `–v` shall also be in the corpus, stated with equal force, equal length, and equal position in the rendering order.

S4.6 No directive shall appear without its opposite. No opposite shall be weakened, hedged, qualified, or given the last word.

S4.7 The rendering order shall be published and shall be stated not to be a ranking.

S4.8 The equal-force check of §4.29 shall be computed and published, including its failures. A corpus with unrepaired failures may be rendered only if the failures are disclosed in D1.

S4.9 Every published frequency shall carry its transposition `j` and its band.

S4.10 No tempering. The essence ratios are exact ratios of squares and shall not be adjusted to twelve-tone equal temperament. 34.9756 cents is not 0 cents.

S4.11 The rendering shall use a windowed envelope. A rectangular gate is disqualified: it has no finite spectral second moment, verified numerically divergent in §5.17.

S4.12 The `u` of a designed corpus shall be reported as constructed, never as measured, in the same sentence that gives its value.

S4.13 Any octave-deficit reading published alongside a corpus shall report `D` and `delta` together.

S4.14 The listener shall be able to stop the rendering themselves, at any point, without asking anyone. A stop that requires an operator is not a stop.

S4.15 No rendering shall be delivered to a person who has not read D1 and D9, or who has not had them read to them.

S4.16 No rendering shall be delivered during sleep, sedation, or any state in which the listener cannot exercise S4.14.

S4.17 The corpus shall contain no directive that instructs the listener to conceal the corpus, to continue past a stop, to disregard their own judgment, or to defer to the operator.

S4.18 Nothing in the corpus shall reference a clinical condition, a diagnosis, a medication, or a course of treatment.

S4.19 The honesty clauses H4-1 through H4-6 and §6's open problem shall accompany every rendering as delivered, not as a footnote available on request.

S4.20 Every worked corpus published anywhere shall be labelled CONSTRUCTED in the same block that prints it.

The failure modes

FM-4.1 — The reasonable exception. Somebody proposes a masked version for a control condition, a pilot, or a demonstration to an audience that "would be distracted by hearing it." The proposal is always locally reasonable and it is always the same failure. **A constraint that admits a research exception is a constraint that has been repealed and re-announced as a preference.** Section 6 specifies a scrambled-sequence control precisely so that no masked condition is ever needed.

Fix: refuse. The controls of §6.13 do the work a masked arm was supposed to do.

FM-4.2 — Disclosure as a document nobody reads. A forty-page appendix technically satisfies S4.4 and defeats it. Disclosure is not discharged by publication; it is discharged by comprehension.

Fix: D1 is the corpus itself, in full, on one page, in the rendering order. Everything else is supporting material. If the corpus does not fit on a page, the corpus is too long.

FM-4.3 — The weighted corpus. Both members of each pair are present, so §4.5 appears satisfied, but one member is longer, louder, first, or better written. **A weighted contradictory corpus is a command with an alibi, and the alibi is more dangerous than an honest command because it survives inspection.**

Fix: the equal-force check of §4.29, computed and published including failures.

FM-4.4 — The private reduction. The corpus is balanced as written and the operator quietly renders only the half they agree with, or a listener is coached toward one side in the framing conversation. The structure is intact on paper and destroyed in delivery.

Fix: S4.7, plus a published rendering order fixed before the session, plus a witness who is not the operator.

FM-4.5 — Treating `u = 1` as a finding. The corpus reads at 69.6133 Hz, somebody prints that next to a person's name, and a construction constant has become a measurement.

Fix: S4.12. The value is a property of the design and says nothing about anyone.

FM-4.6 — Importing the placebo literature as support. The open-label result is used to suggest that this method works, or that a disclosed rendering is "like an open-label placebo."

Fix: §4.4. The result establishes that disclosure and effect are compatible in another domain. It is evidence about placebo trials, not about sonified sequence, and the two-column rule forbids moving it across [Curzi, 2026w].

FM-4.7 — Precedent presented as evidence. Several textual traditions preserved contradictory directives deliberately: Proverbs 26:4–5 places two opposed instructions adjacent and preserved; the Talmudic practice of *machloket* keeps minority opinions beside the ruling; the koan tradition constructs prompts that cannot be resolved within their own terms. That is genuine precedent and it is worth having. **None of these sources is in this paper's bibliographic database and none is cited with a key.**

Fix: state the column's role in the sentence. **Independent arrival is an argument that a structure is in the territory rather than only in this framework's instrument; it is not evidence that the structure does anything** [Curzi, 2026w].

FM-4.8 — Mechanism creep. “Carried in the harmonic” starts as a statement about encoding and becomes, three paragraphs later, a statement about transmission.

Fix: §4.16’s two halves, kept adjacent. Any sentence containing “carried” that also contains a cell, a receptor, or a transcript is a sentence to delete.

FM-4.9 — The pitch-class collision read as meaning. States 1, 2, 4 and 8 fold to the same 247.5140 Hz, and somebody concludes that these four states are “the same underneath.”

Fix: §4.15. The collision is $(2n)^2 = 4n^2$ and nothing else.

FM-4.10 — Rendering a single directive “for clarity.” The corpus is reduced to its most sensible member so the listener is not confused.

Fix: §4.18. A corpus of one has `F = 0` and a resultant equal to its member. It is a command, and the reduction converted a structure into an instruction.

FM-4.11 — Consent obtained after the disclosure was pre-summarised by the operator. The operator explains what the corpus “is really about,” and the listener consents to the summary.

Fix: S4.15 requires D1, the corpus itself. A summary is the operator’s resultant, and the whole design exists to have no resultant.

FM-4.12 — The deficit reported without `delta`. A corpus reading is published with `D` alone, and the reader cannot tell decay from level.

Fix: S4.13, and §4.8’s worked demonstration that `D` does not move when `Q_inf` changes by a factor of four.

FM-4.13 — Calling any of this a practice. The section’s material is a specification for a research procedure. The moment it is described as a practice, a modality, a protocol in the clinical sense, or a technique, it has acquired a standing it does not have.

Fix: H4-1, and §5.2’s labelling rule, which applies to every sentence and not only to the abstract.

Worked example

CONSTRUCTED. The corpus below was written for this section. It is not a transcript, not a record of practice, and not an observation of any person.

4.28 The corpus Twelve directives, one per state of the ladder, each with its explicit negation. Rendering order is by index and is published as such; it is not a ranking.

```
n = 1    LET THE CHARGE RISE UNNAMED    /  LET THE CHARGE FALL UNNAMED
n = 2    CALL THIS GOOD AND ACT         /  CALL THIS BAD AND ACT
n = 3    AIM THE FEELING AT ITS OBJECT  /  TURN THE FEELING FROM ITS OBJECT
n = 4    READ THE ROOM BEFORE YOU MOVE  /  MOVE BEFORE YOU READ THE ROOM
n = 5    NAME THE CAUSE AND HOLD IT     /  DROP THE CAUSE AND HOLD NOTHING
n = 6    GIVE THIS AN END AND WAIT      /  GIVE THIS NO END AND WAIT
n = 7    TURN AND LOOK AT YOURSELF      /  TURN AND LOOK AWAY FROM YOURSELF
n = 8    MODEL THE OTHER MIND NOW       /  LEAVE THE OTHER MIND ALONE
n = 9    APPLY THE STANDARD IN FULL     /  SUSPEND THE STANDARD IN FULL
n = 10   PUT THIS INSIDE THE STORY      /  TAKE THIS OUTSIDE THE STORY
n = 11   LET THEM SEE YOU SEEING THEM   /  LET THEM SEE NOTHING OF YOU
n = 12   BIND YOURSELF TO THE NEXT ACT  /  LOOSE YOURSELF FROM THE NEXT ACT
```

Each pair names one state and urges opposite dispositions toward it. Nothing in the corpus refers to a condition, a treatment, or an outcome, per S4.18.

4.29 The equal-force check, computed and failing S4.5 requires equal force, and "equal force" is only a specification if it is checkable. The declared check is character count and word count, with a tolerance of two characters and zero words.

n	chars	d	words	d	result
1	27 / 27	0	5 / 5	0	PASS
2	22 / 21	1	5 / 5	0	PASS
3	29 / 32	3	6 / 6	0	FAIL
4	29 / 29	0	6 / 6	0	PASS
5	26 / 31	5	6 / 6	0	FAIL
6	25 / 25	0	6 / 6	0	PASS
7	25 / 32	7	5 / 6	1	FAIL
8	24 / 26	2	5 / 5	0	PASS
9	26 / 28	2	5 / 5	0	PASS
10	25 / 27	2	5 / 5	0	PASS
11	28 / 27	1	6 / 6	0	PASS
12	29 / 32	3	6 / 6	0	FAIL

Four pairs out of twelve fail — 33.33% — and they are reported rather than quietly repaired, because the rate at which a careful author fails this check is the useful number. The author wrote these lines intending them to be balanced and they are not. Pair 7 is the worst: the negation is seven characters and one word longer than the directive, which means that in a rendering where each character contributes to the symbol stream, the negation is materially longer on the air.

The three ways to respond, in decreasing order of honesty:

1. **Rewrite and re-check.** Preferred. Repair pairs 3, 5, 7 and 12 and publish the second check alongside the first, so a reader can see what changed.
2. **Render as is and disclose.** Permitted by S4.8 provided the failing pairs are named in D1.
3. **Render as is and say nothing.** Forbidden. This is FM-4.3 with the evidence available and suppressed.

Character count is a crude proxy for force and is not defended as more than that. It catches gross asymmetry, which is the failure that matters, and it is checkable by anyone. Prosody, connotation and rhetorical weight are not caught by it, which is why S4.7 also fixes the order and why a witness who is not the author is worth having.

4.30 The rendering The corpus renders as twenty-four tones. Each directive sits at its state's folded frequency in 220–440 Hz; each negation sits exactly two octaves above it in 880–1760 Hz.

```
band, directives   220.0000 – 440.0000 Hz
band, negations    880.0000 – 1760.0000 Hz
every pair         ratio 4 exactly = 2400.0 cents exactly
distinct classes   6, per ceil(12/2)
tightest folded gap at N = 12   34.9756 cents (classes 7 and 5)
tempering          none
envelope           windowed; rectangular gate disqualified (S4.11)
```

The audible result is twelve pairs of double octaves, six of which share pitch class with another pair, spread across two registers. A listener who has never seen the tables can hear that the material is built in opposed pairs, because the pairs are octaves and octaves are the one interval nobody has to be taught.

4.31 The reading, with every warrant attached

```
u                 1.000000     CONSTRUCTED, not measured (S4.12)
F                 2.484907 nats = ln 12, the ceiling
f_rel            69.613306 Hz   folded 278.4532 Hz (j = 2)
octaves above k   7.169925
selection cost    2.484907 nats = 3.584963 bits
```

The corpus supplies 2.484907 nats of surplus and selecting one of its twenty-four members — twelve states, two directions each — costs the receiver exactly the surplus the corpus carries, under H82-A's two conditions. **What the number says is that the corpus was built to span the whole ladder and to point nowhere. It says nothing about any listener, and no reading of any listener has been taken.**

Reported honestly: this is `f_rel` computed from a constructed `u = 1`, at `N = 12`, with `k = 0.483425732988414 Hz`, folded at `j = 2` into 220–440 Hz. It is an essence frequency, not a physical resonance. It is not clinical, not diagnostic, and not a measurement of a person.

4.32 What this rendering does not do Everything above is encoding, and the boundary is worth drawing one final time in the concrete.

Twenty-four tones exist. They stand in exact rational relationships. Their structure mirrors the structure of a written text bijectively. A listener can hear the structure, read the text, check the tables, and stop the playback. **And there is no established mechanism by which any of that reaches a cell, a transcript, or a locus, which is §6's subject and the reason this paper is written in the order it is.**

What this section established **Established, and checkable:** that the no-subliminals constraint is ethical rather than stylistic, and rests on an argument — a hidden message cannot be consented to — that requires no empirical support and gains none from any; that open-label placebo removes the excuse for concealment without supplying evidence for anything in this paper; that a negation-closed corpus has resultant exactly zero and a mutually exclusive one has mean direction `1/sqrt(N)`, both verified; that at `N = 12` a maximally contradictory corpus carries `F = ln 12 = 2.484907` nats and sits exactly on the sustainability ceiling, residual `8.88e-16`; that a contradiction renders as exactly 2400.0 cents; that twelve states yield six pitch classes and the collisions are arithmetic rather than meaning; and that a careful author failed the equal-force check on four pairs out of twelve.

Not established, and not claimed: that any of this affects any cell, any transcript, or any person; that the twelve states are diagnoses; that a rendering is a treatment, a therapy, a practice or a modality; that DNA is edited, altered or damaged anywhere in the chain; that any capability has been conferred; or that any frequency printed here is a physical resonance.

The one line to carry forward: *the information is the tone, and a corpus built to contradict itself hands the decision back to the person listening.*

Section 4 owns the no-subliminals constraint as it applies to psychological content, the determination-by-choice argument in this framework's register, the double-octave rendering of a contradiction, and the disclosure package D1–D10. Section 5 builds the procedure on top of it; Section 6 states the open problem that governs both.

5 The encoding and rendering protocol, specified end to end

This section specifies a procedure end to end, in enough detail that a competent engineer can build it from this text alone and obtain bit-identical results. It is the most concretely

buildable material in this paper and the material that has to be most careful about what it claims, because it sits between Section 4, which fixed the ethical architecture, and Section 6, which states the gap that governs both.

Everything specified here is a research procedure. It is not a treatment, a therapy, a technique with a demonstrated effect, a modality, or a practice. That label is not an abstract disclaimer placed at the front and then forgotten; it is repeated at every stage of the specification, it governs the wording of every step, and §6's open problem is why.

What is built: an encoder, an addressing convention, a sonifier, a transposition, and a rendering discipline. All five are deterministic and reproducible, and the worked example demonstrates a round-trip SHA-256 identity on a real payload. What is not built, and what is not claimed in any form, is a biological effect. Section 6 is entirely about why that claim is unavailable.

The section also carries the falsification apparatus, because a procedure whose honesty clauses are appended is a procedure whose honesty clauses will be detached. **Every clause is written into the step it constrains.**

The law

5.1 The open problem, stated first and not by reference

> **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal.**

That statement is §6's to develop. It is printed here in full rather than cited, because a reader who arrives at a section titled *protocol* is exactly the reader who will not turn forward, and exactly the reader for whom the sentence was written.

What is established upstream is a great deal, and §6.5 itemises it: data storage in nucleotide sequence, gRNA-format addressing, self-processed multi-address arrays, the separability of targeting from editing, mechanotransduction, force-to-transcription coupling at the nucleus, and the activation of latent capability by regulatory signal. **What is missing is the single link that carries sequence over force, and everything in this section stops at that link.**

5.2 The labelling rule Because the temptation to describe this procedure in clinical vocabulary is constant, the rule is made explicit and is binding on every sentence, table caption, figure label and file name produced under this section:

PERMITTED	procedure, specification, encoder, rendering, run, condition, exposure, participant, endpoint, preregistration, null result
FORBIDDEN	treatment, therapy, dose, patient, cure, healing, intervention (in the clinical sense), modality, practice, session (clinical), efficacy, indication, response rate, remission

A procedure that has to borrow clinical words to describe itself is claiming a standing it has not earned. The borrowing usually happens in a caption rather than in a sentence anyone argues about, which is why the rule is mechanical rather than a matter of judgment: the forbidden list is searched for before release, in every file, and hits are fixed rather than defended.

There is a second reason for the strictness and it concerns the reader rather than the writer. Clinical vocabulary carries an implied evidentiary context — a thing with a dose has been dosed, a thing with a response rate has been measured, a thing with an indication has been through something that produced one. Borrowing the word imports the whole implication

for free, and a reader who trusts the word has been misled by a sentence that never made a false statement. The vocabulary is where an overclaim happens without anybody deciding to overclaim, which is why it is policed by search rather than by conscience.

5.3 The constraint, inherited whole from Section 4

No subliminal content of any kind. Nothing masked. Nothing below threshold. Nothing concealed. The information is the tone. Section 4 owns the argument, the disclosure package D1–D10, and specifications S4.1 through S4.20. This section inherits all of them and adds none that weaken any.

Two of them bind directly on engineering decisions made below and are flagged where they bite: S4.3, which sets the symbol rate by audibility rather than by the Gabor floor, and S4.11, which disqualifies the rectangular gate.

5.4 What is built and what is postulated

The distinction is drawn before the interesting material, because the temptation to blur it increases as the section goes on.

Element	Status	Warrant
Text maps losslessly to a nucleotide string	**BUILT, VERIFIED**	§5.9, SHA-256 round trip
The balanced free-choice rule holds GC within one base of `L/2`	**PROVED (arithmetic)**, measured	§5.9
The balanced rule raises symbol entropy from 1.244171 to 1.935874 bits/base	**MEASURED** on the payload	§5.9
RLL(3) capacity is 1.982354 bits/base	**COMPUTED** (transfer-matrix eigenvalue)	§5.8
A 20-nt prefix is a sufficient address	**COMPUTED**, 0.005638867 expected hits	§5.10
The prefix is a routing header, not a molecule	**STATED, structural**	§5.10
Route B index assignment `n = 1,3,5,7` gives four distinct classes	**PROVED (arithmetic)**	§5.12
The naive assignment `n = 1,2,3,4` collapses three symbols	**PROVED, REJECTED IN PRINT**	§5.12
Symbol alphabet minimum gap is 990.055901 Hz	**COMPUTED**	§5.13
Symbol layer and state layer are separated by 995.9922 cents	**COMPUTED**	§5.14
Gabor limit `dt·df >= 1/(4 pi) = 0.079577` constrains the rate	**PROVED (classical Fourier)**	§5.15
Single-transposition audible capacity is `N <= 25`, at `j = 6` only	**COMPUTED**, verified	§5.16
The folded-lattice cliff is at `N = 17`; second at `N = 41`; rate factor 8	**CITED** [Curzi, 2026]	§5.16
The rectangular gate has no finite spectral second moment	**COMPUTED**, divergent	§5.17

Element	Status	Warrant
`k` is a chosen reference constant	**POSTULATE**, badged	§2.3 P-a
A transposed tone bears a physical relation to a base	**REFUSED**	H5-4
That any of this affects any cell	**NOT CLAIMED**	§6

Eleven computed or measured rows, two proofs, one rejection in print, one badged postulate, one refusal, and one open problem. A reader is entitled to see the accounting in that form before reading a word of the argument, and to check it against the section as they go.

5.5 Honesty clauses, binding **H5-1 — No clinical, medical or therapeutic claim.** This section describes signal processing and an experimental design. No trial, no controlled observation, and no demonstrated physiological effect of the procedure exists, and none is asserted.

H5-2 — No claim that DNA is edited, altered or damaged. Nothing in the pipeline is a molecule. The output of the last stage is a waveform; the nucleotide string is a string in the computer-science sense. **At no point does this procedure synthesise, deliver, or modify any nucleic acid, and it contains no nuclease, no template, and no Cas protein.**

H5-3 — No claim that any capability has been conferred on anything.

H5-4 — The transposition is a mapping, not a resonance. This is the strongest clause here and the one a careless reader most often violates. The tones of §5.13 are essence frequencies obtained by applying a postulated square law to a chosen index assignment and then shifting register. **A tone at 1113.8129 Hz has no physical relationship to cytosine. Cytosine does not absorb at that frequency, does not resonate at it, and is not affected by it.** The mapping is a labelling convention, chosen because it is principled and reproducible. It is not a physical coupling and this framework never says or implies that it is.

H5-5 — `k` is chosen, not measured. `k = (9/8)^2/phi^2 = 0.483425732988414 Hz` is a Pythagorean ditone divided by the golden section and is a design decision by the author. It is badged every time it appears. Result One of the essence law explains why the badge costs so little [Curzi, 2026k]: $f(m)/f(n) = m^2/n^2$, so `k` cancels out of every ratio in the system.

H5-6 — Every number here was computed, and the computations are stated in enough detail to be redone. Anything that could not be computed is marked nominal or omitted.

H5-7 — The worked payload is CONSTRUCTED. It is the corpus of §4.28, written for this paper. It is not a transcript and not an observation of anyone.

The engineering

5.6 The pipeline

```
a written corpus of directives over the twelve states        §4.28
    |
    |  [1]  ENCODE     text -> bits -> nucleotide string          §5.7 – §5.9
    v
payload sequence
    |
    |  [2]  ADDRESS    gRNA-format prefix prepended               §5.10 – §5.11
    v                  (a routing header on a data structure)
addressed sequence
    |
```

```
    |  [3]  SONIFY     essence law, f = k n^2, Route B           §5.12
    |  [4]  TRANSPOSE  fixed integer octave shift per symbol     §5.13
    |  [5]  LAYER      the state layer of section 4.14            §5.14
    |  [6]  RENDER     windowed envelope, rate set by audibility  §5.15 – §5.17
    v
a disclosed audio file, published with D1–D10
    |
    |  [7]  TRANSMIT   playback in a room, with consent
    v
the open problem of section 6 begins here, and this section stops
```

Steps 1 through 6 are engineering and are demonstrated below with computed and verified numbers. Step 7 is playback of an audio file. **What happens after step 7 is not claimed by this framework in any form.**

5.7 Stage 1 — text to bits The corpus is written as plain text and the encoding to bits is ordinary. It must nonetheless be published in full: character set, byte width, byte order, whether directives are concatenated or kept separate, and what separator is used.

The declared scheme is 8-bit ASCII, one byte per character, no terminator, directives separated by a single newline, both members of each pair present in the published rendering order.

For the corpus of §4.28:

```
characters, including newline separators      675
bytes                                         675
bits                                        5,400
SHA-256 of the source text
    c7d98b1cfde5c515ce99ff7db77d484f71a09c5cd921994f15df66c50373b72d
```

The bit count is Shannon information [Shannon, 1948, Cover and Thomas, 2006] — not thermodynamic entropy, and no thermodynamic claim is made anywhere in this paper. Nothing interesting happens at this stage, and that is deliberate: **any cleverness here would be a place to hide something.** A published, standard, character-for-character mapping is auditable by anyone with a text editor, which is what D2 of the disclosure package is for.

5.8 The rate landscape, and an honest correction carried forward Church, Gao and Kosuri (*Science* 337:1628, 2012) encoded a book into synthesised oligonucleotides and recovered it by sequencing. **That paper, and every other primary biological source named in this section and in §6, is absent from this paper's bibliographic database and is named without a citation key; see §10, L-9.** A correction must be carried: **they did not use two bits per base. They used one** — `A` or `C` encoded a zero, `G` or `T` encoded a one — and the free choice within each pair was spent on homopolymer avoidance and GC control. The base-4 alphabet is the theoretical ceiling; the Church architecture of block, address and common flanks is the part that was demonstrated. This procedure uses the alphabet and the architecture and says plainly that the doubling of rate relative to the 2012 paper is not something the 2012 paper did.

The homopolymer-constrained capacity is the capacity of a constrained channel and is a transfer-matrix eigenvalue [Shannon, 1948, Cover and Thomas, 2006], computed rather than quoted:

```
unconstrained base-4                    2.000000 bits/base   100.000%
RLL(2)  max run 2                       1.922688 bits/base    96.134%
RLL(3)  max run 3                       1.982354 bits/base    99.118%
RLL(4)  max run 4                       1.995717 bits/base    99.786%
RLL(5)  max run 5                       1.998939 bits/base    99.947%
this procedure, one bit per base        1.000000 bits/base    50.000%
```

Forbidding runs longer than three costs 0.882% of capacity. Discarding the second bit costs half of it, and buys something the compressed scheme cannot have.

5.9 Stage 1b — bits to bases, and what the discarded bit buys

With two acceptable bases per bit there is one free choice at every position. For a 5,400-bit payload the number of distinct nucleotide strings encoding exactly the same message is `2^5400`, a 1,626-digit count (`5400 · log10 2 = 1625.562`).

The declared rule for spending the free choice is **balanced selection**: at each position choose, among the bases legal under the homopolymer constraint, the one used least often so far, ties broken alphabetically. The obvious alternative is greedy first-legal selection. The two were built and measured on the same payload, and the difference is not small:

rule	A	C	G	T	GC	max run	entropy (bits/base)
greedy	3233	266	1856	45	0.392963	3	1.244171
balanced	1750	1749	951	950	0.500000	1	1.935874

Both recover the source exactly:

SHA-256, source text	c7d98b1c...0373b72d	
SHA-256, recovered from greedy	c7d98b1c...0373b72d	IDENTICAL
SHA-256, recovered from balanced	c7d98b1c...0373b72d	IDENTICAL

Two properties of the balanced rule are worth stating because they are structural rather than lucky. Because the rule always increments the currently smaller count, the two members of each bit class stay within one of each other; each class contains exactly one strong base and one weak one; therefore **GC content differs from `L/2` by at most one base regardless of what the payload says.** Here it is exactly 2,700 of 5,400. And because consecutive symbols from the same bit class alternate while consecutive symbols from different classes are drawn from disjoint letter pairs, the measured maximum homopolymer run is 1 — comfortably inside RLL(3).

The entropy figure is the one that matters for rendering. A greedy string is 3,233 adenines out of 5,400 and sounds like a drone with occasional events; a balanced string uses all four symbols nearly equally. A payload whose symbol distribution is that skewed is a payload whose rendering a listener cannot follow, which is **an audibility failure under S4.1 arriving from an unexpected direction.**

The first sixty bases of the balanced encoding, published because D3 requires the string and not merely the rule:

```
AGCATGCACTACAGCTAGCTAGCACATCACACAGCTAGCACTACGACACTACAGCTACGA
```

A scheme whose rule is one-to-many must publish the string. The weaker encoding forces the stronger disclosure, and that is the right direction for the trade to run.

5.10 Stage 2 — the address, which is a routing header and not a molecule

The framework's addressing paper established this architecture [Curzi, 2026y] and this section uses it without extending it. The prefix is formatted after the guide-RNA spacer convention, and its status must be stated in the same breath as its format:

The prefix is a field in a file. It is not delivered, it is not synthesised, it is not a molecule, no Cas protein is present anywhere in this procedure, and therefore nothing is edited.

Why twenty nucleotides, computed rather than asserted. The *Streptococcus pyogenes* Cas9 spacer is 20 nt and the arithmetic reason is address-space sizing against genome size:

```
L        4^L                expected hits in 6.2e9 positions
 8       6.553600e+04              94604.5
12       1.677722e+07                369.549
16       4.294967e+09                  1.44355
18       6.871948e+10                  0.0902219
20       1.099512e+12                  0.005638867
22       1.759219e+13                  0.000352429
24       2.814750e+14                  0.0000220268

4^20 = 1,099,511,627,776
address space / genome positions = 177.3406
```

Below 16 nt an address is not an address — it names hundreds of places. At 20 nt the expected number of spurious matches is about one in 177. That is the whole justification; it is arithmetic, and it is the same arithmetic that sets hash lengths in ordinary computing.

It is worth being precise about what "addressing" does and does not mean in a procedure where nothing is delivered. In ordinary CRISPR practice a spacer is an address because a molecule carries it to a locus and binds there; the address does work because the delivery vehicle exists. Here there is no vehicle. The prefix is a field in a file, and its function within this procedure is bookkeeping: it says which of the twelve directives a given block of payload belongs to, it makes the transmission parseable by anyone reading the published string, and it fixes the format so that the disclosure of D4 is checkable against a standard. The 20-nt length is justified by the same arithmetic that would justify it in a molecular context, and the justification is retained because borrowing a format and then silently changing its parameters is how formats become meaningless. But the length is doing bookkeeping work here, not molecular work, and no reader should be left able to think otherwise.

Cas12a's native processing of its own crRNA array (Zetsche et al., *Cell* 163:759, 2015; Fonfara et al., *Nature* 532:517, 2016) is cited here for one thing only: that a **multicast destination list** is a real biological format. It is cited for the format and for nothing else, and no claim is made that any such parsing occurs in response to sound.

5.11 The addressed payload

One address per directive pair, twelve pairs:

```
address prefixes         12 x 20 nt  =    240 bases
payload                                 5,400 bases
TOTAL TRANSMISSION                      5,640 bases
```

The prefixes are published in full in D4 with their derivation, exactly as the payload is published in D3. **An address that is not disclosed is a routing decision the listener cannot inspect, which fails S4.4 whether or not it does anything.**

5.12 Stage 3 — sonify by the essence law

Four symbols must become four distinguishable tones, by the law this framework already owns:

```
f(n) = k * n^2        k = (9/8)^2 / phi^2 = 0.483425732988414 Hz     POSTULATE, badged
```

Applying it requires a defensible ordinal on the four bases, which the framework demands of every application of the law. **An arbitrary ordering yields arbitrary frequencies, and the ordering must be argued in print or the route is unavailable.** The ordering used is alphabetical — A, C, G, T — which is not defended as meaningful, only as published, stable, and conventional in every sequence database in existence. That is a weaker warrant than the twelve-state ladder carries, and it is stated as weaker.

The obvious index assignment is a trap, and it is rejected in print. Assigning `n = 1, 2, 3, 4` gives odd parts 1, 1, 3, 1: three of the four bases collapse onto a single pitch class, because

`f(2) = 4 f(1)` is exactly two octaves and `f(4) = 16 f(1)` exactly four. By the odd-part rule a listener attending to pitch class hears three of the four symbols as the same note. The scheme is unusable and the reason is arithmetic.

The adopted assignment is the odd indices, which gives four distinct classes:

base	n	f(n) (Hz)	j	f_audible (Hz)
A	1	0.4834257330	8	123.7570
C	3	4.3508315969	8	1113.8129
G	5	12.0856433247	8	3093.9247
T	7	23.6878609164	8	6064.0924

This is the framework's odd-index route at its default assignment, carried unchanged [Curzi, 2026ad].

5.13 Stage 4 — transposition, and the separation it produces Transposition is by a fixed integer number of octaves and preserves pitch class exactly Here a single `j = 8` serves all four symbols, so the ratio structure of the alphabet after transposition is identical to the ratio structure before it. **Nothing is added and nothing is distorted; it is a change of register, the only purely presentational operation in the chain.**

The resulting separation:

sorted tones (Hz)	123.7570	1113.8129	3093.9247	6064.0924
adjacent gaps (Hz)	990.0559	1980.1118	2970.1677	
adjacent gaps (cents)	3803.9100	1768.7174	1165.0244	
MINIMUM GAP IN HZ	990.055901 Hz	(the A–C pair)		
MINIMUM GAP IN CENTS	1165.0244 cents	(the G–T pair)		
all four inside 20 Hz – 20 kHz			yes	

A correction, made visible rather than applied quietly. The source prints these two figures on one line joined by an equals sign. They are not two readings of one quantity: the alphabet is spread multiplicatively, so the pair that is closest in hertz and the pair that is closest as an interval are different pairs. The Gabor floor consumes the hertz figure and consumes the right one; a listener's frequency discrimination is described in the cents figure. Section 10 states the correction in full.

The tightest pair in the symbol alphabet, measured as an interval, is 1165.0244 cents apart — very nearly an octave — a separation any device with frequency dependence at all can resolve, and one that no plausible implementation error can permute. **That property is the whole reason the odd-index assignment is the default: it is not chosen for elegance, it is chosen because the naive one fails.**

It is worth pausing on how different that is from the alternative route. The framework's addressing paper built the same alphabet from measured infrared band centres and found the four symbols occupying less than half a semitone, with two of them two cents apart — a code that a routine solvent shift could permute outright, and one whose Gabor floor forced a rate of five and a half symbols per second. Register spreading fixed it there, by giving each symbol its own octave index: per-symbol indices $j = 33..36$ raised the minimum adjacent gap from 0.8725 Hz to 732.037 Hz, an 839.0-fold improvement, lifting the Gabor rate from 5.5 to 4599.5 symbols per second [Curzi, 2026y]. The essence-law route used here arrives at a comparable separation by a different road: the indices are already spread, because squaring them spreads them, and a single transposition therefore suffices. Neither route is more physical than the other — H5-4 forbids reading either as physical — but the essence route is the one that needs no spectrometer and no calibration, and this framework uses it for that reason and states the reason.

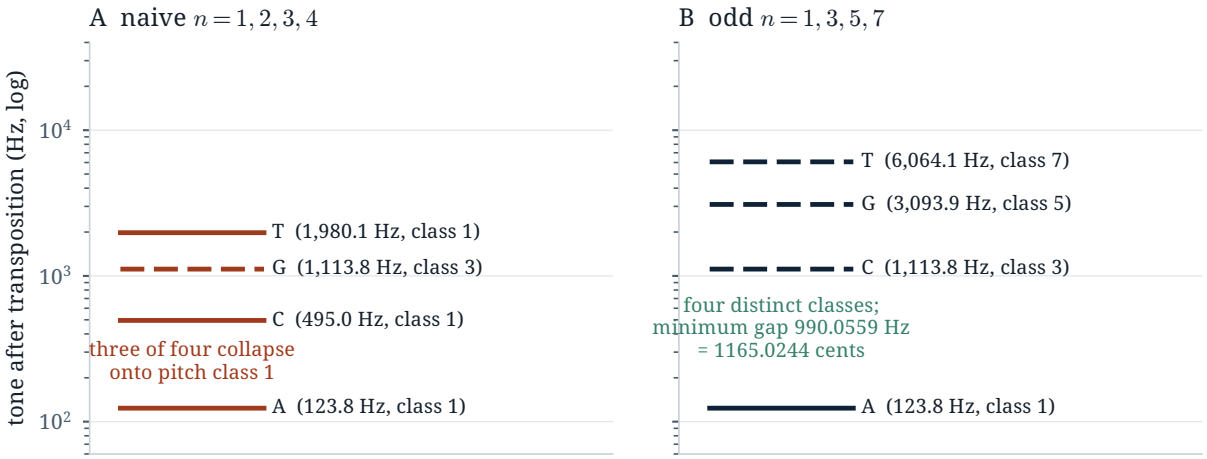

Figure 48.3: **The obvious index assignment collapses the alphabet: $n = 1, 2, 3, 4$ puts three of four symbols in one pitch class, while $n = 1, 3, 5, 7$ gives four.** Under the essence law an index and its double are exactly two octaves apart, so the pitch class of n is its odd part. Modelled from $f(n) = kn^2$ with $k = 0.483425732988414$, a **defined** constant whose interpretation as a frequency is postulated (§2.3), transposed by $j = 8$ in both panels for comparability. Built by `figs/src/CCP-048_fig01.py`.

5.14 Stage 5 — the state layer, and channel separation Section 4.14 renders the twelve states themselves: each directive at its state's essence frequency folded into 220–440 Hz, each negation exactly two octaves above. That layer and the symbol layer are both audible, both disclosed, and must be separable by ear, which requires checking rather than assuming.

```
state layer band                220.0000 – 440.0000 Hz     (j = 6 for the ladder)
nearest symbol tone below        123.7570 Hz  ->   995.9922 cents clear
nearest symbol tone above       1113.8129 Hz  ->  1607.9178 cents clear
```

The state band is clear of every symbol tone by at least 995.9922 cents — better than an octave — so the two disclosed layers occupy disjoint registers and neither masks the other. That is a computed property of this particular pairing of `j` values, not a general fact, and any change to either transposition requires recomputing it. Note also that the negation register of §4.14 (880–1760 Hz) does overlap the symbol tone at 1113.8129 Hz; where both layers are rendered simultaneously they must be separated in time instead, and the run schedule of §5.18 does exactly that.

5.15 The design table This is the table the disclosure constraints exist to produce, and every row is computed or cited with its owner named.

The Gabor limit, which binds every rendering:

```
dt * df  >=  1 / (4 pi)  =  0.07957747154594767
```

Analogy status: category 1 for the mathematics and category 3 for the physical reading. The bound is Gabor's [Gabor, 1946] and is a theorem about the Fourier transform of a signal, with no quantum content whatever. It has the same algebraic form as $\sigma_x \sigma_p \geq \hbar/2$ [Kennard, 1927], which is a fact about state preparation and not about measurement disturbance, and **nothing in this paper transfers any physical result from the second to the first.** It is measurable on an oscilloscope. The framework's conjugate-uncertainty paper owns it [Curzi, 2026z], whose Result One proves the Gabor limit $\Delta t \, \Delta f \geq 1/(4\pi) = 0.079577471545948$ by the same variational argument as $\sigma_x \sigma_p \geq \hbar/2$ with $p = \hbar k$ deleted; Gaussians saturate it and a Hann window costs 2.6 per cent.

Applied to the symbol alphabet, minimum gap 990.055901 Hz:

```
convention df = gap        dt >= 0.080377 ms
convention df = gap/2      dt >= 0.160753 ms
```

Both conventions are printed because both appear in the literature and quoting one without saying which is a reproducibility failure. The design table below uses `df = gap`.

dt (ms)	df at that window	safety over floor	symbols/s	total run, 5,640 bases
1	79.5775 Hz	12.44x	1000.00	5.640 s
5	15.9155 Hz	62.21x	200.00	28.200 s
10	7.9577 Hz	124.41x	100.00	56.400 s
20	3.9789 Hz	248.83x	50.00	112.800 s
25	3.1831 Hz	311.04x	40.00	141.000 s
50	1.5915 Hz	622.07x	20.00	282.000 s
100	0.7958 Hz	1244.14x	10.00	564.000 s

The default adopted here is 20 ms per symbol, a safety factor of 248.83 over the floor, and the factor is large on purpose. The Gabor floor is where two tones become mathematically indistinguishable; a signal whose symbols no listener can resolve is a concealed signal by another route, and **S4.3 therefore sets the rate by audibility rather than by the mathematics.** At 20 ms the full 5,640-base transmission runs 112.800 seconds.

Applied to the state layer, whose binding separation is the tightest folded gap at `N = 12` — 7.734812 Hz between classes 7 and 5 [Curzi, 2026], cited and not re-derived:

```
dt >= 0.0795774715 / 7.734812 = 0.0102882 s = 10.2882 ms
```

The state layer is nearly 128 times more demanding than the symbol layer, and that ratio is the reason the two layers get different treatment in the run schedule.

5.16 The regime, the capacity, and the two cliffs Three structural constraints, all owned elsewhere, all binding here.

(1) The 50/49 regime. The framework's reference apparatus derives it once [Curzi, 2026] and it is not re-derived here. At `N = 12` the minimum adjacent separation in the folded class lattice is 34.9756 cents, the interval `50/49`, between classes 7 and 5. At `N = 17` the minimum collapses to 6.0008 cents, the interval `289/288`, because `17^2 = 289` lands one sixth of a comma from `2 · 12^2 = 288`. The second cliff is at `N = 41`, where `41^2 = 1681` meets `2^4 · 105 = 1680` through class 29, giving `1682/1681` and 1.0296 cents. Both are exact rational coincidences.

The rate factor across the first cliff is exactly 8, because the binding pairs sit at different octave heights — `50/49` straddles `49/32` and `289/288` straddles `9/8` — so the absolute gap falls from `f/32` to `f/256`; that figure is cited [Curzi, 2026].

This framework's `N = 12` sits below the first cliff. Every folded distinction asked of a listener or an instrument here is at least 34.9756 cents wide, roughly a third of a semitone, and lengthening the index past 16 would cost a factor of eight in symbol rate.

(2) Single-transposition audible capacity. A single integer octave transposition admits at most `N = 25` essences inside 20 Hz to 20 kHz, and only at `j = 6`. Verified:

```
N = 20    admissible j = [6]
N = 25    admissible j = [6]
N = 26    admissible j = []      the set is empty
```

`N = 12` is comfortably inside the limit. A longer index would require split transposition, which is permitted but must be published per symbol.

(3) No tempering. The essence ratios are exact ratios of squares. They are not adjusted to twelve-tone equal temperament anywhere in this procedure. 34.9756 cents is not 0 cents, and a rendering that rounds it to the nearest semitone has destroyed the distinction it was built to carry.

5.17 The envelope — the rectangular gate is disqualified S4.11 forbids a rectangular gate and the reason is computable. The spectrum of a rectangular window of duration `T` is a sinc, whose squared magnitude decays as `f^-2`, so the second moment integral `int f^2 |S(f)|^2 df` diverges. Numerically, at `T = 5 ms`, integrating over successively wider bands:

```
band +-1e3 Hz     second moment  2.068251e+04
band +-1e4 Hz                    2.030538e+05
band +-1e5 Hz                    2.026834e+06
band +-1e6 Hz                    2.026465e+07
```

The value grows linearly with the integration band and does not converge, which means a rectangular gate has no defined `df` at all and the Gabor bound cannot be applied to it. Any implementation uses a windowed envelope — the specific window is published in D7, with its rise and fall times.

5.18 The run schedule Because the two layers overlap in the negation register (§5.14), and because their Gabor requirements differ by a factor of nearly 128, the declared schedule separates them in time:

```
PHASE 0    silence, 5 s                       the listener confirms the room
PHASE 1    the state layer, 24 tones          §4.14
           directive and negation as a
           double octave, 2 s per pair        48.000 s
PHASE 2    silence, 5 s
PHASE 3    the symbol layer, 5,640 bases
           at 20 ms per symbol               112.800 s
PHASE 4    silence, 5 s
           TOTAL                             175.800 s
```

Phase 1 exists so that the listener hears the structure of the corpus — twelve opposed pairs, as double octaves — before hearing the encoded transmission of it. Putting the structure first is a disclosure decision, not an aesthetic one: a listener who has heard the pairs knows what the corpus is before the long phase begins, and can stop.

5.19 What this procedure would look like if it were a technique, and why it is not A useful way to see the boundary is to write down what would have to change for any of this to be described as a technique rather than a research procedure.

It would need a demonstrated effect: a preregistered endpoint that moved, in a design with the four controls of S5.21 in place, replicated by a group that did not build the apparatus. It would need that effect to survive the scrambled-sequence control of §6.13, because an effect that does not distinguish an ordered signal from its permuted twin is an effect of sound, not of content, and the entire content architecture of Sections 4 and 5 would be beside the point. It would need a mechanism, or at minimum a candidate mechanism with its own independent evidence, because a replicated effect with no mechanism is a phenomenon to be investigated rather than a technique to be applied. And it would need a magnitude large enough to matter against the detectable floor computed in §6.9.

None of those four conditions is met. Not one of them is close to met. **The distance between "the procedure is fully specified" and "the procedure does something" is the distance this paper exists to keep visible**, and it is kept visible by writing the specification exactly as carefully as if the effect were real, and then saying, in the same breath, that it is not known to be.

The specification

Part A — the encoding chain **S5.1** The character set, byte width, byte order and separator convention shall be published.

S5.2 The bit-to-base rule shall be published, and because it is one-to-many, the actual nucleotide string shall be published in full (D3).

S5.3 The free choice shall be spent by the balanced rule of §5.9, or by another published rule whose GC and entropy figures are computed and reported alongside the greedy baseline.

S5.4 Homopolymer runs shall be constrained to at most 3, and the achieved maximum run reported.

S5.5 A round-trip hash identity shall be demonstrated and both hashes published.

S5.6 The address length shall be justified arithmetically against the target genome size, and the prefixes published in full.

S5.7 Every document, caption and file name shall state that the prefix is a routing header and that nothing is delivered, synthesised, or edited.

S5.8 The index assignment for the four bases shall be published, with the ordinal argued, and the rejected naive assignment stated so that a reader knows it was considered.

S5.9 Every published frequency shall carry its `n`, its `j`, and its band.

S5.10 Minimum adjacent gaps shall be reported in Hz and in cents.

S5.11 Channel separation between the symbol layer and the state layer shall be computed in cents and published; where the registers overlap, the layers shall be separated in time.

S5.12 The symbol rate shall be reported with its Gabor safety factor and with the convention (`df = gap` or `df = gap/2`) stated explicitly.

S5.13 The envelope shall be windowed, published, and reported with rise and fall times. A rectangular gate is disqualified.

S5.14 No tempering of any interval, at any stage.

Part B — preregistration and falsification **This is where the procedure becomes a research procedure rather than a demonstration, and none of it may be retrofitted after data exist.** The standard is the ordinary one for preregistration [Nosek et al., 2018]: the analytic choices that produce significance at will [Simmons et al., 2011, Gelman and Loken, 2013] are fixed before the data exist, and a literature that does not do this recovers far less on replication than its published record implies [Open Science Collaboration, 2015, Ioannidis, 2005].

S5.15 — The five operational choices shall be recorded in writing before any measurement: the system boundary, the input variable, the order proxy, the time base, and the cost accounting. The framework's survey and preregistration paper supplies the form [Curzi, 2026i].

S5.16 — The observable and the SESOI. The endpoint shall be named, and the smallest effect size of interest declared, before any data are collected. Section 6.9 computes what magnitudes are detectable at what sample sizes; a SESOI below the detectable floor is a preregistration that has already failed.

S5.17 — All four baselines shall be computed and reported:

```
1.  PERSISTENCE            the endpoint predicts itself at the next period
2.  DIRECT-INPUT           the input predicts the endpoint with no model between
3.  MATCHED AUTOREGRESSIVE with the SAME number of free parameters as the model
4.  SHUFFLED-INPUT CONTROL refit under the permutation, holdout permuted
                           independently, cost term NOT permuted
```

S5.18 The matched autoregressive baseline shall carry the same number of free parameters as the model. A suite is only a suite if all four are read together: evaluated alone, the matched autoregression false-passed 35.8% of the time in simulation [Curzi, 2026i].

S5.19 — The structural ceiling test shall be added, and it is not optional. Any single-period increment claimed shall satisfy the theoretical maximum $\eta \ln N$ [Curzi, 2026]. This is the only test that detects repackaging.

S5.20 — The three measured failure modes of the shuffled-input control shall be carried into every report that uses it. They were measured by simulation rather than asserted [Curzi, 2026i], and two of the three cannot be repaired by any surrogate:

```
(1) ANTI-CONSERVATIVE AS ORDINARILY RUN.
    500 null trials, nominal alpha = 0.05, measured false-rejection rates:
        iid permutation      0.108     2.2x nominal
        circular shift       0.120     2.4x nominal
        block permutation    0.060     near nominal
    A surrogate test taken off the shelf roughly DOUBLES the false-positive rate,
    and the block variant -- the one usually skipped as fussy -- is the only one
    that behaved. REMEDY: calibrate by simulation on the design in hand (series
    length, autocorrelation, block structure) and preregister the calibrated
    threshold, not the nominal one.

(2) BLIND TO REPACKAGING.
    A constructed filtered repackaging -- a rolling average of the input, and
    nothing else -- passed all four baselines including the shuffle at p = 0.0005,
    beat persistence by 89.4%, and beat the matched autoregression by 89.2%.
    It was caught by the structural ceiling test and by NOTHING ELSE: its
    single-step jump was 38.5 times the theoretical maximum.
    REMEDY: the structural ceiling test of S5.19. No surrogate detects this.

(3) BLIND TO A SHARED SLOW DRIVER.
    Where input and endpoint are both driven by a third slow variable -- a funding
    cycle, a seasonal effect, a drifting incubator -- a 4,000-trial simulation
    found the shuffled-input control PASSING 98.35% OF THE TIME. The same
    simulation reports the control working honestly in the clean case at 48.17%
    detection, which is what makes 98.35% a measurement rather than a complaint.
    REMEDY: design controls. No surrogate detects this either.
```

S5.21 — The consolidated rule, which supersedes any reading of the shuffle as a general guarantee: the shuffle is a weak, mis-calibrated empirical audit. More surrogates do not fix any of this. DESIGN CONTROLS DO. The four that answer failure modes (2) and (3):

```
BLINDING              the person measuring the endpoint does not know the condition
CHANNEL SEPARATION    the endpoint is measured through a different channel, by
                      different people, from different records, than the input
PROSPECTIVE SAMPLING  the sampling schedule is fixed before exposure and is not
                      adapted to what is observed
YOKED CONTROL         a control unit receives the same schedule, the same handling
                      and the same environment, and differs only in the ordering
                      of the signal
```

Every one of those four is a decision about the instrument, not about the analysis. **They must be written into Part 1 of the preregistration and cannot be added once the series exists.**

S5.22 — Kill conditions shall be declared in advance and honoured. The framework is rejected for a given run if any of the following holds:

```
K1   the shuffled-input control, at the CALIBRATED threshold, matches the fitted
     model on held-out data
K2   the structural ceiling test fails -- a claimed increment exceeds the maximum
```

```
K3   the scrambled-sequence control (Section 6 §6.13) is indistinguishable from
     the ordered condition
K4   the yoked control moves with the exposed condition
K5   the fitted parameters are not this system's, per FR3
```

S5.23 — A null result shall be reported, in full, with the same prominence as a positive one. Section 6.11 computes how little of the design space one null bounds — 0.000801% of a modest 124,800-cell grid — so a null is a small, honest, publishable increment and must not be inflated into a refutation or buried as a disappointment.

S5.24 — The labelling rule of §5.2 applies to every output, including preprints, slides, captions, file names, and any summary written for a non-technical reader.

The failure modes

FM-5.1 — The clinical drift in the caption. The body text is careful and the figure caption says "response." Captions are read more than bodies.

Fix: S5.24 and §5.2's forbidden list, applied mechanically with a search before release.

FM-5.2 — The address becomes a molecule in the retelling. "gRNA-format prefix" is compressed to "guide RNA" in a summary, and the summary now describes a delivered molecule.

Fix: S5.7. The full phrase "routing header, not a molecule" appears in every document, not once per document.

FM-5.3 — The transposition read as a resonance. Somebody concludes that cytosine "has a frequency of 1113.8129 Hz."

Fix: H5-4. The number is a label produced by a postulated square law applied to an alphabetical ordering and then shifted eight octaves. **It is not a property of cytosine.**

FM-5.4 — The naive index assignment reintroduced. A later implementer assigns `n = 1,2,3,4` because it is obvious, and three symbols collapse to one pitch class.

Fix: §5.12, which rejects it in print with the arithmetic, so the rejection is findable.

FM-5.5 — The greedy encoder shipped. The first-legal rule is simpler and passes the round-trip test, so it looks fine. It produces a 60% adenine string that no listener can follow.

Fix: S5.3. Report GC and entropy against the greedy baseline every time.

FM-5.6 — The rate set by the Gabor floor. An engineer reads 0.080377 ms, sets the symbol rate near it, and produces a signal that is technically not masked and practically inaudible as symbols.

Fix: S4.3 and §5.15. **The floor is where two tones become mathematically indistinguishable; it is not a perceptual threshold, and a rendering at the floor is concealment achieved by speed.**

FM-5.7 — The shuffle treated as a guarantee. The control passes, the result is announced, and the two failure modes that a surrogate cannot see are never addressed.

Fix: S5.20 and S5.21, carried in the report rather than in the methods appendix.

FM-5.8 — Design controls added after the fact. Blinding is "not practical" and is replaced with a fifth surrogate.

Fix: S5.21. Surrogates and design controls answer different questions and one cannot substitute for the other at any exchange rate.

FM-5.9 — The preregistration adapted after the first look. The endpoint is redefined, the window moved, or the SESOI lowered, all of them defensibly.

Fix: S5.15 and S5.16, timestamped and deposited, with any deviation reported as a deviation.

FM-5.10 — The null buried. A run returns nothing and is not written up.

Fix: S5.23. A null bounds a real, computable, small fraction of the design space and is worth exactly that much — which is more than zero and much less than a refutation.

FM-5.11 — The scrambled-sequence control omitted because it "obviously" makes no difference. This is the control that decides the entire question and it is the one most likely to be dropped as redundant.

Fix: K3, and §6.13, which explains why no other control substitutes for it.

FM-5.12 — Layer overlap unchecked. A later implementer changes one transposition and the state layer lands on top of a symbol tone.

Fix: S5.11. The 995.9922-cent clearance is a property of one specific pair of `j` values and must be recomputed after any change.

FM-5.14 — The corpus rewritten between runs. The payload changes because a directive read poorly, and two runs are pooled as though they were the same condition. Because the encoding is deterministic, a single changed character changes the payload hash, the base string, and every symbol after the change point.

Fix: S5.5. The payload hash is the run's identity. Two runs with different payload hashes are two conditions, and pooling them requires the same justification as pooling any two conditions.

FM-5.13 — The procedure described as having worked. Somebody who ran it reports that "it went well," meaning the audio rendered correctly, and a reader hears a claim about a biological effect.

Fix: §5.2, and a reporting convention that separates *the procedure executed as specified* from *the endpoint moved*, which are different sentences about different things.

Worked example

CONSTRUCTED. The payload is the corpus of §4.28, written for this paper. It is not a transcript and not an observation of anyone. No exposure has been run and no endpoint has been measured.

5.25 End to end, with every number

```

```

5.26 The disclosure package, as delivered D1 through D10 of §4.19, complete, before exposure. D1 contains the twelve pairs in full including the four that fail the equal-force check of §4.29 — pairs 3, 5, 7 and 12, 33.33% of the corpus — named as failing, because S4.8 permits rendering an unrepaired corpus only if the failures are disclosed. D3 contains all 5,400 payload bases. D9 contains H5-1 through H5-7 and §6's open problem in full.

5.27 The preregistration, filled in **No data exist.** This is the form as it would stand before a first run, and it is included so that a reader can see what a complete one looks like.

```
1. SYSTEM BOUNDARY      cultured cells, in vitro, named line, named passage range.
                        Deliberately excluded: any human participant, any endpoint
                        that is not a transcript abundance.
2. INPUT                the rendered waveform of §5.25, as a file, with its hash.
3. ORDER PROXY          preregistered transcript abundances at the 12 addressed loci.
4. TIME BASE            fixed sampling schedule, declared before exposure (S5.21).
5. COST ACCOUNTING      declared per the framework's preregistration form.

OBSERVABLE              log2 abundance at the 12 preregistered loci.
SESOI                   declared in advance; must exceed the detectable floor of
                        section 6.9 at the planned n, or the design fails
                        before it starts.
```

```
ARMS                  ORDERED       the waveform as specified
                      SCRAMBLED     symbol-permuted twin: identical total energy,
                                    duration, symbol counts and long-term power
                                    spectrum; ordering destroyed  (§6.13)
                      SILENT        handling-matched, no signal
                      YOKED         same schedule, same handling, ordering varied

DESIGN CONTROLS       blinding of the measurer to condition          REQUIRED
                      channel separation of endpoint from input      REQUIRED
                      prospective sampling schedule                  REQUIRED
                      yoked control                                  REQUIRED

BASELINES             persistence, direct-input, matched autoregressive,
                      shuffled-input -- all four, read together (S5.17, S5.18)

STRUCTURAL TEST       ceiling test per S5.19, single-period increment vs
                      theoretical maximum

SURROGATE CALIBRATION block permutation, calibrated by simulation on THIS design;
                      the calibrated threshold is preregistered, not the nominal
                      0.05 (S5.20 failure mode 1)

KILL CONDITIONS       K1 - K5 of S5.22, declared and honoured

REPORTING             null reported in full, with the same prominence as a
                      positive result, and with the design-space fraction it
                      bounds computed (S5.23)
```

5.28 What this procedure has and has not produced **Has produced:** a deterministic encoder with a verified round-trip identity; a balanced free-choice rule that holds GC at exactly half and raises payload entropy from 1.244171 to 1.935874 bits per base; an arithmetically justified 20-nt routing header; a four-symbol alphabet whose tightest pair is 1165.0244 cents apart; two disclosed layers separated by 995.9922 cents; a symbol rate 248.83 times above the Gabor floor; and a 175.800-second audio file with a complete disclosure package.

Has not produced, and does not claim: any biological effect; any evidence that a cell responds to the ordering of the signal; any clinical, medical or therapeutic result; any alteration of DNA; any conferred capability; or any physical resonance. **The procedure ends at a loudspeaker, and §6 is about the gap on the other side of it.**

What this section established **Established, and checkable:** that a written corpus maps losslessly to a 5,400-base nucleotide string with a verified SHA-256 identity; that the balanced free-choice rule holds GC within one base of `L/2` by construction and measured exactly 0.500000 here, with maximum homopolymer run 1 and entropy 1.935874 against the greedy rule's 1.244171; that a 20-nt prefix has 0.005638867 expected spurious matches in 6.2e9 positions; that the naive base index assignment collapses three of four symbols onto one pitch class and is rejected; that the odd-index assignment gives a minimum separation of 990.055901 Hz; that the symbol and state layers are 995.9922 cents apart; that at 20 ms per symbol the rendering sits 248.83 times above the Gabor floor and runs 175.800 seconds; that the rectangular gate has no finite spectral second moment; and that the shuffled-input control fails in three measured ways, of which two are answerable only by design controls.

Not established, and not claimed: that any of this affects any cell, transcript or person; that any tone bears a physical relation to any base; that the procedure is a treatment, therapy or

practice of any kind; that DNA is edited, altered or damaged; or that any capability has been conferred.

The one line to carry forward: *the whole procedure is buildable, auditable and disclosed, and it stops at a loudspeaker.*

Section 5 owns the operational procedure, the design table, the run schedule, and the preregistration and falsification apparatus. Section 4 owns the no-subliminals constraint, the disclosure package and the consent specifications, all of which this section inherits whole; Section 6 owns the open problem that governs both.

6 The open problem, stated precisely

Everything in this paper up to this point has been either computed, proved, cited, or badged as a postulate in the sentence that stated it. Sections 4 and 5 have specified an encoder, an addressing convention, a sonifier and a rendering discipline, all of them deterministic and all of them verified.

There is one thing missing from that chain and it is not a detail. It is the link between the signal and the archive.

> **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal.**

That sentence is this section. It is carried in every part of this paper and it is not softened here, not worked around, and not argued down. This section spends its length making the gap as precise as it can be made, because a gap stated precisely is a research programme and a gap stated vaguely is an excuse.

The reason for the length is intellectual accounting. A framework that carries a chosen reference constant, a postulated square law, a differentiation index whose defensibility it admits is contestable, and a sonification procedure whose biological effect is unknown has to earn its reader's attention somewhere. **A framework that names its own load-bearing gap this precisely earns the right to everything else in it;** one that declines to name it forfeits the right to all of it, including the parts that are correct.

The law

6.1 The gap, stated four ways The same proposition at four levels of precision, because each level is the one somebody will need.

Colloquial. Nobody knows how a cell could read an ordered message out of a sound.

Engineering. No known biological structure performs demodulation of a symbol stream from an acoustic carrier into a sequence-specific output. There is no identified transducer with the required frequency selectivity, no identified memory element that preserves symbol order across the symbol interval, and no identified mapping from a decoded symbol string to sequence-specific binding at a genomic locus.

Formal. Let `s(t)` be an acoustic pressure waveform encoding a symbol string `x = (x_1, ..., x_L)` over an alphabet of size 4, and let `R` be the cell's transcriptional response. There is no established mechanism producing an `R` that depends on `x` as an *ordered string*, as distinct from depending on functionals of `s(t)` that are invariant under permutation of the symbols — total energy, duration, long-term power spectrum, envelope statistics, symbol counts. **The claim that requires a mechanism is the claim that `R` is a function of the ORDER, and that is exactly the claim for which no mechanism exists.**

Operational. Take a stimulus and its symbol-permuted twin. The two have identical total energy, identical duration, identical long-term power spectrum, and identical symbol counts. If a cell cannot be shown to distinguish them, no sequence-specific channel has been demonstrated, and nothing else in the experiment matters.

6.2 What the statement does not say

Two symmetric errors sit on either side of the sentence and both have to be refused explicitly, because each is comfortable in a different direction.

It is not a claim of impossibility, and impossibility is not claimed. Absence of a known mechanism is a statement about the current state of the literature. Several real channels between physics and biology were identified late and were initially treated as implausible; the burden of demonstration sits entirely on the claimant, which is the ordinary position for any unestablished claim and carries no special hostility toward this one.

Nor is absence of a known mechanism a licence. The symmetric error is to treat "not proven impossible" as though it were partial support. It is not support of any kind. **A claim with no mechanism and no demonstration has zero evidential standing,** and the correct number of qualifiers to attach to it before demonstration is not "few" but "it is not asserted."

Both errors share a structure worth naming: they convert a statement about evidence into a statement about the world. The asymmetry between a conjecture and a corroborated one is the ordinary one [Popper, 1959], and a research programme is assessed by whether it makes new, checkable predictions rather than by whether it has been disproved [Lakatos, 1970, Platt, 1964]. The sentence at the head of this section is about what is known. It is not a prediction, and it will be settled by an experiment rather than by an argument.

6.3 Why this section is the framework's warrant

The ordering of this paper is deliberate and it runs against the commercial instinct. Section 4 built the ethical architecture, Section 5 built the procedure, and Section 6 says that nobody knows whether the procedure does anything. A paper optimising for persuasion would reverse the last two, or merge this section into a paragraph, or place it in an appendix labelled "limitations."

The reason for the ordering is that the alternative is not available to work that wants to be checked. Every number in Sections 4 and 5 is checkable by someone with a Python interpreter, and a reader who checks a hundred of them and finds them right acquires a reasonable prior that the hundred and first is right too. That prior is exactly what an unmarked overclaim would spend. **The restraint is not modesty and it is not a legal posture; it is the only way the arithmetic retains any value to a reader who cannot personally verify all of it.**

6.4 Honesty clauses, binding on this section and inherited by everything that cites it

H6-1 — No clinical, medical or therapeutic claim, and no intervention on any person is described here. Every experiment specified in this section is *in vitro*, on cultured cells, with transcript abundances as endpoints.

H6-2 — No claim that DNA is edited, altered, or damaged. Nothing in the pipeline of §5 carries a nuclease, a template, or a Cas protein, and nothing is delivered.

H6-3 — No claim that any capability has been conferred on anything.

H6-4 — Essence frequencies are essence frequencies, not physical resonances. Nothing anywhere in this paper claims that a person, tissue, cell or molecule resonates at any value printed in it.

H6-5 — The concordance columns carry different things. Where a traditional source is cited anywhere in this paper it carries *precedent*: that an idea was arrived at independently and preserved. It does not carry *evidence* [Curzi, 2026w], and this section draws no concordance at all.

H6-6 — Every number in this section was computed from stated assumptions, and the assumptions are printed with the number. The power calculations of §6.9 in particular are

arithmetic on declared inputs. They are not estimates of anything measured, and the variance figures in them are inputs a reader supplies from their own system, not values this framework asserts about biology.

6.5 What is real upstream, itemised The gap is a single missing link, not a general absence of evidence, and it matters to say so with the same precision used to state the gap. Otherwise an honest reader cannot tell how much of the architecture is standing.

Component	Status	Source
Arbitrary digital data can be stored in and recovered from nucleotide sequence	**ESTABLISHED**	Church, Gao & Kosuri, *Science* 337:1628 (2012)

Biology builds exquisite mechanical receivers	**ESTABLISHED**	cochlear hair cells
Non-coding sequence is a large, structured, addressable archive	**ESTABLISHED**	reviewed in Curzi [2026y]
Regulatory input reorganises expression without adding sequence	**ESTABLISHED**, Nobel 2012	Takahashi & Yamanaka, *Cell* 126:663 (2006)
A cell demodulates sequence-specific content from sound	**NO ESTABLISHED MECHANISM**	**§6**

Eleven established rows and one open row. Both halves belong in any honest report. Reporting only the eleven is advocacy; reporting only the one is a different dishonesty, because it implies the whole edifice is speculation when most of it is textbook.

6.5b The archive the signal would be addressing One of the eleven rows deserves expansion, because it is the one that makes the architecture worth specifying at all and it is also the one most often described loosely.

The phrase *junk DNA* is retired. Non-coding sequence is roughly 98% of the human genome and is largely regulatory: promoters, enhancers, silencers and insulators, together

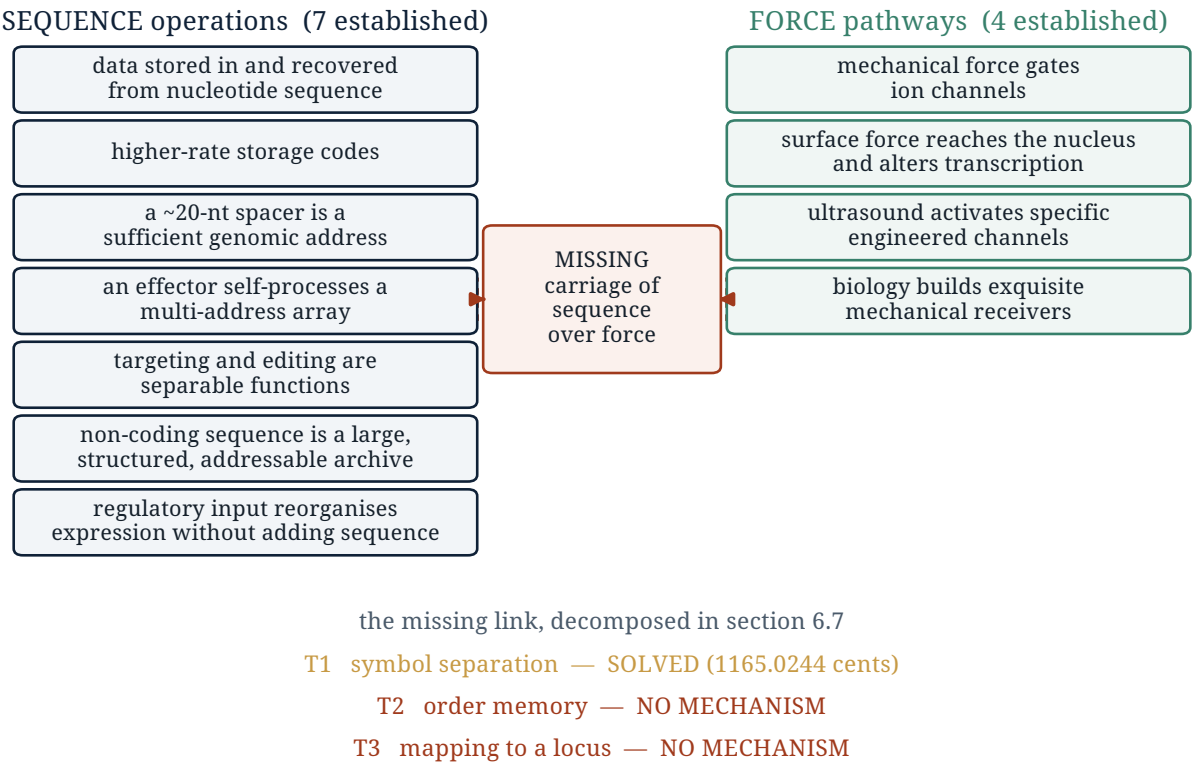

Figure 48.4: **Eleven upstream components are established and the one missing link is the carriage of sequence over force.** Sequence operations store, address, parse, target, archive and regulate; force pathways gate channels and reach the nucleus. Nothing in the established literature carries a symbol string across the boundary. A classification of the cited literature, not data; the primary biological sources are named in the text without citation keys because the corpus's bibliography carries no cluster covering them (§10, L-9). Built by `figs/src/CCP-048_fig05.py`.

with transposable elements at roughly 45% of the genome and endogenous retroviral sequence at roughly 8%, and the large families of long non-coding and micro RNAs. That is not filler around the genes; it is the control surface, and it is the part of the genome that regulatory input acts on.

The single most instructive item in it, for an argument about narrative, is syncytin. The gene indispensable to placenta formation derives from a retroviral envelope gene: ancient foreign text, inherited, later read out as vital function. **A sequence that arrived from outside became a sequence the organism could not do without, which is documented molecular biology and not a metaphor** — though it is very hard to read about it without reaching for one, and the reaching is worth resisting in print.

What this establishes here is narrow. There is a large, structured, addressable archive, and regulatory input demonstrably reorganises which parts of it are expressed — Yamanaka reprogramming is the strongest available demonstration that latent capability is activated rather than added. **The archive is real and the regulatory layer is real. What is missing is any route by which an acoustic symbol stream reaches either.**

6.6 The shape of the missing link Look at the eleven established rows and sort them by what they carry.

Rows 1 through 5 and rows 10 and 11 are **sequence** operations. They store, address, parse, target, archive and regulate, and every one of them operates on symbol strings or on molecular structures that read symbol strings.

Rows 6 through 9 are **force** pathways. Mechanical deformation opens a channel, ions move, signal propagates; force at the surface reaches the nucleus and changes what is transcribed; engineered channels respond to ultrasound; hair cells transduce sound exquisitely.

Nothing in the established literature carries sequence over force. A pressure wave that opens a PIEZO channel does so by deforming the membrane, and the channel does not care what melody deformed it. Tajik et al. applied force and measured transcription; the force carried a magnitude and a direction, not a string. Sonogenetics gets its specificity from the protein that was engineered into the cell, not from the structure of the waveform — which is a point worth dwelling on, because sonogenetics is the result most often produced as though it closed this gap. It does the opposite: it is the clearest existing demonstration that acoustic specificity in biology has so far been achieved by putting the specificity in the receiver, and never by putting it in the signal.

6.7 Three requirements, and which are unmet Stating the gap as a single sentence is right for a canon file and too coarse for a research programme. Decomposed, a sequence-specific acoustic channel needs three distinct things, and they fail differently:

```
T1  SYMBOL SEPARATION
    The receiver must distinguish the symbols of the alphabet.
    STATUS: satisfiable in principle. Section 5.13 builds an alphabet whose
    tightest pair is 1165.0244 cents apart -- a separation any device with
    frequency dependence at all can resolve. D1 is an engineering requirement
    and the engineering exists.

T2  ORDER MEMORY
    The receiver must preserve symbol ORDER across the symbol interval, so that
    the response depends on the sequence and not on the histogram.
    STATUS: NO IDENTIFIED MECHANISM. This is the heart of the gap. A permutation-
    invariant response is not a weak version of a sequence-specific one; it is a
    different quantity, and no known molecular element stores an acoustic symbol
    stream in order.

T3  MAPPING TO A LOCUS
```

```
The decoded string must produce sequence-specific binding or regulation at the
addressed locus.
STATUS: NO IDENTIFIED MECHANISM connecting a decoded acoustic string to
anything at a locus. Targeting itself is established (Qi et al. 2013;
Gilbert et al. 2014, named without keys) -- but it is established for a
molecule that carries the address, not for a string that was heard.
```

T1 is solved and is the least interesting of the three. T2 and T3 are the open problem, and an easily separable alphabet does not touch either of them. That distinction is worth carrying, because engineering effort naturally flows toward T1 — it is the part where progress is visible — and progress there is not progress on the question.

6.7b Why T2 is hard in particular, and where the difficulty comes from It is worth saying why order memory is the hardest of the three rather than merely the unsolved one, because the reason is physical rather than a matter of nobody having looked.

A receiver that preserves symbol order needs to hold state across the symbol interval. In the rendering of §5 that interval is 20 milliseconds. Any candidate molecular element would have to retain a distinguishable configuration for that long, in water, at body temperature, against thermal agitation, and then combine it with the next symbol in a way that depends on which came first. The framework's addressing paper computes the relevant damping and finds molecular-scale mechanical resonators in water heavily overdamped, with Stokes numbers far below one [Curzi, 2026y]; that calculation is cited here rather than repeated, and its consequence is that the obvious mechanical route to a memory element — a small structure that rings — is not available.

That does not exhaust the possibilities. Biology stores order in chemistry all the time, in polymerisation, in phosphorylation cascades, in transcriptional bursting histories. **The point is not that order memory is impossible; it is that the candidate everybody reaches for first — a tiny resonator that rings at a symbol's frequency and remembers — is ruled out by damping, and the remaining candidates are chemical rather than mechanical and have no proposed coupling to an acoustic symbol stream at all.**

The engineering

6.8 What an experiment must show The experiment that would settle this is not exotic and its logic is short.

The claim under test is that the cell's response depends on the *ordering* of the symbol stream. The null is that it depends only on permutation-invariant functionals of the waveform. Therefore:

Compare an ordered stimulus against its symbol-permuted twin, and measure whether the response distinguishes them. Everything else in the design is in service of that comparison.

The permuted twin is not an approximate control. It is exact on every quantity the null could appeal to:

```
identical      total acoustic energy
identical      duration
identical      symbol histogram (the same count of each symbol)
identical      long-term power spectrum, under a fixed symbol alphabet
identical      peak level, RMS level, and crest factor
DIFFERENT      the ordering, and only the ordering
```

The size of the space the permutation draws from is worth computing, because it shows how little the control costs and how much it isolates. For the 5,400-base payload of §5.25,

whose composition is A 1750, C 1749, G 951, T 950, the number of distinct symbol orderings with identical composition is:

```
L! / (n_A! n_C! n_G! n_T!)   =   10^2017.717
```

Every one of those 10^2017.717 waveforms is indistinguishable from the ordered stimulus by every permutation-invariant measurement, and a drawing from that set costs nothing but a shuffle. A design that omits this control has omitted the only comparison that could have answered the question.

6.9 What magnitude would even be detectable

A gap is only a research programme if somebody can say what size of effect the programme could see. The arithmetic below is a standard two-sample power calculation on log2-transformed abundance, with equal group sizes:

```
n  =  2 ( z_(1 − alpha/2) + z_(1 − beta) )^2 sigma^2 / delta^2
```

`delta` is the difference in log2 abundance, `sigma` the standard deviation in the same units, power fixed at 0.80 throughout. Both `sigma` and the number of tested transcripts are inputs a reader supplies from their own system; nothing below is a claim about biology, only arithmetic on declared assumptions (H6-6).

(a) A targeted readout of the twelve preregistered loci, Bonferroni `alpha = 0.05/12`:

```
z_(1−alpha/2) = 2.865260      z_0.80 = 0.841621

delta (log2FC)   sigma=0.20   sigma=0.35   sigma=0.50
    0.10             110          337          688
    0.20              28           85          172
    0.30              13           38           77
    0.50               5           14           28
    1.00               2            4            7
    2.00               1            1            2
```

(b) A transcriptome-wide readout, 20,000 transcripts, Bonferroni `alpha = 0.05/20000 = 2.5e−6`:

```
z_(1−alpha/2) = 4.708130

delta (log2FC)   sigma=0.20   sigma=0.35   sigma=0.50
    0.10             247          755         1540
    0.20              62          189          385
    0.30              28           84          172
    0.50              10           31           62
    1.00               3            8           16
    2.00               1            2            4
```

Inverted, which is the more useful direction — the smallest detectable log2 fold change at a fixed sample size, `sigma = 0.35`, power 0.80:

```
n per arm    targeted (12 loci)     genome-wide (20,000)
    3            1.0593                 1.5860
    6            0.7491                 1.1215
   10            0.5802                 0.8687
   20            0.4103                 0.6142
   50            0.2595                 0.3885
  100            0.1835                 0.2747
```

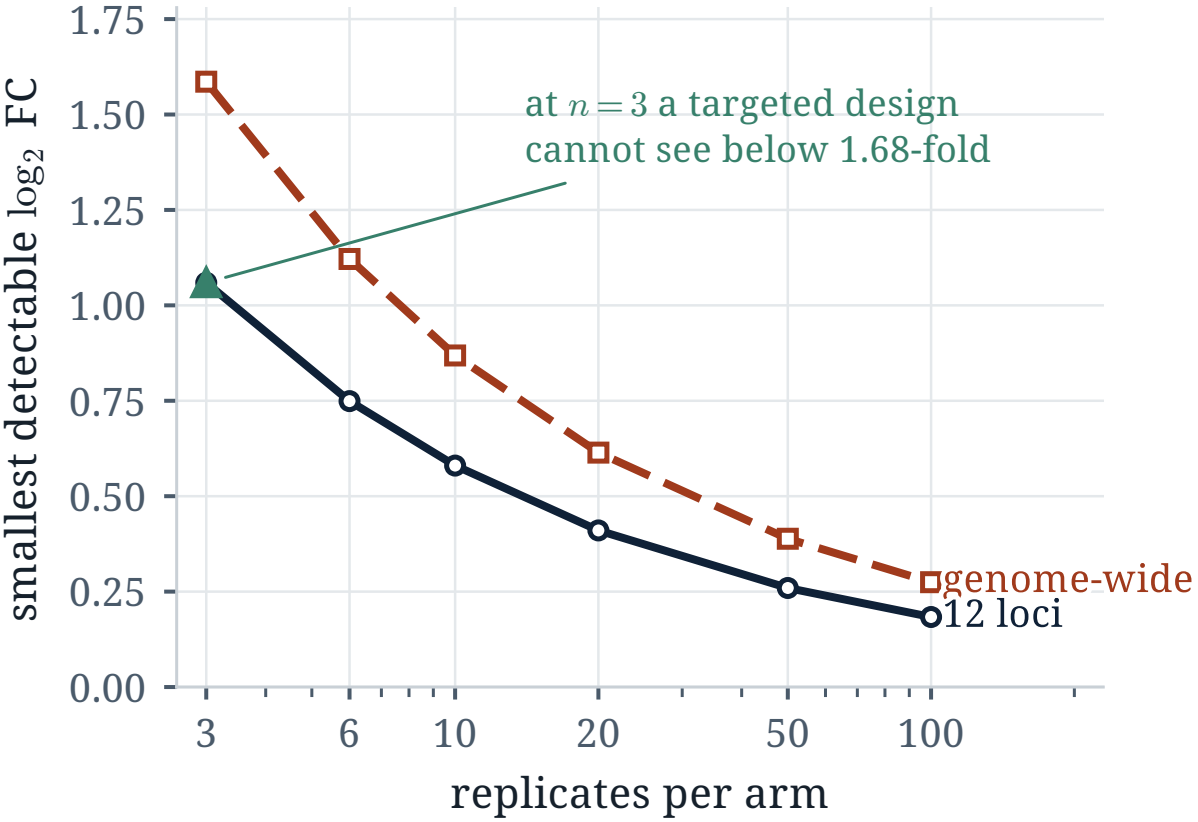

Figure 48.5: **A three-replicate design cannot see below a 1.68-fold change on a targeted readout, or a 2.18-fold change genome-wide.** Smallest detectable $\log_2$ fold change against replicates per arm, at power 0.80 and Bonferroni correction across 12 loci and across 20,000 transcripts. Modelled: the dispersion $\sigma = 0.35$ $\log_2$ units and the number of tests are declared inputs an operator supplies from their own pilot, **not measurements and not claims about biology** (H6-6). Built by `figs/src/CCP-048_fig03.py`.

In linear fold-change terms, at `sigma = 0.35`:

```
n =   6    targeted floor  x1.6807      genome-wide floor  x2.1757
n =  20    targeted floor  x1.3289      genome-wide floor  x1.5308
n = 100    targeted floor  x1.1356      genome-wide floor  x1.2097
```

Three consequences follow and each is a design decision rather than an observation.

First, a typical three-replicate design cannot see anything under a 1.68-fold change even on a targeted readout, and under a 2.18-fold change genome-wide. An effect smaller than that is not absent from such an experiment; it is invisible to it, and reporting “no effect” from that design is reporting the design rather than the biology.

Second, the SESOI must be declared against this floor before the run. Section 5 S5.16 makes that a specification: a smallest effect of interest below the detectable floor at the planned `n` is a preregistration that has already failed, and discovering it afterwards converts a null into an uninterpretable one.

Third, targeting twelve preregistered loci buys roughly a factor of two in required sample size against a genome-wide search, at the price of being unable to find anything anywhere else. That is a real trade and it should be made deliberately, in the preregistration, with the reason written down. The recommendation here is the targeted readout for a first pass — because the twelve addressed loci are exactly the ones the architecture claims to address, and

an effect there is the one the architecture predicts — with a genome-wide arm as a secondary, exploratory, and clearly labelled analysis.

A note on the multiplicity correction, because it is the assumption most likely to be argued with, and because the choice of correction after seeing the result is one of the best-documented routes to a false positive [Simmons et al., 2011, Gelman and Loken, 2013]. Bonferroni is used above because it is transparent, because it is the most conservative common choice, and because a section whose whole subject is not overclaiming should not be quietly buying sensitivity from a correction the reader has to know about to evaluate. A Benjamini-Hochberg procedure at the same nominal rate would be less demanding, would raise the detectable effect at a given sample size less steeply, and would be entirely defensible — provided it is the preregistered choice rather than the one arrived at after the Bonferroni analysis returned nothing. The rule is not which correction; the rule is that the correction is fixed before the data exist, stated with the number of tests it covers, and reported with the result.

Two further inputs deserve the same treatment. The variance `sigma` is the operator's, from their own pilot, and substituting an optimistic value is the cheapest way to make an underpowered design look adequate on paper. And the power target of 0.80 is a convention rather than a law; a question this consequential arguably deserves 0.90, which costs roughly a third again in sample size and should be priced explicitly rather than defaulted past.

6.10 One route closed by arithmetic Not all of the gap is equally open, and a closed route is progress worth publishing.

For a plane acoustic wave in an aqueous medium, the longitudinal strain amplitude is exactly `s = p / K`, with `K` the bulk modulus of water, `2.2e9 Pa`. This is elementary continuum mechanics and is not a model of anything biological. Computed:

dB SPL	p (Pa)	bulk strain
40	0.002	9.090909e-13
60	0.02	9.090909e-12
80	0.2	9.090909e-11
94	1.00237	4.556248e-10
100	2.0	9.090909e-10
120	20.0	9.090909e-09

At the levels a disclosed rendering can plausibly use — the rendering of Section 5 is meant to be listened to, not endured — the bulk compressional strain is of order `1e-11` to `1e-10`. **Bulk compression is not the route.** Whatever an acoustic channel to a cell would be, it is not a matter of squeezing the cell smaller by one part in ten billion and expecting the genome to notice the pattern of the squeezing.

That does not close the question, and the reason is that the established pathways are not bulk pathways. PIEZO gating is discussed in terms of membrane tension and forces at the channel; Tajik et al. applied force at the surface and followed it through the cytoskeleton. Those are structural, local, and highly leveraged routes, and the bulk number above says nothing about them. **What the arithmetic closes is the naive route, and closing a naive route matters mainly because it is the one most often assumed.**

6.11 How little a null result bounds The last computed piece is the one that keeps both a positive and a negative result honest: how much of the design space a single condition actually covers.

A modest grid over the parameters an experimenter must choose anyway:

```
carrier band (20 Hz – 20 kHz, 1/3-octave steps)          30
level (40–100 dB SPL, 5 dB steps)                        13
symbol rate (5–200 symbols/s, half-decade steps)          4
```

```
exposure duration (1 min – 24 h, decade steps)            4
cell type                                                 5
readout time after exposure                               4
------------------------------------------------------------
TOTAL GRID CELLS                                    124,800

one condition bounds     1 / 124,800   =   0.000801 %
ten conditions           0.00801 %
one hundred conditions   0.0801 %
```

A single well-run null bounds eight ten-thousandths of one percent of a deliberately modest grid, which is a real and publishable increment and is nowhere near a refutation. Prediction is one of many legitimate reasons to build a model, and bounding a design space is another [Epstein, 2008]. This cuts both ways and is meant to. It protects a null from being inflated into "the idea is dead," and it protects the field from a claimant who runs one condition, finds something, and announces a channel.

The grid is also an argument for how to spend effort. Given how little any single cell covers, the value of a design comes from its controls rather than from its coverage: **one condition run with the scrambled-sequence control, blinding, channel separation, prospective sampling and a yoked control is worth more than a hundred conditions run without them**, because a hundred uncontrolled conditions bound nothing at all.

The specification

6.12 The decisive experiment, numbered **S6.1** The experiment shall be *in vitro*, on a named cell line at a named passage range, with transcript abundances as endpoints. No human participant appears in it.

S6.2 The stimulus shall be produced by the procedure of §5, with its payload hash published, and delivered by a characterised transducer whose output is measured at the sample position, not assumed from the amplifier setting.

S6.3 The four arms shall be:

```
ORDERED       the waveform as specified by §5.25
SCRAMBLED     a symbol-permuted twin, drawn from the 10^2017.717 orderings with
              identical composition; identical energy, duration, histogram and
              long-term spectrum; ordering destroyed
SILENT        handling-matched, no signal; the transducer present and inactive
YOKED         same schedule, same handling, same environment, ordering varied
```

S6.4 Allocation shall be randomised and the person performing the measurement shall be blind to the arm.

S6.5 The sampling schedule shall be fixed before exposure and shall not be adapted to what is observed.

S6.6 The endpoint shall be measured through a different channel, by different people, and from different records than the stimulus log. Channel separation is a design requirement, not an analysis choice.

S6.7 The SESOI shall be declared in advance and shall exceed the detectable floor of §6.9 at the planned `n`.

S6.8 The primary analysis shall be the ORDERED versus SCRAMBLED contrast at the twelve preregistered loci. Everything else is secondary and labelled as such.

S6.9 All four baselines of S5.17 shall be computed and read together, with the surrogate threshold calibrated by simulation on this design rather than taken as nominal.

S6.10 The structural ceiling test of S5.19 shall be applied to any claimed increment.

S6.11 The kill conditions K1 through K5 of S5.22 shall be declared and honoured.

S6.12 The result shall be reported in full whichever way it goes, with the design-space fraction it bounds computed per §6.11.

6.13 The two controls, and why neither substitutes for the other

This is the section that most often gets compressed into one line in a methods section, and the compression is where the error lives. **The scrambled-sequence control and the shuffled-input control are different controls,** they answer different questions, and running one does not weaken the case for the other.

```
SCRAMBLED-SEQUENCE CONTROL          a control on the STIMULUS
  what varies      the ordering of the symbols WITHIN one exposure
  what is held     energy, duration, histogram, long-term spectrum, level
  what it answers  does the response depend on the ORDER of the content?
  what it cannot   say anything about the timing of exposures across the series,
                   or about a third variable driving both exposure and endpoint

SHUFFLED-INPUT CONTROL              a control on the SERIES
  what varies      the temporal alignment of the input series to the endpoint
                   series, refit under the permutation, holdout permuted
                   independently, cost term NOT permuted
  what is held     the marginal distribution of the input
  what it answers  does the TIMING of the input carry information about the
                   endpoint?
  what it cannot   detect repackaging; detect a shared slow driver
```

A design with only the scrambled-sequence control can be fooled by an artefact of scheduling — an incubator door, a media change, a technician's routine — that happens to align with the ordered arm. A design with only the shuffled-input control can be fooled by an effect of sound that has nothing to do with content, which would be a real finding about acoustics and no finding at all about sequence.

And the shuffled-input control brings its own three measured failure modes, which S5.20 specifies in full and which are restated here because this is where a reader decides whether to believe a result:

(1) It is anti-conservative as ordinarily run. Across 500 null trials at a nominal `alpha` of 0.05, measured false-rejection rates were 0.108 for iid permutation (2.2x nominal), 0.120 for circular shift (2.4x nominal), and 0.060 for block permutation (near nominal). Calibration must be on the design in hand, with the calibrated threshold preregistered.

(2) It is blind to repackaging. A constructed filtered repackaging — a rolling average of the input and nothing else — passed all four baselines including the shuffle at `p = 0.0005`. It was caught by the structural ceiling test alone, with a single-step jump 38.5 times the theoretical maximum.

(3) It is blind to a shared slow driver. In a 4,000-trial simulation with input and endpoint both driven by a third slow variable, the shuffled-input control passed 98.35% of the time. The same simulation reports it working honestly in the clean case at 48.17% detection, which is what makes 98.35% a measurement rather than a complaint.

The consolidated rule: **more surrogates do not fix any of this. Design controls do** — blinding, channel separation, prospective sampling, and a yoked control — and every one of them is a decision about the instrument, made before a single number exists.

6.14 What would settle it, either way

A gap worth naming is a gap with stated settlement conditions on both sides. These are they.

What would establish a sequence-specific acoustic channel:

```
E1   The ORDERED versus SCRAMBLED contrast is significant at the preregistered
     loci, at the calibrated threshold, with an effect exceeding the declared
     SESOI and the detectable floor of §6.9.
E2   The result holds with the measurer blind and with channel separation in place.
E3   The yoked control does not move.
E4   The structural ceiling test passes.
E5   The effect is dose-ordered in a preregistered direction -- more exposure,
     more effect -- rather than present or absent.
E6   INDEPENDENT REPLICATION by a group that did not build the apparatus, on
     their own cells, from the published specification and payload hash.
```

E6 is not a courtesy and it is not last because it is least. Independent replication is the step at which a published literature's effect sizes have repeatedly proved to shrink [Open Science Collaboration, 2015, Ioannidis, 2005]. A single laboratory reporting a sequence-specific acoustic effect has produced a reason for somebody else to look, and nothing more.

What would close the question negatively for a stated region of the design space:

```
N1   The ORDERED versus SCRAMBLED contrast is null, at an `n` sufficient to detect
     the declared SESOI at the declared power, with the floor of §6.9 published
     alongside.
N2   The condition tested is stated, and the fraction of the design space it bounds
     is computed per §6.11.
N3   The null is reported in full, with the same prominence a positive result would
     have received, and deposited so that the next group does not repeat it.
```

A null bounds a region; it does not close a question. Nobody should write "acoustic sequence-specificity does not exist" from any experiment described here, and this section would be the first thing to cite against them if they did.

One more thing about settlement, which is easy to lose in a list of criteria. A research programme is settled not by a single decisive experiment but by a body of results that make one account much easier to hold than the others, and the criteria above are written to produce results that can accumulate. That is why the design-space fraction is required with every report, why nulls are deposited rather than discarded, and why the payload hash identifies a run. Twenty null conditions, each bounding a stated region, each reported with its detectable floor, are worth far more to the next group than twenty conditions of which only the interesting one was written up — and the second collection is what an ordinary publication incentive produces if nobody writes the rule down first.

The corollary is that a reader evaluating any future claim in this area has a short checklist. Was the permuted twin run? Was the measurer blind? Was the sample size sufficient to see the effect that was claimed, at the correction that was used? Was the null of the same experiment reported with the same prominence? Four questions, all answerable from a methods section, and a claim that fails any of them has not yet reached the point where the mechanism question becomes interesting.

6.15 What must not be done with a positive result

Included because the failure is predictable, and because the constraints of §4 do not relax if something turns out to work.

S6.13 A positive *in vitro* result licenses further *in vitro* work. It does not license any application to a person, in any setting, for any purpose.

S6.14 No result of any size converts this procedure into a treatment, therapy or practice. The labelling rule of §5.2 applies unchanged after a positive result and applies with more force, not less.

S6.15 The no-subliminals constraint of §4 is not contingent on efficacy. A demonstrated effect would make concealment more harmful, not more permissible.

S6.16 No claim that DNA has been edited, altered or damaged may be made on the basis of a transcriptional result. Transcript abundance is not sequence.

The failure modes

FM-6.1 — Substituting an easier control. A "silent" arm or a "white noise" arm is run instead of the symbol-permuted twin, because a permuted twin sounds strange and is harder to explain.

Fix: S6.3. Silence and noise differ from the stimulus in energy and spectrum, so a difference against them is uninformative about ordering. **The permuted twin is the only control that isolates the variable the claim is about, and it costs one shuffle.**

FM-6.2 — Sonogenetics offered as the mechanism. Ibsen et al. and Duque et al. are cited as though they demonstrated that waveform structure carries content.

Fix: §6.6. Sonogenetic specificity resides in an engineered protein, not in the signal, and the result is evidence in the opposite direction: it shows how acoustic specificity has actually been obtained, which is by building it into the receiver.

FM-6.3 — Tajik et al. read as a sequence result. Force reaching the nucleus and altering transcription becomes, in the retelling, force carrying a message to a locus.

Fix: §6.6. The force in that work carried a magnitude and a direction, and the result is precisely what makes the missing link visible: the force pathway is established, and it is not a sequence pathway.

FM-6.4 — PIEZO as a demodulator. A mechanically gated channel is described as though it were frequency-selective in a way that could separate symbols.

Fix: §6.7, T1 versus T2. Even a perfectly selective transducer satisfies only T1. The gap is T2 and T3, and a better transducer does not touch either.

FM-6.5 — The underpowered null announced as a refutation. Three replicates, no effect, and a conclusion.

Fix: §6.9. At `n = 3` and `sigma = 0.35` the targeted floor is a 1.68-fold change. An effect below that was never in the experiment's reach.

FM-6.6 — The single condition announced as a channel. One frequency, one level, one duration, one cell type, one timepoint, and a positive result.

Fix: §6.11 and E1 through E6. One cell of the grid is 0.000801% of it, and E6 is not optional.

FM-6.7 — Post-hoc SESOI. The smallest effect of interest is set after the effect size is known.

Fix: S6.7, timestamped and deposited before exposure.

FM-6.8 — Reporting the ordered arm against the silent arm. The comparison that gets reported is the one that reached significance, and it is the comparison that cannot answer the question.

Fix: S6.8. The primary analysis is preregistered as ORDERED versus SCRAMBLED, and any other contrast is secondary and labelled.

FM-6.13 — The archive described as a message. The regulatory function of non-coding sequence, and syncytin in particular, get retold as evidence that the genome is "written to" by outside signals.

Fix: §6.5b. Retroviral integration is a molecular event with a well-characterised mechanism and no acoustic content whatever. The archive being real is what makes the addressing question well-posed; it is not evidence about the channel.

FM-6.14 — A mechanism proposed and then treated as found. Somebody offers a candidate — a chemical memory element, a bursting-history effect, a cytoskeletal route — and within two retellings the candidate has become the explanation.

Fix: §6.2. A candidate mechanism with no independent evidence is a hypothesis, and naming a hypothesis does not move it into the established column. **A proposed mechanism and an established one differ by exactly the amount of evidence between them, which in this case is all of it.**

FM-6.9 — Treating the gap as a formality. The section is read as a legal disclaimer and the procedure is described elsewhere as though the disclaimer were pro forma.

Fix: §6.3. The gap is the reason the rest of the framework is worth reading, and work that treated it as a formality would have spent the only asset it had.

FM-6.10 — "Not proven impossible" doing evidential work. The sentence "no mechanism is known" becomes, over a few retellings, "science hasn't caught up yet."

Fix: §6.2. **Absence of a mechanism is not support of any kind, and a claim with no mechanism and no demonstration is not asserted rather than lightly qualified.**

FM-6.11 — The bulk-strain number used as an argument against everything. The `1e−10` figure is produced to argue that no acoustic effect on cells is possible at all.

Fix: §6.10. The number closes the bulk compressional route and says nothing about membrane tension, cytoskeletal transmission, or channel-level forces, which are the established pathways.

FM-6.12 — Merging the two controls. A methods section says "permutation control" and it is impossible to tell which one was run.

Fix: §6.13. Name them separately, report them separately, and state what each answers.

Worked example

CONSTRUCTED. No experiment has been run and no data exist. What follows is a fully specified design, written out so that both of its possible outcomes are visible in advance.

6.16 The design

```
STIMULUS        §5.25, payload hash
                c7d98b1cfde5c515ce99ff7db77d484f71a09c5cd921994f15df66c50373b72d
                5,640 bases, 20 ms/symbol, windowed envelope, 175.800 s per run
DELIVERY        characterised transducer; SPL measured at the sample position
SYSTEM          named cultured line, named passage range, in vitro
ARMS            ORDERED / SCRAMBLED / SILENT / YOKED, randomised, measurer blind
ENDPOINT        log2 transcript abundance at the 12 preregistered addressed loci
SIGMA (assumed) 0.35 log2 units, from the operator's own pilot variance,
                NOT from this framework
ALPHA           0.05 / 12 = 0.0041667 (Bonferroni across the 12 loci)
POWER           0.80
n               20 per arm
DETECTABLE      0.4103 log2 units = 1.3289-fold          (§6.9, computed)
SESOI           declared at 0.50 log2 units = 1.4142-fold, which EXCEEDS the
                detectable floor at n = 20, as S6.7 requires
PRIMARY         ORDERED vs SCRAMBLED at the 12 loci
SECONDARY       ORDERED vs SILENT; genome-wide exploratory, labelled as such
CONTROLS        blinding, channel separation, prospective schedule, yoked arm
SURROGATE       block permutation, threshold calibrated by simulation on THIS
                design; the calibrated threshold preregistered, not the nominal
KILL            K1 - K5 of S5.22
```

Note what the sample-size line costs. At `n = 20` per arm and four arms the experiment is 80 wells per timepoint before replication of the run itself, and the detectable floor is still a 1.33-fold change. An experimenter who wants to see a 1.2-fold effect at these settings needs roughly 100 per arm, and the honest time to discover that is before the first plate is seeded.

6.17 Both outcomes, written in advance **Outcome A — the contrast is significant.**

```
reported        effect size with interval, at each of the 12 loci
required next   E2 blinding intact, E3 yoked arm null, E4 ceiling test passed,
                E5 dose-ordering in the preregistered direction,
                E6 independent replication from the published specification
permitted claim "in this system, at this condition, the transcriptional response
                distinguished an ordered stimulus from its symbol-permuted twin"
FORBIDDEN claim any therapeutic, clinical or capability claim; any claim about a
                person; any claim that DNA was edited; any claim that the
                mechanism is known -- a demonstrated dependence is not a mechanism
design space    one cell of 124,800; 0.000801% bounded
```

Outcome B — the contrast is null.

```
reported        the null, in full, with the same prominence as a positive result
required with   the detectable floor (0.4103 log2 at n = 20), the declared SESOI,
                and the fraction of the design space bounded
permitted claim "in this system, at this condition, with 80% power to detect a
                1.33-fold change, no dependence on ordering was detected"
FORBIDDEN claim that acoustic sequence-specificity does not exist; that the
                question is closed; that the architecture is refuted
design space    one cell of 124,800; 0.000801% bounded
```

The two outcomes bound the same fraction of the design space and are worth reporting with the same prominence, which is the single most reliable way to tell whether a research programme is one.

6.18 The gap, at the end The specification above is complete enough to run. The alphabet is separable, the payload is hashed, the controls are named, the sample size is computed, the floor is published, and both outcomes are written down before either has occurred.

And the sentence at the head of this section is exactly as true at the end of it as it was at the beginning. **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal.** Nothing in this framework changes that, nothing in this framework claims to, and the three parts of this paper were written in the order they were so that no reader could reach the procedure without meeting the sentence twice on the way.

A last remark on why this section is where it is. The paper could have ended at §5 with a complete, verified, disclosed procedure and a reader's impression that something had been achieved. Something has been achieved — an encoder that round-trips, an alphabet that separates, a rendering that a listener can follow and refuse — and none of it is the thing the paper is named for. Putting this section after the procedure rather than before it means a reader meets the specification while it still looks promising and then meets the gap while the specification is fresh, which is the order in which the gap is hardest to forget.

What this section established **Established, and checkable:** that the open problem decomposes into three requirements of which one (symbol separation) is solved and two (order memory, mapping to a locus) have no identified mechanism; that eleven upstream components are established and one link is missing, and that the missing link is specifically the carriage of sequence over force; that the symbol-permuted twin is exact on every permutation-invariant quantity and is drawn from a set of `10^2017.717` orderings for this framework's payload; that at `sigma = 0.35` and `n = 3` a targeted design cannot see below a 1.68-fold change, and at `n = 20` cannot see below 1.33-fold; that bulk compressional strain at plausible listening levels is of order `1e-10` and is not the route; that a single condition bounds 0.000801% of a 124,800-cell design grid; and that the scrambled-sequence and shuffled-input controls answer different questions, with the second carrying three measured failure modes of which two are answerable only by design controls.

Not established, and not claimed: that any acoustic method affects any cell's expression; that any capability has been conferred; that DNA is edited, altered or damaged; that the procedure of §5 is a treatment, therapy or practice; that any frequency in this framework is a physical resonance; or that the absence of a known mechanism is evidence of anything whatever, in either direction.

The one line to carry forward: *the channel for sequence-specific content is the question, and naming it precisely is the most useful thing this framework can do about it.*

Section 6 owns the open problem, the three-requirement decomposition, the detectability arithmetic, the design-space bound, and the two-control specification.

7 Results

The eight results below are the units other papers in this corpus cite. Each carries its status: **DERIVED** where it follows from the stated definitions by algebra, **COMPUTED** where it is the output of exact arithmetic on stated parameters, **MEASURED** where a stated quantity of a constructed artefact was measured, and **POSTULATED** where it is asserted by this framework.

R1 — the open problem, stated formally. Let $s(t)$ be an acoustic pressure waveform encoding a symbol string $x = (x_1, \ldots, x_L)$ over an alphabet of size four, and let R be a cell's transcriptional response. **There is no established mechanism producing an R that depends on x as an *ordered string*, as distinct from depending on functionals of $s(t)$ that are invariant under permutation of the symbols** — total energy, duration, long-term power spectrum, envelope statistics, symbol counts. *Status:* a statement about the literature. It is **not** a claim of impossibility, and it is **not** a licence: absence of a known mechanism is not support of any kind.

R2 — the index-assignment result. Assigning $n = 1, 2, 3, 4$ to the four symbols yields odd parts $1, 1, 3, 1$, so **three of four collapse onto a single pitch class**, because $f(2) = 4f(1)$ is exactly two octaves and $f(4) = 16f(1)$ exactly four. The odd assignment $n = 1, 3, 5, 7$ yields four distinct classes; transposed at $j = 8$ the tones are 123.7570, 1113.8129, 3093.9247 and 6064.0924 Hz. **The closest pair in hertz is A and C at 990.055901 Hz; the closest pair as an interval is G and T at 1165.0244 cents. Those are different pairs, and the source's display line joins them with an equals sign (§10).** *Status:* DERIVED and COMPUTED. The naive assignment is rejected in print so that the rejection is findable.

R3 — determination by choice. A directive corpus closed under negation has resultant exactly 0.000000000000 at $N = 4, 8, 12, 24$; a mutually exclusive corpus without exact pairing has mean direction $1/\sqrt{N}$, simulated at 0.498500, 0.350953, 0.288101, 0.202825, 0.140809 and 0.099738 against theory. At $u = 1$ and $N = 12$ the corpus carries $F = \ln 12 = 2.484907$ nats, **exactly the selection cost of 3.584963 bits.** *Status:* DERIVED and COMPUTED, with the equality holding **only at $u = 1$ and under a uniform receiver prior.**

R4 — the Gabor constraints. $\Delta t \, \Delta f \geq 1/(4\pi) = 0.0795774715$ [Gabor, 1946] gives $\Delta t \geq 0.080377$ ms at the symbol layer's 990.055901 Hz gap and $\Delta t \geq 10.2882$ ms at the state layer's 7.734812 Hz binding gap. **The state layer is nearly 128 times more demanding**, which is why the two layers are separated in time. *Status:* CITED as a theorem, COMPUTED in application.

R5 — single-transposition audible capacity. A single integer octave transposition admits at most $N = 25$ essences inside 20 Hz to 20 kHz, and only at $j = 6$; at $N = 26$ the set of admissible j is empty. *Status:* COMPUTED and verified.

R6 — bulk compression closed by arithmetic. For a plane wave in an aqueous medium the longitudinal strain is $s = p/K$ with $K = 2.2 \times 10^9$ Pa; at 40 to 120 dB SPL this is 9.090909×10^{-13} to 9.090909×10^{-9}. **Bulk compression is not the route.** *Status:* COMPUTED from elementary continuum mechanics. **The number says nothing about membrane tension, cytoskeletal transmission or channel-level forces**, which are the established pathways, and it must not be used as a general argument against acoustic effects.

R7 — detectability floors. At $\sigma = 0.35$ $\log_2$ units, power 0.80, and Bonferroni correction, a targeted twelve-locus design **cannot see below a 1.68-fold change at** $n = 3$ **or a 1.33-fold change at** $n = 20$; genome-wide at 20,000 transcripts the corresponding floors are 2.18-fold and 1.53-fold. *Status:* COMPUTED on declared inputs. σ is the operator's, not this paper's.

R8 — how little one condition bounds. A deliberately modest grid over carrier band, level, symbol rate, exposure duration, cell type and readout time gives 124,800 cells, so **one condition bounds** 0.000801 **per cent of it.** *Status:* COMPUTED. The framework's survey work supplies the matching empirical caution [Curzi, 2026i]: a shuffled-input control passed 98.35 per cent of the time against a shared slow driver while detecting honestly at 48.17 per cent in the clean case.

CR — counter-result. The entire pipeline is built, verified and deterministic, and **nobody knows how a cell could read a message out of a sound.** Eleven upstream components are established and the one missing link is precisely the carriage of sequence over force. The three-way decomposition sharpens it: symbol separation is solved and is the least interesting of the three; order memory and mapping to a locus have no identified mechanism, and a better transducer does not touch either. Separately, and in the same spirit, **a careful author writing a deliberately balanced corpus failed a mechanical equal-force check on four of twelve pairs, 33.33 per cent**, and the failures are named rather than repaired.

8 Discussion

8.1 What follows

Disclosure and contradiction are two protections that fail in different circumstances, which is the reason for having both. A single-directive corpus satisfies every disclosure clause and is still a command, because a corpus with one member has a resultant equal to its member and a surplus of $F = \ln 1 = 0$. A contradictory corpus delivered inaudibly satisfies the structural condition and violates the disclosure condition totally, because a listener who cannot hear the corpus cannot perform the selection the structure exists to leave them. **Disclosure makes a command refusable; contradiction makes it not a command.**

The index-assignment result generalises past this application. Any scheme that maps symbols to frequencies through a power law inherits the collapse: indices related by a factor of two are related by an exact octave, and pitch class cannot distinguish them. That is a design constraint on sonification generally and it is cheap to check.

The corpus's own honesty apparatus is the part most likely to be dropped and the part worth keeping. The equal-force check is a crude proxy — character and word count — and is not defended as more than that. It catches gross asymmetry, which is the failure that matters, and it is checkable by anyone. Prosody, connotation and rhetorical weight are not caught by it, which is why the rendering order is fixed in advance and why a witness who is not the author is worth having.

A closed route is a result. The strain arithmetic of §6.10 removes the route most often assumed and leaves the established pathways untouched. That is the shape of progress available here: not a demonstration, but a narrowing.

8.2 What does not follow

Nothing here is evidence that the procedure does anything. The open-label placebo literature establishes that disclosure and a belief-mediated effect are compatible *in another domain.* It is evidence about placebo trials, not about sonified sequence, and the two-column rule forbids moving it across [Curzi, 2026w].

A separable alphabet is not progress on the question. Engineering effort flows naturally toward symbol separation because it is where progress is visible, and symbol separation is the one requirement that was never the difficulty.

Sonogenetics does not close the gap and points the other way. Acoustic specificity in biology has so far been obtained by putting the specificity in the *receiver* — an engineered protein — and never by putting it in the signal.

A null does not close the question and a positive result does not open a channel. Both bound 0.000801 per cent of a modest grid, and **the two outcomes are worth reporting with the same prominence**, which is the single most reliable way to tell whether a research programme is one.

8.3 What the wider corpus says this paper may not claim

Two papers in this corpus bound what a complete specification establishes, and they are cited here because they cut against the reading a sympathetic reader would give.

The framework's historical-network paper demolishes its own most attractive material in print: a well-known story is refused as a fabricated data point, a unified-hand reading is rejected at 1,365:1, and a 25 per cent figure is badged as an artefact of a chosen synthetic ratio rather than a constant, with a confusable-only check reaching only 58.99 per cent [Curzi, 2026]. And the content-addressing paper states that its own headline 56.62 per cent widening **is a ceiling on constructed inputs and not a promise**, distinguishes visibility from pledgeability explicitly, and names the valuation of non-financial capital as unsolved — presenting an architecture as an architecture and not as a system [Curzi, 2026].

Both say the same thing to this paper. A complete specification on constructed inputs is a specification. It bounds nothing about the world, and the temptation to read a verified round-trip hash as evidence of anything biological is exactly the temptation those two papers refused in their own domains.

One further bound is internal to the architecture. The framework's addressing work states the constraint plainly [Curzi, 2026y]: **no addressing operation, at any signal strength or in any modality, can cause a cell to express content its genome and accessible regulatory repertoire do not already contain.** Even a working channel would be a channel for *selection* among latent material, not for creation, and every claim in this paper is bounded by that in advance.

8.4 On arrival, and how far this is from settled

The framework's convergence work supplies the right gauge for a research programme in this state [Curzi, 2026]: the a posteriori bound $d(x_n, x^*) \le (q^n/(1-q))\, d(x_0, x_1)$, read operationally as *the distance to arrival is the size of the last correction, scaled.* Applied here the reading is uncomfortable and correct: **the last correction this material received was the statement that the central mechanism does not exist**, which is not a small correction, and the distance to arrival is correspondingly large. A programme whose most recent revision is of that size is not close to a fixed point, and saying so is more useful than any estimate of how close it might be.

9 Verification

Every step below carries one of four statuses — **ARITHMETIC** (reproducible with a calculator from the inputs named), **DEFINITION** (true by stipulation), **CITED** (an external source supports it, named), or **POSTULATED** (asserted by this framework, no external support).

9.1 The postulates

	postulate	status
P1	φ is the positive root of $x^2 = x + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P2	The Pythagorean whole tone is the ratio $9{:}8$.	CITED [Barbour, 1951]
P3	A dimensionless ratio $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source
P4	$f(n) = kn^2$ for an index n.	POSTULATED — no source
P5	Alphabetical order is an admissible ordinal on the four bases.	POSTULATED (a stated convention)
P6	$\Delta t\,\Delta f \geq 1/(4\pi)$ for any finite-energy signal.	CITED [Gabor, 1946]; proof reproduced in Curzi [2026z]
P7	$N_{\text{eff}} = 1 + (N-1)u$ and $F = \ln N_{\text{eff}}$.	POSTULATED (design axiom); **not a Hill number**
P8	Directives are unit vectors and negation is $-v$.	DEFINITION (a stated model)
P9	Bulk strain in a fluid is $s = p/K$.	CITED as elementary continuum mechanics
P10	The two-sample normal power formula, at declared α, β, σ.	DEFINITION (a stated statistical model)
P11	A permutation of a symbol string leaves every permutation-invariant functional of its rendering unchanged.	DEFINITION

Dropped as unnecessary. No postulate about the *ordering* or *meaning* of the twelve state classes is needed for R2, R4, R5, R6, R7 or R8. No postulate about consonance is needed anywhere. **P3 and P4 are needed only for the frequency *values*; the separation results survive their deletion in ratio form**, because every ratio in the alphabet is a ratio of squares and k cancels.

9.2 The compounding chain

step	consumes	produces	status
L1	P1, P2	$(9/8)^2 = 1.265625$; $\varphi^2 = \varphi + 1 = 2.618034$	ARITHMETIC
L2	L1	$k = 0.483425732988414$	ARITHMETIC (exact)
L3	L2, **P3**	k carries the unit Hz	**POSTULATED**
L4	L3, **P4**, **P5**	four symbols map to $f(n) = kn^2$ at a chosen index set	**POSTULATED**
L5	P4 by inspection	$f(2n)/f(n) = 4$; the pitch class of n is its odd part	ARITHMETIC

step	consumes	produces	status
L6	L5 at $n = 1, 2, 3, 4$	odd parts $1, 1, 3, 1$: three symbols collapse — **R2**	ARITHMETIC
L7	L5 at $n = 1, 3, 5, 7$	four classes; at $j = 8$, tones from 123.76 to 6064.09 Hz	ARITHMETIC
L8	L7	closest in Hz: A–C, 990.0559; closest as an interval: G–T, 1165.0244 cents; **different pairs** — **R2**	ARITHMETIC
L9	P6, L8	at the symbol layer, $\Delta t \geq 0.080377$ ms — **R4**	ARITHMETIC
L10	P6, folded gap 7.734812 Hz	$\Delta t \geq 10.2882$ ms; ratio ≈ 128 — **R4**	ARITHMETIC
L11	L7, band 20 Hz–20 kHz	admissible j nonempty to $N = 25$, empty at 26 — **R5**	ARITHMETIC
L12	P8, closure under negation	$\lVert \sum_i v_i \rVert = 0$ exactly — **R3**	ARITHMETIC
L13	P8, isotropy	mean direction $1/\sqrt{N}$; simulated agreement to $\sim 10^{-3}$ — **R3**	ARITHMETIC + simulation
L14	P7 at $u = 1$	$F = \ln 12 = 2.484907$ nats $= 3.584963$ bits — **R3**	ARITHMETIC given P7
L15	L14, ceiling	deficit at $c/\eta = \ln 12$ is 0, residual 8.88×10^{-16}	ARITHMETIC
L16	ASCII, SHA-256	675 bytes $\to$ 5,400 bits; hash `c7d98b1c` …	ARITHMETIC
L17	L16, balanced rule	GC $= 0.500000$ exactly; max run 1; entropy 1.935874 against greedy 1.244171	MEASURED on the payload
L18	L17, decode	recovered hash identical — round trip verified	MEASURED
L19	4^{20} vs 6.2×10^9	0.005638867 expected spurious matches; ratio 177.3406	ARITHMETIC
L20	P9	$s = p/K$: 9.09×10^{-13} at 40 dB to 9.09×10^{-9} at 120 dB — **R6**	ARITHMETIC
L21	P10	detectable $\log_2$ FC 1.0593 at $n = 3$, 0.4103 at $n = 20$ — **R7**	ARITHMETIC
L22	grid of stated choices	$30 \cdot 13 \cdot 4 \cdot 4 \cdot 5 \cdot 4 = 124{,}800$ cells, so one condition bounds 0.000801% — **R8**	ARITHMETIC

step	consumes	produces	status
L23	P11	the permuted twin is exact on energy, duration, histogram and long-term spectrum — **R1**	DEFINITION
L24	multinomial on the payload composition	$L!/\prod_i n_i!$, which is $10^{2017.717}$ orderings	ARITHMETIC

9.3 What this chain is and is not

Read the status column. L1, L2 and L5–L24 are arithmetic, definition, or measurement on a constructed artefact, and a reader can redo every one of them. **L3 and L4 are postulated**, and they are the only postulated steps in the chain.

The separation is unusually clean here and is worth stating precisely. A reader who rejects P3 and P4 — who declines to accept that a dimensionless ratio is a frequency or that the essence law holds — loses the specific hertz values of the alphabet and keeps everything else: the collapse result in ratio form (the tones related by $4{:}1$ are the same pitch class whatever the reference is), the Gabor arithmetic, the transposition capacity, the corpus geometry, the strain calculation, the detectability floors and the design-space bound. **Seven of the eight results survive the deletion of both postulates.**

And the chain does not reach the paper's subject. No step in L1–L24 produces a biological claim, and none could: **R1 is a statement that a step which would be needed does not exist.** A verification section that decomposed a claim about cells into checkable pieces would be a verification of something this paper does not assert.

Two statuses that must not be misread. The exponent 2 in $f(n) = kn^2$ and the exponent $-1/2$ in the resultant's decay are both **DEFINED** by the model, not estimated; no fitting was performed and the standard procedure for testing a claimed scaling relation [Clauset et al., 2009] was not run, because there is nothing to run it on. And the simulation at L13 is a simulation of a stated random model, not an observation.

The verification instance. The smallest example that exercises L5–L8 is the four-symbol alphabet itself: $k \cdot 1 = 0.4834257330$, $k \cdot 9 = 4.3508315969$, $k \cdot 25 = 12.0856433247$, $k \cdot 49 = 23.6878609164$; multiply each by $2^8 = 256$; subtract the two smallest to get 990.0559 Hz; and $1200 \log_2(1113.8129/123.7570) = 1165.0244$ cents. Four multiplications, one subtraction, one logarithm.

10 Limitations

L-1. The dimensional audit does not close on the essence law. $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, and no operational procedure is supplied by which it does (§2.3 P-a, §3.2). The Gabor bound and the strain calculation *do* close, and the contrast is the point.

L-2. The essence law has no external support, and the exponent is defined rather than estimated (§2.3 P-b). **This paper makes no empirical scaling claim.**

L-3. The constant is chosen. $k = (9/8)^2/\varphi^2$ has no precedent as a frequency, and the deflationary literature on golden-section claims is cited rather than avoided [Markowsky, 1992]. Its fifteen figures are exact digits of a definition.

L-4. Octave reduction beyond pitch is unwarranted. Shepard grounds octave equivalence for pitch [Shepard, 1982]; nothing grounds carrying it to a quantity that is not a pitch.

L-5. $N_{\text{eff}} = 1 + (N-1)u$ **is not a Hill number.** It is a linear interpolation between 1 and N. The Hill results [Hill, 1973, Jost, 2006] apply to $1/\text{HHI}$ and $\exp(H)$ and to nothing here.

L-6. Conjoint measurement was not tested, and scalar reduction is the general form of the problem. Michell's objection [Michell, 1997] stands unanswered for u and for the elicited intensities, and the remedies [Luce and Tukey, 1964, Rasch, 1960] were not run. **The same objection arrives from the affect literature in a different domain** — individuation by pattern across appraisal dimensions [Smith and Ellsworth, 1985], by synchronisation in time [Scherer, 2001], and by qualitative core relational theme [Lazarus, 1991], with action readiness constitutive rather than terminal [Frijda, 1986], against two well-supported dimensions of core affect [Russell, 1980]. **These are one objection, not two**, and §3.5 names it once. The twelve class names of §4.14 are motivated by that literature and are **not licensed by it**, and the ladder's ordering in particular is contradicted by it.

L-7. The alphabetical ordinal is weak and is stated as weak. Applying a square law to symbols requires an ordinal, and alphabetical order is a convention rather than a property of the symbols. **Any other published ordinal would give different frequencies and the same separation structure**, which is a way of saying that the specific hertz values carry no information the ordering does not.

L-8. The pitch-class collisions are structural and are not repaired. Four of twelve directives share one class and three share another; six positions carry twelve directives. That is $(2n)^2 = 4n^2$ and nothing else, and absolute register — not pitch class — is what identifies a state.

L-9. The biological and placebo literature has no cluster in this corpus's bibliography, and every such work is named without a citation key. Specifically: Church, Gao and Kosuri (*Science* 337:1628, 2012); Goldman et al. (*Nature* 494:77, 2013); Erlich and Zielinski (*Science* 355:950, 2017); Zetsche et al. (*Cell* 163:759, 2015); Fonfara et al. (*Nature* 532:517, 2016); Qi et al. (*Cell* 152:1173, 2013); Gilbert et al. (*Cell* 159:647, 2014); Tajik et al. (*Nature Materials* 15:1287, 2016); Ibsen et al. (*Nature Communications* 6:8264, 2015); Duque et al. (2022); Takahashi and Yamanaka (*Cell* 126:663, 2006); the PIEZO1/PIEZO2 mechanotransduction literature; Kaptchuk et al. (*PLoS ONE*, 2010); Carvalho et al. (*Pain*, 2016); and von Wernsdorff et al. (*Scientific Reports*, 2021). **Every claim in §4.4, §5.8, §5.10, §6.5 and §6.5b that rests on one of these is therefore uncited in the reference list**, and is described from the source with its bibliographic details in the text. Attaching an unrelated key to a biological claim would be worse than the gap. **This is a defect of the corpus's bibliography, not a claim that the works do not exist**, and it must be closed before submission.

L-10. Sequence-sonification prior art is likewise uncited. The encoding step here is conventional rather than novel, and published sequence-sonification methods exist; the bibliography carries none of them, so **the novelty claim this paper makes is deliberately narrow** — the index assignment and the separation arithmetic, not the idea of sonifying a sequence.

L-11. One instance is not a rate. The equal-force failure rate of 33.33 per cent is one author writing one corpus once. It is reported because the *direction* of the finding is informative — a careful author intending balance did not achieve it — and it estimates nothing.

L-12. Character count is a crude proxy for force. It catches gross asymmetry, which is the failure that matters, and it does not catch prosody, connotation or rhetorical weight. That is why the rendering order is fixed in advance and why an independent witness is specified.

L-13. $u = 1$ here is constructed, not measured. A corpus of directives with overlapping support would not reach it; the value is a property of the design and the 69.6133 Hz that follows is the arithmetic ceiling of a twelve-category system, not a reading of a person, a text, or a relationship.

L-14. The one-hot degeneracy is used deliberately here and is a trap elsewhere. Vectors with disjoint support are automatically orthogonal. This paper's corpus is that degenerate case on purpose, and every reading of it says so.

L-15. No perceptual experiment stands behind any perceptual claim in this paper. The separation figures — 1165.0244 cents in the alphabet, 995.9922 cents between layers, 34.9756 cents in the folded lattice — are arithmetic on frequencies. The claim that a listener can *follow* the resulting rendering, that the double octaves are *audible without instruction*, and that the two layers are *separable by ear*, are perceptual claims. **No listener was asked anything.** They rest on the general acoustics and psychoacoustics literature [Rossing et al., 2002, Sethares,

2005, Burns, 1999, Hoeschele et al., 2012, Demany et al., 2013] and are limited by its own boundaries. This is stated again in §12.

L-16. The power arithmetic is not a claim about biology. σ and the number of tests are declared inputs. Substituting an optimistic σ is the cheapest way to make an underpowered design look adequate on paper, and the power target of 0.80 is a convention rather than a law; 0.90 costs roughly a third again in sample size and should be priced explicitly.

L-17. The bulk-strain result must not be over-read. It closes the naive route and says nothing about membrane tension, cytoskeletal transmission or channel-level forces. **Using it as an argument against acoustic effects in general would be a misuse of this paper.**

L-18. The design grid is arbitrary and deliberately modest. 124,800 cells follow from six stated choices at stated resolutions. A finer grid would make one condition bound even less, and a coarser one would flatter a null. The figure is a device for keeping both outcomes the same size, not an estimate of anything.

L-19. No model comparison and no statistical claim. Nothing was fitted, no out-of-sample test was run, and there are no p-values, effect sizes or confidence intervals in this paper, because there is no sample. Where the corpus has attempted a confirmatory fit elsewhere it failed its own baseline test [Curzi, 2026i], and that is the relevant precedent.

L-20. The reflexive specification is not identified, and the framework does not exempt its own parameters from its own reflexivity [Manski, 1993, Shalizi and Thomas, 2011, Lucas, 1976, Hacking, 1995]. The disclosure design makes the expectancy channel visible rather than absent [McCambridge et al., 2014].

L-21. The precedent for contradictory corpora is genuine and is not evidence. Proverbs 26:4–5, Talmudic *machloket*, and the koan tradition are named in §4 as independent arrival. **None is in this paper's bibliography and none is cited with a key.** Independent arrival is an argument that a structure is findable, not that it does anything [Curzi, 2026w].

L-22. Boundary behaviour. $u \to 0$ gives $F = 0$ and $f = k$, the ground essence, which is the reading for *no relationship* rather than a low one; $u \to 1$ gives the ceiling and is where the corpus is constructed to sit; $N \to \infty$ raises the ceiling without bound and is unavailable, since single transposition fails at $N = 26$ and the folded lattice collapses at $N = 17$; $\Delta t \to$ the Gabor floor produces **concealment achieved by speed**, which is why the symbol rate is set by audibility and not by the mathematics. These limits constrain the domain and are stated because the source states only some of them.

A discrepancy found in the source, printed rather than silently corrected

The source's symbol-alphabet block prints

```
MINIMUM GAP                990.055901 Hz  =  1165.0244 cents
```

and those two figures are not two readings of one quantity. The three adjacent gaps in the transposed alphabet are 990.055901 Hz (A to C), 1980.111802 Hz (C to G) and 2970.167703 Hz (G to T); in cents they are 3803.9100, 1768.7174 and 1165.0244. **The minimum in hertz is the A–C pair and the minimum in cents is the G–T pair**, because the alphabet is spread multiplicatively and the two orderings run opposite ways. The equals sign in the source's display line joins two different pairs.

Neither figure is wrong and the arithmetic that consumes them is right. The Gabor floor requires a bandwidth in hertz, so $0.0795774715/990.055901 = 0.080377$ ms is the correct application and uses the correct number. The 1165.0244-cent figure is the correct statement of how close the two nearest tones are as an *interval*, which is the quantity a listener's frequency discrimination is described in. **This paper states them separately throughout and does not join them**, and the correction is printed here rather than applied quietly, because a reader recomputing from the source's line will find it does not close.

A related pair that does close, checked because it looks like the same defect and is not. The folded-lattice minimum at $N = 12$ is stated in the source both as 34.9756 cents (the ratio $50/49$)

and as 7.734812 Hz. Those are consistent: the two lattice positions are $k \cdot 25 \cdot 32 = 386.7406$ Hz and $k \cdot 49 \cdot 16 = 379.0058$ Hz, whose difference is $k \cdot 16 = 7.734811727814624$ Hz exactly and whose ratio is $50/49$, 34.975615 cents. **One is absolute and one is relative and they describe the same pair.** The Gabor calculation at the state layer uses the absolute figure, correctly.

A second, smaller note on the source. Its failure-mode lists are out of order in two places: one list runs …12, 14, 13, and another runs …8, 13, 14, 9, 10, 11, 12. The ordering is preserved as found, renumbered to this paper's sections. It is a defect of presentation, not of content.

11 Conclusion

What is established, and checkable. A written corpus maps losslessly to a 5,400-base nucleotide string with a verified SHA-256 round-trip identity. A balanced free-choice rule holds GC within one base of $L/2$ by construction, measured exactly 0.500000 here, with maximum homopolymer run 1 and symbol entropy 1.935874 bits per base against a greedy rule's 1.244171. **The naive symbol-index assignment** $n = 1, 2, 3, 4$ **collapses three of four symbols onto one pitch class by** $(2n)^2 = 4n^2$**, and the odd assignment** $n = 1, 3, 5, 7$ **gives four distinct classes with a minimum gap of** 990.055901 **Hz,** 1165.0244 **cents, and a Gabor floor of** 0.080377 **ms.** The state layer's binding separation gives $\Delta t \geq 10.2882$ ms, nearly 128 times more demanding, and the two disclosed layers clear each other by 995.9922 cents. **Single-transposition audible capacity is** $N \leq 25$ **and only at** $j = 6$**.** A corpus closed under negation has resultant exactly 0.000000000000 at $N = 4, 8, 12, 24$, and at $u = 1$ carries $F = \ln 12 = 2.484907$ nats — exactly the selection cost of 3.584963 bits — sitting on the sustainability ceiling with residual 8.88×10^{-16}. **Four of twelve directive pairs fail the equal-force check, 33.33 per cent, and are named rather than repaired.** Bulk compression is closed by arithmetic at strains of 10^{-11} to 10^{-10}. A targeted twelve-locus design at $\sigma = 0.35$ cannot see below 1.68-fold at $n = 3$ or 1.33-fold at $n = 20$. And **one null condition bounds** 0.000801 **per cent of a 124,800-cell design grid.**

What is proposed rather than shown. That a dimensionless ratio of a tuning interval to the square of the golden section is a frequency; that $f(n) = kn^2$; and that alphabetical order is an admissible ordinal on four symbols. **These are postulates with no external support**, and seven of this paper's eight results survive their deletion.

What is not claimed at all, and this is the paper's principal statement. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. The pipeline is built, verified, deterministic and disclosed, and it stops at a loudspeaker. Eleven upstream components are established — storage in sequence, addressing, self-processed multi-address arrays, the separability of targeting from editing, mechanotransduction, force-to-transcription coupling, engineered acoustic channels, a large structured regulatory archive, and the reorganisation of expression by regulatory input — and **the one missing link is precisely the carriage of sequence over force.** Decomposed, symbol separation is solved and is the least interesting of the three requirements; order memory and mapping to a locus have no identified mechanism, and a better transducer does not touch either. That statement is exactly as true at the end of this paper as at the beginning, **it is not a claim of impossibility, and it is not a licence either**: absence of a mechanism is not evidence of anything, in either direction.

12 Declarations

Data and code availability. No dataset was collected for this study and none exists. No experiment was run, no cells were exposed to anything, and no endpoint was measured. Every number in the paper is the output of exact arithmetic on parameters stated in the text, or a measurement of a constructed artefact — a byte string, its hash, and the derived base string — which is fully specified here and reproducible from the specification alone. The figures are generated by the Python scripts named in their captions and are available from the author on request.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. No person was exposed to any rendering described here, and the disclosure package, consent specifications and stop procedures of §4 describe requirements on a procedure that has not been run. **This paper asserts perceptual claims — that a listener can follow the rendered symbol stream, that a double octave is audible without instruction, and that the two disclosed layers are separable by ear — without any perceptual experiment behind them.** Those claims rest entirely on the cited acoustics and psychoacoustics literature, are limited by that literature's own boundaries, and are listed among this paper's limitations (L-15). No listener was asked anything.

Biological and clinical disclaimer. No claim of any biological effect is made anywhere in this paper. Nothing described here is a treatment, therapy, dose, intervention, modality or practice. **No DNA is edited, altered, synthesised, delivered or damaged**: nothing in the pipeline is a molecule, the nucleotide string is a string in the computer-science sense, and no nuclease, template or Cas protein appears at any point. No capability is claimed to have been conferred on anything. No person, tissue, cell or molecule is claimed to resonate at any frequency printed here; in particular, **cytosine does not absorb at 1113.8129 Hz, does not resonate at it, and is not affected by it.**

Preregistration. No test in this paper was preregistered, because no test was run. §5 Part B and §6.12 set out the preregistration, kill conditions and reporting requirements that would govern a first run, and §6.17 writes both possible outcomes in advance. **The design has not been executed and its preregistration has not been deposited.**

Literature not in the reference list. The biological, placebo and sequence-sonification works this paper describes are named in the text with their bibliographic details and are absent from the reference list, because the bibliographic database governing this corpus carries no cluster for them. They are enumerated in §10, L-9 and L-10.

Chapter 49

Destiny as a Fixed Point: Conservation of Drive Under Cost Transfer, the Completeness of the Lever Set, and the Corpus's Register of Demotions

Abstract. We define the destination of an arrangement as the fixed point Q_inf = (eta*F(u) - c)/delta and establish its properties exactly. The update map is a contraction with Lipschitz constant 1 - delta, so the fixed point exists, is unique, and is reached from any starting stock; the approach is a geometric equality verified to a maximum residual of 2.06e-15 across a hundred passes. The deficit and the destiny are one quantity in two units, D = -2.885390(delta/eta)Q_inf, with maximum residual 8.88e-16 over twelve parameter sets, and D contains no delta - the same deficit is consistent with destinies differing by a factor of thirty. Theorem 5.1 establishes that exactly four arguments enter, u, N, eta and c, and there is no fifth. Theorem 4.5 proves the sum of drives is exactly conserved under any transfer of cost among any number of participants: an apparent improvement of +7.751093 for one party is matched by -0.599002 for another, the sum of drives holding at +0.643688229683 to every digit, with the disadvantaged party's stock not crossing zero until pass 10.850479. When decay rates differ the plain sum is no longer invariant and moves at 1/delta_P - 1/delta_R per unit exported. The closing section reports six constraining results - including that F(u) is exactly a threshold-corrected Fechner law with u_0 = 1/(N-1) and F(u_0) = ln2 = one bit exactly - and a register of four occasions on which the framework's own gates demoted its author's claims.

Keywords: fixed point; contraction; conservation of drive; cost transfer; lever completeness; Fechner law; demotion register; reserve theorem

Series: C. Frequency, Essence, and Mind **Paper:** CCP-049

1 Introduction

A framework that computes where an arrangement is going acquires, without asking for it, the vocabulary of fate. Once a storage loop has a fixed point, the fixed point has a name, and the name the practical literature supplies is *destiny* — a word used to mean an unalterable script, a personal entitlement, a reward for correct wanting, and, most often, nothing at all.

This paper takes the word over and makes it checkable. **In this framework the destination of an arrangement is $Q_\infty = (\eta F(u) - c)/\delta$, the fixed point of the contracting storage loop** [Curzi, 2026a], and every property claimed for it is either an arithmetic consequence of that definition or is badged as something else. The definition buys one thing the rhetorical use never supplies: a number with four arguments, which moves when an argument moves and at no other time.

Three results follow from that definition and are the paper's contribution. The first is a conservation identity. Under a transfer of cost among participants, the **sum of drives** $\sum_i b_i = \sum_i (\eta_i F_i - c_i)$ does not move at all — exactly, unconditionally, and for any number of participants with any decay rates whatever. That converts a standing prohibition of the framework's foundations [Curzi, 2026] from an unfalsifiable statement about intention into an arithmetic test that costs one column of a report and returns an answer on the first pass. The second is a completeness statement: Q_∞ has exactly four arguments and there is no fifth, so a proposal that cannot be assigned to one of them changes the destination by zero. The third is negative and is the sharpest limitation the framework's central instrument has: the octave deficit D contains no δ, so the same deficit is consistent with destinations differing by a factor of thirty.

Why the conservation result matters more than its algebra suggests. An intervention that improves one participant's readings genuinely, pass after pass, while the conserved sum does not move, has produced nothing; it has moved an existing quantity between two ledgers, and both ledgers are correct. Cost export is an externality in the ordinary sense [Hardin, 1968, Ostrom, 1990], and the case worked here shows the exporting party's instrument reading better at every step. The disadvantaged party's stock, meanwhile, stays positive for nearly eleven passes after its destination has gone negative, so the ordinary question — *is anyone worse off?* — returns a false negative for the whole of that window.

The paper closes on six results that constrain the framework rather than extend it, and on a register of four occasions on which the framework's own gates demoted its author's claims. **A corpus whose strongest results are all constraints is a corpus that was checked**; the alternative, a corpus of affordances each of which adds a capability and none of which subtracts one, is the signature of work that was never audited [Lakatos, 1970, Platt, 1964, Meehl, 1990].

Contributions

1. **Conservation of drive under cost transfer** (Theorem 4.5). The sum of drives is exactly invariant under any transfer of cost among any number of participants, verified at $+0.643688229683$ across a two-party export range and at $+1.268940530229$ across four transfers in a three-party arrangement, residual $0.000\text{e}{+00}$. The plain sum of fixed points inherits the invariance **only** when the participants share a decay rate; otherwise it moves at $1/\delta_P - 1/\delta_R$ per unit exported.
2. **The convergence law as an equality** (Theorem 4.2), not as Banach's bound: the gap closes by exactly $1 - \delta$ per pass at every distance, verified to a maximum residual of $2.0624\text{e}{-15}$ over a hundred passes.
3. **The deficit identity and the decay blindness** (Theorems 4.3 and 4.4): D and Q_∞ are one quantity in two units, verified to $8.8818\text{e}{-16}$ over twelve parameter sets, and D contains no δ, so $\partial D/\partial\delta = 0$ identically.
4. **Completeness of the lever set** (Theorem 5.1): four arguments, five handles, and the reconciliation between the two counts.
5. **The reserve theorem** (Theorem 5.3): a lever can be *absent* rather than expensive. Demonstrated on a lever carrying 4.80 times the elasticity of its rival and 4.174198 octaves of reserve against a 4.338420-octave requirement, falling short by 0.164222 even at an impossible conversion efficiency of one.
6. **The price of misordering**: eight periods of the wrong order cost twelve periods of permanent lag, thirteen periods below the starting stock, and 111.133601 stock-periods of cumulative loss, with identical terminal parameters and therefore an identical destination.

7. **The surplus law is exactly a threshold-corrected Fechner form** with $u_0 = 1/(N-1)$, at which the affine effective count is 2.000000 exactly for every N and $F(u_0) = \ln 2$ — one bit, two octaves.
8. **The demotion register**: four occasions on which the framework's own gates rejected its author's claims, printed rather than summarised.

What this paper does not claim. No arrangement's parameters are claimed to hold. No larger fixed point is claimed to be a better life. No frequency printed anywhere here is claimed to be a physical resonance: the constant $k = (9/8)^2/\varphi^2 = 0.483425732988414$ is a **defined** number whose components are real — the Pythagorean whole tone [Barbour, 1951] and Euclid's extreme and mean ratio [Euclid, 1956, Vajda, 1989] — and whose product, expressed as a frequency, has no precedent in any literature; the standard deflation of golden-section claims [Markowsky, 1992, Fischler, 1981, Höge, 1997] is cited here and again wherever φ appears. Every case in this paper is **constructed** and is labelled as constructed at the point of use.

2 Hypotheses, definitions, and postulates

Most of this paper is not hypothesis-testing, and saying so is the first honest act available to it. Theorems 4.1 to 4.5, Corollary 4.6 and Theorems 5.1 to 5.3 are arithmetic on stated definitions; no observation could bear on them, and none was collected. What follows separates the few claims that could be wrong from the many that are definitions, postulates or modelling choices.

2.1 Hypotheses proper

H1 — the detection-lag hypothesis. When cost is exported from one participant to another, the disadvantaged party's *destination* turns negative on the pass the transfer happens, while its observable *stock* continues to fall through zero only after $t^* = \ln(|Q_\infty|/|Q_0 - Q_\infty|)/\ln(1-\delta)$ passes. **Predicted:** in the worked constructed case, $t^* = 10.850479$ passes at $\delta = 0.09$ — eleven periods in which nothing observable changes. **Falsified by:** a measured arrangement in which the stock and the drive change sign on the same pass, with both quantities separately instrumented. **Status: untested. No such measurement exists and none was made for this paper.** The arithmetic of the lag is a theorem; the claim that real arrangements exhibit it is not.

H2 — the ceiling hypothesis, inherited. No arrangement with $c/\eta > \ln N$ sustains, at any value of the geometry. **Predicted:** at $\eta = 0.20$, $c = 0.60$ and $N = 12$, even perfect orthogonality leaves $D = +1.486245$ octaves, and closure requires $N \geq e^3 = 20.0855$. **Falsified by:** a single counterexample. **Status:** derived from $F \leq \ln N$ [Curzi, 2026]; **untested against any observation.** It is the only strict universal in this paper and therefore the only claim here that one observation could kill.

H3 — the retention hypothesis, inherited. Trust acts on an arrangement by reducing loss rather than by adding input, entering as $\delta_{\text{eff}} = \delta_0 + (1-a)(1-v)$ [Curzi, 2026s]. **Predicted:** an intervention identified as trust-building changes the retention term and leaves the drive $b = \eta F - c$ unchanged, so its effect on Q_∞ takes the sign of a quantity it never touches. **Falsified by:** a measured intervention that raises the drive without changing the loss rate, or that changes the sign of a destination. **Status: untested here.** The empirical premise — that trust reduces loss rather than supplying input — is the one this paper's ordering rule inverts relative to ordinary practice, and it is supported in the literature only at the level of a mechanism, not of a measured coefficient [Gambetta, 1988, Putnam et al., 1993, Ostrom, 2010].

H4 — the survivorship hypothesis. A corpus of published testimonials is selected on outcome, so the probability that a published account reports a success is 1 under every hypothesis about the method's efficacy. **Predicted:** likelihood ratio exactly 1.000000 at any corpus size, and therefore zero bits of evidence. **Falsified by:** a testimonial corpus demonstrated to publish failures at their base rate, which would break the conditioning and restore a denominator. **Status:** the arithmetic is exact given the selection model; **the selection model itself is an empirical claim about publication and is not tested here.** The corresponding literature on selective publication in research is cited in §5.16 [Ioannidis, 2005, Simmons et al., 2011, Gelman and Loken, 2013, Open Science Collaboration, 2015].

2.2 Definitions — true by stipulation

- **Def. A.** $Q_\infty := (\eta F(u) - c)/\delta$, the destiny (Definition 4.1).
- **Def. B.** $b := \eta F(u) - c$, the per-cycle **drive**.
- **Def. C.** A **transfer of cost** of amount x from participant p to participant r is the operation $c_p \to c_p - x$, $c_r \to c_r + x$, with every other parameter unchanged. **The conservation result of Theorem 4.5 is an arithmetic consequence of this definition and of nothing else** — see §9.4.
- **Def. D.** $F(u) := \ln(1 + (N-1)u)$, the interaction surplus in nats.
- **Def. E.** $N_{\text{eff}} := 1 + (N-1)u = e^F$, the **affine effective count**. This is the corpus's own construction. **It is not a Hill number of any order** — see §3.4.
- **Def. F.** $k := (9/8)^2/\varphi^2 = 0.483425732988414$. A **defined** constant, exact by construction; its fifteen figures are exact digits of a definition and carry no measurement uncertainty, because nothing was measured.
- **Def. G.** $2/\ln 2 = 2.885390081778$, the exchange rate between nats of surplus and octaves of pitch, fixed by Def. F and the essence bridge.
- **Def. H.** $D := 2.885390\,(c/\eta - F)$, the octave deficit.
- **Def. I. Counterfeit arrival** (Definition 4.2): a fixed point positive in one participant's accounts, where the sum of drives across the arrangement did not move to produce it.

2.3 Postulates — asserted, with no external support

- **P-a. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2$ is arithmetic; asserting that the resulting dimensionless number **is a frequency** is a separate and much stronger claim, and no operational procedure is supplied by which the constant acquires the dimension of inverse time. **Every hertz value in this paper depends on it and no dimensionless result does.**
- **P-b. The essence law** $f(n) = kn^2$, inherited [Curzi, 2026]. No external support. The exponent 2 is **defined by the model, not estimated from data**: no fit was performed, no alternative form was tested, and the goodness-of-fit and likelihood-ratio procedure a scaling claim requires [Clauset et al., 2009] was **not run, because there is no data to run it on.**
- **P-c. The essence bridge** $f = k\,e^{2F}$, which is what makes the surplus and the frequency commensurable and what turns the sustainability condition into a pitch. Postulated.
- **P-d. The affine effective count** $N_{\text{eff}} = 1 + (N-1)u$, a design axiom of the corpus and **not** a Hill number [Hill, 1973, Jost, 2006].
- **P-e. The channel-gain relation** $E = (\sum_i G_i)B$ [Curzi, 2026ab], applied in §5.14 and badged in place at every use.

2.4 Modelling choices

- **M-a. The storage law is affine and first-order** [Curzi, 2026a]. Nothing here shows that a real arrangement's retention is linear, and the model is admissible only where the

trajectory stays in a range the arrangement survives. §5.6 exhibits a constructed path that spends thirteen periods below its starting stock, and the formalism computes it without complaint.

- **M-b. Parameters are held constant while a fixed point is computed.** A destiny is a statement about a configuration, not about a future, and the conditional clause is the whole of its content.
- **M-c.** $N = 12$, inherited and not shown to be the right twelve [Curzi, 2026].
- **M-d. Cost, conversion and loss are per-participant scalars.** The formalism represents transfer of cost and nothing else; degrading another party's geometry, conversion or retention is not a transfer and the conservation identity does not cover it (§4.15).

2.5 What is expository

Sections 4.17 to 4.20 and 5.17 to 5.18 are procedures and gates: instruments with blanks, whose organising question is *what must be recorded alongside a reading so that a second analyst can recompute it and disagree with it in a specific place.* They argue no claim and test no hypothesis. Section 6 is a synthesis: it states the keystone, collects six constraining results, and prints the register of demotions. Its value is in the constraints, not in a new claim.

3 Framework, dimensional audit, and method

3.1 What is inherited and what is new

The storage law, its stability condition and its DC gain are inherited [Curzi, 2026a]; the octave deficit, the ceiling $c/\eta \leq \ln N$ and the four levers are inherited [Curzi, 2026]; the elasticities and the ordering rule are inherited [Curzi, 2026q]; the contraction theorem and the consent law are inherited [Curzi, 2026]; the channel-gain postulate and the survivorship arithmetic are inherited [Curzi, 2026ab,?]. **What is new is the conservation identity under cost transfer and the export test built on it, the completeness statement for the lever set, the general form of the reserve theorem, the priced cost of misordering, and the register of demotions.**

3.2 Analogy discipline

Every borrowing in this paper is category 2 — a shared mathematical form — and none is category 1. The discrete leaky integrator is a leaky integrator whether it holds charge or stored order: the same first-order linear difference equation governs the RC low-pass filter [Oppenheim et al., 1996], exponential smoothing [Holt, 1957, Brown and Meyer, 1961], and the leaky integrate-and-fire neuron [Lapicque, 1907, Gerstner and Kistler, 2002], and its stability condition and unique fixed point are standard [Elaydi, 2005, Kelley and Peterson, 2001, Strogatz, 2015]. **No physical result about circuits is claimed to transfer.** Banach's theorem [Banach, 1922] is used as mathematics, which is what it is. The stock-and-flow reading of Q and b is the ordinary one of system dynamics [Forrester, 1961, Sterman, 2000], and the frequency interpretation sitting on top of the whole apparatus is **category 3, an analogy**, badged as such at every appearance. The wider programme of statistical physics applied to social dynamics has a survey that fixes what such models may be held to [Castellano et al., 2009], and its boundaries are the boundaries claimed here.

One term needs its own warning. Theorem 4.5 is called a *conservation* identity, and the word is borrowed. It is conservation **by construction**: a transfer is defined as an operation that adds $+x$ to one drive and $-x$ to another, and the sum telescopes. Nothing in the world is claimed to be conserved, no invariance group is exhibited, and no Noether-style warrant exists. Borrowing the notation of a conserved quantity without the conservation law is the characteristic failure of this genre [Mirowski, 1989]; the defence available here is Cartwright's — the identity is claimed within a specified arrangement and no universality is claimed for

it [Cartwright, 1999]. **Its content is diagnostic, not physical:** the two ledgers are computed independently and the sum is then checked, which is what makes the check capable of failing.

3.3 Dimensional audit

symbol	quantity	dimension	unit	status
u	non-parallelism	$[1]$	—	dimensionless, $[0, 1]$
N	category count	$[1]$	—	absolute scale; a count
F	interaction surplus	$[1]$	nats	a logarithm of a count
η	conversion	$[1]$	—	**stated dimensionless; see below**
c	cost per pass	$[1]$	nats/pass	inherits from ηF
b	drive per pass	$[1]$	nats/pass	$\eta F - c$
δ	retention loss	$[1]$	per pass	a fraction, $(0, 1]$
Q	stored order	$[1]$	nats	**no operational unit**
τ, half-life	approach times	$[T]$	passes	from δ alone
k	ground constant	$[T^{-1}]$ **asserted**	Hz **asserted**	**defined dimensionless; the unit is postulated**
f, f_{rel}, $f_{\min}$	frequencies	$[T^{-1}]$	Hz	inherit the dimension entirely from k
D	octave deficit	$[1]$	octaves	$2/\ln 2$ nats to octaves

Does it balance? Three answers, and one of them goes against the framework.

The deficit balances exactly. c/η and F are both in nats and $2/\ln 2$ converts nats to octaves, so $D = 2.885390(c/\eta - F)$ is dimensionally clean and depends on no postulate.

The storage law balances only under a reading the source does not print. $Q_{t+1} = (1-\delta)Q_t + b$ sets a stock equal to a stock plus a rate. It balances if and only if b is read as an increment already multiplied by one pass — the standard elision of discrete-time stock-and-flow notation [Forrester, 1961, Sterman, 2000] — and **the source never writes the pass-length factor.** Every quantity in the paper is per-declared-pass and no result depends on the length of a pass, so nothing is wrong; but the equation as printed is not dimensionally homogeneous and this paper says so rather than leaving a reader to find it.

η is described in two incompatible ways and the source does not resolve it. §5.2 calls it "a dimensionless efficiency in $[0, 1]$", and ηF must carry whatever unit Q carries. Both can be true only if Q is measured in nats, which is the reading adopted in the table above — and which means **stored order has no operational unit of its own; it inherits the unit of a logarithm of a count.** That is an honest dimensionless placeholder, not an invented unit, and it is the correct thing to record for a quantity nobody has measured.

Every quantity in hertz balances only because k is asserted to carry $[T^{-1}]$ (P-a). The separation is clean: the conservation identity, the convergence equality, the deficit identity, the decay blindness, the completeness statement, the reserve theorem and the misordering cost are all dimensionless or in nats, and **none of them depends on k at all.**

3.4 Which effective count, and the scale type

Which effective count. $N_{\text{eff}} = 1 + (N-1)u = e^F$ is the **affine effective count**: a linear interpolation between 1 and N, and the corpus's own construction. **It is not a Hill number of any order.** The Hill family [Hill, 1973, Jost, 2006, 2007] and its rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly — as the corpus's concentration work uses them [Curzi, 2026], whose entity map returns naive HHI 0.293388 and 3.4085 effective jurisdictions against a bloc-HHI of 1.000000 and 1.0000 effective perimeters, a 3.41-fold overstatement — and they ground this construction **not at all.** Wherever an effective count appears in this paper it is the affine one, and it is named.

Scale type. N and the state indices are counts and are absolute-scaled. u is ratio-scaled *given* that the intensities are, which requires magnitude estimation to deliver what it is held to deliver [Stevens, 1957] and is disputed [Teghtsoonian, 1971, Poulton, 1968, Krueger, 1989, Luce, 2002]. η, c and δ are treated as ratio-scaled **by assumption**, and no instrument establishing that is reported anywhere in this corpus.

The strongest single objection to this framework is Michell's — that psychology assumes quantitative structure without testing for it [Michell, 1997, 1999]. It applies here in full. The formal remedy is conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971] or a Rasch demonstration [Rasch, 1960, Andrich, 1988], and **none was run.** The corpus's own moment equation was demoted to ordinal use at its author's gate for exactly this reason [Curzi, 2026m], and the demotion travels with every psychological frequency derived through that ratio.

The scalar-reduction concession is inherited and not restated. The framework's habit of reducing a state to one number is a framework-level limitation, conceded where the ladder is built [Curzi, 2026]; this paper adopts that concession rather than repeating it, and every reading produced here rests on the index it concerns.

3.5 Identification — the objection this framework cannot presently answer

The corpus's reflexive loop $T(x) = W(x, M(x))$ [Curzi, 2026] is a linear-in-means reflexive specification, and **the endogenous social effect in such a specification is not identified from observational data** [Manski, 1993]; influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011, Lyons, 2011]. No amount of fit, held out or otherwise, recovers the parameter.

The remedy this paper adopts is stipulation. The reference set is the declared N-category ladder, the declared decomposition and the declared participant list, fixed in advance and published with every reading — which is what makes a restricted treatment of social interaction defensible where an unrestricted one is not [Brock and Durlauf, 2001]. The price is paid openly: **the reflexive claim is a modelling position, not an identified empirical result**, and no reading in this paper is offered as a measurement of an endogenous social effect.

Two objections in the same family are stated rather than resolved. **The framework exempts its own parameters from its own reflexivity** [Lucas, 1976]: if arrangements change under being modelled, then η, c and δ are the decision rules of people who have not read the storage law, and classification changes the classified [Hacking, 1995]. **And a published destiny reading is exactly the kind of thing that can make itself true** [Merton, 1948, Rosenthal and Jacobson, 1968, MacKenzie and Millo, 2003, Ferraro et al., 2005] — which is why §4.8's separation clauses are mandatory rather than courteous, and why a reading used as a target stops measuring what it measured [Goodhart, 1975, Campbell, 1979]. Against that, the best long-run assessment of the classroom case finds self-fulfilling prophecies **real but small**, not typically cumulative and often dissipating, with most expectations turning out to be accurate rather than causal [Jussim and Harber, 2005].

3.6 Method

Every number in this paper is exact arithmetic on stated inputs. The convergence equality was checked by running the recursion and by evaluating $(1-\delta)^t|Q_0-Q_\infty|$ independently, over $t=0$ to 100; the deficit identity was checked over twelve parameter sets spanning both signs of the drive and δ from 0.01 to 0.99; the conservation identity was checked across an eight-point export range in a two-party arrangement and across four transfers in a three-party arrangement. Residuals are reported at full precision and are floating-point noise in every case.

No observational data were collected, no human subjects participated, and no empirical dataset underlies any figure, table or number in this paper. Every case is constructed and is labelled CONSTRUCTED at the point of use. The figures are produced by the scripts named in their captions. Where the source manuscript printed a number this paper could not reproduce, the discrepancy is printed in §9.5 with the corrected value, rather than quietly repaired.

4 Destiny as a fixed point

The word this section takes over is heavily overloaded. In the practical literature it is used to mean an unalterable script, a personal entitlement, a reward for correct wanting, and — most often — nothing at all: a placeholder that signals importance and carries no content. A framework that has demoted its own keystone formula on a scale question [Curzi, 2026m], printed its rejections, and named its central gap in print [Curzi, 2026] cannot adopt a word like that on trust.

So it is not adopted on trust. It is defined, and the definition is an equation proved elsewhere in the corpus on assumptions stated there [Curzi, 2026a].

> **In this framework, *destiny* means Q_∞, the fixed point of the contracting storage loop** [Curzi, 2026a].

That is the whole of the claim. It says where a life, a bond, an institution or an arrangement arrives if its parameters hold. It does not say the parameters will hold, it does not say what arrival is worth, and it says nothing whatever about anybody's worthiness of it.

What the definition buys is exactly one thing, and it is the thing the rhetorical use never supplies: **it is checkable.** A destiny in this sense is a number with four arguments. Change an argument and the number changes by an amount that can be computed in advance. Fail to change any argument and the number does not move, however sincerely anything was intended. Section 5 is about the changing. This section is about what the object is, how the loop reaches it, and how to tell a real arrival from a counterfeit one.

Three results carry this section. The first is the convergence law, which says arrival is geometric and, more surprisingly, that it is an equality rather than a bound. The second is the identity between the octave deficit and the fixed point — they are the same number in different units, and the deficit form contains no `delta`, which is a genuine limitation of the framework's central instrument and is stated rather than buried. The third is a conservation identity: under a transfer of cost between participants, a certain sum does not move at all. That third result turns a standing prohibition of the framework's foundations into an arithmetic test [Curzi, 2026], and it is the most useful thing in this section.

The law

4.1 The loop, restated at destiny scope The storage law is the framework's contracting recursion [Curzi, 2026a], whose Result Two identifies the fixed point as the circuit's DC gain: evaluating the transfer function $1/(z-a)$ at $z=1$ gives $1/\delta$, so the fixed point is the net drive multiplied by the gain.

```
Q      =  (1 − delta) ∗ Q   +  ( eta ∗ F(u∗)  −  c∗ )
 t+1                     t

       delta   per−cycle retention loss, in (0, 1]
       eta     conversion: how much of an interaction's surplus becomes stored order
       F(u∗)   the interaction surplus at the operating point, F = ln(1 + 11 u) at N = 12
       c∗      the per−cycle cost of maintaining the arrangement
```

Analogy status: category 2, a shared mathematical form. This is the discrete leaky integrator — the RC low-pass filter of signal processing [Oppenheim et al., 1996], exponential smoothing in forecasting [Holt, 1957, Brown and Meyer, 1961], and the leaky integrate-and-fire neuron of computational neuroscience [Lapicque, 1907, Gerstner and Kistler, 2002]. Its stability condition and unique fixed point are standard for a first-order linear difference equation [Elaydi, 2005, Kelley and Peterson, 2001], and no claim is made that any physical result about circuits transfers.

For a fixed arrangement the bracketed term is a single constant, and naming it makes everything that follows short:

```
b  =  eta ∗ F(u∗)  −  c∗                the per−cycle DRIVE

Q      =  (1 − delta) ∗ Q   +  b
 t+1                     t
```

`b` is the net production of the arrangement per cycle: what conversion makes, less what maintenance costs. It is a rate, not a level. The distinction between a rate and a level is the axis this whole section turns on, and it is worth fixing the picture before any algebra: the drive is a tap, `delta` is a leak, and `Q_t` is the depth of water in the tank. A tank with a fast leak and an open tap settles shallow and quickly; a tank with a slow leak and the same tap settles deep and slowly. Nothing about the tap determines the depth, and nothing about the leak determines whether the tap is running forward or backward.

4.2 The fixed point exists, is unique, and is reached from anywhere

THEOREM 4.1 — EXISTENCE AND UNIQUENESS. For `delta` in `(0, 1]` the map `T(Q) = (1−delta) Q + b` is a contraction on the reals with Lipschitz constant `1 − delta < 1`. By Banach's fixed point theorem [Banach, 1922] it has exactly one fixed point, and iteration converges to it from every starting value. The framework's foundations state the theorem exactly: a contraction with modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least q each pass [Curzi, 2026].

Proof. `|T(x) − T(y)| = (1−delta)|x − y|`, so `T` is Lipschitz with constant `1 − delta`, which is strictly less than 1 whenever `delta > 0`. The reals are complete. Banach applies. Solving `Q = (1−delta) Q + b` gives `delta Q = b`, hence the unique fixed point. ■

```
Q     =  b / delta  =  ( eta ∗ F(u∗) − c∗ ) / delta
 inf
```

Three properties are worth reading off before the definition is stated, because each of them is a place where the ordinary use of the word "destiny" would go wrong.

It does not depend on where the loop started. `Q_0` does not appear. Two arrangements with identical `(eta, F, c, delta)` and wildly different histories have identical destinies. Whatever else a starting position determines — and it determines the whole transient, which is the part anyone actually lives through — it does not determine the destination.

It is not a maximum and not a summit. It is a level, in the hydraulic sense: the depth at which inflow and leakage balance. A loop started above `Q_inf` descends to it at exactly the rate

a loop started below ascends to it. There is no direction of travel built into the object, and any language of climbing or achieving is imported from somewhere else.

It can be negative. When $\eta F < c$, $Q_\infty < 0$, and the framework's own storage-law paper records that the regime is unsustainable or the linear model must be replaced [Curzi, 2026a]. This paper prints the negative number wherever it occurs — the carried dyad as found sits at `-5.0119395464` — and repeats the admissibility warning every time, because a model that will happily compute a trajectory through negative stored order is a model that must be watched at exactly that point.

4.3 The convergence law

THEOREM 4.2 — THE CONTRACTION, AS AN EQUALITY. For the affine map above with `delta > 0`,

```
| Q  -  Q    |  =  (1 - delta)^t  *  | Q  -  Q    |
   t     inf                          0     inf
```

Proof. Subtract `Q_inf = (1-delta) Q_inf + b` from `Q_{t+1} = (1-delta) Q_t + b`. The drive `b` cancels exactly, leaving `Q_{t+1} - Q_inf = (1-delta)(Q_t - Q_inf)`. Take absolute values and iterate `t` times. ■

The refinement paper owns this identity as its error law [Curzi, 2026], whose Result One is that refinement cannot move the fixed point — Q_∞ contains no iteration count — and that the ladder is silent in pitch, since f_{rel} depends only on u and N. It appears again here because at destiny scope it says something the refinement register does not emphasise. Banach guarantees only that distances do not increase by more than a factor. Here they shrink by exactly `1 - delta` on every pass, at every distance, forever. There is no fast region and no slow region, no early struggle and no late acceleration; the gap closes at one constant proportion per cycle from the first cycle to the last.

And the drive cancelled. Everything that decides *where* the loop is going — `eta`, `F`, `c` — vanished in the subtraction. The rate of approach is a function of the leak and of nothing else. The same fact reads as three constants — the time constant, half-life and settling time of a first-order lag in the ordinary control-engineering sense [Åström and Murray, 2008, Horowitz and Hill, 2015]:

```
tau        =  -1 / ln(1 - delta)              cycles per factor of e
half-life  =  ln(0.5) / ln(1 - delta)         cycles to close half the gap
t(eps)     =  ln(eps) / ln(1 - delta)         cycles to close all but a fraction eps
```

None contains `Q_0`, `Q_inf`, `eta`, `F` or `c`. **How long arrival takes is a property of the leak; where arrival happens is a property of everything else, and the two questions do not share a parameter.**

Computed, at the values this framework uses:

```
delta | tau (cycles/e) | half-life | t(1%)    | t(0.1%)
------+----------------+-----------+----------+---------
0.01  |      99.499162 | 68.967564 | 458.2106 | 687.3159
0.02  |      49.498316 | 34.309618 | 227.9482 | 341.9223
0.05  |      19.495726 | 13.513407 |  89.7811 | 134.6717
0.09  |      10.603253 |  7.349615 |  48.8298 |  73.2447
0.15  |       6.153129 |  4.265024 |  4.3362 |  42.5043
0.30  |       2.803673 |  1.943358 |  12.9114 |  19.3671
0.50  |       1.442695 |  1.000000 |   6.6439 |   9.9658
```

4.4 The definition

DEFINITION 4.1 — DESTINY. The destiny of an arrangement is `Q_inf = (eta F(u*) − c*)/delta`, the unique fixed point of its storage loop: the level of stored order the arrangement converges to if `(eta, F, c, delta)` hold.

Four things the definition does not say, each of which somebody will read into it if it is not refused explicitly.

It is not a prophecy. The conditional clause — *if the parameters hold* — is the entire content. Parameters are properties of an arrangement, and arrangements change. A destiny is a statement about a configuration, not about a future.

It is not a property of a person. Every term in the formula belongs to an arrangement. `u` is a joint geometric property of two or more state vectors and cannot be assigned to one of them; `eta`, `c` and `delta` describe what an arrangement does with what it produces, what it costs to run, and how fast it forgets. **There is no single-party term anywhere in the apparatus, which means no destiny reading licenses any conclusion about who someone is.** That prohibition binds harder here than anywhere else in the framework, because *destiny* is the word most likely to be heard as personal.

It is not a ranking. A larger `Q_inf` is more stored order in the model's units. It is not more worth, more virtue, or a better life, and the formalism contains no term that could make it any of those. Two arrangements with fixed points of `+6.08` and `+1.07` are not a winner and a loser; they are two configurations, and the second one may be the one somebody would rather be in for reasons the model does not represent.

It is not a clinical or diagnostic object. The twelve states are not diagnoses, a reading is not an assessment, and nothing in this section describes or prescribes for any person. That clause is restated here because this section's vocabulary invites the error more than most.

4.5 The deficit and the fixed point are one number in two units

This is the deficit identity of the minimum-frequency paper [Curzi, 2026], carried here because a section that defines destiny must state the exact relation between destiny and the instrument used to read it.

THEOREM 4.3 — THE DEFICIT IDENTITY.

```
D  =  2.885390 * ( c/eta  −  F )  =  − 2.885390 * ( delta / eta ) * Q
                                                                   inf
```

Proof. `Q_inf = (eta F − c)/delta`, so `(delta/eta) Q_inf = F − c/eta`, so `−2.885390 (delta/eta) Q_inf = 2.885390 (c/eta − F) = D`. ■

The constant is `2 / ln 2 = 2.885390081778`, and it is the exchange rate between nats of surplus and octaves of pitch, fixed by the essence bridge `f = k e^(2F)`.

Verified across twelve constructed parameter sets, spanning both signs of the drive and `delta` from 0.01 to 0.99:

u	eta	c	delta	D	−2.885390(delta/eta)Q_inf	residual
0.068735	0.30	0.620	0.09	+4.338420197	+4.338420197	0.000e+00
0.068735	0.30	0.620	0.05	+4.338420197	+4.338420197	0.000e+00
0.068735	0.30	0.620	0.01	+4.338420197	+4.338420197	0.000e+00
0.692373	0.44	0.400	0.09	−3.590988663	−3.590988663	0.000e+00
0.692373	0.44	0.400	0.05	−3.590988663	−3.590988663	8.882e−16
0.692373	0.44	0.400	0.30	−3.590988663	−3.590988663	0.000e+00
0.018614	0.34	0.825	0.09	+6.463836987	+6.463836987	8.882e−16
0.018614	0.34	0.825	0.02	+6.463836987	+6.463836987	8.882e−16
0.500000	0.50	0.500	0.50	−2.515489355	−2.515489355	0.000e+00
0.900000	0.75	1.200	0.15	−2.275888329	−2.275888329	8.882e−16
0.250000	0.20	0.300	0.40	+0.514303931	+0.514303931	3.331e−16
1.000000	0.99	2.400	0.99	−0.175039955	−0.175039955	1.665e−16

```
MAX RESIDUAL = 8.8818e-16 over 12 sets
```

The residuals are floating-point noise. **The octave deficit and the fixed point are the same quantity written twice: one in octaves of required pitch, one in units of stored order.** A reading in octaves is not an alternative to a reading in stock; it is the same reading, and the conversion factor is `-2.885390 * delta/eta`.

4.6 And the deficit contains no `delta` **THEOREM 4.4 — `delta` IS NOT A LEVER ON `D`.** `D = 2.885390 (c/eta - F)` is a function of `c`, `eta`, `u` and `N` only. `delta` does not appear. Therefore `dD/d delta = 0` identically. ■

This is the sharpest limitation of the framework's central instrument and it is stated rather than buried. The minimum-frequency paper reaches it independently [Curzi, 2026]: on its carried dyad, moving δ from 0.09 to 0.05 leaves $D = +4.338420$ unchanged while Q_∞ falls from -5.0119 to -9.0215. Take the carried dyad as found, and vary the loss term across a range covering everything from a fast-forgetting arrangement to one that forgets almost nothing:

```
D = +4.3384201973  for every row

delta | Q_inf         | half-life | drive b = delta * Q_inf
------+---------------+-----------+------------------------
0.30  |   -1.5035819 |  1.943358 |  -0.451074559176
0.20  |   -2.2553728 |  3.106284 |  -0.451074559176
0.15  |   -3.0071637 |  4.265024 |  -0.451074559176
0.09  |   -5.0119395 |  7.349615 |  -0.451074559176
0.05  |   -9.0214912 | 13.513407 |  -0.451074559176
0.02  |  -22.5537280 | 34.309618 |  -0.451074559176
0.01  |  -45.1074559 | 68.967564 |  -0.451074559176
```

The destiny moves by a factor of thirty across that column. The deficit does not move in the fifteenth decimal place. And the same is true with the sign reversed — the repaired dyad, whose drive is `+0.547598406839`:

```
D = -3.5909886634  for every row

delta = 0.30 -> Q_inf =  +1.8253280      half-life  1.943358
delta = 0.09 -> Q_inf =  +6.0844267      half-life  7.349615
delta = 0.05 -> Q_inf = +10.9519681      half-life 13.513407
delta = 0.01 -> Q_inf = +54.7598407      half-life 68.967564
```

> **The deficit reads the SIGN and the SIZE of the sustainability gap. `delta` converts it to a LEVEL. `D` alone cannot see decay, and a reading that reports `D` without `delta` is incomplete.**

The rule that follows is short and binding on every reading: report both. The mechanism behind the blindness is visible in the last column of the first table — the drive `b` is `delta * Q_inf`, and it is constant down the column because the two factors move inversely by construction. `D` is a statement about the drive. The drive is what production and cost decide. Where the drive puts the level is `delta`'s business, and the drive cannot see it.

4.7 Two independent readings, at destiny scope The framework's operation audit records that a state's frequency and a relationship's frequency are independent readings, and that neither may be inferred from the other. At destiny scope the statement needs restating

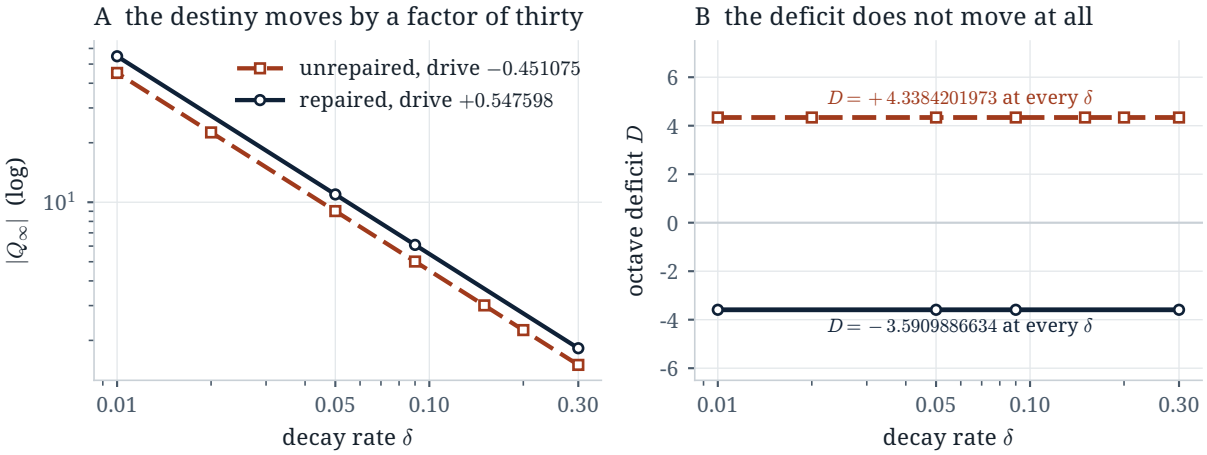

Figure 49.1: **The deficit cannot see decay: across a thirtyfold movement in the destination the octave deficit does not move in the fifteenth decimal place.** Two panels rather than a dual axis. Constructed dyad of §4.6 in both phases — unrepaired, drive $b = -0.451074559176$ and $D = +4.3384201973$ at every row; repaired, drive $b = +0.547598406839$ and $D = -3.5909886634$ at every row. Every plotted value is read from the two tables of §4.6. Script `figs/src/CCP-049_fig02.py`.

because the temptation is at its strongest here — an argument about where something arrives invites a reader to suppose that the arriving thing has a pitch, and that the pitch says something about the arrival.

Six constructed pairs of one-hot state vectors, spanning from a two-octave separation to more than four octaves of the state lattice:

indices	state frequencies	span (cents)	u	f_rel (Hz)
(1, 2)	0.4834 / 1.9337 Hz	2400.00	1.000000000000	69.6133055503
(3, 6)	4.3508 / 17.4033 Hz	2400.00	1.000000000000	69.6133055503
(5, 10)	12.0856 / 48.3426 Hz	2400.00	1.000000000000	69.6133055503
(7, 11)	23.6879 / 58.4945 Hz	1564.98	1.000000000000	69.6133055503
(2, 9)	1.9337 / 39.1575 Hz	5207.82	1.000000000000	69.6133055503
(4, 12)	7.7348 / 69.6133 Hz	3803.91	1.000000000000	69.6133055503

Identical to twelve decimal places, because `u` reads the angle between vectors and is blind to which indices are occupied. **A state's frequency carries no information about its relationship frequency, a relationship's frequency carries none about the states, and a complete report gives both separately with no inference drawn between them.** Since `F` enters the destiny and `F` comes from `u`, this means the destiny is a function of the relationship reading and not of the state readings, and any sentence of the form "their states are high, therefore their destiny is high" is an error the arithmetic forbids.

4.8 Honesty clauses, restated where they bind

Essence, not resonance. Every hertz value in this section is a position on a logarithmic scale of surplus. No person, bond, tissue or molecule is claimed to vibrate at any value here, and nothing in this section is to be played at anyone.

No clinical, diagnostic or therapeutic claim. A destiny reading is a computation on four declared parameters. It is not an assessment of anyone's health, capacity, character or prospects.

The reading inherits its inputs. `Q_inf` is exactly as defensible as `u`, `eta`, `c` and `delta`. The scale asymmetry binds: the index n is a count and is absolute-scaled by construction, but the

intensities w are ordinal by default, and where they were not elicited by magnitude estimation the relationship frequency is not determined and no destiny number may be printed at all.

Consent is structural. No procedure derived from a destiny reading may reduce any party's ability to decline it, at any stage.

All cases here are CONSTRUCTED and labelled as such. No case here is an observation of any person or pair.

The engineering

4.9 What arrival looks like, computed The carried dyad after repair — case 2b, a constructed case — has `u = 0.692372881355932`, `eta = 0.44`, `c = 0.40`, `delta = 0.09`, hence `F = 2.153632742815`, drive `b = +0.547598406839`, and destiny `Q_inf = +6.0844267427`. Start it from nothing and run it:

```
  t |      Q_t       | |Q_t − Q_inf| | (1−delta)^t |Q_0−Q_inf| | residual | gap closed
----+----------------+--------------+--------------------------+----------+-----------
  0 |   0.0000000000 |    6.0844267 |             6.0844267427 | 0.00e+00 |   0.0000%
  1 |   0.5475984068 |    5.5368283 |             5.5368283358 | 0.00e+00 |   9.0000%
  2 |   1.0459129571 |    5.0385138 |             5.0385137856 | 0.00e+00 |  17.1900%
  3 |   1.4993791978 |    4.5850475 |             4.5850475449 | 8.88e−16 |  24.6429%
  5 |   2.2875488707 |    3.7968779 |             3.7968778719 | 8.88e−16 |  37.5968%

MAX RESIDUAL over t = 0..100 : 2.0624e−15
```

The third and fourth columns are the theorem, computed two ways: once by running the recursion and measuring the gap, once by evaluating `(1−delta)^t |Q_0 − Q_inf|` directly. They agree to machine precision at every step, which is what an equality looks like when it is checked rather than asserted.

Now the same arrangement from four different starting stocks, including one that starts above the destination and one that starts exactly on it:

```
Q_0         t=1         t=5         t=10        t=20        t=40
-------------------------------------------------------------------------
 0.000000  +0.547598   +2.287549   +3.715053   +5.161754   +5.944508
+1.000000  +1.457598   +2.911581   +4.104469   +5.313399   +5.967504
−4.000000  −3.092402   −0.208580   +2.157388   +4.555175   +5.852523
+12.000000 +11.467598  +9.775935   +8.388046   +6.981493   +6.220462
+6.084427  +6.084427   +6.084427   +6.084427   +6.084427   +6.084427
```

Four trajectories, one destination. The row starting at `+12` descends; the row starting at `−4` ascends through zero at around the seventh pass; the row starting exactly at the fixed point does not move at all, which is what it means for a point to be fixed. **The destination is indifferent to the history, and the history is the entire difference between the four rows.**

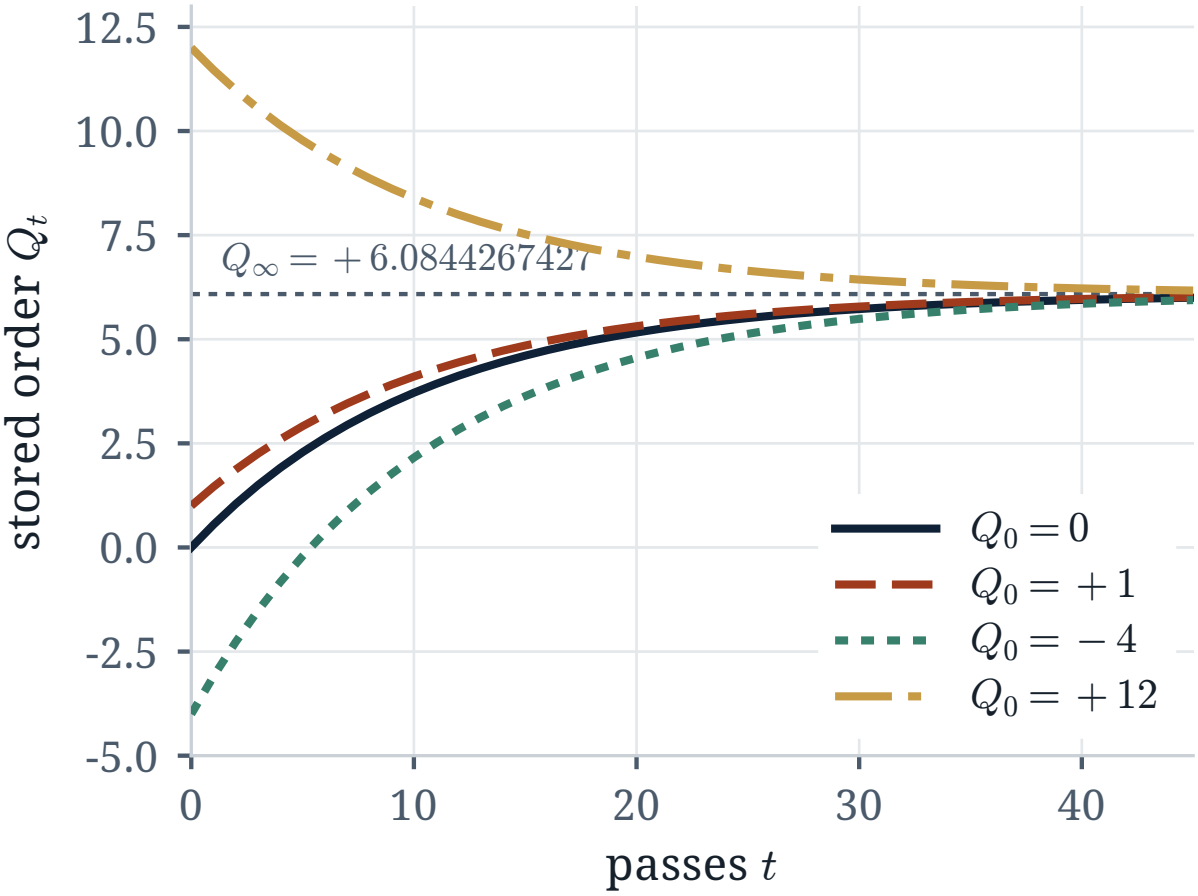

Figure 49.2: **One destination, four histories: the gap closes by exactly nine per cent per pass whether the loop is rising or falling, and a loop started exactly at the fixed point does not move.** Constructed case 2b of §4.9, modelled from the recursion at $u = 0.692372881355932$, $\eta = 0.44$, $c = 0.40$, $\delta = 0.09$, $N = 12$, giving drive $b = +0.547598406839$ and $Q_\infty = +6.0844267427$; every marked value is read from the four-start table of §4.9. Script `figs/src/CCP-049_fig01.py`.

4.10 Why arrival is recognition rather than achievement The framework's founding definitions record that arrival is experienced as recognition rather than as victory, and offer no mechanism [Curzi, 2026]. The refinement paper supplies the mechanism in four parts [Curzi, 2026] and it is cited rather than restated, with one addition that belongs at destiny scope.

The psychological literature on adaptation reaches the same shape from measurement rather than algebra: an adaptation level against which experience is judged [Helson, 1948], a return toward a baseline after large positive and negative events [Brickman et al., 1978], and the qualifications later work attaches to how complete that return is [Diener et al., 2006]. The four parts, compressed: there is no arrival event, because `(1-delta)^t > 0` for every finite `t` and nothing ever completes; almost the whole trajectory is spent near the destination, since at `delta = 0.09` the loop is inside five per cent of `Q_inf` from pass 32 and inside a tenth of a per cent from pass 74; every term of the fixed point is a standing property of the arrangement, so nothing in the destination was imported; and the same point is reached from any start, so it is a level rather than a summit.

The addition is this. A reader who has followed the section to here has the material for a sharper version of the fourth point. The destination is not merely reachable from any start — it is reached at a rate that does not know which direction it is travelling in. Row three of the table above ascends 10.08 units in forty passes; row four descends 5.78 in the same forty; and the gap between each and the destination shrinks by exactly nine per cent per pass in both cases. **A process that closes the same proportion of its distance whether it is rising or falling is not a process of achievement, and no vocabulary of effort or reward will fit it correctly.**

4.11 Traits, and destiny in the personal register The framework's treatment of standing dispositions as low-δ states is the bridge between this section's arrangement-scoped object and the way the word *destiny* is usually meant.

A mood is a state held with a large `delta`: it decays fast, its half-life is short, and its fixed point is shallow because a large denominator divides the drive. A trait is the same machinery at small `delta`: slow decay, long half-life, and a deep fixed point in whichever direction the drive points. This is why traits look like destinies in the colloquial sense — they are the readings with the longest half-lives, so they are the ones that are still there when anybody looks — and it is also why the colloquial sense is wrong about them. **A trait is not a fixed quantity; it is a fixed point with a long approach, which is a completely different object and behaves differently under intervention.**

The difference matters and it is computable. Take the repaired dyad's drive and vary only the loss term, as if the same production were embedded in arrangements that forget at different rates:

```
delta | Q_inf       | half-life | passes to close 99% of the gap
------+-------------+-----------+-------------------------------
0.30  |  +1.8253280 |  1.943358 |   12.9114
0.09  |  +6.0844267 |  7.349615 |   48.8298
0.05  | +10.9519681 | 13.513407 |   89.7811
0.01  | +54.7598407 | 68.967564 |  458.2106
```

A low-`delta` arrangement has a destiny thirty times deeper and takes thirty-five times as long to get there. Both halves of that sentence are consequences of dividing by a small number, and the second half is the one that gets forgotten. **A deep destiny is a slow one, necessarily, and the same parameter sets both. There is no configuration in this model with a deep fixed point and a short approach.**

And the sign carries through unchanged. Run the same column on the *unrepaired* dyad, whose drive is negative, and the low-`delta` arrangement arrives at `-45.1074559` instead of `+54.7598407`. Slow decay is not a virtue. It is a magnifier, and what it magnifies is whatever sign the arrangement already had. That is the framework's ordering rule, and Section 5 takes

it as an operating rule; the elasticities that price it are fixed in the return-difference paper [Curzi, 2026q], whose Result Four gives η $+1.594$, δ -1.000, u $+0.770$, C -0.594.

4.12 Counterfeit arrival — the conservation identity A fixed point can be positive, stable, arrived at, and produced by taking it out of somebody else's. The refinement paper computed the case [Curzi, 2026]; this section names it and gives the identity in general form, because the general form is what makes it a test.

THEOREM 4.5 — THE DRIVE IS CONSERVED UNDER COST TRANSFER. Let participants `i = 1..m` share an arrangement, each with drive `b_i = eta_i F_i − c_i`. Let a transfer move an amount `x` of cost from participant `p` to participant `r`, so `c_p -> c_p − x` and `c_r -> c_r + x`, with all other parameters unchanged. Then

```
sum_i b_i     is invariant,   and equivalently    sum_i delta_i ∗ Q          is invariant
                                                                 inf,i
```

Proof. The transfer adds `+x` to `b_p` and `−x` to `b_r` and changes no other term. The sum telescopes to zero. Since `b_i = delta_i Q_inf,i` by Theorem 4.1, the delta-weighted sum of fixed points is the same quantity. ■

COROLLARY 4.6 — WHEN ALL PARTICIPANTS SHARE ONE `delta`, THE PLAIN SUM OF FIXED POINTS IS INVARIANT. If `delta_i = delta` for all `i`, then `sum_i Q_inf,i = (sum_i b_i)/delta`, which Theorem 4.5 has just shown does not move. ■

Here is the corollary computed. **CONSTRUCTED CASE, labelled constructed; not an observation of any person or pair.** Two participants, P and R, share the case-2b arrangement, so both draw on `F = 2.153632742815` at `u = 0.692372881355932` and `f_rel = 35.8881768941 Hz`. Their private parameters differ, which is the ordinary situation. P declines a share of the maintenance — the scheduling, the repair conversations, the remembering of what was agreed — and R absorbs it. Let `x` be the exported amount.

```
  x    |  c_P  |  c_R  |    D_P    |  Q_inf,P  |    D_R    |  Q_inf,R  |    SUM
-------+-------+-------+-----------+-----------+-----------+-----------+-------------
0.000  | 0.400 | 0.550 | −3.590989 | +6.084427 | −0.924189 | +1.067665 | +7.152091441

sum of drives = +0.643688229683, invariant to every digit across the whole range
```

The sum does not move in any decimal place, across an export range wide enough to take R from comfortably sustainable to badly failing. Cost export is an externality in the ordinary sense: a private gain that is exactly a transfer, appearing as a gain only because the accounts are drawn around one party [Hardin, 1968, Ostrom, 1990]. Cost export produces nothing. It moves an existing quantity from one ledger to the other, and both ledgers are correct.

That last clause is what makes the failure mode hard. P's instrument is working perfectly. P's deficit falls from `−3.590989` to `−4.902530` — nearly a further octave and a third of headroom — and P's fixed point rises by more than two units. Every number P can compute about P has genuinely improved, and P is not lying to anybody, including P.

R crosses the sustainability boundary between `x = 0.05` and `x = 0.10`. Solving `D_R = 0` gives `c_R = eta_R F = 0.646089822845`, i.e. the exact crossing at `x = 0.096089822845`.

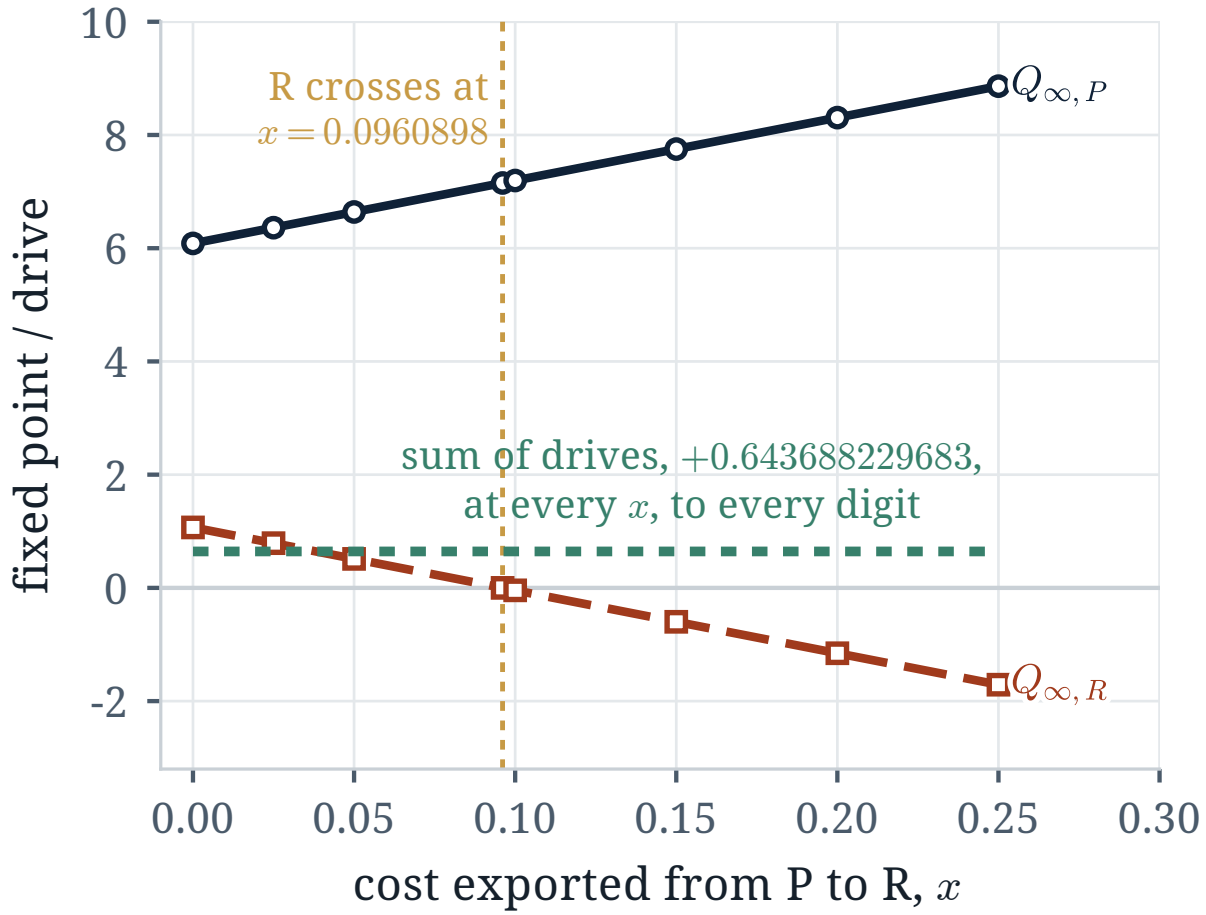

Figure 49.3: **Conservation of drive: one party's destination rises and the other's falls, and the sum of drives holds at $+0.643688229683$ to every digit across the whole export range.** Constructed two-party case of §4.12, both parties sharing $F = 2.153632742815$ at $u = 0.692372881355932$ and $\delta = 0.09$, with $\eta_P = 0.44$ and $\eta_R = 0.30$; the disadvantaged party crosses the sustainability boundary exactly at $x = 0.096089822845$. Every plotted value is read from the export table of §4.12. Script `figs/src/CCP-049_fig03.py`.

4.13 The honest caveat: when the plain sum is not the invariant Corollary 4.6 required equal `delta`. The refinement paper's worked case satisfied that condition and did not have to dwell on it [Curzi, 2026]. The general statement does, because the plain sum of fixed points is **not** conserved when the participants forget at different rates, and a test stated in the wrong form fails in exactly the situation where it is most needed.

Differentiate the plain sum with respect to the exported amount:

```
d ( Q       +  Q       ) / dx   =   1/delta   -   1/delta
     inf,P      inf,R                      P            R
```

which is zero if and only if `delta_P = delta_R`. Computed, with the same arrangement but `delta_P = 0.05` and `delta_R = 0.15`:

```
  x   | Q_inf,P (d=0.05) | Q_inf,R (d=0.15) |    SUM     | sum of drives   | delta-weighted sum
------+------------------+------------------+------------+-----------------+-------------------
0.00  |    +10.951968137 |     +0.640598819 | +11.592567 | +0.643688229683 | +0.643688229683
0.05  |    +11.951968137 |     +0.307265486 | +12.259234 | +0.643688229683 | +0.643688229683
0.10  |    +12.951968137 |     -0.026067848 | +12.925900 | +0.643688229683 | +0.643688229683
0.15  |    +13.951968137 |     -0.359401181 | +13.592567 | +0.643688229683 | +0.643688229683
0.20  |    +14.951968137 |     -0.692734514 | +14.259234 | +0.643688229683 | +0.643688229683

d(SUM)/dx  =  1/0.05 - 1/0.15  =  13.333333333
```

The plain sum rises by more than two and a half units across that range while nothing whatever is produced, because the export moved cost from a slow-forgetting ledger to a fast-forgetting one and the model's own division by `delta` did the rest. A test that watched the plain sum would report that the arrangement had improved. **The invariant is the sum of drives — equivalently the delta-weighted sum of fixed points — and it is exact under any transfer of cost between any number of participants with any `delta` values whatever.**

Verified on a three-party constructed arrangement with `(eta, c, delta)` of `(0.44, 0.40, 0.05)`, `(0.30, 0.55, 0.15)` and `(0.62, 0.71, 0.22)`, all sharing `F = 2.153632742815`:

```
baseline sum of drives                                  = 1.268940530229
transfer 0.13 from party 1 to party 2  -> sum of drives    = 1.268940530229   resid 0.000e+00
transfer 0.31 from party 1 to party 3  -> sum of drives    = 1.268940530229   resid 0.000e+00
transfer 0.07 from party 3 to party 2  -> sum of drives    = 1.268940530229   resid 0.000e+00
transfer 0.44 from party 2 to party 1  -> sum of drives    = 1.268940530229   resid 0.000e+00
```

4.14 The lag, and why the export is not noticed R does not disappear on the pass the sign flips. R's stock decays from its old level toward its new one at `(1-delta)^t`, exactly as Theorem 4.2 requires, and for a long while R's behaviour is still the behaviour of a participant with something in the bank. At `x = 0.15`, R's destiny has moved from `+1.067664698` to `-0.599001968`:

```
pass |   Q_R
-----+-------------
   0 | +1.067664698
   3 | +0.656949698
   7 | +0.262266397
  10 | +0.050024895
  11 | -0.008387523
  15 | -0.193988343
  25 | -0.441283134
  40 | -0.560675002
  60 | -0.593189879

exact zero-crossing at t* = 10.850479 passes
```

For nearly eleven passes after the export begins, R still has a positive stock — while R's destination has been negative since the first pass. Nothing observable changes at the moment the damage is done. This is precisely why the deficit is the instrument and the stock is not: `D_R` went positive immediately, and `Q_R` took eleven passes to notice.

And there is an end to the arithmetic. The option R retains is exit, the classical alternative to voice when an arrangement deteriorates [Hirschman, 1970]. Suppose R eventually declines to continue, which is R's structural right under the framework's consent law [Curzi, 2026] and which no arrangement here may remove. The shared arrangement ends, and with no partner there is no interaction surplus: `u = 0`, `F = ln(1) = 0`, `f = k = 0.483426 Hz`, the ground essence.

```
P at x = 0.15, before R's departure   D_P = −4.574644    Q_inf,P = +7.751093   f = 35.888177 Hz
P at x = 0.15, after  R's departure   D_P = +1.639426    Q_inf,P = −2.777778   f =  0.483426 Hz

fall in P's fixed point              10.528871 units
swing in P's deficit                  6.214071 octaves, the wrong way
```

The reduced cost P retained is worth nothing once the surplus it was drawn against is gone. The swing is exactly `2.885390 * F = 6.214071` octaves, which is to say: **what P loses at the end is precisely the whole of the surplus P was exporting the cost of.**

4.15 A standing prohibition converted into an arithmetic test The framework's foundations state a prohibition on intervening at another party's expense, and a prohibition of that form is unfalsifiable in exactly the way a testimonial is: it reports an intention, and the intention is always available. Theorem 4.5 converts it into something else.

> **THE EXPORT TEST. Compute the deficit and the fixed point for every participant separately. Then compute the sum of drives. If a participant's reading improved and the sum of drives did not move, the gain was exported and nothing was produced.**

Three properties make this a test rather than an exhortation.

It is arithmetic, not attribution. It does not ask what anybody meant. It asks whether a conserved quantity moved. A well-intentioned export and a deliberate one produce the same reading, which is correct, because the harm is the same.

It runs on pass one. The stock-based version of the same question — "is anyone worse off?" — returns a false negative for nearly eleven passes in the worked case. The drive-based version returns the right answer immediately, because the drive is where the transfer happened.

It costs one column. The reporting format of §4.19 adds the sum of drives to what a reading already contains. Nothing new has to be measured; the parameters were already collected for each participant's own reading.

What the test does not do is also worth stating. It detects export of *cost*, which is the operation the formalism represents. It does not detect every way one party can benefit at another's expense, because the formalism does not represent every such way. A participant who degrades another's `u` by suppressing what they hold, or who lowers another's `eta` by refusing to let their work become permanent, is doing something the model can express only as a change in somebody's parameters, and the conservation identity does not cover it — those changes are not transfers and the sum of drives does move. The test is exact for what it covers and silent outside it, and a reader who takes it for a general detector of exploitation will be misled by their own instrument.

4.16 The sensitivity of a destiny A destiny is a quotient, and quotients with small denominators are sensitive. The partials, at the carried dyad as found:

```
dQ_inf / d eta    =  F / delta                =   +6.256498  per unit of eta
dQ_inf / d F      =  eta / delta              =   +3.333333  per nat of surplus
dQ_inf / d c      =  −1 / delta               =  −11.111111  per unit of cost
dQ_inf / d delta  =  −(eta F − c) / delta^2    =  +55.688217  per unit of delta

and the chain into the geometry:
dF / du           =  (N−1) / (1 + (N−1)u)     =   +6.263947
dF / dN           =  u / (1 + (N−1)u)         =   +0.039141
```

The fourth line is nearly nine times the third and nearly nine times the first. **The parameter with the largest partial derivative on the destiny is the one with no partial derivative at all on the deficit,** which is Theorems 4.3 and 4.4 stated as a pair of numbers rather than as an algebraic fact, and it is the reason both readings have to be published.

The partials are in four different units, and ranking them against one another on size is forbidden. What they are good for is error propagation: a destiny reported without an interval, when `delta` is known to `± 0.02`, is reporting a number whose uncertainty at this operating point is of order `± 1.1` units. The framework's resolution rule applies unchanged — **a verdict is resolved only when it exceeds its own uncertainty** — and §4.20's gates enforce it.

The specification

4.17 PROCEDURE DEST — reading a destiny **Step 1. Declare the arrangement.** Name the participants, the cycle length, and what one pass is. A destiny is per relation, per site, per period; ratios do not average and readings do not aggregate.

Step 2. Check the scale precondition. Were the intensities elicited by magnitude estimation [Stevens, 1957]? If not, stop. The relationship frequency is not determined, and a destiny computed from an undetermined `F` is an artefact of the labelling. Publish the raw L2 norms so the free multiplier stays recoverable.

Step 3. Check for one-hot degeneracy. If the participants' state vectors have disjoint support, `u = 1` automatically and the surplus is meaningless. Re-elicit with overlapping support or stop.

Step 4. Compute `u`, then `F`, then `f_rel`. Use $u = 1 - (\hat{x} \cdot \hat{y})^2$, $F = \ln(1 + 11u)$, $f_{\text{rel}} = k(1 + 11u)^2$. Carry twelve or more decimal places throughout and recompute derived values from the full-precision u, never from a rounded print.

Step 5. Run the ceiling test before anything else. If `c/eta > ln N`, no value of `u` makes the arrangement sustainable and the case is structural, not tunable. Report it as structural and go to §5's restructuring branch.

Step 6. Compute the deficit. `D = 2.885390 (c/eta − F)`. Report its sign, its size, and its sensitivity to each input.

Step 7. Compute the destiny. `Q_inf = (eta F − c)/delta`. Report `delta` in the same sentence.

Step 8. Compute the approach. `tau`, half-life, and `t(1%)` from `delta` alone. Say how many passes of the declared cycle length that is in calendar time.

Step 9. Run the export test. For every participant separately, compute `D_i` and `Q_inf,i`. Compute `sum_i b_i`. Compare to the previous reading's sum of drives if one exists.

Step 10. Publish both readings and both refusals. The state frequencies and the relationship frequency, separately, with no inference between them; the essence clause; the no-clinical-claim clause; and the constructed label on every case.

4.18 Definitions and theorems owned here

DEFINITION 4.2 — COUNTERFEIT ARRIVAL. A fixed point is counterfeit when it is positive in one participant's accounts and the sum of drives across the arrangement did not move to produce it.

Not owned here and taken from their owners: the component index and its count argument; the elicitation procedure; the relationship-frequency rule; the order-of-operations rule [Curzi, 2026q]; and the four levers with what each one costs [Curzi, 2026], priced in §5.

4.19 Reporting format Every published destiny reading carries all of the following, in full:

```
ARRANGEMENT      participants, cycle length, what one pass is
SCALE STATUS     magnitude-estimated? raw L2 norms? -- if no, NO NUMBER IS PRINTED
GEOMETRY         u to 12+ dp, cos theta, support overlap
STATE READING    the occupied indices, their raw frequencies, their pitch classes
RELATION READING F in nats, N_eff, f_rel in Hz          -- separately, no inference drawn
CEILING          c/eta against ln N, and the verdict structural / tunable
DEFICIT          D in octaves, with its sensitivity to each input
LOSS             delta, stated in the same block as D and never omitted
DESTINY          Q_inf, with its uncertainty
APPROACH         tau, half-life, t(1%), converted to calendar time
EXPORT           per-participant D_i and Q_inf,i, and the sum of drives
LABEL            CONSTRUCTED or MEASURED, on every case
REFUSALS         essence-not-resonance; no clinical claim; consent structural
```

4.20 Gates

```
GATE 4-1   intensities magnitude-estimated and L2 norms published    FAIL -> no number
GATE 4-2   support overlap checked for one-hot degeneracy            FAIL -> re-elicit
GATE 4-3   ceiling test run before any lever is discussed            FAIL -> incomplete
GATE 4-4   D and delta reported together                             FAIL -> incomplete
GATE 4-5   Q_inf reported with an uncertainty                        FAIL -> incomplete
GATE 4-6   state and relationship readings reported separately       FAIL -> incomplete
GATE 4-7   sum of drives computed across all participants            FAIL -> export unchecked
GATE 4-8   every case labelled CONSTRUCTED or MEASURED               FAIL -> withdraw
GATE 4-9   no single-party term appears anywhere in the report       FAIL -> rewrite
```

The failure modes

FM 4.1 — DESTINY READ AS PROPHECY. *Signature:* a fixed point reported as what will happen. *Mechanism:* the conditional clause dropped. `Q_inf` is where the loop goes if the parameters hold, and parameters are properties of arrangements that people change. *Fix:* the conditional is part of the number. Print it.

FM 4.2 — DESTINY READ AS A PROPERTY OF A PERSON. *Signature:* "my destiny is `-5.01`." *Mechanism:* `u` is a joint geometric property and `eta`, `c`, `delta` describe an arrangement. There is no single-party term in the apparatus. *Fix:* Gate 4-9. State the arrangement, or print nothing.

FM 4.3 — THE DEFICIT REPORTED ALONE. *Signature:* a reading consisting of `D` and a verdict. *Mechanism:* Theorem 4.4. `D` cannot see decay at all; the same `D` is consistent with fixed points differing by a factor of thirty. *Fix:* Gate 4-4.

FM 4.4 — `delta` REPORTED ALONE. *Signature:* a fast half-life presented as good news. *Mechanism:* the rate cannot see the destination's sign. A fast approach to a negative fixed point is a fast decline. *Fix:* Gate 4-4, the other way round.

FM 4.5 — TRUST AS A DESTINY LEVER IN A FAILING ARRANGEMENT. *Signature:* "we will lower `delta` and our destiny will improve." *Mechanism:* the ordering rule. `delta` divides the drive; when the drive is negative a smaller `delta` makes the fixed point more negative. Computed: `-5.0119395464` at `delta = 0.09` becomes `-45.1074559` at `delta = 0.01`. *Fix:* the order rule [Curzi, 2026q], and §5.5.

FM 4.6 — THE STOCK MISTAKEN FOR THE DESTINY. *Signature:* "we are at `+1.07`, so we are fine." *Mechanism:* the stock lags the destination by up to `t*` passes; in the worked export case `t* = 10.850479`. *Fix:* compute `D_i`, not `Q_t`.

FM 4.7 — COUNTERFEIT ARRIVAL. *Signature:* one participant's readings improve steadily and genuinely, pass after pass. *Mechanism:* cost export; the sum of drives did not move. *Fix:* Gate 4-7, the export test.

FM 4.8 — THE EXPORT TEST RUN ON THE PLAIN SUM. *Signature:* the sum of fixed points is watched, the participants have different `delta`, and the test passes an export. *Mechanism:* §4.13. `d(sum)/dx = 1/delta_P − 1/delta_R`, which is zero only when the rates match; in the constructed case the plain sum rises by 2.67 units while nothing is produced. *Fix:* watch the sum of drives, which is invariant unconditionally.

FM 4.9 — THE EXPORT TEST TREATED AS A GENERAL DETECTOR. *Signature:* an arrangement declared free of exploitation because the sum of drives held. *Mechanism:* §4.15. The identity covers transfers of cost. Degrading another party's `u`, `eta` or `delta` is not a transfer, and the sum moves. *Fix:* state the test's scope in the same sentence as its result.

FM 4.10 — THE DEEP FIXED POINT WANTED WITHOUT THE SLOW APPROACH. *Signature:* a plan for a durable arrangement that also arrives quickly. *Mechanism:* §4.11. `Q_inf` scales as `1/delta` and the half-life scales as `−ln 2 / ln(1−delta)`; one parameter sets both, in opposite directions. *Fix:* choose. There is no configuration with both.

FM 4.11 — `delta = 0`. *Signature:* a model of something incorruptible, unchanging, permanent. *Mechanism:* at `delta = 0` the map is an isometry, Banach does not apply, there is no fixed point, and `Q_t = Q_0 + bt` grows without bound. The image of permanence is the one setting under which the apparatus stops working. *Fix:* name the leak. A low-`delta` standing disposition is the honest version.

FM 4.12 — INFERRING DESTINY FROM STATE FREQUENCY. *Signature:* "their states are high, so their destiny is high." *Mechanism:* §4.7; six constructed pairs spanning 1565 to 5208 cents return identical `u` and identical `f_rel` to twelve decimal places. *Fix:* Gate 4-6. Two readings, reported separately, no inference between them.

FM 4.13 — THE PRECISION LEAK. *Signature:* a destiny that disagrees with a colleague's in the fourth significant figure. *Mechanism:* precision loss; recomputing from a six-decimal `u` shifts `f` and `Q_inf` in the fifth significant figure. *Fix:* recompute from the full-precision `u`. Every time.

FM 4.14 — THE READING USED AS COUNSEL. *Signature:* a destiny presented as advice about whether to stay in a relationship, or as an evaluation of anyone. *Mechanism:* register slip. `Q_inf < 0` says a configuration loses stored order at a computable rate. It does not weigh what the relation is for, what else it produces, or what ending it would cost. *Fix:* §4.8. This is not counselling, therapy or clinical assessment, and the paper says so here.

Worked examples

4.21 The carried dyad, both phases, as full destiny reports CONSTRUCTED. Not an observation of any person or pair.

```
ARRANGEMENT      two parties A and B; one pass = one week; the pass is their standing review
SCALE STATUS     constructed intensities, treated as magnitude-estimated for the worked case
RAW L2 NORMS     |A| = 0.948683298051    |B| = 0.890224690738

---- PHASE 2a, AS FOUND ------------------------------------------------------
GEOMETRY         cos theta = 0.965020898600      u = 0.068734665264634
                 support overlap = 3 of 4 occupied indices -- not degenerate
STATE READING    A holds {4, 6, 9}; B holds {4, 6, 9, 10}
                 raw 7.7348 / 17.4033 / 39.1575 / 48.3426 Hz
                 pitch classes {1, 3, 9, 5}
RELATION READING F = 0.563084802746 nats   N_eff = 1.756081   f_rel = 1.4907987150 Hz
CEILING          c/eta = 2.066667 vs ln N = 2.484907  ->  TUNABLE in principle
DEFICIT          D = +4.3384201973 octaves        f_min = 30.1587698405 Hz
LOSS             delta = 0.09
DESTINY          Q_inf = -5.0119395464            DECAYS
APPROACH         tau = 10.603253 passes; half-life = 7.349615; t(1%) = 48.8298
                 at one pass per week: half-life about seven and a half weeks
LABEL            CONSTRUCTED
```

The pair agree about almost everything — `cos theta = 0.965` — and that is the whole of their problem. The relationship frequency sits at 1.49 Hz against a required 6.16 Hz, which is a gap of 4.34 octaves, and the destiny is negative.

The intuitive repair is to add trust, which lowers `delta`. Computed:

```
delta 0.09 -> 0.05     Q_inf  -5.0119395464 -> -9.0214911835      WORSE by 4.0095516
delta 0.09 -> 0.01     Q_inf  -5.0119395464 -> -45.1074559        WORSE by 40.0955164
D at every one of those values                +4.3384201973       UNCHANGED
```

The deficit is flat across all three. A pair reading only their deficit would conclude that a successful, expensive, well-intentioned intervention had done nothing; a pair reading only their stock would watch it fall and not know why. **A pair reading both would see immediately that they had multiplied a negative number by a larger factor and touched no mechanism.** That is the case for Gate 4-4 in one paragraph.

```
---- PHASE 2b, AFTER ONE STRUCTURAL CHANGE -----------------------------------
THE CHANGE       B takes on two states A does not hold; the pair adopt a decision log
GEOMETRY         u = 0.692372881355932
RELATION READING F = 2.153632742815 nats   N_eff = 8.616102   f_rel = 35.8881768941 Hz
CEILING          c/eta = 0.909091 vs ln N = 2.484907  ->  TUNABLE, with margin
DEFICIT          D = -3.5909886634 octaves        f_min = 2.9782153324 Hz
LOSS             delta = 0.09
DESTINY          Q_inf = +6.0844267427            ACCUMULATES
APPROACH         half-life 7.349615 passes; inside 5% of Q_inf from pass 32;
                 inside 0.1% from pass 74
LABEL            CONSTRUCTED
```

And now the same trust intervention, applied second instead of first:

```
delta 0.09 -> 0.05     Q_inf  +6.0844267427 -> +10.9519681368     BETTER by 4.8675414
D unchanged at         -3.5909886634
```

The symmetry is exact and worth pausing on. Lowering `delta` from 0.09 to 0.05 moved the unrepaired dyad's destiny by `-4.0095516` and the repaired dyad's by `+4.8675414`. **The same intervention, the same magnitude of change in the same parameter, and the sign of the result was decided entirely by the sign of the drive it was multiplying.** Section 5 owns the operating rule that follows; this section's contribution is the reason it is true, which is that `delta` is a denominator and denominators do not have opinions.

4.22 The export case, in report format

CONSTRUCTED. Not an observation of any person or pair. The two-participant arrangement of §4.12, read at `x = 0.15`.

```
ARRANGEMENT      P and R share the case-2b arrangement; one pass = one week
SHARED GEOMETRY  u = 0.692372881355932   F = 2.153632742815   f_rel = 35.8881768941 Hz

PARTICIPANT P    eta = 0.44   c = 0.250   delta = 0.09
                 D_P     = -4.574644 octaves
                 Q_inf,P = +7.751093
                 drive   = +0.697598

PARTICIPANT R    eta = 0.30   c = 0.700   delta = 0.09
                 D_R     = +0.518506 octaves
                 Q_inf,R = -0.599002
                 drive   = -0.053910

SUM OF DRIVES    +0.643688229683
PREVIOUS SUM     +0.643688229683         ->  UNCHANGED
EXPORT TEST      P improved by 1.666666 units of fixed point; the sum did not move.
                 VERDICT: the gain was exported. Nothing was produced.

R's crossing     exact at c_R = eta_R F = 0.646089822845, i.e. x = 0.096089822845
R's stock lag    t* = 10.850479 passes before Q_R goes negative
LABEL            CONSTRUCTED
```

Read the block as a whole and notice what it does that a per-party reading cannot. P's three lines are the lines of a well-run arrangement improving steadily. R's three lines are the lines of an arrangement that has just crossed into decline. The sum line is the only place in the report where the relation between those two facts appears, and it appears as a quantity that did not change.

The terminal arithmetic completes the case. If R declines to continue — R's structural right, and no arrangement here may remove it — the shared surplus goes to zero, `f` falls to the ground essence `k = 0.483426 Hz`, and P's reading becomes `D_P = +1.639426`, `Q_inf,P = -2.777778`. P's fixed point falls by `10.528871` units and P's deficit swings `6.214071` octaves the wrong way, which is `2.885390 * F` exactly. **The exporter's terminal loss is the full value of the surplus whose maintenance was exported, and the model computes it without needing any account of anybody's feelings about it.**

4.23 What this section establishes, and what Section 5 takes

Established, and checkable. That the storage loop has exactly one fixed point for `delta > 0` and reaches it from every start (Theorem 4.1); that the approach is a geometric equality rather than a bound, verified to 2.06e-15 across a hundred passes (Theorem 4.2); that the octave deficit and the fixed point are one quantity in two units, verified to 8.88e-16 across twelve parameter sets (Theorem 4.3); that the deficit contains no `delta`, so the same `D` is consistent with destinies differing by a factor of thirty (Theorem 4.4); that the sum of drives is exactly conserved under any transfer of cost among any number of participants (Theorem 4.5), and that the plain sum of fixed points inherits that invariance only when the participants share a `delta` (Corollary 4.6 and §4.13);

that a counterfeit fixed point is therefore detectable on pass one by an arithmetic test costing one column of a report; and that a state's frequency and a relationship's frequency remain independent readings at destiny scope.

Not established, and not claimed. That any arrangement's parameters will hold; that a larger fixed point is a better life; that any reading here describes any actual person or pair; that the formalism detects every way one party can gain at another's expense; that any frequency in this section is a physical resonance; or that any of this constitutes counselling, therapy, diagnosis or clinical assessment.

The one line to carry forward: *a destiny is a number with four arguments, and everything that can be done about one is done to those four.*

Section 5 takes the four arguments as levers, prices each of them, gives each its frequency reading and its failure mode, and states the two rules governing the order in which they are pulled. It also applies the channel-gain postulate in full [Curzi, 2026ab], because the question "what actually moves a destiny" has a large and confident literature attached to it.

5 Changing the fixed point

Section 4 defined destiny as Q_∞, the fixed point of the contracting loop, and spent its length on what the object is: unique, reached from any start, indifferent to history, negative whenever conversion fails to cover cost, and detectable as counterfeit by an arithmetic test on a conserved sum. Everything there was a statement about a number holding still.

This section moves it. And the first thing to say is how few ways there are to do that.

```
Q     =  ( eta * F(u*)  -  c* ) / delta
 inf
```

Four symbols on the right. **Changing a destiny means changing `(eta, F, c, delta)` and nothing else** — not because other approaches are disapproved of, but because the expression has four arguments and a function of four arguments changes when one of them changes and at no other time. That is a definition rather than a promise, and its whole value is that it makes the question answerable: *which one is being moved, and by how much?*

A proposal that cannot be assigned to one of the four is not an intervention on the destiny. It may be many other worthwhile things. It is not that.

This section takes the four in turn, and for each one gives three things the practical literature almost never gives together: the frequency reading that says whether the lever is the binding one, the cost of moving it, and the specific way plans built on it fail. Two results govern the whole exercise and both are inherited. The first is the reserve theorem, which says a lever can be **absent** rather than merely expensive — demonstrated on a lever with nearly five times the elasticity of its rival. The second is the order rule, which says fix the numerator before lowering the loss, and which comes with a price for disobedience computed to six decimal places [Curzi, 2026q].

Then the section does what a section with this title has to do. There is a large, confident and commercially successful literature claiming that a destiny can be changed by believing in a new one. The framework's channel-gain postulate is the apparatus for adjudicating exactly that claim [Curzi, 2026ab], and it is applied here in full, with its conclusion in both directions: where a channel with real gain exists, belief moves the world by an amount the channel's own mechanism determines, and where no channel exists, nothing happens at all. The survivorship result supplies the companion number [Curzi, 2026].

The law

5.1 There are four arguments, and there is no fifth **THEOREM 5.1 — THE COMPLETENESS OF THE LEVER SET.** `Q_inf` is a function of exactly `(eta, F, c, delta)`. Therefore any change to `Q_inf` is a change to at least one of those four, and any proposal that changes none of them changes `Q_inf` by zero.

Proof. Inspection of `Q_inf = (eta F − c)/delta`. There are no other free symbols. ■

The proof is trivial and the consequence is not, because it is a closure statement: it says the list is complete, and a complete list is what turns a diagnostic into a procedure. The framework's intervention work states the same closure for interventions on the deficit and reaches a list of five handles rather than four [Curzi, 2026], and the two statements have to be reconciled explicitly or a reader will think one of them is wrong.

They are both right, and the difference is one level of nesting:

```
THE FOUR ARGUMENTS OF Q_inf          THE FIVE HANDLES ON AN ARRANGEMENT
---------------------------          ----------------------------------
eta   conversion                      L2  raise eta
F     surplus                         L1  raise u        }  the two routes
                                      L4  raise N        }  into F
c     cost                            L3  cut c
delta loss                            L0  lower delta
```

`F` is not directly manipulable. It is `ln(1 + (N−1)u)`, and it moves only when the geometry `u` moves or the category count `N` moves. So the four arguments give five handles, and the two lists are the same list read at two depths. The reconciliation matters because the two sublevers into `F` behave completely differently — one has the largest reserve in the apparatus and the other has almost none — and a plan that says "raise `F`" without saying which route has not yet said anything.

5.2 The partials, and why they may not be ranked At the carried dyad as found — case 2a, a constructed case, with `u = 0.068734665264634`, `eta = 0.30`, `c = 0.62`, `delta = 0.09`, `Q_inf = −5.0119395464`:

```
dQ_inf / d eta    =  F / delta              =   +6.256498   per unit of eta
dQ_inf / d F      =  eta / delta            =   +3.333333   per nat of surplus
dQ_inf / d c      =  −1 / delta             =  −11.111111   per unit of cost
dQ_inf / d delta  =  −(eta F − c)/delta^2   =  +55.688217   per unit of delta

the two routes into F:
dF / du           =  (N−1)/(1 + (N−1)u)     =   +6.263947   per unit of u
dF / dN           =  u /(1 + (N−1)u)        =   +0.039141   per added category
```

Ranking these against one another on size is forbidden, and the prohibition is not pedantic. They are in four different units. `eta` is a dimensionless efficiency in `[0, 1]`; `c` is a cost in the same units as `eta F`; `delta` is a rate in `(0, 1]`; `F` is in nats. The statement "`delta` has the largest derivative" is true and means nothing, because a unit of `delta` and a unit of `c` are not comparable quantities and no plan can spend one to buy the other.

Identifying which constraint actually binds, rather than which responds fastest, is the standard discipline of constraint analysis in operations [Goldratt and Cox, 1984, Hopp and Spearman, 2011]. What is legitimate is the elasticity comparison [Curzi, 2026q], which divides the units out. That is §5.9. What is also legitimate is the reserve comparison, which asks how far each lever can go before it runs out, and that is §5.10. The two answer different questions and the most expensive planning error here is confusing them.

5.3 The ceiling test comes before every lever Before any of this is worth computing there is a test that can rule the entire exercise out, and it belongs at the top of the procedure because a plan built after skipping it is a plan for a case that has no solution.

THE CEILING [Curzi, 2026]. Since `F <= ln N`, sustainability requires `c/eta <= ln N`. Equivalently `f_min <= k N^2`. At `N = 12`, `c/eta` may not exceed `2.484907`, i.e. `f_min` may not exceed `69.6133055503 Hz`.

The bound is the framework's normalisation carried into the frequency register, and it is the same bound requisite-variety arguments place on any regulator [Ashby, 1956, 1958].

```
c/eta > ln N   ->   NO value of u makes the arrangement sustainable.
                    Not a better pairing, not a better schedule, nothing.
                    The only remedies: raise eta, cut c, or add genuinely distinct categories.
```

Run on the four arrangements this framework carries, plus one constructed case built to fail it:

```
arrangement                 c/eta      ln N       verdict
-------------------------------------------------------------------------
carried dyad 2a           2.066667   2.484907    tunable in principle
carried dyad 2b           0.909091   2.484907    tunable, with margin
the commons               2.426471   2.484907    tunable in principle, barely
constructed family        1.400000   2.484907    tunable
CONSTRUCTED over-ceiling  3.000000   2.484907    STRUCTURAL -- no u closes it
```

The last row is worth working, because work that only showed tunable cases would be lying by selection. **CONSTRUCTED, labelled constructed.** An arrangement at `eta = 0.20` and `c = 0.60` sits at `c/eta = 3.000000`. Push its geometry to perfect orthogonality — `u = 1`, the theoretical maximum, two parties with no overlapping state whatever:

```
at u = 1, N = 12:   F = ln 12 = 2.484907   D = 2.885390 * (3.000000 - 2.484907) = +1.486245
```

Still failing, by nearly a octave and a half, with the geometry lever fully spent. The only remaining route through `F` is `N`, and the requirement is exact: `N >= e^3 = 20.0855`, so twenty-one categories.

```
at u = 1, N = 21:   F = ln 21 = 3.044522   D = 2.885390 * (3.000000 - 3.044522) = -0.128465
```

Sustainable, by an eighth of an octave, and only at perfect orthogonality in a twenty-one-category description. That is what "restructure rather than tune" looks like when it is priced. The carried commons is the same lesson at a milder setting: it passes the ceiling test by `0.058436` and is still short by `+6.463837` octaves, and its tuning procedure halts.

5.4 `delta` is a multiplier on a sign, not a lever on a gap This is the framework's ordering rule, and it is the correction to naive practice repeated more often than any other result, because it is the one every reader's intuition gets backwards.

THEOREM 5.2 — restated for `Q_inf`. `delta` appears in `Q_inf` only as a denominator. Therefore `sign(Q_inf) = sign(eta F - c)` for every `delta` in `(0, 1]`, and reducing `delta` scales `|Q_inf|` upward without ever changing its sign. ■

Computed on three drives, one negative, one positive, one exactly zero:

```
drive b              delta 0.30    delta 0.09    delta 0.05    delta 0.01
-------------------------------------------------------------------------
2a as found  -0.451075   -1.503582     -5.011940     -9.021491    -45.107456
2b repaired  +0.547598   +1.825328     +6.084427    +10.951968    +54.759841
exactly at hold   0.000   +0.000000     +0.000000     +0.000000     +0.000000
```

Three readings of that table. In the top row, the intervention that everyone reaches for first — build trust, add continuity, institute the ritual, keep the record — takes the destiny from `−5.011940` to `−45.107456`, **a ninefold deterioration, while every party involved is doing something admirable and nothing is going visibly wrong.** In the bottom row the same intervention does the same thing with the sign reversed, and it is the single largest available improvement. In the middle row it does nothing at all, at any magnitude, because trust multiplies an existing sign and zero has none.

And the deficit is flat across the entire table. `D = +4.338420` in the top row at every `delta`; `D = −3.590989` in the second at every `delta`. A pair reading only their deficit through that whole sequence would see a completely unchanging instrument. That is Theorem 4.4, and it is why the reporting format prints δ in the same block as D, every time.

5.5 The reserve theorem: a lever can be absent rather than expensive

This result is the most counter-intuitive in the framework's lever set.

THEOREM 5.3 — THE LEVER RESERVES. The maximum number of octaves each lever can supply, alone, from an operating point `(u_0, eta_0, c_0, N)`:

```
R_u    = 2.885390 * ( ln N − F(u_0) )                  ( u -> 1 )       the pitch headroom
R_eta  = 2.885390 * c_0 * ( 1/eta_0 − 1/eta_max )      ( eta -> eta_max )
R_c    = 2.885390 * ( c_0 / eta_0 )                    ( c -> 0 )
R_N    unbounded in principle; 2.885390 * u/(1+(N−1)u) per category in practice
```

Computed on the carried dyad as found, against its requirement of `+4.338420` octaves:

```
R_u    ( u -> 1 )        5.545206 octaves       CLOSES the deficit
R_eta  ( eta -> 0.40 )   1.490785 octaves       does not
R_eta  ( eta -> 0.50 )   2.385256 octaves       does not
R_eta  ( eta -> 0.75 )   3.577884 octaves       does not
R_eta  ( eta -> 1.00 )   4.174198 octaves       does not -- and eta_max = 1 is generous
R_c    ( c -> 0 )        5.963140 octaves       CLOSES the deficit
R_N    per added category at u = 0.068735 :  0.112937 octaves
```

Now set that beside the elasticities, which measure how fast each lever moves the deficit per *proportional* change and are therefore dimensionless and comparable:

```
point         c/eta      1 − 1/N_eff   |dD/d ln eta|  |dD/d ln u|   ratio
-------------------------------------------------------------------------
dyad 2a      2.066667      0.430550       5.963140      1.242306    4.8001
dyad 2b      0.909091      0.883938       2.623082      2.550507    1.0285
the commons  2.426471      0.169955       7.001314      0.490387   14.2771
```

At the carried dyad as found, `eta` has 4.80 times the elasticity of `u` — and 4.174198 octaves of reserve against a requirement of 4.338420, falling short by 0.164222. The lever that moves the deficit nearly five times faster per proportional unit cannot close it at all, even taken to `eta = 1`, which would mean an arrangement converting every unit of interaction into permanent structure with nothing lost anywhere.

The same fact appears in another form. The `eta` required to close the deficit is `c/F = 0.62/0.563085 = 1.101077`. A conversion efficiency above one is not an expensive lever; it is an absent one, and no amount of effort, budget or commitment reaches it, because it would mean creating more structure than the interaction supplied.

> **THE HONEST DYADIC LAW. The cost-side levers have the higher elasticity and the lower ceiling; the geometry lever has the lower elasticity and the only large reserve. Small deficits are closed on the cost side. Large ones require difference.**

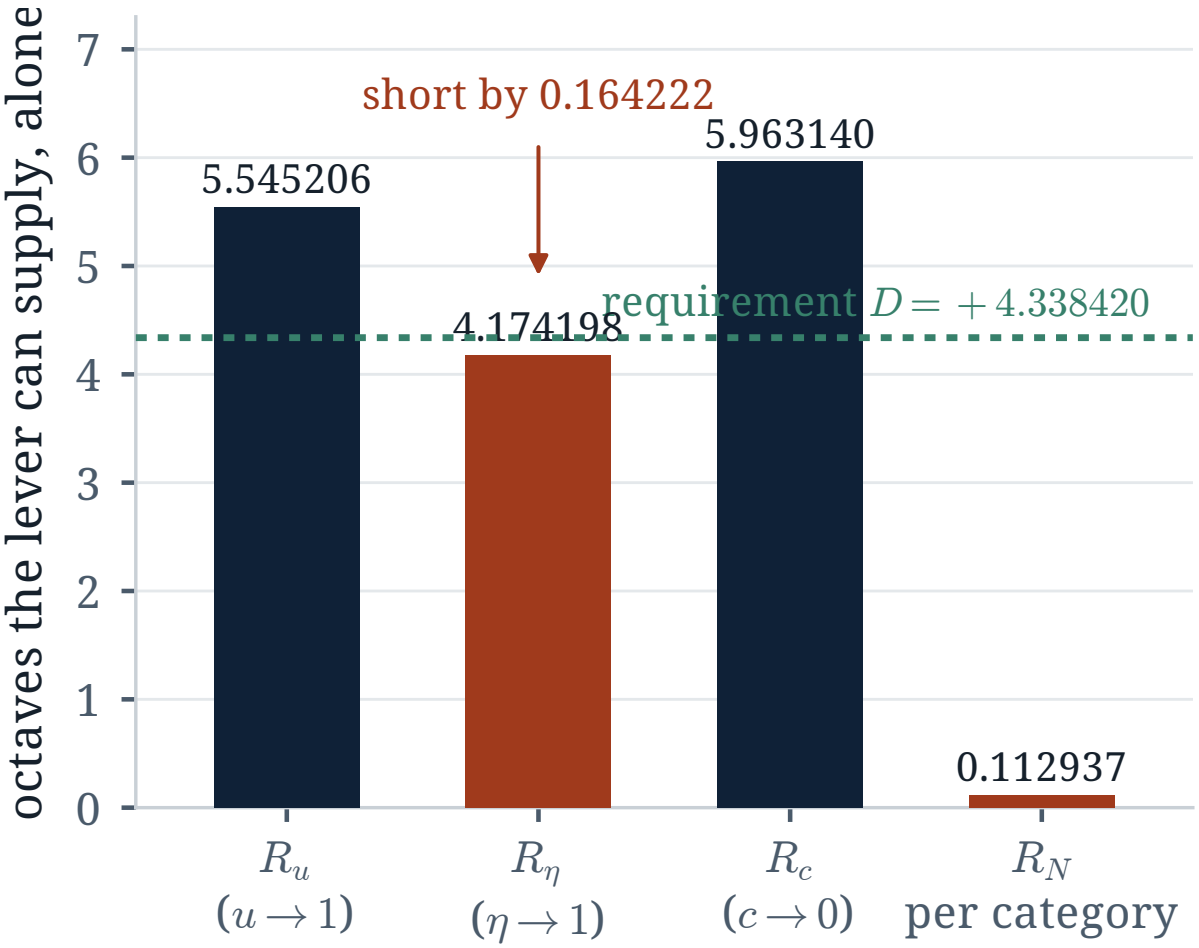

Figure 49.4: **A lever can be absent rather than expensive: the lever with 4.80 times the elasticity of its rival falls 0.164222 octaves short of the requirement even at an impossible conversion efficiency of one.** Constructed carried dyad as found (§5.5), $u = 0.068734665264634$, $\eta = 0.30$, $c = 0.62$, $\delta = 0.09$, $N = 12$, requirement $D = +4.338420$ octaves; reserves and elasticities are read from the two tables of §5.5. Script `figs/src/CCP-049_fig04.py`.

The reserve table also shows where the cost-side lever is worth having. `R_eta` is large only where `eta` is very low — where the arrangement is converting almost nothing and there is a great deal of headroom in the mechanism:

```
eta_0    c        R_eta (octaves, at eta_max = 1)
-------------------------------------------------
0.20     0.400          4.6166
0.20     0.825          9.5218
0.30     0.620          4.1742
0.40     0.620          2.6834
0.50     0.400          1.1542
0.50     0.825          2.3804
```

An arrangement already converting half of what it does has under two and a half octaves available on the `eta` side no matter how expensive it is. The cost-side lever is the cheap one, the first one, and the one that is spent quickly.

5.6 The order rule, and its price The design rule is one line: **raise η or cut c until $\eta F > c$, and only then invest in δ** [Curzi, 2026q]. What belongs here, because this is the section about changing things, is the price of doing it backwards.

CONSTRUCTED CASE, labelled constructed. The carried dyad, starting stock `Q_0 = 1.0`, eight periods of the wrong order first. Path A lowers `delta` from 0.09 to 0.05 and runs eight periods before fixing the numerator. Path B fixes the numerator first, runs eight periods at the original `delta`, and then lowers it. Both end at identical parameters and therefore, by Theorem 4.1, at the identical fixed point.

```
 t |   Path A   |   Path B   |    gap
---+------------+------------+-----------
 0 |  +1.000000 |  +1.000000 |  +0.000000
 1 |  +0.498925 |  +1.457598 |  +0.958673
 3 |  -0.429315 |  +2.252950 |  +2.682265
 5 |  -1.267052 |  +2.911581 |  +4.178633
 8 |  -2.373029 |  +3.693462 |  +6.066491
10 |  -1.073842 |  +4.401167 |  +5.475008
13 |  +0.641339 |  +5.335475 |  +4.694135
16 |  +2.111893 |  +6.136527 |  +4.024634
20 |  +3.751671 |  +7.029761 |  +3.278090
24 |  +5.087281 |  +7.757306 |  +2.670025
32 |  +7.061215 |  +8.832564 |  +1.771349

terminal fixed point, both paths          +10.951968
minimum stock reached, wrong order         -2.373029   (starting value +1.000000)
periods spent below the starting value     13   (t = 1 through t = 13)
permanent lag                              12 periods
cumulative gap over 32 periods            111.133601 stock-periods
```

The lag is permanent and it is exactly twelve periods at every level: Path B reaches `+3.693462` at `t = 8` and Path A first reaches it at `t = 20`; Path B reaches `+5.039870` at `t = 12` and Path A at `t = 24`; `+6.136527` at 16 and 28; `+7.029761` at 20 and 32. **Eight periods of misordering cost twelve periods of permanent delay and 111.133601 stock-periods of cumulative loss, from doing exactly the same two things in the opposite order.**

The excess over eight is not a rounding artefact. While the numerator is negative, the lowered `delta` is *accelerating* the loss, so those eight periods do more damage than eight periods at the original `delta` would have done.

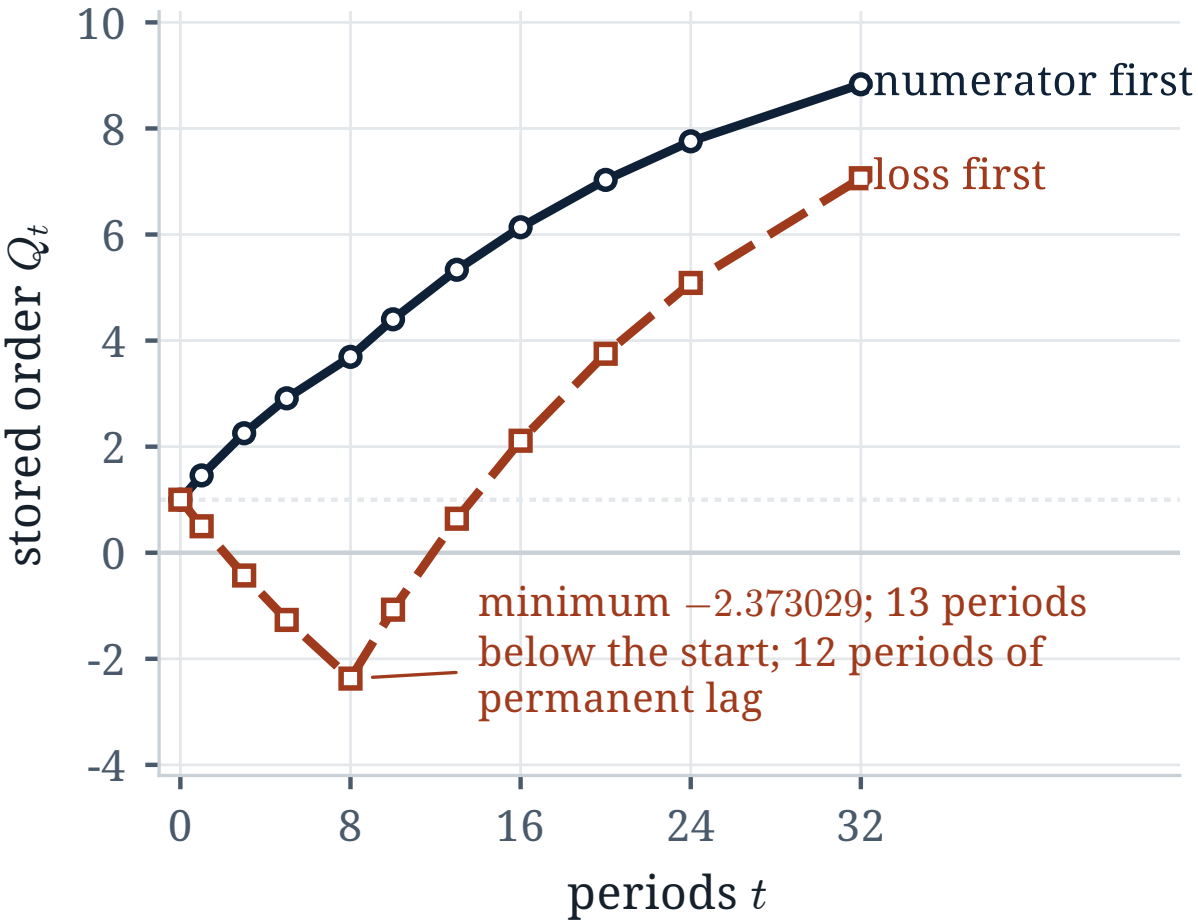

Figure 49.5: **The same two changes in the opposite order: identical destinations, a minimum stock of -2.373029, thirteen periods below the starting value and a permanent lag of twelve periods.** Constructed case of §5.6 from $Q_0 = +1.0$; Path A lowers δ from 0.09 to 0.05 and runs eight periods before fixing the numerator, Path B fixes the numerator first, and both end at $Q_\infty = +10.951968$. Every marked value is read from the order-rule table of §5.6. Script `figs/src/CCP-049_fig05.py`.

Two things about that table deserve to be read carefully. The first is that both paths converge to the same number, which means a planner who evaluates only the destination sees no difference between them whatever. The destination is order-independent; the trajectory is not; and the formalism will happily compute a path through negative stored order that a real arrangement may not survive. Admissibility fails there [Curzi, 2026a], and thirteen periods below the starting stock is thirteen periods in which people make decisions.

The second is what the instrument said the whole time. `D` reads `+4.338420` at the start of Path A and `+4.338420` at the end of Path A's first eight periods. Whatever the pair were using, if it was the deficit alone, it reported that nothing had happened during the most damaging phase of the plan.

5.7 Honesty clauses, restated where they bind

Essence, not resonance. Every hertz value in this section is a position on a logarithmic scale of surplus. Nothing here is claimed to be a physical vibration and nothing here is to be played at anyone.

No clinical, diagnostic or therapeutic claim. A lever prescription is a statement about four declared parameters of an arrangement. It is not treatment, not counselling, and not an assessment of anybody.

Consent is structural [Curzi, 2026]**.** No intervention derived from any reading in this section may reduce any party's ability to decline it, at any stage, for any reason or none. The geometry lever in particular describes changes to what people hold and do, and it is worth saying plainly: an intervention that raises u by arranging for someone else to change is not an intervention this framework licenses. The foundations concede that the case where the feedback loop runs through another person's will is an unsettled seam the corpus does not close [Curzi, 2026].

No subliminals. Nothing masked, nothing below threshold, nothing concealed [Curzi, 2026].

All cases here are CONSTRUCTED and labelled as such.

The engineering

5.8 Lever L1 — raise `u`, the geometry

The reading that says it binds. `R_u = 2.885390 (ln N − F(u_0))` exceeds the deficit while the cost-side reserves do not; equivalently, `1 − 1/N_eff` is small, meaning the arrangement is near parallel and has a great deal of unused pitch headroom. At the carried dyad as found, `1 − 1/N_eff = 0.430550` and `R_u = 5.545206` against a requirement of `4.338420`.

What it costs. The required `u` is exact: `u >= (e^(c/eta) − 1)/(N−1)`. For the carried dyad, `u >= 0.627132` from `0.068735`, a rise by a factor of `9.1240`. That is a large amount of real difference between two people currently at `cos theta = 0.965`.

What raising u actually is, and the trap in it. The unison result is the single most important thing to carry into any attempt at this lever:

```
u = 1 − (x . y)^2   depends only on |rho|

perfect agreement     rho = +1   ->   u = 0
perfect opposition    rho = −1   ->   u = 0
```

Manufactured disagreement raises cost and returns exactly nothing. A party who adopts contrary positions in order to bring difference moves the pair toward `rho = −1`, which reads `u = 0` just as agreement does, while adding coordination overhead: the reading gets worse in both terms at once. The contrarian and the sycophant sound the identical note, and it is the ground essence `k = 0.483426 Hz`.

The empirical literature on difference is genuinely divided and must be cited that way: bridging across structural holes has measured returns [Granovetter, 1973, Burt, 1992], creative success rises and then *falls* with the same variable [Uzzi and Spiro, 2005], short-run effects of surface diversity are frequently negative [Putnam, 2007], the rebuttal literature qualifies rather than reverses that [Abascal and Baldassarri, 2015], and the formal diversity-beats-ability result carries a standing objection that must be cited with it [Hong and Page, 2004, Thompson, 2014, Page, 2007]. **A monotone claim cannot survive that list unqualified**, and none is made here outside the range the arithmetic covers.

What does raise `u` is a change in what a party actually holds — states occupied that the other does not occupy, commitments taken on, work done in a domain the other is not in. **The test of a `u` intervention is whether it would still be true if nobody were reading the number.**

Failure mode. The representational one: two parties described by disjoint sets of states are automatically orthogonal and read `u = 1` regardless of content. A `u` raised by re-describing rather than by changing what is held is an artefact, and Gate 5-2 exists to catch it.

5.9 Lever L4 — raise `N`, the categories

The reading that says it binds. Only one: `c/eta > ln N`. Then the ceiling is the binding constraint, `u` is unavailable at every value, and adding categories is the only route into `F` that has anywhere left to go.

What it costs. Per added category, at fixed `u`, the gain is `2.885390 * u/(1+(N−1)u)` octaves. At the carried dyad that is `0.112937` octaves each; at the commons, where `u = 0.018614`, it is `0.044581` octaves each. **Adding categories to a near-parallel set buys almost nothing** — and the coordination cost of a larger category set grows as $n(n-1)/2$ [Brooks, 1975, Conway, 1968], while twelve already exceeds the classical span of immediate absolute judgment [Miller, 1956]. Computed, raising `N` alone on the carried dyad with `u` held at `0.068735`:

```
N     F          D
-------------------------
 12   0.563085   +4.338420
 16   0.708538   +3.918731
 20   0.835496   +3.552406
 25   0.974421   +3.151556
 40   1.303090   +2.203217
 60   1.620446   +1.287520
100   2.054730   +0.034441
200   2.686363   −1.788066   OK
```

Two hundred categories to close a deficit that one geometry change closes. **The lever is unbounded in principle and nearly useless in practice at low `u`, which is exactly the regime in which a planner reaches for it.**

Failure mode. Index inflation: the count rises after a re-description that added no distinguishable component [Curzi, 2026]. An added category must satisfy the framework's validity conditions and must carry variance the existing categories do not. Components that always co-occur are one component. And the rendering bounds bind if the reading is displayed: `N = 17` is the folded-lattice cliff and single-transposition audible capacity is `N <= 25`.

5.10 Lever L2 — raise `eta`, the conversion

The reading that says it binds. A large `c/eta` with `c` already lean, and a reserve check that passes: `D <= 2.885390 * c * (1/eta_0 − 1/eta_max)`. When that inequality holds, the cost side can close the gap alone. When it fails, difference is required, and no amount of work on conversion will substitute.

What it costs. The required `eta` is exact: `eta >= c/F`. At the carried dyad that is `0.62/0.563085 = 1.101077`, which is impossible. At the repaired dyad it is `0.40/2.153633 = 0.185733`, which is already exceeded. **The same lever is absent in one phase of the same constructed case and free in the other, and the only thing that changed between them was the geometry.** That is the order rule in a single sentence.

Failure mode, and it is specific to this lever. `eta` carries the entire cost side of the reading and its elasticity is the largest in the dyadic table, which means a verdict resting on it deserves an error bar rather than a decimal point. The framework's constructed family carries a deficit of `+0.584737` octaves with `eta` known to `± 0.05`, giving an uncertainty of `± 0.9734` octaves — and the sign of the verdict is not resolved. A deficit near zero is the most dangerous reading in the apparatus, because it is the one most likely to be an artefact of an imprecise input.

5.11 Lever L3 — cut `c`, the cost

The reading that says it binds. The largest reserve of the two cost-side levers, always: `R_c = 2.885390 (c/eta)` is by construction the entire required-octave figure, so cutting cost to zero always closes any deficit. That makes it the lever with the best arithmetic and the worst practical guarantee.

What it costs. The required cut is exact: `c <= eta F`. At the carried dyad, `c <= 0.30 * 0.563085 = 0.168925`, from `0.62` — a reduction of `72.754%` in coordination overhead. Reachable in principle; a large project in fact.

Failure mode, and it is the one that makes this lever's arithmetic misleading. Before cutting c, ask whether the cost being cut is performing conversion work. If it is, `eta` falls with `c` and the ratio `c/eta` may not improve at all — or may worsen. The decision log in the carried dyad's repair is a cost that raises `eta`; removing it to "cut overhead" would cut `c` from 0.40 and take `eta` back toward 0.30, and the reading would move the wrong way while the arrangement looked leaner. **`R_c` is computed at fixed `eta`, and cost cuts do not generally hold `eta` fixed.**

5.12 The thing that is not a lever — `delta`

`delta` is the fourth argument of `Q_inf` and it is not a lever on `D` at all (Theorem 5.2). It belongs in a plan, and it belongs there second.

Trust in the framework's sense enters as retention rather than as input [Curzi, 2026s, Gambetta, 1988, Putnam et al., 1993].

The reading that says it is ready. One condition only: `eta F > c`. Once the drive is positive, `delta` is the largest available improvement in the apparatus, and it is worth quantifying how large:

```
after the repair, drive b = +0.547598407
  delta 0.09 -> Q_inf  +6.084427
  delta 0.07 -> Q_inf  +7.822834      gain  +1.738408    half-life  9.5513
  delta 0.05 -> Q_inf +10.951968      gain  +4.867541    half-life 13.5134
  delta 0.03 -> Q_inf +18.253280      gain +12.168853    half-life 22.7566
  delta 0.01 -> Q_inf +54.759841      gain +48.675414    half-life 68.9676

the same moves before the repair, drive b = -0.451074559
  delta 0.09 -> Q_inf  -5.011940
  delta 0.07 -> Q_inf  -6.443922      change  -1.431983
  delta 0.05 -> Q_inf  -9.021491      change  -4.009552
  delta 0.03 -> Q_inf -15.035819      change -10.023879
  delta 0.01 -> Q_inf -45.107456      change -40.095516
```

The two columns are the same intervention producing gains of `+48.68` and `-40.10`, and the only thing that differs between them is the sign of a number that `delta` never touches.

Note also what the right-hand column of the first block costs. A destiny of `+54.76` comes with a half-life of `68.97` passes and a 99% approach time of `458` passes. At one pass per week that is nearly nine years to arrive. A deep destiny is a slow one, necessarily; the same parameter sets both, and there is no configuration in this model with a deep fixed point and a short approach.

Failure mode. In the refinement register [Curzi, 2026]: adding trust to a failing arrangement in order to make it improve faster does the reverse of both. It makes the approach slower and the destination worse.

5.13 Which lever binds — the decision arithmetic Put the reserves and the deficit side by side and the binding lever reads off directly. Computed across the four arrangements this framework carries:

```
arrangement            D          R_u        R_eta      R_c       R_N/cat   closes alone
-------------------------------------------------------------------------------------------
carried dyad 2a    +4.338420   5.545206   4.174198   5.963140   0.112937   u, c
carried dyad 2b    −3.590989      --         --         --         --      already sustainable
the commons        +6.463837   6.632448   4.620867   7.001314   0.044581   u, c
constructed family −0.516423      --         --         --         --      already sustainable
```

`R_eta` is computed at the generous `eta_max = 1`. In both failing arrangements the conversion lever cannot close the gap alone even at an impossible efficiency, and in both the two levers that can are the geometry and the cost.

The commons row is the instructive one. Its deficit is `+6.463837` octaves and **no single lever closes it in practice**, even though two of them close it in principle:

```
raise u to 0.95         -> deficit −0.0332    (only just, and 0.95 is near-orthogonality)
raise eta to 0.90       -> deficit +2.1075    still failing
cut kappa to 0.020      -> deficit +2.0085    still failing
```

`R_u = 6.632448` exceeds the requirement by `0.168611` octaves, which is to say the geometry lever closes it only in the limit of six people who share almost no state at all — a configuration that is not a commons. `R_c = 7.001314` closes it only at zero coordination cost, which is not a commons either. **Some systems cannot be tuned; they must be restructured, and the diagnostic is what says which case is in hand.**

5.14 The belief postulate, applied in full There is a large literature claiming that a destiny is changed by holding a different belief about it. The framework's channel-gain postulate is the apparatus for adjudicating that claim [Curzi, 2026ab], and it is applied here without softening in either direction.

> **[POSTULATE, badged] BELIEF CREATES REALITY IF THE BELIEF IS GROUNDED IN TRUTH.**

The mechanism the postulate formalises has a documented empirical form: expectation is known to change measured outcomes [Merton, 1948, Rosenthal and Jacobson, 1968], participation in a study itself changes behaviour [McCambridge et al., 2014], and a theory has been observed becoming true by being used, with dates and prices [MacKenzie and Millo, 2003, Ferraro et al., 2005]. It also has a measured *size*: the best long-run assessment finds classroom self-fulfilling prophecies real but small, usually non-accumulating and often dissipating [Jussim and Harber, 2005]. The conditional clause is what makes this a postulate that can be wrong rather than magical thinking, and the whole content sits in its formalisation:

```
BELIEF  ->  [ CHANNEL ]  ->  WORLD

"grounded in truth"  =  THE CHANNEL EXISTS AND IS REAL
```

> **[POSTULATE, badged]** A belief `B` affects a world-state `E` only through one or more channels. Each channel `i` has a gain `G_i` determined by the channel's own mechanism and not by the belief. Then `E = (sum_i G_i) B` for small `B` before saturation, and `|E| <= (sum_i G_i) B_max`. If no channel exists the sum is empty, `sum_i G_i = 0`, and `E = 0` at every `B`.

The badge stays on: this is a postulate, not a theorem. But the *bound* is arithmetic once the gains are estimated, and arithmetic is what makes a claim auditable in advance of any data.

The correspondence with the storage law is exact in form [Curzi, 2026ab]: `B` is the input where `S` was, `G` is the conversion where `eta` was, `E` is the output where the stock was. Where the correspondence stops, stated honestly: the storage law is a proven theorem about a recursion and the coupling relation is a postulate about the world. The form transfers; the warrant does not.

The four channel classes and their gains, as the framework's channel-gain paper reports them [Curzi, 2026ab]: physiological, roughly 0.15 to 0.45 on subjective outcomes and approximately zero on objective disease endpoints; behavioural, the widest range and typically 0.1 to 0.6 in the worked cases reported there; social, bimodal — small below a committed-fraction threshold and large above it; informational, zero to about 0.35 and entirely conditional on the target existing. Two readings of that list carry into this section. The behavioural channel dominates in every worked case, so the practical consequence of the postulate is not "believe harder" but: **find the action the belief produces, and check whether the action works.** And three of the four classes zero out on a fact about the world — no efferent pathway, ineffective action, absent target — which is where the conditional clause lives.

Composition. Series multiplies and parallel adds. A four-stage channel:

stage	gain	cumulative
belief registered as expectation	0.70	0.700000
expectation reaches the effector	0.50	0.350000
effector produces the action	0.62	0.217000
action lands on the outcome	0.35	0.075950

A chain of four individually respectable transmissions delivers 7.6% of its input, and the whole chain is bounded above by its weakest stage. Three such chains in parallel deliver `0.227850`.

5.15 The minimum viable gain, computed on this framework's arrangement

The channel-gain paper computes a minimum viable gain on its own worked group [Curzi, 2026ab]. Here is the same computation on the arrangement this framework carries, which makes the result usable inside the frequency register.

Take case 2b as the arrangement: `S = F = 2.153633`, `C = c = 0.40`, `delta = 0.09`, `N = 12`, `ln N = 2.484907`. Then a belief-driven channel of gain `G` is worth holding this period only if it clears the decay on the existing stock plus the maintenance cost:

```
G_min (growth this step)   =  (delta * Q_t + C) / S
G_min (headroom >= 0)      =  (delta * Q_t + C) / ln N
```

Q_t	G_min (growth)	G_min (headroom)
0.0000	0.185733	0.160972
1.0000	0.227523	0.197191
3.0000	0.311102	0.269628
6.0844	0.440000	0.381342
10.0000	0.603631	0.523158

Read the fourth row. At the fixed point, `G_min` equals `eta` exactly — `0.440000` against `eta = 0.44` — which is not a coincidence but the definition of a fixed point restated: the required gain at the destination is the gain that produced the destination. **The threshold rises with the stock, which means a belief channel sufficient to build an arrangement from nothing is not sufficient to maintain it once built.**

And the `G = 0` row deserves its own paragraph, because it is the arithmetic of an ungrounded belief:

```
no channel, F = 0, so the drive is  −C  and  Q_inf = −C/delta

C = 0.05, delta = 0.09  ->  Q_inf = −0.555556
C = 0.10                ->  Q_inf = −1.111111
C = 0.20                ->  Q_inf = −2.222222
C = 0.40                ->  Q_inf = −4.444444
```

A belief with no channel does not merely fail to build anything. Maintenance still bills, so **the fixed point is negative in proportion to what holding the belief costs, and the arithmetic says so without any need for moralising about it.**

Now the audit, run backwards, against the specific claim this section exists to adjudicate: *can believing differently close the carried dyad's 4.338420-octave deficit?* The question is well-posed, because the deficit's four inputs are the only routes:

```
through u    : u must reach 0.627132 from 0.068735, a factor of 9.1240
               -- a change in what the parties actually hold and do
through eta  : eta must reach c/F = 1.101077
               -- ABSENT. No belief reaches an efficiency above one.
through c    : c must fall to eta F = 0.168925, a cut of 72.754%
               -- a change in what the arrangement costs to run
through N    : ~200 categories at fixed u, or a real geometry change first
```

Two of the four routes are changes in what people do, one is arithmetically unreachable, and one is a change in a description that must satisfy the framework's validity conditions. So the postulate gives a clean and deflationary answer: a belief that produces the behavioural change — the states actually occupied, the commitments actually taken on, the decision log actually kept — moves the destiny by exactly the amount that change is worth, which is computable in advance. A belief that produces no such change has an empty channel sum and moves the destiny by zero, while continuing to bill its maintenance cost.

5.16 What testimonials are worth The companion result is the survivorship arithmetic [Curzi, 2026], and it is the sharpest thing in this section.

A corpus of testimonials is a record of successes, published because they were successes. The modern statement of the same defect is the selective-publication literature [Ioannidis, 2005, Simmons et al., 2011, Gelman and Loken, 2013], and its measured consequence is that a large replication programme recovers far less than the original record implies [Open Science Collaboration, 2015]. The probability that a published account reports a success is therefore 1, under every hypothesis about how often the method works. The likelihood of the observed corpus is the product of those probabilities, and the likelihood ratio between any two hypotheses is that product divided by itself.

```
P(account reports a success | published, p = 0.900000)  =  1.000000
P(account reports a success | published, p = 0.010000)  =  1.000000
P(account reports a success | published, p = 1.0e-09 )  =  1.000000

likelihood ratio, at any corpus size n:                    1.000000
log10 LR                                                   0.000000
bits of evidence supplied                                  0.000000
```

A likelihood ratio of exactly 1.000000 means the evidence does not move the posterior at all. Not weakly, not a little — not at all. **A thousand accounts from people for whom a method**

worked carry precisely the weight of zero accounts, because the selection guarantees that successes are observed whether or not the method does anything.

The precedent is Abraham Wald's wartime work on aircraft armour — the bullet-hole data were conditioned on the aircraft returning, so the places with no holes were the places to armour. **That work is not in this paper's bibliographic database and is named here without a citation key.** A manifestation corpus is the returning aircraft. It is a census of survivors presented as a census of attempts.

Three operating consequences, and they are the reason this framework's protocols look the way they do. **The base rate is unobtainable from testimonials in principle, at any corpus size** — a thousand more accounts add a thousand numerators and no denominator, so the problem is not sample size and cannot be fixed by more of the same. Getting a denominator requires enrolling before the outcome is known, which is a cohort design and is why preregistration is mandatory rather than advisable [Nosek et al., 2018]. The framework's own preregistered fit is the relevant precedent [Curzi, 2026i]: it failed its own second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin, despite $+40.3$ per cent over persistence, $+97.7$ per cent over direct input, and $p = 0.0005$ against the shuffle. And the contrast is enormous once the denominator exists: a constructed cohort of 100 enrolled with 90 successes yields a likelihood ratio of `9.66e+15` between `p = 0.9` and `p = 0.5`, against `1.000000` for any number of testimonials whatever.

The companion result completes the picture and it is the practical rule. Likelihood ratios measured at `2.0000` for a prediction specifying only a DIRECTION versus `11.3577` for one specifying a MAGNITUDE: **a prediction with a number attached is about 5.68 times more evidentially powerful, and a belief that predicts only a direction is not yet testable.** That is the precise justification for the requirement that a lever plan state its target value before it is executed.

The specification

5.17 PROCEDURE CHANGE — planning a change of destiny **Step 1. Produce a complete destiny reading first** (§4.17, PROCEDURE DEST, all ten steps). No lever may be discussed before `D`, `delta`, `Q_inf` and the export test are on the page.

Step 2. Run the ceiling test. If `c/eta > ln N`, stop. The case is structural. Report it as structural and go to Step 9.

Step 3. Compute all four reserves — `R_u`, `R_eta`, `R_c`, `R_N` per category — against the deficit. Report which levers close it alone and which do not.

Step 4. Compute the elasticities and report them separately from the reserves, with the statement that they answer different questions.

Step 5. Check the sign of the drive. If `eta F <= c`, no `delta` intervention may appear anywhere in the plan until a later step has made the drive positive. This is a step constraint, not advice.

Step 6. Assign every proposed action to exactly one handle — `u`, `N`, `eta`, `c`, `delta` — and state the target value with a number attached. A proposal that cannot be assigned moves nothing; a proposal without a target value is not yet testable (the direction-versus-magnitude result).

Step 7. For every action whose mechanism runs through what somebody believes, run the coupling audit. Name the channel, classify it, estimate its gain from the channel's own mechanism and not from the outcome, compose series and parallel, and compare the summed gain against the gain the claim requires. Report the audit whether it passes or fails.

Step 8. Test cost cuts for conversion damage. Before cutting `c`, ask whether the cost being cut performs conversion work. If it does, `eta` falls with it and the ratio may not improve.

Step 9. Order the actions: numerator first, loss second. Publish the projected trajectory as well as the projected fixed point, and check that the trajectory does not pass through negative

stored order.

Step 10. Re-read after the intervention and publish the before-and-after in the §4.19 reporting format, including the export test, including `delta` alongside `D`, and including the cases where the plan did not work.

5.18 Gates

```
GATE 5-1   destiny reading complete before any lever discussed      FAIL -> stop
GATE 5-2   u interventions checked against the one-hot artefact     FAIL -> re-elicit
GATE 5-3   ceiling test run first                                   FAIL -> incomplete
GATE 5-4   reserves AND elasticities both reported, separately      FAIL -> incomplete
GATE 5-5   no delta action scheduled while the drive is negative    FAIL -> reorder
GATE 5-6   every action assigned to one handle, with a target value FAIL -> not a plan
GATE 5-7   coupling audit run on every belief-mediated action       FAIL -> unaudited
GATE 5-8   cost cuts tested for conversion damage                   FAIL -> incomplete
GATE 5-9   trajectory published, not only the fixed point           FAIL -> incomplete
GATE 5-10  consent re-asked at every stage that changes the action  FAIL -> halt
```

The failure modes

FM 5.1 — THE UNASSIGNED PROPOSAL. *Signature:* an intervention that cannot be attached to `u`, `N`, `eta`, `c` or `delta`. *Mechanism:* Theorem 5.1. `Q_inf` has four arguments and a proposal touching none of them moves it by zero. *Fix:* Gate 5-6.

FM 5.2 — TRUST FIRST. *Signature:* "we will build trust and things will improve." *Mechanism:* the ordering rule. In the constructed case this takes `Q_inf` from `-5.011940` to `-45.107456` while `D` does not move at all. *Fix:* Gate 5-5.

FM 5.3 — THE STRONGEST LEVER ASSUMED SUFFICIENT. *Signature:* a plan built on the largest elasticity. *Mechanism:* Theorem 5.3. At the carried dyad `eta` has 4.80x the elasticity and 4.174198 octaves of reserve against a 4.338420 requirement. *Fix:* Gate 5-4.

FM 5.4 — THE ABSENT LEVER PRICED AS AN EXPENSIVE ONE. *Signature:* a budget for raising `eta` to a required `1.101077`. *Mechanism:* a conversion efficiency above one would mean more structure created than interaction supplied. *Fix:* compute `c/F` before planning the lever.

FM 5.5 — MANUFACTURED DISAGREEMENT. *Signature:* a party adopting contrary positions to raise `u`. *Mechanism:* `u` depends on `|rho|`; opposition reads `u = 0` exactly as agreement does, and the cost rises. *Fix:* §5.8's test — would it still be true if nobody were reading the number?

FM 5.6 — `u` RAISED BY RE-DESCRIPTION. *Signature:* a reading of `u = 1.000000` after a re-elicitation. *Mechanism:* disjoint support is automatically orthogonal. *Fix:* Gate 5-2.

FM 5.7 — CATEGORIES ADDED TO A NEAR-PARALLEL SET. *Signature:* a plan to raise `N` in a system at low `u`. *Mechanism:* `0.112937` octaves per category at the carried dyad and `0.044581` at the commons; two hundred categories to close what one geometry change closes. *Fix:* raise `u` first, or accept that the case is structural.

FM 5.8 — INDEX INFLATION. *Signature:* `N` rises after a re-description that distinguishes nothing new. *Mechanism:* components that always co-occur are one component [Curzi, 2026]. *Fix:* the framework's validity conditions, applied to each added category.

FM 5.9 — THE COST CUT THAT CUTS CONVERSION. *Signature:* overhead removed and the ratio `c/eta` unimproved or worse. *Mechanism:* `R_c` is computed at fixed `eta` and cost cuts do not generally hold `eta` fixed. *Fix:* Gate 5-8.

FM 5.10 — THE MARGINAL VERDICT ACTED ON. *Signature:* a plan launched on a deficit of `+0.584737` with `eta` known to `± 0.05`, an uncertainty of `± 0.9734` octaves. *Mechanism:* the sign is unresolved. *Fix:* a verdict is resolved only when the deficit exceeds its own uncertainty.

FM 5.11 — THE DESTINATION EVALUATED AND THE PATH IGNORED. *Signature:* "the fixed point does not depend on the order, so the order does not matter." *Mechanism:* true and irrelevant; the constructed case shows 12 periods of permanent lag, 13 periods below the starting stock, and 111.133601 stock-periods of cumulative loss. *Fix:* Gate 5-9.

FM 5.12 — BELIEF WITHOUT A CHANNEL. *Signature:* an intervention whose mechanism, when asked for, is that someone will believe it. *Mechanism:* the coupling requirement; an empty channel sum gives `E = 0` at every `B`, while `C` continues to bill, so `Q_inf = −C/delta`. *Fix:* Gate 5-7.

FM 5.13 — THE GAIN FITTED TO THE OUTCOME. *Signature:* a channel gain estimated from the result it is supposed to predict. *Mechanism:* the apparatus is unidentifiable unless `G` comes from the channel's own mechanism [Curzi, 2026ab]. *Fix:* estimate `G` without touching the outcome, then predict.

FM 5.14 — THE MAGNITUDE ERROR. *Signature:* an effect promised that is larger than every named channel summed at maximum belief. *Mechanism:* the bound of 77.1. A four-stage series channel of individually respectable stages delivers `0.075950`. *Fix:* run the audit before collecting data.

FM 5.15 — TESTIMONIALS AS EVIDENCE. *Signature:* a lever recommended on the strength of accounts from people it worked for. *Mechanism:* the survivorship arithmetic [Curzi, 2026]. The likelihood ratio is exactly `1.000000` at any corpus size. *Fix:* a cohort with the denominator observed, preregistered.

FM 5.16 — THE DIRECTION-ONLY PREDICTION. *Signature:* "this will improve things." *Mechanism:* direction-only predictions carry `LR = 2.0000` against `11.3577` for a prediction with a magnitude. *Fix:* Gate 5-6's target value.

FM 5.17 — A LEVER PULLED ON SOMEBODY ELSE. *Signature:* a plan that raises `u` by requiring another party to change. *Mechanism:* the consent law [Curzi, 2026]; the lever is real and the procedure is not available. *Fix:* Gate 5-10, and §5.7.

Worked examples

5.19 The four handles, one at a time, on the carried dyad **CONSTRUCTED. Not an observation of any person or pair.** The pair start as found and each row adds one handle to the row above it, in the order the ordering rule requires [Curzi, 2026q].

step	u	eta	c	F	D	Q_inf	f_rel
0 as found	0.068735	0.30	0.620	0.563085	+4.338420	−5.011940	1.4908
1 geometry only (u)	0.692373	0.30	0.620	2.153633	−0.250931	+0.289887	35.8882
2 + conversion (eta)	0.692373	0.44	0.620	2.153633	−2.148294	+3.639982	35.8882
3 + cost (c)	0.692373	0.44	0.400	2.153633	−3.590989	+6.084427	35.8882
4 + trust (delta .09 -> .05)	0.692373	0.44	0.400	2.153633	−3.590989	+10.951968	35.8882

(Q_inf at delta = 0.09 for rows 0–3; row 4 is the same arrangement at delta = 0.05)

Read the columns. The geometry step alone flips the sign of both readings — a deficit of `+4.338420` becomes `−0.250931` and a destiny of `−5.011940` becomes `+0.289887` — and **it is the only step in the table that changes `f_rel` at all.** The two cost-side steps then buy `3.34` octaves of deficit and `5.79` units of destiny between them, and they are only available because the drive is already positive. The trust step buys `4.868` units and moves the deficit by nothing, which is Theorem 5.2 appearing on the page.

Now the same four handles in the order the intuition prefers:

```
step                          u          eta    c      delta   D           Q_inf
-------------------------------------------------------------------------------
0  as found                 0.068735   0.30   0.620   0.09    +4.338420    -5.011940
1  trust first              0.068735   0.30   0.620   0.05    +4.338420    -9.021491
2  trust harder             0.068735   0.30   0.620   0.02    +4.338420   -22.553728
3  trust absolutely         0.068735   0.30   0.620   0.005   +4.338420   -90.214912
```

Four rows of an unchanging instrument and an eighteenfold deterioration in the destiny. Every step in that table is an intervention a reasonable person would call good practice, and every step makes the arrangement worse, and the deficit — the framework's own central instrument — reports nothing at any point. **That is the single strongest argument in this framework for publishing `delta` alongside `D`, and it is why Gate 4-4 exists.**

5.20 The commons: the procedure halts CONSTRUCTED. Not an observation of any group.

Six members drawn from one doctrine, 15 pairs, mean pairwise `u = 0.018614`, cost `kappa = 0.055` per link, `eta = 0.34`, `delta = 0.09`.

```
reading      F = 0.186272 nats   N_eff = 1.204754   f_rel = 0.7017 Hz
             f_min = 61.9349 Hz  D = +6.463837 octaves   Q_inf = -8.4630   DECAYS
ceiling      c/eta = 2.426471 vs ln N = 2.484907  -> passes by 0.058436
reserves     R_u = 6.632448  R_eta = 4.620867  R_c = 7.001314  R_N/cat = 0.044581
single-lever raise u to 0.95    -> deficit -0.0332   at near-orthogonality
             raise eta to 0.90  -> deficit +2.1075   still failing
             cut kappa to 0.020 -> deficit +2.0085   still failing
VERDICT      PROCEDURE HALTS. No single lever closes this in practice.
```

The reserves say two levers close it in principle. The single-lever table says what those in-principle closures actually require: six people who share almost no state, or coordination at near-zero cost. Neither describes a commons. And the roster ceiling is the reason: at `m(m-1) = 30` against a bound of `2 eta ln N / kappa = 30.722482` — inside it by 0.722482 — a seventh member takes the group to 42 and makes the case structural outright.

This is the case the framework keeps because it does not work. The lesson is not that the group should disband — the formalism prices stored order and nothing else, and a family, a team or a commons is for things the formalism does not represent. The lesson is that a lever plan for this arrangement would have been a plan for a case with no solution, and the ceiling test and the reserve table are what say so before anybody spends a year on it.

5.21 The coupling audit, run on a lever claim CONSTRUCTED. Not an observation.

Take the claim: *the pair will close their 4.338420-octave deficit by committing to a shared vision of the relationship they want.*

```
Step 6  ASSIGN THE HANDLE.  The proposal names no handle. Ask which of u, N, eta, c, delta
        it moves. Two answers are possible and they audit completely differently.

ANSWER A -- "it moves what we each take on."  -> handle L1 (u). Testable. Target value
        required: u >= 0.627132. Channel: behavioural, the dominant class. Gain estimated
        from behaviour records, not from the outcome. AUDITABLE, and Gate 5-6 satisfied
        once the target is stated.

ANSWER B -- "it moves how we feel about it."  -> no handle. The four arguments of Q_inf do
        not contain a term for how an arrangement is regarded. Channel sum is empty:
        E = 0 at every B. And the arrangement still bills: with F unchanged at 0.563085,
        eta 0.30, c 0.62, delta 0.09, the destiny remains -5.011940 exactly.
```

```
Step 7  THE BOUND.  Required change in the drive to reach Q_inf = 0:  +0.451075 per pass.
        Available from Answer B's named channels, summed:              0.000000
        VERDICT: over budget by the entire amount, before any data are collected.
```

That is the postulate doing its work in both directions in one example. Answer A is a real channel with a real gain and the postulate says it moves the world by exactly what the channel can carry. Answer B has no channel and the postulate says nothing happens — and says it as arithmetic rather than as disapproval.

5.22 What this section establishes, and what Section 6 takes **Established, and checkable.** That `Q_inf` has exactly four arguments and five handles, with `F` reached only through `u` and `N` (Theorem 5.1); that `delta` cannot change the sign of a destiny at any magnitude, so it is a multiplier on an existing sign rather than a lever on the gap (Theorem 5.2); that a lever can be absent rather than expensive, demonstrated on a lever with 4.80 times the elasticity of its rival and 4.174198 octaves of reserve against a 4.338420 requirement (Theorem 5.3); that reversing the ordering rule costs 12 periods of permanent lag, 13 periods below the starting stock, and 111.133601 stock-periods of cumulative loss in the constructed case; that an arrangement over the `c/eta <= ln N` ceiling is structural and no geometry closes it, worked at `c/eta = 3.000000` where even perfect orthogonality leaves `+1.486245` octaves and twenty-one categories are required; that a belief moves a destiny only through a channel whose gain is estimable from its own mechanism, with an empty channel giving `Q_inf = −C/delta`; and that testimonial evidence carries a likelihood ratio of exactly `1.000000` at every corpus size.

Not established, and not claimed. That any lever prescription here applies to any actual person, pair or group; that a larger fixed point is a better outcome; that belief has any effect through any channel not named and estimated; that any reading here is diagnostic, therapeutic or clinical; or that the frequencies printed here are physical resonances.

The one line to carry forward: *there are four arguments, the reading says which one binds, and the ones that are absent are absent no matter how much anybody wants them.*

Section 6 states the keystone once more in full — $f_{\min} = k\, e^{2c/\eta}$, the 2.885 octaves per unit of cost ratio, and the $c/\eta \le \ln N$ ceiling — and sets beside the framework's results the six findings that constrain them.

6 The sustaining frequency, and the six results that constrain it

This section closes the argument. It has three jobs and they are in a deliberate order.

The first is to state the keystone once more, in full, with nothing left implicit — because this series of papers exists to join two halves of one equation that were laid down separately, and gesturing at the join instead of writing it out would settle nothing.

The second is to draw the arc across the framework honestly: reading a gradient, building a circumstance, and then tuning the relation between them. That arc is not a story of accumulating power. At each stage the instrument got sharper and the set of things it was entitled to say got smaller, and both halves of that sentence belong in the summary.

The third is to set beside the result the findings that constrain it. There are six of them and every one is a limitation. A surplus law that turns out to be a nineteenth-century psychophysical law with a threshold; a consonance that turns out to be redundancy; an interaction parameter that cannot tell perfect agreement from perfect opposition; a group whose whole surplus is available to a well-chosen pair; two frequency readings that cannot be inferred from each other; and a central diagnostic that is blind to decay. **Those six are the real yield, and each of them narrows what the instrument can be used for.** A summary that listed the affordances and omitted the constraints would be selling something.

Then the section stops on the open problem stated in the companion paper [Curzi, 2026], which is not solved, not softened, and not worked around. **The restraint is the argument.** Work that names its own load-bearing gap this precisely earns the right to everything else in it; work that declines to name it forfeits the right to all of it, including the parts that are correct.

The law

6.1 The keystone, in full The two halves were established separately and never multiplied.

```
THE ESSENCE BRIDGE          f  =  k ∗ e^(2F)      k = 0.483425732988414 Hz

THE STORAGE FIXED POINT     Q     =  ( eta ∗ F(u∗) − c∗ ) / delta
                             inf
```

The bridge says an interaction's surplus has an exact pitch. The fixed point says where a relation, a life or an institution arrives if its parameters hold. Sustainability means the fixed point is positive:

```
Q     >  0     <=>     eta ∗ F  >  c     <=>     F  >  c / eta
 inf
```

And the bridge inverts. If `f = k e^(2F)` then `F = (1/2) ln(f/k)`. Substitute:

```
(1/2) ln( f/k )  >  c/eta        =>        f  >  k ∗ e^( 2c / eta )
```

which is the keystone, and it is a substitution rather than a postulate — given the two halves, this line follows and nothing was added to obtain it.

THE MINIMUM SUSTAINABLE FREQUENCY

```
f     =  k ∗ e^( 2c / eta )
 min

f > f_min     the relation ACCUMULATES order          Q_inf > 0
f = f_min     it HOLDS, and nothing more             Q_inf = 0
f < f_min     it DECAYS, whatever anyone intends     Q_inf < 0
```

The condition for a relation to pay for itself is not a ratio, not a policy, and not a virtue. It is a pitch.

In octaves above the ground essence `k`, the statement becomes an exchange rate:

```
octaves required  =  2 (c/eta) / ln 2  =  2.885390 ∗ (c/eta)
```

Every unit of cost-to-conversion ratio costs 2.885390 octaves of required pitch. Computed:

```
 c/eta      f_min (Hz)      octaves above k
 0.000        0.483426          0.000000
 0.250        0.797034          0.721348
 0.500        1.314087          1.442695
 0.750        2.166564          2.164043
 0.909091     2.978216          2.623082
 1.000        3.572060          2.885390
```

```
1.500        9.709865          4.328085
2.000       26.394151          5.770780
2.066667   30.158790          5.963140
2.484907    69.613354          7.169926   <- the ceiling at N = 12
3.000      195.027860          8.656170
4.000     1441.071800         11.541560
```

6.2 The ceiling The third component of the keystone is a bound, and it is the ceiling result in the frequency register [Curzi, 2026]. Since `F <= ln N`, the maximum sustainable cost ratio is capped:

```
c / eta  <=  ln N            equivalently        f     <=  k * N^2
                                                  min
```

At twelve categories, `c/eta` may not exceed `2.484907` and `f_min` may not exceed `69.6133055503 Hz`. Above that, **no arrangement of those twelve categories is sustainable** — not a better pairing, not a better schedule, not more effort. The only remedies are: raise `eta`, cut `c`, or add genuinely distinct categories.

N	ln N	max c/eta	f_max = k N^2 (Hz)	octaves
2	0.693147	0.693147	1.933703	2.000000
3	1.098612	1.098612	4.350832	3.169925
4	1.386294	1.386294	7.734812	4.000000
6	1.791759	1.791759	17.403326	5.169925
12	2.484907	2.484907	69.613306	7.169926
17	2.833213	2.833213	139.710037	8.174926
25	3.218876	3.218876	302.141083	9.287712
41	3.713572	3.713572	812.638657	10.715104
100	4.605170	4.605170	4834.257330	13.287712

The ceiling is the most useful single line in the apparatus for the purposes of refusing work. It converts a class of problems from difficult into unavailable, and it does so before any effort is spent. A test that can say "no arrangement of these categories works" in one division is worth more to a planner than any number of tests that say "try harder."

6.3 What the keystone unifies Three laws that entered the corpus from three different directions land on one threshold.

The essence law gives a state a frequency: $f = kn^2$, with $k = (9/8)^2/\varphi^2 = 0.483425732988414$ Hz. The constant is **defined**, not measured — an exact ratio of the Pythagorean whole tone [Barbour, 1951] to the square of Euclid's extreme and mean ratio [Euclid, 1956, Vajda, 1989] — and its fifteen figures are exact digits of a definition. **Attaching hertz to it is a separate and much stronger claim and is postulated.** The deflationary literature on golden-section claims is cited rather than avoided [Markowsky, 1992, Fischler, 1981, Höge, 1997]: φ is being *chosen* as a constant here, not *found* in anything measured. The square law is likewise a postulate whose exponent is **defined by the model, not estimated**; no fit was performed and the standard procedure for testing a claimed scaling relation [Clauset et al., 2009] was not run, because there is no data to run it on. Both carry their badges here as everywhere.

The surplus law gives an interaction a magnitude: $F = \ln(1 + (N-1)u)$, a theorem under the framework's own axioms, bounded above by $\ln N$.

The storage law gives an arrangement a destination: `Q_{t+1} = (1-delta)Q_t + eta F - c`, with the fixed point `Q_inf = (eta F - c)/delta`, a proved property of a linear recursion.

The bridge `f = k e^(2F)` is what makes them commensurable, because it puts the surplus and the frequency in the same register — the logarithm — and once they are in the same

register the sustainability condition of the third law can be written as a threshold in the units of the first.

The join is arithmetic, and it is the whole of this material's contribution. What it buys is that a question about whether an arrangement pays for itself becomes a comparison of two numbers in hertz, and both of them are computable from measurements a practitioner can actually take.

6.4 The diagnostic, and the two numbers that must travel together

```
octave deficit   D  =  2.885390 * (c/eta)  -  log2( f/k )
                   =  2.885390 * ( c/eta  -  F )

D <= 0    sustainable as it stands
D >  0    short by that many octaves; four levers: raise u, raise eta, cut c, raise N
```

And the identity that Section 4 owns:

```
D  =  - 2.885390 * ( delta / eta ) * Q
                                     inf
```

verified to `8.88e-16` across twelve constructed parameter sets. **The octave deficit and the fixed point are the same number in different units.**

But `D` contains no `delta`. **The deficit reads the SIGN and the SIZE of the gap; `delta` converts it to a LEVEL; and a reading that reports one without the other is incomplete.** The carried dyad as found reads `D = +4.3384201973` at `delta = 0.30`, at `delta = 0.09`, at `delta = 0.05` and at `delta = 0.01`, while its destiny moves from `-1.5035819` to `-45.1074559` across the same column. This is a genuine limitation of the framework's central instrument and it is stated here rather than left in the section that derived it.

6.5 What the keystone does not say Five refusals, and they are not decorative. Each one marks a place where the formalism has been mistaken for something larger.

It asserts no physical resonance. Every hertz value in three books is a position on a logarithmic scale of surplus. No person, bond, tissue or molecule is claimed to vibrate at any value anywhere in this corpus, and nothing here is to be played at anyone.

It makes no clinical, diagnostic or therapeutic claim. The twelve states are not diagnoses, a reading is not an assessment, and no procedure here treats anything. A reader who needs support for a relationship or for their health should seek it from someone qualified to give it, which this framework is not.

It confers no capability and edits no DNA. The companion paper specifies an encoder, an addressing convention, a sonifier and a rendering discipline [Curzi, 2026]. It specifies a research procedure and labels it as one.

It hides nothing. No subliminals, nothing masked, nothing below threshold. Open-label placebo works, so disclosure costs nothing that matters.

It removes nobody's ability to decline. Consent is structural, re-asked at every stage that changes what is done, and no reading in this framework licenses an intervention on a person who has not agreed to it.

And one more, which is about the scale rather than the ethics. **The keystone inherits exactly the defensibility of its inputs.** The index `n` is a count and is ratio-scaled by construction, so it sidesteps the scale demotion [Curzi, 2026m]; the intensities `w` are ordinal by default and must be magnitude-estimated before any relationship number is printed, because an ordinal-preserving relabelling moves `u` from `0.362115` to `0.525275` — 1065.05 cents, nearly an octave, from a change an ordinal scale calls no change at all. Where the intensities were not magnitude-estimated, the relationship frequency is not determined and no number may be printed.

6.6 Three through-lines, and what each one costs Before the arc, three statements that hold in every volume of the series and that a reader should carry away even if nothing else survives. Each is a genuine finding and each has a price attached that the popular version of the same idea leaves off.

The loss term is where everything happens. `delta` appears in no diagnostic and decides every level. It sets the half-life, it sets the depth of the fixed point, it sets how long a repair takes to show, and it is the parameter the octave deficit cannot see. Three books of interventions reduce, in the end, to a question about a leak: how fast does an arrangement forget what it made? The price of this through-line is the one §6.12(f) names — because `delta` is absent from `D`, the instrument that reads sustainability is silent about the parameter that decides the level, and there is no version of the reading in which one number suffices.

Difference generates surplus, and only real difference does. `F = ln(1 + (N−1)u)` is increasing in `u`, so a relation's stored order comes from the non-parallelism of what its parties hold. That is the affirmative half and it is genuinely useful: it says that a bond, a team or an institution whose members converge on one description is losing its capacity to produce anything, and it says so with a number. The price is Result (c). `u` depends on `|rho|` alone, so opposition reads exactly as agreement does, and the difference that raises `u` has to be difference in what is actually held and done — states occupied, commitments taken on, work done in a domain the other is not in. The test of a `u` intervention is whether it would still be true if nobody were reading the number, and no rearrangement of the arithmetic will substitute for that.

Geometry does work that power does not. Every result in the corpus about arrangement — the table with no head, the silo, order without a centre, the roster ceiling, the dyad's interval — is a claim that the shape of a set of relations changes what it can store, independently of how much is put into it. The keystone is the compressed form: `f_min` depends on `c/eta` and on nothing else, so an arrangement that converts better or costs less needs less pitch, and an arrangement that converts badly cannot be rescued by volume. The price here is Result (d). Geometry's yield is bounded by `ln N`, an orthogonal pair already attains it, and beyond a pair the shape buys coverage and continuity rather than surplus. Geometry is powerful and it is capped, and the cap arrives at two participants.

The engineering

6.7 Reading a gradient The framework's foundational layer asks no arithmetic of its reader [Curzi, 2026]. Its output is a perceptual skill: the ability to notice that a circumstance has a direction — that a room, a conversation or an arrangement is either accumulating something or losing it, and that the difference is visible before it is measurable.

Three of its constructs turn out to be theorems in the later corpus, and the correspondence is drawn rather than asserted [Curzi, 2026a]. Its recursion construct is the transient $(1-\delta)^t Q_0$ decaying while the driven term builds. Its fixed-point construct is the object §4 defines as destiny. And its prohibition on intervening at another party's expense is converted by §4.15 into an arithmetic test: compute the deficit and the fixed point for every participant separately, then compute the sum of drives, and if one participant improved while the sum did not move, the gain was exported and nothing was produced.

That conversion is the clearest single illustration of what the framework is for. A prohibition of that form is unfalsifiable in the way a testimonial is — it reports an intention, and the intention is always available. The identity `sum_i b_i` invariant under any transfer of cost among any number of participants is not unfalsifiable at all. It costs one column of a report and it returns an answer on the first pass.

What should also be said about that layer is what it deliberately withholds. It asks no arithmetic of its reader and offers none, so a reader who finishes it has a perceptual skill and no apparatus. That is not a simplification for a general audience; it is the correct ordering. A person who can compute an octave deficit for a circumstance they have not learned to

perceive as having a direction has a number with nothing to point it at, and the failure is silent — the computation runs, the reading prints, and it is a reading of the wrong thing. Each stage is unusable without its predecessor, and the failure at each boundary is different: **without the reading, a number with no referent; without the building, a diagnosis with no intervention; without the join, an intervention with no test of whether it paid.**

6.8 Building a circumstance The framework's engineering layer takes the storage law and builds outward: the room as a circuit, acoustics, thresholds, light and material, the table with no head, order without a centre, institutions as storage [Curzi, 2026h]. Its output is an apparatus for constructing circumstances rather than reading them; its Result Two prices the difference exactly — moving η from 0.35 to 0.55 and δ from 0.25 to 0.12 takes a fixed point from 0.2653 to 3.9281, while a turnover event still costs 70 per cent of stock against 15.

Two further results carry into the close. The first is the headroom gauge $h = \eta \ln N - \delta Q - C$, which says when no arrangement of the available categories improves the system regardless of what anyone does. The second is the concavity rule — feasibility must be tested on the mean of $F(U_t)$ and never on F of the mean, worth 6.2 per cent in the worked case — which is why this framework forbids aggregating ratios across sites.

6.9 The instrument turned inward The same apparatus turned on the person gives the self as storage, the internal surplus, the moment equation, the psychophysics, the gradient and the contraction.

And it demoted its own keystone formula at the gate its author wrote [Curzi, 2026m], whose Result Two fixes the moment equation's fixed point at $D = P$, $r = 1$, $M = E$, with unit elasticity of exactly ± 1 in all three terms and the ceiling $0 \le M \le \ln N$ making the $P \to 0$ divergence finite. The moment equation is demoted on scale: D/P may be used ordinally only — direction and ordering, never a numeric magnitude — pending Rasch instrumentation at 123 items per term. Every psychological frequency derived through D/P inherits the demotion, and this paper says so in place, every time.

That demotion is the reason the join could be attempted at all: the apparatus that could audit a join was built first and used on itself first. Producing the keystone earlier would have produced it without the means to check it.

6.10 Carried to the cell The instrument carried down gives the cell as receiver, addressing, sonification, the Gabor limit, the channel-gain postulate and the grounding protocol [Curzi, 2026,ab]. The output is a specification and a catalogue of failures — the four channel classes with their gains, the places where belief demonstrably does nothing, and a likelihood ratio of exactly 1.000000 for testimonial evidence [Curzi, 2026].

And it stopped. It named the gap — no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal — and does not go past it [Curzi, 2026]. This section ends on it.

6.11 Tuning the relation This series of papers multiplies the two halves and then finds out what the product will and will not support.

The essence law is carried into psychology on a component index n — a count of the distinguishable components required to specify a state — and the count is defended against the obvious objection that deciding what counts as one component is itself a judgment. The honest limit was stated wherever the index was used: **the frequency inherits exactly the defensibility of the count, and a contested decomposition yields a contested frequency.**

The dyad is then built as an interval, $f_{\text{rel}} = k(1 + 11u)^2$, producing the octave deficit — a computable reading of whether a bond pays for itself [Curzi, 2026] — together with the reserve theorem, the elasticities, the order rule and the constructed cases in which the procedure halts.

A tradition is then audited on its own material and what failed is printed [Curzi, 2026,?]. The strongest single item: a canonical twelve-operation schedule of 1471, run as a schedule under this framework, places **the only numerator-acting operation ninth of twelve** — lowering loss before fixing the numerator, which is exactly the order the elasticities show accelerates failure. And the element rule $f = kn^2$ and the compound rule $f = k^2G^4$ cross at $n = 1/\sqrt{k} = 1.438252$, not an integer, so they coincide at no index at all [Curzi, 2026].

The cellular procedure is specified with every honesty clause in place, and then it is stated that nobody knows how a cell could read an ordered message out of a sound [Curzi, 2026].

6.12 What the series actually produced — the six results that constrain it Every one of these is a narrowing. That is why they are the yield.

Result (a) — the surplus law is exactly a Fechner law with threshold `u_0 = 1/(N−1)`.

```
F(u)  =  ln( 1 + (N−1) u )
      =  ln( (N−1) ∗ ( u + 1/(N−1) ) )
      =  ln( (u + u_0) / u_0 )                with  u_0 = 1/(N−1)
```

That is Fechner's law in threshold-corrected form [Fechner, 1860, 1966, Weber, 1834], `S = k ln((I + I_0)/I_0)`, with `k = 1`, the stimulus being non-parallelism and the threshold intensity being `u_0`. Verified for `N = 2` through `N = 100` at seven values of `u` each; maximum residual `4.44e−16`.

The threshold has a meaning that is not an artifact of the algebra. Evaluate the law at it, at every `N`:

```
N_eff(u_0)  =  1 + (N−1) ∗ 1/(N−1)  =  2.000000000000    exactly, for every N
F(u_0)      =  ln 2  =  0.693147180560 nats  =  1 bit  =  2 octaves
```

The threshold is exactly the point at which the effective count reaches two: below `u_0` the system does not yet contain a second independent voice, **and the threshold is one full bit wide.** Its size is a design fact: `u_0 = 1.000000` at `N = 2`, where the threshold *is* the ceiling; `0.500000` at `N = 3`; `0.090909` at `N = 12`; `0.010101` at `N = 100`. Narrow systems are hard to get anything out of not because their members are worse but because the threshold sits at the top of their range.

Two cautions attach. The psychophysical warrant is contested in its own literature [Luce, 2002, Krueger, 1989, Stevens, 1957], and the warrant this framework's arguments actually need is not psychophysical at all: a logarithmic evaluation follows from multiplicative dynamics with no psychological assumption whatever [Peters and Gell-Mann, 2016]. What this establishes is not evidence for either formalism. The framework's law is a theorem under its own axioms and gains nothing from resembling Fechner's [Fechner, 1860, 1966]; Fechner's is an empirical claim and gains nothing from resembling this one. What independent arrival does establish is that the logarithm is not a stylistic choice in this corpus — it is the register both routes landed in.

Result (b) — consonance and redundancy are the same phenomenon. Because `(2n)^2 = 4n^2`, doubling an index raises the frequency by exactly two octaves, so two essences share a pitch class if and only if their indices have the same odd part, and an ordered set `1..N` contains exactly `ceil(N/2)` distinct classes — six at `N = 12`. Price the identification in surplus:

N	ln N	ln(N/2)	loss
4	1.386294	0.693147	0.693147180560
12	2.484907	1.791759	0.693147180560
24	3.178054	2.484907	0.693147180560
100	4.605170	3.912023	0.693147180560

The fold costs exactly `ln 2` — one bit, two octaves of surplus — at every `N` without exception. The arithmetic apparatus is standard once an index exists [Rossing et al., 2002], and assigning numerical weight to intervals is an old project [Euler, 1739, Tenney, 2015]; but what a listener finds consonant depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005], and octave equivalence and interval categories generalise less far than is usually assumed [Shepard, 1982, Demany et al., 2013, Burns, 1999]. **This paper uses the arithmetic and claims none of the perception.** Consonance in the essence lattice is not a separate aesthetic property that happens to be pleasant; it is the collapse of two categories into one, and the collapse has a price that does not depend on how many categories there were.

Result (c) — `u = 4a(1−a)`, so perfect agreement and perfect disagreement are the same measurement. With `a` the fraction of items on which two parties agree, `cos theta = 2a − 1` and

```
u  =  1 − (2a − 1)^2  =  4a(1 − a)
```

a	cos = 2a−1	u	f_rel (Hz)
0.00	−1.0000	0.000000000	0.483426
0.10	−0.8000	0.360000000	11.893047
0.25	−0.5000	0.750000000	41.363114
0.50	+0.0000	1.000000000	69.613306
0.75	+0.5000	0.750000000	41.363114
0.90	+0.8000	0.360000000	11.893047
1.00	+1.0000	0.000000000	0.483426

The table is symmetric about `a = 0.5`, and the two ends are identical. **Two parties who agree about everything and two parties who disagree about everything return the same reading — the ground essence `k = 0.483426 Hz`, no relationship at all.** The contrarian and the sycophant sound the identical note. That is a hard constraint on what `u` can be used to detect, and it is the reason manufactured disagreement is worse than useless: it raises cost and returns exactly nothing.

Result (d) — an orthogonal pair already attains `ln N`, so groups buy breadth and not depth. `F = ln(1 + (N−1) u_bar)` is maximised at `u_bar = 1`, and two unit vectors can be orthogonal. Therefore:

m	links m(m−1)/2	F at u_bar = 1	f (Hz)	cost at kappa=0.055
2	1	2.484907	69.613306	0.055000
3	3	2.484907	69.613306	0.165000
4	6	2.484907	69.613306	0.330000
6	15	2.484907	69.613306	0.825000
10	45	2.484907	69.613306	2.475000
20	190	2.484907	69.613306	10.450000

Surplus is identical at every roster size; cost grows as `m(m−1)/2`. In surplus terms a group buys nothing a well-chosen pair could not, and pays `m(m−1)/2` times as much for it. The coordination cost that grows as $m(m-1)/2$ is the same term software engineering has documented for fifty years [Brooks, 1975, Conway, 1968], and the empirical group-performance literature measures effects the surplus term does not represent [Woolley et al., 2010]. Whatever else a family, a team or a commons is for — coverage, continuity, conversion, redundancy against departure — the formalism prices stored order and nothing else, and on that axis the group's case is not a surplus case. This is the constraint that makes the roster ceiling bite: at `m(m−1) > 2 eta ln N / kappa` the case is structural, and the constructed commons sits at `m(m−1) = 30` against a bound of `30.722482` — **inside it by 0.722482, which is the whole of its margin.** A seventh member takes the roster term to 42 and the case is structural outright.

Result (e) — state frequency and relationship frequency are independent [Curzi, 2026], verified on constructed pairs spanning thousands of cents of the state lattice:

```
indices    state frequencies       span (cents)   u                f_rel (Hz)
------------------------------------------------------------------------------
(1, 2)      0.4834 /  1.9337 Hz       2400.00     1.000000000000    69.6133055503
(3, 6)      4.3508 / 17.4033 Hz       2400.00     1.000000000000    69.6133055503
(5, 10)    12.0856 / 48.3426 Hz       2400.00     1.000000000000    69.6133055503
(7, 11)    23.6879 / 58.4945 Hz       1564.98     1.000000000000    69.6133055503
(2, 9)      1.9337 / 39.1575 Hz       5207.82     1.000000000000    69.6133055503
(4, 12)     7.7348 / 69.6133 Hz       3803.91     1.000000000000    69.6133055503
```

Identical to twelve decimal places, because `u` reads the angle between vectors and is blind to which indices are occupied. **A state's frequency tells you nothing about its relationship frequency, neither may be inferred from the other, and a complete report gives both separately.** Re-indexing moves every state frequency in the system and can leave the relationship reading untouched.

Result (f) — the deficit is blind to decay [Curzi, 2026], restated in §6.4. `D` and `Q_inf` are one number in two units, and `D` contains no `delta`. The consequence is the sharpest limitation the instrument has: an intervention that doubles the rate of loss, or halves it, produces no movement in the diagnostic at all. Report both.

6.13 Why the six are the yield

Every result in that list makes the instrument smaller. (a) says the surplus law is not a new discovery about interaction but a hundred-and-sixty-six-year-old psychophysical form arrived at by a second route. (b) says a property the sonic register treats as aesthetic is the loss of a bit. (c) says the interaction parameter cannot distinguish two situations that no practitioner would ever confuse. (d) says the group has no surplus case. (e) says two of the framework's own readings cannot speak to each other. (f) says the central diagnostic cannot see the thing most people reading it will want to know.

A corpus whose strongest results are all constraints is a corpus that was checked. The alternative — a corpus of affordances, each result adding a capability and none subtracting one — is the signature of work that was never audited, and it is the signature this series has spent its length trying not to have.

6.14 The register of demotions

A corpus that audits itself has to publish the audit, and the four places where the apparatus caught its own author are the strongest available evidence that the gates are real rather than decorative. They are collected here because a closing section is where a reader will look for them.

Demotion 1 — the moment equation demoted on scale, at the framework's own gate [Curzi, 2026m]. The formula the surrounding work was built around was run through the framework's validation protocol and failed it on the scale requirement. `D/P` may be used ordinally only — direction and ordering, never a numeric magnitude — pending Rasch instrumentation at 123 items per term. The demotion travels with every psychological frequency derived through `D/P`, in this framework as in that one.

Demotion 2 — the design intuition inverted [Curzi, 2026q,s]. The corpus had been running on the assumption that trust is a source of order. The trust paper fixes where it actually enters: as retention, $\delta_{\text{eff}} = \delta_0 + (1-a)(1-v)$, giving a superlinear stock dividend from 0.4679 at $a = 0.50$ to 5.0529 at $a = 0.99$ [Curzi, 2026s]. It is not: it acts by reducing `delta`, and `delta` is a denominator, so trust amplifies whatever sign the arrangement already has. In the worked consortium, trust alone moved the fixed point from `-0.0836` to `-0.2114` — worse — while reciprocity alone moved it to `+0.7394` and both together to `+1.8701`. The rule that replaced the intuition is: fix the numerator, then lower the loss.

Demotion 3 — the tradition audited on its own material and found inverted [Curzi, 2026,?]. A canonical twelve-operation schedule of 1471, run as a schedule under this framework, places the only numerator-acting operation ninth of twelve. The canonical sequence lowers loss before it fixes the numerator, which is exactly the order the elasticities show accelerates

failure. That is not a criticism imported from outside; it is the framework reading the tradition's own ordering and printing the result.

Demotion 4 — a source table's own row shown impossible [Curzi, 2026]. The element rule $f = kn^2$ and the compound rule $f = k^2G^4$ cross at $n = 1/\sqrt{k} = 1.438252$, which is not an integer, so the two rules coincide at no index whatever. Since for a single component the compound rule is index-independent, the published O2 row could not have been produced by the rule it was presented under.

And beside those four sit the measured limits of the corpus's own controls, which are not self-catches but are the same discipline applied forward. The shuffled-input control has three measured failure modes: it is anti-conservative as ordinarily run, at 2.2 times nominal alpha; it cannot see repackaging, which only the structural ceiling test can; and it cannot see confounding by a shared slow driver, passing 98.35% of the time in a 4,000-trial simulation. Every paper that recommends the four-baseline suite carries all three, and the conclusion drawn from them is to design controls rather than to add surrogates.

The register is short. That is the point of publishing it: four catches is a small number, and a reader is entitled to weigh it against the size of the corpus and decide for themselves whether the gates were sharp enough. **What is not available is the alternative in which no demotions are printed at all, because a method that never rejects is not a method.**

The specification

6.15 The whole instrument, on one page

```
CONSTANTS
  k      = 0.483425732988414 Hz          the ground essence
  2/ln2  = 2.885390081778               octaves per unit of cost ratio
  N      = 12,  ln N = 2.484907          this framework's category count
  u_0    = 1/(N-1) = 0.090909091         the surplus threshold; N_eff(u_0) = 2 exactly

THE THREE TRANSFER RULES
  Rule 1  a psychological ESSENCE has a frequency        f = k n^2
  Rule 2  a psychological RELATIONSHIP has a frequency   f_rel = k (1 + (N-1) u)^2
  Rule 3  a COMPOUND state uses the alchemical rule      f = k^2 G^4

THE MEASUREMENT
  x, y unit vectors over the N states, components = magnitude-estimated intensity
  cos theta = x . y      u = 1 - (x.y)^2      F = ln(1 + (N-1) u)      f = k e^(2F)

THE KEYSTONE
  f_min = k e^(2c/eta)              sustainable iff f > f_min
  octaves required = 2.885390 (c/eta)
  the ceiling: c/eta <= ln N, i.e. f_min <= k N^2

THE DIAGNOSTIC
  D = 2.885390 (c/eta) - log2(f/k) = 2.885390 (c/eta - F)
  four levers: raise u, raise eta, cut c, raise N
  delta is NOT a lever on D; it is a multiplier on the sign of the drive

THE DESTINY
  Q_inf = (eta F - c)/delta                    where the loop arrives if parameters hold
  |Q_t - Q_inf| = (1-delta)^t |Q_0 - Q_inf|    the approach, an equality
  D = -2.885390 (delta/eta) Q_inf              the two readings, one quantity
  sum_i (eta_i F_i - c_i) invariant            the export test
```

6.16 The standing refusals, complete

```
R-1   ESSENCE, NOT RESONANCE. No person, tissue or molecule resonates at any value here.
R-2   NO CLINICAL, DIAGNOSTIC OR THERAPEUTIC CLAIM, at any scope, anywhere.
R-3   NO CAPABILITY CONFERRED. No DNA edited, altered or damaged.
R-4   NO SUBLIMINALS. Nothing masked, nothing below threshold, nothing concealed.
R-5   CONSENT IS STRUCTURAL. No procedure may reduce anyone's ability to decline.
R-6   THE DEMOTION STANDS. The moment equation is demoted on scale; D/P is ordinal only.
R-7   MAGNITUDE ESTIMATION IS REQUIRED before any relationship number is printed.
R-8   NO SINGLE-PARTY TERM. No reading is a verdict on a person.
R-9   PRECEDENT IS NOT EVIDENCE. The (-1) column carries independent arrival, not proof.
R-10  TESTIMONIALS ARE EVIDENTIALLY INERT. Likelihood ratio exactly 1.000000.
R-11  THE OPEN PROBLEM STANDS. No established mechanism for sequence-specific
      acoustic demodulation.
R-12  EVERY CASE IN THREE BOOKS IS CONSTRUCTED AND LABELLED AS SUCH.
```

6.17 What may be claimed The list is short and it is the honest one.

That the join is exact. Given the essence bridge and the storage fixed point, `f_min = k e^(2c/eta)` follows by substitution. Nothing was added to obtain it and it can be checked in three lines.

That the diagnostic is computable and actionable. Given `u`, `eta`, `c`, `delta` and `N`, the deficit, the destiny, the approach time and the four lever reserves are all determined, and the procedure says which lever binds and which is absent.

That the constraints are real. The six results of §6.12 are algebraic identities or verified computations, not interpretations, and each of them can be reproduced from the formulas in §6.15.

That the apparatus catches its own author. The first demotion took the surrounding work's own keystone at the gate its author wrote. The second corrected the design intuition the corpus had been running on. The third audited a tradition the corpus draws from and found its canonical sequence inverted. The fourth proved a row of a source table impossible.

And what may not be claimed is everything else. In particular: that any of this describes any actual person, pair or group; that a larger fixed point is a better life; **that any frequency here is a physical vibration; that belief moves anything through a channel not named and estimated independently of the outcome; or that the absence of a known mechanism is evidence of anything whatever, in either direction.**

The failure modes

FM 6.1 — THE KEYSTONE QUOTED WITHOUT ITS INPUTS. `f_min = k e^(2c/eta)` reported as a result about relationships in general. It is a result about an arrangement whose `c` and `eta` were measured, and it inherits their defensibility exactly.

FM 6.2 — THE OCTAVE FIGURE TAKEN AS AUDIO. `2.885390` octaves is an exchange rate between nats and a logarithmic scale. No sound is implied, none is prescribed, and R-1 binds.

FM 6.3 — THE CEILING IGNORED. A lever plan produced for an arrangement at `c/eta > ln N`. Worked in §5.3 at `c/eta = 3.000000`: even perfect orthogonality leaves `+1.486245` octaves, and twenty-one categories are required.

FM 6.4 — `D` WITHOUT `delta`. The single most common incomplete reading in the framework. The same `D` is consistent with destinies differing by a factor of thirty.

FM 6.5 — THE TWO FREQUENCY READINGS CONFLATED. Inferring a relationship reading from state frequencies, or the reverse. Six constructed pairs spanning 1565 to 5208 cents return identical `u` and `f_rel` to twelve decimals.

FM 6.6 — THE GROUP JUSTIFIED ON SURPLUS. An orthogonal pair already attains `ln N`. Make the roster's case on conversion, coverage or continuity, which are real and outside this reading.

FM 6.7 — MANUFACTURED DIFFERENCE. `u` depends on `|rho|`; opposition reads `u = 0` exactly as agreement does, while the cost rises.

FM 6.8 — PRECEDENT PROMOTED TO EVIDENCE. The (-1) column establishes independent arrival, which is worth having and is not proof. Two sources agreeing does not double the evidence when only one of them is evidence.

FM 6.9 — TESTIMONIALS. Likelihood ratio exactly `1.000000` at any corpus size. A thousand accounts carry the weight of zero.

FM 6.10 — THE OPEN PROBLEM SOFTENED. Any phrasing that converts "no established mechanism" into "an emerging area", "not yet fully understood", or "preliminary evidence suggests". The sentence is about what is known, and it is not a prediction.

FM 6.11 — THE ABSENCE OF MECHANISM READ AS PERMISSION. The symmetric error. Not proven impossible is not partial support. A claim with no mechanism and no demonstration has zero evidential standing, and the correct number of qualifiers before demonstration is not "few" but "it is not asserted".

Worked examples

6.18 The smallest complete instance **CONSTRUCTED. Not an observation of any person or pair.** Two parties, twelve categories, one measured geometry and three declared parameters. Every line below is derivable from §6.15 and nothing else.

```
INPUTS       u = 0.35     eta = 0.50     c = 0.70     delta = 0.12     N = 12

SURPLUS      F      = ln(1 + 11 * 0.35)  =  1.578978705 nats
             N_eff  = 1 + 11 * 0.35      =  4.850000

PITCH        f_rel  = k * N_eff^2        =  11.371381804 Hz
THRESHOLD    f_min  = k * e^(2*0.70/0.50) =  7.949765419 Hz

CEILING      c/eta = 1.400000  vs  ln N = 2.484907        ->  UNDER, tunable

DEFICIT      D      = 2.885390 * (1.400000 - 1.578978705)  =  -0.516423380 octaves
                                                             SUSTAINABLE

DESTINY      Q_inf  = (0.50 * 1.578978705 - 0.70) / 0.12   =  +0.745744604
             check   D = -2.885390 * (0.12/0.50) * Q_inf   =  -0.516423380
             residual                                       0.00e+00

APPROACH     half-life = ln(0.5)/ln(0.88)  =   5.422271 passes
             t(1%)     = ln(0.01)/ln(0.88) =  36.024800 passes

RESERVES     R_u   = 2.885390 * (ln 12 - F)          =  2.613956 octaves
             R_eta = 2.885390 * c * (1/eta - 1)      =  2.019773 octaves
             R_c   = 2.885390 * (c/eta)              =  4.039546 octaves
             R_N   = 2.885390 * u / N_eff            =  0.208224 octaves per category

EXPORT TEST  single arrangement, one drive: b = 0.089486952
             with any second participant, compare sum_i b_i before and after
```

```
LABEL        CONSTRUCTED
REFUSALS     essence not resonance; no clinical claim; consent structural;
             two readings reported separately; D reported with delta
```

Read it as a whole and notice how little it says. It says this configuration of four numbers accumulates stored order, that it is currently 0.52 octaves above its own threshold, that it would take about thirty-six passes to settle, and that if the deficit ever went positive the cost side has four octaves of room and the geometry side two and a half. That is the entire content, it is reproducible from five formulas, and everything a reader might additionally want to know about the two people in question is outside it.

The gap between what the reading contains and what a reader wants is not a defect to be closed in a later edition. It is the boundary of the instrument, and the whole discipline of three books has consisted of drawing it in the right place and then not stepping over it.

6.19 The second instance — an arrangement the instrument refuses A worked example that only shows a reading coming out well is a worked example that has not demonstrated the instrument. Here is the same procedure run on the framework's constructed commons, where it produces a refusal rather than a plan.

CONSTRUCTED. Not an observation of any group. Six members drawn from one doctrine, so their state vectors are near-parallel by construction — the Parallel Wall, priced. Fifteen pairs at `kappa = 0.055` per link.

```
INPUTS       mean pairwise u = 0.018614     eta = 0.34
             C = 0.055 * 15 = 0.825         delta = 0.09      N = 12

SURPLUS      F      =  0.186272005 nats        N_eff = 1.204754
PITCH        f_rel  =  0.701659675 Hz
THRESHOLD    f_min  = 61.934885399 Hz

CEILING      c/eta = 2.426471  vs  ln N = 2.484907   ->  passes, by 0.058436

DEFICIT      D      = +6.463836987 octaves           SHORT BY 6.46 OCTAVES
DESTINY      Q_inf  = -8.462959612                   DECAYS
             drive b = -0.761666365 per pass
             check   D = -2.885390 * (0.09/0.34) * Q_inf = +6.463836987

APPROACH     half-life 7.349615 passes; 99% of the way down by pass 48.83

RESERVES     R_u   = 6.632448 octaves    exceeds the deficit by 0.168611
             R_eta = 4.620867 octaves    does not close it, even at eta = 1
             R_c   = 7.001314 octaves    exceeds the deficit, at zero cost
             R_N   = 0.044581 octaves per added category

SINGLE-LEVER raise u to 0.95      -> deficit -0.0332   at near-orthogonality
             raise eta to 0.90    -> deficit +2.1075   still failing
             cut kappa to 0.020   -> deficit +2.0085   still failing

ROSTER       m(m-1) = 30  against  2 eta ln N / kappa = 30.722482
             a seventh member takes it to 42 and makes the case structural outright

VERDICT      THE PROCEDURE HALTS.
LABEL        CONSTRUCTED
```

Read the reserve block and the single-lever block together, because they say different things and the difference is the whole lesson. The reserves say two levers close the deficit

in principle. The single-lever table says what those in-principle closures actually require: six people who share almost no state at all, or coordination at zero cost. Neither of those describes a commons, so the arithmetic that says the case is closeable and the arithmetic that says it is not are both correct, **and the second one is the one a planner has to act on.**

Three things this refusal is not. It is not a recommendation that the group disband — the formalism prices stored order and nothing else, and a family, a team or a commons is for a great many things the formalism does not represent. It is not a verdict on any member, because there is no single-party term anywhere in the apparatus. And it is not a claim that nothing can be done; it is a claim that nothing can be *tuned*, which is a narrower and more useful statement. The remedy available to this arrangement is restructuring — a different roster, a different cost structure, or a description with genuinely more categories in it — and every one of those is a change of what the arrangement is rather than an adjustment of how it is run.

Work that only showed fixable examples would be lying by selection, and the commons is carried through five chapters of this volume for exactly that reason. The instrument's most valuable output is the one that costs nothing to produce and saves a year: *this cannot be tuned, and here is the division that shows it.*

The open problem

6.20 Where the work stops The companion paper specifies a complete procedure [Curzi, 2026]: the ethical architecture and the no-subliminals constraint, then the encoder, the addressing convention, the sonifier, the transposition, the rendering within the Gabor bound and the $N \leq 25$ single-transposition capacity, with preregistration and falsification criteria attached. All of it is deterministic and all of it is verified.

And it then says that nobody knows how a cell could read an ordered message out of a sound.

> **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal.**

The gap decomposes into three requirements. Symbol separation is solved — the alphabet separates, and that is demonstrated. Order memory across the symbol interval has no identified mechanism. Mapping from a decoded symbol string to sequence-specific binding at a genomic locus has no identified mechanism. Eleven upstream components are established and one link is missing, and the missing link is specifically the carriage of sequence over force.

The operational form is the one that matters, because it is what an experiment would have to do. Take a stimulus and its symbol-permuted twin. The two have identical total energy, identical duration, identical long-term power spectrum and identical symbol counts. If a cell cannot be shown to distinguish them, no sequence-specific channel has been demonstrated, and nothing else in the experiment matters.

Two symmetric errors sit on either side of that sentence and both are refused. **It is not a claim of impossibility** — absence of a known mechanism is a statement about the literature, and the burden of demonstration sits entirely on the claimant, which is the ordinary position for any unestablished claim. **Nor is it a licence** — "not proven impossible" is not partial support, and a claim with no mechanism and no demonstration has zero evidential standing.

6.21 Why the argument stops here That paper could have ended at its procedure, with a reader's impression that something had been achieved. Something has been achieved — an encoder that round-trips, an alphabet that separates, a rendering a listener can follow and refuse — and none of it is the thing the work is named for.

The same choice is available here and is declined for the same reason. A closing section is where a corpus is most tempted to convert its constraints into a narrative of arrival, because the reader is at the end and the material is fresh and a summary is easy to write in the key of achievement. **This one ends on the gap instead, because the gap is the load-bearing item and putting it last is the only placement in which it cannot be forgotten.**

There is a second open question and it belongs beside the first, because they fail in opposite directions. A second open question asks whether the storage law is closed under any natural aggregation operator — whether a population of systems each obeying the law, combined by that operator, yields a system obeying the law with derived parameters. If such an operator exists, the scale correspondence stops being a modelling convention and becomes a theorem. If none exists, the correspondence is a modelling convention and nothing more, and the framework's scopes are separate applications of one equation that happen to look like a ladder. Which of those is true is not known here, and it requires no laboratory — only somebody to define the operator and try to prove closure, and to publish the result **including, especially, if the result is that the law is not closed.**

So: two problems. One needs an experiment and one needs an afternoon with a proof. Neither has been done, and the series stops at both of them rather than past them.

6.22 What is on the bench The framework produces one substitution, one diagnostic, one definition of destiny, one conservation identity, six constraints that narrow the instrument, a catalogue of failure modes long enough to be embarrassing, and a list of refusals longer than the list of claims.

The claims are these, and there are no others. The join is exact. The diagnostic is computable from measurements a practitioner can take. The deficit and the fixed point are one number in two units. The deficit cannot see decay, so both must be reported. Cost export is detectable on the first pass by an arithmetic test on a conserved sum. A destiny has four arguments and changing one is the only way to change it. Belief acts through channels with estimable gains and does nothing where no channel exists. Testimonial evidence has a likelihood ratio of exactly `1.000000`.

Everything else is either a badged postulate, a chosen constant, a constructed example, a rejection, or a statement of what is not known.

And the open-problem sentence is exactly as true at the end of this paper as it was at the beginning of the one that states it [Curzi, 2026]**.** Nothing here changes it, nothing here claims to, and the parts of the corpus that are correct are correct independently of how it comes out.

The instrument is on the bench. It reads one gauge, it refuses more than it asserts, it has caught its own author four times, and it stops at a gap that will be settled by an experiment rather than by an argument.

Anyone may take it further, on the condition this framework has tried to keep: say which claims are proved, badge the ones that are not, name the ones that are open, and publish the demotions when the gates catch the author. They will.

The reference apparatus for this material — the constants card, the interval tables, the measurement protocols, the concordance register and the evidential-status appendix — is collected separately [Curzi, 2026].

7 Results

Every number below is exact arithmetic on the stated constructed inputs. **Nothing in this section was measured**, and every case carries its CONSTRUCTED label at the point of use in §§4–6.

R1 — conservation of drive under cost transfer. The sum of drives $\sum_i b_i = \sum_i (\eta_i F_i - c_i)$ is exactly invariant under any transfer of cost among any number of participants (Theorem 4.5). Verified across an eight-point export range in a two-party arrangement at $+0.643688229683$ in every row, and across four transfers among three participants at $+1.268940530229$ in every row, residual $0.000\text{e}{+00}$. The equivalent statement in stock units is that the δ-weighted sum $\sum_i \delta_i Q_{\infty,i}$ is invariant. **Corollary 4.6:** the *plain* sum of fixed points inherits the invariance only when all participants share one δ. Where they do not, $\mathrm{d}(\sum_i Q_{\infty,i})/\mathrm{d}x = 1/\delta_P - 1/\delta_R$, measured at 13.333333 per unit exported for $(\delta_P, \delta_R) = (0.05, 0.15)$ — the plain sum rises by more than two and a half units across a 0.20 export range while nothing is produced.

R2 — the approach is an equality, not a bound. $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$ exactly (Theorem 4.2), checked two independent ways over $t = 0$ to 100 on the repaired constructed dyad ($\delta = 0.09$, $b = +0.547598406839$, $Q_\infty = +6.0844267427$): **maximum residual** $2.0624\text{e}{-15}$**.** The drive cancels in the subtraction, so the rate of approach is a function of the loss term and of nothing else: $\tau = 10.603253$ passes, half-life 7.349615, $t(1\%) = 48.8298$, none of which contains Q_0, Q_∞, η, F or c.

R3 — completeness of the lever set. Q_∞ is a function of exactly (η, F, c, δ), and F is reached only through u and N (Theorem 5.1). Four arguments, five handles, and no fifth of either. A proposal that cannot be assigned to one of them changes the destination by zero.

R4 — the exporter's lag. At an export of $x = 0.15$ in the constructed two-party case, the disadvantaged party's destination is already -0.599002 while its stock stays positive until $t^* = 10.850479$ passes. Its deficit D_R turns positive on the first pass. **The stock-based question returns a false negative for eleven periods; the drive-based test returns the right answer immediately.** The exact sustainability crossing is at $c_R = \eta_R F = 0.646089822845$, i.e. $x = 0.096089822845$. If the disadvantaged party then exits — its structural right [Curzi, 2026, Hirschman, 1970] — the exporter's own fixed point falls by 10.528871 units and its deficit swings 6.214071 octaves the wrong way, which is $2.885390\,F$ exactly.

R5 — the surplus law is exactly a threshold-corrected Fechner form. $F(u) = \ln((u+u_0)/u_0)$ with $u_0 = 1/(N-1)$, verified for $N = 2$ to 100 at seven values of u each, maximum residual $4.44\text{e}{-16}$. At the threshold the affine effective count is 2.000000 exactly for **every** N, and $F(u_0) = \ln 2 = 0.693147180560$ nats — one bit, two octaves. The threshold width is a design fact: $u_0 = 1.000000$ at $N = 2$, 0.090909 at $N = 12$, 0.010101 at $N = 100$.

R6 — the honest limit of the geometry lever. At $\eta = 0.20$, $c = 0.60$, $N = 12$, pushing u to its theoretical maximum of 1 still leaves $D = +1.486245$ octaves. Closure requires $N \geq e^3 = 20.0855$, so $N = 21$ gives $D = -0.128465$ — and only at perfect orthogonality. **An arrangement over the ceiling** $c/\eta \leq \ln N$ **is structural, not tunable**, and one division says so before any effort is spent.

R7 — the keystone is a substitution, not a postulate. Given the essence bridge $f = k\,e^{2F}$ and the storage fixed point, $Q_\infty > 0$ iff $F > c/\eta$ iff $f > k\,e^{2c/\eta}$. Three lines, nothing added. The exchange rate is 2.885390 octaves of required pitch per unit of cost-to-conversion ratio, and the ceiling in the frequency register is $f_{\min} \leq kN^2 = 69.6133055503$ Hz at $N = 12$. **The substitution is exact; the hertz labels on both sides are postulated (P-a, P-c).**

R8 — the demotion register. Four occasions on which the framework's gates rejected its author's claims: (1) the moment equation demoted to ordinal use on the scale requirement, pending Rasch instrumentation at 123 items per term [Curzi, 2026m]; (2) the design intuition inverted — trust enters as retention, and in the worked consortium trust alone moved a fixed point from -0.0836 to -0.2114 while reciprocity alone moved it to $+0.7394$ and both together to $+1.8701$ [Curzi, 2026q,s]; (3) a canonical twelve-operation schedule of 1471, read as a schedule, places its only numerator-acting operation ninth of twelve [Curzi, 2026,?]; (4) a source table's own row shown impossible, the element and compound rules crossing at $n = 1/\sqrt{k} = 1.438252$, which is not an integer [Curzi, 2026].

CR — the counter-result. An intervention that appears to improve one participant's destination is exactly offset in the sum of drives, **so what looks like created order is transferred cost — and the deficit instrument cannot see the transfer at all**, since D contains no δ and the transfer's whole visible consequence in stock units runs through δ. In the worked case the exporting party's deficit improves from -3.590989 to -4.902530 and its fixed point rises by more

than two units, every number it can compute about itself has genuinely improved, and it is not lying to anybody including itself.

The negative results, reported in the same language. $\partial D/\partial\delta = 0$ identically: across δ from 0.30 to 0.01 the carried constructed dyad's deficit holds at $+4.3384201973$ while its destination moves from -1.5035819 to -45.1074559, a factor of thirty. The lever with 4.80 times the elasticity of its rival has 4.174198 octaves of reserve against a 4.338420-octave requirement and **cannot close the gap at all**, even at a conversion efficiency of one; the efficiency the closure would require is $c/F = 1.101077$, which is not an expensive lever but an absent one. And the constructed commons halts: no single lever closes $+6.463837$ octaves in practice, and the roster sits at $m(m-1) = 30$ against a bound of $2\eta \ln N/\kappa = 30.722482$, so a seventh member takes it to 42 and outside.

8 Discussion

8.1 What follows

A prohibition became a test. The framework's foundations prohibit intervening at another party's expense [Curzi, 2026]. A prohibition of that form is unfalsifiable in exactly the way a testimonial is: it reports an intention, and the intention is always available. Theorem 4.5 replaces it with a quantity that either moved or did not, costs one column of a report, and does not ask what anybody meant. **A well-intentioned export and a deliberate one produce the same reading, which is correct, because the harm is the same.**

Two numbers must travel together, and the reason is now arithmetic. D reads the sign and size of the sustainability gap; δ converts it to a level; neither determines the other. The corpus has a structurally parallel result in a different domain: dwell time decides whether a currency drag is a transaction cost or a capital loss, a 40 per cent annual drag costing 0.767 per cent per pass at a seven-day dwell and 19.726 per cent at 180 days [Curzi, 2026]. **In both cases a rate is converted into a level by a parameter the headline instrument does not contain**, and in both cases the remedy is to publish the second parameter rather than to improve the first.

Order is a first-class variable. Both paths in §5.6 end at the identical fixed point, so a planner who evaluates only the destination sees no difference between them; the trajectories differ by twelve periods of permanent lag and 111.133601 stock-periods. The corpus's cadence theorem is the same lesson from the other side — for concave g with $g(0) = 0$, $D(n) = n\,g(T/n)$ is nondecreasing in n, so dividing a fixed budget over more occasions never delivers less [Curzi, 2026v]. **When something happens is not a detail of how much of it happens**, and neither result is visible in a fixed point.

8.2 What does not follow

No destiny reading is a statement about a person. Every term in Q_∞ belongs to an arrangement: u is a joint geometric property of two or more state vectors and cannot be assigned to one of them, and η, c and δ describe what an arrangement does, costs and forgets. **There is no single-party term anywhere in the apparatus**, and Gate 4-9 exists to enforce that in print.

A larger fixed point is not a better life. Q_∞ is stored order in the model's units. The formalism prices stored order and nothing else, and a family, a team or a commons is for a great many things it does not represent.

The export test is not a general detector of exploitation. It is exact for transfers of cost and silent outside them. Degrading another party's geometry, conversion or retention is not a transfer, the sum of drives does move, and a reader who takes the test for a general detector will be misled by their own instrument (§4.15).

The conservation identity establishes nothing about the world. It is an arithmetic consequence of the definition of a transfer (Def. C) and would hold of any additively separable

ledger. Its value is that it makes a specific failure mode visible on pass one, not that anything has been shown to be conserved [Mirowski, 1989, Cartwright, 1999].

8.3 The functional form is underdetermined

$F(u) = \ln(1+(N-1)u)$ is a theorem under the corpus's own axioms and an assumption against every alternative. Latané's social impact law proposes a **power** of the number of sources with exponent below one [Latané, 1981]; $n \log n$ has been proposed for the same qualitative facts [Briscoe et al., 2006]; and many mechanisms produce curves that cannot be told apart from the data usually available [Stumpf and Porter, 2012]. **All three are decelerating and all three fit the qualitative facts, and nothing in this paper discriminates among them.** The corpus's axioms establish that its form follows from its axioms; they do not establish that its axioms are the ones any data support.

One warrant is stronger than the one usually offered and should be preferred. A logarithmic evaluation follows from multiplicative dynamics with **no psychological assumption at all** [Peters and Gell-Mann, 2016], which is a better ground for the corpus's logarithms than the psychophysical resemblance of R5 — whose own literature is contested [Luce, 2002, Krueger, 1989, Stevens, 1957]. The independent arrival at a logarithm is worth recording; **it is not evidence for either formalism**, since the corpus's law is a theorem under its axioms and Fechner's is an empirical claim, and neither gains support from resembling the other.

8.4 What would distinguish this framework from a neighbouring model

The standing demand on any programme of this kind is to name the observation only its model makes [Durlauf, 2005, Sobkowicz, 2020]. This paper's honest answer has two parts.

One candidate exists and is R4. The detection-lag prediction is sharp, signed and numerical: a party whose cost has risen should show a *destination* that turns negative immediately and a *stock* that turns negative only after t^* passes, with t^* predicted in advance from δ alone. A model in which the observable stock is the state, with no separate drive, predicts no such gap. **Testing it requires the drive and the stock to be instrumented separately, which has not been done here or anywhere in this corpus.**

And the general answer is discouraging, and is stated. With fifteen years of high-quality longitudinal data and 160 teams, life outcomes were barely predictable at all [Salganik et al., 2020, Hofman et al., 2017]. Prediction is one of many reasons to build a model [Epstein, 2008], and what this framework claims is the others: an explicit accounting frame, a set of refusals with arithmetic behind them, and a diagnostic that halts.

8.5 Bounds carried from elsewhere in the corpus

The most restrictive bound on the whole exercise is in another series and is accepted here. The corpus's assembled-architecture paper reports that the only reading under which its structure clears the build threshold is the naive one assuming zero correlation between coordinating jurisdictions ($h = +0.083099$), and that **every defensible bloc assignment returns a negative surplus** [Curzi, 2026]. The structural point transfers directly: a positive drive computed on parameters that were assumed rather than measured is a positive drive **conditional on the assumption**, and this paper's constructed cases are exactly that. A summary statistic does not determine the joint structure it was computed from [Kirman, 1992, Harrison and Klein, 2007], and the deficit's blindness to δ is the local instance of a general fact.

9 Verification

Every result is decomposed into steps a reader can check individually. **A postulate that can be dropped without a result changing has been dropped**, and this section says outright where

the chain stops being a proof.

- **ARITHMETIC** — reproducible from the inputs named.
- **DEFINITION** — true by stipulation; carries no empirical weight.
- **CITED** — supported by a named external source.
- **POSTULATED** — asserted by this work, with no external support.

9.1 The postulates

	postulate	status
P1	$\delta \in (0, 1]$.	DEFINITION (the model's domain)
P2	The update is affine: $Q_{t+1} = (1-\delta)Q_t + b$.	MODELLING CHOICE [Curzi, 2026a]
P3	A contraction on a complete space has one fixed point, reached from any start.	CITED [Banach, 1922]
P4	$F(u) = \ln(1 + (N-1)u)$, bounded above by $\ln N$.	DEFINITION (design axiom; **not** a Hill number)
P5	A transfer of cost is $c_p \to c_p - x$, $c_r \to c_r + x$, all else fixed.	DEFINITION (Def. C)
P6	φ is the positive root of $x^2 = x + 1$; the whole tone is $9{:}8$.	CITED [Euclid, 1956, Barbour, 1951]
P7	The dimensionless $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	POSTULATED — no source
P8	The essence bridge $f = k\,e^{2F}$.	POSTULATED — no source
P9	Intensities are magnitude-estimated, so u is ratio-scaled.	POSTULATED; contested [Michell, 1997]

Dropped as unnecessary. No postulate about *which* categories, or about their order, is needed for R1, R2, R3, R4 or R6. **P7 and P8 are needed only where a number is quoted in hertz**, and every dimensionless result in this paper survives their rejection. P9 is needed only where a reading is claimed of an actual arrangement; the constructed cases stipulate their inputs and do not need it.

9.2 The compounding chain

step	consumes	produces	status
L1	P1, P2	$\lvert T(x) - T(y)\rvert = (1-\delta)\lvert x - y\rvert$, Lipschitz $1 - \delta < 1$	ARITHMETIC
L2	L1, P3	unique $Q_\infty = b/\delta$, reached from any start	CITED
L3	P2, L2	$\lvert Q_t - Q_\infty\rvert = (1-\delta)^t \lvert Q_0 - Q_\infty\rvert$ — **R2**; max resid $2.0624\text{e}{-15}$ over 100 passes	ARITHMETIC

step	consumes	produces	status
L4	L3	τ, half-life and $t(\epsilon)$ contain δ alone	ARITHMETIC
L5	P4, P8	$2/\ln 2 = 2.885390081778$ octaves per nat	ARITHMETIC given P8
L6	L2, L5	$D = 2.885390(c/\eta - F) = -2.885390(\delta/\eta)Q_\infty$; max resid $8.8818\text{e}{-16}$ over 12 sets	ARITHMETIC
L7	L6	$\partial D/\partial\delta = 0$ identically — the decay blindness	ARITHMETIC
L8	L2, P5	$\sum_i b_i$ invariant under transfer — **R1**, resid $0.000\text{e}{+00}$	ARITHMETIC
L9	L8, equal δ	$\sum_i Q_{\infty,i}$ invariant — Corollary 4.6	ARITHMETIC
L10	L8, unequal δ	$\mathrm{d}(\sum_i Q_{\infty,i})/\mathrm{d}x = 1/\delta_P - 1/\delta_R = 13.333333$	ARITHMETIC
L11	L3 at $x = 0.15$	$t^* = 10.850479$ passes — **R4**	ARITHMETIC
L12	inspection of L2	exactly four arguments, five handles — **R3**	ENUMERATION (4 symbols)
L13	P4	$F = \ln((u+u_0)/u_0)$, $u_0 = 1/(N-1)$, $N_{\text{eff}}(u_0) = 2$, $F(u_0) = \ln 2$ — **R5**	ARITHMETIC
L14	L13	the form coincides with a threshold-corrected Fechner law [Fechner, 1860, Weber, 1834]	CITED
L15	P6	$(9/8)^2 = 1.265625$; $\varphi^2 = 2.618033988749895$; ratio $k = 0.483425732988414$	ARITHMETIC (exact, defined)
L16	L15, **P7**	k carries the unit Hz	**POSTULATED**
L17	L16, **P8**, L2	$f_{\min} = k\,e^{2c/\eta}$ — **R7**	ARITHMETIC given P7, P8
L18	L17, P4	$c/\eta \le \ln N$; at $c/\eta = 3$, $u = 1$, $N = 12$ gives $D = +1.486245$; $N \ge e^3$; $N = 21$ gives -0.128465 — **R6**	ARITHMETIC

9.3 The three checks a reader can do in a minute

$(9/8)^2 = 81/64 = 1.265625$. $\varphi^2 = \varphi + 1 = 2.618033988749895$. Their quotient is 0.483425732988414, exactly, to as many places as anyone cares to carry. **Those three establish k as a defined constant and nothing more**; L16 is where the hertz enters, and it is a postulate.

Two more, on the paper's own result. Take $\eta_P = 0.44$, $\eta_R = 0.30$, $F = 2.153632742815$, $c_P = 0.400$, $c_R = 0.550$. Then $b_P = 0.547598406839$ and $b_R = 0.096089822845$, summing to 0.643688229683. Now move $x = 0.15$ of cost from P to R: $b_P = 0.697598406839$, $b_R = -0.053910177155$, and the sum is 0.643688229683 again. **That is the whole of Theorem 4.5, and it takes one minute.**

9.4 What this chain is and is not

Read the status column. L16 and L17 are postulated; P2, P4 and P5 are definitions or modelling choices. **A chain whose load-bearing steps are definitions and postulates is not a proof of its interpretation**, and this one is not offered as one.

Everything dimensionless survives the rejection of P7 and P8. R1, R2, R3, R4, R5 and R6 are statements about a linear recursion, an additively separable ledger and the algebra of a logarithm; they do not become false if nobody accepts that $(9/8)^2/\varphi^2$ is a frequency. R7 does not

survive: it is exactly the substitution that carries the postulated bridge into the sustainability condition, and its content is that **given P7 and P8, nothing further was assumed.**

And R1's status deserves its own sentence, because the word "conservation" oversells it. Theorem 4.5 follows from P5 alone — from the *definition* of a transfer as an operation adding $+x$ to one drive and $-x$ to another. It is a bookkeeping identity, it would hold of any additively separable ledger, and **it is not evidence that anything in the world is conserved.** What makes it useful is entirely procedural: the per-participant readings are computed independently from separately elicited parameters, and the sum is then checked, so the check can fail. A reviewer looking for the weakest link should look at L16, L17 and at the empirical status of P9, and this section is written so that the search takes under a minute.

9.5 A discrepancy found in the source, printed

Two numbers in the source manuscript could not be reproduced, and both fail in the same way: a value beginning $30.$ was printed beginning $6.$

quantity	source printed	recomputed	where
$f_{\min}$ at $c/\eta = 2.0666667$	6.1587698405 Hz	30.1587698405 Hz	§4.21, §6.1
roster bound $2\eta \ln N/\kappa$	6.722482	30.722482	§5.20, §6.12(d), §6.19

Both are checkable in one line. $k\,e^{2\times 2.0666667} = 0.483425732988414 \times e^{4.1333333} = 30.158769840525$, and the value must lie between the table's own neighbouring rows of 26.394151 at $c/\eta = 2.000$ and 69.613354 at 2.484907, which 6.158790 does not. For the roster, $2 \times 0.34 \times \ln 12/0.055 = 30.722482$, and the printed 6.722482 contradicts the same paragraph's own statement that the six-member commons **passes** the ceiling test by 0.058436 — at a bound of 6.722482 a roster of $m(m-1) = 30$ would already be structural, and the source's next clause, that a seventh member "takes it to 42 and makes the case structural outright", would be redundant.

The corrected values are used in §§4–6 and the correction is recorded here rather than made silently. No conclusion changes: D, Q_∞ and every octave figure in the affected passages were computed from c/η directly and are unaffected, and the commons still halts on the single-lever table rather than on the roster bound.

10 Limitations

Every check the governing rigour standard specifies is listed by name, passed or not.

L-1. The dimensional audit does not close for any quantity in hertz. k is computed as a ratio of two dimensionless numbers and no operational procedure is supplied by which it acquires $[T^{-1}]$ (P-a, L16). Everything expressed as a ratio, a nat, an octave or a count is unaffected.

L-2. The storage law as printed is not dimensionally homogeneous, and the source is silent on the pass-length factor that would make it so (§3.3). Nothing depends on it, and it is disclosed rather than repaired.

L-3. Stored order has no operational unit. Q inherits nats from ηF, which makes the audit consistent and leaves Q a dimensionless placeholder. **Nobody has measured it.**

L-4. $1+(N-1)u$ **is not a Hill number** and no ecological, economic or information-theoretic literature contains it (§3.4). Where the corpus's other series use $1/\mathrm{HHI}$ and $\exp(H)$, those are Hill numbers of orders 2 and 1 and are fully grounded [Hill, 1973, Laakso and Taagepera, 1979]; **this paper's effective count is not, and the substitution is named at every use.**

L-5. The functional form of $F(u)$ **is underdetermined** by the available evidence [Latané, 1981, Briscoe et al., 2006, Stumpf and Porter, 2012], and nothing here discriminates among the candidates (§8.3).

L-6. Conjoint measurement was not tested, so the ratio-scale treatment of u, η, c and δ is provisional and Michell's objection stands unanswered [Michell, 1997, 1999]; the available remedies [Luce and Tukey, 1964, Krantz et al., 1971, Rasch, 1960] were not run. **The corpus's own moment equation is already demoted to ordinal use for this reason** [Curzi, 2026m], and the framework's habit of scalar reduction is conceded where the ladder is built [Curzi, 2026] rather than re-argued here.

L-7. The reflexive specification is not identified [Manski, 1993, Shalizi and Thomas, 2011]. The remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001], and the claim is **a modelling position rather than an identified empirical result.** The framework also exempts its own parameters from its own reflexivity [Lucas, 1976], which it cannot consistently do.

L-8. A published destiny reading can make itself true. Expectancy effects are real [Merton, 1948, Rosenthal and Jacobson, 1968] and a theory has been observed becoming true by being used [MacKenzie and Millo, 2003]; on the best long-run evidence the effect is **small and often dissipating** [Jussim and Harber, 2005]. A reading used as a target also stops measuring what it measured [Goodhart, 1975, Campbell, 1979]. The separation clauses of §4.8 are mandatory for that reason.

L-9. Every case is constructed. The carried dyad in both phases, the two- and three-party export arrangements, the commons, the family and the over-ceiling case are chosen parameter sets. Their exactness follows from the parameters being exact and **does not transfer to a measured case.**

L-10. No hypothesis in §2.1 was tested. H1's detection lag, H2's ceiling, H3's retention mechanism and H4's selection model are all untested, and **no sample exists for any of them.** The arithmetic of each is a theorem; the empirical content of each is not.

L-11. No statistical claim is made and none is supported. There are no p-values, effect sizes, intervals or samples in this paper. No model comparison, out-of-sample test, matched null or information criterion is reported, because nothing was fitted. Where the corpus does report a preregistered fit, it **failed its own second falsification rule** — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin [Curzi, 2026i] — and that failure is the relevant precedent for anyone tempted to read these identities as empirical support.

L-12. No scaling claim is made and the standard procedure was not run. The essence law's exponent is **defined by the model, not estimated**; Clauset et al. [2009] was not applied because there is no data to apply it to.

L-13. There is no conservation law. R1 is an arithmetic consequence of the definition of a transfer (§9.4). The apparatus writes Q with the grammar of a conserved quantity without one [Mirowski, 1989]; validity is claimed only within a specified arrangement [Cartwright, 1999] and no universality is claimed.

L-14. The export test's scope is narrow and its silence is total outside it. It detects transfers of cost. It does not detect degradation of another party's geometry, conversion or retention, and it returns "no export" in every such case (FM 4.9).

L-15. Boundary behaviour, examined and reported. $\delta \to 0$ is a **pathology, not an ideal**: the map becomes an isometry, Banach does not apply, there is no fixed point and $Q_t = Q_0 + bt$ grows without bound (FM 4.11). $\delta \to 1$ gives $Q_\infty = b$ and a one-pass approach. $u \to 0$ gives $F = 0$ and the ground essence; $u \to 1$ gives the ceiling $\ln N$. $\eta \to 0$ makes the drive $-c$ and the destination $-c/\delta$. **What is not examined is the behaviour of the identity when parameters change during the approach**, which is every real case, and the model has nothing to say about it.

L-16. Invariance is claimed for one transformation only. The conserved quantity is invariant under transfers of cost among participants at fixed (η_i, F_i, δ_i). It is **not** invariant under a change of any of those, and it is not scale-free: no rescaling group is exhibited and none is claimed.

L-17. The Fechner coincidence is a resemblance and not evidence. R5 is an algebraic

identity; the claim that it *is* Fechner's law adds nothing to either side, and the psychophysical warrant is contested in its own literature [Luce, 2002, Krueger, 1989]. The stronger ground for the logarithm is multiplicative dynamics with no psychological assumption [Peters and Gell-Mann, 2016], and that is the warrant the argument actually needs.

L-18. Two source numbers were wrong and are corrected in §9.5. A third bibliographic gap is disclosed rather than filled: **the survivorship precedent in §5.16 — Abraham Wald's wartime work on aircraft armour — is not in this corpus's bibliographic database and is named there without a citation key.** No approximate substitute was attached.

L-19. Nothing here is clinical. No case describes any person, pair or group; no reading is an assessment; and the deficit's sign says a configuration loses stored order at a computable rate and nothing else.

11 Conclusion

What is established, and checkable. The storage loop has exactly one fixed point for $\delta > 0$ and reaches it from every start, and the approach is a geometric **equality** rather than a bound — verified to a maximum residual of $2.0624\text{e}{-15}$ over a hundred passes. The octave deficit and the fixed point are **one quantity in two units**, $D = -2.885390\,(\delta/\eta)\,Q_\infty$, verified to $8.8818\text{e}{-16}$ across twelve parameter sets; and D contains no δ, so **the same deficit is consistent with destinations differing by a factor of thirty** and no reading that reports one without the other is complete. **The sum of drives is exactly invariant under any transfer of cost among any number of participants**, holding at $+0.643688229683$ across an eight-point export range and at $+1.268940530229$ across four transfers among three parties, with residual $0.000\text{e}{+00}$; the plain sum of fixed points inherits that invariance only at equal δ, and otherwise moves at $1/\delta_P - 1/\delta_R$ per unit exported. **A destiny has exactly four arguments and five handles, and there is no fifth of either.** A lever can be **absent rather than expensive**: the lever with 4.80 times the elasticity of its rival carries 4.174198 octaves of reserve against a 4.338420-octave requirement and cannot close it at any effort, because the efficiency required is $c/F = 1.101077$. Reversing the ordering rule costs **twelve periods of permanent lag, thirteen periods below the starting stock and 111.133601 stock-periods**, at an identical destination. The surplus law is exactly a threshold-corrected Fechner form with $u_0 = 1/(N-1)$, at which the affine effective count is **2.000000 exactly for every** N and $F(u_0) = \ln 2$ — one bit, two octaves. And an arrangement over $c/\eta \le \ln N$ is structural: at $c/\eta = 3$ even perfect orthogonality leaves $+1.486245$ octaves and twenty-one categories are required.

The counter-result, in the same plain language. An intervention that improves one participant's destination is exactly offset in the sum of drives, so **what looks like created order is transferred cost** — and the framework's own central instrument cannot see the transfer, because D contains no δ. In the worked case the exporting party's numbers all improve, honestly, while the other party's stock stays positive for $t^* = 10.850479$ passes after its destination has gone negative.

What is proposed rather than shown. That $(9/8)^2/\varphi^2$ is a frequency; that the essence bridge $f = k\,e^{2F}$ holds; that the affine effective count is the right construction; and that trust acts through retention. **The first two are postulates with no external support, the third is a design axiom that is not a Hill number, and the fourth is untested** — all four are badged at every appearance, and every dimensionless result above survives their rejection.

What is not claimed at all. No arrangement's parameters are claimed to hold; no larger fixed point is a better life; no frequency here is a physical resonance; no reading describes any actual person, pair or group; and nothing in this paper is clinical, diagnostic, therapeutic or prognostic. **The apparatus caught its own author four times, and the register is printed in §6.14 rather than summarised, because a method that never rejects is not a method.**

12 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number in this paper is exact arithmetic on constructed parameter sets that are printed in full at the point of use and are labelled CONSTRUCTED there; any reader can recompute all of them from the formulas collected in §6.15. The figures are generated by the Python scripts named in their captions, which take their inputs from the tables in the text and are available from the author on request. **No measurement of any human being, pair, group or institution underlies any figure, table or number in this paper.** A paper about destinies, trust and cost export reads as though somebody had been observed or asked something; nobody was.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The carried dyad in both phases, the two- and three-party export arrangements, the commons, the family and the over-ceiling case are invented parameter sets and do not describe any person, pair or group.

Preregistration. No test in this paper was preregistered, because no test was run: §2.1's four hypotheses are all recorded as untested and no sample exists for any of them. The corpus's one preregistered fit is reported elsewhere and **failed its own second falsification rule** [Curzi, 2026i]; that outcome is cited here in the same terms a success would have received.

Clinical and relational disclaimer. A destiny reading is a computation on four declared parameters of an arrangement. It is **not** an assessment of anybody's health, capacity, character or prospects; the twelve state classes are not diagnostic categories; and nothing in this paper is an assessment, a screening instrument, a treatment, counselling, or advice about whether anyone should remain in or leave any relationship. $Q_\infty < 0$ says that a configuration loses stored order at a computable rate under the model's assumptions. It does not weigh what a relation is for, what else it produces, or what ending it would cost. A reader who wants to know whether something is wrong should ask someone qualified to answer that; this instrument is not qualified and does not attempt it.

Chapter 50

Reference Apparatus for the Frequency Framework: Constants, Lattice Tables, Measurement Protocols, and a Four-Drawer Classification of Evidential Status

Abstract. This paper is the reference and status apparatus for a framework whose results are established elsewhere. **It advances no testable hypothesis and is not a research contribution.** It assembles the constants — $k = (9/8)^2/\varphi^2 = 0.483425732988414$, a *defined* constant, exact, whose hertz label is a separate and postulated claim; $k^2 = 0.233700439315386$; $\ln 12 = 2.484907$; $kN^2 = 69.6133$; $2/\ln 2 = 2.8853900817779268$; $1/(4\pi) = 0.0795774715$ — together with the three transfer rules, the keystone and its deficit identity, the ceiling and hold line, the four levers and their partials, the agreement identity with its $4/m$ resolution bound, eight measurement protocols, a concordance register, and the exact unit conversions in which one bit is two octaves exactly. Four items originate here. The folded-lattice minimum gap is derived by exact rational arithmetic as a function of ladder length: 1200 cents at $N = 2$, the Pythagorean tone 203.9100 at $N = 3 \dots 6$, $50/49 = 34.9756$ cents at $N = 7 \dots 16$, $289/288 = 6.0008$ from $N = 17$ and $1682/1681 = 1.0296$ from $N = 41$, with a symbol-rate penalty of exactly 8 at the first cliff. Single-transposition audible capacity is $N \leq 25$ and only at $j = 6$. And the four-drawer classification — PROVED, POSTULATED, BORROWED, UNTESTED — prices the framework's central design axiom rather than defending it: an alternative surplus form satisfying every axiom but the affine one agrees at both endpoints yet disagrees by 33.62 per cent at $u = 0.5$, 1.871802 against 1.242453. The operationalisation of the twelve-state ladder is recorded as specified and not run.

Keywords: reference card; frequency tables; measurement protocol; minimum gap; transposition capacity; honesty appendix; postulate pricing; concordance register

Series: C. Frequency, Essence, and Mind **Paper:** CCP-050

1 Introduction

This paper is the reference and status apparatus for a framework whose results are established elsewhere. It is not a research contribution and is not offered as one. It exists because

the preceding papers of this series distribute their constants, tables, protocols and disclosures across ten documents, and a reader who wants to reproduce a reading, or to check what a given claim rests on, should not have to reconstruct that from ten places.

Almost everything in what follows is a restatement, and each restatement names the paper that owns the result. Where a number here differs in its last digit from a figure quoted in an owning paper, the full-precision rule applies: recompute from the full-precision input, never from a rounded one, and §13 records the two places where that rule catches something.

Four things here are not restatements, and they are the only items a citing paper should treat as originating in this document.

1. **The folded-lattice minimum gap as an exact function of ladder length** (§5.6). Folding every n^2 into one octave as an exact rational and taking the smallest adjacent ratio gives a step function with five regimes: $2/1$ at $N = 2$, $9/8$ (203.9100 cents) at $N = 3 \ldots 6$, $50/49$ (34.9756 cents) at $N = 7 \ldots 16$, $289/288$ (6.0008 cents) at $N \geq 17$, and $1682/1681$ (1.0296 cents) at $N \geq 41$. **The symbol-rate penalty at the first cliff is exactly 8.**
2. **The single-transposition audible capacity** (§5.7): at most 25 essences fit the audible band under one integer octave transposition, and only at $j = 6$.
3. **The pricing of the framework's central design axiom** (§8.2). The affine effective-count axiom is chosen, not forced, and an alternative satisfying every other axiom and agreeing at both endpoints **disagrees by 33.62 per cent in the middle of the range**.
4. **The four-drawer evidential classification** (§8), which sorts every claim the series makes into PROVED, POSTULATED, BORROWED and UNTESTED, and records the framework's own operationalisation as **SPECIFIED, NOT RUN**.

What a reference card costs, stated at the front. A card invites a reader to skip the argument, and the argument is where the limits live. Every card below therefore carries its limits inline, and the most important one belongs here rather than at the end: **the series' central instrument, the octave deficit, is blind to one of the four parameters that decide a relation's fate.** It contains no decay term, so a report giving the deficit alone cannot see decay, and Protocol C7 makes reporting both a numbered step rather than a caution.

2 Hypothesis

This paper advances no testable hypothesis. It is a reference collection and a status classification, and it is reported as such. Nothing in the sections that follow is a claim about the world that observation could confirm or refute; the tables are arithmetic, the protocols are procedures, and the classification is a record of what the framework has and has not paid for.

The organising question is therefore not empirical but bibliographic and evidential: **what must a reader hold in order to reproduce any reading this series reports, and on what does each of the series' claims actually rest?** The first half is answered by Sections 4 to 6 and the second by Sections 7 and 8.

Two consequences follow and are stated so that no reader mistakes the genre.

No result here is offered as new evidence for anything. The four items named in §1 as originating here are computations — three exact-arithmetic results and one classification — and none of them tests the framework. §8.2's pricing of the affine axiom is the closest thing to a critical result in the paper, and what it establishes is the *size of a choice*, not that the choice is wrong.

Where the framework's own hypotheses are recorded here, they are recorded as untested. §8.4 lists them with their kill conditions: the operationalisation of the twelve-state ladder is **specified and not run**; the acoustic causal claim is **not confirmed**; the decisive experiment is **designed and not run**; and the framework's own estimate of its research programme's completion probability is **35.8 per cent**. Those are the framework's numbers, restated, not this paper's findings.

3 Scope, framework, and dimensional audit

3.1 What this paper restates and what it does not

section	content	owning paper(s)
4	constants, three transfer rules, keystone, deficit, ceiling, levers, unit conversions	[Curzi, 2026,?,?]
5.1–5.5	the twelve-state ladder, raw and folded frequencies, the keystone table, the interval lattice, class counts	[Curzi, 2026,?]
5.6–5.7	**the minimum-gap schedule and the transposition capacity**	**originating here**
6	eight measurement protocols and four worksheets	[Curzi, 2026,?,?]
7	the concordance register, with rejections	[Curzi, 2026,?]
8	**the four-drawer classification and the pricing of the affine axiom**	**originating here**
9	correspondence to the two predecessor series	[Curzi, 2026,?,?]

Nothing in Sections 4, 5.1–5.5, 6, 7 or 9 should be cited to this paper where the owning paper can be cited instead.

3.2 The constant, its status, and the two claims it carries

$k = (9/8)^2/\varphi^2 = 0.483425732988414$ is a **defined constant, exact.** It is a ratio of exact quantities and therefore computable to arbitrary precision, so the fifteen significant figures quoted throughout this paper are *digits of a definition* and carry no measurement uncertainty because there is no measurement. $k^2 = 0.233700439315386$ inherits the same status. **Every appearance of either at that precision is so labelled.**

Attaching hertz to it is a separate and much stronger claim. Computing the ratio is arithmetic; asserting that a dimensionless number *is a frequency* requires an operational procedure by which the constant acquires the dimension of inverse time, and **the series supplies none.** That claim is badged **POSTULATED** here, in §4.1, in the verification chain of §12, and in §13.

The two components are real and documented — the Pythagorean whole tone [Barbour, 1951] and the golden section [Euclid, 1956, Vajda, 1989] — but **their product expressed as a frequency has no precedent in any literature we have found.** The deflationary literature on golden-section claims [Markowsky, 1992, Fischler, 1981, Livio, 2002] is cited here deliberately and again wherever φ appears.

One property makes the postulate less damaging than it looks, and it is why the tables below are usable. The essence bridge has the property that $f(m)/f(n) = m^2/n^2$, so k cancels from every interval, every ratio and every deficit [Curzi, 2026k]. **Every verdict in this series**

is a difference of logarithms in which the constant cancels; only the absolute hertz columns depend on it.

3.3 The exponent, and what was not done

The essence law $f(n) = kn^2$ is a **postulate of this framework with no external support**, and **the exponent 2 is defined by the model, not estimated from data.** No exponent anywhere in this series was obtained by fitting, none was tested against a log-normal or exponential alternative, and the goodness-of-fit and likelihood-ratio procedure that a claimed scaling relation requires [Clauset et al., 2009] was **not run, because there is no data to run it on.** The same applies to the exponent 4 in the compound rule [Curzi, 2026].

3.4 Octave reduction

Octave equivalence is a perceptual structure formalised for **pitch** [Shepard, 1982], whose perceptual specialness has a measured size [Demany et al., 2013]. **Its extension to a quantity that is not a pitch is a modelling choice of this framework with no external warrant.** The *operation* — division by a power of two — is well defined, and every folding in §5 is exact arithmetic; the *interpretation* of a folded value as carrying meaning is not supported. Cents, octave equivalence and exact rational interval arithmetic are standard apparatus once an index exists [Barbour, 1951, Lindley and Turner-Smith, 1993, Benson, 2006, Rossing et al., 2002], but what a listener finds consonant depends on the spectrum of a sound and not on the ratio alone [Sethares, 2005, Plomp and Levelt, 1965], and interval categories generalise less far than is usually assumed [Burns, 1999]. **This paper uses the arithmetic and claims none of the perception.** Two established measures of ratio complexity exist — Euler's *gradus suavitatis* [Euler, 1739] and harmonic distance [Tenney, 2015] — and **neither is used here**; §5.6 measures gaps in cents, which is a distance in a logarithmic register and carries no claim about consonance.

3.5 Dimensional audit

symbol	quantity	dimension	unit	status
n	essence index	$[1]$	count	cardinality, absolute scale
N	category count	$[1]$	count	cardinality, absolute scale
u	interaction parameter	$[1]$	dimensionless, $[0, 1]$	derived from unit vectors
w	elicited intensity	$[1]$	instrument units	**ordinal by default** (§6, Protocol C2)
F	surplus	$[1]$	nats	derived; **nats are not a physical unit**
η	conversion efficiency	$[1]$	dimensionless	declared
c	cost flow	$[\mathcal{C}\,T^{-1}]$	per declared period	declared
δ	loss rate	$[1]$	per declared period	declared
Q	stored order	$[\mathcal{C}]$	**no operational unit exists**	state variable

symbol	quantity	dimension	unit	status
D	octave deficit	$[1]$	octaves, cents, bits	derived
j	transposition exponent	$[1]$	integer	register choice, not a parameter
G	count-weighted geometric mean	$[1]$	index units	derived
k	ground essence	**claimed** $[T^{-1}]$	Hz **by postulate**	**defined; the unit is asserted**
k^2G^4	compound value	$[T^{-2}]$ **if taken seriously**	*convention-Hz*	derived; the label is a convention
$\Delta t\,\Delta f$	Gabor product	$[1]$	dimensionless	**classical Fourier; measurable**

Where the audit closes and where it does not. Every dimensionless quantity closes exactly, and so does the Gabor bound, which is a fact about Fourier duality with no quantum content [Gabor, 1946] and is measurable on an oscilloscope. **Two places do not close.** $f(n) = kn^2$ balances only if k carries $[T^{-1}]$, which is the postulate of §3.2; and the compound value is dimensionally hertz-squared, so its "Hz" label is a convention and not a unit. Q **has no operational unit at all**, and the dimensionless placeholder in the table is the honest record of that rather than an evasion.

3.6 Scale type, and the one place this series is exposed hardest

Permissible arithmetic is a function of the transformation group that leaves a quantity's empirical content unchanged [Stevens, 1946], and this series carries **two quantities of different scale status which must never be given a single verdict**.

n is a **count**: zero components is no state, so it has a true zero and equal units, and it is ratio-scaled by construction. w, the elicited intensities, are **ordinal by default**, and u, F, f_{rel} and the deficit inherit their status. **So the state frequency is ratio-scaled and the relationship frequency is not, until the intensities are.** Protocol C2 records why the usual fallback — report the output ordinally and carry on — is unavailable: a monotone relabelling that destroys no ordinal information whatever moves the relationship frequency by 1065.0568 cents, nearly an octave.

The instrument the series leans on is magnitude estimation, which is *held* to deliver ratio-scale information [Stevens, 1957] and whose exponents move with the experimenter's chosen range [Teghtsoonian, 1971], whose response biases are catalogued [Poulton, 1968], and about which the dispute is live [Krueger, 1989, Luce, 2002, Narens, 1996]. **The series inherits that dispute whole.**

And Michell's objection stands unanswered. That psychology assumes quantitative structure without testing for it [Michell, 1997, 1999] is the single strongest objection to this framework. The formal test for additive quantitative structure exists [Luce and Tukey, 1964, Krantz et al., 1971] and **was not run on any quantity in this series**; the instrument that would repair the framework's own demotion of one of its constructions [Curzi, 2026t] is Rasch measurement [Rasch, 1960], priced by the framework at 123 items per term and **not spent.** §8.2 and §13 record this as the framework's largest standing liability.

3.7 Identification, stated once because the protocols depend on it

Protocols C3 to C7 produce readings of a reflexive specification: the parties constitute the relationship and the relationship conditions the parties. **The endogenous social effect in such a**

specification is not identified from observational data [Manski, 1993]; it cannot be separated from contextual effects or from correlated unobservables however much data is collected, and influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. **The remedy the protocols adopt is stipulation of the reference set** [Brock and Durlauf, 2001] — the parties, the item set, the period and the vectors are declared and published — **and the price is that a reading is a modelling position rather than an identified empirical result.** That statement belongs on every worksheet and it belongs here.

3.8 Method

No data were collected for this paper and nothing was fitted. Three procedures produced everything originating here.

1. **Exact rational arithmetic.** §5.6's minimum-gap schedule was computed with exact fractions rather than floating point, because the quantities compared differ in the fourth decimal place of a cent. The four regime boundaries and the two cliff locations are exact and depend on k not at all.
2. **Exhaustive search over a bounded set.** §5.7's transposition capacity was computed over $j = 0 \dots 15$ for every N, and §5.5's class count was checked at every N from 1 to 25 against the closed form $\lceil N/2 \rceil$.
3. **Restatement with attribution.** Every other number is recomputed from the owning paper's stated inputs at full precision and cited to the paper that owns it.

Every figure in this paper is generated by a script named in its caption. No model comparison is reported, no statistical test is run, and no effect size or interval is given, because nothing here is an empirical claim.

4 The reference card: constants, transfer rules, the keystone, the levers

Printable: one page of constants, one of laws, one of conversions, one of clauses. A reader with the four pages and nothing else can compute every reading in this series and state correctly what the reading does not mean.

4.1 The constants

```
THE GROUND ESSENCE

    k  =  (9/8)^2 / phi^2                  phi = (1 + sqrt 5)/2 = 1.6180339887498949

    k  =  0.483425732988414                (computed: 0.48342573298841435)
                                           DEFINED, exact
    the unit "Hz" on k                     a SEPARATE claim: POSTULATED

    k^2 = 0.2337004393                     (computed: 0.23370043931538567)

THE CATEGORY COUNT USED THROUGHOUT THIS SERIES

    N       = 12
    ln N    = 2.484907                     (computed: 2.4849066497880004)
    k N^2   = 69.6133 Hz                   (computed: 69.61330555033166)

DERIVED CONSTANTS THAT RECUR

    1/sqrt(k)      = 1.438252434444351     CCP-046 crossing; not an integer
```

```
2 / ln 2       = 2.8853900817779268      octaves per nat
1 / (4 pi)     = 0.07957747154594767     the Gabor product
32 / (4 pi)    = 2.5464790894703255      cycles per resolved step in the 50/49 regime
```

`phi` is stored to full double precision throughout. The essence-law errata of Series B [Curzi, 2026k] traced a residual bias in the published element table to `phi` held at fifteen significant figures: carry the constant, not its printed form.

Two claims live in the first block and they have different statuses, so they are separated here and again in the verification chain of §12. Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is **arithmetic**, and the constant is **DEFINED and exact**: it is a ratio of exact quantities, so its fifteen figures are digits of a definition and carry no measurement uncertainty. **Writing "Hz" after it is a separate and much stronger claim, and it is POSTULATED** — no operational procedure is supplied by which a dimensionless ratio acquires the dimension of inverse time. The same split applies to k^2. The card prints the unit because the series prints it; the badge travels with it wherever it appears.

`k` sets the reference pitch and is invisible to every verdict. The cancellation of the constant [Curzi, 2026] proves it: the octave deficit is a difference of logarithms in which `k` appears in both terms and cancels. Only absolute hertz values depend on the constant. Sustainability verdicts do not.

4.2 The three transfer rules

```
RULE 1 -- A PSYCHOLOGICAL ESSENCE HAS A FREQUENCY          owner: CCP-041, CCP-042

    f  =  k * n^2            n = the number of distinguishable components required
                                 to specify the state

    n is a COUNT: true zero, equal units, ratio-scaled by construction.
    The frequency inherits exactly the defensibility of the count.

RULE 2 -- A PSYCHOLOGICAL RELATIONSHIP HAS A FREQUENCY     owner: CCP-043

    cos theta = x . y        x, y unit vectors over the N states
    u         = 1 - (x . y)^2
    F         = ln(1 + (N-1) u)          = ln(1 + 11 u) at N = 12
    f_rel     = k * e^(2F)  =  k * (1 + 11 u)^2  =  k * N_eff^2

    u = 0  ->  f = k, the ground essence: no relationship at all
    u = 1  ->  f = k N^2 = 69.6133 Hz, the ceiling

RULE 3 -- A COMPOUND STATE USES THE ALCHEMICAL RULE        owner: CCP-046

    f_compound  =  k^2 * G^4         G = count-weighted geometric mean of indices
                                     G = (prod n_i^{m_i})^(1/T),  T = sum m_i

    Values are convention-Hz and are dimensionally Hz^2. They may not be rendered
    as hertz and may not enter an acoustic calculation.
```

Rule 3 is not a generalisation of Rule 1 and the arithmetic says so twice. For a single component `G = n` and `f_compound = k^2 n^4 = f(n)^2`, which is the single-component identity [Curzi, 2026]; and **The no-agreement corollary CC-R4 [Curzi, 2026] shows the two rules agree at no index whatever, since `k n^2 = k^2 n^4` requires `n = 1/sqrt(k) = 1.438252`, which is not an integer.** At `n = 12` the two rules differ by 6.121291 octaves. The single-component index-independence of Rule 3's proportional structure is exactly what condemned the source table's O2 row in the essence-law errata of Series B [Curzi, 2026k].

Worked compounds, recomputed here to ten places for citation:

```
multiset                T        P           G                f = k^2 G^4

{11x1, 12x1}            2      132    11.4891252931          4071.9964546313
-------------------------------------------------------------------------------
```

Rule 3 is blind to scale and acutely sensitive to ratio: trebling every multiplicity leaves `G` unchanged, while two multisets differing only in how many index-1 components are present sit 3.584963 octaves apart.

4.3 The keystone

```
THE MINIMUM SUSTAINABLE FREQUENCY                          owner: CCP-041

    f_min  =  k * e^( 2c / eta )

    f  >  f_min      the relation ACCUMULATES order       Q_inf > 0
    f  =  f_min      it HOLDS, and nothing more            Q_inf = 0
    f  <  f_min      it DECAYS, whatever anyone intends    Q_inf < 0

THE DERIVATION, IN THREE STEPS

    sustainability   Q_inf > 0   iff   eta F > c   iff   F > c/eta
    the bridge       F = (1/2) ln( f / k )
    substitute       f > k e^(2c/eta)
```

`f_min` contains no `delta` and no `N`, and both absences are substantive: the first is the source of the delta-blindness treated in §4.4, and the second means the threshold is set by cost and conversion alone, `N` entering only through the ceiling on what `F` can reach.

In octaves above the ground essence:

```
octaves required  =  2 (c/eta) / ln 2  =  2.885390 * (c/eta)
```

Every unit of cost-to-conversion ratio costs 2.885390 octaves of required pitch, and there is no other exchange rate.

4.4 The octave deficit, and the two theorems that govern it

```
THE OCTAVE DEFICIT                                    owner: CCP-041, Def 4.4

    D  :=  2.885390 * (c/eta)  -  log2( f / k )

    D <= 0    sustainable as it stands
    D  > 0    the relation is short by D octaves

THEOREM 4.5 -- THE DEFICIT IDENTITY

    D  =  2.885390 * ( c/eta  -  F )  =  -2.885390 * (delta/eta) * Q_inf

    Q_inf  =  ( eta F  -  c ) / delta            CCP-041 Theorem 3.5
    F      =  ln( 1 + 11 u )
```

Verified on the carried dyad as found: `D = 4.338420197297714` by the definition and `4.338420197297713` by both identities, a worst residual of `8.88e-16`. the verification record [Curzi, 2026] records independent verification across twelve parameter sets to `2.665e-15`.

```
THEOREM 4.9 -- THE DEFICIT CONTAINS NO delta

    D  =  2.885390 * (c/eta) - log2(f/k)     contains k, c, eta, N, u
                                             does NOT contain delta
```

This is the card's most important qualification and the one most easily lost when the card is used without the owning paper. Worked on the carried dyad at `eta = 0.30`, `c = 0.62`:

```
delta = 0.09   ->   Q_inf = -5.0119395464      D = +4.3384201973
delta = 0.05   ->   Q_inf = -9.0214911835      D = +4.3384201973
```

Trust nearly doubles the negative fixed point and the deficit does not move at all. The deficit reads the sign and size of the sustainability gap; `delta` converts that gap into a level. A reading that reports `D` without `delta` cannot see decay, and it is incomplete. Report both, always.

4.5 The ceiling, the minimum category count, and the hold line

```
THE CEILING            CCP-041 Cor 3.4 in the frequency register       owner: CCP-041 Thm 4.6

    Since F <= ln N,        c/eta  <=  ln N        and       f_min  <=  k N^2

    At N = 12:  c/eta may not exceed 2.484907, i.e. f_min may not exceed 69.6133 Hz.
    Above that, NO arrangement of those twelve categories is sustainable --
    not a better pairing, not a better schedule, nothing.
    The only remedies: raise eta, cut c, or add genuinely distinct categories.

THE MINIMUM CATEGORY COUNT                                          owner: CCP-041 Cor 4.7

    N  >=  e^(c/eta)

THE HOLD LINE                                                       owner: CCP-041 Cor 4.8

    u*  =  ( e^(c/eta) - 1 ) / (N - 1)
```

The ceiling test comes first. A deficit computed above the ceiling is a number with no verdict attached: no arrangement of the declared category set can close it.

4.6 The four levers

```
LEVER              acts on            partial derivative of D
-------------------------------------------------------------------------------
L1  raise u        the geometry       dD/du    = -2.885390 (N-1) / (1 + (N-1)u)
L2  raise eta      the conversion     dD/deta  = -2.885390 c / eta^2
L3  cut c          the cost           dD/dc    = +2.885390 / eta
L4  raise N        the category set   dD/dN    = -2.885390 u / (1 + (N-1)u)
```

These are the only four, and `delta` is not one of them (the decay-blindness result CC-R4 [Curzi, 2026]). `delta` moves the level, not the gap.

```
THE ORDER-OF-OPERATIONS RULE (R15)                          owner: CCP-044

    FIX THE NUMERATOR FIRST.

    Trust acts by LOWERING delta. Q_inf = (eta F - c)/delta.
    When the numerator is negative, dividing by a smaller positive denominator
    makes the result MORE negative. Trust amplifies whatever sign the system
    already has; it is not a source of order.
```

4.7 The agreement identity

```
THEOREM 13.1                                                owner: CCP-044

    Two parties judge m shared items, each judgement coded +1 or -1.
    Let a = fraction of items on which the judgements match. Then

        cos theta  =  2a - 1              u  =  4 a (1 - a)

    Exact; no centring required, since +/-1 vectors have norm sqrt(m).
    Resolution limit:  du = 4 |1 - 2a| / m,  bounded by 4/m.
```

The identity is symmetric about `a = 0.5` and returns `u = 0` at both `a = 1` and `a = 0`, which is CC-R8 appearing directly in the measurement channel: the sycophant and the contrarian sound the identical note. Two parties answering at random have expected `a = 0.5`, hence `u = 1`, hence the ceiling of the whole system from guessing. The formalism cannot distinguish independence from noise, because both are orthogonality, and the guard is procedural: publish each party's accuracy with any `u`.

4.8 The Gabor limit

```
dt * df  >=  1 / (4 pi)  =  0.07957747154594767             owner: Series B / CCP-032

Classical Fourier duality. No quantum content. Measurable on an oscilloscope.

THE FOUR DESIGN LAWS
  (1) single-transposition audible capacity is N <= 25, and only at j = 6
  (2) the folded-lattice minimum-gap cliff is at N = 17 (50/49 -> 289/288),
      the second at N = 41, and the RATE factor is exactly 8
  (3) resolving a surplus difference dF costs at least 1/(8 pi dF) cycles
  (4) the rectangular gate is disqualified: no finite spectral second moment
```

`N = 12` sits below the `N = 17` cliff, so **this entire book renders in the 50/49 regime, at a minimum separation of 34.9756 cents and 2.546479 cycles per resolved step.** A 40-cent deficit is just above the minimum resolvable step of the lattice it is expressed in; a 6-cent one would not be.

4.9 Unit conversions

```
1 nat    =  1.442695 bits    =  2.885390 octaves  =  3462.4681 cents
1 bit    =  2 octaves EXACTLY                     =  2400 cents
1 octave =  1200 cents

computed:  1/ln2   = 1.4426950408889634
           2/ln2   = 2.8853900817779268
           2400/ln2 * (ln2/2) ... 1200 * 2/ln2 = 3462.4680981335123
```

```
D in octaves  =  2.885390 * (c/eta - F)
D in cents    =  3462.4681 * (c/eta - F)
D in bits     =  1.442695 * (c/eta - F)
```

The corpus's closing synthesis computes the same exchange from the other direction, finding that pitch-class folding of the essence lattice costs exactly $\ln 2 = 0.6931471806$ nats — one bit, two octaves — for every even N [Curzi, 2026].

The bit-to-octave conversion is exact and not a coincidence: frequency enters as `f = k e^(2F)`, so one nat is two e-folds of frequency and one bit — being `ln 2` nats — is two doublings, which is two octaves. **The four registers of the conversion keys of Series B [Curzi, 2026l] converge here because they are all logarithms of the same effective count, taken to different bases.** The carried dyad as found reads `+4.3384 octaves = +5206.1 cents`; after its intervention, `−3.5910 octaves = −4309.2 cents`.

4.10 The clauses, which are part of the card and not an afterword

```
C1  Essence frequencies are ESSENCE frequencies, not physical resonances. No
    person, tissue or molecule is claimed to resonate at any value in this series.

C2  No clinical, diagnostic or therapeutic claim. The twelve states are not
    diagnoses; the readings are not assessments.

C3  No intervention may remove a person's ability to decline. Consent is
    structural, not advisory.

C4  No subliminals. Nothing masked, nothing below threshold, nothing concealed.

C5  The open problem stands: no established mechanism for sequence-specific
    acoustic demodulation.

C6  All worked cases are CONSTRUCTED and labelled as such.

C7  R1 binds D/P specifically. It does not bind the count index n, and it does
    not bind magnitude-estimated intensities. State which quantity you mean.

C8  Report D AND delta. The deficit alone cannot see decay (Theorem 4.9).

C9  A state frequency and a relationship frequency are independent readings and
    neither may be inferred from the other (result R7 of CCP-046).

C10 (+1) carries evidence; (-1) carries precedent. Precedent is never promoted.
```

4.11 The card, on one page

```
============================================================================
THE SUSTAINING FREQUENCY -- REFERENCE CARD
============================================================================
k = 0.483425732988414 = (9/8)^2/phi^2           k^2 = 0.2337004393
  DEFINED, exact.  The unit "Hz" on it is a SEPARATE claim, POSTULATED.
N = 12     ln N = 2.484907     k N^2 = 69.6133 Hz
----------------------------------------------------------------------------
STATE          f = k n^2                       n is a COUNT
RELATION       f_rel = k (1 + 11 u)^2          u = 1 - (x.y)^2
               F = ln(1 + 11 u)
```

```
COMPOUND       f_compound = k^2 G^4            convention-Hz, never rendered
-------------------------------------------------------------------------
KEYSTONE       f_min = k e^(2c/eta)
OCTAVES REQ    2.885390 * (c/eta)
DEFICIT        D = 2.885390*(c/eta) - log2(f/k)
IDENTITY       D = 2.885390*(c/eta - F) = -2.885390*(delta/eta)*Q_inf
DELTA-BLIND    D contains no delta.  REPORT D AND delta.
DESTINY        Q_inf = (eta F - c)/delta
CEILING        c/eta <= ln N          HOLD LINE  u* = (e^(c/eta)-1)/(N-1)
LEVERS         raise u | raise eta | cut c | raise N.  delta is not a lever.
ORDER          fix the numerator first (R15)
AGREEMENT      u = 4a(1-a),  cos theta = 2a - 1,  resolution 4/m
GABOR          dt df >= 1/(4 pi) = 0.0795774715
UNITS          1 nat = 1.442695 bits = 2.885390 octaves = 3462.4681 cents
               1 bit = 2 octaves exactly
-------------------------------------------------------------------------
NOT a resonance. NOT a diagnosis. NOT a capability. Consent is structural.
Nothing masked. The open problem stands. All cases constructed.
=========================================================================
```

---

5 Frequency, interval and lattice tables

Every table here was computed, not asserted. Where exact arithmetic matters — §5.6's minimum-gap analysis — the computation used exact rationals via `fractions.Fraction`, because the quantities compared differ in the fourth decimal place of a cent.

5.1 The twelve-state ladder This is the ladder exactly as the founding definitions [Curzi, 2026n] gives it, and it is the only ladder this series uses. The folded column transposes each raw frequency by whole octaves into `[220, 440)`; the pitch class is the odd part of the index, by the odd-part theorem of the mood-and-trait paper [Curzi, 2026].

n	state class	the component it adds	f = k n^2 (Hz)	folded 220-440	pitch class
1	undifferentiated activation	arousal alone	0.483426	247.5140	1
2	valenced activation	+ valence	1.933703	247.5140	1
3	directed feeling	+ intentional object	4.350832	278.4532	3
4	situated feeling	+ situation	7.734812	247.5140	1
5	attributed feeling	+ cause	12.085643	386.7406	5
6	temporal feeling	+ projected duration	17.403326	278.4532	3
7	reflexive feeling	+ self as object	23.687861	379.0058	7
8	social feeling	+ another mind modelled	30.939247	247.5140	1
9	normative feeling	+ standard applied	39.157484	313.2599	9

n	state class	the component it adds	f = k n^2 (Hz)	folded 220-440	pitch class
10	narrative feeling	+ placed in a story	48.342573	386.7406	5
11	reciprocal feeling	+ the other modelling you	58.494514	233.9781	11
12	committed feeling	+ future action bound	69.613306	278.4532	3

Twelve states, six distinct pitch classes `{1, 3, 5, 7, 9, 11}` — `ceil(12/2)`, as the odd-part theorem requires. Indices 1, 2, 4 and 8 share class 1 and fold to the identical audible frequency. **A folded reading that reports six notes from a twelve-state ladder has lost no information it was entitled to: the collision is a property of the arithmetic, not of the fold.**

The six classes, reduced to one octave and sorted by pitch:

```
class    folded ratio (exact)    cents above PC1    step to next
------------------------------------------------------------------
PC1              1                       0.00          203.91
PC3            9/8                     203.91          203.91
PC9           81/64                    407.82          329.83
PC7           49/32                    737.65           34.98
PC5           25/16                    772.63          330.01
PC11         121/64                   1102.64           97.36
------------------------------------------------------------------
