| Reviewer #1 | measured with short (under two hours) <sup>71</sup> incubations of seawater samples inoculated with <sup>14</sup> C.  | Why short incubations under two hours? The literature does not agree on this, so I wouldn't state it as "the better option". It depends if you want to measure gross or net PP among other things.  | Minor<br>Edit | <input type="text"/> |
| Reviewer #1 | photosynthetic parameters could provide a better option to <sup>107</sup> estimate primary production under sea ice compared to traditional in situ incubations per- <sup>108</sup> formed at single locations using seawater samples inoculated with <sup>14</sup> C or <sup>13</sup> C. | This is confusing because photosynthetic parameters are also derived from <sup>14</sup> C <sup>13</sup> C in situ inoculated samples, the only difference is that they are incubated under a range of different irradiances and not just under one light intensity. This needs to be clarified because as it is it reads as if the <sup>13</sup> C or <sup>14</sup> C incubation method is not appropriate to measure PP. | Minor<br>Edit | <input type="text"/> |
| Reviewer #1 | Due to instrument failure of the <sup>136</sup> Magna Probe, no snow measurements were available for stations 46 and 47.  | As you mention in your reply, this data was not used in the statistical analysis and therefore the lack of data on these two stations has no influence on the manuscript. I would add this information here.  | Minor<br>Edit | <input type="text"/> |
| Reviewer #1 | different irradiance levels   | Specify the different irradiance levels used for the PE curve incubations.  | Minor<br>Edit | <input type="text"/> |
| Reviewer #1 | integrating <sup>262</sup> daily primary production over the first 40 m of the water column.  | Add here the information that you provided in the answers to the reviewers, stating that this depth roughly coincides with the depth of the euphotic zone.  | Minor<br>Edit | <input type="text"/> |

| Reviewer #1 | <p>maximum depth of winter mixing<sup>397</sup>(which determine the amount of nutrients available for summer primary production)</p>   | <p>The maximum depth of winter mixing determines the amount of nutrients available for that years PP which happens in spring-summer. So here you are talking about annual primary production and not about individual daily rates of carbon uptake which is what you are talking about before. The comparison is therefore not valid for your argument about the variability of daily PP.</p>   | <p>Minor<br/>Edit</p> | <input type="text"/> |
| Reviewer #1 | <p>In our<sup>399</sup>approach, the impact of light history, nutrients, temperature, and community composition<sup>400</sup>are implicit in photosynthetic parameters and chl a concentration. The instantaneous effect<sup>401</sup>of light variations is explicit.</p>                                 | <p>Correct, but to constrain the variability in PP estimates and improve their accuracy, which is the aim of this paper, you need to take into account the variability in photosynthetic parameters due to all these factors. I know that in this paper you are just focusing on light, but you need to state somewhere that to improve the accuracy of PP estimates it is not only necessary, as you very nicely show, to improve our under-ice light field measurements, but also to have a seasonally and regionally extensive set of PE curves to constrain the variability due to nutrient availability.</p> | <p>Minor<br/>Edit</p> | <input type="text"/> |
| Reviewer #1 | <p>dynamic approach</p>  | <p>I am glad that you added this paragraph. What do you mean here by "dynamic?" Please specify.</p>   | <p>Minor<br/>Edit</p> | <input type="text"/> |
| Reviewer #1 | <p>o reasonably capture the spatial variability of sea ice transmittance to derive average primary production estimates over a given area. This shows, that local primary<sup>477</sup>production estimated from just a single or even a handful of light observations has limited<sup>478</sup>value.</p> | <p>And a similar study to capture the variability of photosynthetic parameters should be conducted in the future to test if a handful of PE curves is enough to estimate PP correctly or we need as many as we can get seasonally and spatially resolved to improve Arctic PP estimates.</p>  | <p>Minor<br/>Edit</p> | <input type="text"/> |

| Reviewer #1 | to obtain the best possible estimates of primary production | In your guideline to obtain the best possible estimates of primary production, you should remember the reader that the number of in situ PE curves measured is also very important to constrain the photosynthetic parameters under different nutrient conditions. If you only have one PE curve to calculate PP for the entire Arctic, the estimates will not be very accurate even if you have a super high resolution light transmission dataset. | <div data-bbox="1165 380 1260 436">Minor</div> <div data-bbox="1165 436 1236 481">Edit</div> <input data-bbox="1324 414 1484 448" type="text"/> |
