# Organisation

---

## Congress Presidents

- Aage Radmann (SWE)
- Susanna Hedenborg (SWE)

## ECSS Executive Board

- Marco Narici - President (GBR)
- Sigmund Loland – Past President (NOR)
- Tim Cable – President Elect (GBR)
- Joan Duda (GBR)
- Stephen Seiler (NOR)
- Gisela Sjøgaard (DEN)

## ECSS Scientific Board

- Anton Wagenmakers - Chair (GBR)
- Flemming Dela - Co-Chair (DEN)
- Jan Cabri - Secretary (NOR)
- Paul Greenhaff (GBR)
- Martin Halle (GER)
- Susanna Hedenborg (SWE)
- Luc van Loon (NED)
- Jose Antonio Lopez Calbet (ESP)
- Abigail Louise Mackey-Sennels (DEN)
- Erich Müller (AUT)
- Nicole Wenderoth (SUI)

## ECSS Scientific Committee

- Natalia Balague (ESP)
- Wilhelm Bloch (GER)
- Annalisa Cogo (ITA)
- Wim Derave (BEL)
- Peter Federolf (NOR)
- Taija Finni (FIN)
- Daniel Green, FECSS (GBR)
- Michael Grey (GBR)
- Markus Gruber (GER)
- Jørn Wulff Helge (DEN)
- Ylva Hellsten (DEN)
- Pierre-Nicolas Lemyre, (NOR)
- Johannes van Lieshout, (NED)
- Mike McNamee, FECSS (GBR)
- Maria Francesca Piacentini (ITA)
- Afroditi Stathi (GBR)
- Cecilie Thogersen-Ntoumani (AUS)
- Janice L. Thompson (GBR)

## ECSS Office

- Thomas Delaveaux (GER)
- Elias Tsolakidis (GRE)
- Steffen Neubert (GER)
- Juliane Melber (GER)
- Tuulia Hokkanen (FIN)

## Organizing Committee

- Jan-Eric Ekberg (SWE)
- Per Eriksson (SWE)
- Jenny Damgaard (SWE)
- Christopher Johansson (SWE)
- Annika Larsson (SWE)
- Mikaela Färnqvist (SWE)
- Joakim Åkesson (SWE)

## Chairs Local Scientific Committee

- Susanna Hedenborg (SWE)
- Biomechanics and Neurology**
- Anna Maria Drake (SWE)
- Physiology and Sport Medicine**
- Jens Bangsbo (DEN)
- Social Sciences and Humanities**
- Aage Radmann (SWE)

## Local Scientific Committee

- Eva Ageberg (SWE)
- Bo Carlsson (SWE)
- Urban Johnson (SWE)
- Tomas Peterson (SWE)
- Gertrud Pfister (DEN)
- Per Nilsson (SWE)
- Johan Norberg (SWE)
- Jens Bangsbo (DEN)
- Nikolai Nordsborg (DEN)
- Ingrid Svensson (SWE)
- Aage Radmann (SWE)

## Additional reviewers

- Ingrid Svensson (SWE)
- Andreas Jacobsson (SWE)
- Anna Maria Drake (SWE)
- Åsa Tornberg (SWE)
- Birgitte Høier (DEN)
- Elisabeth Apelmo (SWE)
- Eva Ageberg (SWE)
- Eva Horneij (SWE)
- Frida Eek (SWE)
- Gerald Gems (USA)
- Hanna Isaksson (SWE)
- Hans Hoppeler (SUI)
- Henrik Gustavsson (SWE)
- Ingegerd Ericsson (SWE)
- Ingrid Svensson (SWE)
- Jan Lexell (SWE)
- Jan-Eric Ekberg (SWE)
- Jenny Wikman (SWE)
- Jesper Fundberg (SWE)
- Jesper Lövind Andersen (DEN)
- Jesper Lundbye Jensen (DEN)
- Joakim Åkesson (SWE)
- Jyri Backman (SWE)
- Karin Book (SWE)
- Kasper Skriver (DEN)

- Katja Heinemeier (DEN)
- Kelly Knez (SWE)
- Kutte Jönsson (SWE)
- Lars Holm (DEN)
- Lasse Christiansen (DEN)
- Lasse Gliemann Hybholdt (DEN)
- Mark Andersen (SWE)
- Michael Nyberg (DEN)
- Mikael Londos (SWE)
- Mogens Theisen Pedersen (DEN)
- Natalia Stambulova (SWE)
- Per Wollmer (SWE)
- Peter Magnusson (DEN)
- Peter Møller Christensen (DEN)
- Richard Thomas (DEN)
- Simon Graner (SWE)
- Sofia Bunke (SWE)
- Stephen Fritzdorf (SWE)
- Svend Sparre Gertsen (DEN)
- Sverker Fryklund (SWE)
- Torbjörn Andersson (SWE)
- Torsten Buhre (SWE)
- Wade Knez (SWE)

#### **Head of Volunteers**

- Annika Larsson (SWE)

# Welcome

---

On behalf of the Department of Sport Science, Malmö University, Sweden, the Department of Health Sciences, Lund University, Sweden, and the Department of Nutrition, Exercise and Sport, University of Copenhagen, Denmark, it is our pleasure to invite you to attend the 20th Annual Congress of the European College of Sport Science – ECSS Malmö 2015.

The multidisciplinary ECSS Congress will be celebrating its 20th anniversary. The 2015 congress theme of Sustainable Sport will permeate the academic programme as well as the arrangements: the three universities co-hosting the event all emphasize sustainability

In education and research, and will work together with the City of Malmö, a fair trade city, to make ECSS 2015 a sustainable sport congress.

The ECSS congress especially emphasises exchange of knowledge through oral and mini-oral presentations, and we are convinced that all attendees will find interesting topics and participate in creating new knowledge within the broad field of Sport Sciences. Once again, the Young Investigators Award will be one of the highlights of the congress.

We look forward to seeing you all in Malmö and the Öresund Region, an area with tremendous social, political, and economic potential in the area of sustainability. Together, we will create an outstanding congress, where we shall develop the broad perspective of sustainable sport.

*Susanna Hedenborg & Aage Radman, Congress Presidents*

# TABLE OF CONTENTS

<b>ORGANISATION.....</b>	<b>3</b>
<b>WELCOME.....</b>	<b>8</b>
<b>WEDNESDAY, JUNE 24TH, 2015.....</b>	<b>17</b>
<b>13:00 - 14:00.....</b>	<b>17</b>
MO-PM01 TRAINING & TESTING .....	17
OP-PM76 GSSI NUTRITION AWARD.....	19
OP-PM77 ASPETAR EXCELLENCE IN FOOTBALL AWARD.....	22
OP-BN13 COACHING: TEAM SPORT I .....	23
MO-BN01 MOTOR LEARNING & BIOMECHANICS.....	25
MO-PM03 MUSCLE, MOLECULAR BIOLOGY AND BIOCHEMISTRY .....	28
MO-SH01 SOCIAL SCIENCES AND HUMANITIES IN SPORT.....	30
MO-SH04 PSYCHOLOGY I .....	32
MO-PM07 ADAPTED PHYSICAL ACTIVITY: CHALLENGES.....	35
MO-BN04 MIXED.....	37
MO-PM06 ADAPTED PHYSICAL ACTIVITY: SPORT & DISABILITY.....	38
MO-PM11 HEALTH & FITNESS: AGE.....	40
MO-BN06 COACHING: MIXED SESSION .....	44
MO-SH02 PHYSICAL EDUCATION AND PEDAGOGICS I.....	47
<b>14:00 - 15:00.....</b>	<b>49</b>
MO-PM02 NUTRITION, TRAINING ADAPTATION AND PERFORMANCE .....	49
MO-BN03 KINEMATICS .....	52
MO-PM05 OXYGEN TRANSPORT, VO2MAX AND ENERGY EXPENDITURE .....	55
MO-SH06 PHILOSOPHY & ETHICS .....	57
MO-SH05 PSYCHOLOGY II.....	59
MO-PM08 ADAPTED PHYSICAL ACTIVITY: DISABILITIES.....	61
MO-BN05 MOTOR LEARNING.....	63
MO-PM10 ADAPTED PHYSICAL ACTIVITY: NUTRITION.....	66
MO-PM12 HEALTH & FITNESS: AGEING, GENDER, STRENGTH .....	69
MO-BN07 COGNITIVE IMPAIRMENTS AND FATIGUE DURING EXERCISE .....	73
MO-SH03 PHYSICAL EDUCATION AND PEDAGOGICS II .....	77
<b>15:00 - 16:30.....</b>	<b>79</b>
IS-PM02 THE BENGT SALTIN TRIBUTE SYMPOSIUM.....	79
IS-PM10 THE ATHLETE'S BIOLOGICAL PASSPORT – WHAT'S THE STATUS? * .....	81
IS-PM06 SKELETAL MUSCLE ADAPTATIONS TO ENDURANCE TRAINING: IS TISSUE HYPOXIA THE MAIN SIGNAL?.....	82
OP-PM02 HEALTH, TRAINING & PERFORMANCE .....	82
IS-BN04 QUALITY OF MOVEMENTS – MORE THAN MEETS THE EYE?.....	85
IS-BN06 TENDON ADAPTATION.....	86
IS-SH01 FEPSAC SYMPOSIUM - THE DEVELOPMENT OF EXPERTISE AND COMPETENCIES OF APPLIED SPORT PSYCHOLOGISTS IN EUROPE.....	87
IS-SH02 ANIMALS, SPORT AND HEALTH - A SUSTAINABLE RELATIONSHIP?.....	88

OP-PM05 MUSCLE METABOLISM & NITRATE INGESTION .....	89
OP-BN01 NEUROMUSCULAR CONTROL.....	91
OP-PM36 SPORTS MEDICINE & TECHNOLOGY.....	93
OP-PM35 SPORT TECHNOLOGY: MIXED SESSION.....	96
OP-SH05 PSYCHOLOGY (PHYSICAL EXERCISE, FOOTBALL PERFORMANCE).....	97
OP-SH01 SPORTS PEDAGOGY AND HISTORY.....	99
<b>16:45 - 18:00.....</b>	<b>102</b>
PS-PL01 CHANCES AND CHALLENGES FOR PHYSICAL ACTIVITY AND LEARNING - SUSTAINABLE MOVEMENTS AND MOVEMENT CULTURES.....	102
<b>THURSDAY, JUNE 25TH, 2015 .....</b>	<b>103</b>
<b>08:30 - 10:00 .....</b>	<b>103</b>
OP-PM63 NUTRITION: FAT, GLUCOSE AND METABOLISM.....	103
OP-PM06 TRAINING INDUCED ADAPTATION.....	104
OP-PM01 SPORTS MEDICINE.....	107
OP-PM03 EXERCISE METABOLISM, MITOCHONDRIAL FUNCTION AND BODY COMPOSITION.....	109

#### RISK FACTORS FOR ANKLE SPRAINS SUSTAINED DURING NETBALL PARTICIPATION

Attenborough, A.S.1, Sinclair, P.J.1, Sharp, T.1, Stuelcken, M.2, Greene, A.3, Smith, R.M.1, Hiller, C.E.1

*1 The University of Sydney, Australia. 2 University of the Sunshine Coast, Australia. 3 Anglia Ruskin University, England*

**Introduction** Netball is a sport that places high physical demands on players, requiring them to perform jumping, bounding, pivoting and cutting manoeuvres at high speed. Ankle injuries account for approximately 40% of all netball injuries, with sprains being the most diagnosed ankle injury (Fong et al., 2007). The identification of risk factors that predict the occurrence of ankle sprains within netball is necessary for the development of future prevention programs. **Methods** Ninety-six netball players were assessed prior to the netball season for the following outcome variables; vertical jump, perceived ankle instability, previous sprain history, arthrometry inversion-eversion angles, star excursion balance test (SEBT) reach distances, number of foot lifts during unilateral stance and demi-pointe balance test. Participants were followed for one netball season and ankle sprains were determined using a time-loss injury definition. A forward sequential logistic regression model determined outcome variable risk factor status. **Results** Eleven ankle sprains were reported by eleven players. Three outcome variables made a statistically unique contribution to ankle sprain risk; a posterior-medial reach distance of  $\leq 77.5\%$  of leg length in the SEBT (OR=3.87, 95% CI=0.90-16.60), an inversion-eversion arthrometry angle of  $\geq 36.8$  degrees (OR=3.86, 95% CI=0.95-15.64) and an inability to maintain unilateral static balance during the demi-pointe balance test (OR=3.46, 95% CI = 0.87-13.80). Possessing all three risk factors would render a player 52 times more likely to sustain an ankle sprain. **Discussion** The posterior-medial reach distance, which is considered to be the most representative of overall SEBT performance (Hertel et al., 2006), was found to be a risk factor for ankle sprain. Research to create a risk profile screening tool for netball injuries has questioned the inclusion of the SEBT in the assessment (Reid et al., 2014). The current study refutes this and suggests that the posterior-medial direction of the SEBT should remain within the proposed screening tool. Two of the three identified risk factors were balance tests that could be easily administered during preseason preparations for the identification of 'at-risk' players. Interestingly, a previous ankle sprain and the presence of perceived ankle instability had no association with the ankle sprains sustained by the netball players. **References** Fong DT, Hong Y, Chan LK, Yung P, Chan KM (2007) *Sp Med*, 37(1), 73-94 Hertel J, Braham R, Hale S, Olmsted-Kramer L (2006) *J Orthop Sports Phys Ther*, 36(3), 131-7 Reid D, Vanweerd R, Larmer P, Kingstone R (2014) *J Sci Med Sport*, DOI:10.1016/j.jsams.2014.05.008 Contact aatt4376@uni.sydney.edu.au

#### EFFECTS OF UNSPECIFIC ENDURANCE EXERCISE ON SPECIFIC SPRINT PERFORMANCE IN INLINE SPEED SKATING

Stangier, C., Abel, T., Hesse, C., Claßen, S., Strüder, H.K.

*German Sports University*

**Introduction:** A highly developed aerobic performance level enables inline speed skaters (ISS) to sustain a high average of speed (40 km-h<sup>-1</sup>) during competition. Since the appropriate period to develop this ability is the winter preseason, due to the weather sport-specific training is not possible. A previous study has shown that unspecific endurance training improves specific endurance capacity (Hildebrand et al. 2014). Generally, a high aerobic capacity is negatively correlated with the sprint performance. However, to be competitive and successful, ISS also require power and swiftness to generate most effective sprints for the mass start, tactical attacks and the finish. Hence, we investigated the influence of nonspecific endurance training (cycling, running) on ISS' sport specific sprint performance. **Methods:** 14 high level ISS (7 male, 7 female, 24±8 yr, 175.4±9.7 cm, 67.5±11.2 kg) were randomly divided in two groups (running, cycling). Training was completed at 60% of VO<sub>2</sub>max over 7 weeks with 2 sessions per week (81-90 min) each on treadmill or cycle ergometer, respectively. Before and after the training intervention all subjects performed a specific (300 m) and nonspecific (30 s cycling or running) all-out sprint test. To determine the production rate of blood lactate (BLA) and glucose (BGL) one arterialized blood sample (20 µl) was taken at rest, as well as ten at one minute intervals after the sprint test. **Results:** The production rate of BLA decreased significantly (p=0.02) after the specific sprint test without any group effect. The production rate of BGL only showed a significant decrease (p=0.04) after the specific sprint test in the running group. However, the sport-specific sprint performance remained unchanged (29.4±2.7s, 29.6±3.7s). No significant changes were found from pre to post for the production rates after the unspecific sprint tests. **Conclusion:** Since the study was conducted during the preseason, the absent loss of sprint performance can be considered as positive, indicating that nonspecific training at 60% of VO<sub>2</sub>max stabilises ISS' sprint performance. Moreover, the decreased production rate for BLA enables the athletes to recover faster from high intensity sprints. The lower production rate of BGL for all athletes who trained in the running group should be considered for optimal endurance training. The results suggest this type of unspecific training presents a greater stimulus for the sport-specific fat metabolism than cycling, resulting in a more economic energy supply (Jeukendrup, 2002). **References:** Hildebrand C, Abel T, Hesse C, Claßen S, Strüder HK. ## THE IMPACT OF DATA AVERAGING STRATEGIES ON VO<sub>2</sub>MAX

Martin-Rincon, M.1, Perez-Valera, M.1, Rodríguez-Afonso, K., Cherouveim, E., Curtelin, D., Losa-Reyna, J., Sanchez Torres-Peralta, R., Ponce, J.G., Morales, D., Dorado, C., De Pablos, P., Calbet, J.A.

<sup>1</sup>Univ. of Las Palmas de G. Canaria, Spain; <sup>2</sup>Univ. Athens, Greece.

**Introduction** Given the high breath-to-breath variability of respiratory variables, it is considered that including a greater number of breaths in averaging intervals will reduce variability between tests. However, the VO<sub>2</sub>max is only achieved during a short interval and therefore long averaging intervals may result in underestimation of the actual VO<sub>2</sub>max. The aim of the study was to determine the impact of the number of breaths included in the averaging interval on the reliability of VO<sub>2</sub>max measurements and on the absolute VO<sub>2</sub>max value. **Methods** After familiarisation, 40 men and 22 women performed two incremental exercise (IE) tests to exhaustion in two weeks. Five different IE protocols were used: ramp (15 or 20W/min) and steps (25, 30 or 35 W/2min) (Lode, Excalibur, Netherlands), all adjusted to reach a minimal IE duration of at least 6 min. Respiratory variables were measured breath-by-breath (Vmax N29; SensorMedics). The last two minutes of IE were analysed to determine the VO<sub>2</sub>max using rolling averages including from 6 to 60 breaths. The individual coefficient of variation (CV) was determined for each averaging strategy. **Results** The highest mean CV value (5.93%, range:0.04-21.8%) was obtained with 6 breaths and the lowest with 21 (4.85 %, range: 0-23.5%, n=61). For more than 21 breaths the CV increased progressively with the number of breaths. No significant differences in CVs were observed between sexes, protocol or fitness status. The averaging strategy had a major influence on the imputed VO<sub>2</sub>max values. VO<sub>2</sub>max values were higher, the lower the averaging interval (P<0.05). For 6, 21 and 60 breaths averages the mean VO<sub>2</sub>max was 2.89±0.74 (±SD), 2.72±0.70, and 2.63±0.69 l/min, respectively (P<0.05). In percentage, the difference in imputed VO<sub>2</sub>max between 6 and 21 breaths was 6.5%. The following equation can be used to determine the impact of the averaging strategy on VO<sub>2</sub>max:  $A=0.3947 + 0.863*B - 0.0511*B^2 + 0.00168*B^3 - 0.00002518*B^4 + 0.000001504*B^5$  (R<sup>2</sup>=0.999, P<0.001) Where A is the correction factor (in %), and B is the number of breaths above 6. For example, to calculate the difference in VO<sub>2</sub>max between one test having 6 and another 20 breaths, B=14, and the calculated A=6.04%. **Discussion and conclusions** The number of breaths included in the averaging interval when measuring VO<sub>2</sub>max with metabolic carts has a major impact on the absolute VO<sub>2</sub>max values, which may completely distort the assessment. However, the impact on variability is small. Our data indicate that the highest reliability is achieved by using 21 breaths averaging intervals. **Acknowledgements** ISCIII Spain (PI14/01509). **Contact** marcos.martinrincon@gmail.com

## INFLUENCE OF A DIFFERENT FAMILIARISATION ON TIME TRIAL PACING IN NOVICE PARTICIPANTS

Hibbert, A.W.1, Varley, M.C.1, Billaut, F.1,2, Polman, R.C.J.1,3

<sup>1</sup>ISEAL, Victoria University <sup>2</sup> Université Laval <sup>3</sup> Bournemouth University

**INTRODUCTION** Cycling time trial pacing is reproducible in athletes (Thomas et al., 2012). Conversely, less familiar participants exhibit greater inconsistency in pacing (Foster et al., 2009). To reduce variability, it is considered beneficial for more experienced participants to complete at least one familiarisation prior to experimental testing. However, there are no clear guidelines for familiarising novices to a time trial; therefore, findings from novice populations may still be influenced by experience of the task. Consequently, the aim of this study was to investigate the effectiveness of differing familiarisations (length or type) in developing a stable performance and pacing strategy over multiple trials. **METHODS** 30 participants, with no prior experience of a time trial (TT), performed a 20-km cycling TT on five separate occasions, after completing one of three different familiarisations; Full familiarisation (FF, 20-km TT, n=10), Half familiarisation (HF, 10-km TT, n=10) or Equipment familiarisation (EF, 5-min cycling, n=10). Repeated measures ANOVA and coefficients of variations (CV) were used to find differences and variability in performance (total duration and mean power (W/PPO)) and pacing (mean power over 2-km intervals) between trials. **RESULTS** The lowest variation in performance was observed in the FF group after two trials (CV, 1.5-4.3%), compared to the HF (1.8-7.9%) and EF (2.2-5.9%) groups. Pacing in all groups followed a J-shaped pattern with an end spurt. For all groups, the greatest variation in pacing occurred in the first 2-km between TT1 and TT5 (CV, 15.1-17.5%). The HF group showed difference in overall performance from TT1 to TT4 and TT1 to TT5. This was possibly due to an increase in power in the latter stages of subsequent trials, with a lower power output at 14-km observed in TT1 vs TT4 (-11.7%). The EF group displayed the highest variation in end spurt power (CV, 11.6%) between TT4 and TT5. **DISCUSSION** For novel participants in experimental testing, the use of a FF and a further two practice trials is superior in reducing learning effects on performance and pacing. In contrast, HF and EF can have an inhibitory influence on pacing strategy development and consistency, characterised by greater variation in both performance and pacing between trials. This data supports anticipatory regulation theory (Tucker, 2009) and provides recommendations for familiarising novice participants to a 20-km TT. **REFERENCES** Foster C, Hendrickson K J, Peyer K, et al. ## HIGH-INTENSITY DISTANCE IN ELITE FEMALE SOCCER PLAYERS BASED ON A GENDER-SPECIFIC THRESHOLD

Bellistri, G.1,2, Porcelli, S.2, Marzorati, M.2, Sforza, C.1,2, Giudici, A.2, Bradley, P.S.3

<sup>1</sup>Università degli Studi di Milano (Italy), <sup>2</sup>Istituto Nazionale di Fisica Nucleare (Italy), <sup>3</sup>Leeds Beckett University (UK)

**Introduction** The total distance covered in elite matches by female soccer players is relatively lower than their male counterparts (Bradley et al. 2014). The majority of female match play is spent in low-intensity activities with high-intensity distance been 30% lower than male players (Andersson et al. 2010). To date, studies on female players utilized the same absolute velocity threshold of male players despite female player having a lower physical capacity than male players (Bradley and Vescovi, 2015). The aim of this study was to examine high-intensity distance covered during matches by elite female soccer players using different thresholds. **Methods** Nineteen elite female players participated in this study (age 23±4 yr; height 165±7 cm; body mass 54.7±6.5 kg). Maximal oxygen consumption (VO<sub>2</sub>max) and respiratory compensation threshold (VT<sub>2</sub>) were determined by graded exercise test to exhaustion on a motorized treadmill. Players activities across 6 friendly matches (32 observations) were tracked by Global Positioning System (K-Gps 10hz, K-Sport, Italy). Distance covered in total (TD) and at high-intensity (HID) were evaluated. The latter was calculated using both the typical male speed threshold of 15 km·h<sup>-1</sup> (MALE) and an individual speed threshold (IND) corresponding to VT<sub>2</sub> (Hunter et al. 2015). **Results** Players VO<sub>2</sub>max was 49.1±3.7 mL·kg<sup>-1</sup>·min<sup>-1</sup> and occurred at a speed value of 14.7±0.8 km·h<sup>-1</sup>. VT<sub>2</sub> corresponded to a running speed of 13.5±0.9 km·h<sup>-1</sup>. The total distance covered was 7726±891 m with HID higher (p<0.0001) in IND (1125±533 m) than in MALE (785±353 m). When expressed as percentages of TD, HID was 14.4±5.8% in IND and 9.9±3.8% in MALE. **Discussions** These data demonstrate in female soccer that the quantification of high-intensity running activities during match play can be impacted by applying relative or absolute speed thresholds. Even if arbitrary speed thresholds enable longitudinal monitoring of match-demands and comparison within and between play-

ers/teams/gender, the utilization of individualized speed threshold should be pursued in order to quantify the correct exercise stimulus in female soccer players. Further studies are needed to understand the best method characterizing the multiple transitions between intensity-domains in female soccer. ## ASSOCIATIONS BETWEEN VARIOUS INTENSITIES OF PHYSICAL ACTIVITY AND PHYSICAL FITNESS IN ADOLESCENTS

Kidokoro, T.1, Yanaoka, T.1, Kashiwabara, K.1, Yamagami, J.1, Tanaka, H.2, Miyashita, M.1

1: *Tokyo Gakuji University (Tokyo, Japan)*; 2: *Yokohama National University (Kanagawa, Japan)*

**Introduction** While a positive association between physical activity and physical fitness has been established in adults, the association appears less clear in adolescents (Dencker and Andersen, 2011). The purpose of this study was to examine associations between objectively measured various intensities of physical activity and eight physical fitness tests in Japanese adolescents. **Methods** A total number of 289 Japanese adolescents (age,  $13 \pm 1$  (mean  $\pm$  SD) years; 140 boys and 149 girls) participated in this cross-sectional study. To evaluate the amount of time spent in moderate to vigorous ( $\geq 3$  Mets) physical activity (MVPA), and vigorous ( $\geq 6$  Mets) physical activity (VPA), participants were asked to wear a uniaxial accelerometer (Lifecoder-EX, Suzuken Co. Ltd.) for 14 consecutive days. Physical fitness tests are comprised of eight tests including 1) distance running, 2) 50 m sprinting, 3) grip strength, 4) bent-leg sit-up, 5) side step, 6) sit-and-reach, 7) standing long jump and 8) handball throw. Based on data obtained through accelerometers (i.e., MVPA and VPA), the participants were grouped into quartile categories (Q1 (Least active) ~ Q4 (Most active)). Adjusted logistic regression analyses were performed to examine the odds ratios (ORs) and 95% confidence intervals (95% CI) of being in the lowest physical fitness quartile categories for each variable according to physical activity quartile categories (Q1 ~ Q4). **Results** In both sexes, MVPA was negatively associated with distance running time ( $r < -0.24$ ,  $p < 0.05$ ), and the association was stronger between VPA and distance running time ( $r < -0.33$ ,  $p < 0.001$ ). Adjusted logistic regression (reference category: VPA-Q1) revealed that there was a significant difference in bent-leg sit-up (ORs = 0.18, 95% CI: 0.05-0.69) and handball throw (ORs = 0.20, 95% CI: 0.05-0.81) in VPA-Q4, and distance running (QRs = 0.22, 95% CI: 0.06-0.79) in VPA-Q3 for boys. For girls, there was a significant difference in distance running (QRs = 0.03, 95% CI: 0.01-0.20), 50 m sprinting (QRs = 0.24, 95% CI: 0.07-0.82), bent-leg sit-up (QRs = 0.10, 95% CI: 0.02-0.40), side step (QRs = 0.11, 95% CI: 0.03-0.47) and handball throw (QRs = 0.30, 95% CI: 0.09-0.99) in VPA-Q4 compared to VPA-Q1. **Discussion** These findings may suggest that increasing the amount of time spent physical activity, in particular vigorous physical activity, appears to be an effective strategy for improving physical fitness in this population. ## THE CONTRIBUTION OF SKELETAL MUSCLE VOLUME AND ARCHITECTURE TO SOCCER-SPECIFIC POWER IN ELITE AND RECREATIONAL YOUTH SOCCER PLAYERS

Murtagh, C.F.1,2, Nully, C.1, Stubbs, M.1, Vanrenterghem, J.1, O'Boyle, A.2, Morgans, R.1,2, Drust, B.1,2, Erskine, R.M.1

1-Liverpool John Moores University, Liverpool, UK. 2-Liverpool Football Club, Liverpool, UK

**Purpose:** The activity profile in elite soccer match-play is characterised by frequent bursts of explosive activity most often performed in the horizontal direction. The physiological determinants of horizontal explosive performance in elite soccer players have yet to be elucidated. Such information may inform talent identification, physiological assessment protocols and training prescription. This study investigated the potential differences in kinetic and kinematic variables between elite and non-elite soccer players during unilateral horizontal countermovement jump (ULHCMJ) performance and the physiological factors that underpin these differences. **Methods:** A cohort of elite ( $n=23$ ; age,  $18 \pm 1$  yrs; BMI,  $23.1 \pm 1.8$ ) and recreationally trained non-elite ( $n=20$ ; age,  $22 \pm 3$  yrs; BMI,  $23.8 \pm 1.8$ ) soccer players performed three ULHCMJs on a force platform. Ultrasonography was used to measure the volume (Vm) and anatomical cross-sectional area (ACSA) of the quadriceps femoris muscle (QF), and the architecture (fascicle length, Lf; fascicle pennation angle, FPA) of the vastus lateralis muscle (VL). The contributions of these characteristics to horizontal jump performance were assessed using bivariate correlation analyses. **Results:** Elite soccer players elicited greater jump distance (Elite:  $216.0 \pm 14.9$  cm, Non-elite:  $196.1 \pm 15.9$  cm;  $P < 0.001$ ), peak vertical power (Elite:  $1768.2 \pm 389.6$  W, Non-elite:  $1439.2 \pm 278.5$  W,  $P = 0.004$ ) and take-off velocity (Elite:  $216.0 \pm 14.9$  ms<sup>-1</sup>, Non-elite:  $196.1 \pm 15.9$  ms<sup>-1</sup>,  $P = 0.013$ ) compared to non-elite players. They also had greater QF Vm (Elite:  $2853 \pm 508$  cm<sup>3</sup>, Non-elite:  $2429 \pm 232$  cm<sup>3</sup>;  $P = 0.001$ ) and QF ACSA (Elite:  $80.8 \pm 15.8$  cm<sup>2</sup>, Non-elite:  $69.8 \pm 6.7$  cm<sup>2</sup>,  $P = 0.006$ ). There were no differences in VL Lf (Elite:  $12.7 \pm 1.8$  cm, Non-elite:  $12.8 \pm 1.7$  cm;  $P = 0.908$ ) or FPA (Elite:  $14.9 \pm 2.2$  deg, Non-elite:  $14.6 \pm 2.0$  deg;  $P = 0.722$ ). QF Vm and ACSA correlated with CMJ distance (Vm:  $r = 0.366$ ,  $P = 0.016$ ; ACSA:  $r = 0.348$ ,  $P = 0.022$ ) and peak vertical power (Vm:  $r = 0.554$ ,  $P < 0.0003$ ; ACSA:  $r = 0.519$ ,  $P = 0.001$ ). Muscle architecture (neither Lf nor FPA) correlated with any measure of ULHCMJ performance (all,  $P > 0.05$ ). **Conclusion:** Unilateral horizontal explosive capability appears to be an important characteristic of elite youth soccer, and QF Vm and ACSA play significant roles in determining soccer-specific power performance. Practitioners working with talent development programmes should consider the inclusion of regular assessment and development of QF Vm to optimise performance in youth soccer players.

#### EFFECT OF THE SOURCE OF DIETARY NITRATE SUPPLEMENTATION ON PLASMA NITRITE CONCENTRATIONS AND BLOOD PRESSURE

Jonvik, K.L.1,2, Nyakayiru, J.1, Pinckaers, P.J.M.1, Senden, J.M.G.1, van Loon, L.J.C.1,2, Verdijk, L.B.1

1: *Maastricht University* 2: *HAN University of Applied Sciences*

**BACKGROUND** Dietary nitrate (NO<sub>3</sub><sup>-</sup>) has recently received increased attention due to its potential ergogenic and clinical benefits. The ingestion of dietary nitrate from different inorganic sources (e.g. NaNO<sub>3</sub>, beetroot juice) has been shown to result in elevated plasma nitrate and nitrite levels, thereby increasing the bio-availability of NO. However, it is currently unknown to what extent the actual source of nitrate may affect the subsequent physiological effects upon ingestion. **PURPOSE:** To assess the acute effects of different nitrate-rich food

sources on plasma nitrate and nitrite levels and resting blood pressure in healthy individuals. **METHODS** Using a randomized cross-over design, 11 male and 7 female recreationally active subjects ( $28 \pm 1$  y, BMI  $23 \pm 1$  kg/m<sup>2</sup>) ingested four different beverages, each providing 800 mg ( $\sim 12.9$  mmol) nitrate: sodium nitrate (1.1 g dissolved in water; NaNO<sub>3</sub>), concentrated beetroot juice (116 g; BRJ), a rocket salad beverage (196 g; RS), and a spinach beverage (365 g; SP). Blood pressure was measured at baseline, 2.5 h and 5 h following ingestion. Blood was drawn before, and up to 5 h following ingestion and was analyzed for plasma nitrate and nitrite concentrations. Data were analyzed using repeated measures ANOVA with time and treatment as within-subject factors, with Bonferroni-corrected post hoc testing. Plasma nitrite concentrations represent preliminary data from n=9. **RESULTS** Peak plasma nitrite concentrations were higher in SP ( $794 \pm 148$  nM) compared with NaNO<sub>3</sub> and BRJ ( $541 \pm 80$  and  $515 \pm 76$  nM, respectively;  $P < 0.05$ ), with intermediate values observed for RS ( $645 \pm 114$  nM). Additionally, time to peak nitrite concentration occurred earlier following ingestion of SP ( $120 \pm 26$  min) compared with NaNO<sub>3</sub>, BRJ and RS ( $210 \pm 23$ ,  $203 \pm 25$ ,  $230 \pm 24$  min, respectively;  $P < 0.05$ ). Systolic blood pressure significantly declined 2.5h after ingestion of BRJ and RS ( $-5 \pm 1$  and  $-6 \pm 2$  mmHg, respectively;  $P < 0.05$ ) and 5h after ingestion of SP ( $-7 \pm 2$  mmHg,  $P < 0.05$ ), but did not change with NaNO<sub>3</sub> ( $P = 0.11$ ). Diastolic blood pressure significantly decreased 2.5h after ingestion with all treatments ( $-4 \pm 1$ ,  $-8 \pm 1$ ,  $-7 \pm 1$  and  $-4 \pm 1$  mmHg for NaNO<sub>3</sub>, BRJ, RS and SP, respectively;  $P < 0.05$ ), and remained lower at 5h after ingestion of RS and SP ( $P < 0.05$ ). **CONCLUSION** Ingestion of dietary nitrate from different sources acutely results in substantial increases in plasma nitrite concentrations and a reduction in blood pressure. However, the effects appear to be more pronounced when using vegetable food sources naturally high in nitrate. We conclude that the bio-availability of nitrite is dependent on the nitrate source ingested, thereby affecting subsequent physiological effects. ### INGESTION OF GLUCOSE OR SUCROSE DURING PROLONGED ENDURANCE TYPE EXERCISE PREVENTS A DECLINE IN LIVER BUT NOT MUSCLE GLYCOGEN CONCENTRATION

Gonzalez, J.T.1, Fuchs, C.J.2, Smith, F.E.3, Thelwall, P.E.3, Stevenson, E.J.4, Trenell, M.I.3, van Loon, L.J.C.2

1: University of Bath (UK), 2: Maastricht University Medical Centre+ (The Netherlands), 3: Newcastle University (UK), 4: Northumbria University (UK).

**Introduction** Carbohydrate (CHO) ingestion during prolonged exercise enhances performance, increases CHO oxidation and may spare muscle glycogen stores (Cermak and van Loon, 2013). Few data are available on the impact of CHO ingestion on liver glycogen stores. When trying to maximize CHO availability during exercise, it may be preferred to ingest a combination of different carbohydrate sources eg. glucose (GLU) and fructose. As sucrose (SUC) provides both glucose and fructose, we hypothesize that sucrose ingestion during exercise may allow greater carbohydrate uptake, resulting in greater sparing of liver and/or muscle glycogen stores when compared to the ingestion of glucose only. **Methods** Fourteen cyclists (VO<sub>2</sub>peak:  $58 \pm 1$  mL/kg/min) completed two 3-h bouts of cycling at 50% W<sub>max</sub> while ingesting either GLU or SUC at a rate of 1.7 g/min. Four cyclists (VO<sub>2</sub>peak:  $60 \pm 3$  mL/kg/min) performed a third test in which only water was consumed for reference. We used <sup>13</sup>C magnetic resonance spectroscopy to determine liver and muscle glycogen concentrations before and after exercise. Expired breath was sampled during exercise to estimate whole-body substrate use. All data are means  $\pm$  SEM. Pre- vs post-exercise liver and muscle glycogen concentrations in the water trial were compared by paired t tests. Liver and muscle glycogen concentrations in the GLU and SUC treatments were assessed by two-way (treatment x time), repeated measures ANOVA with treatment (GLU vs SUC) and time (pre- vs post-exercise) as within-subject factors. **Results** Both liver (from  $454 \pm 17$  to  $283 \pm 41$  mmol/L;  $P < 0.05$ ) and muscle (from  $111 \pm 23$  to  $67 \pm 15$  mmol/L;  $P < 0.01$ ) glycogen concentrations declined during exercise when only water was ingested. Following GLU and SUC ingestion, liver glycogen levels did not show a significant decline following exercise (from  $325 \pm 45$  to  $345 \pm 55$  mmol/L and from  $321 \pm 47$  to  $348 \pm 56$  mmol/L, respectively;  $P > 0.05$ ) with no differences between treatments. Muscle glycogen concentrations declined (from  $101 \pm 11$  to  $60 \pm 9$  mmol/L and from  $114 \pm 13$  to  $67 \pm 9$  mmol/L, respectively;  $P < 0.05$ ), with no differences between treatments. Whole-body CHO utilization was greater with SUC ( $2.03 \pm 0.11$  g/min) vs GLU ( $1.66 \pm 0.10$  g/min;  $P < 0.05$ ). **Discussion** Ingestion of glucose or sucrose (1.7 g/min) during prolonged exercise prevents a decline in liver but not muscle glycogen concentrations. Sucrose ingestion during prolonged exercise does not lead to greater sparing of endogenous muscle or liver glycogen stores when compared to glucose ingestion. **References** Cermak NM, van Loon, LJ (2013). *Sports Med*, 43: 1139. ### EFFECT OF CARNOSINE LOADING AND HIGH-INTENSITY INTERVAL TRAINING ON ENDURANCE CYCLING PERFORMANCE

Chung, W.1, Rouffet, D.1, Derave, W.2, Bishop, D.1

1: Victoria University (Melbourne, Australia); 2: Ghent University (Ghent, Belgium)

**EFFECT OF CARNOSINE LOADING AND HIGH-INTENSITY INTERVAL TRAINING ON ENDURANCE CYCLING PERFORMANCE** Chung, W.1, Rouffet, D.1, Derave, W.2, Bishop, D.1 1: Victoria University (Melbourne, Australia); 2: Ghent University (Ghent, Belgium) **Introduction** Carnosine loading via beta-alanine supplementation is well documented to improve short duration, high-intensity exercise performance [1], but has minimal effect on 1-h cycling time trial performance [2]. In addition to its proposed ergogenic effects on performance, beta-alanine supplementation may also have an ergogenic effect on the training sessions leading into competition performances. Such an outcome could be achieved via an increase in training capacity (i.e. athletes can train harder or longer) or an increase in the adaptive response to the same training load. Indeed, we have reported that reducing metabolic acidosis during training can produce greater improvements in performance and mitochondrial adaptations [3, 4]. It is therefore possible that an increase in muscle buffer capacity as a result of beta-alanine supplementation may reduce the muscle pH during training and promote greater adaptations to training. However, to date, this hypothesis has not been tested. Therefore, our aim was to determine if there was an additive effect of carnosine loading, in combination with high-intensity interval training, on 30-km cycling time trial performance. **Methods** Utilizing a double-blind, placebo-controlled, design, 13 active males (n=7 v 6) were matched and split into two groups (W<sub>max</sub>= $271 \pm 43$  v  $259 \pm 54$  W; VO<sub>2</sub>peak= $51.5 \pm 9.1$  v  $51.6 \pm 5.2$  mL/kg/min) that were supplemented with either 6.4 g/day of beta-alanine or a placebo for 3 weeks in combination with continuous training (loading phase). This was followed by 6 weeks of high-intensity interval training (HIT phase). A graded exercise test (GXT), 30-km time trial (TT) and an assessment of maximal coupled mitochondrial respiration (MR) were performed at Week 0, 3 and 9. **Results** Exercise performance and MR from both groups remained similar during the loading phase ( $p > 0.05$ ), but were improved after 6 weeks of HIT (W<sub>max</sub>=5 and 7% higher, 30 km TT=3 and 3% quicker, MR=43 and 40% higher respectively;  $p < 0.05$ ). There were no significant differences between groups for any of these measures. **Discussion** The combination of carnosine loading and HIT demonstrated no additive effect of beta-alanine supplementation on either exercise performance or improvements in mitochondrial respiration. This can possibly be attributed to the potent physiological adaptations to HIT which may have overshadowed any ergogenic effect upon the response to training. The ergogenic benefit of beta-alanine supplementation for exercise performance appear limited to short-duration, high-intensity

activities. References 1. Hobson R, et al. (2012). *Amino Acids*, 43(1):25-37. 2. Chung W, et al. (2014). *Int J Sports Nutr Exerc Metab*, 24:315-324. 3. Edge J, et al. ### DELAYED INSULIN ACTION DURING OGTT IN HABITUAL LOW-CARBOHYDRATE HIGH-FAT CYCLISTS

Leith, D., Webster, C., Smith, J., Noakes, T.

*University of Cape Town*

Introduction Low-Carbohydrate High-Fat (LCHF) diets have recently received attention for their potentially positive influence on prolonged endurance performance and athlete well-being (Noakes et al., 2014). Literature is scarce on the macronutrient composition and metabolism of competitive athletes habitually consuming a LCHF diet compared to matched athletes on a diet higher in carbohydrate content. This study sought to compare the dietary intake and insulin sensitivity of trained cyclists having habitually consumed (> 6 months) either a LCHF or mixed 'control' (CON) diet. Methods Fourteen (7 LCHF, 7 CON) endurance-trained male cyclists (VO<sub>2</sub>max 61 ± 5 ml·kg<sup>-1</sup>·min<sup>-1</sup> LCHF; 63 ± 8 ml·kg<sup>-1</sup>·min<sup>-1</sup> CON), matched for age (36 ± 6 LCHF; 32 ± 5 CON), body composition (BMI 23.6 ± 1.8 LCHF; 23.4 ± 2.0 CON) and relative peak power output (4.8 ± 0.4 W·kg<sup>-1</sup> LCHF; 5.0 ± 0.4 W·kg<sup>-1</sup> CON), were recruited. Participants completed a 3-day dietary record - analysed by the Automated Self-Administered 24-hour Recall (ASA24) analysis software. After an overnight fast, a resting blood sample was taken, followed by a 2-hour 75g oral glucose tolerance test (OGTT). Insulin-sensitivity was assessed by the Homeostatic Model Assessment (HOMA-IR) and the Matsuda Index. Results Dietary intake was similar between groups except fat and carbohydrate consumption (Protein/Fat/Carbohydrate: 21%, 1.9 g·kg<sup>-1</sup>·d<sup>-1</sup> / 72% / 7% LCHF; 16%, 1.8 g·kg<sup>-1</sup>·d<sup>-1</sup> / 33% / 51% CON). HOMA-IR scores were not significantly different between groups (1.04 ± 0.52 LCHF; 0.89 ± 0.40 CON, p=0.80). LCHF tended to have a lower Matsuda Index compared to CON (1.53 ± 0.64 LCHF; 2.29 ± 0.85 CON, p = 0.07). At all OGTT time points after baseline, plasma glucose was significantly higher in the LCHF group (p<0.01). The insulin profile was significantly different between groups: CON insulin peaked at 30 min and returned to baseline by 60 min; LCHF insulin peaked at 60 min and returned to baseline at 120 min (p=0.03). Discussion LCHF cyclists obtained the majority of their energy (>70%) from fat - in line with prescribed high-fat athletic diets. LCHF cyclists did not present with insulin-resistance (Gayoso-Diz et al., 2013) nor impaired glucose tolerance (Nathan et al., 2007). However, delayed glucose disposal in response to elevated insulin suggests reduced metabolic flexibility: specifically a reduced capacity to metabolise ingested carbohydrate. This is likely due to adaptation to fat as a preferred fuel source and concomitant down-regulation of enzymes involved in carbohydrate oxidation (Phinney et al., 1983). ### EFFECTS OF BLOOD DONATION AND NITRATE INGESTION ON THE PHYSIOLOGICAL RESPONSE TO MODERATE-INTENSITY AND INCREMENTAL EXERCISE

McDonagh, S.T.J., Vanhatalo, A., Fulford, J., Wylie, L.J., Bailey, S.J., Jones, A.M.

*University of Exeter*

Introduction Nitrate-rich beetroot juice (BR) can reduce the oxygen (O<sub>2</sub>) cost of moderate-intensity exercise and enhance tolerance to severe-intensity exercise (Bailey et al., 2009). A derivative of nitrate (NO<sub>3</sub><sup>-</sup>), nitric oxide, plays a significant role in the regulation of skeletal muscle blood flow, contraction and efficiency. A reduction in blood O<sub>2</sub> carrying capacity, as a result of blood donation, reduces the tolerance to severe-intensity exercise (Burnley et al., 2006). The aim of this study was to determine whether BR supplementation alters the haemodynamic response, efficiency and tolerance to cycling exercise post blood donation. Methods In a randomised and double blind experimental design, 22 recreationally active volunteers performed moderate-intensity and ramp incremental cycle exercise tests prior to and post withdrawal of ~450 mL of whole blood. Before donation, all subjects (n=22) consumed 7 x 70 mL of NO<sub>3</sub><sup>-</sup>-depleted beetroot juice shots (~0.04 mmol NO<sub>3</sub><sup>-</sup> per 70mL) as a placebo (PL) in the 48 h preceding the exercise tests. Immediately after blood donation and during the 48 h prior to exercise, subjects consumed 7 shots of either BR (~6.2 mmol NO<sub>3</sub><sup>-</sup> per 70 mL; n=11) or PL (n=11). Blood pressure (BP), plasma NO<sub>3</sub><sup>-</sup> and nitrite (NO<sub>2</sub><sup>-</sup>) concentrations, haemoglobin concentration ([Hb]), haematocrit (Hct) and pulmonary V<sub>O</sub><sub>2</sub> responses to exercise were measured during each visit to the laboratory. Results BR supplementation resulted in an increased plasma [NO<sub>3</sub><sup>-</sup>] (PL: 50±14 vs. BR: 845±350 μM; P<0.05) and [NO<sub>2</sub><sup>-</sup>] (PL: 72±21 vs. BR: 619±363 nM; P<0.05) post blood donation. Systolic BP was reduced in BR post blood donation when compared with baseline. [Hb] and Hct decreased significantly from pre to post blood withdrawal, however, no difference was noted between PL and BR. Compared with pre donation, the steady state V<sub>O</sub><sub>2</sub> during moderate-intensity exercise was ~4% lower post donation in BR only (P<0.05). The ramp test peak power decreased from pre donation (PL: 341±70 vs. BR: 331±68 W) to post donation (PL: 324±69 vs. BR: 322±66 W) in both groups (P<0.05). However, the decrement in performance was less in BR compared with PL (P<0.05). Discussion Nitrate supplementation reduces the O<sub>2</sub> cost of moderate-intensity exercise and lessens the decline in ramp incremental performance after blood donation. The results from this study may have implications for improving functional capacity in conditions where normal blood O<sub>2</sub> carrying capacity is impaired. #### LOW VOLUME SPEED-ENDURANCE TRAINING IMPROVES INTERMITTENT EXERCISE CAPACITY IN HIGHLY TRAINED FOOTBALL PLAYERS IN SEASON: ROLE OF SKELETAL MUSCLE ADAPTATIONS.

Gunnarsson, T., Fiorenza, M., Nyberg, M., Piil, P., Lund, A.P., Rømer, T., Bangsbo, J.

*University of Copenhagen*

**Introduction.** The present study examined, whether 9 weeks of speed-endurance training (SET) in season would improve the intermittent exercise capacity and running economy in highly trained football players and, to what extent this improvement was associated with training-induced muscular adaptations in regards to muscle ion transport capacity and glycolytic metabolism in type I and II fibers. **Methods.** Thirteen highly trained football players completed (means $\pm$ SD) 9.4 $\pm$ 1.7 training sessions of SET during the last 9 weeks of the season corresponding to an adherence of 72.2 $\pm$ 13.1 % of total number of planned SET sessions. SET consisted of 2-3 sets of 6-10 x 5 s all-out sprinting interspersed by 10 s of recovery with 2 min of recovery between sets. SET was always performed at the end of training sessions and the average number of sprints per training session was 20 $\pm$ 3. A resting muscle biopsy was obtained from m. vastus lateralis before and after the 9-week intervention period. In addition, running economy was measured before and after the intervention period on a motorized treadmill during two successive running bouts for 6 and 4 minutes at 10 and 16 km-h<sup>-1</sup>, respectively. **Results.** As a result of the intervention period, the Yo-Yo Intermittent Recovery Test level 1 (YYIR1) performance improved ( $p < 0.05$ ) from 2803 $\pm$ 330 to 3127 $\pm$ 383 m. Running economy at 10 km-h<sup>-1</sup> was ~2.0 % better ( $p < 0.05$ ) after than before the intervention period with no change at 16 km-h<sup>-1</sup>. Protein expression of phosphofructokinase (PFK) and ryanodine receptors (RyR) was unchanged following the intervention period. **Discussion.** The present study demonstrated that a low weekly volume of SET, towards the end of the season, can improve the intermittent exercise capacity in highly trained football players. This part of the season has previously been associated with a decrement in YYIR1 performance (1). The ~2 % improved running economy at 10 km-h<sup>-1</sup>, but not expression of PFK and RyR, may in part explain the improved YYIR1 performance following the implementation of low volume SET in highly trained football players in season. However, other factors may be responsible for a large part of the observed performance improvement. Therefore, we will further investigate the potential role of muscle ion transport capacity, with emphasis on K<sup>+</sup> handling, as an explanatory model for the improved YYIR1 performance, investigating adaptations in single fibres. **Reference List 1.** Mohr, M. and P. Krstrup. Yo-Yo intermittent recovery test performances within an entire football league during a full season. *J. Sports Sci.* 32:315-327, 2014.

#### REPEATED-SPRINT TRAINING IMPROVES O<sub>2</sub> UPTAKE KINETICS AND PERFORMANCE IN HIGHLY TRAINED FOOTBALL PLAYERS: ROLE OF FIBER TYPE SPECIFIC ADAPTATIONS IN SKELETAL MUSCLE

Nyberg, M., Fiorenza, M., Gunnarsson, T.P., Lund, A., Rømer, T., Piil, P., Bangsbo, J.

*University of Copenhagen*

**Introduction.** The present study examined whether additional repeated sprint training (RST) would improve intermittent high-intensity performance in highly trained football players during the season and to what extent this improvement was associated with training-induced elevations in oxidative metabolism in type I and II fibers. **Methods.** Thirteen highly trained (semi-professional) football players completed two weekly sessions of RST during the last nine weeks of the season. RST consisted of 2-3 sets of 5 s of sprinting interspersed by 10 s of recovery (repeated 6-10 times per set). To assess V $\dot{O}_2$  kinetics when predominantly type I fibers are recruited, subjects completed three identical running tests before and after the training intervention, each consisting of standing followed by a step increment to moderate-intensity (10 km h<sup>-1</sup>) work rate. Furthermore, to assess V $\dot{O}_2$  kinetics when a greater recruitment of type II fibers would be expected, a step increment from moderate- to high- intensity (16 km h<sup>-1</sup>) work rate was also performed. In addition, a skeletal muscle biopsy was obtained at rest before and after the intervention period. **Results.** After the training intervention, the Yo-Yo Intermittent Recovery Test level 1 performance improved ( $P < 0.05$ ) by 11.6 $\pm$ 6.4% (pre, 2803 $\pm$ 330 m; post, 3127 $\pm$ 383 m;  $\pm$ SD). After training, phase II pulmonary V $\dot{O}_2$  kinetics were 11.4 $\pm$ 16.5% faster (pre, 19.2 $\pm$ 3.9 s; post, 16.7 $\pm$ 3.1 s;  $P < 0.05$ ) in the step transition from standing to moderate-intensity work rate. There was no change in phase II pulmonary V $\dot{O}_2$  kinetics in the high-intensity domain. To investigate local skeletal muscle adaptations, analysis of fiber type distribution and protein content of oxidative enzymes in type I and II fibers will be conducted. **Conclusion.** These findings demonstrate that the ability to perform repeated high-intensity work can be improved in highly trained football players during the last part of the season normally associated with performance decrements by implementing RST. This effect of RST appears to be, at least in part, related to enhanced oxidative metabolism in type I fibers.

#### NATURAL ALTITUDE TRAINING AT 1380 M COMBINED WITH 9 H PER DAY AT 3000 M IS AN EFFECTIVE ALTITUDE TRAINING MODE

Carr, A.1, Saunders, P.2, Vallance, B.2, Garvican-Lewis, L.2,3, Gore, C.2

*1: Deakin University (Melbourne, Australia), 2: Australian Institute of Sport (Canberra, Australia), 3: Research Institute for Sport and Exercise (Canberra, Australia)*

**Introduction** Classically, athletes perform altitude training by living and training at moderate altitude (2000-3000m) for several weeks (Bonetti and Hopkins, 2009). An alternative is to use a live high: train low (LHTL) protocol, inducing hypoxia either naturally or using altitude tents or chambers (Wilber, 2007). The aim of this study was to examine effects of a classical altitude training camp and a modified LHTL protocol (combining natural and simulated modalities) on haemoglobin mass (Hbmass), maximum oxygen consumption (VO<sub>2</sub>max) and time to exhaustion (TTE). **Methods** Eighteen elite-level race-walkers performed 21 days of either classical altitude training (CLASSIC; continuous exposure to 1380 m; n = 10) or LHTL combined with classical altitude training (LHTL+C; 1380 m plus 9 h.day<sup>-1</sup> (overnight) at 3000 m simulated altitude; n = 8). A control group of elite race-walkers (CON; n = 11) lived and trained at 600 m altitude. Hbmass and performance testing was performed before and after the 3-wk intervention. Pair-wise comparisons were made between the two experimental groups, and where possible between the experimental and control data, in relation to the likelihood of the magnitude of the effect exceeding the smallest worthwhile change (SWC) for each variable. The SWC was set at 1.4% for Hbmass, 2.0% for VO<sub>2</sub>max and 3.0% for TTE. Statistical significance for each variable was also tested at  $p < 0.05$ , using paired t-tests. **Results** There was a 3.7% increase in

Hbmass in LHTL+C compared with CON ( $p = 0.03$ ).  $VO_{2max}$  increased by ~3% within both CLASSIC and LHTL+C but was not statistically greater than the 1% increase in CON. There was a ~9% increase in TTE after LHTL+C and a ~8% increase after CLASSIC; both increases were likely greater than the smallest worthwhile change of 3.0%. Discussion These findings indicate that, for elite athletes undertaking altitude training, our combined classic and LHTL method is an effective alternative to conventional camps at moderate altitude. This is especially relevant in countries in which the topography is less than 2000 m. We recommend that low altitude (1380 m) combined with sleeping in altitude tents (3000 m) is a time efficient method to improve Hbmass and  $VO_{2max}$ , with the advantage of less compromised training intensity compared with traditional altitude methods typically conducted at higher altitudes of 2000-3000m. ### MENTAL FATIGUE IMPAIRS SOCCER-SPECIFIC SKILL PERFORMANCE

Smith, M.1,3, Merlini, M.2, Marcora, S.2, Deprez, D.3, Lenoir, M.3, Coutts, A.1

1: UTS (Australia), 2: University of Kent, UK, 3: UGent (Belgium).

**Introduction** Recent research has shown that mental fatigue impairs intermittent running performance in a task with similar demands to a soccer match (Smith et al. 2015). Further research has reported reductions in perceptual and motor skills of mentally fatigued athletes (Duncan et al. 2015). However, it is unknown whether these results from laboratory-based investigations directly translate into impairments in soccer-specific performance. Therefore, this study investigated the effects of mental fatigue on soccer-specific skill performance. **Methods** In this double-blind, randomized, counterbalanced cross over investigation, we tested soccer-specific skill performance in 14 male soccer players (age:  $19.6 \pm 3.5$  y; experience:  $13.6 \pm 3.2$  y). Players performed the Loughborough Soccer Passing (LSPT) and Shooting Tests (LSST) on two occasions, separated by a minimum of 48 h. The LSPT and LSST were preceded, in a randomised order, by 30 min of mentally fatiguing reading (Stroop task) or emotionally-neutral reading (magazines; control). Subjective mental fatigue was recorded on visual analogue scales before and after reading. Subjective reports of mental effort (for the reading task) and motivation (for the skills tests) were also recorded after reading. LSPT performance was assessed using original time, penalty time, and performance time (original time + penalty time). LSST performance was assessed using shot accuracy, shot speed, and shot sequence time. **Results** Reports of mental fatigue and effort were higher following the Stroop task than the magazines (both  $P < 0.001$ ), while motivation was similar between conditions. LSPT original time was not different between conditions but penalty time was significantly higher in the mental fatigue condition ( $4.9 \pm 7.6$  s vs.  $0.0 \pm 6.2$  s;  $P = 0.005$ ,  $d = 0.71$ ), resulting in a slower performance time ( $52.6 \pm 6.6$  s vs.  $47.9 \pm 7.7$  s;  $P = 0.014$ ,  $d = 0.66$ ). Players performed less accurate ( $1.3 \pm 0.6$  points vs.  $2.0 \pm 0.5$  points;  $P = 0.006$ ,  $d = 1.20$ ) and slower ( $81.8 \pm 4.7$  km/h vs.  $85.0 \pm 5.6$  km/h;  $P = 0.024$ ,  $d = 0.63$ ) shots when mentally fatigued. Average shot sequence time was not significantly different between conditions ( $P = 0.08$ ). **Discussion** Mental fatigue impaired soccer-specific skill performance. Indeed, players made more passing and ball control errors, and performed slower, less accurate shots on goal when mentally fatigued. Combined with recent findings that mental fatigue impairs intermittent running performance (Smith et al. 2015), this novel finding has several important implications for soccer players and coaches. #### TACKLE TECHNIQUE AND RISK OF INJURY IN HIGH-LEVEL UNDER-18 SOUTH AFRICAN RUGBY UNION PLAYERS

Burger, N., Lambert, M.I., Readhead, C., Viljoen, W., Brown, J.C., Hendricks, S.

*University of Cape Town*

**Introduction** The incidence of injury in rugby union is high in comparison to other team sports (Brown et al., 2012). Tackle technique has been identified as a major injury risk factor (McIntosh et al., 2010). Previous research has reported on tackle characteristics associated with injury but not specifically on technical tackle criteria (McIntosh et al., 2010; Fuller et al., 2010). Therefore, the aim of this study was to assess tackle technique proficiency in youth rugby union players. **Methods** Injury surveillance was conducted at the 2011-2013 under-18 Craven Week rugby tournaments. Video footage of 49 tackle injury events (23 ball-carries, 26 tackles) and 249 non-injury events (126 ball-carries, 123 tackles) were identified. Each ball-carry/tackle was analysed using standardised technical proficiency criteria. Overall and individual criteria score means and standard deviations were calculated for front-on and side-on/behind tackles for ball-carriers and tacklers. T-tests and effect sizes were calculated to compare injury and non-injury events. The level of significance was set at  $p < 0.05$ . **Results** Overall, front-on and side/behind score for ball-carrier proficiency was significantly lower for injury versus non-injury tackles (effect size=0.85, large;  $p < 0.05$ , and effect size=1.86, large;  $p < 0.0001$ , respectively). Fending away from contact was significantly associated with non-injury outcome for ball-carriers (effect size=1.14, large;  $p < 0.05$ ). For tacklers, overall front-on and side/behind proficiency score was significantly lower for injury and non-injury tackles (effect size=1.03, large;  $p < 0.05$ , and effect size=1.59, large;  $p < 0.0001$ , respectively). Pulling the ball-carrier to the ground was significantly associated with non-injury outcome for tacklers (effect size=1.33, large;  $p < 0.0001$ ). **Discussion** Certain individual technical criteria were associated with a non-injury outcome. For example ball-carriers fending away from contact and tacklers pulling the ball-carrier to ground. This highlights that the failure to execute certain techniques may increase the risk of injury. This study provides applicable information for stakeholders in rugby union and these technical criteria should be emphasized from an early age during tackle technique training (Hendricks et al., 2012). ## TRAINING PROCESS OPTIMIZATION BASED ON GAME SUCCESS PREDICTION IN ENGLISH PROFESSIONAL RUGBY UNION

Fomin, R.1, Grainger, A.2, Nasedkin, V.1, Bork, A.3, Huttunen, P.4

1: Omegawave (Espoo, Finland), 2: Sale Sharks, Sale Rugby Union Football Club (Eccles, UK), 3: Otto von Guericke University (Magdeburg, Germany), 4: Loughborough University (Loughborough, UK)

**Introduction** Efficient management of athlete preparation can only be realized through a comprehensive analysis of all components of the training process; including daily physiological feedback. The purpose of this study was to determine the most important training and non-training related contributors to game success and the optimization of the training process to achieve the best results. **Methods** The study examined 14 players of a professional rugby team during the 2013-14 season. The data contained anthropometrical, physiological, performance, training load and self-reported wellbeing variables. Physiological readiness of the Central Nervous System, Cardiac System (CS) and Autonomic Nervous System (ANS) were frequently monitored by Omegawave Team+ (Finland). A new analytical logic with Primary, Internal and External contributors' identification was developed. Supervised Learning - Augmented Naive Bayes (ANB) - was used to predict targets. Irrelevant parameters were excluded based on their deterministic relationship with other variables. Predictive accuracy of the models was confirmed with the area under the Receiver Operating Characteristic curve (ROC index) and with a Confusion Matrix of cross-validation  $K=3$ . Normalized Mutual Information (NMI) was used to determine the relative influence of variables on the target. **Results** The initial ANB model for game success included 59 parameters. Predictive accuracy was excellent; average ROC index was 93% computed by cross-validation. Eleven significant predictors were found ( $p < 0.1$ ). Three Primary direct predictors were: Hours Travelled (NMI=11.5%); Resistance Training Load - Sets x Reps (NMI=7.8%); Training Orientation (NMI=7.2%). Internal (physiological) contributors that could improve the Primary contributors (i.e.: Hours Travelled) were identified. An ANB model for Hours Travelled with 26 physiological parameters was created (ROC=84%). Two of the most important contributors involved the CS and ANS: Low Frequency ( $p < 0.05$ ) and High Frequency in Normalized Units ( $p < 0.1$ ). Certain External contributors (i.e. Nutrition and Training Load) were found to be the most significant for optimizing Internal contributors (i.e. CS and ANS), thereby improving a player's trainability. Using predictive biological modeling, an optimal roadmap to successful performance was developed. **Discussion** The analytical modeling enabled effective utilization of recent innovations in big data and data mining in sports science. This process can be implemented by constantly re-evaluating the predictive models by using newly generated external and internal data. Contact roman.fomin@omegawave.com

## LOADS VOLUME AND INTENSITY IN FEMALE HIGH-PERFORMANCE HANDBALL MATCH-PLAY

Skarbalius, A.

Lithuanian Sports University

**Introduction** Indices of intensity and volume are the very important factors for implementation right training programme in order to prevent overtraining and optimize sport performance. There are different methods for identity training loads volume and intensity in sports (Scott et al., 2013). Assessment of internal loads during handball match-play is a great problem because of prevailed intermittent loads character (Wagner et al., 2014). The aim of this study was to assess load volume and intensity during handball match-play in female high-performance handball field players. **Methods** Match-play volume (total heart beats per match including warm up, break between halves, and cooling down) and intensity was quantified by monitoring heart rate (HR) using Polar Team System (Finland) during 16 matches of semi-professional female handball players ( $n = 14$ ; age  $21.4 \pm 2.7$ ;  $VO_{2max}$  ( $46 \pm 5.8$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) and was expressed in relation to the individual maximal HR (%HRmax), % $VO_{2max}$  obtained through an incremental laboratory test. **Results** HR of the players during playing was  $172 \pm 7.2$  beats.min<sup>-1</sup>, but  $149 \pm 9.1$  beats.min<sup>-1</sup> of the total load (including warming-up, break between halves, and cooling-down). The same alteration was found in %HRmax =  $86.5 \pm 4.5\%$  ( $78.4 \pm 3.7\%$  respectively), corresponding to value of  $VO_{2max}$   $79.4 \pm 6.4\%$  ( $71.5 \pm 5.7\%$ ). Total heart beats per match was  $11125 \pm 270$ , but  $13134 \pm 472$  (including warming-up, break between halves, and cooling-down). **Discussion** Research findings are in line to others researchers studies (Michalsik et al., 2011), there were found a relative workload of 65–80% of %HRmax, a mean of HR 160–170 beats.min<sup>-1</sup>. Wagner with co-authors (2014) suggest that  $VO_{2max}$  during competition players need 55–60 ml.kg<sup>-1</sup>.min<sup>-1</sup>. Nevertheless, that  $VO_{2max}$  of subjects were nearly 10 ml.kg<sup>-1</sup>.min<sup>-1</sup> less compared to elite handball players, values expressed in percentage were at the same level as elite handball. We conclude, that physiological demands during handball match-play is in the same requirements, when mastership of competitive teams is homogeneous. We did not find any publication related to total heart beats per handball match. Such kind of indices would be useful in order to design right training programme in order to simulate training loads similar to competition needs. **References** Michalsik LB, Aagaard P, Madsen K. ## LOAD AND RECOVERY DURING AN IN-SEASON INTENSIVE GAME PHASE; PERCEPTIONS OF PLAYERS AND COACH.

Doeven, S.H.

Hanzehogeschool Groningen, University of Applied Sciences

**Purpose:** A good relationship between training load and recovery is crucial to maximize performance and prevent overtraining. This balance is especially delicate during intensified phases of training and competition. Research shows that players can perceive the training load heavier than intended by the coach (Brink et al 2014). Up to now, it is unknown if coaches are able to observe the perceived exertion of games adequately and to what extent players are able to recover for the next stimulus. Therefore, the purpose of this study is to investigate to what extent coaches can observe the perceived exertion and recovery of players during an intensive competition period. **Methods:** Rate of perceived exertion (RPE) and Total quality of recovery (TQR) of 13 professional basketball players (age  $27 \pm 3$  y, height  $197.2 \pm 13$  cm, weight  $100 \pm 15$  kg, body fat  $10.3 \pm 3.6\%$ ) were compared with observations of the coach. During an in-season phase of 14 games within 6 weeks (2.3 games/week), each player rated their perceived exertion after each game. TQR scores were filled out before the first training session after a game. The coach rated the observed exertion (ROE) and recovery of each player. **Results:** The perceived load of players was lower than rated by the coach ( $15.3 \pm 2.7$  and  $15.8 \pm 2.0$ ;  $p < 0.05$ ). Furthermore, players perceived lower recovery than what was observed by the coach ( $12.7 \pm 2.9$  and  $15.4 \pm 1.6$ ;  $p < 0.05$ ). The correlations between players' and coaches' load ( $r = .46$ ) and recovery ( $r = .23$ ) were mild/moderate to weak. **Conclusion:** Results show that games were experienced less intense by the players than estimated by the coach. On the contrary, players felt less recovered than observed by the coach before the first training after the game. Differences in perception of exertion and recovery by players and coach can lead to inadequate planning of future training sessions.

Accurately monitoring individual game load and the subsequent recovery may better guide the training process and prevent overtraining.

### WHEN MORE DOES NOT MEAN BETTER - THE VALUE OF WORK-LIFE BALANCE WITHIN A PROFESSIONAL FOOTBALL ARENA

Saunders, J., Pink, M.

*Australian Catholic University*

**Introduction** One of the oldest concerns about athletes' personal development has been around difficulties experienced following retirement from elite sporting careers. Current career transition literature has brought a broader lens to athlete careers and their transitions as well as relevant dimensions of personal and professional development. Stambulova et al (2014). Particular focus has been on the notion of dual career development as a pre-requisite to adaptation after retirement. However, realisation of the salience of conceptualising the professional sport arena as a workplace has led to a concern with players' ongoing well-being and considering work-life balance issues alongside the commitment required to perform at the highest level. The study reported here has therefore undertaken a preliminary examination of how AFL players spend their time when away from the football club and how that might facilitate high levels of engagement in their football activities. **Methods** Data concerning how players spent their committed and free time away from their contracted time as a professional footballer was collected as part of a survey into off-field activities and club support in the middle of the 2013 season. Four hundred and thirty players (Mean age=22.93, SD =3.35) participated from 14 of the 18 clubs within the national league. Results Three quarters of the sample (74.8%) reported that they were involved in activities related to dual career development. The average time committed to this was 4.4 hours per week but with a fairly high standard deviation of 2.75 hours. In total the players reported having an average of 26.08 hours per week that they were able to commit to non-football activities during the season. When amount of time was added to other off-field life variables and controls were added for the club ladder position and players athletic social identity and exclusivity, Multiple Hierarchical Regression showed that 17% of the variance of the players' experience of athlete engagement (Lonsdale et al., 2007) was predicted by the quality of their free time (which was in turn predicted by the perceived level of club support) and the amount of time spent in social activities. **Discussion** These findings provide evidence that time spent in social activities and more significantly perceptions of the quality of the players overall time away from the playing field was able to contribute significantly to the level of their engagement in their work as footballers. Within the context of the length of season the notion of finding a work-life balance would seem to be relevant to achieving better work outcomes for your playing staff. **References:** Lonsdale, C, Hodge, K, Jackson, S.A. #### ATTENTION CONTRIBUTES TO LOW FIDELITY IMITATION OF BIOLOGICAL KINEMATICS IN AUTISM SPECTRUM DISORDERS

Andrew, M., Bennett, S.J., Elliott, D., Gowen, E., Hayes, S.J.

*Liverpool John Moores University*

**Introduction** Attentional control processes that modulate imitation of biological kinematics have been linked to compromised imitation fidelity in autism spectrum disorders (autism). Using a novel protocol, we manipulated control by directing attention to a non-human agent displaying atypical and typical kinematics in which peak velocity (PV) was achieved at 18% and 44% of the movement duration, respectively. **Objectives** Examine whether imitation of biological kinematics is modulated by attention. **Methods** Fifteen adults with autism (confirmed using ADOS-2) and fifteen controls participated. Participants in a general-attention condition observed a random sequence of atypical and typical models with the intention to "observe and copy the model", whereas during selective-attention participants were instructed to "observe and copy exactly how the dot moves". Perception of biological kinematics was also examined using a judgement task, and general attention was assessed using a multiple-object tracking protocol. **Results** Although groups did not differ when imitating typical kinematics, the control group ( $28 \pm 8\%PV$ ) imitated atypical kinematics more accurately ( $P < 0.01$ ) than the autism group ( $32 \pm 10\%PV$ ). The control group became 11% more accurate ( $P < 0.01$ ) at imitating atypical kinematics during selective-attention compared to general-attention, whereas there was no attentional modulation in the autism group ( $P > 0.05$ ). The autism ( $74 \pm 17\%$  accurate) and control ( $70 \pm 16\%$  accurate) groups were equally successful at judging biological kinematics ( $P = 0.17$ ). The control group ( $96 \pm 3\%$  accurate) was more successful ( $P = 0.01$ ) than the autism group ( $84 \pm 7\%$  accurate) during the multiple-object tracking task. **Conclusion** Although the autism group made accurate perceptual judgements of biological kinematics, their imitation of those kinematics was compromised. Unlike the control group, imitation fidelity did not improve by manipulating attentional control. Post experimental debriefing confirmed the autism group did intend to imitate how the dot moved. In conjunction with the group difference in multiple-object tracking, and the normal ability in perceiving biological kinematics, these findings are the first to demonstrate low fidelity imitation in autism is linked to attentional processes associated with sensorimotor integration and representation of biological kinematics.

#### AGE RELATED DEPENDENCY ON VISUAL INPUT IN ORDER TO MENTALLY SIMULATE POSTURAL TASKS: AN FMRI STUDY

Mouthon, A.1, Ruffieux, J.1, Mouthon, M.2, Waelchli, M.1, Keller, M.1, Hoogewoud, H.M.3, Annoni, J.M.2, Taube, W.1

1: DMMSS (Fribourg, Switzerland), 2: DMUN (Fribourg, Switzerland), 3: HFR (Fribourg, Switzerland)

**Introduction** Aging induces structural and functional changes in the central nervous system leading to greater cortical activity during manual tasks (Calautti et al., 2001) and cortical disinhibition during postural tasks (Papegaaij et al., 2014). This study aims to further explore age-related differences in postural control by means of fMRI in order to detect cortical and subcortical changes. **Methods** For this purpose, subjects were asked to apply motor imagery (MI), action observation (AO) or the combination of both (AO+MI) to mentally simulate two postural tasks: upright stance (static) or compensation of a medio-lateral perturbation (dynamic). Data from 16 elderly and 16 young (7 females; mean  $\pm$  SD =  $72 \pm 4.58$ ; 6 females; mean  $\pm$  SD =  $27 \pm 4.81$ ) were acquired with a 3T MRI scanner and analyzed with

SPM8. A full factorial model was used to analyze differences between elderly and young. Significant differences were recognized at  $p < .05$  FWE corrected at the cluster level. Results When AO+MI is compared with AO of the dynamic task, elderly displayed larger activation in SMA and PMC, whereas young did not reveal higher activation. For the contrast MI versus AO of the dynamic task young presented higher activity in the cerebellum and putamen than elderly. Inversely, when contrasting AO with MI of the dynamic task elderly exhibited greater activity than young in cerebellum and putamen. Discussion There is a common notion of increased cortical activity in elderly compared to young for mental simulation of movements in general (Nedelko et al., 2010) and for postural control in particular (Papegaaij et al., 2014). However, although elderly showed increased activity in the SMA and PMC in the present study, this was only true for the conditions with visual input (AO+MI and AO). In the condition without visual input (MI), there was no facilitation of cortical areas in the elderly and they even demonstrated a decrease in activity in subcortical areas such as the putamen and the cerebellum. Our results indicate that elderly indeed increase activity in cortical centers probably to compensate for age-related deteriorations in postural control. However, this seems to be only true when they are sufficiently guided by visual input indicating a stronger dependency on vision than young; particularly to activate subcortical brain centers. ## COMPARISON OF MUSCLE SYNERGIES DURING TREADMILL RUNNING BETWEEN DIFFERENT FOOT STRIKE PATTERNS

Nishida, K.1, Hagio, S.1,2, Kibushi, B.1, Moritani, T.1, Kouzaki, M.1

1: *Kyoto Univ. (Kyoto, Japan)*, 2: *JSPS (Tokyo, Japan)*

Introduction Runners fall into two broad categories based on foot strike patterns: a fore-foot strike (FFS), in which the ball of the foot lands before the heel comes down; and a rear-foot strike (RFS), in which the heel lands first. The differences between FFS and RFS have been only studied in terms of ground reaction forces (Lieberman et al., 2010), knee loading (Kulmala et al., 2013), and running economy (Gruber et al., 2013). The aim of this study was to compare FFS with RFS based on muscle synergies (Hagio et al., 2015). Methods Six healthy male subjects ran on a treadmill at different speeds (5, 7, 9, 12, and 15 km/h). At each speed, subjects were asked to run both in FFS and RFS. Surface electromyogram (EMG) activity was recorded from 12 muscles on both sides of the trunk and lower body. Muscle synergies were extracted from an EMG data matrix using non-negative matrix factorization (Lee and Seung, 1999). Results Both in FFS and RFS, six synergies (Syn1-6) were extracted. The general characteristics of the synergies were similar between FFS and RFS. However, in all subjects, Syn3 and Syn6, which were activated just before touchdown, recruited tibialis anterior (TA) much more in RFS than in FFS. In a subject, Syn1 and Syn4, which were activated around touchdown, recruited triceps surae (TS) slightly more in FFS than in RFS. Moreover, in two subjects, Syn2 and Syn5, which mainly recruited TS and were activated during stance, showed bi-modal activation patterns in FFS while mono-modal in RFS, so that they were also activated around touchdown in FFS. Discussion The difference of TA seems to come from the necessity of the dorsal flexion of ankle joint just before touchdown in RFS. On the other hand, the reason of the differences of TS and activation patterns seems to be because the activity of TS absorbed touchdown impact in FFS. In conclusion, the results suggest that the central nervous system controls running rhythmically activating six muscle synergies, switches from FFS to RFS changing the weighting in specific synergies, and adjusts the absorption of touchdown impact changing the weightings or the activation patterns. ## POSTACTIVATION POTENTIATION INDUCED BY REACTIVE JUMPS COUNTERACTS STRETCH-INDUCED MUSCLE TWITCH DECLINES IN THE TRICEPS SURAE MUSCLE

Kümmel, J., Kramer, A., Gruber, M.

*University of Konstanz*

Introduction Warm-up procedures often include conditioning activities that serve to enhance performance in a subsequent sport-specific movement. Recently, it has been shown that repetitive reactive jumps (hops) induce postactivation potentiation (PAP) in electrically evoked twitches of the triceps surae muscle (Bergmann, 2013). This potentiating effect might be related to a higher stiffness of the muscle-tendon complex, allowing a higher force contribution from the active components of the muscle (Maloney, 2014). In contrast, stretching reduces the muscle-tendon stiffness, and causes a decline in the electrically evoked muscle twitches (Morse, 2008). Until now, there is no study that looked at the combination of those activities with regard to changes at the muscle-tendon level. Therefore, we designed the present study to test the hypothesis that 10 hops before or after stretching the muscle-tendon unit are able to counteract the stretch-induced decrease of the muscle twitches. Methods Twenty subjects completed 10 electrically evoked twitches of the triceps surae muscle subsequent to 4 different conditioning activities and a resting control in a counterbalanced order. The conditioning included either 10 hops, 20s static stretching of the triceps surae muscle, 20s stretching followed by 10 hops and 10 hops followed by 20s stretching. We determined the isometric twitch peak torque for each twitch response of the triceps surae muscle. Results A repeated measure ANOVA revealed a significantly higher twitch torque immediately after the hops (+22%) and a significantly lower twitch torque after stretching (-7%) compared to control. The combinations stretching after hops and hops after stretching both significantly increased the twitch torque compared to control. Interestingly, the stretching followed by hops revealed a significantly higher increase (+17%) compared to the hops followed by the stretching (+9%). Discussion In this study we were able to show that 10 hops are able to counteract stretch-related declines of the muscle twitch force. Furthermore we clearly demonstrated that the overall potentiating effect is dependent on the order of the conditioning activities. Most likely, the observed counteracting effect takes place on the muscular level, since it has been shown that 20s of static stretching affect the muscle but not the tendon properties (Morse, 2008). Thus, the findings of the present study provide further evidence for the effect of the muscle's activation history on its capacity in generating force. From an applied perspective our results have relevance for tailoring warm-up routines that include sport-specific conditioning activities. ### KNEE MUSCLE TENDON COMPLEX FORCES RATIO AND BIOMECHANICAL ANALYSIS IN SQUATTING

Berdajs, M.1, Djordjevic, S.1, Modic, Z.1, Gerbec Cucek, M.1, Stancin, S.2, Sodnik, J.2, Tomazic, S.2

1:TMG-BMC d.o.o, Ljubljana,Slovenia,2:University of Ljubljana, Faculty of Electrical Engineering (Ljubljana, Slovenia)

**Introduction** Mechanical properties of the Muscle-tendon complex (MTC) are an important element in studying human performance. A primary aim in training and rehabilitation is developing balanced and simultaneous muscle and tendon adaptation. Understanding of the force distribution in different joint angle is crucial for training and rehabilitation process. The MC sensor (Sensmotion PT2 device, TMG-BMC, Slovenia) [1] is a wearable ( $m < 1.5$  g) biosensor that measures muscle and tendon tension/force. In our research, we focus on quadriceps muscles and tendon and the patellar tendon (PT) force ratio by using MC sensor. We measured the vastus medialis (VM) and lateralis (VL), quadriceps (QT) and patellar tendon (PT) forces during squatting. **Methods** Ten international level athletes (five male and five female, age 20-31) were measured during squatting using Smith machine. Tension forces of VM, VL, QT and PT were measured with the MC sensor with 1 kHz sampling rate. Athlete's movements were captured with Qualisys MCS consisting of 8 Oqus 3+ cameras, with resolution of 1.3 million pixels and 0.5 kHz sampling rate. Ten passive markers were placed on the head, neck, shoulder, elbow, hips, thigh, knee, ankle, foot and weights enabling calculation of the knee angle (KA) and torques (KT) [3]. Muscle and tendon tension forces ratio was then calculated. Results Exponential relation between QT and PT force ratio and KA (in the range from  $20^\circ$  to  $80^\circ$ ) was found, which is below 0.5. On the other hand, linear relation between sum of VM and VL force and PT force ratio was found, which is from 0.2 to 1.55. **Discussion** The reason of this low ratio between QT and PT force in different KA is that the angle between torso and femur is getting lower, causing rectus femoris loosening (nevertheless the activity of rectus femoris is high). In lower angles, the ratio between the sum of VM and VL force and PT force is lower due to low influence of very complex force transmission through the knee joint. In the highest angles, the ratio is above 1, meaning the higher muscle force is required and more force is lost in the transmission path [2]. The idea for the future testing is to make some additional testing and measurements and then describe our results with some mathematical equations that are related to knee joint biomechanics. **References** [1] S.Đorđević et al, MC sensor-a novel method for measurement of muscle tension. *Sensors*, vol. 11, no. 10, 2011. ### A DESCRIPTIVE OBSERVATIONAL STUDY OF STROKE CHARACTERISTICS IN TEAM BOAT SPRINT KAYAKING

Tay, C.S., Kong, P.W.

*Nanyang Technological University*

**Introduction** In team boat sprint kayaking, paddlers compete in the K2 (two-seater) and K4 (four-seater) over distances of 200-, 500-, and 1000-m. As an interacting team sport (Widmeyer & Williams, 1991), crew members must coordinate their efforts throughout the entire race to produce a collective outcome. While it is generally accepted that successful performance requires good synchronisation in strokes between the crew, little has been documented about team boat sprint kayaking. The aim of this study was to identify the stroke characteristics for a K2 200-m crew. **Methods** High-speed (120 Hz) video of a K2 200-m crew from a national team was recorded from the sagittal view during an important selection time trial. Video analysis was performed to identify stroke characteristics of each paddler in a K2, including stroke rate and a four-phase stroke breakdown according to McDonnell and colleagues' model (2012) of Entry, Pull, Exit and Aerial sub-phases. In addition, an offset variable, defined as the timing difference between the back paddler compared to the front, was obtained for each of the phase-defining positions (Catch, Immersion, Extraction and Release). Mean and variability of the stroke characteristics were calculated to compare between the two paddlers. Results Within a K2, both paddlers performed at the same stroke rate of 79 double strokes per minute, but varied considerably when analysed through the four-phase breakdown. For example, the back paddler spent about 50% longer in the Pull sub-phase compared to the front paddler (147 ms versus 96 ms). Coefficient of variations for each paddler were also noted to be larger (10 to 16%) when stroke characteristics were analysed using the four-phase breakdown, as compared to the two-phase breakdown (6%). Also, while there was a noticeable timing offset at the Catch (-24 ms) and Immersion (-42 ms) positions, whereby the back paddler reached the positions before the front paddler did, the offset was negligible by the time the Exit occurred. **Discussion** The results show that stroke characteristics in team boat sprint kayaking are more complicated than previously thought; paddlers in a team boat may paddle at the same stroke rate yet have very different stroke profile when analysed in greater detail. Interestingly, while the general belief is that stroke synchronisation at the Catch position is important for successful team boat paddling, our results found an uncanny similarity at when the Exit position was reached by both paddlers. Further investigations are warranted as to whether reaching the Exit position at the same time can distinguish successful team boat sprint kayaking crews. **References** McDonnell LK, Hume PA, Nolte V (2012). *Sports Biom*, 11(4), 507-523. ### MECHANICAL AND MORPHOLOGICAL PROPERTIES OF THE HUMAN QUADRICEPS MUSCLE-TENDON UNIT AFTER WHOLE-BODY VIBRATION TRAINING

Rieder, F.1, Wiesinger, H.P.1, Kösters, A.1, Müller, E.1, Seynnes, O.R.2

1: PLUS (Salzburg, Austria), 2: NIH (Oslo, Norway)

**Introduction** Animal studies suggest that regular exposure to whole-body vibration induces an anabolic response in connective tissue (e.g. bones or tendons; Rubin et al., 2001; Sandhu et al., 2011). Changes in material properties of series elastic elements may alter the muscle force-length relationship (Lieber et al., 1992). However, the effects of this type of intervention on human tendon properties and its possible influence on the function of the muscle-tendon unit have never been investigated. Hence, the aim of this study was to investigate the effect of chronic whole body vibration exposure on the patellar tendon mechanical, material and morphological properties, the quadriceps femoris muscle architecture and the knee extension torque-angle relationship. **Methods** Healthy adults were recruited for an eight-week intervention study and randomized into one of three groups: whole-body vibration, active controls and inactive controls. Subjects of the whole-body vibration and the active control group performed isometric squats on a vibration platform with and without vibration, respectively. Using ultrasonography and dynamometry, the following outcome variables were measured before and after the intervention in 46 subjects: tendon stiffness, Young's modulus and cross-sectional area, muscle thickness, pennation angle and fascicular length and torque-angle relation of the knee extensor muscles. Results Vibration training induced an increase in proximal (6.3%;  $P < 0.01$ ) and mean (3.8%;  $P < 0.01$ ) tendon cross-sectional area, without any appreciable change in tendon stiffness and Young's modulus or in muscle architectural parameters. Isometric torque at a knee angle of  $90^\circ$  increased in active control subjects (6.7%,  $P < 0.05$ ) only and the

torque-angle relation remained globally unchanged in all three groups. No significant changes were observed in muscle and tendon parameters of the two control groups. Discussion The present protocol of whole-body vibration training did not appreciably alter knee extension torque production or the musculotendinous parameters underpinning this function. Nonetheless, this study shows for the first time that whole body vibration elicits tendon hypertrophy in humans. References Lieber RL, Brown CG, Trestik CL (1992). ### INTERACTION BETWEEN HIP ANGLE, KNEE ANGLE AND KNEE ANGULAR VELOCITY WHEN MEASURING ISOKINETIC KNEE TORQUE

Jongerius, N., Bissas, A.  
*Leeds Beckett University*

Introduction Three main mechanical factors influence single joint torque values: joint angle, angular velocity and adjacent joint angle when biarticular muscles are involved. Whilst the individual effects of each factor on joint torque have been thoroughly investigated (Bohannon et al., 1986; Kawakami et al., 2002), research around the question of the combined effect of all three factors is still scarce. Methods Following two practice sessions, knee flexion and extension torques were measured on a Cybex NORM dynamometer in 10 males. Participants performed a number of submaximal trials prior to the execution of 3 maximal repetitions (seated) at velocities of V30, V90, V150 & V210°/s for each muscle group and under three hip angle conditions: 0° (H0), 45° (H45) & 90° (H90). Overall peak torque was measured for all hip and velocity conditions whereas knee angle specific torques at K30°, K45°, K60° & K75° were obtained for all three hip angles but only for V30 and V90 as the higher velocities limited the range of the isokinetic movement. Results Knee extension values showed no effect of hip angle across all tested angular velocities while the effect of knee angle on torque production was not influenced by the tested hip angle, angular velocity or their combined effect. For knee flexors, the H45 and H90 facilitated significantly higher (velocity normalised) peak torque values than the H0 condition (31% and 27% respectively,  $p < 0.01$ ) but there was no interaction between hip angle and velocity. Furthermore, as the knee angle increased peak torque decreased for all hip conditions, however the rate of decrease for the H45 and H90 was lower than H0, with H45 and H90 producing statistically higher values ( $p < 0.01$ ) than H0 for each selected knee angle (K30° = 52% and 63%, K75° = 73% and 100% respectively). When values were expressed as a percent reduction of the K30° values, H90 showed a smaller magnitude of drop than H0 at K75° (34% vs. 47%,  $p < 0.01$ ). Discussion Whilst knee extensor torques are not affected by different hip positions, hip angles of 45° and 90° are superior in producing higher flexor torques across all knee angles and angular velocities with the hip at 90° suggested as the optimal position. The differences between flexion and extension torques in response to changes in hip angle are likely to be caused by different relative contributions of biarticular muscles. Therefore, when a full picture of knee isokinetic functionality is needed, the relation of the three input variables (hip angle, knee angle, angular velocity) with respect to the output knee torque value should be always documented. #### EXERCISE INDUCES ADAPTIVE GENE EXPRESSION THROUGH NOX2-DEPENDENT REACTIVE OXYGEN SPECIES IN SKELETAL MUSCLE.

Henríquez-Olguín, C., Valladares, D., Díaz-Vegas, A., Utreras-Mendoza, Y., Campos, C., Arias-Calderón, M., Altamirano, F., Jaimovich, E.  
*Universidad de Chile*

Reactive oxygen species (ROS) participate as signaling molecules in exercise training adaptation. A physiological ROS production is required to activate redox sensitive pathways that may modulate acute and chronic responses to exercise training. It has been recently reported that exogenous dietary antioxidants can impair early or long-term effects of exercise. However, the ROS source and the molecular mechanisms involved in these phenomena are still not completely understood. The aim of this work was to study the role of NADPH oxidase (NOX2) in response to endurance exercise. BALB/c mice (6-wk-old), pretreated with either apocynin (3 mg/Kg) or saline for 3 days, were swim-exercised for 60 min. Exercise significantly increased NOX2 complex (p47-gp91 interaction) demonstrated by proximity ligation assay in flexor digitorum brevis cryosections (FDB) and by co-immunoprecipitation. In addition, p-p47phox levels were significantly upregulated by exercise in FDB whole lysates. Activation of NOX2 was completely inhibited by apocynin treatment, and it was associated with a reduced activation of p38, ERK 1/2, and NF- $\kappa$ B signaling pathways after exercise training. On the other hand, exercise increased the gene expression of Interleukin-6 (IL-6), manganese superoxide dismutase (MnSOD), glutathione peroxidase (GPx), and mitochondrial transcription factor A (Tfam) in FDB muscles, which was blocked by apocynin treatment. Moreover, the increase in plasma IL-6 elicited by exercise was decreased in apocynin-treated mice compared with the exercised group ( $p < 0.001$ ). This same result was obtained in vitro exercise using gp91-dstat (NOX2 inhibitor), but not with a mitochondrial-targeted antioxidant (EUK 134). In conclusion, the present investigation showed for the first time that NOX2 is activated by exercise inducing the activation of redox sensitive pathways, suggesting a major role of NOX2 in ROS-dependent muscle adaptations. This is a novel mechanism that may explain previous reports related with antioxidant supplementation and exercise effects.

## MYOSIN HEAVY-CHAIN 2X EXPRESSION INTERACTS WITH ACUTE REGULATION OF PGC-1ALPHA SPICE-4 FOLLOWING STRENGTH EXERCISE WITH LOW AND MODERATE VOLUME

Hammarström, D.1,2, Rønnestad, B.R.1, Blomstrand, E.2, Ellefsen, S.1

1. Lillehammer University College, 2. GIH, The Swedish School of Sport and Health Sciences, Stockholm Sweden

**Introduction** PGC-1alpha splice-4 (-S4) has been implicated as a positive regulator of muscular hypertrophy in response to strength training[1]. The aim here was to explore gene expression of PGC-1 $\alpha$ -S4 in response to an acute strength-exercise session of low (1-set per exercise), and moderate volume (3-sets per exercise), and to explore effects of muscle fiber-type characteristics on gene regulation patterns, using a within-participant model. **Methods** Eight female (mean $\pm$ sd for age, 23  $\pm$  0.6 yrs; weight, 62  $\pm$  4.2 kg; height, 169  $\pm$  3.7 cm) and seven male (23  $\pm$  1.1 yrs, 83  $\pm$  8.1 cm, 180  $\pm$  6.7 cm) recreationally active university students performed one strength training session consisting of three unilateral leg exercises (leg press, leg curl and leg extension), wherein one leg performed a single set per exercise and the contralateral leg performed three sets at an intensity of 10-repetition maximum (balanced for leg dominance). Skeletal muscle biopsies were obtained from m. vastus lateralis prior to exercise, and 1h, 4h and 48h after completion of exercise. To evaluate relative abundances of PGC-1alpha4, RNA was isolated and analyzed by means of qRT-PCR using RPL-32 as the reference gene. MyHC2X expressions were expressed as percentage of overall MyHC-family expression[2]. **Results** There was a main effect of time, PGC-1alpha4 mRNA was increased 1h (1-set, 1.5-fold, CI: 1.2-1.9; 3-sets, 1.8-fold, CI: 1.5-2.1,  $p < 0.05$ ) and 4h following exercise (1-set 2.4-fold, CI: 1.6-3.7; 3-sets, 3-fold, CI: 2.2-4.2,  $p < 0.01$ ), and decreased 48h following exercise (1-set, 0.7, CI: 0.5-1; 3-sets 0.7, CI: 0.5-0.9,  $p < 0.01$ ). There was no general effect of exercise volume. Using baseline MyHC2X expression as an independent variable provided a significantly improved model fit by explaining PGC-1alpha4 regulation at 4h, estimating a 1.1-fold change in PGC-1alpha4 per unit increase in MyHC2X expression ( $p < 0.01$ ). There was no interaction effect between exercise volume and MyHC2X expression on PGC-1alpha4 regulation. Expression of other MyHC-isoforms or sex did not contribute significantly in explaining PGC-1alpha4 regulation. Conclusions PGC-1alpha4 responses did not differ between strength exercise with low and moderate volume. However, training-induced alterations in PGC-1alpha4 interacted with relative MyHC2X expression, highlighting the importance of accounting for muscle fiber characteristics when assessing the adaptive profile to strength training. **References** 1. Ruas et al. (2012) Cell 151(6): 1319-1331. 2. Ellefsen et al. (2014) Scand J Med Sci Sports 24(5): e332-342.

## ASSOCIATION BETWEEN THE IGF2/ACE GENOTYPE COMBINATION AND JUDO STATUS

Itaka, T.1, Agemizu, K.2, Aruga, S.3, Machida, S.1

1: Juntendo University, 2: Tokai University, 3: Tokai University

**Introduction** Genetic polymorphism is shown to be associated with human physical performance. The angiotensin I converting enzyme (ACE) polymorphism and the  $\alpha$ -actinin-3 (ACTN3) R577X polymorphism have been most widely studied for the analysis of such associations. We have recently found that insulin-like growth factor 2 (IGF2) G/A polymorphism may be associated with judo status. There is a possibility that the combinations of genetic polymorphisms are more effective than alone. Accordingly, the purpose of this study was to evaluate the association between the ACTN3/ACE, ACTN3/IGF2, or ACE/IGF2 genotype combinations and judo status. **Methods** The subjects included 156 male judo players belonging to top-level universities in Japan. They were divided into three groups based on results in national or international competitions. Sixteen athletes were classified as "international level", 37 as "national level", and 103 as "others". DNA was extracted from their saliva and genotyping using PCR-RFLP was conducted to detect ACTN3 (rs1815739), ACE (rs1799752), and IGF2 (rs680) gene polymorphisms. The relative frequencies of these combinations of genetic polymorphisms were compared between the "international-level" and "other" categories using chi-square test. **Results** There was no significant difference in the relative frequencies for the ACTN3/ACE genotype combination (Massidda et al., 2012; Ahmetov et al., 2013). However, those for the ACE/IGF2 genotype combination differed significantly between judo athletes placed into "international-level" and "other" categories (I-GG: 43.8% vs. 26.3%, I-A: 31.3% vs. 55.3%, DD-GG: 18.8% vs. 2.9%, DD-A: 6.3% vs. 15.6%,  $p = 0.01$ ). There was a trend in the relative frequencies of the ACTN3/IGF2 genotype combination in the "international-level" category as compared to those of the same combination in the "other" category (R-GG: 43.8% vs. 19.5%, R-A: 31.3% vs. 43.7%, XX-GG: 18.8% vs. 9.7%, XX-A: 6.3% vs. 27.2%,  $p = 0.06$ ). **Discussion** It has been reported that the best combined genotype for the greatest strength is ACE DD-ACTN3 RR. However, we found an association between the IGF2/ACE but not the ACTN3/ACE genotype combination and judo status. The combination of ACTN3 and ACE is suggested to be associated with performance in closed-skill sports such as swimming or track. The findings of the present study suggest that the combination of IGF2/ACE but not that of ACTN3/ACE may be the candidate combination of genetic polymorphism associated with judo status. **Reference** Massidda M et al. ## ACTOVEGIN, A NON-PROHIBITED DRUG, MAKES HUMAN SKELETAL MUSCLE MORE OXIDATIVE

Søndergård, S.1, Dela, F.1, Helge, J.W.1, Larsen, S.1

1: Xlab, Center for Healthy Aging, Faculty of Health and Medical Sciences

**Introduction** The non-prohibited drug Actovegin, a deproteinized hemodialysate of calf blood, is suggested to have ergogenic properties, but this potential effect has never been investigated in human skeletal muscle. Instead, these speculations have emerged because Actovegin has been used as a performance-enhancing drug by Tour de France riders and by Olympic athletes (1). To explore a possible mechanistic explanation for the purported ergogenic effect, we investigated the ex vivo effect of Actovegin on the mitochondrial respiratory capacity in human skeletal muscle. We hypothesized that Actovegin would increase the mitochondrial respiratory capacity in a dose dependent manner. **Methods** Muscle biopsies were obtained from m. vastus lateralis of 8 middle aged, overweight and sedentary subjects. Mitochondrial respiratory capacity was measured by means of high-resolution respirometry (Oxygraph-2k; Oroboros, Innsbruck, Austria) in permeabilised human skeletal muscle fibers acutely exposed to two doses (10 $\mu$ l/ml and 50 $\mu$ l/ml) of Actovegin prior to (for 50min) and during the respiratory measurements (for ~90min). Respiration was stimulated by sequential addition of malate, glutamate, ADP, succinate and FCCP. **Results** In the presence of complex I-linked substrates, Actovegin increased the oxidative phosphorylation (OXPHOS) capacity significantly in a concentration dependent manner (19 $\pm$ 3, 31 $\pm$ 4 and 45 $\pm$ 4pmol/mg/s). Maximal OXPHOS capacity with complex I and II-linked substrates was increased by Actovegin with the high dose (62 $\pm$ 6, 69 $\pm$ 6 and 77 $\pm$ 6pmol/mg/s) ( $P < 0.05$ ). Actovegin also increased ( $P < 0.05$ ) the respiratory capacity of the electron transfer system, the maximal rate of mitochondrial ATP production and the mitochondrial ADP sensitivity in a concentration dependent manner (70 $\pm$ 6, 79 $\pm$ 6 and 88 $\pm$ 7pmol/mg/s; 13 $\pm$ 2, 25 $\pm$ 3 and 37 $\pm$ 4pmol/mg/s; 0.08 $\pm$ 0.02, 0.21 $\pm$ 0.03 and 0.36 $\pm$ 0.03mM, respectively). **Discussion** To our knowledge we report for the first time that

Actovegin has a marked effect on the mitochondrial respiratory capacity in human skeletal muscle. This was in line with our hypothesis and in line with an earlier study in rat hepatic mitochondria reporting an increased mitochondrial respiration after exposures to Solcoseryl; another calf blood extract (2). Whether this improvement translates into an ergogenic effect in trained individuals and thus reiterates the need to include Actovegin on the World Anti-Doping Agency's active list remains to be investigated. ## **TWO BLOCKS OF HIGH FREQUENCY LOW-LOAD BLOOD FLOW RESTRICTED RESISTANCE EXERCISE INCREASED MYONUCLEAR NUMBER IN TYPE I FIBERS IN NATIONAL LEVEL POWERLIFTERS**

Bækken, L., Bjørnsen, T., Kirketeig, A., Wernbom, M., Paulsen, G., Samnøy, L., Berntsen, S.

*Norwegian School of Sport Sciences*

**Introduction:** Low-load blood flow restricted resistance exercise (BFRE) is shown to induce muscle hypertrophy, mainly in untrained individuals, but also in some athletic populations (1). Noteworthy, high frequency BFRE has been shown to increase the number of satellite cells and myonuclei in untrained subjects (2). This adaptation might be an important part of the hypertrophic process. So far, BFRE has not been investigated in highly trained competitive strength athletes. Thus the purpose of the present study was to investigate whether two blocks of practical low-load BFRE (pBFRE) during six weeks of periodized strength training could influence the number of satellite cells and myonuclei in powerlifters. **Methods:** Seventeen national level powerlifters (25±6 years (mean±SD); 15 men) volunteered for the study and were randomly assigned to either a pBFRE group (n=9) or a control group (CON; n=8). The 6-week periodized strength program was similar for both groups, except for two blocks (week 1 and 3) where the pBFRE group performed five sessions of low load pBFRE (25-30% of 1 repetition maximum (1RM)) front squats while the CON group performed normal front squats (~70% of 1RM). The pBFRE protocol consisted of four sets to voluntary failure (30 s rest between sets). To restrict the blood flow elastic knee bands were wrapped around the proximal end of the thighs to a pressure of ~120 mmHG (verified with an underlying pressure cuff in the first session). Thickness of the m. vastus lateralis (VL) was measured using ultrasound imaging. Strength was assessed in 1RM front squat. Muscle biopsies were obtained from VL before and after the 6-week intervention and analyzed for satellite cell and myonuclei content. **Results:** The pBFRE showed significant larger increase in thickness for VL compared to the control group (4.7±3.3%, vs. -0.8±5.0%, respectively, p=0.02). Changes in front squat did not differ significantly between groups. Immunohistochemical analyses showed that NCAM/Pax7-positive satellite cells per muscle fiber increased more in the control group than in the pBFRE group (24.7±27.1% vs. -7.9±15%, respectively, p=0.01), whereas the number of myonuclei in type I fibers increased more in pBFRE group than in the control group (17.8±12.8% vs. 0.4±12.9% respectively, p=0.01). **Discussion:** Firstly, the results showed that pBFRE had a hypertrophic effect on m. vastus lateralis, which can have been mediated through the myonuclear addition in type I fibers. Surprisingly, the satellite cell number was not increased with BFRE, but early satellite cell proliferation is nevertheless the most likely cause of the increase in myonuclei in the pBFRE group (3). **Conclusion:** pBFRE during front squat induced hypertrophy in m. vastus lateralis in powerlifters, and the hypertrophic response seemed to be related to type I specific addition of myonuclei. **References:** 1 Yamanaka et al. *J Strength and Cond Res* 26(9): 2523-2529, 2012 2 Nielsen et al. *J Physiol* 590 (17): 4351-4361, 2012 3 Snow. *Anat Rec.* 227(4): 437-46, 1990

#### **DROPOUT IN GERMAN AGE-GROUP SWIMMING**

Staub, I., Brixius, K., Bieder, A.

*German Sport University Cologne*

**INTRODUCTION** German Swimming has lost connection to the increasing world class level. Reasons are seen in complex deficits of the training processes (Pfützner, 2013). On one hand there is a claim for earlier training start and higher training volume at young age (Güllich, 2013; Lambertz, 2014; Rudolph et al., 2006) on the other hand scientific finding emphasize the successful "side-enteres" in the system (Güllich & Emrich, 2012; Sokolovas, 2006). The longitudinal investigation of careers of German age-group swimmers may reveal evidences for the long term development. Therefore, we investigated drop-out rate in age-group swimming. **METHODS** For the calculation 100 best age-group swimming performances (longcourse) in eight subsequent years (2004-2013) were dissected. The age-groups 1993 - 1995 (m/f) were observed (male n = 1.862; female n = 1.993). For calculating the dropout rate swimmers ranked, in thirteen different events, at the age of 11 where followed until the age of 18. **RESULTS** The mean dropout rate was 68.2 ± 6.5%, independent from the age-group, strokes and sex. Less than one of three swimmers who were ranked in the top-100 in their age-group with 11 years is still in at least one event ranked at the age of 18. About 33% of all swimmers were ranked only one time in the observed years, and only 11.2% were ranked in every single year. **DISCUSSION** We conclude that there are only a few continuous carriers among age-group-swimmers. This is in contrast to the German support system and long term development planning and should be addressed in future research. **REFERENCES** Güllich, A. (2013). *Talente im Sport*. In A. ## COACH LEADERSHIP AND GENDER IN NORWEGIAN AMATEUR BOXING

Tjønnndal, A.

*Norwegian University of Science and Technology*

**Introduction** Coach leadership is a substantial factor in developing talent, sport expertise and motivational climate among athletes (Riemer, 2007; Young & Medic, 2008). Worldwide, coaching is a male preserve and female coaches are a rare exception in elite sport. Gender has been shown to affect coach leadership (Pfister, 2013). Therefore, the purpose of this study was to examine styles and forms of coach leadership and how these are influenced by constructs of gender. **Methods** A national sample of 59 boxing coaches (53 male, 6 female) from Norway participated in this study. The methods of investigation were an online quantitative survey using the Leadership Scale for Sports (Chelladurai & Saleh, 1980) and qualitative interviews focusing on leadership and meanings of gender. 8 coaches (5 male, 3 female) were chosen for interviews. **Results** The most frequent self-reported dimensions of leadership behaviour among the coaches were positive feedback ( $M=4.36$ ,  $SD=.41$ ), training and instruction ( $M=3.85$ ,  $SD=.45$ ) and democratic behaviour ( $M=3.32$ ,  $SD=.59$ ). No significant gender differences in coach leadership among Norwegian boxing coaches were found in the survey data ( $p=0.05$ ). The qualitative results indicated that male coaches perceived themselves as more autocratic, while female coaches emphasised a democratic leadership style. Female coaches were seen as exceptional and often associated with traditional female roles such as caretakers. The male dominated culture affected the way good leadership was defined and assessed. A consequence of this was that women's approaches to leadership were not included in the definition of good leadership. **Discussion** Boxing is a male dominated sport. This is likely to affect leadership and meanings of gender among coaches and athletes. My research is limited to how coaches experience leadership and gender. How this affects the coach-athlete relationship, athlete motivation and development would be relevant topics for further research. **References** Chelladurai, P. & Saleh, S.D. (1980). ## INCREASED PHYSICAL ACTIVITY IN SCHOOL IMPROVES SCHOOL RESULTS IN BOYS

Fritz, J., Cöster, M., Nilsson, J., Rosengren, B.E., Karlsson, M.K.

*Clinical Sciences*

**Introduction** The proportion of Swedish children who finishes the 9th and final year of compulsory school without sufficient grades (defined as enough to be eligible for higher education) has increased during recent decades. As physical activity (PA) has been associated with favorable intellectual performance, increased physical education (PE) in school may contribute to reverse this negative trend. **Methods** We conducted a nine-year prospective population based controlled intervention study where the intervention school increased the level of PE from Swedish standard of 60 minutes per week to 40 minutes daily (200 min per week) during all 9 compulsory school years in 339 children. This cohort finished elementary school 2007 to 2012. Two control groups continued with the Swedish standard of 60 minutes of PE per week during the school years, (i) children attending the intervention school before intervention was initiated, from 2003 to 2006 ( $n=569$ ) and (ii) all Swedish children (except those attending the intervention school) who finished elementary school during the study period of 2003 to 2012 ( $n=1\ 161\ 523$ ). We obtained official final grades and recorded (i) proportion of individuals with sufficient grades to be eligible for higher education and (ii) the sum of the grades of the 16 compulsory school subjects, which could vary from 0 (no subject with accepted grade), to 320, (the highest grade in all subjects). Data are reported as means with standard deviations (SD) and changes from before to after the intervention as means with 95% confidence intervals. No measurement of dispersion is given for the control group (ii), as it is no sample. **Results** The proportion of boys in the intervention school with sufficient grades was 88.6% before intervention and 95.7% with the intervention, a 7.1% (95% CI 1.9, 12.2) increase. The average sum of all grades in boys in the intervention school was  $195 \pm 56$  before intervention and  $211 \pm 45$  with the intervention, a 16.1 point (95% CI 6.5, 25.6) increase. In all Swedish boys (control group ii) the proportion with sufficient grades decreased from 88.2% to 87.4%, a decrease with 0.8%, while the average sum of all grades increased from 195.7 to 198.4, an increase with 2.7 during the same period. In girls, we found similar trends but without statistical significance. **Discussion** Daily school-based PE during all nine compulsory school years improves, in boys, grades and eligibility to higher education. Similar, but non-significant, trends were found in girls. Contact [jesper.fritz@med.lu.se](mailto:jesper.fritz@med.lu.se)

## DEVELOPMENT OF EXCELLENCE IN YOUNG NORWEGIAN ATHLETES - THE IMPORTANCE OF SELF-DETERMINED MOTIVATION AND SELF-REGULATORY COMPETENCIES

Jordalen, G., Lemyre, P.N.

*Norwegian School of Sport Sciences*

**Introduction** In sport, self-regulatory competencies and a more autonomous form of motivation positively influence development and performance level (e.g., Gillet, Vallerand, & Paty, 2013; Toering, Elferink-Gemser, Jordet, & Visscher, 2009). Hence, this study examine how motivation and self-regulatory competencies combined relate to performance level among youth winter-sport athletes attending different elite sport colleges in Norway. **Methods** 199 winter sport athletes participated in this cross-sectional study (16-20 years ( $M = 18$ ,  $SD = .97$ ), 36.9 % women). The study examines the athletes' different regulations of autonomous motivation, key self-regulatory competencies, and performance level at the beginning of the competitive season. Descriptive analyses, ANOVA, and Structural Equation Modeling were performed. **Results** Preliminary analyses (ANOVA) revealed that international level athletes demonstrated more self-determined motivation (i.e., intrinsic and integrated regulation,  $p < .001$ ) and higher levels of self-regulatory competencies (i.e., planning, reflection, evaluation,  $p < .01$  and consideration of future consequences,  $p < .05$ ) in comparison to national and regional level athletes in Norway. Primary analyses underlined these results during confirmatory factor analysis. The measurements (motivation and self-regulation) demonstrated acceptable fit,  $\chi^2(317) = 477.22$ ,  $p > .05$ ,  $RMSEA = .05$ , 90 % CI [.04, .06],  $CFI = .92$ ,  $TLI = .91$ , and  $SRMR = .07$ . Factor loadings especially underlined the importance of intrinsic regulated motivation and three key self-regulatory competencies; planning, reflection, and evaluation ( $p < .001$ ). **Discussion** The current study revealed that autonomous forms of motivation and self-regulatory competencies combined describe athletes at higher competitive performance levels. These associations have been investigated separately (e.g., Gillet et al., 2013, Toering, Elferink-Gemser, Jordet, & Visscher, 2009), whereas this study underline the importance of emphasizing the

interaction between motivation and self-regulation during youth athlete development. References Gillet, N., Vallerand, R. J., & Paty, B. (2013). ### THE MEDIATION ROLE OF BARRIER EFFICACY WITHIN TASK EFFICACY-PHYSICAL ACTIVITY AND ENJOYMENT-PHYSICAL ACTIVITY RELATIONSHIP

Zhang, S., Lau, W.C.

*Hong Kong Baptist University*

**Introduction** The promotion of health behavioral change towards active lifestyle has been one of the public health priorities. Exercise-related Self-efficacy and enjoyment have been recognized as important psychological variables that influence physical activity (PA) behaviors and has been widely adapted in theoretical-based interventions. However, the outcomes of existing interventions are mixing and the role of exercise-related task and barrier efficacy (as subtypes of self-efficacy) and enjoyment in PA behavior is still not fully understood. This study aimed to : 1) explore the mechanism of task efficacy, barrier efficacy, and enjoyment in children's PA behavior; 2) provide practical hints for future theoretical-based interventions. Method 224 schoolchildren aged from 9 to 11 (male=117, female=105) were recruited voluntarily in a local primary school. Self-Efficacy Scale (McAuley & Mihalko, 1998) and Physical Activity Enjoyment Scale (Kendzierski & DeCarlo, 1991) were adapted to measure task efficacy, barrier efficacy, and enjoyment. ActiLife accelerometer was applied to measure PA level. All participants wore the accelerometer for a full calendar week. Wear time validation was done and Evenson et al.'s (2008) cut points for moderate-to-vigorous physical activity (MVPA) was used to analyze accelerometer data. Results Mediation analysis using bootstrap method revealed that barrier efficacy fully mediated the positive relationship between task efficacy and daily total PA (Adjusted  $R^2 = .52$ ,  $F=120.09$ ,  $p<0.01$ ), task efficacy and daily MVPA (Adjusted  $R^2 = .55$ ,  $F=136.97$ ,  $p<0.01$ ), enjoyment and daily total PA (Adjusted  $R^2 = .51$ ,  $F=119.53$ ,  $p<0.01$ ), enjoyment and daily MVPA (Adjusted  $R^2 = .56$ ,  $F=138.29$ ,  $p<0.01$ ), respectively. Discussion Barrier efficacy, though received few attentions in previous studies, was highlighted given the above results. Without barrier efficacy, establishing task efficacy and enjoyment only may not lead to effective adaption and maintenance in PA behavior. Future interventions may consider how to adapt barrier efficacy as a theoretical construct to promote PA behavior. References Evenson, K. R., Catellier, D. J., Gill, K., Ondrak, K. S., & McMurray, R. ### INFIELDERS OF BASEBALL AND SOFTBALL HAVE AN OUTSTANDING PERFORMANCE ON ATTENTION SHIFTING TASK

Chiang, C., Chen, W., Chang, Y., Wu, S.

*National Taiwan University of Sport*

**Introduction:** Fielding positions of baseball or softball may have a great impact on the ability of attention shifting for athletes. For example, outfielders may involve less attention shifting than infielders and pitchers during the game because outfielders usually pay more attention on the flying ball, but others have to switch their attention between the flying ball and the runners. This study investigated whether athletes of distinct fielding positions differed in their abilities of attention shifting. Methods: Thirty-seven pitchers (23 male baseball athletes; 14 female softball athletes), 34 infielders (18 males; 16 females), 24 outfielders (13 males; 11 females), and 37 non-athletes (17 males; 20 females) were recruited in this study. Athletes in national levels were undertaking regular training at least 20 hours per week for at least 7 years. Participants were measured with the Covert Orienting of Visual Attention (COVAT) paradigm (Posner, 1980) for testing their ability of attention shifting (simple task). To increase the difficulty of task, we asked participants doing the modified COVAT task by responding with upper- extremities in half trials, and responding with lower- extremities in others (complicate task). The Invalid Cue Effect size (ICE), which was defined as the difference between the median reaction time for invalid and valid trials, was collected to interpret the speed of attention shifting. Three tasks were separately analyzed with a two-way ANOVA, containing groups (pitchers, infielders, outfielders, non-athletes) and genders (male, female) as a between-subject factor, and ICE as the dependent variable. Results: A significant main effect of groups in both simple ( $F(3,124)=3.786$ ,  $p=0.012$ ) and complicated ( $F(3,124)=2.901$ ,  $p=0.038$ ) tasks was found. LSD post-hoc analysis showed the ICE value of infielders was significantly smaller than the non-athletes in the simple task ( $p=0.001$ ). When the task became complex, the post-hoc analysis showed that the infielders had significantly smaller ICE values than pitchers ( $p=0.026$ ) and non-athletes ( $p=0.01$ ). Moreover, the main effect of genders only had significance in the complicated task, not in the simple task. Discussion: The findings revealed that infielders have a better performance in attention shifting than pitchers and non-athletes. This may due to that infielders have to switch their attention from the bat to the location of flying ball, and catch the ball in a limited time. Additionally, males have a better performance than females when the task became difficult, it may represent the simple tasks cannot distinguish their difference of performance in attention shifting. #### PHYSICAL ACTIVITY INTENSION MODEL THROUGH EXTRAVERSION AND NEUROTICISM TRAIT OF PERSONALITY AND BODY IMAGE

Naritasari, I., Ramdhani, N.

*Universitas Gadjah Mada*

**Introduction** Intention is known as motivational factor prior to certain behaviour. Extravertion and neuroticism are hypotesised as the antecedent of intention. Some research about physical activity intension showed that body image might also be a potential factor influ-

encing the intention. Apparently extraversion, neuroticism and body image could altogether predict the intention behind doing physical activity. Theory of Planned Behaviour (TPB) is one of theory invented by Ajzen to explain intention behind behaviour. This study aimed to discover how TPB can effectively explain the relation of body image, neuroticism and extraversion toward physical activity. Model of physical activity intention was proposed. Following Rhodes & Nigg (2011)'s suggestion, subjective norm was eliminated from the model because it was the weakest predictor to explain physical activity intention. Methods Total number of 261 young adults aged 20 to 30 years old were asked to complete online survey which comprised three scales: intention scale, personality scale, and body image scale. Intention scale was developed following Ajzen's theory of intention (TPB) and consisted of three components: attitude toward physical activity, perceived control behaviour, and physical activity intention. The collected data were then analysed using Structural Equation Modelling Results The proposed model in the study was not entirely supported by data ( $\chi^2$  (5, N= 261)= 27.445,  $p = .000$ , CFI =.915, RMSEA=.131). As the model did not show a good fit, some revisions on the model were conducted. Upon some modification was the best model shown with  $\chi^2$  (1, N= 261)= .037,  $p = .847$ , CFI = 1.000, RMSEA=.000 Discussion The hypothetical model proposed was not supported by data because there were variables which were not related to model. The study contradicted Rhodes & Nigg (2011)'s finding which pointed out that neuroticism was related with intention. As opposed to Ajzen's TPB modelling, the study showed that attitude toward behaviour could not explain physical activity intention. Body image as well as two other variables did not directly relate to intention but it could explain intention through PBC. References Rhodes, R.E., & Nigg, C. R. (2011). Advancing physical activity theory: a review and future directions. *Exercise and Sport Sciences Reviews*, 39(3), 113-119

## THE IMPORTANCE OF SELF-REGULATION IN ATHLETE DEVELOPMENT

Green, D.K., Weissensteiner, J.R.

*Australian Institute of Sport, Canberra, Australia*

Introduction Self-regulation refers to the level of control learners have over their thoughts and behaviour in their own learning environment (Zimmerman, 1986). This is affected by a learner's motivation levels as well as his or her ability to plan, self-monitor, evaluate and reflect throughout the learning process. High levels of self-regulation have been associated with successful performance in a range of domains including academic achievement, music and more recently sport (Jonker et al., 2010, 2011). The aim of this study was to examine the self-regulation skills of Australian athletes from numerous sports, across the developmental spectrum and identify whether elite athletes are distinguishable from their recreational sport counterparts. Methods The Self-regulation of Learning Self-Report Scale (SRL-SRS; Toering et al., 2012) has been found to be a reliable and valid measure of self-regulation in athletes. The SRL-SRS was administered to over 500 Australian able-bodied athletes and athletes with a disability. The cohort included athletes of a recreational level (Foundational 3 FTEM level) and senior elite national level athletes (Elite and Mastery FTEM levels; Gulbin et al., 2013). Results Preliminary findings revealed differences in the self-regulation profiles of athletes across development levels and sports. The results also provided elite benchmarks specific to Australian athletes in the following elements of self-regulation: motivation (self-efficacy and effort), planning, self-monitoring, evaluation and reflection. Discussion The findings provide further evidence of the importance of self-regulation in the development of sport expertise. It is therefore important to monitor and improve the self-regulation skills of developing athletes. Future research should identify effective strategies to improve each of the elements of self-regulation in these athletes. References Gulbin JP, Croser MJ, Morley EJ, Weissensteiner JR. (2013). ## PSYCHOLOGICAL ASPECTS, INFLAMMATORY AND INJURY BIOMARKERS AFTER THE SÃO PAULO INTERNATIONAL MARATHON

Jones, J.1, Sierra, W.2, Azevedo, D.G.1, Cavallini, B.M.1, Vilela, M.1, Ghorayeb, N.3, Benetti, M.4, Boaventura, M.F.C.5, Sierra, C.A.3, Kiss, M.A.P.D.M.4, Sierra, A.P.R.3,4,6

*1.Mackenzie, 2.NiHumana, 3.IDPC, 4. EFFE-USP, 5. ICAFE, 6. UNINOVE-Medicine*

It is unlikely that the physiological changes completely explain the performance benefits associated with success in a marathon. The performance in a marathon is the result of a conscious effort with the contribution of psychological and motivational factors. The aim of this study was to investigate the mood changes in marathoners after the 2014 São Paulo International Marathon and the relationship with injury and inflammatory biomarkers. Methods: 71 male marathoners, aged 24 to 54 years old were evaluated. Blood samples to analyse creatine kinase (CK), c-reactive protein (RCP), lactate and lactate dehydrogenase (LDH) were collected 24h before and immediately after the marathon. The Brunel Mood Scale (BRUMS) was applied 24h before and immediately after the marathon. Results: The marathoners completed the marathon in  $282.31 \pm 52.9$  minutes. We observed an increase in CK, RCP, lactate and LDH immediately after the marathon comparing with basal values. About the mood scores, tension and stamina decreased after marathon comparing with basal values. Depression, anger, and fatigue increased and confusion did not change. We found a negative correlation between the changes in tension with lactate and CK and between depression and LDH. The increase in anger was positive correlated with RCP. Conclusion: Marathon induces changes in mood scores, which are correlated with physiological changes of injury and inflammatory state. We can conclude the modulation of psychological responses can influence physiological changes and maybe improve the performance.

## THE ROAD TO SUCCESS: ANALYSING THE PROGRESSION OF MALE HANDBALL PLAYERS AND CONSTANT YEAR EFFECT IN DANISH NATIONAL TEAMS.

Lilholt, R.M., Rossing, N.N., Hansen, G., Wrang, C., Karbing, D.S.

*Aalborg University*

The relationship between date of birth and expertise in various sports is well established. The phenomenon is known as the relative age effect (RAE). The International Handball Federation (IHF) has structured international youth tournaments in two-year age cohorts. The difference between the relative youngest and the oldest players is therefore fixed with up to two years of difference in birth date. The constant

difference, which likely creates an effect connected to RAE often called the Constant Year Effect (CYE), may favor the oldest players in selection processes due to increased physical and mental maturity. The Danish Handball Federation (DHF) has implemented the IHF structure with fixed two-year age cohorts in Danish National Teams. Currently, DHF operates with three national teams, namely Y (under 19), U (under 21) and A (senior). The aims of this study were to examine whether or not there was a CYE on the Danish Handball national teams, and to examine the rate of success in DHF talent development. The sample from DHF's database included 244 players, born from 1980-91, whom all participated on at least one national team. The cohorts were divided into 8 birth quarters with quarters 1-4 and 5-8 representing the even and odd years, respectively. Chi Squared analysis was used to determine whether a significant CYE was seen in the selection of players on the Y, U and A national teams, when compared to the expected equal distribution of players across the 8 birth quarters. The number of players who participated on all three national teams and the number of players who participated on Y was used to calculate the rate of success, which refers to the percentage of players who succeeded in being selected for all three national teams. Statistical results were considered significant if  $P < 0.05$ . CYE was significant in the Y ( $P < 0.05$ ) with players born in the 1 and 2 birth quarters being overrepresented, and with players born in the 6, 7 and 8 birth quarters being underrepresented. CYE was also significant at U ( $P < 0.05$ ) with players born in the 1 birth quarters being overrepresented, and with players born in the 8 birth quarters being underrepresented. There was not a significant CYE at the A ( $P = 0.42$ ). The rate of success was 28%, which means that approximately every fourth player who debuts on Y also get their debut at U and A. This is a much higher success rate compared to previous results in Danish Soccer, which is only 3%. The constant year effect was significant in the youth Danish national teams, that is, the selection of players for the youth national team's favors relatively older players rather than younger players. The effect was not significant on the senior national team indicating that the biased selection of players is not repeated at this level. The relatively high success rate of players progressing through all three national teams indicate that DHF has a successful talent development program. Taking steps towards minimizing the CYE in youth national teams would likely increase this success rate.

### **SPORT INJURY PERCEPTIONS AND COPING STRATEGIES: A STUDY WITH MALE YOUTH SOCCER PLAYERS OF BELGIAN ELITE TEAMS**

De Cuyper, B., Van Kerkhove, F., Feys, J.

*KU Leuven*

**Sport injury perceptions and coping strategies: A study with male youth soccer players of Belgian elite teams**

**Introduction** The purpose of the present investigation was to test the impact of injury perceptions and cognitions on the ways in which athletes cope with the stress of an injury. **Methods** Participants included 72 youth soccer players of a national or international level between 10 and 21 years of age. The team physician approached injured players. Participation was voluntary. They completed the Illness Perception Questionnaire Revised for Sports (van Wilgen, Kaptein & Brink, 2010) and a multidimensional coping inventory (COPE, Carver, Scheier & Weintraub, 1989). **Results** Our results show that a perceived sense of control can be a predictor for adaptive coping mechanisms in injured athletes. The perception of personal and treatment control was associated with active coping, thereby motivating injured players to actively work their way out of their injury. Focus on and venting of emotions as a coping mechanism was mostly predicted by the absence of injury coherence. Injury coherence is the comprehension of every facet of the injury by the injured player. The score on the scale 'emotional representation of the disease' was the best predictor of denial. This means that a strong emotional representation of the disease (e.g. when I think about my injury I get depressed) will lead to more denial as a coping strategy. **Discussion** Injury perceptions and cognitions are related to behavioral responses to the injury. It seems warranted that clinicians are aware of athletes' views about their injuries and communicate about the impact on their coping behavior, in order to increase the chance of an efficient recovery. Our findings support the use of cognitive restructuring interventions for enhancing rehabilitation outcomes. **References** Carver, C., Scheier, M., & Weintraub, J.K. (1989). ### **VARIATION OF BURNOUT AND SELF-ESTEEM IN ACCORDANCE WITH SPORTS EXPERIENCE**

Cantú-Berrueto, A.1, López-Walle, J.1, Tristán, J.1, Cocca, M.1, Castillo, I.2

*(1)UNIVERSIDAD AUTONOMA DE NUEVO LEON, (2)UNIVERSIDAD DE VALENCIA*

**Introduction** Sports participation contributes to psychological well-being. However, inappropriate constraint from coaches as well as intense physical demands and high psychological pressures can provoke negative consequences for the athletes (Reinboth & Duda, 2005). The aim of this study is to analyse the influence of experience (years training with the same coach and participation in national competition) on self-esteem and burnout in university athletes. **Methods** Participants were 2,413 Mexican university athletes (57.1% men, 39.4% female), aged ranged from 18 to 28 years ( $M = 21.26$ ;  $SD = 1.99$ ) that were engaged in 9 individual sports and 7 team sports. Average time spent with the same coach was 3 years ( $SD = 1.32$ ). Participants fulfilled the Questionnaire Burnout Athlete (Raedeke & Smith, 2001) and the Self-Description Questionnaire (Marsh et al., 1994). **Results** Self-esteem was altered by number of participations in national university ( $F(6, 2200) = 4.40$ ,  $p < .001$ ). Athletes competing for the first time obtained higher scores than those who had been competing for more years ( $p < .01$ ). Moreover, university athletes having spent less than one year with the same coach reached higher self-esteem than those spending one to two years ( $p < .001$ ) and three to four years ( $p < .05$ ). Significant differences were found in burnout by years competing in national events ( $F(4, 1588) = 4.35$ ,  $p < .05$ ), athletes competing for less than five years showing lower levels of burnout than those participating for more than 15 years ( $p < .05$ ). **Discussion** Our findings showed that athletes with less sports experience and years training with the same coach had the best profile in terms of both self-esteem and burnout. These results are in contradiction with previous research (Kristiansen & Roberts, 2009). In our sample, results suggested that the longer athletes spent with the same coach, the more their psychological well-being was negatively affected. Thus, further research should focus on motivational climate and coaches' behaviour during practices and competitions. **References** Kristiansen, E., & Roberts, G.C. (2009). ## BURNOUT CORRELATES IN GRASSROOTS FOOTBALL COACHES: PERFECTIONISM AND UNCONDITIONAL SELF-ACCEPTANCE

Castillo, I., Fabra, P., González, L., Balaguer, I.

*University of Valencia*

Unidad de Investigación de Psicología del Deporte. University of Valencia (Spain) Introduction Burnout might have adverse consequences for coaches but also, via implications for their interactions, can affect the quality of the sport experience of athletes. Consequently, understanding the antecedents of this negative emotion is of great interest in the sport context. Hill, Hall, Appleton and Kozub (2008) have proposed that perfectionism could be a vulnerability factor for burnout in athletes and that unconditional self-acceptance would mediate this relationship. In this study, focused on grassroots coaches, and based on Hill et al. (2008), two objectives were pursued: (1) to examine the influence of self-oriented (SOP) and socially prescribed (SPP) perfectionism on burnout, and (2) to examine whether the association between perfectionism and burnout is mediated by unconditional self-acceptance (USA). Participants Participants were 124 grassroots coaches (114 male and 10 female) from 28 football clubs of Spain, between 17 and 60 years old ( $M=31.05$ ;  $SD=10.48$ ). Participants completed a questionnaire package tapping the variables of interest. Results As expected, correlational analyses indicated that both SPP and SOP were positively related to burnout and negatively related with USA. USA was negatively associated with burnout. Results of path analysis demonstrated a poor fit of the data ( $\chi^2=20.73$ ;  $SRMR=0.12$ ;  $IFI=0.84$ ;  $CFI=0.83$ ). Following modification indices a direct path from SPP to burnout was added. The revised model revealed a good fit of the data ( $\chi^2=0.76$ ;  $SRMR=0.02$ ;  $IFI=0.99$ ;  $CFI=1.00$ ). The standardised path coefficients indicated a significant direct positive path from SPP to burnout ( $B=0.45$ ) and also revealed a significant indirect path from SPP to burnout via a negative association with USA ( $B=-0.22$ ), supporting partial mediation. The model also showed a significant indirect path from SOP to burnout via a negative association with USA ( $B=-0.39$ ). As expected, a significant negative path from USA to burnout was observed ( $B=-0.18$ ). Discussion With some exceptions, results of this study with grassroots coaches are similar to those obtained with junior elite soccer players in the research of Hill et al. (2008). This study provided support for the role of USA as a partial mediator of the relationship between SPP and burnout and a total mediator of the association between SOP and burnout. Findings suggest that both dimensions of perfectionism may be critical antecedents of burnout in grassroots coaches and that unconditional self-acceptance can reduce the impact of perfectionism on coaches' burnout symptoms. References Hill, AP, Hall, HK, Appleton, PR, Kozub, SR (2008). Perfectionism and burnout in junior elite soccer players: The mediating influence of unconditional self-acceptance. *Psychol Sport Exerc*, 9, 630-644. Contact Email: Isabel.Castillo@uv.es

## EXERCISE FOR CLINICAL DEPRESSION: A SYSTEMATIC REVIEW ANALYZING SEVERAL QUESTIONS

Carneiro, L.1, Fonseca, A.4, Vieira-Coelho, M.3, Mota, M.2, Vasconcelos-Raposo, J.2

1:CIDESD (Portugal), 2:UTAD (Vila Real, Portugal), 3:CHSJ, EPE (Porto, Portugal), 4: CIFI2D, FADEUP (University of Porto, Porto Portugal)

Introduction The goals of the present study were to analyze characteristics of physical exercise (PE) programs of published studies, independently of the results obtained; in other words, whether PE programs had significant effects in the decrease of depressive symptomatology or not. This paper also intends to analyze many questions, which should be taken into account in future trials. Detailed approach focusing several questions, such as: (a) how are participants recruited into trial, (b) which scales should be chosen to measure the severity of depressive symptoms, (c) which are the recommendations to prescribe physical exercise for patients with depression, (d) the importance of analyzing changes in physiological markers, body composition and functional capacity before and after the PE intervention, (e) discuss the use of the potential anti-depressant effect in relation to the placebo groups. Answers to these questions could be a potential contribution for understanding the effects of PE as a therapeutic approach for patients with depression. Methodology The databases PUBMED, CINAHL, MEDLINE, PSYCINFO, PSYARTICLES and COCHRANE DATABASE were searched (2003-2014). Results Fourteen references fulfilled the broad inclusion criteria, and the methodological evaluation according to PEDro scale (Sherrington, Herbert, Maher, & Moseley, 2000) revealed that 93% of the studies met 50% score over or equal to 6. A total of fourteen randomized controlled trials (RCTs), which met the inclusion criteria, were reviewed and ten (71.4%) of them reported a significant contribution effect in the treatment of depression. Discussion / Conclusion New RCTs with new designs are needed to assess the efficacy of the PE intervention. Future trials should (a) recruit patients into trials referred from general practitioners or psychiatrists, (b) opt for scales used to measure the severity of depressive symptoms according to the questions that researchers want to clarify, (c) adopt PE programs with new trial designs that apply principles of training, (d) assess physiological markers, body composition and physical functions before and after the PE intervention as it is crucial to test the effectiveness of a PE program, and (e) clinical trials that used PE as a placebo group must be carefully analyzed. It is hoped that this review could be seen as stimulation to improve methodological quality of future researches based on the questions and answers made. References Sherrington, C., Herbert, R. D., Maher, C. G., & Moseley, A. M. (2000). PEDro. A database of randomized trials and systematic reviews in physiotherapy *Manual Therapy* (Vol. 5, pp. 223-226). Scotland. ### MO-PM07 Adapted physical activity: Challenges

#### AEROBIC 3-MONTH PHYSICAL ACTIVITY PROGRAM IN BREAST CANCER SURVIVORS: EFFECTS ON SLEEP BEHAVIOR, ANTHROPOMETRIC INDICES OF ADIPOSITY AND FASTING GLUCOSE METABOLISM.

Vitale, J.A.1, Roveda, E.1, Bruno, E.1, Montaruli, A.1, Galasso, L.1, Berrino, F.2, Caumo, A.1,3, Carandente, F.1

*University of Milan*

1 UNIMI, Milan, Italy. 2 INT, Milan, Italy. 3 IRCCS Policlinico San Donato Milanese, Milano, Italy. Background: Evidences exist that sleep disorders are associated with an increased risk of cancer, including breast cancer (BC) (Verkasalo et al., 2005). Also adiposity and hypersulinemia have been acknowledged as factors involved in cancer mortality including BC (Pisani, 2008). Physical activity (PA) has the potential to counterbalance all of these risk factors. In fact, PA has been shown to produces beneficial effects on sleep quality and BC prognosis, as well as on adiposity and glucose metabolism (Mann et al., 2014). We thus designed a randomized controlled trial to test the effect of an aerobic PA program on sleep behavior, anthropometric indices of adiposity and fasting glucose metabolism in BC women included in a dietary intervention trial for prevention of BC recurrences. Subjects and Methods: 42 BC women, aged 35-70 years, were

randomized into an intervention (IG=19) and control group (CG=23). The IG had to participate in a 3-month active PA program that included two sessions of one-hour brisk walking per week. At baseline and after 3-month, all women were requested to undergo an anthropometric visit, to collect a blood sample for determination of fasting insulin and glucose levels, to wear the Actigraph Actiwatch for one week for sleep parameters evaluation (Actual Sleep Time (AST), Actual Wake Time (AWT), Sleep Efficiency (SE); Sleep Latency (SL); Mean Activity Score (MAS); Movement and Fragmentation Index (MFI) and Immobility time (IT)). Results: At the end of the 3-month PA program, CG showed an overall worsening of sleep behaviour. In fact, SE, IT and AST decreased ( $p<0.01$ ), while AWT, MAS and MFI increased ( $p<0.01$ ). In contrast, IG did not show any sign of sleep deterioration. As for the indices of adiposity, a significant reduction in waist circumference ( $p<0.05$ ) and % fat mass ( $p<0.01$ ) was observed in IG, but not in CG. Although fasting glucose and insulin levels did not show any significant change in either group, it was nevertheless encouraging that the two groups displayed an opposite trend as far as the changes in fasting insulin were concerned: fasting insulin showed a mean reduction ( $-0.9 \mu\text{U}/\text{ml}$ ) in the IG group and a mean increment in the CG ( $+0.7 \mu\text{U}/\text{ml}$ ). Conclusion: Our results suggest that a standardized PA program in BC survivors prevents sleep deterioration, reduces anthropometric indices of adiposity and may prove useful in preventing the development of hyperinsulinemic levels. ### DEVELOPMENT OF A TWO-PART EXERCISE MODEL TO ENHANCE PHYSICAL ACTIVITY LEVELS IN PEDIATRIC CANCER PATIENTS DURING ACUTE CANCER TREATMENT

Götte, M., Kesting, S.V., Rosenbaum, D., Boos, J.

*Universitätsklinikum Münster*

**Introduction** Reduced physical activity levels in children with cancer (Winter et al. 2009) additionally increase the cancer-related burden and presumably lead to further persisting problems like reduced motor performance (Götte et al. 2015). The first objective was to evaluate the current need of exercise interventions by comparing intra-individual physical activity levels before and during treatment and evaluating patient-related barriers and motivations with respect to exercise. Furthermore, we developed a two-part model to promote physical activities during hospital stays and at home. **Methods** Physical activity levels were assessed with a standardized physical activity questionnaire in 130 pediatric cancer patients (aged  $12.2\pm 4.7$  years; 61% male;  $3.0\pm 1.6$  months since diagnosis, mixed tumor entities). Patients' opinions, barriers and motivations regarding exercise were assessed in a qualitative approach with guideline interviews in 40 pediatric cancer patients (aged  $13.2\pm 4.1$  years; 53% male;  $5.5\pm 2.3$  months since diagnosis, mixed tumor entities). Results Daily physical activities (walking, playing) and minutes of exercise per week decreased significantly during treatment ( $p<0.001$ ). The most pronounced reductions in physical activities were identified for bone tumor patients, older age and hospital stays in which 50% of the patients left their bed for  $<1\text{h}/\text{d}$ . In the interviews the patients emphasized the importance of supervised training sessions and individual support in order to be motivated for exercise. **Discussion** These results underline the importance of individually-tailored and supervised exercise programs during treatment. Therefore, we are currently evaluating a two-part model to enhance physical activity levels. This model consists of 1) a supervised exercise intervention during hospital stays and 2) a personal training plan comprising individual goals and exercises for home stays. An activity tracker (fitbit) provides feedback about daily steps during home stays and regular contact (by email, phone, face-to-face) ensures support and safety. ### IMPACT OF A SOCIAL MEDIA EXERCISE SERVICE ON PHYSICAL FITNESS, PHYSICAL ACTIVITY, WELLBEING AND BODY WEIGHT

Santtila, M., Räisänen, J., Grönqvist, K., Kyröläinen, H.

*National Defence University*

**Introduction.** Previous studies have demonstrated that inactivity is one of the biggest challenges for health promotion in the world. According to the World Health Organization, sedentary behavior is currently the fourth leading risk factor for premature mortality (WHO, 2010). All tools that increase physical activity among people around the world are useful including social media exercise services. The purpose of the present study was to investigate the impact of a social media platform on physical fitness, physical activity, wellbeing and body weight among users of a social media exercise service. **Methods.** The subject group consisted of 2862 male ( $n=799$ , 27.2 %) and female ( $n=2083$ , 72.8 %) service users (HeiaHeia) that voluntarily participated in the web survey (SurveyMonkey, Palo Alto, California, USA). Surveys were available for the service users for a period of one month on the HeiaHeia web page. Age, gender, body mass index, physical fitness and activity information were self-reported for background information. Changes in physical fitness, physical activity, wellbeing and body weight of the users were also self-estimated. **Results.** Most service users (78.1%) exercised more than three times a week. About 75% of the users reported to be at least in good physical fitness and about 50% were overweight. Almost half of the service users (46.4%) reported that use of the social media had advanced their perceived physical fitness, and more than half (64.6%) reported that their perceived physical activity increased due to use of the service. In addition, 54.0% of the users responded that their perceived well being increased. Every fifth (21.3%) service user reported decreases in their body weight as a result of using the service. Users with lower physical fitness, lower physical activity and overweight were more likely to report that use of this online service was useful when compared to their more active counterparts. **Discussion.** Use of this social media exercise service seems to lead to improvements in physical fitness, increases in physical activity and enhanced wellbeing. In addition, HeiaHeia had a positive impact on users' body weight. Use of this social media service is especially well-suited for overweight, unfit and sedentary customers. In conclusion, it is important to have targeted marketing campaigns to get more inactive and overweight people interested in these kinds of services. References. ### ETHNIC DIFFERENCES IN MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY IN PREGNANCY AND POSTPARTUM

Richardsen, K.R.1,2, Jenum, A.K.2,3, Berntsen, S.4

*Norwegian National Advisory Unit on Women's Health*

1: The Norwegian National Advisory Unit on Women's Health; Department for Women's and Children's Health; Oslo University Hospital (Oslo, Norway), 2: Faculty of Health Sciences; Oslo and Akershus University College of Applied Sciences (Oslo, Norway), 3: Faculty of Medicine; University of Oslo (Oslo, Norway), 4: Department of Public Health, Sport and Nutrition; Faculty of Health and Sport Sciences;

University of Agder (Kristiansand, Norway). Introduction: Analyses of objective data on moderate-to-vigorous physical activity (MVPA) in pregnancy rarely cover MVPA accumulated in bouts. We aimed to compare MVPA minutes per day (min/day) accumulated in bouts  $\geq 10$  minutes (MVPA bouts) and total MVPA accumulation (total MVPA) during pregnancy and postpartum across four ethnic clusters. Methods: Data originate from the Stork Groruddalen Cohort study (Oslo, Norway) which included 823 pregnant women between 2008-2010. Data was collected at three visits (V1-3) at local child health clinics; before 21 (V1) and at 28 (V2) weeks' gestation, and, three months postpartum (V3). Following each visit free-living MVPA minutes were recorded with SenseWear™ Pro3 Armband (SWA). Women were asked to wear the SWA over 4 days, and only remove it during water activities. Ethnicity was reported in interviews and categorised as South Asian, Middle Eastern, Western and other. Results are presented as median min/day. Ethnic differences in MVPA were analysed with Kruskal-Wallis. Results: The sample consisted of 327 women with  $\geq 1$  day at each visit with  $\geq 19.2$  hours of SWA wear time. The sample was younger, had lower bmi, and higher proportion with Western background and university education compared with the remaining cohort. Median values dropped from V1 to V2 for total MVPA (70 to 57 min/day) and bouts (15 to 9 min/day). At V3, medians for total MVPA and bouts had risen to 73 and 18 min/day, respectively. Differences between ethnic clusters were significant only for MVPA bouts; at all visits South Asian and Middle Eastern women recorded fewer min/day than Western women. At V1, V2 and V3 Western women spent 20, 12 and 26 min/day, respectively. For South Asian women at V1, V2 and V3 the difference was -11 ( $p=0.002$ ), -6 ( $p=0.01$ ) and -18 ( $p<0.001$ ) min/day, respectively. For Middle Eastern women the difference was -10 ( $p=0.03$ ), -8 ( $p=0.01$ ) and -19 ( $p<0.001$ ) min/day. Discussion: Estimates of MVPA min/day are influenced by whether bouts or total MVPA are considered. The differences between bouts and total MVPA underlines the need for a consensus on how to operationalize objective measures of MVPA in research. The results suggests South Asian and Middle Eastern women are at increased risk of low levels of MVPA bouts. Promotion of MVPA in these groups must build on insight into underlying behavioural determinants of MVPA. E-mail: kareri@hioa.no

#### BIOMECHANICAL ASSESSMENT OF SWISS PRESS HANDSTAND TECHNIQUE IN COLLEGIATE MALE GYMNASTS.

Kashiwagi, Y.1, Mizutori, H.2, Hakamada, N.3, Funato, K.4

1: Graduate school of Health and Sport Science, Nippon Sport Science University, 2: Keio University, 3: Japan institute sports science, 4: Nippon Sport Science University, Tokyo

Introduction Swiss press handstand movement is one of the fundamental techniques as the element which is necessary for all items except vaulting in gymnastics. Biomechanical mechanism of static handstand balance was reported by Kerwin[1] and Yeadon[2] till now, but swiss press handstand technique is not clear. The purpose of this study was to investigate swiss press handstand technique by using joint kinetics in collegiate male gymnasts. Methods Eleven male collegiate gymnasts (Age:  $19.1 \pm 1.5$  yr, BH:  $164.5 \pm 6.6$  cm, BW:  $62.6 \pm 6.1$  kg) were participated in this study. Each subject performed swiss press handstand movement on a force plate (Kistler, 1kHz) and kinematics data was recorded by high-speed camera (Basler, 100fps). Reflective marker were attach on the subject's anatomical landmark points. Center of mass (COM) was calculated by using Dempster [3] body segment data. Joint kinetics data (Wrist, Shoulder, Hip) were calculated from 2D inverse dynamics methods to refer the preliminary research in Yeadon, 2003[2]. Athletics performance of swiss press handstand movement were judged by the person who has physical exercises experience more than ten years, and subjects were divided into two groups (Skill: five subjects, Unskill: six subjects). Duration of swiss press handstand movement was normalized from toe-off to handstand. All statistical analysis were used by student's t-test (welch) performed on selected means to detect significant differences (effective  $P < 0.05$ ) between Skill and Unskill (JMPver. 8.0 : SAS inc.). Results and discussion Larger shoulder angle were observed in Skill (Skill:  $139.9 \pm 5.4$  deg VS UnSkill:  $131.5 \pm 3.1$  deg,  $P < 0.05$ ). Skill indicated large wrist palmar flexion torque than Unskill during movement ( $P < 0.05$ ). On the other hand, Unskill's shoulder extension torque was larger than Skill ( $P < 0.05$ ). Hip torque, in particular, showed great difference between Skill and Unskill throughout toe-off to finish. Skill indicated hip torque changes from flexor to extensor one, however Unskill indicated only hip flexor torque. Although wrist strategy as wrist palmar flexion torque plays an important role in a handstand [1,2], swiss press successful technique was different between Skill and Unskill, in particular larger shoulder extension at toe-off may be important movement to use hip torque effectively. Conclusions Technical factor developing hip extensor torque is important in swiss press handstand and this might be caused by the flexibility of a shoulder joint. #### SPRINGY BEHAVIOR OF THE LONGITUDINAL FOOT ARCH DURING ANKLE BENDING EXERCISE AT DIFFERENT MOVEMENT FREQUENCIES

Iwanuma, S., Hirayama, K., Kawakami, Y.

Teikyo university of science

Introduction The longitudinal foot arch constitutes various elastic structures that serve as a spring in human locomotion (Alexander, 1991). The behavior of elastic structures in a muscle-tendon unit (i.e. tendinous tissues) depends on movement frequency under stretch-shortening cycle movements (Sakuma et al., 2012). This study aimed to investigate the influence of the frequencies of ankle bending exercise on the springy behavior of longitudinal foot arch. Methods Seven male volunteers performed ankle bending exercise at two movement frequencies (0.5 and 2.0 Hz) on a sledge apparatus which was inclined by  $30^\circ$  from the horizontal direction. Five reflective markers (anterior tip of first metatarsal bone, anterior vertex of talus, calcaneal tuberosity, and two markers on the tibia to define its longitudinal direction) were captured by a video camera at 300 fps. The height of longitudinal foot arch was determined as the perpendicular distance from the anterior vertex of talus to the line connecting the anterior tip of first metatarsal bone and calcaneus tuberosity. The compression load on the longitudinal foot arch was calculated from the ground reaction force on the ball of the foot recorded by a force plate operating at 2,000 Hz. The relationship between the change in the height of the longitudinal foot arch and the compression load was used to estimate the elastic strain energy stored and released in the longitudinal foot arch. Results and Discussion The changes in the height of the longitudinal foot arch were similar over the two movement frequencies (0.5 Hz:  $18.6 \pm 3.3$  mm, 2.0 Hz:  $19.3 \pm 6.5$  mm),

while the compression load at 2.0 Hz ( $2045 \pm 452$  N) was significantly larger than that at 0.5 Hz ( $330 \pm 69$  N). Thus, the longitudinal foot arch behaved as a stiffer spring at higher frequency. The elastic strain energy stored in the longitudinal foot arch in the dorsiflexion phase at 2.0 Hz ( $12.1 \pm 5.4$  J) was significantly larger than the corresponding value at 0.5 Hz ( $3.3 \pm 1.5$  J). The elastic strain energy stored in the dorsiflexion phase was almost identical to those released in the plantar flexion phase both at 0.5 and 2.0 Hz, suggesting no energy dissipation in the longitudinal foot arch during the present exercise regardless of movement frequencies. These results strongly suggest that the longitudinal foot arch plays an important role as a spring under a stretch-shortening cycle movement, the role being greater at higher frequency. ### RUNNING PATTERN ADJUSTMENTS DURING UNWEIGHING AND RELOADING TRANSITION PHASES

Chavet, P., Sainton, P., Cabri, J., Berton, E., Nicol, C.

*ISM UMR7287*

**Introduction** As gravity plays an essential role in terrestrial locomotion, several studies have investigated the effects of reducing gravity on locomotion kinematics and kinetics (for a review, Sylos-Labinis et al. 2014). On a lower body positive pressure (LBPP) treadmill, 3 min of unweighing have been demonstrated to be sufficient for updating the running pattern (Sainton et al., 2015). The present study focused on the adjustments during the unweighing and the reloading transition phases. **Methods** Seven healthy males (mean age: 21.7 years  $\pm$  3.6; body height: 172.7 cm  $\pm$  5.7; body mass: 64.6 kg  $\pm$  7.5) performed 2 randomized treadmill running series at preferred speed. Each series included 3 successive running conditions of 3 min [at 100 % body weight (BW), either 60 or 80 % BW, and 100 % BW]. Vertical ground reaction forces, center of mass accelerations and treadmill chamber pressure were analyzed for each of the successive left and right steps. The analyses concentrated on the temporal and kinetics changes during the 10-15 s transition phases as compared to their mean values during the preceding stable state. **Results** Amongst all measured parameters, only a few changed significantly and in a reversed way during the unweighing and the reloading phases. For instance, from the start of the unweighing transition, the active peak force and mean push-off impulse decreased progressively while the flight and stride durations increased. The contact time was remarkably stable. The braking impulse also remained stable, except in the reloading phase from 60% BW where it increased. The impact peak force showed large inter-individual variability. **Discussion** This study of the transition phases during LBPP treadmill running confirmed the existence of both stable and varying parameters after 3 min of unweighing and reloading as reported by Sainton et al. (2015). The progressive changes of the active peak force, mean push-off impulse, flight and stride durations were mostly attributed to the pressure variations inside the treadmill chamber. The consistency of the contact time despite unweighing differs from the predictions by the linear mass-spring model of the body and leg (McMahon and Cheng 1990). This could result from the modified leg length at impact and take-off once the chamber is inflated (He et al. 1991). However, the lack of similarities between the braking and push-off impulse changes supports their distinct regulation through muscle activation (Sainton et al. 2015). ### MO-PM06 Adapted physical activity: Sport & disability

#### CARDIORESPIRATORY RESPONSE DURING WHEELCHAIR DANCE AND AUTONOMOUS REGULATION IN BEDRIDDEN INDIVIDUALS

Terada, K.1, Satonaka, A.2, Terada, Y.3, Suzuki, N.2,4

*1:Nagoyacollege (Toyoake) 2:Nagoya Univ.(Nagoya) 3:Nagoya Univ.Jr.College of Economics (Inuyama) 4:Tokoha Univ.(Hamamatsu)*

**Introduction** Aerobic fitness (assessed by oxygen pulse during dance) was not improved by wheelchair dance exercise for 5 to 15 min at a time, more than 3 times a week, for 6 months in 7 individuals with cerebral palsy rated in GMFCS (Gross Motor Function Classification System) level V (averaged  $54 \pm 10.0$  years old) (Terada, et al., 2014). The aim of this study was to evaluate the heart rate variability right before and right after the wheelchair dance in bedridden individuals. **Methods** The participants were 4 individuals with cerebral palsy rated in GMFCS level V (41 to 66 years) and an 11 year old participant with Fukuyama muscular dystrophy (FMD). Heart rate (HR) and oxygen uptake ( $VO_2$ ) were measured during rest, the waltz, the jive, and rest again for 5 min respectively. **Results** HR and  $VO_2$  were slightly increased during the waltz and the jive in 3 individuals with cerebral palsy, and the ratio of low frequency power to high frequency power (LF/HF) was also slightly increased right after the dance. A 45 year old participant with cerebral palsy looked very relaxed and showed little change in HR and  $VO_2$  during the dance and LF/HF right after the dance was decreased. In contrast, HR and  $VO_2$  were increased in the waltz, and were markedly increased in the jive in the FMD participant. LF/HF was also markedly increased right after the dance. **Discussion** Although she was not with cerebral palsy but with FMD, the youngest participant showed high LF/HF right after the dance as well as good cardiorespiratory responses during the dance being different from other older participants with cerebral palsy. While there are few reports on autonomous regulation in bedridden individuals, it was reported that the autonomous nervous system would fail to keep blood pressure steady with heart rate being increased when a long term bedridden individual was placed into lower body negative pressure (Mita, et al., 1994). Therefore, it may be possible that long term recumbency would also harm the individual's autonomous regulation on cardiac function while wheelchair dance to expect positive effect of wheelchair dance on cardiorespiratory fitness. It may be important to consider to commence physical activity programs like wheelchair dance for bedridden individuals as soon as possible. References Terada K, Satonaka A, Terada Y, Suzuki N. ## COMPARISON OF ADAPTIVE AND COMPETITIVE SWIMMING INSTRUCTIONS

Bokor, J.

*University of West Hungary*

**Introduction** The social demands on swimming has been changing, and, as a consequence its goals as well. The dominance of the previous aim has been relayed by health recuperation, preservation and development. These new aims made it necessary to re-think swimming categories and, as a consequence, competitive swimming, recreation swimming and adaptive swimming were separated from each other. Different aims of swimming require different instructing activities. Therefore the aim of this study was to analyse two different kinds of instructions, namely the competitive and adaptive ones. Are there any differences between the instructions during the two types of swimming? And if so, which ones? **Methods** To answer the above questions we applied the method of written questioning, questionnaires, and Cheffers' (1973) adaptation of categorical observation. The samples were provided by qualified swimming instructors ( $N_a=8$ ,  $N_u=8$ ) and children attending adaptive swimming lessons ( $N_a=147$ ,  $N_u=140$ ). We applied 21 teaching categories (Table 1) using Bíró's system of categories (Bíró et. al. 2007) who adapted the FIAS (Flanders, 1965), the CAFIAS (Cheffers, 1983) and the modified versions of Svoboda's (1977) observation systems in his research. **Results** On the basis of our results it can be stated that there is a significant difference between instruction activities in adaptive and competitive swimming lessons, and, on the other hand, the atmosphere is also different. Teaching methods like explanation, fault correction, assistance and praising appeared in a higher proportion during adaptive swimming lessons than in the course of competitive swimming lessons. Regarding the atmosphere of training sessions, a more informal, more relaxed mood could be experienced in the case of adaptive swimming compared to competitive swimming. **Discussion** As a consequence of the above mentioned results we can state that instructors of adaptive swimming should adopt a different approach and attitude as children taking part in adaptive swimming lessons are quite sensitive and have different personality types compared to the participants of competitive swimming training sessions; and they often become marginalized in their age group due to their particular disabilities. **References** Bíró M, Bíróné N.E, Fügedi B, Révész L, Szabó B. ## FUNDAMENTAL MOVEMENT SKILLS MASTERY OF BOYS WITH AND WITHOUT INTELLECTUAL DISABILITY IN THE PHILIPPINES

Eguia, K.F.1, Capio, C.M.2, Simons, J.3

*1:Therabilities Inc. (Philippines), 2:University of Hong Kong (Hong Kong), 3:University of Leuven (Belgium)*

**Introduction** In the Philippines, children with intellectual disability (ID) attend special schools where limited time is allocated for physical education (PE) and motor skills training. Recent studies from developed regions show that fundamental movement skills (FMS) of children with ID are less proficient relative to typically developing (TD) peers (Westendorp et al., 2011). However, the proportion of children with ID who display FMS mastery has yet to be examined. Such evidence is important to identify the need for FMS programs, but is currently limited in developing countries. This study aimed to compare the FMS mastery of children with and without ID in the Philippines, focusing on boys who make up the majority of special schools' enrollment in the country. **Methods** Participants include boys with ID ( $n=56$ ; mean age =  $7.95 \pm 0.82$  years) and an age-matched TD group ( $n=84$ ; age =  $7.65 \pm 0.91$  years). FMS proficiency was tested using ten components of the Test of Gross Motor Development-2 (Ulrich, 2000). Locomotor skills included run, hop, leap, horizontal jump and slide, while object control skills included dribble, catch, kick, overhand throw and underhand roll. Raw scores and percentage of mastery for each skill component were calculated. **Results** Multivariate analysis of variance showed a significant effect of disability ( $F(2,132)=67.74$ ,  $p<.001$ ,  $\eta^2=.51$ ) on both locomotor and object control skills. Participants with ID had mean scores of 22.07 ( $SE=.98$ ) for locomotor, and 18.66 ( $SE=.75$ ) for object control skills. The TD group had mean scores of 31.81 ( $SE=.82$ ) for locomotor, and 30.16 ( $SE=.15$ ) for object control skills. Analysis of each skill component showed that locomotor skills mastery ranged from 4% to 38% for those with ID, and from 19% to 80% for the TD group with jumping least mastered by both groups. Object control skills mastery ranged from 2% to 7% for those with ID with throwing least mastered; and from 24% to 60% for the TD group with rolling least mastered. Chi-square tests showed that mastery levels for all skills were significantly lower for the ID group relative to the TD group (all  $p<.05$ ). **Discussion** Boys with ID displayed lower FMS mastery relative to TD peers, providing evidence that underpins the value of FMS training programs for children with ID. Specifically, object control skills were found to have larger differences in mastery between the two groups. An important contribution of this study is the population-specific evidence that would serve as an impetus for special schools in the Philippines to address motor development via adapted PE curricula. **References** Westendorp M, et al. (2011). *Res Dev Disabil*, 32(3), 1147-53. Ulrich D. (2000). Texas: Pro-Ed.

## THE EFFECTS OF SKIN SCUBA PROGRAM ON CONCENTRATION AND SELF-REGULATION OF AUTISTIC CHILDREN

Hwang, Y.S.1, Lee, S.B.1, Kwon, O.R.1, Park, H.W.2, Kim, S.I.1, Moon, S.W.1, Yoo, H.J.1

*1 Pusan National University, 2 Chonnam University*

**Introduction** It is well known that autistic children have social problems such as self-regulation, concentration and adaptive behaviour (APA, 2000; Kogan et al., 2009). The purpose of this study is to investigate how skin scuba program affects self-regulation, concentration and adaptive behavior of autistic children and to provide baseline data on making a variety of programs for training and rehabilitation facility for autistic children. **Methods** A total of 20 children with autism were recruited for this study. The participants were divided into two groups; ten for the experimental and ten for the control group. The experimental group participated in scuba diving twice a week, on every Wednesday and Saturday for 2 hour sessions, 8 times a month for 4 months, totalling up to 32 sessions. Psychological measurements were taken pre and post participation in the scuba diving program. Results Two way repeated measures ANOVA was carried out on all the variables with SPSS (version 21). The results for the cognitive regulation and the emotional regulation, sub-areas of self-regulation, were improved in the experimental group. There were no statistical differences in the selective attention and the self-regulation, sub-areas of concentration. Finally for the conceptual adaptive behavior, the social adaptive behavior and the practical adaptation actions, sub-areas of adaptive behavior, there were significant improvements in the experimental group. **Discussion** The results of this study suggest that the participation in a skin scuba program may affect the on self-regulation, concentration and adaptive behavior of autistic children. This study provides empirical evidence supporting the participation of a skin scuba program for children with autism

for exercise and rehabilitation training. References American Psychiatric Association. (2000). Diagnostic and statistical manual of mental disorders. Washington. ### MO-PM11 Health & Fitness: Age

#### CHANGES IN FIRE FIGHTER FITNESS AND PERFORMANCE OVER AN 18 YEAR PERIOD

Williford, H., Esco, M., Reilly, E., Herron, R., Schaefer, G., Foo, C., Walker, A.

*Auburn University Montgomery and The University of Alabama*

**Introduction:** Firefighting is a demanding occupation that requires a high level of physical fitness and job performance. As firefighters age they may experience changes in both fitness and performance. Aging may be associated with decreases in muscle strength, endurance, and cardiovascular fitness. Job performance that is related to physical fitness (FFJP) may also be compromised. The scientific literature indicates that men in general lose 40% of their muscle mass with a 30% decrease in strength by age 70 (Rogers & Evans, 1993). Maximal oxygen uptake decreases approximately 9% per decade for sedentary men (Elia, 1991). The purpose of this investigation was to evaluate firefighter fitness and performance over an 18 yr. period. **Methods:** Twenty-four firefighters were evaluated in 1996 and again 18 years later in 2014. They were evaluated for the following: height, weight, maximal push-ups, maximal sit-ups, 1.5 mile run, and simulated job performance (FFJP). Each fire fighter performed a maximal FFJP test, wearing turnout gear and self-contained breathing apparatus (SCBA). The FFJP test consisted of the following: stair climb, hoist, forcible entry, hose drag, and dummy drag. A paired T-test was performed to evaluate changes physical fitness and job performance over time ( $p < .050$ ). **Results:** The respective pre and post mean  $\pm$  SD values were: age (yrs.)  $27.75 \pm 4.14$  &  $45.79 \pm 3.62$ , height (m)  $1.77 \pm 0.06$  &  $1.77 \pm .07$ , weight (kg)  $79.75 \pm 9.39$  &  $90.32 \pm 11.90$ , push-ups  $48 \pm 12$  &  $50 \pm 20$ , sit-ups  $44 \pm 8$  &  $47 \pm 8$ , and 1.5 mile run (min)  $11.31 \pm 1.6$  &  $12.78 \pm 1.53$ . The FFJP times were  $4.18 \pm 0.67$  &  $5.55 \pm 1.47$  (min). Results indicated that there were significant differences in fitness and performance over time. Age increased  $18.04 \pm 1.62$  yrs. ( $p = .000$ ), no significant change in height ( $p = .497$ ), weight increased  $10.56 \pm 8.80$  kg ( $p = .000$ ), no significant change in push-ups ( $p = .622$ ) or sit-ups ( $p = .162$ ), 1.5 mile run times were slower  $1.47 \pm 1.97$  min ( $p = .015$ ), and FFJP was slower  $1.36 \pm 1.32$  min ( $p = 0.000$ ). The percent changes over time were: weight + 13%, push-ups + 4.26%, sit-ups + 6.82%, 1.5 mile run time + 13%, and FFJP + 32%. **Conclusions:** This investigation found changes in fitness and performance variables over time. The major changes were related to cardiovascular fitness, weight, and job performance. Muscular strength and endurance did not significantly change. It should be noted that the Montgomery, AL Fire and Rescue Department has a mandatory fitness and weight control program for all firefighters. The ability of the firefighters to maintain their strength and endurance was likely related to the fitness program and the leadership of the department. Weight increased 0.58 kg per year and cardiovascular fitness decreased 13% over an 18 year period. While the job task performance times were slower, they were still well within acceptable standards. Results indicate that it is important for fire departments to monitor changes in physical fitness and performance related to the aging process.

#### DIVERSITY OF ADOLESCENTS' SPORT PARTICIPATION AS A PREDICTOR OF LEISURE-TIME PHYSICAL ACTIVITY IN ADULTHOOD

Mäkelä, S.1, Aaltonen, S.1, Korhonen, T.1,2,3, Rose, R.J.4, Kaprio, J.1,2

*University of Helsinki*

1 University of Helsinki, Finland 2 National Institute of Health and Welfare, Finland 3 University of Eastern Finland, Finland 4 Indiana University, USA **Introduction:** Some evidence suggests that in adolescence improving diversified skills or participation in more than one type of activity simultaneously enhances adults' leisure-time physical activity (LTPA). The aim of this study is to explore whether the diversity of sports in adolescence predicts the level of LTPA in adulthood. **Material & Methods:** This study comprised 3363 Finnish twins born in 1975-77 and surveyed in the FinnTwin16 Study. Baseline questionnaire took place when twins aged 16 and follow-ups of interest at the age of 17 and on average 35 years. Exclusion criteria considered participants having a disability or an illness preventing normal physical activity participation. Health behavior questionnaire at age of 17 provided information about adolescents' leisure-time physical activities with a multiple choice question of 18 different sports and an open question. We formed four categories based on the amount of participated sports: 1, 2, 3-4, and 5+. We also divided activities based on their type into four groups for qualitative analysis as follows: endurance, power, games and others. LTPA in adulthood was calculated as Metabolic Equivalent of Time (ltMET) (h/day) including active commuting. Due to skewed distribution of ltMET we used statistical method to divide participants into four activity classes for the analysis. We controlled the clustering of correlated observations from twin pairs when computing standard errors for the coefficients using robust estimators of variance in the regression models. We conducted models separately for men ( $N=1324$ ) and women ( $N=1828$ ) with adjustment for multiple confounders. **Results:** Association between the amount of participated sports in adolescence and ltMET in adulthood had no significance in men. Participation in several physical activities simultaneously, however, significantly predicted placement in a more active class in adulthood in women. Odds ratios (OR) for being in the most active versus the least active class having 2, 3-4, and 5+ participated sport activities in adolescence, compared to one activity only, were respectively:  $OR=1.62$  ( $p=0.050$ ),  $OR=1.90$  ( $p=0.024$ ), and  $OR=3.29$  ( $p<0.001$ ), based on a multinomial regression model. Mean ltMET was 4.25 h/day for men and 3.86 h/day for women whereas with participants simultaneously active in all groups (endurance, power, games, and others) or in the first three it was 5.18 and 4.88, or 5.17 and 4.89, respectively. **Discussion:** The results show that diversity of leisure-time sport activities in adolescence predicts greater leisure-time physical activity in adulthood in women, but not in men. In addition to quantity of physical activities, also quality of those activities may be relevant. Contact: sara.makela@helsinki.fi

### THE SEASONAL-RELATED VARIATION ON PHYSICAL FITNESS IN AGED POPULATION

Bezerra, P.1,2, Rodrigues, L.P.1,2, Silva, B.1, Fernandes, F.1, Rodrigues, T.M.1, Costa, N.M.C.1

1) IPVC (Viana do Castelo Polytechnic Institute); 2) CIDESD

Introduction Studies in aging have considered either exercise type or time lasting from pre to post testing. Despite having training and timing control, these studies have not investigated the season variation impact. Whether autumn/winter environmental conditions have negative impact on health promotion in aged population it is not well established. Therefore, the aim of the study was to examine the autumn/winter environmental conditions effects on physical fitness level, in both trained and non-trained aged population. Methods 456 volunteers (age, 79±6y; height, 1.54±0.08m; weight, 69.6±12.9Kg), male (N = 130) and female (N = 326), were divided in four groups – Exercise (EG), non-Exercise (nEG), Winter exercising (WG) and summer exercising (SG). Participants were assessed three times – October/November, as baseline, April/May, after winter season, and October/November, after summer season and as one year later. Both handgrip and isometric knee extension tests were used to assess muscle strength, while 6 minutes walking test was used to assess cardiorespiratory capacity. GLM two factor, time, group and time\*group was performed to investigate differences between groups and within group, over the time. Significant differences was set at  $p < 0.05$ . Results Significant differences between groups were found over the time ( $F=27.75$ ,  $p<0.001$ ). Post-hoc analysis with Bonferroni adjustment indicated that 1) EG showed higher scores in both muscle strength and cardiorespiratory capacity than other groups, over the time ( $p<0.05$ ); 2) both SG and WG were significantly higher than nEG no cardiorespiratory capacity ( $p < 0.05$ ) but not on muscle strength; 3) SG did not show significant differences from WG, on both muscle strength and cardiorespiratory capacity. Also, no significant changes within group were found over the time. Discussion Regular exercising improves physical capacities. Seasonal exercising, winter or summer season, seems not influence differently the individual physical capacity. However, it was found a trend showing that better scores on those who exercising on winter in comparison with summer group. The findings also emphasize that more than muscle strength, on upper and lower limb, the cardiorespiratory capacity may have important improvement even when individual exercises seasonally.

### EFFECTS OF CIRCUIT TRAINING ON PHYSICAL PERFORMANCE, BODY COMPOSITION FOR THE FRAIL ELDERLY LIVING IN A RESIDENTIAL CARE FACILITY

Hou, M.T., Chen, J.J.

*Physical Therapy and Assistive Technology*

Introduction: A combination of aerobic exercise, strength training, balance/posture and flexibility training is recommended to optimize health and delay frailty. This study aimed to compare the dose-response effects of 12-wk "circuit exercise" and "chair-based exercise" with "usual care group" on physical performance and body composition for the elders who lived in a residential care facility and were classified as frail or pre-frail based on Fried criteria. Methods: This study was a two-staged study design; a mass frailty screening using the Fried frailty criteria was conducted in the Taipei Municipal Haoran Senior Citizens Home prior to the subsequent quasi-experimental exercise intervention trial. Physical performance and body composition were repeatedly measured before and after the intervention. Results: Two-hundred and twelve subjects participated in the first-staged frailty screening battery. In total, 20.8 % of the subjects were classified as frail, 67.0 % were pre-frail. Sixty-nine subjects enrolling in the subsequent exercise intervention trial were allocated into circuit training group (N=23, mean age: 77.0±8.8 years), chair-based exercise group (N=23, mean age: 81.1±9.8 years) and control group (N=23, mean age: 81.9±7.6 years). After 12-wk exercise intervention, the circuit training group demonstrated significant improvements on physical functions including functional reach test ( $P=.016$ ), grip strength ( $P<.001$ ), knee extensor strength ( $P<.001$ ); upper limb ( $P<.001$ ) and lower limb muscle endurance ( $P<.001$ ), 6-minute walking distance ( $P<.001$ ), as well as 5-m walking time ( $P=.008$ ). The lighter chair-based exercise group mostly kept their baseline physical performance level. In contrast, the control group revealed significant decline on grip strength ( $P=.016$ ), upper limb muscles endurance ( $P=.029$ ) and 6-min walking distance ( $P=.022$ ). There were significant between-group differences in changes from pre-test to post-test based on the group×time interaction effects ( $P<.05$ ). Regarding body compositions, the circuit training group mostly kept their limb muscle mass while both chair-based and usual care group demonstrated significant loss of muscle mass ( $P<.05$ ). Conclusions: After 12-wk exercise intervention, the more intensive circuit training group showed significant improvements on most measures of physical performance and physical fitness along with keeping their baseline muscle volume. The lighter chair-based exercise group tended to maintain their baseline physical performance level but decreased muscle mass somewhat. The usual care group declined significantly on physical performance, fitness and muscle mass simultaneously. There was obviously a dose-response effect of exercise training for the frail or pre-frail elderly. Reference: Chen X, Mao G, Leng SX. (2014): *Clin Interv Aging*, 19, 433-41. ### EFFECTS OF 12 WEEKS OF MULTI-COMPONENT VS. WBV TRAINING ON STRENGTH IN POSTMENOPAUSAL WOMEN

Alcaraz, P.E., Rubio-Arias, J.A., Marín-Cascales, E.

*Universidad Católica San Antonio*

INTRODUCTION The increment of muscular strength of lower limbs decreases the likelihood of a fall, sprain or fracture (Fox et al., 2008; Pizzigalli et al., 2011). Whole body vibration (WBV) and multi-component training (MT) are effective ways to avoid loss of strength. Therefore, the aims of the present study were to analyze the effects of two different training protocols (vibratory platform and multi-component training) and to determine what kind of training creates greater adaptations on the isokinetic strength of the stabilizer muscles of the ankle joint in postmenopausal women. METHODS Thirty-eight women (59.8 ± 6.2 years) were randomly assigned to whole body vibration group (WBVG), multi-component training group (MTG), or a control group (CG). The experimental groups performed an incremental training for 12 weeks, 3sessions/week. The subjects in WBVG remained on the platform in a static semi-squat position with a hip/knee angle of 120° and performed ankle plantar flexion every 6 times (100bpm). Participants in MTG combined aerobic exercise with drop jumps. Isokinetic peak torque of ankle joint for eversion and inversion (60°•s-1 and 120°•s-1) was assessed. RESULTS In the training groups was found a significant increase for eversion at 60°•s-1 (WBVG:  $p = 0.001$ ; and MTG:  $p = 0.003$ ), inversion at 60°•s-1 (WBVG:  $p = 0.015$ ; and MTG:  $p = 0.044$ ) and eversion at 120°•s-1 only in the WBVG ( $p = 0.012$ ) from pre-test to post-test. There were no significant differences between WBVG and MTG in ankle strength tests. Significant changes were not observed in CG in any of the strength measurements. DISCUSSION The instability that adopts the ankle to make the dynamic pattern on the vibratory platform and the dorsiflexion position for cushion the impact during the landing in MT, could justify the improvement on the strength of the ankle evertors and invertors. Furthermore, the passive activation of the ankle stabilizers is necessary during the drop jump to the imbalance occurs (McCaw and Cerullo,

1999). In this sense, these results are considered very important, as the falls are a major cause of morbidity and mortality in actual society, especially in postmenopausal women. The training programs produced significant adaptations on strength. However, the improvements were similar for both groups and we cannot claim that WBVG is better than MTG, or viceversa. ### **FACILITATING DAILY PHYSICAL ACTIVITY, COGNITIVE EXECUTIVE FUNCTION, AND MENTAL HEALTH AMONG ELDERLY PEOPLE: A ONE-YEAR INTERVENTION**

Kimura, K.1, Yasunaga, A.2

1: *Tokyo Denki University (Tokyo, Japan)*, 2: *Bunka Gakuen University (Tokyo, Japan)*

**Introduction** It has been reported that daily physical activity (PA), plays an important role in maintaining psychological health of the elderly. However, it is not clear exactly what intensity and amount of daily PA are most effective in guarding against psychological decline. The present study conducted a 1-year intervention study to reveal the effects of daily PA on psychological wellbeing, with a focus on cognitive executive function and mental health. **Method** More than 120 people aged 65 or over participated in this study. They wore an electronic accelerometer throughout their waking hours for a year to assess the amount and intensity of their individual daily PA. The accelerometer recorded the number of steps they walked and the duration of PA per day as either Low (<3Mets) or Moderate (≥3Mets) activity. Participants randomly divided into three groups: Low active (LA), Moderate active (MA), and Control (Co) groups. The LA group was instructed to spend more time walking daily than they had done previously before the study. The MA group was instructed to increase their amount of time engaging in moderate PA. The cognitive executive function was tested by using a task-switching test. Mental health was examined with the questionnaire SF-36. These outcomes were measured at two periods of baseline and one-year follow-up. **Result** The time (minutes) spent per day at both Low and Moderate PA levels was averaged over quarterly time periods throughout 1-year in order to take into account seasonal deference of daily PA. 2-way ANOVA (Season vs. Group) showed that fluctuations in the amount of PA based on seasonality were highly-correlated between all 3 groups. Psychological results were tested using 2-way ANOVA (Time vs. Group) and showed that significant interactions between factors were non-existent. Additional analysis was conducted by further dividing participants into two groups: the first being the MA+ plus group consisting of participants who increased their moderate PA time throughout 1-year, the other being the MA- minus group made up of participants who decreased their moderate PA during the 1-year period. The results showed that task-switching performance was significantly improved among the MA+ group compared with the MA- group. In addition, the SF-36 scores of Physical functioning, Role physical, and Role emotion were significantly improved within the MA+ group compared with the MA- group. **Discussion** The present study demonstrated that over the course of a year this exercise intervention partially contributed to a small community of elderly people increasing the amount of time spent engaged in moderate PA. Moreover, we realized that increasing the amount of moderate PA over 1 year improved the executive cognitive function and QOL. Contact:kimura@cck.dendai.ac.jp

### **THE EFFECTS OF RESISTANCE, AEROBIC AND COMBINED TRAINING AND DETRAINING ON MUSCLE STRENGTH IN CORONARY ARTERY DISEASED PATIENTS**

Panayiotou, G.1, Theodorou, A.1, Volaklis, A.K.2, Douda, E.2, Paschalis, V.3, Nikolaidis, M.3, Toubekis, G.A.2, Smilios, I.2, Tokmakidis, P.S.2

1: *EUC (Cyprus)* 2: *DUTH (Greece)* 3: *AUTH (Greece)*

**Introduction** Every year an increasing number of individuals are diagnosed suffering from coronary artery disease (CAD). For combating CAD exercise training and the avoidance of sedentary life style is recommended (Tully et al., 2005; Booth et al., 2012), in order to avoid skeletal muscle atrophy and impaired muscle strength. The purpose of the present investigation was to compare the effects of three types of chronic exercise on muscle performance in aged patients suffering from CAD. **Methods** Fifty-six elderly diagnosed with CAD participated in the study and allocated in the aerobic exercise (n=15), the resistance exercise (n=11), the combined exercise (n=15) and the control (n=15) groups. The three exercise groups carried out 8 months of aerobic, resistance or combined training. Before, at 4th and at 8th month of the training period as well as at 1st, 2nd and 3rd month after the training cessation, muscle knee extensors peak torque was measured. **Results** By the 4th and 8th month of training, muscle strength was increased in all groups compared to baseline. More specifically, after 8 months of aerobic, resistance or combined exercise peak torque of knee extensors was increased by 13.8%, 41.1% and 26.5%, respectively, while peak torque of knee flexors was increased by 7.7%, 40.3% and 24.8%, respectively. At 8th month of training, peak torque was significantly higher in resistance and combined exercise groups compared to the aerobic exercise and the control group. At the 3rd month of the detraining period, peak torque of knee extensors and flexors in the resistance group (19.5% and 14.5% respectively) and the combined group (16.0% and 12.5% respectively) was still significantly higher compared to the baseline values. **Discussion** To our knowledge, this is the first "year round" intervention that investigated the effects of chronic aerobic, resistance and combined exercise training and detraining on muscle strength in elderly individuals with CAD. It was found that muscle strength has been increased mainly by resistance and combined chronic exercises, with the former to cause the greatest alterations as it was expected. Resistance and combined training seems to counterbalance the impaired muscle strength in elderly which is associated with an increased risk of functional impairments that may lead to decreased independence and mobility. **References** Tully MA., Cupples ME., Chan WS., McGlade K., Young IS. ### **PARTICIPATION OF SENIORS IN LONG-DISTANCE RUNNING RACES IN POLAND AND SWEDEN.**

Czajka, K.1, Pluta, B.2, Stannard, A.B.

1. *University school of Physical Education in Poznan (Poland)*, 2. *Michigan State University (East Lansing, Michigan, USA)*

**Introduction** Recreational running, as a form of physical activity, has gained popularity in Poland since lifting the amateur runner license in early 90's. Over the last several years, according to annual data of the Polish Running Association, we have observed a significant increase in the number of participants in organized running events (Pascal, 2014) in Poland. The purpose of the study was to examine the participation of senior runner (60+ yrs) in half marathon and marathon races between 2011 - 2014 in Poland and Sweden. **Methods** The study was conducted based on the officially announced results of the most popular running events in Poland and Sweden. Six half marathons and six marathons were studied, three from each in each country. **Monographic method** was used, document analysis techniques

and statistical analysis to examine the changes in the proportion of senior runners in these races between 2011 - 2014. A comparison of these changes between both countries was made. Results There were no significant differences in participation between the percentage of senior runners from Poland in Poznan Marathon (3,09%) and Swedish runners in ASICS Stockholm Marathon (2,66%) in those years. Discussion Despite expected perceived difference in health awareness and health care in Poland and Sweden no difference was found in the proportion of seniors participating in half marathon and marathons. Liquidation of Polish amateur runner license by Athletics Association has increased the popularity of recreational races at half marathon and to a lesser extent in marathons. These changes indicate appreciation of physical activity as a determinant of health, which results in increased health awareness of runners in Poland in comparison with the number of runners in Sweden. #### **APPLICABILITY OF ULTRASOUND MUSCLE THICKNESS MEASUREMENTS FOR PREDICTING QUADRICEPS FEMORIS MUSCLE VOLUME IN MIDDLE-AGED AND ELDERLY POPULATION.**

Nakatani, M.1, Takai, Y.1, Akagi, R.2, Wakahara, T.3, Sugisaki, N.4, Ohta, M.5, Kawakami, Y.6, Fukunaga, T.1, Kanehisa, H.1  
1: National Institute of Fitness and Sports in Kanoya, 2: Shibaura Institute of Technology, 3: Doshisha University, 4: Chiba University, 5: Chukyo University, 6: Waseda University.

**Introduction** Age-related decline in the muscle volume of quadriceps femoris (QFMV) attenuates the activities of daily living in elderly (Fujita et al. 2011). In order to assess physical working capacity in elderly from the viewpoint of physical resource, therefore, it is essential to develop method which can accurately estimate QFMV in elderly. In an earlier study using young adult men (Miyatani et al. 2004), it was shown that ultrasound muscle thickness (MT) measurement at the mid-thigh is useful to predict QFMV. For elderly population of both sexes, however, whether the MT at the mid-thigh can be applicable to predict QFMV is unknown. The purpose of this study is to examine the applicability of MT at the mid-thigh for predicting QFMV in middle-aged and older individuals. **Methods** A total of 60 Japanese subjects (51 to 77 yr, 30 males and 30 females) participated in this study. QFMV were determined by magnetic resonance imaging (MRI-QFMV). MT at anterior mid-thigh was measured with a brightness-mode ultrasound. A stepwise multiple regression analysis was used to produce a prediction equation of MRI-QFMV with MT, sex (male = 1, female = 0), thigh length as independent variables. In addition to the examination of the difference between MRI- and estimated QFMV values, systematic error was confirmed by the Bland-Altman plot. **Results & Discussion** The regression analysis produced a prediction equation:  $\text{MRI-QFMV (cm}^3\text{)} = (\text{sex} \times 251.539) + [\text{MT (cm)} \times 233.377] + [\text{thigh length (cm)} \times 47.256] - 1817.430$ . The R<sup>2</sup> and the standard error of estimate (SEE) of the developed equations were 0.896 and 119.2 cm<sup>3</sup> (11.7%), respectively. There was no significant difference between the MRI- and estimated QFMV values, without a significant systematic error. The observed SEE value was similar to those reported in earlier studies using young population (11.1-11.9%, Miyatani et al. 2002, 2004). These results suggest that the prediction equation with MT at the mid-thigh, sex, and thigh length is useful to estimate QFMV in middle-aged and elderly population. **Conclusion** Ultrasound MT measurement at the mid-thigh is applicable to predict QFMV in middle-aged and elderly population. **References** Fujita et al. #### **COMPARISON OF POLAR LOOP AND ACTIGRAPH ACTIVITY MONITORS IN DETECTING PHYSICAL ACTIVITY AND SEDENTARY TIME IN DAILY LIVING AMONG ADULTS**

Tanskanen, M.M.1, Kulmala, J.2, Tammelin, T.2, Hakonen, H.2, Puurunen, J.3, Virtanen, P.3

1: University of Jyväskylä (Jyväskylä, Finland), 2: LIKES – Research Center for Sport and Health Sciences (Jyväskylä, Finland), 3: Polar Electro (Kempele, Finland).

**INTRODUCTION** Daily physical activity (PA) and sedentary time (ST) have diverse influence on health. Accelerometry has been proposed as a method to objectively quantify time spent sedentary in addition to generally used measures of PA. Reliability and validity of the measurement as well as feasibility of the device are essential to draw the conclusion of PA and ST. The purpose of this study was to compare wrist worn Polar Loop (Loop) and hip worn Actigraph (AG) activity monitors. **METHODS** Eighteen voluntary executives (9 females and 9 males, aged 48±10 yrs.) wore simultaneously tri-axial Loop and AG for 8-10 days in free living conditions. Troiano (1) and Freedson (2) cut-off points were used for AG and personally set cut-off points for Loop for dividing PA into four categories; sedentary time (ST), and light, moderate and vigorous PA. Furthermore moderate to vigorous PA (MVPA) was calculated and total daily PA was calculated as a sum of light PA and MVPA. Data was analysed tracking each data collecting day as a single case. **RESULTS** Totally 175 days were monitored and the average simultaneous wearing time was 14:45 h:min/day. Daily sedentary time was 71%, and time spent in light, moderate and vigorous PA was 23%, 6%, and 1%, respectively. Correlations between Loop and AG monitors were 0.95 for ST, 0.86 for light PA, 0.74 for moderate PA, 0.25 for vigorous PA, 0.83 for MVPA and 0.89 for total daily PA (all p-values < 0.001). Mean differences between Loop and AG were: ST 31±47 min, light PA -41±44 min, moderate PA 8±27 min, MVPA 10±25 min, total daily PA -31±47 min (all p-values < 0.001) and vigorous PA 2±18 min (p=n.s.). Bland & Altman analysis (3) showed that there was no significant correlation between the mean value and the difference between Loop and AG in ST, moderate PA, MVPA and total daily PA. A significant correlation was found only in light PA (r=0.15, p<0.05) and vigorous PA (r=0.18, p<0.05) while using Troiano cut-off points, but not while using Freedson cut-off points. **DISCUSSION** These findings indicate that both Polar Loop and Actigraph measured and categorized total daily PA, ST, moderate PA and MVPA equally. Depending on used cut-off points, differences were seen only in light and vigorous PA. However, vigorous activity has minor role in daily life and in general, cut-off points play an important role when comparing PA results and different PA categories. In conclusion, both studied accelerometers can be used in measuring daily PA equally. **REFERENCES** 1) Troiano RP et al. MSSE 40(1), 2008. 2) Freedson PS et al. #### A STUDY ON NATIONAL QUALIFICATION TRAINING PROGRAMS FOR SPORTS INSTRUCTOR IN SOUTH KOREA

Kim, S.H., Jun, H.M.

*Mokpo National University*

The purpose of this study was to investigate the current state of and problems with the qualification training programs in south korea, which make up the final process in the qualification examination newly reorganized in 2015. Researcher conducted a literature study, collected the standard qualification training programs documents of 2015, and analyzed by content analysis. The qualification system of sports instructor includes a national qualification for professional sports instructors, sports for all instructors, health and exercise managers, sports instructors for the disabled, sports instructors for youth, and sports instructors for the elderly. Each of the qualification examinations qualification training programs to those who have passed the theory and practice tests. A certificate is issued to those who have completed qualification training courses. Qualification training programs is the core process in the qualification system. Qualification training programs have different aspects according to the qualification types and are comprised of sports ethics, sports, health and safety management, instruction capabilities, sports management, and field practice. The newly qualification training programs have such problems as content that is not fit for the qualification types, absence of leader qualities and roles, and absence of field practice content. Based on those findings, the study proposed that there should be program diversification and differentiation, reinforcement of leader qualities, and systematic field practice.

#### TRAINING RELATED TO ALTERATIONS: POSTURAL ANALYSIS AND BIOMECHANICS OF GAIT IN BALLET

Coppola, S., Vastola, R., Palumbo, C., Flauti, D., Viscione, I., D'Elia, F.

*University of Salerno*

**Introduction** The dominant element in ballet is the search for flawless performance. Requiring specific training from early years, this may cause some changes compared to the normal human anatomy and physiology, particularly to the spine and lower limbs (Green Haas, 2013). The object of this study concerns the assessment of the fundamental gesture of this discipline: the en dehors. The biomechanical evaluation of en dehors, and more specifically the nature of postural compensation employed by the dancer in the search for an optimal execution, appears to be of fundamental importance in understanding the changes that can occur due to a teaching that does not take into account the morphofunctional characteristics of the subject (Howse & McCormack, 2009). **Methods** The initial phase of the research included a postural test carried out on a sample of ten dancers, chosen according to their professional level, with the aims of assessing posture in a static condition and identifying possible alterations and compensations generated. Two types of data were collected: in a natural position to highlight possible alterations of the main body segments involved in the technical implementation of en dehors and in an en dehors position to verify the eventual accentuation of the same alterations and to confirm, therefore, how these can be a result of the practice of this technical position. For the collection of data, the system Bts Smart D for integrated multifactor analysis of human movement and the Davis clinical protocol for gait analysis were used (Davis, 1991). **Results** The study revealed some postural alterations in the dancers both in a natural position and during normal ambulation. The biomechanical gait analysis in en dehors showed substantial changes compared to normal walking. Compensations have also been identified, which may be linked to training. **Discussion** Considering the sample size and the absence of a control group, this research can be considered a pilot study. The critical aspects which emerged from this research indicate the need of an approach to teaching that would enable the coach to plan the training consciously and adequately, in relation to the morphofunctional characteristics of the dancer. **In conclusion**, the scientific comparison among experts and those working in the field of motor performance can make an important contribution to prevent morphofunctional alterations and generally to promote the health of those who ballet at professional levels. **References** - Davis, R. #### WHAT IS HUMANISTIC LITERACY FOR COACHES?

Kim, J.

*Andong National University*

The aim of this study is to clarify the meaning of coach humanities literacy and its educational implications. The humanistic literacy for coach, a concept unifying humanities and literacy, means the literacy in the humanities. Specifically, it means the ability to read and write humanistic texts by coaches. Humanistic literacy pursues critical thinking and experience as free men, the telos of humanities. At the same time, it involves all efforts being done by educators to develop students' literacy for humanistic texts in order to make them critical and free thinkers. For higher education, humanistic literacy for a coach has educational implications. First of all, it lets us understand the roles of coach humanistic education as an initiation into the traditional practices. Second, it restates reading and writing in coach education, which are sometimes dealt with individually, in terms of concrete activities, through which it makes possible the meaningful cycle of reading and writing. Moreover, it helps achieve one of the goals of coach education, developing basic ability to gain an insight into life through a humanistic perspective. Third, it can be used as a guide for structuring educational experiences, helping educators and pre-coaches clearly understand educational goals and activities.

#### PASSIVE DRAG IN YOUNG SWIMMERS

Ciapparelli, C., Romagialli, B., Caspani, M.

*Università degli Studi di Milano*

**INTRODUCTION** Passive Drag is very important factor to obtain a high performance in swimming sprint events. The focus of this paper is evaluate  $k$  (as hydrodynamic coefficient) about swimmers who present similar passive drag and assess any improvements linked to the reduction of  $k$  (Chatard et al., 1990). Some factors that influence  $k$ , refer to body position in the water, buoyancy and swimmer's anthropometric characteristics. System modeling of  $k$  is not particularly complex because the swimmer is not engaged in advancing and his

hydrodynamic set-up is constant. However setting a precise attitude, improvements to performance are generated by dissipation of the same swimmer. The improvements of glide capacity can be used for a good performance in swim sprint events. METHODS Eight national male swimmers who are specialists into 50 m freestyle (age  $15.0 \pm 0.00$  years; height  $178.6 \pm 3.70$  cm; weight  $66.4 \pm 3.90$  kg) participated in the study. The swimmer in hydrodynamic position will wear a belt around the waist which will be connected to the Speed R. Between the hands holding the end part of the elastic previously characterized, which has been fixed to the opposite side of the pool. The swimmer without going off the wall will leave to bring forth from the strap, simultaneously the Speed RT acquires data in real time that will be then processed with a special software (Bixler et al., 2007). The exercises to improve hydrodynamic coefficient were: glide phases in different depth (4x8 rip), awareness of glide position with the head low, medium and high (4x8 rip), ranges floating to vary buoyancy and hydrodynamic position (4x8 rip). Swimmer dedicated 20 minutes extra to training to perform specific exercises with a frequency of four times a week. After three months training used to improve the hydrodynamic profile and thus the decrease of k we repeated the measurements to assess whether hydrodynamic qualities improvements produced performance improvements. Data analysis was performed with the Student's t-test, whose significance was placed at  $p < 0.05$ . RESULTS Hydrodynamic coefficient (k) passed from pre-training ( $38.8 \pm 0.70$ ) to post-training ( $38.6 \pm 0.72$ ), with  $p=0.00$ . Training improved the time of 50 m, that passed from ( $24.42 \pm 0.33$  s) to ( $24.35$  to  $\pm 0.00.34$  s) with a statistical significance of  $p=0.00$ . Performing a good glide phases, achieved with a special training, is useful for a sprint swimmer to go faster. DISCUSSION Improving hydrodynamic coefficient can bring benefit to performance. Spending part of the training to improve hydrodynamic position during start and turn phases could be decisive in sprint events. REFERENCES Bixler B, Pease D, Fairhurst F. ### EFFECT OF HAND PADDLES ON INTRA-ABDOMINAL PRESSURE DURING MAXIMAL FRONT CRAWL SWIMMING

Moriyama, S.1, Kanazawa, S.1, Kitagawa, Y.1, Natsui, H.1, Shibata, Y.2, Ogita, F.3

1: Japan Women's College of Physical Education (JAPAN), 2: Tokyo Gakugei University (JAPAN), 3: National Institute of Fitness and Sports (JAPAN)

Introduction Intra-abdominal pressure (IAP) increases with swimming velocity within subjects (Moriyama et al., 2014c). When maximal swimming velocity ( $V_{max}$ ) is compared, paddle-aided swimming (P) is generally higher than normal swimming (H). Therefore, we hypothesized that IAP during maximal P is higher than that during maximal H, and compared IAP between two conditions. Methods Nine highly trained competitive collegiate female swimmers ( $1.61 \pm 0.03$  m,  $52.1 \pm 4.3$  kg) participated as subjects in this study. Experiments were carried out in a competitive swimming pool. Subjects performed front crawl swimming with or without hand paddles with maximal effort. IAP was taken as the difference between minimum and maximum values using the mean of 4 stable front crawl stroke cycles. Stroke rate (SR) and length (SL) served as stroke indices. Results  $V_{max}$  (H ;  $1.50 \pm 0.03$  m · s<sup>-1</sup>, P ;  $1.53 \pm 0.02$  m · s<sup>-1</sup>) and SL (H ;  $1.62 \pm 0.10$  m, P ;  $1.72 \pm 0.12$  m) were significantly higher in the P than in the H ( $P < 0.05$ ). The SR (H ;  $0.93 \pm 0.06$  Hz, P ;  $0.89 \pm 0.06$  Hz) was significantly higher in the H than in the P ( $P < 0.05$ ) whereas no significant difference was observed in IAP (H ;  $1.7 \pm 0.5$  kPa, P ;  $1.6 \pm 0.3$  kPa). Discussion Using hand paddles, swimmers could swim faster than not using them. However, no significant difference was observed in IAP between P and H, and our hypothesis was not verified. Additionally, we have reported that IAP at maximal swimming velocity does not differ between skilled and unskilled swimmers (Moriyama et al. 2014a,b). Further, swimming technique is more important factor to swim faster than the ability to generate metabolic power. (Ogita et al. 2006). In conclusion, it is revealed that increased swimming velocity with hand paddles elicits no significant increase in IAP. References Moriyama S, Kanazawa S, Yamagata K, Kitagawa Y, Ogita F. (2014a). ### BASKETBALL GAMES LOAD MEASUREMENT USING COMMERCIAL ACCELEROMETRY

Moreno, D., Peña, J., Fortet, J., Buscà, B.

Club Joventut de Badalona

Introduction The Adidas miCoach is a commercial accelerometer presenting accuracy levels and proper design to quantify physiological loads in professional team sports like basketball (Porta et al., 2012). Some research has been conducted in the past to determine the physiological demands of basketball (Ben Abdelkrim et al., 2007), their differences according to game positions (Sallet et al.; 2005) and the effects of fatigue throughout the games (Leite et al., 2013). The present study uses this technology to provide additional data about top-level basketball players. Methods During 125 Spanish Division I matches two players from the same team, selected at random, wore a miCoach Speed\_CellTM sensor attached to the right shoelaces during the entire game. Data inclusion criteria considered players with at least 5 active minutes per half (excluding warm-up exercises). Players were divided into three groups according to their playing position (46 centers, 34 forwards, 44 guards). The Speed\_CellTM provided the amount of high-intensity efforts/active minute ratio (HIER), distance covered in high-intensity efforts/active minute ratio (HIERm) and the overall distance/ active time ratio (DAT). We compared these variables between first and second halves of the game and among different game roles. Results Players perform more HIER, HIERm and DAT during the first half when compared to the second ( $p < .001$ ). Comparison between roles only showed significant differences in HIERm favoring forwards when compared to centers. Discussion In a previous study using accelerometry forwards were revealed as the players with higher physical demands within the game (Moreno et al., 2013), differing from earlier studies where guards were pointed out as the players with higher intensity demands (Ben Abdelkrim et al., 2007). Forwards covered more meters during HIE compared to centers. When comparing halves, first half seems to involve more efforts in a consistent manner, more distance covered at a high intensities and more overall distance covered. These results agree with those presented by Leite et al. (2013) who pointed fatigue as the main factor for such a significant decrease. References Porta JP, Acosta DJ, Leher AN, Miller JT, King GA. ## CONTACT TECHNIQUE AND CONCUSSIONS IN THE SOUTH AFRICAN UNDER-18 COCA-COLA CRAVEN WEEK RUGBY TOURNAMENT

Hendricks, S., O'Connor, S., Brown, J., Burger, N., McFie, S., Readhead, C., Viljoen, W., Lambert, M.  
*University of Cape Town and South African Rugby Union*

**Introduction** In rugby, understanding the techniques and events leading to concussions are important because of the nature of the injury, and the severity and potential long-term consequences, particularly in junior players. Proper contact technique is a prerequisite for successful participation in rugby and is a major factor associated with injury. However, the execution of proper contact technique and its relationship to injury has yet to be studied in matches. Therefore, the aim of this study is to compare contact techniques leading to concussion with a representative sample of similarly matched non-injury contact events. **Methods** Injury surveillance was conducted at the 2011-2013 under-18 Craven Week Rugby tournaments. Video footage of 10 concussive events (5 tackle, 4 ruck and 1 aerial collision) and 83 non-injury events were identified (19 tackle, 61 ruck, 3 aerial collisions). Thereafter, each phase of play was analysed using standardised technical proficiency criteria. The Student t-test and effect sizes were used to compare scores for each technical criterion on the list, and overall for ruck, tackler, ball-carrier, and aerial contact proficiency. Statistical significance was set at  $p < 0.05$ . **Results** Overall score for ruck proficiency in concussive events was 5.67 (out of a total of 15) versus 6.98 for non-injury events ( $n=54$ ) ( $p > 0.05$ , effect size=0.52, moderate). Overall average score for tackler proficiency was 7.25 ( $n=4$ ) and 6.67 ( $n=15$ ) for injury and non-injury tackles, respectively (out of 16) ( $p > 0.05$ , effect size=0.19, small). **Conclusion** This is the first study to compare concussion injury contact technique to a player matched sample of non-injury contact techniques. Certain individual technical criteria had an effect towards a non-injury outcome, and others had an effect towards a concussive event, highlighting that failure to execute certain techniques may substantially increase the opportunity for concussion. ## FROM MILITARY NORMS TO INDIVIDUAL COACHING: A CHANGING EDUCATIONAL DISCOURSE AS AN ANSWER TO COMMERCIAL CHALLENGES IN SWEDISH RIDING SCHOOLS

Thorell, G., Morgan, K., Hedenborg, S.

*The Swedish national Equestrian centre at Strömsholm*

**Introduction** Research show that the Swedish stable environment is characterized by a military discourse even though equestrian sport has passed through a paradigm shift concerning gender (Forsberg&Tebelius, 2011; Hedenborg, 2009; Thorell&Hedenborg, forthcoming). There is, however, a lack of previous research on teaching and leadership in riding schools. It seems that the historical, military, educational stable culture signified by respect and discipline is challenged today by the expectations of society. The aim of this study was to identify critical issues in the profession of a riding instructor concerning this shift in relation to youngsters' view of the riding school. **Method** The source material consists of written documents, interviews with riding instructors and focus group interviews with young people. A constructivist grounded theory method have been use to collect and analyze the data. The theoretical frame originated in a sociocultural perspective on learning and situated learning (Lave & Wengers 1991). **Results** Interviewed riding instructors point out that there has been a change the last decade. Development of the society and economic factors has moved the instructors to change to a educational model built on a sensitive and humble approach to make their pupils stay at the riding school. The youngsters' reasons for spending time at the riding school were feelings of affinity, comradeship and to be part in an organisation with horses. **Discussion** An increased commercialisation of all sports for youngsters has moved the riding schools towards an adaption to the market. The interviewed riding instructors' points to that teaching today are characterised by an individualisation and coaching. This coincides with what the interviewed youngster valued. The riding instructors can develop their teaching through a broader pedagogical and didactical perspective. A more coaching and reflective approach is seemingly needed in order to reach the youngsters and generate a life-long interest. The outcomes of this project are useful for riding instructors and trainers in the horse business, it is also important to discuss the pedagogical content in the education of future riding instructors. **References** Forsberg L. & Tebelius U. ## GOLF - PATHWAYS AND SCORES, CLUBS AND HOLES

Brito, A., Abreu, J.

*ISMAI - Instituto Superior da Maia*

**Introduction:** Various Golf Courts offer to Players several holes' challenges which imply different technical behaviors and game characteristics, allowing each player to select the more adequate club to his physical and technical performance. In order to evaluate performance related to this club selection, an analysis of most used clubs is made and pattern of clubs' selected was verified. **Objective:** Analysis of the score of each player, relation with handicap, Hole Pair, Golf Court and Clubs used, as well as evaluation of Hole' difficulty degree related to Pair. **Methodology:** This quantitative, exploratory and transversal study, was configured by data provided from Scorecards. Sample intentionally comprised 38 golfers with Handicap properly approved and presenting age average 41,13 years and a standard deviation 8,4. Used SPSS20 ( $p \leq 0, 05$ ). Data processing was made by descriptive analyzes, TTest, Factorial Analyzes to define Strong-lines of the interviews, and finally ANOVA was made to test average parity corresponding to each IMC level. **Results:** Verified that Vidago Golf Course is constituted by 10-"Pair4", 4-"Pair3" and 4-"Pair5". Also confirmed that the obtained score varies between one shot below the Pair, or the same number of shots and the Pair. The most used clubs are Drive and Putter. Amarante's Golf Course has 8-"Pair4", 7-"Pair3" and 3-"Pair5". Verified that there are significant differences between scores referents to Holes "Pair5". Most used clubs are Drive and Putter. Fôjo Golf Course is composed by 12-"Pair3" and 6-"Pair4". Calculated that there are significant differences between the scores referent to holes "Pair3". Most used club is Putter. Vale Pisão Golf Course has in its course 9-"Pair4", 6-"Pair5" and 3-"Pair3". We found that there are significant differences between the scores referent to holes "Pair4" and "Pair5". Used most club is Putter. There are significant differences between scores register at different Golf Courses levels, both for holes "Pair3", "Pair4" and "Pair5" at a level of each different Pairs and between Players Scores with different handicaps. Found that most used clubs are Putter in 44% of the shots and Drive in 17,2%. Beyond these, SW and Iron7 assumed some relevance. Verified a strong connection between players' Scores and course, hole, pair and handicap, which allowed us to create a model of linear regression that predicts the player score in function of his handicap, the pair, the hole and the course where the game is going to take over. The final model estimated is given by:  $SCORE = 1,184 + 0,799 \times (PAIR) + 0,028 \times (HANDICAP) - 0,197 \times (COURSE) + 0,022 \times (HOLE)$ . **Conclusion:** The final Score in each hole is intrinsically

related with the hole pair, the player's handicap, the Golf Course and the hole in question. At the Golf Courses studied we noticed that the holes of each pair have all different difficulty levels. We also verified that there are several significant differences between the Scores reached by Professionals and Amateurs. Regarding to the clubs' frequency, we found that the most used are Drive, Putter and Iron7.

### MO-SH02 Physical Education and Pedagogics I

#### EFFECT OF USING VISUAL INFORMATION IN SELF-CHECK STYLE ON GRAB START SKILL RETENTION, KNOWLEDGE, AND ANXIETY LEVEL.

Coşkun, H.

*Hacettepe University*

The purpose of this study was to determine the effect of using visual information in self-check style on grab start skill retention, knowledge, and anxiety level of university students. The research was done at TED Ankara Collage Sport Facility swimming pool in 2008. It was pre-mid-post test design with control group and retention test was delivered 10 days later. Sixty university students involved in the study that were randomly assigned one of the three group 20 (M=10; W=10) in each. Qualitative written examination were used to determine knowledge level. To determine the Grab Start skill level a check list were used which was prepared by experts. Spielberger State-Trait Anxiety Inventory (STAI) were used to determine the anxiety level of the students. Repeated Measure ANOVA were computed to determine the pre-mid-post test knowledge and skill acquisition level. Bonferroni Comparison Tests were applied when F value were significant. In order to determine the retention Pared Two Saple T Test were computed between post test and retention test. One Way ANOVA were computed to determine the difference between groups on knowledge and skill acquisition. Scheffe were calculated when the obtained F value were significant. The results showed that there was a significant difference among the pre-mid-post test knowledge scores of the visual feedback group (F = 78.51; p = 0.000). Mid and post test scores were similar (p = 0.874) and significantly different from pretest scores (p = 0.000) and there was a significant difference among the pre-mid-post test skill acquisition scores of the visual feedback group (F = 119.65; p = 0.000). Mid and post test scores were similar (p = 1.000) and significantly different from pretest scores (p = 0.000). Moreover, there was a significant difference among the pre-mid-post test knowledge scores of the nonvisual feedback group (F = 94.72; p = 0.000). Mid and post test scores were similar (p = 0.542) and significantly different from pretest scores (p = 0.000) and there was a significant difference among the pre-mid-post test skill acquisition scores of the nonvisual feedback group (F = 64.28; p = 0.000). Mid and post test scores were similar (p = 1.000) and significantly different from pretest scores (p = 0.000). Finally, there was statistically significantly difference between posttest and retention test knowledge scores of the nonvisual feedback group's (t = 3.06; p = 0.006). As a result, we can say that there was skill and knowledge acquisition at both group regardless of delivering visual information or not. On the other hand, the retention test was revealed that visual information were more effective at the acquisition of knowledge comparing to nonvisual information group. State and trait anxiety level of the students were high throughout the study at both groups.

#### DANCE PERFORMANCES ON SPORTS DAY IN JAPANESE SCHOOLS

Hatano, Y.

*Kobe Shinwa Women's University*

**Introduction** In the 2008 update of the Guidelines for the Course of Study provided by the Japanese Ministry of Education and Science, dance, was changed to a compulsory subject, suggesting that it has been positioned as an increasingly important subject. In this study, dance means an element of physical expression for education in a wide range of ages: officially called "expression" in kindergarten, "expression activity" in elementary school, and "dance" as an independent subject in junior high school, high school and college or university. Practical researches on teaching methods of the main areas of dance included in the Guidelines have already been extensively conducted, but there are few studies on dance on sports day, which is a big event in school. This report examines recent research trends concerning dance on sports day and its practices in Japanese school education and clarifies the future outlook for dance education in conjunction with school events such as sports day. **Methods** The JNII database was used to search research papers, academic presentation abstracts, and other written sources concerning dance on sports day. Also, teachers who taught dance on sports day were interviewed. **Results** Since the early 1990s, reports concerning dance on Sports Day have been identified in the database, but very few. Most were practical reports on dance choreographed by school teachers to seek a bridge between dance classes and school events. Interestingly, there were two research papers on how dance classes should be organized for sports day from two elementary schools affiliated with universities. For example, group-based (not age-based) longitudinal classes were employed as a part of integrated studies to create their own musical and to present their achievement on sports day. The interviewee who worked at the school also emphasized the importance of the practice by the whole school to build its own curriculum focusing on the musical dance performances on Sports Day. In contrast, the other interviewee, who worked as a member of a dance research group at an elementary school, indicated that most schools did not create classes specialized for dance in conjunction with sports day, but simply provide a choreographed dance for all students, e.g. Yosakoisoran, gymnastics, mass games and so on. **Discussion** Based on these results, the author believes that the content and results of daily dance classes should be considered to be linked to Sports Day, not only on the case of choreographed dance, but also creative free movement using the students' individual creative abilities and group dynamics of many students. It is hoped that more substantial programs for dance classes will be developed in the future through the practice of education in various directions, verification approach and other activities not only in Japan but all over the world. **References** Ministry of Education, Culture, Sports, Science and Technology-Japan, Course of Study, [http://www.mext.go.jp/a\\_menu/shotou/new-cs/youryou/chu/hotai.htm](http://www.mext.go.jp/a_menu/shotou/new-cs/youryou/chu/hotai.htm) Contact hata-no@kobe-shinwa.ac.jp

**EMPIRICAL RESEARCH ON THE DEVELOPMENTAL LEVEL AND DOMAIN OF SPORTSMANSHIP**

Park, J.

*Incheon National University*

Introduction Sportsmanship which resides within sports activities beholds moral conduct. Thus physical education holds an advantage in moral character development. Nonetheless, participating in sports activity alone does not guarantee character development. It is only possible with careful preparation and goal planning. The purpose of this study was to examine the developmental level and domain of sportsmanship in middle school P. E classes. Methods 250 second grade students of middle school in Seoul were applied to the 'Integrated sportsmanship education program'(Park, 2012) developed within basketball, relay and badminton. For data collection: student journals, open questionnaires, participant observation, in-depth interview were done, and these data analyzed in terms of Patton(2002)'s inductive analysis to discover patterns, themes and categories. Also frequency analysis was applied for examining the ratio of sportsmanship developmental level and domain. Results The sportsmanship development of middle school students was analysed following two aspects. First, the developmental level of sportsmanship was categorized as: (a) cynical exploration stage, (b) selfish competition, (c) fair achievement, (d) limited caring, (e) conscientious respect. Second, the developmental domain of sportsmanship was labeled as both mindset-behavior and P. E class-daily life. Discussion & Conclusion sportsmanship education should be developed and implemented for students to experience from social character to moral character and from selfishness to altruism. And they have to reflect their thoughts, attitude, behaviors through practical learning(choi, 2010; Lickona, 1991). Systemic approach is needed for enlarging the sportsmanship to daily life. **RELATIONS OF PHYSICAL ACTIVITY LEVEL AND MOTOR COMPETENCE OF CHILDREN AGED TEN**

Serbetar, I.

*Faculty of Teacher Education Zagreb*

RELATIONS OF PHYSICAL ACTIVITY LEVEL AND MOTOR COMPETENCE OF CHILDREN AGED TEN Introduction There are many evidences that level of physical activity of the children is declining. Engagement in physical activity is of crucial importance of children's motor, social and cognitive development (Strong et al., 2005). Inactivity, on the other hand, could lower opportunities of acquiring proficiency in motor skills. Such a lifestyle may lead to vicious circle concerning health problem and related movement difficulties (D'Hondt et al., 2009). Although physical activity level is not such directly related to health as fitness is, it is important health related construct (Hands et al., 2008). Present study aimed to investigate relations of motor competence and self-reported physical activity. Methods Research was carried out in North West Croatia and 103 children aged 10 were involved (42 boys and 61 girls). Movement Assessment Battery for Children-2 (MABC-2; Henderson et al., 2007), was applied, as well as The Physical Activity Questionnaire for older Children (PAQ-C; Kowalski et al., 2004). Results In PAQ-C children reported their level of involvement in motor activities in school but also in their spare time. According to the descriptive data of PAQ-C, children were more engaged in sedentary than in movement activities. There were no significant differences between boys and girls neither in PAQ-C nor in MABC-2 total scores, but girls performed significantly better than boys in fine motor skills ( $p=.01$ ). Although low in magnitude, inter-correlations of MABC-2 motor domains were significant (.24 to .30). Correlation between MABC-2 total score and PAQ-C average score was positive but not statistically significant. Discussion Most of the studies proved the positive association of the physical activity and motor competence in children (Wrotniak et al., 2006; Fisher et al., 2005) which was not the case here. It may be the issue of study sample size but it could be also speculated that more valid and objective measure of physical activity than self-report should be used in that age. However, motor competence is not only determinant of physical activity but also the outcome, so it may be the result of high level of physical activity. Unlike motor competence, physical activity is behavior which may be determined by more psychosocial influence than motor competence (Rowland, 2005). Complex causality of these relationships still has to be established. References Henderson, S. E., Sugden, D. A., Barnett, A. L. (2007). *Movement Assessment Battery for Children-2. (Movement ABC-2). **MARTIAL ARTS AND COMBAT SPORTS AS SCHOOL EDUCATION SUBJECT**

Correia, W.

*University of Sao Paulo*

INTRODUCTION In Brazil, martial arts and combat sports are considered contents of physical education programs of elementary/high schools. Among other relevant activities and learning topics such as sports, gymnastics, dance, games and body health issues, martial arts and combat sports have also been included in the Brazilian public schools curriculum. Moreover, the martial arts include a huge variety of cultural expressions with inherent logic and particular purposes. However, such purposes have been demonstrated to be significantly different from the current physical education teaching process. Therefore, the main aim of this study is to propose invariant criteria for aid in the adoption of the martial arts as a subject of the physical education at elementary and high school. METHOD This study involved a survey of bibliographical and documentary researches from official curriculum documents and literature on curriculum theory applies to physical education, followed by the analysis of features which could be useful to the improvement of learning of martial arts at the school. RESULTS Five relevant items for adequacy of martial arts and combat sports as school education subject were identified: 1) specificity of the school environment; 2) cultural context of the students and their previous interests; 3) growth characteristics and development of children and adolescents; 4) specificity of martial arts and combat sports; 5) training and teaching knowledge. DISCUSSION The results of present study suggest the need for an investment in the pedagogical preparation of physical education teachers taken into account the 5 relevant items for adequacy of martial arts and combat sports as school education subject in a didactic and pedagogical point of view.

## MO-PM02 Nutrition, training adaptation and performance

**EFFECT OF PROTEIN SUPPLEMENTATION ON MUSCULAR ADAPTATIONS IN RESPONSE TO STRENGTH TRAINING IN ELDERLY ADULTS.**

Stragier, S.1,2, Baudry, S.2, Poortmans, J.1, Duchateau, J.2, Carpentier, A.1  
*Université Libre de Bruxelles - Faculté des sciences de la motricité*

**Introduction** Ageing is associated with a progressive decrease in maximal force, in part due to a loss of muscle mass (2). Previous work underscores the relevance to combine essential amino acids supplementation with strength training to increase muscle mass in young men (3). As the increase in muscle mass was greater in subjects with low initial nitrogen balance, such combination may provide more efficient intervention to prevent muscle loss in elderly adults. However, scientific literature on such a topic remains scarce. Therefore, this study investigated the benefits of protein supplementation on muscular adaptations and maximal force in response to strength training in elderly adults. **Methods** 35 elderly adults (>60 yrs) completed the study. Two groups performed a strength training (2 session/week) for 24 weeks. One group (n=13) received placebo (27g carbohydrate) and the other group (n=12) received protein supplementation enrich in leucine (20g protein – 7g carbohydrate). In addition, 10 subjects composed a control group (no training and with placebo). Muscle thickness and pennation angle were recorded by ultrasonography of the gastrocnemius medialis to document changes in muscle mass and architecture. Lean body mass was assessed by DXA. The force of the ankle plantar flexors was assessed during maximal voluntary contractions (MVC). **Results** Training resulted in significant ( $P<0.05$ ) increase in MVC force without any difference between placebo and supplemented groups (24% and 33%, respectively). A similar increase ( $P<0.05$ ) was found in both placebo and supplemented groups for muscle thickness (9.4% and 8.5 %), angle of pennation (13.7% and 15%) and lean body mass (2.5% and 3.4%). However, a negative linear regression ( $r^2=0.33$ ,  $P<0.05$ ) was found between initial lean mass and gain in lean mass after training only for the supplemented group. **Discussion** The results indicate that part of the increase in maximal force is due to muscular adaptations. The lack of a significant effect of protein supplementation may reflect an age-related decrease in sensitivity or responsiveness of intramuscular signalling pathways regulating protein synthesis (1). However, the greater gain in lean mass for subjects having the lower initial value suggests that protein supplementation may have a greater effect on sarcopenic elderly adults. **References** 1. **CAFFEINE AND EXERCISE PERFORMANCE IN ALTITUDE**

Stadheim, H.K., Nossum, E.M., Spencer, M., Jensen, J.  
*Norwegian School of Sport Sciences*

Research on the physiological effects following caffeine (CAF) ingestion on exercise performance in normoxia at sea level is extensive. However, there is limited research related to sports performance when athletes are exposed to acute hypoxia. The aim of the present study was therefore to test the effect of placebo and CAF (4.5 mg•kg<sup>-1</sup>) on endurance performance when subjects were exposed to acute hypoxic conditions (2h at 2000m). **Methods:** 13 highly endurance trained male cross-country skiers (VO<sub>2</sub>max-run 72.6±5.68 mg•kg<sup>-1</sup>•min<sup>-1</sup>) participated in the study which had a randomized double-blinded, placebo-controlled, cross-over-design. Performance was assessed as time to complete a 8 km cross-country double poling test (C-PT), and time until task failure at 90% of VO<sub>2</sub>peak-pol-alt. All hypoxic testing where carried out in a hyperbaric chamber where air pressure was reduced to 800 mBar, equivalent of 2000 meters above sea-level at 17 C. **Results:** Ingestion of CAF improved time until task failure during the 90% C-PT ( $P=0.05$ ). During the 8 km C-PT CAF ingestion resulted in improved velocity over the first 4 km, but a non-significant effect was observed for the overall performance ( $P=0.22$ ). However, a 0.9±1.3 (mean ±90% CL) improvement was observed during CAF trials. Improved performance was during all tests associated with increased hear rate peak/mean, VO<sub>2</sub>-consumption, blood lactate, glucose, adrenaline and a decrease in bicarbonate during CAF compared to PLA testing. In addition, during the standardized warm-up prior to each C-PT subjects reported lower perception of pain in arms, and rate of perceived exertion following CAF ingestion. **Discussion/Conclusion:** The present study demonstrates for the first time that CAF ingestion can improve double poling performance when subjects are exposed to acute hypoxic conditions. Mechanisms underpinning observed improvements are due to reduced pain sensation affecting physiological mechanisms for optimal endurance performance. Importantly, the unique design of the study highlights the importance of subjects controlling pacing strategy following CAF ingestion prior to exercise. Especially this seems to be importance during trials where subjects complete a set amount of work, such as during time trial performances (e.g. 8 km C-PT).

**COMBINED INGESTION OF GLUCOSE AND FRUCTOSE DOES NOT FURTHER ACCELERATE POST-EXERCISE MUSCLE GLYCOGEN REPLETION IN TRAINED CYCLISTS**

Trommelen, J., Beelen, M., Pinckaers, P.J.M., Senden, J.M., Cermak, N.M., van Loon, L.J.C.  
*Maastricht University*

**Introduction** Post-exercise muscle glycogen synthesis rate represents one of the more important factors determining the time needed to recover from prolonged exercise. Muscle glycogen synthesis rates are largely determined by the amount of exogenous carbohydrate provided. Carbohydrate absorption from the gut may be accelerated by the ingestion of multiple transportable carbohydrates when compared to the ingestion of glucose or glucose polymers only. We hypothesised that the combined ingestion of glucose and fructose or sucrose further increases post-exercise muscle glycogen repletion rates when compared with the ingestion of an isocaloric amount of glucose only. **Methods** Fourteen male cyclists (age: 28±2 y; Wmax: 4.8±0.1 W•kg<sup>-1</sup>) were studied on 3 different test days. Each test day started with a glycogen-depleting exercise session. This was followed by a 5 h recovery period, during which subjects ingested 1.5 g•kg<sup>-1</sup>•h<sup>-1</sup> glucose (GLU), 1.2 g•kg<sup>-1</sup>•h<sup>-1</sup> glucose + 0.3 g•kg<sup>-1</sup>•h<sup>-1</sup> fructose (GLU+FRU), or 0.9 g•kg<sup>-1</sup>•h<sup>-1</sup> glucose + 0.6 g•kg<sup>-1</sup>•h<sup>-1</sup> sucrose

(GLU+SUC). Blood samples were collected frequently and muscle biopsies were obtained at 0, 2, 5 h after cessation of exercise. Repeated measures ANOVA with time and treatment as within-subjects factors was used to determine differences in muscle glycogen content over time between treatments. Results Post-exercise muscle glycogen content averaged  $207 \pm 30$ ,  $219 \pm 29$  and  $236 \pm 32$  mmol·kg<sup>-1</sup> dry weight in the GLU, GLU+FRU and GLU+SUC treatment, respectively, with no significant differences between treatments ( $P=0.362$ ). Muscle glycogen concentrations increased over time to  $261 \pm 26$ ,  $289 \pm 35$  and  $315 \pm 28$  mmol·kg<sup>-1</sup> dry weight in the GLU, GLU+FRU and GLU+SUC treatment, respectively ( $P<0.001$ ), with no differences between treatments (time x treatment,  $P=0.757$ ). Conclusion Combined ingestion of glucose plus fructose or glucose plus sucrose does not further accelerate post-exercise muscle glycogen repletion in trained cyclists when ample carbohydrate (1.5 g·kg<sup>-1</sup>·h<sup>-1</sup>) is ingested.

### **SUPPLEMENTATION WITH MILK PROTEIN PROMOTES SIMILAR CHANGES IN STRENGTH AND MUSCLE MASS AS ISOCALORIC SUPPLEMENTATION OF NATIVE WHEY DURING 11 WEEKS OF STRENGTH TRAINING IN ELDERLY**

Johansen, M., Hamarsland, H., Seeberg, F., Raastad, T.  
*Norwegian School of Sport Sciences*

**Introduction** Milk proteins, and especially the whey fraction of milk protein, have gained interest because of their effectiveness in stimulating muscle protein synthesis in the first hours after ingestion (1). Whey protein is rapidly digested and absorbed; giving a rapid increase in plasma leucine concentration, which seems to be one of the triggers of muscle protein synthesis (2). Whey protein isolated by a new filtration technique may be a potent stimulator of muscle anabolism because proteins are preserved in a more native form (native whey) and it has a higher concentration of leucine than regular whey. Elderly seems to need higher dosages of the same protein to achieve similar increases in protein synthesis as younger subjects (3). However the 'leucine trigger' hypothesis suggests that fast digestible proteins with high leucine concentrations could lower the optimal protein dose in elderly and thereby promote increases in muscle mass in combination with strength training (4). In this study we investigate whether ingesting native whey protein leads to greater hypertrophy during 11 weeks of strength training than normal milk protein in elderly subjects. **Methods:** A total of 26 elderly subjects (70-88 years) were randomized to either a milk protein or a native whey supplemented group. Both groups performed heavy load strength training over a period of 11 weeks consisting of three supervised exercise sessions per week, following a daily-undulating linear progression. Subjects were supplemented with two doses of 20g of protein per day only differing in protein type (native whey vs. milk protein). The experiment was conducted as a double blinded-randomized controlled trial. **Results** The Native Whey and the Milk protein supplemented group achieved similar gains in lean body mass (measured by DXA) with mean gains of  $1.8 \pm 1.1$  kg (3.7%) and  $2.4 \pm 1.2$  kg (5.2%) respectively. Regional measurements showed an increase in m. vastus lateralis thickness (US) of  $13 \pm 9$ mm (6.1%) for Native Whey, and  $15 \pm 11$  mm (7.2%) for Milk. Strength measured as 1RM in leg press increased by  $37 \pm 16$  % ( $p<0.01$ ) for Native whey, and by  $31 \pm 14$ % for Milk and 1RM in chest press increased by  $22 \pm 7$  % for Native Whey, and  $24 \pm 18$ % for Milk. All changes were significantly different ( $P<0.05$ ) from pre-values, but there were no significant differences between the two groups. The groups were not different in any variables at baseline. Conclusion Our results suggests there was no added effect of consuming native whey protein compared to normal milk on the accumulation of lean mass and increases in strength when given in two 20 g protein doses per day in addition to a normal healthy diet. **References** 1. ### **DIETARY DETERMINANTS OF THE MAXIMAL CAPACITY FOR FAT OXIDATION DURING EXERCISE**

Fletcher, G.1, Glover, E.I.2, Eves, F.F.1, Thompson, J.T.1, Wallis, G.A.1  
*1 University of Birmingham, 2 GSK, UK*

**Introduction** Substantial inter-subject variation exists in the maximal capacity to oxidize fat (MFO) during exercise, which may have implications for metabolic health and athletic performance. Venables et al (2005) reported that non-nutritional factors (maximal aerobic capacity [VO<sub>2</sub>max], self-reported physical activity level [SRPAL] and sex) explained 12% of the variability in MFO. Habitual diet is known to affect the metabolic response to exercise yet its influence on MFO has not previously been determined. **Methods** Healthy volunteers (150 Men, 155 Women; age  $25 \pm 6$  yrs.; BMI  $23 \pm 2$  kg/m<sup>2</sup>; VO<sub>2</sub>max  $50 \pm 8$  ml/kg/min [data are mean  $\pm$  SD]) performed an incremental treadmill exercise test with indirect calorimetry employed to determine MFO and VO<sub>2</sub>max. Dual-energy x-ray absorptiometry (DXA) was used to assess body composition. SRPAL and dietary intake (weighed food intake) was recorded for the four days prior to exercise testing. Significant bivariate correlations between MFO and predictor variables were entered into hierarchical multiple linear regression models to quantify each independent variable's influence on MFO. An exploratory analysis of the determinants of MFO within each sex was also performed. **Results** Mean MFO was  $10 \pm 3$  mg/kg fat free mass (FFM)/min (range: 3-20 mg/kg FFM/min), and was greater in women than men ( $11 \pm 3$  vs.  $10 \pm 3$  mg/kg FFM/min,  $P<0.05$ ). VO<sub>2</sub>max (L/min) ( $\beta = .14$ ), sex ( $\beta = .14$ ), fat mass (FM) ( $\beta = -.14$ ) and SRPAL ( $\beta = .26$ ) explained 17.4% ( $P<0.01$ ) of the inter-subject variability in MFO, with dietary carbohydrate (CHO) ( $\beta = -.19$ ), protein ( $\beta = -.13$ ) and fat ( $\beta = .15$ ) intake explaining an additional 3.1% ( $P<0.01$ ) of the variance. In men, the majority of the explained variance in MFO could be attributed to VO<sub>2</sub>max ( $\beta = .18$ ) and SRPAL ( $\beta = .22$ ) (12.6%,  $P<0.01$ ), with the intake of protein ( $\beta = -.17$ ) and CHO ( $\beta = -.15$ ,  $P=0.10$ ) explaining an additional 2.5% ( $P<0.05$ ). In women, the majority of the explained variance in MFO could be attributed to SRPAL ( $\beta = .32$ ) and FM ( $\beta = -.18$ ) (19.3%,  $P<0.01$ ), with the intake of CHO ( $\beta = -.21$ ) and fat ( $\beta = .19$ ) explaining an additional 4.3% ( $P<0.01$ ). **Discussion** Previously identified non-nutritional determinants of MFO comprised the majority of the explained inter-subject variation in MFO while habitual dietary intake of CHO, fat and protein made modest additional contributions. Our exploratory analyses suggest that the intakes of protein for men but fat and CHO for women make additional contributions to MFO. In conclusion, habitual macronutrient intake is an additional modifiable factor to the previously identified determinants of MFO, which could be targeted in interventions aiming to optimise metabolic health and athletic performance. **References** Venables et al (2005). *J Appl Physiol* 98:160-167 Contact GXF243@bham.ac.uk

### **EFFECTS OF DIFFERENT TIMING OF ICE SLURRY INGESTION BEFORE EXERCISE ON ENDURANCE EXERCISE CAPACITY AND THERMOREGULATION**

Takeshima, K., Onitsuka, S., Zheng, X.Y., Hasegawa, H.  
*Hiroshima university*

**Introduction** Ice slurry ingestion has been recently attracted attention as precooling procedure before exercise. It may not cause the decrease in muscle temperature, so it may be more effective to ingest ice slurry immediately before exercise. However, most previous

studies using ice slurry treated precooling only before warm-up (W-up) and the appropriate timing of ice slurry ingestion has been unclear. The purpose of this study was to investigate the effect of difference in the timing of ice slurry ingestion before or after W-up on endurance exercise capacity and thermoregulatory response in a warm environment. Methods Nine active male subjects completed three experimental cycling trials at 55% maximum voluntary exercise to exhaustion at 30°C and 80% relative humidity. Three experimental conditions set for thermoneutral water (37°C) ingestion both before and after W-up (CON), ice slurry (−1°C) ingestion before W-up and water ingestion after W-up (PRE), water ingestion before W-up and ice slurry ingestion after W-up (POST). Subjects ingested 7.5 g/kg drinks within 15 min both before and after W-up. Exhaustion was considered to have occurred when the subject was unable to keep pace (60 rpm) or rectal temperature reached at 39.5°C. Results In POST, time to exhaustion was significantly longer than CON (POST : 59.8±9.8 min, CON : 52±12.6 min,  $P < 0.05$ ). Rectal temperature (Tre) and mean skin temperature (Tsk) at the beginning of exercise in POST was significantly lower than CON and PRE ( $P < 0.05$ ). Tre at exhaustion in PRE tended to be higher than CON ( $P = 0.099$ ) and POST ( $P = 0.069$ ). The rate of increase in Tre during exercise ( $\Delta$ Tre) in PRE tended to be higher than CON ( $P = 0.051$ ). Heart rate, thermal sensation and rating of perceived exertion during exercise were not different among the three conditions. Discussion Endurance exercise capacity in POST was improved due to the following two mechanisms. First, the decrease in Tre increased heat storage capacity (Siegel et al., 2012) and led to delay reaching the exhaustion. Second, the decrease in Tsk increased peripheral heat storage capacity (Kay et al., 1999) and this may prevent larger  $\Delta$ Tre by easier core-to-skin heat transfer. On the other hand, endurance exercise capacity in PRE was not improved because of larger  $\Delta$ Tre. Some previous studies which ingested ice slurry also reported larger rate of increase in core temperature. This may impair the effect of precooling. Moreover, many subjects in PRE completed exercise with higher Tre, so ice slurry ingestion before W-up may cause heat illness. Therefore ice slurry ingestion after W-up is more safety and effective for the exercise capacity in the heat. References Siegel R et al. (2012) J Sports Sci 30(2): 155-65. Kay D et al. ### THE INFLUENCE OF BEETROOT JUICE ON RECOVERY FROM A SINGLE BOUT OF STRENUOUS EXERCISE

Clifford, T., Bell, O., West, D.J., Howatson, G., Stevenson, E.J.

*Northumbria University*

Introduction Exercise induced muscle damage (EIMD) is characterised by muscle soreness, acute inflammation and impaired muscle function. These symptoms can persist for several days, and subsequently hamper recovery. Emerging evidence suggests that supplementation with antioxidant rich foods might attenuate EIMD and hasten the recovery of muscle function. Red beetroot is a rich source of phenolic compounds and also contains a group of bioactive pigments known as betalains, which possess potent antioxidant and anti-inflammatory functions that might facilitate recovery following strenuous exercise. Thus, the aim of this study is to investigate the effects of beetroot juice on recovery following a single bout of muscle damaging exercise. Methods This study employed a double blind, placebo controlled, independent groups design. Thirty recreationally active males were allocated to consume a high dose beetroot juice (250 ml), a low dose beetroot juice (125 ml), or an isocaloric placebo immediately after, 24 and 48 h following 100-drop jumps. Muscle function (maximal voluntary contraction: MVC, countermovement jump: CMJ, reactive strength index: RSI), muscle soreness (visual analogue scale: VAS, pressure-pain threshold: PPT) and blood indices of skeletal muscle damage (creatinase: CK) were measured pre, post, 24, 48 and 72 h following the drop jumps. Results CMJ performance recovered quicker in the high beetroot juice group vs. placebo at 48 (-8.3 ± 12.4% vs. -25.6 ± 13.14% of baseline value;  $P = 0.008$ ) and 72 h post exercise (-6.6 ± 7.7% vs. -14 ± 5.9% of baseline value;  $P = 0.046$ ). There were no significant group differences for MVC and RSI ( $P > 0.05$ ). PPT was significantly reduced in the placebo vs. both the high and low beetroot juice groups at 24, 48 and 72 h post exercise ( $P < 0.001$ ). No group differences were detected in subjective muscle soreness, as measured with the VAS, or CK ( $P > 0.05$ ). Discussion The primary findings of this study were that beetroot juice; 1) attenuated the loss in muscle force generating capacity, as measured by improved CMJ performance, and; 2) reduced muscle soreness, as indicated by an increase in PPT. Furthermore, a dose-dependent response was also evident given that only the high beetroot juice dose improved CMJ performance. Potentially, beetroot juice blunted the acute inflammatory response, which may have limited further structural damage to the muscle cell; however, we did not measure inflammation and therefore further studies are required to confirm the current observations and to clarify the potential mechanisms behind these findings. Notwithstanding, beetroot juice may serve as a useful strategy to accelerate recovery following strenuous exercise, at least in recreationally active males. Contact tom.clifford@northumbria.ac.uk

### ACUTE EFFECTS OF GUM CHEWING AND HIGH INTENSITY EXERCISE ON APPETITE-REGULATING HORMONES AND ENERGY INTAKE

Kashiwabara, K., Odagiri, Y., Sakata, N., Kidokoro, T., Edamoto, K., Hasegawa, M., Hisabori, S., Yanaoka, T., Yamagami, J., Miyashita, M.

*Tokyo gakugei university*

Introduction An acute bout of exercise is one important strategy that has been shown to consistently induce a reduction in relative energy intake, taking into account the cost of exercise (1), and alter appetite-regulating hormones, including ghrelin and peptide YY (PYY) (2) in humans. However, the acute effects of increased mastication by gum chewing on appetite-regulating hormones and energy intake are unclear. In addition, no data are available regarding the combined effects of gum chewing and exercise on appetite-regulating hormones and energy intake. The main purposes of this study were to examine the effects of gum chewing/the combined effects of gum chewing and exercise on appetite-regulating hormones and energy intake. Methods Fourteen healthy young men (age 21.4 ± 1.2 years) underwent five, 1-day trials in a randomised order: 1) control, 2) gum chewing, 3) exercise, 4) gum chewing + exercise and 5) exercise + gum chewing. In trials that include gum chewing, the participants chewed gum 60 times per minutes for 30 minutes between 0800 and 0900 depending on the trial order. In trials that include exercise, the participants ran for 30 minutes at 80.0 ± 5.6% of heart rate reserve between 0800 and 0900 depending on the trial order. The participants then rested 3 hours until an ad libitum buffet lunch provided between 1200 and 1300. Energy intake was measured in ad libitum buffet lunch between 1200 and 1300. Plasma concentration of ghrelin and P YY were measured at 0800, 0830, 0900, 1030, 1200 and 1300. Results There were no between-trial differences in appetite-regulating hormones (two-factor ANOVA, ghrelin,  $P > 0.05$ ; PYY,  $P > 0.05$ ) and absolute energy intake (one-factor ANOVA,  $P > 0.05$ ) among trials, including the gum chewing trial. The combination of gum chewing and exercise did not alter appetite-regulating hormones (two-factor ANOVA, ghrelin,  $P > 0.05$ ; PYY,  $P > 0.05$  for trial effects) and absolute energy intake (one-factor ANOVA,  $P > 0.05$ ). Relative energy intake was lowered in the exercise trials (Gum chewing + exercise, 336 ± 169 kJ; Exercise + gum chewing, 278 ± 140 kJ) than the gum chewing (440 ± 123 kJ) (one-factor ANOVA,  $P \leq 0.137$ ) and/or control trials (446 ± 145 kJ) (one-factor ANOVA,  $P < 0.05$ ). Discussion These findings suggest that gum chewing may not play a role in short-term appetite regulation. Our findings, however, support the previous study (1) that in response to an acute bout of high intensity exercise, individuals do not compensate for the expended energy by increas-

ing their food intake at least 3 h afterward. References 1. King JA, Miyashita M, Wasse LK, Stensel DJ. *Appetite*. 2010;54:492-498. 2. Kawano H, Mineta M, Asaka M, Miyashita M, et al. *Appetite*. 2013;48:26-33.

#### SPECIFIC BIOMECHANICAL DIFFERENCES EXIST ACROSS SKILL LEVELS FOR HIGH VELOCITY FOOTBALL KICKS

Bauer, M.1, Trudeau, M.B.1, Nigg, S.R.1, Coza, A.2, Nigg, B.M.1

1: *UCalgary (Calgary, AB, Canada)*; 2: *adidas group (Portland, OR, USA)*

**Introduction** One of the most important movements in a football game is the kick, yet little is known about specific biomechanical variables that differ between skill levels. Variables that have been found to affect performance for high velocity kicks include a high knee angular velocity and a plantarflexed ankle (Shan and Westerhoff, 2005). Quadriceps and hamstring muscles are most active during the terminal stage of backswing and prior to ball contact (De Proft et al., 1988). This study's objective was to understand functional aspects of technique that differ between athletes. We hypothesized that biomechanical variables would differ between skill levels, particularly at the foot/ankle level. **Methods** Ten male participants were classified into a high and a low level group. They were instructed to perform ten high velocity kicks each. Muscular activity was measured from 6 muscles of the kicking and support leg using electromyography (EMG), full body kinematics were obtained using 3D motion capture, and the velocity of the ball was recorded using a radar gun. Wavelet analysis was used to resolve EMG data into intensities, and joint angles and segment angular velocities were calculated from the kinematic marker trajectories. **Results** High level athletes had less deviation of the foot angular velocity at contact with the ball ( $p=0.03$ ), a greater thigh angular velocity throughout the kick ( $p=0.01$ ), and a more abducted kicking leg at ball contact ( $p=0.045$ ) compared to low level athletes. The EMG intensity of the high level group was greater for the gastrocnemius and biceps femoris muscles ( $p=0.07$  and  $0.03$ , respectively) throughout the kick. **Discussion** The results support the hypothesis that high and low level football players display distinct biomechanical differences. The lower deviation in the foot's angular velocity at ball contact for the high level group indicates their ability to stiffen the ankle, which they achieve through greater muscle activity of the gastrocnemius muscle. We speculate that the greater hip abduction allows the athlete to impact the ball at a different location and orientation of the foot. The greater biceps femoris muscle activation was likely a consequence of actively extending the hip during backswing, and slowing down the leg at the end of follow-through. These findings, combined with a real time foot swing and orientation monitoring device, can be used in the development of a virtual coaching system aimed at helping recreational football players achieve a greater ball velocity. **References** De Proft E, Clarys J, Bollens E, Cabri J, Dufour W (1988). #### DIFFERENCES IN RANGE OF MOTION AND FEET PRESSURE BETWEEN SKIING WITH AND WITHOUT RIFLE IN FEMALE BIATHLETES.

Jonsson, M., Laaksonen, M.S.

*Swedish Winter Sports Research Center, Mid Sweden University*

**Introduction** Biathlon combines cross-country skiing (CCS) while carrying a rifle and rifle marksmanship. During CCS the biathletes use skating technique. In skating the most used gear is gear 3 (Andersson et al. 2010) that is used in light and moderate uphill. Carrying the rifle during CCS affects the biomechanical responses (Stöggl et al. 2014) but less is known about how carrying a rifle affects the range of motion and feet pressure during CCS in gear 3. **Methods** Seven well trained female biathletes (19±1 years, 1,65±0,07 m, 62±6 kg) were skiing 4 laps on snow using gear 3 skating technique on a 1250 m long track. The skiing velocity was as to be "racing speed" and two laps were skied with rifle (R) and two laps without (NR) in a randomized order. The weight of the subjects rifles was 4,0 ± 0,2 kg. The athletes were wearing a 3D-suit (Noraxon) with 16 measuring points (sampling frequency, SF, 200 Hz) and pressure insoles (Moticon) in their shoes (SF 50 Hz). **Results** The skiing times for the laps was shorter with NR compared to R (196±12 vs 201±12 s,  $p<0,01$ ) although the average heart rate was similar (89±3% of HRmax for both NR and R). In a specific uphill section, six cycles of gear 3 skating technique were analyzed. No difference in cycle time was found between R and NR (1,88±0,10 vs 1,87±0,14 s). Range of motion was smaller for R than NR in knee flexion (left: 30±7 vs 32±5°,  $p<0,05$ ; right: 31±4 vs 33±4°,  $p<0,05$ ), shoulder flexion (left: 74±13 vs 88±10°,  $p<0,05$ ; right: 59±18 vs 85±5°,  $p<0,01$ ) and hip flexion (left: 32±8 vs 42±3°,  $p<0,01$ ). Feet pressure was higher in the two zones in the center of the medial part of the feet in R compared to NR (left: 2,4±1,3 and 5,1±1,2 vs 2,2±1,3 and 4,9±1,1 N/cm<sup>2</sup>,  $p<0,05$  and  $p<0,01$ ; right: 2,02 ± 1,22 and 3,22 ± 1,27 vs 1,85 ± 1,21 and 2,96 ± 1,15 N/cm<sup>2</sup>, both  $p<0,05$ ). **Discussion** Carrying a rifle decreases the range of motion in shoulder, knee and hip flexion for female biathletes. In addition, the increased pressure in the medial part of the feet indicates changed balance pattern during skiing with rifle. These findings are in line with Stöggl et al. (2014) who showed changed skiing biomechanics when carrying rifle. These aspects should also be considered in biathlon training. **References** Andersson, E., Supej, M., Sandbakk, Ø., Sperlich, B., Stöggl, T. & Holmberg, H.C. (2010). #### GAIT ANALYSIS OF OBESE ADOLESCENT'S UPHILL WALK: KINEMATIC AND KINETIC ADAPTATIONS COMPARED TO NORMAL WEIGHT ADOLESCENTS

Strutzenberger, G.1, Graf, E.1,2, Bamboschek, D.1, Nußdorfer, A.1, Alexander, N.1, Langhof, H.3, Schwameder, H.1

1: *University of Salzburg, Austria*, 2: *German Sports Institute Cologne, Germany*, 3: *Klinik Schönsicht (Berchtesgaden, Germany)*

**Introduction** Obesity can already contribute in childhood and adolescents to orthopaedic problems (e.g. Shultz et al., 2009). Weight loss programs often include walking and hiking, however, limited knowledge about the joint loading induced by inclined gait exists. Obese adults are exposed to lower joint loading when walking uphill with slower gait velocity (Ehlen et al., 2011), but it is not known which mechanism occur for adolescents walking with same speed of normal weight peers. **Methods** Ten obese (15 ± 2 yrs, 88.6 ± 16.8 kg) and 16 normal weight adolescents (15 ± 2 yrs, 52.4 ± 5.9 kg) were asked to walk a with two force plates (AMTI, 1000 Hz) instrumented ramp with

the inclinations 0°, 6° and 12° with a speed of 1.1 m/s. Kinematic data were analysed with an 8 camera motion capture system (Vicon, 250Hz). Temporo spatial gait parameters, maximal vertical ground reaction force (vGRF) and sagittal knee angle and joint moment were statistically analysed using a 2 factor ANOVA (weight x inclination). Kinetic data was normalized to bodyweight. Results Inclination had a significant effect on all parameters except step width, while the obese adolescents showed significantly longer relative stance times, higher peak absolute vGRF (peak 1 and 2), but lower relative vGRF (peak 2). Additionally higher knee flexion angles were observed in all inclinations for obese participants. However, the relative sagittal knee joint moment was similar between both weight groups. Discussion Ehlen et al. demonstrated that walking uphill with equal metabolic cost results in lower walking speed, but also lower knee joint moments for obese adults. This study demonstrates, that using the same gait velocity, obese adolescents walk uphill with higher knee flexion angles (approx. 10°) than their normal weight peers, but that their relative knee joint moment was equal to their normal weight counterparts. This supports the theory of DeVita & Hortobágyi (2003) from level walking that obese individual can reorganize their neuromuscular function during gait to maintain skeletal health, even though the strategy chosen differed in this study's population. ### DAILY CHANGES OF INDIVIDUAL GAIT PATTERNS

Horst, F., Kramer, F., Schäfer, B., Eekhoff, A., Hegen, P., Schöllhorn, W.I.

*Johannes Gutenberg University Mainz*

Introduction Biomechanical diagnoses and clinical interventions typically assume nearly constant movement patterns in their subjects. Clinical gait analysis often seeks to evaluate intervention related changes in walking by averaging the data from a number of trials and compare these average values to control subjects that did not undergo an intervention or to previous measurements in a pre-post-design. Despite the knowledge of continuous changes in living systems, movement variability without an intervention is neglected as insignificant in many approaches of movement analysis (Newell et al., 2006). The aim of this study is to look for the reliability of gait patterns from different test days by means of support vector machines. Methods Eight healthy and physically active subjects (23.5 ± 2.3 years) performed 15 gait trials at a self-selected speed on each of the eight test days within two weeks under barefoot conditions. For each trial, the continuous ground reaction forces (Kistler, 1000 Hz) and lower body joint angles (Qualisys, 250 Hz) of one gait cycle were analyzed. An eight-day-classification and one-on-one-classification of support vector machines were carried out for each subject individually. The classification rates were provided by the Liblinear Toolbox 1.4 (Fan et al., 2008) using a leave-one-out cross-validation. Results The mean classification rates for the eight-day-classification are sagittal (71.4 ± 10.4%), frontal (90.7 ± 8.4%), coronal (92.1 ± 8.2%) and combined (95.9 ± 5.8%) joint angles. The mean classification rates for the eight-day-classification are fore-aft (49.6 ± 9.2%), medial-lateral (49.5 ± 9.9%), vertical (48.4 ± 8.7%) and combined (60.1 ± 9.2%) ground reaction forces. The mean classification rates for the one-on-one-classification are sagittal (88.7 ± 5.7%), frontal (95.9 ± 2.2%), coronal (96.9 ± 2.1%) and combined (98.1 ± 1.1%) joint angles. The mean classification rates for the one-on-one-classification are fore-aft (82.5 ± 7.7%), medial-lateral (80.9 ± 6.1%), vertical (83.2 ± 8.2%) and combined (86.1 ± 6.7%) ground reaction forces. Discussion The eight-day-classification rates of 95.9% and 60.1% clearly differ from a random classification of 12.5% and show natural differences between the gait patterns of different days. Hence, changes in gait patterns appear naturally without a specific intervention between the test days. Additionally, the one-on-one-classification points out a general problem of studies with pre-post-design. ### A KINEMATIC COMPARISON OF NON-MOTORIZED TREADMILL AND OVERGROUND WALKING

Hirano, T.1, Kashiwagi, Y.1, Hakamada, N.2, Yamagishi, M.1, Kaneko, K.3, Funato, K.1

*1: Nippon Sport Science University (Tokyo, Japan), 2: Japan institute of sports science (Tokyo, Japan), 3: Tokushima Bunri University (Tokushima, Japan)*

Introduction Motor-driven treadmill is often used in gait analysis and gait training. Many researchers compared gait parameters such as step frequency and step length as well as kinematic and kinetics during gait on treadmill to normal gait on ground. Recently, curve-shaped non-motorized treadmill was developed for walking. However, the special configuration (curve-shape) which gives to human body during walking movement has not well understood. The purpose of this study was to compare the kinematic parameters during walking on curve-shaped non-motorized treadmill (TM) to those of obtained from normal overground (OG) at identical speed condition. Methods Ten health young subjects (age: 25.0±3.7yrs, BH: 172.3±3.5cm, BW: 68.9±7.8kg) walked 12m walkway at preferred speed. Motion capture (VICON MX20 Oxford: 200fps) and force plate data (Kistler: 1000Hz) for full gait cycle were recorded. The average walking speed of OG trials was used for the TM trials (Curve: Woodway) and TM belt speed were visual feedback to a subject. Spatio-temporal parameter, lower limb joint angle and joint angular velocity data were compared with between TM and OG conditions. Results and Discussion Walking speed of both conditions were quite similar. Significant higher stride frequency and shorter stride length on TM walking was indicated compare with OG condition (p<0.001). Flexion angles at hip and knee were significantly different between TM and OG walking during swing phase (p<0.05). Peak angular velocities at hip and knee were higher in TM than OG (p<0.05). Conclusions Curve-shaped non-motorized treadmill was characterized as higher stride frequency as well as higher flexion angular velocities at hip and knee during swing phase. ### USE OF MOTION CAPTURE SYSTEM IN RUSSIAN TEAMS TRAINING FOR SOCHI OLYMPIC GAMES

Shestakov, M.

*Training Center of Russian Teams*

Introduction A Qualisys Motion Capture System was part of a testing complex used by the Russian national teams during their preparation for the Winter Olympic games 2014. Methods The test complex consisted of 18 cameras Oqus 300 (AB Qualisys, Sweden), two AMTI force plates (AMTI, USA), and Cortex gas analyzer (Cortex, Germany), extra-wide treadmill (Fitnex, USA). Top Russian athletes, candidates for National Olympic teams in cross-country skiing (n=18), bobsleighbing (n=24), ski jumping (n=8), Nordic combined (n=8), freestyle skiing moguls (n=18), curling (n=6), luge (6), biathlon (12), speed scating (8), curling (6). As a rule, testing was done at the end of each stage of a year-long training cycle. Testing procedures were adjusted taking into account specificity of every sport discipline. Specific software pack-

ages for data processing and generating of final protocols for coaches were developed. Results For cyclic sports high-speed video records helped to estimate mechanical efficacy of the locomotion at each stage of the test taking into account intra-cyclic angular and temporal parameters of displacement of lower extremities' joints and the center of mass, as well as changes in potential and kinetic energy of the athlete's body. Functional capacity and effectiveness of energy supply in skiers and biathletes was estimated during a graded exercise test performed Sports based on strength&velocity qualities. Biomechanical parameters registered in specific tests helped to reveal peculiarities of movement control in movements with complex coordination, estimate realization efficacy of competitive exercise technique, and assess strength and velocity qualities in athletes. Results help coaches to estimate potential abilities of the athletes and develop individual plans of strength training for each of them. Contact mshtv@mail.ru

### ALGORITHM FOR BIOMECHANICAL RESEARCH OF A COMPETITIVE ROUTINE IN TRAMPOLINE

Angelov, V.

*National Sports Academy*

Introduction In recent years, the biomechanical research in sport, including gymnastic disciplines, played a major role in the science research. The review of the information sources [1-13] on the issue showed that the technique of single exercises is mainly studied. This fact led to the idea to explore the whole competitive routines in trampoline. The purpose of this paper was to explore the main kinematic parameters of sports technique in trampoline during the execution of the competitive routine. In order to achieve the objective the following tasks were decided: 1. Video shooting of the first trampoline routine by observing the special requirements of biomechanical research. 2. Preparation of the video for working with computer programs. 3. Kinematic study of a competitive routine by using specialized software. 4. Elaboration of algorithm to study the technique of a whole routine in trampoline. Methods The study was realized by using the following scientific methods: videocyclegraphy, acselelography, kinematic analysis and others. Results Results include an analysis of the kinematic parameters, which were registered during the implementation of first routine in trampoline. It contains ten exercises. The analysis of collected data caused several conclusions. On this base, an algorithm for researching the technique of execution of the whole competitive routine was presented. Bibliography: 1. ### EFFECT OF BODY MASS ON KINETIC VARIABLES DURING A BASKETBALL LAYUP

Nin, Z.D., Lam, W.K., Cheung, J.T., Kong, P.W.

*Nanyang Technological University*

Introduction Basketball is a sport which places a considerable amount of stress on the lower extremities of players. Inability to attenuate excessive impact forces on the body might lead to injury (Lephart, 2002). Individual characteristics such as body mass, joint stiffness or landing technique might have an effect on landing forces. The aim of this study was to investigate if an individual's body mass would influence kinetic variables during the performance of a basketball layup. Methods Thirty male university basketball players (age: 21.80 ± 2.77 years) participated in this study. Only participants with a foot length of US size 9.0 ± 0.5 for both feet were recruited. Participants were categorised into two different groups according to their body mass: "heavy" (mass: 82.66 ± 4.31 kg, height: 1.81 ± 0.03 m) and "light" (mass: 63.11 ± 2.79 kg, height: 1.74 ± 0.04 m). Each participant performed five layups in the same size US 9.0 shoe (Li Ning prototype with a plain midsole of shore 42C). Vertical ground reaction forces (vGRF) of the first step (right leg) and landing (double-leg) of the layup were captured at 1 kHz using two 0.9 m x 0.9 m wood-top force platforms. Peak vGRF and mean loading rate (LR), normalised to body weight (BW), were analysed. Results Rearfoot mean LR during the first step of the layup was significantly higher ( $p = .027$ ) in the "heavy" group (77.8 ± 24.8 BWs-1) compared to the "light" group (57.6 ± 22.4 BWs-1). There were no significant differences in rearfoot peak vGRF, forefoot peak vGRF and forefoot LR between groups during the layup first step. During the landing of the layup, no significant differences in any kinetic variables were found. Discussion For all participants, the initial ground contact of the layup first step was made with the heel and this contact with the ground is also known as the impact phase of a step. Higher rates of loading during this impact phase have been found to correlate with higher incidences of lower limb injuries (Hamill et al., 2008). This suggests that heavier players may be exposed to a greater risk of overload injuries at the lower limbs than lighter players when performing layup maneuvers. Conclusion Heavier players and their coaches should be mindful of the higher loading during movements similar to a basketball layup. Proper footwear and landing technique could help attenuate these impact forces and their effect on cushioning deserves further investigation. It would also be useful to examine how body mass affects lower limb kinematics and multiple joint loadings during realistic sporting tasks. References Lephart S. (2002). J Athl Training, 37, 71-79. ## Mini-Orals

MO-PM05 Oxygen transport, VO<sub>2</sub>max and energy expenditure

## OXYGEN TRANSPORT, DIFFUSION AND UTILIZATION DURING SPRINT EXERCISE IN HUMANS

Pérez-Suárez, I., Losa-Reyna, J., Torres-Peralta, R., Ponce-González, J.G., Morales-Álamo, D., Lundby, C., Calbet, J.A.

*University of Las Palmas de Gran Canaria*

**Introduction** The contribution of the aerobic metabolism has been considered almost negligible for all-out sprint exercise lasting up to 10s. However, leg VO<sub>2</sub> during whole body sprint exercise has never been measured in humans. Therefore, the aim of this study was to determine the contribution of convective and diffusive limitations to VO<sub>2</sub>peak during sprint exercise in humans. We hypothesised that in severe hypoxia (Hyp), but not in normoxia (Nx), sprint performance is limited by O<sub>2</sub> delivery, the kinetics of O<sub>2</sub> off-loading from the hemoglobin (Hb) and muscle O<sub>2</sub> diffusing capacity (MDO<sub>2</sub>). **Methods** Oxygen transport and haemodynamics were measured during incremental exercise to exhaustion (IE) and 120 min later, Wingate test, both in Nx (PIO<sub>2</sub>:143 mmHg) and severe hyp (PIO<sub>2</sub>:73 mmHg) in 11 men (22±2 yr). Isokinetic Wingate tests (Lode, 80 rpm) were carried out with 6-7% carboxihaemoglobin (COHb) in blood to left-shift the oxyhaemoglobin dissociation curve. Leg VO<sub>2</sub> was measured by the Fick method, and leg blood flow (BF) with thermodilution. MDO<sub>2</sub> was calculated by numerical integration (PMID: 15919729). **Results** The mean power output (MPO) during the 30s sprint was reduced by 7% in Hyp (P<0.05). During the first 10 s of sprint, MPO was 12% lower in Hyp than Nx (567±90 and 499±86 w, P<0.05). This suggests a central (neural) limiting mechanism at the start of sprint, since leg VO<sub>2</sub> was similar in Nx and Hyp (131±34 and 129±26 ml, respectively P=0.87), and pulmonary VO<sub>2</sub> as well (452±145 and 478±108 ml, P=59). Wingate peak leg BF, leg O<sub>2</sub> delivery and leg VO<sub>2</sub> were, 5, 28 and 23% lower in Hyp than Nx (P<0.05). Peak Wingate MDO<sub>2</sub> was 20.5±3.0 and 51.5±9.7 ml min<sup>-1</sup> mmHg<sup>-1</sup>, in Nx and Hyp (P<0.05). Despite similar PaO<sub>2</sub> during IE and Wingate tests in Hyp (33 and 34 mmHg), as well as similar mean capillary PO<sub>2</sub>, peak perfusion, and vasodilation near exhaustion, peak MDO<sub>2</sub> was 12% higher during sprint than IE in Hyp. Apparently, MDO<sub>2</sub> was insensitive to COHb (0.7 vs 7%, in IE Hyp and Wingate Hyp, P<0.05). At exhaustion, the Y equilibration index was well above 1.0 in both conditions, reflecting greater convective than diffusive limitation to the O<sub>2</sub> transfer in Nx and Hyp. **Discussion and conclusions** We have shown that muscle VO<sub>2</sub> during sprint exercise is not limited by O<sub>2</sub> delivery, the O<sub>2</sub> off-loading from the haemoglobin or structure-dependent diffusion constrains in the skeletal muscle of young healthy men. Moreover, a remarkable functional reserve in muscle O<sub>2</sub> diffusing capacity still available at exhaustion during exercise in Nx, which is recruited during exercise in Hyp. Severe hypoxia reduces sprint performance by central mechanisms even in short sprints. **Acknowledgements** MINECO Spain (DEP2009-11638).

## ENERGY COST OF BACKWARD RUNNING AT POSITIVE GRADIENTS

Rasica, L.1, Pavei, G.2, Bellistri, G.1,2, Ramaglia, M.1, Crociani, B.1, Marzorati, M.1, Porcelli, S.1

*1: CNR, Segrate (MI), Italy 2: University of Milan (MI), Italy*

**Introduction** Backward walking (BW), on level, has a greater (100%) energy cost (C) than forward walking (FW) due to an impaired ability to exchange potential and kinetic energy. On gradients (+15-32%), C of FW increases according to a reduced capacity to use the pendulum-like mechanism, and the difference between BW and FW is reduced to 5-8% (Minetti & Ardigò, 2001). As for running on level, C of backward running (BR) is 30% higher than forward running (FR) (Flynn et al, 1994). A greater external work, and an higher stride frequency (SF) (internal work) explain only part of the higher C in BR. A lower efficiency in BR attributable to a reverse landing-take off asymmetry, and therefore a lower elastic recoil, seems to be another possible explanation for this discrepancy (Cavagna et al., 2011). To our knowledge, C during BR on gradient has not yet been determined. **Aim** of this study was to compare C of BR and FR on positive gradients. Since in FR store and release of elastic energy decrease with gradient, we hypothesized that the difference in C between BR and FR reduces with the gradient. **Methods** Tests were performed on 10 young (age 26±3 yr) male athletes (V̇O<sub>2</sub>peak 64.5±2.1 ml\*kg<sup>-1</sup>\*min<sup>-1</sup>). Subjects ran both forward and backward several 5-min bouts on an electrically driven treadmill. Gradient was modified from 0% to 20%. Breath-by-breath oxygen consumption (V̇O<sub>2</sub>) was measured and C was calculated using resting and steady-state V̇O<sub>2</sub> values. SF was obtained by analysing the periodicity in the 30-s video recording (240 Hz). **Results** On level, C was significantly (p<0,01) higher in BR than in FR (5,41±0,67 vs 3,70±0,43 J\*kg<sup>-1</sup>\*m<sup>-1</sup>). A linear relationship between C and slope was found both in BR (r<sup>2</sup>=0,98, p=0,001) and in FR (r<sup>2</sup>=0,99, p<0,001). The difference in C between BR and FR did not decrease with the gradient, setting to a value of 35%. SF did not change with the gradient in FR, and it was significantly (p<0,05) higher in BR than in FR on every gradients. **Discussion** This is the first study showing C of BR on gradient. Differently from walking, gradient did not affect the difference in C between BR and FR. These results confute our hypothesis and lead to suspect that elastic energy utilization is not the main responsible for the higher C of BR. The difference in C between BR and FR could be partially explained by a different internal work, as suggested by a higher SF in BR. Further studies are needed to better clarify the biomechanical aspects of BR at different gradients. **References** Minetti AE & Ardigò LP (2001) Pflügers Arch-Eur J Physiol 442:542-546 Flynn TW, Connery SM, Smutok MA, Zeballos RJ, Weisman IM (1994) Med Sci Sports Exerc 26:89-94 Cavagna GA, Legramandi MA, La Torre A (2011) Proc R Soc Lond B 278:339-346

IS THE VO<sub>2</sub>MAX INTENSITY AN EFFECTIVE STIMULUS FOR THE 2000M ROWING RACE?

Sousa, A.1, Oliveira, E.1, Machado, L.1,2, Vilas-Boas, J.P.1,2, Fernandes, R.J.1,2

*1: CIFI2D, Faculty of Sport (University of Porto, Portugal), 2: LABIOMEP (University of Porto, Portugal)*

**Introduction** Olympic rowing races are conducted over a 2000m distance, with 85% of estimated aerobic energy contribution (Mello et al., 2009). In fact, the power associated with the maximal oxygen consumption (VO<sub>2</sub>max) intensity has been described as an important determinant of the 2000m rowing performance and frequently used as a training stimulus for the 2000m race (Ingham et al., 2013). However, the comparison of the VO<sub>2</sub> kinetics between these two intensities has not been done, still being unanswered if the corresponding physiological mechanisms are similar. **Methods** Six highly trained male subjects (mean ± SD; age: 22.3 ± 3.5 yrs, height: 181.2 ± 7.1 cm and body mass: 75.6 ± 3.8 kg) performed, in a rowing ergometer (Concept II, Model D, CTS, Inc.), two experiments: (1) a square wave transition exercise from rest to VO<sub>2</sub>max intensity until exhaustion, determined 24-48h before through an incremental protocol, and (2) a 2000m all-out exercise. Gas exchange parameters were assessed breath by breath (averaged 5s) using a portable and telemetric gas analyser (K4b2, Cosmed, Italy) and their peak values assessed during the last 60s of exercise. Capillary blood samples for peak blood lactate concentrations ([La]<sub>peak</sub>) analysis were collected from the earlobe at 3 and 5 min after exercise. VO<sub>2</sub> kinetic responses were

modelled using a double exponential model  $[VO_2(t)=A_0+A_1(1-\exp(-t-TD_1/\tau_1))+A_2(1-\exp(-t-TD_2/\tau_2))]$ . Results The following mean ( $\pm$ SD) values for VO<sub>2</sub>max vs 2000m tests were similar: HR<sub>peak</sub> (179.1 $\pm$ 15.1 and 181.7 $\pm$ 11.3 bpm), A<sub>1</sub> (40.6 $\pm$ 3.7 and 44.9 $\pm$ 5.1 ml.kg<sup>-1</sup>.min<sup>-1</sup>),  $\tau_1$  (11.6 $\pm$ 3.2 and 11.6 $\pm$ 2.1 s), A<sub>2</sub> (3.6 $\pm$ 1.3 and 3.9 $\pm$ 0.9 ml.kg<sup>-1</sup>.min<sup>-1</sup>) and  $\tau_2$  (28.7 $\pm$ 10.2 and 26.1 $\pm$ 6.9 s). Although of the same order of magnitude, differences between tests were found ( $p < 0.05$ ): time (215.2 $\pm$ 30 and 391.3 $\pm$ 4.1 s), power (398.3 $\pm$ 9.9 and 372.7 $\pm$ 11.7 W), VO<sub>2</sub>peak (65.7 $\pm$ 2.2 and 69.1 $\pm$ 1.2 ml.kg<sup>-1</sup>.min<sup>-1</sup>), [La]<sub>peak</sub> (10.2 $\pm$ 1.1 and 13.8 $\pm$ 1.4 mmol.l<sup>-1</sup>), TD<sub>1</sub> (6.6 $\pm$ 2.1 and 11.7 $\pm$ 1.2 s) and TD<sub>2</sub> (66.7 $\pm$ 12.8 and 107.6 $\pm$ 13.9 s). Discussion Results indicate that the VO<sub>2</sub> kinetics is similar in-between tests, with the exception of some ventilatory and metabolic differences. Data suggest that the VO<sub>2</sub> steady-state phase occurs at the same rate and with the same amplitude following a step increase in ATP turnover, in both fast and slow phases, irrespective of the intensity performed in both tests. Therefore, the VO<sub>2</sub>max intensity can be used as an effective training stimulus for the 2000m race in highly trained male subjects. ### VALIDITY OF THE DETERMINATION OF ENERGY COSTS DURING A SOCCER SPECIFIC INTERMITTENT SHUTTLE RUN TEST BY MEANS OF METABOLIC POWER CALCULATION - A PILOT STUDY

Venzke, J., Kirmse, M., Erlemann, N., Platen, P.

*Ruhr-University Bochum*

Introduction: The metabolic demands of soccer and other team sport players during matches have been widely studied during the last years. There is no data for energy expenditure during official matches. A new mathematical calculation can be used to estimate instantaneous metabolic loads during a match. Using this method, it may be possible to calculate the energy costs by velocity and acceleration data, measured by global positioning system technology (GPS). The aim of this study was to validate this new approach for the assessment of metabolic demands from GPS data against direct measurements with spirometry (SM) during the Loughborough intermittent shuttle test (LIST) which reflects the physiological and metabolic demands during intermittent high-intensity exercise, like in team sports. Methods: 8 healthy male sport students agreed to participate (25.5 $\pm$ 5.9 y, 179.8 $\pm$ 3.4 cm, 76.0 $\pm$ 7.1 kg). Subjects performed the LIST with 5 sections of 15 min, split by 3 min breaks, followed by one section to exhaustion. Each section consists of 10-12 repetitions of a 20m shuttle with different velocities (5.5 km/h, maximal sprints, 55% and 95% of maximal speed). Simultaneously, GPS and SM data were recorded for comparing direct vs. indirect measurement of energy costs (EC). Accelerations and decelerations were calculated from the velocity, monitored by a portable GPS system (5 Hz). Data were analyzed by means of a paired t-test and Pearson's chi-squared test. Results: Energy costs were significantly higher in SM measurements compared to the calculated energy costs (11.24  $\pm$  0.96 kcal/kg vs. 12.68  $\pm$  2.00 kcal/kg, 2p < .05 for calculated vs. directly measured values). The correlation between the calculated EC from GPS data and SM were highly significant in the exhaustion section ( $r = 0.96$ , 2p < .01) and significant in the total test ( $r = 0.77$ , 2p < .05). Discussion: The data confirms that the determination of EC during the LIST from GPS seems to be possible and valid, however, the results underestimate the real energy costs. This pilot study is a first approach for the analysis of the validity of the formula for the calculation of the EC in official soccer and other team sport matches. Further validity studies comparing direct and indirect measurements of energy expenditure during matches are necessary before using the formula for detailed analysis. Also further study is needed which includes different factors that can not be measured by GPS like passing and shooting. References: di Prampero, P. E., Fusi, S., Sepulcri, L., Morin, J. ### EFFECTS OF 8 - WEEK HIGH INTENSITY INTERVAL TRAINING ON ANAEROBIC AND AEROBIC CAPACITY IN TAEKWON-DO ITF ATHLETES

Batra, A., Zatoń, M.

*University School of Physical Education in Wrocław*

INTRODUCTION Repeated maximal actions (punching or kicking) may result in extremely high muscle lactate concentrations thus in an effort to enhance anaerobic power and capacity, combat sports athletes may perform high intensity interval training (HIT). Much of this form of training aims to improve anaerobic function, particularly glycogenolysis, but aerobic contributions and adaptations are also involved. The aim of this study was to investigate the effects of eight weeks of specific high intensity interval training on the anaerobic and aerobic capacity in Taekwon-do ITF athletes. METHODS To test the hypothesis that HIT improve both aerobic and anaerobic performance a pre- to postintervention training study was executed. Each subject in our study completed Wingate test (WAnT) and incremental VO<sub>2</sub>max treadmill test before and after the 8 - week of training program. Thereafter, fighters were randomly allocated into interval training group (HIIT, n = 10) and control group (CON, n = 10). Subjects of HIIT group during 8 week intervention, 2 times per week (at least 48 hours rest between training sessions), participated in 30 - s maximum efforts interspersed with 90 - s rest. RESULTS The HIIT group is characterized by significantly increase in anaerobic peak power, total work done, time of maximal power maintenance and increase in lactate plasma values during Wingate. In HIT group we reported significant increase in VO<sub>2</sub>max during treadmill incremental test. The HIIT group also was characterized by lower oxygen uptake and minute ventilation during running with submaximal speed. In control group results did not differ between pre and post training period. DISCUSSION Previous research has shown that HIT is an effective training method for improving buffering capacity, anaerobic power, VO<sub>2</sub>max and delaying time of fatigue during long - endurance type exercises (MacDougall 1998 , Creer 2004, Burgomaster 2005). The Wingate test have shown that in HIT group was an increase in peak power (PP), phase of power maintenance (MP), total work done (W) and higher plasma lactate values which indicates improved anaerobic capacity. The higher VO<sub>2</sub>max during treadmill incremental test and lower oxygen uptake and minute ventilation during running with submaximal speeds after HIT training shows improved aerobic metabolism and better economy of work (exercise). ## DETERMINATION OF ENERGY COSTS DURING TWO-DIRECTIONAL MULTI-STAGE SHUTTLE RUNNING USING A NOVEL CALCULATION – A PILOT STUDY

Kirmse, M., Venzke, J., Praetorius, A., Platen, P.  
Ruhr-University Bochum

Introduction: The physiological demands imposed on soccer and other team sport players during official matches and training sessions has been the subject of research since many years, but most available methods are not able to estimate instantaneous metabolic loads during a match. Recently, a mathematical method for the determination of energy costs (EC) during soccer matches using velocity and acceleration data has been described<sup>1</sup>. This method, however, has not been validated against direct measurements of EC during controlled running so far. The aim of this study is to analyze the validity of the mathematical calculation of EC from velocity and acceleration data against direct measurements of EC with spirometry during two-directional shuttle running with different shuttle lengths. Methods: 8 healthy sport students agreed to participate (w:n=3, m:n=5, 25.1±2.5y, 178.7±6.1cm, 68.8±12.9kg). Subjects performed 3 separate shuttle run tests to exhaustion with a shuttle length of 10m(n=7), 20m(n=7), and 30m(n=6), respectively (start with 8 km/h, increase of 0.5 km/h per min, randomized order). Each test was performed with spirometry for the direct determination of EC. Accelerations and decelerations were analyzed from GPS-monitored velocities (5 Hz) and data were entered into the formula<sup>1</sup> to get calculated EC. Results: Total EC of shuttle running varied broadly between subjects due to the large variation in aerobic performance. Total EC increased with increasing shuttle length from 10m to 30m. Calculated EC from GPS data resulted in 10% to 30% lower values compared to directly measured EC (10m: 81.8±29.7 kcal vs. 107.0±39.3 kcal; 20m: 136.1±49.2 kcal vs. 151.2±55.0 kcal; 30m: 144.8±54.7 kcal vs. 175.4±77.9 kcal, 2p<0.05 for calculated vs. directly measured values, respectively). Correlations between GPS-determined and spirometry-determined EC data were highly significant in all three shuttle distances (10m: r=0.96; 20m: r=0.86; 30m: r=1.0, 2p<0.05). Discussion: Determination of EC during multi-stage shuttle running from GPS velocity and acceleration data by means of mathematical calculation is possible and seems to be valid, however results in 10% to 30% underestimation of real EC. Further validity studies comparing direct measurements of EC with formula-derived values using defined run distances, velocities and run directions, including indirect and direct determination of EC during soccer and other team sport test matches is necessary before using the formula for detailed metabolic analysis in real matches. ### MO-SH06 Philosophy & Ethics

#### ETHICAL VALUE OF ORIENTAL MARTIAL ARTS

Oh, J.D.1, Kim, D.G.2, Park, H.W.3, Hwang, Y.S.1, Kwon, O.R.1

1: PNU (Busan, Republic of Korea), 2: YNU (Daegu, Republic of Korea), 3: JNU (Kwangju, Republic of Korea)

Introduction Oriental martial arts have the distinct value of enabling the practitioner to transcend from physical motion to the introspective self-examination and train the spirit (Cua, 1998; Eui, 2000). The use of oriental martial arts training to foster modern humanistic education, morals and ethics is a very interesting tool that has drawn much attention lately (Cho, 2011). The purpose of this study is to investigate the ethical value and implementation of practical ethics as a result of participating in oriental martial arts. By examining these ethical aspects suggestions for ethical standards can be developed. Methods A literature review focusing on the concepts, history, philosophy, and ethics of Oriental martial arts was carried out. Results First, the ethics of oriental martial arts involves both the mental and physical understanding of our daily habits. For epistemic comprehension of orientation martial arts it is vital for our bodies to be perfectly familiar with the somatic learning of ethics. Second, one may achieve virtue through somatic learning and the increase in their mental capability. Third, if one can attain the both epistemic comprehension and somatic learning then one will be able to behave ethically correct in every situation and recognize the values of such behaviour. Discussion To signify the practical value of oriental martial arts ethics we focus on epistemic comprehension and somatic learning. It is possible to foster enlightenment via martial arts in epistemic meaning, a comprehension stage, and it is also possible to achieve virtue in somatic meaning, a learning stage. Natural somatic expression appears through the realization of the mind in the learning process of epistemology. Ways to foster virtue by the ethical ideals of Confucius, Mencius and Xunzi in Xianqin Rujia and Laozi in Taoism are also discussed. This study also draws comparison between the oriental acquisition of enlightenment and Aristotle's practical wisdom considering practical actions in detail. One of the commonalities of Confucius, Mencius, Hsuntzu and Aristotle's is the necessity to learn without the exception of practical ethics. References Cua A. #### COMPARATIVE STUDIES ON THE SPORTSMANSHIP AND SWORDSMANSHIP

Zhou, J., Zhou, W., Zhao, Y., Wang, Y., Wang, H.

China University of Petroleum

Introduction Since the swordsmanship has enjoyed a long history in China since the ancient times, it is said that swordsman is the idol of all the Chinese people. And the swordsman movies and martial arts fictions are still the most popular elements in the Chinese culture today. In reality, various sports events such as the Olympic Games are also in their full swing. However, at the same time, the literary works with sports as the main topic are rather few. Why it is hard for the eye-catching sports in the reality to be favored by the writers and film directors? The research will focus on the originality of the swordsmanship and sportsmanship as well as their differences and associations. As far as the author is concerned, it is beneficial to emphasize the swordsmanship advocated in the ancient times as the therapeutic means for self-interest and dishonest—the two malignant tumors in the sports circle—which are getting epidemic nowadays to reflect the relativity of the sportsmanship. Methods The research methods such as literature review and logical analysis will be adopted in the research. Conclusions Sportsmanship is generally regarded as the sign of the modern civilization and swordsmanship can manifest the ideal of people as well as the pursuit of people for freedom and equality in the films and literature. Compared with swordsmanship, sportsmanship, the so-called product of the compromise to the reality, is the game rules in the human society, representing the progress

of the society ruled by law. Discussions Originality of swordsmanship: Swordsmanship boasted to be the outcome of the hope and the swordsmen became the embodiment of the "absolute justice". (Chen Ping yuan: Dream of Swordsmanship since the Ancient Times—Studies on the Genre of Martial Arts Novels). In short, swordsmanship was a reflection of the dream of the people of equality, freedom and justice in the chaotic times. Relativity of swordsmanship: In the chaotic days, people admired swordsmen but few wanted to be one of them. Originality of sportsmanship: Based on the theory of school of psychology, people are aggressive in nature subconsciously. "The pugnacity of the human being, also called the invasiveness, as a really basic instinct of unconsciousness, has its own release mechanism. Like lust and other basic instincts of human being, it would arouse peculiar but rather intense euphoria. Relativity of sportsmanship: Sportsmanship is quite similar to a kind of social contract under some occasions. As a matter of fact, the uninhibited individuality, the sentiment of justice and the heroism of the swordsman signify the vitality and passion of life. Besides, in the secular society where people are restrained by the rules created by themselves and are busy with making a living and trifles, it is a reflection of the people who are eager for freedom and equality. References 1. Chen Ping yuan: Dream of Swordsmanship since the Ancient Times—Studies on the Genre of Martial Arts Novels. People's Literature Publishing House. March 1992, Edition 1,1-2

## RESEARCH REGARDING THE OCCURRENCE OF NEW ELEMENTS FOR VAULTING TABLE PERFORMANCE IN MEN'S ARTISTIC GYMNASTICS

Nakasone, M.

*University of Biwakoseikei sports*

Introduction More recently a total of 800 elements have been recorded in the Gymnastics Code of Points. However there are few theses on elements of gymnastics history. As such we wonder by whom, when or where these various elements are performed. The purpose of this study was to collate data elements on the Vaulting Table (VT) in men's artistic gymnastics and to suggest new elements in the future. Methods The method of study was undertaken by bibliographic analysis. This article refers mainly to journals that were published by the Japan Gymnastic Association, and a list that was made regarding the occurrence of new elements on VT in men's artistic gymnastics. Results From the analysis, the author gathered data regarding various elements that were performed. For example, Handspring sideward with 1/4 turn and salto backward tucked (Tsukahara) was performed by TSUKAHARA.M in the 1969 Japan National competition. Hand-spring sideward with 1/4 turn and salto forward tucked with 1/2 turn (Kasamatsu) was performed by KASAMATSU.S in the 1974 World Championships. The Kasamatsu stretch with a full twist was performed by AKOPIAN.A in the 1981 World Championships. Another example, Handspring forward with 1/2 turn and salto backward tucked (Cuervo) was performed by CUERVO.J in the 1973 Universiade in Moscow. Additionally, in recent years, the round off, handspring backward and salto backward stretched with triple twist was performed by SHIRAI.K and KIM.H.H in the 2013 World Championships. Discussion In conclusion, developments of VT elements are greatly influenced by the improvement of apparatus, rules of the era and improved skills of men's gymnastics. As a result, we have to pay attention to changes to the Men's Code of Points and the improvement of apparatus. In the near future, directions of new occurring elements on the VT may add twists to the existing elements. References Tagawa, T. (1982). Japan gymnastics association Study of information, 50 59-81. ## KUNG FU CANTON: CULTURE OF MARTIAL ARTS IN GUANGDONG, CHINA

Guo, Y., Leblanc, X.

*Guangzhou university, Sport Science Institute China*

Introduction "Canton" original meaning was capital in English. At the time Guangzhou was the capital of Guangdong and Guangxi regions, therefore was later named 'Canton' by foreigners. In modern era, Canton gradually refers to China Guangdong region. Kung fu is a Chinese term referring to any study, learning or practice that requires patience, energy, and time to complete, often used in the West to refer to Chinese martial arts, also known as Wu Shu. Methods literature research was conducted using Guangdong library and Guangdong national archive computerized database back to 1900. The primary free-text terms entered were "Wu Shu," "Kung Fu," "culture of Lingnan Kung Fu." Various relevant articles and documents were selected in abundant traditional culture fields that included physical activity, art, medicine and architecture. Field research also be used in this study to gain an intimate perspective of Kung fu culture within Guangdong area. Multiple sources of information were obtained by participant observation in local martial club, TCM clinics and historical sites. Results This study shows that Chinese Kung fu plays an integral part into shaping cultural, artistic and medicinal landscape in southern China. Indeed cultural events such as opera and lion dance draw their inspiration from Kung fu. Kung fu movement and terms are also transposed to Chinese traditional medicine because of the deep understanding of human body and meridians it requires. Because Kung fu draws from social and historical sources, it never stops evolving while still remaining deeply anchored in Chinese cultural heritage. We can conclude that Kung fu is a sustainable martial art and in many aspects a valuable and healthy way of life. Discussion Kung fu is a word borrowed from the Chinese word gongfu, which translates as accomplished or cultivated skill. Wu Shu would be a more accurate word to have borrowed, but it's still just an umbrella term for a whole myriad of Chinese martial art, ranging from drunken boxing to the Fujian white crane. Perhaps the most famous style in Guangdong is Wing Chun, which was taken by the now legendary Ip Man to Hong Kong, from where it spread out across the world via Hong Kong Kung fu flicks. Religion beliefs, traditional moral, legend of Kung Fu hero, even Lingnan architectural style and Hong Kong Kung Fu film, multiple elements contribute to the unique culture of Guangdong martial art. ### MO-SH05 Psychology II

#### DEVELOPMENT OF THE CHINESE VERSION OF THE SPORT MOTIVATION SCALE-II: A PILOT STUDY

Li, C.

*Hong Kong Institute of Education*

Self-Determination Theory (SDT; Deci & Ryan, 1985) has been popularly used for studying athlete motivation. The Sport Motivation Scale-II (SMS-II; Pelletier, Rocchi, Vallerand, Deci, & Ryan, 2013) is a SDT-based multidimensional scale recently developed to measure athlete motivation. This pilot study was to develop the Chinese version of the SMS-II. The SMS-II was translated into Chinese language by two bilingual sport psychologists. Chinese university athletes (N = 223) participating in a variety of sports were recruited. The results showed that the scale had adequate internal reliability ( $\alpha = .70$  to  $.78$ ). The factorial validity of the scale was generally adequate based on the findings of confirmatory factor analysis. Future research on the Chinese version of the SMS-II was discussed.

#### PARTICIPANT MOTIVATION: A COMPARISON ACROSS WORLD MASTERS INTERNATIONAL COMPETITIONS

Heazlewood, I.

*Charles Darwin University*

Do not insert authors here Introduction Motivation is defined as "the directions and intensity of one's effort" and is important in the selection of sport. Participant motivation evaluates factors that enhance or inhibit motivation to participate (Marcus & Forsyth, 2009). Some research has been conducted on masters athletes at the level of individual competitions, however comparisons between competitions is rare (Heazlewood et al., 2011; Heazlewood et al., 2012). The research aim was to compare participant motivation of athletes across three international masters' competitions, 2009 World Masters Games (WMG), 2010 Pacific Masters Games (Pan Pac) and 2010 Golden Oldies Rugby Festival (GORF) develop sport psychological strategies to enhance participation in these international competitions. Methods Athletes volunteered and were from WMG, Pan Pac and GORF. The athletes completed the 56 item Motivations of Marathoners Scale (MOMS), using a 7-point Likert scale. The nine factors were health orientation, weight concern, personal goal achievement, competition, recognition, affiliation, psychological coping, life meaning and self-esteem (Masters et al., 1993; Ogles, et al., 2000). Results Predominant factors for cohorts were, WMG goal achievement, health orientation and affiliation; Pan Pac affiliation, health orientation and goal achievement; and GORF affiliation, health orientation, psychological coping and goal achievement. Factors of self-esteem and weight control of moderate importance and recognition, life meaning and competition of low importance with all cohorts. Psychological coping of low importance with WMG and Pan Pac athletes. Discussion All cohorts identified factors of health orientation and affiliation as important. Goal achievement was more important to WMG and Pan Pac athletes than for GORF who identified psychological coping as moderately important. These data highlight the participant motivation factors motivating athletes to compete and will enable the articulation of marketing strategies with the participant motivation needs of these international athletes. #### PSYCHOPHYSIOLOGICAL AROUSAL, INDIVIDUAL DIFFERENCES AND PERFORMANCE IN ATHLETES

Üngür, G., Bayazıt, O., Türkmen, S., Arkan, A.

*Dokuz Eylül University, School of Sport Sciences and Technology*

Introduction Arousal, is a degree of increase in bodily activation presenting with hormonal changes and other physiological variances related to thoughts and feelings (Zaichkowsky and Naylor 2004). Factors evoking stress reactions affect a person's arousal level. The regulation of arousal level in sports is important in regard to performance. This study aimed to investigate the possible effects of personality and emotional intelligence (EI) on the association between arousal and performance. Methods Schutte Emotional Intelligence Scale and short form Five Factors Personality Inventory were completed by 58 elite athletes. The maximal voluntary contraction (MVC) and strength of the athlete's triceps surae muscle was recorded with surface electromyography (EMG) and force sensor respectively. These parameters were continuously recorded during stages in which athletes were subjected to negative visual stimuli, and performed a cognitive task. In each stage the three measurements were carried out with two minute breaks in between. In all stages autonomic nervous system reactions were evaluated with skin conductance response (SCR). A portable biopotential amplifier was used for recording. Results MVC and strength levels increased during negative visual stimulation, and decreased during the cognitive task. Athletes with high openness scores experienced a lower decrease in performance during cognitive tasks. There was a positive correlation between extroversion scores and SCR during negative visual stimulation. Discussion Results imply that performance varies in different levels of arousal, and arousal level and performance may be related to some individual characteristics. The increase in athlete's MVC and strength during the presentation of negative pictures, and their decrease during cognitive tasks supports the Inverted U hypothesis (Yerkes and Dodson, 1908). The lower decrease in performance observed in those with high openness implies that performance in these individuals may be less affected by challenging conditions. This finding may be related to greater use of avoidance coping strategies in athletes with lower openness to experience (Allen et al 2011). Eysenck (1967) reports stimulus seeking in extroverts due to lower cortical arousal levels. Therefore extroverts may be said to be more prone to arousal and may have been more aroused during visual stimulation. References Allen MS, Greenlees I, Jones M. (2011). ### TO BE IN THE ZONE - MEASUREMENT OF STRESS LEVEL WITH EGIG THROUGH ELITE MX ATHLETES

Balogh, L., Nagy, A., Almasi, D., Petrovszki, Z., Molnar, A.

*University of Szeged, Faculty of Juhász Gyula Pedagogy*

**Introduction** According to Hanin's theory every people have their own individual zones of optimal functioning. A new innovation called electro-gastro-intestinograph (EGIG) is able to measure gastric and intestinal motility on a non-invasive way. This EGIG could surpass the paper and pencil testing as it provides objective numeric data of anxiety. This study is the first step of examining the anxiety level of A-level motocross (MX) athletes. **Methods** 3 MX athletes whose age is 18 (sd=3,5) and 4 non-athletic regular people (NARP) whose age is 24 (sd=2,4) took part in the examination. The applied EGIG has a Hungarian patent and developed by the EXPERIMETRIA Ltd. The gastric and intestinal motility and its response to a single sound stimulus was monitored. Each monitoring took 40 minutes on empty stomach with a sound stimulus exactly at 20 minutes. The unit of the measured data is cycles per minute (CPM). **Results** The greatest variance was measured on the large intestine. The MX athletes' resting average was 5,22 CPM (sd=1,14) which is higher than the NARP's 2,47 CPM (sd=0,55). However the maximal value followed by the sound stimulus was 10 CPM (sd=1,1) of the MX athletes which is 191% of their resting average. The NARP maximal value was 8,33 CPM (sd=1,77) which is 304% of their resting average. The resting average of the two groups are fairly close. The MX athletes' resting average was 4,81 CPM (sd=0,47) and the NARP's was 4,6 CPM (sd=1,07). The athletes resting average was 92% of their resting average and the NARP's was 167% of their resting average;  $t(6) = -5,819$ ;  $p=0,002$ . **Conclusion** The higher resting CPM of a MX athlete can explain a prepared status to an unknown event. This is confirmed by the athletes' lower maximal CPM in proportion to their resting averages, and by the close resting average of the athletes and NARP. According to my results the examined MX athletes have lower stress level than the NARP. I would confirm these results by further studies.

### HYPERTHERMIA-INDUCED ALTERATION IN COMPLEX COGNITIVE TASK PERFORMANCE IS REVERSED BY 11 DAYS OF HEAT ACCLIMATION

Gaoua, N.1,2, Periard, J.D.2, Wilson, M.G.2, Racinais, S.2

*1.School of Applied Sciences, London South Bank University, United Kingdom / 2.Athlete Health and Performance research centre, Aspetar Orthopaedic and sport Medicine Hospital, Qatar*

**Introduction:** Major sporting events are organised during summer months where environmental conditions can be extreme. Consequently, the International Olympic Committee has highlighted the need and importance to heat acclimate. The physiological responses to acclimation are well investigated and occur approximately within one to two weeks, allowing to improve the physical work capacity in hot environments. However, despite a deleterious effect of hyperthermia on complex cognitive tasks in unacclimated athletes, it remains unknown if heat acclimation can improve cognitive functions in hot environments. **Aim:** The aim of this study was to investigate if acclimation had a protective effect on cognitive functions. **Methods:** 9 male subjects (37.0±8.9 years; 176.3±8.6cm and 72.0±8.1kg) voluntarily participated to the study. Subjects performed a simple (OTS-4) and complex (OTS-6) planning task (OTS: One Touch Stocking of Cambridge) under hot (HOT: 46–48°C) and control (CON: 24°C) conditions in a counterbalanced order, both before and after 11 days of passive heat acclimation (1h a day of heat exposure). Subjective measures of thermal comfort (TC) and thermal sensation (TS) were recorded in each condition. Core (T<sub>core</sub>) and skin surface (T<sub>skin</sub>) temperatures were recorded throughout the cognitive test by a rectal probe and 4 surface thermistors. **Results:** HOT test were performed at a T<sub>core</sub> clamped at 39°C. Consequently, T<sub>core</sub>, T<sub>skin</sub>, TS and TC were similar before and after acclimation ( $p>0.05$ ) but significantly higher in HOT compared to CON ( $p<0.05$ ). Cognitive performance during the simple task (OTS-4) was not affected by hyperthermia. Cognitive performance during the complex task (OTS-6) was altered by hyperthermia before ( $p=0.016$ ) but not after ( $p=0.397$ ) heat acclimation. This was due to a significant improvement of the performance in HOT ( $p<0.001$ ) but not CON ( $p=1.000$ ) following acclimation. **Conclusion:** One hour of passive heat exposure daily for 11 days allows protecting complex cognitive task performance in hot environments. The mechanisms behind this protective effect are still unclear.

### ACUTE PHYSICAL EXERCISE PERFORMED IN HYPOXIC CONDITIONS IMPROVES EXECUTIVE FUNCTIONS

De Mello, M.T.1,2, Lemos, V.A.1,2, Santos, R.V.T.2,3, Bittar, I.G.L.2, Souza, W.Y.G.3, Antunes, H.K.M.2,3, Lira, F.S.1,2, Tufik, S.1,2

*1:UNIFESP (São Paulo, Brasil), 2: CEPE (São Paulo, Brasil), 3: UNIFESP (Santos, Brasil)*

**Introduction** The body's acute and chronic responses to the effects of hypoxia can alter physiological and brain functions due to decreased O<sub>2</sub> intake. However, the effect of acute exercise in hypoxic conditions on executive functions has never been evaluated. The aim of this study was to evaluate the influence of acute physical exercise under hypoxic conditions on executive functions. **Methods** The participants of this study were 38 healthy men, distributed randomly into 4 groups (Normoxia n=10, Hypoxia n=10, Exercise in Normoxia n=10 and Exercise in Hypoxia n=10), aged 23 ± 8 years, with a weight of 71 ± 7 kg, height of 1.76 ± 1 m, BMI of 22 ± 9 kg/m<sup>2</sup> and VO<sub>2</sub> peak of 47 ± 4.2 ml/kg/min. The executive function was evaluated using the Random Number Generation Test (Towse et al., 1998), which was applied on the first day in all groups and reapplied on the second day, immediately after the exercise session of 60 minutes at 50% of peak VO<sub>2</sub>. The hypoxia and exercise in hypoxia groups were exposed to hypoxic conditions equivalent to 4500-m for 29 hours (Colorado Altitude Training™/12 CAT-Air Unit). Two-way ANOVA was used to determine differences between the groups. The statistical significance was determined as  $p<0.05$ . **Results** There was a significant improvement in executive functions ( $p = 0.001$ ) in the exercise in hypoxia group when compared with the hypoxia group. In the hypoxia group a significant worsening in executive functions was observed ( $p=0.003$ ), compared with the normoxia group. The normoxia and exercise in normoxia groups did not differ significantly. **Discussion** These results suggest that acute physical exercise performed in hypoxic conditions can improve executive functions. This may occur due to the effect of exercise on improving blood viscosity (Conti et al., 2013), thus improving executive functions. However, more studies are necessary for a better understanding of the mechanisms involved. **References** Conti AA, Macchi C. (2013). Clin Ter, 164(4), 293-4. Towse JN, Neil D. (1998). ## THE EFFECT OF MANIPULATING EXERCISE INTENSITY AND SPEED - ACCURACY INSTRUCTIONS ON COGNITIVE PERFORMANCE

Joyce, J.1,2, Donnelly, A.E.2, Smyth, P.J.2, Davranche, K.3

1: University of Limerick (Ireland), 2: University of Worcester (UK), 3: CNRS & Université de Provence (Marseille, France)

**INTRODUCTION** Exercise has been identified as a strategy to promote cognitive maintenance in advanced age. The manipulation of dose-response components during acute bouts of exercise will help elucidate this complex relationship. Exercise intensity is a key modifiable parameter in this relationship. A meta-analysis by Chang and et al., (2012) suggested that various exercise intensities conferred different post exercise cognitive effects. Also, older adults reportedly experience stereotype inflated age related deficits in reaction time (RT) (Mazerolle et al., 2012) which may influence strategy selection on speeded RT tasks (Joyce et al., 2014), with strategies being more cautious with performance characterised by slower RT and high levels of accuracy. The effect of such strategies on performance during different exercise intensities should be investigated. **METHODS** Thirty - two participants (16 young: 20 ± 3 years; 16 old: 64 ± 2 years) completed the study which aimed to investigate the impact of different intensities of exercise (light & moderate) on RT and cognitive control as measured by the Simon task during exercise (30 minutes of cycling at either 50-55 % age predicted maximal heart rate (HRmax) or 65 % HRmax) and for 25 minutes post exercise. Use of RT distributional analysis allowed for the accurate examination of conflict resolution mechanisms and how these were affected by the speed or accuracy instructions. **RESULTS** Results confirmed an age - associated deterioration in processing speed (420ms vs 360ms) ( $p < 0.001$ ), while highlighting an equivalent cognitive control for older and younger adults (30ms vs 28ms,  $p = 0.57$ ). The hypothesised benefit of exercise on RT was not observed in this study ( $p = 0.26$ ) but the manipulation of speed-accuracy instructions had a considerable effect on performance, resulting in reduced RTs and accuracy levels for speed ( $p < 0.001$ ) as compared to accuracy directives for both age groups. **DISCUSSION** Results showed that under favourable conditions older adults can appreciably reduce the magnitude of the typical age - related deterioration in processing speed. The design complexity of the study may have precluded an exercise-induced facilitation which has previously been reported in the literature. Future studies should focus on manipulating moderator variables in isolation to better disentangle their contribution to improved performance. **REFERENCES** Chang et al (2012) Brain Res, 1453, 87-101. ### MO-PM08 Adapted physical activity: Disabilities

#### EFFECTS OF STRENUOUS EXERCISE ON SALIVARY HUMAN NEUTROPHIL PEPTIDES 1-3 AND BLOOD NEUTROPHILS IN YOUNG MALE SUBJECTS

Hanaoka, Y.1, Shimizu, K.2, Oikawa, S.1, Kimura, F.1, Sone, R.1, Watanabe, K.1, Akama, T.3, Kono, I.1, Miyamoto, T.1

1: University of Tsukuba, 2: University of Tsukuba, 3: Waseda University

**Introduction** In the field of athletics, the risk of upper respiratory tract infection (URTI) is one of the most important problems in athletes. Salivary human neutrophil peptides 1-3 (HNPI-3) have anti-virus activity, thereby preventing URTI. HNPI-3 are predominantly expressed in neutrophils. There is only one report about HNPI-3 in response to exercise. However, this response did not examine immediately after exercise. The aim of this study was to examine salivary HNPI-3 and neutrophils responses to strenuous exercise until 24 hours after exercise. **Methods** 8 healthy young male subjects (23.4 ± 0.6 years) participated in this study. The subjects performed exercise experiment (exercise on a cycle ergometer at 75% VO<sub>2</sub>max for 60 min). Saliva and blood samples were collected pre exercise (7:30 A.M.), post exercise (8:30), post 1 h (9:30), post 2 h (10:30), post 3 h (11:30), and post 24 h (next 8:30 A.M) after the bout of exercise. HNPI-3 concentrations were measured by the enzyme-linked immunosorbent assay. Counts of neutrophils were obtained using an automated cell counter. The visual analogue scale for subjective fatigue was used at the same points as sample collections. **Results** Mean salivary HNPI-3 concentration at pre, post, post 1h, post 2h, post 3h and post 24h were 36.2 ± 8.9, 60.6 ± 14.4, 38.0 ± 7.4, 27.9 ± 6.1, 36.3 ± 7.8, 35.3 ± 12.9 ng/ml respectively. Salivary HNPI-3 concentration changed in this study (effect size:  $\eta^2 = 0.128$ ;  $p = 0.312$ ). Mean absolute number of blood neutrophils was at pre, post, post 1h, post 2h, post 3h and post 24h were 4088.4 ± 651.8, 4915.5 ± 932.8, 6127.0 ± 976.1, 7140.3 ± 1120.3, 6984.2 ± 1079.3, 3133.5 ± 350.0 cells/μl respectively. Blood neutrophils significantly changed in this study (effect size:  $\eta^2 = 0.285$ ,  $p < 0.05$ ). Subjective fatigue significantly increased at post exercise compared with pre exercise (effect size:  $\eta^2 = 0.501$ ,  $p < 0.01$ ). **Discussion** In this study, HNPI-3 temporarily increased after exercise and immediately returning to a baseline value at post 1h, whereas neutrophils gradually increased after the exercise and maximized at post 2h. Therefore, there might be the time lag between increased HNPI-3 and neutrophils responses to strenuous exercise. **Reference** Davison G, Allgrove J, Gleeson M.(2009) . Eur J Appl Physiol. 106(2): 277-284.

#### INSTRUMENTAL ANALYSIS AS A SUPPORT FOR THE EVALUATION SCALES USED IN GAIT ANALYSIS

Viscione, I., D'Elia, F., Vastola, R., Coppola, S., Sibilio, M.

University of Salerno

**INTRODUCTION** Project Freedom (Function of research on exergames to expand opportunities for educational mobility of the elderly) is a pilot project which aimed at promoting physical activity and mobility in old age. Adapted physical activity (APA) aims to prevent disease and to counter the damage caused by the physiological decline of psychomotor function in old age. Among the elderly, in fact, activity restriction is an independent predictor of decline in physical function. To practice adapted physical activity can slow down the motor decline in old age, which is evident also in gait characteristics. Typical characteristics of gait among the elderly are: speed reduction, rotation of the foot to increase the support base and decrease in the length of the step. Therefore, the aim of this study is the correlation of gait data in older adults using two tests: the Short Physical Performance Battery (SPPB) (Guralnik et al., 1994) and G Walk. **METHODS** During this project, a study was carried out with the aim of correlating data collected on gait parameters of 16 adults between the ages of 67 and 94 years. The participants were chosen on the basis of a number of tests carried out to analyse their levels of autonomy, intellectual capacities and motor functioning. Motor skills were investigated using the Short Physical Performance Battery evaluation scale and G Walk. The former is an objective assessment tool for evaluating lower extremity functioning, in terms of static balance, gait and sit-to-stand, whereas the latter can objectively evaluate the parameters of the gait. **RESULTS AND DISCUSSION** The results show that adaptive

physical activity can have positive effects in elderly. The study opens up interesting prospects for the future, because shows that the instrumental analysis is a useful support for the evaluation scales. ### RELIABILITY AND VALIDITY OF THE CHINESE VERSION OF THE PREGNANCY PHYSICAL ACTIVITY QUESTIONNAIRE

Mi, X., Masayuki, K., Huanhuan, H., Mio, N., Karina, A., Hyeon-Ki, K., Hiroki, T., Hisao, S., Takashi, A., Shizuo, S.

*Sport Sciences*

**Introduction** Physical activity of pregnant women tends to be of lower intensity, frequency, and duration as compared with prepregnancy levels (Hinton et al., 2001). Several researches support that it is an important part of physical activities during pregnancy to promoting health. Participation in physical activity during pregnancy may reduce the risk of gestational diabetes mellitus (Dempsey et al., 2004) and preeclampsia (Safflas et al., 2004) and help to prevent excess gestational weight gain (Skouteris et al., 2010). However, because of the lack of an appropriate measurement instrument, the physical activity status of Chinese pregnant women remains unknown. The association between physical activity during pregnancy and pregnancy-related outcomes is unclear. Therefore the aim of this study was to translate the English version of the pregnancy physical activity questionnaire into Chinese, and to examine its reliability and validity for Chinese pregnant women. **Methods** 224 pregnant women during the first, second and third trimesters of pregnancy were recruited. The participants were instructed to complete the Chinese version of the pregnancy physical activity questionnaire (PPAQ-C) first visit and to wear the uniaxial accelerometry sensor (Lifecorder; Suzuken Co. Ltd) for the 7 days. One week after the first visit, we collected the data from the uniaxial accelerometer records and the women were asked to complete the PPAQ-C again. **Results** The intraclass correlation coefficients (ICCs) used to measure reproducibility of PPAQ-C were 0.73 for total activity (light and above), 0.74 for sedentary, 0.72 for light and 0.58 for moderate and above intensity activities. It was 0.73 for "Household and Caregiving" and 0.73 for "occupational" activities. Spearman correlation coefficients (SCCs) between the PPAQ-C and accelerometry were 0.34 ( $P < 0.01$ ) for total activity (light and above), 0.32 ( $P < 0.01$ ) for light intensity. **Discussion & Conclusions** The PPAQ-C is reliable and moderately accurate for the measure of physical activity of various intensities and types among pregnant women. **References** HINTON, P. ### THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY, PHYSICAL FITNESS AND OVERWEIGHT AND OBESITY IN CHILDHOOD

Maxhuni, K., Llapashtica, F., Zenuni, Z.

*Health House in Vushtrri*

**Abstract Introduction:** Overweight and obesity have become a global epidemic, the main cause of obesity is considered to have a strong genetic influence but both overweight and obesity also are strongly influenced by physical activity. High prevalence of overweight, obesity and the high body fat percentage have been proven to have adverse effects on childhood and adolescent's health and contribute to many health problems later in life. **Objectives:** The purpose of this study is to gather information regarding the level of overweight, obesity and its relationship with physical activity in childhood. **Methods:** This thesis aims to review the scientific literature related with overweight and obesity, and tries to highlight its relation to physical activity with special focus on childhood. **Results:** The prevalence of overweight and obesity at childhood has grown dramatically in almost all countries independent of their economic development. One of the most important reasons in this respect is that physical activity dramatically declined and inactive behavior such as watching TV or spending time in front of the computer increased radically. At the same time nutrition habits changed dramatically with much more high caloric food available. **Conclusion** A physical active lifestyle together with balanced nutrition plays a significant role in controlling body weight and body fat in childhood. Public health and education strategies have to include these important aspects to reduce the future health burden related with overweight and obesity. **Reference** Ajzen J: The theory of planned behavior. *Organ Behav Hum Decis Process* 1991, 50(2):179-211. ### THE ELEVATION OF SERUM IRISIN LEVEL AFTER SINGLE BOUT OF EXERCISE DOES NOT MODULATE DIET-INDUCED THERMOGENESIS IN HEALTHY YOUNG ADULTS.

Naghavi, N., Yokoyama, H., Yamashina, Y., Hirasawa, Y., Takeda, R., Ota, A., Imai, D., Okazaki, K., Miyagawa, T.

*Osaka City University, Graduate School of Medicine*

**INTRODUCTION** The effect of physical activity on diet-induced thermogenesis (DIT) is still controversial. Irisin is a new protein, known as cleaved from muscle to circulation by acute exercise, and as inducing browning of adipocytes. The aim of the study was to examine whether the changes in serum irisin level following single bout of exercise could modulate DIT. **METHODS** Nine normal-weight healthy young volunteers participated in two experiments in random order. In the exercise trial (EX), 40-min exercise on bicycle ergometer at 60% of heart rate reserve were performed on the day before the assessment of energy expenditure (EE) by indirect calorimetry. Blood concentration of irisin, glucose and insulin were measured before and after the intake of meal. Serum irisin levels were also examined before and immediately after the exercise. In the no exercise trial (NOEX), EE were assessed without previous exercise. **RESULTS** Serum irisin level was increased following exercise with borderline significance ( $P=0.054$ ). Postprandial irisin levels were higher in the EX than in the NOEX, whereas diet intake itself affected serum irisin levels in neither trial. Mean DIT as well as resting EE was not different between the trials. No differences were found in postprandial glucose and insulin levels between the trials. **DISCUSSION** We observed that the serum irisin level

was increased in response to single bout of exercise. Our result was consistent with the findings by Huh et al. and by Bostrom et al., which demonstrated acute increase in plasma irisin level after a sprint run and 10 week of endurance training, respectively. In the present study, DIT as well as resting EE was not affected by the exercise in the previous day, in spite of the prolonged elevation of serum irisin level. From this result, it does not seem that irisin modulates either DIT or resting EE. On the other hand, several reports have shown that acute exercise increased DIT and resting EE (JAMES O. HILL), and the increases were mainly due to the enhanced activity of sympathetic nervous system (M. GLEESON). Therefore, the discrepancy in the results might be explained by the difference in the intensity and modality of exercise as well as in the contents of test meal and the subjects' race. ### MO-BN05 Motor learning

#### ANALYSIS OF THE NO RETURN OF POINT HYPOTHESIS: THE EFFECT OF AUDIO AND VISUAL STIMULI IN THE FAST MOVEMENTS INHIBITION

Saberi Kakhki, A., Kheyrandish, A.

*Ferdowsi University of Mashhad*

**Introduction** Various studies have been conducted in the conformation of the no return of point hypothesis. Almost in many studies, motor program's concept and inability to stop after the start point can be seen. Gao and Zilaznig (1991) evaluated the Henry and Harrison's hypothesis in detail. They showed that maybe the task type, the scaling and the data analysis methods for motor pattern are affecting the results. Therefore, due to this study we controled the task type and stimulus presented. This study intends to answer this question that does the no return of point change by changing the nature of variables (task type, stimulus type). **Methodology** Participants were 50 graduate student volunteers. In three experiment we examined difference between stimulus in reaction time (experiment 1) and effect of stimulus type on stop-signal paradigm (experiment 2) also, we examined effect of task type with changing the stop-go time and both analogue and digital stopwatch (experiment 3). The experiments were designed similar to Slater and Hammel's pattern and consist of a software and a hardware of a stopwatch with visual, audio and combined stimuli. **Results** Data was analyzed by ANOVA and analysis of variance with repeated measures. The results of experiments showed that the difference between groups in audio and visual stimuli are significant ( $F=8.323$ ,  $P=0.00$ , experiment 1). Participants have learned the presented pattern in retention stage. In the transfer stage, they were compared about each of the time provided. In some of the times, differences between groups were significant (experiment 2). The third experiment results showed A significant advantage in favor of the visual analogue was found ( $p = 0.041$ ). **Discussion** In first experiment participants in audio group were better than the others. (Shelton and Kumar 2010). In the second experiment, The groups behave the same and the parameters affected by the times are the same. This shows that a motor program is active before and after the stop time and is run on the time spectrum the time of no return point is longer than Slater-Hammel's report (210 msec). Moreover, based on the third experiment result, participant's response to the stop time is highly dependent on task type. Probably, the Slater-Hammel's results have influenced by task type and also the used variable of statistical analysis. Finally, we suggest that intentional behavior may be controlled by top-down hierarchical mechanism, while the participant does not expect the stop time, it follows the direct perception process. **Reference:** 1. #### CHANGES IN COORDINATION DURING LEARNING A GYMNASTICS SKILL

Williams, G.K.R.1, Irwin, G.2, Kerwin, D.2, Hamill, J.3, Van Emmerik, R.E.A.3, Newell, K.M.4

*1: ARU (Cambridge, UK); 2: CMU (Cardiff, UK); 3: UMass (MA, USA); 4: PSU (PA, USA).*

**Introduction** During skill learning technique of a performer must better satisfy the mechanical demands of the task for performance to improve. Motor control, and synonymously motor learning, research is interested in understanding, explaining in terms of control, and predicting technique changes during learning. However, there are a number of missing links between our biomechanical understanding of skills and motor learning theory in the natural physical setting of sports skill learning. This work explores changes in characteristics of technique that are underpinned by the dynamical systems theory of motor control, how they contribute to our understanding of skill learning and the subsequent practical implications of this research. **Methods** Two groups of novices; one successful ( $n = 4$ ), and one unsuccessful ( $n = 4$ ), performed the gymnastics longswing on high bar during five practice sessions. Two expert gymnasts performed five sets of longswing a during one testing session. Kinematic data (Coda motion) were collected during swing attempts. Continuous Relative Phase (CRP) of the hip and shoulder motions was examined for the longswing a performed by the two groups of novices and the two expert gymnasts. Principal Component Analysis (PCA) was used to identify changes in the CRP profiles of novices over practice, and to investigate the characteristics that distinguished successful from unsuccessful novices. **Discussion** PCA did not distinguish successful from unsuccessful novices CRP profiles. When examining hip and shoulder CRP profiles of successful novices in comparison with those of expert gymnasts PCA showed that successful novices technique became more out-of-phase over the practice period, and less similar to the closely in-phase technique of the elite gymnasts. These findings support the proposition that at the level of inter joint coordination a technique emerges over practice that facilitates successful performance for novices but is less like that of elite gymnasts performing the skill. The findings questions the appropriateness of inferring development towards a 'gold champion' technique when defined by movement coordination.

## DO JUMP ABILITY, SPRINTING AND BALANCE INFLUENCE AGILITY OF JUNIOR HIGH AND HIGH SCHOOL FEMALE SOCCER PLAYERS?

Inoue, Y.

*Kobe International University*

**Introduction** Agility that can change direction quickly is important for soccer players. A purpose of this study was to examine factors to influence agility of female soccer players. **Methods** The participants were 29 junior high and high school female soccer players. Two kinds of agility tests that Japan Football Association recommends were measured, which were Agility test 1 to assess agility corresponded to defense and Agility test 2 to assess agility corresponded to offence. Isometric maximum muscle strength of hip abduction and extension, and isokinetic peak torque of knee flexion and extension (60 degrees /sec) on a pivot leg were measured. Other tests included linear sprints (40m), hopping test (the distance of three steps jumping with one leg) and Modified Star Excursion Balance Test (MSEBT). We examined the correlation of the times of two agility tests and the results of other tests using Pearson's product-moment correlation coefficient. **Results** The times of Agility test 1 were significantly related to the knee extension peak torque ( $r = -.45, p < .05$ ), the knee flexion peak torque ( $r = -.61, p < .01$ ), the right hopping test ( $r = -.57, p < .01$ ), the left hopping test ( $r = -.61, p < .01$ ), linear sprint times ( $r = .51, p < .01$ ), the hip abduction muscle strength ( $r = -.37, p < .05$ ), the hip extension muscle strength ( $r = .37, p < .05$ ). The times of Agility test 2 were significantly related to the knee extension peak torque ( $r = -.41, p < .05$ ), the knee flexion peak torque ( $r = -.50, p < .01$ ), Right hopping distance ( $r = -.39, p < .05$ ), Left hopping distance ( $r = -.47, p < .01$ ), linear sprint times ( $r = .57, p < .01$ ), the hip abduction muscle strength ( $r = -.44, p < .05$ ). The results of both agility tests did not show any correlations with the MSEBT. **Discussion** The agility of the junior high and high school female soccer players did not show any correlations with the ability for dynamic balance (MSEBT) shew comparatively higher Pearson's correlations between knee flexion peak torque, hopping distance and linear sprint times. Seulic et al. reported agility was significantly related to the balance for males but not for females and the female agility had weak correlation with power. The Vescovi et al. report linear sprint times and the vertebral jump correlated with agility of the female athletes. Our research suggested ability was related to the power, such as knee muscle strength, jumping performance and linear sprints, should be considered to improve agility of junior high and high school female soccer players. **References** Sekulic D, Spasic M, Mirkov D, Cavar M, Sattler T. ## LEARNING MOVEMENT PHASES DURING EARLY STAGES OF MOTOR LEARNING

Ghorbani, S., Bund, A.

*Aliabad Katoul Islamic Azad University., Luxembourg University*

**Introduction** Traditionally, in motor learning research the process of learning a new motor skill is evaluated by measuring repeatedly the performing of the to-be-learned motor skill as whole (e.g., Hodges, Hayes, Horn, & Williams, 2005). However, it is not clear if the individuals learn various phases of a new motor skill, i.e., preparatory, main, or end phases similarly or differentially. Principally, a lack of a detailed analysis of movement phases during the process of motor skill learning can be determined in the motor learning literature. Therefore, the present study attempts to bridge this gap and provide some new data on learning movement phases by the example of a complex throwing skill. **Methods** Participants were eight male and female young adults. Due to its clear movement phase structure, Baseball-pitch was chosen as motor task. To introduce motor task to participants, they were shown instruction material consisted of static pictures of pitch phases and additional notes related to each phase. Participants were then asked to perform five trials in a pretest followed by three blocks of ten trials in the acquisition phase. Two retention test, each with five trials, were conducted ten minutes and seven days after last block. All trials of pretest and retention tests and first three trials of each acquisition block were filmed by four synchronized digital cameras for later kinematic analysis. Intra- and inter-limb coordination of upper- and lower body segments were measured as dependent variables. **Results** Data of movement phases were compared to each other (PHASE) and from pretest to acquisition blocks and retention tests (TIME). Moreover, data of intra- and inter-limb coordination were also compared to each other (LIMB) and from pretest to acquisition phase and retention tests (TIME). Results of comparing the movement phases showed that there was a significant main effect for PHASE ( $F = 4.62, p < .05$ ), TIME ( $F = 3.70, p < .01$ ), INTERACTION ( $F = 4.48, p < .001$ ). In this regard, there were significant differences between the stride phase and the other phases. Results of comparing the intra- and inter-limb coordination showed that there was no significant main effect for LIMB (intra- and inter-limb coordination) ( $F = 2.17, p > .1$ ), TIME ( $F = 3.70, p > .1$ ), or INTERACTION ( $F = 1.02, p > .1$ ). **Discussion** Results indicate that the participants had more problem with coordinating the stride phase than the other pitch phases (as shown by significant main effect for PHASE) while performed the pitch and became gradually better with practice (as shown by significant main effect for TIME). One explanation for these results might be that the stride phase is the only segment in which the participants had to move upper and lower body parts (right arm and left leg) simultaneously. Due to this feature, they needed to unfreeze more degrees of freedom, which led to inferior coordination performance in this phase (Bernstein, 1967).

## THE ROLE OF VIDEO MANIPULATION IN SKILL ACQUISITION

Crowther, R.G.1, Woolley, T.L.2, Doma, K.2, Conner, J.D.3,4, Pohlmann, J.1

1: USQ (Springfield, Australia), 2: JCU (Townsville, Australia), 3: ISEAL (Melbourne, Australia), 4: CA (Brisbane, Australia)

**Introduction** The use of temporal and spatial occlusion are well established methods to obtain visual information and subsequent mechanisms underlying sport skills when comparing athlete levels and progression of learning. Although temporal occlusion may meet ecological validity, the use of spatial occlusion in research (Panchuk & Vickers, 2009; Williams & David, 1998) where sections of the body are no longer visible may cause concerns for poor ecological validity. Therefore, the aim of this abstract is to discuss the use of video manipulation as a tool for analysing anticipation. **Methods** This abstract involves data taken from a previous study by the authors where video of a striker kicking a penalty kick was digitally manipulated by changing the standing leg depending on direction. Three groups depending on skill where used, goalkeepers ( $n = 17$ ), field players ( $n = 20$ ) and control group ( $n = 20$ ). An eye tracker was worn whilst watching 40 videos of a striker kicking at the goal in randomised placement order (left or right and high or low). All 40 videos were temporally occluded at foot-to-ball contact and the non-kicking leg of 20 videos were spatially manipulated. **Results** As shown in Tamara et al., (2015), the results of using a video spatial manipulation method for the football penalty kick showed similar effects as previous research (Savelsbergh et al. 2002) for predominately final fixations occurring at the stance foot (37.6%) and the ball (33.7%). There was no significant difference for goalkeepers' prediction the direction of the ball in either the manipulated or controlled condition. **Discussion** This is the first time that video spatial manipulation has been used and it appears that the results mimic previous research with spatial occlusion. However, it has been shown that once the stance leg is occluded performance decreases, this was not the case when the video was manipu-

lated. Future research should look at comparing the methods to determine which would be more useful from an ecological point of view. References Panchuk, D., & Vickers, J. N. (2009). ### **HOW TO MAXIMIZE PERFORMANCE? INFLUENCE OF COMBINING AUGMENTED FEEDBACK WITH AN EXTERNAL FOCUS OF ATTENTION AND WITH REWARD**

Wälchli, M., Bourquin, Y., Ruffieux, J., Keller, M., Taube, W.

*University of Fribourg*

**Introduction** It was previously demonstrated that jump height could be improved in the short and long-term when providing augmented feedback (aFB) (Keller et al. 2014a). Furthermore, aFB was superior to an internal (IF) or external focus (EF) of attention for maximizing jump performance (Keller et al. 2014b). For the present study, we introduced a monetary reward condition (RE) and combined aFB with an EF and with RE. We hypothesised that if the underlying mechanisms of aFB, EF and RE are not redundant, we should see most beneficial effects when combining these conditions. **Method** 18 adults (26.6±8.9 years, 1.74±0.09 m, 71.4±12.7 kg; 8 female and 10 male) were performing counter movement jumps (CMJs). Participants were told to jump as high as possible in each single trial and to respect the additional instructions. Each participant executed 16 series of six maximal CMJs distributed to the following six conditions: Neutral (NE), aFB, RE, aFB+EF, aFB+RE and aFB+EF+RE. Each condition was repeated twice and the order was randomized for each participant. **Results** Participants showed the highest jump heights with aFB+EF (39.30±6.65 cm) and, as expected, the worst in the NE condition (38.15±7.05 cm). A one-way ANOVA with repeated measures revealed significant differences between conditions ( $F_{5,45} = 9.092$ ;  $p < 0.01$ ;  $n_2p = 0.348$ ). Post-hoc analysis with Bonferroni corrected t-tests indicated clear differences between NE and aFB+EF ( $p < 0.01$ ), NE and aFB+EF+RE ( $p < 0.01$ ), NE and aFB+RE ( $p = 0.044$ ), aFB and aFB+EF ( $p = 0.014$ ) and RE and aFB+EF ( $p = 0.014$ ). No significant differences between conditions concerning force production, muscular activity or movement kinematics were observed. **Discussion** Three conditions (aFB+EF, aFB+EF+RE and aFB+RE) showed significantly superior performance compared to the NE condition. The aFB+EF condition was, however, the only condition that was significantly superior compared to aFB and RE alone and may therefore be considered as the most efficient approach to maximize jump performance.

### **BEHAVIORAL DIFFERENCES IN PRESCHOOL CHILDREN WITH VARYING LEVELS OF MOVEMENT ABILITY DURING FREE PLAY**

Sasaki, R., Ishizawa, J.

*Keio University*

**Introduction** Early childhood is a critical period for the development of fundamental movement skills (FMS). FMS acquisition is developmentally sequenced and contingent upon the acquisition process occurring through a range of active play experiences. FMS competency may be associated with physical activity level. However, sufficiently rich repertoires of movement often do not occur in daily physical activity. In this study, we clarify differences between movement variations of children with greater FMS and children with lower FMS in early childhood in order to determine what support FMS acquisition may require. **Methods** Participants were typically developing preschool children aged 4–6 years. We made video recordings of participants during free play in preschool for roughly 30 minutes consecutively. From these video recordings, we observed children's movements in terms of moment-to-moment changes in all behaviors, and categorized roughly 30 movements, for example, "walk," "run," "jump," "throw," and "lie down." We analyzed the number of times each movement occurred, each movement's frequency, and the time duration of each movement occurrence. The behavioral patterns of children with different FMS levels were examined. **Results** Generally, larger repertoires of movement were observed in children with greater FMS than in children with less. However, age and gender differences were also observed. Overall, locomotive movements such as 'walk' and 'run' were most commonly observed during free play activities. However, certain movements, such as some object control skills, were observed at very low rates in all video recordings. **Discussion** In this observational study, children with greater FMS, particularly boys, performed a larger repertoire of movement than children with lower FMS. Previous research has indicated positive associations between FMS competency and physical activity level (Fischer et al, 2005, Williams et al, 2008). In contrast, it has been reported that object control skill competence was not associated with moderate-to-vigorous physical activity. Preschool children's FMS are still somewhat rudimentary. Hence, during the preschool period, various physical activities may drive the development of motor skill competence (Stodden et al. 2008). From our findings, we suggest the need to provide structured opportunities that facilitate children's acquisition of FMS, which may include providing unfamiliar movement activities, games, equipment and spaces. **References** Fisher et al. ### **THE MOTOR PROFICIENCY OF ADOLESCENTS USING MABC-2 AGE BAND 3**

Tan, S.Y.J.

*Republic Polytechnic*

**THE MOTOR PROFICIENCY OF ADOLESCENTS USING MABC-2 AGE BAND 3** **Introduction** Motor assessment plays a vital role in the comprehension of motor development of children and adolescents. Many studies have used the Movement Assessment Battery for Children-2 (MABC-2; Henderson, Sugden & Barnett, 2007) of different age bands to evaluate motor proficiency of children and adolescents. The only relevant study conducted in Singapore was to identify the young children with coordination problems using the first version of MABC. However, information of the motor proficiency of adolescents in Singapore, including the use of MABC-2 age band 3 has not been well documented. Therefore, the objective of this study was to evaluate the motor proficiency of Singaporean adolescents using MABC-2. **Methods** Thirty adolescents ( $n = 30$ ; 15 males, 15 females; age range: 13 – 16 years), without pre-existing medical or health conditions, from different regular schools in Singapore volunteered for this study. Ethics procedures via internal institutional review committee were conducted and approved. Parental consent was obtained. The eight motor tasks of MABC-2 (Henderson, Sugden & Barnett, 2007) were grouped according to three task components of 1) manual dexterity, 2) aiming and catching and 3) static and dynamic balance to evaluate the motor proficiency of the participants. **Results** The results showed no significant gender difference between male and female

adolescents ( $p > .05$ ). However, one-sample t-test revealed that the participating adolescents performed significantly poorer balance component as well as total standard scores as compared to the MABC-2 normative data ( $p \leq .05$ ) which was established based on UK population. Discussion While the maturation of balance control has been documented to stabilise by the age of 10, the poorer balance abilities of Singaporean adolescents suggests that they were not as proficient as they should be. While this could be explained by varied PE lessons in different cultural settings, it could be mitigated because the norms were based on a UK population. Given that there is no significant difference for other task components between participating adolescents and the MABC-2 normative sample, it is recommended that more balance-focused physical activities could be incorporated during PE lessons in Singapore. The effects of low and high carbohydrate diet on weight and fat loss during energy restriction for athletes in short-term Makiko Toguchi<sup>1</sup>, Hiroyuki Sagayama<sup>1</sup>, Takaya Hirota<sup>2</sup>, Kouhei Shimada<sup>2</sup>, Ikumi Yamazaki<sup>2</sup>, Yasuki Higaki<sup>2,3</sup>, Akira Kiyonaga<sup>2,3</sup>, Hiroaki Tanaka<sup>2,3</sup>  
<sup>1</sup>Graduate School of Sports and Health Science, Fukuoka University, Fukuoka, Japan. <sup>2</sup>Faculty of Sports and Health Science, Fukuoka University, Fukuoka, Japan. <sup>3</sup>Fukuoka University Institute for Physical Activity, Fukuoka, Japan. Introduction Low carbohydrate (LC) diet is one of the popular diets to decrease weight loss. For some athletes, it is desired to decrease their body weight (BW) to optimize performance. To reduce the BW, an energy deficit is needed and the amount of weight loss depends on energy deficit. Therefore, BW could be reduced when energy expenditure (EE) increases, energy intake (EI) decreases, or combination of the two. If it is under the same energy deficit conditions, the same amount of BW and fat reduction could be achieved whether diet contents are low or high carbohydrate (HC). The objective in the study was to investigate the effects of LC and HC diet on weight and fat loss during energy restriction for athletes in a 1-week. Methods The subjects were eleven (7 men and 4 women, age: 20.1±1.1 years; height: 171.9±6.8 cm; BW: 65.0±7.2 kg). They participated in weight loss intervention program for a 1-week and were assigned randomly to 2 groups (LC (n=6) and HC diet group (n=5)). Daily EI were 1100~1400kcal, which was based on individual body mass index. LC diet was set 40% fat, and 30% carbohydrate. HC diet was set 20% fat, and 50% carbohydrate. Both diets were set 30% protein (1.4~1.5g/kg/day). In addition to their usual training, they conducted interval-jogging program for 1 hour (repeated cycles of running for 1 minute and walking for 30 seconds) twice every day. Body composition and Total EE were measured by the doubly labeled water method before and after the intervention. Results BW and fat mass (FM) were significantly decreased in both groups during intervention, respectively (BW and FM, LC:1.9±1.0 and 1.7±1.3 kg, HC:1.8±1.0 and 1.7±0.6 kg). But total body water and fat-free mass was not changed in the both group. Total EE was 3416±416kcal/day for the LC group, 3424±444kcal/day for the HC group. EI was 1285±95kcal/day for the LC group, 1335±150kcal/day for the HC group. Physical activity level was 2.6±0.3 for the LC group, and 2.4±0.2 for the HC group. Discussion BW and FM were decreased in LC and HC diet groups but not significant difference in groups. But fat-free mass did not change in both groups. Therefore, LC diet and HC diet would be same effect of weight loss under the same energy deficit. It could be possible to choice of meal for athletes who want to lose weight. References Stuart M. #### LACTOTRIPEPTIDES SUPPLEMENTATION AFFECTS BRACHIAL ARTERIAL DIAMETER AND MAXIMAL ISOMETRIC FORCE FOLLOWING HIGH-INTENSITY ECCENTRIC EXERCISE.

Tagawa, K., Ra, S.G., Choi, Y., Maeda, S.

*University of Tsukuba*

Introduction Maximal isometric force (MIF) decreases following high-intensity eccentric exercise (ECC). Brachial arterial diameter increases following ECC. Lactotripeptides (LTP), two active tripeptides, valine-proline-proline and isoleucine-proline-proline, have vasodilative effect. The purpose of this study was to investigate that whether LTP supplementation improves MIF and brachial arterial diameter following ECC. We hypothesized that LTP supplementation would increase brachial arterial diameter and suppress decreased MIF following ECC. Methods 22 young healthy men (age, 23.8 ± 1.7 years) were randomly assigned to two groups (placebo + ECC: placebo group, LTP + ECC: LTP group) and given a 4.8 mg/day placebo or LTP, thirty minutes before ECC, one hour following ECC, and three hours following ECC. In the next day, placebo or LTP supplementation ingested in the morning, evening, and night. All subjects performed 50 repetition unilateral maximal-effect ECC of the elbow flexors on the Biodex isokinetic dynamometer, with each contraction lasting 1 sec with one repetition performed 12 sec as described previously (Choi et al. 2014). Blood pressure (SBP, MBP, DBP, and PP), heart rate (HR), MIF in the biceps brachii, and brachial arterial diameter in the exercised arm assessed before and 2 days after ECC. Results There were no differences in blood pressures and HR between two groups during experiment. MIF following ECC significantly decreased in placebo group ( $p < 0.01$ ) and LTP group ( $p < 0.05$ ). The decreased MIF tended to be depressed by LTP ingestion ( $p = 0.15$ ). Brachial arterial diameter following ECC did not change in placebo group. In contrast, brachial arterial diameter following ECC significantly increased in LTP group ( $p < 0.01$ ). The change in MIF significantly related to change in brachial arterial diameter after adjusting for weight ( $p < 0.05$ ). Discussion This study showed that LTP supplementation improved changes in brachial arterial diameter following ECC. Previous study showed that LTP supplementation significantly increased nitric oxide production in a dose-related fashion (Hirota et al. 2011). Nitric oxide has vasodilative effect. Therefore, LTP supplementation may have beneficial effect on MIF via its vasodilative effect following ECC. Conclusion The present results suggest that LTP supplementation may have beneficial effect on MIF and brachial arterial diameter following ECC. **DOES CAFFEINE SUPPLEMENTATION LEAD TO DEHYDRATION IN TENNIS PERFORMANCE IN CAFFEINE-NAÏVE PLAYERS?**

Mesquita, R., Alves, B.

*Faculty of Human Kinetics - University of Lisbon*

Introduction: It has been suggested that ingestion of caffeine at least 1 hour prior to a tennis match may improve performance and the ergogenic effects remain present until 6 hours after ingestion, without any significant effects on hydration status. One limitation to these studies is that they did not ascertain the effects of caffeine when consumed on a regular basis. Therefore the purpose of this investigation was to determine the effect of pre-match consumption of caffeine by caffeine-naïve players on hydration status during a tennis match, through a within-subjects placebo-controlled design. Methods: Six highly skilled tennis players between the ages of 18-25 participated in this study. Participants had a daily caffeine consumption below 50mg. Participants performed three tennis matches. In one match the players received 5mg.Kg<sup>-1</sup> of caffeine 1 hour prior to it ('Caffeine'), in another one they received an inert placebo ('Placebo') and in the other they didn't consume anything beyond water ('Baseline'). The degree of dehydration was assessed through the fluid loss during the match: nude body weight (BW) was measured using a digital scale (GSE Scale Systems, Model 550) before and after the match. Repeated measures analysis of variance (ANOVA) was used to test differences in mean scores under the three conditions and Wilcoxon signed-rank test was used to compare the repeated measurements of BW before and after match. Results: No differences between conditions were observed for fluid loss during the match. There was no significant difference between the BW before and after match in any condition and therefore the frequency and amount of water ingestion are sufficient to prevent dehydration under the climatic conditions experienced during the study. Discussion: A caffeine dose of 5mg.Kg<sup>-1</sup> does not lead to a significant degree of dehydration among caffeine-naïve tennis players. Thus, the diuretic effects of caffeine are not sufficiently significant to depreciate its ergogenic effects on performance. In this study there were significant differences between the sweat rates of the participants, suggesting that tennis players should follow an individualized hydration plan in order to optimize their hydration levels during training sessions or competitions. **A SEVEN-DAY HIGH-FAT, HIGH-ENERGY DIET IMPAIRS GLYCAEMIC CONTROL BUT DOES NOT DISRUPT THE POST-PRANDIAL ACYLATED GHRELIN RESPONSE TO A MIXED MEAL**

Parry, S., Smith, J.R., Hulston, C.J.

*Loughborough University*

Introduction: Insulin resistance is a major characteristic of obesity and type II diabetes. Although the obesity epidemic is undoubtedly caused by a chronic positive energy balance, the early metabolic responses to overeating are poorly described in humans. Thus, the aim of this study was to determine changes in glycaemic control after 7 days high-fat overfeeding. Method: Nine healthy individuals performed a MTT before and after consuming a high-fat (65%) high-energy (+50%) diet for seven days. Daily energy requirements were estimated using equations for resting energy expenditure corrected for reported physical activity. This value was then used as a baseline to calculate the amount of food required for the overfeeding period. The MTT provided 3227 kJ; 30 g fat, 112 g carbohydrate and 19 g protein. Plasma glucose and serum insulin concentrations were determined at baseline and at 30 min intervals throughout MTT for assessment of whole-body glycaemic control. Plasma triglyceride and acylated ghrelin concentrations were also determined at 30 min intervals; with acylated ghrelin being used as a biological marker for potential changes in appetite regulation. Results: Estimated daily energy requirements were 10717 ± 481 kJ. During the 7-day overfeeding period, subjects were provided with 16075 ± 722 kJ per day; 10449 ± 465 kJ (277 ± 12 g) from fat. Body mass increased by 0.79 ± 0.14 kg after 7-days overfeeding (p < 0.0005). Fasting plasma glucose increased from 5.5 ± 0.12 mmol/L before overfeeding to 5.8 ± 0.08 mmol/L after (p = 0.016), whereas fasting plasma insulin was unaffected (71 ± 8 and 82 ± 9 pmol/L before and after overfeeding, respectively, p > 0.05). Glucose AUC increased by 11.6% (1020 ± 74 vs. 1138 ± 56 mmol/L/180 min, p = 0.009) and insulin AUC increased by 25.9% (53267 ± 6375 vs. 67046 ± 6849 pmol/L/180 min, p = 0.006). Plasma acylated ghrelin decreased following ingestion of the MTT, with the lowest concentrations being observed at 30 min and remaining suppressed for 180 min; however, this response was not affected by overfeeding. Conclusion: A 7-day high-fat, high-energy diet rapidly disrupts whole-body glycaemic control. Therefore, this experimental model may be useful when studying the early responses and underlying mechanisms behind the development of insulin resistance and type II diabetes in humans without the confounding factors associated with obesity. The postprandial acylated ghrelin response to MTT was unaffected by 7 days of overfeeding, suggesting that either a longer diet challenge may be needed to disrupt appetite regulation or that acylated ghrelin levels do not respond to changes in energy balance, but this requires further investigation.

**EFFECT OF LACTOFERRIN ON LIPOLYTIC ACTIVITY UPON CATECHOLAMINE STIMULATION IN 3T3-L1 ADIPOCYTES**

Sakamoto, S.1, Ono, T.2, Murakoshi, M.2, Hashimoto, T.1,3

*1: Ritsumeikan University, 2: Lion Corporation, 3: FISS*

Introduction Lactoferrin (LF) is a multifunctional glycoprotein in mammalian milk. In a previous report, we showed that an 8-week administration of LF resulted in decreased visceral fat accumulation in Japanese men and women with abdominal obesity. Furthermore, we also found that the LF treatment to mature adipocytes elevated basal lipolytic activity concomitant with increased intracellular cAMP. However, it is not clear whether LF treatment could increase lipolytic activity upon catecholamine stimulation in adipocytes. The aim of this study was to examine the effect of LF treatment on lipolytic activity upon catecholamine stimulation in 3T3-L1 adipocytes. Methods 3T3-L1 cells were grown in 12-well dishes. Differentiated cells were treated with DMEM containing with (LF) or without (CON) 1mg/mL LF for 3 days. After the treatment, lipolytic activity was analyzed by incubating cells with DMEM containing 2% fatty acid-free BSA/20 mM HEPES-NaOH (pH 7.4) with 0.5 mM IBMX and 10 µM isoproterenol at 37°C. After incubation for 3 hrs, aliquots of the medium were collected and assayed for glycerol and fatty acid (FA) contents using TG E-test kit and NEFA C-test kit, respectively. Triacylglycerol (TAG) was also measured using a TG E-test kit. The expressions of lipid-associated proteins were analyzed by western blotting. Results The TAG content in mature adipocytes treated with LF for 3 days was significantly decreased upon catecholamine stimulation as compared with CON (p < 0.01), although lipolytic activity as estimated by the glycerol release was not increased by LF treatment. On the other hand, LF significantly increased the FA release as compared with CON (p < 0.01). The expression of diacylglycerol acyltransferase1 (DGAT1), one of the lipid

synthesis-associated proteins, was significantly decreased in mature adipocytes treated with LF for 3 days as compared with CON ( $p < 0.05$ ). Discussion These results suggest that LF inhibits resynthesis of FA into TAG during lipolysis via the reduction of DGAT1, thereby decreasing TAG content upon catecholamine stimulation in 3T3-L1 adipocytes. ### LONG-TERM VITAMIN D3 SUPPLEMENTATION PREVENTS VITAMIN D DEFICIENCY

Backx, E.1, Tieland, M.1, Maase, K.2, Meima, R.3, Kies, A.3, Mensink, M.1, van Loon, L.4, Groot, L.1

1: Wageningen University, Wageningen, The Netherlands, 2: NOC\*NSF, Arnhem, The Netherlands, 3: DSM Biotechnology Center, Delft, The Netherlands, 4: Maastricht University, Maastricht, The Netherlands

Background: Vitamin D deficiency is highly prevalent among athletes, especially during winter months [1]. Recent studies show that a sufficient vitamin D status can increase sports performance [2, 3]. It remains unclear what dosage of vitamin D3 is needed to achieve a sufficient vitamin D status in elite athletes. Purpose: To assess the prevalence of vitamin D deficiency in Dutch athletes and to define the required dosage of vitamin D3 to prevent vitamin D deficiency over the course of a year. Method: A total of 128 highly trained athletes were recruited and blood samples were collected to assess 25(OH)D status. Of these 128 athletes, 54 male and 48 female athletes (18-32 y) were included in a randomized, double blind, dose-response study. Athletes with a deficient (<50 nmol/L) or insufficient (50-75 nmol/L) 25(OH)D status were randomly assigned to take 400, 1100 or 2200 IU vitamin D3 per day for one year. Athletes who had a 25(OH)D status above 75 nmol/L received no supplements and were monitored only. Serum 25(OH)D was assessed every 3 months as well as vitamin D intake and sunlight exposure. For subjects who reached a 25(OH)D level of >125 nmol/L dose was adjusted to a maintenance dose of 400 IU/d. Results: Nearly 70% of all athletes showed an insufficient (50-75 nmol/L) or deficient (<50 nmol/L) 25(OH)D status at baseline. After 12 months, serum 25(OH)D increased more in the 2200 IU/d group (50±27 nmol/L) compared to the sufficient group (4±17 nmol/L;  $P < 0.01$ ) and the 1100 IU/d group (25±23 nmol/L;  $P < 0.05$ ), as analyzed using linear mixed models. Vitamin D supplementation with 2200 IU/d resulted in a sufficient vitamin D status in 85% of the athletes after 3 months and in 80% of the athletes after 12 months. Conclusion: Vitamin D deficiency is highly prevalent in athletes. Supplementing 2200 IU vitamin D3 per day prevents vitamin D deficiency throughout the course of the year. References: 1. ### INFLUENCE OF A 5-DAY FASTING PERIOD ON ISOMETRIC MAXIMAL STRENGTH AND JUMPING HEIGHT OF HEALTHY YOUNG ADULTS

Hentz, C.1, Limmer, M.2, Eibl, A.1, Krusche, T.1, Felker, K.1, Sonnefeld, H.1, Platen, P.1

1 RUB, Bochum, 2 DSHS, Cologne

Introduction Fasting is the abstinence from eating or drinking over a defined period of time for one or several days or a longer period. It is a traditional method to support the treatment of cardiometabolic diseases, to improve general physical and psychological wellbeing (Li et al., 2013) and has a beneficial effect on inflammation and oxidative stress (Dannecker et al., 2013). More and more physically active people use fasting for improvement of wellbeing or other reasons. It is not known in detail how short-lasting nutrient restriction affects performance. The aim of this study was to analyze the influences of a 5-day fasting period on isometric maximal grip strength (IMGS) and strength of knee extension (IMSK), and jumping height (JH) in the counter-movement jump (CMJ) and squat jump (SJ). Methods 20 healthy young physically active adults (n=10 male, n=10 female, age: 24.6±/-6.7 years, height: 1.76±/-0.09 m, weight: 73.9±/-11.9 kg) volunteered to participate in a 5-day fasting period according to the Buchinger method, which allows fruit and vegetable juices, honey and vegetable broth with a total caloric intake of maximally 500 kcal per day. IMGS, IMSK and JH were analyzed 2 days before, on the 5th day within and 2 days after the fasting period. IMGS was tested by the JAMAR hydraulic hand dynamometer with a 3-sec maximal voluntary contraction followed by a 15 second break. IMSK was determined in a fixed sitting position by means of a force transducer with 6-sec maximal voluntary contraction followed by a 30 sec break. 3 trials were assessed. IMGS and IMSK were conducted separately for the right and left hand and leg. For statistics we used the mean values of the 3 trials. JH was assessed via contact mats with 2 tests for CMJ and SJ, respectively, and the mean value being used for statistics. Statistics included ANOVA and paired t-Test. The level of significance was set as  $p < 0.05$ . Results Grip strength of both hands increased after the fasting period (right hand: 6.5%, left hand: 6.0% ( $2p < 0.05$ )). Isometric maximal strength of knee extension and jumping height in CMJ and SJ remained unaffected. Discussion A 5-day fasting period did not negatively influence isometric maximal strength of knee extension and jumping height in CMJ and SJ. Slight increases in grip strength are probably due to learning effects but not due to metabolic alterations during and after the fasting period. A short-lasting fasting period according to the Buchinger method does not negatively influence muscle strength and might be used by healthy physically active people. ### CURCUMIN SUPPLEMENTATION LIKELY ATTENUATES DELAYED ONSET MUSCLE SORENESS

Rowlands, D., Nicol, L., Fazakerly, R., Kellett, J.

Massey University, SportsMed Canterbury, Australian Institute of Sport

Oral curcumin decreases inflammatory cytokines and increases muscle regeneration in mice. Purpose. To determine effects of curcumin on muscle damage, inflammation, and delayed onset muscle soreness (DOMS) in humans. Method. Seventeen men completed a double-blind randomized controlled crossover trial to estimate the effects of oral curcumin supplementation (2.5 g twice daily) versus placebo on single-leg jump performance and DOMS following unaccustomed heavy eccentric exercise. Curcumin or placebo were taken 2-d before to 3-d after eccentric single-leg press exercise, separated by 14-d washout. Measurements were made at baseline, and 0, 24, and 48-h post-exercise comprising: (a) limb pain (1-10 cm visual analogue scale; VAS), (b) muscle swelling, (c) single leg jump height, and (d) serum markers of muscle damage and inflammation. Standardized magnitude-based inference was used to define outcomes. Re-

sults. At 24-h and 48-h post-exercise, curcumin caused moderate-large reductions in pain during single-leg squat (VAS scale -1.4 to -1.7; 90%CL:  $\pm 1.0$ ), gluteal stretch (-1.0 to -1.9;  $\pm 0.9$ ), squat jump (-1.5 to -1.1;  $\pm 1.2$ ), and small reductions in creatine kinase activity (-22% to 29%;  $\pm 21\%$  to 22%). Associated with the pain reduction was a small increase in single-leg jump performance (15%; 90%CL  $\pm 12\%$ ). Curcumin increased interleukin-6 concentrations at 0-h (31%;  $\pm 29\%$ ) and 48-h (32%;  $\pm 29\%$ ) relative to baseline, but decreased IL-6 at 24-h relative to post-exercise (-20%;  $\pm 18\%$ ). Conclusions. Oral curcumin likely reduces pain associated with DOMS with some evidence for enhanced recovery of muscle performance. Further study is required on mechanisms and translational effects on sport or vocational performance.

### COMPLEX SPORTS DRINK ENHANCES RECOVERY FROM PLYOMETRIC EXERCISE

Bargetto, M.1, Raoux, J.2, Caillaud, K.1, Ennequin, G.1, Andrieux, F.2, Sirvent, P.1

1 *Université Blaise Pascal (Aubière, France)*, 2 *Oxsiis (Clermont-Ferrand, France)*

**Introduction** Post-exercise nutrients timing and selection are essential for glycogen replenishment, muscle protein synthesis and performance recovery (Manninen A., 2006). This study examined the effects of a complex sports drink beverage compared to placebo on recovery from a plyometric and drop jump exercise training session. **Methods** In a randomized, double blind two-arm controlled trial, 19 male active subjects performed an exercise training session with drop-jumps and plyometric jumps, and then immediately drank a complex sports drink beverage (SPD, n=9) or isovolumetric non-caloric placebo (PLA, n=10). The complex sports drink beverage contained amino acids, whey, carbohydrates,  $\beta$ -hydroxy  $\beta$ -methylbutyrate (HMB), green tea extract, ginseng extract, vitamins and electrolytes. Jump performance, 20m sprint, perceived muscle soreness and blood creatine kinase concentration were assessed before the training session, immediately after and 1, 2, and 3 days post training. **Results** Overall ANOVA showed a significant time x group interaction for jump performance and perceived muscle soreness. Post-hoc analysis showed that jump performance was greater 24h after the exercise training session in the SPD group compared to placebo ( $p < 0.05$ ). Perceived muscle soreness was significantly lower in the SPD group 2 and 3 days following the exercise training session compared to placebo ( $p < 0.05$ ). There were no significant differences in the 20m sprint test and in blood creatine kinase concentration among groups. **Discussion** In conclusion, consuming a complex sports drink beverage immediately after plyometric and drop jump training session may offer a recovery advantage regarding jump performance and perceived muscle soreness. However, the complex sports drink failed to enhance recovery assessed by 20m sprint test and a muscle damage blood marker any differently than what was observed with a placebo drink. **References** Manninen A (2006). *Br J Sports Med* 40(11), 900-905. ### EFFECT OF FENUGREEK SEEDS DRIED POWDER ON GLYCOGEN RESYNTHESIS

Ataei, L.

*University of Nicosia*

**1. Introduction** Exercise promotes the consumption of energy sources such as glycogen by mobilizing internal energy metabolism to the maximum and using and depleting the energy source (1). Fenugreek (*Trigonell foenum graecum*) is an annual plant from the family Leguminosae, cultivated in Mediterranean countries and India (2). The main component of this extract is the amino acid 4-hydroxyisoleucine in the form of fenugreek, which has been shown to influence the insulin cell-signaling pathway increasing glucose uptake in insulin sensitive tissues, along with the up-regulation of metabolic enzymes and increased muscle and liver glycogen storage (3). The study was designed to determine the effects of ingesting an oral supplement containing fenugreek seeds dried powder (*Trigonella foenum-graecum*) with a glucose beverage on rates of post-exercise muscle glycogen resynthesis in normoglycemic male endurance athletes. **2. Materials and methods** The research included 30 competitive male kayakers with an average age  $18.2 \pm 2.8$  years and body height  $170.2 \pm 6.7$ cm, body mass  $70.3 \pm 4.3$  kg, divided into 2 groups of 15 subjects. Subjects completed a 90-minute glycogen depletion by paddling on ergometer machines following a 12 hour overnight fast. Immediately after exercise and 2 hours after, the muscle biopsy was obtained from the vastus lateralis. After 4hrs exercise subjects received an oral dose of 2 g.kg BW(-1)dextrose (Glu) or 200 mg.kg(-1) Fenugreek supplement and the same oral dose of dextrose, with the third muscle biopsy. Post exercise muscle glycogen concentration was similar for both trials. **3. Results** The results showed a significant increase in glucose and insulin rate from time 0 throughout the 4-hour recovery period. Although there was no significantly increased on muscle glycogen concentration from immediately post exercise to 4 hr of recovery for both trials. This data demonstrates that when the fenugreek supplement is added to a high oral dose of dextrose, rates of post-exercise glycogen resynthesis are enhanced above the effect of dextrose alone. **4. Discussion:** Clinical studies conducted on the fenugreek seed Supplementary have shown 4-hydroxy Isoleucine Aminoacid (4-OH-Ile) in this supplement may increase glycogen synthesis levels. In conclusion, this Supplement may enhanced the carbohydrate loading. However further study is needed to elucidate the more exact mechanism of effect of the Fenugreek on exercise durability. **References:** 1. Grenhaff PL, Timmonns JA. 1998. #### DIFFERENCE IN DUAL-TASK PERFORMANCE BETWEEN FALLERS AND NON-FALLERS IN OLDER PEOPLE

Brustio, P.R.1, Magistro, D.1, Rabaglietti, E.1, Liubicich, M.E.2

*University of Torino (Italy)*

**Introduction** Approximately one third of the individuals aged 65 and over experiences falls at least once a year with serious injuries (Zijlstra et al., 2008). Recently, dual task paradigms were used to assess the risk of falling in older adults with contrasting results (Zijlstra et al., 2008). The aim of this cross-sectional study was to examine the difference on mobility tasks under single-task and dual cognitive-task conditions and the difference in dual-task cost (DTC) between fallers and non-fallers. **Methods** Seventy-four older adults (44 non-fallers, 30 fallers; mean age =  $72.63 \pm 5.57$  yrs) were enrolled in the study. Participants performed the Timed Up and Go Test (single-task) and

Timed Up and Go Test while counting backward 7 (dual cognitive-task conditions). A 2 X 2 repeated measure with between-factor History of falling (non-faller vs faller) and within-factor Tasks condition (single-task and dual cognitive-task) was performed to examine mobility performance differences between fallers and non-fallers. One-way ANOVA was conducted to assess the difference in DTC between fallers and non-fallers. The level of significance was set at  $p < .05$ . Results The repeated measure showed a statistically significant interaction between the History of falling and Tasks condition ( $F(1,72) = 6.399, p < .05$ ). Moreover, a significant difference between faller and non-faller older adults was observed ( $F(1,72) = 5.735, p < .05$ ), as well as a significant reduction in mobility performance in all two groups ( $F(1,72) = 132.687, p < .05$ ). One-way ANOVA showed a significant difference ( $F(1,72) = 4.758, p < .05$ ) in DTC ( $M = 37.8 \pm 27.0\%$  for fallers and  $M = 27 \pm 17.7\%$  for non-fallers). Discussion The results of this study underlined that an additional cognitive-task affected the mobility performance in older adults with history of fall as reported in literature (Springer et al., 2006). Specifically, a slower performance in mobility performance while counting backward was associated with recurrent falls (Shumway-Cook et al., 2000), suggesting that changes in mobility performance during dual tasks might be challenging for fallers (Beauchet et al., 2008). ### DEVELOPMENT OF ADJUSTABLE RESISTANCE MECHANISM TO PHYSICAL FITNESS EQUIPMENT FOR ELDERLY IN NEIGHBORHOOD PARKS.

Tai, T.Y., Liu, C., Kuo, C.Y.

*Institute of Mechanical Engineering*

An adjustable resistance mechanism has been developed to apply for upper limb outdoor fitness equipment. Together with "aging in place" policy, the older adult can be natural aging in the community, and independence, self-esteem and open living space can be created. This hydraulic damper resistance mechanism employed water instead of oil to avoid doing harm to the environment. The transmission cam driven damper piston moves up and down to adjust the resistance. The results reveal that under 30 rpm frequency, the developed adjustable resistance mechanism can produce 24.6 to 26.8 kg resistance. In contrast, the physical fitness equipment right now already established in parks for elderly can only produce 4.7 kg resistance. This new developed mechanism has more stimulation to Brachioradialis, Triceps Brachii muscle, and Trapezius, therefore active ageing can be achieved by promotion of physical fitness, muscle strength and cardiopulmonary function. The aim of this project is to design and develop the adjustable resistance physical fitness equipment for older adults, and provides a constant, regular and effective exercise in the neighborhood park.

### ASSOCIATION BETWEEN SEDENTARY BEHAVIOR AND HEALTH VARIABLES IN ACTIVE BRAZILIAN ELDERLY

Nakamura, P., Sposito, L.A.C., Silva, T.F., Carvalho, D.M., Ferreira, A., Reis, S.A.M., Freitas, W.Z., Silva, E.

*Federal Institute of Education, Science and Technology, Muzambinho, MG, Brazil*

Introduction Sedentary behavior has received widespread scientific attention in recent years. Several recent studies showing associations between sedentary behavior and all-cause mortality and other outcomes (Thorp et al., 2011). Therefore, the aim of this study was to analyse the association between sedentary behavior and variables health in active Brazilian elderly. Methods The sample was 24 active elderly women ( $67 \pm 5.2$  years) from "Projeto Pró-Saúde" (Project Pro-Health) of the Federal Institute of Education, Science and Technology, Muzambinho, MG, Brazil. The project occurs three times a week with 60 min of duration. All participants answered the following questionnaires: a) Sedentary Behavior Questionnaire (Mielke et al., 2013); b) Lifestyle profile (Quality of life) (Nahas et al., 2000). The anthropometric variables (Body Mass Index-BMI), waist hip ratio-WHR, % of fat and visceral fat were evaluated through bioimpedance (InBody 720). The Pearson analysis was used to verify the association between time of TV and time of sedentary transport (TST) and quality of life domains. Further, the Anova linear trend was used to verify the association between time of TV (0 to 180 min and >180 min) and TST (0 to 30 min and >30 min) with anthropometric variables. All analysis were performed through Stata 12.0. Results The time of TV showed a negative correlation with prevent domain of Quality of life ( $r = -0.42, p=0.04$ ). Only TST was positive associated with anthropometric variables. The TST increase 6.53 min/day ( $p=0.03$ ), 10.65 min/day ( $p=0.04$ ) and 36.46 min/day ( $p=0.03$ ) when occurs shift of category to BMI, % of fat and visceral fat, respectively. Discussion The results showed negative association between time of TV and Quality of Life and positive association between TST and anthropometric variables in active Brazilian elderly. Thus, even the participants being active, it was not enough to prevent against the harm of sedentary behavior. References Mielke G, Silva ICM, Owen N, Hallal PC. ### DIET AND FAST WALKING-BASED INTERVENTION TO TREAT OBESITY AND IMPROVE CARDIO-RESPIRATORY FITNESS

Bauer, P.

*University of Vienna*

Introduction: Positive effects of endurance training in the treatment of overweight and obesity are well known. Previous research has shown that fast walking close to preferred transition speed (PTS) can lead to significant weight loss in overweight and obese subjects [1]. However, the effect of this type of training on maximal oxygen uptake ( $VO_{2max}$ ) in overweight and obese is still unknown. The purpose of the current pilot study was therefore to test if fast walking close to PTS would aid in weight loss, improve cardio-respiratory fitness and has favorable effects on overall health status of overweight and obese individuals. Methods: The study included eight middle aged overweight and obese women (age: 30-50 yrs.; BMI:  $29.8 \pm 3.3$  kg/m<sup>2</sup>). Body composition, measured by bioelectrical impedance, body height (cm), body mass (kg), waist circumference (cm), resting heart rate (bpm), blood pressure (mmHg) and  $VO_{2max}$  ( $ml \cdot kg^{-1} \cdot min^{-1}$ ) were measured at baseline and following 16 weeks of training program. Exercise was performed 3 days/week consisting 40 minutes of fast walking close to PTS. Subjects followed a moderate diet (1200-1500 kcal/day) based on recommendations for weight loss in obese adults [2]. Results: A paired t-test revealed significant reductions in body weight ( $-15.3 \pm 4.1$  kg;  $p < 0.001$ ), BMI ( $-5.3 \pm 1.2$ ;  $p < 0.001$ ), fat mass ( $-14.5 \pm 3.7$  kg;  $p < 0.001$ ), waist circumference ( $-16.1 \pm 4.7$  cm;  $p < 0.001$ ), systolic blood pressure ( $-8.3 \pm 4.5$  mmHg;  $p = 0.001$ ), diastolic blood pressure ( $-5.9 \pm 2.8$  mmHg;  $p = 0.001$ ) and resting heart rate ( $-8.5 \pm 3.5$  bpm;  $p < 0.001$ ). Over the same period  $VO_{2max}$  improved significantly ( $11.5 \pm 1.6$   $ml \cdot kg^{-1} \cdot min^{-1}$ ;  $p < 0.001$ ). Discussion: Our preliminary findings suggest that fast walking close to PTS along with moderate diet

can substantially lower body weight, body fat and waist circumference and has positive effects on several other health aspects of overweight and obese individuals. Additionally, the training protocol has demonstrated to be strenuous enough to improve endurance performance. Nonetheless, trials with larger sample sizes and different exercise modalities may be needed to confirm these findings. References: [1] Ilic, D., et al. (2012). ### **A TAILORED SUPERVISED EXERCISE PROGRAM REDUCES LOSS OF FAT-FREE MASS IN BARIATRIC SURGERY PATIENTS**

Marc-Hernández, A., Aracil, A., Fernandez-Fernandez, J., García-Valverde, A., Guillen, S., Mateo-Cubo, F., Martínez-Cantó, A., Moya, M.

*Miguel Hernández University*

**INTRODUCTION** Although the beneficial effects on bariatric surgery (BS) on weight loss in the short term are widely proved, the exercise effects on patients who have gone through BS have been less studied. The objective of the current study is to know the effects of a tailored supervised exercise program on the subject's anthropometrical variables, in recently BS operated patients. **MATERIALS AND METHODS** After signing an informed consent, 33 Caucasian adult BS operated patients were included and distributed in two groups: a) an experimental group (GE, n=17), and b) a control group (CG, n=16). The EG realized a 6 months tailored supervised exercise program, while the CG followed the general lifestyle recommendations for BS patients. Three evaluations were performed: a) after the first month of BS (E1); b) once the exercise program had finished (E2); and c) six months after the end of the intervention (E3). "Post hoc", the EG subjects were divided on 2 subgroups: the one that did more than 50% of the scheduled sessions (EG1) and a second subgroup that did less than 50% of the sessions (EG2). **RESULTS** In comparison with E1, at E2 the EG kept the fat free mass (FFM, 54.4 vs 53.8 kg, p=0.406), while the CG significantly lost it (58.3 vs 55.2 kg, p=0.006). Correlations between weight at the end of the program and minutes of aerobic completed activity were found (r=0.517; p=0.049). On the other hand, the EG1 had a higher loss of fat mass than the CG (12.5 vs 8.9, effect size=0.67). At E3, six months after ending the intervention, the EG had a significant loss of FFM in comparison with E2 (53.8 vs 51.8 kg, p=0.002). **DISCUSSION** Bariatric surgery generates great reductions of corporal weight of BS patients (Moya et al., 2014), that can be accompanied by significant loss of FFM (Chaston, Dixon, & O'Brien, 2007). In our study, the tailored supervised exercise program prevented the FFM loss in the EG. However, once the training ceased, the EG showed a significant reduction of the FFM. Because of this, it can be suggested that the strength training during the exercise program could explain this observation. On the other hand, the volume of aerobic exercise seems to influence the weight loss. **REFERENCES** Chaston, T. B., Dixon, J. B., & O'Brien, P. E. (2007). ### **KOREA YOUTH FITNESS CRITERION FOR OBESITY PREVENTION**

Ko, B.1, Sung, B.1, Song, H.1, Park, S.1, Jung, J.1, Lee, G.2, Lee, S.3, Kang, E.4

*1: Korea Institute of Sport Science(Seoul, Korea), 2:Chosun University(Gwangju, Korea), 3:Hanyang University(Seoul, Korea), 4: Korea National Sport University(Seo*

**Introduction** That there is a negative relationship between obesity and physical fitness is well known through several researches (Laurson, K. et al, 2011; Liao, Y. et al, 2013; Welk, G. et al, 2011). It was needed to address the minimum fitness level required to prevent obesity for Korean youth. Therefore, the purpose of this study was to set a fitness absolute evaluation criteria for youth to conform to the standards of the Korea Youth Obesity established by empirical evidence in 2013 and to verify the validity and effectiveness. **Methods** Using an established adolescent obesity criteria based on 2013 results and 3938 adolescence fitness values involved in the national physical fitness 100 project, it was carried out difference analysis and receiver operating characteristic (ROC) between the normal group and the obese group. In accordance with this result, it was presented as minimum required fitness standards by genders and age for preventing overweight of Korean adolescents. The validity and effectiveness was analysed in physical standards set for each criterion of obesity; body fat rate, skinfold sum, and the waist. **Results** There is a significant difference between the normal group and the obese group in 20m round run, the maximum grip strength, relative grip strength, sit-ups, and repeated jump in male. In conclusion, absolute evaluation criterion of cardiorespiratory endurance, muscular strength and endurance are useful for obesity prevention. For female, it is reasonable to utilize the absolute criteria of only cardiorespiratory endurance and strength for obesity prevention. 20m round run, the maximum grip strength, and relative grip strength have shown significant difference between the normal group and the obese group. **Discussion** Physical fitness criteria established in this study will be able to be used as a criterion of the minimum strength for juvenile obesity prevention. Criterion considering the validity or maximum efficacy will be selectively used according to the purpose. In other words, if you only consider validity you can choose the high relationship between absolute valuation of obesity and physical variables. Or another variable can be chosen if the impact of maximum utility is more important than that the social impact of misclassification wrong to classify obesity as normal or the relative impact of what well to classify obesity as obese could be the reference value selected. **References** Laurson, K., Eisenmann, J., & Welk, G. ### **MORNINGNESS AND EVENINGNESS IN MAXIMAL STRENGTH PERFORMANCE**

Küüsmaa, M.1, Sedliak, M.2, Häkkinen, K.1

*University of Jyväskylä*

**1: Department of Biology of Physical Activity, University of Jyväskylä, Finland 2: Faculty of Physical Education and Sport, Comenius University, Slovakia** **Introduction** It has been clearly established that maximal voluntary force varies during the day in human muscles (e.g. Sedliak et al., 2008) but the exact mechanisms behind the diurnal rhythms are still unclear. The aim of this study was to examine the diurnal rhythms in maximal isometric force production in a larger group of subjects and also by separating the morning types and evening types based on their maximal force levels. **Methods** 72 men were measured in the morning (6:00-10:00) and in the evening (16:00-20:00) for maximal bilateral isometric leg press force (MVCLP) together with myoelectric activity (EMGLP), maximal unilateral isometric knee extension force (MVCKE) and maximal voluntary activation level (VA%) during maximal unilateral isometric knee extension force (MVCVA) to-

gether with myoelectric activity (EMGVA). Morning (n=8) and evening types (n=19) were separated from the large group based on the mean morning/evening difference in MVCLP and MVCKE. Results In the total group of subjects MVCLP and MVCKE were  $4.4 \pm 12.9\%$  ( $p < 0.01$ ) and  $4.3 \pm 10.6\%$  ( $p < 0.01$ ) higher in the evening compared to the morning. MVCVA and VA% did not show significant diurnal variation. The morning types showed 6-11% ( $p < 0.05$ ) higher force values in the morning for MVCLP and MVCKE. No significant diurnal variation was observed for MVCVA and VA%. The evening types showed 14-16% ( $p < 0.05$ ) higher force values in the evening with a concomitant higher VA% in the evening ( $p < 0.05$ ). EMGLP and EMGVA did not show significant diurnal fluctuations in any group. Between-group differences were observed for MVCLP ( $p < 0.001$ ), MVCKE ( $p < 0.001$ ) and EMGVA ( $p < 0.05$ ). Discussion In the total group of subjects our results were consistent with previous studies (e.g. Sedliak et al., 2008) as force was higher in the evening compared to the morning. Lack of diurnal rhythms in EMG and VA% suggest that peripheral rather than central mechanisms could explain the morning to evening variation in force production. However, diurnal variations in strength performance seem to be multi-factorial and mechanisms behind the rhythms seem to vary between the individuals (Chtourou & Souissi 2012). Higher evening force values observed in the present evening type group could be partly explained by increased central nervous system drive to the thigh muscles as VA% was also higher in the evening. It seems that in the morning types peripheral factors affect diurnal variations as central mechanisms did not show any time of day effect. However, the exact mechanisms still need further investigation. References Chtourou H & Souissi N (2012). J Strength Cond Res 26: 1984-2005. Sedliak M, Finni T, Cheng S, et al (2008). Int J Sports Med, 29(3):217-24.

### THE ACUTE EFFECT OF THREE DIFFERENT WARM-UP TYPES IN THE ELBOW MAXIMUM ISOMETRIC STRENGTH

Cheng, M.H., Lin, H.T.

*Kaohsiung Medical University*

Introduction: Warm-up such as static stretch and jogging usually used to prevent injuries before exercise. Previous study indicated that long-term whole body vibration (WBV) training could improve muscle strength (Verschuere et al. 2005). However, few studies discuss the effect of vibration in upper extremity and as a warm-up. Therefore, the aim of this study was to investigate the acute effect of vibration in upper extremity, static stretch and jogging in elbow maximum flexion strength. Methods: Six healthy males with physically active (age :  $21.5 \pm 1.1$  years, height:  $169.3 \pm 7.3$  cm, weight:  $68.3 \pm 8.9$  kg) participated in this randomized cross-over trial. All participants received three warm-up programs (vibration, static stretch, and jogging). The subject received vibration at modified push-up posture with the amplitude 2 mm and frequency 30 Hz by 1 minute vibration with 30 seconds rest for three sets. The biceps stretch 30 seconds with 30 seconds rest for three sets as static stretch while jogging was running for three minutes at 8 m/sec. The isometric elbow flexion strength was measured by the dynamometer before and just after three types of warm-up. One-way ANOVA was used to analyze the differences of muscle strength change before and after warm-up between three warm-up programs. Result: There was also no significant difference between pre-test muscle strength and post-test muscle strength in three kinds of warm-up programs vibration, static stretch, and jogging programs ( $p = 0.204$ ,  $p = 0.113$ ,  $p = 0.921$ , respectively). The maximal muscle strength before and after warm up programs were static stretch (pre-test:  $52.7 \pm 11.2$ , post-test:  $50.8 \pm 10.6$  N-m), vibration (pre-test:  $54.1 \pm 12.7$ , post-test:  $56.4 \pm 14.2$  N-m) and jogging (pre-test:  $51.8 \pm 10.7$ , post-test:  $51.6 \pm 7.9$  N-m). Discussion: In this study, the results showed that the elbow maximum flexion strength was not changed after three types of warm-up. Previous study had shown that static stretch may decrease muscle power and performance (Behm et al., 2001), that is not consistent with study. Different stretch muscle may have various effects. Previous study demonstrated lower frequency WBV (20 Hz) would enhance jump height, but showed contrast results in high frequency WBV (40 Hz) (Cardinale et al., 2003). Different vibration amplitude, frequency and training target may also influence the results. From this study, using the vibration, static stretching and jogging as warm-up may not change the muscle strength of upper extremity. ### EATING DISORDERS AND MENSTRUAL IRREGULARITIES AMONG FEMALE FOOTBALL PLAYERS IN HUNGARY

Molnár, A.H., Vidiczki-Doczi, A., Balogh, L.

*University of Szeged, Gyula Juhasz Faculty of Education*

Introduction: Numerous publications suggest the connection between eating disorders (ED) and sport (Sundgot-Borgen, 2007). Risk factors include restrained eating and training, frequent weight cycling, early sport-specific training, personality factors, injury, a sudden increase in training volume and the impact of coaching behaviour. A number of factors, such as energy balance, EDs, exercise intensity and training practices, body weight and body composition, and physical and emotional stress, may contribute to the development of athletic menstrual dysfunction (MD) (Sundgot-Borgen, 2007). Aims: In the present study the occurrence of ED and MD was examined among physically inactive women (C) [n=65] and elite female football players (FP) [n=65] in Hungary. Methods: ED was investigated by EDI (Garner, 1983) and SCOFF (Morgat, 1999) tests. MD was measured by questions on menstrual history. Statistics: Bonferroni-test, Mann-Whitney U-test. Results: The first three subscales of EDI are capable to detect ED. Although there were a few participants in both groups whose scores reached the critical limits in 'Drive for Thinness' (C: 4.61%; FP: 6.15%) and 'Body Dissatisfaction' (C: 3.08%; FP: 4.61%) subscales, there were no significant differences between the rates. None of the participants of both groups passed the critical limit in the 'Bulimia' subscale. There was no significant difference between the average scores of first three subscales of EDI in the two groups. The next five subscales of EDI measure psychopathology commonly associated with, but not unique to, ED. We could observe significant difference only between the average score of 'Interpersonal Distrust' (C:  $2.4 \pm 0.39$ ; FP:  $3.75 \pm 0.46^{**}$ ). Depending on the SCOFF-test we could not observe any significant difference between the incidence of EDs in the groups (C: 16.92%; FP: 12.31%). We could not detect primary amenorrhea among the participants. In the FP group the menarche age was significantly older (C:  $12.9 \pm 0.17$  yrs; FP:  $13.81 \pm 0.2$  yrs\*\*\*). Less FPs had oligomenorrhea (C: 36.92%; FP: 13.85%), but there was no significant difference between the rate of secondary amenorrhea (C: 10.77%; FP: 3.08%). The common incidence of EDs and MDs was the same in both groups (C: 7.69%; FP: 7.69%). Conclusion: We could detect a few differences between the incidence of MDs and the 'Interpersonal Distrust' was higher in FP group, but these results suggest that there is no significant difference between the common incidences of these problems among the investigated groups. ## A RESEARCH INTO THE EFFECT OF DIFFERENT EXERCISE TYPES ON ECHOCARDIOGRAPHY AND SOME BLOOD PARAMETERS IN SEDENTARY WOMEN

Cicek, G., Imamoglu, O., Gullu, A., Celik, O., Ozcan, O., Gullu, E., Yamaner, F.

*Hittit university; Ondokuz Mayıs University; Inonu University ;Mustafa Kemal University*

Introduction: Lipid and lipoprotein abnormalities play a major role in the development and progression of coronary artery disease. In this survey, it was aimed to search the impact of aerobic-step and core exercises on echocardiography and blood parameters in sedentary women. Methods : 45 voluntary women (aerobic-step (n=25) and core exercise group n=20) at the age of between 25 and 45 participated in the study. Two different exercises were applied to these women for 4 days a week, throughout 16 weeks, within 60 minutes for each exercise with the intensity of 60-70 percent. The physical and physiological characteristics, echocardiography and some blood parameters of the women were measured before and after the exercise. Paired Samples-t test and Independent-Samples- t test were used for statistical analysis. Results: Following the exercise programme, there is a meaningful decrease in the body weight, BMI, fat mass, value of waist region and hip circumference of the women as well as in the values of glucose, creatinin, total cholesterol, LDL-K averages and hs-CRP and Hcy ( $p<0,05$  and  $p<0,01$ ). In addition, it has been found that the values of VO<sub>2</sub>Max in both exercise groups increased, that the functions of left ventricular systolic meaningfully improved. The left ventricular diastolic functions of the aerobic-step group improved more. Discussion: It is widely accepted that exercise affects blood cholesterol and other lipids in a positive way, by regulating the metabolism of all lipids in the blood (Kokkinos and et al. 1995). With regular and prolonged exercise, the heart undergoes changes. These changes constitute the cardiac adaptability in response to physical training or some physiological causes. Several studies have shown that structural and functional changes in the left ventricle during exercise are greater than in other parts of the heart (Hosseini and et al. 2012; Middleton and et al. 2006). According to the result of the study , the decrease in the inflammatory markers of hs-CRP and Hcy and echocardiographic results along with the increase in VO<sub>2</sub>Max and the decrease in LDL stemming from the exercise have revealed that both two exercise types can be effectively used in order to improve physical fitness of sedentary women. ## Mini-Orals

### MO-BN07 Cognitive impairments and fatigue during exercise

#### MENTAL EXERTION DOES NOT AFFECT ELITE CYCLISTS

Martin, K., Staiano, W., Menaspa, P., Marcora, S., Halson, S., Martin, D.T., Thompson, K.G., Keegan, R., Rattray, B.

*University of Canberra*

Introduction: Mental fatigue (MF) increases perceived exertion (RPE) and impairs endurance performance in recreationally-trained athletes (Marcora 2009; Pageaux 2014). The effect of MF on elite athletes is unknown. The aim of the study was to assess the performance, physiological and psychological responses of elite cyclists following a bout of mental exertion. Methods: Nine elite road cyclists completed 30 min of an incongruent Stroop colour-word task, previously used to induce MF in recreational runners (Pageaux 2014), or 30 min of a passive control task in a double blind cross-over study. Following each treatment, participants completed a standardised warm-up and a 20 min cycling time trial (TT). Performance, physiological and psychological measures were recorded throughout the Stroop task and TT. Results: The Stroop task was rated as more mentally demanding ( $p<0.001$ ), requiring more effort ( $p<0.001$ ) and eliciting greater subjective ratings of fatigue ( $p=0.005$ ) than the control task. Blood glucose concentration tended to increase throughout the Stroop task ( $p=0.053$ ). During the TT, there was no difference between conditions for mean power ( $p=0.983$ ), total distance covered ( $p=0.491$ ) or pacing profile ( $p=0.777$ ). RPE increased over time ( $p<0.001$ ) but was identical between conditions ( $p=1.00$ ). Discussion: Mental exertion did not affect RPE or TT performance in elite cyclists. These findings contrast those observed in recreational athletes (Pageaux 2014). The negative impact of MF on endurance performance has been attributed to an accumulation of adenosine in the anterior cingulate cortex, the primary sensory input for RPE (Pageaux 2014). Adenosine accumulates under periods of increased energy demand and reduced energy availability. Training-induced increases in basal cerebral glycogen levels have been observed in rats following 4 weeks of endurance training (Matsui 2012). A similar adaptation in the elite cyclists would subsequently minimise adenosine accumulation and disruption to RPE and performance. In support of this hypothesis, blood glucose concentration in this study tended to increase throughout the Stroop task, also in contrast to findings in recreational athletes (Marcora 2009; Pageaux 2014). Elite athletes therefore may possess training-induced adaptations and experience which afford them the ability to reproduce exercise performance following mental exertion. #### ADAPTATION OF LEG EXTENSOR MUSCLE ACTIVITY TO REPEATED MAXIMAL CONTRACTIONS

Takenaka, M., Yamaguchi, K., Nagaoka, D., Takishita, W., Tokui, M., Ogiso, K.

*Kogakkan University*

Introduction Rapid knee extension is crucial for support and movement of the body in various physical activities. Knee extension is closely related to performance so it is necessary to repeatedly perform this motion as long and stably as possible. The preparatory process for force generation with proper timing is vital for both voluntary and reflex behavior. This study was designed to investigate how the vastus lateralis (VL) and medialis (VM) muscles are activated to prevent the decline in knee extension force during prolonged repetition and whether prediction of the correct timing to exert force influences muscle activation patterns. Methods Fifteen male subjects performed 100 isokinetic extensions (90°/s) with 50 performed at maximal voluntary contraction (MVC) cued by a light at 60° knee angle. In condition 1 (C1), MVC was performed on every second trial (50 in total), while in C2, the 50 MVC trials were randomly interspersed. In addition, only in C1 were subjects informed beforehand of the light cue timing. Electromyographic (EMG) activity from VL/VM, knee joint angle, and knee

joint torque (KJT) were recorded. After each measurement, the subjects rated the degree of muscle fatigue. After the experiment, subjects graded the force and timing of MVC performance for repetitions 1–10, 21–30, and 41–50 on a scale of 1 to 5. Results In C1, EMG pre-activity from VL and VM increased significantly with the number of MVC repetitions while latencies decreased, and there were strongly negative exponential relationships between pre-activities and latencies. Similar results were not observed in C2. Electromechanical delay (EMD) remained unchanged during repetition both in C1 and C2. Maximum KJT showed no significant changes with repetition but was uniformly larger in C1. The EMG burst induced by MVC was occasionally preceded by a tiny EMG burst, which was more frequent in C1 than C2. There were no significant differences in the self-evaluation of MVC performance between C1 and C2, but self-evaluation of timing significantly improved with the number of repetitions in C1 but not C2. However, a significantly greater degree of fatigue was reported in C1. Discussion Pre-activity induced by a cue for predicting the timing of MVC reduced reaction time and compensated for the decline in muscle function during MVC repetition, although fatigue increased. Extending the knee joint passively increases VL and VM slack. Pre-activity may have reduced the stimulus-response delay by compensating for this muscle slack beforehand, resulting in higher peak KJT. ## CHANGES IN MAGNITUDE AND ORIGIN OF FATIGUE DURING REPEATED MAXIMAL KNEE EXTENSIONS

O'Bryan, S.J.1, Bourke, R., Rouffet, D.M.

*Victoria University*

**Introduction** Many sports require athletes to produce repeated maximal contractions. Previous results suggest that maximal contractions completed at high velocities lead to a rapid and higher level of peripheral fatigue, whereas at low contraction velocities central fatigue develops progressively [2, 3]. This study investigated changes in the magnitude and origin of fatigue observed during the repetition of maximal knee extensions (KEXT) performed at a very low contraction velocity (15°/s) and with a large work to rest ratio (4.6s/1.4s). **Methods** Seven active subjects performed 120 KEXT on an isokinetic dynamometer. Electromyography activity was recorded from vastus lateralis muscle. Torque, electromyography amplitude (EMG), median frequency (MF) and EMG/torque ratio were extracted every 30 repetitions (R1-R30-R60-R90-R120). Neuromuscular testing (NMT) was administered at baseline and immediately following each 30 repetitions to extract maximal voluntary torque (MVT), voluntary activation (VA), potentiated quadriceps twitch (Qtw), maximal M-wave amplitude (MMAX), and EMG/MMAX. One-way ANOVA evaluated the effect of repetition on changes in KEXT and NMT variables ( $P < 0.05$ ). Results MF decreased (R1:  $62 \pm 7$ ; R30:  $56 \pm 6$  Hz) and EMG/torque increased (R1:  $0.6 \pm 0.2$ ; R30:  $1.1 \pm 0.4$ ) at R30; torque (R30:  $53 \pm 8$ ; R60:  $60 \pm 7$ ; R90:  $62 \pm 9$  %) and EMG (R30:  $22 \pm 5$ ; R60:  $27 \pm 8$ ; R90:  $33 \pm 7$  %) decreased until R90 (all  $P < 0.05$ ). MVT was lower after each 30 repetitions (R30:  $28 \pm 16$ ; R60:  $37 \pm 25$ ; R90:  $41 \pm 25$ ; R120:  $48 \pm 26$  %;  $P < 0.05$ ). Qtw reduced at R30 ( $41 \pm 21$  %); VA decreased after R60 (R60:  $22 \pm 18$ ; R90:  $29 \pm 17$ ; R120:  $38 \pm 21$  %;  $P < 0.05$ ); EMG/MMAX was lower after R30 and R120 (R1:  $0.06 \pm 0.02$ ; R30:  $0.044 \pm 0.01$ ; R120:  $0.037 \pm 0.01$ ) (all  $P < 0.05$ ). MMAX did not change ( $P = 0.7$ ). **Discussion** We observed faster and more pronounced reductions in knee extensor torque during KEXT which was associated with greater variations in peripheral and central fatigue indicators when compared to previously reported results for comparable exercise protocols [2, 3]. An early development of peripheral fatigue was evidenced by a reduction in Qtw and MF, associated to an increase in EMG/torque; presumably in response to an increase in metabolic perturbations caused by the repetition of maximal contractions. A delayed onset of central fatigue was identified by a decrease in VA, likely resulting from peripheral fatigue and an increase in group III/IV afferent feedback leading to reduced neural drive and motoneuronal excitability [1], as suggested by the decreases in EMG and EMG/MMAX. 1. ## IS PERCEPTION OF EFFORT IMPACTED BY ELECTROMYOSTIMULATION DURING MUSCLE CONTRACTION?

Pageaux, B.1,2, Lepers, R.2, Marcora, S.1

*1, University of Kent, UK; 2, Université de Bourgogne, FR*

**INTRODUCTION** Perception of effort defined as “the conscious sensation of how hard, heavy and strenuous a physical task is”, plays an important role in the regulation of exercise performance (Pageaux, 2014) and is well used for exercise prescription (Marcora, 2010). However, its neurophysiology is poorly understood. To date, the two main models of perception of effort generation are the corollary discharge (CD) model and the afferent feedback (AF) model. In the present study, we investigated the validity of these models using electromyostimulation (EMS) to manipulate the magnitude of central motor command/CD and AF during voluntary (V), evoked (EMS) and combined (V+EMS) contractions at same force output. We hypothesised that perception of effort would reflect the magnitude of the central motor command/CD, independently of AF stimulated by EMS. **METHODS** Ten subjects with previous experience of EMS volunteered in this study. V, EMS and V+EMS contractions were performed during isotonic (5% and 20% maximal voluntary contraction, MVC) and isometric contractions (10 and 20% MVC). Subjects were asked to report perception of effort, perceived force and muscle pain for each contraction. **RESULTS** For the same force output, subjects reported effort only during voluntary contractions. The effort was perceived lower (isometric:  $P=0.036$ ,  $d_z=1.062$ ; isotonic:  $P<0.001$ ,  $d_z=1.725$ ) during combined contractions (low central motor command/CD) than during voluntary contractions (full central motor command/CD). Contrary to perception of effort, subjects perceived the force during all kind of contractions. Muscle pain was higher during EMS than during voluntary contractions ( $P<0.05$ ). **DISCUSSION** Subjects rated independently perception of effort, perceived force and muscle pain. The ability of the subjects to perceive force and muscle pain during evoked contraction confirms that AF contributes to these sensations during evoked and combined contractions. The lower perception of effort during the combined contraction (low central motor command/CD and higher AF) compared to voluntary contraction (full motor command/CD and lower AF) supports the hypothesis that AF is not the sensory signal generating perception of effort. These findings provide further support in favour of the proposal that perception of effort is generated by neurocognitive processing of CD, i.e. efferent copies of the central motor command. **REFERENCES** Marcora, S.M. ## BENEFITS OF HIGH INTENSITY INTERVAL TRAINING FOR ENHANCING HIPPOCAMPUS-DEPENDENT SPATIAL LEARNING AND MEMORY

Oharazawa, A., Lee, M.C., Okamoto, M., Soya, H.

*University of Tsukuba*

**Introduction** Exercise has beneficial effects on hippocampal-related learning and memory. However, the optimum exercise condition for such effects remains controversial. Recently, it has been reported that high-intensity interval training (HIT) is more effective for improving aerobic capacity than is endurance training (ET) (Gibala et al., 2006). Moreover, we have also found that intermittent and high-intensity of voluntary resistance-wheel running enhances spatial memory (Lee et al., 2012). These results lead us to hypothesize that HIT should improve learning and/or memory based on the possible mechanisms underlying hippocampal BDNF signaling through its receptor (TrkB). We thus aimed to clarify whether HIT effectively enhances hippocampal-related spatial learning and memory compared with ET. **Methods** Male Wistar rats (10 weeks old) were separated into three groups: HIT (n=10), ET (n=10), and sedentary control (n=8). The rats were trained for four consecutive weeks with five sessions per week. HIT consisted of ten 30-sec bouts of exercise, interspaced with 2.5 min of recovery. The initial treadmill speed was 30-40 m/min for the first week and the speed was increased gradually to 60 m/min by the final week. ET consisted of 30 min of continuous running at 20 m/min. The ratios of HIT to ET were 1:6 for exercise time and 1:2~1:4 for exercise volume. We used Morris water maze (MWM) to evaluate spatial learning and memory. The protein levels of BDNF and TrkB, were detected using western blotting. **Results and Discussion** Muscular enlargement (soleus and plantaris) were found in both exercise groups, although body mass was slightly reduced which validate our HIT protocol as a resistance exercise. We also found that both HIT and ET groups had significantly enhanced spatial learning and memory compared to the control group; in particular, only the HIT group exhibited faster escape latency (acquisition of learning) compared to the control group in trials on day 2, but the percentage of time spent in the platform quadrant during the probe trial (memory of learning) significantly increased in both HIT and ET groups compared to the control group. Furthermore, the HIT group had significantly increased hippocampal TrkB protein, even though there was no difference in the hippocampal BDNF protein between groups. These results suggest that HIT protocol, which consists of a lower volume and shorter time of exercise compared to ET, is more effective for enhancing hippocampus-dependent learning and memory associated with hippocampal BDNF signaling. **References** Inoue et al., *Int J Sports Med.* In press. ## CENTRAL SENSORIMOTOR ACTIVATION DURING ECCENTRIC VS. CONCENTRIC QUADRICEPS FEMORIS CONTRACTIONS

Vogt, T.I, Fry, A.2, Folland, J.2, Strüder, H.K.1

*1German Sport University Cologne, 2Loughborough University*

**INTRODUCTION:** Eccentric (ECC) and concentric (CON) contractions are widely thought to involve different neuromuscular activation strategies that result, at least in part, from central sensorimotor modulations. However, the underlying neuroelectric processes associated with different contraction types (i.e. ECC, CON) remain to be elucidated. **PURPOSE:** This study directly determined central sensorimotor activation during ECC and CON contractions at equivalent relative torques. **METHODS:** Following familiarization, maximum voluntary torques (MVTs) and associated EMG amplitudes were determined during three maximal isometric (ISO) contractions, and each phase of four reciprocal CON-ECC contractions ( $60^\circ \cdot s^{-1}$ , analyzed range of motion:  $29-101^\circ$ ). Thereafter 16 healthy males ( $24 \pm 5$  yrs,  $180 \pm 7$  cm,  $76 \pm 10$  kg) performed a cyclic series of 36 reciprocal CON-ECC contractions of the right quadriceps femoris, including 5 sets of 4 contractions at 25% and 4 sets of 4 contractions at 50% of CON MVT, with 60/90-s rest between sets. ECC and CON torque, quadriceps femoris EMG and EEG were recorded at rest and during all contractions. A 32-channel active-electrode cap collected EEG (entire frequency range of 0.5-50 Hz). Voxel-based standardized low-resolution brain electromagnetic tomography analysis (sLORETA) calculated cortical activation for the entire frequency range, as well as for the constituent frequency bands delta, theta, alpha, beta and gamma. **RESULTS:** Alpha (7-13 Hz) activation was greater in the sensorimotor cortex during ECC compared to CON contractions at both 25% (critical threshold (t-critical): 5.343,  $p < 0.01$ ) and 50% of MVT (t-critical: 4.755,  $p < 0.01$ ), but not within other cortical areas. Activation within the other frequency bands, or for the entire frequency range, was not modulated by contraction type. Peripheral neuromuscular activation (i.e. quadriceps femoris EMG amplitude) was lower during ECC compared to CON contractions at 25% ( $33.5 \pm 9.3$  vs.  $37.3 \pm 8.3$  %EMG@ISO\_MVT, paired t-test:  $p < 0.001$ ) and 50% of MVT ( $49.7 \pm 11.2$  vs.  $61.7 \pm 10.8$  %EMG@ISO\_MVT,  $p < 0.001$ ). **CONCLUSION:** Increased sensorimotor alpha activation was observed during ECC quadriceps femoris contractions, which may reflect central inhibitory processes compared to CON contractions. ## PERIPHERAL AND CENTRAL ADJUSTMENTS DIFFER BETWEEN PROXIMAL AND DISTAL MUSCLES OF THE UPPER LIMB DURING FATIGUE

Abdelmoula, A., Baudry, S., Duchateau, J.

*Université Libre de Bruxelles*

**Introduction.** Biomechanical and intrinsic characteristics of muscles involved in sustained contractions influence the time to failure (1). Whether or not muscles work synergistically within a muscle group (elbow flexor), as well as the characteristics of the neural activation should also modulate fatigability. For example, biceps brachii (BB) is characterized by a motor unit recruitment range up to 90% of the maximal voluntary contraction (MVC) force whereas it is limited to ~50% MVC in hand muscles (3). This should influence intramuscular pressure and metabolites accumulation during sustained contraction, inducing thereby distinct neural adjustments (2). To document the muscle-related aspects of fatigability, this study investigated peripheral and central adaptations during a submaximal voluntary contraction performed with either the elbow flexors or the abductor pollicis brevis (APB). **Methods.** 13 subjects sustained an isometric contraction until failure at 35% of MVC torque with either the elbow flexors or APB in separate sessions. Surface electromyography (EMG), motor evoked potentials (MEP) induced by transcranial magnetic stimulation, and muscle tissue oxygenation assessed by means of near infrared spectroscopy was recorded for BB and APB. MVC force was measured before the sustained contraction and at failure. **Results.** The time to task failure ( $p=0.19$ ) and the decrease in MVC force ( $p=0.99$ ) were similar in both muscle groups. During the sustained contractions, EMG did not vary significantly in APB (from  $51.3 \pm 15.1\%$  to  $58.3 \pm 16.7\%$  MVC;  $p=0.25$ ) but increased from  $29.8 \pm 10.3\%$  to  $60.0 \pm 25.4\%$  MVC;  $p < 0.001$ ) in BB. The MEP amplitude increased more in APB (+43%;  $p < 0.001$ ) than in BB (+15%;  $p=0.009$ ) whereas muscle tissue oxygenation decreased more in APB (-77%;  $p < 0.001$ ) than in BB (-8%,  $p=0.025$ ). **Discussion.** The higher initial EMG activity in APB likely reflects greater motor unit recruitment in APB (3), inducing more intramuscular pressure, and favoring thereby metabolites accumulation,

as suggested by the larger decrease in muscle oxygenation for this muscle. This should have increased spinal and supraspinal inhibitory mechanisms by group III/IV afferents, requiring a greater increase in descending drive to maintain motor output in APB, as suggested by the greater increase in MEP for this muscle. These results suggest that even though time to failure and decline in MVC force were similar between the two muscle groups, the mechanisms leading to task failure involve large differences in the extent of changes at the peripheral and central levels. ### THE EFFECT OF HIGH-INTENSITY INTERVAL EXERCISE AND MODERATE-INTENSITY CONTINUOUS EXERCISE ON EXECUTIVE FUNCTION IN POST-EXERCISE RECOVERY

Tsukamoto, H., Suga, T., Takenaka, S., Takeuchi, T., Tanaka, D., Hamaoka, T., Isaka, T., Hashimoto, T.  
*Ritsumeikan University*

**Introduction** Cognitive executive function (CEF) is acutely improved by aerobic moderate-intensity continuous exercise (MCE) (Ogoh et al., 2014). On the other hand, high-intensity interval exercise (HIIE) more efficiently improves fitness level and protects against the risk factors of the metabolic syndrome than MCE (Tjønnå AE et al., 2008). However, the effect of HIIE on CEF is unclear. Furthermore, the effect of HIIE as well as MCE on CEF during post-exercise recovery also remains unknown. We hypothesized that HIIE could improve CEF more efficiently than MCE, and that improvement would be sustained longer following HIIE than MCE. To address these hypotheses, we aimed to examine the CEF following HIIE and MCE. **Methods** Twelve young healthy male subjects performed 2 aerobic exercises: MCE and HIIE. MCE condition was cycle ergometer exercise at 60% VO<sub>2</sub>max for 40 min. HIIE condition was cycle ergometer exercise at 60% and 90% VO<sub>2</sub>max for 17 min and 16 min, respectively: initially, 5 min of exercise at 60% VO<sub>2</sub>max, followed by 4 × 4 min of interval cycle ergometer exercise (4 min of exercise at 90% VO<sub>2</sub>max followed by 3 min of active resting at 60% VO<sub>2</sub>max). HIIE and MCE were same exercise volume. Subjects undertook a color-words Stroop task (CWST) at each of the examined time points (pre-exercise and post-exercise recovery at 0 min (immediate after the end of exercise), 10 min, 20 min and 30 min). **Results** The CEF as evaluated using a reverse-Stroop interference score in CWST was significantly improved at immediate after the end of either HIIE or MCE compared with pre-exercise ( $P < 0.01$ ), although there was no significant differences in CEF between 2 conditions. The improved CEF was sustained until 30 min following HIIE, while the improvement of CEF was diminished at 30 min following MCE. Interestingly, improved CEF at 30 min post-exercise recovery was correlated with augmented area under the curve of blood lactate concentration during the experimental periods ( $r = 0.57$ ,  $P < 0.01$ ). **Discussion** These results suggest that HIIE could improve CEF, and that improvement might be sustained longer following HIIE than MCE in young healthy subjects. HIIE-induced high blood lactate, which is an important energy source for the human brain (van Hall et al., 2009), may be involved in improved CEF even at 30 min post-exercise recovery. The present findings may provide an impetus to develop an optimum exercise method for the clinical treatment of CEF. **References** Ogoh S et al. (2014). *Physiol Rep*, 2(9), e12163. Tjønnå AE et al. ### MUSCLE ACTIVATION OF DIFFERENT PORTIONS OF THE TRICEPS BRACHII DURING EXERCISES WITH ELASTIC AND PULLEY

Sartorio, G., Melillo, J.G.T., Mezzarane, R.A., Hagström, L., Carmo, J.C., Bezerra, R.F.A., Russomanno, T.G.  
*University of Brasília, Brasília, DF, Brazil.*

**INTRODUCTION** The relative contribution of the two heads of the triceps brachii muscle (TB) is important to define training and rehabilitative protocols (1). Elastic band is a versatile and low-cost equipment, but it is not widely used as compared to machines (2). The purpose of this study is to evaluate the contribution of the long and lateral heads of the TB muscle during triceps pushdown (TP) and lying triceps extension (TL), with both imposed elastic resistance (ER) and constant resistance (CR). **METHODS** Eleven trained male volunteers (21.4 ± 2 yrs; 80.3 ± 11 kg; 177.3 ± 0.8 cm) were studied. Maximal voluntary isometric contraction (MVIC) was measured with elbow at 90° for both exercises. Participants performed one set of 10-12 repetitions for each condition. All conditions, which resulted in four sets, were randomly presented. The intensity chosen was 30% MVIC measured by a load cell. This intensity was set at the mid way of the excursion for ER. A custom made electrogoniometer was used to measure the joint angle. A metronome was used as a reference to keep the whole movement at 0,25Hz. The activity of the TB heads was measured using surface electrodes and an EMG system (sample: 2 kHz; cutoff frequency of the low-pass filter: 500Hz). The root mean square (RMS) was averaged throughout the repetitions. A 3 × 2 mixed factorial ANOVA was performed to detect possible differences and interactions among conditions with a significance level set at  $p < 0.05$ . **RESULTS** There was no difference in muscle activation between the heads of the TB ( $p = 0.178$ ) and between exercises ( $p = 0.05$ ). A significant difference was found between the types of equipment ( $p = 0.008$ ) with the CR presenting higher activation than ER. **DISCUSSION** Muscle activation during TP was higher than TL. However, this difference produced a marginal p-value. Thus, TL and TP are not able to isolate the TB heads. Interestingly, muscle activation was significantly greater in CR than ER. During CR, the greater the angle at the eccentric phase, the smaller the force required to overcome the resistance. The resistance varies according to the length (or joint angle) during ER (the higher the angle, the higher is the resistance). However, the force (or the torque) needed to overcome the ER is nearly constant along the movement (3), but at the beginning of the movement it is lower as compared to CR. This might explain the higher RMS values found during CR. **REFERENCES** 1. Page P, Labbe A, Topp RV. *J Orthop Sports Phys Ther.*(2000);A30:47-48. 2. G. Melchiorri, A. Rainoldi. ### A NEW COMBINED APPROACH OF FATIGUE ANALYSIS DURING 100 METRES SPRINTS

Modic, Z.1, Djordjević, S.1  
*TMG - BMC Ltd*

**Introduction** A phenomenon known under the term fatigue is an exercise-induced reduction in the maximal force capacity of muscles. Fatigue occurs in central and peripheral locations, and it depends on the intensity and time.[1] Compounding different measuring methods (3x3-D accelerometer and gyroscope, Tensiomyography), we would like to identify most significant fatigue related parameters, during the last 30-meter phase of 100meter sprints. **Methods** Twenty national level sprinters participated in the study. They ran three times 100m with 10 minute break in between. Sprinter motions were captured with data logger at 1 KS/s in the lower lumbar area and on each foot instep. Accelerometer (±24 G) and gyroscope signals from Sensmotion loggers (TMG Ljubljana) were filtered with a Butterworth

lowpass filter (cutoff: 150 Hz, order: 5). Sprinting track was divided into two nearly steady states, the first state from 40m to 70m and the second from 70m to 100m, within which running velocity and stride rate were monitored. We used TMG system to measure biceps femoris (BF) contractile properties before first and after each sprint in 30-second increments for 1 minute. A Fast Fourier Transform (FFT) was used as an estimator of a stride rate for data logger signals. We used a new approach called maximal rate of force development in time (mRFDt). mRFDt algorithm determines the changes of TMG displacement (Dm) over time within 5 ms time window.[2] To determine statistically significant differences we used a Student T-test. Results All three sprints contain a statistically significant drop in stride rate in second section of approximately 2 %, in the first sprint from 4.35 to 4.25, in the second sprint from 4.33 to 4.24 and in the third sprint from 4.29 to 4.22. Results showed a significant statistical difference ( $p < 0.01$ ) between the first and the second section. Results of mRFDt algorithm showed a statistically significant drop in BF muscle twitch force development abilities. The mRFDt analysis in the first sprint statistically significantly decreases from 0.73 to 0.61 mms<sup>-3</sup> ( $p < 0.01$ ), in the second sprint from 0.72 to 0.58 mms<sup>-3</sup> ( $p < 0.01$ ), and in the third sprint from 0.62 to 0.52 mms<sup>-3</sup> ( $p < 0.01$ ). Discussion Testing protocol is an overall known method of developing specific velocity endurance. Many studies showed that athletes lower stride rate and extended stride length under the influence of fatigue in the last 20m of the sprint[1]. mRFDt shows a drop of contractile speed (decrease of mRFDt) of BF muscle, which is one of the most important muscles for a maximal velocity development in sprint. The decline of stride rate and a drop in contractile speed of the muscle indicate the presence of fatigue. Decrease in mRFDt of BF inside each set from the first to third measurement was also observed. Further studies are necessary to understand the mechanism of twitch contractile speed decrease during first 70 seconds of resting period. References 1. Ross A, et al. ## Mini-Orals

### MO-SH03 Physical Education and Pedagogics II

#### ASSESSMENT IN PHYSICAL EDUCATION

Sebelius, S.

*Faculty of Education, Malmö University*

ASSESSMENT IN PHYSICAL EDUCATION Introduction For some years, there has been discussions in Sweden about assessment in physical education and the problems surrounding it; teachers are not assessing according to the governing standards (Quennerstedt, Öhman & Eriksson, 2008) and students have little knowledge about the basis of the assessment (Redelius & Hay, 2012). These aspects are crucial for assessment efficacy in physical education (Hay & Penney, 2009). The aim of the project is to investigate and problematize teachers statements about how they mediate to the students the basis of the assessment and how they assess students, with focus on "...the ability to move comprehensively in different physical contexts"(Skolverket, 2011, p. 51). Methods The empirical sample of this qualitative study consists of three parts: individual interviews with three teachers who teach physical education, questionnaires from their students in three classes in grade nine (74 students) and observations of the teachers lessons in physical education with the same classes in grade nine (13 lessons). Results The teachers state that they inform the students about upcoming assessments, both orally and in writing, a couple of times each semester. The students are unsure about how the basis of the assessment is being mediated to them. The teachers also state that they assess the students every lesson. During the lessons, the assessments visible to the students primarily consist of interjections like 'well done' and feedback on techniques. The students are unsure about when they are being assessed and on what basis they are being assessed. Discussion There is a conflict between what the teachers and the students state concerning when the students are being assessed and how they are being informed about the basis of it. The teachers say that they assess the students every lesson but the students are unsure about when they are being assessed. Why is there an inconsistency between the teachers and the students' statements and why are the teachers assessing the students every lesson? #### FOCUS GROUPS DISCUSSION ABOUT ASSESSMENT IN PHYSICAL EDUCATION AND HEALTH

Bexell, S.

*Malmö högskola*

Introduction Many studies in Physical Education and Health have shown a lack of equivalence, transparency and validity in assessment and grading. At the same time, there is a great expectation that teachers can make fair and equal assessments. National Agency for Education (2011) has set up a perspective for a fair and equitable assessment and grading, and writes that the curriculum for primary schools (Läroplan för grundskolan 2011) are clearer and provides greater clarification of requirements for assessment. According to National Agency for Education (2011) teachers have thereby more opportunities to make similar assessment. The study is a project with a group of teachers at local level, working for a common interpretation of assessment issues according to curriculum for primary schools 2011. The teachers who participated in the project did so voluntarily and most of them have long experience of being a teacher in physical education and health. The purpose of the study is to examine the process where teachers in PEH are working for a common understanding of assessment issues based on the curriculum for primary schools and thereby problematise the process and make it visible. Method The project design is based on action research principles of planning, acting, observing and reflecting. It consist of three cycles. In cycle one educational assessment – support (Skolverket, 2012) is used as a basis for group discussions, in cycle two teachers own video filming are used and in the third cycle the teachers made a number of there own actions in different areas of work with a model that was based on research and group insights during the project. The empirical results consist essentially from focus group discussions on all the different cycles. Results The process and the focus group have been analyzed critically from a social constructionist perspective to the concept of dramaturgy as a theoretical lens (Goffman, 2009). The results show that the beliefs teachers bring into the project are difficult to change. Instead the teachers look on the process and social interaction support for what they consider to be important in both teaching and how knowledge is interpreted. The individual teachers' background, history and personal experiences have a major impact on how they interpret and perceive assessment and grading. There are indications in the results that it seems to be easier to absorb a

change in the assessment process rather than to agree on how the proficiency key values are interpreted. The teachers' statement after the project also shows that they have benefited from the project in their work with assessment issues. stefan.bexell@mah.se

## BACKGROUND AND SIGNIFICANCE OF ADOPTING RHYTHMIC DANCE AS CURRICULUM OF PE IN JAPAN

Park, K., Murata, Y.

*University of Tsukuba*

**Introduction** In Japan, rhythmic dance (RD) such as rock'n'roll and hip-hop has been adopted as a part of dance curriculum of PE. Therefore, this study aims to examine background and educational significance with which RD was adopted as curriculum of PE in Japan. **Methods** This study reviewed Japan's Course of Study, its manual and related teaching materials. Results RD was born with the rhythm and movement of popular music that was in fashion at a certain time combined each other and is at the center of dance boom of the present age. Socially, this dance is easily accessed with great interest by students with plenty of opportunities to be exposed to dance through diverse media and with music played in their daily lives all the time. Against this backdrop, RD was newly adopted in Japan's Course of Study of 1998. In the Course of Study, RD is defined as a dance to modern rhythm and exciting free-style dance of thinking about how to get into rhythm, how to move one's body and how to react to others. As for rhythms covered by RD, samba, rock'n'roll and hip-hop are suggested. Examining the significance of adopting RD as curriculum from the viewpoint of teaching, first of all, RD puts emphasis on dancing to a rhythm by whole body. In particular, it focuses on expressing the characteristics of each rhythm with entire body such as bound of body and after-beat of rock'n'roll, syncopation of samba and up/down beat of hip-hop. Getting into rhythm means dancing with body and music becoming one as if even a hair is dancing. A joy of dancing to a rhythm comes from pleasure of being intoxicated by rhythm and pleasure of dance routine that human beings have by nature, which is related with what makes people realize that they are naturally beings of dancing. Second, RD makes much of dancing freely by getting into rhythm spontaneously rather than dancing by memorizing certain choreography. Based on this, students can make original pattern of rhythm or continuation of movement and select the music they are fond of to create their original dance, which can lead to activities that they can observe together and exchange. This leads to the third point of teaching, which is dancing with friends. This enables students to feel the joy of dancing in reaction to the other party through activities such as lead and imitating movement. **Discussion** As such, RD was introduced in Japan as a result of carefully selecting content of teaching to have clear educational significance and realize the significance instead of simply dancing to the music of popular singers by memorizing dance routine. This also seems to reflect an intention of flexibly responding to music and dance of changing times. The Japan's case can be a good example of reflecting the requirement of society and students and valuing the meaning of school education. **References** Park, K. (2013) Comparison of the dance-related contents in the physical education of Japanese and Korean national curricula. ## ACTION RESEARCH IN EXPLORING HOW PE TEACHERS ORIENTATE THEIR "VALUE OF PHYSICAL EDUCATION" IN SCHOOLS

Sum, K.

*The Chinese University of Hong Kong*

This action research explored how physical education teachers can orientate their values of physical education in the Hong Kong secondary and primary schools where they teach. One primary school PE teacher and one secondary school PE teacher participated in this study. With the help of research tools including the Teaching Perspective Inventory(TPI) (Collins & Pratt, 2011) and the Value Orientation Inventory (VOI) (Ennis & Chen, 1993), they underwent two cycles of intervention assisted by the researchers which offered group-reflection, extensive sharing of experience and academic findings. The researchers intentionally consisted of physical education teachers from different settings and offered opportunities to expand the scope of and reflect on their 'value of physical education'. In each cycle, they planned and implemented one physical education lesson focusing the specific rationale behind, engaged in self-reflection and group reflection after the lesson, and developed corresponding strategies for the next cycle of teaching. All the lessons and reflection meetings were video-taped. Through the process, the two participants were able to realise how their teaching styles may have been personalised according to their intentions and beliefs. This in turn allowed the researchers to appreciate how cultural and social variations of teaching physical education is understood and valued. In conclusion, a model was proposed to conceptualize how physical education teachers can orientate their value of physical education in the schools they teach. Further, the reflection process in group consisting of teachers of physical education from different settings allowed the participants to clarify their self-understanding on teaching perspectives and reinforce their values towards physical education.

## THE PUPILS' UNDERSTANDING FOR AND ATTITUDE TOWARDS THEIR OWN HEALTH

Ahlberg, A.

*Malmö University*

**Introduction** The concept of health should not be viewed as one-dimensional, but rather a complex interplay between physical, psychological and social factors (World Health Organization, 2014). This is important because it is more reflective of the 'messy' nature of pupil's lived experiences. Further to this, the Swedish curriculum highlights that the school's responsibilities is to support pupil's knowledge and promote health, through developing pupil's habits in a positive way, as well as connecting concepts surrounding physical activity with mental and physical well being. The purpose of this study, therefore, was to consider the pupil's understanding for and attitudes towards their own health. This was explored through the following questions: 1) What is health for pupils? 2) What do the pupils think is relevant to learn about health in the school subject Physical education and health? 3) What opportunities and challenges do pupils experience around health in everyday life? **Methods** Data was collected through the use of focus groups, questionnaires, epistolary dialog and conclusive questionnaires. The pupils' way of describing health was analysed through Zygmunt Bauman's (2008) consuming theory and Thomas Ziehe's (1986, 1999) conceptions cultural liberation, cultural expropriation, performance principle and authenticity. **Results and Discussion** The result shows that the pupils in the study had a good level of knowledge about health. They described health as a complex concept in physical, psychological and social terms. This knowledge affected the pupils in different ways. For example a feeling of pleasure for those pupils who appear well grounded and spontaneous. While among the pupils who experience pressure in their daily life, the contribution of their knowledge instead placed a feeling of higher demands. **Conclusion** When it comes to health and education about health, it is not primarily a varied level of knowledge the teacher needs to take into account, but the variation in students' self-images. It is not theory of health that primary should support the teacher, it is theory about young people and their lives. If the school helps students to

develop a positive self-image, then they are susceptible and can learn to manage their health in a good way. References Bauman, Zygmunt (2008). Konsumtionsliv. Goteborg: Daidalos. ## 15:00 - 16:30

### Invited symposia

#### IS-PM02 THE BENGT SALTIN TRIBUTE SYMPOSIUM

##### PROFESSOR BENGT SALTIN'S LEGACY AND CONTRIBUTION TO THE ECSS

Narici, M.V.

*University of Nottingham*

In 1995, the Faculty of Sport Science of the University of Nice Sophia Antipolis, hosted the 5th International Symposium on Exercise and Sports Biology, as part of a series of quadrennial congresses organized by Professor Pierre Marconnet. The symposium ended with an event of major importance: the foundation of the European College of Sport Science (ECSS) by a group of fourteen leading exercise and sport scientists. Amongst these was Professor Bengt Saltin, appointed as first ECSS President. The College held its first congress in 1996 in Nice, in cooperation with the Faculty of Sport Science of the University of Nice. The founding members of the ECSS could not have made a better decision in electing Bengt Saltin as College President, for he had the quintessential nature of a true exercise scientist backed by extremely solid foundations in human and applied physiology. When elected in 1996, Prof Saltin was author of more than 250 papers and was already ranking as one of the most acclaimed international leaders in Muscle and Environmental Physiology of the 20th Century. Professor Saltin brought to the ECSS his deep knowledge, his rigor in empirical research, his passion for integrative physiology through a mechanistic approach and a remarkable ability to act as catalyst for research initiatives and scientific debate. His knowledge and expertise in human physiology had tremendous breadth: these covered, i) cardio-vascular and cardio-respiratory physiology, ii) aerobic and anaerobic metabolism, iii) muscle energetics and muscle fatigue, iv) muscle fibre composition, metabolic and functional properties, v) exercise endocrinology, vi) glucose metabolism and obesity, vii) exercise nutrition, viii) neuromuscular performance in health and disease, ix) impact of ageing on aerobic and anaerobic metabolism and muscle performance, x) altitude physiology, xi) space physiology, xii) thermoregulation during exercise, xiii) cellular and molecular mechanisms of muscle performance in health, disease and in different environmental conditions, xiv) doping detection and prevention in sports. Undoubtedly, Bengt Saltin was a true pioneer in exercise physiology, the depth and innovative nature of his work always placed him at the forefront of integrative physiology research. His seminal work inspired and guided thousands of research scientists and students and made a major contribution to the development of the ECSS as a society dedicated to excellence in sport science and research at the European level. As current President of the ECSS, I feel honoured and humbled by Professor Saltin's contribution, his spirit and legacy will always be the motor of our College. Acknowledgement: my sincere gratitude to Professor Pierre Marconnet for his invaluable help in reconstructing the early history of the ECSS.

##### INTEGRATIVE PHYSIOLOGICAL APPROACHES FOR OPTIMIZING MUSCULAR PERFORMANCE AND HEALTH

Sjogaard, G.

*University of Southern Denmark*

Bengt Saltin was appointed professor at the at the University of Copenhagen's August Krogh Institute in 1972 after formative years in Stockholm at the Department of Physiology, Karolinska Institutet at GIH. He remained closely connected to these institutes throughout his life. His research from start evidenced basic physiological mechanisms (Bergström et al 1967) and at the same time launched methods to address applied health related issues (Saltin and Grimby 1968). Human muscle physiology was his special focus and he succeeded to invent a human in situ muscle model that allowed revealing integrative cardiovascular mechanism as well as reductionist subcellular structures and electrolyte distributions (Sjogaard and Saltin 1982, Andersen et al 1985). Applied studies on sports performances ranged from running, skiing, cycling to camel racing, increasing our understanding of fatigue mechanisms and adequate training regimes. Studies were undertaken under extreme conditions such as heat stress or high altitude (Nielsen et al 1990, Savard et al 1995). He was eminent in applying novel analytical tools and techniques but always turned research questions back into integrative in vivo human conditions. Physical activity and health had his highest interest and he spent much energy to evidence guidelines for health promotion (Pedersen and Saltin 2006). In some of his latest publications he addressed the working population among whom sedentary behavior and musculoskeletal disorders are frequent. Repetitive stressful work was shown to decrease mRNA levels of key regulators for growth and oxidative metabolism in the painful muscles while in contrast strengthening exercises performed at the worksite for health promotion improved the capacity of carbohydrate oxidation and muscle performance (Sjogaard et al 2013, Gerdle et al 2014, Andersen et al 2014). Bengt Saltin's scientific contributions are extreme in breadth and depth; specifying some is not to ignore all the others - many of which will be presented by many of his numerous collaborators at this conference. **ROLE OF MUSCLE GLYCOGEN IN EXERCISE METABOLISM AND PERFORMANCE**

Graham, T.

*Univ. of Guelph*

Early in his career, Saltin and coworkers (Bergstrom et al 1967, Hermansen et al, 1967) investigated the metabolism of human muscle glycogen during exercise and recovery as well as responses within fibre type and even single fibres (Gollnick et al 1974). Today glycogen super compensation, exponential catabolism of glycogen with exercise duration, the association between fatigue and glycogen, and the fibre type-specific differences could be viewed as simplistic and not insightful. However, in the 1970's the findings were remarkable, represented the first invasive investigations of metabolism of human muscle, the body of work integrated our physiological understanding and, in hindsight, the data were remarkably precise. This work presented questions such as why is there an upper limit to glycogen stores, how does glycogen limit exercise capacity and how is the breakdown and resynthesis of glycogen regulated? In the next 20-25 years advancement in our understanding of glycogen metabolism advanced slowly and most studies were descriptive, providing limited further insight. However, in the last 20 years, scientists (some collaborating with Saltin : Graham et al, 2001, Nielsen et al, 2011, Ørtenblad et al ,2011) began to address important questions using advances in molecular biology as well as computer technology for microscopic image analysis (Marchand et al, 2007). We now realize that the glycogen granules have specific subcellular locations that reflect function. The granules have a very complex structure, are associated with a family of proteins and at least some of which are capable of dynamic subcellular translocation. These findings demonstrate that metabolic regulation of glycogen occurs within subcellular pools specific to location and that key proteins can quickly move from one location to another (Graham, 2009, J Nielsen and N Ørtenblad, 2013) , . Scientists are now positioned such that they can and should follow Saltin's example designing the protocols to address the important issues, including those questions generated over 40 years ago. **EXERCISE TRAINING-INDUCED REGULATION OF MITOCHONDRIAL BIOGENESIS AND MITOPHAGY**

Pilegaard, H.

*University of Copenhagen*

Bengt Saltin performed together with his colleagues in 1966 the Dallas bed rest study, which became a classical study within human physiology (Saltin et al 1968). The study demonstrated pronounced effects of only 3 weeks of physical inactivity on cardiovascular function. Over the years he was also involved in numerous studies examining skeletal muscle metabolism with emphasis on exercise training adaptations. At the end of the 1990's and the years that followed, Bengt Saltin contributed to taking a step further into the understanding of the molecular mechanisms behind exercise training-induced adaptations in skeletal muscle metabolism. The studies showed that a single exercise bout induces transient transcriptional activation of a broad range of genes encoding proteins in metabolism and transcriptional regulators in skeletal muscle (Pilegaard et al. 2000; Pilegaard et al. 2003). Further studies examined the potential role of muscle glycogen and plasma free fatty acids in the regulation of exercise-induced mRNA responses in human skeletal muscle. Bengt Saltin was also a major player in a bed rest study conducted in Copenhagen with the main purpose to investigate the underlying mechanisms behind physical inactivity-induced insulin resistance and the impact of physical inactivity on exercise-induced mRNA responses in human skeletal muscle (Ringholm et al 2011). Furthermore, he took part in studying the impact of age and lifelong exercise training on mitochondrial oxidative capacity and exercise-induced mRNA responses in human skeletal muscle (Iversen et al 2011). Over the last 10 years, we have examined the impact of the transcriptional co-activator PGC-1 $\alpha$  on basal and exercise training-induced regulation of metabolic proteins in skeletal muscle at young and old age (Leick et al 2008; Ringholm et al 2013). Current studies focus on the potential role of PGC-1 $\alpha$  in exercise and exercise training-induced regulation of mitochondrial quality control in skeletal muscle. **THE ESSENTIAL OF INTERDISCIPLINARY RESPECT IN RESEARCH FOR A SUSTAINABLE UNDERSTANDING OF HUMAN PHYSICAL ACTIVITY AND SPORT**

Hedenborg, S., Radmann, A.

*European College of Sport Science*

Physical exercise is essential for the human body and diets should be adapted to how many calories, minerals, vitamins, proteins, carbohydrates etcetera that the body is in need of. This is known worldwide, it seems, however, extremely difficult for most of us to live according to this knowledge. Many people all over the world are not physically active as much as they ought to and many of us eat more or less than we are supposed to. Why? This question and many others related to an interdisciplinary understanding of the human body, PA and diets signified our work together with Bengt Saltin in the project World Village of Women Sport. Bengt was involved in many sports related projects all over the world and it was possibly this that made him aware of the importance of understanding the social and cultural context of sport and sportsmen and women. Problems of doping pointed to the importance of understanding a wide sport context and questions regarding obesity taught him that in some parts of the world obesity is seen only in the upper class, whereas in other parts obesity is connected to the working class. Even though the physiological status may be the same – the programs for solving problems related to doping or obesity have to be designed in many different ways to actually reach the goals. Since 2008 Bengt Saltin was deeply involved in developing the project World Village of women sports in his role as chair of the World Village of Women Sports (VWWS) Scientific Board. The purpose of World Village of Women Sports (VWWS) was to significantly advance the position of women's sports through

new knowledge generated within an international research and development centre in Malmö. A starting point for the project was that women and men, girls and boys should have the same opportunities, rights and obligations within sport and that this is not the case. Women and girls do not have the same opportunities to participate in sport, nor have they had such opportunities historically. Neither have they had access to the same resources within sport as men and boys. Saltin acknowledged that this also applies to sports research and not the least interdisciplinary research was discussed within the project. How can women's knee injuries in football be understood from an interdisciplinary perspective – what can our knowledge on women's physiology teach us? What about biomechanical knowledge? And from our perspective, the humanities and social sciences, questions regarding whether the lack of economic resources can be connected to knee injuries can be posed. Let us work in the spirit of Bengt Saltin for a sustainable solution to problems related to physical activity and sport!

## Invited symposia

### IS-PM10 THE ATHLETE'S BIOLOGICAL PASSPORT – WHAT'S THE STATUS? \*

#### THE ATHLETES BIOLOGICAL PASSPORT - WHAT'S THE STATUS

Morkeberg, J.

*Uni Copenhagen*

The Hematological Module of the Athlete Biological Passport (ABP) was approved by the World Anti-Doping Agency (WADA) in 2009 with the objective of indirectly detecting doping substances or methods used to increase the body's oxygen carrying capacity such as erythropoiesis stimulating agents (ESAs) or autologous blood transfusions. Biomarkers affiliated to the hematopoietic system are monitored on the individual level over time and atypical fluctuations are evaluated by an expert panel. ABP results are either used to sanction athletes or target additional tests or analyses. An evaluation of hematological data obtained from professional cyclist showed a marked decrease in abnormal hematological values after the introduction of the ABP by the Union Cyclist Internationale (UCI). In addition there has been a decrease in the number of ABP cases since the introduction of the passport. This could either indicate a decreased abuse of blood manipulation or a shift towards other substances of changed manipulation practices. The sensitivity of the blood passport could be increased by the introduction of plasma volume independent biomarkers, while the use of an alternative EPO detection method (MAIA test) and different 'omics' approaches have shown potential as well.

#### THE STEROIDAL MODULE

Schulze, J.

*Nordic Athlete Passport Management Unit*

Detection of doping with endogenous steroids, such as testosterone, has been and continues to be a challenge. To overcome the problem of separating testosterone doping from endogenous testosterone the urinary ratio between the glucuronides of testosterone and epitestosterone (T/E) is used. This T/E ratio was introduced in doping tests with an authorized upper limit of 4. Interestingly, the mean T/E ratio in Caucasian men is approximately 1, whereas in Asians, the mean ratio is considerably lower. The ethnic disparity in the T/E ratio was shown to be strongly associated with a deletion polymorphism in the gene for testosterone glucuronidation (UGT2B17). Individuals homozygous for this deletion (del/del) rarely reach a T/E ratio of 4 when doped with testosterone. The deletion polymorphism is much more common in East Asian populations (70-85 %) as compared to Caucasians and Africans (around 10-20 %). There are also individuals that have naturally high T/E ratios due to decreased excretion of epitestosterone, partly also explained by a genetic polymorphism. In addition to genetic variation, other factors, such as hormonal contraceptives, have been shown to impact the steroid profile. The steroid module of the Athlete Biological Passport, the newest innovation in doping testing, was finalized and implemented in January 2014. Instead of the population based cut off ratio, every athlete now has their own individual cut-off limit of the T/E ratio. In addition to the T/E ratio, other ratios of testosterone metabolites are used as markers, e.g. the androsterone/etiocholanolone and the 5 alpha and 5 beta androstenediol ratios. Using the steroidal module of the passport the sensitivity of the doping test has considerably improved and the need for expensive and time-consuming confirmation analyses has decreased.

#### THE ENDOCRINE MODULE

Dehnes, Y.

*Oslo University Hospital*

Testing for growth hormone (GH) has been a major issue for most anti-doping organizations for several years. The GH-isoform differential assays have been in use since 2008 and are currently used by all the WADA (World Anti-Doping Agency) accredited laboratories, however, direct detection of GH-misuse is complicated because it is an endogenously produced hormone and because its half-life is very short. An indirect detection method for rhGH misuse using GH-dependent markers was under development for well over a decade. Measurement of the GH biomarkers insulin-like growth factor-1 (IGF-1) and N-terminal peptide of type III procollagen (PIIINP) in combination with discriminant function analysis was found to differentiate between doped and not doped. This test was validated - using population-based thresholds - prior to the Olympic Games in London 2012. In the fall of 2008, Norwegian Doping Control Laboratory, Anti-doping Norway and the Norwegian School of Sports Science started up a research project aimed at establishing individual GH biomarker profiles and to determine within-subject variability. The rationale behind this was an assumption that GH testing would benefit greatly from combining the direct method (the isoform approach) with longitudinal profiles of the indirect method (GH biomarkers IGF-1 and PIIINP). A critical parameter for increased sensitivity with longitudinal profiles is significantly lower within-subject than between-subject variability. To determine this, a group of national level athletes were followed over a period of 2 years. Further, we wanted to see how GH-doping would alter the longitudinal biomarker profiles, but a long-term GH-application study would never be approved by Norwegian ethical committees. We therefore recruited bodybuilders who had a private consume of GH to an uncontrolled study. Promising results from this study motivated Anti-Doping Norway to start monitoring athletes from their national and registered testing pools in the beginning of 2011. The results from both the research project and the monitoring of Norwegian elite athletes - with GH-marker profiles up to 4 years long - will be presented.

## Invited symposia

### **IS-PM06 SKELETAL MUSCLE ADAPTATIONS TO ENDURANCE TRAINING: IS TISSUE HYPOXIA THE MAIN SIGNAL?**

---

#### **CARDIAC AND SKELETAL MUSCLE METABOLISM IN HIGH ALTITUDE HYPOXIA**

Murray, A.J.

*University of Cambridge*

In most tissues of the body, cellular ATP production predominantly occurs via mitochondrial oxidative phosphorylation of reduced intermediates, which are in turn derived from substrates such as glucose and fatty acids. In order to maintain ATP homeostasis, and therefore cellular function, the mitochondria require a constant supply of fuels and oxygen. In many disease states, or in healthy individuals at altitude, tissue oxygen levels fall and the cell must meet this hypoxic challenge to maintain energetics and limit oxidative stress. For oxidative tissues such as heart or skeletal muscle, cellular hypoxia necessitates changes in gene and protein expression that alter mitochondrial function. It is known that lowlanders returning from high altitude have decreased muscle mitochondrial densities, yet the underlying transcriptional mechanisms and time course were not fully understood. To explore these, we measured gene and protein expression plus ultrastructure in muscle biopsies of lowlanders at sea level and following exposure to hypobaric hypoxia. Subacute exposure (19 d after initiating ascent to Everest base camp, 5300 m) was not associated with mitochondrial loss. After 66 d at altitude and ascent beyond 6400 m, mitochondrial densities fell by 21%, with loss of 73% of subsarcolemmal mitochondria. Correspondingly, levels of the transcriptional coactivator PGC-1 $\alpha$  fell by 35%, suggesting down-regulation of mitochondrial biogenesis. Sustained hypoxia also decreased expression of electron transport chain complexes I and IV and UCP3 levels. We suggest that during subacute hypoxia, mitochondria might be protected from oxidative stress. However, following sustained exposure, mitochondrial biogenesis is deactivated and uncoupling down-regulated, perhaps to improve the efficiency of ATP production.

#### **SKELETAL MUSCLE HIF-1 AND EXERCISE**

Rundqvist, H.

*Karolinska Institutet*

**Introduction** Skeletal muscle tissue exhibits a remarkable ability to adjust to altered demands. Training adaptations include increased capillarisation, altered glycolytic flux and increased mitochondrial density and occur in response to repeated bouts of exercise. Exercise induced skeletal muscle hypoxia has been addressed as one possible primary stimulus for adaptation to training. Hypoxia Inducible Factor-1 (HIF-1) is an evolutionary conserved master regulator of hypoxic transcription and suggested as a candidate for mediating hypoxia induced training adaptation. **Methods** Skeletal muscle biopsies were obtained from m. vastus lateralis in three human experimental set ups; a single bout of exercise, six weeks of endurance training and elite athletes. In addition, a skeletal muscle specific HIF-1 $\alpha$  KO mouse model exposed to six weeks of endurance training was used to further evaluate the role of HIF-1 in skeletal muscle adaptation. **Results** Results showed that acute exercise activated HIF-1, including protein stabilization, translocation to the nucleus, and increased target gene expression in both human and mouse skeletal muscle. However, the HIF-1 $\alpha$  KO mice showed several of the features typically associated with a trained muscle, especially in respect of mitochondrial characteristics, mediated partly through decreased levels of pyruvate dehydrogenase kinase 1 (PDK-1). In elite athletes, expression of several negative regulators of HIF-1 was significantly higher than in moderately active individuals, while the response gene PDK-1 was lower. Similar results were observed in the six-week training study. **Discussion** We suggest that an initial activation of HIF-1 may drive angiogenesis adaptation in the early phase of training, but the seeming attenuation of the HIF-1 response later in a training period and in elite athletes may represent a switch toward a higher capacity to activate the oxidative system.

#### **TISSUE HYPOXIA AND THE HUMAN SKELETAL MUSCLE**

Lundby, C.

*University of Zürich*

Mitochondrial volume density MitoVD is increased with endurance training. In this presentation the following will be discussed i) Whether tissue hypoxia is involved or not has been difficult to answer since on one hand humans exposed to high altitude hypoxia for several weeks in the Himalayas demonstrate a decrease in MitoVD whereas exercise training studies in which hypoxia has been added to the training (Live Low – Train High) approach has revealed an superimposing effect of hypoxia on the training induced increase in MitoVD. This discrepancy will be discussed and favor hypoxia to stimulate mitochondrial biogenesis ii) Assuming that mitochondrial oxidative capacity (OXPHOS) exceeds systemic O<sub>2</sub> transport then what is the consequence for an improved MitoVD with exercise training? Recent findings suggest that the improvements are of no relevance for VO<sub>2</sub>max type of exercise and this will be discussed.

#### **THE INFLUENCE OF ANTHROPOMETRIC AND MATURATIONAL CHARACTERISTICS ON THE RELATIVE AGE EFFECT IN ALPINE SKI RACING**

Müller, L.1, Hildebrandt, C.1, Müller, E.2, Raschner, C.1

*1 University of Innsbruck, 2 University of Salzburg*

**Introduction** A relative age effect (RAE), which consists of an over-representation of athletes born early in a selection year, was shown to be present in all age categories of national and international alpine ski racing (Müller et al., 2015). Before strategies in the talent devel-

opment systems can be changed to minimize the RAE, it is necessary to find the most important causal mechanisms of it. Methods The study included the investigation of 695 Austrian pupils (10-13 years): 234 (131 males, 103 females) provincial youth ski racers of skiing specific schools (P-SR), 84 (42 m, 42 f) youth ski racers of national final races (N-SR) and 413 (173 m, 240 f) pupils of a secondary modern school (comparison group of non-athletes, CG). Anthropometric measurements were performed, the age at peak height velocity (APHV) (Mirwald et al., 2002) was calculated and the birth months (divided into 4 quarters) were examined. ANOVA or Kruskal Wallis H-Tests assessed differences in anthropometrics and APHV between the pupils born in the single relative age quarters (RAQ). Differences between the 3 groups (P-SR, N-SR, CG) were assessed by t-Tests and Mann-Whitney U Tests. Results A significant RAE was present in the P-SR ( $\chi^2(3, N=234)=8.02$ ;  $p=0.046$ ) and the N-SR ( $\chi^2(3, N=84)=9.00$ ;  $p=0.029$ ). The RAQ-distribution of the CG showed a nearly equal distribution. The P-SR born in RAQ 1 and 2 were taller (Q1: U(76,101)=3721; Q2: U(59,110)=2925.5;  $p<0.001$ ) and heavier (Q1: U(76,101)=3653; Q2: U(59,110)=2827;  $p<0.001$ ) compared to the CG. P-SR born in RAQ 1 were taller ( $\chi^2(3, N=234)=13.06$ ;  $p=0.005$ ) and heavier ( $\chi^2(3, N=234)=9.07$ ;  $p=0.028$ ) compared to P-SR born in RAQ 2-4. P-SR born in one of the four quarters did not significantly differ in APHV from each other and they did not significantly differ in APHV from the CG, neither. The N-SR were significant ( $p<0.001$ ) taller (U(84,413)=15702) and heavier (U(84,413)=15388) compared to the CG and they will reach their individual peak growth spurt at a significant earlier age compared to the P-SR (m: t(171)=2.15,  $p=0.033$ ; f: t(128.7)=4.14,  $p<0.001$ ). Discussion The SR were taller and heavier compared to the CG. The N-SR were advanced in biological maturation compared to the P-SR. The higher the level in youth ski racing, the likelihood for selection of relatively older and more mature athletes increases. Hence, anthropometric and maturational characteristics seem to influence the selection process and seem to be influential mechanisms on the RAE in alpine ski racing. ### THE EFFECTS OF A MULTIFACTORIAL INJURY PREVENTION INTERVENTION ON PHYSICAL EDUCATION TEACHERS' PREVENTIVE BEHAVIOR AND THEIR SPORTS AND WORK RELATED INJURIES

Vercruyse, S., Haerens, L., Verhagen, E., Goossens, L., De Clercq, D.

*Ghent University*

Background: Due to the high physical work load (1) and sporting experiences of physical education teachers (PETs), a high injury rate has already been reported among this population (2). Injuries bring along personal and work-related consequences and therefore a multifactorial injury prevention intervention was conducted. The content of the intervention was optimized in 2013 (3) and included the self-determination theory (4) in the way of delivery to enhance teachers' adherence to the proposed strategies. Methods: 104 PETs out of 62 schools in Flanders (Belgium) initially participated in the randomized-controlled trial (RCT). After randomization at school level, and excluding PETs with insufficient registrations, data of 29 PETs in the intervention group (7 men, 22 women;  $47.41 \pm 9.86$  years) and 26 PETs in the control group (15 men, 11 women;  $48.68 \pm 8.50$  years) were analysed. The intervention was delivered to the intervention group exclusively on two separate days, one in September (theoretical + practical) and one in December (practical). Further access was given to the injury prevention website, didactical posters, exercise schedules and regular reminders. Both groups filled out some baseline questions prior to the study and weekly registered preventive behaviour, injuries and time of exposure (being active as teacher, as trainer or practicing sport) during the study. Objective. We wanted to investigate the effect of an intervention on teachers preventive behavior and on the injury prevalence density (total number of sports and work related injuries relatively to 1000h of time of exposure). Results: Intervention group ( $46.6$  min/week) did not significantly differ from the control group ( $36.4$  min/week;  $p=0.254$ ) in the mean time spent in preventive behaviors, but showed a greater variety of strategies (strength, balance, core stability, dynamic and static stretching) being applied, than the controls (warming up). Poisson distribution showed a significant lower injury prevalence density in the intervention group compared to the control group (INT:0.510; CON:1.083;  $p=0.047$ ), with main impact on non-contact injuries (INT=0.185; CON:0.855;  $p=0.007$ ). Discussion and conclusion: Our intervention, first in his kind in PETs, resulted in a more balanced use of the different strategies and significantly reduced injury prevalence density in PETs. Our focus on the intrinsic prevention strategies, might explain the biggest effect on non-contact injuries. References: 1. Sandmark et al (1999). *Appl Ergon*. 30(5): 435-442. 2. Pihl et al. ### LEFT AND RIGHT VENTRICULAR AREA-DEFORMATION LOOPS: A NEW NON-INVASIVE TOOL APPLIED TO THE CONCEPT OF EXERCISE-INDUCED CARDIAC FATIGUE

Lord, R., George, K., Somauroo, J., Stenbridge, M., Jain, N., Hoffman, M.D., Shave, R., Haddad, F., Ashley, E., Jones, H., Oxborough, D.

*Liverpool John Moores University*

Introduction Concurrent evaluation of cardiac structure and function can be assessed invasively with pressure-volume loops. We propose a new non-invasive method with simultaneous measurement of ventricular area and tissue deformation that provides temporal mechanical data throughout the same cardiac cycle. We report reliability data for this novel technique and apply this tool to the assessment of exercise-induced cardiac fatigue to develop mechanistic insight. Methods Fifteen participants (body mass  $70.1 \pm 8.8$  kg, height  $179 \pm 6$  cm, age  $40 \pm 8$  years) were recruited to take part in the study. Echocardiograms were performed before, immediately after and 6 hours into recovery from a 100 mile trail race. Standard and speckle-tracking echocardiography assessed right ventricular (RV) and left ventricular (LV) area and longitudinal tissue deformation, respectively. Intra-observer reliability of data was assessed within the physiological range for area and deformation. Following cubic spline interpolation area and deformation were plotted across the same cardiac cycle to construct loops. Results Coefficients of variation for area and tissue deformation ranged from 7 to 21%. The RV area-deformation loop demonstrated a rightward shift post-race with increased RV area ( $26.0$  to  $27.1$  cm<sup>2</sup>,  $P<0.05$ ) and reduced peak RV  $\epsilon$  ( $-28.6$  to  $-25.8\%$ ,  $P<0.05$ ). A leftward shift was observed in the LV longitudinal area-deformation loop post-race secondary to reduced LV area ( $35.8$  to  $32.5$  cm<sup>2</sup>,  $P<0.05$ ) and reduced peak  $\epsilon$  ( $-18.3$  to  $-16.6\%$ ,  $P<0.05$ ). Of interest, the RV area-deformation loop remained displaced at 6 hr recovery, however LV area-deformation values returned towards baseline. Conclusion A new concurrent assessment for cardiac area and deformation has acceptable intra-observer reliability and is sensitive to changes induced in cardiac function by ultra-endurance exercise. Current data suggest dissociation between LV and RV functional changes post-exercise and on-going application of this tool may provide further mechanistic insight into this phenomenon. *Radboudumc*

**INTRODUCTION** Regular physical activity (PA) reduces cardiovascular morbidity and mortality in the general and athletic population (Chakravarty, Hubert et al. 2008). Recent studies, however, suggest the existence of a J- or U-shaped curve between PA levels and health status, indicating that high doses of PA may abolish the beneficial effects of exercise (Schnohr, O'Keefe et al. 2015). The aim of this study was to assess the relationship between the dose of lifelong physical activity levels and the incidence of cardiovascular risk (CVR) factors (hypertension and hypercholesterolemia) and cardiovascular diseases (CVD) (myocardial infarction, stroke, and heart failure) in an athletic population. **METHODS** Between 2011 - 2014, participants of the 15K Seven Hills Run were invited to complete an online survey regarding their lifelong exercise exposure (time PA per week and exercise intensity) and cardiovascular health. CVR and CVD cases were matched to controls by age and sex. Lifelong exercise exposure (metabolic equivalent of task minutes [METmin]) was calculated from age 18 to the age of CVR/CVD diagnosis. Subjects were categorized into quintiles (Q1 – Q5) based on METmin. Odds ratios (OR) of CVR or CVD were calculated with Q1 as the reference category of exercise. **RESULTS** 1184 participants with CVR (53±7 years old) were matched to 5285 controls and 133 CVD participants (56±7 years) to 4406 controls. The rates of CVR occurrence across quintiles were 19.5%, 18.9%, 18.3%, 17.4%, and 17.5%, respectively. The association between METmin and CVR occurrence (OR [95%-CI]) was for Q2) 1.0 [0.8-1.2], Q3) 0.9 [0.8-1.1], Q4) 0.9 [0.7-1.1], and Q5) 0.9 [0.7-1.1]. Regarding CVD, the rates across quintiles were 3.3%, 2.8%, 2.5%, 2.3%, and 3.8%, respectively. The association between METmin and CVD occurrence (OR [95%-CI]) was for Q2) 0.8 [0.5-1.5], Q3) 0.8 [0.4-1.3], Q4) 0.7 [0.4-1.2], and Q5) 1.2 [0.7-1.9]. **DISCUSSION** The dose of lifelong exercise exposure did not have a significant impact on the occurrence of CVR or CVD. Therefore, our results do not support an upper limit of exercise health benefits. With physical inactivity as one of the most influential risk factors for morbidity worldwide (Lee, Shiroma et al. 2012), we recommend to keep on running. **REFERENCES** Chakravarty EF, Hubert HB, Lingala VB, Fries JF. **INTELLIGENT PHYSICAL EXERCISE TRAINING PROVES EFFECTIVE IN ENHANCING MUSCLE STRENGTH AND REDUCING MUSCULOSKELETAL PAIN IN A WORKPLACE SETTING: A RANDOMIZED CONTROLLED TRIAL**

Dalager, T., Justesen, J.B., Sjøgaard, G.

*University of Southern Denmark*

**Background:** Physical exercise training interventions at the workplace may cause health benefits but not all employees may benefit from the same program despite having the same occupational exposure. The present aim was to individually tailor Intelligent Physical Exercise Training (IPET) for office workers based on health checks and to assess the effect on musculoskeletal health (Sjøgaard G et al. *BMC Public Health* 2014, 14:652). **Methods:** Office workers were at each of 6 companies randomized 1:1 to a training group, TG (N=194) or a reference group, REF (N=195). TG received one-hour supervised high intensity IPET every week within working hours for one year. The training program was based on baseline health check measures of muscle strength, musculoskeletal pain (self-reported on a 0-9 numeric box-scale), cardiorespiratory fitness and health risk indicators, as well as functional capacity including balance. In total 32 individual training programs were developed but 9 of those covered more than 85 % of the participants' needs, most of which included neck/shoulder strength training and cardio training. Trial registration was in ClinicalTrials.gov, number: NCT01366950. **Results:** There were no baseline differences between groups with overall mean±SD: shoulder elevation strength (right 494±173 N; left 478±171 N), arm abduction strength (right 250±101 N; left 244±102 N), neck pain (past 3 mth 3.2±1.9; 7 d 2.5±1.9), right shoulder pain (past 3 mth 2.4±1.7; 7 d 2.3±1.7), and left shoulder pain (past 3 mth 1.9±1.5; 7 d 2.0±1.5). An intention-to-treat analysis showed significant improvements for TG compared with REF in muscle strength with ~ 9 % increases (range: 3 % - 12 %), reduced neck pain past 7 d of 1.4±1.6, right shoulder pain past 3 mth of 0.6±1.4 and 7 d of 1.3±1.4, and left shoulder pain past 7 d of 1.1±1.0. Neck pain and left shoulder pain past 3 mth were found significant in a per protocol analysis among employees in TG with a compliance of ≥70 % compared with REF. Further, the proportion of employees who reduced pain intensity past 7 d with ≥1 was for all body regions ~ 90 % in TG and significant compared with REF (~ 20 %). **Discussion:** High intensity IPET during working hours significantly reduced musculoskeletal pain in neck and shoulders as well as increased muscle strength among office workers. Of note is the large proportion of employees in TG who had pain reductions of ≥1, which is considered of clinical relevance and was attained with different combinations of IPET. When targeting the workplace as a setting, it is important to not only address the occupational exposure but also to tailor the training to the diversity of the employees' capacity and disorders. **CIGARETTE SMOKING INTERFERES WITH DIETARY NITRATE METABOLISM AND ITS EFFECTS ON BLOOD PRESSURE AND EXERCISE TOLERANCE**

Wylie, L.J.1, Blackwell, J.R.1, Jones, A.M.1, Bailey, S.J.1

*1: (SHS) University of Exeter*

**Introduction** Cardiovascular diseases (CVDs) are the leading cause of mortality globally with cigarette smoking a major risk factor for the development of CVDs and the leading preventable cause of mortality worldwide. Increasing inorganic nitrate (NO<sub>3</sub><sup>-</sup>) intake can lower CVDs risk factors with the efficacy of NO<sub>3</sub><sup>-</sup> dependent on its uptake into the salivary circulation and subsequent reduction to nitrite (NO<sub>2</sub><sup>-</sup>) and nitric oxide (NO) (Kapil et al., 2014). Thiocyanate (SCN<sup>-</sup>), a competitive inhibitor of salivary NO<sub>3</sub><sup>-</sup> uptake (Edwards et al., 1954), is abundant in cigarette smoke. Therefore, this study tested the hypothesis that dietary NO<sub>3</sub><sup>-</sup> supplementation would increase salivary and plasma [NO<sub>3</sub><sup>-</sup>] and [NO<sub>2</sub><sup>-</sup>], lower BP and improve exercise tolerance to a lesser extent in cigarette smokers (S) than non-smokers (NS). **Methods** Nine (5 males) healthy S and eight (4 males) healthy NS controls reported to the laboratory for initial baseline assessment (CON) and following six day supplementation periods with 140 ml·day<sup>-1</sup> NO<sub>3</sub><sup>-</sup>-rich (8.4 mmol NO<sub>3</sub><sup>-</sup>·day<sup>-1</sup>; NIT) and NO<sub>3</sub><sup>-</sup>-depleted (0.08 mmol NO<sub>3</sub><sup>-</sup>·day<sup>-1</sup>; PLA) beetroot juice in a cross-over experiment. During each laboratory visit, resting blood pressure (BP) was assessed, saliva and venous plasma samples were collected, and a cycling incremental test to exhaustion was completed. **Results** Plasma and salivary [SCN<sup>-</sup>] were elevated in S compared to NS in all experimental conditions (P<0.05). Relative to CON, salivary [NO<sub>3</sub><sup>-</sup>] (3.5 ± 2.1 vs. 7.5 ± 4.4 mM), plasma [NO<sub>3</sub><sup>-</sup>] (484 ± 198 vs. 802 ± 199 μM) and plasma [NO<sub>2</sub><sup>-</sup>] (218 ± 128 vs. 559 ± 419 nM) increased with NIT in both S and NS,

but the magnitude of these increases was lower in S ( $P < 0.05$ ). Salivary [NO<sub>2</sub>-] was similarly increased above CON with NIT in S and NS ( $P > 0.05$ ). Systolic BP was lowered with NIT ( $100 \pm 10$  mmHg) relative to CON ( $107 \pm 7$  mmHg) and PLA ( $103 \pm 8$  mmHg) in NS ( $P < 0.05$ ), but not S ( $P > 0.05$ ). Peak aerobic power (AP<sub>peak</sub>) and oxygen uptake (VO<sub>2</sub><sub>peak</sub>) were not significantly impacted by NIT in S ( $P > 0.05$ ). In NS there was no difference in VO<sub>2</sub><sub>peak</sub> with NIT ( $P > 0.05$ ), but AP<sub>peak</sub> was higher in NIT compared to both PLA and CON ( $P < 0.05$ ). Discussion These findings suggest that the metabolism of dietary NO<sub>3</sub>- is compromised in S leading to attenuated blood pressure reductions and exercise tolerance gains relative to NS. These observations may provide novel insights into the cardiovascular risks associated with cigarette smoking and suggest that this population is less likely to improve cardiovascular health if they conform to global initiatives to increase fruit and vegetable consumption. ### IS-BN04 QUALITY OF MOVEMENTS – MORE THAN MEETS THE EYE?

#### WHAT IS CLINICAL ASSESSMENT OF MOVEMENT QUALITY?

Crossley, K., Ageberg, E., Creaby, M.

*University of Queensland*

Altered movement patterns of the lower extremities after injury are common, but constitute a challenge to assess. Three-dimensional (3D) motion analysis is the gold standard for quantifying movements. However, clinically feasible measures are needed for large scale studies and clinical use. Visual observation of movement quality during functional tasks can be used for these purposes. One aspect of movement quality is postural orientation, which has received increased interest in recent years. Postural orientation is the ability to maintain an appropriate position of the joints in relation to each other and to the environment when performing a dynamic task. For example, in athletes with or at high risk of knee injury, the knee relative to the foot is often evaluated; a “knee-over-foot” position is considered appropriate, whereas a “knee-medial-to-foot” position is deemed inappropriate. In this talk I will present and discuss different approaches to how movement quality can be measured clinically, validity and reliability of clinical assessment of movement quality and the association between altered movement quality and injury

#### WHAT ARE THE SENSORIMOTOR AND BIOMECHANICAL MECHANISMS ASSOCIATED WITH GOOD AND POOR PERFORMANCE IN CLINICAL TESTS OF MOVEMENT QUALITY?

Creaby, M.W.

*Australian Catholic University*

In this talk I will present and discuss sensorimotor and biomechanical mechanisms associated with good and poor performance in clinical tests of movement quality. This will include data on links between poor movement quality, muscle size, strength, control, activation patterns, and gait mechanics. With links between movement patterns during clinical tests, such as a single leg squat, and sport-related lower limb injuries, an understanding of the mechanisms that contribute towards poor movement patterns during clinical tests is imperative. This knowledge may help in guiding the development of approaches to correct poor performance, and thus reduce the risk of future injury. This talk will draw on evidence from across the literature that highlights a consistency in movement patterns between clinical tests and sports specific skills such as running and landing. The likely importance of this consistency in movement patterns will be explained within the context of common acute and overuse knee injuries. Further, emerging evidence indicates that various modifiable factors may play an important role in the quality of movement, including muscle size, strength, control and activation patterns. Of particular interest, it is not just the local muscles that influence movement quality. For example, the lumbopelvic muscles are thought to play an important role in the quality of movement at the knee.

#### USING CLINICAL ASSESSMENT OF MOVEMENT QUALITY IN THE INJURY REHABILITATION AND RETURN-TO-SPORT

Ageberg, E.

*Lund University*

Single clinical tests are commonly used for assessing movement quality. Given that the responsiveness and discriminative ability are usually greater for several tests than for single tests, a test battery of functional tasks would be of value. Tasks with increased level of difficulty to be used at different stages after the injury, during the rehabilitation period, and for determining return to sports would be useful. Preventing a medial position of the knee is suggested to reduce the risk of traumatic knee injuries, especially in female athletes, and therefore forms an integral component of prevention and rehabilitation through neuromuscular training interventions. However, the possible influence of rehabilitation on movement quality has not yet been studied. Also, altered movement quality may be revealed in other body parts apart from the knee, e.g., the trunk, pelvis and hip, but this phenomenon requires further study. In this talk, I will present and discuss findings on selecting the appropriate clinical tests for assessing movement quality, the association of worse movement quality with symptoms, function, and gender and whether altered movements can improve by rehabilitation and predict the outcome after rehabilitation.

## Invited symposia

### IS-BN06 TENDON ADAPTATION

#### TENDON RESPONSE TO EXERCISE TRAINING

Bojsen-Møller, J.

*Norwegian School of Sports Sciences*

In vivo studies over the last decade has indicated that force transmitting tissues and/or their immediate surroundings respond instantly to sustained loading with increased blood flow and glucose uptake (Bojsen-Møller et al., 2006). Moreover, augmented collagen synthesis rate has been observed within hours to days of one strenuous exercise bout, and overall gains in collagen synthesis has been demonstrated in response to periods of exercise training (Langberg et al 2001). Taken together there seems to be firm evidence that tendinous tissues respond acutely to training induced loading. At the same time recent evidence suggests that human tendons or at least parts of human tendons exhibit an extremely slow turnover that in fact indicates that tendons are hardly renewed over the course of a lifetime (Heinemeier et al. 2013). Previous training studies on humans and animals have not been clear with respect to changes in tendon dimensions and mechanical properties, however, more recent evidence suggests that in fact tendon dimensions do increase after especially strength training, and also mechanical properties seem to change in response to habitual increases in loading (Couppe et al. 2008; Kongsgaard et al. 2007; Seynnes et al. 2009). Gains in imaging techniques, resolution and improved analyses are likely to have contributed to these newer findings. This presentation reviews the existing knowledge on tendon response to loading in an attempt to elucidate how the force bearing tissues adapt to habitual exercise training. #### THE RELATIONSHIP BETWEEN TENDON MECHANICAL PROPERTIES AND DAILY STRESS LEVELS

Seynnes, O.

*Norwegian School of Sport Sciences*

Tendon composition and mechanical properties are often defined as a compromise between their functions for an effective force transmission to the skeleton and for the storage/release of elastic energy. Consistent with this paradigm, short-term studies have shown that alterations in tendon function via training results in metabolic and structural adaptations, which in turn may modify tendon material properties (1). However, cross-sectional comparisons from animal studies indicate comparable elastic moduli in tendons fulfilling different functions, independently from species and body mass (2, 3). Instead, results from these studies suggest that tendon cross-sectional area is the only parameter related to daily stress level. These findings are consistent with theoretical models placing tendon morphology and stiffness as principal variables of adjustment to daily stress levels, but they contrast with inconsistent reports of human tendon hypertrophy in training studies (4). This presentation will summarise - and attempt to conciliate - theoretical concepts of tendon long-term adaptation, based on the study of animal specimen and on in vivo testing of human tendons. 1. #### EFFECTS OF AGING AND DISUSE ON TENDON

Stenroth, L.

*University of Jyväskylä*

Aging is commonly associated with decreased loading of tendon tissue due to decreased physical activity and muscle strength. Thus, both aging and disuse are hallmarked by reductions in tendon loading, which leads to changes in tendon tissue composition and in mechanical/morphological properties (Magnusson et al., 2008; Reeves, 2006). In vivo human studies have shown that disuse alters tendon mechanical properties but the effects of aging are unclear. The relative contributions of the effects of aging and disuse in age-related modifications of tendon properties have been studied by examining master athletes with life-long physical activity background. These studies have not shown a significant effect of habitual high levels of physical activity on tendon mechanical properties (Couppe et al., 2014; Karamanidis and Arampatzis, 2006). However, tendons do respond to strength training even in old age (Reeves et al., 2003) indicating that loading type is important factor to be considered. Effects of aging and disuse on tendon dimensions are unclear and inconsistent with effects on mechanical properties suggesting that tendon material properties are altered with aging and disuse. Collagen cross-linking and non-collagenous matrix may play a significant role in these modifications. Recent studies on tendon micromechanics (Thorpe et al., 2013; Depalle et al., 2015) may provide a link between tendon matrix and whole tendon properties, by helping to explain some of the inconsistent findings and pointing out possible alterations in load transmission within tendon structures which are specific to aging or disuse. This presentation will concisely review the current literature to highlight similarities and differences between the effects of aging and disuse. Finally, functional consequences of the tendon adaptations with aging and disuse will be discussed. ## Invited symposia

### IS-SH01 FEPSAC SYMPOSIUM - THE DEVELOPMENT OF EXPERTISE AND COMPETENCIES OF APPLIED SPORT PSYCHOLOGISTS IN EUROPE

#### THE PROFESSIONAL DEVELOPMENT OF THE ASP PRACTITIONER

Wylleman, P., de Caluwé, D., Reints, A.

*Vrije Universiteit Brussel*

Using a qualitative methodology 12 applied sport psychology (ASP) providers were questioned on the competences important (a) to the quality of ASP support service and (b) throughout the ASP practitioner career. First, respondents provided 57 different concepts which were subcategorized in (a) attitudes/beliefs competencies (e.g., flexibility, being part of sport culture, reticence, modesty); (b) knowledge competencies (e.g., clinical and other psychology disciplines, sport, sport psychology, sport sciences); and (c) skills including personal (e.g., creativity, mental skills, self-confidence), social/interpersonal (e.g., communication skills, networking), and therapeutic skills (e.g., empathy, individual counselling). Second, respondents felt novice professionals should acquire most attitudes/beliefs required (e.g., interest in people, openness, passion for/interest in sport, perseverance, modesty) as well as having self-knowledge, knowledge on how to (initiate) work with people and on mental skills. Knowledge of (the requirements of) sport was related to mature ASP practitioners. Counselling, communication and social/interpersonal skills were deemed important throughout the career. Diagnostic skills was more linked to the novice professional, while being able to work individually, use and learn from experience, and provide supervision were linked to the experienced professional. These findings will be used to enhance the education and professionalization of ASP providers.

#### WORKING EFFECTIVELY IN YOUTH SPORT: REFLECTIONS OF A LEAD SPORT PSYCHOLOGIST

Harwood, C.

*Loughborough University*

Childhood and Adolescence are key developmental stages within which to influence the growth of psychosocial skills and attributes in young sports performers. National Sport Federations and Professional sports academies are increasingly recognising the opportunity to employ sport psychologists in their programmes (Harwood, 2008). The sport psychologist in these settings face a range of challenges and a diversification of organisational roles given the number of stakeholders and policies to consider (i.e., coaches, parents, peers, funding). In this presentation, the Lead Psychologist (with 18 years of experience) of a National Federation and a Professional youth soccer academy will offer his reflections of the competencies required when working in youth sport settings. The synergy of humanistic and cognitive-behavioral approaches to sport psychology will be discussed given the significance of self-concept, self-identity and self-regulation to the health of the talented young person in sport. Additionally, the opportunity to develop strategic initiatives incorporating technology will be appraised. Finally, the ability to create effective working relationships within and between interdisciplinary support staff, coaches, and parents will be considered in light of a range of personal and organisational skills demanded of the practitioner. These reflections will sport scientists, researchers and young psychologist's insights into some of the real world issues facing psychologists.

#### BECOMING A COMPETENT PRACTITIONER IN SPORT PSYCHOLOGY: TYPICAL CHALLENGES AND EFFECTIVE LEARNING EXPERIENCES

Hutter, V.

*VU University Amsterdam*

As highlighted in the other presentations of this symposium, specific competencies are required for sport psychologists. Aspiring sport psychologists need to develop a wide range of skills and competencies to become effective professionals. Novice sport psychologists struggle with generic, typical issues and common challenges during their training and first professional steps. In sport psychology, first professional experience is usually obtained in a supervised practicum. Analyses of 369 questions that novice sport psychologists asked their supervisors during supervised practice resulted in a model of supervisory issues in applied sport psychology. These supervisory issues reflect which skills, competencies and aspects of service delivery are particularly difficult to master for novice sport psychologists. Next, novice sport psychologists were interviewed about the model's supervisory issues and were asked what learning experiences helped them resolve the supervisory issues and thus added to professional development. Qualitative analyses revealed the importance of different learning experiences inside, as well as outside education and classroom settings. From these results implications are drawn for the education and training of sport psychologists. The methodology used is applicable to the education and training of other professionals in sport sciences, and therefore of interest if educators in (applied) sport sciences.

#### 'FEPSAC SYMPOSIUM 'THE DEVELOPMENT OF EXPERTISE AND COMPETENCIES OF APPLIED SPORT PSYCHOLOGISTS IN EUROPE''

Johnson, U.

*Halmstad University*

Within the field of applied sport psychology (ASP) interest in professional practice is growing, and we are faced with the challenge of developing not only our professional status but also the competencies and level of expertise of providers. In three presentations, this symposium will highlight the latest research and the most salient aspects of ASP support provision in general, and the expertise and competencies required and used by ASP support providers, in particular. In the first presentation Professor Paul Wylleman from Free University, Brussels, Belgium will present "The Professional Development of the ASP Practitioner." Using a qualitative methodology, 12 ASP

providers were questioned about their competences. Respondents felt novice professionals should attempt to acquire self-knowledge, knowledge on how to (initiate) work with people, and competencies with mental skills. Knowledge of (the requirements of) sport was related to mature ASP practitioners. Counselling, communication, and social/interpersonal skills were deemed important throughout the career. Diagnostic skills was more linked to the novice professional, whereas being able to work individually, use and learn from experience, and provide supervision were linked to the experienced professional. In the second presentation Associate Professor Chris Harwood from Loughborough University, England will present, "Working Effectively in Youth Sport: Reflections of a Lead Sport Psychologist." Childhood and adolescence are key stages within which psychosocial skills and identity are developing in young sports performers. In this presentation, the Lead Psychologist (with 18 years of experience) of a National Federation and a professional youth soccer academy will offer his reflections of the competencies required when working in youth sport settings. The synergy of humanistic and cognitive-behavioral approaches to sport psychology will be discussed along with the significance of self-concept, self-identity, and self-regulation to the health of the talented young person in sport. In the third presentation Dr Vana Hutter from University Amsterdam, the Netherlands will present "Becoming a Competent Practitioner in Sport Psychology: Typical Challenges and Effective Learning Experiences." Novice sport psychologists struggle with many challenges during their training and first professional steps. Analyses of 369 questions, which novice sport psychologists asked their supervisors during supervised practice, resulted in a model of supervisory issues in applied sport psychology. From this model implications are drawn for the education and training of sport psychologists. The methodology used is applicable to the education and training of other professionals in sport sciences, and therefore of interest to educators in (applied) sport sciences. Professor Urban Johnson from Halmstad University, Sweden will chair the session.

### IS-SH02 ANIMALS, SPORT AND HEALTH - A SUSTAINABLE RELATIONSHIP?

---

#### YOUTH EQUESTRIAN SPORT: INTERSPECIES RELATIONS IN TIME AND SPACE

Gillet, J.

*MacMaster University*

The purpose of this lecture is to explore the changes in youth equestrian sport that have occurred in Canada since the introduction of the pony club in 1934. I argue that before the 1980's equestrian sport served, for women, many of the same purposes as bicycling and golf. It was emancipatory and liberating while safely within the culturally acceptable confines of the privileged group. Beginning in the late 1970's and early 1980's, a shift towards neoliberal economic logic led to social and cultural changes in Canada. In sport, there was a movement away from volunteer sport organizations towards private forms of organized sport. These changes were reflected in the equine industry as the role and perceived utility of the Canadian pony club began to change. This late modern shift created a market for sport and encouraged the privatization of equestrian sport. Today members of the equestrian community contest the value of pony club as a youth sport. The organization still offers cultural capital through education and training but in a late modern society its ability to produce capital through competition has declined due to the introduction of new equestrian sport organizations and changes in the consumption of sport.

#### THE HORSE AS A HEALTH WORKER?

Sörensen, M.

*Norwegian School of Sport Sciences*

The horse as a health worker? Introduction Several studies have demonstrated health benefits in humans from contact with animals, but most studies in this area have been on smaller pets like dogs and cats. The purpose of this study was to investigate the associations between human health and contact with horses. The specific research question was: Are there any differences between individuals who have regular contact with horses, those who have occasional contact and those who have no contact with horses on indicators on physical and psychological health? Methods Data come from a population survey by questionnaire and health examinations by the National Health Institute in Norway in cooperation the municipalities in two counties in the years of 2001 – 2002. Around 4450 participants answered the questions related to work related or leisure time contact with horses (Small variations in N for the different questions). Due to consistent gender differences, data were analysed for each gender separately. Results Preliminary analyses indicated differences in reported health indicators both between genders but also between having contact with horses professionally and in leisure time as well as between those who had contact with horses occasionally, and those who were in contact with horses on a regular basis (weekly or daily). Males with contact with horses both in leisure time and professionally reported more skeletomuscular pain, but were more physically active than those with no contact, and those with a regular contact demonstrated lower blood pressure than the others. Females with regular horse contact in leisure time, reported less psychological problems than the others. Females with horse contact both professionally and in leisure time were more physically active and demonstrated lower blood pressure than those with no horse contact. Discussion Contact with horses seems to have both its benefits and costs, and some of them are similar for the genders, but others differ. One common trend is that contact with horses seem to make people more physically active, but that in particular for men in this population, it may also mean hard work that is associated with more skeletomuscular pain. This may be related to differences in how men and women work with or use horses in leisure time. The tendency of women with regular leisure time horse contact to report less psychological problems than those with no or occasional contact could be explained with the need for a certain frequency of contact for psychological benefits. Contact [marit.sorensen@nih.no](mailto:marit.sorensen@nih.no)

#### ETHICS IN HORSE RIDING

Dashper, K.

*Leeds Metropolitan University*

The riding of horses for human sport and pleasure is a controversial issue. Unlike human participants, horses cannot give informed consent to take part in these activities and are necessarily in a subordinate position in relation to their human rider who (a) understands the terms of engagement in the sport or leisure activity, (b) can choose to take part in the activity, or not, and (c) can choose to cease

participation at any point. But does this make the involvement of horses in human pleasure inherently unethical? In this presentation I draw on data from two linked studies – one with professional riders and one with leisure of amateur riders – to consider this issue in more detail. Through riding the horse is subject to human will but this does not mean that the horse lacks agency in these human-animal relationships. The participants in my research think and care deeply for the horses with whom they interact, although these interactions are influenced by the varying demands of the sport or leisure context in which they take place. I argue that whether or not it is ethically acceptable for humans to ride horses is a complex issue and one that riders at different levels consider daily in their interactions with their equine partners.

### OP-PM05 Muscle Metabolism & Nitrate Ingestion

#### CELLULAR MECHANISMS OF VITAMIN D IN SKELETAL MUSCLE REPAIR: A LIVE CELL IMAGING ANALYSIS

Owens, D., Polydorou, I., Alwan, N., Fraser, F., Tang, J., Morton, J., Sharples, A., Stewart, C., Close, G.

*Liverpool John Moores University*

**Purpose:** Association studies have demonstrated a correlation between Vitamin D status and muscle force recovery following damaging exercise (Barker, Henriksen, et al., 2013; Barker, Schneider, Dixon, Henriksen, & Weaver, 2013). The present study investigated vital cellular aspects of the regeneration process to establish a causal relationship between Vitamin D and skeletal muscle repair. **Methods:** Muscle biopsy samples were obtained from the Vastus Lateralis of 14 young males with Vitamin D concentrations <50 nmol.L<sup>-1</sup>. Muscle derived cells (MDCs) were isolated from biopsies, characterised by immunocytochemistry and cultured to confluence prior to mechanical scrape damage (Dimchev, Al-Shanti, & Stewart, 2013) in the presence of vehicle (CON), 10 nmol (Lo) or 100 nmol (Hi) 1 $\alpha$ 25-dihydroxyvitamin D<sub>3</sub>, the biologically active form of Vitamin D. MDC migration velocity (V), accumulated (AD) and Euclidean distance (ED) and directionality (DIR) were assessed via live cell imaging over 48hrs following injury. **Results:** Live cell imaging analysis revealed significant improvements (P < 0.05) in V for Lo (0.30  $\pm$  0.10  $\mu$ m.min<sup>-1</sup>), and Hi (0.32  $\pm$  0.11  $\mu$ m.min<sup>-1</sup>) vs CON (0.2  $\pm$  0.1  $\mu$ m.min<sup>-1</sup>). Similar significant improvements (P < 0.05) were seen for AD (858  $\pm$  290, 909  $\pm$  315 vs 691  $\pm$  326  $\mu$ m) and ED (459  $\pm$  204, 450  $\pm$  204 vs 339  $\pm$  203  $\mu$ m in Lo & Hi vs CON). **Conclusions:** Our data provide the first insights into the cellular mechanisms by which Vitamin D deficiency may impair muscle regeneration. These findings warrant further investigation into the molecular signalling mechanisms dictating such changes in human muscle cell behaviour in the context of Vitamin D. Moreover, populations in which muscle regeneration may already be impaired (i.e. elderly or dystrophic) require research efforts to explore the possibility that Vitamin D deficiency exacerbates existing regenerative dysfunction. **References -** Barker, T., Henriksen, V. #### DIURNAL DIFFERENCES IN THE MYOFIBRILLAR PROTEOME OF HUMAN VASTUS LATERALIS

Malik, Z.A.1,2, Shepherd, S.O.1, Iqbal, Z.3, Vanrenterghem, J.1, Edwards, B.J.1, Burniston, J.G.1

*1Research Institute for Sport & Exercise Sciences, Liverpool John Moores University, Liverpool, UK; 2Universiti Pendidikan Sultan Idris, Perak, Malaysia; 3Liverpool Football Club, Anfield, Liverpool,*

**Introduction** The ability of skeletal muscle to produce force is significantly greater in the evening than in the morning. However, the mechanisms underpinning this diurnal variation have not been resolved. The protein complement (i.e. proteome) of muscle underpins its functional properties; therefore we reasoned the diurnal difference in performance is associated with changes in muscle myofibrillar proteins. **Methods** Ten physically active men (mean  $\pm$  SD; age 26.7  $\pm$  3.7 y, height 1.77  $\pm$  0.08 m, body mass 74.9  $\pm$  9.8 kg) completed the protocol after providing informed consent to the ethically approved procedures. Participants were familiarised prior to performing experimental sessions in the morning (0800 h) and evening (1700 h) that were counterbalanced in order of administration and separated by at least 72 h. Each session included 5 min cycling at 150 W, 4 measurements of maximal voluntary contraction (MVC; including twitch-interpolation) and 10 measurements of the maximum rate of force development (RFD) of their knee extensors. Muscle samples were then collected under local anaesthetic (0.5 % Marcain) by percutaneous needle biopsy from the vastus lateralis of the exercised leg. Myofibrillar proteins were resolved by 2-dimensional gel electrophoresis. Gels images were analysed in SameSpots (TotalLab v3.3) and proteins identified by mass spectrometry. Statistical analysis was conducted by repeated measures one-way analysis of variance. **Results** Muscle force in the evening (754.4  $\pm$  112.9 N/m) was significantly (P<0.01) greater (11 %) than in the morning (679.9  $\pm$  104.9 N/m). RFD was also significantly (P<0.01) greater (15.7 %) in the evening (7030.5  $\pm$  1100.7 N/s) than in the morning (6077.3  $\pm$  1371.7 N/s). In total, 122 proteins were analysed and the abundance of 8 spots was statistically (P<0.05) different from morning to evening. In the evening greater abundances were observed in myosin binding protein C1 (80 %), glycogen phosphorylase (43 %) and beta enolase (24 %), whereas the abundances of nebulin (-48 %), troponin T slow (-22 %), and 3 spots identified as keratin II (average -30 %) was less in the evening compared to morning. **Discussion** The diurnal variation in muscle performance was associated with significant differences in the myofibrillar proteome. The slow isoform of myosin binding protein C (MyBPC1) exhibited the greatest difference and is known to modulate the activity of actin-bound myosin ATPases. MyBPC1 was resolved to 6 species, therefore the difference in abundance reported here may represent a change in post-translational modification. Contact Z.Ab-Malik@2011.ljmu.ac.uk

**INFLUENCE OF BEETROOT JUICE AND SODIUM NITRATE ON OXYGEN CONSUMPTION IN TRAINED MEN**

Flueck, J.L.1, Bogdanova, A.2, Mettler, S.3, Perret, C.1

1: *Institute of Sports Medicine, Swiss Paraplegic Centre Nottwil*; 2: *Institute for Veterinary Physiology, University of Zurich*;

**Introduction:** The influence of dietary nitrate such as beet root juice (BR) on exercise performance is controversially discussed in sport science these days. It was shown, that nitrate may reduce oxygen consumption (VO<sub>2</sub>) during exercise (Bailey et al., 2009; Vanhatalo et al., 2010; Wylie et al., 2013). To date, it is not clear, if the ingestion of sodium nitrate (NIT) shows the same effect on VO<sub>2</sub> as BR. Secondly, it remains unclear, whether the same dose of NIT leads to similar plasma nitrate ([NO<sub>3</sub>-]) and nitrite ([NO<sub>2</sub>-]) concentrations as BR. The aim of our study was to investigate the influence of different dosages of BR and NIT on VO<sub>2</sub> and on plasma [NO<sub>3</sub>-] and [NO<sub>2</sub>-]. **Methods:** Ten healthy, trained men (median [minimum; maximum]; age: 33years [19; 46]; height: 182cm [170; 187]; body mass: 73.5kg [60.7; 78.0] and VO<sub>2</sub>peak: 60.2ml/min/kg [40.5; 67.0]) participated in this study. Subjects completed seven trials of 5min cycling at 50% VO<sub>2</sub>peak followed by 8min cycling at 80% VO<sub>2</sub>peak. 3 hours before each trial, subjects ingested either a dosage of BR (3, 6 or 12mmol), of NIT (3, 6 or 12mmol) or placebo (PLC, plain water) in a random order. Blood samples were taken before and 3 hours post-ingestion for [NO<sub>3</sub>-] and [NO<sub>2</sub>-] analysis. Gastrointestinal tolerance was recorded. **Results:** Exercise at 50% VO<sub>2</sub>peak showed no significant differences in VO<sub>2</sub> between the trials (p=0.186), whereas exercise at 80% VO<sub>2</sub>peak showed a significantly lower VO<sub>2</sub> (p=0.050). Significant differences between the 6mmol BR and the PLC (p=0.028) trial as well as between the 6mmol BR and NIT trial (p=0.008) were found. Plasma [NO<sub>3</sub>-] and [NO<sub>2</sub>-] were significantly increased 3 hours post-ingestion of nitrate compared to PLC (p<0.001). The comparison of plasma [NO<sub>3</sub>-] and [NO<sub>2</sub>-] between the same dosage of BR and NIT showed no significant differences for 6 and 12mmol. Gastrointestinal tolerance did not differ between interventions (p=0.172). **Discussion:** Our study results showed a significantly lower VO<sub>2</sub> in severe-intensity exercise after consumption of nitrate. The ingestion of 6mmol BR induced a significantly lower VO<sub>2</sub> compared to PLC. Astonishingly, the ingestion of 6mmol BR showed a significantly lower VO<sub>2</sub> compared to the NIT trial. In contrast, plasma [NO<sub>2</sub>-] showed no significant differences between these two dosages 3h post-ingestion. **References:** Bailey SJ, Winyard P, et al. (2009). *J of Appl Physiol*, 1144-1155. Vanhatalo A, Bailey SJ, et al. (2010). *Am J Physiol Regul Integr Comp Physiol*, R1121-1131. Wylie LJ, Kelly J, et al. **EFFECTS OF ACUTE VERSUS 6-DAY SODIUM NITRATE SUPPLEMENTATION ON TIME-TRIAL PERFORMANCE IN TRAINED CYCLISTS**

Nyakayiru, J., Jonvik, K.L., Pinckaers, P.J.M., Senden, J.M.G., van Loon, L.J.C., Verdijk, L.B.

*Maastricht University*

**BACKGROUND:** Previous work has shown that ~6 days of dietary nitrate (NO<sub>3</sub>-) supplementation can lower oxygen uptake (VO<sub>2</sub>) during submaximal cycling exercise, and improve exercise performance in trained cyclists [1]. More recently, it was reported that even ingestion of a single dose of dietary nitrate prior to exercise can improve subsequent performance [2]. The purpose of this study was to compare the impact of acute versus 6-day sodium nitrate supplementation on oxygen uptake during submaximal exercise as well as time-trial performance in highly trained cyclists. **METHODS:** Using a randomized, double blind, cross-over design, 17 male cyclists (25±1 y, VO<sub>2</sub>peak 65±1 mL/kg/min, Wmax 411±9 W) were subjected to 3 different trials, including 6 days of sodium nitrate supplementation (6-DAY); 5 days of placebo and 1 day of sodium nitrate supplementation (1-DAY); 6 days placebo supplementation (PLA). Nitrate was administered as sodium nitrate (1.1 g NaNO<sub>3</sub>), providing ~12.9 mmol NO<sub>3</sub>-/day. Placebo consisted of 1.1 g sodium chloride per day. On the last day of each supplementation period and 3 h after consuming the last supplement, subjects performed 30 min of exercise at 45% Wmax and 30 min at 65% Wmax on a cycle ergometer, followed by a simulated ~10 km time-trial. Indirect calorimetry was performed during submaximal exercise, and blood samples were drawn up to 5 h following ingestion of the last supplement. Data were analyzed using repeated measures ANOVA with time and treatment as within-subjects factors. **RESULTS:** Plasma nitrate and nitrite concentrations increased from baseline to 3 h post-ingestion of the nitrate-containing supplements, resulting in significantly higher plasma nitrite levels immediately before exercise in both the 6-DAY and 1-DAY trial when compared with the PLA trial (501 ± 50 nM and 553 ± 67 nM versus 239 ± 18 nM, respectively; P<0.001). Time-trial performance (1004±15, 1022±17, 1017±17 s) and power output (316±9, 310±9, 312±9 W) were not significantly different between the 6-DAY, 1-DAY, and PLA trials, respectively (P=0.28 and P=0.33, respectively). No significant differences in submaximal VO<sub>2</sub> were observed during exercise at the 45% (2.56±0.06, 2.58±0.07, 2.54±0.06 L/min) and 65% Wmax workload (3.53±0.08, 3.51±0.09, 3.51±0.09 L/min) in the 6-DAY, 1-DAY and PLA trial, respectively (P=0.60 and P=0.89, respectively). **CONCLUSION:** Acute and 6-day sodium nitrate supplementation (~12.9 mmol NO<sub>3</sub>-/day) do not improve time-trial performance in highly trained cyclists. 1. **EFFECTS OF BLOOD DONATION AND NITRATE INGESTION ON THE PHYSIOLOGICAL RESPONSE TO MODERATE-INTENSITY AND INCREMENTAL EXERCISE**

McDonagh, S.T.J., Vanhatalo, A., Fulford, J., Wylie, L.J., Bailey, S.J., Jones, A.M.

*University of Exeter*

**Introduction** Nitrate-rich beetroot juice (BR) can reduce the oxygen (O<sub>2</sub>) cost of moderate-intensity exercise and enhance tolerance to severe-intensity exercise (Bailey et al., 2009). A derivative of nitrate (NO<sub>3</sub>-), nitric oxide, plays a significant role in the regulation of skeletal muscle blood flow, contraction and efficiency. A reduction in blood O<sub>2</sub> carrying capacity, as a result of blood donation, reduces the tolerance to severe-intensity exercise (Burnley et al., 2006). The aim of this study was to determine whether BR supplementation alters the haemodynamic response, efficiency and tolerance to cycling exercise post blood donation. **Methods** In a randomised and double blind experimental design, 22 recreationally active volunteers performed moderate-intensity and ramp incremental cycle exercise tests prior to and post withdrawal of ~450 mL of whole blood. Before donation, all subjects (n=22) consumed 7 x 70 mL of NO<sub>3</sub>--depleted beetroot juice shots (~0.04 mmol NO<sub>3</sub>- per 70mL) as a placebo (PL) in the 48 h preceding the exercise tests. Immediately after blood donation and during the 48 h prior to exercise, subjects consumed 7 shots of either BR (~6.2 mmol NO<sub>3</sub>- per 70 mL; n=11) or PL (n=11). Blood pressure (BP), plasma NO<sub>3</sub>- and nitrite (NO<sub>2</sub>-) concentrations, haemoglobin concentration ([Hb]), haematocrit (Hct) and pulmonary V'O<sub>2</sub> responses to exercise were measured during each visit to the laboratory. **Results** BR supplementation resulted in an increased plasma [NO<sub>3</sub>-] (PL: 50±14 vs. BR: 845±350 µM; P<0.05) and [NO<sub>2</sub>-] (PL: 72±21 vs. BR: 619±363 nM; P<0.05) post blood donation. Systolic BP was reduced in BR post blood donation when compared with baseline. [Hb] and Hct decreased significantly from pre to post blood withdrawal, however, no difference was noted between PL and BR. Compared with pre donation, the steady state V'O<sub>2</sub> during moderate-intensity exercise was

~4% lower post donation in BR only ( $P < 0.05$ ). The ramp test peak power decreased from pre donation (PL:  $341 \pm 70$  vs. BR:  $331 \pm 68$  W) to post donation (PL:  $324 \pm 69$  vs. BR:  $322 \pm 66$  W) in both groups ( $P < 0.05$ ). However, the decrement in performance was less in BR compared with PL ( $P < 0.05$ ). Discussion Nitrate supplementation reduces the O<sub>2</sub> cost of moderate-intensity exercise and lessens the decline in ramp incremental performance after blood donation. The results from this study may have implications for improving functional capacity in conditions where normal blood O<sub>2</sub> carrying capacity is impaired. ### LOW MUSCLE GLYCOGEN IMPAIRS POST-EXERCISE P70S6K ACTIVITY DESPITE HIGH LEUCINE AVAILABILITY: THE CRITICAL GLYCOGEN HYPOTHESIS

Impey, S.G.1, Hammond, K.M.1, Shepherd, S.1, Jeromson, S.2, Hamilton, D.L.2, Close, G.L.1, Morton, J.P.1

*Liverpool John Moores, Stirling University*

**Introduction** Reduced carbohydrate (CHO) availability during training augments mitochondrial biogenesis (Bartlett, et al. 2015) and ingestion of leucine rich protein elevates (Pasiakos et al. 2011) muscle protein synthesis (MPS). We tested the hypothesis that reduced CHO but simultaneous high leucine availability enhances cell signalling responses associated with regulation of mitochondrial biogenesis and MPS. **Method** In a repeated measures crossover design, eleven males completed an exercise-nutrition protocol to modulate muscle glycogen prior to completing 45 min cycling at 50% peak power output (PPO) followed by an exercise capacity test (1-min bouts at 80% PPO interspersed with 1-min bouts at 40% PPO) in conditions of high CHO and protein availability (HIGH) or low CHO but high protein (leucine enriched) availability (LOW). Vastus lateralis biopsies were obtained pre-, post- and 3 h post-exercise to assess muscle glycogen content and activity of p70S6K, AMPK and PKB using kinase assays. Two way RM ANOVA was used to compare differences between conditions and across time. **Results** Muscle glycogen was different ( $P < 0.05$ ) pre-exercise (HIGH:  $583 \pm 158$ , LOW:  $271 \pm 84$  mmol/kg), similar post-exercise (HIGH:  $114 \pm 72$ , LOW:  $85 \pm 59$  mmol/kg) and different ( $P < 0.05$ ) 3 h post-exercise (HIGH:  $216 \pm 132$ ; LOW:  $116 \pm 60$  mmol/kg). Despite differences ( $P < 0.05$ ) in exercise capacity (HIGH:  $98 \pm 29$ , LOW:  $40 \pm 17$  min), exercise increased AMPK ( $P < 0.05$ ) at exhaustion in both groups (HIGH:  $6 \pm 4$ , LOW:  $9 \pm 5$  mU/mg). In accordance with elevated leucine availability in LOW, p70S6K activity was different ( $P < 0.05$ ) pre-exercise (HIGH:  $45 \pm 23$ , LOW:  $65 \pm 24$   $\mu$ U/mg) whilst exercise suppressed activity at exhaustion (HIGH:  $22 \pm 16$ , LOW:  $22 \pm 13$   $\mu$ U/mg). However, despite elevated leucine availability post-exercise in LOW, PKB activity was reduced ( $P < 0.05$ ) at 3h in LOW (HIGH  $49 \pm 24$ , LOW  $29 \pm 6$   $\mu$ U/mg) accordingly p70S6K activity was not restored at 3 h post-exercise (HIGH:  $53 \pm 38$ , LOW:  $28 \pm 14$   $\mu$ U/mg). **Discussion** We show for the first time that the post-exercise recovery of p70S6K activity is impaired when muscle glycogen remains low despite high leucine availability. Although reduced CHO availability augments mitochondrial adaptations, we also suggest that post-exercise glycogen stores should not remain depleted ( $< 150$  mmol/kg) to restore activity of p70S6K; we suggest there is a 'critical glycogen threshold' below which remodelling is impaired following exercise. Athletes should minimise time spent below this threshold during periods of low CHO training to augment the adaptive response to training. References Bartlett JD et al. ### OP-BN01 Neuromuscular Control

#### VISCOELASTIC CONTROL FOR HUMAN STANDING

Tomida, S.1, Tanabe, H.1,2, Hagio, S.1,2, Moritani, T.1, Kouzaki, M.1

*1: Kyoto Univ. 2: JSPS*

**Introduction** Human stable standing needs complicated control of joint torques sustainably. The viscoelasticity which is stiffness and viscosity resulted intrinsically from muscles, tendons, and ligament gives the stability and may reduce the liability of the central nervous system (CNS). The purpose of this study is to determine the multi-directional postural control based on viscoelastic ellipses. **Methods** Five subjects stood on the force platform on the disturbance machine, and maintained standing against the disturbance. The displacement, velocity and acceleration of the disturbance were 50mm, 500mm/s, and 0.6G, respectively. The directions were equally distributed in 30° increments to evenly cover the entire horizontal plane and were selected at random. During tasks ground reaction force (GRFs) and surface electromyogram (EMG) of lower limbs were recorded. The Viscoelastic ellipse was calculated from GRFs data by means of a second-order model (Tsuji et al., 1995). **Results & Discussion** The major axis of ellipses fitted in the direction of each disturbance, suggesting that humans stabilize their posture of standing by the resisting force resulted from stiffness and viscosity in response to the disturbance. To my knowledge, this is the first study examining the impedance of the lower limbs during human standing. The length of the major axis of ellipses, which represents the magnitude of the maximal stiffness and viscosity, was long in the front-back and lateral disturbance directions. This result indicates that human standing has relatively large viscoelasticity in the front-back and lateral directions. On the other hand, the major axis of ellipses was short in the diagonal disturbance directions. From a result of the analysis of EMG data, many muscles had the preferred directions in the diagonal directions as if the lowness of viscoelasticity in the diagonal directions was compensated. These results suggest that (1) the most of the total torque to need the postural control are produced by the passive torque resulting from the viscoelasticity, and (2) the postural control generated by viscoelasticity depends on the disturbance directions of bipedal posture. #### EFFECTS OF ALPINE SKIING ON PATELLAR TENDON PROPERTIES IN OLDER PATIENTS WITH TOTAL KNEE ARTHROPLASTY

Wiesinger, H.P.1, Kösters, A.1, Rieder, F.1, Müller, E.1, Seynnes, O.R.2

**Introduction** Total knee arthroplasty (TKA) is a common and efficient surgical procedure in patients with knee joint disorders. The procedure is accompanied by alterations of knee geometry (Ward et al., 2012), with under-investigated implications for the patellar tendon loading and properties despite the essential role of tendinous function in daily activities. Hence, the aim of the study was to investigate

the side-to-side difference in patellar tendon properties of TKA patients and ii) to analyse the training responsiveness of the tendon in operated (OP) and non-operated (NOP) legs. With alpine skiing, we chose a physical activity that enhance patients' health and life-style (Müller et al., 2011), while being an effective means to safely increase tendon loading (Seynnes et al., 2011). Method Thirty-one adults (70.4 ± 4.7 yrs) with unilateral TKA were recruited 2.7 ± 0.9 years after surgery and assigned to an intervention (IG) or a control group (CG). The IG underwent a 12-week supervised skiing program, while the CG did not change their daily routines. Patellar tendon stiffness, Young's modulus and CSA were measured before and after the intervention, with combined ultrasonography and dynamometry. Results In both groups, mean tendon CSA was 28% (P<.001) larger in the OP than in the NOP leg at baseline, without any difference in other tendon properties. Tendon stiffness in IG subjects was 5.8% and 15.8% larger, respectively, in the OP and NOP legs. Likewise, mean CSA increased in the IG by 2.9% in the OP and 3.8% in the NOP leg, whereas no significant changes were found for the Young's modulus. None of the tendon parameters changed in the CG. Discussion The present results suggest that patellar tendon loading patterns are altered following TKA, inducing changes in morphological and mechanical properties. Yet tendinous tissue seems to retain its adaptation capacity in these patients. Further, alpine skiing appears to offer a suitable rehabilitation strategy for TKA patients. ### EFFECTS OF DIFFERENT STRETCHING TECHNIQUES ON MUSCLE- AND TENDON PROPERTIES

Konrad, A., Tilp, M.

*Karl- Franzens- University Graz*

Introduction The three most common stretching methods are static, ballistic, and proprioceptive neuromuscular facilitation (PNF) stretching (Magnusson et al. 1996). Many studies have shown an increase in range of motion (RoM) following a stretching training for several weeks. However, it is not yet well understood if structural adaptations of the muscle-tendon-unit (MTU) could be responsible for the observed increase in RoM. Therefore, the purpose of this study was to investigate the effects of a six-week stretching training with the different stretching techniques on the MTU of the gastrocnemius medialis (GM). Furthermore, we determined if there is any difference between the effects of the most common stretching methods. We hypothesized a gain in RoM and adaptations in the MTU (e.g. more compliant tendon and/or muscle tissue) in all three stretching techniques. Moreover, we expected different functional and structural adaptations in the three stretching techniques. Methods Sixty-eight healthy male (mean ± SD; 23.4±2.6 years, 179.9±5.6cm, 77.2±7.7 kg) and 30 healthy female (mean ± SD; 22.9±3.3 years, 170.5±4.8cm, 62.5±5.7 kg) police cadets participated in the studies. They were randomly assigned to a static stretching group (n=25), a ballistic stretching group (n=24), a PNF stretching group (n=25), and a control group (n=24). Before and after the six-week intervention, the RoM, passive resistive torque, maximum voluntary contraction, and several parameters of the muscle and tendon structures (e.g. muscle stiffness, tendon stiffness, pennation angle, fascicle length) of the GM were determined with a dynamometer and ultrasound. To test the effects of the stretching interventions paired t-tests were used. Differences between the effects of the three stretching techniques were tested with MANOVAs. Results Whereas no adaptations were found in the control group, there was an increase in RoM due to static stretching from 30.9° to 36.3° (p=0.00), due to ballistic stretching from 33.8° to 37.8° (p=0.00), and due to PNF stretching from 31.1° to 33.1° (p=0.02). However, only in the PNF stretching group the increased RoM could be partly explained by decreasing active (p=0.04) and passive (p=0.01) tendon stiffness and increasing pennation angle (p=0.01). MANOVAs showed no significant different effects of the three stretching techniques. Discussion Based on the results of this study the major reason for the increase in RoM in all stretching techniques is more likely an altered perception of stretch and pain or stretch tolerance (Magnusson et al. 1996), than a structural adaptation of the MTU. ### INTERMITTENT CONTROL OF TIPTOE STANDING: POSTURAL ROBUSTNESS BASED ON JOINT VISCOELASTICITY

Tanabe, H.1,2, Fujii, K.2,3, Suzuki, Y.4, Kouzaki, M.1

*1: Kyoto University (Kyoto, Japan), 2: Japan Society for the Promotion of Science (Tokyo, Japan), 3: Nagoya University (Nagoya, Japan), 4: Osaka University (Osaka, Japan)*

Introduction Tiptoe standing is easily destabilized due to its narrow base of support, and its robust control strategies are an attractive theme for balance control training. Joint coordination of human body segments during bipedal standing has been reported to change due to factors such as aging and training. The questions of whether this plasticity is the outcome of the change in passive joint properties (that is, joint viscoelasticity), and whether the change in postural robustness is caused by changes in joint viscoelasticity or control strategies, are still unsolved and cannot be answered experimentally. Our objective is to investigate whether joint viscoelasticity and joint control strategies affect joint coordination and the robustness of the model by creating a quadruple inverted pendulum with intermittent control as a model of tiptoe standing in the sagittal plane. Methods We simulated the motion of a quadruple inverted pendulum model for four links representing metatarsophalangeal (MP)-ankle, ankle-knee, knee-hip, and head-arm-trunk segments in the sagittal plane during tiptoe standing. We set three kinds of simulation parameters: three pairs of passive viscoelasticity coefficients, three kinds of joint control strategies for each joint (continuous active control, intermittent control, and no active control), and two values of  $\alpha$  representing the switching boundary for intermittent control. We assumed that the active torques are generated by linear PD feedback controllers with a delay of 200 ms. First, we validated our model by comparing the time series of angular displacements of simulation data with those from experiments with seven female participants from our previous study. Then we investigated the pairs of simulation parameters that stabilized the inverted pendulum and the differences in postural robustness between those pairs by examining the region of active feedback gain  $P$ . Results Among 480 pairs of simulation parameters, we found that 30 pairs stabilized the quadruple inverted pendulum; the amplitude and frequency characteristic of angular displacements of these pairs were similar to those of experiment data. For all of the 30 pairs, the hip was controlled intermittently, and the MP joint was either controlled intermittently or not actively controlled. Also, the simulation parameters (viscoelasticity, utilization of the stable manifold of the system, and joint control strategy) affected joint coordination patterns and the robustness of the model. Discussion In this study, we first found the plausible joint viscoelasticity coefficients of tiptoe standing by making the fluctuation of the inverted pendulum similar to actual human body fluctuations. The robustness of our model varied depending on joint viscoelasticity, and each viscoelasticity parameter had a joint control strategy that best produced model robustness.

This suggests that there are unique optimal joint control strategies for postural robustness because passive joint properties may change due to factors such as aging and training.

### **INNOVATIVE VIDEO FEEDBACK ON JUMP-LANDING STRATEGIES IMPROVES LANDING TECHNIQUE IN MALE TEAM SPORT ATHLETES**

Dallinga, J.M.1, Benjaminse, A.1,2, Gokeler, A.1, Cortes, N.3, Otten, E.1, Lemmink, K.A.P.M.1,2

1:UMCG,RUG (Groningen, the Netherlands), 2:Hanze University Groningen (Groningen, the Netherlands), 3:GMU (Manassas, USA)

**Introduction** The use of instructions or feedback has been shown to assist in learning movement patterns, such as jump and landing technique (Makaruk et al., 2012; Wulf and Dufek, 2009). Feedback with an external focus of attention, for instance video feedback, stimulates automatic learning processes and may be beneficial in learning these tasks (Benjaminse and Otten, 2011). The purpose of this study was to evaluate the effect of video feedback on drop vertical jump (DVJ) landing strategies in team sport athletes. **Methods** Forty male and forty female athletes were randomly assigned to the video feedback (VI) or control (CTRL) group. Pretest (5 DVJ's), 2 training sessions (TR1 and TR2) including 15 DVJ's and a posttest (5 DVJ's) were conducted. In TR1 and TR2, video feedback by means of an expert overlay movement of the athlete was provided to the VI group, while the CTRL group did not receive feedback. To determine differences between time, groups and sex, repeated measures ANOVAs were conducted. Outcome variables were 3D kinematics and kinetics during pre- and posttest and percentage overlap of expert and athlete performance during TR1 and TR2. **Results** At posttest, males in the VI group showed greater hip flexion angles ( $p=0.001$ ) and greater range of motion, smaller vertical ground reaction force (vGRF) and smaller ankle dorsiflexion moment ( $p<0.001$ ) compared to pretest. At posttest, males in the VI group demonstrated smaller vGRF ( $p=0.031$ ) and smaller ankle dorsiflexion moment ( $p=0.001$ ) compared to the males in the CTRL group. The VI group increased percentage overlap during TR1 ( $p<0.001$ ,  $ES=3.32$ ), TR2 ( $p<0.001$ ,  $ES=2.48$ ) and from start of TR1 to end of TR2 ( $p<0.001$ ,  $ES=3.33$ ). **Conclusion** Video feedback with overlay method changed DVJ landing strategy favorably in males and can therefore be recommended for use in practice. This implies less time investment from medical and training staff and the athlete can pay more attention to the constantly changing environment. Although females were able to imitate the expert model, their landing biomechanics did not change significantly. Potentially females need additional verbal feedback. Further research is necessary to evaluate the effect of a combination of video and verbal feedback on jump-landing patterns in females. How the results of this study relate to ACL injury risk is topic for future studies. **References** Benjaminse A, Otten E. (2011). *Knee Surg Sports Traumatol Arthrosc*, 19(4):622-7. ### **CLASSIFICATION OF ICE HOCKEY SKILL LEVEL BASED ON PRINCIPAL MUSCLE RECRUITMENT STRATEGIES**

Buckeridge, E., von Tscharnar, V., Nigg, B.M.

*University of Calgary*

**Introduction** Ice hockey is characterized by explosive movement patterns, where players able to increase their speed at greater rates than their rivals can gain substantial performance advantages. Principal component analysis (PCA) and support vector machines (SVM) are pattern recognition methods that enable identification of movement features, and classification of skill levels (Eskofier et al., 2011). The purpose of this study was to (1) characterise principal muscle activation patterns during accelerative hockey skating, and (2) classify players' skill level based on these principal patterns. **Methods** EMG was recorded at vastus medialis (VM), vastus lateralis (VL), gluteus medius (GM), tibialis anterior (TA) and medial gastrocnemius (MG) during 30m maximum effort skating in nine elite and nine recreational hockey players. EMGs were wavelet transformed to obtain signal intensity across time and frequency space. The 2nd (acceleration) stride was extracted and muscle coordination patterns were analysed with PCA. PC scores for each group were obtained by projecting the original data onto each PC vector, and subsequently entered into a linear SVM to classify skill level. **Results** The dominant muscle activation strategy was the sequential activation of the hip and knee extensor muscles; GM, VM and VL. This was followed by contributions from MG and VM with an inverse contribution from VL. SVM classified 83% of acceleration strides correctly according to skill level ( $p<0.05$ ). Expressing PC scores in the original coordinate space revealed hip-knee extensor activity to be the dominant strategy in elite hockey skating, whereas recreational players showed greater reliance on ankle plantar flexor activity. **Discussion** Hip abductor activation, combined with rapid recruitment of the knee extensors was the primary muscle activation strategy during accelerative skating. This reflects a characteristic strategy for power production, starting with a low centre of mass, and rapidly abducting the hip and extending the knee to achieve propulsion of the centre of mass. Inverse activation of VM and VL was a secondary feature of muscle co-ordination, providing the knee with greater mechanical stability to counteract the large applied loads during explosive acceleration strides. This study saw significant classification of ice hockey skill levels based on the above principal patterns of muscle activity. Classification and functional interpretation of muscle coordination is important for athletes and coaches to understand the differences in muscle recruitment strategies across skill levels, and monitor changes that result from training. **Reference** Eskofier BM, Federolf P, Kugler, PF, Nigg BM (2011). *Comput Methods Biomech Biomed Engin*, 1-8. #### **MEASUREMENT OF VERTICAL JUMP HEIGHT WITH AN ON-SHOE 3D ACCELEROMETER SENSOR IN DIFFERENT TYPES OF ATHLETES**

Pääkkönen, J.1, Karavirta, L.2, Linnamo, V.1, Piirainen, J.M.1

1: NMRC, University of Jyväskylä (Finland), 2: Polar Electro Oy (Finland)

**Introduction** Athletes have an interest for vertical jump height and a jump test is often used as an indicator of lower body performance and explosive strength (Bosco et al., 1983). Different sensors have been used widely in sports testing over the past years and practical solutions would be useful for coaching. The purpose of this study was to investigate the validity of an on-shoe 3D accelerometer sensor in jump height evaluation in athletes' own sport. **Methods** Athletes from cycling, orienteering and basketball were studied to examine the suitability of the on-shoe 3D sensor method for different types of athletes. Subjects ( $n=29$ ) performed three squat jump (SQJ) and three

countermovement jump (CMJ) tests twice. Jump heights were assessed with a Stride Sensor Bluetooth® Smart (Polar Electro Oy, Kempele, Finland) attached to a shoe when jumping on a force plate (FP). A FP flight time method was used as reference for jump height and a FP take of velocity method was used for comparing the maximum jump results (Linthorne, 2001). Results The paired correlation between the 3D sensor and the FP flight time method was 0.97-0.99 ( $p < 0.001$ ). Jump height for SQJ ( $n=174$ ) with the sensor was  $30.4 \pm 5.6$  cm and with the FP method  $29.1 \pm 5.2$  cm. In CMJ ( $n=167$ ) the corresponding values were  $33.5 \pm 6.3$  cm and  $32.1 \pm 5.9$  cm with the sensor and FP, respectively. Single measurements showed high consistency ( $p < 0.001$ ) also with SQJ ICC: 0.95, 95% CI: 0.50-0.98 and with CMJ ICC: 0.95, 95% CI: 0.51-0.98. The correlation of the maximum jumps between the 3D sensor and the FP take of velocity methods was 0.88 ( $p < 0.001$ ). The maximum jump heights with sensor method for the basketball players was  $37.1 \pm 6.1$  cm, which was significantly higher ( $p < 0.001$ ) than the orienteers  $32.0 \pm 4.9$  cm and mountain bikers  $30.3 \pm 5.7$  cm. Discussion The 3D sensor and the FP methods correlated highly significantly in the evaluation of SQJ and CMJ height results of three different types of athletes. However, there was a small but systematic difference in jump height between the methods. The SQJ showed slightly better correlation and less variability with smaller bias of height results than CMJ. The correlation of the 3D sensor method was better with FP flight time than with take of velocity method. These results indicate that a 3D accelerometer sensor implemented on-shoe can be used for jump height evaluation and for maximum jump test. The 3D sensor method would likely offer a practical solution for jump height follow up in coaching. References Bosco, C., Luhtanen, P. & Komi, P. ### USING 3D MOTION CAPTURE TO ANALYZE ICE-HOCKEY SHOOTING TECHNIQUE ON ICE

Swarén, M.1, Soehnlein, Q.2, Holmberg, M.3, Stögl, T.4, Björklund, G.1

1: Swedish Winter Sports Research Centre, MidSweden University, Östersund, Sweden; 2: EHC Red Bull Munich, Munich, Germany; 3: Qualisys AB, Gothenburg, Sweden; 4: University of Salzburg, Aus

Introduction: Numerous studies have investigated shooting and skating technique in ice hockey. Studies performed on ice (Goktepe et al. 2010, *Sci Res Essays*) mostly have used high speed cameras to capture kinematic data while studies using 3D motion capture systems have been executed off ice by simulating real ice condition by using e.g. synthetic ice (Worobets et al. 2006, *Sport Eng*, Michaud-Paquette et al. 2011, *Sport Biomech*). Upjohn et al. (2008, *Sport Biomech*) stated that passive marker systems for motion capture have limited applications for collecting data in a field setting. Hence, the aims of the current study are to use a passive marker motion capture system to collect data of professional ice hockey players on ice in order to compare shooting techniques. Method: Two professional ice hockey players from EHC Red Bull Munich, in the top division in Germany, were recruited for the study. Both players used their own skates, gloves, helmets and sticks and wore tight fitting compression clothes. 56 reflective markers were placed on each player, including the stick, to facilitate full body analysis. Markers were also placed on the pucks for velocity measurements. Each player performed 10 slap shots and 10 on-timers, where the puck is hit directly from a pass and often used in power play. Data was collected by 20 Qualisys Uqus 7+ cameras (Qualisys AB, Gothenburg, Sweden) at 240 Hz, within a volume of  $60 \times 15 \times 2$  m. Results: Mean puck velocity for slap shots was  $36.9 \pm 1.0$  m/s for player one and  $36.0 \pm 0.9$  for player two. Larger differences were observed for the one-timers where player one had an average puck velocity of  $39.3 \pm 2.5$  m/s versus  $35.4 \pm 1.0$  for player two. The total mean puck velocity was higher for one-timers compared to slap shots ( $37.3 \pm 2.8$  vs.  $36.4 \pm 1.0$  m/s). Although one-timers had both a higher peak and mean puck acceleration than the slap shoots it was at the same time performed with a much less repeatability indicated by a larger CV for both players (34 and 14 % vs. 7 and 9 %) Discussion: In contrast to previous studies full body 3D data were successfully acquired from ice hockey players on ice by using passive markers and 20 infrared cameras. The system performed well for on ice measurements but the setup time of approximately 15 h should be taken in consideration for future studies. The collected data enables numerous possibilities to investigate different movements where puck velocity only is the first basic analysis performed with the data from the current study. Motion capture technology enables accurate 3D kinematic analysis and in the present study there were clear differences between highly skilled subjects in regard to performance and technique.

### AN ADAPTIVE, REAL-TIME STRIDE DETECTION METHOD FOR SMARTPHONES WITH UNCONSTRAINED PLACEMENT

van Oeveren, B.T., de Ruiter, C.J., Beek, P.J., Rispens, S.M., van Dieën, J.H.

MOVE Research Institute Amsterdam, VU University Amsterdam, The Netherlands

Introduction Smartphone accelerometers can be used for estimating frequency of cyclic movements. Estimation of the fundamental frequency provides basis for physical activity assessment and movement recognition and analysis. Previous studies developed methods for frequency estimates, resulting in reasonable to good results during walking and running. However, test protocols were often overly simplified; limited to a few conditions (e.g. walking only) and over small speed ranges. In addition, most often methods were designed to operate for specific sensor locations or required a priori knowledge (calibration, thresholds) in order to work. Smartphones sensors can be used to provide real-time feedback. However, one cannot assume a fixed smartphone location and orientation. In addition, acceleration patterns from left and right steps can differ greatly depending on sensor location. To overcome these limitations, we aimed to detect complete cycles, i.e. strides, in walking and running. Here, we describe a real-time method for stride detection from tri-axial accelerations of unconstrained smartphones. Methods 22 volunteers completed 12 courses (140, 200m) with walking, running, sprinting and related activities such as: stair climbing, turning, slalom, small steps and answering the phone. True Positives (TP) and False Positives (FP) were found by comparison with a second method, based on foot sensors (golden standard). The stride detection method was evaluated for 10 different sensor placements, on the trunk and limbs, among which three were smartphones (hip, arm, trouser pocket). The local ethics committee approved the study and subjects signed informed consent. Results For the smartphone placements in walking, running and sprinting, TP ranged from 93 to 100% and FP from 8 to 27%. For the remaining seven sensors, we obtained TP from 90 to 100% and FP from 4 to 30%. Including all activities and sensor locations tested, we obtained TP from 84% to 100% and FP from 5 to 48%. Discussion In this study, we included multiple walking and running related events to simulate free-living conditions. To simulate the unconstrained smartphone placement, a variety of sensor placements was used. Even with those challenges, our on-line algorithm provided accurate feedback about stride frequency. Conclusion The novel algorithm provides accurate feedback on stride frequency in walking and running related events, independent of smartphone (sensor) location/fixation on the body. These results encourage exploring the possibilities of generalizing usage of the method for other repetitive activities, such as rowing, swimming, cycling and skating. Contact B.t.van.oeveren@vu.nl

### A NOVEL METHOD TO ANALYSE INTER-TEAM COORDINATION IN SOCCER USING BIRD'S EYE VIEW VIDEO FOOTAGE

Santos, R., Berger, M., Mantovani, L., Brandão, A., Duarte, R., Teoldo, I.

*Universidade Federal de Viçosa (Brazil); Universidade de Lisboa (Portugal)*

**Introduction** The study of interpersonal coordination patterns in soccer is nowadays a trendy research topic. Previous investigations identified the importance to evaluate the number of players from each team in the different sub-areas of play as a means to capture teams' performance profiles (Vilar et al., 2013). However, there is a need to develop practical tools to quantify players' positional data from video footage, which may enhance the usability and generalization of these objective methods. Therefore, the aim of this study is to present a novel method to analyse inter-team coordination patterns in soccer from video footage. **Method** The video footage used for this procedure was obtained through a common video camera positioned on the top of a stadium, behind one of the goals. Placing the camera in this position enabled the observers to have a bird's eye view of the entire pitch, including all players involved in the match. From the location of all outfield players in each time frame, the Effective Play-Space (EP-S) is calculated through the utilization of a Matlab® convex hull computation. For this, 19 control points corresponding to some of the pitch line markings were employed to calibrate the system and obtain accurate positional data, using the 'makeform' Matlab® function. The observation procedure implies select four control points in each time frame to determine all players' positions in the field at a given instant. The EP-S was divided into seven sub-areas of play (% of the total EP-S area): Right Defensive (12.5%), Central Defensive (12.5%), Left Defensive (12.5%), Central Area (25%), Right Offensive (12.5%), Central Offensive (12.5%) and Left Offensive (12.5%). The analysis considers the distribution of players in this dynamically adaptive area of play, changing from frame to frame during the match (Vilar et al., 2013). The script generates, through a spatial transformation, a 2D reconstruction of the players' pitch coordinates, the EP-S area and the location of the players within the seven sub-areas of play. As so, we obtain automatically: i) the number of players from each team inside the different sub-areas of play in each time frame, ii) the difference between the number of players from both teams, iii) the net team numerical advantage (disadvantage in case of negative values), and; iv) the uncertainty of each team numerical advantage in each sub-area of play. This latter measure is calculated through the utilization of Shannon's entropy, H (Shannon, 1948). The mentioned outcome measures are generated by frequency and entropy histograms for different game periods the user may define. All computations are performed through Matlab® 2012b. **References** Shannon CE. (1948). *Bell Syst Tech J*, 27(1), 379-423, 623-656. Vilar L, Araújo D, Davids K, Bar-Yam Y. ### AUTOMATIC DETERMINATION OF BIOMECHANICALLY RELEVANT EVENTS IN FIGURE SKATING SINGLE JUMPS WITH UNIAXIAL ACCELERATION DATA

Schäfer, K., Bichler, S., Alt, W.

*Universität Stuttgart*

**Introduction** To improve technique in sports, precise capturing of biomechanically relevant events is essential. In figure skating, it is challenging to identify events like toe-pick (E1), release of glide leg (E2), take-off (E3) and landing (E4) in single jumps. Video-based procedures are used for this purpose as state of the art (Albert & Miller, 1996; King, Smith, Higginson, Muncasy, & Scheirman, 2004). However, accuracy and usability of these procedures are limited. Therefore the purpose of this study is to develop and validate a software algorithm to determine biomechanically relevant events in single jumps by uniaxial acceleration data. **Methods** Data sets of over 400 figure skating jumps in the six jumping techniques are available from previous research. Data sets contain uniaxial acceleration signals from both feet and time values of E1-E4 and were considered as reference. E1-E4 were defined by an experienced observer with respect to characteristic acceleration signals, validated by synchronised high speed video sequences. Different software algorithms were developed in Matlab to determine time values of E1.c-E4.c based on the input of uniaxial acceleration data. Computed time values of E1.c-E4.c are tested for agreement with E1-E4 (reference) by Bland-Altman-Plots (Bland & Altman, 1999). Accepted limits of agreement (LoA) are set to +/-2ms by practical considerations of reliable diagnostics in figure skating jumps. Results Bland-Altman-Plots were computed for all jump techniques and all events (E1-E4). Algorithms were optimized to get all jump techniques to systematic LoA < +/-2ms. Algorithms show already high reliability for E4, E1 (LoA -1,2ms; 1,9ms) and good reliability for E3 (LoA -3,4ms; 2,7ms). Further results will be presented at the conference (work in progress). **Discussion** Validity of reference time values E1-E4 in available data sets was already shown in our previous research. Automatic, objective and reliable determination of biomechanically relevant events in figure skating jumps by software algorithms enable objective live feedback about flight time and contact time during the training process on ice, which is beneficial in long term performance improvements by efficient training. **References** Albert, W. ### PREDICTION OF THE SOCCER BALL TRAJECTORY BY ITS PANEL SHAPES

Hong, S., Asai, T.

*University of Tsukuba*

**Prediction of the soccer ball trajectory by its panel shapes** **Introduction** Soccer ball panels have evolved significantly beyond the conventional in terms of their shape and design. However, there has been no study on the flow of air around soccer balls with respect to the shape, number, and orientation of their panels. Therefore, in this present study, we clarified how the panel characteristics affect the flight of a soccer ball, which enables the prediction of the trajectory. **Methods** We used wind tunnel tests and a kick-robot to examine the relationship between the panel shape and orientation of soccer balls and their aerodynamic and flight characteristics. Also, the air flow on the surface of the ball was examined using a PIV (Particle Image Velocimetry). Micro-droplet particles with diameters of 1µm were generated by an aerosol generator, and were introduced into the flow from the sirocco fan in the wind tunnel. A high repetition-rate pulsed ND:Yag laser illuminated the microdroplet particles. A high-speed camera was used to record tiff images at a sampling frequency of 1000Hz. Furthermore, we tested PIV using a cylinder to confirm the effect of the panel shapes. **Results** The position of the separation points differed according to the position of the seams and their number in the sagittal plane of the soccer ball. First, in the case when there were 2 seams with a spacing of about 80mm between them, the separation point was in a position of about 120°. In the panel type with 3 seams on the surface of the ball and the spacing between the successive seams was about 45mm, the airflow around the soccer ball re-attached in seam2 and seam3, and the separation point was about 145° having moved to the rearmost position. Further-

more, the lift force was measured while rotating the single-seam cylinder from 0° to 150°. The largest force (-14.1 N) was observed when the position of the seam was at 75°. Thus, the PIV measurements showed that the boundary separation varies depending on its orientation. Therefore, the positions of the seams on the surface of a soccer ball are considered to have a significant impact on the aerodynamic characteristics and flight trajectory. Discussion The change in the air flow on the surface of the ball, caused by the shape of the panel, has an impact on the aerodynamic characteristics and flight trajectory of the ball, which supports the findings from previous studies (Goff et al., 2014; Hong and Asai, 2014). It is believed that from these results the aerodynamic characteristics and flight trajectory of a ball could be predicted based on the shapes of the panels. Furthermore, the observed effect of the surface shapes (numbers and orientations of the panels) on the flight characteristics is beneficial for practical soccer coaching and the design of new soccer balls. #### COMPARISON OF THE RELIABILITY OF TWO ELECTRONIC CHEST PROTECTOR AND SCORING SYSTEMS IN OLYMPIC TAEKWONDO

O'Sullivan, D.M.1, Lee, Y.L.2, Fife, G.P.3

*Pusan National University*

**Introduction** In Taekwondo, the most frequent area to score points is on the chest protector (O'Sullivan et al., 2009). As taekwondo kicking is very fast and competitions have had issues with the unfairness of judging in sparring competition (Chi et al., 2004; Moon, 2003), the electronic protector and scoring system was introduced in 2010 (Ko et al, 2011). The aim of this study was to investigate the reliability of the electronic chest protector and scoring system using a mechanical system. **Methods** Two World Taekwondo Federation (WTF) recognized electronic chest gear size 1 and size 4 (same company) were selected for testing. Each of the chest gears were hung upside down and secured to a 30kg sandbag. An aluminium tube striker (weight 4.5 kg; length 500mm; diameter 80mm) mounted to a ball bearing pivot point rotating about a solid aluminium pipe which was connected to a drop weight of 100kg. Each of the electronic chest protectors were subjected to 60 impacts by the striker at various velocities, between 4.1 m/s and 8.5 m/s, which was verified by a photoelectric light sensor (Autonics, USA). The outputted variables were the striker's velocity just before impact and the electronic chest protector and scoring system score. Results The striker's velocities ranged from 4.14 to 8.42 m/s, while the electronic chest protector and scoring system registered scores from 11 to 52 (units are unknown). The Pearson's correlation coefficient R2 for the chest gear size 1 was 0.41 and for the size 4 was 0.31. **Discussion** The results show a weak (0.3 – 0.39) to moderate positive (0.4-0.69) relationship for the electronic chest protector and scoring system (Dancey and Reidy, 2004). These low correlations indicate that the scoring system may not be reliable between measurements and maybe a cause of concern when used in competition. With the expense of the electronic chest protector and scoring systems our research was limited to the data collection for only two chest protector's size 1 and 4. Future research should investigate the reliability of all the different sizes of electronic chest protectors for the companies that are currently WTF recognized. References Chi EH, Song J, Corbin G. #### DIFFERENCES IN MOTIVES FOR RUNNING AND PERCEIVED IMPORTANCE OF APP FUNCTIONALITIES BETWEEN FAST AND SLOW RUNNERS

Baart de la Faille, M., Dallinga, J.M., Vervoorn, C., Mennes, M., Bijwaard, H.

*University of Applied Science Amsterdam (Amsterdam, The Netherlands), Inholland University of Applied Sciences (Haarlem, The Netherlands), UMCG.RUG (Groningen, The Netherlands)*

**Differences in motives for running and perceived importance of app functionalities between fast and slow runners** **Introduction** Use of mobile applications (apps) is emerging in individual sports and may have the potential to stimulate physically activity (Stephens and Allan, 2013; Glyn et al., 2014). The question is which motives and app functionalities are important for less trained athletes to engage in running. The purpose was to examine differences in motives for running and perceived importance of app functionalities between fast and slow runners. **Methods** A random selection of 15,000 runners (of 54,000 participants) of a 4 and 10 EM recreational run (Dam tot Damloop) in the Netherlands was invited to participate in an online survey two days after the run. The following issues were addressed: age, gender, experience with running, time to complete distance, motives for running and importance of app functionalities. Based on their performance, runners were divided into four groups. For males and females, the fastest and slowest group were compared by using Mann-Whitney tests. Results There were 4307 respondents (28%), of which 1341 were 4 EM runners. Compared to fastest runners, the slowest males (n=32) and females (n=195) were older (45.49±11.96 y and 37.88±10.50 y respectively), more often overweight (BMI>25) (68.8% and 69.9% respectively) and performed sports less often (88.27±56.63 n/year and 85.88±58.78 n/year respectively). For slower males, losing weight was a more important motive, while for faster male runners competition was more important (p<0.05). For slower females, losing weight and status were more important reasons (p<0.05). Competition, improving own performance, relaxation and being outside were more important reasons for faster female runners (p<0.05). Faster males found monitoring speed, heart rate, progression and personal records more important functionalities (p<0.05). Also, monitoring speed was more important for faster females (p=0.005). Slower females valued training suggestions more as well as following a training schedule, suggestions for running technique, suggestions for development of training and stimulus to hold on (p<0.05). **Conclusion** Losing weight was a more important reason to participate in running for slowest runners. Additionally, slower females valued functionalities that provide information about how to train and thought a stimulus to complete a training was more important. These results can be used to develop an app for stimulating physical activity in inactive individuals. References Glynn LG, Hayes PS, Casey M, et al. (2014). *Br J Gen Pract*, 64(624):e384-91. ### INFLAMMATION RESPONSE, HEPATIC AND PANCREATIC FUNCTIONALITY DURING PROLONGED EXERCISE IN A PANCREATIC CANCER PATIENT: A CASE STUDY.

Pedrinolla, A.1, Schena, F.1, Salvagno, G.S.2, Mazzi, P.3, Caveggio, E.3, Li Volti, G.4, Galvano, F.4, Ardigò, L.P.1

1: DNMS (Verona, Italy), 2: LCBDLRS (Verona, Italy), 3: SGPDPD (Verona, Italy) 4: DBCU (Catania, Italy)

Introduction: Pancreatic adenocarcinoma (PAC) is relatively uncommon, nevertheless it has been proven to be the most unyielding of adversities (Oberstein et al, 2013). Despite of evidence about physical activity correlated with prevention and improvement of quality of life in cancer patients (Cormie et al, 2014), studies about the inflammatory response during exercise in PAC were not found. This study aimed to understand whether prolonged exercise is featured by a so high intensity to trigger a pro-inflammation response, as well as to worsen pancreatic and hepatic functionality in a pancreatic cancer patient. Methods: A controls-supported case study was performed on a 67-year-old man diagnosed with stage IV pancreatic cancer. He performed a 24-hour non-stop ultra-endurance walking (24NS) just before diagnosis (D) and during chemotherapy (D+C). During 24NS blood samples were collected every 6 hours and analyzed for interleukin-1 $\beta$  (IL-1 $\beta$ ), interleukin-1ra (IL-1ra), interleukin-6 (IL-6), interleukin-8 (IL-8), interleukin-10 (IL-10), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), monochemoattractant protein-1 (MCP-1), C-reactive protein (CRP), albumin, alanine aminotransferase (ALT), and pancreatic amylase. The patient was compared with two healthy subjects (CS). Results: No adverse events occurred during 24NS. IL-1 $\beta$  and TNF- $\alpha$  did not change in D and D+C. IL-6, IL-8, MCP-1, and CRP increased in the same way in D, D+C, and CS. IL-10 increased in D, but it did not change in D+C and CS. IL-1ra decreased in D, but increased in D+C and CS. Albumin did not change in D and D+C. ALT and pancreatic amylases did not change in D and D+C, but the former increased meanwhile the latter decreased in CS. Conclusion: Ultra-endurance non-stop walking (24NS) is associated with a change in inflammatory response in a PAC patient undergoing and not undergoing chemotherapy, as well as in healthy subjects. Consequently, we suppose ultra-endurance non-stop events are featured by an overall intensity not so high to trigger a pro-inflammatory response when the subject underwent chemotherapy. In addition, although the pancreatic and hepatic functionality of PAC patient were already compromised by the cancer, prolonged exercise does not have such a high intensity to worsen the situation. ### ELIMINATION OF TRIAMCINOLONE IN URINE FOLLOWING ORAL ADMINISTRATION OF TRIAMCINOLONE

Chen, T.T., Tseng, Y.C., Wu, Y.T., Chang-Chien, G.P., Lin, S.F., Hsu, M.C.

*Yuanpei University of Medical Technology*

Triamcinolone is often used to relieve inflammation and treat arthritis, severe allergies and asthma, but it is classified as a glucocorticoid which is banned in-competition when administered orally, intravenously, intramuscularly or rectally by World Anti-Doping Agency (WADA). The Minimum Required Performance Level (MRPL) for the detection and identification of glucocorticoids is 30 ng/mL. Purpose: The purpose of this study was to investigate the eliminated pattern of triamcinolone after administration of a single dose of triamcinolone by oral route and to resolve whether it would cause a positive result in human urine. Methods: Twelve healthy volunteers participated in this study and received a single 4 mg-dose of triamcinolone orally and urine samples were collected according to fixed time intervals for 24 hours. A liquid chromatography-tandem mass spectrometry (LC-MS/MS) method validated to quantify triamcinolone was applied to analyze the urine samples. Results: The results show that the concentrations of triamcinolone in all urine samples were much higher than 30 ng/mL after taking a single dose of triamcinolone. The peak urinary concentration (C<sub>max</sub>) of triamcinolone was 3211.4  $\pm$  860.3 ng/mL (mean  $\pm$  SD), the time to peak concentration (T<sub>max</sub>) was 1.7  $\pm$  0.9 h, the estimated elimination half-life (t<sub>1/2</sub>) was 4.4  $\pm$  2.8 hr in participants receiving a single 4 mg-dose of triamcinolone orally. About 27.76% (1.11mg) of oral dose was eliminated via urine within 24 hours after ingesting. Conclusion: After an oral administrations, the concentrations of triamcinolone in urine would exceed 30 ng/mL for more than 24 hours. This information could be useful for limiting the misuse of triamcinolone by athletes. We suggest that athletes should be aware when using triamcinolone during a competition period and must acquire approval for therapeutic use exemption prior to using it.

### OP-SH05 Psychology (Physical exercise, football performance)

#### VARIATION IN THE ABILITY TO MEET RECOVERY DEMANDS EXPLAINS SUSCEPTIBILITY TO BURNOUT IN ELITE SOCCER COACHES

Bentzen, M., Lemyre, P.N., Kenttä, G.

*Norwegian School of Sport Sciences; The Swedish School of Sport and Health Sciences*

Introduction Elite soccer coaches have inconvenient work hours and have to meet a wide range of demands (Rhind, Scott, & Fletcher, 2013). These coaches are also highly passionate and motivated about their work. Highly motivated coaches working under excessive demands are at risk for burnout when recovery is insufficient (Maslach & Leiter, 2007). The current study aims to assess how goal attainment, financial resources, quality of motivation, and workload-related variables contributes to development of burnout in elite soccer coaches during the course of a competition season. Methods A longitudinal mixed method design was used to investigate the hypotheses. Elite soccer coaches from Norway participated in the study (T1: N = 92; T2: N = 61). First, data was collected with an online survey at the start and the end of the season, assessing the burnout dimensions, perceived goal attainment, perceived workload, work home interference (WHI), recovery, and quality of motivation. Financial resources were objectively measured bases on the budget of the soccer clubs. Additionally, four head coaches were purposefully selected for follow-up interviews based on their scores on exhaustion and cynicism assessed at seasons end. Coaches with the two highest and the two lowest scores were selected. Individual profiles of the interviewed coaches were created based on their quantitative data: High-Burnout Coaches (HBC) or Low-Burnout-Coaches (LBC). Their scores on all study variables were compared to the total sample, and evaluated to be different if they were one standard deviation below or above the mean. Qualitative data was analyzed systematically based on the topics found to differentiate between the HBC and LBC profiles. Results HBC and LBC yielded no difference in regard to financial resources, goal attainment, and perceived workload although as a whole HBC offered more maladaptive motivational profiles when compared to LBC. HBC were higher in WHI and lower in recovery. Discussion From a motivational perspective, HBC were more driven by internal pressure and less by interest and fun. LBC were clearly

motivated by their genuine interest and joy for coaching. A clear difference was found between the burnout profiles when it came to WHI and recovery. HBC clearly experienced higher levels of WHI and expressed difficulties finding effective recovery strategies. The current findings highlight the importance of providing elite soccer coaches with strategies to better meet their recovery demands. References Maslach, C., & Leiter, M. P. (2007). Burnout. *Encyclopedia of stress*, 368-371. Rhind, D. J. A., Scott, M., & Fletcher, D. (2013). ### **SPORT PRACTICE, CARDIORESPIRATORY FITNESS AND VIGILANCE IN YOUNG ADULTS: AN EVENT-RELATED BRAIN POTENTIAL STUDY**

Luque-Casado, A.1, Perakakis, P.1, Guerra, P.1, Llorens, F.2, Kao, S.C.3, Hillman, C.H.3, Sanabria, D.1

(1) University of Granada, Spain. (2) Catholic University of Valencia, Spain. (3) University of Illinois at Urbana-Champaign, USA.

Introduction Luque-Casado et al. (2013) found better vigilance performance in young athletes than in non-athletes, indexed by shorter reaction times (RTs) in a 9' version of the Psychomotor Vigilance Task (PVT). This result extended previous research that has shown a positive relationship between sport practice, cardiovascular fitness and cognitive performance to the case of young adults and vigilance. Here, we used event-related potentials (ERPs) to investigate neural mechanisms related to improved vigilance performance in athletes reported in our previous study. Importantly, we used a 60' version of the PVT to investigate the time course of these group differences. Methods Two groups of participants (athletes and non-athletes) completed a 60' version of the PVT. Behavioural and ERP indices were acquired using a 64 channel ActiveTwo Biosemi system. After the experimental session, they performed an incremental exercise test in order to assess their fitness level using a Jaeger Master Screen gas analyzer and a Viasprint150P cycle-ergometer. Results The PVT results showed that athletes responded with shorter RTs than non-athletes, but only in the first part of the task. Crucially, and in keeping with the behavioural results, athletes showed greater contingent negative variation (CNV) than non-athletes mainly at the beginning of the task. Additionally, athletes maintained similar target-related P300 amplitudes throughout the task, while non-athletes showed a linear decrement. Discussion Together with our previous findings (Luque-Casado et al., 2013), these results support a positive relationship between physical exercise and cognitive performance (Hillman et al., 2008). Athletes showed improved RT performance at the beginning of the task, presumably due to their better response preparation as indexed by the larger CNV. The P300 result point to greater attentional vigilance in athletes compared to non-athletes. These results are discussed along the two most widespread hypotheses in the literature (i.e., the "cardiovascular fitness and selective improvement" and the "cognitive component skills"). ### **DISPOSITIONAL MINDFULNESS AND INHIBITORY FUNCTION AMONG ELITE MALE SOCCER PLAYERS.**

Meland, A., Kazuma, I., Høgmø, P.M., Pensgaard, A.M.

*Norwegian School of Sport Sciences*

Soccer is characterized by continuous and unpredictable change. Players are required the ability to control attention for quality observation and decision-making in ever-changing situations. The level of intrapersonal mindfulness is suggested to be a performance enhancing factor in demanding situations (Meland et al., 2015), and different facets of mindfulness have been found to be associated with either perceptual attunement or executive control mechanisms (Annicha et al., 2012). However, to our knowledge, little is known about the association between inhibitory control functions and mindfulness in high performance cohorts. Therefore, we tested 42 elite soccer players on the Sustained Attention to Response Task (SART; Robertson et al., 1997), and the Attentional Capture Task (AC; Theeuwes & Chen, 2005), and a multidimensional self-report mindfulness questionnaire (FFMQ; Baer et al., 2006). Our main findings were that players high on the observe factor of mindfulness made fewer errors on the SART and demonstrated more efficient use of relevant stimuli on the target location on the AC test. For the non-judgemental factor of mindfulness we found an opposite trend. Higher scores on the non-judgemental factor were associated with more errors on the SART and less use of relevant stimuli on the target location on the AC. The underlying mechanisms and applied implications are discussed.

### **THE BURDEN OF EXPERTISE**

Hofseth, E., Toering, T., Jordet, G., Ivarsson, A.

*Norwegian School of Sport Sciences, Halmstad University*

Evolutionary research indicates that underestimating one's capabilities maximizes individual fitness in extremely competitive conditions (Johnson & Fowler, 2011). Further, it has been reported that the top performers tend to underestimate their performance attributes in reference to their peers, which has been labeled as "the burden of expertise" (Dunning, 2005). With respect to athletes' performance, however, the general stand has been that positive self-perceptions about one's capabilities, even if they exceed one's actual capabilities, are adaptive (Bandura, 1997). This study compared youth elite players' and coaches' perceptions of players' skill level, and examined the relationship between this comparison and players' past and future record of playing international matches (N = 338, Mage = 17.8, SD = 1.1). A latent class analysis (Nylund, Asparouhov, & Muthén, 2007) was performed in order to identify subgroups within the population based on the players' and the coaches' ratings of the players' skills. The model with three classes was determined to be optimal (entropy = .76, likelihood ratio test  $p = .02$ ). The classes consisted of 77 (class 1), 90 (class 2), and 100 (class 3) participants. Participants in both class 1 and class 2 indicated higher scores on all skills in comparison to the coaches' scores. The opposite pattern was obtained among the participants in the class 3, where the coaches' scored higher than the participants on all skills. Further, while controlling for age, a multinomial regression analysis ( $X^2(6, N = 266) = 49.39, p < .01$ ) revealed that in comparison to the participants in class 3, both the participants in class 1 (OR = 0.66,  $p < .05$ , 95% CI = 0.46, 0.95) and the participants in class 2 (OR = 0.82,  $p < .05$ , 95% CI = 0.71, 0.91) had a reduced likelihood of playing international matches the next two years. Thus, the "burden" of expertise seems to be a phenomenon in youth elite soccer, predicting a high future performance level. Unrealistically positive self-perceptions concerning skills should therefore be discouraged. Consequently, coaches should provide players with feedback and experiences that gives them insight into the limitations of their skills. References Bandura, A. ### **MOTRICITY LEVEL AS AN EXPRESSION OF PRACTICING PHYSICAL EXERCISES- ARGUMENT IN PSYCHOSOCIAL ADJUSTMENT OF ADOLESCENTS**

Mosoj, A., Balint, L.

*Transilvania University of Brasov*

**Introduction:** Physical exercise as an expression of conscious motricity, oriented towards well-defined goals, can be shaped in the most natural form of an individual's adaptation to new realities of society, especially at the adolescence age, at which young people possess very few tools to support decently the expected social behavior. Our research aims to identify valences which controlled motricity may affect adolescents with integration issues - subjects with conduct problems and subjects with disabilities - by linking their level of psychomotor (investigated some of its components) with their psychosocial attitude and behavior, which they manifest and/or self-evaluate. **Methodology:** Our preliminary study was conducted on a sample of 40 students, with an average age of 14,2 and standard deviation of 1.09, divided into four groups: group 1, adolescents who practice sports every day, group 2, teenagers who do not practice sport, group 3, adolescents with conduct problems (psychiatric clinical cases) and group 4, adolescents with psychomotor disabilities. Each adolescent/group membership was involved in a test protocol, which included two ways of investigation: psychological (personality test EPQ Junior, test motivation PM – Teresa Amabile, self-perception test) and motor test (test of 15 seconds – Opto Jump). **Results:** The ANOVA procedure gave following results: teenagers with conduct disorders and adolescents that practice sports,  $F = 3.29$ ,  $df_3$ ,  $p = .033$ . There were no differences at motivational level. But there were differences in self-perception among students who do not practice sports and those who practice sports,  $F = 3.05$ ,  $df_3$ ,  $p = .043$  and differences at motor level between all four groups,  $F = 25.17$ ,  $df_3$ ,  $p = .000$ . **Discussion:** Motor development of individuals is varying by the level of daily practice of sport activities in an organized way in certain directions (Richardson et al. 2005). Very important to note is to provide information to adolescents about the dangers of not practicing sports daily (Trudeau et. Shepard, 2009). Comparing the level of physical and psychical development between these groups might help teenagers to develop education through physical exercises and among adolescents with conduct problems (Maian et al.2007) and even among those with psychomotor disabilities. **ACKNOWLEDGEMENT:** This paper is supported by the Sectoral Operational Programme Human Resources Development (SOP HRD), financed from the European Social Fund and by the Romanian Government under the Project number POSDRU / 159 / 1.5 / S / 134378 and we hereby acknowledge the structural funds project PRO-DD (POS-CCE, O.2.2.1., ID 123, SMIS 2637, ctr. #### **CHILDREN AND PARENTS' PERSPECTIVES ON INCLUSIVE PHYSICAL EDUCATION: PROBLEMATIZING SELF-DETERMINATION AND SHARED RESPONSIBILITY**

Wilhelmsen, T., Sørensen, M.

*Norwegian School of Sport Sciences*

**Introduction** Inclusion of children with disabilities in physical education (PE) as repeatedly been examined. However, majority of studies has focused on pre- and in-service teachers (Qi & Ha, 2012), while research with children and their parents have been given less attention. Based on research carried out with children with disabilities and their parents, this presentation aims to problematize current practices of inclusive PE in Norwegian elementary schools in terms of self-determination (SD) and shared responsibility. **Methods** In this study we used purposive sampling to recruit families through a governmental habilitation center. Data presented is based on semi-structured interviews and drawings with children and their parents. The data was first coded inductively with descriptive open coding, followed by deductive coding (Miles & Huberman, 1994) informed by SD theory (Deci & Ryan, 2004) and research on home-school collaboration (Bæck, 2007). The following results are based on preliminary analysis of interviews with 11 families: 6 boys, 3 girls in the age range 8-13, and 8 mothers and 4 fathers. End date for data collection is March, 2015. **Results** Preliminary analysis indicated that parents' received very limited information about PE compared to other schools subjects, which affecting their ability to contribute to their child's situation. Environmental factors such as school administrators' and teachers' attitudes, planning and opportunity for self-determined behavior in teacher-child/teacher-parents relationships were emphasized as more important facilitators or barriers for inclusion than children's degree or form of disability. **Discussion** The initial analyses indicate that children and parent's knowledge and experiences were not used to its full potential in terms of planning, preparing and organizing PE. Interestingly, children reported wanting to be self-determined, but at the same time they problematized the balance between autonomy, responsibility and dependency. Both parents' and children's accounts demonstrate the ambiguous and contextual nature of perceived appropriateness of shared responsibility and SD in the planning and implementation processes of PE. **References** Bæck, U. ## SKIING AND SCIENCE – PRACTICE, THEORY AND CO-PRODUCTION OF TRAINING KNOWLEDGE IN CROSS-COUNTRY SKIING SINCE THE 1950S

Svensson, D.

*Royal Institute of Technology KTH*

Introduction Elite endurance athletes of today use specialized, scientific training methods and the increasing role of science in sports is undeniable. This is especially true for cross-country skiing. But how and when did scientists and educated coaches gain power? Scientification of training methods in cross-country skiing accelerated in the 1950s and cross-country skiing was an early adopter, even if not all skiers were (Svensson 2013). Still, the experiential knowledge of skiers remain important. How have these different knowledge traditions merged? How has it changed training in theory and practice? Methods This paper analyzes how physiologists and skiers interacted in the transformation of training methods. Material from archives, interviews and previous research will be studied using theories of bio-power (Foucault 1998), sportification (Yttergren 2006, Guttmann 1978) and STS (Knorr-Cetina 1999, Latour 1987) Skiers from Sweden and Norway are the main examples. Results and discussion Training methods were developed through meetings between practitioners and theoreticians. Scientification of training was driven by hardening international competition. The creation of "rational" training methods was a co-production of knowledge between different knowledge traditions: the traditional, local, tacit knowledge (Polanyi 1958), of skiers and the scientific, written knowledge with universal claims that scientists stood for. The co-production of training knowledge was a matter of control over bodies. Should they be subjected to bio-power (Foucault 1998, 2001) or should they remain under the control of the practitioner? The relationship between skier and scientist resembled that of patient and doctor. Interaction between the expert on the local level (skier /patient) and the universal level (physiologist/doctor) resulted in a knowledge-base that affected both practice and theory. Rational training was in practice not built only on science but also on the individual experience of elite skiers. References Foucault, M.(1998), *The Will to Knowledge. ## TALENT DEVELOPMENT AS AN ECOLOGY OF GAMES: A CASE STUDY OF NORWEGIAN HANDBALL

Bjørndal, C.T., Ronglan, L.T.

*Norwegian School of Sports Sciences*

Introduction Structured talent identification and development (TID) is suggested as a key pillar in international sporting success (De Bosscher, De Knop, Van Bottenburg, & Shibli, 2006) and many modern elite sport systems have applied normative TID models (Bailey & Collins, 2013). However, Norwegian handball has been highly successful although representing an alternative approach, characterized by a heterarchical organizational structure with several key actors that function highly autonomous, constituting a complex web of activities that can be better understood as an ecology of games (Long, 1958). The aim of the study was twofold: (a) to describe and discuss how aims and strategies vary across and within key actors directly involved in TID, and to (b) identify the inherent organizational characteristics that influence TID processes. Methods The case study focused on TID processes within the organizational context of Norwegian handball, and included two units of analysis: (i) key actors and their characteristics and (ii) key actor's inter-communication and collaboration. Sources of data included (a) document analysis and (b) interviews with 11 key informants. Informants were strategically selected and represent experienced coaches and professionals from multiple organizational units. The main theoretical concepts were used to develop a focused code-scheme and all interviews was analysed using MAXQDA (v.11.1.5). Results The National Handball Federation (NHF) provide a broad-based model for TID were 23% and 15% of male and woman handball players participate in regional level initiatives from age 13 to 17 years, in addition to their daily practice in community-based volunteer sport clubs and sport schools. Actor's primary objectives vary (e.g. qualifying for tournaments, winning a medal, selecting players to special teams) and talent development is often a secondary consequence of team performance goals rather than the sole purpose of practice. Discussion The joint efforts from multiple actors involved in TID provide a broad range of developmental influences that can be exploited. The organizational context shapes developmental pathways towards elite sports and the broad base of TID initiatives creates multiple access points to the talent pipeline during adolescence. However, because the heterarchical structure involves many actors the unintended consequences is often related to properly managing training and competition loads, supporting the need for well-developed coordination mechanisms and good communication between key actors. ## MOVEMENT ASSESSMENT TOOLS: A CRITICAL EXAMINATION

Tidén, A., Redelius, K., Lundvall, S.

*The Swedish School of Sport and Health Sciences*

Movement Assessment Tools: A Critical Examination Introduction In contemporary society there are calls to increase young people's physical activity. In the wake of this concern we find a growing interest in studying and assessing children's and adolescents' movement abilities. Consequently, there are a number of tools developed for assessing children's movement abilities. However, many scholars have suggested that ability is far from a neutral concept and the notion of ability is often taken for granted as simply a measureable and observable capacity. The aim with this study is to critically examine assessment tools used for healthy and typically developed children. (Evans, 2004; Hay & Macdonald, 2013; Wright & Burrows, 2006). Methods The examination comprises ten tools from six different countries. In the study we pay special attention to selected movement tasks in the tools and the evaluation methods. The theoretical framework is inspired by Bourdieu's concepts of habitus and capital, (Bourdieu, 1988) which are used as analytical tools. The analysis explores and discusses what kind of movement ability the tools may construct. Results The findings show both a great variation of concepts and evaluation methods and a narrow view of what is regarded as valuable to assess. The assessment tools are strongly related to traditional sports and represent a specific form of physical capital. Rhythm and dance, for example, are never or seldom assessed, neither

movements in a broader perspective as open skills or movement tasks taking place in an outdoor environment. The examined tools and tests assess a limited number of decontextualised movements and produce a narrow view of movement ability. Discussion The study gives an overview of what kind of movements and abilities that is valued and promoted in movement assessment. Evaluation processes often promotes a child who is physically mature and benefits those who have experience of traditional sports. In other words, the assessed 'taste for sport' and the 'embodied physical capital' construct what is considered to be legitimate knowledge in relation to movement culture. Accordingly, the construction of movement ability through assessment tools could affect how children see themselves and their 'ability'. The results raises questions about how the assessments influence children's desire to move or their interest for physical activity in broader perspectives. References Bourdieu, P. (1988). ## SOCIETY GAINS FROM DAILY PHYSICAL EDUCATION

Ericsson, I.

*Malmö University*

Society Gains of Daily Physical Education The Commission for a Socially Sustainable Malmö (2013) recommends institutions to strengthen the subject of Physical Education and Health (PEH) to all pupils in Malmö schools and the Bunkeflo intervention could serve as a model. The Bunkeflo Model The Bunkeflo project – a health promoting lifestyle was launched in the south of Malmö. PEH was made a daily compulsory subject for all pupils in two schools. Motor skills observations were conducted school years 1, 2, 3, and 9 according to the Motorisk Utveckling som Grund för Inläring (MUGI) checklist. Pupils in need of extra support were given adapted motor training one hour per week. All teachers in the project were educated in the MUGI model of motor skills observing and training. Statistical analyses after nine years showed that both girls and boys improved in motor skills (balance and coordination) and their learning performance became significantly better, with eight percent more pupils being eligible for upper secondary school in the group with daily PEH (n=129) compared with a control group (n=91) (Ericsson & Karlsson, 2012). Health-economic Analysis of Daily Physical Education Health-economic analyses (Gerdtham, Ghatnekar, & Svensson, 2012) of the Bunkeflo intervention show that daily PEH in all Malmö schools would increase the potential production value by SEK 59 million (Euro approx. 6.4 million) during the 10-year period after compulsory school. The higher levels of physical activity would reduce morbidity costs by SEK 56 million (> Euro 6 million). These values exceed the SEK 16 million (Euro 1.2 million) that costs of staff and premises amount to. An investment per pupil of SEK 4,600 (Euro 500) for all nine compulsory school years would give productivity gains and reduced morbidity costs of SEK 38,000 (Euro 4,130) over the 10 years after leaving school. Conclusion The health-economic evaluation of the project shows that the investment was clearly profitable for the municipality (Gerdtham, Ghatnekar, & Svensson, 2013). ## MOVEMENT ANALYSIS OF PLAYING EXERGAMES IN PE

Meckbach, J., Gibbs, B., Almquist, J., Quennerstedt, M.

*The Swedish School of Sport and Health Sciences*

Introduction Exergames inspire participants to be physically active in order to play. Several scholars pay attention to that the games have become popular among young people and may lead to an attractive alternative for promoting a healthy, active lifestyles, not at least in school (Gao et al 2013, Ennis 2013). In Sweden, PE should offer a variety of movement activities and movement qualities. Interesting to explore is then if exergames can be seen as a teaching resource to learn different movement's qualities? Research question With a new artifact that has been introduced in PE and new policy documents emphasising development of different movement qualities, this paper aims to explore students' movement qualities when they use exergames in PE with support of Laban's movement analysis (LMA) and socio-cultural learning theory. Method The empirical data include video-recordings from three PE lessons. The games offered were of three different characters, and the recorded material for this study includes a total of 24 events of sports games, fitness games and dance games. In the study, we are inspired by the LMA framework and explore students' movement qualities on the basis of four aspects; body, - effort - space and relations. Further, with socio-cultural learning theory, recognition of artifacts, other people and the offered content of the exergames are also involved in the analysis. The learning explored is therefore about aspects where the game, the player and the social environment interact in learning of different movement qualities. Results and discussion Our findings show that exergames are creating opportunities for PE teachers and students to pay attention to different movement qualities. When comparing the three games both similarities and differences in movement qualities emerge in relation to the learning of movement qualities that occurs in the interaction between the game, the learner and the learning environment. In PE the player is accordingly involved in a complex context of movement qualities, interacting with the game and with other student. References Ennis, C. D. (2013). **EXERCISE, LEARNING AND MEMORY**

Nielsen, J.

*University of Copenhagen*

It is now firmly established that learning and memory – from learning how to ride a bike to remembering one thousand decimals of pi – rest on physical changes in the synaptic connections of the networks in the nervous system involved in the execution of the relevant functions. The activity-dependency of these plastic changes generally dictates a close relation to prior experience with execution of the specific function by the network. Recent progress in computational and experimental motor neuroscience has resulted in development of fundamental principles of how this learning proceeds in the case of acquisition of new motor skills and how specific changes in synaptic connectivity become consolidated as lasting changes (memory) in network function of the motor areas in the nervous system. Given the established network specificity of learning and memory, it has been surprising that animal experiments have repeatedly documented that exercise may facilitate learning and memory of cognitive as well as motor content (riding a bicycle may facilitate your ability to remember the thousand decimals of pi). Evidence from humans is less convincing, but still supports that exercise performed in close temporal relation to a learning session may facilitate consolidation of the learned material. The exact mechanisms responsible for these effects are still unclear, but neurotrophic factors released from active muscles and the nervous system during exercise are involved. The possibility that muscle metabolites such as lactate and/or activation of monoaminergic pathways in the nervous system play central roles, are presently explored.

**PHYSICAL EDUCATION, EXERCISE SCIENCE AND THE IDEA OF THE OBESITY CRISIS: A MEMETIC CONSIDERATION**

Tinning, R.

*University of Queensland*

The obesity crisis is a major issue that both orients and galvanizes the fields of physical education and exercise science. We can think of the obesity crisis as having a biological dimension, a psychological dimension, and a socio-cultural dimension. This presentation offers a socio-cultural approach to understanding the obesity crisis as an idea. A crisis is a characterization of the perceived severity or urgency of a particular problem, but “problems are not just ‘out there’ like objects of nature; they are socially constructed” (Lawson, 1984). Naming something as a crisis is not simply a benign public reaction to an issue or phenomenon of serious concern. It can be used as a tool for shaping/influencing particular agenda. Importantly, this is not the result of a conspiracy of scientists and politicians, but occurs instead through a complex process of the social production of knowledge. Whatever its multi-factorial causes, the idea of an obesity crisis has certainly “caught on.” But why has it caught on, and why now? In order to investigate this question, I will apply a memetic analysis that is based on the concept of a meme. A meme, a term first coined by evolutionary biologist Richard Dawkins, is claimed to be the cultural equivalent of a gene and a unit of cultural transmission.

#### **DOES A 15% DIFFERENCE IN CARBOHYDRATE INTAKE AFFECT CYCLING PERFORMANCE AND PHYSIOLOGICAL RESPONSE IN TRAINED ATHLETES?**

El-Chab, A., Simpson, C., Lightowler, H.

*Oxford Brookes University*

**Introduction** Although researchers often inform human subjects to maintain a strict diet before multi-day experiments, the typical subject is likely to vary their carbohydrate intake by 15% or more. We examined the effect of a 15% difference in the carbohydrate intake of trained cyclists on performance, nutrient oxidation during exercise, and blood biomarkers. **Methods** Ten male cyclists completed familiarisation tests and fitness evaluation. On two separate occasions, subjects completed both a prolonged cycle task to exhaustion in order to deplete muscle glycogen (day 1) followed by an endurance capacity test where subjects cycled at 70% VO<sub>2</sub>max until fatigue (day 2). These procedures were replicated in a double blind cross-over design when subjects consumed either a diet containing 4.65 g.kg BM<sup>-1</sup> of carbohydrate (Low) or an energy matched diet containing 5.35 g.kg BM<sup>-1</sup> of carbohydrate (High) between the GD test and TTE test. The two occasions were separated by at least 7-days. Blood glucose and lactate levels were measured at baseline and every 30 min while the respiratory exchange ratio (RER) was measured every 15 min till the end of the TTE test. **Results** Time to completion was not affected by High (88.4 ± 17.7 min) compared to Low (88.6 ± 15.7 min). The High diet also did not have any significant effect on blood lactate and glucose levels, and RER at any time point (except at minute 60 for RER) compared to Low diet. **Conclusion** This study suggests that a variability in carbohydrate intake by up to 15% do not have any effect on cycling performance, nutrient oxidation, blood glucose and lactate levels.

#### **EFFECT OF DIFFERENT SOLUTIONS CONSUMED DURING EXERCISE ON POST-EXERCISE APPETITE**

Sun, F.H., Si, G.Y., Shi, Y., Chen, W.P.

*Hong Kong Institute of Education*

The purpose of the present study was to investigate whether the different solutions consumed during moderate intensity exercise will affect the post-exercise ad lib food intake. Totally 12 healthy active male participants (Mean ± SD, Age: 20 ± 1 yr; Height: 176 ± 6 cm; Weight: 63.6 ± 5.3 kg; VO<sub>2</sub>max: 51.2 ± 7.1 ml/kg/min) completed three main experimental trials in a randomized cross-over design. In each main trial, participant completed one hour ergometer cycling at 60% VO<sub>2</sub>max after an overnight fast, followed by 2-hour recovery. During exercise, the participants were required to consume one of three different solutions every 15 min: water (W), carbohydrate-electrolyte solution (CE), carbohydrate-electrolyte-protein solution (CEP). The energy content was matched between the latter two solutions. After recovery period, all participants were provided with an ad lib pizza lunch, and the amount consumed for each participant was recorded. During the experimental trials, subjective appetite scores, blood glucose, body weight, and several other subjective feelings were measured. No differences were found in either pizza amount consumed (W vs. CE vs. CEP: 607 ± 128 vs. 592 ± 119 vs. 599 ± 125 g, p>0.05) or subjective appetite score before pizza consumption (W vs. CE vs. CEP: 14 ± 9 vs. 12 ± 14 vs. 14 ± 10, p>0.05) among three trials. During exercise, the blood glucose concentrations were higher in CE and CEP trials than those in W trial. In conclusion, different solutions consumed during one hour moderate intensity exercise did not affect appetite after two hours' recovery. The present study was supported by Start-up Research Grant (RG 62/2013-2014R) and Internal Research Grant (RG 64/2013-2014R), Hong Kong Institute of Education.

#### **EXOGENOUS AND ENDOGENOUS CARBOHYDRATE OXIDATION FOLLOWING INGESTION OF GLUCOSE AND FRUCTOSE DURING PROLONGED CYCLING: EFFECT OF CARBOHYDRATE DOSE**

King, A.1, O'Hara, J.1, King, R.1, Morrison, D.2, Preston, T.2

*1: Research Institute for Sport, Physical Activity and Leisure, Leeds Beckett University, UK 2: Scottish Universities Environmental Research Centre, Glasgow, UK*

**Introduction** There appears to be a dose dependent curvilinear exercise performance response to ingested carbohydrate (CHO), with an optimum of 78 g/h (Smith et al., 2013). However, the physiological mechanisms underpinning performance gains are unclear and fuel use responses to glucose and mixtures including fructose have not been investigated fully. This study investigated the effect of CHO dose on fuel selection during exercise, in particular exogenous and endogenous (liver and muscle) CHO oxidation. **Methods** Ten trained male cyclists (VO<sub>2</sub>max: 61.6 ± 7.4 ml/kg/min) cycled on 4 occasions at 77% VO<sub>2</sub>max for 2 hours after an overnight fast. From 15 min into exercise and every 15 min thereafter, either 60 g/h glucose (LG), 75 g/h glucose (HG), 90 g/h glucose/fructose (LGF; 2:1 ratio) or 112.5 g/h glucose/fructose (HGF; 2:1 ratio) was ingested in a double-blind randomised order. The formulations contained <sup>13</sup>C tracers and were designed to saturate and over saturate intestinal transporters for each hexose. Total, exogenous, endogenous (muscle and liver) CHO oxidation, and total fat oxidation were computed using indirect calorimetry and isotope ratio mass spectrometry. **Results** Total CHO oxidation was elevated, and total fat oxidation suppressed in HGF relative to all other conditions (CHO 24.9-41.8 g/h higher, Fat 7.9-11.3 g/h lower: both ES > 0.78). Exogenous oxidation was unchanged with higher dose glucose (LG = 41.2, HG = 41.4 g/h, ES = 0.02) and reduced with higher dose glucose/fructose (LGF = 67.7, HGF = 59.2 g/h ES = 0.48). Increasing CHO dose beyond intestinal saturation increased muscle glycogen utilisation for both glucose and glucose/fructose ingestion (125.1±22.6 vs. 109.9±26.9 g/h for glucose, ES=0.59; 129.5±22.6 vs. 100.3±23.1 g/h for glucose/fructose, ES=1.28). Liver glycogen oxidation was reduced with LG vs. HG (20.9±5.6 vs.

24.4±10.1 g/h; ES=0.43), but increased with HGF vs. LGF (30.5±17.7 vs. 19.3±9.4 g/h; ES=0.43). Discussion Increasing CHO ingestion rate for each hexose was not associated with higher exogenous oxidation. When the CHO dose was increased for both glucose and glucose/fructose, endogenous glycogen oxidation was increased, primarily due to an increased reliance on muscle glycogen. This with high liver glycogen and reduced fat oxidation for very high dose glucose/fructose is not ideal for exercise performance. Curvilinear Dose-Response Relationship of Carbohydrate (0-120g/h) and Performance. *Med Sci Sports Exerc* 45(2): 336-341 Contact A King; a.k.king@leedsbeckett.ac.uk

### THE EFFECTS OF A 5-DAY FASTING PERIOD ON ENDURANCE RELATED PARAMETERS IN HEALTHY ADULTS

Eibl, A.1, Limmer, M.2, Hentz, C.1, Krusche, T.1, Felker, K.1, Sonnefeld, H.1, Platen, P.1

1 RUB Bochum, 2 DSHS Cologne

Introduction: Deliberate fasting with restriction to consumption of solid food has a long worldwide tradition. It is conducted for cultural, religious, spiritual or medical reasons. It is known to reduce oxidative damage and inflammation and helps reduce obesity and some chronic diseases (Longo et al., 2014; Varady et al., 2007). However, the effects of fasting on physical performance have mainly been studied for Ramadan intermittent fasting (Chaouachi et al., 2009), whereas the body of evidence regarding effects of other forms of fasting on physical performance is still weak. The purpose of this study was to analyse the effects of a 5-day fasting period following the Buchinger regimen on performance and health related parameters. Methods: 20 healthy normal weight subjects (10 men, 10 women) aged 24.4±6.8 years, baseline BMI 23.6±1.9 kg/m<sup>2</sup>, underwent several medical and physical fitness tests before, during and shortly after the fasting period. Besides analyses of body weight and body composition, subjects performed a ramp treadmill test to determine V<sub>O</sub>2max and RQ at 60% V<sub>O</sub>2max. An incremental step test until exhaustion using the mCAFT protocol was performed (stage duration 5 minutes) to assess performance, heart rates and blood lactate concentrations. Further, a 15-second skipping test was performed to calculate maximum lactate production rate (V<sub>L</sub>max). Statistical analysis included ANOVA and paired t-test, alpha level was set at p<0.05. Results: Body weight decreased by 5.1% (2p<0.001) and body fat percentage decreased by 7.4% (2p<0.001) pre vs. post. Relative V<sub>O</sub>2max increased by 4.7% (2p<0.001) and RQ at 60% V<sub>O</sub>2max decreased from 0.89±0.05 to 0.83±0.07 (2p<0.05) pre vs. post. Time until exhaustion in the step test decreased from 27.8±2.3 min to 26.3±3.1 min (2p<0.05) during fasting, and V<sub>L</sub>max decreased from 0.68±0.15 mmol/l\*s (pre) to 0.57±0.16 mmol/l\*s in this period (2p<0.001). Discussion: After a 5-day Buchinger fasting period, relative V<sub>O</sub>2max increased due to a decline in body weight, and submaximal RQ decreased, indicating a shift in substrate oxidation from glucose towards more fatty acids. During fasting subjects exhausted earlier in the step test, indicating a negative effect of fasting on endurance performance probably due to glycogen depletion. This is in line with the decline in V<sub>L</sub>max. Altogether results indicate effects of fasting on aerobic performance resulting in impairment during and improvement after the fasting period. ### FRUCTOSE-INDUCED HYPERTRIGLYCERIDEMIA DOES NOT ENHANCE POST-EXERCISE RESYNTHESIS OF INTRAMYOCYLLULAR LIPID STORES.

Rosset, R., Lecoultre, V., Kwygart, K., Dokumaci, S., Boesch, C., Kreis, R., Schneiter, P., Tappy, L.

University of Lausanne, Lausanne, Switzerland

Introduction Resynthesis of intramyocellular lipid (IMCL) stores after exercise is stimulated by fat feeding. It remains however unknown which of blood non-esterified fatty acids (NEFA) or triglyceride-rich lipoprotein (TRL-TG) concentrations is the main precursor for IMCL. We therefore compared the effects of high fat, high fructose (HFHF) or high fat, high glucose (HFHG) diets on IMCL and glycogen resynthesis after a strenuous, IMCL depleting exercise. Methods Nine endurance-trained males were studied on two occasions in a 2-day experimental protocol. On each occasion, they performed a 2,5-h exercise at 50% of maximal aerobic power to lower their IMCL and glycogen stores on day 1, and their IMCL and glycogen concentrations in muscle vastus medialis were measured by <sup>1</sup>H-MRS 2 hours later (5 pm). Then, and during day 2, they remained at rest in a bed and were fed in randomized order two experimental diets providing 42.6% energy requirements as fat, 17.7% as protein, 5.2% as glucose and 34.8% as either fructose (HFHF) or glucose (HFHG). Net carbohydrate and lipid oxidations were measured by indirect calorimetry, and whole body glycogen synthesis was calculated as total CHO intake – net CHO oxidation. Their muscle IMCL and glycogen stores were measured again at 5 pm. Results On Day 1, IMCL (7.4 ± 1.1 vs 6.5 ± 0.9 mmol/kg ww) and muscle glycogen were similarly depleted on both occasions. On day 2, HFHF diminished average blood glucose and insulin concentrations, increased circulating TG (all p<0.01) but did not alter NEFA levels as compared to HFHG. Net carbohydrate oxidation was 50.8 ± 12.0% higher (p<0.01), and net glycogen synthesis lower with HFHF. At the end of day 2 and compared to day 1, IMCL (+40.4 ± 9.1 vs. +41.1 ± 8.7 %, p=0.96) and glycogen (+31.4 ± 6.8 vs. +38.1 ± 7.4 %, p=0.40) concentrations were significantly (p<0.01) but similarly increased in HFHF and HFHG respectively. Discussion These data indicate that ingestion of fat + fructose increases blood TRL-TG concentration, but not IMCL resynthesis compared to ingestion of fat + glucose. This suggests that IMCL synthesis is not dependent on plasma TG, glucose or insulin, but rather on circulating NEFA concentrations. Muscle glycogen resynthesis was similar with fructose and glucose, but whole body net glycogen synthesis was lower with fructose. This suggests that hepatic glycogen synthesis was lower with fructose. Contact Robin.Rosset@unil.ch

#### EFFECTS OF AN INSPIRATORY MUSCLE TRAINING VS A CONVENTIONAL EXERCISE THERAPY ON RESPIRATORY FUNCTION AND FUNCTIONAL EXERCISE CAPACITY IN COPD PATIENTS

Wright, P.R.1, Hummel, S.2

1. Chemnitz University of Technology; 2. MEDIAN Clinic Heiligendamm

Introduction According to GEDDES et al. (2008) it is important in pulmonary rehabilitation to use Inspiratory Muscle Training (IMT) in combination with other interventions. However, there is mostly evidence for the effects of IMT in a longer term outpatient setting, but not in a

hospitalised phase. This study therefore investigated if IMT in combination with conventional exercise therapy can improve respiratory function during a 3 week hospitalisation and if it has positive effects on endurance performance and on HRQL in COPD patients. Methods 44 hospitalised COPD patients (GOLD stages II-IV) were stratified according to their severity stages and allocated to an intervention group (n=21) and a comparison group (n=23). The following test were conducted at baseline and after the 3 week intervention - respiratory function test, 6-Minute-Walk-Test (6MWT), HRQL using the CRQ and a strength test (12-RM). The exercise intervention 3 times a week consisted of strength training, endurance training, breathing therapy and ball games. The intervention group completed additionally an IMT five times a week using the RespiFit S device. Results This study found a significant improvement in respiratory function in the intervention group (IMT) in FEV1. The respiratory strength also increased as expected significantly in the IMT group ( $p < 0.01$ ). Similar results were found in the same group regarding the respiratory strength and respiratory minute volume ( $p < 0.01$ ). The overall cohort of COPD patients showed significant increases in all components of exercise ( $p \leq 0.01$ ) ranging from 11% improved endurance to 25% strength increases. In regards to clinically relevant effects in HRQL the IMT group scored significantly higher in the items mastery and emotional function compared to the comparison group. Discussion Regardless of the effects of IMT, this study confirms the effectiveness of a three week hospitalised rehabilitation programme. It can be concluded that IMT in addition to conventional exercise therapy improves FEV1 as well as inspiratory muscle strength and endurance, functional exercise capacity (6MWT) and HRQL. However, further research is needed to explore the impact that different training protocols may have on outcomes as well as different intervention times during common hospitalisation durations, i.e. 3 weeks vs. 4 vs. 5 weeks. ### COMPARISON OF THE EFFECTS OF TWO SHORT-TERM CARDIAC REHABILITATION PROGRAMS WITH AEROBIC TRAINING ON CARDIAC FITNESS INDICES AFTER CORONARY ARTERY BYPASS SURGERY

Hematfar, A.

*Islamic Azad University Broujerd Branch*

Objective Cardiac rehabilitation after coronary artery bypass surgery (CABG) is one of the well-known and effective methods in increasing physiologic function and functional capacity of patients. In this study, we compared the effects of two short-term (8-session and 24-session) cardiac rehabilitation programs accompanied by aerobic trainings on cardiac fitness indices after CABG. Methods This was a quasi-experimental study. Among the patients who presented to the Research Center of Imam Ali Heart Center in Kermanshah, 24 patients range of 45-74 years old were selected. They were randomly divided into two groups: 12 patients in 8-session group and 12 patients in 24-session group. Before rehabilitation and after echocardiography, the training tolerance test (ETT) was performed and then left ventricular ejection fraction (LVEF), diastolic function, and maximal oxygen consumption ( $VO_2$  max) using the Bruce protocol were calculated and compared between two groups. The data were analyzed by the SPSS software (version 19). Results There was no significant difference between mean LVEF ( $P = 0.8$ ) and diastolic function ( $P = 0.1$ ) before and after rehabilitation in 8-session group. However, a significant difference existed in terms of  $VO_2$  max before and after 8-session rehabilitation ( $P = 0.000$ ). There was also significant differences before and after 24-session cardiac rehabilitation in terms of mean LVEF ( $P = 0.001$ ), diastolic function ( $P = 0.01$ ), and  $VO_2$  max ( $P = 0.000$ ). However, the comparison between two groups showed that there was no significant difference in LVEF ( $p = 0.09$ ), diastolic function ( $p = 0.27$ ), there was significant in  $vo_2$  max ( $p = 0.03$ ). Conclusion The results indicated that as the duration of trainings increases, its beneficial effects will be more prominent. These effects will be more obvious as time passes on both systolic and diastolic functions. Although, 24-session group obviously showed better results in terms of in LVEF and diastolic function, there is only a significant difference in terms of  $VO_2$  max between two groups ( $p = 0.03$ ). email: lahematfar@yahoo.com

### WALKING CAPACITY IS INVERSELY ASSOCIATED TO AMBULATORY BLOOD PRESSURE IN PATIENTS WITH INTERMITTENT CLAUDICATION

Lima, A.H.R.A.1, Chehuen, M.R.1, Soares, A.H.G.2, Cucato, G.G.3, Ritti-Dias, R.M.2, Wolosker, N.3, Forjaz, C.L.M.1

1- University of São Paulo; 2- University of Pernambuco; 3- Hospital Israelita Albert Einstein

Introduction: Patients with intermittent claudication (IC) present impaired walking capacity and high levels of blood pressure (BP). Ambulatory blood pressure (BP) is known as an important cardiovascular prognostic tool. Nevertheless, to the better of our knowledge, its relationship with walking capacity in patients with IC has not been investigated. Thus, the aim of this study was to assess this relationship. Methods: In 73 patients with IC ( $63 \pm 9$  years), ambulatory BP was recorded for 24 h with measured taken every 15 min, and means of 24-hour, awake and asleep periods were calculated. Claudication onset distance (COD) and total walking distance (TWD) were obtained by a progressive treadmill test (2 mph and increments of 2% every 2 min) conducted to maximal claudication pain. Pearson correlations were calculated. Results: COD was negatively correlated with 24h ( $r = -0.41$ ;  $p < 0.01$ ), awake ( $r = -0.42$ ;  $p = 0.01$ ) and asleep ( $r = -0.37$ ;  $p = 0.01$ ) diastolic BP, while TWD was negatively correlated with 24 h ( $r = -0.23$ ;  $p < 0.05$ ) and asleep ( $r = -0.29$ ;  $p = 0.01$ ) systolic BP, as well as with 24 h ( $r = -0.27$ ;  $p < 0.02$ ), awake ( $r = -0.24$ ;  $p < 0.04$ ) and asleep ( $r = -0.33$ ;  $p < 0.01$ ) diastolic BP. Conclusion: Walking capacity is inversely associated with ambulatory BP in patients with IC, which suggest that improving walking capacity may improve cardiovascular prognostic in these patients. ### NO EFFECT OF SIX MONTHS OF TRAINING ON THE HEMODYNAMIC RESPONSE TO METABOREFLEX ACTIVATION IN MULTIPLE SCLEROSIS PATIENTS

Marongiu, E., Marcelli, M., Olla, S., Magnani, S., Loi, A., Corona, F., Tocco, F., Crisafulli, A.

*University of Cagliari*

Introduction One key symptom in patients with multiple sclerosis (MS) is exercise-related fatigue. Chronic deconditioning probably plays an important role in the genesis and progression of this phenomenon. Another important factor could be the MS-induced dysautonomia and cardiovascular dysregulation. Exercise training is a well established tool to counteract deconditioning and to improve physical capacity in MS patients (Moil 2010). However, its effect on the cardiovascular regulation in these patients is less known. The muscle metaboreflex activation is a well established tool to study the hemodynamic regulation during exercise (Crisafulli et al. 2003). We hypothesized that 6-months period of training, along with physical capacity, would also improve the hemodynamic response to the metaboreflex activation in MS patients. Methods The hemodynamic response to metaboreflex of 11 subjects with MS (5 females,  $46.8 \pm 10$  yrs, EDSS scale between 3 and 5.5) were studied by means of the post-exercise muscle ischemia at the beginning of the investigation (T0) and after 6-months (T6) period of supervised training (MSST group). Hemodynamic variables were collected by impedance cardiography. Patients'

physical capacity was also assessed by means of cardiopulmonary test (CPX). The same protocol was conducted on a control group of 11 patients with MS (CTL group, 3 females, 43.2±12.3 yrs, EDDS scale between 3 and 5.5) who did not participate in any training program. Results Training significantly affected the MSST group' physical capacity, as maximum VO<sub>2</sub> increased (+5.3±5.1 ml·kg<sup>-1</sup>·min<sup>-1</sup> at T<sub>6</sub> with respect to T<sub>0</sub>), whereas this phenomenon was not present in the CTL group. However, hemodynamic response was similar between groups at T<sub>0</sub>, and did not change at T<sub>6</sub>. Actually, stroke volume, cardiac output, systemic vascular resistance, and mean blood pressure were all unaffected by group and/or intervention. Conclusion This investigation demonstrates that supervised physical training programs can successfully enhance physical capacity in MS patients. However, this effect is unrelated to the cardiovascular regulation during exercise. Probably muscle deconditioning is the key factor in the progressive impairment of physical capacity in MS patients. ### **SPECIFIC TYPE 1 FIBRE HYPERTROPHY AND MYONUCLEAR ADDITION AFTER LOW-LOAD BLOOD FLOW RESTRICTED RESISTANCE EXERCISE IN NATIONAL LEVEL POWERLIFTERS**

Bjørnsen, T., Kirketeig, A., Wernbom, M., Paulsen, G., Samnøy, L., Bækken, L., Berntsen, S., Raastad, T.

*University of Agder*

**INTRODUCTION:** Blood flow restricted resistance exercise (BFRE) is known to induce muscle mass gains in athletes (Takarada et al. 2002). However, BFRE has not been investigated in highly trained strength athletes. The present study investigates the effects of two blocks of low-load BFRE on muscle area, myonuclear responses and strength during six weeks of periodized strength training in powerlifters. **METHODS:** Seventeen national level powerlifters (25±6 yrs (mean±SD); 15 men) volunteered for the study. They were randomly assigned to either a BFRE group (n=9) performing two blocks (wk 1 and wk 3) of five BFRE front squat sessions during the 6-week strength training period, or a control group (CON; n=8) performing normal front squats (~70% of one repetition maximum (1RM)). The BFRE protocol consisted of four sets to voluntary failure (30 s rest between sets) at 25-30% of 1RM. To restrict the blood flow, elastic knee bands were wrapped around the upper thighs to a pressure of ~120 mmHg (verified with an underlying pressure cuff in the first session). Muscle biopsies were obtained from m. vastus lateralis and analysed for muscle fibre area (MFA), fibre type and myonuclei. Cross sectional area (CSA) of m. vastus lateralis and m. rectus femoris was measured using ultrasound imaging. Strength was measured as isokinetic peak torque in knee extension at 60 deg/s. **RESULTS:** The BFRE group showed a significantly larger increase of type 1 fibre MFA (BFRE: 11.7±8.2% vs. CON: 0.1±5.3%; p=0.003) and myonuclear number (BFRE: 17.8±12.8% vs. CON: 0.4±12.9%; p=0.01). No changes were observed in type II fibre MFA or myonuclear number. CSA of m. vastus lateralis increased more in the BFRE group than in the CON group (7.7±6.5% vs. 0.5±4.3%, p=0.04) and m. rectus femoris CSA also tended to increase more in the BFRE group (BFRE: 6.8±7.5% vs. CON: 1.4±3.9%; p=0.09). Although isokinetic peak torque in knee extension did not change significantly in any of the groups, we observed a significant correlation between the changes in isokinetic peak torque, and the changes in MFA of the type 1 fibres in the BFRE group (r=0.77; p=0.014). Furthermore, the changes in isokinetic peak torque was also correlated with the mean summed CSA of m. vastus lateralis and m. rectus femoris (r=0.68; p=0.045). **DISCUSSION:** We speculate that the type 1 fibre specific hypertrophy and increase in myonuclear number were due to a greater metabolic stress in these fibres during the BFRE protocol. Indeed, Cumming et al. (2014) showed that local stress responses were more pronounced in type 1 than in type 2 fibres after low-load BFRE. In conclusion, the larger gains in muscle CSA after low-load BFRE appeared to be caused by preferential hypertrophy of the type 1 fibres. Thus, it may be that using BFRE in combination with traditional strength training can be of importance to optimizing adaptation of both fibre types in highly strength-trained individuals. ### **MUSCLE LACTATE AND H<sup>+</sup> ACCUMULATION FACILITATES EARLY RECOVERY AFTER INCREMENTAL EXERCISE TO EXHAUSTION: DEMONSTRATION IN HUMANS.**

Perez-Valera, M., Martin-Rincon, M., Morales-Alamo, D., Losa-Reyna, J., Torres-Peralta, R., Santana, A., Curtelin, D., Calbet, J.A.

*University of Las Palmas de Gran Canaria*

**Introduction** The aim of this study was to determine if task failure during whole body incremental exercise (WBIE) is caused by muscle metabolite accumulation leading to metabolic blockade or reduced availability of energy resources. We hypothesized that task failure is not primarily caused by muscle lactate and H<sup>+</sup> accumulation. **Methods** Sprint performance (10s all-out isokinetic) and muscle metabolites were measured before (control) and immediately after a WBIE in normoxia (Nx, PIO<sub>2</sub>:143 mmHg) or severe hypoxia (Hyp, PIO<sub>2</sub>:73 mmHg) in 22 physically active men (22±3 years). For the sprint test after WBIE, subjects recovered for either 10 or 60s, with open circulation or bilateral leg occlusion (OC) (300 mmHg applied instantaneously, Hokanson). Immediately after the 10 or 60s OC the cuff was released and the 10s sprint performed. NIRS was used to monitor oxygenation changes. Leg VO<sub>2</sub> was measured by the Fick method. Results Peak (W<sub>peak</sub>) power output during post-WBIE sprints was higher than the W<sub>max</sub> at the end of the WBIEs (P<0.05). Compared to the control sprints, W<sub>peak</sub> was more reduced after recovery with OC than without (P<0.05). The mean reductions in W<sub>peak</sub> without OC were: 38±9 and 22±10% (P<0.05) and 61±8 and 47±10% (P<0.05) with OC, following 10 and 60s recoveries, respectively. In the sprint after 10s recovery, W<sub>peak</sub> was lower after WBIE in Nx than Hyp. At 10s post WBIE, muscle lactate ([La]) was increased (112±29 and 106±32 mmol.kg d.w.<sup>-1</sup>, in Nx and Hyp, respectively, P<0.001) and PCr and ATP reduced (Nx vs Hyp: P>0.10). From the 10th s to the 60th s OC period, [La] increased by 29 and 26 mmol.kg d.w.<sup>-1</sup> in Nx and Hyp, respectively (P<0.01), and pH decreased by ~0.10 units (P<0.05). Exercise performance and the mean rate of anaerobic ATP resynthesis were greater during the sprint that followed 60 compared to 10s occlusions, despite the higher [La] and [H<sup>+</sup>] after 60s than 10s OC recovery (P<0.05). The mean rate of ATP turnover during the 60s OC was 0.216±0.160 mmol.kg d.w.<sup>-1</sup>·s<sup>-1</sup>, i.e., equivalent to 40% of leg VO<sub>2peak</sub> (the energy expended by the ions pumps). **Discussion and conclusions** During WBIE task failure is not due to metabolite accumulation or lack of energy resources. Compared to Hyp, a greater level of fatigue is observed at exhaustion during the WBIE in Nx. Anaerobic metabolism, despite lactate and H<sup>+</sup> accumulation, facilitates early recovery after exhaustive exercise, even in anoxia, as indicated by NIRS. However, a greater degree of recovery is achieved with O<sub>2</sub>. These experiments indicate that task failure at the end of WBIE is predominantly caused by central mechanisms both in normoxia and hypoxia. Acknowledgements MINECO Spain (DEP2009-11638).

#### IS NERVE DEGENERATION A FEATURE OF TENDINOPATHY? STUDIES ON MIDPORTION ACHILLES TENDINOPATHY AND TENNIS ELBOW

Spang, C.1, Alfredson, H.2, Forsgren, S.1

*Umea University*

**Introduction** Chronic tendinopathy with marked pain is a troublesome condition that is frequently occurring for sports-active individuals. The mechanisms behind the pain are still unclear. It is likely that the peripheral nervous system is involved but it is not clear in what way. There are frequent nerves outside tendon tissue, i.e. in the peritendinous connective tissue (Andersson et al., 2007). They can signal pain. However, are the nerves that are present subjected to changes, such as nerve degeneration, in relation to the chronic tendinopathy? **Methods** Samples from the midportion of the Achilles tendon and the nearby located plantaris tendon in individuals with midportion Achilles tendinopathy and samples from extensor muscle origin at the lateral epicondyle of the humerus in patients with tennis elbow were investigated. Immunohistochemistry and markers for innervation were applied. Much focus was devoted to the reaction patterns for the general nerve marker PGP9.5 in relation to the Schwann cell marker S-100 $\beta$ . **Results** There was a marked PGP9.5 innervation in the peritendinous connective tissue located inbetween the Achilles and plantaris tendons. To some extent there was also an innervation in the connective tissue spaces within the plantaris tendon. There was also a pronounced innervation in the connective tissue related to the extensor muscle origin of the epicondyle. Most interestingly, it was noted that parts of some of the nerve fascicles in both Achilles/plantaris and epicondyle regions lacked PGP9.5 immunoreaction. There was on the other hand an overall and homogenous S-100 $\beta$  immunoreaction. These nerve fascicles did not show a normal morphology, as evidenced via staining for morphology markers (Htx-eosin). **Discussion** The observations show that there is not only a large amount of innervation in the tendon/muscle origin regions examined but also signs favouring that nerve degeneration has occurred. This is a new aspect in relation to nerve involvement in chronic tendinopathy. It is thus possible that there is a reorganization of the innervation in chronic cases of tendinopathy that includes the occurrence of nerve degeneration. This can be a drawback for the overall function in the tendon regions, including a drawback for sport activities. **References** Andersson G, Danielson P, Alfredson H, Forsgren S. (2007). *Knee Surg Sports Traumatol Arthrosc*, 15(10), 1272-1279. Contact Christoph.spang@umu.se

#### THE EFFECTS OF SHORT-TERM LOW ENERGY AVAILABILITY ON BONE TURNOVER IN WOMEN

Papageorgiou, M., Elliott-Sale ,K.J., Greeves, J.P., Fraser, W.D., Sale, C.

*Nottingham Trent University*

A dose-response relationship between energy availability (EA) and bone turnover at a threshold of 30 kcal/kgLBM/d has been shown in sedentary women (Ihle and Loucks, 2004). Bone turnover has not been assessed in physically active women under low EAs, which might be more relevant to those achieved in practice (Thong et al., 2000). **PURPOSE:** To investigate the short-term effects of low EA through combined dietary restriction (DR) and exercise energy expenditure (EEE) on bone turnover in women. **METHODS:** Using a randomised cross-over design, 11 women (age: 26  $\pm$  5y; mean SD) completed two 9-day trials with controlled (CON) or restricted (RES) (45 or 15 kcal/kgLBM/d) EA. A 3-day lead-in period (habitual dietary intake and no exercise) was followed by a 5-day experimental protocol (Days 4-8) at one of the two EAs. Participants started Day 4 in the early follicular phase of two menstrual cycles. They ran daily on a treadmill at 70% VO<sub>2</sub>max, resulting in an EEE of 15 kcal/kgLBM/d and consumed diets providing 60 and 30 kcal/kgLBM/day in order to achieve the CON and the RES EAs. Blood samples were collected on Days 1, 3, 5, 7 and 9. Plasma or serum was analysed for bone turnover markers: CTX and PINP and regulatory markers (sclerostin, PTH, leptin, IGF-1, GLP-2, T3 and insulin). Percentage changes from baseline (BAS) were calculated and used to determine the area under the curve (AUC) for all variables during both trials (% BAS change x time (in days)). **RESULTS:** Body mass was significantly reduced in the RES trial (D4: 60.2 $\pm$ 6.2; D9: 58.6 $\pm$ 6.2 kg; p<0.001) but maintained in CON (D4: 59.9 $\pm$ 6.5; D9: 59.5 $\pm$ 6.7 kg; p=0.237). PINP was significantly lower with RES (CON:-27.0 $\pm$ 34.2; RES: -56.1 $\pm$ 29.0 % BAS change x day; p<0.05), whereas CTX approached significance (CON: 14.5 $\pm$ 71.3; RES: 82.5 $\pm$ 66.5 % BAS change x day; p=0.061). Sclerostin, leptin, T3 and insulin decreased significantly in response to low EA (p<0.05), but PTH, IGF-1 and GLP-2 did not change (p>0.05). **CONCLUSION:** Five days of 15 kcal/kgLBM/day EA through DR and EEE, decreased bone formation in women, with a trend towards increased bone resorption. The level of EA in this study has been observed in amenorrhoeic athletes who are at high risk of bone disorders. The disruption in bone turnover with short-term energy restriction may lead to a net loss of bone and, in the long-term, impaired bone health. This study supports the importance of avoiding low EA and ensuring adequate dietary intake during training in women. **References** Ihle R, Loucks AB. (2004). *J Bone Miner Res*, 19(8):1231-40. #### EXERCISE TRAINING REDUCES ACUTE PHYSIOLOGICAL SEVERITY OF MENOPAUSAL HOT FLASHES

Bailey, T.G.1,2, Cable, N.T.1,4, Aziz, N.3, Low, D.A.1, Jones, H.1

*1Liverpool John Moores University, UK 2University of the Sunshine Coast, Aus 3Liverpool Women's Hospital, UK 4ASPIRE, Doha, Qatar*

**INTRODUCTION:** Menopausal hot flashes (HFs) occur due to the reduction in oestrogen that causes thermoregulatory and vascular dysfunction. A HF consists of a feeling of intense heat, skin reddening, profuse elevations in cutaneous vasodilation (CVC), sweating and heart rate, accompanied by reduced blood pressure and brain blood flow (Lucas et al., 2013). It is the combination of these factors that define HF severity. Exercise training enhances thermoregulatory control of sweating, CVC and improves brain blood flow. It is currently unknown whether the acute physiological severity of HFs is responsive to intervention. Our aim was to examine the impact of exercise training on HF-induced thermoregulatory and (cerebro)vascular perturbations. We hypothesised that exercise training would reduce the exaggerated thermoregulatory and (cerebro)vascular changes that occur during HFs. **METHODS:** Seventeen symptomatic post-menopausal females underwent a passive heat stress (48°C water-perfused suit) to induce HFs before and after a 16-week supervised exercise training intervention (n=10, 52 $\pm$ 4y, 29 $\pm$ 6 kg/m<sup>2</sup>) or no-exercise control (n=7, 52 $\pm$ 6y, 30 $\pm$ 7 kg/m<sup>2</sup>). Sweat rate (capacitance hygrometry), CVC (laser Doppler flowmetry), blood pressure, heart rate and middle cerebral artery velocity (MCAv; transcranial Doppler) were measured during the HFs that occurred with heating. The HFs were objectively identified based upon change in chest sweat rate and divided into eight equal segments, with each segment representing 12.5% of HF duration for analysis. Females also subjectively

rated severity of HFs over a 7-day period prior to and following the intervention. Data were analysed using linear mixed models and are presented as mean (95% CI). RESULTS: Exercise training decreased HF duration by 63s (95% CI: 14, 113) compared to 17s (95% CI: -43, 66) following control (P=0.08). Exercise training reduced subjective HF severity compared to control [101 (121, 80) vs 9 (37, 20) AU] (P<0.005). During the HFs sweat rate decreased by 0.04 mg·cm<sup>2</sup>·min<sup>-1</sup> (95% CI: 0.02, 0.06; P=0.01) and 0.03 mg·cm<sup>2</sup>·min<sup>-1</sup> (95% CI: 0.02, 0.05; P=0.03) at the chest and forearm following exercise training compared to no change in control. This was accompanied by a reduction of 9 %CV<sub>Cmax</sub> (95% CI: 6, 12; P=0.01) and 7 %CV<sub>Cmax</sub> (95% CI: 4, 9; P=0.05) at the chest and forearm following exercise training compared to no change in control. MCA<sub>v</sub> was attenuated by 3.4 cm/s (95% CI, 0.7, 5.1) during a HF following exercise training compared to control [0.6 cm/s (95% CI, -0.7, 1.8) P=0.04]. CONCLUSIONS: This is the first study to demonstrate that objectively measured physiological responses that occur during HFs can be reduced with an exercise intervention. The reduction in HF severity in symptomatic menopausal females is likely mediated via improvements in thermoregulatory and systemic vascular function, altering the exaggerated responses typically observed during HFs. Lucas R et al. (2013). *Menopause*, 20, 299-304.

### URINARY CONCENTRATIONS OF SINGLE AND MULTIPLE ADMINISTRATION OF INHALED AND ORAL TERBUTALINE: INFLUENCE OF GENDER AND ETHNICITY

Molphy, J., Dickinson, J.W., Chester, N.J., Loosemore, M., Whyte, G.

*Liverpool John Moores University*

Introduction Elite athletes have a higher prevalence of Exercise-induced bronchoconstriction (EIB) than the general population. Treatment for asthma and EIB includes inhalation of short-acting β<sub>2</sub>-agonists (SABA). The World Anti-Doping Agency (WADA) has permitted the use of the SABA salbutamol for inhalation in therapeutic doses since 2010. In contrast, therapeutic doses of the inhaled SABA terbutaline still require a therapeutic use exemption. The purpose of the present study was to measure the urine concentrations of terbutaline following single and repeated doses of oral and inhaled terbutaline in Caucasian males, Caucasian females, Afro-Caribbean males and Asian males to distinguish between routes of administration and to allow for comparisons between gender and ethnicity. Methods Twenty-two male and eight female subjects (8 male & 8 female Caucasian, 6 male afro-Caribbean, 6 male Asian) were recruited for the study. All participants were free from asthma, EIB and AHR confirmed by no history of disease and a negative eucapnic voluntary hyperpnoea (EVH) challenge. Participants were assigned to one of four groups in a cross-over design: 1. Single dose of 5 mg oral terbutaline. 2. Single dose of 4 inhalations of 0.5 mg terbutaline totalling 2mg inhaled. 3. Repeated doses of 1 mg (2 x 0.5 mg inhalations) of terbutaline at 08:00h, 12:00h, 16:00h and 20:00h for 2 days. 4. Repeated doses of 5 mg oral terbutaline at 10:00h and 18:00h for 2 days. Participants were required to provide urine samples at 1h, 3h, 6h and 12h time-points post-final dose. Results The study identified upper thresholds following inhaled (1,500 ng·ml<sup>-1</sup>) and oral (2,000 ng·ml<sup>-1</sup>) administration which could be used to identify the use of supra-therapeutic doses of terbutaline. Gender differences existed (406.9±45.4 vs. 678.8±94.8 ng·ml<sup>-1</sup>; P=0.018) for male vs. female Caucasians, respectively following multiple oral administration. Ethnic differences (372.14 ± 69.7 vs. 131.8 ± 19.7 ng·ml<sup>-1</sup>; P=0.005) were identified following single inhaled administration for male Caucasians and male Asians, respectively. Discussion All trials resulted in the presence of terbutaline in urine. Upper thresholds for urinary terbutaline following inhaled and oral administration were observed along with gender differences between male and female Caucasians, and ethnic differences between male Asians and Caucasians. These upper thresholds could be useful in establishing anti-doping limits that can distinguish between routes of administration. Further investigation is warranted in order to fully elucidate these findings. Future research should examine urine concentrations following a minimum therapeutic dose of inhaled terbutaline versus oral terbutaline to provide further distinction between routes of administration.

### FOLLOWING PHYSICAL ACTIVITY RECOMMENDATIONS AND NORMAL WEIGHT ARE ASSOCIATED WITH LOW STRESS AND GOOD RECOVERY

Föhr, T.I., Pietilä, J.2, Mutikainen, S.I, Myllymäki, T.I, Kujala, U.M.1

*University of Jyväskylä*

1:JYU(Jyväskylä, Finland), 2:TUT(Tampere, Finland) Introduction Physical inactivity and work-related stress are major concerns in today's society. However, physical activity is one of the factors that protects against stress. As known, psychological stress causes sympathetic responses such as reduced heart rate variability (HRV) as for repeated bouts of exercise lead to physiological adaptations, including increased parasympathetic activity. The aim of this study was to investigate the prevalence of HRV-based stress and recovery according to the individuals' compliance with general aerobic physical activity recommendations and body mass index (BMI). Methods The participants of this cross-sectional study consisted of a sample of 9200 Finnish employees (4056 men and 5144 women; age 18-65 years; BMI 18.5-40.0 kg/m<sup>2</sup>) who participated in wellbeing assessment related to occupational health promotion. The novel methodology used to determine the prevalence of stress, recovery and physical activity was provided by Firstbeat Technologies Ltd (Jyväskylä, Finland) and is based on HRV data from beat-to-beat R-R interval recording over 1-3 workdays (Mutikainen et al., 2014; Teisala et al., 2014). Physical activity was calculated on the basis of ≥10-minute bouts and participants were divided in the following groups: inactive (0 min), low (0<150min), medium (150-300min), high (>300min), based on weekly physical activity. BMI was calculated from the self-reported weight and height. BMI groups were following: 18.5-<25 kg/m<sup>2</sup>, 25-<30 kg/m<sup>2</sup> and 30-40 kg/m<sup>2</sup>. Results Moderate physical activity at least 150min/week was adhered to by 54.5 percent of men and 33.0 percent of women. Furthermore, 32.0 percent of the men and 15.6 percent of the women were classified as highly physically active. Stress percentage during the day decreased and the magnitude of recovery reactions during sleep increased with increasing physical activity and decreasing BMI (P<0.001 for all, in both men and women). Discussion Regular physical activity is known to reduce the risk of many adverse health outcomes. Furthermore, activity exceeding the level of general recommendations is suggested to have additional health benefits. This is supported by our results which suggest that high physical activity and low BMI are associated with objectively measured low stress and high recovery. ## GLUCOSE AND HORMONE RESPONSE TO INTERMITTENT VS. CONSTANT LOAD EXERCISE IN TYPE 1 DIABETES MELLITUS USING NEW ULTRA-LONG-ACTING INSULIN

Moser, O.3, Tschakert, G.1, Mueller, A.1, Groeschl, W.1, Pieber, T.R.2, Obermayer-Pietsch, B.2, Koehler, G.2, Hofmann, P.1  
1: University of Graz (AUT), 2: Medical University of Graz (AUT), 3: University of Potsdam (GER)

Introduction Blood glucose (BG) decrease was shown to be lower in high-intensity exercise compared to moderate exercise in T1DM (Iscove and Riddell, 2011). In healthy subjects no difference in acute metabolic response between short high-intensity interval exercise (HIIE) and constant load exercise (CON) matched for mean load (Pmean) and duration could be found (Tschakert et al., 2015). The aim of this study was to investigate BG and hormone response in patients with T1DM performing HIIE and CON matched for Pmean and duration applying new ultra-long-acting insulin. Methods 7 male subjects with T1DM (24.7 ± 5.3 years, HbA1c: 7.4 (57) ± 0.6 (6.3) % (mmol.mol<sup>-1</sup>)) were adjusted to insulin Degludec (Tresiba/ Novo Nordisk, Denmark). Subjects performed a maximal incremental cycle ergometer exercise test to determine exercise intensities for subsequent CON and HIIE (Hofmann et al., 1994). Pmean was set at 5% of maximal power below (A) and above (B) the first lactate turn point (LTP1) and below the second lactate turn point LTP2 (C). Short-acting insulin reductions of 25% (A), 50% (B), and 75% (C) were applied after standardized meals according to Pmean. Adrenaline, noradrenaline, dopamine, cortisol, glucagon and IGF-1 were determined from venous blood samples. BG was obtained every 5 min and pulmonary gas-exchange variables were measured for indirect calorimetry. Continuous glucose monitoring (CGM) was used 24h pre- and post-exercise. Results were compared with paired Student's t-test or Wilcoxon signed-rank test (p<0.05). Results In HIIE, BG decrease was significantly lower compared to CON for B (1.51 ± 0.91 vs. 3.00 ± 1.54 mmol.l<sup>-1</sup>, p<0.05) and tended to be lower for A (1.27 ± 0.96 vs. 2.01 ± 1.04 mmol.l<sup>-1</sup>) and C (2.90 ± 1.35 vs. 3.42 ± 2.34 mmol.l<sup>-1</sup>). No difference was found for hormones and carbohydrate consumption. 24h post-exercise interstitial glucose was significantly less decreased in HIIE compared to CON for A, B and C. Discussion Despite the same short-acting insulin administration, matched Pmean and duration and no differences in hormonal response, BG was higher in HIIE during- and 24h after exercise compared to CON. Therefore, we suggest, short-acting insulin adaptation is also dependent on exercise mode and has to be regarded to avoid post-exercise glycemic disturbances when applying ultra-long-acting insulin Degludec. ### OP-PM03 Exercise Metabolism, Mitochondrial Function and Body composition

#### MODERATE INTENSITY EXERCISE TRAINING RAPIDLY INCREASES INSULIN STIMULATED INTESTINAL GLUCOSE UPTAKE IN SEDENTARY INDIVIDUALS.

Motiani, K.K., Savolainen, A., Eskelinen, J.J., Virtanen, K.A., Parkkola, R., Knuuti, J., Nuutila, P., Kalliokoski, K.K., Hannukainen, J.C.

University of Turku

Abstract: Recently it has been shown that insulin is a potent stimulator of glucose uptake (GU) in intestine and that intestinal insulin resistance manifests in obesity and type 2 diabetes. Exercise improves whole body glycaemia and insulin stimulated skeletal muscle GU. Thus, we aimed to study the tissue specific effects of exercise training and training intensity on insulin stimulated intestinal GU. Materials and methods: Healthy individuals (n=26, aged=48 [SD 5] yrs, BMI=26.1 [SD 2.4] kg•m<sup>-2</sup>, VO<sub>2</sub>peak=34.2 [SD 4.1] ml•kg<sup>-1</sup>•min<sup>-1</sup>) and patients with IFG/IGT/T2D (n=20, aged=49 [SD 4] yrs, BMI=30.1 [SD 2.7] kg•m<sup>-2</sup>, VO<sub>2</sub>peak=28.3 [SD 4.6] ml•kg<sup>-1</sup>•min<sup>-1</sup>) were randomized into high intensity interval training (HIT) and moderate intensity training (MIT) groups. The groups were studied before and after two weeks and six sessions of HIT (4-6x30 s all out sprints on cycle ergometer with 4 minutes of recovery) or MIT training (40-60 min cycling with ergometer at 60 % of VO<sub>2</sub>max). Insulin-stimulated intestinal GU was studied during euglycemic hyperinsulinemic clamp using positron emission tomography and 18F-FDG. Results: In healthy individuals, VO<sub>2</sub>peak and whole body insulin sensitivity improved and visceral fat decreased similarly in both groups (all p<0.05), following intervention. Training increased GU in colon and tended to increase in small intestine in MIT group, whereas opposite was observed in HIT group [GU: HIT - 2%, MIT 30% (p=0.02) and GU: HIT - 9%, MIT 10% (p=0.08), respectively]. The GU in the small intestine correlated positively with the VO<sub>2</sub>peak [Pre: r= 0.46 p=0.03; Post: r=0.45 p= 0.03] and negatively with visceral fat mass [Pre: r=-0.42 p=0.05; Post: r=-0.45 p=0.03]. The results for IFG/IGT/T2D group are under analysis and will be presented in the congress. Conclusion: This study suggests that MIT rapidly enhances insulin stimulated intestinal GU already after two weeks of training in sedentary individuals.

#### GENDER DIFFERENCES IN MITOCHONDRIAL OXIDATIVE CAPACITY AFTER WEIGHT REGAIN FOLLOWING A LIFESTYLE INTERVENTION

Jørgensen, S., Dandanell, S., Dela, F., Larsen, S., Helge, J.W.

University of Copenhagen

Introduction: The study aim to examine muscle mitochondrial oxidative capacity, in subjects who successfully maintained a weight loss following a lifestyle intervention (LI), versus subjects who regained weight. We hypothesized that those who maintained weight loss would have been more compliant to the lifestyle changes and therefore would show a higher mitochondrial oxidative capacity than those who regained weight after the LI. Methods: In a cross-sectional study, we included 59 subjects who had completed a LI of 10-14 weeks, focusing on diet and physical exercise and the average time to follow up was 4.8 ± 0.4 yrs. All had lost at least 5 % of bodyweight during the LI (11.9 ± 0.5 %). 17 females (33 ± 3 yrs.) and 10 males (39 ± 4 yrs.) had maintained the entire weight loss from the LI and were grouped as Maintainers (M). 18 females (36 ± 4 yrs.) and 14 males (39 ± 2 yrs.) had regained the entire weight loss and were grouped as Non-Maintainers (NM). A muscle biopsy was obtained from m. vastus lateralis and permeabilized before examination for maximal mitochondrial respiratory capacity (state 3 respiration) using high resolution respirometry (Oxygraph-2k, Oroboros, Innsbruck, Austria). VO<sub>2</sub>PEAK was measured by a graded cycle exercise test until exhaustion. Body composition was determined by DXA. Statistical analysis was performed by 2-way ANOVA (Sigmaplot 12) and data are presented as mean ± SEM. Results: Female M vs. female NM showed no differences in mitochondrial state 3 respiration (59.6 ± 4.3 vs. 59.6 ± 4.3 pmol/mg/sec, p=0.995) and in uncoupled respiration (70.6 ± 4.9 vs.

73 ± 4.9 pmol/mg/sec,  $p=0.725$ ). In contrast, male M showed a significantly higher state 3 respiration (68.4 ± 5.6 vs. 45.9 ± 5 pmol/mg/sec,  $p=0.004$ ) than male NM, and a higher uncoupled respiration (79 ± 6.3 vs. 58 ± 5.7 pmol/mg/sec,  $p=0.019$ ). The VO<sub>2</sub>PEAK adjusted to fat free mass (FFM) was significantly higher in M vs. NM among males (153.1 ± 13 vs. 78.7 ± 12,  $p<0.001$ ml/min/kg FFM) but not females (66 ± 11 vs. 48.7 ± 10.1,  $p=0.245$ ). Discussion: In the male group we found an expected lower VO<sub>2</sub>PEAK/FFM in NM than in M, but we did not find the same significant difference between M and NM in the female group. This might explain why the hypothesized lower oxidative capacity in muscle mitochondria is found among the NM men but not among the NM women. It seems that women, who regain weight after a LI, still manage to maintain their mitochondrial oxidative capacity whereas men do not.

### CHRONIC NON-STEROIDAL ANTI-INFLAMMATORY DRUG INGESTION BLUNTS INCREASES IN MUSCLE MITOCHONDRIAL FUNCTION DURING RESISTANCE EXERCISE TRAINING IN HUMANS

Gaffney, C.J., Mallinson, J.E., Constantin-Teodosiu, D., Greenhaff, P.L.

*University of Nottingham*

**Introduction** Non-steroidal anti-inflammatory drugs (NSAIDs) regulate the inflammatory response by inhibiting cyclooxygenase-mediated prostaglandin production. NSAIDs have been associated with the impairment of mitochondrial function in vitro (Mingatto et al., 1996) and in rodent cardiac muscle (Moreno-Sanchez et al., 1999). NSAID use by athletes is unregulated and extensive (Tscholl et al., 2008). Whether NSAIDs affect training-induced mitochondrial adaptation in human skeletal muscle is unknown and was the focus of this study. **Methods** Following local ethics approval, 16 resistance exercise-familiar males matched for strength were randomly assigned to either placebo ( $n=7$ , age 25 ± 5 yrs, ht 1.83 ± 0.04 m and mass 78.7 ± 8.4 kg) or NSAID ( $n=9$ , age 26 ± 4 yrs, ht 1.80 ± 0.03 m and mass 80.6 ± 9.7 kg) treatment groups. Volunteers consumed 75 mg slow-release diclofenac and 15 mg lansoprazole per day or placebos for 12 wk. Concomitantly, subjects completed 5 × 30 maximal concentric isokinetic knee extensions 3d/wk for 12 wk (randomly assigned leg). Vastus lateralis biopsies were taken at baseline, 4 and 12 wk for analysis of maximal ATP production rates (MAPR) and activities of electron transport chain (ETC) complexes. Data were normalised for mitochondrial protein content and were analysed using two-way ANOVA with Bonferroni post-hoc tests. **Results** There was an increase in succinate dehydrogenase (SDH; complex II) activity in placebo (mean ± SEM; 4 wk 37 ± 27 % and 12 wk 80 ± 54 %) that was blunted by NSAID administration at 4 (1.7 ± 14 %) and 12 (-16% ± 14 %) wk of training (treatment effect:  $P<0.01$ ). Moreover, there was a greater increase in succinate MAPR in placebo than NSAID treatment at 4 (252 ± 118 % vs. 48 ± 10 %,  $P<0.05$ ) and 12 wk (223 ± 78 % vs. 95 ± 35 %,  $P=0.01$ ). There was no change in the activity of complex I, I and III, II and IV or IV and no change in MAPR with substrates which deliver to complex I over 12 wk training or between treatments. **Discussion** NSAID administration specifically blunted exercise-induced increases in SDH activity and succinate mediated MAPR. This inhibitory effect therefore appears to be localised to complex II of the ETC. The relevance of these findings to muscle physiology and athletic performance warrants further investigation. **References** Mingatto FE, Santos AC, Uyemura SA, Jordani MC, Curti, C. (1996). ### MAXIMAL FAT OXIDATION DURING EXERCISE IS POSITIVELY ASSOCIATED WITH 24-HOUR FAT OXIDATION AND INSULIN SENSITIVITY IN YOUNG, HEALTHY MEN

Robinson, S.L.1, Hattersley, J.2,3, Frost, G.S.4, Chambers, E.S.4, Wallis, G.A.1

1: University of Birmingham (UK), 2: University Hospitals Coventry and Warwickshire (UK), 3: University of Warwick (UK), 4: Imperial College London (UK)

**Introduction** An elevated 24-hour (24-h) respiratory quotient (RQ; indicative of a low relative fat oxidation) has been associated with an increased risk of body mass gain (Zurlo et al., 1990) and regain of body fat mass after diet-induced weight loss (Ellis et al., 2010), while impairments in fat oxidation have been linked to metabolic disorders such as insulin resistance (Kelley & Simoneau, 1994). There is large inter-subject variability in the capacity to oxidise fat when physically active (Venables et al., 2005) although the significance of this for metabolic health is unclear. We investigated whether the maximal capacity to oxidise fat during exercise is related to 24-h fat oxidation and insulin sensitivity. **Methods** Maximal Fat Oxidation (MFO; determined from indirect calorimetry applied during incremental exercise) and insulin sensitivity (Quantitative Insulin Sensitivity Check Index) was determined in 53 healthy men (age 24±7 y; BMI 24.2±2.6 kg/m<sup>2</sup>; VO<sub>2</sub>max 52±6 ml/kg/min). 24-h Fat Oxidation (24-h FO) was assessed in 16 of these men by indirect calorimetry during a 36-h stay in a whole-room respiration chamber. **Results** MFO (g/min) was positively correlated with 24-h FO (g/d) ( $R=0.65$ ,  $P=0.003$ ;  $R=0.46$ ,  $P=0.041$ ) when controlled for VO<sub>2</sub>max (L/min), 24-h % energy from FO (%EnFO) ( $R=0.58$ ,  $P=0.009$ ) and insulin sensitivity ( $R=0.33$ ,  $P=0.007$ ). MFO (g/min) was negatively correlated with 24-h fat balance (g/d) ( $R=-0.51$ ,  $P=0.021$ ) but was not significantly correlated with 24-h RQ ( $R=-0.29$ ,  $P=0.142$ ). The findings were similar when MFO expressed relative to FFM (mg/kg FFM/min) was correlated with 24-h FO (g/kg FFM/d,  $R=0.70$ ,  $P=0.001$ ), 24-h %EnFO ( $R=0.60$ ,  $P=0.007$ ), 24-h RQ ( $R=0.31$ ,  $P=0.12$ ), and insulin sensitivity ( $R=0.39$ ,  $P=0.002$ ). **Discussion** The positive associations between MFO and 24-h fat oxidation, and MFO and insulin sensitivity, in healthy young men suggest that a high capacity to oxidise fat whilst physically active could be advantageous for the long-term maintenance of metabolic health. Future work should seek to establish if this is a causal relationship and address in a variety of subject populations the long-term implications of the apparent inter-subject variation in MFO during exercise and risk for disorders associated with disturbances in fat metabolism, such as obesity, insulin resistance and type II diabetes. **References** Ellis et al (2010). ### STATIN MYALGIC PATIENTS HAVE IMPAIRED MITOCHONDRIAL RESPIRATORY FUNCTION IN SKELETAL MUSCLE

Dohlmann, T., Helge, J.W., Dela, F., Larsen, S.

*University of Copenhagen*

**Introduction** Statins reduce endogenous cholesterol synthesis and is widely consumed to decrease the risk of cardiovascular events. However, a common side effect to statins is muscle ache and pain (myalgia), which is aggravated by exercise. Thus, statin therapy is a potential barrier to exercise. It has previously been demonstrated that statins decrease the muscle mitochondrial oxidative phosphorylation (OXPHOS) capacity (Larsen et al., 2013). However, the mechanism behind statin induced myalgia remains unclear. Thus, the aim of this study was to investigate if statin induced myalgia is coupled with impaired mitochondrial respiratory function in human skeletal muscle. We hypothesized that statin myalgic patients have impaired intrinsic mitochondrial respiratory function. **Methods** Two groups of healthy adults in continuous simvastatin treatment (40 mg/day) were recruited for this study. One group ( $n=9$ ) experienced myalgia (SM)

with a VAS score of  $4.5 \pm 0.8$ , and the other group ( $n=9$ ) without side effects (VAS  $0.4 \pm 0.3$ ) served as control (SC). The groups were matched for age, BMI, and  $VO_{2max}$  ( $61 \pm 2$  vs  $59 \pm 2$  yrs,  $30 \pm 2$  vs  $28 \pm 2$  kg/m<sup>2</sup> and  $26 \pm 2$  vs  $29 \pm 2$  ml O<sub>2</sub>/min/kg, respectively). Habitual physical activity level was determined using the International Physical Activity Questionnaire (IPAQ). Mitochondrial respiration was measured in permeabilized muscle fibers from the vastus lateralis using high-resolution respirometry. The protocols investigated maximal mitochondrial respiration with electron flow through complex (C) I, CII, CI+II simultaneously (OXPHOS capacity), and electron transport system (ETS) capacity. Results Maximal mitochondrial CII respiration, OXPHOS capacity, and ETS capacity were reduced in SM compared to SC ( $48 \pm 2$  vs  $54 \pm 2$  ( $P=0.015$ ),  $59 \pm 3$  vs  $69 \pm 5$  ( $P=0.028$ ), and  $68 \pm 3$  vs  $84 \pm 6$  ( $P<0.001$ ) pmol/mg/s, respectively). IPAQ-score was similar between groups ( $2603 \pm 758$  ( $n=8$ ) vs  $2368 \pm 606$  MET-min/week in SM and SC, respectively). In SM, the degree of myalgia (VAS) correlated with IPAQ-score ( $R=0.71$ ,  $P=0.03$ ). Discussion Interestingly, we found a coupling between myalgia and impaired mitochondrial respiratory function in skeletal muscle. Though statins are potent inhibitors of hepatic cholesterol synthesis, inhibition of the mevalonate pathway reduces synthesis of Ubiquinone (Q10) as well. Due to the lipophilic nature of simvastatin, it can easily penetrate the lipid membrane bilayers, and we speculate that accumulation of statin in muscle fibers decreases the amount of Q10, thereby impairing the intrinsic mitochondrial respiratory function, which may lead to myalgia. ## DETERMINATION OF BODY FAT AND MUSCLE MASS IN UPPER BODY ATHLETES – A COMPARISON OF METHODS

Morris, T.E., Stimpson, S.A., van Someren, K.

GlaxoSmithKline

**Introduction** Body composition is a key determinant for athletic performance, particularly where a large muscle mass is required to maximise power output and lower body fat is beneficial. Creatine (methyl-d3) dilution (D3-creatine) is a novel technique for the estimation of muscle mass in humans and has recently been reported (Clark et al, 2014). The method uses a dose of D3-creatine to determine total skeletal muscle mass via estimation of total body creatine pool size. This study is the first to apply the D3-creatine method in athletic populations; further, it compares techniques for the determination of body fat and muscle mass in well-trained upper body athletes. **Methods** Fifteen male and five female national level kayakers (stature:  $182.0 \pm 13.1$  and  $170.0 \pm 9.0$  cm; body mass:  $80.6 \pm 9.9$  and  $66.4 \pm 6.0$  kg;  $VO_{2max}$ :  $56.5 \pm 7.0$  and  $49.6 \pm 4.4$  ml•kg<sup>-1</sup>•min<sup>-1</sup> for males and females, respectively) underwent body composition assessment at the start of pre-season training. Body fat was determined using three methods: whole body Magnetic Resonance Imaging (MRI); prediction from skinfolds (Yuhasz, 1962); and air displacement plethysmography (Cosmed, BodPod). Muscle mass was determined via two methods: MRI and D3-creatine. The D3-creatine technique required participants to ingest two 30mg capsules and total urine was collected at 0-4 and 4-24 hour time periods over four days. Urine aliquots were analysed for creatine, creatinine, D3-creatine and D3-creatinine using a triple quadrupole mass spectrometer. **Results** There was a significant difference ( $F = 8.904$ ,  $P = 0.000$ ) in body fat between measures (MRI =  $16.7 \pm 3.9$  %; prediction from skinfolds =  $10.6 \pm 3.8$ %; Bodpod =  $11.9 \pm 6.3$ %), with MRI being significantly different to prediction from skinfolds ( $P = 0.001$ ) and BodPod ( $P = 0.007$ ). Muscle mass data from the D3-creatine technique and comparison to MRI data ( $36.3 \pm 6.2$  kg;  $47.4 \pm 4.3$  %) will be presented. **Discussion** The D3-creatine technique is a novel and validated method for the determination of muscle mass in humans. This study is the first to have applied the technique in an athletic population, for whom the accurate and sensitive assessment of muscle mass is critical. Muscle mass measurements from the D3-creatine technique and comparison to MRI will be discussed. Prediction of body fat from skinfolds and BodPod was significantly lower than MRI measures in well-trained upper body athletes. Further research is required to determine the sensitivity of the D3-creatine technique to changes in muscle mass in athletic populations. **References** Clark, R.V., Walker, A.C., O'Connor-Semmes, R.L., Leonard, M.S., Miller, R.R., Stimpson, S.A., Turner, S.M., Ravussin, E., Cefalu, W.T., Hellerstein, M.K., Evans, W.J., (2014). ### OP-PM61 Health & Fitness: Age III

#### TELOMERE LENGTH IS ASSOCIATED WITH MOBILITY IN OLDER WOMEN, BUT DOES NOT PREDICT MOBILITY DECLINE DURING 11 YEAR FOLLOW-UP

Sillanpää, E., Rantanen, T., Kaprio, J.2, Hovatta, I.3, Törmäkangas, T., Sipilä, S.

University of Jyväskylä

(2) Hjelt Institute, Department of Public Health, Institute for Molecular Medicine (FIMM), University of Helsinki and National Institute for Health and Welfare, Helsinki, Finland (3) Department of Biosciences, Viikki Biocenter, University of Helsinki and National Institute for Health and Welfare, Helsinki, Finland **Introduction** Biological aging can be characterized by telomere shortening, which can lead to uncapping of chromosome ends and activation of DNA damage pathways. Telomere length is associated with mortality rates (Cawthon 2003), but it is not clear how it is related to age-associated functional limitations and development of mobility disability. Our aim was to examine associations between leukocyte telomere length and mobility in older women. **Methods** 386 twin sisters (age 68.3, SD 3.2) participated in the study (Tianen 2004). Relative leukocyte telomere length was measured by qPCR at baseline. Mobility was measured by 6-min walking test and amount of leisure time physical activity (PA). 6-min walking distance was measured at baseline and after 3-year follow-up. Standardized 7-level questionnaire about participants' leisure time PA was collected at baseline and after 3- and 11-year follow-up. Baseline regression analysis was adjusted for twin-pair dependence. Longitudinal analysis was based on a path model with unstructured correlation matrix for the outcome variables and adjustment for mortality and within-pair dependence of the twin pairs. Analyses were carried out in Mplus version 7. **Results** At baseline telomere length was associated with PA (est. 0.14 SE 0.06  $p=0.011$ ), but not with walking distance (est. 5.26 SE 4.32  $p=0.223$ ). Longitudinal analysis revealed that telomere length was not associated with walking distance (est. 7.44 SE 5.08  $p=0.143$ ) or PA (est. 0.04 SE 0.04  $p=0.320$ ) over follow up time (3 and 11 years, respectively). When MZ ( $n=186$ ) and DZ ( $n=200$ ) twins were analysed separately, telomere length was associated with baseline walking distance (est. 15.47 SE 6.62  $p=0.019$ ) and PA (est. 0.26 SE 0.09  $p=0.006$ ) in MZ, but not in DZ twins. Longitudinally telomere length was also associated with overall level of walking distance (est. 17.86 SE 7.36  $p=0.015$ ) in MZ twins, and this association did not change over time (est.1.04 SE 3.65  $p=0.776$ ), while

no associations were observed in DZ twins. Conclusions Leucocyte telomere length is associated with PA level cross sectionally, but does not predict mobility decline in older females. Current findings that associations between telomere length and mobility tended to be stronger in MZ twins may suggest some genetic influences. ### EFFECTS OF A PROGRAM OF PHYSICAL ACTIVITY IN ELDERLY WOMEN

Freitas, G.

FEDERAL UNIVERSITY OF VIÇOSA

Introduction Functional capacity decreases in the elderly and generally limits their Activities of Daily Living (ADL). The objective of this study was to apply a program of physical activity in elderly women to preserve or increase their physical fitness. Methods Thirty-five physically active women over 60 years (+/- 67years) performed a systematic physical activity program(3 times/week,50 min/session). The periodization (I) was divided in 3 blocks(8-12weeks): 1st Block-cardiorespiratory function; 2nd Block-flexibility, coordination and balance; and 3rd Block-strength. We evaluated their physical capacity three times: pre-testing (T1); at the end of the 2nd (T2); and the 3rd block (T3) (VO2max-1600m walk test, BMI, Waist-hip ratio (WHR), Bank of Wells test, Sock test, Get up from the floor test, Agility/Dynamic balance, Sitting-Rising test and Abdominal strength)(I2). We verified the normality and sphericity of the data (Shapiro-Wilk and Mauchly's) and applied the ANOVA test with repeated measures ( $p < 0.05$ ) to analyze the effectiveness of the training. Since the tests related to the evaluation of strength capacity were not performed after the 2nd block, we used a paired t-test ( $p < 0.05$ ). Results No significant difference was found in the mean values of the VO2max and Bank of Wells test. A significant increase was observed in the Floor Test and Agility/Dynamic balance (after 2nd Block). After T3, we found a significant improvement in the mean values of the Sitting-Rising, Abdominal test, the Sock Test, BMI and WHR. The mean value of Floor Test and Agility/Dynamic balance significantly decreased in T3 compared to T2; however, these values were not different compared to the pre-testing values. Discussion Each year the VO2max can decrease 1% and the loss of flexibility could limit the capacity to move thus increasing the probability of injury risk(3). Our results show that these capacities were maintained such that no physical capacity was lost. Because there was an increase in the mean values of T3 and BMI, we can assert that these women may have improved their ADL(I). WHR is considered a marker for the probability of having cardiovascular diseases, the decrease of this variable is a remarkable result. Since the elderly generally have an emphasized loss of their physical capacities, our results highlight the importance of regular physical activity which is indicated to be effective for the maintenance or improvement of their capabilities for this group. ### 12 WEEKS OF FLOORBALL TRAINING LOWERS BODY FAT IN ELDERLY UNTRAINED MEN

Vorup, J.

Faculty of Science

Aging is associated with adverse changes in body composition and physical function. Loss of muscle mass and a concomitant gain in body fat may consequently increase the risk of chronic diseases. However, it may be difficult to separate the effects of "true aging" (i.e. inherent aging) and a physical inactive lifestyle. This is supported by studies showing that life-long trained elderly subjects do not decline in physical function compared to age-matched sedentary counterparts (Lazarus & Harridge, 2010). Furthermore, exercise training can reverse the physiological degeneration observed with aging (Melov et al., 2007). Typical exercise training interventions for an elderly population include aerobic activities, e.g. cycling, walking, or strength training activities. Results from recent studies suggest that small-sided football training may represent a motivating and health promoting exercise alternative (Krustrup et al., 2010). However, none of these studies have so far investigated the effect of floorball training on body composition in elderly untrained men. Thus, the aim of the present study was to investigate the effects of floorball training on body composition in elderly untrained men. Twenty untrained subjects aged 65-77 years took part in the first round of a 12-week training intervention study. Of note, the study is on-going and fifty subjects total are expected to complete the training intervention, hence, the present results are preliminary. Subjects were randomized to either a floorball group (FLO; n=10) or a control activity group playing petanque (CON; n=10). Whole body fat content and fat free mass were determined before and after the 12-week training intervention using Dual-energy X-ray Absorptiometry (DXA), and fat free mass to fat mass ratio was calculated. Data are presented as mean  $\pm$  S.E.M compared by ANOVA. Visceral fat content and physical function, i.e. maximal oxygen uptake (VO2max), time to exhaustion during incremental cycling, and 6 min maximal walking distance were also examined (results not shown in abstract). In FLO, after 12 weeks of training, whole body fat content was 8.5% lower ( $25.8 \pm 3.4$  vs.  $28.0 \pm 3.3$  kg,  $P < 0.05$ ), whereas no change was observed in CON ( $24.9 \pm 2.8$  vs.  $25.2 \pm 2.8$  kg). In FLO, fat free mass to fat mass ratio tended to be higher with a 10.1% increase ( $2.65 \pm 0.54$  vs.  $2.40 \pm 0.46$ ,  $P = 0.08$ ), with no change observed in CON ( $2.48 \pm 0.29$  vs.  $2.44 \pm 0.27$ ). No change was observed in fat free mass in either FLO ( $57.8 \pm 2.4$  vs.  $56.9 \pm 2.1$  kg) or CON ( $55.1 \pm 1.6$  vs.  $55.4 \pm 1.6$  kg). Preliminary results indicate that 12 weeks of floorball training lowers whole body fat content, leading to a more favorable body composition in elderly untrained men. The on-going intervention study will add more knowledge to whether floorball training also positively affects visceral fat content and physical function.

### EXERCISE INTERVENTION CAN CHANGE SEDENTARY BEHAVIOR TO PHYSICAL ACTIVITY IN MIDDLE TO OLDER ADULTS BASED ON OBJECTIVELY-MEASURED HOURLY ACCELERATION

Ayabe, M.1,2, Kumahara, H.2,3, Morimura, K.2, Tanaka, H.2

1: Okayama Prefectural University (Okayama, Japan), 2: Fukuoka university (Fukuoka, Japan), 3: Nakamura Gakuen University (Fukuoka, Japan)

Introduction The recent technological advances enable us to assess objectively the behavioral patterns under free-living condition. Although the accelerometer-based investigations have demonstrated the whole day habitual physical activity and sedentary behavior, the hourly patterns remains unclear. Therefore, the purpose of the present investigation was to examine the effects of 8-week exercise intervention on time spent in inactive/active time in middle to older adults based on objectively determined hourly physical activity. Methods A total of 30 adults participated in the present investigation, and were divided to exercise group and control group. The participants in the exercise group were instructed to increase the walking volume with targeting 23 METs  $\cdot$  hour/week according to the Japanese Exercise and physical activity reference for health promotion. All participants wore a pedometer with a one-axial accelerometer (Lifecorder, Kenz,

Japan) during all waking hours for 7 days, in order to determine their frequency (bouts) and duration of physical activity (min), and physical activity was divided by the intensity (Sedentary; <1.7 METs, Light; 1.7-3.0 METs, Moderate; >3METs). The bout and min of physical activity evaluated in hour-by-hour, thereafter, the sum of the hourly values was defined as the 24-hour indexes. Results The subjects in exercise group successfully improved the daily total amount of physical activity calorie expenditure, the number of steps, and the time spent in moderate to vigorous intensity physical activity ( $p < 0.05$ ). As results of the analysis in the hourly acceleration pattern, there were significant effects of exercise intervention on the time spent in sedentary behavior at 12:00 to 13:59 ( $p < 0.05$ ), similarly, the time spent in physical activity was increased at the same period ( $p < 0.05$ ). These significant changes were found in weekly days (Mon to Fri), but were not in weekend days (Sat and Sun). Discussion The exercise intervention can change the sedentary behavior to physical activity on day-time in middle to older-aged adults. The present investigation could not find the daytime transition from the sedentary behavior to the moderate to vigorous intensity physical activity. Contact ayabe@ss.oka-pu.ac.jp

### PHYSIOLOGICAL RESPONSES OF MEN IN RECREATIONAL SWIMMING AFTER A MAXIMAL SPRINT TEST - A PILOT STUDY

Lampadari, V.1, Rozi, G.1, Thanopoulos, V.1, Okicic, T.2, Dopsaj, M.3, Geru, E.4

*National & Kapodistrian University of Athens*

Introduction One of the most important health problems in modern people is the repulsion from physical activity. Previous studies in master swimmers notice that before the age of 70, there are no significant differences in blood lactate (Benelli, et al., 2007; Tanaka & Seals, 1997), but lactate levels differ between middle age men that do physical activity and men that do not (Korhonen, Suominen & Mero, 2005). The aim of the present study was to determine differences in physiological responses between two male age groups, (29-37years) and (38-51years) after a sprint test of 100m freestyle swimming. Methods The sample of the research consisted of 20 health men and it was separated in two groups: a) 29-37 years and b) 38-51 years. They participated in a recreational swimming program 3 times per week lasting 60 min. The participants were not following other physical activity program. Their job was sedentary. They swam 100m freestyle swimming with maximum intensity. Total performance time and heart rate were measured. Furthermore, velocity drop from 1st to 4th 25m was calculated. After the effort, capillary samples were taken in the 3rd, 5th and 7th minute and were analyzed with scout Lactate Germany. Results For the identification of differences between the two groups, statistical analysis ANOVA was applied. Mean performance time in 100m was  $101,09 \pm 11,5$ sec and  $111,7 \pm 18,4$ sec for the first and the second group respectively. Blood lactate was  $11,4 \pm 2,7$ mmol/L and  $12,01 \pm 2,5$ mmol/L respectively. The results showed that there are no statistical significant differences between the two groups in the measured variables. Discussion Recreational swimming seems to reserve men's physical fitness level till the age of 50. This field needs further research with more variables, different tests in both genders in order to identify the benefits on people of middle age. References 1. ### FLIPPING THE CLASSROOM IN AN UNDERGRADUATE SPORTS COACHING COURSE

Reddan, G., McNally, B., Chipperfield, J.

*Griffith University*

Introduction There are increasing concerns in higher education of the need to move away from the traditional lecture format in order to more effectively prepare students as future leaders. Research in active learning has encouraged many tertiary educators to experiment with the flipped classroom approach that has been used extensively in K-12 educational programs. This paper describes the design, implementation and outcomes of a flipped classroom approach that was put into practice in Sports Coaching, a second-year course in the Bachelor of Exercise Science. Methods In semester 1, 2014, the redesigned course was delivered to 35 students. Three essential elements were implemented to support student learning in this change to the flipped classroom approach: (a) first exposure to content prior to class, (b) student-centred in-class activities; and (c) appropriately aligned assessment. In the final weeks of the course 32 students completed a questionnaire requiring responses to statements about their perception of the course, using a Likert scale and open-ended questions. Results The students reported that they experienced more constant and positive interactions with lecturers/peers than in other courses. Overall, a high level of commitment to the course was indicated, whilst group work, discussions and practical applications were also identified as positive aspects of the course. The mean total score for the quizzes undertaken in class was significantly higher than in previous years ( $p < 0.05$ ). Compared to the traditional lecture method, the perceived contributions of courses of the 'flipped classroom' used in this course were significantly different ( $p < .002$ ) in all aspects measured. The most common suggestions for improvement included providing more time for group tasks to allow increased discussion between classmates. A significant difference ( $p < 0.05$ ) in the responses of the 12 female and 23 male students was also found. However, no significant difference was noted between those students with English as their first language and NESB students. Discussion The positive outcomes of this curriculum change suggest that the flipped classroom model warrants consideration when planning courses to maximize student learning and engagement. Evidence suggests that students generally preferred the flipped classroom approach to a traditional lecture scenario. It is hoped that this research will stimulate tertiary educators to consider teaching and learning strategies to enhance the effectiveness of the flipped classroom approach. ### OP-BN14 Coaching: Team sport II

#### DEVELOPMENT OF WORKING MEMORY TRAINING PRINCIPLES AND INTEGRATION INTO 'ONE ON ONE' FOOTBALL COACHING

Hall, J.

*University of Canterbury*

This research is an investigation on the effects of working memory training (WMT) on skill performance and psychosocial state in adult football players. Current practice in coaching allows for the pursuit of physical, technical, tactical and psychosocial outcomes in any exercise. This research is investigating how WMT will be combined with football coaching practice to produce neurological outcomes that will increase performance. WMT is used to affect working memory, which deals with the manipulation of information and the making of decisions under five seconds. A systematic literature review was performed on the field of WMT and data analysis revealed trends in effective methodology. The review found that WMT creates performance gains in both task-specific and task transfer tests. Further qualitative analysis, using a clinical methodology, identified trends that were used to form a series of training principles and pinpoint key WMT tasks required for integration into periodised training. The WMT principles identified account for task specificity, recovery, training duration and difficulty progression. The N-back and digit span forward/backward tasks have been identified as the key tasks for successful WMT, and have subsequently been organised into specific difficulty levels for the purpose of periodisation and assessment. The WMT principles have been used to theorise the future of coaching footballers in a one on one format -found in TA (Talent Acceleration) programs encouraged by national associations. The research aims to improve the benefits of coaching footballers individually outside of team training to improve performance and accelerate development.

#### COACHES' BEHAVIOR IN BASQUE TRADITIONAL ROWING

Leon Guereño, P.

*DEUSTO UNIVERSITY*

**COACHES' BEHAVIOR IN BASQUE TRADITIONAL ROWING** Introduction Traditional rowing is a type of rowing that is practiced in the sea, where the main modality is the traineras, crewed by 13 rowers and a coxswain (León Guereño, 2014). A coach's role in sport is very important, and their behaviors are related to athletes' performance and satisfaction (Chelladurai & Riemer, 1998). However, a successful leader in a certain sport does not have to be necessarily good at managing other sport organizations (Smoll & Smith, 2009), which means that each sport is considered unique. Therefore, the aim of this study was to analyse the leadership of traineras' formal coaches. Methods Sixty-six athletes and four coaches participated in this study (33% of the main league). To assess the coaches' leadership, athletes were administered the three versions of the Leadership Scale for Sports (Chelladurai & Saleh, 1980) in its Spanish adaptation (Sánchez Bañuelos, 1996). Both, rowers' preferences and perceptions about their coaches and the coaches' self-perceptions were measured at the end of the season. Results Statistically significant differences were observed between athletes' preferences and perceptions ( $p < .001$ ) in every dimension except in the "initiative margin" dimension ( $p = .827$ ). No significant differences were observed in the six dimensions between coaches' self-perception and rowers' preferences. Two factors showed significant differences between coaches' self-perception and athletes' perception: permeability to opinion ( $p < 0.05$ ) and individual attention ( $p < .001$ ). Discussion Differences found among athletes' preferences, perceptions, and coaches' self-perception are in consonance with previous studies carried out in several team sports (León Guereño, 2014; Sánchez Bañuelos, 1996), so that coaches see themselves with better behaviors than their athletes do, and therefore athletes' needs with reference to the coach are not fulfilled. Our research gathers coaches' leadership data at a certain moment of the year, and at a certain sport level but apart from that very little has been done in relation to how to improve coaches' behaviors in order to achieve excellence, consequently future studies are necessary (Riemer, 2007). #### THE PENALTY IN FOOTBALL: RELATE TO SUCCEED

Vicente, A.1,3, Fernando, C.2,3, Lopes, H.2,3

*1) UBI, Covilhã - Portugal; 2) UMA, Funchal - Portugal; 3) CIDESD, Portugal*

**INTRODUCTION** The penalty kick is an important situation in football. It is commonly accepted that this situation relies on luck. It is easy to admit that strikers need to be fast to be successful. The same goes with the goalkeeper. Some believe that being fast seems to help players to have luck. However, previous studies (e.g. Vicente et al., 2014) showed that there are time relations between players that must be taken into account in football. Players need to be aware of the opponent's actions (stimulus) and possibilities in order to take decisions and make the right choice. The aim of this study was to verify whether a correlation exists between the goalkeeper and the striker in a penalty kick situation in football comparing both players' responses to stimulus. **METHODS** We've used a software (MeSiR1.5) designed to measure the relation between the velocity of the stimulus and the time to respond to it. Test (A) had a goalkeeper (GK) that moved from the center of the goal to each side at different velocities (1 and 3 m/s) randomly. 84 university football players had to press 1 of 4 matching letters in a keyboard, opposite to the goalkeeper displacement (B or V when GK moved right; N or M when GK moved left) for two possible ball velocities (B & N - 50km/h; V & M - 100km/h) for 20 trials. The same players held a second test (B) where a striker (ST) kicked a ball from the penalty kick spot to each side of the goal at different ball velocities ( $\pm 40$ km/h and  $\pm 90$  km/h) randomly and had to press 1 of 4 matching letters according to the ball trajectory (B or V to the left corner; N or M to the right one) for two possible ball velocities perceived (B, N for 40km/h and V, M for 90km/h) for 20 trials. **RESULTS** From the 3360 trials performed from both tests, results showed that players took the right decision in 82% of the situations in A test and in 86% of the situations from test. For the fastest stimulus the average response time in A was 328 milliseconds (ms) and 393ms in B; and for slowest stimulus the time was 375ms in A and 418ms in B. Players choose the faster ball velocity in 73% of the fastest stimulus in A and in 78% of the B situations, and 76% of the times the slowest ball speed in the parallel slowest stimulus in A and 87% in B. **DISCUSSION** Data showed that the stimulus velocity influenced the response

time and the response itself. As the stimulus was faster or slower the response was also faster or slower respectively. The results tend to corroborate previous studies (Vicente et al., 2014) and other ecological studies that we are still carrying out. This suggests that in the penalty in football players should be trained to relate with the opponents being aware that they can influence their actions and their response time in order to take advantage and increase their chances of success. ### **PLYOMETRIC FOUR WEEK TRAINING BEFORE IN-SEASON TRAINING PROGRAM ON POWER PERFORMANCE IN MALE AMATEUR SOCCER PLAYERS**

Thawichai, K.

*Suranaree University of Technology*

**Introduction** In the past, research studies recently found that practicing plyometric four week training that can be used as an effective way to enhance the power performance in male amateur soccer players (Srikrew, Khaothin and Prachakul, 2014; Khaothin, 2014). The confusion about a difference in short-term plyometric training period for developing power performance before in-season training program in male amateur soccer players has led to this research study. Therefore, the objective of this study was to examine the effect of plyometric four week training on power performance before in-season training program in male amateur soccer players. **Methods** The participants were male amateur soccer players of the Faculty of Sports Science Team, Kasetsart University, Nakhon Pathom, Thailand, and in the period before participating in-season training program. All participants were randomly assignments into two groups in a plyometric training group (n=10) and a control group (n=10). Participants were tested in power performance by the squat jump and countermovement jump test before beginning participates in plyometric training. After all participants completed four weeks plyometric training period and were retested. **Results** The results of this study show that there were no significant improvements in power performance test by the squat jump and countermovement jump test between plyometric training and control groups. And there were no significant differences in the pre and post plyometric training before in-season training program in male amateur soccer players. **Discussion** From data obtained in this study not supported the past research studies found that plyometric four week training can result is sufficient enough to show improvements of power performance before in-season training program in male amateur soccer players (Srikrew, Khaothin and Prachakul, 2014; Khaothin, 2014). These two studies suggested that power performance increases by four weeks plyometric training period before in-season training program is sufficient enough for the development of muscle strength is considered to be the basic quality that influences muscular power (Schmidtbleicher, 1992). This will be developed during the first 3-4 weeks of training periods by neurological adaptations from the program (Pearson and Gordon, 2000). References Khaothin T. (2014). 5th ICSES Proceeding, 47. Pearson K, Gordon J. (2000). Principles of Neural Science, 713-736. Schmidtbleicher, (1992). Strength and Power in Sports, 169-179. Wisarut S, Khaothin T, Prachakul W. (2014). ### **KEY DRIVERS OF CUSTOMER EXPERIENCE IN THE PLAYERS OF PREMIER LEAGUE FOOTBALL CLUBS**

Khodamoradpoor, M.

*Islamic Azad University Sanandaj branch*

**Introduction:** Organizations to improve quality of service and increase competitive power by identifying the forces driving the customer experience will enable, in every time interact of customers with the organization ,to create a rewarding experience and with managing this experience will present a better product or service(Moharamzadeh, Akbari,2013). Customer experience, however, is a wide term, and encompasses both expectations to and perception of the customers. Better customer experiences will lead to better satisfaction and to an increase in loyalty (Klaus et al 2012). A good customer experience was also believed to create competitive advantage (Johnston, Kong , 2011).The aim of this study was to identify the key driving customer experience in the players of Premier League Football Clubs. **Method:** 236 football players in the Premier League clubs participated in this study as an example. The standardized questionnaire of customer experience by Sandersen and Lian (2011) was used (Sandersen, Lian, 2011). The validity of the questionnaire was confirmed by experts and the internal consistency of the questionnaire in a pilot study gain  $r = 0/88$ , factor analysis method was used to confirm of each factors. **Result:** Results revealed a total of seven operating flexibility, knowledge and personal contact, understanding customer needs, follow up, promise fulfillment and responsiveness was explained % 87/5 of total variance of customer experience. Cronbach's alpha for the seven factors gains respectively, 0.92, 0.87, 0.89, 0.86, 0.88, 0.87, and 0.85. **Conclusion:** Results showed that a good Customer Experience can be created through flexibility, knowledge and personal contact, understanding customer needs, follow up, promise fulfillment and responsiveness by club managers in football players .club managers can use of customer experience as a competitive strategy. Build a better experience for players makes feel worthy and this feel will lead to loyalty (Tsiros et al, 2006).

### **THE RELATIONSHIP BETWEEN DIFFERENT HITTING REGIONS ON A TENNIS RACQUET AND ACCURACY ON THE COURT-THE COURT**

Tan, Y., Atalag, O., Pekunlu, E., Unierzyski, P.

*Girne American University, Ege University, University School of Physical Education*

**Introduction** Contact point (CP) has been known as an important factor for making a better stroke in both forehand and backhand in tennis. However, effect of different hitting regions on the racquet has been controversial. Aim of this study is to examine the relationship between different hitting regions of a tennis racquet and hitting accuracy on the tennis court. **Methods** This is a pilot study including 10 professional level male tennis players (age:  $20.9 \pm 3.41$  years, training experience:  $9.30 \pm 2.31$  years, weekly training volume:  $8.20 \pm 1.75$  hours, height:  $1.80 \pm 0.04$  m, mass:  $75.7 \pm 5.2$  kg). A  $5.50 \times 2.05$  m area on backhand side (BHS) and forehand side (FHS) was drawn on the court for accuracy measurements. A ball machine (Spinfire Pro II®) was placed on the baseline for standardized ball delivery. Players completed a 5 set of 10 forehand shots to BHS and FHS, completing 100 forehand shots in total (50 BHS / 50 FHS). Racquet head was divided into 5 different regions for CP assessment: Region 1: middle (R1), Region 2: lower mid (R2), Region 3: mid left (R3), Region 4: upper mid (R4) and Region 5: mid right (R5). Data collection was performed with Babolat Play Pure Drive® tennis racquet. **Results** No significant difference was found in maximal racquet head speed (MRS), average racquet head speed (ARS), number of shot on target, number of shot performed in each of five different regions of racquet between shots directed to different targets ( $p > 0.05$ ). Number of shot on FHS target was negatively correlated with number of shot performed with R2 and R3 of racquet ( $p < 0.002$ ), whereas positively correlated with that in R4 ( $p < 0.001$ ). However, number of shot on BHS target was negatively correlated with only number of shot performed with R2 of racquet ( $p = 0.039$ ). In general, number of total shot on target was negatively correlated with number of shot performed with R2 and R3

( $p < 0.02$ ), whereas positively correlated with R4 ( $p = 0.03$ ) Discussion Although for many years, middle of the racquet head (R1) was taught as the sweet spot for better control, feel and produces less vibration in the joints (Carello C. et al. 1999, Haake S. 1996, Hatze H. 1994) according to the results of this study, for total shots; accuracy increased with CP on R4 but not on R1. For FHS, if CP was on R1 and R4, accuracy increased. if CP was R2 and R3, accuracy decreased. On the BHS however, accuracy decreased if only CP was on R2 and there was no positive correlation between different regions and accuracy. Although these results are preliminary, this might mean, as long as ARS stays similar, accuracy might not be affected with CP for BHS but not for FHS. ### OP-SH02 Sport Psychology and Motor/Cognitive Function

#### A THREE-WAVE CROSS LAGGED PANEL TEST OF SELF-DETERMINATION THEORY'S PSYCHOLOGICAL NEEDS-MEDIATED MODEL OF ENGAGEMENT AND DISAFFECTION IN YOUTH SPORT

Curran, T., Hill, A.P., Hall, H.K., Jowett, G.E.

*University of Bath*

Engagement in youth sport provides an important source of physical, psychological and social health for adolescents. Adopting self-determination theory (SDT), research has found support for a mediation model whereby the motivational style (viz. autonomy support and interpersonal control) of coaches predicts athletes' engagement and disaffection via the satisfaction of three psychological needs; autonomy, competence and relatedness. The current study extends this research by examining SDT's needs-mediated model longitudinally. A three-wave cross-lagged panel design was adopted in which 252 adolescent youth sports participants (Mage = 12.98; female  $n = 67$ ) completed measures at the start, middle and end of a competitive youth soccer season. Analyses revealed that the associations between the two coach motivational styles and adolescent engagement in soccer were mediated by psychological need satisfaction. In addition, there was evidence of reciprocal causation between psychological need satisfaction and engagement over time. In an important extension to extant research, this study supports the temporal assumptions underpinning SDT's needs-mediated model and evidences the dialectical interplay of psychological needs and engagement.

#### REFLECTION AND BALL CONTROL IN YOUTH BASKETBALL PLAYERS FOR DIFFERENT POSITIONS

Te Wierike, S.C.M.1, Stoter, I.K.1, Huijgen, B.C.H.1, Jonker, L.1,2, Elferink-Gemser, M.T.1,3, Visscher, C.1

*1UMCG (Groningen, the Netherlands), 2KNVB (Zeist, the Netherlands), 3HAN (Nijmegen, the Netherlands)*

Introduction Reflection and ball control are important skills for performing at elite level in basketball<sup>1,2</sup>. However, their importance for reaching elite level might differ between positions (guard, forward, center). This study examines differences between positions regarding the development of reflection and ball control and for the importance of both skills in reaching elite level at age >20 years. Method Talented male basketball players ( $n=73$ ; age range 13-20) completed the self-regulation of learning self-report scale to measure reflection (range 1-5), and the STARtest to measure ball control from 2008-2012. Pearson correlations were calculated between age, reflection and ball control to investigate the development of both skills and their interdependence. Differences between correlations were calculated with Z-scores. A multivariate analysis of variance is performed for a subgroup with players of >20 years in 2014 to examine differences between players who reached elite level ( $n=11$ ) and non-elite level of performance ( $n=18$ ). Performance level and position were added as fixed factors, and reflection and ball control as dependent variables. Results Reflection ( $4.03 \pm .54$ ) did not correlate with age in either position ( $p > .05$ ). Regarding ball control, players improved their performances over time, with the strongest development for guards ( $r = .65$ ). A higher score on reflection related to better ball control in guards ( $r = .19$ ) and forwards ( $r = .18$ ) in contrast to centers ( $r = .34$ ). Regardless of position, players who reached elite level at age >20 scored higher on reflection ( $4.29 \pm .29$ ) during their adolescent years compared to players who reached non-elite level ( $4.04 \pm .31$ ;  $p = .03$ ). For ball control, no differences were found between elite ( $19.62 \pm 1.14s$ ) and non-elite ( $19.67 \pm 1.02s$ ). However, positional differences were found, in favour of guards and forwards ( $p < .01$ ). Discussion This study showed no positional differences for the development of reflection, while guards showed the strongest development regarding ball control. For reaching the elite level, very good reflective skills are important regardless of position. These reflective skills are thought to be important for guards and forwards to improve their ball control performances, while centers use them to improve skills that are more important for their position. This suggests that players use position-generic reflective skills for improving position-specific skills. #### BREATH SLOWER, BE SMARTER? THE EFFECTS OF SLOW PACED BREATHING ON COGNITIVE EXECUTIVE FUNCTIONING

Laborde, S.

*German Sport University*

Slow paced breathing has been found to increase cardiac vagal tone, creating a resonance state in the cardiovascular system when the individual breathes at 6 cpm. According to the neurovisceral integration model, cardiac vagal tone is positively associated with executive performance (Thayer, Hansen, Saus-Rose, & Johnsen, 2009). However, it is still unknown whether an increase in cardiac vagal tone provoked by slow paced breathing would result in an increase of executive performance. Moreover, the most optimal inhalation/exhalation ratio and the duration of the effects of slow paced breathing are still unknown. Therefore the aim of this research project was twofold: first to clarify the most optimal way to realize slow paced breathing as well as the duration of its effects, and second to investigate its influence on executive performance. This research project comprised of five experiments. Cardiac vagal tone was assessed through heart rate variability and more specifically with the root mean square of the successive differences (RMSSD). Respiratory rate was controlled for in all analyses. The first two experiments aimed to investigate the parameters of slow paced breathing and the duration of its effects. Experiment 1 ( $N=63$ ) showed that the best ratio was obtained with longer exhalation and shorter inhalation, provok-

ing a higher activation of the vagal brake. Experiment 2 (N = 15) showed that the effects of slow paced breathing on cardiac vagal tone lasted at least 1h, with a higher increase in comparison to a video control condition. Regarding the second aim, we investigated the effects of slow paced breathing on the three core executive functions (Diamond, 2012): inhibition (experiment 3), working memory (experiment 4), and cognitive flexibility (experiment 5). Based on similar within-subject designs (N = 30 for experiments 3, 4, 5), we found that performance on all executive functions increased after slow paced breathing in comparison to a video control condition, and RMSSD was found to mediate this increase. In summary, this research project showed that slow paced breathing can increase executive performance through vagal tone increase, based on the most optimal inhalation/exhalation ratio, and that those effects may last at least for 1h. Given the protective properties of a higher vagal tone for health and against stress (Thayer et al., 2009), slow paced breathing may play a very important role regarding health on a larger society scale. ## THE NUMBER OF COMPETITORS AFFECTS PACING AND PERFORMANCE IN SHORT-TRACK SPEED SKATING COMPETITIONS

Konings, M., Schoenmakers, P., Hettinga, F.

*University of Essex*

THE NUMBER OF COMPETITORS AFFECTS PACING AND PERFORMANCE IN SHORT-TRACK SPEED SKATING COMPETITIONS Introduction The presence of opponents is inextricably linked to sports performance. However, the required actions for an athlete to outperform the others depend on the way a competition is structured (Stanne et al., 1999). In this perspective, the number of competitors in a race might influence pacing behaviour and performance, as one seems relatively more dependent on the actions of the opponents with a lower number of competitors. The present study aimed to analyze how the number of competitors influenced pacing and tactics in short-track speed skating, a sport setting in which athletes directly compete within the same race. Methods Finishing and split times, as well as start, intermediate and final rankings of 500m, 1000m, and 1500m races were collected from short-track speed skating World Cups, European/World Championships, and the Olympic Games during the season 2012/13 (n=1141 races) and 2013/14 (n=973 races). To explore if pacing behaviour differed depending on the number of competitors, lap and finishing times were analyzed using a MANCOVA (P<0.05) in which the number of competitors was the independent variable and stage of competition, sex, and final-ranking were added as covariates. To explore if tactical positioning differed depending on the number of competitors, intermediate rankings at a particular lap were correlated with the final rankings for each number of competitors using Kendall's Tau b correlations. Cohen's Q was used to compare the correlations for each number of competitors (with Q>.30: medium or large effect). Results Finishing times (t) were slower when the number of competitors (nc) was lower for the 500m (t=44.65±1.7s, nc=3; t=43.71±1.7s, nc=4; t=43.61±1.7s, nc=5; P=.002), 1000m (t=93.79±3.4s, nc=3; t=91.06±3.5s, nc=4; t=90.62±3.4s, nc=5; P<.001) and 1500m (t=160.4±12.5s, nc=4; t=148.3±7.6s, nc=5; t=145.5±6.1s, nc=6; t=142.3±5.0s, nc=7; P<.001). For the 1000m and 1500m, especially the beginning stages of a race were slower for a lower compared to a higher nc. In addition, the first part of a race showed lower correlations between intermediate and final rankings for a lower compared to a higher nc (e.g. Q>.35 for lap 1-6 of 1000m when comparing nc=3 vs nc=5). Discussion A lower number of competing opponents led to slower lap times in the beginning stages of the race and slower final times. Moreover, higher final-ranked athletes positioned themselves in the foremost positions earlier in the race if more opponents were competing. In conclusion, the number of competitors seems to influence pacing, tactics and performance in a sport involving a direct form of competition. ## TO IMPROVE OR NOT TO IMPROVE; THE PSYCHOLOGICAL PROFILE OF ELITE YOUTH SPEED SKATERS

Stoter, I.K.1, Elferink-Gemser, M.T.1,3, Jonker, L.1,2, Te Wierike, S.C.M.1, Visscher, C.1

1:UMCG (Groningen, the Netherlands), 2:KNVB (Zeist, the Netherlands), 3: HAN (Nijmegen, the Netherlands)

Introduction Improving performance is essential for elite youth athletes to eventually reach the top. Why some keep improving and others do not, remains hard to explain. This study investigates for three age categories whether psychological characteristics associated with learning (goal orientation, motivation and self-regulation) can distinguish between improving and non-improving elite youth speed skaters on the 1500m. Methods At baseline Dutch elite youth speed skaters (international top) in the age categories 13-14 (n=23), 15-16 (n=91) and 17-18 year (n=40) completed the Task and Ego Orientation in Sport Questionnaire (TEOSQ), the sport motivation scale (intrinsic and extrinsic motivation), and the self-regulated learning – self-report scale (planning, self-monitoring, evaluation, reflection, effort and self-efficacy). Performance was defined as the time the season best time is above the world record (WR) of the corresponding gender (male 101.04s, female 111.79s) at baseline and two years later. Based on two year performance improvement, speed skaters were divided into improvers (improve > 5%, n=85) and non-improvers (decline > 5%, n=43). (Multivariate) analysis of variance was used to find differences between improvers and non-improvers on baseline performance and the psychological variables. Results There was no difference in baseline performance between improvers and non-improvers for all age categories (above WR: 13-14 year 26.6±5.2s, 15-16 year 17.6±4.0s, 17-18 year 14.15±4.4s). At 13-14 year TEOSQ (range 1-5) distinguishes improvers (n=16) from non-improvers (n=6; p<.05), with improvers scoring a combination of higher ego orientation (4.2±.5 vs 3.6±.7) and somewhat lower task orientation (4.3±.5 vs 4.6±.4). At 15-16 year no differences were found. At 17-18 year improvers (n=23) scored higher than non-improvers (n=12) on self-efficacy (3.3±.4 vs 2.8±.5, range 1-4; p<.05). Discussion To improve or not to improve is not dependent on baseline performance for elite youth speed skaters. Both improvers and non-improvers scored high on all psychological variables compared to previous literature (Jonker et al., 2010; Elferink-Gemser et al., in press), indicating very good psychological characteristics relevant for learning. Nevertheless, it appears important for elite youth speed skaters to focus on winning at age 13-14, and to believe in their own ability to complete tasks and reach goals at age 17-18 to improve 1500m performance the consecutive two years. **ASSESSING PERSONAL TALENT DETERMINANTS IN YOUNG RACQUET SPORT PLAYERS: A SYSTEMATIC REVIEW**

Faber, I.R.1, Bustin, P.M.J.1, Oosterveld, F.G.J.1, Elferink-Gemser, M.T.2, Nijhuis-van der Sanden, M.W.G.3

1: Saxion University of Applied Science; 2: HAN /University Medical Centre Groningen; 3: Radboud University Medical Centre

Introduction Selecting and monitoring young racquet sport players in the context of talent developmental programmes is extremely difficult. Since junior performances have little predictive value for future success, other solutions are sought to assess a young player's potential. The objectives of this systematic review are 1.) to provide an overview of instruments measuring personal talent determinants of young players in racquet sports, and 2.) to evaluate these instruments regarding their validity for talent development. Methods Electronic searches were conducted in PubMed, PsychINFO, Web of Knowledge, ScienceDirect, and SPORTDiscus (1990-31th March 2014). Search terms represented tennis, table tennis, badminton, and squash, the concept of talent, methods of testing, and children. An overall methodological quality check of the included articles was conducted (Law et al., 1998). All instruments assessing personal talent determinants, that were found in the articles, were classified using Gagné's Differentiated Model of Giftedness and Talent 2.0 (2010). Instruments' validity for talent developmental purposes was checked by their capacity to discriminate between elite and non elite players, to predict future performance, and to provide directions for talent development. The specific level of evidence regarding validity was evaluated using the COnsensus-based Standards for the selection of health Measurement Instruments checklist (Mokkink et al., 2010). Results Thirty articles with information regarding over 100 instruments were included. Validity evaluation showed that instruments focusing on intellectual and perceptual abilities, and coordinative skills discriminate elite players from others and/or are related to current performance, but their predictive validity is not confirmed. There is moderate evidence that the assessments of mental and goal-management skills predict future performance. Data on instruments measuring physical characteristics prohibit a conclusion due to conflicting findings. Discussion This systematic review yielded an ambiguous endpoint. The value of instruments as part of talent development programmes depend on the context and the player's developmental phase. The lack of longitudinal studies preclude verification of the instrument's capacity to forecast future performance. Future research should focus on instruments assessing multidimensional talent determinants, and their predictive value in longitudinal designs. **Oral presentations****OP-SH03 Sport management (Sustainability and Sport events)****SPECTACLE MEETS SUSTAINABILITY: THE RELATIONSHIP BETWEEN EVENTS AND SPORT-FOR-DEVELOPMENT PROGRAMS**

Schulenkorf, N., Schlenker, K.

*University of Technology Sydney (UTS)*

Sport-for-development (SFD) programs are seen as promising vehicles for improved communication and celebration within and between communities (Sugden, 2010). Particularly in disadvantaged community settings, government agencies, aid organizations and NGOs have been implementing SFD projects for several years. Most of these initiatives also include special events such as cultural festivals, sport tournaments and educational conferences as part of the overall program portfolio. However, there is little specific understanding of the role and effectiveness of these initiatives in contributing to overall community development. The belief that events have a role to play in SFD stems from arguments around event leverage and ripple effects. First, to achieve leverage, SFD organizers need to move beyond the planning of immediate impacts and instead focus on strategic paths to maximize sustainable outcomes for host communities (Schulenkorf & Edwards 2012). Second, Sugden's (2010) Ripple Effect model suggests that just like a stone dropped into a still pool of water, a community intervention has its strongest impact on those directly involved in a program or event. However, community activities may also influence related stakeholders (e.g. families, communities, policymakers etc.) as the ripples will wash over the shoes of those who walk in the corridors of power. Our study investigated the contribution of special events within the football-based Just Play initiative which promotes physical activity, healthy living and community involvement across ten Pacific Islands. The study builds on 38 interviews and three focus group discussions with Just Play stakeholders from Vanuatu, Samoa and the Cook Islands. We found that one-off 'highlight events' have the ability to play an important role within the context of ongoing, regularized SFD programs; they can provide much needed excitement, animation, enthusiasm and vibrancy. These findings can also be linked to the different dimensions of social capital (see Putnam 2000); they can renew interest among local participants (bonding), but also arouse interest among those who have yet to engage (bridging and linking). In other words, regular programs are able to deepen existing relationships and networks, while 'highlight events' allow for the widening of participation and program scope. References Putnam, R. D. **FROM LONDON TO RIO: CAN SUSTAINABILITY BE SUSTAINED?**

Hatlem, P.

*Saint Leo University*

In 1996 the International Olympic Committee (IOC) amended its charter to recognize the environment as the third pillar of "Olympism," joining sport and culture (London Strives). A key element of this pillar is sustainability, and the Olympic Movement's efforts to set new standards at large sports events and beyond (Sustainability). While all Olympic host cities since 1996 did, to varying success, address environmental issues, it was not until the 2012 Olympic and Paralympic Games in London that the concept of sustainability was at the forefront (London Strives). It was the ambition of the British government for the 2012 Games to be genuinely sustainable; it believed that "the Olympic Park would be a blueprint for sustainable living, inspiring individuals to live more sustainably as a result of the Games" (UK). Following the completion of the 2012 Olympics and Paralympics, the Commission for a Sustainable London 2012 (CSL2012) said the Games had "raised the bar for sustainability" and was, in fact, the most sustainable Olympics Games ever held (London 2012). We now

must look forward to the 2016 Olympic and Paralympic Games in Rio de Janeiro. Rio is planning even greater levels of sustainability for the 2016 Games, including higher levels of renewable energy, extensive bike paths connecting Olympic venues, and a goal of 100 percent biodiesel fuel (Report). However, there is now skepticism that this will occur, due in part to a lack of coordination and communication among those charged with these tasks (Rio). Will Rio be able to match or surpass the success of London? Or will the London legacy of sustainability both during and after the Games be a singular success? In this study the author will examine what role the success of the 2012 London Games in upholding the third pillar of Olympism will have on the 2016 Rio de Janeiro Games. ### ACADEMIC RESEARCH COLLABORATION FOR RISK MANAGEMENT IN SPORTS EVENTS

Benetti, M., Sierra, A.P.R., Jones, J.M., Boaventura, M.F.C., Kiss, M.A.P.D.M., Rocco, A.J., Bastos, F.C.

*EEFE-University of Sao Paulo, UNINOVE - Medicine and Sports Management, Cruzeiro do Sul University and Mackenzie.*

Long distance races are becoming increasingly popular, probably because of the awareness regarding the benefits of physical activities. However, risk management in these events is still not fully explored, and its relationship with researches in the physiology area is still non-existing. Therefore, the objective of this study was to analyze the influence of the participation in academic researches for risk management in sports events. Methods: 104 male runners, aged  $34.53 \pm 8.01$ , participating in two research projects in the area of physical exercise physiology with medical evaluation, performed with half marathons and marathon, who answered a self-administered questionnaire, 24 hours prior to the race in which they were to participate. Results: of the runners evaluated, 60.58% have completed higher level of education. Regarding modifiable risk factors, such as diabetes and dyslipidemia, none of the runners presented these pathologies since this was a criterion for being included in the study; however, 1.92% (2) were smokers and 2.88% (3) were hypertensive. Regarding not modifiable risk factors, 52.88% had family history of hypertension, 40.38% of diabetes, and 21.15% of dyslipidemia. Considering this scenario, where there is a great number of risk factors, only 77% undergo periodic physical evaluations and only 18.27% is assisted by a sports advisory team with  $5.51 \pm 4.84$  years of experience in training, being that all runners participate in sports events and have participated in at least one marathon in their sports life. Conclusion: We may conclude that people who participate in long duration sports events are exposed to high risks. Nonetheless, a large number of runners do not undergo periodic medical evaluations and do not receive assistance from sports advisory teams, further increasing the risk when participating in long duration sports events such as marathons and half-marathons. We still do not know if the large number of runners not assisted by sports advisory teams found in academic researches results from concern regarding controlling their risk factors, since they do not have a sports advisory team, or if those who are assisted by sports advisory teams do not participate in the researches because their coach does not authorize them to do so. Thus, participation in academic researches contributes to a thorough evaluation and damage control regarding the runner's participation in this modality of sports events and may be better explored for more effective risk management.

### ON THE PERIPHERY: NEW PERSPECTIVES ON THE OLYMPIC AND PARALYMPIC MOVEMENT

Baka, R., Hess, R.

*Victoria University*

Introduction Major sporting festivals, such as the Olympic Games, continue to change both at the core and the periphery. Changes at the core include the inclusion of new sports and nations in the Games. How the Games are mediated, consumed and interpreted and what happens on the fringe of the Games represent some examples of changes on the periphery. This paper explores two topics which fall within this 'periphery' category. One new concept is the emergence of 'Olympic Houses' organised by various NOCs during the time of the Games. This comparative investigation of several nations traces the historical background and the motives behind their establishment, structure, sponsorship and internal evaluations. The second part of the paper is an examination of the early Paralympic Games, initially a very peripheral event to the Olympic Games. Methods Primary and secondary written sources associated with these topics were examined. Extensive use was made of interviews of key Olympic House staff, Olympic athletes, their families, sponsors of National Olympic Committees and Paralympic athletes and officials. Participant observation techniques were employed with the authors attending the 2008 Beijing Summer Olympic Games, the 2010 Vancouver Olympic Winter Games and the 2012 London Summer Olympic Games. Results Olympic Houses were found to be a relatively new concept and are primarily the domain of the more established and successful Olympic nations, although the format, programs and services of Olympic Houses varied considerably. It was found that most Olympic Houses served a very valuable role of "distraction management" for Olympic athletes. They also were a means of giving a larger profile to sponsors of National Olympic Committees as well as a "home away from home" for key individuals associated with an Olympic Team. Based on recent interviews with some of the leading athletes from the 1960 and 1964 Paralympic Games, some fresh historical perspectives on the pioneers of disability sport are offered as this major sports event eventually transitioned from a very peripheral part of the Olympics to a more formalised status. Discussion It appears that Olympic Houses are here to stay as part of the overall Olympic movement. Although they are still very much on the periphery, the International Olympic Committee is only interested at this point in time in monitoring not governing this area. In contrast, the Paralympic Games have altered their status and moved from a peripheral role to very much being an integral part of the Olympic Games. References Baka, R. and Hess, R. ### OP-PM19 Physiology: Fatigue, Muscle damage & repair

#### CONTRALATERAL PROTECTIVE EFFECT CONFERRED BY LOW-INTENSITY ECCENTRIC EXERCISE AGAINST MAXIMAL ECCENTRIC EXERCISE-INDUCED MUSCLE DAMAGE

Chen, T.C.1, Lin, M.J.2, Yu, H.I.3, Chen, H.L.2, Nosaka, K.4

1: National Taiwan Normal University (Taipei, Taiwan), 2: National Chiayi University (Chiayi, Taiwan), 3: Chiayi Christian Hospital (Chiayi, Taiwan), 4: Edith Cowan University (Joondalup, Australia)

**Introduction** Eccentric exercise-induced muscle damage is reduced by performing non-damaging eccentric exercise within 2 weeks prior to the damaging exercise [1]. Some studies showed that the magnitude of muscle damage induced by maximal eccentric contractions (MaxEC) of the elbow flexors (EF) was smaller for the arm that was used in the second than the first bout, which is referred to as the contralateral repeated bout effect (CL-RBE) [2,3]. However, it is not known whether non-damaging eccentric contractions can provide any preconditioning effect on the contralateral arm. This study investigated whether low-intensity eccentric contractions would reduce the magnitude of muscle damage after MaxEC performed by opposite arm within 2 weeks later. **Methods** Seventy-eight untrained young men were assigned (n=13/group) to five preconditioning groups that performed 5 sets of 6 low-intensity eccentric contractions with a load equivalent to 10% of maximal voluntary isometric contraction strength (10%EC) for the first bout, followed 1 day (1d), 2 days (2d), 1 week (1w), 2 weeks (2w) or 3 weeks (3w) by 5 sets of 6 MaxEC of the other arm, or one control group that performed MaxEC only. Changes in maximal voluntary concentric contraction torque, range of motion, upper arm circumference, muscle soreness, plasma creatine kinase activity and myoglobin concentration and B-mode ultrasound echo-intensity of the exercised muscles after MaxEC were compared among the groups by a two-way repeated measures ANOVA. **Results** 10%EC did not change any variables. Changes in all dependent variables after MaxEC were significantly ( $P < 0.05$ ) smaller for the 1d, 2d and 1w groups than the control group, without significant difference between the 1d and 2d groups, but with significant differences between 1d/2d and 1w groups. Changes in the variables were not significantly different among the 2w, 3w and control groups, except for muscle soreness showing significantly ( $P < 0.05$ ) smaller changes for the 2w/3w groups than the control group. **Discussion** These results showed that 10%EC conferred potent protective effect on the contralateral arm to attenuate the magnitude of muscle damage, and the effect lasted for 1 week but was reduced between 2 days and 1 week. When compared with the effect found for the ipsilateral arm in the previous study [1], the contralateral protective effect appears to be smaller and shorter-lived, but was still effective for substantially reducing muscle damage. **References** 1) Chen et al. #### EFFECT OF COMPRESSION GARMENTS ON RECOVERY OF EXERCISE PERFORMANCE FOLLOWING DOWNHILL RUNNING

Mizuno, S., Tsuchiya, Y., Goto, K.

*Ritsumeikan University*

**Introduction** Growing evidences suggest that wearing a compression garment (CG) promotes recovery after strenuous resistance exercise (Kraemer et al. 2010; Goto and Morishima, 2014). However, the effect of CG on recovery following endurance exercise has not been fully understood so far. **Purpose** The present study was designed to investigate effect of wearing lower body CG for 24h on time course of changes of exercise performance following downhill running. **Method** Nine males conducted 30 min downhill (gradient: -10%) running at 70% of  $VO_{2max}$  in two trials, wearing either a CG or a placebo garment (CON) for 24 h after exercise. Time courses of changes of height of counter movement jump (CMJ), running economy, scores of muscle soreness and subjective fatigue, and circumferences of upper and lower limb muscles were compared between the trials. **Results** No significant difference was observed in CMJ height between the trials at any time points ( $P > 0.05$ ). However, in the CG trial, CMJ height recovered to pre-exercise value at 24h after the exercise, whereas not in the CON trial ( $P < 0.05$  vs. pre-exercise value). Running economy at 70, 80 and 90% of  $VO_{2max}$  did not differ significantly between the trials at 24h after exercise. No significant difference was observed in time course changes of muscle soreness, subjective fatigue or muscle circumferences between the trials throughout post-exercise periods. **Discussion** To our knowledge, this is the first study to examine the efficacy of CG on recovery following downhill running. In the present study, we were not able to observe significant interaction (trial  $\times$  time) or main effect (trial) for the changes in CMJ height, running economy, or scores of muscle soreness and subjective fatigue. However, the CG trial showed faster recovery of CMJ height at 24h after the exercise, while the CMJ height remained significantly lower in the CON trial. The mechanism underlying promotion of recovery remains unclear, but augmented venous return of lower limbs by the use of CG for 24 h might be involved. **Conclusion** Wearing CG following downhill running did not facilitate the recoveries of running economy or muscle soreness. However, the use of CG might be beneficial for promotion of recovery of maximal power output for lower limbs. **Reference** Goto K, Morishima T. #### TEN MAXIMAL ISOMETRIC CONTRACTIONS DO NOT ATTENUATE DOWNHILL RUNNING-INDUCED MUSCLE DAMAGE AND EFFICIENCY LOSS

Lima, L.C.R., Assumpção, C.O., Caritá, R.A.C., Bassan, N.M., Greco, C.C., Denadai, B.S.

*UNESP - Rio Claro*

**Introduction** Downhill running-induced muscle damage (EIMD) has been proven to compromise strength production, running efficiency (RE) and promote muscle soreness and swelling. Recent evidence showed that, when performed prior to an eccentric damaging bout, maximal isometric contractions (MIC) attenuate EIMD symptoms in untrained populations. The aim of this study was to investigate if performing 10 MIC before a downhill running bout (DRB) would attenuate EIMD and, most importantly, decreases in RE. **Methods** Twenty untrained male volunteers were randomly assigned to either a control (CON) or an experimental (ISO) group. All participants ran downhill (-15%) for 30 minutes at 70% of their maximal oxygen consumption. Volunteers in the ISO group performed 10 MIC in a leg press machine 2 days before the DRB while those in the CON remained inactive during this period. EIMD [isometric peak torque (IPT), perceived muscle soreness (SOR), thigh circumference (CIR)] and RE (oxygen consumption, minute ventilation, lactate concentration, perceived exertion)

parameters were assessed before, immediately after and 1-4 days after the DRB. Results Significant decreases in IPT were identified immediately (CON: 22% vs. ISO: 20%) and 1 day (CON: 23.1% vs. ISO: 20.1%) after the DRB, with no differences between groups. SOR increased equally for both groups 1 (CON: 7.3 cm vs. ISO: 8.1 cm) and 2 (CON: 7.6 cm vs. ISO: 9.1 cm) days after the DRB. CIR remained unaltered throughout the whole experiment. All RE parameters increased significantly immediately and 1 day after the DRB, with no difference between groups. Discussion Increases in EIMD and RE markers for the CON group of the present study were similar to those reported in previous studies, with faster recovery. However, no significant interactions were found between groups. This indicates that performing MIC previous to a DRB does not attenuate EIMD, which has been described to compromise RE. To our knowledge, no previous studies investigated the use of MIC as a protective strategy against EIMD in the lower limbs. It has been reported that lower limb muscles are less susceptible to EIMD than their upper limbs counterparts. Moreover, the repeated bout effect conferred by eccentric contractions is more accentuated in upper than in lower limbs muscles. Since the protection conferred by MIC is less effective than that conferred by eccentric contractions, we suggest that this strategy might not be potent enough for muscle groups that frequently perform eccentric contractions and are, therefore, already well protected against EIMD. Finally, RE parameters were altered at the same time points as IPT, which corroborates to the knowledge that muscle strength is related to RE.

## THE ROLE OF BRAIN-DERIVED NEUROTROPHIC FACTOR IN THE EXERCISE-INDUCED SKELETAL MUSCLE INJURY AND REPAIR

Yu, T.I, Chang, Y.I, Arevalo, J.C.2

1: China Institute of Sport Science, China; 2: INCYL, Spain

**Introduction** Skeletal muscle has been found to be a source of brain-derived neurotrophic factor (BDNF) outside nervous system. However, its role in the skeletal muscle has not been fully elucidated. Here we studied the exercise-induced BDNF expression in the rats in order to explore the possible role of BDNF in skeletal muscle injury and regeneration. **Methods** Sprague-dawley rats were subjected to downhill running at 17m/min for 90 minutes. We first evaluated skeletal muscle injury by histology and serum creatine kinase (CK) activity and tested skeletal muscle regeneration by the expression of MyoD in satellite cells through immunohistochemistry. Then, the level of BDNF was measured in serum and soleus by ELISA and real time RT-PCR, respectively. Finally, we studied the TrkB expression through immunohistochemistry and real time RT-PCR and its phosphorylation through immunohistochemistry in the soleus. T-test was employed to compare the difference among distinct groups using SPSS software and  $p < 0.05$  was considered statistically significant. **Results** Besides skeletal muscle fiber disruption, a temporally increased serum CK activity was found following downhill running, indicating the skeletal muscle injury. In addition, we observed the expression of MyoD, the molecular marker of satellite cell activation, in the soleus the first day following the downhill running, showing the regeneration process. Elevated serum BDNF level was present from day 2 and maintained for two weeks in the serum following the downhill running. Similarly, enhanced mRNA level of BDNF was found in the soleus in response to the exercise. In addition, we observed that TrkB, the high affinity receptor of BDNF, is located on the membrane of skeletal muscle cells and immune cells, however its mRNA level didn't show significant alterations following the downhill running. Surprisingly, phosphorylation of TrkB was not present in the skeletal muscle cells, but in the immune cells, suggesting that BDNF may participate in the skeletal injury and regeneration through regulating immune cell functions. **Discussion** BDNF has been found capable of regulating satellite cells in skeletal muscle injury and regeneration. Here we observed enhanced BDNF expression and satellite cell activation in the rats in response to downhill running. In addition, our study showed that increased BDNF could activate TrkB in the immune cells. Although skeletal muscle can release BDNF in response to exercise as a secretory organ, it is not the only source of BDNF, immune cells could also express BDNF and TrkB. Our study suggests that in addition to regulating satellite cells, BDNF could play an important role in the process of skeletal muscle repair by modulating immune cell functions.

## EFFECT OF HYPOXIA AND DIETARY NITRATE SUPPLEMENTATION ON ADAPTATIONS TO SPRINT INTERVAL TRAINING

De Smet, S., Van Thienen, R., Deldicque, L., Bishop, D.J., Hespel, P.

KU Leuven

**INTRODUCTION:** Endurance training in hypoxia elicits unique molecular adaptations in skeletal muscle tissue (Hoppeler et al., 2008). However, less is known about skeletal muscle adaptations to sprint interval training (SIT), where, unlike endurance training, there is little effect of hypoxia on power output (Calbet et al., 2003). Furthermore, although dietary nitrate supplementation is known to increase exercise tolerance in hypoxia (Vanhatalo et al., 2011), it is not known if dietary nitrate supplementation affects adaptations to SIT performed in hypoxic conditions. The aim of this study was to investigate the effect of hypoxia, alone or in conjunction with nitrate, on muscular adaptations and exercise performance responses to SIT. **METHODS:** Twenty-seven moderately-trained participants were randomly allocated to 3 SIT groups: (1) normoxia + placebo (N), (2) hypoxia + placebo (H) or (3) hypoxia + oral nitrate (H-Ni). All participants performed 5 weeks of SIT on a cycle ergometer (4-6 reps, 30-s sprints, recovery intervals of 4 min and 30 s). The normobaric hypoxic facility was set at 20.9% FiO<sub>2</sub> (sea-level) for N, versus 15.0% FiO<sub>2</sub> (~2750 m) for H and H-Ni. Nitrate (6.5 mmol dose) was administered in the form of NaNO<sub>3</sub> capsules 3 h before each training session. Before and after the training period, a biopsy was taken from m. vastus lateralis and the participants completed a maximal incremental exercise test, a 30-min simulated time trial (TT30) and a 30-s all-out Wingate test (W30). **RESULTS:** Power output during the training sessions was similar between the groups. However, compared to N blood lactate concentration in the first sprint, but not in the final sprint of the sessions, was higher ( $P < 0.05$ ) in H and H-Ni. SIT increased neither muscular buffer capacity (Bm) nor the protein content of carbonic anhydrase 3 (CA3) or monocarboxylate transporters 1 and 4 (MCT1 and 4). However, the training intervention increased W30 performance more in H-Ni (+12%,  $P < 0.05$ ) than in N or H (both +6%). SIT increased ( $P < 0.05$ ) muscular citrate synthase activity (+34%), VO<sub>2</sub>max (+12%), power output at OBLA (+8%), and mean power output during TT30 (+6%), but there were no significant differences between groups. **DISCUSSION:** Regardless of whether SIT training was performed in normoxia or hypoxia, alone or in conjunction with oral nitrate intake, SIT increased neither Bm, nor muscle MCTs and CA3 protein expressions. Nonetheless, SIT in H-Ni increased performance in W30 more than SIT in N or H. The mechanism underlying this improvement in anaerobic capacity remains, however, to be elucidated. **REFERENCES:** Hoppeler H. et al., Scand J Med Sci Sports (2008) Calbet J. et al., J Appl Physiol (2003) Vanhatalo A. et al., J Physiol (2011) **CONTACT:** Stefan.desmet@kuleuven.be

**CYCLING POWER MEASUREMENT: LAB TESTS VS INDOOR TRACK TESTS**

Cupido Santos, A.1, Dias Carrilho, J.2, Ruivaco Mendes, G.1, Gameiro da Silva, M.2

*Universidade de Coimbra*

**Introduction** There are indications that an assessment performed in the field produces different results than one performed in the laboratory, and that it might be closer to the real conditions that the athlete encounters (Blake and Wakeling, 2012). In recent years, there has been an increased availability of bicycle power meters, in the consumer market, such as the well-known SRM training system, which has been shown to measure power output accurately (Jones and Passfield, 1998; Wooles et al. 2005). The aim of this paper is to report on a study comparing power measurements performed in the laboratory, using an SRM system mounted on a cycle ergometer, and in an indoor track using the same SRM system mounted in a bicycle. **Methods** Maximal protocol tests were performed by steady intensity levels, during periods of 4 min, starting at 100 W with increments of 50 W. The power output was measured in two different situations with the same SRM Professional system, mounted on a cycle ergometer (Monark 828E) in the laboratory, and mounted on a training bicycle (Look 585) in an indoor cycling track. Target cadence was 90 rpm. The capillary blood lactate concentration was measured, at the end of each of the 4 min intensity level tests, with a Vario Photometer II DP 310. Results For the laboratory tests, power levels of (mean±SD) 98.4±4.7, 149.0±5.1, 198.8±6.4, 248.8±7.6, 299.1±8.4, 351.1±10.6 and 390.9±15.1 W produced, respectively lactate concentration values of 1.1, 0.9, 1.2, 1.2, 2.6, 6.8, 14.3 mmol/l. For the indoor track tests, power levels of 97.9±15.0, 148.5±22.9, 203.1±25.3, 255.1±29.1, 292.0±23.3, 341.8±26.5, 384.0±24.2 W produced, respectively lactate concentration values of 1.2, 1.2, 1.2, 1.4, 2.2, 4.3, 9.3 mmol/l. **Discussion** Observations indicate no difference in the power output at the anaerobic threshold. However, for intensities above the anaerobic threshold, the lactate concentration increased much faster in the laboratory tests compared to the field tests, despite the intensity levels being comparable. One possible explanation for this observation might be the lower thermal stress the athlete is exposed to in the track, since the flow of air helps the body thermoregulation mechanism through forced convection. In the authors' experience, however, this does not seem to completely explain such large differences. The observed variability of the measured power might also have some effect on the lactate measurements, possibly due to different muscle recruitment patterns. The extent to which this effect can explain the differences observed will be explored in future work. **References** Blake OM, Wakeling JM. (2012). **Oral presentations****OP-PM11 Thermoregulation I****REGULAR COLD-WATER IMMERSION AFTER HIGH-INTENSITY INTERVAL TRAINING DOES NOT HINDER THE ADAPTIVE RESPONSE IN HUMAN SKELETAL MUSCLE**

Broatch, J.R., Petersen, A., Bishop, D.J.

*Victoria University*

**Introduction** Debate currently exists surrounding the merit of cold-water immersion (CWI) in athletic training regimes. While better recovery may allow for greater training quality and stimulus (Versey et al. 2013), there is suggestion that CWI may attenuate long-term skeletal muscle adaptations (Yamane et al. 2006). Conversely, CWI may stimulate gene expression of key proteins involved in mitochondrial biogenesis (Ihsan, et al. 2014). The aim of this study was to investigate the underlying molecular mechanisms by which CWI may alter the signalling pathways and training adaptations associated with mitochondrial biogenesis following high-intensity interval training (HIT). **Methods** Sixteen males performed six weeks of HIT (4-6 x 30-s all-out cycling efforts), with each session immediately followed by one of two 15-min recovery conditions: CWI (10°C) or a passive room-temperature control (CON; 23°C). To determine both the acute and training molecular responses following HIT and CWI, muscle biopsies were obtained pre-exercise, post-recovery and 3 h post-recovery during the first training session, and at rest 48 h after the final training session. Results When compared with CON, CWI resulted in larger increases in phosphorylated p53 and PHF20 content 3 h post-recovery. Gene expression of p53-downstream targets Mfn2, AIF, and SCO2, as well as the antioxidant catalase, were all elevated 3 h post-recovery for CWI as compared with CON. Training increased PGC-1 $\alpha$ , p53, and PHF20 protein content, CS activity, mitochondrial respiration, VO<sub>2peak</sub> and cycling performance for both conditions, with no difference between groups. HSP70 protein content increased post-training in the CWI group, and remained unchanged in the CON group. **Discussion** We provide novel data demonstrating that post-exercise CWI augments the post-exercise response of a number of signalling proteins and genes associated with mitochondrial adaptations. We hypothesise that the oxidative stress imposed by a hypothermic shock and subsequent rewarming may serve to augment p53 activation post-exercise, leading to a greater upregulation of some of its downstream targets. However, despite these differences following a single bout of exercise, repeated post-exercise CWI following training did not promote a greater adaptive response to HIT, as measured by markers of mitochondrial biogenesis and other endurance-related adaptations. **References** Ihsan M, Watson G, Choo H, Lewandowski P, Papazzo A, Cameron-Smith D, Abbiss C. **A COMPARISON BETWEEN CONDUCTIVE AND INFRARED DEVICES FOR MEASURING MEAN SKIN TEMPERATURE AT REST, DURING EXERCISE IN THE HEAT, AND RECOVERY**

Costello, J.T.1, Bach, A.J.2, Disher, A.E.2, Stewart, I.B.2

*1: UoP (Portsmouth, UK), 2: QUT (Brisbane, Australia)*

**INTRODUCTION** Skin temperature assessment has historically been undertaken with conductive devices affixed to the skin. With the development of technology, infrared devices are increasingly utilised in the measurement of skin temperature. Therefore, our purpose was to evaluate the agreement between four skin temperature devices at rest, during exercise in the heat, and recovery. **METHODS** Mean skin temperature was assessed in thirty healthy males during 30 min rest (24.0 ± 1.2°C, 56 ± 8%), 30 min cycle in the heat (38.0 ± 0.5°C, 41 ± 2%), and 45 min recovery (24.0 ± 1.3°C, 56 ± 9%). Mean skin temperature was assessed at four sites using two conductive

devices (thermistors, iButtons) and two infrared devices (infrared thermometer, infrared camera). RESULTS Bland–Altman plots demonstrated mean bias  $\pm$  limits of agreement between the thermistors and iButtons as follows (rest, exercise, recovery):  $-0.01 \pm 0.04$ ,  $0.26 \pm 0.85$ ,  $-0.37 \pm 0.98^\circ\text{C}$ ; thermistors and infrared thermometer:  $0.34 \pm 0.44$ ,  $-0.44 \pm 1.23$ ,  $-1.04 \pm 1.75^\circ\text{C}$ ; thermistors and infrared camera (rest, recovery):  $0.83 \pm 0.77$ ,  $1.88 \pm 1.87^\circ\text{C}$ . Pairwise comparisons of mean skin temperature found significant differences ( $p < 0.05$ ) between thermistors and both infrared devices during resting conditions, and significant differences between the thermistors and all other devices tested during exercise in the heat and recovery. CONCLUSION These results indicate poor agreement between conductive and infrared devices at rest, during exercise in the heat, and subsequent recovery. Infrared devices may not be suitable for monitoring mean skin temperature in the presence of, or following, metabolic and environmental induced heat stress.

### **HYPERTHERMIA ALTERS PROPRIOCEPTION AND BALANCE**

Mtibaa, K., Nichols, D., Hautier, C., Racinais, S.

*University of Lyon, France*

Background: Poor proprioception has been proposed to result in a lower level of performance and a higher incidence of injury. Proprioception depends on muscle properties, nerve conduction velocity, spinal function and brainstem activity. However, recent studies showed that these factors are all negatively affected by hyperthermia. The aim of this study is to investigate the effect of passive hyperthermia on proprioception and balance. Methods: Following a familiarization trial, 14 volunteers (8 males, 6 females,  $176 \pm 7$  cm,  $73 \pm 8$  kg,  $32 \pm 4$  yrs) underwent 2 experimental sessions in temperate (CON,  $24^\circ\text{C}$ ) and hot (HOT,  $48$ – $50^\circ\text{C}$ ) conditions, in a counterbalanced order. During each session, participants performed a proprioception test (movement discrimination of ankle dorsiflexion), a balance test (SEBT: Star Excursion Balance Test, in medial, antero-medial and postero-medial directions), and a neural assessment (electrically evoked M-wave and H-reflex on the soleus -SOL- and the gastrocnemius -GM- muscles), in randomized order. Rectal and mean skin temperatures (chest, arm, leg, shin) were continuously monitored. Results: Core temperature was clamped at  $39^\circ\text{C}$  during HOT. Both core ( $39.0 \pm 0.3$  vs.  $36.9 \pm 0.6^\circ\text{C}$ ) and skin ( $37.9 \pm 1.0$  vs.  $32.0 \pm 2.7^\circ\text{C}$ ) temperatures were significantly higher in HOT than CON ( $p < 0.05$ ). The mean error during the proprioception test was significantly higher in HOT ( $0.6 \pm 0.1$  deg) than CON ( $0.5 \pm 0.1$  deg,  $p < 0.05$ ). In addition, hyperthermia significantly decreased the average distance reached during the SEBT ( $90.9 \pm 6.1$  vs.  $88.6 \pm 7.9$  cm in CON and HOT respectively,  $p < 0.05$ ) due to a significant decrease of the distance reached in the postero-medial direction ( $98.4 \pm 6.3$  vs.  $94.1 \pm 8.6$  cm in CON and HOT respectively,  $p < 0.05$ ). Maximal amplitude of H-reflex was reached at a similar intensity of stimulation in CON and HOT ( $p < 0.05$ ). However, maximal H-reflex amplitude was significantly lower in HOT than CON (SOL:  $2.5 \pm 1.1$  vs.  $4.3 \pm 1.9$  mV, GM:  $1.6 \pm 0.8$  vs.  $2.4 \pm 1.4$  mV, in HOT and CON respectively,  $p < 0.05$ ), without significant differences in M-wave. The alterations in proprioception, balance and neural functions were not correlated between themselves. Conclusion: The current study demonstrated that hyperthermia alters both proprioception and balance.

### **THE WHOLE BODY CRYOSTIMULATION DOES NOT CHANGE IRISIN CONCENTRATION BUT REDUCES INFLAMMATION IN MIDDLE AGED, OBESE MEN.**

Ziemann, E.1, Olek, R.A.2, Flis, D.2, Dulian, K.2, Grzywacz, T.1, Kujach, S.1, Laskowski, R.1

*Gdansk University of Physical Education and Sport*

Introduction Irisin has been proposed to mediate the beneficial effects of exercise on metabolism, inducing browning of adipocytes as well as thermogenesis by increasing uncoupling protein 1. This newly discovered peptide in a study by Böström et al. (2012) might be secreted by muscle and released into the blood flow in response to exercise. Similarly to physical exercise, exposure to extremely low temperature potentiates thermogenesis and muscle contractions, which might also lead to the secretion of irisin. Consequently, the aim of this study was to investigate the effect of the whole body cryostimulation on irisin concentration in middle aged men. Methods A group of middle aged men ( $38 \pm 9$  years old,  $\text{BMI} > 30 \text{ kg}\cdot\text{m}^{-2}$ ) participated in the study. Subjects were exposed to a series of 10 sessions in a cryogenic chamber (once a day at 9:30am, for 3 min, at temperature  $-120^\circ\text{C}$ ). Prior to treatment body composition and fitness level were determined. Blood samples were collected before the first cryostimulation and after completing the last one. Results Most of our participants exhibited low grade systemic inflammation in response to the elevated fat tissue. Thus, the enhanced values of C-reactive protein ( $3.2 \pm 1.8 \text{ mg}\cdot\text{l}^{-1}$ ) and hepcidin ( $96.8 \pm 32.9 \text{ ng}\cdot\text{ml}^{-1}$ ) were recorded. The whole body cryostimulation significantly reduced the CRP concentration, which dropped 2.3fold compared to the baseline. It also decreased the pro-inflammatory, iron-regulating protein- hepcidin, however, the differences observed did not significantly affect iron or ferritin status. On the other hand, the applied series of 10 whole body cryostimulation sessions did not modify blood irisin concentration. Discussion The investigation revealed that a series of 10 whole body cryostimulation sessions resulted in a significant decrease of the pro-inflammatory proteins in middle aged men. Therefore, the whole body cryostimulation might act as an anti-inflammatory strategy, which is in agreement with our previously published study (Ziemann et al., 2013). Oppositely to our expectations, the whole body cryostimulation did not change irisin concentration in the group of obese subjects, which rules this treatment out as a factor enhancing energy expenditure. References 1. Bostrom et al (2012) A PGC1- $\alpha$ -dependent myokine that drives brown-fat-like development of white fat and thermogenesis. *Nature* 2012 Jan 11;481(7382):463-8 2. ### **EFFECT OF ISCHEMIC PRECONDITIONING ON SWIMMING PERFORMANCE IN A HIGH-INTENSITY INTERVAL TRAINING SET: A RANDOMIZED, PLACEBO AND NOCEBO-CONTROLLED STUDY**

Ferreira, T.N.1,2, Lopes, T.R.1,2,3, Sabino-Carvalho, J.1,2, Freitas, T.O.1,2, Silva, A.C.1,2, Silva, B.M.1,2

*1. Federal University of Sao Paulo, 2. Olympic Center for Training and Research, 3. Sao Paulo Association for Medical Development*

Introduction Recent studies have shown that ischemic preconditioning (IPC) improved competitive swimming performance (1.1% in 100-m and 200-m time trials; Jean-St-Michel et al. 2011). But, it is conceivable that IPC can also improve performance in training sessions, which could be valuable to enhance training tolerance and adaptations. Moreover, no study has adequately controlled possible placebo/nocebo effects of IPC. Thus, our aim was to study the effect of IPC on swimming performance in a high-intensity interval training (HIT) set. Methods Well-trained swimmers were recruited. Group 1 ( $n = 13$ ,  $24 \pm 3$  years) was randomly submitted to IPC and control (CT). IPC: cuffs positioned on the thighs were inflated to 220 mmHg for 5 min and deflated to 0 mmHg for 5 min. CT: the cuffs were inflated to 10 mmHg for 5 min and deflated to 0 mmHg for 5 min. Group 2 ( $n = 6$ ,  $24 \pm 2$  years) was randomly submitted to placebo (PL) and CT. PL: the cuffs were inflated to 10 mmHg for 2 min, 220 mmHg for 1 min and 10 mmHg for 2 min, and then deflated for 5 min. Each cycle of inflation/deflation was repeated three times per day on each leg, at 48h, 24h and 45 min before a HIT set (six 50-m all out efforts, repeated every 3 min). Subjects were informed that both IPC and PL would improve performance compared to CT. The improvement expectation

with IPC and PL was 92% (12 out of 13 subjects) and 83% (5 out of 6 subjects), respectively. Measurements included: swimming time [best time (BT), total time (TT), and percent decay (%DC)], swimming kinematics [mean velocity (MV), stroke rate (SR) and stroke length (SL)], blood lactate concentration [La] and rating of perceived exertion (RPE). Results IPC did not change BT ( $P = 0.37$ ), %DC ( $P = 0.41$ ), [La] ( $P = 0.30$ ), RPE ( $P = 0.24$ ) and swimming kinematics ( $P = 0.70, 0.25$  and  $0.44$ ). Conversely, it tended to decrease TT ( $-0.8\%$ ;  $P = 0.11$ ). No difference occurred between CT and PL. Discussion These preliminary results show that the trend for improvement in performance with IPC was not accompanied by change in [La]. Thus, it may be explained by enhancement in oxidative metabolism and/or overall efficiency for ATP resynthesis (Cabrera et al. 2012). Noteworthy, no previous study has avoided the placebo/nocebo effect of IPC on exercise performance. The lack of difference between PL and CT procedures in our study indicates, for the first time, that IPC can per se improve performance. References Cabrera JA et al. (2012). *Am J Physiol Heart Circ Physiol*, 302, 1974-82. Jean-St-Michel E et al. (2011). *Med Sci Sports Exerc*, 43, 1280-6.

### EFFECTS OF EXTERNAL MOTIVATION ON CYCLING TIME TRIALS

Skorski, S.1,2,3, Abbiss, C.R.3, Meyer, T.1, Thompson, K.G.3

1. Saarland University, 2. University of Canberra, 3. Edith Cowan University

Introduction: Motivation is a key element of an athlete's success. Intrinsic motivation seems to have a positive influence on concentration and effort whilst high external motivation may decrease intrinsic motivation and possibly compromise performance (Deci et al., 1999). This has further been associated with the adoption of an aggressive pacing pattern (Hulleman et al., 2007). Therefore, the aim of this study was to determine the influence of altering external motivation through a financial reward on pacing and performance in short and long cycling time trials. Methods: 23 cyclists (6 ♀, 17 ♂) completed 4 time trials (TT) on an electromagnetically braked cycle ergometer. Participants were separated in 2 groups based at 2 separate universities. Prior to the first TT, cyclists within one group ( $n=11$ ; PRI) were informed that prize money is available based on the highest mean power output (Pmean) in all TTs. Cyclists within the other group ( $n=12$ ; CON) were not provided with a financial reward. Groups were matched based on their maximum power output determined from an incremental cycling test (PRI:  $392.0 \pm 46.2$ , CON:  $397.8 \pm 41.2$ ;  $p=0.75$ ). In a randomised order and separated by 3 to 7 days all participants performed 4 self-paced TTs. TTs consisted of two long (20 km & 30 min) and two short (4 km & 6 min) trials. Heart rate (HR) and rating of perceived exertion (RPE) were collected every 10% and power output averaged every 10% of each trial. Distance/duration covered was the only feedback provided. Results: No significant differences between motivation types were observed in Pmean, total time and/or total distance duration in either the short ( $p>0.72$ ) or long TTs ( $p>0.81$ ). No significant difference was found in HRmean and RPEmean ( $p>0.07$ ). Compared with CON, power output of PRI was significantly lower upon commencement of both short TTs ( $p<0.02$ ) and the 20 km TT ( $p=0.01$ ; first 10% of each trial). No significant difference in pacing was found between groups in the 30 min TT ( $p=0.95$ ). Discussion: External motivation in the form of a financial reward does not affect overall performance of trained cyclists performing in short and long time trials. Nonetheless, it seems that cyclists pace themselves in a more conservative manner when competing for a reward, which is in contrast to existing theories assuming a more aggressive pace when external motivation is high (Hulleman et al., 2007). The change in pace might be related to decreased internal motivation resulting in lower effort at the start of the trials. #### THE INFLUENCE OF A MILD THERMAL CHALLENGE AND SEVERE HYPOXIA ON SERUM BDNF.

Tonoli, C., van Cutsem, J.1, Pattyn, N.1, Vissenaeken, D.3, Dhondt, G.3, De Pauw, K.1, Meeusen, R.1,4, Roelands, B.1,5

1VUB (Brussels, Belgium), 2: UL (Lille, France), 3Military Hospital Queen Astrid, (Brussels, Belgium), 4James Cook University, (Queensland, Australia) 5 FWO (Belgium).

Introduction A thermal challenge deteriorates not only exercise performance, but also cognitive performance. One of the key neurotrophins involved in exercise-induced long-term potentiation, growth, and survival of new neurons, is Brain-Derived Neurotrophic Factor (BDNF). BDNF inhibits cell apoptosis and promotes repair processes and is therefore an important mediator for maintaining homeostasis. Levels of BDNF show consistent increases due to exercise in ambient temperatures of  $\pm 18^\circ\text{C}$  in humans and animals [1], mainly through an increased release from the brain [2]. However, very few studies looked at the combined effects of altitude and environmental temperature-induced stress on the serum levels of BDNF. The purpose of the present study was to examine the effects of different environmental stressors on levels of BDNF. Methods Nine trained male athletes (Age:  $23 \pm 3$ y; Wmax:  $333 \pm 45$ W) completed 4 experimental trials (CON:  $15^\circ\text{C}/0\text{m}$ , ALT:  $15^\circ\text{C}/3800\text{m}$ , TEMP:  $25^\circ\text{C}/0\text{m}$ , ALT+TEMP:  $25^\circ\text{C}/3800\text{m}$ ) in a double blind, randomized, cross-over design. Subjects cycled for 30min, starting at  $75\%W_{\text{max}}$ . Blood samples were collected to determine the level of serum BDNF pre and post exercise. Statistical analysis were performed using a two-way (temperature x altitude) repeated measures analysis of variance (ANOVA). Differences were considered significant when  $p<0.05$  was achieved. Results There were no interaction effects between time, altitude and temperature for BDNF ( $P>0.30$ ). We did observe a significant main effect of time ( $P=0.005$ ; Fig. 4b). BDNF concentration was greater post exercise ( $26.5 \pm 10.9\text{ng/mL}$ ) compared to pre exercise ( $21.8 \pm 8.4\text{ng/mL}$ ) in all conditions. Discussion Both acute exercise and a thermal challenge have already been observed to increase BDNF concentrations [1,3]. The current study, however, was the first to examine the effect of acute altitude exposure on BDNF. We observed that 90min in a hypoxic condition did not change BDNF concentration. In line with previous literature, exercise significantly increased BDNF in the present study. Yet, contradictory to the findings of Goekint et al. [3] we did not observe a significantly higher increase in BDNF by adding a thermal stressor. In the present study, a smaller magnitude of thermal stressor was used ( $25^\circ\text{C}$  vs  $30^\circ\text{C}$ ), what might explain the smaller response of BDNF. ### PHYSICAL EXERCISE ACTIVATES THE MU-OPIOID SYSTEM IN HUMAN BRAIN

Saanijoki, T., Tuominen, L., Nummenmaa, L., Arponen, E., Kalliokoski, K., Hirvonen, J.

*University of Turku*

**Objectives:** Physical endurance exercise reduces stress and anxiety, elevates mood, and relieves pain, but the underlying neurobiological mechanisms responsible for these beneficial psychophysical effects remain largely unknown. The central opioidergic mechanisms likely modulate these effects and play an important role in exercise-induced euphoria ("runner's high") [1]. In this study, we sought to the opioid hypothesis of exercise-induced euphoria by measuring mu-opioid receptor availability in vivo in healthy males twice, before and after aerobic exercise. **Methods:** Eleven recreationally active healthy men (age:  $25 \pm 4$  years, BMI:  $22.8 \pm 1.2$ ,  $VO_{2max}$ :  $50.1 \pm 6.3$  mL/kg/min) were studied with positron emission tomography (PET) and a bolus injection of [ $^{11}C$ ]carfentanil. Participants underwent two consecutive [ $^{11}C$ ]carfentanil PET scans in random order: after rest and after 60 min of aerobic endurance cycling, on separate days. Cycling was performed at a workload between aerobic and anaerobic thresholds ( $154 \pm 41W$ ) predetermined individually in maximal oxygen uptake test. Voxel-wise mu-opioid receptor availability was quantified with simplified reference tissue model using occipital cortex as the reference region, and statistical parametric mapping was used to compare availability maps between the two conditions. **Results:** Acute exercise increased the availability of mu-opioid receptors in anterior cingulate cortex, prefrontal and temporal cortex (cluster-level FDR-corrected  $p$ -value  $< 0.05$ ). ROI analysis indicated that exercise increased mu-opioid receptor availability 7-10% in these regions. **Conclusion:** This study provides preliminary evidence that acute exercise modulates the brain mu-opioid system in recreationally active men. Activation of the brain mu-opioids may be responsible for various beneficial psychophysical effects of physical exercise. Individual differences in these mechanisms may reveal why some people enjoy physical exercise more than others, and may therefore have important public health implications. **Research support:** Academy of Finland, Sigrid Juselius Foundation, Turku Collegium of Science and Medicine, Turku University Hospital (EVO) **References:** [1] Boecker, H et al. *Cereb Cortex* 2008, 18:2523-253

### VISUAL ACUITY AND CONTRAST SENSITIVITY ARE NOT AFFECTED BY HYPOXIC CONDITIONS IN SHORT-TERM AND LONG-TERM ACCLIMATIZED HIKERS

Krusche, T., Krause, S., Fisch, M., Jendrusch, G., Platen, P.

*Ruhr-Universität Bochum*

Department of Sports Medicine and Sports Nutrition, Faculty of Sports Science, Ruhr-Universität Bochum, Germany **Introduction** Morphological and functional changes of the visual system, e.g. a reduction of color discrimination or altered retinal blood flow, have been shown during hypoxic conditions (Grimm et al., 2012). Central (static) visual performance is an essential basic requirement for optimal visual perception and acting in sport (Schnell, 1999). Movement control and balance regulation require central and peripheral visual information. In the context of modern mountaineering these skills are obligatory. But it is unclear so far in which way hypoxic exposure has an effect on visual acuity (VA) and contrast sensitivity (CS). The aim of the study was to analyze VA and CS during hypobaric hypoxic conditions in short-term and long-term acclimatized healthy young hikers. **Methods** 10 eye-healthy moderately trained students (male:  $n=8$ , female:  $n=2$ ;  $23.0 \pm 2.9$  years; refraction error s.c.  $< 1.6$  dpt) were investigated during and 3 months after (d+90: 156 m) a 9-day Mt. Kilimanjaro ascent (d1-d9; sleeping level: 890-3995 m, total height 5895 m). We measured VA and CS with the help of a computer-based Landolt- and Sine Wave Contrast-test as developed by Bach (1996) on a high definition notebook in a light-impermeable tent. VA and CS were analyzed on days 1 and 9 (d1/d9: 890 m), day 3 (d3: 3829 m) and day 6 (d6: 4530 m). In addition, morning oxygen saturation ( $mSaO_2$ ) and Lake Louise score (LL) were determined. **Results** VA and CS remained constant during altitude on d3 and d6 compared to d1/d9/d+90 ( $p > 0.05$ ) (mean  $\pm$  SD: d1, d3, d6, d9, d+90); VA:  $1.85 \pm 0.57 / -0.43$ ,  $1.75 \pm 0.60 / -0.45$ ,  $1.88 \pm 1.05 / -0.67$ ,  $1.84 \pm 0.70 / -0.51$ ,  $1.96 \pm 0.85 / -0.59$ ; CS (grating threshold; 15 cpd):  $0.37 \pm 0.11$  %,  $0.47 \pm 0.24$  %,  $0.49 \pm 0.30$  %,  $0.33 \pm 0.02$  %,  $0.45 \pm 0.41$  %, respectively). On d3 and d6 10 % of the subjects were diagnosed with mild acute mountain sickness (LL=4; 90 %  $< 3$ ; =3), and all had  $mSaO_2$  values  $> 89$  % (range=89.4-96.9 %). **Discussion** Our data suggest that hiking in hypobaric hypoxia does not affect VA and CS in short-term and long-term acclimatized healthy young students. However, in the context of prior studies it can be suggested that good acclimatization also benefits visual perception performance at high altitude and reduces the risk of accidents because of vision loss (Willmann et al., 2010). This is in line with studies demonstrating the sensitivity to acute hypoxic stimuli of mainly peripheral and not central vision (e.g. Horng et al., 2008). **References** Bach M (1996). *Optom Vis Sci*, 73(1), 49. ### PHYSICAL AND MENTAL EXERTION REDUCE COGNITIVE PERFORMANCE ON PROFESSIONAL FOOTBALL PLAYERS

Angius, L.

*University of Kent*

**Introduction** Modern football requires periods of high intensity intermittent physical efforts (Stølen T. et al., 2005) and sustained attention to perform optimally. This physical and mental exertion may negatively affect cognitive performance. Recent studies have shown an association between mental fatigue and reductions of both cognitive (Boksem MA, Tops M. 2008) and endurance performance (Mancora S. et al., 2009). Accordingly, the purpose of this field study was to measure the effect of mental and physical exertion on cognitive performance on professional football players. **Methods** In a double-blind, randomized crossover experimental study, 17 male professional football players were recruited. Players underwent a repeated sprint exercise (RSE) consisting in 10 maximal shuttle sprints of 20+20 m interspaced by 20 s of recovery. RSE test was performed after 30 min of demanding cognitive task (Stroop test) in the experimental condition (EXP) or 30 min of non-demanding cognitive task (watching a documentary) in the control condition (CON). Running speed, heart rate (HR) and rating of perceived exertion (RPE) were monitored after each sprint. A 3 min Psychomotor Vigilance Test was performed at rest, after the cognitive tasks, and after RSE test to quantify their effect on cognitive performance (CP). Brain oxygenation level was monitored by near infrared spectroscopy (NIRS) on left prefrontal cortex during RSE. **Results** HR and RPE significantly increased, while running speed decreased over sprints ( $p < 0.05$ ) but there were no significant differences between conditions ( $p > 0.05$ ). CP was significantly reduced in EXP condition after the Stroop task ( $p < 0.05$ ). RSE reduced CP in both conditions ( $p < 0.05$ ) with follow-up tests revealing a significantly lower CP in the EXP condition ( $p < 0.05$ ). No significant differences were found regarding NIRS between conditions ( $p > 0.05$ ). **Discussion** The results of this study suggest that both RSE and prolonged mental exertion negatively affect CP in professional football players. However, mental fatigue does not affect RSE performance. In conclusion, we suggest that in addition to physical training, other strategies should be employed to reduce the cognitive impairment associated with intensive physical and mental exertion commonly encountered within

football matches. References 1 Stølen T. et al (2005) Sports Med. 2005 35:501-36; 2 Boksem MA, Tops M. (2008) Brain Res Rev. 2008 59:125-39; 3 Marcora S. et al (2009) J Appl Physiol. 2009 106:857-64;

### DOES EXERCISE PREFERENCE OR ADAPTATION MATTER FOR THE EFFECT ON BRAIN CORTICAL ACTIVITY?

Abeln, V.1, Klein, T.1,2, Schneider, S.1

(1) German Sport University Cologne, Germany; (2) Faculty of Science, Health, Education and Engineering, University of the Sunshine Coast, Australia

A previous study showed differences between post-exercise brain cortical activities dependent on exercise mode (Brümmer et al. 2011). Because a decrease of brain cortical activity was revealed following running exercise but not bicycling, arm-cranking or isometric strength exercise, it was hypothesized that exercise preference or adaptation might play a role for the post-exercise effect on brain cortical activity. The present study aimed to proof the preference/adaptation hypothesis by testing a group of triathletes, who are adapted to both running and bicycling, but who prefer one of the two exercises. Ten professional triathletes were asked to perform two modes of triathlon (bicycling and running), each at their individual self-chosen intensity under field conditions. Electroencephalography (EEG) was recorded for 3min by 32 surface electrodes under rest conditions before (PRE), directly after (POST=0), 15min (POST15) and 30min (POST30) after exercise. Low-resolution brain electromagnetic tomography (LORETA) was applied to localize and export mean current density values ( $\mu\text{V}2/\text{mm}4$ ) of the frontal, parietal, occipital and temporal lobe. The effect of exercise mode (bicycling, running), time (PRE, POST0, POST15, POST30) and preference (preferred, non-preferred) was calculated by ANOVA. Brain cortical activity decreased following running exercise comparing PRE and POST0, POST15 and POST30 within the frontal ( $p < .001$ ), parietal ( $p < .001$ ), occipital ( $p < .001$ ) and temporal lobe ( $p < .001$ ). No differences were found for bicycling exercise. No effect of exercise mode but an interaction of time and mode has been found for all regions of interest (frontal  $p = .012$ , occipital  $p = .048$ , parietal  $p < .001$ , temporal  $p = .005$ ). PRE measurements of running and bicycling exercise did not differ ( $p > .27$ ). Comparing the trials of the preferred with non-preferred mode revealed no difference for all regions of interest (frontal  $p = .943$ , occipital  $p = .438$ , parietal  $p = .987$ , temporal  $p = .664$ ). The previously shown effect of exercise mode could be confirmed. This study shows that brain cortical activation state after exercise is not adaptation dependent. The hypothesized effect of exercise preference was disproven on the basis of the present group of triathlon athletes. Further studies using athletes with one concrete exercise preference should be used for verification. It is suggested that brain cortical activity after running exercise decreases due to the characteristics of running exercise.

### OP-BN12 Musculoskeletal & Fatigue

#### PREDICTIVE MUSCULOSKELETAL SIMULATION OF UPHILL AND DOWNHILL RUNNING

Dorschky, E., van den Bogert, A.J., Schlarb, H., Eskofier, B.M.

Friedrich-Alexander University Erlangen-Nuremberg

**Introduction** Predicting human responses to environmental changes is necessary for biomechanical analysis and sports product design. If case studies, environmental conditions or prototypes cannot be realized, modeling and simulation can be used instead. The aim of this work was to evaluate a method of predictive musculoskeletal simulation (van den Bogert et al., 2012) for uphill and downhill running. The predicted energy costs for running at different slopes were compared to literature (Minetti et al., 2002). **Methods** The 2D model consisted of seven body segments: trunk, thigh, shank and foot in each leg. In the model, 16 Hill-type muscles and passive joint structures generated joints moments. Slopes in the range of  $-30^\circ$  to  $30^\circ$  were modeled. A case study was simulated with 20 "subjects" by randomly changing the muscle parameters. The predictive simulation was formulated as an optimal control problem: The objective function consisted of a tracking and an effort term. The constraints were given by the implicit formulation of musculoskeletal dynamics and the periodic forward movement. The resulting optimal control problem was solved for each "subject" independently by using IPOPT (<http://www.coin-or.org>). **Results** The metabolic power was estimated from the average power done by the modeled muscle fibers based on Margaria, 1968. As a result, the metabolic energy costs (MEC) were obtained by dividing the metabolic power by the "subject's" mass and the forward speed. Its mean and standard deviation over all "subjects" in [J/kg/m] for the slopes  $-30^\circ:5^\circ:30^\circ$  were  $6.59 \pm 1.88$ ,  $5.66 \pm 2.34$ ,  $4.81 \pm 1.06$ ,  $4.68 \pm 0.88$ ,  $4.56 \pm 0.70$ ,  $4.88 \pm 0.60$ ,  $5.85 \pm 0.54$ ,  $8.30 \pm 0.86$ ,  $12.01 \pm 1.12$ ,  $15.73 \pm 2.05$ ,  $19.32 \pm 2.20$ ,  $23.04 \pm 2.95$ ,  $26.88 \pm 4.10$ . For uphill running, the mean MEC was increasing directly proportional to the slope. The optimal downhill slope and the increase of the MEC for uphill running were in agreement with literature (Minetti et al., 2002). **Discussion** For further evaluation, the estimation of the MEC from the mechanical power should be avoided. Future work should consider muscle models that include equations to directly calculate the MEC (e.g. Umberger et al., 2003). **References** Margaria, R. (1968). *Int Z Angew Physiol*, 25(4), 339-351. #### SEASONAL VARIATIONS IN SKIING ECONOMY IN ELITE CROSS-COUNTRY SKIERS ARE ASSOCIATED WITH CHANGES IN SKIING TECHNIQUE

Myklebust, H., Losnegard, T., Hallén, J.

Norwegian school of sport sciences

**Introduction** Oxygen cost (O<sub>2</sub>-cost) is associated with athletes' performance level in cross-sectional studies of cross-country (XC) skiers (e.g. Sandbakk et al., 2010). Further, reduced O<sub>2</sub>-cost during the season was associated with improvement of performance during treadmill ski skating (Losnegard et al., 2013). The aim of this study was to determine how seasonal variations in technical factors was related to changes in O<sub>2</sub>-cost and 1000 meter time-trail performance (1000-m time) in elite XC-skiers. **Methods** Eleven male elite XC-skiers (all top 30 in the Norwegian Championship) performed submaximal and maximal tests on a roller ski treadmill in June, August, October, and January. Pole and hip acceleration was assessed by 3D-accelerometers for determination of cycle characteristics and total hip accelerations (root-mean square (RMS) of resultant acceleration) during treadmill V2 ski-skating at a high load ( $6^\circ$ , 3.5 m/s, oxygen

demand 74-76 ml/(kg•min)). Log-transformed changes from individual mean values were used for Pearson's correlations between technique parameters and sub-maximal O<sub>2</sub>-cost and 1000-m time. Results Changes in O<sub>2</sub>-cost was highly associated with changes in CT ( $r = -0.71$ ) and CT changes were highly associated with changes in RMS hip acceleration during the gliding phase (phase between leg kick and pole thrust) ( $r = -0.80$ ). Further, changes in hip acceleration during the gliding phase were highly associated with changes in 1000-m time ( $r = 0.64$ ) and oxygen cost ( $r = 0.63$ ). Discussion As shown previously (Losnegard et al., 2013), improvement in performance (1000-m time) is associated with change in exercise economy (O<sub>2</sub>-cost). Here we show that changed O<sub>2</sub>-cost is highly associated with hip acceleration, especially during the gliding phase. The findings indicate that better balance during the unsupported ski gliding phase is important for improving O<sub>2</sub>-cost and performance in elite cross-country skiers. References Losnegard T et al. (2013). Seasonal variations in VO<sub>2</sub>-max, O<sub>2</sub>-cost, O<sub>2</sub>-deficit, and performance in elite cross-country skiers. *J Strength Cond Res*, 27(7), 1780-1790. Sandbakk Ø et al. (2010). ## CHARACTERISTICS OF MUSCLE AND TENDON MECHANICAL PROPERTIES FOR SPURTERS AND SWIMMERS

Kunimasa, Y.1, Sano, K.1, Makino, A.1, Akiyama, M.1, Ito, A.1, Komi, P.V.2, Ishikawa, M.1

1: Osaka University of Health and Sport Sciences (Japan), 2: NMRC and Likes Research Center, University of Jyväskylä (Finland)

Introduction The regulation of joint stiffness can play important roles for sport activities. On land, for example, the sprint runners can utilize high impact force to utilize elastic energy during contact of running. Specific muscle-tendon interaction have been examined during human running and jumping (e.g. Ishikawa & Komi 2008). In swimming, however, the stress of Achilles tendon (AT) is low and the joint flexibility is very high for swimmers. With these different impact stress conditions, their muscle-tendon properties of triceps surae muscles may be adapted to their specific sport environments. Therefore, the purpose of this study was to examine the muscle architectures and mechanical properties of triceps surae for sprinters and swimmers. Methods Forty-eight young male subjects (21.1±2.8 yr, 1.72±0.05 m, 65.8±5.5 kg) including the twenty-one sprint runners (SPRT), the seventeen swimmers (SWIM), and the ten healthy control subjects without any competitive sport experiences (CTRL) were participated in this study. To stretch plantar flexor muscles passively, their ankle joint were dorsiflexed from 20 degree plantar flexion (-20°) to 10 degree dorsiflexion (+10°) at the seated position with the knee straight on a dynamometer. To measure the AT stiffness, the isometric maximal voluntary plantar flexion contraction (MVC) at 0 degree of ankle joint (0°) was performed. Changes of passive and active plantar flexor joint torque (PFTQ) as well as the fascicle length (L<sub>Fa</sub>), pennation angle and tendinous tissue length (L<sub>TT</sub>) of medial gastrocnemius muscle (MG) and AT length (LAT) by ultrasonography were measured during passive stretching and MVC. Results/ Discussion The passive PFTQ did not show any significant differences between groups. However, the elongations of the muscle and tendon parts in the passive PFTQ measurements were different between groups. In the passive PFTQ measurements, the stiffness of AT did not show any significant differences. However, the stiffness of the MG fascicles and tendinous tissues were significantly greater in SPRT than in SWIM. The MG L<sub>Fa</sub> and L<sub>TT</sub> stretching were significantly greater in SWIM than in SPRT. In the active MVC measurement, the AT stiffness and Young's modulus were significantly greater in SPRT than in SWIM and CTRL. From morphological parameter, the MG L<sub>Fa</sub> was significantly longer in SWIM than in SPRT and CTRL. These results suggested that stiff AT and muscle in SPRT may play important roles for high ankle joint stiffness during sprint running and that longer MG L<sub>Fa</sub> and compliant muscle in SWIM may play important roles for kicking movements during swimming. ## EMG ACTIVITY OF THE LOWER LIMB MUSCLES DURING SPRINT CYCLING AT MAXIMAL CADENCE

Rudsits, B.L., Rouffet, D.M.

Victoria University

Introduction Performances produced during exercises of maximal intensity strongly influence our ability to maximally activate those muscles contributing to the movement. When the movement frequency of maximal exercises is increased, the time window available for activating and deactivating the muscles becomes narrower. According to results of a simulation study, activation-deactivation dynamics could limit sprint cycling performance when cadences increase above optimal cadence (1). The aim of this study was to investigate activation and deactivation of the lower limb muscles during sprint cycling at maximal cadence. Methods Twelve physically active males performed a torque-velocity test and a maximal sprint against no external resistance on a stationary cycle ergometer. Surface EMG (Noraxon, US) was measured from six muscles [gluteus maximus (GMAX), rectus femoris, vastus lateralis (VAS), semitendinosus and biceps femoris, medial gastrocnemius, tibialis anterior]. Normalized peakEMG, minEMG and activation duration (in % of pedalling cycle duration) were calculated for all muscles at two cadences: optimal cadence (C<sub>opt</sub>) and maximal cadence (C<sub>max</sub>). Finally a co-activation index (2) was also computed for two pairs of contralateral muscles (GMAX and VAS) at C<sub>opt</sub> and C<sub>max</sub>. One-way ANOVAs with repeated measures were performed to analyse the effect of cadence on the various EMG variables. Results A reduction in peakEMG (88 ± 16% vs. 74 ± 21%, P<0.05), an increase in minEMG (3 ± 2% vs. 5 ± 4%, P<0.05) and an increase in activation duration (64 ± 13% vs. 75 ± 11%, P<0.05) of the lower limb muscles was observed from C<sub>opt</sub> to C<sub>max</sub>. Co-activation indexes increased for both GMAX (5 ± 3% vs. 17 ± 9%, P<0.05) and VAS (3 ± 2% vs. 7 ± 3%, P<0.05) muscle pairs from C<sub>opt</sub> to C<sub>max</sub>. Participants' C<sub>max</sub> was 218 ± 17 rpm and C<sub>opt</sub> 124 ± 8 rpm. Discussion The EMG results indicate a reduction in the maximal level of activation of the muscles combined with a reduction in their level of relaxation at maximal cadence. In addition, the relative duration of activation of the muscles was increased, leading to a rise in the co-activation of contralateral power producer muscles that probably caused an augmentation of the negative work produced during the pedaling cycle (3). Finally, larger standard deviation values were seen at C<sub>max</sub> compared to C<sub>opt</sub>, indicating greater inter-individual differences in the ability of subjects to perform at high movement frequencies. ## POST-ACTIVATION POTENTIATION DURING AN ISOMETRIC TRAINING SESSION: CONTRIBUTION OF PERIPHERAL AND CENTRAL MECHANISMS

Xenofondos, A.1, Patikas, D.2, Vrabas, I.S.2, Bassa, E.1, Hatzikotoulas, K.1, Kotzamanidis, C.1

1:AUTH (Thessaloniki, Greece), 2:AUTH (Serres, Greece)

Introduction Various hypotheses have been investigated in the past to explain the increment of twitch torque after a conditioning contraction, the so called post-activation potentiation (PAP). Recent research highlights the need for recurring activations to optimize the PAP

effect (Froyd, Beltrami, Jensen, & Noakes, 2013). However, there is a lack of literature in the topic of examining peripheral (muscular) and central (neural) factors using a series of isometric maximum voluntary contractions (iMVC), as assessed during an isometric training protocol. Methods Fourteen professional handball male players were tested on twitch torque, H reflex and Mmax of the med. gastrocnemius and soleus muscles. An isometric maximum protocol was applied, which was consisted of 4x6 iMVC plantar flexions of 6s duration, with 15s and 2min interval between the repetitions and sets, respectively. Baseline measurements were assessed after warm-up for 5 minutes before the beginning of the isometric session. Twitch torque and Mmax were captured every 30s while H reflex, every 10 sec during a 5% iMVC contraction. Data were captured with stimulation pattern during the baseline measurements, and 2s after the end of each MVC and during the whole rest interval between each repetition and set, starting with a supramaximal stimulation evoking the twitch torque and Mmax. The best repetition in peak twitch torque within each set was determined and analyzed using ANOVA, with  $\alpha$  set at 0.05. Results Twitch torque for all sets, was significantly greater ( $p < 0.05$ ) compared to the baseline values, with a significant decline ( $p < 0.05$ ) during the 3rd and 4th set compared to the 1st set. Mmax decreased significantly in a similar pattern in both plantar flexor muscles ( $p < 0.05$ ), while there was an increase ( $p < 0.05$ ) in gastrocnemius muscle during the 1st set compared to the baseline values. The H/Mmax ratio of both muscles did not change significantly during the whole experiment ( $p > 0.05$ ). Discussion The results of the current study demonstrate quantitatively the co-existence of PAP and peripheral fatigue. The contribution of central mechanisms in terms of reflex excitability assessed with H-reflex technique was not verified which is in agreement with previous findings using a single iMVC (Xenofondos et al., 2014). It is concluded that peripheral fatigue and changes in the excitation-contraction coupling during and after an isometric training session should be taken into account to optimize performance and the outcome of training protocols. ### ACTIVATION OF 5HT1A RECEPTORS: A PLAUSIBLE CONTRIBUTOR TO CENTRAL FATIGUE?

D'Amico, J.M., Butler, A.A., Butler, J.E., Gandevia, S.C., Taylor, J.L.

*Neuroscience Research Australia*

Introduction: Human performance is limited by central fatigue. During maximal isometric efforts, there is intense descending drive to the motoneurons but motoneuronal output decreases over time. In the adult turtle spinal cord, intense descending drive results in serotonin spillover to the axon initial segment of the motoneurons which activates inhibitory 5HT1A receptors and inhibits action potential generation (1). This has been proposed to contribute to central fatigue. We examined whether activation of 5HT1A receptors can depress motoneurone excitability in humans by examining the effects of a 5HT1A receptor partial agonist, buspirone, on F-waves and cervicomedullary motor evoked potentials (CMEPs). Methods: Participants ( $n=10$ , 4F) attended two experimental sessions where either placebo or a 20mg dose of buspirone was administered orally. Investigators and participants were blinded and the order of drug delivery was randomized. The ulnar nerve was stimulated supramaximally to evoke F-waves in abductor digiti minimi (ADM). Electrical cervicomedullary stimulation elicited CMEPs of ~10-20% of the maximal M-wave (Mmax) in biceps brachii and Mmax was elicited by brachial plexus stimulation. Measurement blocks consisted of 60 F-waves, 5 CMEPs and 2 biceps Mmax. These measurements were repeated 3 times at 10-min intervals prior to pill intake, and every 10 min from 25 to 105 min after pill intake. F-wave and CMEP areas were normalized to Mmax and averaged for each measurement block. F-wave persistence was also measured. Post-drug measurements of F-wave and CMEP areas were normalized to baseline values. Two-way repeated measures ANOVAs were performed for statistical analysis. Results: ADM F-waves were different between treatment conditions with F-wave area  $98 \pm 10\%$  of baseline after placebo and  $69 \pm 12\%$  of baseline after buspirone (mean  $\pm 95\%$  CI,  $p < 0.01$ ). ADM F-wave persistence also decreased after buspirone intake (placebo:  $91 \pm 5\%$  vs. buspirone:  $81 \pm 8\%$ ,  $p < 0.05$ ). Biceps CMEPs after buspirone were also smaller when compared to those after placebo (placebo:  $92 \pm 32\%$  vs. buspirone:  $60 \pm 17\%$ ,  $p < 0.05$ ). ADM and biceps maximal M-waves were unchanged. Conclusion: Activation of 5HT1A receptors with buspirone decreases motoneurone excitability as measured by F-waves and CMEPs. Moreover, F-waves are decreased immediately following sustained maximal contractions in the hand and leg (2). Taken together these results show that activation of 5HT1A receptors through serotonin spillover during voluntary contractions is a plausible contributor to central fatigue. #### SPORT INJURIES IN SCHOOL PE AND IN LEISURE TIME. A STUDY AMONG ADOLESCENTS IN SWEDEN, GERMANY, NEW ZEALAND AND IN THE US.

Sollerhed, A.C.1, Horn, A.2, Culpan, I.3, Lynch, J.4

1. Kristianstad University, Sweden. 2. Hochschule, Schwäbisch Gmünd, Germany. 3. University of Canterbury, New Zealand. 4. Florida Southern College, USA

Introduction Sport is a large contributing factor to injury among young people. At school most injuries occur during PE (Abernethy & MacAuley, 2003). Sports injuries are highly disadvantageous for students (Van Beijsterveldt et al, 2014) and cause disruption to school and sport. Injuries can lead to physical discomfort, physical inactivity and unnecessary absence from school. Methods A questionnaire including items about self-reported sport participation in leisure time and PE, injuries in leisure time and PE was used among 1011 teenagers aged 15-16 years in Sweden, Germany, New Zealand and in the US. The chi squared test was used, carried out by PASW. Results In total 66% of the students ( $n=1011$ ) reported injuries in leisure time sport and 55 % reported in the school PE. No differences were found among boys and girls, nor in leisure time or school PE. Active students reported injuries to a higher extent, both in leisure time and in school PE. 24 % reported severe injuries from leisure time sport that led to continuous trouble. Students who participated in leisure time sports participated in school PE more frequently than non-sporting students (86 % vs 66 %;  $p=0.000$ ). Students who didn't participate in PE (18%;  $n= 1011$ ) were injured as much as those who always participated in PE. Discussion School PE is not risk free and accounts for a significant

part of all injuries in children and adolescents (Abernethy & MacAuley, 2003). However, all sport injuries among children don't occur in the PE setting. In this study it was shown that a higher prevalence of injuries occurred in leisure time sport than in school PE. Students who were active in leisure time were also active in the school PE, and there might be a transfer effect from unhealed injuries caused in leisure time to the activity in PE. New injuries also occurred in the school setting so PE is not free from incidents. An interesting finding was that students who didn't participate frequently in PE reported injuries in PE to the same extent as students who always participated in PE. This might show that students who participate never or seldom in PE are more inactive in leisure time and are unaccustomed to exercise and might be more fragile and vulnerable for injuries in the PE setting. The active students are more prone to renew old injuries or get new ones when they are active often and to a high extent. References Abernethy, A, MacAuley, D. (2003). ### THE VALIDITY AND FEASIBILITY OF AN ATHLETIC SKILLS TRACK AMONG 6- TO 12-YEAR-OLD CHILDREN

Hoeboer, J.J.A.A.M., De Vries, S.I., Krijger-Hombergen, M., Wormhoudt, R., Savelsbergh, G.J.P.

*The Hague University of Applied Sciences*

**Introduction** In order to investigate the relationship between children's motor skills and people's physical activity level on the long term (Lloyd et al., 2014), valid assessment tools are needed. The purpose of this study was to examine the feasibility and validity of a new tool: an Athletic Skills Track (AST) to assess fundamental movement skills among 6- to 12-year-old children in a physical education (PE) setting. **Methods** During a PE lesson 463 Dutch children (211 girls, 252 boys; 6-12 years old) completed three tests: the Körperkoordination-Test für Kinder (KTK) (Vandorpe et al., 2011) and two Athletic Skill Tracks (AST-1, AST-2). AST-1 includes manipulative and locomotive skills. AST-2 contains locomotive skills. The validity of AST-1 and AST-2 was examined by correlating the time needed to complete the tracks and the KTK Motor Quotient (MQ) in seven age groups. Differences between boys and girls and between age groups were tested using One-way ANOVA. **Results** The average time to complete AST-1 was  $44 \pm 11$  seconds and  $45 \pm 12$  seconds for AST-2. Overall, there was a moderate correlation between AST-1 and the KTK MQ ( $r = -0.474$  ( $p = 0.01$ )) and a strong correlation between AST-2 and the KTK MQ ( $r = -0.502$  ( $p = 0.01$ )). In general, the correlation coefficients were higher when split up for gender; except the correlation between AST-2 and the KTK MQ for girls ( $r = -0.448$ ). The associations between the Athletic Skill Tracks and the KTK MQ were strongest for 12-year old children (AST-1:  $r = -0.767$ ; AST-2:  $r = -0.727$ ) and weakest for 8-year olds (AST-1:  $r = -0.501$ ; AST-2:  $r = -0.469$ ). **Discussion** The results suggest that children's motor skills can be assessed with a quick, convenient, and low-cost motor competence test in a PE setting. The Athletic Skill Tracks are more valid than most existing assessment tools (Cools et al., 2009) and provide an indication of the fundamental movement skills of children aged 6-12 years. ### USING DRAWING AS A GATEWAY TO UNDERSTANDING CHILDREN'S BODILY LEARNING

Suominen, L., Moe, V.F., Engelsrud, G.

*Sogn og Fjordane University College*

**Introduction** We study children's bodily learning as a part of the ASK-intervention study (Active Smarter Kids). Bodily learning is central to the ASK study, and also a timely topic for Physical Education (PE) research and policy. Because of increasing societal pressure related to fitness, health and achievement, it is important to ask what and how children learn about their bodies and movement capacities, and how this knowledge might impact their developing identities **Methods** We presume that bodily learning encompasses more than children are able to express verbally and as well as more than researchers are able to observe. Thus we have chosen to use drawings as a research tool complementary to interview and observation. We ask how drawing may be used to examine children's lived realities and to stimulate interviews. We asked children to draw something they like very much in PE and something else that they like less. We also asked them to write a short explanation of their drawings. Drawings were analyzed and later used in interviews both to stimulate the subject and as a source for themes **Results** Children expressed that they like different activities for varying reasons. Mirroring normative and cultural expressions of physical activity (PA), the words fun and boring were repeatedly associated with activity, task mastery, playing together with others vs getting exhausted and not mastering the task. A few children said that they liked to express themselves, create their own world or help others. Further focus group and individual interviews with children exposed these submerging themes, and taught us more about how children had interpreted the drawing task. In some cases, the children's drawings illustrated meaningful, lived experiences of PA/PE, while with some other children a similarly complex expression was only drawn out in the interview portion of the research **Discussion** Combining drawing with interviews and observation helped us to form a broader perspective on bodily learning, thus proving it an applicable method in studying this phenomenon. It became clear that drawings need to be interpreted in their cultural and situational context. Also, different methods may be necessary to help different children to reflect on meaningful, lived experiences, and the nature of the knowledge produced needs to be discussed References Azzarito, L (2010). ### STUDY OF THE PE TEACHERS' CONFLICT MANAGEMENT STRATEGIES

Németh, Zs.

*University of Pécs, Institute of Sport Science and Physical Education*

**Introduction** The physical education teachers are faced with a lot of conflicts during their work. This is natural, because interpersonal relationships already contain the conflicts (Coleman et al., 2014). If these conflicts get on surface, PE teachers try to solve them in a variety of ways. In my opinion, the quality of the management of conflicts is strongly influenced by the teaching-learning process efficiency, so we need a deeper analysis of the most common conflicts. **Methods** I made 16 interviews with physical education teachers of different

ages and different types of schools. Among the participants there were men and women who were at the beginning, the middle and the end of their career of physical education teaching. The questions referred to the different types of physical education classes and the most common places, causes and conflict-resolving methods during different competitions. Results The consequence of their interviews was that conflict management strategies were influenced the best by the situations, the students communication style, the type of physical education and age characteristics of the age groups. Such exercises should be differentially planned for the skill-developing lessons during the implementation of which all participants can achieve experience of success (Shimon, 2011). Physical education teachers need to create an atmosphere that reduces the probability of conflicts to the minimum. The personal exemplary of physical education teachers may improve the situation. Discussion The aim of my lecture is to call attention to the factors which can influence the PE teachers' attitude in teaching-learning process efficiency. By this research I would like to help my PE teacher colleagues to develop effective conflict management. References Shimon, Jane (2011): Introduction to Teaching Physical Education. ## **TALENT PRODUCTION IN INTERACTION - USING PERFORMANCE APPRAISAL INTERVIEWS IN TALENT SELECTION CAMPS**

Kilger, M.1, Jonsson, R.2

*Faculty of Social science*

Introduction In sport, the practice of identifying young talents has become increasingly important as sports for decades are far more than a leisure activity for children; it is a potential professional career (McGarry, 2010). Therefore, Sport Associations need to construct sustainable systems for talent identification in order to legitimize child selection (Helle-Valle, 2008). Critics of the selection attempts are not lacking, however; both the low accuracy of the sample as well as the social costs associated with the activity, has been critically discussed (Anshell & Lidor, 2010; Peterson, 2011). One obvious difficulty is the need to, not only evaluate an individual's current ability, but also her ability to develop and make progress in the future. Therefore, different types of performance appraisal interviews (henceforth, PAI) are becoming increasingly common (MacLean, 2001). The interview has been regarded as a tool for mapping the interviewee's performances and development and what is said is considered to say something important about the child's attitudes or characteristics. Data and Methods Departing from fieldwork in two selection camps for the youth national teams and district teams in ice-hockey and soccer, we will take a closer look at the PAIs, as it is employed during these camps. The empirical material is based on 26 individual PAIs, between the coach and the young participants. This paper takes on a narrative approach, emphasizing PAI as a narrative genre with its own particular characteristics, which sets the framework for a specific form of interaction (Bamberg, 2006). Results and Discussion The material display how eligibility is performed in interaction through different kinds of practices or acts of balance. One practice deals with balancing between praising the camp and the coaches without turning into flattery. Another practice deals with balancing between current deficiencies and possible progression, in order to appear as a 'subject under development' and therefore be perceived as selectable. This paper tells us a lot about PAI as genre, but also the discursive production of talent and eligibility in sports. References Anshell, MH, Lidor, R. (2012). ## **URBAN LIVING ENVIRONMENTS AND CHILDREN'S PHYSICAL ACTIVITY. RESULTS OF A PILOT STUDY.**

Knechtl, S., Giess-Stueber, P.

*University of Freiburg, Institute of Sport Science*

Introduction Urban spaces are an important determinant of physical activity and behavior. Space is not solely a physical-material container; it is generated, confirmed, and changed by cultural, social, and individual action and design (Löw, 2008). In the appropriation of space, children's social life situation, corporeality, subjective, situation-related interests, and the structures of society play a major role. Thus, urban social spaces enable the experience of places, PA, and encounters with the unknown (Graumann, 2002) as well as promoting active and healthy lifestyles. The pilot study focused on method development for the research on the connection of urban space and children's PA (Spatscheck & Wolf-Ostermann, 2009). Methods The needle-method (Deinet, 2009) was modified and conducted at three German schools (n=31, 16♀/15♂; 10-15ys). Participants specified individually frequented or avoided locations on a city map by marking them with colored needles (according to gender, places, homes). The comments and conversations were recorded, transliterated, analyzed and combined with the marked locations. Results Results show differences between gender and age in mobility and PA. Boys mostly quoted PA as their leisure time activity, while girls were scarcely physically active. Former marked places in broader distances, whereas girls mostly marked their homes. The majority commuted to school via public transport, only a few travelled to school actively. Also, a number of statements were given concerning avoided and scary spaces, hampering PA. Discussion The findings confirm and differentiate established assumptions on the utilization of public space in gender research. The applied method proves to enable the identification of children's habits, preferences and also phobia regarding the utilization of urban space. Next, objective data (e.g. collection of area maps/GIS) and subjective data (e.g. cognitive maps, observations, interviews) will be gathered and intermingled.

**10:20 - 11:50****Invited symposia****IS-PM12 THE IMPACT OF PHYSICAL ACTIVITY ON CARDIOVASCULAR FUNCTION IN LIFESTYLE RELATED DISEASE \*****PHYSICAL ACTIVITY AND CARDIOVASCULAR DISEASE IN YOUNG PEOPLE: CAN CVD BE PREVENTED IN HIGH RISK POPULATIONS?**

Green, D.J.

*The University of Western Australia*

Rapid increases in the prevalence of obesity, type 2 diabetes, inactivity and sedentary behaviour in young people may limit future gains in the fight against cardiovascular disease, the major causes of mortality, morbidity and healthcare costs in the Western world.<sup>1</sup> Currently, 50% of adults who die suddenly from heart disease have no prior symptoms and 70% of coronary events occur as a result of culprit lesions that are angiographically undetectable.<sup>2</sup> Approaches to detection (angiography, stress testing) focus on ischaemia, not atherosclerosis, a disease of the vessel wall that only occasionally encroaches on the lumen.<sup>3</sup> Whilst these facts emphasise the importance of early prevention, and recent studies suggest that 80% of heart attacks may be preventable,<sup>4</sup> research focusing on optimal approaches to prevention remains a cardiovascular "blind-spot".<sup>5</sup> The evidence-base to establish early intervention targets for the prevention of future cardiovascular disease is not well established and the relative importance of the fetal environment, in relation to risk factor exposure during childhood and adolescence, is unclear. This symposium report will review the evidence for atherosclerosis as an important, if nascent, disease of young people, developmental studies of the antecedents factors that place adults at high risk and evidence regarding the mitigating impact of exercise interventions on macro and microvascular function and health in high risk children and adolescents. **THE INFLUENCE OF PHYSICAL ACTIVITY ON VASCULAR FUNCTION IN LIFESTYLE RELATED DISEASE**

Hellsten, Y.

*University of Copenhagen*

Life style related diseases, such as essential hypertension and Type II diabetes, are associated with impaired vascular function as evidenced by a poor vasodilator response to mechanical and chemical stimuli. Poor vascular control in skeletal muscle can result in an inadequate oxygen supply, limiting the ability to conduct daily activities, but has also implications for total peripheral vascular resistance and increases in blood pressure. Regular physical activity is well known to improve vascular function in several organs including skeletal muscle and to effectively reduce blood pressure. Both exercise of moderate and high intensity have been shown to be effective in this regard. This talk addresses the effect of physical activity interventions on changes in vascular function and the regulation of vascular tone and discusses the functional and cellular changes that occur in the vasculature with regular physical activity. An important factor in the regulation of vascular tone is the balance between, on one hand, vasoconstricting sympathetic activity and circulating vasoconstrictors such as endothelin-1, and, on the other hand, locally formed vasodilators, e.g. nitric oxide (NO) and prostacyclin. Evidence suggest that one of the beneficial effects of exercise training is an enhanced capacity to form vasodilators and a reduced presence of vasoconstrictors, leading to an improvement in the vasodilator to vasoconstrictor balance.

**FUNCTIONAL SYMPATHOLYSIS AS A CAUSE OF REDUCED SKELETAL MUSCLE BLOOD FLOW IN CARDIOVASCULAR DISEASE AND THE ROLE OF PHYSICAL ACTIVITY**

Mortensen, S.

*University of Southern Denmark*

Skeletal muscle can modulate sympathetic vasoconstrictor activity (functional sympatholysis) in young, healthy individuals. This mechanism is thought to play an important role in securing that O<sub>2</sub> delivery is sufficient to match the metabolic demand and is likely to be mediated by locally released substances that modulate the effect of noradrenaline on the alpha adrenergic-receptor. Several cardiovascular disease states are characterized by increased levels of sympathetic vasoconstrictor activity as well as impaired O<sub>2</sub> delivery leading to a reduced tissue function and early fatigue, but the role of functional sympatholysis in this malperfusion remains largely unexplored. Sedentary individuals with essential hypertension have impaired functional sympatholysis. The ability to induce functional sympatholysis is tightly coupled to the training status of the skeletal muscle and exercise training improves functional sympatholysis in individuals with essential hypertension, whereas inactivity impairs functional sympatholysis. Improving functional sympatholysis by exercise training could therefore be important to normalize skeletal muscle perfusion and function.

## Invited symposia

### IS-PM01 SPORTS NUTRITION EXCHANGE: ADVANCES IN THE APPLICATION OF SCIENCE IN THE SPORTING ENVIRONMENT sponsored by GSSI

#### TRANSLATING SUBSTRATE METABOLISM SCIENCE AND APPLYING IT IN THE ELITE SPORTING ENVIRONMENT

Spriet, L.L.

*University of Guelph*

Our current understanding of substrate metabolism has been driven by whole body and organ specific studies in a variety of animal models, including the human being. The most precise information on the capacity and regulation of energy provision in skeletal muscle via substrate and oxidative phosphorylation comes from invasive experiments during exercise. In the human, these are normally performed on recreationally active or sub-elite individuals and not on elite athletes. However, we use this information to guide training and competition nutritional strategies. The assumption is that most elite athletes have maximized their training, nutritional and rest strategies and adaptations in preparation for competition. The storage and delivery of fuel are maximized, the capacities and rates of metabolic energy pathways are maximized, the recovery of these systems between bouts of exercise are maximized and best performances are achieved. However, in elite athletes this is not enough and for many sports or athletic endeavours, it is clear that the human body is not optimally designed to achieve greater performances. So, we experiment further - does increasing oxygen provision increase oxidative energy provision and performance, does training with low carbohydrate or following a high fat diet lead to greater adaptations, can we augment substrate phosphorylation through creatine supplementation and enhanced buffering, does amino acid consumption enhance muscle function, does consuming nitrates reduce the cost of performance, do novel nutritional and training techniques increase muscle mass gain, etc.? Information gained from non-elite athletes can be applied to elite athletes without invasive measures and disruption to training, but positive findings in recreationally trained subjects and sub-elite athletes are not always seen in elite athletes.

#### NEW LESSONS IN THE REGULATION OF FAT METABOLISM AND IMPLICATIONS FOR ATHLETES.

Kiens, B.

*University of Copenhagen*

Lipids serve several important functions in the organism like structural components of cell membranes, in cellular signaling, and represent the largest storage pool for energy. The contribution of lipids to the total energy utilized during exercise is dependent on a variety of factors including exercise duration and intensity. The maximal contribution of lipids as energy substrate is reached at approximately 60-65% of maximal oxygen uptake. Furthermore, the use of FA for energy gradually increases during prolonged exercise when exercise lasts for more than 1-1½ h. It is also worth noticing that a higher FA oxidation is often observed in endurance trained females during prolonged exercise at moderate exercise intensities (60-65%) than in well matched male subjects. This is likely due to the on average higher percentage of type I muscle fibres and higher capillarization in females than males. How lipid oxidation is regulated during exercise is still under debate. Several possibilities have been proposed. The transport across the plasma membrane and thus the lipid binding proteins located in the membrane has been discussed playing a role in regulation of FA oxidation. CD36 is one of the plasma-membrane bound proteins, which might play a role in lipid handling during exercise. When CD36 is deleted in mice, the contraction induced increase in lipid uptake into the muscle, is absent. Also when AMPK, a fuel sensor, is lacking, CD36 protein content is decreased and so is the fatty acid uptake and oxidation. Together this indicates that transport of fatty acids into the muscle cell during exercise, when fuel for energy is needed, is an important step in fatty acid oxidation, though it might not be rate limiting. Rather, regulation around the mitochondria seems to be the more important step. Many athletes are concerned with either attaining or maintaining an optimal body weight and body composition for their sport. This leads to efforts to reduce body fat without losing muscle mass. A ketogenic diet has been proposed for athletes as a weight loss strategy without impairing strength and performance. A ketogenic diet comprises a fairly high protein intake, a very low carbohydrate intake and a large amount of fat. It is evident from the literature that an increased fat availability transfers into higher rates of both whole-body and muscle lipid utilization during standardized submaximal aerobic exercise. However, even in the face of substantially greater rates of fat oxidation, these dietary protocols consistently fail to improve endurance exercise capacity and/or performance outcomes compared with when consuming a carbohydrate-rich diet. With regard to the effect of a KD on strength performance, our knowledge is limited.

#### NOVEL REGULATORY MECHANISMS IN THE REGULATION OF GLUCOSE METABOLISM AND POTENTIAL INNOVATIVE NUTRITION STRATEGIES FOR ATHLETES.

Richter, E.A.

*University of Copenhagen*

During exercise, muscle utilizes glucose taken up from the blood. The molecular mechanisms responsible involve several signalling pathways including AMP activated protein kinase (AMPK) and the GTPase Rac1 (1-3). Endurance training leads to higher muscle cell content of the glucose transporter GLUT4, but at the same absolute submaximal exercise intensity, trained individuals display lower muscle glucose uptake than untrained. Yet, at high exercise intensities, trained subjects utilize their greater GLUT4 muscle content and display higher muscle glucose uptake than untrained individuals. Rac1 is an important regulator of exercise-induced muscle glucose uptake by regulating GLUT4 translocation to the cell membrane. It is also known, that stretch of muscles increases muscle glucose uptake, and we have recently shown that stretch-induced muscle glucose uptake is partly dependent upon Rac1. Since muscle glucose uptake is important for glycogen resynthesis following exercise, a translational perspective from this finding is that stretching of muscles may enhance post-exercise glycogen resynthesis. Still, in the post-exercise period, muscle glycogen resynthesis is enhanced primarily due to increased sensitivity to insulin due to combined increased insulin signalling in the muscles and increased microvascular flow. ### OP-PM07 Carbohydrate and Performance

#### CARBOHYDRATE DEPENDENCE DURING HALF-MARATHON RUNNING

Leckey, J.J.1, Burke, L.B.1,2, Morton, J.P.3, Hawley, J.A.1,3

1: Australian Catholic University, 2: Australian Institute of Sport, 3: Liverpool John Moores University

**Introduction** Many athletes and coaches steadfastly believe that fat plays an important role while training for and competing in endurance events and that training and/or nutritional strategies that “spare” carbohydrate-based fuels and enhance the oxidation of fat-based fuels will improve exercise capacity. However, few studies have investigated substrate utilisation during prolonged, intense exercise. This study tested the hypothesis that carbohydrate is the major fuel source during prolonged intense running. We also determined the effect of suppressing lipolysis on rates of whole-body substrate utilisation and performance in well-trained individuals during simulated half-marathon races. **Method** Six (of 12) well-trained male runners ( $\text{VO}_2\text{max}$   $63.9 \pm 4.6$  mL/kg/min, personal best half-marathon  $80.13 \pm 5.10$  min) completed 4 experimental trials using a single-blinded Latin square design. Subjects ran to volitional fatigue on a motorised treadmill at a speed of 95% of individual best half-marathon (21.1 km) time attained in the last 6 months, and a gradient of 1%. The 4 experimental conditions were a carbohydrate breakfast (CHO), a carbohydrate breakfast plus Nicotinic acid (CHO+NA), an overnight fast (FAST), an overnight fast plus Nicotinic acid (FAST+NA). Carbohydrate gels (44 g/h) were provided during the CHO and CHO+NA trials. **Results** There was no effect of diet or NA ingestion between conditions for distance covered (CHO  $21.82 \pm 1.40$ , CHO+NA  $21.51 \pm 2.25$ , FAST  $20.77 \pm 2.56$ , FAST+NA  $20.13 \pm 1.09$  km). Total rates of carbohydrate oxidation were unaffected by diet or NA (CHO  $323.80 \pm 26.05$ , CHO+NA  $332.2 \pm 25.09$ , FAST  $313 \pm 18.54$ , FAST+NA  $330.32 \pm 31.45$   $\mu\text{mol/kg/min}$ ). Carbohydrate was the primary fuel source for oxidative metabolism, contributing 81-87% to total energy expenditure. No significant difference for diet or NA was reported for heart rate, rate of perceived exertion or loss in body mass between the 4 performance trials. **Discussion** During prolonged, intense running (~80%  $\text{VO}_2\text{max}$ ) carbohydrate was the major fuel source for oxidative metabolism regardless of pre-exercise carbohydrate or fat availability. When carbohydrate availability is high, reducing free fatty acid availability was not detrimental to intense running performance. **Contact:** jill.leckey@acu.edu.au

#### A TWO WEEK LOW GLYCEMIC INDEX DIET AFFECTS METABOLIC PARAMETERS OF SPORT STUDENTS AT REST AND DURING EXERCISE WITHOUT AFFECTING ENDURANCE PERFORMANCE

Oertzen-Hagemann, V., Fisch, M., Eibl, A., Platen, P.

Ruhr-Universität Bochum

The glycemic index (GI) is an intensively discussed topic in sports nutrition, however the effects of single high glycemic index (HGI) or low glycemic index (LGI) meals on metabolic or performance outcomes are still controversially discussed. Regarding single pre-exercise meals, LGI food has been postulated to enhance endurance capacity because of a higher fat oxidation rate and thus reducing carbohydrate (CHO) storage decline during exercise. Long term LGI diets are an important issue in health related studies with patients, but no study compared the more chronic effects of a HGI or LGI diet in athletes so far. **Aim** of the present study was to investigate the combined effects of a two week diet with CHO of either LGI or HGI and a single LGI test meal on endurance capacity and metabolic parameters 90 min after the LGI test meal. 19 young and healthy sport students (14 male and 5 female; age:  $25.8 \pm 3.2$  years; body mass:  $73.1 \pm 11.8$  kg; height:  $178.0 \pm 8.5$  cm;  $\text{VO}_2\text{max}$ :  $52.3 \pm 6.4$  mL $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ ) completed four trial days separated by at least two weeks wash-out in a randomized crossover design, one on the day before and one on the last day of 14 days LGI and HGI intervention, respectively. Based on the information of a four day food diary, the two different dietary schedules were calculated for each subject by exchanging specific foods from their normal diet resulting in either HGI diet with a  $\text{GI} > 70$ , or LGI diet with a  $\text{GI} < 50$ , respectively. The mean GI was calculated for each meal. The trial days started with a venous blood sampling followed by an identical LGI test meal containing 2 g CHO per kg body weight ( $\text{GI} = 40$ ) after an overnight fast (12 h). 90 min postprandial (PP) the participants ran 60 min at 65%  $\text{VO}_2\text{max}$  and subsequently at 95%  $\text{VO}_2\text{max}$  until exhaustion. Body weight was lower after the LGI- compared to the HGI-intervention (LGI:  $72.8 \pm 12.3$  kg, HGI:  $74.0 \pm 12.5$  kg,  $p < 0.05$ ). PP rest and exercise respiratory quotients became lower in LGI- compared to HGI-intervention (PP: LGI:  $0.85 \pm 0.05$ , HGI:  $0.88 \pm 0.04$ ; exercise: LGI:  $0.89 \pm 0.02$ , HGI:  $0.91 \pm 0.03$ ,  $p < 0.05$ ). Triglyceride values were lower after LGI compared to HGI (LGI:  $0.85 \pm 0.30$  mmol/L, HGI:  $1.09 \pm 0.50$  mmol/L,  $p < 0.05$ ). Blood lactate rest values were lower in LGI compared to HGI after ingestion of the test meal ( $p < 0.05$ ) without any differences during exercise. Endurance capacity and parameters of glucose metabolism remained unaffected. To summarize, a two week LGI diet in combination with a single LGI test meal reduced body weight and triglycerides and caused a shift from CHO to fat oxidation at rest and during exercise without effects on glucose metabolism or performance.

#### CARBOHYDRATE SUPPLEMENTATION DOES NOT IMPROVE A 10 KM SWIM PERFORMANCE

Baldassarre, R., Piacentini, M.F., Patrizio, F., Nicolò, A., Scotto di Palumbo, A., Sacchetti, M.

University of Rome Foro Italico

**Introduction** For exercise lasting more than 2h, it is well established that carbohydrate (CHO) ingestion during exercise can improve exercise performance by preventing hypoglycemia, maintaining high rates of CHO oxidation and therefore increasing endurance capacity (Jeukendrup 2014). While most research focused on running and cycling, there is a lack of studies focusing on open water endurance swimming. Therefore, the aim of the present study was to evaluate the effects of the ingestion 60 g $\cdot$ h $^{-1}$  of carbohydrates on a 10km swim performance. Moreover, the present study represents the first attempt to monitor glycemia continuously during an endurance swimming event. **Methods** Ten elite open-water swimmers (6 male and 4 female;  $22 \pm 5$  yrs,  $1.76 \pm 0.05$  m,  $70.5 \pm 7$  kg) volunteered for the present study. In two difference occasions in a random order, they were asked to perform a 10km swim (20x500m) in a 25m indoor pool, ingesting every 2.5km either water (WAT) or a solution of water and 60 g $\cdot$ h $^{-1}$  of CHO. Every 1000m athletes had to rate their perceived exertion (RPE) on the 6-20 scale. Glycemia was monitored throughout the test with continuous glucose monitoring (CGM) (iPro 2, Medtronic). A two-way ANOVA was used to analyze the effect of trial on parameter time course ( $p < 0.05$ ). **Results** Performance was not different between the two trials (1:54:26 $\pm$ 0:04:09 h:m:sec CHO; 1:54:27 $\pm$ 0:04:26 h:m:sec WAT). RPE increased significantly throughout both trials, with no differences between CHO or WAT. No signs of hypoglycemia were found during the WAT trial. Glycemia increased the last 3km of the CHO trial (107.5 $\pm$ 7.7; 113.0 $\pm$ 7.0; 118.7 $\pm$ 9.1 mg $\cdot$ dl $^{-1}$ ) and was significantly higher compared to the same time points in the WAT trial (101.4 $\pm$ 11.4;

104.3±12.5; 105.8±13.8 mg.dl<sup>-1</sup>). Discussion Open water events longer than 5-km may be considered glycogen depleting (Costill et al. 1988). However, supplementation with 60 g.h<sup>-1</sup> of CHO did not increase a simulated 10 km swimming performance or influence RPE in elite swimmers. Although this represents the first analysis in continuum of glycemia in elite endurance swimmers, which suggests that 10km swimming at a racing pace does not lead to hypoglycemia, the need and/or effectiveness of CHO supplementation on endurance performance in open water should be further explored. References Jeukendrup A. (2014). *Sports Medicine*, 44(Suppl 1):S25–S33 Costill et al 1988. *J. Swimming Research*. 4, 15–18

### THE ACTIVATION OF ADENOSINE RECEPTORS INHIBITED CAFFEINE-AFFECTED EXERCISE PERFORMANCE, THERMOREGULATION AND BRAIN NEUROTRANSMISSION

Zheng, X., Hasegawa, H.

*Hiroshima University*

**Introduction** Caffeine (CAF) is widely consumed to improve exercise performance. However, this mechanism remains elusive. Recently, we reported that CAF improved endurance exercise performance, overrode the critical level of core body temperature (T<sub>core</sub>), and increased extracellular dopamine (DA) release in the preoptic area and anterior hypothalamus (PO/AH) in exercising rats (Zheng et al., 2014). We also found that blockage of dopaminergic pathways inhibited CAF-affected exercise performance, hyperthermia and DA release in the PO/AH (Zheng & Hasegawa, 2014). However, it's difficult to conclude that CAF-improved exercise performance is due to blockage of brain adenosine receptors. The purpose of this study was to examine the effects of an adenosine receptor agonist on CAF-affected thermoregulation, neurotransmitter release, and endurance exercise performance. **Methods** T<sub>core</sub>, tail skin temperature (T<sub>tail</sub>: an index of heat loss), oxygen consumption (VO<sub>2</sub>: an index of heat production), DA, noradrenaline (NA) and serotonin (5-HT) were measured. One hour before the start of exercise, rats were intraperitoneally injected with either saline, 10 mg/kg of CAF, a non-selected adenosine receptor agonist NECA (0.5 mg/kg) or the combination of CAF and NECA. Rats ran until fatigue on the treadmill with a 5% grade at a speed of 18 m min<sup>-1</sup> at 23°C. **Results** The run time to fatigue (RTTF) was significantly increased by the administration of CAF and decreased by the injection of NECA (SAL: 91 ± 14 min; CAF: 130 ± 23 min; NECA: 31 ± 14 min; CAF+NECA: 87 ± 16 min, p < 0.05). In addition, injection of CAF inhibited NECA-induced decrease in RTTF, T<sub>core</sub>, VO<sub>2</sub>, T<sub>tail</sub>, and extracellular DA release. Neither CAF nor NECA affected extracellular NA or 5-HT release. **Discussion** Consistent with Davis et al. (2003), we observed that NECA inhibited CAF-increased RTTF in the present study. Moreover, it has been shown that decreased brain DA release inhibits both improved exercise performance and overridden the critical T<sub>core</sub> caused by CAF (Zheng & Hasegawa, 2014). In the present study, we observed that NECA inhibited CAF-increased DA release in the PO/AH, and overridden the critical T<sub>core</sub>. One possible mechanism of CAF's ergogenic effect is CAF blocks increased adenosine receptors, increases DA release in the PO/AH, improves heat tolerance and overrides the critical level of T<sub>core</sub>. Our results elaborate on both the improved endurance performance and the overridden body limitation caused by CAF are reliable, and the ergogenic effects of CAF may be due to blockage of adenosine receptors increased brain DA release. ### THE EFFECT OF AN 8-DAY CYCLING TOUR ON PERFORMANCE, HEART RATE AND POMS IN 30 RECREATIONAL CYCLISTS

ten Haaf, T.1, Meeusen, R.2,3, Foster, C.1,4, Roelands, B.2,5, Piacentini, M.F.2,6, van Staveren, S.7, Van Bruaene, N.8, de Koning, J.J.1,4

**INTRODUCTION** Between 10-35% of athletes face at least one episode of non-functional overreaching (NFOR) or the overtraining syndrome (OTS) throughout their career. Athletes with NFOR/OTS often suffer from psychological and physical symptoms, which only rest can restore. Therefore, the prevention and early diagnosis of NFOR/OTS is of utmost importance. A multistage cycling tour such as Tour for Life (TfL; an 8-day fundraising bicycle tour, 1264 km with 18.550 altitude meters) provides an excellent, ecological, experimental model to study intensified training possibly leading to NFOR/OTS. Participants are well-trained cyclists but unfamiliar with this magnitude of exercise. The aim of this part of the study is to monitor the effect of an 8-day cycling tour on performance, maximal heart rate and Profile of Mood State (POMS). **METHODS** 30 recreational cyclists (19 male; 11 female) with an average age of 41y, BMI of 23.6 kg/m<sup>2</sup>, and self-reported training volume in preparation for the TfL of 190 km per week (range 75-300 km) were included in the study. The TfL was on average a 7-fold increase of the training volume. Peak power output (W) and maximal heart rate (bpm) were measured in a double exercise test before, immediately after, and 5 weeks after the TfL. Additionally, subjects filled in a POMS questionnaire before, during and after the TfL. **RESULTS** On group level the participants performed significantly (p<.01) worse on the post-TfL exercise test (320±57 W) than pre-TfL (308±60 W). Only 6 subjects performed better after the TfL than at baseline. Also, maximal heart rate was significantly (p=.02) lower after the TfL (pre: 181±10 bpm, post: 176±11 bpm). Analysis of the POMS questionnaire revealed that fatigue increased more during (72%) than after (44%) the TfL compared with baseline. Tension decreased during (-26%) and after (-32%) TfL, while anger increased during (21%) the TfL and returned to baseline values after the event. **DISCUSSION** In this study we were able to demonstrate decreased performance and maximal heart rate, and alterations in mood states after the TfL. However, it is important to note that these results are all on group level. Further analyses will focus on the individual response of the participants on the cycling event. Moreover, other measurements performed in this study (e.g. physiological, biochemical, immunological, psychological) will be studied together and related to the individual performance changes. **CONTACT** tpg.ten.haaf@vu.nl

### INGESTION OF GLUCOSE OR SUCROSE DURING PROLONGED ENDURANCE TYPE EXERCISE PREVENTS A DECLINE IN LIVER BUT NOT MUSCLE GLYCOGEN CONCENTRATION

Gonzalez, J.T.1, Fuchs, C.J.2, Smith, F.E.3, Thelwall, P.E.3, Stevenson, E.J.4, Trenell, M.I.3, van Loon, L.J.C.2

1: University of Bath (UK), 2: Maastricht University Medical Centre+ (The Netherlands), 3: Newcastle University (UK), 4: Northumbria University (UK).

**Introduction** Carbohydrate (CHO) ingestion during prolonged exercise enhances performance, increases CHO oxidation and may spare muscle glycogen stores (Cermak and van Loon, 2013). Few data are available on the impact of CHO ingestion on liver glycogen stores. When trying to maximize CHO availability during exercise, it may be preferred to ingest a combination of different carbohydrate sources

eg. glucose (GLU) and fructose. As sucrose (SUC) provides both glucose and fructose, we hypothesize that sucrose ingestion during exercise may allow greater carbohydrate uptake, resulting in greater sparing of liver and/or muscle glycogen stores when compared to the ingestion of glucose only. Methods Fourteen cyclists ( $VO_{2peak}$ :  $58 \pm 1$  mL/kg/min) completed two 3-h bouts of cycling at 50%  $W_{max}$  while ingesting either GLU or SUC at a rate of 1.7 g/min. Four cyclists ( $VO_{2peak}$ :  $60 \pm 3$  mL/kg/min) performed a third test in which only water was consumed for reference. We used  $^{13}C$  magnetic resonance spectroscopy to determine liver and muscle glycogen concentrations before and after exercise. Expired breath was sampled during exercise to estimate whole-body substrate use. All data are means  $\pm$  SEM. Pre- vs post-exercise liver and muscle glycogen concentrations in the water trial were compared by paired *t* tests. Liver and muscle glycogen concentrations in the GLU and SUC treatments were assessed by two-way (treatment  $\times$  time), repeated measures ANOVA with treatment (GLU vs SUC) and time (pre- vs post-exercise) as within-subject factors. Results Both liver (from  $454 \pm 17$  to  $283 \pm 41$  mmol/L;  $P < 0.05$ ) and muscle (from  $111 \pm 23$  to  $67 \pm 15$  mmol/L;  $P < 0.01$ ) glycogen concentrations declined during exercise when only water was ingested. Following GLU and SUC ingestion, liver glycogen levels did not show a significant decline following exercise (from  $325 \pm 45$  to  $345 \pm 55$  mmol/L and from  $321 \pm 47$  to  $348 \pm 56$  mmol/L, respectively;  $P > 0.05$ ) with no differences between treatments. Muscle glycogen concentrations declined (from  $101 \pm 11$  to  $60 \pm 9$  mmol/L and from  $114 \pm 13$  to  $67 \pm 9$  mmol/L, respectively;  $P < 0.05$ ), with no differences between treatments. Whole-body CHO utilization was greater with SUC ( $2.03 \pm 0.11$  g/min) vs GLU ( $1.66 \pm 0.10$  g/min;  $P < 0.05$ ). Discussion Ingestion of glucose or sucrose (1.7 g/min) during prolonged exercise prevents a decline in liver but not muscle glycogen concentrations. Sucrose ingestion during prolonged exercise does not lead to greater sparing of endogenous muscle or liver glycogen stores when compared to glucose ingestion. ### OP-PM04 Adaptation and Movement Analysis

#### SPRINT INTERVAL TRAINING OF ARMS AND LEGS ELEVATES PEAK VO<sub>2</sub> AND IMPROVES ARM EXERCISE ECONOMY

Zinner, C.1,2, Willis, S.J.1, Morales-Alamo, D.3, Larsen, F.J.5, Schiffer, T.A.5, Boushel, R.4, Ørtenblad, N.1,6, Calbet, J.A.3, Holmberg, H.C.1

1: Swedish Winter Sports Research Centre, Department of Health Sciences, Mid Sweden University, Östersund, Sweden 2: Department of Sport Science, Julius Maximilians University Würzburg, Germany

1: Swedish Winter Sports Research Centre, Department of Health Sciences, Mid Sweden University, Östersund, Sweden 2: Department of Sport Science, Julius Maximilians University Würzburg, Germany 3: Department of Physical Education, University of Las Palmas de Gran Canaria, Spain 4: Swedish School of Sport and Health Sciences, Stockholm, Sweden 5: Department of Physiology and Pharmacology, Karolinska Institute, Stockholm, Sweden 6: Institute of Sports Science and Clinical Biomechanics, SDU Muscle Research Cluster, University of Southern Denmark, Odense, Denmark Introduction Interval cycle sprint training (SIT) has been shown to improve anaerobic capacity,  $VO_{2max}$  and biomarkers of muscle oxidative capacity in as little as 2 weeks in previously untrained adults. The present study was designed to characterize and compare systemic  $VO_2$  and exercise performance after SIT engaging the arms and legs. Methods Sixteen healthy, untrained men ( $23.9 \pm 3.7$  yrs;  $183.8 \pm 6.8$  cm;  $80.3 \pm 14.1$  kg) performed six sessions of 4-6x30 sec all-out sprints with the legs then arms (or vice versa) separated by a 1-h recovery over an 11-day period. Limb-specific  $VO_{2peak}$ , anaerobic capacity (2x30-sec Wingate tests with 4 min of recovery), a 4-min submaximal work economy test, and a 5-min all-out time trial (TT) were conducted before and after the training program. Muscle biopsies (from the m. vastus lateralis and m. triceps brachii) were taken before and after the training period. Results  $VO_{2peak}$  increased by 10.6% and 5.9% with arm and leg training, respectively ( $p < 0.05$ ), with the increase in the arms significantly greater than in the legs ( $p = 0.02$ ). Work economy was improved for the arms (-9.8%,  $p < 0.05$ ), but not for the legs (-0.9%). Mean power during the TT rose by 13.5% for the arms and 11.8% for the legs ( $p < 0.05$ ). Peak power output and mean power during the two Wingate tests were elevated in both the arms (PPO: 6.7% ( $p < 0.01$ ) and 13.3% ( $p < 0.01$ ); MPO: 6.1% ( $p < 0.01$ ) and 8.4% ( $p < 0.01$ )) and legs (PPO: 3.1% ( $p = 0.07$ ) and 7.1% ( $p = 0.02$ ); MPO: 3.3% ( $p < 0.01$ ) and 5.6% ( $p < 0.01$ )). The activity of 3-hydroxyacyl-CoA dehydrogenase (HAD) and levels of muscle glycogen were unchanged in both limbs. Discussion Sprint interval training with arm or leg cycling exercise increased peak pulmonary  $VO_2$  during their respective modes over an 11-day training period with a greater increase in the arms. Sprint performance rose to a similar extent in both extremities, yet work economy was improved only in the arms. These findings suggest some limb-specific responsiveness to SIT training. #### INDIVIDUAL RESPONSES TO A NOVEL EXERCISE INTERVENTION IN OLDER ADULTS WITH MULTIMORBIDITY: A PILOT RANDOMISED CONTROLLED TRIAL

Taylor, K.L.1, Hurst, C.1, Batterham, A.M.1, Prentis, J.M.2, Snowden, C.P.2,3

1 Teesside University (Middlesbrough, UK). 2 Department of Perioperative & Critical Care Medicine, Freeman Hospital (Newcastle upon Tyne, UK). 3 Newcastle University (Newcastle upon Tyne, UK).

Introduction Individual differences in the response to exercise training are important, though quantification attempts are rare and often deficient (Hopkins, 2015). We aim to quantify mean and individual responses of older adults with multimorbidity to a novel exercise intervention. Methods 15 adults (14 male;  $71.8 \pm 6.2$  y [mean  $\pm$  standard deviation, SD]) with multimorbidity were randomised to intervention ( $n = 7$ ) and control ( $n = 8$ ). The intervention was four sets of 4-min high-intensity exercise with 3-min rest between, thrice-weekly for six weeks. Exercises (squat, clean/press, step-up/press) were performed on a double-concentric device. Outcomes were anaerobic threshold (AT) and peak oxygen uptake ( $VO_{2peak}$ ). Using a linear mixed model with a random effect allowing extra variance in the change scores in the intervention group, we calculated the probability that the true population effect was  $>$  the minimum clinically important difference (MCID, 1.5 mL.kg.min<sup>-1</sup> and 2 mL.kg.min<sup>-1</sup> for AT and  $VO_{2peak}$ , respectively). The model was adjusted for baseline value of the outcome and age. We derived the SD for individual differences in response to the intervention (vs control). We calculated the likely range for the true response (free from noise) in each subject in the intervention group using the SD of the change in the controls, and obtained the probability that the subject was a true responder (improvement  $>$  MCID) (Hopkins, 2015). This novel method identifies responders by accounting for variability in the change scores in the control group rather than inappropriately using the change scores from the intervention group alone. Results A likely beneficial increase for AT of 3.2 mL.kg.min<sup>-1</sup> (90% confidence interval -0.1 to 6.5 mL.kg.min<sup>-1</sup>), and a possibly beneficial increase for  $VO_{2peak}$  of 3.2 mL.kg.min<sup>-1</sup> (-0.1 to 6.5 mL.kg.min<sup>-1</sup>) was observed in the intervention group compared to

controls. The SD of the individual responses was very large for AT (3.8 ml.kg.min<sup>-1</sup> [-1.7 to 5.7 ml.kg.min<sup>-1</sup>]), and large for VO<sub>2</sub>peak (2.9 ml.kg.min<sup>-1</sup> [-2.6 to 4.8 ml.kg.min<sup>-1</sup>]). For AT, two subjects were almost certainly responders, two were likely, one was possibly, and two were probably not. For VO<sub>2</sub>peak, one subject almost certainly responded, two likely, three possibly and one probably not. Discussion Six weeks of high-intensity exercise induces likely-possible improvements in AT and VO<sub>2</sub>peak in older adults with multimorbidity, with apparently substantial individual responses. A definitive trial is required to confirm and explain these effects. References Hopkins, WG (2015). *J Appl Physiol*, In press.

### **DISCRIMINANT MUSCULO-SKELETAL LEG CHARACTERISTICS BETWEEN ELITE CAUCASIAN SPRINT AND ENDURANCE RUNNERS.**

Bex, T., Aerts, P., De Clercq, D., Derave, W.

*University Ghent*

**Aim** The question whether a runner is more suited for sprint vs. endurance disciplines and whether he/she has the talent to reach national or even international top level, depends in part on the musculo-skeletal characteristics of the legs. The main limiting factor for sprinting is power generation, which is directly related to muscle volume and fascicle length. On the other hand, endurance running requires excellent running economy, which is in part negatively influenced by inertia of the legs during swing phase (Weyand & Davis, 2005). This study aims to directly compare the physiological and functional anatomical characteristics of the leg of male sprinters and endurance runners of Caucasian ethnicity in order to discover the largest discriminants. **Methods** Eight male sprinters (60m - 200m) and 11 male endurance runners (3000m – 5000m) volunteered to participate in this cross-sectional study. Personal best performances ranged between 6.95 and 7.07 sec for 60m or 10.68 and 10.99 sec for 100m in sprinters and 7.54 and 8.53 min for 3000m or 13.32 and 14.55 min for 5000m in endurance runners. They underwent magnetic resonance imaging (MRI) from the iliac crest to the calcaneus. After data collection, the MR images were transferred to 3D slicer for digital reconstruction to calculate muscle volumes and bone lengths. Ultrasonography was used to determine muscle architecture (pennation angle and fascicle length). **Results** Sprinters have a higher total upper leg volume compared to endurance runners (7340 vs. 6265 cm<sup>3</sup>, P = 0.020). Specifically, the rectus femoris, vastus lateralis and hamstrings showed significantly higher muscle volumes in the sprint group. For the lower leg, only a higher muscle volume was found in the gastrocnemius lateralis for the sprinters (206 vs. 170 cm<sup>3</sup>, P = 0.017). No differences were found in muscle volume distribution, center of mass in the different muscles, pennation angle or fascicle length, nor relative bone lengths. There was a significant positive correlation between ratio hamstrings/quadriceps volume and best running performance in the sprint group (R = 0.811, P = 0.015). **Conclusions** The main discriminants among the musculo-skeletal leg characteristics between sprinters and endurance runners of the same ethnicity (Caucasian) are situated in muscle volumes, rather than muscle orientation or skeletal measures. Sprinters show higher volumes in mainly the proximal and lateral leg muscles than endurance runners. Our data support the notion that the hamstrings muscles are an important factor in sprint running performance. References Weyand, P. G., & Davis, J. A. (2005). Running performance has a structural basis. *The Journal of Experimental Biology*, 208, 2625–2631.

### **THE EFFECT OF HEAVY RESISTANCE TRAINING ON SKELETAL MUSCLE STRENGTH AND FUNCTION IN VERY OLD INDIVIDUALS**

Bechshøft, R., Malmgaard-Clausen, N., Wøjdemann, E., Bayer, N., Holm, L., Kjær, M.

*Bispebjerg Hospital, Copenhagen, Denmark*

**Background:** The proportion of European citizens aged at least 65 years will increase from 18% in 2013 to around 28% in 2050. The skeletal muscle mass and –strength decrease with up to 2%/yr from the age of 50 and around half of the population above the age of 80 years cannot perform daily activities satisfactorily due to decreased muscle strength. This increases the need for personal care and strategies to keep the elderly self-reliant are demanded. The aim of this study is to investigate the effect of heavy resistance exercise on skeletal muscle strength and mass in very old individuals. **Methods:** 30 subjects aged at least 83 years were randomized to 12 weeks of either heavy resistance training of the lower extremities three times weekly (HRT+PRO) or no exercise (PRO). Both groups were offered two daily nutrient supplementations each containing 1260kJ including 20g of milk protein. Before and after the intervention thigh power, isometric and isokinetic strength were measured. Further, blood samples, thigh MRI scans and m. vastus lateralis biopsies were obtained before and after intervention. **Results:** 28 subjects completed testing and 26 completed interventions as scheduled. Per-protocol analysis (two-way ANOVA with repeated measures) revealed interaction (P<0.05) and post-hoc gain in thigh power (17±5W / 15±8%), isometric (16±6Nm / 13±5%) and isokinetic (11±3Nm / 13±4%) strength in HRT+PRO respectively, whereas the PRO did not change (P=0.68). Rate of force development revealed interaction (P<0.05) and decreased 86±36Nm/s (16±7%) in PRO. Plasma cholesterol decreased (time, P<0.05) 0.7±0.2mM (14±4%). MRI- and biopsy results are pending. **Conclusion:** Heavy resistance training for 12 weeks improves muscle strength and power, and maintains rate of force development. Mixed nutrient supplementation with 20g of dairy protein improves plasma cholesterol. Due to the physical strain caused by the training, subjects' health, expected gain and risk of injuries have to be considered thoroughly before applying a training regime like this in the very old.

### **STRENGTH TRAINING IMPROVES CYCLING PERFORMANCE THROUGH IMPROVED FRACTIONAL UTILIZATION OF VO<sub>2</sub>MAX AND CYCLING ECONOMY**

Vikmoen, O.1, Rønnestad, B.R.1, Ellefsen, S.1, Raastad, T.2

*1. Lillehammer University College 2. Norwegian School of Sport Sciences*

**Introduction** Heavy strength training (HST) of a sufficient volume and lasting 8 weeks or longer have been reported to improve cycling performance in trained cyclists (1,2,3). However, the mechanisms behind improved performance after HST is unclear. The objective of the current study was to investigate the mechanisms behind improved cycling performance after HST. **Methods** Nineteen well-trained female cyclists (33 ± 8 years, 64 ± 7 kg, VO<sub>2</sub>max: 54 ± 3 ml.kg<sup>-1</sup>.min<sup>-1</sup>) were randomly assigned to either normal endurance training only (E, n=8) or normal endurance training combined with HST (E+S, n=11). The HST consisted of lower body exercises [3 x 4-10 repetition maximum (RM)], performed twice a week for 11 weeks. Cycling performance was evaluated as mean power output during a 40 min all-out test. To investigate mechanisms behind changes in performance, 1RM, muscle cross sectional area (CSA), VO<sub>2</sub>max, cycling economy, and fractional utilization of VO<sub>2</sub>max was measured. In addition, muscle biopsies were taken from m. vastus lateralis. **Results** E+S increased 1RM in leg exercises (40 ± 15%, p = 0.0001) and quadriceps femoris CSA (7 ± 5%, p = 0.0004). E+S increased body mass adjusted power output during the 40 min all-out test (6 ± 8%, p = 0.002), cycling economy (4 ± 3%, p = 0.004) and fractional utilization of

VO<sub>2</sub>max (from  $79 \pm 3\%$  to  $82 \pm 4\%$ ,  $p = 0.05$ ). The proportion of type IIX muscle fibers in m. vastus lateralis was reduced in E+S from  $9 \pm 7\%$  to  $0\%$  ( $p = 0.005$ ) with an concomitant increase in type IIA fibers from  $39 \pm 13\%$  to  $51 \pm 10\%$  ( $p = 0.002$ ). The protein content of aerobic enzymes in m. vastus lateralis did not change in E+S. No changes occurred in E. The change in 40 min all-out performance correlated with change in the proportion of IIX fibers ( $r = -0.63$ ,  $p = 0.009$ ) and change in muscle CSA ( $r = 0.73$ ,  $p = 0.0004$ ). Discussion The main finding of this study was that adding HST improved cycling performance because of improved fractional utilization of VO<sub>2</sub>max and cycling economy in well-trained female cyclists. Physiological mechanisms behind these changes seemed to be a fiber type transition from type IIX to pure type IIA fibers and increased muscle CSA. Improved cycling economy and performance is in accordance to earlier studies (1,2,3) using similar HST interventions. This is the first study showing that improved fractional utilization of VO<sub>2</sub>max is one of the main mechanism behind improved performance after HST. Conclusion Based on these results trained cyclist should add HST to their normal training for maximal gains in cycling performance. References 1. Aagaard et al., *SJMSS*, 2011; 21:298-307 2. ## HIGH-INTENSITY MOVEMENTS IN ELITE TEAM HANDBALL: MATCH ANALYSIS

Luteberget, L., Spencer, M.

*Norwegian School of Sport Sciences*

Introduction High intensity movements have typically been recorded at high running velocities, and thereby do not take into account all accelerations or high intensity actions occurring at low speed (Varley & Aughey, 2013). High-intensity micro movements that are present in team handball match play are difficult to quantify using traditionally time motion analysis. This study aims to quantify the positional specific, high-intensity actions in elite women's team handball match play using accelerometers. Methods Player movements were observed from 16 players (backs, pivots, wings, and goal keepers (GK)) during six international matches of the Norwegian women's national team. Tracking devices (Catapult Optimeye S5, Australia) with 100 Hz accelerometer, magnetometer, and gyroscope were used for data collection. The devices were placed in a vest and were located on the upper back of all players. Efforts were measured and categorized into the following categories: acceleration, deceleration, change of direction (CoD), and jump. Efforts were divided into intensity zones of low (1.5 -2.5 m.s<sup>-1</sup>), medium (2.5-3.5 m.s<sup>-1</sup>), and high (> 3.5 m.s<sup>-1</sup>). Differences between positions were deemed likely when there was a likelihood of >75 % of the difference exceeding an effect size of 0.2. Results On average (mean  $\pm$  SD), when intensity zones were combined, team handball players accelerate  $1.6 \pm 0.8$  times per min, decelerate  $2.3 \pm 0.8$  times per min, execute a CoD  $8.9 \pm 3.2$  times per min, and jump  $0.3 \pm 0.2$  times per min in match play. The numbers of efforts performed in all categories were position dependent. Back players had the most accelerations per min ( $2.1 \pm 0.7$ ), which was likely different from wings ( $1.2 \pm 0.1$ ) and GK ( $0.38 \pm 0.1$ ), but not from pivots ( $1.8 \pm 0.3$ ). No differences were found between pivots and backs for decelerations (pivots:  $3.3 \pm 0.9$ , backs;  $3.0 \pm 0.5$ ) and CoD (pivots:  $10.9 \pm 2.6$ , backs:  $10.5 \pm 1.9$ ), but both were very likely to be different from wings (decelerations:  $1.73 \pm 0.3$ , CoD:  $8.51 \pm 1.5$ ) and GK (decelerations:  $0.91 \pm 0.2$ , CoD:  $3.0 \pm 0.4$ ). Back players performed most jumps per min ( $0.38 \pm 0.2$ ), very likely different from wings ( $0.22 \pm 0.1$ ), pivots ( $0.15 \pm 0.1$ ) and GK ( $0.1 \pm 0.1$ ). Discussion A high amount of high intensity actions in match play was shown, which has not previously been reported in team handball. These actions are important to acknowledge when designing training programs for team handball players. Furthermore, there are likely differences between the four different playing positions. Therefore, the positional differences in high-intensity movements should be accounted for when developing specific conditioning drills. References Varley, M., & Aughey, R. ### IS-BN10 LATERALITY IN LOCOMOTION AND SPORT SPONSORED BY ADIDAS

#### INTERLIMB TRANSFER OF LEARNED DYNAMICS

Stein, T.

*Karlsruhe Institute of Technology*

Motor learning is an essential function of the human nervous system that is still not fully understood. In literature, two distinct types of motor learning are discussed: skill learning and motor adaptation. Skill learning (e.g., learning to play tennis) involves the acquisition of new patterns of muscle activations and thereby achieving a higher level of performance (Shmuelof et al., 2012). In motor adaptation, the human motor system responds to new environmental conditions (e.g., the use of a new tennis racket) to regain the former level of performance (Shadmehr et al., 2010). In my talk I will focus on motor adaptation, which is most often studied in laboratory settings. Thereby, subjects most commonly adapt their reaching movements to either kinematic perturbations (visuomotor rotations or prism-induced displacements) or dynamic perturbations (robot-induced forces, rotations of the body or attached inertial loads) (Stockinger et al., 2014). What is typically observed in these adaptation tasks is that subjects' show initially – when exposed to the perturbation – large performance errors. However, subjects' performance improves rapid followed by a slower increase to steady state close to baseline performance (Shadmehr & Mussa-Ivaldi, 1994). Based on these classifications I will focus in my talk on the interlimb transfer of learned dynamics. Interlimb transfer refers to the generalization of motor skills across hands. In studies (e.g. Criscimagna-Hemminger et al., 2003; Wang & Sainburg, 2004; Joiner et al., 2013) on the interlimb transfer of learned dynamics, subjects usually adapt their reaching movements to a dynamic perturbation and are subsequently checked for transfer to the contralateral untrained arm. In my talk I will review and discuss experimental results on the following aspects: (1) the direction of interlimb transfer (e.g., bi- or unidirectional), (2) the coordinate frame of transfer (e.g., extrinsic versus intrinsic) and (3) interlimb transfer and consolidation (e.g., stabilization of the transfer). **LATERALITY IN DAILY LIFE, SPORT AND LOCOMOTION ACTIVITIES**

Schwameder, H., Strutzenberger, G., Alexander, N.

*University of Salzburg*

Motor laterality is defined as a morphological and/or functional preference of one side in motor tasks. The arrangement of the extremities in pairs leads to several and substantial advantages of the human species. This is even more distinct in the morphological characteristics and functional preference of one limb in ability, strength and motor tasks. The laterality expressing this preference is quite differently pronounced between humans and might even differ between motor tasks within one individual. It is well known that in daily life and sport activities individuals show a characteristic of laterality or symmetry. Laterality also has an important function regarding performance, comfort, injury prevention, rehabilitation and equipment design in elite and leisure sport. Specific attention should be paid to the effect of unilateral vs. bilateral motor skills of particular sports on the amount of lateral characteristics and their relation to performance and injury prevention in daily living and sport activities (Loffing, 2014; Stöckel & Vater, 2014; Zago et al., 2014; Furlong & Harrison, 2015; Loffing & Hagemann, 2015). Another important issue is the change of laterality due to accidents with severe morphological or functional effects on single limbs (e.g. fracture, tears of ligaments, muscles or tendons, amputation) or strokes (Gosser & Rice, 2015). One of the key questions in this regard is the detection of the border line from there on the amount of laterality is assessed to be excessive and might cause more or less severe health problems in terms of pain, overloading or unilateral abrasion. Examples will be presented regarding the amount of laterality in daily living activities (level and inclined walking, stair climbing, cycling) and sport activities (running, cycling, jumping, leg extension strength) including the discussion of specific aspects, training issues as well as advantages and disadvantages of laterality with respect to performance, comfort and injury prevention. This will be completed by covering aspects of laterality in amputees and unilaterally injured individuals on the feasibility of locomotion, performance and rehabilitation issues. Another aspect will cover the lateral design and lateral tuning of sport equipment focusing on the adjustment of laterality regarding performance enhancement and injury reduction. **FUNDAMENTALS OF LATERALITY**

Bryden, P.

*Wilfrid Laurier University*

Laterality is generally defined as the preference most humans show for one side of the body over the other. It is expressed as lateral preference to the left or right side and specialization of certain functions, such as language and spatial skills, to the left or right hemisphere of the brain. More specifically, handedness can be defined as the hand one prefers or selects to perform unimanual tasks (Annett, 1970), where individuals usually perform tasks faster and more accurately with this hand (e.g., Roy, Bryden & Cavill, 2003). In a similar fashion, footedness can be defined as the lower limb that an individual prefers to perform various tasks, including balancing, stepping, and kicking, where the selected foot is generally more adept (Peters, 1988). One aspect of lateral preference that has garnered significant attention is the finding that certain tasks provoke stronger preferences than other tasks and that such variability is noted across the lifespan (Scharoun & Bryden, 2014;). Individuals have strong preferences for the hand they use to write, but show weaker preferences for tasks requiring less skill (Steenhuis & Bryden, 1999). Parallel findings have been reported for lower limb preference, where individuals tend to show stronger preferences for mobilizing tasks such as kicking, but weaker preference for which foot is used stabilization tasks (Teixeira & Teixeira, 2008), with the magnitude, or even the existence, of the difference in performance abilities between the feet varying depending on the task (Huurnink et al., 2013). Notably, both the strength of lateral preference and the relative magnitude of performance abilities also vary across the lifespan (Musalek, 2015), for both hands (Gooderham & Bryden, 2013) and feet (Riskowski et al., 2012). The focus of this talk will be to review the methods of measurement of lateral preference and performance, describe the basic findings of laterality across the lifespan with respect to skilled movement, and discuss the possible explanations for why individuals prefer one limb over the other, and why performance differences also depend on task and age. ---

**IS-BN09 RATE OF FORCE DEVELOPMENT: NEW IDEAS ON MEASUREMENT, MECHANISMS AND TRAINABILITY**

---

**EXPLOSIVE MUSCLE STRENGTH: MEASUREMENT AND FUNCTIONAL RELEVANCE**

Folland, J.

*Loughborough University*

The ability to rapidly develop muscular force ("explosive muscle strength") is considered important in a range of functional situations where the time available to develop force is limited. This includes explosive athletic events (e.g. sprinting, punching) and stabilisation of the musculoskeletal system following a mechanical perturbation that could cause injury (e.g. landing, impact or slip). In addition to this logical rationale there is evidence that explosive strength correlates with, and discriminates for, athletic performance and musculoskeletal stabilisation. However, a direct link between explosive strength and the risk of specific sports injuries (e.g. ACL rupture, hamstrings strain) has not been investigated in prospective epidemiological trials. The purpose of the explosive strength measurement (i.e. to track training and performance or assess underlying physiology) influences the choice of task (e.g. single v multiple joint, and muscle group) and the dynamometer utilised. Explosive muscle strength has typically been measured isometrically. Minimising compliance and max-

imising sensitivity, including use of a high sampling rate, are significant considerations. Data collection using specific explosive contractions with a singular purpose, instructions that emphasise 'fast' or 'explosive' contraction, quantitative feedback on explosive performance and multiple attempts to maximise reliability are recommended. Explosive strength has been quantified with a variety of indices that can be expressed in absolute or relative (to maximum strength or body mass) terms. These include the force (or torque) produced at specific time points from contraction onset; the time to specific forces; the rate of force development (RFD; either maximum, from onset, or over sequential periods); or the impulse/integral (area under) the force-time recording. The choice of the measured variable and its expression should be informed by the purpose of the measurement. Many of these indices are sensitive to the precise definition of contraction onset as well as the initial contractile conditions (rest, pre-tension, countermovement). Given a sufficiently sensitive dynamometer a systematic method of manual onset detection may offer better validity and sensitivity, although being less time efficient for the investigator. The reliability of explosive strength measurements may be contraction phase dependent with lower reliability during the early phase of contraction. Dynamic explosive strength may have more functional relevance to dynamic actions, but is methodologically challenging in order to achieve consistent joint angle and angular velocity conditions that if uncontrolled confound the measurement of explosive strength. Using iso-accelerations to produce standardised mechanical conditions we recently found the ability to express the available torque generating capacity to be greater in concentric than isometric or eccentric explosive actions.

### **NEUROMUSCULAR FACTORS INFLUENCING RATE OF FORCE DEVELOPMENT**

Blazevich, A.J.

*Edith Cowan University*

Muscular force production is the mechanical output resulting from a complex series of physiological events, originating in the central nervous system and ending at the skeleton. However, this process is non-linear, with numerous feedback loops and influences from both internal and external stimuli complicating its progression. Understanding the factors influencing this process is important if we are to develop strategies to improve the rate at which this force is produced, which is a primary goal in many clinical and exercise/sporting contexts. It is well documented that training-induced increases in central (neural) drive, leading to a faster activation of the motor unit pool, and at higher motor unit discharge rates (particularly at the onset of contraction), result in higher rates of force development (RFDs). However, on-going research is attempting to demonstrate how alterations in monoaminergic drive from supraspinal centres such as locus coeruleus and raphe nuclei might influence this drive, and consequently influence RFD. Also changes in afferent feedback, particularly from muscle spindles (stretch-sensitive receptors) via the Ia feedback loop, should theoretically influence motor neurone excitability and thus the ability to drive them maximally. Therefore, the combination of Ia activity and significant monoaminergic drive might provide perfect conditions for fast rates of muscle activation to be achieved through voluntary (i.e. supraspinal/cortical) drive. In this presentation, an overview of these hypotheses and preliminary data showing the potential importance of these factors will be presented. Even after fast rates of activation are achieved, muscular forces must be developed and these forces must be rapidly transmitted through the tendon(s) to the bone(s). At the muscular level, it is well known that the proportion of fast myosin within, and overall size (and therefore strength) of, muscles influences RFD. However, factors such as intra-muscular osmotic pressure, muscle architecture and inter-fascicular and inter-muscular force transmission efficiency are potentially key players. At present little is known about the relative influence of these factors, partly because they are difficult to study. Some consideration will therefore be given to future lines of research that might elucidate the importance of these factors. Additionally, tendon stiffness may also play a role in mediating the rate of force rise, as tendons provide the conduit through which the muscular forces are transmitted to the bone. Substantial evidence in favour of the importance of tendon stiffness for fast RFDs has been published. However, other lines of evidence suggest that force transmission through the tendon is too rapid (a few milliseconds) and changes in this transmission time so small that its influence on RFD is unlikely to be practically meaningful. This conflict of evidence will be considered in the current presentation.

### **RATE OF FORCE DEVELOPMENT: ITS RESPONSE TO ACUTE EXERCISE AND CHRONIC PHYSICAL TRAINING**

Maffiuletti, N.A.

*Schulthess Clinic*

A burgeoning of research has led to an increase in the quantity of data influencing our understanding of the effect of acute and chronic exercise on RFD. Such data has indicated that chronic strength and plyometric-type training can elicit significant increases in RFD, however they also indicate that heavier (and thus slower) forms of training elicit the greatest improvements in RFD; such data are not consistent with current hypotheses of how RFD should be best trained (i.e. using faster movement speeds). However, the results of recent research examining the impact of both acute exercise and chronic strength training, stretching and other interventions, as well as a reflection on the neuromuscular factors that influence force development, has helped us to better explain these findings. It has also led to the development of testable hypotheses as to new ways of improving RFD in a range of populations (e.g. clinical, elderly, child, injured). In this presentation, an overview of the results of studies examining the influence of exercise and chronic physical training (including strength, speed, plyometrics, muscle stretching, etc.) on RFD will be presented. Subsequently, an in-depth analysis of the effects of training on the key factors influencing RFD will be described, which should provide the basis of hypotheses for further research in the area; an important aim is to develop new ideas as to methods of RFD enhancement in a variety of subject populations.

## **Invited symposia**

### **IS-SH06 SPORT AND PHYSICAL ACTIVITY IN LATER LIFE**

#### **FROM SEDENTARY SENIORS TO ELITE ATHLETES – CHANGING PRACTICES AND IMAGES OF OLDER ADULTS**

Pfister, G.

*University of Copenhagen*

Since several decades, statistical information about the physical activity patterns of different age groups is available in Europe. The accessible data clearly reveal a large increase of sport participants among the older populations. In some countries, e.g. in Denmark, the percentage of physical active women over 70 is as high as among much younger age cohorts. In addition, the participation of seniors in

sport competitions has increased, as demonstrated by the popularity of the “master games movement” and the upswing of sport events for older participants. The participation and the performances of older athletes are covered positively in the mass media. However, we do not know if this new interest in the master sport movement has an effect on ageism, stereotypes about the abilities of older people. In this presentation, I will provide a short overview about the history of ageing and the opportunities and challenges of seniors to participate in sport. Based on the results of a media analysis, I will show how the media coverage of senior sport participants has changed and which new images and messages are conveyed. The findings are interpreted on the backdrop of current trends in Western societies, in particular of the new enhancement discourses and the marketing of health, youth and beauty. The paper ends with a discussion about the benefits and problems connected with the new life styles of older adults.

### **SPORT AND PHYSICAL ACTIVITY IN LATER LIFE - METHODOLOGICAL AND GERAGOGICAL ISSUES**

Diketmüller, R.

*University of Vienna*

In recent years a large number of programs promoting physical activity for older people has been developed. Nevertheless, sedentary older and very old people are hardly to be reached. To achieve the personal needs and interests of this group a more enriched body of knowledge (Grant & Kluge, 2007) is necessary to focus not only on lived experiences of physically active elderly, but especially on those who are inactive for different reasons. To know more about their meanings of (not) being active in old age, seems to be crucial for research and promotional approaches as well. On the other hand, being categorized and defined as ‘old’ seems to be already a barrier itself for a number of elderly people who don’t identify with ‘that’ age group and are not interested in age-specific offers. Sport and physical activity in old age as a challenge for staying healthy, young and independent can also be seen a meaning of struggle against the ageing process. Addressing the critique that studies of exercise and aging have been dominated by positivist approaches (Markula et al. 2001), this paper examines methodological and ethical issues in the research with elderly people and its significance for data collection. Based on the results of different studies (interview, focus group discussion) with elderly active and inactive men and women geragogical approaches for (health) promoting programs are discussed (Kolb & Diketmueller, 2006; 2008).

### **PARTICIPATION IN PHYSICAL ACTIVITY AND SPORT AMONG OLDER NORWEGIANS: A LONGITUDINAL STUDY FROM 1985 TO 2013.**

Fasting, K.

*Norwegian School of Sport Sciences*

Research from most countries, indicates that physical activity participation levels decrease with age, and that men are considerably more likely to take part in sports than women. But in Norway, particularly when sport and physical activities are broadly defined, women seem to be as active as men. The question is if this also holds for elderly people? The purpose is therefore to find out more about the development in the participation rate, performance level and the types of physical activity and sport among Norwegian women and men older than 65 year of age. The data analysed is from the study “Norwegian Monitor on Social and Cultural Change”, which has been carried out by Ipsos MMI every second year since 1985, and covers representative samples of the Norwegian population 15 years and above. For this paper the age group 65 and higher has been analysed. The physical activity level was measured through the following question: “How often would you say that you participate in physical activity either as training or as exercise?” In measuring the type of activity the participants were confronted with a list of activities and asked to answer the following question: “Which of these different physical activities on the list below do you participate in at least once a month during the season in your leisure time? » The results show that elderly women in 2013 are as active as men, respectively 80 and 79 %, defined as exercise more than once per week. The equivalent numbers from 1985 were 45 and 59 %. Accordingly the gender gap has disappeared. This seems to hold independently of how often women and men exercise. The largest increase in activity level was found among women who exercised 3-4 times per week, from 7% in 1985 to 31% in 2013. But when we look at participation in competitions a gender difference in favor of men emerge. In 2013 only 6% of the women compared to 12% of the men had participated in competitive sport. The most popular activity for both women and men are walking in the woods, followed by cross-country skiing in the woods and hiking in the mountains. The last ten years women who walk in the woods have increased from 46 to 69 %. Another major increase in women’s physical activity since 1985 has taken place in gymnastics/jazz/aerobics/freestyle (+ 13%), followed by swimming and dance (+ 8% in both), activities that also in 2013 many more women are participating in than men. These results will be discussed in relation to social constructivist theory which looks upon gender, ageing and sport preferences as socially constructed. In the discussion the question is raised whether elderly women experience a glass ceiling in relation to participation in competitive sport, and if these results may be a production of the gender stereotypes in society at large.

## **Invited symposia**

### **IS-SH05 GOOD GOVERNANCE IN SPORTS**

#### **ACTION FOR GOOD GOVERNANCE IN INTERNATIONAL SPORTS ORGANISATIONS**

Houlihan, B.

*Loughborough University*

The paper is based, in part, on research led by the Play the Game organisation and reports the work of the Action for Good Governance in International Sport Organisation (AGGIS) research consortium. The aim of the paper is twofold: first, to present the framework developed by the Play the Game research consortium which was designed to provide an assessment of the quality of governance in international sport organisations; and second, to evaluate the implementation and potential impact of the framework within the contemporary political and business environment. The paper begins with a discussion of the four main elements of ‘good governance’ (transparency, democracy, checks and balances and solidarity) before moving on to analyse the challenges of achieving compliance with higher standards of governance and holding international sport organisations to account. A variety of conceptualisations of accountability are examined including hierarchical, market-based and horizontal. The paper then considers the roles and responsibilities of stakeholders in relation to the achievement of higher standards of governance. The main conclusions drawn from the analysis are: a) few international

sport organisations recognise good governance as beneficial to their business; b) horizontal accountability through stakeholder action is weak; c) upward accountability does not exist; and d) downward accountability to the market might be the only effective way of trying to raise standards of governance.

## TRANSPARENCY AND ACCOUNTABILITY IN INTERNATIONAL SPORT ORGANIZATIONS

Schenk, S.

*Transparency International*

When I became a member of the Management Committee of the International Cycling Union (UCI) in summer 2000 I was just naïve: Proud to be the first woman ever in such a position of the cycling world, optimistic with regard to what this step would mean: Change is possible. I soon learned otherwise. While the President of UCI, Hein Verbruggen, was happy to present a woman, thus showing his federation's good will with regard to gender equality, and welcomed any critical question I raised, he as well told me: "Whatever you may want to discuss, Sylvia, in the end I expect you to vote with yes. I will never accept a dissenting vote." And so he did – he stopped any voting in our board as soon as he feared me not consenting with him. Five years experience in UCI told me all one needs to know about (non-)transparency and (non-)accountability in international sport organizations. But how can one use this knowledge in practice, how can real change in sport be achieved? To develop a strategy for Good Governance, i.e. transparency and accountability in sport the power of sport organizations as well as their monopoly position, the mechanisms of their structure, and their specific membership should be taken into account. Measuring administrative key performance indicators without looking onto the power play behind the scenes can lead to results that hide more than they disclose. The interdependence of sport, business, politics and media with manifold conflicts of interests on all sides is one of the biggest obstacles to integrity in sport. This is exemplified by the ongoing discussion on FIFA as well as in other sport organizations. With its Agenda 2020 process the International Olympic Committee has taken a first step to reform itself and promote transparency and accountability. But the work has just begun. ## GOOD GOVERNANCE FROM A NATIONAL PERSPECTIVE: THE CASE OF SWEDEN

Norberg, J.

*Idrottsvetenskap*

In recent years, good governance has been established as an overarching concept for the struggle against corruption and abuse of power in both international sports organizations and the hosting of major championships. Still, in Sweden, the concept is to a large extent unknown. This can partly be explained by the fact that Swedish sport is weakly represented in international sports organizations, and rarely hosts major sporting events. Further, a strong popular movement tradition and limited commercialization have fostered a notion that Swedish sport has been spared from such economic and democratic problems. However, a new study regarding economy and ethics in local sport clubs indicates the occurrence of financial irregularities and the need for increased awareness of the principles of good governance. Method The study was conducted by The Swedish National Centre for Research in Sports (CIF) and United Minds as part of CIF's assignment to monitor government support to sport. A web-based questionnaire concerning financial management and ethics was sent to the treasurers of all local sports clubs within The Swedish Confederation of Sports. 5480 treasurers responded, representing a response rate of 34 percent. A non-response analysis showed that the questionnaire replies were evenly distributed across the country and that all sports were represented. Results The treasurer's description of Swedish sports confirms the picture of a non-profit movement with low degree of professionalization and commercialisation. A majority of the sports clubs are small (fewer than 200 members) and primarily engaged in youth sports. Their turnover is low and member fees are their main source of revenue. Only three out of ten clubs have employees and a majority of the cashiers lack professional experience in the areas of finance and accounting. According to the cashiers, economic irregularities are common among Swedish sports clubs. Most common are unaware irregularities, caused by carelessness, ignorance or stress. But one out of four also state that it is common with conscious financial fouls with the aim to support the clubs non-profit endeavours. Discussion The study indicates a perception in Swedish club sports that financial irregularities can be justified if they serve a good purpose. Increased awareness of Good governance can be an important strategy to counteract such views. References Centrum för idrottsforskning 2014:3 Etik och ekonomi i idrottsföreningar

### OP-PM20 Physiology: Muscle metabolism, Interval training

#### MITOCHONDRIAL FUNCTION AND CONTENT ARE INCREASED BY DIFFERENT TYPES OF TRAINING IN HUMAN SKELETAL MUSCLE.

Bishop, D.J., Granata, C., Oliveira, R.S.F., Little, J.P., Renner, K.

*Victoria University*

Introduction Mitochondria are key components of skeletal muscles, as they provide the energy required for almost all cellular activities and play an important role in ageing and cell pathology. Exercise is one factor that has been shown to provide a powerful stimulus to increase both mitochondrial content and/or respiratory function, yet little is known about the optimal exercise dose, and whether mitochondrial content and respiratory function are altered by the same or different exercise prescriptions. It has been hypothesised that changes in mitochondrial content seem to depend on training volume, whilst changes in mitochondrial respiratory function seem to be related to training intensity (Bishop et al., 2014). The aim of the present study was to investigate this hypothesis. Methods Twenty-nine healthy men ( $21 \pm 2$  y,  $46 \pm 6$  mL O<sub>2</sub>/min/kg) took part in 12 cycling sessions (4 weeks) of either: sprint interval training (SIT, 4-10 X 30-s "all-out" bouts (~204% WPeak); n=9), high-intensity interval training (HIT, 4-7 X 4-min intervals at ~89% WPeak; n=11), or sub-lactate threshold continuous training (STCT, 20-36 min at 90-97.5% WLT (~69% WPeak); n=9). The STCT and HIT group were also matched for total work. Following the 4 wk of training, the HIT group then continued HIT twice a day for 20 consecutive days (High Volume Training; HVT). Resting muscle biopsy samples were obtained before and after training for all groups. Results Maximal mitochondrial respiration in permeabilised muscle fibres increased significantly only following SIT ( $25 \pm 20\%$ ,  $P < 0.05$ ). However, citrate synthase activity, and the protein content of PGC-1 $\alpha$  and subunits of ETS complexes, only increased following HVT (all  $P < 0.05$ ). The protein content of PGC-1 $\alpha$ , p53 and PHF20

was increased following both SIT and HVT ( $P < 0.05$ ). Discussion Our findings suggest that training intensity is a key factor regulating exercise-induced changes in mitochondrial respiration, whereas training volume is more important for exercise-induced changes in mitochondrial content. Furthermore, there exists an apparent dissociation between training-induced changes in mitochondrial respiration and content. While further research is required, it is possible that the increase in mitochondrial respiratory function, without a change in mitochondrial content, may be the result of matched changes in protein synthesis and degradation resulting in the replacement of damaged proteins with newly synthesised ones (Mai et al., 2012). ### EFFECT OF HIGH INTENSITY TRAINING ON INSULIN SENSITIVITY IN OVERWEIGHT, SEDENTARY ELDERLY SUBJECTS

Søgaard, D.

*Copenhagen University*

Søgaard, D., Lund, MT., Dehlbæk, MS., Dideriksen, SG., Abildskov, CV., Dela, F., Helge, JW. Xlab, Dept. Biomedical Sciences, University of Copenhagen, Denmark Introduction High intensity training (HIT) induces beneficial changes on insulin sensitivity evaluated by the Matsuda index in young adults (Whyte LJ et al. 2010), but it is not clear if HIT can be applied to elderly subjects with positive effects on metabolism. This study aims to investigate the effect of 6 weeks of HIT on insulin mediated glucose uptake rates in elderly, overweight and sedentary subjects. We hypothesized that HIT would improve insulin whole body insulin action in both male and female elderly subjects. Methods Thirteen (6 M/7 F,  $62 \pm 1$  yrs., BMI  $> 27$  kg/m<sup>2</sup>) subjects performed supervised HIT training 3 sessions a week in 6 weeks in this ongoing study. Each session consisted of 5 intervals of 60 sec. of HIT on a bicycle ergometer with 90 sec. break after each interval. A hyperinsulinemic, euglycemic clamp and a VO<sub>2</sub>max test were carried out before and after the intervention. Statistics: Two way repeated measurements ANOVA was applied to the data. Results Six weeks of HIT induced a significant increase in VO<sub>2</sub>max (ml • min<sup>-1</sup> • kg<sup>-1</sup>) (pre:  $25.9 \pm 1.3$ , post:  $28.0 \pm 1.5$ ,  $p=0.032$ ,  $n=13$ ). Glucose infusion rates (GIR, mg • min<sup>-1</sup> • kg<sup>-1</sup>) overall increased (pre:  $7.4 \pm 0.4$ , post:  $8.0 \pm 0.6$ ,  $p=0.008$ ,  $n=13$ ), which was caused by an improved GIR in males (pre:  $7.7 \pm 0.5$ , post:  $8.7 \pm 0.7$   $p=0.002$ ,  $n=6$ ) but not females (pre:  $7.2 \pm 0.7$ , post:  $7.3 \pm 0.9$ ,  $p=0.676$ ,  $n=7$ ). Glucose clearance rate (ml • min<sup>-1</sup> • kg<sup>-1</sup>) was increased overall (pre:  $7.3 \pm 0.4$ , post:  $8.1 \pm 0.6$ ,  $p=0.032$ ,  $n=13$ ). Discussion HIT is feasible in elderly subjects and improve VO<sub>2</sub>max and insulin action. Insulin mediated glucose uptake in elderly subjects completing a HIT intervention has not previously been measured. The findings of our study do agree with a study reporting an increase in insulin sensitivity in young sedentary males in response to HIT (Richards JC et al. 2010). We only see an improvement in males and not females and therefore our present results only partly support our hypothesis. In conclusion, HIT can be applied to elderly but males may benefit more than females. Gender specific differences in the adaptation to HIT training should be studied further to elucidate a possible mechanism. References Whyte LJ, Gill JMR, Cathcart JA. ### BROWN ADIPOSE TISSUE GLUCOSE UPTAKE IS DECREASED BY TWO WEEKS OF EXERCISE TRAINING IN HEALTHY MIDDLE AGED MEN

Motiani, P., Motiani, K., Savolainen, A., Eskelinen, J., Boström, P., Parkkola, R., Knuuti, J., Nuutila, P., Virtanen, K., Kalliokoski, K., Hannukainen, J.

*University of Turku*

Objective: We have previously shown that brown adipose tissue (BAT) glucose uptake is stimulated by insulin. The aim of this study was to evaluate whether exercise improves BAT insulin sensitivity as it does in skeletal muscle. Materials and methods: Healthy middle-aged men ( $n=18$ , aged= $47.2$ (SD 4.6) yrs, BMI= $25.3$ (SD 2.4) kg·m<sup>-2</sup>, VO<sub>2</sub>max= $34.8$ (SD 4.5) ml·kg<sup>-1</sup>·min<sup>-1</sup>) were recruited. Glucose uptake (GU) in BAT and quadriceps femoris muscles were measured during euglycemic hyperinsulinemic clamp before and after two weeks of bicycle exercise training intervention using positron emission tomography and [<sup>18</sup>F]FDG. From these, individuals were divided into two groups BAT positive ( $n=6$ ) with high BAT GU ( $\geq 2.9$  μmol/100g/min) and BAT negative group ( $n=12$ ) with BAT GU ( $\leq 2.9$  μmol/100g/min) at baseline. Plasma irisin levels were measured before and after the intervention. Results: After intervention VO<sub>2</sub>max (pre  $34.8$ (SE 1.2) vs. post  $37.0$ (SE 1.2),  $p=0.0005$ ) and quadriceps femoris muscle GU (pre  $8.2$ (SE 1.2) vs. post  $11.9$ (SE 1.2),  $p=0.001$ ) improved in both groups with no significant differences between the groups. Training decreased BAT GU in BAT positive group whereas opposite was observed in BAT negative group ( $4.0$ (SE 1.2) vs.  $2.6$ (SE 1.2) and  $1.5$ (SE 1.1) vs.  $1.6$ (SE 1.1),  $p=0.02$ , respectively). Irisin levels did not change. Conclusion: The effects of short term bicycle exercise training are different on skeletal muscle and BAT insulin sensitivity. Against our hypothesis, insulin stimulated BAT GU decreased in BAT positive subjects, suggesting that short term exercise training is not effective strategy to enhance BAT metabolism. ### THE ASSOCIATION OF SNAP23 WITH THE MITOCHONDRIAL NETWORK IS REDUCED IN SKELETAL MUSCLE OF OBESE SEDENTARY FEMALES

Strauss, J.A., Shaw, C.S., Davis, E., Pilling, J., Wagenmakers, A.J.M.

*Liverpool John Moores University*

Introduction SNAP23 is a SNARE protein involved in GLUT4 docking at the skeletal muscle plasma membrane. However, it has also been proposed that, under high lipid flux (e.g. obesity), SNAP23 can be sequestered away from the plasma membrane for fusion of growing lipid droplets (LD). It is thought that this results in decreased plasma membrane SNAP23 content limiting the capacity for GLUT4 docking and therefore glucose entry into the cell. This is known as the hijacking hypothesis (Sollner, 2007). The present study aimed to investigate the distribution of SNAP23 in skeletal muscle of non-obese and obese older women using immunofluorescence microscopy. We aimed to generate evidence for the hijacking hypothesis and also to investigate the potential role of SNAP23 in mitochondrial fatty acid (FA) oxidation. Methods Participants were six non-obese ( $m \pm SD$ , age:  $62 \pm 3$  years, BMI:  $22.6 \pm 1.4$ , HOMA-IR  $3.9 \pm 1.2$ ) and six obese older women (age:  $68 \pm 3$  years, BMI:  $33.3 \pm 1.6$ , HOMA-IR:  $6.2 \pm 1.3$ ) undergoing elective orthopaedic surgery. Biopsies were obtained from the m. gluteus maximus during hip arthroplasty. Cryosections ( $5 \mu m$ ) were labelled with antibodies targeting SNAP23, mitochondria (anti-cytochrome c oxidase) and the plasma membrane (anti-dystrophin). LD were visualised using oil red O. Results SNAP23 partially colocalised with the plasma membrane in both non-obese and obese individuals (Pearson's correlation non-obese:  $r = 0.39 \pm 0.01$ , obese:  $r = 0.37 \pm 0.03$ ,  $P=0.64$ ). SNAP23 also partially colocalised with mitochondria with significantly more colocalisation in non-obese women than obese women (non-obese:  $r = 0.34 \pm 0.03$ , obese:  $r = 0.27 \pm 0.03$ ,  $P=0.04$ ). SNAP23 weakly colocalised with LD in both non-obese and

obese individuals (non-obese:  $r = 0.12 \pm 0.02$ , obese:  $r = 0.07 \pm 0.02$ ,  $P = 0.28$ ). Discussion This study did not confirm the hypothesis that LD hijack SNAP23 from the plasma membrane. The association of SNAP23 with LD was low and the association of SNAP23 with the plasma membrane was not reduced by obesity. SNAP23's presence at the mitochondria supports its proposed role to channel FA released from LD hydrolysis into the mitochondria for oxidation. The reduced association between SNAP23 and the mitochondria in obesity may suggest a decreased capacity for FA oxidation in these individuals which would be expected to lead to greater insulin resistance in skeletal muscle.

### **ANABOLIC STEROID DETECTION BY PROTEOMICS IN HUMAN SKELETAL MUSCLE**

Malm, C., Yu, J., Granlund, I., Eriksson, A., Tegner, Y., Bonnerud, P.

*Umeå University*

This project proposes to use a sensitive proteomic methodology to detect deviations in human skeletal muscle protein profiles between muscles of doped and clean athletes. Testosterone increases muscle mass as well as muscle fibre area in a dose dependent response. We have shown a higher number of nuclei per muscle fibre is observed in doped, compared to clean athletes that may give permanent, life-long performance advantages even when AAS intake has been withdrawn for many years. Detection of AAS in human urine and blood may not at all be sufficient to reveal the use of banned substances, and the benefits of their actions. The LC/MS/MS method is used for doping analysis of biological samples such as urine, blood, plasma, serum, hair and saliva. We will extend the use to human skeletal muscle, where doping can be detected many years after secession of intake, and not limited to short-lived metabolites of banned substances detectable in urine and blood. The amount of tissue needed for the analysis is  $< 2$  mg, and the sampling procedure equivalent to a regular venous blood sampling, resulting in  $> 6000$  identified and quantified peptides. Detection and quantification of permanent effects of AAS abuse when metabolites have been excreted, and for years after secession of AAS intake, requires analysis of muscle tissue. The small amount of tissue needed allows the use of fine needle biopsies that are safe, minimally invasive and cause limited or no pain and discomfort. The present study will therefore be the first to develop a valid and reliable test for the detection of long-term effects of AAS abuse on muscle tissue. In addition, the proposed approach may be the only possibility to detect future, or on-going, genetic doping.

### **EXERCISE TRAINING ACTIVATES NRG1/ERBB PATHWAY IN GASTROCNEMIUS OF OBESE RATS**

Chavanelle, V., Ennequin, G., Caillaud, K., Gerbaix, M., Metz, L., Etienne, M., Walrand, S., Masgrau, A., Guillet, C., Courteix, D., Niu, A., Li, Y., Capel, F., Boisseau, N., Sirvent, P.

*AME2P - EA 3533*

Introduction Some studies suggest that the signaling pathway of neuregulin 1 (NRG1), a protein involved in skeletal muscle metabolism regulation, could be altered by nutritional and exercise interventions (Miller T et al., 2009; Lebrasseur et al., 2005). We hypothesized that diet-induced obesity could be associated with alterations of the NRG1 signaling pathway and that chronic endurance exercise could improve NRG1 signaling in rat skeletal muscle. Methods Male Wistar rats were fed a high fat/high sucrose (HF/HS) diet for 16 weeks. At the end of this period, NRG1 and ErbB expression/activity were assessed in skeletal muscle of obese rats suffering from glucose intolerance induced by the HF/HS diet and compared to control rats (non-obese, well-balanced diet). Then, the obese rats continued the HF/HS diet or were switched to a well-balanced diet. In both cases, two subgroups were made: rats were assigned to a sedentary group or a chronic exercise group for another 8 weeks and NRG1 and ErbB expression/activity in skeletal muscle were tested again. Results First, we found that a 16-week HF/HS diet induced obesity, but did not significantly affect the NRG1/ErbB signaling pathway in rat skeletal muscle. Conversely, after the switch to a well-balanced diet, NRG1 cleavage ratio and ErbB4 amount were increased. Chronic exercise training also induced NRG1 cleavage, resulting in increased ErbB4 phosphorylation. This was associated with increased protein expression and phosphorylation ratio of the metalloprotease ADAM17, which is involved in NRG1 shedding. Similarly, in vitro stretch-induced activation of ADAM17 in rat myoblasts induced NRG1 cleavage and ErbB4 activation. Discussion These results showed that endurance training and well-balanced diet activates the NRG1-ErbB4 pathway in skeletal muscle of diet-induced obese rats. This effect seems mediated by the cleavage of NRG1 by the metalloprotease ADAM17.

### **OP-BN02 Motor learning**

#### **MOTOR IMAGERY OF TONIC AND BALLISTIC CONTRACTIONS ACTIVATES DIRECT AND INDIRECT CORTICOSPINAL PATHWAYS DIFFERENTLY BUT IN A SIMILAR WAY THAN REAL TONIC AND BALLISTIC CONTRACTIONS**

Keller, M.1, Lauber, B.2, Taube, W.1

*1: SMS (Fribourg, Switzerland), 2: IFSS (Freiburg, Germany)*

Introduction It is well accepted that motor imagery (MI) and actual movements share overlapping activation of motor areas (Jeannerod 2001). One possibility to assess neural activation during MI is to apply transcranial magnetic stimulation (TMS) over the primary motor cortex. This technique showed that MI and actual movements modulate motor cortex excitability similarly (Stinear CM, Byblow WD 2003). It is, however, not known if MI also affects the activity of different corticospinal pathways in a contraction-specific way as was shown for actually executed movements (Taube et al. 2011). The aim of the present study was therefore to elucidate whether MI of tonic and ballistic contractions leads to differential activity of direct and indirect corticospinal pathways. Methods Ten healthy participants volunteered for the present study. Activity of the different corticospinal pathways was assessed at rest and during MI of ballistic (MIbal) and tonic (MIton) contractions using the H-reflex conditioning technique. Therefore, the soleus H-reflex was conditioned with TMS using different interstimulus intervals. In order to avoid biased MEP / H-reflex amplitudes due to voluntary or involuntary contractions, trials with enhanced EMG levels prior to stimulation (time window: 5 to 55 ms before stimulation; criteria:  $> 4$  times standard deviation) were removed. Results The conditioned H-reflexes of the early facilitation, which indicate the contribution of direct corticospinal pathways, were not different between rest, MIbal and MIton ( $F_{2,18} = 0.67$ ;  $p = 0.52$ ). The conditioned H-reflexes that reflect activity of indirect, slower corticospinal pathways were significantly different ( $F_{2,18} = 4.25$ ;  $p < 0.05$ ) between conditions, revealing highest facilitation in MIton, followed by rest and MIbal. Discus-

sion Previous studies have shown that slow corticospinal pathways are differently affected by ballistic and tonic contractions (Taube et al. 2011, Nielsen & Petersen 1995, Nielsen et al. 1993). The authors showed for physical task execution a late inhibition for ballistic contractions but a late facilitation during tonic contractions. Thus, the present study shows for the first time that MI of ballistic and tonic contractions activates corticospinal pathways in a contraction-specific way that resembles activation patterns during physical task execution. ### IN SITU EXAMINATION OF DECISION MAKING SKILLS AND GAZE BEHAVIOUR OF BASKETBALL PLAYERS

van Maarseveen, M.J.J., Savelsbergh, G.J.P., Oudejans, R.R.D.

*VU University*

**Introduction** Several studies have revealed that experts possess superior decision making skills, i.e., they make more accurate and faster decisions than non-experts (e.g., Vaeyens et al., 2007). However, using video projection and artificial responses most of these studies lacked representative design and natural perception-action couplings (Travassos et al., 2013). The aim of the current study was to examine expertise effects in decision making and gaze behaviour in situ. **Methods** Highly talented youth basketball players participated as ball carrier in a specific 3 vs 3 pick-and-roll basketball play. Facing three types of defensive play, the ball carrier chose and performed one of four options: shoot, drive to the basket, pass to the screener/roller or pass to the corner player. Players wore eye tracking glasses and performed trials on the left and right side of the field. The chosen options, quality of decisions and gaze behaviour were analysed. Successful and less-successful decision makers were compared. Results Different defensive plays led to differences in options chosen. A loglinear analysis indicated that the side x defensive play x option interaction was almost significant,  $\chi^2(8) = 15.130$ ,  $p = .057$ . For one defensive play, the shot was chosen more often on the left side than on the right side while for another defensive play the ball was more often passed to the screener on the left side and to the corner on the right side of the field. Successful players more often chose the best option compared to less-successful players,  $p < .001$ . The final fixation of successful players was more often on the chosen option,  $p < .05$ , and tended to be longer,  $p = .099$ , than of the less-successful players. **Discussion** We showed that it is possible to measure decision making skills and gaze behaviour in situ. The decisions were affected by the defensive play and the side of the field, of which the latter may be due to hand dominance. Within the group of highly talented players, the successful and less-successful decision makers could be differentiated. Further analyses of gaze behaviour may give insight into why some players make better decisions than others. **References** Travassos, B., Araújo, D., Davids, K., O'Hara, K., Leitão, J., & Cortinhas, A. ### A COMPARISON OF LOWER EXTREMITIES ANATOMICAL AND FUNCTIONAL ASYMMETRIES IN ELITE AND SUB-ELITE FENCERS.

Kotsasian, A., Tsolakis, C., Drake, A.M.

*Lund University, University of Athens, Lund University*

**Introduction** In order to design effective and appropriate training programs there is a need to examine sport specific skills in all levels of athletes. The aim of this study was to investigate and compare possible lower extremity asymmetries in elite and sub-elite level fencers. **Methods** Anthropometric and functional parameters were tested in 27 (12 female and 15 male) members of the Greek National Fencing team (M age = 19.9 yr., SD = 3.5 yr, M height = 175.6 cm., SD = 7.6 cm., M weight = 66.1 kg., SD = 9.1 kg.) and classified as elite (n=10) or sub-elite (n=17) fencers, according to their international standard. The anthropometric parameters included weight, height, mid- thigh skinfold and thigh circumference. Mid-thigh muscle cross-sectional area (CSA) on the dominant (D) and non dominant (ND) side was calculated from an anthropometric formula incorporating limb circumference and skinfolds. Countermovement jump (CMJ) and hip flexibility (FLEX) were measured on the dominant (D) and non-dominant (ND) side using a Chronojump platform and a Lafayette goniometer. Results Elite fencers were significantly superior to sub-elite fencers in CSA-D (6.9%,  $p < 0.001$ ), FLEX-D (18.9%,  $p < 0.05$ ) and FLEX-ND (18.3%,  $p < 0.05$ ), while there were no significant differences for CMJ performance and the rest of anthropometric parameters. Also, significant differences were observed for elite fencers between the D and ND side for CMJD - CMJND (18.6%,  $p < 0.05$ ) and CSAD-CSAND (8.7%,  $p < 0.001$ ). Smaller significant differences were observed for sub-elite fencers between the D and ND side for CMJD - CMJND (14.7%,  $p < 0.05$ ) and CSAD-CSAND (6%,  $p < 0.001$ ). CMJ asymmetries were not correlated with the relevant asymmetries in CSA in both groups of fencers. **Discussion** Based on the above results, we conclude that both anatomical and functional asymmetries differentiate elite from sub-elite fencers in forward body propulsion. These asymmetries are most likely developed as a consequence of the specificity of the fencing training program. The observations in this study confirm different leg quality requisites all of which seem to be important in functional power characteristics of fencing performance, especially in elite fencers. Also, this observed superiority of elite fencers to sub-elite fencers may be useful for athletes and coaches to design more effective talent development training programs. ### SPATIAL ANALYSIS OF HIT DISTRIBUTION IN RECURVE ARCHERY

Ertan, H.1, Er, F.1, Callaway, A.J.2

*1 Anadolu University, Turkey; 2 Bournemouth University, UK*

**Introduction** An end consists of 3 to 6 arrows, which are typically written on paper without information on the location of each arrow (Ertan et al., 2005). The arrows are only scored from highest to lowest leading to limited analysis possibilities. Distribution patterns of the hits on the target allow identification and analysis of spatial patterns (Callaway & Broomfield, 2012). Callaway and Broomfield (2012) validated an input method for these hits to analyse underlying continuous spatial distributions (Johnson, 2001). The purpose of the current study is to test whether marksmanship characteristics derived from hit distribution patterns can be used to differentiate archers at different performance levels. **Methods** Archers comprised of 3 groups (9 high-level, 13 middle-class and 7 beginner archers). Each archer shot 72 arrows at a 40cm target standing at 18 m. The hits on the target were photographed after each end and digitized using Matlab to create a coordinate system of arrow locations. Accuracy (variable & constant), precision, group locations, and straight-line distance (from the center) were calculated for each group and analysed using ANOVA and post-hoc LSD. Results Accuracy (AVE) showed elite were the

closest to the center with 3.02cm, intermediate = 7.75cm and beginner = 17.1cm. Group X locations showed elite and intermediate to the left of the target (-0.79cm & -4.18cm) and beginners to the right (1.57cm). Beginners showed a closer group to the center of the target than intermediate, but also the largest SD of 8cm. Group Y location showed that Intermediate and Beginner both shot 1.03 and 1.43cm high of the center with no significant difference between them. Elite shot -1.24cm low of center. Precision resulted in elite = 2.42, intermediate = 5.38 & beginner = 12.3cm size groups. Statistical differences were found between all factors, for all groups ( $p < 0.001$ ) except between intermediate and beginner group Y location. Discussion As predicted, there were significant differences between elite, intermediate and beginner hit distribution. This demonstrates that the methods proposed previously (Callaway & Broomfield, 2012) can be useful for analysis in archery. Score alone ignores good groups in the wrong location on the target. Measures such as accuracy and precision offer a great benefit to future work. These measures here can be useful to archer, coach and analyst for performance improvements and equipment setup. If all archers had moved their sights in line with the results here, all could have scored higher overall. References H. Ertan, A.R. Soylu and F. Korkusuz (2005). *J. Elec. & Kin.*, 15, 222–227. A.J. ### **'THE LEFT HAND HAS TO GO BACK A BIT MORE, LIKE THIS': INTERACTION ANALYSES OF COMMUNICATIVE STRATEGIES IN DRESSAGE COACHING**

Lundgren, C., Zetterqvist Blokhuis, M.

*Linköping University*

In the equestrian sports, the communication between horse and rider is considered paramount to good riding. At the same time, riding is a very complex activity. Because of this, many riders, including those who use their horses exclusively for recreational activities, regularly participate in training sessions led by professional trainers. In the study reported in this paper, video recordings of dressage training sessions have been analysed. Participating in these 15 training sessions are five different trainers, each coaching three equipages (one trainer and one equipage per training session of 45-60 min). Combining theories and methods from linguistics and communication theory, the study sheds light on communicative strategies deployed by the trainers in their work in the riding hall. The focus of each of the training sessions varies depending on the rider's and the horse's respective educational level, the short and long term goals of the human participants and the current shape of rider and horse. The training sessions also vary depending on the scope of the training session (to achieve suppleness and balance in the horse (or/and the rider) or to perform a specific exercise). In coaching the riders, the trainers use a wide repertoire of verbal, paraverbal and nonverbal communicative strategies. Some of these strategies are 1) giving verbal instructions aimed at modifying the horse-rider communication (sometimes expressed in metaphors), 2) using their own bodies as models (by miming what they want the rider to do), 3) moving around in the riding hall (miming aspects such as rhythm, pace and direction), 4) intervening physically by for instance altering the posture of the rider, the position of parts of the rider's body or showing the correct degree of pressure to be applied in a certain situation and 5) mounting the horse themselves to show something from the saddle with the rider standing in the riding hall watching the trainer ride their horse. Para-verbal strategies include humming or singing in order to help the rider and the horse to relax, as well as using repetition of sound items to convey rhythm and pace. Although it seems that each trainer has his/her own favourite 'modes' of coaching, linguistic cues used to convey rhythm and pace is used by all trainers - a finding which may be explained by the prominent place rhythm and pace holds in assessing dressage riding. During the presentation, extracts from the video material will be used as illustrations of some of these findings. The extracts also show how the strategies can be combined and intertwined. Dressage riding is a complex activity, and so - the interaction analysis reveals - is dressage coaching. This study is a part of a larger study concerning communication in the horse-rider-trainer triad.

### **COACHING DRESSAGE RIDERS: A QUALITATIVE INTERVIEW STUDY EXAMINING THE CHANGING PARADIGMS OF EQUESTRIAN TRAINING**

Zetterqvist Blokhuis, M., Lundgren, C.

*Södertörn University*

The proposed paper reports how coaches in dressage riding describe their methods for teaching riders to communicate with their horses, an ability which is considered paramount to an equipage's success at all levels of dressage test riding. The dominating description of dressage riding is anchored in a behaviourist paradigm, where the rider is seen as a provider of signals to the horse through a combination so called aids (weight, leg, reins and voice), to which the horse responds. The rider's combination and timing of the aids is thus the focus of the training. The role of the horse is simply to react to these signals. This paradigm, together with the close ties to the uses of horses within the military, has favoured command-oriented methods in the training of horses and riders alike. However, during the last fifteen years, the interest in alternative ideas about training horses as well as when it comes to the role of the coach and their communication with the riders, has begun to grow. To begin examining how this shift-in-process affects dressage training today, data has been collected through semi-structured, in-depth interviews with five dressage coaches. Transcriptions of the interviews have been analysed from a phenomenographical perspective, an approach favouring qualitative investigations of how people experience and think about a phenomenon. The analyses reveal that the coaches work within a field of tensions between ideas pertaining from different theories on learning as well as different 'horseologies' (a term which we introduce to describe ideas about the role of the horse, about how horses learn and about horse-human relations which form an ideological core in the various traditions within the equestrian communities). All coaches stress that their primary task and goal is to improve the riders' ability to communicate with their horse and thus to improve their 'equestrian feel'. They also point to the importance of involving the rider in the communicative work of the coaching situation. Some seem to be basing their work more firmly on the traditional understanding of the role of the horse as an object responding to the rider's signals, whereas others emphasize a somewhat more symmetrical relation, where the rider's role is that of a guide rather than that of a commander. In the coaches' accounts of their training practices, adaptations to the needs of each equipage are also central. Such adaptations take into account aspects such as the equipage's educational level, the short- and long term development goals and the current shape of horse and rider alike. The study reported in this paper is a part of a larger study concerning communication in the horse-rider-trainer triad.

### OP-PM12 Thermoregulation II

#### PRACTICAL COOLING STRATEGIES ENHANCE ENDURANCE RUNNING PERFORMANCE AND INCREASE SKELETAL MUSCLE ACTIVATION

Stevens, C.1, Taylor, L.2, Callister, R.3, Sculley, D.3, Dascombe, B.1,3

*University of Newcastle*

1: ASSET LABORATORY UON (Ourimbah, Australia), 2: ISPAR UOB (Bedford, UK), 3: PRC PAN UON (Callaghan, Australia) Introduction Endurance exercise performance is impaired in hot compared to temperate conditions. Researchers have typically experimented with cooling the body prior to (pre-cooling) and during exercise (mid-cooling) to minimize such performance decrements. There has been much debate about the mechanisms that cause early fatigue in the heat and the maintenance of performance with cooling. Exercise in the heat has been shown to decrease skeletal muscle activation in an anticipatory manner to ensure thermal homeostasis (Tucker et al., 2004). Others have argued exercise in the heat is impaired due to lowered oxygen delivery to the skeletal muscles (Cheuvront et al., 2010). It is currently unclear if practical cooling strategies alter muscle activation or oxygenation. Methods In a randomised, cross-over design, nine trained male runners performed familiarisation then three 5 km running time trials on a non-motorised treadmill in hot conditions (32.5±0.1°C). The trials consisted of control (CON), pre-cooling (PRE) by cold-water immersion (24°C for 30 min) or mid-cooling (MID) by intermittent facial water spray (1 spray.km<sup>-1</sup>). Selected physiological responses were measured throughout each trial. Results Performance time was significantly faster in both PRE (24.5±2.8 min; p=0.01) and MID (24.6±3.3 min; p=0.01) compared to CON (25.2±3.2 min), but no differences were observed between PRE and MID (p=0.66). Summated integrated electromyography was significantly higher in PRE (2.36±0.55 V.s<sup>-1</sup>; p=0.03) and MID (2.24±0.55 V.s<sup>-1</sup>; p=0.03) when compared to CON (2.06±0.44 V.s<sup>-1</sup>). Forehead temperature was significantly lower in PRE and MID compared to CON (p<0.05). Cold-water immersion significantly reduced rectal temperature by 0.5°C and remained lower throughout the trial. There were no significant changes in heart rate, VO<sub>2</sub> or tissue saturation index. Discussion Self-paced endurance running performance was improved by a similar magnitude (~3%) with cold-water immersion and intermittent facial water spray. Both interventions lowered forehead temperature, increased muscle activation and increased running speed predominantly in the first half of the time trial. Hence, it is proposed that the cooling interventions delayed any anticipatory reduction in skeletal muscle activation until heat storage surpassed a threshold mid-way through the running time trial. There was no evidence of improved cardiovascular or peripheral metabolism efficiency with either intervention. References Cheuvront S, Kenefick R, Montain S, Sawka M. #### SELF-PACED EXERCISE IS REGULATED BY THE MAINTENANCE OF %VO<sub>2</sub>PEAK WITHIN A NARROW RANGE IN HOT AND COOL CONDITIONS

Périard, J.D., Racinais, S.

*Aspetar Orthopaedic and Sports Medicine Hospital*

Introduction A decrease in peak oxygen uptake (VO<sub>2</sub>peak) has been suggested to regulate self-paced exercise in the heat by mediating adjustments in absolute workload (i.e. power output) to maintain relative exercise intensity (i.e. %VO<sub>2</sub>peak) within a narrow range (Cheuvront et al., 2010; Périard et al., 2011). However, the time course and extent of decrease in VO<sub>2</sub>peak have yet to be determined. Thus, we examined these parameters during self-paced exercise in HOT (35°C and 60% RH) and COOL (18°C and 40% RH) conditions. Methods Ten well-trained cyclists completed four consecutive 16.5 min time trials (15 min self-paced effort followed by 90 s maximal end-spurt to determine VO<sub>2</sub>peak) interspersed by 5 min of recovery in each condition. Results Rectal temperature increased significantly more in HOT (39.4 ± 0.7°C) than COOL (38.6 ± 0.3°C; P<0.001), while heart rate was higher throughout HOT (P<0.05), and ratings of perceived exertion higher during trials three and four in HOT (P<0.05). Power output was lower throughout HOT compared with COOL (P<0.05). The decrease in power output from trial one to four was ~15% greater in HOT (P<0.001). VO<sub>2</sub> was lower in HOT than COOL except at 5 min and during the end-spurt in trial one (P<0.05). In HOT, VO<sub>2</sub>peak reached 96, 89, 87 and 87% of pre-determined VO<sub>2</sub>max, whereas in COOL 97, 95, 93 and 92% was attained. %VO<sub>2</sub>peak was similar between conditions during trials one and two, and lower in HOT during trials three and four (P<0.05), yet heart rate and perceived exertion were higher. Discussion Pacing is a process informed by prior experience, accurate knowledge of a task, an understanding one's abilities, and the interpretation of physiological cues (sensory information) associated with effort. However, it is influenced by a variety of factors (e.g. hyperthermia, neuromuscular function, and metabolism) (Edwards & Polman, 2013; Nybo et al., 2014). Under heat stress, the primary determinant mediating the impairment in performance appears to stem from a thermal strain-mediated rise in cardiovascular strain. Indeed, self-paced exercise appears to be regulated by the maintenance of %VO<sub>2</sub>peak within a narrow range (±2%), which widens (±7%) under heat stress when exercise becomes protracted. This occurs as a disassociation develops between %VO<sub>2</sub>peak, heart rate and ratings of perceived exertion, due to factors associated with temperature regulation, autonomic control, and intrinsic heart rate. #### HEAT ACCLIMATION ATTENUATES PHYSIOLOGICAL STRAIN IN ACUTE NORMOBARIC HYPOXIA

Gibson, O.R.1, Turner, G.1,2, Watt, P.W.1, Maxwell, N.S.1

*University of Brighton*

1 Centre for Sport and Exercise Science and Medicine, University of Brighton, UK. 2 English Institute of Sport, EIS Performance Centre, Loughborough, UK. Introduction Heat acclimation (HA) attenuates physiological strain in hot, humid conditions with evidence supporting HA as an intervention to improve exercise capacity in both temperate and hot conditions. Emerging hypotheses also support reductions in physiological strain and exercise capacity at altitude following thermal interventions. The aim of this study was to determine whether HA reduced the physiological strain in acute normobaric hypoxia. Methods Sixteen males (age 24 ± 5 yr, mass 74.6 ± 6.3 kg, VO<sub>2</sub>peak 4.27 ± 0.63 L.min<sup>-1</sup>) completed ten, 90 min sessions of HA (40°C/40% relative humidity (RH)) or exercise training (EX; 20°C/40% RH) on

cycle ergometers. HA or EX were preceded (HYP1) and proceeded (HYP2) by a normobaric hypoxic exposure ( $FI_{O_2} = 0.12$ ; 10 min of rest, 10 min cycling at 40% $VO_{2peak}$ , 10 min cycling at 65% $VO_{2peak}$ ) with measurement of heart rate (HR), and calculation of stroke volume (SV), cardiac output (Q) and respiratory exchange ratio (RER) utilising online metabolic gas exchange. Plasma volume (PV) and haemoglobin mass (Hbmass) were measured utilising the oCOR-method. Results HA reduced resting rectal temperature (T<sub>rec</sub>; Day1 37.0 ± 0.2°C; Day10 36.5 ± 0.3°C;  $p < 0.001$ ), HR (Day1 74 ± 13 b.min<sup>-1</sup>; Day10 56 ± 8 b.min<sup>-1</sup>;  $p < 0.001$ ) and increased PV (+15.4 ± 9.2%;  $p < 0.001$ ). No changes in resting T<sub>rec</sub> (Day1 37.0 ± 0.3°C; Day10 36.9 ± 0.3°C;  $p = 0.522$ ), HR (Day1 68 ± 14 b.min<sup>-1</sup>; Day10 66 ± 9 b.min<sup>-1</sup>;  $p = 0.398$ ), or PV (+1.8 ± 5.0%;  $p = 0.622$ ) were observed following EX. No change ( $p > 0.05$ ) was observed in Hbmass following HA (Pre 869 ± 92 g; Post 869 ± 96 g), or EX (Pre 865 ± 110 g; Post 857 ± 126 g). SV in hypoxia was greater at rest (HYP1 74.9 ± 15.3 mL; HYP2 83.5 ± 16.8 mL;  $p = 0.002$ ), 40% $VO_{2peak}$  (HYP1 113.5 ± 15.1 mL; HYP2 121.2 ± 9.9 mL;  $p = 0.049$ ) and 65% $VO_{2peak}$  (HYP1 107.6 ± 12.6 mL; HYP2 119.4 ± 7.8 mL;  $p < 0.001$ ) following HA, but was unchanged after EX ( $p > 0.05$ ). HR in hypoxia was lower (HYP1 168 ± 14 b.min<sup>-1</sup>; HYP2 158 ± 13 b.min<sup>-1</sup>;  $p = 0.001$ ) and oxygen saturation higher (HYP1 73 ± 3%; HYP2 76 ± 3%;  $p = 0.006$ ) at 65% $VO_{2peak}$  following HA, but not EX ( $p > 0.05$ ). Q in hypoxia was unchanged in EX or HA ( $p > 0.05$ ). RER reduced at rest in hypoxia (HYP1 0.96 ± 0.07; HYP2 0.90 ± 0.06;  $p = 0.045$ ) following HA, but not EX ( $p > 0.05$ ). Discussion HA is an effective intervention for reducing physiological strain associated with acute normobaric hypoxia, in part through HA derived PV expansion improving cardiac efficiency. Further research is required to determine the benefits of cross-acclimation across a spectrum of simulated and actual altitudes, whilst implementing different work prescription, including performance trials. Contact o.r.gibson@brighton.ac.uk

## THE EFFECT OF USING DIFFERENT REGIONS OF INTEREST ON LOCAL AND MEAN SKIN TEMPERATURE

Bach, A.J.E., Maniar, N., Stewart, I.B., Costello, J.T.

*Queensland University of Technology*

**Introduction** The dynamic nature of tissue temperature and the subcutaneous properties, such as blood flow, fatness, and metabolic rate, leads to variation in local skin temperature. Therefore, we investigated the effects of using multiple regions of interest when calculating weighted mean skin temperature from four local sites. **Methods** Twenty-six healthy males completed a single trial in a thermoneutral laboratory (mean ± SD): 24.0 (1.2) °C; 56 (8%) relative humidity; < 0.1 m/s air speed). Mean skin temperature was calculated from four local sites (neck, scapula, hand and shin) in accordance with International Standards using digital infrared thermography. A 50 x 50 mm square, defined by strips of aluminium tape, created six unique regions of interest, top left quadrant, top right quadrant, bottom left quadrant, bottom right quadrant, centre quadrant and the entire region of interest, at each of the local sites. The largest potential error in weighted mean skin temperature was calculated using a combination of a) the coolest and b) the warmest regions of interest at each of the local sites. Results Significant differences between the six regions interest were observed at the neck ( $P < 0.01$ ), scapula ( $P < 0.001$ ) and shin ( $P < 0.05$ ); but not at the hand ( $P = 0.482$ ). The largest difference (± SEM) at each site was as follows: neck 0.2 (0.1) °C; scapula 0.2 (0.0) °C; shin 0.1 (0.0) °C and hand 0.1 (0.1) °C. The largest potential error (mean ± SD) in weighted mean skin temperature was 0.4 (0.1) °C ( $P < 0.001$ ) and the associated 95% limits of agreement for these differences was 0.2 to 0.5 °C. **Discussion** Despite finding statistically significant differences in neck, scapula and shin, the magnitude of variation at each of these sites was negligible (< 0.3 °C) in healthy young males at rest in a thermoneutral environment. Furthermore, these variations did not introduce a clinically meaningful error (> 0.5 °C) in mean skin temperature. However, further research examining the influence of using different regions of interest to calculate skin temperature during exercise in high ambient environments is warranted.

## HUMAN METABOLIC RESPONSE IN VERY COLD ENVIRONMENT AND ANTARCTICA

Yamauchi, J.1,2,3, Kawada, S., Kinugasa, R., Morita, N., Takizawa, K., Yamaguchi, T., Takada, S., Imura, S.

*1. Tokyo Metropolitan University, JAPAN; 2. Future Institute for Sport Sciences, JAPAN; 3. Khon Kaen University, THAILAND*

Our ancestors survived in an unforgiving environment dominated by ice ages. Nevertheless, because climate change is considered to be one of the largest threats to humanity in the future, how to survive the next ice age is an important topic for study. Humans have evolved the function of sustaining constant temperature in a variety of circumstances. To survive in extreme environments, the body has to adapt physiologically. When the body is repeatedly exposed to different environments, resistance to new stress is increased. In cold-exposed adult humans, significant decreases in body temperature are delayed by reducing rates of heat loss via peripheral vasoconstriction and by increasing rates of heat production via shivering and non-shivering thermogenesis. Shivering is elicited by exposure to cold air and this can increase the resting metabolic rate. Fuel selection mechanisms are responsible for sustaining shivering thermogenesis. It has been reported that over a 3-month trip in Antarctica, subjects lost more than 25% of body weight, despite an average energy intake of 21.3MJ/day (Stroud et al. 1997). However, the adaptation process of the biological systems of humans to Antarctic and other cold environments is not well understood. Cold environments have many different effects on the body, such as pronounced metabolic changes, and we are especially interested in physiological adaptations under those conditions. We are currently studying how cold stress affects human metabolism, carried out in a -15°C cold room and Antarctic environment. The results of this study showed that acute cold environment at -15°C increased resting metabolism and fat oxidation, but carbohydrate oxidation was not influenced. Extreme shivering appeared in some subjects during cold exposure -15°C, but not in all subjects. For psychological stress activities, the levels of s-amylase activity and cortisol showed a significant increase in -15°C. Further investigations are needed to optimize nutrients and energy balance for extreme cold or Antarctic environment and to understand the mechanism underlying the combined effects of physiological and neurological responses to extreme cold stress.

## COVERT OR OVERT CHEMICAL/BIOLOGICAL PROTECTIVE CLOTHING SYSTEM: A PHYSIOLOGICAL COMPARISON IN EXTREME ENVIRONMENTS

Stewart, I.B.1, Costello, J.T.2

*1: QUT (Brisbane, Australia) 2: UP (Portsmouth, UK)*

**Introduction** Ensuring protection of state and national dignitaries means that security personnel are prepared to deal with multiple risks including: arms fire, explosions and/or chemical/biological threats. These security personnel are required to maintain vigilance for extended periods often in challenging environments, as observed recently in Brisbane Australia during the G20 summit where ambient temperatures exceeded 40°C. The combination of a challenging environment and the encapsulating protective clothing may impair heat loss and place the security personnel at risk of heat injury. Therefore, the aim of this study was to compare the physiological tolerance times while wearing a covert or overt chemical/biological protective clothing ensemble, in simulated environmental extremes. **Methods**

Eight healthy males undertook four trials while wearing a Chemical/Biological Protective Clothing System plus flight suit (cover) or an Extended Response Suit (overt) and respirator. These ensembles are certified as Class 3 protection by the National Fire and Protection Association (USA). The trials involved walking on a treadmill at 4 km.h<sup>-1</sup> at 1% grade in 21 and 37°C wet bulb globe temperature (WBGT) environmental conditions, in a randomized controlled crossover design. The trials were ceased if the participants' core temperature reached 39°C, if heart rate exceeded 90% of maximum, if walking time reached 60 minutes or due to fatigue/nausea. Tolerance times were analysed using a two-way (ensemble x environment) repeated measures analyses of variance. Results Significant main effects ( $p < 0.01$ ) were observed in ensemble, environment, and their interaction. Post hoc analysis showed tolerance times in WBGT 21°C were longer than WBGT 37°C (mean $\pm$ sem; 120 $\pm$ 0.0 and 42.8 $\pm$ 1.5 min,  $p < 0.01$ ), and in the covert compared with the overt ensembles (84.2 $\pm$ 0.8 and 78.6 $\pm$ 0.9 min,  $p < 0.01$ ). At WBGT 37°C the tolerance time in the covert were significantly longer than the overt (48.4 $\pm$ 1.6 and 37.3 $\pm$ 1.9 min,  $p < 0.01$ ). There was no difference in tolerance time at WBGT 21°C with all participants in both ensembles reaching the maximum duration of 120min. Core temperature was the termination criteria in 100% of participants in the covert and 75% of participants in the overt trials at WBGT 37°C. Discussion In conclusion, participants were able to wear Class 3 chemical/biological protective clothing ensembles in WBGT21°C conditions for in excess of 120 mins. In the extreme ambient conditions of WBGT37°C both ensembles displayed significantly reduced tolerance times, with the covert ensemble enabling a longer total duration in comparison to the overt ensemble, before participants' core temperatures reached 39°C. Security personnel required to wear chemical/biological protective clothing ensembles should remain cognisant of the environmental conditions and the total time they remain encapsulated. #### AEROBIC FITNESS, STRENGTH AND RATE OF FORCE DEVELOPMENT IN SIMVASTATIN TREATED SUBJECTS WITH OR WITHOUT MYALGIA.

Morville, T., Dohlmann, T., Kuhlman, A.B., Torp, M., Sahl, R., Asping, M., Helge, J.W., Dela, F.

*Xlab, Center for Healthy Aging*

Introduction: Simvastatin is a cholesterol-lowering drug widely used in primary prevention and in treatment to reduce risk of cardiovascular disease. The most prominent adverse effect reported with the use of statins is muscle weakness/ache known as myalgia. To what extent this affects daily living including physical activity levels is not clear. The role of myalgia in regards to physical activity with statin treatment is debated and the impact the two have upon each other is not fully understood. In this cross-sectional study we aim to elucidate whether or not there is a difference in the fitness level, the strength or the rate of force development (RFD) in Simvastatin treated groups with or without myalgia. Methods: 60 comparable subjects in primary prevention using Simvastatin 40mg daily for at least 3 months will be enrolled into two groups of 30 with or without myalgia, respectively. On separate days subjects perform a graded incremental VO<sub>2</sub>max-test on a cycle ergometer, a test of maximal power output (MVC) using a Leg Extensor Power Rig, a test of RFD at different time intervals (0-30 ms, 0-50 ms, 0-100 ms and 0-200 ms) during isometric knee-extension using a Kin-Com Dynamometer, and a test of grip-strength using a Grip Strength Dynamometer. The self-reported myalgia is estimated using a visual analog scale (VAS) and daily physical activity is assessed using the International Physical Activity Questionnaire (IPAQ). Body composition is measured by DXA and anthropometric data are sampled to characterize and compare the groups. Results: So far 18 subjects have completed the study, 10 with myalgia (5 M/5 F; age 59.7  $\pm$  1.8 yrs; weight 90  $\pm$  7.2 kg; BMI 29.5  $\pm$  1.9; lean body mass 52.5  $\pm$  3.8 kg) and 8 without myalgia (5 M/3 F; age 59.5  $\pm$  2.6 years; weight 86.9  $\pm$  6.5 kg; BMI 28.7  $\pm$  1.8; lean body mass 55.4  $\pm$  4.4 kg). There were no differences in VO<sub>2</sub>max ( $p = 0.3$ ), MVC ( $p = 0.5$ ) or grip-strength ( $p = 0.5$ ) between the groups. There was a trend towards higher RFD in the group with myalgia at 0-30 ms and 0-50 ms ( $p = 0.08$  and  $p = 0.06$ , respectively). VAS was as expected significantly higher in the group with myalgia (4.5  $\pm$  0.8 and 0.5  $\pm$  0.4,  $p = 0.5$ ). The IPAQ showed no difference ( $p = 0.24$ ). Discussion: Although myalgia is often reported as an adverse effect when using Simvastatin, this study did not find any differences in aerobic fitness, muscle strength or function. This study is not fully completed and may yet show a different result upon completion. The trend towards higher RFD in the group with myalgia could suggest that myalgia per se does not reflect impaired muscle function. Email address: Thomasmor@sund.ku.dk

#### ACUTE PHYSIOLOGICAL RESPONSES TO NOVEL HIGH-INTENSITY INTERVAL TRAINING IN OLDER ADULTS

Hurst, C., Batterham, A.M., Taylor, K.L., Weston, M.

*Teesside University (Middlesbrough, UK)*

Introduction Traditionally, high-intensity interval training (HIT) has been confined to the laboratory, with cycle ergometry the preferred exercise mode (Weston et al., 2014). Alternative HIT strategies suitable for a range of populations, including older adults, should therefore be explored. A recently developed double-concentric (d-c) multi-joint exercise device offers the potential to elicit a high-intensity physiological response. As such the aim of our study was to assess the viability of the d-c device, in comparison to cycle ergometry, as a mode of HIT. Methods In a randomised crossover design, 20 healthy older adults (10 females; age range 55-76 y) completed a HIT protocol, consisting of 3 sets of 4 repetitions on two different exercise modes; cycle and d-c device. Each set consisted of a 75, 60, 45 and 30-s HIT repetition followed by a passive recovery (1:1 work:rest ratio), with each set interspersed with 2-min passive rest. During cycling, the resistance was 80% of peak power attained during a maximal, incremental cycle test, with a self-determined cadence corresponding to a rating of perceived exertion (RPE) of 7 (CR10 scale; 'very hard'). In the absence of fixed resistance for the d-c device, participants exercised at the same level of perceived exertion and completed 4 multi-joint exercises per set (squat, power clean and press, pulldown to squat and step and press). Heart rate (HR) and expired gas were collected continuously throughout exercise, with blood lactate (BLa) measured following each set. Mean difference ( $\pm$ 95% confidence limits) between protocols was then derived. Using a linear mixed model (random slope and intercept) we derived the within-subject standard error of the estimate (SEE) for predicting cycle HIT physiological response from d-c response. Data are mean  $\pm$  SD. Results For all measures there were no substantial differences in HIT physiological response between cycle and d-c: HRmean (81.7  $\pm$  8.2%HRmax vs 82.5  $\pm$  7.2%HRmax, mean difference -0.8 [ $\pm$ 95% confidence limits 3.1] percentage points), HRpeak (89.7  $\pm$  7.3%HRmax vs 90.1  $\pm$  6.7%HRmax, -0.4 [ $\pm$ 2.6] percentage points), VO<sub>2</sub>peak (84.5  $\pm$  10.6% vs 82.8  $\pm$  11.2%, 1.7 [ $\pm$ 5.6] percentage points) and BLa (5.5  $\pm$  1.7 mmol vs 5.3  $\pm$  1.7 mmol, 0.2 [ $\pm$ 0.9] mmol). The within-subject SEE for HRmean, HRpeak, VO<sub>2</sub>peak and BLa was 3.8% ( $\pm$ 95% confidence limits  $\pm$ 0.4%), 4.1% ( $\pm$ 0.4%), 5.1% ( $\pm$ 0.5%) and 2.7% ( $\pm$ 1.2%). Discussion The d-c device elicited a

high-intensity physiological response consistent with cycle ergometry, suggesting it to be a viable HIT mode in older adults. Future work should examine the effectiveness of the double-concentric muscle contractions elicited by the d-c device as a mode of strength/power training in older adults. References Weston et al. (2014). *Sports Med* 44(7), 1005-17 Contact c.hurst@tees.ac.uk

### EMG-THRESHOLD DETECTION COMPARED WITH THE INDIVIDUAL ANAEROBIC LACTATE THRESHOLD

Ertl, P.1, Schober, P.2, Windhaber, J.M.2, Tilp, M.1

1: UG (Graz, Austria) 2: MUG (Graz, Austria)

**Introduction** Besides approaches using lactate or oxygen consumption, there are electromyographical (EMG) attempts to detect breakpoints during incremental tests. An advantage of EMG thresholds is that they could provide individual muscle-specific feedback during all out tests[3]. The purpose of this pilot study was to compare the individual anaerobic lactate threshold (IAT)[4] with thresholds determined by using the course of the amplitude (root mean square, RMS)[3] and frequency (Mean Power Frequency, MPF)[1] of the EMG signal during exercise on a cycle ergometer. **Methods** Six subjects (16+/-0,8 years) performed incremental exercise on a cycle ergometer. The EMG was recorded from the rect.fem.(RF), vast.lat.(VL), vast.med.(VM) and gastroc.med.(GM) of both legs. A ten second interval was used for the calculation of the EMG-RMS. The course of the MPF was calculated using the average of two manually defined contractions during ten second timeframes. IAT and breakpoints (Muscle Turn Point, MTP) in the EMG-RMS and MPF signals were detected visually by independent and blinded peers. Possible differences between MTP-RMS and MTP-MPF to the IAT thresholds were tested with paired t-tests. Relations between MTP-RMS vs IAT and MTP-MPF vs IAT were verified by Person's correlation coefficients and Bland-Altman Plots. Results MTP-RMS were very well detectable in almost all experiments in VL (100%), RF (91,5%), and VM (83%). Similarly, MTP-MPF were detectable in VL (91,5%), RF (100%) and VM (75%). However, it was barely possible to detect thresholds at the GM. There was no significant difference between the metabolic threshold IAT and the MTP-RMS and MTP-MPF ( $p > 0,05$ ). Mean to good correlations could be detected. MTP-RMS vs IAT (RF:d:0,78;VMd:r=0,67;VLd:r=0,74; RFs:r=0,64;VMs:r=NA;VLS:r=0,75) MTP-MPF vs IAT (RFd:r=0,52;VMd:r=0,90;VLd:r=0,88; RFs:r=0,85;VMd:r=NA;VLd:r=0,86;d=dexter;s=sinister). **Discussion** The determination of the breakpoints using EMG-RMS and EMG-MPF turned out to be a valid method to detect muscle-specific transitions to anaerobic metabolism. Our results match to those in the literature[1] although the detection using the amplitude (RMS) signal seems a more reliable method. For future studies we propose to measure the metabolic thresholds directly at or close to the muscle to discover whether the EMG thresholds fit with the muscle-specific metabolic thresholds. **References** [1] Helal, J. ### END CRITERIA FOR REACHING MAXIMAL OXYGEN UPTAKE IN 13 YEAR OLD BOYS AND GIRLS

Hellelid, K.J., Berntsen, S.

*University of Agder*

**Introduction** Maximal oxygen uptake ( $VO_{2max}$ ) has long been regarded as the gold standard for measurements of aerobic fitness. Several end criteria are commonly used both in adult and younger populations. The present study aimed to describe how many adolescents fulfilled different end criteria for reaching  $VO_{2max}$  during a graded maximal treadmill test to voluntary exhaustion. **Methods** Sixty-nine healthy 13-years old adolescents performed maximal running on a treadmill. Heart rate (HR), ventilation (VE), respiratory exchange ratio (RER) and oxygen uptake ( $VO_2$ ) was recorded continuously. Perceived exertion (RPE) was reported using the Borg Scale 6-20. The test ended when the participants could no longer keep up with the treadmill or they had reached his or her maximal effort. The different end criteria analysed were peak RER  $\geq 1.0$ ,  $VO_{2plateau}$  and  $VO_{2levelling}$  off, peak RPE  $\geq 17$  and HRmax  $\geq 95\%$  of the age-predicted HRmax (208-0.7age).  $VO_{2plateau}$  were defined as no increase in  $VO_2$  despite increase in ventilation during the last two minutes.  $VO_{2levelling}$  off were defined as no more than 2ml increase in  $VO_2$  during the last two minutes. Data are presented as mean values  $\pm$  standard deviation. Multiple t-tests were used to evaluate the effect of the end criteria on  $VO_{2max}$ , when applicable. Statistical tests were conducted using GraphPad Prism 6.0f (GraphPad software, La Jolla, CA, USA). P values of  $\leq 0.05$  were considered statistically significant. Results The average  $VO_{2max}$  was  $54 \pm 9$  ml $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ .  $VO_{2max}$  and VEpeak were 13% ( $57 \pm 10$  vs.  $50 \pm 7$  ml $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ ) and 12% ( $100 \pm 18$  vs.  $89 \pm 10$  L $\cdot$ min $^{-1}$ ) higher in the boys compared to girls ( $p < 0.05$ ). Common end criteria in children, RER  $\geq 1.0$  and RPE  $\geq 17$  were fulfilled by 93% and 99%, respectively. Only 9% achieved a true plateau in  $VO_2$  during the last two minutes of the test, whereas 52% achieved a levelling off in  $VO_2$  during the same time period. Thirty-five percent reached HRmax  $\geq 95\%$  of the age-predicted HRmax. The end criteria had no significant impact on  $VO_{2max}$  except for RER  $\geq 1.0$  in which a higher  $VO_{2max}$  ( $64 \pm 9$  vs  $53 \pm 9$  ml $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ ) was observed in those who did not reach this end criterion. **Discussion** The strict definition of  $VO_{2plateau}$  seems to be untenable, as only 9% achieved this criterion. In contrast, 93 percent achieved RER  $\geq 1.0$  and 99% achieved  $\geq RPE \geq 17$ . Voluntary exhaustion and RER  $\geq 1.0$  and RPE  $\geq 17$  seems to be efficient end criteria for 13 years old adolescents as stricter criteria did not result in higher  $VO_{2max}$  values. ### LUMBAR JOINT POSITION SENSE AND LUMBAR RANGE OF MOVEMENT TEST USING ELECTROGONIOMETER: RELIABILITY STUDY WITH ACTIVE STUDENTS AND HIGH LEVEL SWIMMERS

Solana-Tramunt, M., Morales, J., Cabedo, J., Guerra-Balich, M., Buscà, B., Cumelles, L.

*FPCEE Blanquerna, University Ramon Llull*

**Introduction** Joint position sense (JPS) and lumbar range of movement (ROM) has been used to measure proprioception and evaluate biomechanics of the lumbar spine both in sports men and sedentary people. The spine reposition sense methods use to be very expensive and difficult to manage. The methods to accurate measure of lumbar ROM still use x ray, assuming that the most accurate method is the most aggressive too. Electrogoniometer hasn't been measured lumbar JPS and ROM. Therefore, the aim of this study was to determine the reliability of lumbar joint position sense and lumbar ROM test using electrogoniometer in a seated position in active students and professional swimmers. **Methods** A sample of thirty-four healthy professional swimmers (20.3 $\pm$ 4.1 years) and twenty-seven healthy active students (22.8 $\pm$ 2.9 years) participated in the study. Lumbar ROM was measured in the lumbar spine, summing absolute values of maximal flexion and extension target angles. JPS was measured by Absolute errors, defined by the difference between the absolute value of the perceived mid position and the real mathematical half position. Reliability was determined by the reproducibility or stability on both test-retest data, comparing the scores between 3 trials of each variable on 2 different days, separate by 2-3 days. Intratester reliability was determined by comparing the obtained data by the same tester across 2 different days. **Results** The electrogoniometer was found to

be reliable instrument as both test ( $p=0.999$ ) and retest ( $p=0.999$ ) Intraclass correlation coefficients (ICC) were high. The different flexion, extension and total ROM tested and lumbar position sense were also found to be reliable with ICC ranging from 0.895 to 0.991. No differences were observed between trials for either measure. Intratester reliability was warranted by the application of the same protocol by the same tester during all data collection. Discussion There is a strong relationship between the obtained data with previous lumbar spine studies (Lee et al., 2002; Maduri & Wilson 2009). The results suggest that the electrogoniometer is a reliable and valid instrument to measure the lumbar sagittal ROM and the lumbar position sense on seated position. It could be an easy and less sophisticated way to improve lumbar proprioception and kinematic researches (Ha et al., 2013). Further research is needed to identify the specific mechanism of proprioception during flexion and extension tasks and to establish the concept of relative error instead of absolute error to make a relationship between JPS and total ROM. ### RELIABILITY OF OBJECTIVELY MEASURED SEDENTARY TIME AND PHYSICAL ACTIVITY IN ADULTS

Aadland, E., Ylvisåker, E.

*Sogn og Fjordane University College*

Purpose: To determine the reliability of objectively assessed sedentary behavior (SED) and physical activity (PA) in an adult population. Methods: Eighty-seven adult subjects (28 men; mean (standard deviation) age 31.3 (12.2) years; body mass index 23.7 (3.1) kg/m<sup>2</sup>) wore the GT3X+ accelerometer for 21 subsequent days, for which the reliability of different wear time criteria (8 to 12 h/day and 3 to 5 d/week) was explored. Variance partitioning along with the Spearman-Brown prophecy formula was used as the basis for determining intraclass-correlation coefficients (ICC) and the number of monitoring days needed (N) to achieve an ICC = 0.80. Week-by-week reliability was reported using ICC, Bland-Altman plots and absolute measures of agreement. Results: Seven-10 days of monitoring was needed to reliably assess overall- (axis 1 and vector magnitude (VM) counts per minute (CPM)) and moderate-to-vigorous PA (MVPA), 3-4 days was needed for light PA (LPA), whereas the number of days needed for SED depended on whether adjustments were made for wear time (6-8 days) or not (13-16 days). The week-by-week ICC was  $\geq 0.70$  for all variables, with limits of agreement being  $\pm 267.8$  cpm for CPM,  $\pm 352.3$  cpm for VM CPM,  $\pm 76.8$  min/day for SED,  $\pm 57.8$  min/day for LPA and  $\pm 43.8$  min/day for MVPA, when adjustment was made for wear time. Conclusions: For most variables, more than one week of measurement was needed to achieve an ICC = 0.80. Correcting for wear time was crucial to reliably determine SED. Considerable week-by-week variability was found for all variables. Researchers need to be aware of substantial intra-individual variability in accelerometer-measurements.

### OP-BN03 Swimming, Jumping & Squatting, Coordination

#### PRESSURE DISTRIBUTION ON SWIMMING HANDS WITH FINGER SPREADING

Westerweel, J.

*Delft University of Technology*

It is known that a spreading of fingers during swimming has a favorable effect on the drag coefficient, which can enhance propulsion in swimming [1]. The drag coefficient CD represents the effect of the hand shape in relation to the drag force. The change in geometry changes the flow and subsequently CD. Hence, an increase in CD implies smaller losses in power during a swim stroke. Both experiments and numerical simulations were carried out. The experiments were carried out in a wind tunnel, using solid plates that were cut according to a traced circumference of actual hands with different finger spreading. The hands were placed inside a wind tunnel with the plane of the hands normal to the flow velocity. Wind speed was adjusted so that the air flow corresponds to the flow Reynolds number in water ( $Re=30000$ ). We tested both a closed and hands with finger spreading between 2 and 15 mm. It was found that the drag coefficient increases by about 3% at a 5-10 mm finger spreading, in agreement with previous results [1]. It is noted that spreading fingers also increases the hand frontal surface area, resulting in a net effect of 10% higher CD. CFD was performed on the same hand models, providing the pressure distribution over the front and back surfaces of the hands, in relation to the observed changes in drag coefficient. The results of these simulations provides information on the flow that causes the increase in CD, but also how a swimmer perceives the forces on the fingers. Also, the results provide clues on where to measure forces and pressures for quantitative feedback to swimmers. Reference: 1. Marinho et al., J. Appl. Biomech. 26 (2010) 87 Contact: J.Westerweel@tudelft.nl

#### THE EFFECTS OF A COMPUTERIZED BIOMECHANICAL ANALYSIS AS A TEACHING STRATEGY ON THE RECOVERY SHOULDER OF THE FRONT CRAWL SWIMMING

Ghafourian, L., Banitalebi, E., Rahnama, N.

*Sama organization (affiliated with Islamic azad university)- Shiraz branch*

This study was computed to test for significance of the effects of three teaching strategies on the humerus of rotation and linear displacement of the breathing and non-breathing recovery arms of the front crawl swimming. Seventy registered Iran Swimming boys and girls between the ages of 8 through 12 years were given "intact groups" assignment. The participants were selected from Shiraz Swimming teams. The study included 25 participants for each of the following four groups: (1) control, (2) traditional teaching strategy, (3) traditional and videotape teaching strategy, and (4) traditional and System computerized biomechanical analysis teaching strategy. Participants were individually videotaped while swimming 25 meters of the front crawl swimming. Measurements from the radius of rotation and linear displacement of the radius and glenohumeral joint segment were calculated by the NEAT System software. It was determined that all treatments effected increase in radius of rotation and linear displacement. Therefore, all of the teaching strategies caused significant improvement in the radius of rotation and linear displacement for the breathing recovery arm of front crawl swimming. Physiological benefits included enhanced awareness of correct shoulder elevation that could improve swimming skill and swimming times. Psycholog-

ical benefits might have included increased self-concept. Benefits also included knowledge of better teaching strategies such as computerized biomechanical analysis to enhance motor learning.

### UNSTEADY AERODYNAMICS OF A SKI JUMPER DURING THE TAKEOFF MOTION

Yamamoto, K.1, Tubokura, M.2,4, Baleriola, S.3, Onishi, K.4

1: Hokusho Univ. (Ebetsu, Japan), 2: Hokkaido Univ. (Sapporo, Japan), 3: ENSMA (France), 4: RIKEN AICS (Kobe, Japan)

**Introduction** The ski jumping takeoff motion is the transition movement from the in-run posture to the flight posture. The aerodynamic force acting on a ski jumper varies dynamically because of the postural change in a short period. The ski jumper must perform an appropriate takeoff movement for an aerodynamic force to form a suitable flight posture (Schwameder, 2008). However, force measurement during the motion does not yet lead to quantification. This study was designed to quantify the aerodynamic characteristics during takeoff using computer fluid dynamics (CFD). **Methods** The CFD method adopted for this study is based on Large-Eddy Simulation. Body surface data were obtained by 3-D laser scanning of an active ski jumper. A model was generated by dividing the data into 15 segments with joint mobility. Based on video analysis of the actual takeoff movement at a jumping hill, two sets of motion data were generated (world-class jumper A and less-experienced junior jumper B). The incoming velocity was set to 25 m/s. The aerodynamic force, flow velocity, and vortices for each model were compared between models. **Results** The drag force acting on jumper A was weaker than that acting on jumper B through the whole movement. Regarding the lift force, although jumper A's lift force was less in the in-run posture, it became greater than that of jumper B at the end of the movement. In the latter half of the movement, low air-speed domain expansion was observed at the model's back. This domain of jumper B was larger. The flow structure of the two models on their wake was completely different. Jumper A had two symmetric vortexes, but two disordered vortexes on both sides of the back were observed in jumper B. **Discussion** Comparison of the two models shows that aerodynamic forces acting on models might be influenced by the airflow condition around the model's back. Expansion of the low air-speed domain of jumper B can be caused by a large trunk angle of attack (Meile et al., 2006). The trunk and upper arm motion might cause the flow structure difference of the wake. Larger vortexes were formed for jumper B because wakes formed by the arms and lower limbs were united in the rear. However, the vortexes created by the arms remain at the end of the motion in jumper A because the glenohumeral joint is extended during movement. **Results** of this study suggest that the takeoff movement strongly influences airflow conditions and aerodynamic characteristics around the jumper in a short period. **References** Schwameder, H. ### SKI JUMPING: HOW DO SITTING POSITION AND JUMPING MOVEMENTS AFFECT THE VERTICAL GROUND REACTION FORCE?

Gulbrandsen, Å.M.1, Vereijken, B.1, Bråten, S.2, Federolf, P.A.1,3

*Norwegian University of Science and Technology*

1Norwegian University of Science and Technology, Trondheim, Norway 2Olympiatoppen Midt-Norge, Trondheim, Norway 3Institute of Sport Science, University of Innsbruck, Austria **Introduction** Part of technique training in ski jumping consists of land-based simulation jumps: athletes vary their sitting posture following instructions, such as "high", "low", "offensive", or "defensive", and evaluate the subsequent jump with their coaches. This study addresses three research questions: (1) Do different athletes interpret the different instructions in similar ways? (2) What characteristic variations are seen in the sitting posture and jump kinematics? (3) How do changes in sitting posture and/or jump kinematics affect mechanical performance variables such as vertical ground reaction force (vGRF)? **Methods** Fourteen ski jumpers completed 21 jumps under 6 different conditions: perfect, high, low, offensive, defensive, and free. The sitting posture and jump were recorded with Oqus motion tracking system using 22 reflective markers distributed on the right extremities, pelvis, spine, and head. Two Kistler force plates recorded the vGRF. A principal component analysis (PCA) was performed (Federolf et al. 2013) on a combination of marker trajectories and vGRF waveforms. We assessed how changes in movement patterns (Principal Components, PCs) correlated with changes in the vGRF. The PCA was conducted on the normalized data from all subjects and thus allowed for direct comparisons of movement patterns between subjects. **Results** Despite individual differences, movement variations were overall consistent. PCs 1-3 visualized most clearly the different conditions and characterized larger whole body movements such as wider leg joint angles and elevated spine (high), or a forward position (offensive). The opposite was seen for low and defensive. PCs 4-8 represented different compensatory movements during the sit-to-jump transition, while PCs 9-15 represented mainly arm and head movements. A defensive or low sitting position created lower vGRF peak forces that were more slowly generated, while the opposite was found for offensive and high. **Discussion** Results indicated that athletes largely interpret training instructions similarly, resulting in characteristic variations in sitting posture and jump kinematics. Furthermore, movement patterns and vertical forces are related, although causality cannot be inferred in the present study. Visualization of the PCs can help coaches and athletes to better understand the often ambiguous descriptions of movement patterns and variations. **References** Federolf et al. *Journal of Biomechanics* 46 (2013) 2173-2178 Contact [adnemarl@stud.ntnu.no](mailto:adnemarl@stud.ntnu.no)

### FUNCTIONAL ONE-LEGGED JUMPING HEIGHT IS DETERMINED BY KNEE JOINT POWER AND SWING LEG HIP POWER IN YOUNG FEMALE HANDBALL PLAYERS

Bencke, J., Jensen, M.J., Zebis, M.K.

*Gait analysis lab*

**Introduction** One-legged jumping performance is an important game-changing skill in many ball sports, e.g. handball, and information about the kinematics and kinetics contributing to increased jump height may aid the trainers in designing training regimes. The aim of this study was to investigate which joint power parameters in the take-off leg and the swing-leg, as well as isolated measures of muscle strength and explosive leg power, may be influencing jump height in female handball. **Methods** 27 female handball players aged 16-18 from two top-12 teams in the Danish under-18 volunteered to participate. All subjects were tested for maximal isometric knee extension strength (MVIC) in an isometric dynamometer (Meitür, Finland). The subjects were tested for maximal countermovement jump height (CMJ) and maximal one-legged jump height (OLJ) in a 3D biomechanical laboratory. CMJ height was used as a measure of overall leg extension power. Besides maximal OLJ height, maximal 3D joint moments and - powers for the take-off leg and swing leg hip joint were derived as parameters relevant for jumping performance. Multiple regression analysis was used to identify overall important parameters for OLJ. The kinetic parameters were also compared between the best 9 OLJ performers and the 9 poorest performers using T-tests in order to further elucidate which parameters distinguish good performers from poor performers. **Results** The regression analysis showed

that knee joint power and swing leg hip power were the two most important parameters for OJ performance. The 9 best OJ subjects were significantly superior in knee extensor moment, hip abductor moment, concentric knee joint power, swing leg hip concentric power and swing leg knee concentric hip power. MVIC was not related, while maximal CMJ performance was only weakly related, to OJ performance. Surprisingly, the OJ height was not related to MVIC, and only weakly correlated to total CMJ height. This may imply, that the very dynamic loading of the take-off leg is more related to a task-specific activation, particular of the knee extensors, which is different from isometric MVIC or more symmetric CMJ activation patterns. Furthermore, the increased concentric and eccentric hip joint powers of the swing leg indicates, an importance of a forceful hip flexion of the swing leg followed by a fast breaking of the flexion in the end of the push-off phase, which transfers momentum from the swing leg to the body thus increasing OJ height. Therefore, dynamic power training of the take-off leg and focus on adequate swing leg action may increase OJ height in young female handball players.

### OP-SH15 Physical Education & Pedagogics I

#### IN THE CROSSING OF THE FIELDS OF EDUCATION AND SPORT: SOCIAL SELECTION AMONG PUPILS IN SCHOOL SPORTS

Ferry, M.1, Lund, S.2

1: Umeå University, 2: Linnaeus University

**Introduction** With reference to Bourdieu's theoretical framework, the fields of education and sport can be seen as social fields in which choice and social selection are influenced partly by the possession of capital and habitus and partly by the organisational and structural circumstances. This paper sets out to investigate those pupils who, in the crossing of the fields of education and sports, choose and have been selected to participate in school sports in Sweden. From a cultural sociological perspective, the main purpose of this paper is to identify and analyse how organisational conditions and pupils' social characteristics interact with the different selection processes underlying upper secondary pupils' participation in school sports. **Methods** For the analysis of the selection of pupils on a national level, we use registry data on upper secondary school pupils in Sweden. For the analysis of the selection process on an individual level, data were derived from two questionnaire surveys completed by pupils participating in school sports at 18 strategically selected upper secondary school during 2008 and 2009. In total, the survey data consist of answers from 677 pupils (386 boys and 291 girls). For this paper, the conforming parts of the questionnaires were merged, and include information about the pupils' social background, choice of education, athletic level and parental involvement in sport. Characteristics that can be seen as indications of the possession of an educational capital and sporting capital. Results Swedish school sports are organised primarily in combination with academic study programmes and team sport, and this results in that in comparison the nationwide population pupils who participate in school sports are: to a higher degree boys, attending academic study programs, have Swedish background and whose parents have a higher education level ( $p < 0.05$ ). Furthermore, the result show that the choice between different school sports programmes is related to the pupils' possession of educational capital and sporting capital. School sports programmes with higher demands on athletic ability require larger possessions of capital among the pupils ( $p < 0.05$ ). **Discussion** We argue that school sports, through the crossing of the two fields of education and sports, increase the social selection among the pupil. The organisational condition for school sports makes participation neither reasonable nor possible for all pupils. Instead, the supply of school sport appeals to a narrow or rather specific taste for sport and education. In this sense school sport is generally organized in a way to attract boys with highly educated parents and with an interest in sports. Contact: magnus.ferry@umu.se

#### HEALTH EDUCATION IN HPE TEACHER STUDENTS' BACHELOR/MASTER THESIS

Schenker, K.

*Faculty of Social Sciences*

Research shows that teaching content and power technologies, which rewards certain bodies in the school subject Health and Physical Education (HPE), contribute to inequality. WHO advocates equal health, and states that it is important to improve conditions for peoples' daily life by for instance eliminating the unequal distribution of power, money and resources. Inequality in HPE can therefore be regarded as unhealthy teaching conditions. The research provides no guidance on how teachers should teach pupils who do not experience HPE as positive. The purpose of this study is to investigate how HPE teacher students relate to health in HPE. The study is based on the following questions: - What kind of health-related problems do the students investigate? - What is healthy education in HPE according to teacher students' Bachelor/Master thesis? Health can be part of the teaching content of HPE, but it can also be a part of the didactics, meaning that the ontological and epistemological related decisions in the teaching context can be more or less disciplinizing, regulating and normalizing. The tradition of the German didactics, aligned with epistemological conceptions related to other theories of education, can be of use in this study. Implicit ideological teaching principles can be analyzed using teaching methods and teaching content as empirical material. The research questions demands a qualitative didactical analysis of texts. The study involves 81 thesis, connected to HPE school subject, examined at six different Swedish universities, all of them examined in 2012. The result shows that students are investigating health mainly from two different positions. One is measurements of the body or body performances; either to promote elite sport or public health (like BMI, burnout or fitness results). The theoretical perspectives in these studies are either natural sciences or psychology. When the concern with this perspective is connected to public health, health is understood from a pathogenic horizon. The other position is derived from a described need of learning how to teach health or to teach in a healthy way. It is common that a public health perspective is used to explain why health(y) education is important. HPE is argued to be important especially for those who aren't physically active in their leisure time. The HPE students often search for ways to teach and promote health at an individual level. Here, a salutogenic activity based approach with the individual in center is supported. When the teaching content is activity-based, and when the teacher decides what health promoting activities is, some pupils are rewarded and some are not. HPE education in the interviewed teachers' and the HPE students' context cannot thus be seen as a healthy equality project.

### SWEDISH PE TEACHERS' GRADING PRACTICE IN A STANDARD BASED GRADING SYSTEM

Svennberg, L., Meckbach, J., Redelius, K.

*The Swedish School of Sport and Health Sciences, University of Gävle*

Instead of following the standard based grading system in use, which is supposed to support equality and accountability, PE teachers sometimes grade according to internalized criteria or 'gut feelings' (Hay & McDonald, 2008; Svennberg, Meckbach & Redelius, 2014). Therefore the validity of the grades has been questioned (Annerstedt & Larsson, 2008). The aim of this study is to explore Swedish PE teachers' grading practice and what they value in the grades given to their students. Four PE teachers in compulsory school were interviewed with the Repertory Grid (RG) technique. The RG technique can be used to reveal a person's perception of a specific topic that the person is familiar with, by examining the similarities and differences between well-known elements (Fransella, Bell & Bannister, 2004). First the teacher was asked to select seven to eight students from a class that he or she was teaching and grading in PE. The students selected must represent all possible grades (Fransella et al., 2004). In the second step, the names of three of the students at the time were presented to the teacher who was asked in what way, relevant for the grades, two of the students were similar and different from the third (Fransella et al., 2004). In the third step, the teachers were asked to rate the students on how they corresponded to the similarities and differences mentioned. The resulting grids were analysed with the programme WEBGRID5. Besides knowledge and skills all four teachers valued standard irrelevant criteria. The standard irrelevant criteria generally also matched the grades given. There were differences in how the national standards matched the given grades. and some national standards were not mentioned at all. It seems like some standards have been better implemented than others. The results indicate the need for a discussion of why standard irrelevant criteria such as motivation and effort seem more relevant for teachers to use than the national grading criteria. Bernsteins' interrelated systems of curriculum, pedagogy and assessment (2003) can contribute to the understanding. It is also important to discuss why some national grading criteria are easier for the teachers to implement than others. References Annerstedt C, Larsson S. (2010). ### BRIDGING THE DISCREPANCY? A STUDY OF PETE TEACHER'S PERCEPTIONS OF THE NEW SYLLABUS IN PEH IN SWEDEN.

Ekberg, J.

*Malmö University*

Introduction Physical Education is described as a popular subject, and as being important for both the individual as for the society. Still several studies discuss problems identifying the subject content, in Sweden as in many other countries. For instance, Ekberg (2014) argues, based on a study of physical education and health (PEH) in the prior curriculum in Sweden, that there are discrepancy between the steering documents on the one hand and what teachers says and what occurs in the learning situation on the other hand. The content knowledge of the field of formulation is largely reformulated in the field of transformation, but no major change takes place from the field of transformation to the field of realisation. Ekberg concludes that the prior syllabus for the contemporary school was vague on several points and the relations between sport and health were not made clear. According to the Swedish government, the new curriculum and syllabuses in Sweden, introduced 2011, is supposed to provide better and clearer instructions about objectives, knowledge content and knowledge requirements. The study In the light of this, the aim of the study is to examine if the new syllabus in PEH is perceived to be more consistent than the latter one, and if so, whether and how this might have contributed to bridging the discrepancy between the field of formulation on the one hand and the fields of transformation and realisation on the other hand. This research draws upon curriculum theory and the social construction of knowledge, as inspired by Bernstein, Lundgren and Linde. Interviews are made with experienced physical education teacher education (PETE) teachers in Sweden. The result will contribute with knowledge about the new syllabus for PEH and the perceived consistent and the possible contribution to bridging the discrepancy described. Moreover, the study will offer understanding about what subject content seems to be valid in the subject in Sweden today. References Bernstein, B. 2000. ### CRITICAL THINKING DISPOSITION OF THE STUDENTS STUDYING SPORT SCIENCE AT UNIVERSITY

Sunay, H.

*Ankara University*

Introduction Individuals' adaption to innovation in social life easily, using acquired rights, developing critical thinking skill have an important place understanding of today's modern education. With contemporary education, it is intended to grow individuals who are versatile, productive, investigating, questioning, skeptical and situations faced new information.(Tural and Secgin 2012). The aim of this research is to examine whether the critical thinking disposition of the students studying at university changes or not according to the variables. Methods In this study, it is tried to determine whether the critical thinking level of sport students at university vary according to the individual variables and so the relevant sources has been scanned. Therefore, organized research screening model has a descriptive study. The universe of the research consists of 2800 university students who participated in the sports contests organized by Ankara University in 2013-2014 academic year and intercollegiate contests. The sample group of this study consists of 203 sport students continuing their education at Ankara university in 2013-2014 academic year are selected by random. California Critical Thinking Disposition Inventory (CCTDI) : This scale emerged as a result of Delphin Project organized by Amerikan Philosophy Association in 1990. Discussions In this study, it is the matter to be considered on low curiosity points of the students who should have the qualities such as learning new techniques, establishing cause and effect relationships for competitions. According to these data, it can be said that critical thinking skills is a mechanism which can change according to the process of vocational education, sports experience, personality characteristics, demographic characteristics of the sample. Therefore, the survey data reveals that critical thinking dispositions have been affected by several variables. Having a tendency to search for the truth ,to be able to evaluate different ideas objectively,accepting the thoughts even

if they conflict with his own ideas are important for an athlete. (Tural and Secgin, 2012). Results As a result, it has been identified that students' critical thinking levels didn't change by sex, but the critical thinking levels of sport students who are studying in other faculties and academies are higher than those who are studying in SPES. Moreover, the critical thinking levels of students involved in 1-3 and 4-6 years were lower than those involved in 7 years and over. References Kokdemir D 2003. **'WE SHOULD ALSO HAVE A CHANCE TO BE INCLUDED.' DISABILITY, GENDER AND PHYSICAL EDUCATION**

Apelmo, E.

*Faculty of Health and Society*

The aim of this paper was to explore how young, sporting women with physical impairments experience physical education (PE), drawing on research on PE as well as on critical disability studies. Phenomenology (Ahmed 2006; de Beauvoir 1949/2011; Merleau-Ponty 1945/2013) provides a sociological theoretical framework that includes the body. Ten semi-structured interviews were done with women ages 15 to 28, living in Sweden. Most of interviews took about an hour. In order to grasp the experience of disability from the view points of the young women themselves, three participants were asked to keep video diaries: they were lent a camcorder and a tripod for two months. The diaries were between 85 to 110 minutes long. The stigmatization the young women experienced in their everyday life resulted in a polarization between the weak, which was expressed through the expression of belonging as 'we', and the strong individual. The subject position as positive and capable – as a reaction towards the weak, the negative – was one of the few positions that were available to them. With the positive and strong attitude, the consequence was the difficulty, not only to complain but also to express pain or discomfort in one's everyday life. However, as regards the issue of PE, the participants discussed problems dealing with experiences of exclusion, being singled out, and special treatment. It appeared to be difficult for teachers to see these women as the sports interested youths that they were. The young women used different strategies of resistance. While a pair of them did not participate in some of the aspects, another woman had chosen not to participate in PE at all. Refusing to be physically active is, according to Larsson et. al. a common form of resistance among girls (with or without impairments) and is interpreted by teachers as lack of interest (2005: 21-22). An important difference is, however, that in this study the young women were very physically active in their leisure time. One participant made use of a strategy which has the potential for changing the view as regards disabled pupils: she showed her teacher medals she had won in the Swedish national swimming championship, as a way to receive a higher grade. When the women finally described the stigmatization that they had been subjected to, they avoided positioning themselves as victims, by minimizing the seriousness of the situation or by using in the interview the word 'we' instead of 'I', thus describing the incident in collective terms. **SPORT AND PHYSICAL ACTIVITY FOR A SUSTAINABLE BODY - PAST, PRESENT AND FUTURE CHALLENGES**

Hedenborg, S.

*Malmö University*

Our perceptions of the physically active human body has an interesting history. It has been influenced by what contemporary scientists have discovered as well as social and cultural discourses. In the 18th century statistical methods were developed in Europe in order to keep track of the population sizes and health. An important outcome were the measures developed in order to decrease infant mortality rates. Over time new ideas on how health was to be preserved and how a nation was secured were developed. Sport and physical activity became important tools for governments wanting to shape the modern citizen. Not all bodies were, however, given the same opportunity. Gender, ethnicity, social class and age were important demarcations. There were, for example, strong voices advocating that the female body was not strong enough for sporting activities. An interesting paradox connected to social class developed as some women were seen as strong and capable of hard physical work (women from the working class, or peasantry) whereas others were seen as weak and dependent. Children and young people were affected too. Training advice when it comes to these groups has changed over time. Today the aging body is in focus. In this lecture a fascinating overview of the ideas of the physical active human body will be presented from past to present.

**THE OLDER MUSCLE: AGEING OR DISUSE?**

Harridge, S.

*King's College London*

The prime role of muscle is to act as a biological machine - to produce force and generate power. This is to fulfil a number of different functions from maintaining posture to allowing the performance of all the physical tasks needed for everyday living. But, muscle also has a plethora of other roles which include protein being an important dynamic store, being the largest sink for the storage of glucose and acting as a source of protective padding. As we get older there is an observable reduction in many of these functions. This is primarily related to a loss of tissue mass, which when passing a given threshold is referred to as "sarcopenia". Sarcopenia is associated with an increased risk of falls and sustaining fractures and is an increased risk factor for morbidity and mortality. However, the extent to which sarcopenia and its attendant side effects can be attributed to an inherent biological ageing process are far from clear. At any age muscle

mass and function are acutely sensitive to activity pattern and usage – being highly responsive to both mechanical and metabolic signals. For example, limb immobilisation, bed rest or exposure to microgravity (space flight) all result in muscle loss and weakness- irrespective of age. The effects of many years of a sedentary lifestyle thus seriously confound our understanding of the properties of a muscle we might expect for a given chronological age. For a typical sedentary older person, a smaller muscle seems to relate to both a reduced number of muscle fibres (and motor units) and a selective atrophy of the fast-contracting type II muscle fibres. Muscle “quality” also declines in older sedentary individuals with evidence of fat deposits and connective tissue accumulation. This makes “contractile” tissue mass harder to determine and contributes to the decrease in force potential per unit area (specific force) of a whole muscle in vivo. Furthermore, when rates of muscle protein synthesis are measured using tracer techniques there is evidence of a reduced sensitivity to both exercise and amino acid feeding. What is the cause of the decline in mass and function? To what extent are these phenomena attributable to the biological ageing process and what can be done to ameliorate these deleterious effects? These are some of the key questions that need to be addressed in the light of the dramatic changes in population demographics. Recent experiments on highly active older people have thrown some light on answering these questions. These studies have shown that despite ageing, muscle mass, function and quality can all be well maintained. These data suggest that we need to rethink our perceptions on the interactions between ageing, exercise and physiological function.

##### IS STEPS PER DAY AN ADEQUATE ALTERNATIVE INDICATOR FOR ACHIEVING A TARGET LEVEL OF MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY IN YOUNG ADULT WOMEN?

Kumahara, H.1, Ayabe, M.2

1:Nakamura Gakuen University (Fukuoka, Japan), 2.Okayama Prefectural University (Soja, Japan)

**Introduction** A physically active lifestyle has numerous health benefits. Therefore, several consensus statements have recommended engaging in regular physical activity (PA) with a certain exercise intensity, such as moderate-to-vigorous PA (MVPA), to improve health outcomes. Steps per day (ST) has remained a popular method for evaluating PA recommendations. Several cross-sectional studies have found a correlation between the duration or volume of MVPA (i.e., METs×h) and ST. However, information on the causes of individual variations in the relationships remains scarce. The purpose of the present study was to explore the association between ST and duration of MVPA under free-living conditions. **Methods** Seventy healthy young adult Japanese women (age range 20-29 years) measured their free-living PA using a validated accelerometer for 7 days. **Results** The average ST, MVPA and METs×h were 9297±2705 steps/d, 33.1±14.6 min/d, and 16.6±7.4 METs×h/wk, respectively. Significant correlations were found between ST and MVPA duration and ST and METs×h/wk ( $r=0.81$  and  $r=0.81$ ). ST equivalent to 30 min/d of PA was estimated at 8839 steps/d; however, approximately 1600 steps/d of the standard error of estimates in the regression equations were calculated. A negative correlation was found between individual estimated ST corresponding to 30 min of MVPA and the percentage of MVPA duration of the total daily PA ( $r=-0.67$ ). **Discussion** The findings indicate that the association between ST and MVPA fluctuates depending on individual daily MVPA. Consideration of both the ST and the duration of daily MVPA are necessary to meet PA guidelines and to consequently gain health benefits. The effects of increasing the PA using various PA indicators on several health outcomes will need to be investigated in future studies. Contact kumahara@nakamura-u.ac.jp

##### INFLUENCE OF DOG WALKING ON THE PHYSICAL ACTIVITIES AND LIFE CHANGES OF OWNERS

Furumoto, K.1, Murao, N.1, Onodera, S.2

1 Kurashiki University of Science and The Arts, 2 Kawasaki University of Medical Welfare

**Introduction** Dog walking is a joint physical activity of owner and dog. In comparing non-dog pet owners and non-pet owners with dog owners in Japan, have been reported as more likely to engage in physical activities and walking (Hayakawa, 2008; Oka, 2009; Shibata, 2012). Dog walking has been reported to give a positive influence on the daily life of the dog owner, but there is no detailed report on the relevance of the changes in the dog owner's life and the frequency of dog walking. The objective of this study was to investigate the influence dog walking has on physical activity and the life of the dog owner. **Methods** Dog owners were selected at random and voluntarily participated in this study. The questionnaire contained question items on basic attributes (gender, age), frequency of dog walking, life changes resulting from dog keeping (opportunities for communication with others, amount of exercise, life rhythm, opportunities to go outdoors). **Results and Discussion** The data sample consisted of 347 respondents. 78.4% of owners walked with their dogs. They walked with their dogs 7.3±4.5 (times/week) and the time of dog walking was 41.1±29.2 (minutes/day). These dog owners felt an increase in opportunities for communication with others, an increase in the amount of exercise and they also felt that their over-all life became more well-regulated. These results were always better for dog owners who walked their dogs more often and for longer periods of time. This influence is different by gender, male dog owners obtained more positive influences from walking their dogs than female. In our previous research, male pet owners who had proactively been involved with their pet had better mental health scores. Using the dog walking as a tool for increasing the amount of physical activity, males might effectively.

##### CIRCADIAN RHYTHM OF ACTIVITY LEVELS: INFLUENCE OF CHRONOTYPE.

Bruno, E.1, Roveda, E.1, Vitale, J.A.1, Montaruli, A.1, Caumo, A.1,2, Carandente, F.1

1. UNIMI, Milan, Italy; 2. IRCCS Policlinico San Donato Milanese, Milano, Italy.

**Aim:** The aim of this study is to investigate, by an actigraph monitoring, the differences in the circadian rhythm of activity level in relation to the chronotype for the sake of studying its influence on physical performance. Morning-type (M-type), Evening-type (E-types) and Neither-

type (N-type) are the classified chronotypes; several studies showed the differences between M-types and E-types in the circadian rhythm of different physiological variables: M-types use to wake up and go to bed early and to have their best performances in the first part of the day, otherwise E-types go to bed and wake up late and they have the peak performances in the evening (Vitale et al., 2013). Method: The morningness-eveningness questionnaire (MEQ) was administered to 502 college students to determine their chronotypes. Fifty subjects (16 M-types, 15 N-types and 19 E-types) were recruited to undergo a 7-days monitoring period with an actigraph (Actiwach actometers, CNT, Cambridge, UK) to evaluate their sleep parameters and the circadian rhythm of their activity levels. To evaluate the circadian rhythmicity of activity levels we used the single cosinor method (Halberg et al., 1977) and we define three parameters characteristic of each statistically significant rhythm: M, MESOR (Midline Estimating Statistic Of Rhythm); A, Amplitude;  $\phi$ , acrophase. The population circadian characteristics were determined and then compared using the Hotelling test. Results: Rhythmometric analysis, with the single cosinor method, on the activity data collected by the actigraph revealed a statistically significant circadian rhythm ( $p < 0.001$ ) for all the 50 subjects. The population mean cosinors were calculated grouping the different chronotypes: M-types, E-types and N-types ( $p < 0.001$ ). No statistical differences about MESOR were showed for all group combinations ( $p > 0.05$ ) but a significant difference ( $p < 0.05$ ) was observed if considering the Amplitude-Acrophase test for all groups combinations, in particular M-types had an early acrophase of the circadian rhythm of the activity levels, at 14.37, while E-types showed an acrophase with more than 2 hours late, at 17.04 ( $p < 0.001$ ); the group of N-types showed an intermediate acrophase, at 15.45, between morning-types and evening-types. Conclusion: We can assume that there is a clear difference between "larks" and "owls" and this results are in line with other studies that showed the biological differences among chronotypes. We can conclude that M-types are more active in the early afternoon and that E-types have the peak of their activity in the late afternoon. Further studies are needed to better understand if and how the chronotype influence a physical performance. References 1. Halberg F., Carandente F., Cornelissen G., Katinas G.S. (1977). ### PHYSICAL FITNESS OF MIDDLE-AGED WOMEN: EFFECTS OF SYSTEMATIZED EXERCISE

Silvatti, A., Caldas, L., Rodrigues, M., Rodrigues, I., Bernardina, G., Andrade, A., Hamill, J.

*Universidade Federal de Viçosa*

**Introduction** Since the practice of physical exercises contributes significantly to the maintenance of physical fitness, the objective of this study was to investigate the effects of an annual periodization on physical fitness of middle-aged women. **Methods** 27 physically active middle-aged women (+/-52 years) performed a systematic physical activity program (3 times a week, 50 min/session). The annual periodization (1) was divided in 3 blocks (8 to 12 weeks each): 1st Block - cardiorespiratory function; 2nd Block - flexibility, coordination and balance; and 3rd Block - strength. We evaluated their physical capacity three times: pre-testing (T1); at the end of the 2nd (T2); and the 3rd block (T3) (VO2max-1600m walk test, bank of wells test, sock test, get up from the floor test, Agility/Dynamic balance, Sitting-Rising test and Abdominal) [2,3]. We verified the normality and sphericity of the data (Shapiro-Wilk and Mauchly's) and applied the ANOVA test with repeated measures ( $p < 0.05$ ) to analyze the effectiveness of the training. Since, the tests related to the evaluation of strength capacity were not performed after the 2nd block we used a paired t-test ( $p < 0.05$ ). **Results** The mean values of the VO2max and flexibility significantly increased in T2 compared to T1 and these values were maintained after the strength block. The mean value of BMI significantly decreased between T3 compared to T2. An improvement in the mean value of the sock test was found in the T2 and, in T3, we found a significant decrease of these values compare with T1 and T2. Both tests performed to evaluate strength showed a significant improvement in T3 compare with T1. **Discussion** Our results agree with the literature and highlight that systematized exercise increase physical fitness. Since we found a gain in the strength, flexibility and coordination capacity we can assume that these women improved their autonomy in the Activities of Daily Living. No significant difference was found in the others tests; however, just a preservation of their capacities is significant since there is a general decline in these measures with the aging. Therefore, we conclude that our annual periodization for middle-aged women was effective in improving or maintaining their cardiorespiratory function, flexibility, coordination and strength. **References** (1) American College of Sports Medicine www.acsm.org (2) Clark BA. ### GENETIC AND ENVIRONMENTAL INFLUENCES ON MOTIVES FOR LEISURE-TIME PHYSICAL ACTIVITY BEHAVIOR

Aaltonen, S.1, Kujala, U.M.2, Kaprio, J.1,3, Silventoinen, K.1

*University of Helsinki*

(1) University of Helsinki (Helsinki, Finland) (2) University of Jyväskylä (Jyväskylä, Finland) (3) National Institute for Health and Welfare (Helsinki, Finland) **Introduction** Twin and family studies indicate that physical activity is affected by genetic factors. Also motives for physical activity have been revealed to be important for physical activity behavior. To unite these findings raises a question whether the motives for physical activity can be heritable themselves. A few existing studies have suggested that genetic factors may influence person's motivation to engage in physical activity. The aim of the study was to examine whether genetic and environmental influences act as potential factors explaining the motives for engaging in leisure-time physical activity. **Methods** The participants were identified from the FinnTwin16 study (Finnish twins born between 1974 and 1979) and surveyed with questionnaire at the mean age of 34.1 years. Altogether, 2 972 twins were included in the quantitative genetic analyses. Since a pregnancy can prevent engagement in leisure-time physical activity, twins who were pregnant were excluded. The motives for leisure-time physical activity were assessed using the validated Recreational Exercise Motivation Measure (REMM) consisting eight dimensions (mastery, physical fitness, affiliation, psychological state, appearance, others' expectations, enjoyment, competition/ego). Quantitative genetic models were performed with the OpenMx software. **Results** Among the twins, physical fitness was the most frequently reported motivation dimension, followed by the psychological state. The highest genetic contribution was found to be for the enjoyment motive component in women (52%) and for the mastery motive component in men (28%). Next in order of genetic contribution were the dimensions: enjoyment (27%), affiliation (24%), psychological state (23%) and appearance (23%) in men and appearance (27%), mastery (25%) and affiliation (22%) in women. The lowest genetic contribution was found for the others' expectations both in men (14%) and women (8%). The remaining variances were explained by specific environmental influences, except physical fitness, appearance, enjoyment and competition in men, psychological state and others' expectations in women and affiliation in men and women. Shared environmental factors had a small contribution to those motive dimensions. **Discussion** It is concluded that the enjoyment was heritable motive for leisure-time physical activity behavior in women. The enjoyment was less heritable in men than in women, but still moderate in magnitude. The motives related to appearance, skill improvement and the social aspects of

physical activity were moderately heritable both in men and women. However, specific environmental influences seem to be crucial in explaining motive dimensions. Contact sari.s.aaltonen@helsinki.fi

### HIGH MATERNAL PHYSICAL ACTIVITY DURING LATE PREGNANCY IS ASSOCIATED WITH HIGHER SERUM CONCENTRATIONS OF BDNF IN CORD BLOOD

Ferrari, N.1, Merz, W.M.2, Floeck, A.2, Brockmeier, K.3, Strueder, H.K.4, Graf, C.4

1:UK Cologne, Cologne Centre for Prevention in Childhood & Youth (GER), 2:UK Bonn, Medical School (GER), 3:UK Cologne, Heart Center (GER), 4:DSHS Institute of Movement & Neuroscience (GER)

**Introduction** Physical activity during pregnancy has several positive effects on maternal metabolism and fetal/neonatal development. However the precise mechanisms underlying these effects are largely unknown. Leptin, resistin and brain-derived neurotrophic factor (BDNF) are involved in metabolism and brain development and may thus play a role in the manifestation of these beneficial effects and their transmission to the fetus/neonate. **Methods** A prospective cross-sectional cohort study was conducted between December 2013 and April 2014 at the Cologne Sports University and the University Bonn Medical School, Germany. 112 women who were admitted for delivery, with a singleton pregnancy and gestational age between 36 and 42 weeks were included. Physical activity during late pregnancy (third trimester) was assessed by the Pregnancy Physical Activity Questionnaire (PPAQ). To calculate the average daily total energy expenditure, activity was classified by intensity in METs and divided in tertiles: inactive, moderately or vigorously active. Maternal and cord blood serum levels of BDNF were investigated by a multiplex immunoassay (eBioscience, Frankfurt/Germany). Samples were run in duplicate. **Results** Women who were moderately active during late pregnancy tended to have higher maternal BDNF levels compared to inactive women (986.1+/-566.6 pg/ml vs. 738.6+/-480.6 pg/ml;  $p=0.061$ ). In addition, neonates from mothers who were vigorously active during late pregnancy had higher cord blood levels of BDNF compared to neonates from inactive mothers (766.1+/-454.3 pg/ml vs. 579.7+/-303.3 pg/ml;  $p=0.057$ ). There were no effects of physical activity during late pregnancy on neonatal leptin and resistin levels (data not shown). **Discussion** Within this prospective cross-sectional study higher BDNF levels were present in neonates from mothers who had been active during late pregnancy. No association was found for leptin and resistin. To clarify the mechanisms underlying the observed health benefits further prospective and controlled studies are warranted. ### WHY DO PEOPLE EXERCISE IN NATURE? DIFFERENTIATING ADULT NORWEGIAN'S BELIEFS ABOUT PARTICIPATING IN GREEN EXERCISE, FITNESS AND SPORTS

Calogiuri, G.

Hedmark University College

**Introduction** Understanding beliefs related to physical activity (PA) is a key issue in PA promotion. Different forms of PA are characterized by different motivations, e.g. fitness activities are associated with body- and health-related expectations, while sport participation is associated with enjoyment and interest (Kilpatrick et al., 2005). To date little is known about motivation for green exercise (GE), which is any PA in contact with nature. The aim of this study was to identify PA-related beliefs associated with participation in GE as compared to sport and fitness. **Methods** The data were derived from a survey initiated by Friluftslivets Fellesorganisasjon ([www.frifo.no](http://www.frifo.no)). Stratified-randomized sampling was used to recruit 2168 adult Norwegians (51+/-15 years; 49.6% females). Participants reported socio-demographic information, PA behaviors, and importance given to different factors related to PA participation. Principal component analysis was used to identify the main groups of beliefs. Multinomial logistic analysis was used to assess the likelihood (OR [95%CI]) of participating in each form of PA for 60-149 min/week or 150+ min/week, controlling for socio-demographic variables. **Results** 'Affective beliefs' predicted participation in GE at both cut-off (1.52 [1.22-1.91] and 3.83 [2.87-5.10]). Moreover, those who engaged in GE for 150+ min/week were more likely to assign greater importance to 'Convenience' (1.89 [1.44-2.48]) and less to 'Instrumental beliefs' (0.63 [0.48-0.83]). On the other hand, 'Affective beliefs' predicted participation in sport and fitness only when the higher cut-off was applied (sport= 3.54 [2.04-6.15]; fitness= 2.04 [1.42-2.92]). Sport participation was associated with 'Sociability' at both cut-off (2.09 [1.62-2.70] and 2.34 [1.59-3.43]), while fitness was associated with 'Instrumental beliefs' (2.60 [1.88-3.59] and 3.11 [2.10-4.59]), and both sport and fitness were negatively associated with 'Convenience' (sport= 0.39 [0.29-0.54] and 0.30 [0.19-0.48]; fitness= 0.51 [0.39-0.68] and 0.38 [0.27-0.53]). **Discussion** Green exercisers assign greater importance to affective aspects of PA such as enjoyment and feeling good. Furthermore, people who assign greater importance to convenience are more likely to engage in GE and less likely to participate in sport and fitness. The vitalizing effects of exposure to nature (Ryan et al., 2010) and the fact that people can exercise in green spaces for free, whenever it suits them and with no pressure from others, can be important motivational factors for GE and lead to greater adherence to PA. **References** Kilpatrick M, Hebert E, Bartholomew J (2005). *J Am Coll Health*, 54(2), 87-94 Ryan RM, Weinstein N, Bernstein J, Brown KW, Mistretta L, Gagne M (2010). *J Environ Psych* 30(2), 159-168

### THE RELATIONSHIP BETWEEN HABITS OF DAILY EXERCISE AND THE TENDENCY OF SPIRITUALITY.

Nigorikawa, T.1, Mitsuishi, H.2

(1)Rikkyo University (2)Kyoto Gakuen University

**Introduction** Many previous studies have shown that there should be strong relations between the human's quality of life (QOL) and spirituality. Therefore, it was considered that human's health and spirituality have close relations. There are also many studies that referred the relationships between habits of daily exercise and psychological factors. However, there is hardly any study that mentioned the relations between the habits of daily exercise and the tendency of spirituality which this study tried to investigate. **Methods** The subjects of the study consisted of 220 male and 333 female university students. They were divided into two groups: the Exercise Group (n=218) and the Non-exercise Group (n=335). The Exercise Group consisted of students who habitually performed 30 minutes or more of exercise more than twice a week. The Non-exercise Group was made up of students who undertook less exercise than this. The tendency toward spirituality was measured using The Japanese Youth Spirituality Rating Scale (JYS), The Purpose In Life Test (PIL) and The Views of Life and Death Scale (VLD). **Results** The exercise group showed higher scores of JYS and PIL than those of the non-exercise group. However, there was no significant difference in VLD. This means that the exercise group has stronger tendency of spirituality than the non-exercise group. There was almost no difference in the results between male and female. **Discussion** Our previous study suggested that there was a relationship between habits of daily exercise and the tendency of spirituality. In this study the same investigation was made using different subjects and indicators which estimate one's spiritual tendency. Almost the same results as in the previous research were obtained. Further investigation is demanded to clear what kind of mechanisms lead to this result.

## SOCIO-DEMOGRAPHIC AND PSYCHOLOGICAL VARIABLES INFLUENCING THE APPLICATION OF PHYSICAL ACTIVITY AS A GENERAL RESISTANCE RESOURCE

Lippai, L., Tarkó, K., Benkő, Zs.

*University of Szeged Juhász Gyula Faculty of Education*

Introduction: Aaron Antonovsky's Salutogenic model of health emphasizes the idea of General Resistance Resources (GRRs) – factors that help to reach a Sense of Coherence in our life. Antonovsky's thoughts inspired the Health Promotion Research Group of Szeged, Hungary, to survey the spectrum of resources that can be mobilized in difficult life situations. On the one hand we have analysed the relative position of Physical Activity as a GRR compared to other resistance resources. On the other hand we have studied the way socio-demographic situation and defining factors of psychological life quality affect the chance of applying physical activity as a coping strategy. Methods: A structured assisted questionnaire interview was performed on a large socio-demographically representative sample (N=1839) from among the population of Hódmezővásárhely County town (Hungary). The questionnaire enquired about the mental health status and the GRRs of respondents, from which we will focus on the latter one. Data were processed with the help of SPSS 15.0. Results: Analysing the relative position of physical activity as a GRR has revealed its multiply undervalued role compared to other researched GRRs. The subjective value of this GRR is average: 9th position out of the list of 18 items. When studying factors influencing lifespan, only 1,1% of respondents contributed decisive importance to the lack of physical activity. We have analysed with the help of logistic regression analysis the effect of several socio-demographic (sex, age, level of education, marital status and financial status) and psychological (subjective well-being, depression, hopelessness, vital exhaustion, general self-efficacy, life meaning) independent variables influencing the chance of applying physical activity as a coping method. The logistic regression model we used proved to be significant ( $\chi^2 = 256.315$ ,  $df = 12$ ,  $N = 1839$ ,  $p < .001$ ). On the basis of our model it can be stated, that three socio-demographic variables (age:  $OR = .980$ ,  $p < .001$ , level of education:  $OR = 1.570$ ,  $p < .001$ , marital status:  $OR = 1.628$ ,  $p < .001$ ) and two variables measuring psychological life quality (subjective well-being  $OR = 1.132$ ,  $p < .001$ ; and life meaning  $OR = 1.078$ ,  $p < .007$ ) influenced significantly the odds of physical activity's acting as a coping method. Discussion: Our results could gain importance in designing health promoting programmes making Hungarian population aware of the role of physical activity as a General Resistance Resource. #### CHARACTERISTICS OF RUNNERS WALKING AND/OR STOPPING IN THE SECOND HALF OF MARATHON RACES

Mori, H., Nabekura, Y., Yamamoto, M.

*National Institute of Fitness and Sports in Kanoya, Tsukuba University*

Introduction City marathoners often walk and/or stop after 30 km. In city marathon races, faster runners tend to run continuously until reaching the finish line, whereas slower runners typically walk and/or stop before finishing. The factors influencing the differences in these types of runners are unclear. This study aimed to determine the characteristics of runners who walked and/or stopped in the second half of marathon races. Methods This study was undertaken at two popular city marathons held in Japan: the 34th Tsukuba Marathon and the 21st Senu International City Marathon. A total of 205 male runners (mean age,  $41 \pm 10$  years; height,  $171 \pm 6$  cm; weight,  $63 \pm 7$  kg; finish time,  $3:40:35 \pm 0:42:24$ ) who completed each race were surveyed. The survey questionnaire included queries on the finish time, number card, age, body mass index (BMI), training volume (monthly running distance), exertion to the point of breathlessness and leg fatigue indexes for each 5 km interval from the start line, and whether the respondents walked and/or stopped (not dropped out) during the race. The lap time for each 5 km was recorded from the respondent runners' number cards. Results Walking and/or stopping runners (WSR) totaled 71 and continuous running runners (CRR) totaled 134. The mean race completion time of WSR was significantly slower than that of CRR (4:04:08 vs. 3:28:07). In addition, WSR were younger (39 yrs vs 42 yrs), ran shorter monthly distances (159 km vs 213 km), and had higher BMI (22.1 vs 21.0) than CRR. The exertion to breathlessness indexes for each 5 km did not differ significantly between the groups; however, exertion to leg fatigue indexes (measured between 20 and 40 km), and the decreasing rate for each 5 km lap from 20 km onwards, were greater in WSR than CRR. Discussion This study was consistent with previous research in establishing that the finish time of marathon races was associated with large training volume (Bale et al., 1985; Sjodin et al., 1985). However, previous studies did not consider whether the marathoners were running continuously or walking and/or stopping during the races. In this study, WSR had a slower finish time and shorter monthly running distances than CRR. In addition, exertion to leg fatigue indexes and the decreasing rate for each 5 km lap from 20 km onwards were greater in the WSR than the CRR. Smaller training volume therefore results in much more leg fatigue after 20 km, and reduction in running pace occurs at around the same time. Ultimately, the incremental leg fatigue and reduction in pace induce walking and/or stopping during the races, and result in a slower finish time. Reference Bale P., Rowell S., Colley E. #### 'SLOW WALKING & TURN' TRAINING FOR HEALTH PROMOTION OF THE ELDERLY.

Araki, M., Hatamoto, Y., Matsuda, T., Higaki, Y., Kiyonaga, A., Tanaka, H.

*Fukuoka University*

Introduction Decline of physical functions and activities in daily life in the late elderly, results in long, but unhealthy life that requires some professional care. Principal reason of the long, unhealthy life is aging of the skeletal muscles. Loss of muscle mass and weakness, leads to serious health problems such as lowering of muscle strength and aerobic capacity. It is important for the elderly to start exercising as soon as possible in order to improve physical functions. Light intensity training, such as walking is not effective enough, thus exercise for muscle strength, muscle mass and aerobic capacity improvements should be of moderate intensity. We examined a new exercise pattern: 'Slow Walking & Turn (SWT)' that incorporates turns as an extra load to walking. Subjects and Methods Subjects performed SWT and treadmill walking (TW) in random order. In SWT, subject walked back and forth on a fixed distance with 20 turns per minute. We exam-

ined SWT on a distance of 1.5, 2.0 and 2.5m, at walking pace of 180bpm, 6 steps per straight-line walking and 3 steps per turning. TW speed was set at 2.7, 3.6 and 4.5km/h, adapted to straight walking speed of SWT. Subjects of Study 1 were 8 healthy persons from 22 years old to 37 years old. In order to assure the correct exercise intensity and safety, we measured the oxygen uptake, Rating of Perceived Exertion (RPE) and heart rate during each exercise. Subjects of Study 2 were 6 healthy males. We selected 11 muscles of trunk and lower limbs and measured EMG in SWT and TW in order to compare the muscle activity of the stance phase in turn and TW. In addition, we measured the EMG of isometric maximum muscle strength. The muscle activity of SWT and TW were normalized in order to evaluate muscle activity level. Muscle activity level of turn was averaged five times for SWT and 5 steps were averaged for TW. We used the foot sensor for time measurements. Result In Study 1, metabolic equivalent of SWT was significantly High. At SWT distance of 1.5, 2.0 and 2.5m, metabolic equivalent was 4.0, 4.4, 4.8 (METs) respectively, while at TW velocity of 2.7, 3.6 and 4.5km/h, metabolic equivalent was 2.6, 3.0, 3.5 (METs), respectively. Moreover, according to the relationship of exercise intensity and HR, rise of heart rate due to incorporating of the turn was not observed. In Study 2, muscle activity level was significantly increased in the muscles of Vastus Medialis, Vastus Lateralis and Erector spinae in turns of SWT rather than TW. Discussion Adding turns to walking increased the energy consumption of SWT even at low-speed. SWT supplies moderate intensity in order to improve muscle strength, muscle mass and aerobic capacity for elderly people who cannot walk fast. Furthermore muscle activity level significantly increased in the muscles of Vastus Medialis, Vastus Lateralis and Erector spinae during turns of SWT compared to TW. Thus the results suggest the possibility of muscle strengthening or muscle mass increase with SWT exercise.

### **PACER AEROBIC FITNESS NORMS FOR KASETSART UNIVERSITY STUDENTS**

Outayanik, B.

*Kasetsart University*

The purpose of this study aimed to construct the aerobic fitness norms for healthy Kasetsart University (KU) students' healthy by using the PACER test. The subjects consisted of 3,929 (1,310 male and 2,301 female) KU students whose ages ranged between 18-22 years. The subjects selected using purposive sampling technique from students who registered in general education course in the second semester, 2013. The PACER test was used to assess cardiorespiratory or aerobic fitness following standardized procedures. Data was analyzed using descriptive statistics of mean, standard deviation and raw score. Aerobic fitness norm was divided into 3 levels; excellence, good and poor. The study results found that the means of the PACER test scores of participants significantly differed between sexes ( $p < 0.05$ ), while ages scores was no significant different. This study constructed an aerobic fitness normative data according to age and gender that using the PACER test for healthy KU students. In general, male students had better cardiorespiratory endurance than female students. However, the aerobic fitness norms for KU students were very low compare to the PACER norm of the Cooper Institute. Therefore, the institute should promote more physical activity and exercise for KU students to develop their cardiorespiratory endurance system or aerobic fitness in the future.

### **THE RELATIONSHIP BETWEEN INTRAMYOCYLLULAR OR EXTRAMYOCYLLULAR LIPID CONTENTS AND CARDIOVASCULAR DISEASE RISKS IN DIFFERENT CARDIORESPIRATORY FITNESS LEVELS**

Hasegawa, N., Kurihara, T., Sato, K., Homma, T., Fujita, S., Sanada, K., Hamaoka, T., Iemitsu, M.

*Ritsumeikan University*

BACKGROUND: Ectopic fat accumulation rather than whole-body fat content may be important for predicting cardiovascular disease (CVD) (Lim S et al., 2013). Visceral, subcutaneous, epicardial and hepatic fat accumulations are associated with CVD risks. Additionally, Lipid depots in muscle are located either in interstitial adipose tissue (extramyocellular lipid: EMCL) or in lipid droplets within muscle cells (intramyocellular lipid: IMCL). Habitual exercise brings higher cardiorespiratory fitness, and results in the amelioration of CVD risks with reduction of fat accumulation. However, the relationship between IMCL and EMCL and CVD risks contents in different cardiorespiratory fitness levels remain unclear. PURPOSE: This study aimed to clarify whether IMCL and EMCL contents affect CVD risks in each gender or cardiorespiratory fitness level with a cross-sectional study. METHODS: One-hundred seventy four healthy young, middle-aged and older subjects (18-79 years) were enrolled in this study. The study subjects were divided into 2 groups according to fitness level (high-fitness: HF and low-fitness: LF groups). These groups were divided based on the median value of  $VO_{2max}$  in each sex and decade. IMCL and EMCL contents of the right vastus lateralis muscle were evaluated by  $^1H$ -magnetic resonance spectroscopy. Blood pressure and serum lipids profile were measured as an index of CVD risk. RESULTS: In all subjects, IMCL content was negatively correlated with systolic and diastolic blood pressures (SBP;  $r = -0.21$ ,  $p < 0.01$ , DBP;  $r = -0.18$ ,  $p < 0.05$ ) and total cholesterol level ( $r = -0.20$ ,  $p < 0.01$ ), whereas EMCL content was positively correlated with SBP ( $r = 0.33$ ,  $p < 0.01$ ), DBP ( $r = 0.38$ ,  $p < 0.01$ ), triglycerides ( $r = 0.29$ ,  $p < 0.01$ ) and total cholesterol ( $r = 0.39$ ,  $p < 0.01$ ) levels. As a comparison between fitness levels, significant positive correlation was observed between the EMCL content and total cholesterol level and DBP in the both groups (respectively,  $p < 0.01$ ). IMCL content negatively correlated with the SBP and DBP in the LF group (respectively,  $p < 0.05$ ), but no correlation was seen in HF group. CONCLUSION: These results suggest that EMCL content may be associated with CVD risk without concerning cardiorespiratory fitness levels, while the IMCL content may not be a risk factor of CVD.

### **THE CHARACTERISTICS OF PHYSIQUE AND PHYSICAL FITNESS BETWEEN SOUTH KOREA ELITE NATIONAL TRACK & FIELD MAN PLAYERS**

Sung, B.J., Ko, B.G.

*Korea Institute of sport science*

The characteristics of physique and physical fitness between South Korea Elite National track & field man players Sung, Bong-ju. 1, Ko, Byoung-goo. 1, 1: Korea Institute of Sport Science(Seoul, Korea) Introduction Korea high school sprinters are superior to the other type athlete in power and muscular endurance, Middle-long distance runners are superior to the other type athlete in cardiovascular endurance and muscular endurance, jumpers are superior to the other type athlete in muscular strength, agility, power and balance. Throwers are superior to the other type athlete in muscular strength, agility and power(kim, M., et al., 2000). Meanwhile, south korea national track-field's fitness research is rare. Therefore, the aim of this study was to evaluate the physical characteristics of the south korea national track & field team each event. Methods These subjects were divided into 4 groups(Sprinter, middle and long distance, jumper, Thrower). We want to know about physique and fitness difference between groups. These items consist of physique(height, weight, %body fat), muscular endurance(push-up, sit-up), muscular strength(grip), flexibility(sit- and reach), agility(side-step),power(vertical jump), cardiovascular endurance( $VO_{2max}$ , % $ATVO_{2max}$ , exercise time). The materials from all the measuring items were testified in one way ANOVA

analysis. Results The thrower group showed significantly better result in weight, muscular strength(grip power) and % body fat than the sprinter group, middle and long distance runner group and the jumper group. The middle-long distance runner group showed significantly better result in VO2max and ATVO2max than other group. The sprinter group showed significantly better result in power(vertical jump) than other group. In conclusion, South Korea national middle-long distance runners(VO2max: 72.6ml/kg/min, ATVO2max: 54ml/kg/min) more superior to the other three groups in cardiovascular endurance. Sprinter's group(vertical jump: 63.1cm) were superior to the other three groups in power. Moreover, thrower group(weight : 97kg, grasping power: 81kg) were superior to the other three groups in muscular strength and more heavier than them. Discussion The south korea elite high school throwing players have the most influence on the muscular strength(kim, M.H., et el, 2000), middle-long distance runner have the most influence on the Cardiovascular endurance and muscular endurance(kim, M.H., et el, 2000), In conclusion, south korea elite track and field players have had adequate physical characteristics. To become a global players will try to reach the first excellent fitness level. References Kim, M.H., Choi, M.D., Lee, M.M and Park, S.H.(2000). ### PELVIC FLOOR EXERCISE TECHNIQUE AFTER SIX WEEKS OF TRAINING AMONG HEALTHY PREGNANT WOMEN – A RANDOMIZED CONTROLLED TRIAL

Szumilewicz, A.1, Dornowski, M.1, Rajkowska, N.1, Piernicka, M.1, Worska, A.1, Hopkins, W.G.2

1: *Gdansk University of Physical Education and Sport, Poland*; 2: *Victoria University, Melbourne, Australia*

Introduction: Pregnant women are advised to exercise pelvic floor muscles regularly. The effectiveness of exercises is determined through the correct technique of their execution. The main aim of the study was to examine the pelvic floor exercise technique among pregnant women before and after six weeks of intervention. Methods: Participants were 42 healthy nulliparas (age  $29 \pm 3$  y, mean  $\pm$  SD) in the second trimester of normal pregnancy. The intervention group (n=27) received one EMG biofeedback session and performed the pelvic floor exercises three times a week with an instructor. The controls (n=15) were neither instructed about nor discouraged from performing pelvic floor exercises. We tested all subjects for pelvic floor exercise technique before and after six weeks of intervention using the Noraxon sEMG and sensors system (Scottsdale, AZ) with vaginal probes for the pelvic floor muscles and the surface electrodes for selected synergistic muscles. An EMG test was used to assess the order in which particular muscles were contracted in a given exercise on a 4-point scale, where 1 = incorrect technique and 4 = correct technique (activation of pelvic floor muscles with synergistic muscles relaxed). The test consisted of 11 tasks (exercises). Here we present results from the first and the last tasks. Correct pelvic floor contraction in the first task should reflect ability to prevent urine leakage in unexpected everyday situations. Correct contractions in the last task reflects resistance to fatigue. A smallest important change of 0.3 in the test score was assumed for assessment of the effect of training with magnitude-based inference. Results: During the first EMG test, correct technique was used by most women in the first task (score =  $3.2 \pm 1.1$ , mean  $\pm$  SD) but most women showed fatigue in the last task (score =  $2.9 \pm 0.8$ ). After six weeks, both groups improved performance in the first task, but there was a possibly small improvement in the controls relative to the training group (mean difference 0.3, 90% confidence limits  $\pm 0.5$ ). In the last task there was a likely small improvement in the training group relative to the controls (mean difference 0.6,  $\pm 0.6$ ). Conclusion: Training of the pelvic floor muscles may help maintain urinary function in pregnant women in situations where they experience fatigue of this muscle group due to supporting the growing uterus and fetus.

### EXERCISE TRAINING ON GOTO-KAKIZAKI RATS: INFLAMMATION STATE BEFORE THE BENEFICIAL EFFECTS ?

Macia, M., Pecchi, E., Vilmen, C., Desrois, M., Lan, C., Portha, B., Bernard, M., Bendahan, D., Giannesini, B.

*CRMBM*

Introduction: Physical activity is considered a crucial component of type 2 diabetes mellitus (T2DM) management, along with diet and medication. However, the beneficial effect of exercise on T2DM physiopathology cannot be only explained by weight loss since few years (1). In that context, the impact of regular physical activity on diabetic skeletal muscle function and bioenergetics independently of obesity warrants further investigation. The purpose of this study was to clarify this issue in Goto-Kakizaki (GK) rat, a model exhibiting a moderate T2DM in absence of obesity. Methods: GK rats (n = 8) performed 8 weeks of daily run on a treadmill (60 min at 20 m/min). Energy metabolism and mechanical performance were longitudinally investigated in gastrocnemius muscle through a multidisciplinary approach combining non-invasive techniques (NMR 31-phosphorus spectrometry and imaging), before (t0), at 4 and 8 weeks. In vitro assays were also performed in additional animals for measuring blood glucose and insulin. Results: Four weeks of exercise training decreased maximal oxidative capacity (Qmax: -33%), specific force generation (-45%) and oxidative energy production (-20%) compared to t0. After 8 weeks of exercise training, ATP production by creatine kinase reaction and anaerobic glycolysis pathways were increased by 42% and 26% respectively while Qmax returned at t0 value. However, specific force generation was slightly decreased (-15%) compared to t0. Discussion: Reduction of both oxidative ATP synthesis and maximal oxidative capacity after 4 weeks of exercise training indicates an impaired mitochondrial function that could be caused by the exercise induced transient inflammation state (2). After 8 weeks of training, observed alterations disappeared and beneficial effects on the GK model seem to emerge by enhancing ATP production from creatine kinase and anaerobic glycolysis pathway suggesting better glucose utilization. ### THE ROLE OF THE AFRICAN SWIMMING FEDERATIONS IN THE PROMOTION OF HEALTH: PROTECTION OF THE ATHLETE'S HEALTH AND PROMOTION OF SWIMMING FOR HEALTH OF THE GENERAL POPULATION.

Perez Diaz, C., Cruz-Márquez, J.C.

*University of Granada*

Introduction: Over the last 5 years, international sport federations (IF), non-governmental organisations (NGO), and the United Nations (UN) have become more active and interested in the promotion of health through sport. Some IFs, such as FIFA and FINA have created "sport for all" programmes aimed at increasing general participation. The study "The role of International Sport Federations in the protection of the athlete's health and promotion of sport for health of the general population"(Mountjoy M, Junge A, 2013), showed that IFs aimed to protect the health of their elite athletes through various activities; however not all the IFs were involved in "sport for all" but fo-

cused more on elite athletes. The study "Competing with injuries: injuries prior to and during the 15th FINA World Championships 2013 (aquatics) (Mountjoy M, Junge A, Benjamin S, et al. 2014) concluded that there is a specific need for out-of-competition research. Methods As part of the study a survey was circulated by email and also in person (at the FINA Swimming World Championships 2014 (25m) / FINA Aquatics Convention in Doha) to all the FINA national swimming federations. Specific information was requested in relation to the following: Statistical information on membership, Medical Structure and facilities, Health Promotion activities, guidelines, Health regulations and directives, Development or implementation of any policies. The response rate in Africa was 62% (32 of the 51 African NFs replied). The multi-lingual survey was answered by the appropriate health representative or designated person of each NF. Results The responses indicate that for 41% of the African NFs one of their top priority objectives is to increase the number of elite athletes. For 50%, the top performance of their elite athletes is top priority, while 31% rank the health of elite athletes as a top priority. The results in relation to the general population show a lot of room for improvement; just 6% of the African NFs considers the health of the general population a priority for them. Discussion The analysis of the results obtained shows that there is a lack of awareness about using swimming as a health promotion tool in Africa. African NFs face significant barriers/ challenges; therefore health promotion is not a top priority for them. Swimming is not ranked as a top sport in African countries. Therefore is not considered or used a method of health promotion as much as it is in other developed countries. Conclusion The responses indicate that health promotion is not a priority in African NFs. References: Mountjoy M, Junge A, Alonso JM, et al. ### EFFECTS OF WATER IMMERSION IN VARIOUS WATER LEVELS ON URINE VOLUME AND SUBJECTIVE MICTURITION DURING WATER EXERCISE

Wada, T.1, Murata, Y.2, Kakutani, N.3, Miyamoto, M.4, Tamari, Y.1, Yoshida, N.1, Nose, Y.5, Kremenik, M.J.2, Onodera, S.2  
 1 Graduate school, kawasaki university of medical welfare, 2 Kawasaki university of medical welfare, 3 Ray sports club okayama, 4 Saiseikai fitness and culture club, 5 Yasuda women's university

Purpose: The purpose of this study was to investigate the relationship of in water exercise to urine volume, subjective micturition, rating of perceived exertion (RPE), heart rate, blood pressure and rectal temperature during in water exercise. Methods: Six healthy male (age:  $21.8 \pm 0.4$  years, weight:  $68.5 \pm 7.2$  kg, height:  $176.2 \pm 2.7$  cm) subjects volunteered for this study. Each subject signed an informed consent form. The study was conducted in an indoor pool facility at K University, in 2014. This study consisted of two experimental conditions: the clavicle trial (C) and the greater trochanter trial (G). The water levels were set to the clavicle and the greater trochanter process. Subjects participated in both conditions on different days. Measurement items were urine volume, subjective micturition, RPE, heart rate, blood pressure (SBP: Systolic Blood Pressure / DBP: Diastolic Blood Pressure) and rectal temperature. The water temperature was 30 degrees Celsius. Both conditions began with 30 minutes in a sitting posture on land. Then, for the next 45 minutes, both conditions performed aquatics in water. Finally, for the last 30 minutes, both conditions were back on land in a sitting posture. Results: Urine volume and subjective micturition after immersion in the C condition was higher than that of G ( $p < 0.05$ ). RPE at immersion in the C condition was higher than that of G ( $p < 0.05$ ). Heart rate at immersion and recovery at 5 minutes in the C condition was higher than that of G ( $p < 0.05$ ). Rectal temperature at immersion, recovery at 5 minutes, recovery at 10 minutes and recovery at 15 minutes in the C condition was lower than that of G ( $p < 0.05$ ). SBP and DBP at immersion in the C condition were higher than that of G ( $p < 0.05$ ). Discussion: Venous return increases in water and urine formation rises and then the diuretic effect increases. Previous studies demonstrated that responses to the physical characterizations in water differed from those on land. Conclusion: Urine volume and subjective micturition increases through inundation in water. ### RELATIONSHIP BETWEEN SHORT-FORM HEALTH SF36 QUESTIONNAIRE AND OXYGEN UPTAKE IN HEALTHY WORKERS

Burgos, S., García, O., Duarte, A., Jiménez, A.  
 Universidad Europea de Madrid

Introduction Physical Activity (PA) is associated with better health levels (Sallis, 2009) and the Cardiopulmonary fitness recognized like one of the best indicators of Physical performance, which can be related with some items of Quality of Life (QL), therefore, the aim of this study was to analyze the relationship between the Quality of Life (QL) and cardiorespiratory fitness of health workers. Methods Sample was formed by 74 health workers (31 men, mean age 36.76 and 43 women, mean age 38.46), measured with the Short-Form Health Survey SF36 (Alonso, Prieto y Antó, 1995) and incremental cardiopulmonary test. Results  $Vo_2$ 's Mean values are higher in Men (39.84 ml/kg/min SD 7.91) than in women (30.74 ml/kg/min SD 5.89) but not significant. Men show higher scores than women but significant differences are present only in Physical Functioning, Role Physical ( $P < 0.05$ ) and Role Emotional ( $P < 0.01$ ) scales. Results showed that better cardiorespiratory fitness is related to higher scores in SF36. Discussion These findings suggest that insofar the values of  $Vo_2$ Max. in a healthy adult workers population is higher, are better the results obtained in the different items that the SF36 evaluated as to the perceived QL, therefore can be assumed to have a good fitness means having a better QL. ## Mini-Orals

### MO-PM17 Physiology: Endurance

#### EXERCISE-INDUCED PAIN TOLERANCE PREDICTS TIME TRIAL CYCLING PERFORMANCE

Mauger, A.R., Astokorki, A.H.Y.

*University of Kent*

Purpose: It has previously been suggested that tolerance of pain is an important factor in endurance performance (Mauger, 2014). However, pain sensation-perception is a complex process which is affected by the type of pain elicited. Therefore, to investigate the effect of exercise-induced pain (EIP) on endurance performance, it may be important to use an experimental pain model that reflects the aetiology of EIP. The purpose of this study was to compare the predictive capacity of experimental pain and EIP on exercise performance. Methods: Twenty one recreationally active male (n= 15) and female (n= 6) participants ( $27.5 \pm 5.5$  y;  $1.73 \pm 0.09$  m;  $72.3 \pm 14.3$  kg) were recruited for this study. Over a series of 3 experimental visits, participants completed traditional measures of experimental pain tolerance by cold pressor test (CPT), and pain pressure threshold via algometry (PPT). Participants were also assessed for their tolerance of EIP using an RPE-clamp cycling trial (Tucker et al. 2006). A standard VO<sub>2</sub>max test provided traditional predictors of endurance performance (VO<sub>2</sub>max, anaerobic threshold (AT), peak power output (PO<sub>peak</sub>)). Finally, participants completed a 16.1 km cycling time trial (TT). Results: No correlation was found between experimental pain measures and TT performance (mean pain in CPT;  $R = 0.28$ ; time lasted in the CPT;  $R = 0.35$ ; PPT;  $R = 0.31$ ,  $p > 0.05$ ). However, there was a significant correlation between EIP tolerance and TT performance ( $R^2 = 0.84$ ,  $p < 0.01$ ). Significant correlations were observed between TT performance and traditional measures of performance (VO<sub>2</sub>max;  $R = 0.48$ ,  $p = 0.029$ ; PO<sub>peak</sub>;  $R = 0.89$ ,  $p < 0.01$ ), with the exception of AT. Stepwise regression for pain predictor variables (mean pain in CPT, time lasted in the CPT, PPT, EIP) revealed that a significant model emerged ( $F_{1,19} = 44.65$ ,  $p < 0.01$ ) when only EIP was used to predict TT performance (Adjusted R Square = 0.69, Beta = 0.84). Conclusion: These findings suggest that EIP tolerance plays an important role in endurance performance and that it is an accurate predictor of TT cycling performance. However, traditional models of experimental pain do not predict exercise performance, likely because they represent very different pain pathways to EIP and so are interpreted differently. Consequently, their use in exercise-induced pain research should be treated with caution. References Mauger AR. (2014). Open access journal of sports medicine, 5:209. #### THE EFFECT OF RESPONSE INHIBITION ON CRITICAL POWER AND THE ANAEROBIC WORK CAPACITY

Salam, H., Hopker, J., Marcora, S.

*University of Kent*

The effect of response inhibition on critical power and the anaerobic work capacity The critical power concept is a mathematical model used to define as the highest sustainable rate of aerobic metabolism (CP) and the finite work capacity that is available above CP, known as  $W'$ . However, TTE tests are strongly influenced by perception of effort (PE), defined as "the conscious sensation of how hard, (Marcora, 2009a). Recent studies have demonstrated a negative effect of cognitive tasks involving response inhibition on PE during self-paced endurance tasks (Marcora et al., 2009b; Pageaux et al., 2014). Therefore, higher PE may limit TTE and subsequently alter the CP and  $W'$  independently of changes within the underlying muscle physiology. The aim of this study was to investigate this hypothesis. Methods Eleven trained cyclists completed 5 laboratory visits, first was to determine maximal aerobic power (MAP). In a randomised order, each cyclist completed four CP protocols under two conditions, following a cognitive task involving RI (incongruent Stroop Task) to exacerbate PE, and following a control (CON) task (reading a magazine). Both tasks lasted 30 min followed by a TTE trial. After 30 min of rest, each cyclist commenced a 2nd bout of the same 30 min cognitive task, with a subsequent TTE trial. The required PO for each TTE was at  $\Delta 40\%$ ,  $\Delta 60\%$ ,  $\Delta 80\%$ , and  $100\%$  MAP. RPE and HR were measured during each TTE with the slope of the response being calculated. Results are presented as mean + SD, CP and  $W'$  data were analysed by paired t-tests and all other results by two-way repeated-measures ANOVAs. Results Neither cognitive task induced any change in CP (RI  $253 \pm 51$  vs. CON  $247 \pm 58$ W;  $P > 0.05$ ), although  $W'$  was significantly reduced in the RI condition (RI  $22817 \pm 4487$  vs. CON  $29283 \pm 6266$  J;  $P < 0.01$ ). Perception of mental fatigue significantly increased as a result of RI compared to baseline and the CON task ( $P < 0.05$ ). There was no significant difference in perceived physical fatigue between conditions ( $P > 0.05$ ). However, pre-post BL accumulation was significantly lower after each TTE in RI condition ( $P = 0.03$ ). The slope of the RPE response was significantly lower in the RI condition due to a higher initial rating ( $P = 0.04$ ). Discussion The results of this study demonstrate that RI has no effect of CP, but does reduce the  $W'$  in trained cyclists. This finding is interesting given that the CP concept is traditionally explained using purely physiological parameters. We demonstrate that mental fatigue induced by RI can alter the work-time relationship, reducing  $W'$ . Lower BL accumulation in TTEs following RI suggests that cyclists were not be able to fully expend  $W'$  even though they exercised to exhaustion. Reference Marcora SM (2009a). #### THE VO<sub>2</sub> PLATEAU IS RELATED TO THE VO<sub>2</sub>-WORK RATE SLOPE AT SUBMAXIMAL RAMP EXERCISE

Niemeyer, M., Beneke, R.

*Philipps-University Marburg*

Introduction A plateau in oxygen uptake is the only valid criteria indicating that a maximum oxygen uptake (VO<sub>2</sub>max) has been achieved. However, during cycling exercise only 30-50% of the subjects show a deflection of oxygen uptake before exercise termination. The physiological reasons of the VO<sub>2</sub> plateau occurrence in some but not all subjects are still unclear. From studies observing the VO<sub>2</sub>-work rate slope ( $\Delta VO_2/\Delta W$ ) at submaximal ramp exercise it is well known that there are considerable differences in  $\Delta VO_2/\Delta W$  ( $9-11$  ml\*min<sup>-1</sup>\*W<sup>-1</sup>) between subjects, which may reflect differences in biomechanical efficiency and /or distinct VO<sub>2</sub>-onset kinetics. The latter does affect the O<sub>2</sub>-deficit at increasing workload which may modulate the ability to continue the test at plateauing VO<sub>2</sub> response. Whether the magnitude of  $\Delta VO_2/\Delta W$  affects the manifestation of the VO<sub>2</sub>max, is unknown. Therefore we tested the hypothesis that the incidence of a VO<sub>2</sub> plateau is linked with a high  $\Delta VO_2/\Delta W$  at submaximal exercise. Methods 15 moderately to well-trained male subjects (mean  $\pm$  SD age:  $25.7 \pm 2.4$  yrs; high:  $182.3 \pm 7.3$  cm; body mass:  $81.6 \pm 6.9$  kg; VO<sub>2</sub>max:  $4.1 \pm 0.4$  l\*min<sup>-1</sup>) performed an incremental ramp test ( $25$  W\*min<sup>-1</sup>) and a VO<sub>2</sub>max-verification test (constant load exercise until exhaustion at 95% peak power) on a cycling ergometer. The VO<sub>2</sub>-

work rate slopes have been calculated from the ramp test using linear regression analyses. A VO<sub>2</sub> plateau has been assumed if the increase of VO<sub>2</sub> during the last minute of the ramp test was <2.1 ml\*kg<sup>-1</sup>\*min<sup>-1</sup>. For the quantification of the VO<sub>2</sub> plateau the differences (residuals) between the extrapolated VO<sub>2</sub>max from the submaximal VO<sub>2</sub>-work rate slope and the measured VO<sub>2</sub>max has been calculated. Subjects with a considerable higher VO<sub>2</sub>max value (>100 ml\*min) in the verification test (>100 ml\*min) have been removed from further analyses. Results of 6 of the 15 subjects showed a plateau at VO<sub>2</sub>max (40%). There were no differences with regard to the maximum blood lactate (12.7 ± 1.5 vs. 12.2 ± 1.8 mmol\*l<sup>-1</sup>) maximum respiratory exchange ratio (1.19 ± 0.06 vs. 1.17 ± 0.03) and maximum heart rate (186 ± 7 vs. 189 ± 9 l\*min<sup>-1</sup>) between the groups of plateau and non-plateau subjects (all p>0.05). ΔVO<sub>2</sub>/ΔW is significantly higher in the plateau group than in the non-plateau group (11.6 ± 0.6 vs. 10.8 ± 0.5 ml\*W<sup>-1</sup>; p<0.05). Furthermore the ΔVO<sub>2</sub>/ΔW is significantly correlated with the differences (residuals) between the extrapolated VO<sub>2</sub>max and the measured VO<sub>2</sub>max (r = 0.78; p<0.01). Conclusion Subjects with a steeper ΔVO<sub>2</sub>/ΔW have a greater chance to show a plateau at VO<sub>2</sub>max.

## THE EFFECT OF CARBOHYDRATE MOUTH RINSE ON SIMULATED XC-SPRINT PERFORMANCE

Kårström, A., Björklund, G.

*Swedish Winter Sports Research Center, Mid Sweden University*

**Introduction** In cross country skiing(XC) sprint, lasting ~3min, athletes reaches intensities of >90% VO<sub>2</sub>max, with >12 mmol/L blood lactate and close to 100% of HRmax (Stöggl, Lindinger, & Müller, 2007). Carbohydrate (CHO)mouth rinse protocol have been showing beneficial effects on self paced high intensity endurance performance (Jeukendrup, Rollo, & Carter, 2013), possible by the effect of a central response to an oral stimuli of the CHO(Gibson, Lambert, & Noakes, 2001). The primary aim was to investigate if a 10 sec CHO solution mouth rinsing protocol improved the performance in a simulated (XC) sprint compared with control (CON). **Method** Seven well trained XC skiers (Male, n=4; Female, n=3) attended the laboratory four times in a placebo controlled, randomized double-blind study. The participants completed four simulated sprints, two (CON) and two experimental rinse protocols; one with a CHO solution and one with a placebo (PLA). The control trials were used to calculate the typical error for time and power output (1.1 sec and 17.4 watt respectively). In the experimental protocol the participants rinsed a 6,4% maltodextrin solution before completed a sprint (800 m for female and 1000 m for male). Time to completion, maximal power output, VO<sub>2</sub>, RPE and post capillary blood sample were measured. Data were analyzed by using ANOVA. **Results** Time to completion was not different with CHO compared with PLA or CON (203,0±16,5 sec, 202,3±15,7 sec, 203,3±14,6 sec) respectively (F=0.01; p >.05). Maximal power output was no different between trials (CON 301±87, PLA 301±83, CHO 302±98; F=0.00; p>.05). Post blood lactate at 15 min were similar between CHO, CON and PLA (9,9±3,9 mmol/L, 7,6±4,0 mmol/L, 10,1±3,7 mmol/L respectively, p >.05). There were no differences between groups in VO<sub>2</sub>max (CON 5.1±1.5L, PLA 5.0±1.6L, CHO 4.9±1.3L; F= 0.05; p>.05). **Discussion** CHO mouth rinse does not improve performance in high intensity XC sprint on time to completion, power output or blood lactate parameters. It can be argued that the peripheral fatigue stimuli is greater during a XC sprint than a possible oral stimuli can alter and that there may be an threshold in intensity and duration for a beneficial effect of CHO mouth rinse. **Reference** Gibson, A. ## MYOGLOBIN AND NGAL CHANGES IN ULTRA-MARATHON RUNNERS AFTER THE RACE

Novak, J.1, Topolcan, O.2, Racek, J.3, Smejkal, J.1, Zeman, V.1, Trdlickova, P.1, Stork, M.4

**Do not insert authors here** **Introduction** During vigorous exercise blood is shunted away from major organs including kidneys. Effective renal plasma flow is reduced during exercise. When strenuous work is performed renal blood flow may fall to 25% of the resting value. Several factors can play the role in possible damage the kidney beyond repair during physical exertion. **Methods** The group of volunteers in this study consisted of ultra-marathon runners (n=28). The subjects participated in three ultra-marathon (100 km, 12--h and/or 24-h runs). Prior to and after finishing the race blood samples were obtained from the cubital vein. Wide range of results was achieved. The fastest 100 km runner finished in 7:23 h, the best result in 24-h run was 181 km. The results of myoglobin and neutrophil gelatinase-associated lipocalin (NGAL) are presented in this study. **Results** Following ultra-marathon running performance all participants had significant increased levels in both myoglobin (82.3 to 3072.3 µg/l, P < 0.001) and NGAL (124.5 to 266.7 ng/ml, P < 0.001). There were significant individual differences among the runners, not only in the initial "resting" values, but in post-race values especially. They weren't correlated to the duration of the running time. **Discussion** Muscle damage during ultra-endurance running performance may result in rhabdomyolysis and myoglobinuria (1) and is occasionally associated with acute renal failure. When dehydration, hypovolaemia and other factors are added to the myoglobin load, the kidney may respond by ceasing its excretory and metabolic functions (2). Post-exercise increase of serum creatinine and NGAL met criteria of acute kidney injury in some of ultra-endurance runners. (3) Most cases of rhabdomyolysis do not require hospitalization and individuals recover within one week. However, in certain individuals rhabdomyolysis can be severe. **References** Schiff HB et al.(1978). *QJM. Int. J. ## EFFECTS OF LOW-INTENSITY EXERCISE IN THE MORNING ON PHYSIOLOGICAL RESPONSE DURING UNSTEADY WORKLOAD EXERCISE IN THE EVENING

Nishimura, K., Nagasaki, K., Yamaguchi, H., Yoshioka, A., Onodera, S., Takamoto, N.

*Hiroshima Institute of Technology*

**Aim:** This study aimed to examine the effects of low-intensity exercise in the morning on physiological response during unsteady workload exercise in the evening. **Methods:** The study included 9 healthy men, and they provided written informed consent before participation. We established two experimental conditions: 15 min of bicycle exercise at 40% of maximum oxygen consumption (VO<sub>2</sub>max) at 8:30 AM (morning exercise (ME) condition) and rest in the sitting posture during the same time (control (C) condition). Measurements of physiological parameters were performed at 16:00 with the participant at rest in the supine position. All the participants performed cycling exercises for 32 min at 16:30. The evening exercises were performed in 2 parts: a calibration part and a gradual increase and decrease of workload exercise part. The calibration test consisted of three 4-min bouts of exercise at 20%, 60%, and 40% VO<sub>2</sub>max. The unsteady

exercise test consisted of 4-min bouts of exercise with gradual increases and decreases in workload at 20% and 60% VO<sub>2</sub>max. Heart rate (HR), blood pressure (BP), and oxygen uptake were measured in both experiments. Maximal and minimal values, amplitude, and phase lags were measured with each cycle of unsteady workload exercise. All participants went to bed at 23:00 and awoke at 07:00 on each experimental day. Each participant had breakfast at 07:30 and lunch at 12:30. Results and Discussion: In a resting state before the evening exercises, HR and double product (DP) were significantly higher in the ME condition than the C condition. The BP, oral temperature, and ln HF, an index of cardiac parasympathetic nervous system modulation, of the participants were not compared between the ME and C conditions. HR, systolic BP (SBP), and DP at 60% and 40% VO<sub>2</sub>max were significantly lower in the ME condition than the C condition. However, oxygen uptake did not show a significant difference between 2 conditions. The phase lags of HR and oxygen uptake with the increase and decrease of the workload were significantly shorter in the ME condition than the C condition. The amplitude of oxygen uptake was significantly larger in the ME condition than the C condition. Previous studies have reported that low-intensity exercise in the morning significantly enhanced exercise performance in the evening in terms of the jumping power, bendability, cardiorespiratory endurance, and anaerobic capacity. Our results show that low-intensity exercise in the morning can be considered an effective conditioning method on the day of a sporting event. In conclusion, the physiological response during exercise in the evening is enhanced by low-intensity exercise in the morning.

### LONGER TRAINING EXPERIENCE INDUCED GREATER EFFICIENT SYSTOLIC FUNCTION IN ENDURANCE ELITE ATHLETES

Calle-Herrero, J., Boraita, A., Heras, M.E.

*High Council of Sport*

Introduction High performance in endurance athletics is maintained during a large range of age by elite athletes and depends largely on aerobic capacity which in turn depends in part of the cardiovascular system. The aim of this study was to identify changes in specific cardiac mechanisms related to aerobic capacity along with the training experience in elite athletes. Methods Twenty-eight male elite athletes in endurance with a strict adherence to high performance training for years were divided into two groups according to age and years of training at high level. Short-training experience (STE) group (n=16, aged 25.6±3.0 years and 8.9±3.0 years of high performance training) and long-training experience (LTE) group (n=12, aged 34.7±2.8 years and 15.7±3.9 years of high performance training). All subjects underwent a standard echocardiographic examination at rest and the morphological parameters of the left atrium, left ventricle and systolic function were obtained. Results No changes were found in morphological parameters on left atrium. There were no differences in any morphological parameters of the left ventricle, although a tendency towards statistical significance was found in the left ventricular internal diameter which was higher in LTE than in STE (30.97±1.62 mm; 32.33±2.28 mm, P<0.07). Ejection fraction was ~7% higher in LTE than in STE group (59.81±6.27 %; 64.33±4.09 %, P<0.05) as well as fractional shortening that was ~8.5% higher in LTE than in STE group (32.44±4.44 %; 35.58±3.28 %, P<0.05). Discussion Longer training experience in elite athletes is associated with a higher ejection fraction and a higher fractional shortening despite the similar morphological parameters on the left ventricle. These data suggests an increase of cardiac efficiency associated with a progressive increase in cardiac contractility along the years in high performance training. Systolic function continues to improve with the experience training without significant myocardial structural changes in elite endurance athletes. The improvement could partly explain the maintenance of performance along the years in endurance sports in cardiovascular system. ### EFFECT OF SAMBA DANCE IN CARDIOPULMONARY FITNESS AND BODY COMPOSITION IN WOMEN DANCERS.

Duarte, C., Santos-Silva, P., D'Andrea Greve, J.M.

*Faculty of Medicine of University of São Paulo*

INTRODUCTION Studies have shown that dancing regularly as a physical activity can improve fitness (Di Blasio et al., 2009). However samba, typically Brazilian dance, is not well known about the impact that its practice may cause on individuals who perform it. The objective of this study was to investigate the effect of 12 weeks of samba dance practice in cardiorespiratory fitness and body composition of women dancers who parade in samba schools. METHODOLOGY Longitudinal study, almost experimental. Thirteen sedentary women, 20 to 40 years old, body mass 52,1 and 71,3 kg and height 156 and 175 cm, participants of the pre-carnival trials of a samba school in Brazil. The intervention performed were samba dance sessions, lasting 60 minutes, three times per week for 12 weeks. Maximal heart rate (HR<sub>max</sub>) in the trials ranged from 66% to 85% of HR reached in the stress test and was monitored by a heart rate monitor. Pre and post intervention subjects were evaluated the cardiorespiratory function by ergospirometry and their body composition by skinfold. RESULTS Increased by 17%, 13% and 8% of maximal oxygen consumption (VO<sub>2</sub>max), oxygen pulse rate (PO<sub>2</sub>max) and respiratory exchange rate (RER<sub>max</sub>), respectively (P <0,001). Decreased by 11% body fat percentage (BF%) and 12% fat mass (FM) and lean body mass (LBM) increased by a pound (P <0,001). DISCUSSION Of intermittent characteristic, the intensity and the amount of physical effort required in tests resulted in adjustments that have caused improvements in aerobic system of individuals (Helgerud et al., 2007) and body composition while maintaining the resting metabolic rate at high levels for a long period (Gerber et al., 2014) which contributed to decrease body fat levels. Although the type of exercise is not specific to muscle gain, those found increases (Angioi et al., 2009) corroborate to previous studies where lean body mass indexes for dancers are smaller in relation to sports practitioners in general, but larger than those found in sedentary situation. ## ASSESSMENT OF PHYSICAL PERFORMANCE OF THE POLISH PARALYMPIC TEAM IN NORDIC SIT-SKIING IN THREE CONSECUTIVE PARALYMPIC GAMES <2002, 2006, 2010>

Gawroński, W.

*Department of Internal Medicine and Gerontology, Jagiellonian University Collegium Medicum, Kraków*

Assessment of physical performance of the Polish Paralympic team in Nordic sit-skiing in three consecutive Paralympic Games (2002, 2006, 2010) Background: Systematic and comprehensive long-term follow-up is essential in the assessment of athletes' performance. Monitoring of the training process is necessary to achieve optimal physical fitness. Objective: To present the physiological performance and health condition of cross country sit-skiers with lower-limb disabilities based on ten-year follow-up and to design a comprehensive assessment model in the context of the athletes' disability and relating to the systematic physical training. Methods: The follow-up encompassed three athletes, of whom two participated in all three Paralympic Games (PGs). Each athlete underwent a preparticipation medical examination (PPE), followed by the incremental arm cranking test. The following values were determined: minute ventilation of lungs (VE), oxygen consumption (VO<sub>2</sub>), carbon dioxide production (VCO<sub>2</sub>), heart rate (HR), maximal oxygen uptake (VO<sub>2max</sub>) and lactate threshold (LAT). Body weight (BW) and fat percent (%F) were determined before and after test. Results: The comparison of all results demonstrates their sinusoidal character. The data for various physical, physiological and biochemical measurements showed a gradual increase in the athletes' endurance capacity, reaching the optimal value just before PG. Discussion: Endurance depends on a number of factors, such as: body type and build, effort energetics, psychological factors, muscle and joint coordination, thermoregulation, water and electrolyte metabolism. The impact of these factors on endurance varies depending on the type, intensity and duration of physical activity. In disabled sports, the type of motor disability modifies all of the aforementioned factors. In the available literature, the characteristics of endurance abilities of sit-skiers is most frequently based on the measurement of minute oxygen uptake as the main index of physical fitness. This aspect has gained further importance in view of the current regulations regarding disabled cross-country skiers. Conclusions: Test results depended on the training-related level of endurance at particular points of the follow-up and the general health condition. The increase in endurance parameters shortly before PGs reflects the peak fitness level. The obtained results facilitated a precise analysis of the athletes' adaptation mechanisms. As a result, optimal training was offered, leading to the Paralympic Games. References: Bernardi M, Guerra E, Di Giacinto B, Di Cesare A, Castellano V, Bhambhani Y. (2010). *Med. Sci. #### COMBINED EFFECTS OF HYPERTHERMIA AND CIRCADIAN RHYTHM ON AEROBIC AND ANAEROBIC PERFORMANCES IN THE HEAT

Otani, H.1, Kaya, M.2, Tamaki, A.2, Goto, H.3, Tsujita, J.4

*1: Himeji Dokkyo University (Himeji, Japan), 2: Hyogo University of Health (Kobe, Japan), 3: Kyushu Kyoritsu University (Kitakyushu, Japan), 4: Hyogo College of Medicine (Nishinomiya, Japan)*

Introduction Both aerobic and anaerobic exercise performances have a diurnal variation. As commonly reported in previous studies, circadian rhythm in exercise performance is low in the morning and peaks in the evening. It has been demonstrated that hyperthermia before exercise attenuates subsequent exercise performance in the heat. However, combined effects of passive hyperthermia and the time-of-day on both aerobic and anaerobic exercise performances in the heat have not been systematically evaluated. Therefore, the aim of this study was to examine the effects of passive hyperthermia and circadian rhythm on aerobic and anaerobic exercise performances in the heat. Methods Eight male volunteers completed four trials which involved anaerobic and aerobic cycling performance tests in a climatic chamber (30°C, 50% RH) at two different times-of-day: 08:00 (morning) and 17:00 (evening) h. The anaerobic performance test consisted of 10 sec maximal sprints at 5 kp to determine the maximal anaerobic power. The aerobic performance test consisted of cycling at 80% maximum oxygen uptake until exhaustion to determine exercise time to exhaustion. Participants cycled after: a 30 min seated rest in the morning (AR) and evening (PR), and a 30 min water immersion at 40°C to the upper chest in the morning (AH) and evening (PH). Rectal temperature, skin temperature (chest, upper arm, thigh and calf), heart rate, skin blood flow and blood pressure were recorded at rest and during exercise. Results Rectal temperature [AR 36.8 ± 0.4°C; AH 37.9 ± 0.2°C; PR 37.3 ± 0.3°C; PH 38.0 ± 0.2°C; p < 0.0001] and mean skin temperature [AR 30.9 ± 0.8°C; AH 36.7 ± 1.0°C; PR 31.6 ± 0.8°C; PH 35.9 ± 1.4°C; p < 0.0001] at the start of exercise were higher in AH and PH than in AR and PR. Maximal anaerobic power was not different between the trials (AR 11.5 ± 1.7 W/kg; AH 12.5 ± 1.9 W/kg; PR 11.7 ± 1.4 W/kg; PH 12.0 ± 1.9 W/kg; p = 0.24). Exercise time to exhaustion was reduced in AH (15 ± 8 min) and PH (24 ± 9 min) than in AR (39 ± 16min; p < 0.05), and in AH than in PR (43 ± 24 min; p < 0.05). At the point of exhaustion, rectal temperature, mean skin temperature, heart rate and cutaneous vascular conductance were not different between the trials. Conclusion This study demonstrates that passive hyperthermia before exercise elicits significant reductions in aerobic exercise performance in the heat in the morning, but this response is not observed in the evening. Moreover, hyperthermia and circadian rhythm do not influence anaerobic exercise performance in the heat. Contact hotani@himeji-du.ac.jp

#### IS A PERCEPTUAL STRAIN INDEX SUBSTITUTING THERMAL COMFORT FOR THERMAL SENSATION A MORE APPROPRIATE PREDICTOR OF PHYSIOLOGICAL STRAIN?

Borg, D.N.1, Costello, J.T.2, Bach, A.J.E.1, Stewart, I.B.1

*1: QUT (Brisbane, Australia), 2: UP (Portsmouth, United Kingdom)*

INTRODUCTION: The perceptual strain index (PeSI) has been identified as a practical indicator for predicting physiological strain [1]. The PeSI combines the subjective scales of thermal sensation and rating of perceived exertion (RPE) and expresses strain on a zero to ten metric. While the PeSI shares a moderate association with the physiological strain index (PSI), the correlation between the interrelated variables of thermal sensation and core temperature has been questioned [2]. Therefore, this study aimed to determine if substituting thermal comfort for thermal sensation improved the ability of the PeSI to predict its physiological analogue. METHODS: Seventeen healthy

males (age  $23.4 \pm 2.5$  yrs; height:  $178.2 \pm 5.2$  cm; weight:  $78.5 \pm 7.9$  Kg;  $VO_{2max}$   $57.5 \pm 5.3$  ml/kg/min) wore four separate chemical protective ensembles (weights: 2.05; 3.75; 4.15; 15.4 Kg) and undertook trials in environmental conditions equivalent to wet bulb globe temperature 21, 30 or 37 °C while treadmill walking at 4 km/h and 1% grade. Heart rate, core temperature, thermal sensation, thermal comfort and RPE were recorded during trials. The PSI and the original and revised PeSI were calculated at 15-minute intervals. To determine the ability to predict physiological strain of each PeSI the absolute agreement and paired sample t-tests were calculated: 1) across the entire physiological strain scale, and; 2) using three arbitrary strain categories: No/little (NL): 0-2.9; low-moderate (LM): 3-6.9; and high-very high (HVH): 7-10. RESULTS: The mean bias (95% limits of agreement) between the original PeSI and PSI was  $1.5 \pm 1.5$  (-1.4 to 4.4), between the revised PeSI and PSI was  $-0.6 \pm 1.5$  (-3.5 to 2.3) and for the three arbitrary categories was:  $2.4 \pm 1.0$  (0.4 to 4.36) and  $0.2 \pm 1.1$  (-2.0 to 2.4) for NL;  $1.1 \pm 1.2$  (-1.3 to 3.5) and  $-1.0 \pm 1.2$  (-3.4 to 1.4) for LM; and  $-2.4 \pm 1.1$  (-4.6 to -0.2) and  $-0.4 \pm 1.1$  (-2.6 to 1.8) for HVH. The revised PeSI displayed significantly ( $P < 0.001$ ) less mean bias across the entire scale and during NL and LM strain; and significantly ( $P < 0.001$ ) greater mean bias during HVH strain. DISCUSSION: The revised PeSI was a significantly better predictor across the entire scale and during NL and LM strain. However, when strain was considered HVH, the revised PeSI was a significantly poorer predictor. Due to the increased risk of an adverse health event associated with exposure to HVH levels of strain, the original PeSI remains the most appropriate practical predictor of physiological strain.

### SEX COMPARISON OF LEUKOCYTE HSP72 MRNA UP REGULATION DURING HEAT ACCLIMATION

Mee, J.A.1, Gibson, O.R.1, Taylor, L.2, Tuttle, J.A.2, Watt, P.W.1, Doust, J.1, Maxwell, N.S.1

*University of Brighton*

1: Centre for Sport and Exercise Science and Medicine, University of Brighton, UK. 2: Department of Sport Science and Physical Activity, University of Bedfordshire, UK. Introduction Thermotolerance is acquired following repeated exposure to thermal stress, with phenotypical cellular adaptation, seen - most notably heat shock protein 72 (Hsp72). Thermotolerance reduces disruptions to cellular homeostasis by principally, but not exclusively, increasing basal Hsp72 during and post stress, following transcription of its gene (Hsp72 mRNA), as part of the heat shock response (HSR). Although, stress mediated sex specific differences in the Hsp72 protein have been seen (Morton et al., 2009, Gillum et al., 2013), they have not been examined at an mRNA level via qRT-PCR across the course of heat acclimation (HA). The aim of the current study was to determine whether inhibition of the HSR occurs at an mRNA level via measurement of the leukocyte Hsp72 mRNA response across a heat acclimation programme. Methods Five physically active males ( $45.69 \pm 4.37$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) and females ( $46.23 \pm 4.11$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) performed 10 controlled hyperthermia HA sessions. HA sessions involved a 90 minute exposure to 40°C, 40% relative humidity. Exercise intensity was set at 65%  $VO_{2max}$  and adjusted with work-rest intervals to maintain a rectal temperature ( $T_r$ ) of  $\sim 38.5^\circ\text{C}$ . Leukocyte Hsp72 mRNA was measured pre and post day 1, 5 and 10 of HA via qRT-PCR to determine the HSR. Results No differences were observed in mean  $T_r$  (day 1:  $38.25 \pm 0.19^\circ\text{C}$ , 5:  $37.95 \pm 0.58^\circ\text{C}$ , 10:  $38.21 \pm 0.10^\circ\text{C}$ ;  $p > 0.05$ ) and heart rate (day 1:  $149 \pm 11$  beats.min<sup>-1</sup>, 5:  $146 \pm 9$  beats.min<sup>-1</sup>, 10:  $146 \pm 11$  beats.min<sup>-1</sup>;  $p > 0.05$ ) over time or between sexes since controlled hyperthermia HA was adopted. Mean exercise power increased over time (day 1:  $74 \pm 19$  W, 5:  $101 \pm 27$  W, 10:  $107 \pm 28$  W;  $p \leq 0.05$ ). Hsp72 mRNA increased pre to post on day 1 (1.70  $\pm$  0.76 fold, 3.92  $\pm$  1.78 fold;  $p = 0.040$ ) and 5 (1.63  $\pm$  0.75 fold, 3.51  $\pm$  1.70 fold;  $p = 0.019$ ), there were no differences on day 10 (1.84  $\pm$  0.54 fold, 3.10  $\pm$  1.44 fold;  $p = 0.299$ ). There were no differences in Hsp72 mRNA expression between sexes. Discussion Males and females demonstrate comparable physiological strain and HSR to HA. The comparable transcription of Hsp72 mRNA in all participants' suggests there is no difference in the endogenous criteria to elicit the HSR between sexes. Data suggests translation of leukocyte Hsp72 may be hindered, consequently mitigating the attainment of thermotolerance in females. ### EFFECT OF COLD EXPOSURE ON PROPRIOCEPTION AND COGNITIVE FUNCTION

Racinais, S., Gaoua, N., Mtibaa, K., Hautier, C., Alhammoud, M.

*Aspetar Orthopaedic and Sports Medicine Hospital*

Background: Proprioception has been identified as an important factor of performance and injury prevention in downhill skiing. Recent evidence showed that cold exposure affects balance, which suggests that it might also affect proprioception. Unfortunately, humans have minimal acclimatization capabilities to cold exposure and winter sports athletes are likely to be affected by such alterations. The current study aimed to investigate the effects of cold exposure on proprioception and cognitive function in elite winter sports athletes and recreationally active individuals. Methods: 22 international-level Alpine skiers ( $179 \pm 4$ cm,  $83 \pm 6$ kg,  $26 \pm 4$  yrs) and 14 recreationally active participants ( $178 \pm 5$ cm,  $78 \pm 5$ kg,  $33 \pm 6$  yrs) were tested in a thermoneutral ( $24^\circ\text{C}$ ) and a cold ( $8^\circ\text{C}$ ) laboratory, in a counterbalanced order. Each experimental session included 10 min of rest followed in randomized order by a proprioception test (i.e. ankle eversion movement discrimination,  $\sim 10$ min) and a cognitive test (OTS: one touch stockings of Cambridge,  $\sim 10$ min). Affective (PANAS: positive and negative affect schedule), perceptual (TC: thermal comfort; TS: thermal sensation) and physiological (oral and skin temperatures) responses were also recorded. Results: Cold exposure significantly decreased the oral ( $34.9 \pm 0.7$  vs.  $36.2 \pm 0.4^\circ\text{C}$ ) and skin ( $26.0 \pm 1.8$  vs.  $30.8 \pm 1.0^\circ\text{C}$ ) temperatures as well as TS and TC, and increased the amount of negative affects (negative/positive ratio: 41% vs. 51%) in both groups ( $p < 0.05$ ). Proprioceptive acuity was significantly better in the elite skiers than in the control group (average error:  $0.46 \pm 0.12$  vs.  $0.55 \pm 0.12$  deg,  $p < 0.05$ ), but was not affected by environmental temperature ( $p > 0.30$ ). Cognitive performance during both simple (OTS-4) and complex (OTS-6) tasks were similar between the elite skiers and the recreationally active control in the temperate environment, but decreased with cold exposure in the control group only ( $p < 0.05$ ) becoming lower than in elite skiers in the cold environment ( $p < 0.05$ ). Conclusion: Cold exposure induced similar physiological and affective alterations in elite winter sports athletes and recreationally active individuals. However, these alterations did not affect proprioceptive acuity, which was better in elite skiers than recreationally active controls. Cold exposure impaired cognitive function in recreationally active individuals but not in elite winter sports athletes.

## CORE BODY TEMPERATURE RELATIONSHIPS WITH OTHER PHYSIOLOGICAL VARIABLES DURING INCREMENTAL CYCLING TEST

Dorđević, S.1, Vodičar, J.2, Modic, Ž.1, Rauter, S.2, Milič, R.3

1. TMG-BMC d.o.o., 2. Institute of Sport University of Ljubljana, 3. Institute of Sport, University of Ljubljana, Slovenia

**Introduction** Two basic facts link core body temperature (CBT) and metabolism. The amount of heat muscles produce is related to the amount of work they perform. The more intense is workout, the more heat they produce. Heat dissipation from dynamically contracting muscles consists of heat transfer to the core of the body and to surrounding tissues or environment (1) Using new noninvasive sensor technology (SpotON, 3M, USA) for measurement of CBT (2), our goal was to find how significant can be connection between temperature and oxygen consumption (VO<sub>2</sub>, ml/min/kg) and some other physiological variables in controlled conditions during incremental cycling test. **Methods** Subjects consisted of 20 highly trained male competition cyclists, age  $19.9 \pm 3.0$  yr., body height ( $182.3 \pm 4.4$  cm) and body mass ( $71.2 \pm 5.3$  kg). After 15 min warm-up on their bicycle set up on a cycle ergometer (Cyclus 2, Germany) cyclists proceeded with incremental test (initial load 100W), increase 20 W min<sup>-1</sup> to volitional fatigue. Ambient temperature was between 21.5 C. Heart rate, ventilatory, and gas data were collected during the test with the metabolic cart (Cosmed CPET, Italy). Blood samples (10µl) for determination of lactate values were analyzed (BIOSEN C\_Line, Germany) before warm-up, immediately after test and 5 min after a recovery phase. CBT was measured with SpotOn system (3M, USA). Data from testing were imported into MATLAB (Mathworks, USA) for further analysis. **Results** Interval of data analysis during test was started 60s after beginning of test protocol and collected during next 840s (from 100-400W) for all subjects. Normalized data for 20 subjects show statistically significant high linear correlation between CBT and VO<sub>2</sub> ( $R^2=0.978$ ). Slope of linear regression line between CBT and VO<sub>2</sub> compared with VO<sub>2</sub> max show statistically significant correlation ( $R^2=0.71$ ). **Discussion** The appropriate approach, novel in humans performing dynamic exercise, would be to measure heat production, power output and aerobic and anaerobic energy turnover (1). CBT is not interesting physiological variable not only because it is connected with metabolism but also because it influences other variables by itself (heart rate, oxygen consumption...) and is a factor responsible for reducing voluntary activation during brief voluntary isometric contractions and those temperature-induced changes influence the contractile properties of muscle (3). Our study showed statistically significant very high linear correlation between CBT and VO<sub>2</sub> in incremental cycling test conditions. Another interesting finding is the positive correlation between slope of linear regression line of CBT / VO<sub>2</sub> and VO<sub>2</sub> max.

## HIIT IN THE HEAT: A HOT NEW COMBINATION?

Akerman, A.P.1, Lucas, S.J.E.1, Baldi, C.J.1, Katare, R.1, Cotter, J.D.1

University of Otago, 1:UO (Dunedin, NZ)

**Introduction** High-intensity interval training (HIIT) appears to provide a superior cardio-metabolic conditioning stress to moderate-intensity continuous training (Weston et al. 2014). Heat stress per se also provides a stimulus for adaptation, and has recently been shown to potentiate cardiovascular adaptations to exercise training. The aim of this study was to examine whether HIIT performed in the heat provided an accumulative benefit for cardiovascular conditioning. **Methods** In a randomised crossover design, 10 sedentary participants (5 female; mean  $\pm$  SD;  $33 \pm 9$  y;  $189.4 \pm 9.1$  cm;  $82.5 \pm 15.0$  kg;  $38 \pm 5$  mL/kg/min) completed two 8-wk HIIT regimes (5 d/wk cycle ergometry progressing to 90-95% Heart rate (HR) max, supplemented with resistance band exercises), separated by 8-wk washout. One regime was in temperate (EX+TEMP;  $23 \pm 2^\circ\text{C}$ ,  $36 \pm 5\%$  RH) and one in hot (EX+HEAT;  $40 \pm 0^\circ\text{C}$ ,  $61 \pm 2\%$  RH) conditions. HR and perceived exertion (RPE) were recorded throughout, but are analysed here for just 45-min sessions in weeks 1, 3, 5 and 7. Aerobic power (VO<sub>2</sub>max), body composition (BIA) and arterial pressures were tested before and after each regime. Data were analysed using RM ANOVA. **Results** Average HR tended to be higher in EX+HEAT than EX+TEMP, expressed in both absolute HR (by  $4 \pm 6$  b/min; 95% CI: 0 - 8 b/min;  $p=0.056$ ) and relative to HR max (by  $2 \pm 3\%$ ; 0 - 4%;  $p=0.052$ ). RPE was similar between regimes ( $15 \pm 1$ ; vs  $15 \pm 0$ ;  $p=0.48$ ) and equivalent over weeks ( $p=0.08$ ). VO<sub>2</sub>max increased while HRmax decreased across both regimes (by  $13 \pm 6$  vs.  $18 \pm 14\%$ ;  $p<0.001$ ); and  $5 \pm 3$  vs.  $2 \pm 5$  b/min;  $p=0.003$ ), and by similar extents between regimes (CI: -15 - 5%; and -7 - 0 b/min). Resting mean arterial pressure was reduced in both regimes (by  $7 \pm 5$  and  $10 \pm 6$  mm Hg;  $p<0.0001$ ), to a similar extent (CI: -1 - 8 mm Hg). On average, HEAT+EX caused larger increases than TEMP+EX in fat free mass (by 1%; CI: 0 - 2%;  $p=0.03$ ), total body water volume (by 1%; 0 - 2%;  $p=0.03$ ), and resting metabolic rate (by 1%; 0 - 2%;  $p=0.03$ ). **Discussion** Despite lower absolute work rates required to elicit a target HR during HIIT performed in the heat, cardio-respiratory and functional adaptations were equivalent to those obtained in a temperate environment, whereas body composition adaptations were slightly larger. Elevated tissue temperatures per se in the face of lower work performed may have been responsible (Staib et al. 2007, Yoshihara et al. 2012). **References** Staib JL, Quindry JC, French JP, Criswell DS, Powers, SK. ## THE EFFECT OF MENTAL FATIGUE ON PHYSICAL PERFORMANCE, A SYSTEMATIC REVIEW.

Van Cutsem, J.1, Marcora, S.2, Meeusen, R.1,3, Roelands, B.1,4

Vrije Universiteit Brussel

1 Department of Human Physiology, Vrije Universiteit Brussel, Brussels, Belgium 2 Endurance research group, School of Sport and Exercise Sciences, University of Kent at Medway, Chatham Maritime, Kent ME4 4Ag, UK 3 School of Public Health, Tropical Medicine and Rehabilitation Sciences, James Cook University, Queensland, Australia 4 FWO, Belgium **Introduction** Recently it has been shown that both forms of fatigue, mental and physical, affect one another (Marcora et al., 2009). The rather limited amount of studies available show that mentally fatigued individuals have a decreased physical performance capacity. **Objective** To evaluate the existing literature about the influence of mental fatigue on physical performance. **Data Sources** We searched the electronic databases PubMed and Web of Knowledge (up until December 2014). The search terms we used were 'mental fatigue [MeSH]' and 'cognitive fatigue', in combination with 'exercise [MeSH]' and 'athletic performance [MeSH]'. **Study Selection** Randomized crossover designs investigating the effects of mental fatigue on physical performance in healthy humans were included in this systematic review. Outcomes concerning physical performance and possible peripheral and central mechanisms underlying the effect of mental fatigue were included. **Results** Nine studies of high quality (>67% [Kmet et al., 2004]) were included, all used a randomized crossover design in an athletic adult population. The mean of subjects participating in the study was ( $16 \pm 9$ ). Five studies investigated the effects of mental fatigue on aerobic performance, the other 4 on anaerobic performance. The general finding was a decreased aerobic performance, while anaerobic performance seems not to be affected. The decrease in aerobic performance was accompanied by an increase in ratings of perceived exertion (RPE), while cardi-

orespiratory and musculo-energetic mechanisms were not altered during physical performance due to mental fatigue. Conclusion Although until now only 9 studies could be included, it seems that mental fatigue has a negative effect on prolonged aerobic performance. Anaerobic performances (maximal muscle activation, voluntary maximal strength, explosive power and anaerobic work capacity) are not affected. Mental fatigue decreases aerobic performance through a higher RPE, rather than through cardiorespiratory and musculo-energetic mechanisms. However additional research has to be done in order to determine through which mechanism RPE negatively affects physical performance. References Kmet et al. 2004. ### ARE MOTOR-RELATED ELECTRO-CORTICAL MARKERS MODULATED BY AN ACUTE ENDURANCE EXERCISE?

Spring, J., Borrani, F., Kayser, B., Place, N., Barral, J.

*University of Lausanne*

**Introduction** Among the methods used to investigate the effect of exercise on the brain, the electroencephalography (EEG) seems to be a promising technique in sport sciences (Thompson et al. 2008). Voluntary movements are preceded by a low frequency brain activity that occurs about 1.5 seconds before movement onset. This movement-related cortical potential (MRCP) could be considered as a direct neurophysiological marker of central motor command (Berchicci et al. 2013). The purpose of this study is to investigate the effects of two endurance exercises with moderate and high intensities on the preparatory phase of voluntary movements using the surface EEG. **Methods** Sixteen trained athletes performed two successive exercises on a cycle ergometer consisting in a 30 minutes submaximal exercise at 60% of maximal aerobic power, and a 10 kilometres all-out time trial. Before (PRE), between (MID) and after (POST) the two sessions of exercise, surface EEG was recorded during 60 self-paced leg extensions. The central MRCPs were segmented and averaged into non-overlapping epochs from 2500 ms before and 500 ms after the leg movement onset. Two components before movement were used for the statistical analyses: the readiness potential (RP: -1500 ms to -1000 ms) and the motor potential (MP: -100 ms to peak amplitude). Maximal voluntary contraction (MVC), voluntary activation level (VAL) and the potentiated doublet force were also quantified using the percutaneous neuromuscular stimulation method. **Results** The analyses revealed that MVC decreases between PRE-MID (10.8%) and MID-POST (10.1%). A reduction in the VAL between PRE-MID (6.3%) and MID-POST (4.8%) occurs and was accompanied by a reduction in the potentiated doublet force between PRE-MID (6.4%). The MRCP mean negativity amplitudes during RP decreases both between PRE-MID (+1.09 $\mu$ V) and PRE-POST (+1.33 $\mu$ V), whereas MP shows a decrease only between PRE-POST (+3.1 $\mu$ V) sessions (all  $p$ s<0.05). **Discussion** The results show that an endurance exercise induces a reduction in the MRCP amplitude associated with a significant reduction in force production. While an increase in the negativity has been shown to compensate peripheral fatigue (Dirnberger et al. 2004, Schillings et al. 2006), conversely a decrease seems to be indicative of a reduction in synaptic activity (Deecke, 1996) and a reduction in central motor command. The intensity-dependant reduction of the MRCP components deserves further investigations. **References** Berchicci M., Menotti F. et al. (2013). *Front. Hum. Neurosci.* Deecke, L. ### MO-PM21 Physiology: Energy metabolism

#### THE METABOLIC COST OF CYCLING AT 0 W COMPARED TO PHYSIOLOGICALLY ESTIMATED INTERNAL

Giorgi, H., Andrews, M., Gray, A., Osborne, M.

*The University of Queensland*

**INTRODUCTION** The cost of unloaded cycling, that is, cycling at 0 W external mechanical power (EP), ought to be equivalent to the metabolic cost of the rate of mechanical work that is performed only to move the limbs against gravitational and inertial forces – the internal mechanical power (IP). A number of studies have concluded that this might not be the case, including Gaesser and Brooks<sup>2</sup>, who reported that the metabolic cost measured during unloaded cycling “deviated significantly” from the linear relationship between energy expenditure and other magnitudes of EP at a number of cadences. The aim of this study was to compare the cost of unloaded cycling to the cost of IP determined using a physiological model. **METHOD** Ten elite cyclists performed 0 (no chain), 100, 200 and 300 W on a wind-braked cycle ergometer at 80 and 110 rev · min<sup>-1</sup>. Oxygen consumption was converted to metabolic power (MP), and IP was calculated as the intercept of the MP-EP relationship minus the resting metabolic rate<sup>3</sup>. **RESULTS** The metabolic cost of unloaded pedalling (0 W) was significantly greater than IP at both cadences (80 rev · min<sup>-1</sup>: 222 ± 8 J · s<sup>-1</sup> vs 105 ± 14 J · s<sup>-1</sup>,  $P < 0.001$ ; 110 rev · min<sup>-1</sup>: 367 ± 12 J · s<sup>-1</sup> vs 212 ± 16 J · s<sup>-1</sup>,  $P < 0.001$ ). The slopes of the MP-EP relationships at 80 and 110 rev · min<sup>-1</sup> were significantly greater when the MP at 0 W was included compared to when it was not. There were, however, strong linear relationships at both cadences ( $R^2 = 0.997$  and  $R^2 = 0.991$  at 80 and 110 rev · min<sup>-1</sup>, respectively) with the inclusion of MP at 0 W. **DISCUSSION** The mechanical equivalent of the difference between MP at 0 W and IP is approximately 29 W. This demonstrates the need for careful consideration when choosing a physiological model for determining the metabolic cost of IP – whether predicted through extrapolation or by direct measurement of unloaded cycling. Interestingly, the strong linearity between MP and EP in this group of elite cyclists suggested they might not have encountered coordination difficulties during unloaded cycling, which had been proposed previously<sup>1</sup>, lending support to the direct measurement approach to IP. **REFERENCES** 1Foss, O., & Hallén, J. **HIGH INTENSITY INTERVAL TRAINING IN NON-ALCOHOLIC ESTATOHEPATITIS: A CASE REPORT.**

Mateo-Cubo, F., Martínez-Cañó, A., García-Valverde, A., Hernández, A., Sanchez-Martos, M.A., Guillen, S., López-Grueso, R., Pastor, D., Sarabia, J.M., Fernández-Fernández, J., Moya, M., Aracil, A.

*SPORT RESEARCH CENTRE, MIGUEL HERNANDEZ UNIVERSITY, ELCHE.*

**Introduction:** Non-alcoholic esteatohepatitis (NASHD) is a chronic hepatic disease of unknown etiology, characterized by the anomalous deposition of triglycerides in the liver. The role of exercise as a therapeutic agent in this disease is under discussion. Given the effect of high intensity interval training (HIIT) on lipid mobilization and metabolism, we studied the effects of 8 weeks of HIIT in an adult male diagnosed of NASHD. **Methods:** After signing an informed consent, a recreative physically active 40 years old Caucasian male, diagnosed 18 years before of NASHD, performed an 8 weeks HIIT program. During the first 4 weeks, in addition to the HIIT the subject performed a two hours match of paddel-tennis per week. However, during the resting 4 weeks, the subject only performed the HIIT, without any other recreational exercise. An indirect calorimetry before and after a typical HIIT session was performed, to analyze the effects on lipid oxidation. Before (PRE), and after 4 and 8 weeks of HIIT program (IM and POST, respectively), glycemia, lipidic profile and hepatic enzymes were obtained by blood analysis. Additionally, anthropometries and maximal stress tests were performed both PRE and POST intervention. During the intervention period the subject followed an individualized diet. **Results:** At rest, 35% of Kcal were obtained from fat. For the 15 hours after a single HIIT session, fat represented up to 70% of Kcal production at rest. This value returned to baseline by 23 hours after the session. No differences were observed either at the cardiorespiratory fitness or at the anthropometry after the HIIT program. In the IM blood analysis, fasting glycemia and gamma-glutamyl transpeptidase (GGT) tended to decrease (97 vs 95,5 mg•dL<sup>-1</sup>, 229 vs 179,5, U•L<sup>-1</sup> respectively) while circulating triglycerides tended to increase (308 vs 409,5 mg•dL<sup>-1</sup>). At the POST blood analysis, fasting glycemia still showed a tendency to be reduced (95 mg•dL<sup>-1</sup>), while GGT and circulating triglycerides tended to increase in comparison with the IM evaluation (240 U•L<sup>-1</sup> and 360 mg•dL<sup>-1</sup>). **Discussion:** Despite being an isolated observation, our data suggest that HIIT may contribute to improve the hepatic inflammation seen in NASHD. The removal of the abnormal hepatic deposition of triglycerides, and the increased fat utilization at rest, can be hypothesized as the underlying mechanisms.

**AEROBIC CONTRIBUTION TO THE WINGATE TEST PERFORMANCE: EFFECTS OF A HIGH BRAKING FORCE**

Driss, T., Jaafar, H., Rouis, M.

*Paris Ouest Nanterre La Défense University*

**Introduction** Controversial results have been found about the effects of circadian rhythms on the Wingate test (WT) (Reilly and Down 1992; Souissi et al. 2004). Although WT has been used extensively as an index of anaerobic performance, the rate of aerobic energy contribution is considerable and depends on subjects' anaerobic level (Granier et al., 1995). Therefore, the aerobic contribution to the total work may explain the discrepancies between studies. Moreover, the load traditionally used is likely much low to maximize work output (Driss and Vandewalle, 2013). Our study examined the effects of time of day on WT performance and aerobic contribution to the total amount of energy released during WT using a high braking force. **Methods** 11 active male participated in the study (25±3 years, 183±8 cm, 83±9 kg). They performed two WT tests sessions at 7:30 and 18:30h. The braking force (Monark 894E cycle ergometer) was 11.5% of body mass (11.5% BM). During each test, the expired gasses were measured using a Cosmed K4b<sup>2</sup> analyzer. The net O<sub>2</sub> uptake (VO<sub>2net</sub>) was derived by subtracting the VO<sub>2</sub> at rest from the VO<sub>2</sub> consumed during the test. VO<sub>2net</sub> was converted to work by a factor of 20.92 kJ.l.O<sub>2</sub><sup>-1</sup>. The aerobic contribution (AC%) was calculated from the ratio of aerobic work (WO<sub>2</sub>) to the total work (Wtot). These parameters were averaged over 5-s intervals. **Results** Two-way ANOVA test for repeated measures (time of day x time interval) revealed a significant effect of time interval on Wtot (p<.001). Post hoc test showed that Wtot decreased after 10 s with morning and evening confounded. However, no significant effects of time of day, and time of day x time interval were observed on Wtot. Significant effect of time of day and time interval were observed on WO<sub>2</sub> (p=.018 and p<.001, respectively). A significant interaction effect of time of day x time interval was noted on this parameter (p<.05). Post hoc test showed that WO<sub>2</sub> increased during the test and was greater in the evening compared to the morning at the second half of the test. Similar results were observed for AC (%) (time of day: p=.049, time interval: p<.001, and time of day x time interval: p=.011). **Discussion** Aerobic contribution was greater at the evening compared to the morning. In accordance with Reilly and Down (1992), our results showed no significant effect of daytime variation on total work despite that the work at the first 10-s was greater in the evening by comparison to the morning (p<.05). The use of a high braking force in the present study (11.5% BM vs. 7.5% or 8.7% BM in the literature) could explain this finding. To elucidate the mechanisms responsible of diurnal variations during WT, optimal braking force should be used. **References** Driss T, Vandewalle H (2013). *BioMed Res Int*, 2013, 1-40. **EXPRESSION OF IRISIN IN SERUM AND SKELETAL MUSCLE WERE INCREASED FOLLOWING RESISTANCE TRAINING IN AGING MICE**

Kim, H., So, B., Choi, M., Kim, J., Song, W.

*Seoul National University*

**Introduction** Irisin, a novel myokine as a peptide recently identified, mediates some of the beneficial effects of exercise on fat metabolism by a process named adipocyte browning through inducing uncoupling protein 1. In the present study, we investigate the effect of resistance training on irisin expression in serum and skeletal muscle with improvement of muscle strength and function in aging mice. **Methods** Nineteen months old male C57BL/6 mice were randomly assigned to two groups, old Control group (Old-Con) and old Resistance exercise group (Old-Ex). For exercise group, progressive resistance ladder climbing exercise with tail weight was performed 3 days per week for 12 weeks. Whole body animal dual energy x-ray absorptiometry (DXA) modulation was used to measure body composition after training program. Every two weeks, grip-strength was measured by using Grip Strength Meter. Irisin expressions were evaluated in circulating level and skeletal muscle using ELISA. **Results** There was no significant difference in body weight, fat mass and lean mass between Old-Con and Old-Ex. Grip strength of old mice was significantly increased (14.85%, p=0.02) in Old-Ex compared to Old-Con. The significant improvement (16.34%, p=0.03) of muscle quality following resistance training was found in Old-Ex compared to Old-Con. In circulating level, irisin protein in serum of Old-Ex was higher (p=0.02) compared to Old-Con. The significant increase of irisin protein was found in soleus muscle of Old-Ex compared to Old-Con, whereas, there are no significant changes in extensor digitorum longus, tibialis anterior, and gastrocnemius muscles. **Discussion** Exercise induced irisin secretion by contracting skeletal muscles, which could have evolved from shivering-related muscle contraction, might be a potential target of therapies designed to optimize weight

control and metabolic profile (Lee et al., 2014). Hur et al., (2012) reported that circulating irisin negatively related with age, insulin, cholesterol, and adiponectin levels, indicating a possible compensatory role of irisin in age-related metabolic regulation. Based on our results and the previous reports focusing important role of irisin in aging, resistant training might be an efficient intervention for not only increase the circulating irisin levels, but also prevent the age-related decline of muscle strength. ### LESS PRONOUNCED RESPONSE TO EXERCISE IN HEALTHY RELATIVES TO TYPE 2 DIABETICS COMPARED TO CONTROLS

Ekman, C., Elgzyri, T., Ström, K., Almgren, P., Parikh, H., Dekker Nitert, M., Rönn, T., Manderson Koivula, F., Ling, C., Tornberg, Å.B., Wollmer, P., Eriksson, K.F., Groop, L., Hansson, O.

*Lund University*

Healthy first-degree relatives with heredity of type 2 diabetes (FH+) have been shown to have metabolic inflexibility when compared to subjects without heredity for diabetes (FH-). In this study, we investigate whether FH+ individuals respond differently to an exercise intervention compared to FH-. 16 FH+ and 19 FH- insulin sensitive men similar in age, VO<sub>2</sub>peak and BMI completed an exercise intervention in which the participants were monitored with heart rate measurements during exercise for 7 months. Before and after the exercise intervention, the participants underwent a physical examination, tests for oral glucose tolerance and maximal exercise capacity. Muscle biopsies were taken for gene expression analysis using microarrays. The volunteers participated in on average 39 training sessions during the intervention and spent on average 18.8 MJ on exercise. VO<sub>2</sub>peak/kg increased by 14%, the participants lost 1.2 kg of weight and 3 cm waist circumference. Using regression analysis, exercise volume had significant effect on VO<sub>2</sub>peak, weight and waist circumference in the FH- group, but not in the FH+ group. After exercise, expression of genes involved in metabolism, oxidative phosphorylation and cellular respiration increased more in the FH- group, compared to the FH+ group. This indicates that healthy, insulin sensitive FH+ and FH- participants with similar age, VO<sub>2</sub>peak and BMI respond differently to an exercise intervention. The FH+ background might limit the muscle adaptation to exercise, which may contribute to the increased susceptibility to type 2 diabetes in FH+ individuals. Do not insert authors here

### COMPARISON OF CARBOHYDRATE AND FAT OXIDATION AFTER MAXIMAL INCREMENTAL CYCLE ERGOMETER EXERCISE TESTING IN OBESE AND LEAN ADULTS

Kratzenstein, S.1, Moser, O.1, Otto, C.1, Braun, M.1, Lawrence, J.1, Kotsch, P.1, Marusch, F.2, Mayer, F.1

*1: University of Potsdam (Potsdam, Germany), 2: Ernst von Bergmann Klinikum (Potsdam, Germany)*

Introduction Measuring carbohydrate and fat oxidation (carb and fat ox) terminates in most testing protocols after reaching the final work load. There is evidence that energy metabolism is increased even during post-exercise conditions (Jamurtas et al., 2004). No data exists comparing acute post exercise metabolic response following maximal exhaustion in healthy and obese adults. The aim of this study was to analyze differences in post exercise carb and fat ox in obese and lean adults during a continuous 3 min active and 3 min passive recovery after maximal incremental cycle ergometer exercise testing (ICE). Methods 8 sedentary obese (O) (BMI: 43.9±5.4 kg·m<sup>-2</sup>, 42.6±13.0 yrs, 5 female/3 male) and 8 age- and sex-matched sedentary lean adults (C) (BMI: 22.4±2.1 kg·m<sup>-2</sup>) performed an ICE, after overnight fasting. Carb and fat ox was calculated by indirect calorimetry and given as mg·kg bodyweight<sup>-1</sup>·min<sup>-1</sup> (Peronnet et al., 1991). Gas exchange was measured until maximal exhaustion and during a 3 min active and 3 min passive recovery. Delta carb ox was calculated for the time-dependent reduction of carb ox. Calculations were performed with paired t-test or Wilcoxon signed rank test (α=0.05). Results No detectable fat oxidation was observed during the whole 6min post ICE period. Comparison of mean values for each of the six minutes between groups resulted in a significant higher carb ox in controls during the first 3 minutes (1 min: 57.53±19.74 vs 28.61±15.27, p<0.000; 2 min: 36.43±14.86 vs 22.37±12.01, p=0.019; 3 min: 23.24±11.70 vs 15.76±7.54, p=0.023) and no significant difference in the last 3 min. After min 1, 2 and 3 delta carb ox was significantly different between groups (1min O:6.23±3.59 vs C:21.10±10.60, p=0.002; 2min O:6.62±4.74 vs C:13.19±4.77, p=0.04; 3min O: 3.34±3.58 vs C:7.82±4.28, p=0.045). Relative exercise capacity was 1.2±0.50 in obese and 3.1±0.7 W·kg<sup>-1</sup> in controls. Discussion Higher maximal intensity results in higher carbohydrate oxidation, explaining the investigated difference between controls and obese subjects directly after ICE. Although these differences could be explained, in respect to the time course of carb ox during the first 3 min of active recovery, controls seem to have a faster physiological regulation. During the 3 min passive recovery same reactions were found in both groups, indicating no physiological differences. ### COMPARISON OF CARBOHYDRATE AND FAT OXIDATION RATES DURING MAXIMAL INCREMENTAL CYCLE ERGOMETER EXERCISE TESTING IN OBESE AND LEAN ADULTS

Braun, M.1, Moser, O.1, Otto, C.1, Kratzenstein, S.1, Ruessmann, A.1, Messerschmidt, J.1,2, Marusch, F.1,2, Mayer, F.1

*1 University of Potsdam (Potsdam, Germany), 2 Klinikum Ernst von Bergmann (Potsdam, Germany), \* These authors are contributed equally*

Introduction There is evidence that lipid oxidation is decreased in skeletal muscles in obese individuals during submaximal exercise as well as at rest. In addition accumulation of lipids within muscles could result in insulin resistance, a known site effect of obesity and associated with a variety of health-related risks (Houmard, 2008). The aim of this study was to compare carbohydrate and fat oxidation during maximal incremental cycle ergometer exercise testing between obese and lean controls. Methods Eight sedentary obese (BMI: 43.7 ± 5.5 kg·m<sup>-2</sup>, 42.6 ± 13.0 years, 6 female/2 male) and eight age- and sex-matched sedentary lean controls (BMI: 22.5 ± 2.2 kg·m<sup>-2</sup>, 43.0 ± 13.4 years) performed a maximal incremental cycle ergometer test after overnight fasting to determine the first (LTP1) and second lactate

turn point (LTP2) (Tschakert et al., 2015). Gas exchange variables were measured continuously and blood lactate concentration was determined at rest and at the end of every workload step. Rates of carbohydrate and fat oxidation were calculated using indirect calorimetry (Péronnet and Maissicotte, 1991). Data analysis was conducted through paired t-test or Wilcoxon signed-rank test ( $\alpha = 0.05$ ). Results At LTP1 lean controls used significantly ( $p < 0.05$ ) more energy from fat oxidation than obese adults ( $7.08 \pm 3.91$  vs  $3.37 \pm 2.11$  mg•kg bodyweight (BW)•l•min<sup>-1</sup>) while no difference ( $p > 0.05$ ) for carbohydrate oxidation. Carbohydrate oxidation rates were significantly higher in lean controls compared to obese adults at LTP2 ( $33.05 \pm 13.08$  vs  $14.78 \pm 6.53$  mg•kg BW•l•min<sup>-1</sup>) ( $p < 0.001$ ) and at Pmax ( $61.96 \pm 25.19$  vs  $27.63 \pm 15.68$  mg•kg BW•l•min<sup>-1</sup>) ( $p < 0.001$ ). Obese adults produced more lactate at rest, LTP1 and LTP2 but less at Pmax than lean adults with no significant differences ( $p > 0.05$ ) detected between groups. Discussion Sedentary obese adults, compared to age- and sex-matched lean controls, showed a shift in the balance of substrate oxidation. Both, carbohydrate and fat oxidation at different exercise intensities are significantly impaired in obese in comparison to lean adults. Out of results an individualized exercise prescription in combination with pre-exercise dietary modifications should be recommended for obese people. References Houmard JA. ### EFFECTS OF HYDROGEN-RICH WATER INTAKE ON WORK RATE AT LACTATE THRESHOLD

Yoshimura, S., Ichikawa, M., Kose, Y., Kawasaki, K., Nishimura, S., Ito, A., Nakashima, S., Kiyonaga, A., Tanaka, H., Higaki, Y.

*Fukuoka University*

Introduction Oxidative stress occurs when the production of free radical moieties exceeds the antioxidant capacity. Recent studies have revealed that molecular hydrogen can ameliorate diseases associated with oxidative stress. Further, hydrogen-rich water (HW) intake can prevent an increase in blood lactate, an index of muscle fatigue, without significant changes in blood oxidative injury markers. However, the effect of HW intake of performance in athletes remain unclear. Thus, we examined the effect of HW intake on work rate using the lactate threshold (LT) as an index of endurance performance. Methods This study was a randomized crossover study. Subjects were fifteen healthy males ( $23.2 \pm 2.2$  years,  $170.7 \pm 6.5$  cm,  $65.6 \pm 4.7$  kg). Subjects consumed a packet of HW or placebo water (PW) followed by 30 min rest. Subjects then underwent an incremental exercise test using a bicycle ergometer. The work rate was initially set to 10 W of 60 rpm for the first 4 min of warm-up, and was then increased by 15 W/min during the ramp test. Blood lactate was measured before, during (every 1 min), and after the test (1, 3, 5, and 10 min). Respiratory data, heart rate (HR), and rating of perceived exertion (RPE) were measured during the test. The LT was determined for each subject based on visual inspection, and the average was determined according to the estimations of five experts who were blinded to the conditions. Results The work rate at LT during the test was significantly higher in HW intake than that in PW intake ( $103.6 \pm 14.0$  vs  $97.4 \pm 12.2$  W;  $p < 0.05$ ). There were no differences in oxygen consumption, HR, or RPE at LT between the conditions. Further, maximal oxygen consumption and maximal lactate concentration did not change in either condition. Discussion Despite an improved work rate at LT observed with HW intake, the mechanisms that mediate this important phenomenon remain unclear. It is possible that lactate production in working skeletal muscle during exercise may be reduced by HW intake. Alternatively, increased uptake of lactate into mitochondria following HW intake may be associated with an improved work rate at LT. However, although we cannot rule out a role for mitochondrial function in HW intake, we consider this unlikely as no effects of HW intake on blood lactate were observed at rest. These data suggest that HW intake may improve endurance performance. References Ohsawa I et al. (2007). *Nat Med*, 13, 688-694. Contact dreamaffectionately@yahoo.co.jp

### REPEATABILITY OF THE DEPLETION OF MUSCLE GLYCOGEN AFTER PROLONGED AND HIGH INTENSITY EXERCISE

Osawa, T., Shiose, K., Motonaga, K., Kondo, E., Kamei, A., Taguchi, M., Takahashi, H.

*Japan Institute of Sports Sciences*

Muscle glycogen is the major source of substrate in both prolonged and high-intensity exercise tests, and the depletion of muscle glycogen could lead to fatigue and the limitation of exercise performance. Although muscle glycogen was decreased by various exercise tests in previous studies, the repeatability was little reported. In our previous study, the decrement rates of muscle glycogen after short-duration, high-intensity exercise tests were different between the first and second tests (unpublished data). Purpose: The aim of this study was to investigate the repeatability of the decrement rate of muscle glycogen after exhaustive exercise tests. Methods: After the peak of oxygen uptake (VO<sub>2peak</sub>) of eight endurance-trained male subjects (age,  $20 \pm 1$  yr.) was assessed, the same exercise tests were completed on three separate occasions. The exercise protocols were 60-min cycling exercise at 70% of VO<sub>2peak</sub>, immediately followed by high-intensity intermittent exercise (five 1-min exercises at 100% of VO<sub>2peak</sub> separated by 4-min exercises at 35% of VO<sub>2peak</sub>) and one all-out exercise at 100% of VO<sub>2peak</sub> to exhaustion. Muscle glycogen from the vastus lateralis was non-invasively evaluated by carbon-13 magnetic resonance spectroscopy (13C-MRS) before and immediately after the tests. Blood glucose and lactate concentrations were measured at the fingertip every 15 min during 60-min exercise and immediately after the end of all-out tests. Results: The duration of all-out tests at the first, second, and third occasions were  $163 \pm 86$  s,  $191 \pm 144$  s, and  $202 \pm 142$  s, respectively. There was no significant difference among the three tests. The blood glucose and lactate concentration were not significantly different among three occasions. Muscle glycogen concentrations before and after tests were 72.9 and 22.4 mM, 76.4 and 21.7 mM, and 81.4 and 29.7 mM, respectively. The decrement rate of muscle glycogen in one subject was low ( $35.7 \pm 15.4\%$ ), and the intra-subject coefficient of variation (CV) was 43.2%. Except the subject, the decrement rates of muscle glycogen at the first, second, and third occasions were  $77.8 \pm 5.4\%$ ,  $74.9 \pm 7.7\%$ , and  $72.1 \pm 10.2\%$ , respectively (N.S.). The intra-subject CV of these seven subjects was  $5.6 \pm 5.0\%$  (the range was from 0.9% to 15.5%), and the inter-subjects CV was 10.7%. Additionally, the percent change of all-out test duration between the first and third occasions was not significantly related to the change of decrement rate of muscle glycogen. Conclusion: Muscle glycogen after this exhaustive exercise tests decreased largely in seven of the eight subjects and the high repeatability was achieved despite improving exercise performance. Although further studies are needed to elucidate the exceptional results of one subject, our results imply that the exercise protocol could be effective to decrease the glycogen of main working muscles.

**DOES STRETCHING HAVE A FACILITATIVE EFFECT ON RECOVERY FROM ACUTE STRESS RESPONSE?**

Fukuie, T., Suwabe, K., Hyodo, K., Soya, H.

*University of Tsukuba*

Does Stretching Have a Facilitative Effect on Recovery from Acute Stress Response? University of Tsukuba (Tsukuba, Japan) Introduction There are many psychological stressors in modern society. Though acute stress responses (ASR), such as temporal cortisol elevation via HPA axis activation, to those stressors are essential for maintaining homeostasis, failure to shut off this response and a chronic increase in cortisol could lead to serious conditions such as depression. Thus, it is of great importance to cope with psychological stress effectively. Among several stress release therapies, static stretching (SS) is a leading candidate for facilitating recovery from ASR. A recent study revealed that SS increases parasympathetic activity, which plays an important role in shutting off acute stress response (Pawlowlo et al., 2011). Thus, SS could cause muscle relaxation and facilitate recovery from ASR. To test this, we examined whether SS improved the recovery rate from an ASR induced by a mental stress task. Method Nineteen young, healthy male subjects were randomly divided into stretching (STR, n=10) and control (CTL, n=9) groups. All subjects performed a psychosocial stress task, the Trier Social Stress Test (TSST), consisting of a public speech and an arithmetic task. Twenty minutes after the TSST, the STR did 10 minutes of SS, and the CTL rested for 10 minutes. Saliva was collected before and immediately after the TSST, and every 10 minutes until 50 minutes after the TSST. Salivary cortisol (sC) was analysed with ELISA. In order to confirm the effect of SS on muscle relaxation, muscle hardness in the trapezius were measured with a muscle hardness meter, which evaluates the repulsive force of muscle, before the TSST and after SS. Six subjects (STR: 2, CTL: 4) did not have an increase in sC levels after the TSST and were excluded from this analysis. Results In both groups, sC concentrations were significantly increased after the TSST. Contrary to expectation, SS didn't change muscle hardness in the STR and recovery rates for sC levels after the TSST were no difference between both groups. However, when only subjects with a habit of SS ( $\geq 1$  time per week; n=5) were selected, muscle hardness in the left trapezius was significantly decreased after SS and recovery rates for sC levels after TSST were higher compare to the CTL. Discussion Increased sC levels after the TSST indicate that this mental task could induce a ASR. We found for the first time that SS facilitates the recovery rate for elevated sC levels only in subjects with a habit of SS. Because an significant effect of SS on muscle relaxation could only be seen in subjects with a habit of SS, it is possible that muscle relaxation by SS increases parasympathetic activity and decreases cortisol secretion due to exposure to psychological stress. These results suggest that SS effective for muscle relaxation has beneficial effects on recovery from ASR.

**IS CORTISOL CONCENTRATION DEPENDED ON INTENSITY TRAINING?**

García-Valverde, A., Aracil, A., Fernandez-Fernandez, J., Marc-Hernández, A., Martínez-Cantó, A., Mateo-Cubo, F., Pastor, D., Sabido, R., Sánchez-Martos, M.A., Sarabia, J.M., Moya, M.

*SPORT RESEARCH CENTRE OF MIGUEL HERNÁNDEZ UNIVERSITY*

Introduction The biochemistry control of training with physiological markers, such as salivary cortisol hormone (Crewther et al., 2013), seems to be useful to athletes control of physical stress loads, so that glucocorticoid secretion has been linked to stress response of physical exercise (Kraemer & Ratamess, 2005). Several authors have compared the salivary cortisol's concentration (SCC) produced on training with higher and lower intensities, and they found controversial results (McCaulley et al., 2009; McGuigan, Egan, & Foster, 2004; Stokes, Gilbert, Hall, Andrews, & Thompson, 2013). Our purpose were to know the salivary cortisol response after modifying intensity level training. Methodology Fifteen untrained men took part in this study. Participants were randomly divided into two groups in order to carry out tests, twice per week, during seven weeks. Each group completed a power bench press throw test which consisted of completing 6 series until they there were two consecutive repetitions below a 10% from the maximum value recorded in sets, with 5 minutes recovery between sets. The intensity per week was counterbalanced between both groups. Before power test a sample of saliva was collected and then the subjects performed a standard warm up. Another sample of saliva was collected immediately after the daily protocol. Moreover, the volume training was standardize according to maintenance mechanical power principle and acute fatigue was monitored with lose power. Results Peak power was showed between 40%-70% of 1RM. Moreover, optimal's repetitions decreased significantly twice {30%-40%RM [F(1,13)=6.618; p=0,023;  $\eta^2=0,337$ ]; 50%-60%RM [F(1,13)=6.877; p=0,021;  $\eta^2=0,346$ ]} A significant decrease in SCC for all intensities was showed {30%RM [F(1,14)=33.156; p=0.000;  $\eta^2=0.703$ ]; 60%RM [F(1,14)=18.919; p=0.001;  $\eta^2=0.575$ ]; 90%RM[F(1,14)=19.432; p=0.001;  $\eta^2=0.581$ ]} Conclusion Power data obtained on this study are similar to previous reports at the literature (Cronin, McNair, & Marshall, 2001; Stock, Beck, Defreitas, & Dillon, 2010) In the other hand, SCC is influenced by using different intensities in the training of power under the principle of maintenance of mechanical power. Although, the SCC seems to be sensitive to the intensity, as showed by a similar decrease (25-35%) in all RM percentages, SCC did not show differences between percentages.

**HORMONAL RESPONSES TO SPRINT EXERCISES UNDER DIFFERENT HYPOXIC CONDITIONS**

Kon, M., Nakagaki, K., Ebi, Y., Nishiyama, T., Russell, A.

*Chukyo University*

Introduction: Sprint exercise (Stokes et al., 2013) and hypoxic stimulus during exercise (Kon et al., 2010, Sutton, 1977) are potent factors affecting hormonal responses. However, the effects of different hypoxic levels on hormonal responses during sprint exercise are not known. Here, we examined the effect of different hypoxic conditions on hormonal responses during sprint exercise. Methods: Seven male subjects participated in three experimental trials: 1) sprint exercise under normoxia (NSE), 2) sprint exercise under moderate normobaric hypoxia (16.4% oxygen) (HSE 16.4), and 3) sprint exercise under severe normobaric hypoxia (13.6% oxygen) (HSE 13.6). The sprint exercise consisted of four 30 s all-out cycling bouts with 4-min rest between bouts. Growth hormone (GH), epinephrine (E), norepinephrine (NE), and insulin concentrations were measured before exercised under normoxic and hypoxic conditions, 15 min after exposure to hypoxia, and at 0, 15, 30, 60, 120, and 180 min after the exercise in normoxia and hypoxia. Results: GH, E, NE, and insulin levels significantly increased after all three exercise trials ( $P < 0.05$ ). The area under the curve (AUC) for GH was significantly higher in the HSE 13.6 trial than in the NSE and HSE 16.4 trials ( $P < 0.05$ ). Discussion: Resistance exercise performed during acute severe hypoxia (13% oxygen) causes a larger increase in GH concentrations than that in normoxia (Kon et al., 2010). Additionally, submaximal endurance exercise performed under severe hypoxic conditions (4550 m above sea level; approx. 12% oxygen) increases circulating GH level greater than exercise performed under normoxic condition (Sutton, 1977). In contrast, resistance exercise performed under moderate hypoxia (15% oxygen) or normoxia caused similar levels of GH secretion (Ho et al., 2014). Similarly, submaximal endurance exercise performed under moderate hypoxia (2000 m above sea level; approx. 16.5% oxygen) or normoxia elicited similar GH response (Katayama et al., 2010). Severe hypoxia may be an important factor for the enhancement of GH response to all-out sprint exercise. References Ho JY, Huang TY, Chien YC,

### HIGH-PROTEIN DIETS INDUCE RENAL OXIDATIVE STRESS IN RATS PERFORMING A HIGH INTENSITY EXERCISE

Camiletti-Moirón, D., Aparicio, V.A., Nebot, E., Medina, G., Martínez, R., Kapravelou, G., Andrade, A., Coll-Risco, I., Porres, J.M., López-Jurado, M., Aranda, P.

*University of Granada.*

Introduction In the last decades, the combination of high-intensity exercise (HIE) and the intake of high-protein diets (HPD) have been of great interest, specially among athletes and people interested in gaining muscle mass (Aparicio et al., 2011). Oxidative stress plays a critical role in the pathogenesis and progression of chronic kidney disease (Aminzadeh et al., 2014). Thus, the aim of this study was to analyse the scarce information about the effects of HPD and an HIE protocol based on hypertrophy resistance training, on renal redox status. Methods Forty male Wistar rats were randomly distributed into one of 4 experimental groups (n=10): normal-protein diet (NPD) or HPD (10% and 45% soy protein, respectively) with or without HIE for 12 weeks. Thiobarbituric acid-reactive substances (TBARs) and protein carbonyl content (PCC) were assessed. Total superoxide dismutase (tSOD), manganese superoxide dismutase (Mn-SOD), copper/zinc superoxide dismutase (CuZn-SOD), catalase (CAT) and glutathione peroxidase (GPx) antioxidant enzyme activity were measured. Results The HPD groups showed higher values of TBARs levels when compared to the NPD groups (p<0.001). The HPD groups displayed lower levels of tSOD, Mn-SOD, CuZn-SOD and GPx activity compared to the NPD groups (p<0.001, p<0.001, p=0.020 and p<0.001, respectively). The HIE groups exhibited lower levels of PCC and Mn-SOD activity (both, p<0.05), and higher levels of GPx when compared to the untrained groups (p<0.001). Some protein amount\*HIE interactions were found for PCC and Mn-SOD activity such as the higher HIE-induced increased in the HPD groups that was not observed with the NPD (both, p<0.001). Discussion Overall, HPD induced an oxidative status, since an imbalance between oxidative damage markers and the antioxidant defence system was produced. In agreement with our results, a similar study performed also in Zucker obese rats observed that a HPD intake induced renal oxidative stress due to induced accumulation of lipid peroxidation (Namikoshi et al., 2007). ### EFFECTS OF DAILY AMOUNT OF SPONTANEOUS RUNNING ON STRESS RESPONSE AND THE RELATED BEHAVIORS IN RATS

Yanagita, S., Kubota, N., Takano, Y., Takeda, K.

*Tokyo University of Science*

Regular physical exercise can relief stress response and increase stress tolerance. In animal studies, it has revealed that spontaneous running is particularly effective to enhance anti-stress action. However, little is known about conditions during spontaneous running, such as exercise volume, intensity and frequency, in order to confer the anti-stress activity more effectively. In this study, we focused on the effects of daily amount of spontaneous running, i.e. exercise volume, on neuroendocrinal response to several kinds of stress in rats. We also evaluated the stress related behaviors such as anxiety-like and anti-depression behavior. Male Wistar rats were housed individually in cages with or without an attached running wheel and were randomly assigned to either physically active or sedentary conditions. Physically active rats were allowed voluntary access to their wheels for 4 weeks. The rats were screened into high runner or low runner based on the calculated daily running distance. Following to 4weeks running sessions, the rats in both high and low runners were received severe (foot shock) or mild stress (restraint) stimulations. We assessed the levels of brain corticotrophin releasing hormone (CRH), and plasma ACTH and corticosterone using ELISA following to stress stimulations. We also calculated the body and adrenal weight as an index of chronic stress response. Another rats performed anxiety-like behavioral tests, such as open field and elevated plus maze test after 4 weeks spontaneous running sessions. The results showed that CRH levels in the several brain regions following to severe stress stimulation were not different between high and low runner although CRH levels in both high and low runners s received stress stimulations were lower than that in control rat. Plasma ACTH levels after receiving stress in runners were also higher than controls. These results suggest that daily physical exercise indeed induces anti-stress action, but these reactions are independent of amount of physical exercise. The results of behavioral analysis revealed that high runner represented increasing levels of anxiety-like behavior expressions compared to low runner, and suggesting that there are some kinds of difference between high and low runners in mental conditions. These results of present study suggest that it is require investigating the detail of relationship between exercise conditions and anti-stress action.

### MO-SH12 Social science and sport

#### WOMEN'S FOOTBALL – BETWEEN LOCAL ENTHUSIASM AND GLOBAL SUCCESS

Skogvang, B.

*Hedmark University College*

Sport has a unique position in the Norwegian Society, due to the fact that more than one third of the population of about 5 million is involved with organized sport in some way. Sport has always been organized on a voluntary basis. According to the umbrella organization Norwegian Olympic and Paralympic Committee and Confederation of Sports (NIF), only voluntary organizations can be members of the NIF. The development of women's football in Norway has been substantial from about 1,500 registered players in 1975 to 105,595 players today (29 % of all players); the largest organized sport for women since 1995. From the 1990s the Norwegian women's national team has had significant success both in European Championships, World Cups and the Olympics, but still it struggle with acceptance, inclusion and support at club level. In this paper I address how women's football has to act between the local and the global to build a

sustainable sport for the future. The methods applied in the study were fieldwork and qualitative in-depth interviews. Fieldwork was conducted in Norwegian men's and women's football clubs, which mainly offer both elite and grass-root football. All together six clubs (3 with women's football at elite level & 3 with men's football at elite level) were followed closely throughout one year. Observations and informal interviews were carried out during practices, meetings and matches, and in-depth interviews were conducted with eight elite coaches; four in women's & four in men's football. The sample of in-depth interviews carried out with players' consisted of 22 elite football players (11 men & 11 women) aged 19 to 35 years old. These professional footballers had a variety of skills and experiences from newcomers to well-known and skilled players playing at the Norwegian national teams for men and women. The transcribed interviews were coded with main categories and associated sub-categories and cross-analyzed in order to compare each issue across the sample. The main categories were sport carrier (beginning/future plans), positive/negative with football, everyday life in combination with football, gender, status, media coverage, economic conditions, spectators and conflicts. The number of teams for girls and women in Norway has increased to nearly 7,500 teams. The last few years some female elite teams have emerged into male premier league clubs, some of them successfully, and others not. Each team includes not only the players, coaches and team leaders, but also parents, referees, waffle makers, kit washers, and so on, and a larger club might make the work easier, and may attract more sponsors also to women's football. The field work carried out shows that in general women footballers are strongly dependent of enthusiasts and voluntariness at local level. Local sponsors and media, family and friends are crucial for women's football development in Norway and internationally.

### **WILL IT MAKE ME AN INSIDER? MIGRANT WOMEN'S PARTICIPATION IN SPORTS IN THE HELSINKI AREA**

Grochowski, P.

*Univeristy of Helsinki*

This presentation will explore the pathways to participation of migrant women in the Helsinki capital region in Finland. The research questions are: how do migrant women residing in the Helsinki region experience sport and physical activities? Do sports and physical activities provide means for integration of migrant women living in Helsinki? Do sport and physical activities lead to generating feelings of belonging in Finland? The study explores the environments, social histories and social networks which lead to the activation and sustained participation of migrant women in sports and physical activities and provides a critical assessment from the experience of a migrant woman on how life in sports in a new country. The theory of sports participation and belonging has been explored in the Nordic countries (Walseth, 2006; Aggergaard et al. 2010) and this study hopes to provide a Finnish contribution to that debate. Studies reveal that health, well-being and activities in sports are influenced through maternal lines (Nowaki, Radzinska, Rynkiewicz, 2009), family background, socialization and habitus. The study assesses the common thesis that participation in sports can develop a feeling of belonging among migrant groups in the Nordic countries (Walseth, 2006; 2008, 455, 459; Zacheus, 2014). Twelve women from around the world, living in the Helsinki Capital region participated in the study. Qualitative interviews were used for narrative and contemporary accounts on their lives in sports. The study takes an intersectional approach and a standpoint approach (Harding, 1987), to give a voice to a marginalized and belittled group of sport participants. Figurational perspective and Bourdeausian theory serve as the theoretical framework for the study.

### **WHO HAS THE POWER OF THE DEVELOPMENT OF SPORT, THE MEDIA OR THE SPORT?**

Nybelius, M.

*Dalarna University*

Background and framing of the problem: The research area Sports and Media has grown during the last decade. The power of the media has been highlighted in many investigations out of a media perspective. The investigations have rarely been done out of the perspective of the sports organizations. The main question for this investigation is therefore; who has the power over the development of sport, the sports organization or the media? The organization in focus is the International Ski Federation(FIS). The last decades the society has developed very fast. Two of the areas where this is evident are media and sports. Technology has given new possibilities for both the media and the sport organizations. This has also given opportunities and obstacles to handle for the sport organizations. The scientific base is theories from social science and sport studies, like medialization, media logic and theories of the development of the media and the sport. The theories will be related to empirical data of interviews, articles in the media and statements in the media, both internal and external media. Internal media is the media controlled by the FIS and external media is the media not controlled by the FIS. Other documents related to the questions will be used when necessary, like the Bulletin from the FIS and minutes from their meetings, when possible. Aim and questions This investigation is about how/ if the sports within the International Ski Federation(FIS) have developed in relation to the logic of the media or the logic of the sport during the last decades, how this has affected the development and how officials of the FIS and the agents of media view the development of the sports. The aim is also to analyze the media context and to find out what is expected of a sport in general. How can the sport work in the future and what should it be aware of to be able to take place on the arena of the media and within the awareness of the media audience? What will happen in the future? The subject of the investigation is the International Ski Federation (FIS) and the sport disciplines are ski jumping and cross country skiing. The main questions are: 1. How do the officials in the FIS and the media actors describe ski jumping and cross country skiing? 2. How have the sports developed the last decades; according to the logic of the media and/ or the logic of the sport? 3. Who has the power over the sport development, the sport organization or the media? 4. How does the International Ski Federation's work with internal media channels (website mostly) and with external media.

### **A QUALITATIVE STUDY OF THE FEMALE PRE-SERVICE ELEMENTARY TEACHERS' EXPERIENCES DURING TEACHER TRAINING FOR PHYSICAL EDUCATION**

Shin, K.

*Jeonju National University of Education*

Introduction Female elementary school teachers in Korea are out-numbering their male counterparts across the country. This phenomenon is regarded of the problematic factor that atrophy the physical education(PE) because most of female teachers are unwilling to teach PE. So It's very important to cultivate female teachers' ability of teaching PE. This study focused on the female pre-service elementary teachers(PETs)' experiences during teacher training for physical education(TTPE) to explore the experience which can show possibilities to develop female PETs' ability of teaching PE. Thus the purpose of this study was only to investigate the difficulties that the female PETs have experienced during TTPE, also to understand how they have coped with those difficulties. Methods This study used a phenomenological

research method. Participants were 6 female PETs from the national university of education which is located in a local area in Korea. Data were collected by in-depth interview according to the research design, which was based on the Cresswell(1998)'s phenomenological approach. The interview was processed for 5 months from June to November of 2013. The content of the interview, which was carried on through face-to-face interview, mostly includes difficulties what female PETs have experienced during PETE. And then data were analyzed by the phenomenology method which Lincoln and Guba(1985) presented. Results & Discussion The results of this study were summarized in two aspects. The first, the difficulties that female PETs have experienced during PETE were categorized as following themes: Trauma grabbing own ankle, Tasks cannot be chosen, uneasy accompany with others, and No meaning of studying. The phenomenon what female PETs felt more stress than male PETs was connected to the experience of having more difficulties than male PETs. Second, the coping method against these difficulties were categorized as following themes: Depending on time, Gaining others' sympathy, Trying by oneself, and Problem-solving with other's help. Female PETs have tried to solve the problems they encountered. Remarkably female PETs have shown more strength in a specific area. Especially female PETs have played more meticulous role in planning PE class and making teaching materials than male PETs. Conclusively, The femininity of female PETs is considered not only as the barrier factor, but also as the facilitator factor to the TTPE. Conclusively TTPE should be deliberately prepared so that the positive aspect of the femininity should be promoted while the negative aspect of it should be improved. References Cresswell, J. W. ### RESEARCH ON THE PROMOTION OF SPORT FOR OLDER PEOPLE IN CHINA

Hou, H.

*China Sport Information Center*

Introduction In 2014, the 212.42 million people over 60 in China make up 15.5% of the total population, an increase of 0.6 percentage point from 2013, with the proportion of people over 65 at 10.1%. By 2020, older people in China will reach 248 million. The increase of older people poses great challenges to China's social development, highlighting the importance and urgency of the development of sport for older people. Methods By using the methods of literature research, statistical analysis and investigation at site, this paper aims to research on the basic state of the development of sport for older people, and give suggestions on the future development of sport for older people in China Results In order to guarantee older people's rights to taking exercises and physical activities and adapt to the requirements of an aging society for sports work, China has promulgated and implemented a series of rules, regulation and policies, including Law of the PRC on Physical Culture and Sports, Rights Protection Law of the People's Republic of Elderly People, Regulations on Public Cultural and Sports Facilities, Regulations on National Fitness, National 12th Five-Year Plan for China Ageing Development and National Fitness Program (2011-2015). The General Administration of Sport of China and Chinese Veterans' Sports Association take charge and overall planning of sports work for older people in China, with China Aging Problem National Commission bearing its own share of responsibility. By developing sports organizations and facilities, and encouraging older people to participate in various forms of activities, the authorities concerned try to increase the sport participation rate of older people. Among people aged 20-69, the proportion that exercises or plays sport regularly (at least three times per week, each time for more than 30 minutes and intensity of exercise or sport not below the medium level) rises with the advance of age. Among those who exercise or play sport, older people do so more frequently and for more time. Sport for older people have become an important part of sport for all in China. Discussion Although sport for older people has take shape, there is still more room for development, and policies and measures to promote it need to be perfected and implemented in a more detailed manner. This paper gives the following suggestions: make more efforts to build more older people-friendly sports facilities; train various kinds of social sports instructors in order to meet the different needs of older people; encourage older people to actively participate in voluntary sports activities; strengthen scientific research on sport for older people and actively provide information on opportunities for and benefits of physical activity for older people. References General Administration of Sport of China (2008). "Bulletin About Survey of Participation in Physical Exercises by Urban and Rural Residents in China in 2007". Li X,(2014). ### MIND THE GAP: YOUTH PROFESSIONAL FOOTBALLPLAYERS NEGOTIATING THE GAP BETWEEN DREAMS AND REALITIES.

Fundberg, J.

*Sport Science*

Introduction: The presentation takes its starting point from a project about young professionals in football. I define young professionals as boys who secure youth contracts with football clubs, normally when they are 16 to 18 years old. The project focused upon boys moving from a Swedish club to a club abroad and sought to explore sporting identity and everyday life from a structural level including: globalization, capitalization and professionalization of sports. Methods: The data was collected through semi-structured interviews and observation with 25 youth players, and 25 adults (trainers, agents, scouts, parents). Both the individual micro-level and structural macro-level of sports are used to discuss and analyze general social issues within youth and adult life, masculinity, work and leisure. Discussion: This research, draws attention to the significant gap between young professional footballers dreams, high expectations, and reality. Durkheim's concept of 'anomie' is developed within a sporting context to problematise youth footballplayers everyday-life. Conclusion: The political landscape of professional football is increasingly grounded within a capitalist context. Subsequently, young professional footballers are required to negotiate the 'gap' between dreams, expectations and realities. This research suggests that those athletes who are able to successfully manage this 'gap' are better placed manage both their personal and professional every day lives.

### TURING A SPACE INTO A PLACE: A STUDY OF MIGRANTS' HASHING PRACTICE IN TAIWAN

Chuang, P.

*National Taiwan Normal University*

Introduction Drawing inspiration from Tuan's concept of space and place (Tuan, 2001), this research uses hashing, a non-competitive trail running sport, as a medium, and aims to reveal the connection between migrants' sporting practice and their identity of place. Methods Qualitative in-depth interviews with 8 foreign hashers living in Taiwan were conducted from September to December 2014. Results 1. A common hash is combined with 2 sections; trail running and socializing drinking party, which create barriers to female participants. 2. Most regular hashers come from western countries with deep-rooted outdoor culture. Eastern migrants are rare to see, and attend occasionally by invitation from friends. 3. Hashers travel around in Taiwan, and keen to participate in various trail running and cross-

country running competitions. Hence, they gain more understanding and cultural identification toward this land and local people. Discussion While many policy makers and scholars focus on using sports as a tool for social integration, however, the elements in modern sport such as rules, opponent forms, equipment and facilities, media and governing organizations may produce alienation from diverse migration backgrounds (Hacısoftaoğlu & Pfister, 2012; Ludwig & Schierl, 2012; Taylor, 2001). On the contrary, researches of hiking and wandering in natural environment show strong evidences related with nationalism, environmentalism, equalitarianism, and humanism (Davidson, 2002; Solnit, 2000; Ween & Abram, 2012). Research found that there is no victory or defeat involved in hashing, thus, participants build a genial relationship through the whole process. In addition, low participation fee and easy access location gives these foreign hashers more opportunities to get closer to local places, and then, attach a sense of togetherness and belongs to places through socializing with local people. Moreover, hashers love nature, and shift their sympathy from natural space to social space, and further, make a meaningless foreign space into a place with care and love. References Davidson, L. ## CHILDREN'S CULTURE AND MOTOR SKILLS LEARNING

Mello, A.

*UFRJ - Universidade Federal do Rio de Janeiro*

Introduction Children's culture, object of study of Sociology of Childhood, covers various forms of play, among which are the traditional games practiced by groups of children in the streets, squares and schoolyards such as hopscotch, jump rope, kite, marbles, hide-and-seek, etc. In a dialectic articulation between action and thought, children need to master body movements that require a certain level of learning. Traditional games are activities that provide an exceptional set of motor experiences through which the child learns new moves and bodily possibilities (Mello, 2006). The objective of this study was to analyze the learning process of children in their attempt to master the existing complex motor skills in traditional games. The theoretical framework comprised a trans-disciplinary dialogue between the Sociology of Childhood (Corsaro, 2005; Sirota, 2006) and the historical-cultural theory (Vygotski, 1997). Methods The study followed a qualitative approach of ethnographic orientation. Fieldwork was conducted in a public elementary school located in the city of Rio de Janeiro, with children ranging from 6 to 10 years of age who freely played traditional games in the schoolyard. The tools used included observations of the children during their games, records in field journals, audio, photographs, personal interviews and interviews with groups of children. Discussion of Results Following the theoretical and methodological orientation of the Sociology of Childhood according to which children are actors of social processes (Sirota, 2001; 2006), we collected the children's testimonial statements on how their learnings of motor skills take place in the practice of traditional children's games, being these data central to our research. The observations and statements indicated that the learning of motor skills of traditional games occurs initially by imitation in the group to which the child belongs. The child observes and tries to reproduce the movement made by another child. However, the observation and movement reproduction are not enough for the child to fully master the necessary movements of the games, especially those which are more complex. It is fundamental to have the mediation of peers with a deep knowledge of the movements required by the game so that the child can make progress in his learning. The learning of movements in traditional games occurs under conditions predisposed by the zone of proximal development (Vygotski, 1997) through collaboration and guidance among peers. References CORSARO, W (2005). *The sociology of childhood*. T. Oak: Pine Forge Press. MELLO, AM (2006). *Psicomotricidade, educação física e jogos infantis*. SP: Ibrasa. SIROTA, R (2001). *Emergência de uma sociologia da infância*. Cad. Pesq. 112, 7-31. SIROTA, R (2006). *Éléments pour une sociologie de l'enfance*, Rennes: PUR. VYGOTSKI, L (1997). *Pensé et langage*. Paris: La Dispute.

## HOCKEY... AND THEN WHAT? GENERATIONS OF PLAYERS FACING EDUCATION

Moret, O.

*University of Lausanne*

Introduction This contribution discusses the impact of professionalization on hockey players' choices of post-compulsory education by observing 3 generations of players. It attempts to explore 3 identified dimensions at work in this process: sports commitments, training paths and parental attitudes. The analysis suggests thinking of these dimensions in terms of figurations (Elias, 1985). Methods Our population comprised Swiss hockey players born between 1963 and 1992 who played in one of the two highest levels of the Swiss hockey league system. The players were distributed into 3 cohorts: 1963-1972(C1), 1973-1982(C2) and 1983-1992(C3). 1814 players corresponded to these criteria and 605 players answered our biographic questionnaire. We enhanced the results through 36 in-depth interviews. We created the sampling of the players from the data of the questionnaire, which allowed us to vary profiles in terms of cohort, social origin and type of education. Results The data suggest a progressive empowerment of professionalization' access paths. The market, previously marked by a bigger inertia, registered more circulation and competition over the generations. Career ambitions appear early and have gradually grown from a local to an international radiance and from sports to professional ambitions. The interactions with the parents are determining on choices regarding education. Results show a more elitist social recruitment and a stronger implication of the parents in education but also in the sports activity. Over the cohorts players opted for general training, which allows extending the uncertainty to the choice of their future trade. If the C1 players mainly turned to a manual vocational training, the C2 players, who still do not benefit from adapted structures, turned to arranged training. A significant share of C3 players continues their education in a sport-study structure but also did not pursue a post-compulsory education. Thus we pass gradually from a compartmentalized figuration, where the relations between sport and education are very weak, to an embedded figuration (Granovetter, 1985). Discussion If we learnt a trade for the future by realizing a "sports break", the sports career gradually stands out as a stage of the occupational career, even of education. Engaging in sport means being part of a new universe where progressive adherence to the norms can conflict with education norms. Besides, at comparable social levels, if the parents' attitude influences schooling, then the evolution of the social profile of families furthers greater closeness with the sports space and the sharing of a sports doxa (Bourdieu, 1994). References Bourdieu, P. (1994). *Practical Reason: On the Theory of Action*. Stanford, University Press. Elias, N. (1985). *La société de cour*, Paris, Flammarion. Granovetter, M. (1985). ### MO-SH07 Sport management

#### THE SURVEY OF ORGANIZATIONAL COMMITMENT AND CLIMATE OF ORGANISATION OF TURKISH SPORTS SCIENTISTS

Yıldırım, Ö.D.1, Salman, M.N.2, Akalın, T.C.1

1: BEÜ (Zonguldak, TURKEY), 2: Aksaray Uni. (Aksaray, TURKEY)

**Introduction** The organisational commitment of individuals and climate of organisation which are among the factors affecting success of organisations directly in our quickly developing and complexifying world draw quite a lot of attention of management scientists. The commitment of employees on the organisation is required to be kept in a high level to increase the productivity and quality of universities as in every organisation. This issue mentioned is undoubtedly among the most important factors in increasing the contribution of sports scientists to the universities. In this research which has been carried out in theoretical and empiric level, the relationships between organisational commitment of sports scientists and the climate of organisation have been analysed. Method A questionnaire has been applied to 110 volunteer academicians in order to determine the levels of organisational commitment of the sports scientists who work in the high schools and faculties of Physical Education and Sports of the universities in Turkey within the scope of this research. "The Scale of Organisational Commitment" which was developed by Meyer and Allen (1990) and the scale of "Climate of Organisation" which was developed by Litwin and Stringer (1974) have been used as tools of data collection. The data have been evaluated using SPSS software version 15.0 for Windows, descriptive statistics have been obtained, one way variance analysis was performed for the comparison of more than two groups and t-test was performed in order to find out whether there is statistically significant difference between the mean scores of the variable groups. The results obtained have been evaluated in the range of %95 reliability  $p < 0.05$ . Results When the level of organisational commitment of participants ( $n=73$ ) was analysed, it was seen that their level of commitment is quite high. It was found out that the participants whose levels of commitment are high are the individuals who are more emotionally dependent on the institution  $p < 0.05$ . The fact that 80,3% of the participants, which is quite a high proportion, state that they find opportunities to develop themselves in the institution confronts us as another important matter which increases their organisational commitment. In the analysis which was carried out on the relationship between the perception of climate of organisation and the socio-demographic qualifications, a difference was determined in terms of the variable of position  $p < 0.05$ . Discussion As a result, it can be said that emotional commitment of the participants on their work and institution is intensive. In this context, it can be stated that the participants like their work and institution. In order to create a healthy climate of organisation in Sports Sciences, administrative decision making and involving in processes of policy making, taking the needs of employees and their opinions into consideration and maintaining work and organisational coherence are considered obligatory for high performance. #### MEGA SPORTING EVENTS AND THE DEVELOPMENT OF SPORT SCIENCES IN BRAZIL

Reppold Filho, A.R.

*Federal University of Rio Grande do Sul*

**Introduction** Mega sporting events impact the host cities and countries in different ways. They also generate different types of legacy. Among the most important are: economic, social, cultural, environmental, image and knowledge. In this study, we focused on the effects of the 2014 FIFA World Cup and the 2016 Olympic and Paralympic Games in the development of Sports Science in Brazil. Method Data collection was conducted with the collections and databases of the Federal Government and major Brazilian universities. The effects of mega sporting events in the development of Sports Science in Brazil, were considered with reference to five aspects: a) scientific publications on mega sporting events; b) ongoing research on mega sporting events; c) research in progress that are not about mega sporting events, but were driven by them; d) financial support for research on mega sporting events or driven by them; e) establishment of research and higher education institutions in the country driven by mega sporting events. Results and discussion a) Scientific publications on mega sporting events The analysis of the Brazilian scientific publications showed that until the mid-2000s studies on mega sporting events were scarce in the country. The situation changed significantly by 2007. Since then, researchers from different disciplines, with significant contributions from economics, business administration, tourism, geography, sociology and physical education, have analyzed mega sporting events. b) Ongoing research on mega sporting events There are numerous ongoing researches in the country on mega sporting events. Brazilian universities in partnership with the Federal Government carry most of these studies out. Others are performed at the request of entities linked to the organization of these events. c) Ongoing research driven by mega sporting events Though not dealing directly with mega sporting events, there are several studies underway in the country driven by them. These studies involve the production of knowledge, technology development, and construction of storage systems and availability of information for different segments of the Brazilian sport. d) Financial support for research Driven by the mega sporting events taking place in the country, different government agencies have promoted actions and provided financial support for scientific research and technology projects and innovation in the area of sports, including credit lines for studies on the legacy of mega sporting events. e) Research and higher education institutions In close connection to the mega sporting events occurring in the country, there is national committee discussing the possibility to establish a Brazilian University of Sport dedicated exclusively to the training and qualification of professionals and researchers to work in different areas of sport and sport sciences. Conclusion The results of this study support the conclusion that mega sporting events are producing positive effects on the development of the Sports Science in Brazil.

#### THE INVESTIGATION OF THE FACTORS AFFECTING STADIUM ATTENDANCE OF PROFESSIONAL FOOTBALL CLUB SUPPORTERS

Soyguden, A.1, Barut, Y.2, İmamoglu, O.2

1: Hitit University (Corum, Turkey), 2: Ondokuz Mayıs University (Samsun, Turkey)

**Aim:** The aim of this study is to investigate the factors affecting the stadium attendance of the supporters of professional football clubs that have stadiums fulfilling the UEFA criteria. **Material and Method:** The study population includes the supporters of Galatasaray Sport Club, Fenerbahçe Sport Club and Kayserispor football clubs participating in Spor Toto Super League in 2013-2014 seasons and having stadiums that fulfill the UEFA criteria. The sample consists of randomly selected ( $n=1237$ ) supporters. As well as demographic data of the

supporters, reasons affecting the Stadium Attendance Scale which consists of 30 questions were used to collect the data. Statistical analysis of the data was done using SPSS 16.0 packet program and descriptive statistics, independent t-test and one-way ANOVA test were applied. Results: The reasons affecting the stadium attendance of the supporters are as follows; opportunity for recreational activities, stadium atmosphere and personal relaxation. On the other hand, the variables affecting the supporters' nonattendance are as follows; negative ergonomic environment and unethical situations. Conclusion: Among the other factors affecting the supporters' attendance to the stadiums, the component of 'Opportunity for Recreational Activities' was found to be the most influential factor. This revealed the necessity of increasing the number of high quality organization related to recreational activities in the stadiums. In the study, the component of 'Negative Ergonomic Environment' was found to be the most influential factor influencing the stadium attendance. In conclusion, negative ergonomic environmental conditions need to be improved to increase the stadium attendance.

### **XPLORING THE RELATIONSHIPS AMONG PLACE ATTACHMENT, PLACE IDENTITY, TEAM IDENTIFICATION, AND FAN LOYALTY.**

Tai, W.

*University of Taipei*

Lamigo Monkeys, a Taiwan professional baseball team (formally known as LANEW Bears since 2003). Since Lamigo Monkeys relocated to Tao Yuan new stadium in 2011, Lamigo has clinched 2 Championship titles (2011 & 2014) and the average number of spectators has risen from 3,016 in 2011 to 6,241 in 2014. Comparing to a 16% glide in the average number of spectators from 2013 to 2014 for the entire league, Lamigo Monkeys is the only team to have a 5% growth rate. According to Wann et al. (2001), fans with strong ties to the local team would likely exhibit a more positive psychological profile than those lacking team identification. Identification with a team from a different city and mere sport fandom per se are not expected to provide significant benefits because these factors do not readily lead to social connections. The driving force behind the benefits of team identification with an individual becomes attached to a larger social group. In addition, place attachment and place identity that originate from environmental psychology are the key terms to explain the relationship between residents and place. Place attachment is generally defined as an emotional tie that individuals develop towards their places of residence, with which they generally maintain close relations. Place attachment is seen as a positive affective bond between people and their place of residence. In addition to attachment, identity is another critical concept to relate to place. The importance of the concept of identity stems from being part of the very essence of place and is intimately related to place attachment. Place identity is a major component of the identity of oneself, manifested through own ideas, beliefs, preferences, values, and objectives that are relevant to such a place, as well as through the way place is understood and perceived. Therefore, the objective of this study is focused on exploring the relationship between team identification and fan loyalty, while understanding the moderating effect of place attachment and place identity on team identification and fan loyalty. The hypotheses of this study are: (1) team identification has significant positive influence on fan loyalty, (2) place attachment can moderate the relationship of team identification and fan loyalty significantly, and (3) place identity can moderate the relationship of team identification and fan loyalty significantly. To conclude, spectators of high level of place attachment or high level of place identity can moderate fan loyalty significantly. This study will enhance the understanding of the moderate effect of place attachment and place identity on team identification and fan loyalty.

#### **A PILOT TEST ON THE EFFECT OF STATIC STRETCHING ON REDUCING THE INCIDENCE OF MUSCULOSKELETAL DISORDERS AMONG TEACHERS IN HONG KONG**

Leung, F.L.1, Chui, M.W.2

*The Chinese University of Hong Kong1, Hong Kong Baptist Hospital2*

Purpose: Musculoskeletal disorders (MSD) is a serious and common occupational health problem around the world. With the prevalence rate of 39% to 95%, the adverse impact of MSD on the teaching profession has been reported to be high (Erick & Smith, 2011). Stretching is a potential way to reduce work-related MSD (da Costa & Vieira, 2008). Static stretching is safe and easy to learn. The purpose of study was to evaluate the effectiveness of static stretching on reducing the incidence of musculoskeletal disorders among teachers in Hong Kong. Methods: A total of 47 teachers from 2 primary schools were recruited and participated in the current pilot test. They were group-randomized by school into two groups, i.e. the intervention group (I) and the control group (C). Participants of the I group received the stretching program which was adapted from the "Stretching Exercises to Prevent Musculoskeletal Injury Manual" of the Occupational Safety and Health Council of Hong Kong (2013). The participants were advised to perform a set of 9 static stretching exercises for 15 seconds each and 3 times a day. Log books were provided to record their compliance rates. Participants of group C did not receive any intervention treatment. They were requested to maintain their present lifestyle for 3 months. The assessments of the prevalence rates of MSD were conducted at baseline and third month of the intervention. Results: No statistically significant differences ( $p > 0.05$ ) of prevalence rates of MSD between and within groups were observed. Conclusion: The results showed that static stretching was not effective in reducing the incidence of musculoskeletal disorders among teachers in Hong Kong. The lack of intervention effects might be attributed to the lack of programme contents engagement and small sample size. In order to have more understanding on the effectiveness of static stretching on reducing the incidence of MSD, future studies should be on strategies to increase the compliance rate. ### RELATIONSHIP BETWEEN CHANGE IN MUSCLE STRENGTH AT DIFFERENT MUSCLE CONTRACTION SPEEDS AND CHANGE OF COMFORTABLE GAIT SPEED IN AMBULATORY POST-STROKE PATIENTS

Shimose, R.1,2, Matsunaga, A.2, Hoshi, T.1, Shibata, K.1, Otsuka, T.1, Adachi, S.1, Ichinosawa, Y.2, Shimizu, S.2, Sakamoto, M.2, Suzuki, M.2, Yona, M.3, Muro, M.4

1: Sagami-hara Chuo Hosp. (Kanagawa, Japan) 2: Kitasato Univ. (Kanagawa, Japan) 3: TUPLS (Tokyo, Japan) 4: Toho Univ. (Tokyo, Japan)

**Introduction** One of the main goals of the rehabilitation process in post-stroke patients is to walk independently and practically and it is important to elucidate factors influencing practical walking. Some studies show that gait speed is associated with maximal muscle strength on the affected side. Walking requires instantaneous muscle activity, therefore muscle contraction speed should be considered when the relationship between gait speed and muscle strength is investigated. However, few studies have investigated the relationship between gait speed and muscle strength at different contraction speeds in a cross-sectional and longitudinal manner. We aimed to investigate whether gait speed is associated with muscle strength in slow and fast muscle contraction in acute ambulatory post-stroke patients. **Methods** Eleven post-stroke patients (75 +/- 6 years) who had received inpatient rehabilitation therapy after stroke and could walk independently were enrolled in this study. Exclusion criteria were dementia, low vision, higher brain dysfunction and orthopedic disease. We collected clinical characteristics including age, sex, stroke type and affected side. Comfortable gait speed and isokinetic leg extension torque of affected side at two different constant rates (20 and 40 rpm) were measured twice, on a recumbent cycle ergometer (Strength Ergo 240, Japan), every 2 weeks within one month after the onset of the stroke. Relationships between gait speed and isokinetic peak torque at 20 and 40 rpm were assessed using Spearman's rank correlation coefficient in a cross-sectional and longitudinal manner. **Results** Peak torque of affected limbs significantly correlated with gait speed in both speeds (20rpm;  $r=0.62$ ,  $p<0.05$ , 40 rpm;  $r=0.71$ ,  $p<0.05$ ). Change of peak torque at 20 rpm did not correlate with the change of gait speed ( $r=0.04$ ,  $p=0.9$ ), however change of peak torque at 40 rpm significantly correlated with gait speed ( $r=0.64$ ,  $p<0.05$ ). **Conclusion (Discussion)** An increase in gait speed accompanied by an increase in muscle activity during fast muscle contraction is necessary for improving practical walking. Our results suggest that it is important to increase instantaneous muscle activity of affected lower limbs in order to improve practical gait, and that change of muscle strength during fast muscle contraction could be a suitable parameter for assessing the recovery of neuromuscular function in ambulatory post-stroke patients. ### EFFECTIVITY OF SLACKLINE TRAINING IN PHYSIOTHERAPY

Küng, U., Hohenauer, E., Baeyens, J.P., Clijse, R.

University College Physiotherapy Thim van der Laan

**Introduction** – The prevalence of sustaining a sport injury is high in adults. Deficits in postural control and muscle strength represent important risk factors. Therefore, balance and sensomotorik training do play a critical role in physiotherapy and prevention programs. Slacklines are more and more common to train postural control and coordination not just in sports but also in physiotherapy as an alternative to wobble boards. Thus, the purpose of this study is to investigate the impact of Slackline training on postural control and muscle activation patterns. **Methods** – 10 young healthy and active adults, unskilled (<1h Slackline experience), conduct a Slackline training session of 9 x 30 minutes over a period of 6 weeks. Measurements pre and post the training period will be conducted. Outcome measurements are surface EMG of leg muscles and whole body kinematics such as pelvis, trunk and head rotations and translations. Percentage of maximal voluntary contraction (MVC), EMG wavelet analysis and translational and angular deviation and of the pelvis, trunk and head over the whole trial are analyzed. **Results** – Preliminary results show higher activity in % MVC in ankle muscles (M. tibialis anterior: 118%, M. gastrocnemius medialis 104% & M. peroneus 98%) compared to upper leg muscles (M. biceps femoris: 42%, M. rectus femoris: 41%) and pelvic/low back muscles (M. gluteus medius: 34%, M.erector trunci pars lumbalis: 39%). Wavelet analysis to investigate activation frequency and biomechanical analysis of body kinematics are coming up as a next step. **Discussion** – Higher activation of ankle muscles compared to upper leg and pelvic muscles support the theory of a bottom up strategy in balance correcting mechanisms triggered from changes of the base of support. Since correct (re-) weighting of sensory input is essential for successful postural control (Honegger et al., 2013, Küng et al., 2009), Slackline training can be a reasonable method (Pfusterschmied et al., 2013). Ankle proprioceptors are highly activated and complete visual information in a momentarily way. However, if an improvement of postural control on the Slackline does have a great impact on the risk of sport injuries has to be shown in future research. **References** Honegger F, Tielkens RJM, Allum JHJ (2013). ### INCREASED ENERGY EXPENDITURE DURING ADL BY ELECTRICAL STIMULATION-INDUCED LEG MUSCLE ACTIVATION IN SPINAL CORD INJURY

Janssen, T.W.J., Raaijmakers, K., Van Oost, I., De Groot, S., Smit, C.A.J.

VU University Amsterdam

**Introduction**. Obesity, increasingly common in individuals with spinal cord injuries (SCI), is for a large part due to an inactive lifestyle and a markedly lower resting energy expenditure (EE) as a result of the paralyzed muscle atrophy. A possible contribution to a solution is by increasing EE by electrical stimulation (ES)-induced activation of the paralyzed muscles. The purpose of our study was to evaluate if ES-induced muscle activation can be used during daily activities to increase EE. **Methods**. Nine men with a chronic SCI (C4/5-T11; ASIA A-C) performed 3 standardized daily activities for 30min each: lying on a bed (L), sitting in a wheelchair reading a book (S), and submaximal wheelchair propulsion on a treadmill (WC) while wearing a garment with built-in electrodes. During 20min of each activity, gluteal, hamstring, and quadriceps muscles were simultaneously activated using ES (50Hz) at individually adjusted comfortable current amplitude levels. EE was derived from oxygen uptake measurements using a portable gas analysis system. **Results**. ES-induced activation was well tolerated by all participants and did not hinder the tasks performed. EE during L, S, and WC with ES ( $416\pm 133$ ,  $375\pm 70$ ,  $673\pm 187$  kJ/hr, resp.) was higher ( $p<0.05$ ) than without ES ( $342\pm 81$ ,  $318\pm 38$ ,  $617\pm 177$  kJ/hr). This suggests that  $\pm 3-4$  hr/day of activation is needed to counteract the average 182 kJ/day excess caloric intake found in SCI (De Groot 2010). **Conclusion**. ES-induced paralyzed muscle activation markedly increases EE during daily activities in SCI and might therefore be a potential way to help counteracting the development of obesity.

**HIGH INTENSITY INTERVAL TRAINING TO IMPROVE FITNESS IN CHILDREN WITH CEREBRAL PALSY**

Moholdt, T., Lauglo, R., Lamvik, T., Stensvold, D., Finbråten, A., Vik, T.

*Norwegian University of Science and Technology*

**Introduction** Aerobic exercise capacity is limited in children with cerebral palsy (CP) compared with their typically developing peers (Balemans et al, 2013), and there is limited research on the effect of aerobic training in children with CP. Our aim was to assess the effect of high-intensity interval training (HIT) on aerobic exercise capacity, quality of life (QoL) and body composition in children with CP. **Methods** This was a baseline-control trial. Twelve children (7 boys, 5 girls) with CP, gross motor function classification system (GMFCS) levels I-IV, mean age 14 (10-16) years, performed 24 sessions (2-4 per week) of HIT. They aimed to reach at least 85% of their heart rate maximum for 16 of totally 35 minutes each session. The primary outcome, peak and submaximum oxygen uptake (VO<sub>2</sub>peak, VO<sub>2</sub>submax), were measured at enrolment to the study (T0), after a pre-training period (T1) and after HIT (T2). Secondary outcomes were QoL assessed with the KINDL questionnaire and body composition measured using whole body dual-energy X-ray absorptiometry scanning. Results VO<sub>2</sub>peak increased by 17%, from 34.1 (5.6) to 39.8 (6.1) mL·kg<sup>-1</sup>·min<sup>-1</sup> from T1 to T2 (p = 0.017), and since VO<sub>2</sub>submax did not change, the percentage oxygen utilization was reduced. According to parents, QoL improved (p = 0.008), and in particular their children's self-esteem (p = 0.005), but not according to the children themselves. Body composition did not change. **Discussion** Data from controlled clinical trials on the effect of exercise training on VO<sub>2</sub>peak in children with CP is limited. Another study (Unnithan et al, 2007) found VO<sub>2</sub>peak to increase by 18% after three months of combined endurance and strength training (three weekly sessions of 70 minutes with an intensity of 65-75% of predicted HRpeak). In contrast to this study, the participants in our study only exercised for about 35 minutes each time and fewer sessions in total. We argue that time efficiency is particularly important in children with CP as they usually spend more time on activities of daily life. The observed changes in parent proxy reported QoL are not likely to be explained by various expected short-term emotional changes in adolescence, as parents' reports are not affected by these normal fluctuations. **Conclusions** This pilot study showed that HIT can improve aerobic exercise capacity in children with CP. As such training may also improve the children's QoL it should be considered included in individual (re)habilitation programs. **References:** Balemans AC, et al. (2013) *Med Sci Sports Exerc.* 45: 561-8. Unnithan VB, et al. (2007) *Med Sci Sports Exerc.* 39: 1902-9.

**ACUTE ADAPTATIONS OF SPASTICITY-RELATED IMPAIRMENTS AFTER WHOLE BODY VIBRATION – EFFECTS ON STRETCH REFLEX RESPONSES, VOLUNTARY MUSCLE ACTIVATION AND MOBILITY**

Krause, A., Freyler, K., Gollhofer, A., Ritzmann, R.

*University Freiburg*

**Introduction** Whole body vibration (WBV) training is widely implemented in multifaceted fitness and health settings. While investigations increasingly demonstrate positive effects of WBV within healthy subjects, the transfer of those adapted underlying mechanisms into a clinical setting is still lacking. Evidence about WBV-induced reduction in spinal excitability (Ritzmann et al. 2011) may be associated with benefits in patients suffering from increased reflex activity (spasticity), thus enhancing motor performance (Ahlborg et al. 2006). Therefore, this study aims to provide evidence about acute neuromuscular and kinematic effects of WBV in children with spasticity, such as in cerebral palsy (CP). **Methods** 29 children with spastic CP were recruited. Before and after one-minute of vibration training (16-25Hz, 1-3mm) stretch reflexes (SR), maximal voluntary contraction (MVC) within leg muscles and active range of motion (AROM) were assessed. Therefore, electromyography of five lower limb muscles (m. soleus, SOL; m. gastrocnemius medialis, GM; m. tibialis anterior, TIB; m. biceps femoris, BF; m. vastus medialis, VM) as well as electro-goniometry of the ankle and knee joint during maximal range of active movement were recorded. SR were measured in the SOL and induced by an ankle ergometer dorsiflexing the ankle passively. Results After WBV, SR were reduced (-9±17%, P<0.05) and subjects demonstrated increased MVCs in the lower limb muscles (SOL +25±46%, GM +35±116%, TA +17±86%, BF +25±74%, VM +12±38%, P<0.05). Kinematic data revealed significantly elevated AROM of the knee joint (+13±20%, P<0.05), but no changes in the AROM of the ankle joint (+2±47%, P=0.44). The MVC/SR-ratio of the SOL revealed a significant gain after WBV (+19±41%, P<0.05). **Discussion** Acute exposure to WBV caused (a) diminished spasticity-related reflexes, accompanied by an (b) increased voluntary muscle activation and mobility within the lower limb. The WBV-induced reduction in spinal excitability may help to reduce the exaggeration of the tonic component of the SR, the abnormal spastic muscle tone and consequently could lead to a decreased co-contraction within the patient's antagonistic muscle groups (Ritzmann et al. 2011). The opposing effects of a down-regulated reflex-activation and an elevated voluntary activation of the neuromuscular system emphasize enhanced motor control after WBV. This may result in improved movement training immediately after WBV, thus may be successfully applied for treatment of neuropathological exaggerated SR. **References** Ahlborg L, Andersson C, Julin P (2006). *J Rehabil Med*, 38(5), 302-8. **GOAL-SETTING PRACTICE IN THE SPORT PHYSICAL REHABILITATION SETTING. A PRELIMINARY STUDY ABOUT THE PERCEPTION AND THE USE OF GOAL SETTING AMONG ITALIAN SPORT PHYSICAL THERAPISTS**

Sambruni, A., Conti, C.

*Università degli Studi di Siena*

About the return to sport following injury rehabilitation, an area of increasing research interest is the psychological techniques that physical therapists can use and how these interventions can aid significantly to the rehabilitation (1). In particular Goal Setting process seems to have positive clout in the efficacy of the treatment (2). Despite the fact that goal setting is considered by the clinical standard guidelines as an essential component of rehabilitation, the transferability of this process into practice is highly variable and often problematic (3). The aim of this study is starting to investigate in Italy the perception and attitude about the goal setting intervention and the use into daily practice by the sport physical therapists. Starting from the PSPQ(4) and the AAI(5), we developed a new questionnaire done by three parts. 58 sport physiotherapists were asked to complete this questionnaire concerning their opinions and experiences about use of goal setting. Qualitative analysis of the data showed a high consideration of goal setting: most of them think that will help to faster rehabilitation process and increase the patience adherence. However some data show that probably goal setting is often confused with the process of decision making at the beginning of the treatment program. Among Italian Sport Physical therapists Goal setting was never studied before and so a further and deeper study need to be done in order to explore in more detailed way how this complex intervention is used in the daily practice and to improve professional practice, guidance and education. ### COGNITIVE FUNCTIONS OF PARKINSON'S DISEASE PATIENTS CAN IMPROVE WITH PHYSICAL EXERCISE

Gobbi, L., Lahr, J., Santos, P.C.R., Pelicioni, P.H.S., Batistela, R.A., Rodrigues, M.M.L., Hernandes, F., Beretta, S., Zampier, V.  
*UNESP - Univ Estadual Paulista*

**INTRODUCTION** Decline in cognitive functions can be included as cardinal signs/symptoms of PD. Cognitive functions in this population have been affected to physical exercise interventions. However, none study compared the physical exercise interventions in relation to cognitive intervention. To compare the effects of physical and no physical exercise interventions on cognitive functions in Parkinson's disease (PD) patients. **METHODS** One hundred and twenty PD patients (68.8±8.6 years old) were randomly assigned into three groups: (i) functional capacity exercises (n=40); (ii) mobility program (n=40); and (iii) cognitive intervention (n=40). Patients were in mild to moderate disease stages (1 to 3 of Hohen & Yahr and 41±16 points in the UPDRS) and had the cognitive functions preserved (Mini-Mental State Examination=27.8±2.3 points). The clinical and cognitive functions were assessed before, after 4 and 8 months of intervention. All assessments and practice sessions were done in on-medication state. **RESULTS** Only participants that completed 70% of the practice sessions and all assessments were included in the analysis: (i) functional capacity exercises (n=37); (ii) mobility program (n=32); and (iii) cognitive intervention (n=34). There were neither group differences nor group and moment interactions for any dependent variable. Univariate analysis for moment revealed differences in attention, mental flexibility and memory. Participants increased the score in symbol search (p<0.01), decreased the perseverative errors (p<0.01) and showed higher performance in episodic declarative memory (p<0.001) and immediate memory (p<0.002) from pre to 4 and to 8 months of intervention. **CONCLUSION** Physical and no physical exercise interventions were able to improve cognitive functions in Parkinson's disease patients probably due to the increase of brain oxygenation and stimulation in physical exercise interventions and the specificity of activities in the cognitive intervention. **CONTACT** Itlgobbi@rc.unesp.br

### EFFECT OF RADIOFREQUENCY HYPERTHERMIA TREATMENT IN RUNNING BIOMECHANICAL PARAMETERS

Duñabeitia, I., Arrieta, H., Bidaurrazaga-Letona, I., Torres, J., Gil, J., Gil, S.M., Irazusta, J.  
*University of the Basque Country*

**Introduction** Exhausting training sessions have, in the short term, a negative impact on sport performance. One reason could be the worsening of their running economy associated with alterations in the running biomechanics. Physiotherapy has been used to accelerate recovery and to improve sport performance. However, there is no clear scientific evidence about its effectiveness (Torres et al., 2014). In the last few years, there has been an increasing utilization of radiofrequency hyperthermia (RFH) in sport. This is a widely used technique to facilitate the recovery of muscle function. Thus, the aim of the present study was to determine the effect of RFH therapy in biomechanical parameters related with running economy. **Methods** All the subjects (n=10) performed two protocols (separated by 2 weeks). Both consist of one exhausting training session followed by a treadmill test 1 day after. One hour after this test, in one protocol participants underwent RFH therapy and in the other they did not receive physical therapy. Both groups repeated the test 2 days after the first test. Participants were randomly assigned to begin with RHF or control protocol. The participants in each protocol completed two incremental running tests, which started at 10 km.h<sup>-1</sup>. The speed was increased by 2 km.h<sup>-1</sup> every 6 minutes until 16 km.h<sup>-1</sup> was reached, with a minute of recovery between each stage. Stride angle, ground contact time, swing time and stride length and frequency were measured for every step during the treadmill test using an optical measurement system (Optojump-next, Microgate, Bolzano, Italy) placed at the treadmill belt level (Santos-Concejero et al., 2014a). Data were analyzed statistically using a paired Student's t-test. **Results** Athletes who received RFH increased their stride angle, stride length, swing time and stride height values, after their 48 hour recovery, more than the control group. Accordingly, stride frequency values decreased more after applying RFH. **Discussion** Biomechanical parameters recovered better when athletes were treated with RFH than when they were not treated. Since these biomechanical parameters are related to running performance (Santos-Concejero et al., 2014b), we can conclude that RFH could be a good tool for improving the recovery of athletes after exhausting exercise sessions. **References** Santos-Concejero J, Tam N, Granados C, Irazusta J, Bidaurrazaga-Letona I, Zabala-Lili J, Gil SM. ### MO-PM27 Sports Medicine and Orthopedics: Orthopedics

#### PREVALENCE OF BACK PAIN IN ELITE ROWERS

Felker, K., Fett, D., Platen, P.  
*Ruhr-University Bochum*

**Introduction** Back pain (BP) is a frequent health problem in the general population resulting in enormous costs for the health care system. BP is also one of the most frequently occurring complaints in sports. It is reported by approximately 30% of athletes. Detailed data on prevalence of BP in German sportsmen and women is rare. Elite rowers are exposed to high strain on the musculoskeletal system and especially on the lower back due to their sport-specific loads during training and competition. Currently, there is no information on the prevalence of BP in German elite rowers. This study aims at identifying lifetime prevalence (LP) and point prevalence (PP) of BP in German elite rowers with special emphasis on the exact localization of the pain region. **Methods** N=84 German elite rowers (m=43, f=41; 20.7±3.4 yrs., 183.9±8.3 cm, 77.3±11.5 kg) on international and national competition level were asked to fill out an online questionnaire based on the validated "Nordic Questionnaire" (Kuorinka et al., 1987). The questionnaire included several items on BP, separated in pain

in the cervical, thoracic and lumbar spine region. Further, it included questions on lifetime occurrence of BP and on BP during the last 7 days. Results LP of BP was 96.4% being highest in the lumbar spine (86.9%), followed by the neck (65.5%) and the thoracic spine (57.1%). PP of BP was 67.9% being again highest in the lumbar spine (47.6%), followed by the neck (29.8%) and the thoracic spine (20.2%). Discussion Our findings indicate that BP is a relevant medical problem in German elite rowing. Especially pain in the lumbar spine seems to be omnipresent with a LP of nearly 90% and a PP of nearly 50%. This prevalence data is much higher compared to findings in the literature. Bahr et al. (2004) described a LP of low BP of 63.3% and a PP of 25.3% in elite rowers, and Foss et al. (2012) found a LP of low BP of 68% and a PP of 19%. One possible reason for the very high prevalence values of BP in German elite rowers might be very high sports-specific and strength training loads. This has to be evaluated in further studies. The results underline the necessity of BP prevention programs in addition to the discipline specific training loads. Literatur Bahr, R., Anderson, S.O., Loken, S., Fossan, B., Hansen, T. & Holme, I. ### **MONITORING PERCEIVED STRESS, RECOVERY AND NON-TRAUMATIC LOWER EXTREMITY INJURIES IN COMPETITIVE RUNNERS**

Otter, R.T.A., Brink, M.S., Lemmink, K.A.P.M.

*Hanze University of Applied Sciences Groningen/University of Groningen, UMCG*

Introduction Runners often sustain lower extremity injuries (19-79%) (van Gent et al, 2007). In a theoretical model it has been described that a disturbance in perceived stress and recovery can increase the risk of sustaining an injury (Williams & Andersen, 1998). Therefore, the purpose of this study was to investigate changes in perceived stress and recovery preceding an injury of competitive runners. Methods Twenty-four competitive runners were monitored over one full training season (46 weeks). Every week, the runners filled an on-line RESTQ-sport (Nederhof et al, 2008). Furthermore, runners and their coaches kept a log with injuries and physical complaints. A non-traumatic injury was defined as any pain, soreness or injury that was not caused by trauma and resulted from training and led to a decrease in training duration or training intensity for at least one week (Jacobsson et al, 2013). Because baseline levels of perception of stress and recovery vary largely between runners, the 19 scales of the RESTQ-Sport were normalized to Z-scores based on the runner's individual average and standard deviation of the whole season (excl. injured periods). The normalized scores of 1, 2 and 3 weeks before the first sustained injury were compared to 0, which is the average normalized score, by repeated measures ANOVA's. Results Twenty-two runners sustained a non-traumatic lower extremity injury. Eight of these runners filled out the RESTQ-Sport all 3 weeks preceding the injury and their data was used for further analysis. The injuries sustained were non-traumatic injuries of the knee, Achilles tendon, ankle, foot and shin. It was shown that 1 week preceding the injury, runners scored lower than the average normalized score on "Success" (Z-score:  $-0.68 \pm 0.62$ ) and 2 weeks preceding the injury runners scored higher than their average on "Fitness/Injuries" (Z-score:  $1.04 \pm 1.12$ ). Discussion A decrease in perceived success may be a marker to predict a non-traumatic lower extremity injury. Also an increase in the perception of muscle ache, soreness, pain and vulnerability to injury ("Fitness/Injury") preceded injuries. Thereby, monitoring changes in individual stress and recovery may help to prevent non-traumatic injuries. References Jacobsson, J., et al. (2013) *Br. J. ### **PREDICTIVE VALUE OF LOWER LIMB MUSCULOSKELETAL SCREENING FOR INJURY RISK IN ELITE AUSTRALIAN FOOTBALL PLAYERS**

Quain, D., Dawson, B., Peeling, P., Heasman, J., Rogalski, B.

*The University of Western Australia*

Objectives: To examine the relationship between pre-season musculoskeletal screening test (MST) performance and lower limb (LL) intrinsic injury risk in elite Australian football (AF) players. Design: Prospective cohort study. Methods: Players (n = 71) from one club were involved; screening and injury data was examined from the club's database across the 2011-14 seasons. Pre- and in-season phases were studied, with in-season further separated into rounds 1- 8, 9-16 and 17+. Eight MST were conducted annually at the beginning of pre-season, with performance rated as desirable/undesirable by club physiotherapists. For individual tests, relative risk (RR) was calculated to determine comparative injury risk between desirable/ undesirable MST outcomes. A logistic regression (using odds ratios: OR) determined the best combination of MST for predicting injury. Results: Individually, across pre-season and the whole-season (pre- and in-season combined), groin squeeze was the best predictor of injury. In-season, groin squeeze and Thomas test (TT) hip flexors were the best predictors of injury. In combination, across the whole-season groin squeeze was the best injury predictor. During pre-season, sit and reach was the best injury predictor. In-season, TT hip flexors, groin squeeze and calf raise were the best injury predictors, and for rounds 1-8; TT hip flexors, rounds 9-16; sit and reach, round 17+; none. Conclusions: These findings support the use of several MST in elite Australian football. In particular, groin squeeze, sit and reach, calf raise and TT hip flexors MST may be most useful for predicting injury, particularly in the early in-season, as opposed to the later stages.

### **MUSCULOSKELETAL INJURIES IN ELITE JUNIOR TENNIS PLAYERS**

Fett, J., Ulbricht, A., Ferrauti, A.

*Ruhr-University Bochum*

Introduction In tennis, modern game has evolved from a primary technical sport to the current explosive sport becoming increasingly dynamic and faster with higher stroke and serve velocities which require notably higher demands of physical fitness (Kovaks, 2007). Due to this evolution and a tournament schedule no less demanding it has led to an increased strain for players in training and competition which may concurrently result in a higher risk of overuse injury and drop-out. Therefore, the aim of the present investigation was to identify prevalence of musculoskeletal symptoms in elite junior tennis players with special regard to the upper extremity. Methods Prevalence of musculoskeletal symptoms was recorded in 107 nationally ranked junior tennis players (n=60 males,  $14.9 \pm 2.5$  yrs,  $171.2 \pm 13.9$  cm,  $58.6 \pm 15.4$  kg; n=47 females,  $14.6 \pm 2.1$  yrs,  $166.1 \pm 10.9$  cm,  $54.1 \pm 10.6$  kg) by a questionnaire developed in accordance to the standardized

Nordic Questionnaire (Kuorinka, 1987). The applied questionnaire includes life time prevalence of musculoskeletal symptoms (LPMS), 12-month prevalence (12MP) regarding limitations of the upper extremity and in accordance to defined stroke performance, as well as a pain severity measurement throughout serve performance. Chi-square statistics were used to determine differences in LPMS and 12MP between gender, age group and performance level. Results Highest LPMS was found in the body regions of the knee (54%), shoulder (50%), hand (45%) and lumbar spine (45%) followed by ankle, hip, neck, elbow and thoracic spine (<40%). Reported 12MP of upper extremity limitations revealed the highest scores for shoulder region (32%) followed by the hand (25%) and elbow (19%). Discomforts of the shoulder and elbow are mostly allied to the serve performance (>75%) while limitations occurring in the hand are more likely to be related to forehand strokes (80%). Highest pain score during serve performance was recorded in the body region of the shoulder (4.4). Comparison of gender and age showed no significant differences in any LPMS and 12MP. Significant differences ( $p < .05$ ) between performance level were found in LPMS of lumbar spine (59 vs 27%), hip (50 vs 11%) and elbow (32 vs 11%). Discussion Results obtained indicate high prevalence of musculoskeletal symptoms in elite junior tennis players especially in the upper extremity. Regarding the upper extremity the shoulder being the most frequently involved body region which discomforts are notably allied to the serve performance. Moreover, players of a higher performance level seem to be at a higher risk of injury. More efforts are necessary for developing training prescription for both, prevention strategies and performance enhancement. References Kovaks, M (2007). *Sports Med*, 37, 189-198. Kuorinka, I et al. ## PREVALENCE OF BACK PAIN IN ELITE FIELD HOCKEY PLAYERS

Fett, D., Felker, K., Platen, P.

*Ruhr-University Bochum*

Introduction Back pain (BP) is a frequent health problem in the general population resulting in enormous costs for the health care system. Detailed data on prevalence of BP in German sportsmen and women is rare. From a biomechanical perspective movements in field hockey are characterized by forward flexion and rotation of the trunk. The forward flexed posture must be maintained during most of the duration of a game or training session causing high spinal loads. This might be associated with the development of pain in the back. The aim of the present investigation was to determine the lifetime prevalence and point prevalence of BP in German elite field hockey players to clarify associations between hockey-specific posture and pain generation. Methods A self-reported standardized and validated questionnaire based on the Nordic questionnaire by Kuorinka et al. (1987) was sent to all members of the German field hockey national team and the members of the State-of-Northrhine-Westfalia junior hockey team. The questionnaire included several items on BP, separated in pain in the cervical, thoracic and lumbar spine region. N=107 field hockey players (47.8%) responded (m = 44, f = 51; age:  $19.3 \pm 4.5$  yrs., height:  $174.1 \pm 9.2$  cm, weight:  $66.3 \pm 10.3$  kg, mean  $\pm$  SD). Results The reported lifetime prevalence of BP in field hockey players was 85.3%. Regarding different parts of the spine, lifetime prevalence of pain in the cervical, thoracic and lumbar region were 58.1%, 37.6% and 72.3%, respectively. N=38 field hockey players experienced BP during the previous seven days (40.0%). Seven-day prevalence of pain of the cervical, thoracic and lumbar region revealed values of 18.9%, 12.5% and 27.8%, respectively. Discussion We found a high prevalence of BP in German field hockey players with the most frequent localization in the lower back. Our results clearly revealed much higher prevalence of BP compared to other studies. Murtaugh (2001) reported lifetime prevalence of BP of 59% and of pain in the lumbar region of 54% in field hockey players. Reilly et al. (1990) and Haydt et al. (2012) also found lower prevalence of low BP (53% and 56%, respectively). A possible reason for the higher prevalence in our study could be the high performance level of the players and the associated high training loads. The results of our study underline the necessity of specific prevention programs for BP in elite field hockey players. Acknowledgement The study was supported by the Federal Institute for Sport Science, Germany (ZMVI1-080102A/11-18). References Haydt et al. (2012). *Int J Sports Phys Ther*, 7(3), 296; Kuorinka et al. ## CHARACTERISTICS OF INTRATENDINOUS MICROCIRCULATION SHORTLY AFTER AN ACHILLES RUPTURE AND TREATMENT OUTCOMES AFTERWARD

Wang, H.K.1, Chang, Y.P.1, Shih, K.S.2, Ma, H.L.3, Lin, L.C.4

1: NTU (Taipei, Taiwan), 2: SKM (Taipei, Taiwan), 3: VGH (Taipei, Taiwan), 4: TGH (Taipei, Taiwan)

Introduction Studies have posited that tendon vascular supply is crucial to healing. Therefore, the aim of this study was to observe microcirculation (total hemoglobin [THb] and oxygen saturation [StO2]) values in injured Achilles tendons 1, 2 and 3 months after repair. Furthermore, to investigate the microcirculatory changes between each time point and the correlations with outcomes measured 3 and 6 months post-surgery. Methods Nine subjects (median age: 44 years; range: 34.8–51.9 years) with a repaired Achilles were recruited. The subjects were measured at 1, 2, 3 and 6 months post-surgery. Bilateral measurements of tendon microcirculation were recorded at the first three time points, while outcome measures of tendon stiffness, a Taiwan Chinese version of the Victorian Institute of Sport Assessment Scale-Achilles questionnaire (VISA-A-TC), one-leg hopping distance (OLHD), the star excursion balance test (SEBT) and the heel raise index (HRI) were conducted and/or measured at the third and fourth time points. Correlations between the microcirculatory changes, e.g., between the measurements at 2 and 1 month (2-1) post-surgery, at 3 and 2 months (3-2) post-surgery and at 3 and 1 month (3-1) post-surgery, and the outcome measures were investigated. Results The THb2-1 and 3-2, StO2 2-1 and StO2 3-2 showed correlations with the HRI, SEBT, OLHD and VISA-A-TC scores ( $\rho$  -0.900–0.900). Furthermore, compared to the non-injured tendons, the repaired Achilles demonstrated greater THb (at 1, 2 and 3 months) and StO2 (at 3 months). Discussion This study demonstrated that changes in the microcirculation levels at 1, 2 and 3 months post-surgery were correlated with self-reported symptoms and limb symmetry of functional outcomes afterwards. Our results implied that large changes in THb are associated with great asymmetry of lower extremity functions, including balance and muscle explosiveness as well as a highly symptomatic repaired tendon. This may be because during the initial inflammatory phase after tendon rupture, the angiogenic growth factors are involved in inducing endothelial cell proliferation and migration, as well as the expression of other growth factors and the stimulation of extracellular matrix changes to accommodate cellular migration (Boyer et al., 2001, James et al., 2008). More studies are required to determine whether physical therapies including modalities or exercises would result in improvements in microcirculation for the purposes of recovery in humans. **POTENTIAL UTILITY OF VIBRATIONAL ANALYSIS FOR EARLY DETECTION OF SPONDYLOLYSIS**

Tahara, N.1, Watanabe, H.2, Sakai, R.2, Matsunaga, A.1,2

1: *Kitasato University Graduate School (Sagamihara, Japan)*, 2: *Kitasato University (Sagamihara, Japan)*

Introduction Lumbar spondylolysis refers to a defect of the vertebral pars interarticularis and is among the most common causes of low back pain in adolescent athletes. There is potential for the fracture to heal at an early stage of spondylolysis, but healing is more difficult at an advanced stage (Sairyo et al., 2012). Diagnosis in the early stage is therefore desirable to promote sufficient healing. A diagnostic method has been reported that detects bone fracture by analyzing the vibrational signals produced by stimulating the bone (Singh et al., 1989). Such vibrational analysis may also be applicable to the detection of stress fractures such as spondylolysis. The purpose of this study was to investigate whether vibrational analysis can be used to detect spondylolysis in sham bone. Methods Four versions of a synthetic fifth lumbar vertebra model (Sawbones, SAW1352-10) were created: an intact model of the pars without incision, two unilateral defect models, and one bilateral defect model. In the unilateral defect models, an incision was made either of one half of the diameter (50% defect model) or the entire diameter (100% defect model) of the left pars. In the bilateral defect model, incisions were made of one half of the diameter of the right pars and the entire diameter of the left pars (50%+100% defect model). Hammering was performed five times on each spinous process of fixed sham bone and the vibrational signals were measured using an accelerometer attached to the contralateral side of the hammer. Signals from trials 2 to 5 were analyzed using the fast Fourier Transform technique. The root mean square of electromyography (EMG) amplitude was calculated in the range of 50 to 1000 Hz. One-way analysis of variance (ANOVA) test and Tukey's honestly significant difference test were used to determine significant differences in EMG amplitude among the four models. Results EMG amplitude differed significantly among three of the models ( $F = 107.47$ ,  $P < 0.01$ ). EMG amplitude was significantly lower in the 100% defect model (14.35 dBV) and 100%+50% defect model (9.51 dBV) than in the intact model (30.54 dBV) and 50% defect model (29.32 dBV;  $P = 0.00$ ), as well as in the 100%+50% defect model compared with the 100% defect model ( $P < 0.05$ ). Discussion These findings suggest the potential utility of vibrational analysis in the diagnosis of lumbar spondylolysis in cases of complete unilateral pars fracture and in more progressive disease. **A COMPARISON OF NATURAL KNEE AND TOTAL KNEE ARTHROPLASTY KINEMATICS DURING THE GOLF SWING**

Molloy, M.1, McGrath, D.1,2, Wallace, E.1

1. *Ulster University* 2. *University College Dublin*

Introduction Increasingly younger, more active patients are recipients of total knee arthroplasty (TKA) implants. Golf is a popular post-surgery sport recommended by surgeons. However, discomfort has been reported by 16% of golfers with a TKA during play and 35% after play (Mallon & Callaghan, 1993). The present study was devised to: 1. Determine if persons with a TKA have an equivalent swing period to natural-knee (NK) golfers. 2. Compare when extremes of knee rotation occur in the TKA and NK. 3. Quantify and compare the range of knee rotation in TKA and NK golfers. Methods Twenty-four male golfers were recruited: 12 NK, 4 left TKA (LK), 4 right TKA (RK) and 4 bilateral TKA (BK). All TKA golfers had the Depuy LCS cruciate sacrificing, rotating-platform implant. Bilateral knee kinematics and the golfer's driver were measured in 6DoF. Six trials per subject were captured. The instant min. and max. angle was reached and the absolute range of rotation in each knee axis was identified. Values were expressed in terms of percentage swing between take-away and mid follow-through. Between-group mean swing times were compared using a one-way ANOVA with pairwise group comparisons. Variables exhibiting a normal distribution were compared using the GLM, the remainder were analysed using Kruskal-Wallis. Results No significant differences were found between group mean swing times ( $sig.=0.05$ ). Maximum left knee extension occurred during the back-swing in the BK group, in all other groups this occurred at mid-follow through. Other event timings were similar between groups. Lead knee axial rotation was reduced in BK and LK golfers who presented an average decrease in rotation of 5° and 10°, respectively. Discussion Golfers in all TKA groups demonstrated similar swing periods to those of the NK golfers. Groups exhibited similar timing in when golfers reached extremes of rotation. However, some variables presented a wide range of intra-subject variability. Results suggest the knee implant can provide a sufficient range of rotation to perform the golf swing. Significant differences were identified in bilateral knee-joint flexion between persons with unilateral or BK and NK golfers. However, the flexion range required is within the capabilities of the implant. This may indicate a reduction in knee flexibility in individuals who have had TKA or an unwillingness to load the knees fully. Axial rotation ranges observed in the NK golfers suggest that previous studies may have underestimated the range of rotation demanded of the knees when performing the golf swing. **RELIABILITY AND CONSTRUCT VALIDITY OF VISUAL RATING OF POSTURAL ORIENTATION IN PEOPLE WITH OR WITHOUT MUSCULOSKELETAL DISORDER OF THE LOWER EXTREMITY – A SYSTEMATIC REVIEW**

Älmqvist, J.1, Cronström, A.1, Creaby, M.W.2, Ageberg, E.1

1. *Department of Health Sciences, Lund University, Lund, Sweden*, 2. *School of Exercise Science Australian Catholic University, Brisbane, Australia*

Background Clinical assessment of postural orientation (ability to stabilize body segments in relation to each other and the environment) by visual rating has increased during recent years. Rating the knee position relative to foot (knee abduction angle) is common. The evidence for reliability and construct validity of such assessment has yet to be examined. Aim To systematically review reliability and construct validity of visual rating of postural orientation in people with or without musculoskeletal disorders in the lower extremity. Methods A systematic review was conducted according to the PRISMA guidelines. Systematic searches were performed in Medline (PubMed), CINAHL and EMBASE (OVID) until January 8th 2015. Inclusion criteria were studies investigating reliability and/or construct validity of visual rating of Postural Orientation Errors (POEs) including 1) functional tasks placing demands on the lower extremity 2) men and/or women of any age with or without musculoskeletal disorder of the lower extremity. Results Forty studies were included. POEs were rated live and/or on video. The most commonly determined POEs were the knee medial to foot position (KMFP) ( $n=15$ ) and an overall score based on the orientation of several segments ( $n=48$ ). Inter-rater reliability ( $n=38$ ), intra-rater reliability ( $n=21$ ) and/or construct validity ( $n=14$ ) were evaluated. Reliability: The overall score ranged from moderate to almost perfect agreement in 71% and 86% of all cases for inter-rater ( $n=38$ ) and intra-rater reliability ( $n=22$ ), respectively (Intra Class Correlation (ICC), Kappa, first order agreement coefficient (AC1), 0.43-1.0). The KMFP ranged from substantial to almost perfect agreement in 61% and 67% of all cases for inter-rater ( $n=18$ ) and intra-rater reliability ( $n=9$ ), respectively (ICC, Kappa, AC1, 0.61-1.0). Construct validity: Eight studies validated visual rating of KMFP against 2D or 3D variables. A

greater knee abduction angle, or a greater hip internal rotation, was observed in people with a KMFP than in those without ( $p < 0.001$ ,  $n=2$ , and  $p < 0.049$ ,  $n=2$ , respectively). ROC analysis showed good discriminative ability of visual rating in people with or without KMFP (0.85-0.89,  $p < 0.002$ ,  $n=2$ ). Some high-risk athletes were missed with visual rating (sensitivity 46-87%,  $n=2$ ). Correlations showed moderate to good validity ( $r_s=0.54-0.6$ ,  $r_\rho=0.456$ ,  $k=0.85$ ,  $n=3$ ). Conclusions The overall score and the KMFP were reliable both within and between raters. Visual rating of KMFP seems to have acceptable validity for use in research and clinical practice. Validity for the overall score remains to be determined.

### **BODY CHARACTERISTICS OF PROFESSIONAL JAPANESE KEIRIN CYCLISTS: AN INVESTIGATION OF FLEXIBILITY, PELVIC TILT, AND MUSCLE STRENGTH**

Tashiro, Y., Hasegawa, S., Nishiguchi, S., Fukutani, N., Adachi, D., Morino, S., Hotta, T., Shirooka, H., Nozaki, Y., Hirata, H., Yamaguchi, M., Aoyama, T.

*Kyoto university graduate school*

**INTRODUCTION:** Keirin is one of the track cycling sports. During cycling, body imbalances in the sagittal plane occur, because the trunk and hips are always in flexion. However, the body characteristics (e.g., flexibility, alignment, and muscle strength) of an athlete are not clear. Therefore, the purpose of this study was to investigate the musculoskeletal characteristics of Keirin cyclists. **METHODS:** Sixteen professional male, Japanese Keirin cyclists (mean age,  $32.2 \pm 8.6$  years) and a control group of 16 healthy men (mean age,  $24.3 \pm 2.3$  years) participated. We measured the subjects' pelvic tilt, straight leg raise (SLR) for flexibility of the hamstring, heel-buttock distance (HBD) for flexibility of the quadriceps, finger floor distance (FFD) for the trunk and lower limb flexibility, and hamstring quadriceps muscle strength ratio (H/Q ratio). Differences in the SLR, FFD, and HBD between the two groups were examined using analysis of covariance adjusted for age. The other parameters were compared using the unpaired t test. **RESULTS:** The pelvis of Keirin cyclists was significantly tilted anteriorly in comparison to that of healthy men ( $p < 0.01$ ). The SLR, FFD, and HBD of Keirin cyclists were significantly higher than that of healthy men adjusted for age. For muscle strength, the H/Q ratio of a high angular velocity was significantly greater in Keirin cyclists ( $p < 0.01$ ). **DISCUSSION:** Keirin cyclists have body imbalances in the sagittal plane, and their pelvis of tilts anteriorly in comparison to that of healthy men. We consider that this is caused by tight quadriceps and loose hamstrings. However, the H/Q ratio of high angular velocity is high in Keirin cyclists, and their hamstrings are more activated during high angular velocity than those of healthy men. **CONTACT:** tashiro.y@gmail.com

#### **FOLLOW-UP OF THE QUANTITY OF SLEEP OF 7 FEMALE GYMNASTS IN PREPARATION OF AND DURING THE WORLD CHAMPIONSHIPS ARTISTIC GYMNASTICS 2014**

Dumortier, J.1, Boone, J.1,2, Mariman, A.3, Delesie, L.3, Tobback, E.3, Vogelaers, D.3, Bourgois, J.1,2

*1: Ghent University, Belgium; 2: Centre of Sports Medicine, Ghent University Hospital, Belgium; 3: Department of Internal Diseases, Ghent University Hospital, Belgium*

**Introduction** Sleep is considered to be one of the most important recuperation techniques for elite athletes in both training and competition periods[1][2]. However, little is known about the sleep pattern of elite gymnasts. The main goals of this study were (1) to identify the sleep pattern before and during competition and (2) to recognize the relationship between subjective sleep parameters and performance. **Methods** The Belgian team for the World Championships (WC) 2014 in Nanning, China, (7 elite female gymnasts,  $21.0 \pm 2.6$  years), took part in the study. They completed a daily sleep diary, starting in July until the end of the WC, with registration of the sleep quantity. Final ranking after the qualifications and mean apparatus score were set as objective performance measurements. The nonparametric Wilcoxon test was applied to detect variations in the sleep pattern. To identify the relationship between sleep duration, ranking and mean score, Spearman's rank correlation was used. A linear regression analysis determined the direction of relationship between these variables. **Results** Sleep duration the night before the podium training and the qualification ( $7:17 \pm 0:52$ ;  $7:10 \pm 1:38$ ) were shorter than the mean sleep duration during a baseline training week and during the WC ( $8:23 \pm 1:08$ ,  $p < 0.05$ ;  $8:36 \pm 0:35$ ,  $p < 0.05$ ). Gymnasts with a longer sleep duration, had a higher mean score at the WC ( $R=0.857$ ,  $p < 0.05$ ). Mean sleep duration predicted 64,1 percent of the variation in ranking ( $p < 0.05$ ) and 65,1 percent of the variation in mean score ( $p < 0.05$ ). **Discussion** The shorter sleep duration the night before the podium training and the qualification is in accordance with Erlacher et al. (2011) where 65,8 percent of athletes reported sleep problems the night prior to competition and whereby internal factors such as stress, were given as dominant causes. Sleep duration was least affected in female gymnasts with the best performance which may be due to better stress coping strategies or higher self-confidence. **References** 1. #### **ACTIVE RECOVERY AND COLD-WATER IMMERSION ARE NOT SUPERIOR TO PASSIVE RESTING AFTER ECCENTRIC SQUAT EXERCISE**

Doeweling, A., Wiewelhove, T., Raeder, C., Simola, R., Ferrauti, A.

*Ruhr-University Bochum*

**Introduction** An appropriate balance between training or competition induced stress and recovery is an important factor for optimizing athlete's performance development. Beneficial recommendations for daily recovery routines are currently lacking, especially after bouts of resistance training. Therefore, the aim of this study was to determine the influence of active recovery (AR) and cold-water immersion (CWI) on different markers of fatigue after an eccentric enhanced squat protocol. **Methods** In a randomized repeated-measures design 13 physically active males (Age: 25,0 Years SD: 2,8 Years; Height: 182,9 cm SD: 3,5 cm; Weight: 82,0 kg SD: 6,1 kg) completed an eccentric enhanced squat protocol (six sets of six repetitions with 100% 1RM ecc. and 70% 1RM con.) followed by one of three 15-minute recovery

interventions in a counterbalanced order (i.e. AR, CWI, passive resting / PR). Performance (CMJ), muscle-contraction (Dm, V10 and V90), biochemical (CK) and psychological (DOMS) markers were measured pre-exercise, post-exercise, post-recovery, post 24h and post 48h. Results The squat protocol produced an acute significant ( $p \leq 0.05$ ) reduction in CMJ, Dm, V10 and V90 (post-exercise). Measured values remained decreased for 24 hours (Dm, V10 and V90), respectively 48 hours (CMJ). Concurrently, CK and DOMS raised significantly ( $p \leq 0.05$ ) post 24h. No differences in all markers of fatigue were found between AR, CWI and PR post 24h and post 48h. Additionally, post-hoc tests revealed that CWI led to a significant ( $p \leq 0.05$ ) decline in CMJ, V10 and V90 post-recovery in comparison to AR and PR. Discussion This data suggests that athlete's performance capacity is decreased for up to 48 hours after one bout of an eccentric enhanced squat exercise. Notably, none of the recovery interventions as applied in this study are able to contribute to a faster recovery during the first 48 hours compared to passive resting. On the one hand, this is in line with Goodall & Howatson (2008), but on the other Tufano et al. (2012) observed contrary results. Further, CWI leads to an acute decline of the jump performance and weakens the muscle contractile properties. This should be considered when using CWI between subsequent events at the same day. ### THE EFFECT OF DECEPTIVE INFORMATION ABOUT RECEIVING COOLING ON PACING PATTERN DURING A 20-KM CYCLING TIME TRIAL IN THE HEAT

Levels, K.1, De Koning, J.J.1,3, Foster, C.1,3, Daanen, H.A.M.1,2

1: MOVE, VU University (Amsterdam, The Netherlands), 2: TNO (Soesterberg, The Netherlands), 3: UWLAX (La Crosse, USA)

Introduction: Cooling during exercise in the heat has been shown to be beneficial for performance (Bongers et al. 2014), but it is still unclear to what extent this effect can be contributed to actual physiological or perceptual changes and to what extent the expectation of receiving cooling during cycling plays a role. Therefore, the aim of this study is to investigate the effect of false information about receiving cooling on performance and pacing pattern during a 20-km cycling time trial in the heat. Methods: 16 trained male participants performed three 20-km cycling time trials (TTs) in  $30.5 \pm 0.1^\circ\text{C}$  with  $45 \pm 3\%$  relative humidity. The first two TTs were with (WIND) or without (CONTROL) 4 m/s convective cooling during km 7-13. In the third TT, participants performed one of two trials in which they were deceived about receiving convective cooling during the TT. They either did not expect cooling during km 7-13 but did receive it (FALSE-NEG) or did expect cooling but did not get it (FALSE-POS). Power output (PO), heart rate (HR), rectal temperature (Tre), mean skin temperature (Tsk), thermal sensation (Tsens), thermal comfort (Tcomf), and RPE were measured. Results: During and after cooling, Tsk, Tsens, and Tcomf were lower in WIND than CONTROL, no differences were found in HR and Tre, and PO was lower during the entire TT in CONTROL than in WIND (239 vs. 251 W;  $P=0.02$ ). In FALSE-NEG, physiological parameters followed a pattern similar to CONTROL whereas pacing pattern prior to convective cooling was similar to CONTROL and during the cooling it was similar to WIND. After the cooling, no differences in pacing pattern were found between conditions. In FALSE-POS, no differences in pacing were observed despite higher Tsk, Tsens, and Tcomf. Discussion: Deceiving participants about the occurrence of convective cooling during self-paced exercise alters the pacing pattern of a 20-km cycling time trial in the heat. This shows the importance of expectations regarding thermal load in self-paced exercise. References: Bongers, C. C., Thijssen, D. H., Veltmeijer, M. T., Hopman, M.T., & Eijssvogels T. M. (2014). ### HEATED GARMENTS AND DRYLAND ACTIVATION ROUTINES: THE KEYS TO IMPROVING SPRINT SWIMMING PERFORMANCE

McGowan, C.J.1,2, Pyne, D.B.1,3, Thompson, K.G.1,2, Raglin, J.S.4, Rattray, B.1,2

1,2: University of Canberra, 3: Australian Institute of Sport, 4: Indiana University

Introduction In competitive swimming after the pool warm-up, swimmers must change into their racing suit, confer with their coach and report to marshalling ~15-20 min prior to race start, thus transition phases of 30-45 min are not uncommon. There is a risk of a significant decline in body temperature with a long transition phase given that body temperatures can decline immediately following exercise cessation, with a significant reduction evident after ~15-20 min of recovery (Mohr et al., 2004). We postulate that this decline in body temperature during transition could be ameliorated by combining an athlete's sport-specific warm-up (i.e. pool warm-up) with passive heating and additional active warm-up strategies. Methods In a counterbalanced, repeated measures cross-over design 39 national and internationally competitive swimmers (age:  $20 \pm 2$  yr;  $n=19$  males: stature  $1.85 \pm 0.04$  m,  $79.4 \pm 6.4$  kg;  $n=20$  females:  $1.74 \pm 0.7$  m,  $65.6 \pm 6.3$  kg; mean  $\pm$  standard deviation) completed a standardised pool warm-up (1550 m) followed by a 30 min transition and a 100 m freestyle ( $n=29$ ) or breaststroke ( $n=10$ ) time-trial. Swimmers completed two different warm-up strategies during transition: CON, remained seated wearing a conventional tracksuit jacket and pants, or COMBO, wore an insulated tracksuit jacket (freestyle) or pants (breaststroke) with integrated heating elements and performed a 5 min dryland-based exercise routine. Swimming time-trial performance, core temperature, capillary blood lactate and lower-body power output were assessed. Time variables were normalised relative to the CON (control) condition. Results The COMBO warm-up yielded a  $0.30 \pm 0.19\%$ ; mean  $\pm$  90% confidence limits,  $p=0.04$  faster 100 m time-trial performance than CON. Start times to 15 m were also faster for COMBO ( $-0.10 \pm 0.06\%$ ,  $p=0.02$ ) compared to CON. Core temperature declined less ( $p=0.02$ ) during transition with COMBO ( $-0.27 \pm 0.08^\circ\text{C}$ ) than CON ( $-0.43 \pm 0.06^\circ\text{C}$ ). Lower-body peak power output immediately prior to time-trial commencement ( $p=0.89$ ) and post time-trial blood lactate concentration ( $p=0.66$ ) were not significantly different between conditions. Discussion Sprint swimming performance in national and international level swimmers can be substantially enhanced by combining a traditional pool-based warm-up with the application of heated garments, and the completion of a brief dryland-based exercise routine, during a lengthy transition phase. Attenuation of the decline in core temperature and an improvement in start time appear as the likely mechanisms responsible for faster time-trial performance. #### EXPRESSION OF MICRORNA-208B AND MYOSTATIN ARE INVERSELY CORRELATED, BOTH AFTER SPINAL CORD INJURY IN HUMANS AND IN RESPONSE TO OVEREXPRESSION IN VIVO IN RODENTS.

Boon, H., Sjögren, R.J.O., Massart, J., Egan, B., Kostovski, E., Iversen, P.O., Hjeltnes, N., Chibalin, A.V., Widegren, U., Zierath, J.R.

*Karolinska Institutet*

Spinal cord injury in humans is characterised by marked skeletal muscle atrophy and fiber type transformation towards fast, type II, fibers. MicroRNAs are short, non-coding RNAs that fine-tune target expression through mRNA degradation or by inhibiting protein translation. Intronic to the slow muscle fiber type genes MYH7 and MYH7b, microRNA-208b and microRNA-499-5p are hypothesized to fine-tune expression of genes important for muscle growth, such as myostatin. Here, we investigated the skeletal muscle expression of microRNA-208b, microRNA-499-5p and myostatin in humans after complete cervical spinal cord injury, as well the regulation of myostatin expression by these microRNAs in rodents. A progressive decline in microRNA-208b and -499-5p expression was observed in humans during the first year after spinal cord injury. Expression levels were further downregulated after long-standing injury. Gene expression of myostatin was inversely correlated with microRNA-208b and -499-5p expression. Electroporation of microRNA-208b in mouse skeletal muscle directly decreased myostatin gene expression. In conclusion, expression of microRNA-208b and its previously validated target myostatin are inversely related, both in atrophic skeletal muscle from humans after spinal cord injury, as well as following overexpression in rodent muscle. Our results provide evidence for a role of microRNA-208b and myostatin in regulation of skeletal muscle mass after spinal cord injury.

#### CHRONIC ADAPTATION OF BLOOD CELLS TO TRAINING IN INTERMITTENT, COMBAT AND ENDURANCE PLAYERS

Pralay, M., Srividhya, S.

*Sports Authority of India*

Chronic adaptation of blood cells to training in intermittent, combat and endurance players Sports Authority of India, India Introduction: Acute responses of blood cells to training are evidenced by numerous studies (2, 6). Our present study is to find out the chronic response of blood cells of athletes who were in 5-7 years of training. Methods: Thirty nine hockey, 37 kabaddi and 17 waterpolo male players were volunteered as subjects with the training age of 5-7 years. Venous sample was collected in EDTA tube after an overnight fast and analyzed white blood cell (WBC), platelet, lymphocytes, neutrophils in players by Sysmex pochH100i. Statistics was done by the software MINITAB14. Results: The mean value of WBC ( $\times 10^3/\mu\text{L}$ ), Platelet ( $\times 10^3/\mu\text{L}$ ), neutrophil (%) is significantly high in waterpolo players 8.582, 271.18 and 63.17 than the hockey (6.221, 235.59, 46.68) and kabaddi players (6.962, 259.14, 53.39) respectively. The mean value of lymphocyte (%) is significantly low in waterpolo players (27.72) than the hockey (41.56) and kabaddi (33.11) players. Discussion: Training athletes differs according to the physiological demand of the game. The energy contribution in waterpolo is 60% aerobic, 40% anaerobic, hockey (50% aerobic, 50% anaerobic), kabaddi, being an indigenous game introduced in the Asian games in the year 1990 (55% aerobic, 35% anaerobic system) (Khanna et al., 1996). The mean value of WBC, platelet and neutrophil are significantly higher in waterpolo due to the long term (5-7 years) in high amount of aerobic training. Chronic adaptation of aerobic training, hormones (growth hormone and catecholamine) increases the cytokines TNF- $\alpha$ , IL-1, IL-4, IL-6 that in turn increased the WBC, neutrophil and platelet in waterpolo players. Lowest count of lymphocytes in waterpolo may be due to the mobilization of more neutrophil from bone marrow to blood and the egress of lymphocytes from the blood to the tissue. Literatures evidenced that the cortisol level is more in endurance game which results in low lymphocyte count of waterpolo players. Cortisol inhibits lymphocyte proliferation and activation by directly inhibiting IL-2 and IL-2 receptor production (Cohen et al., 1991). Alterations in gene expression in skeletal muscle adaptation to endurance training are correlated to changes in blood cell gene expression viz PDGFRB, EREG, MIP-1 $\alpha$ , MIP-1 $\beta$ , HSP70, DUSP1 which in turn increases the circulating level of WBC, platelet and neutrophil (Connolly et al., 2004, Zeibig et al., 2005). #### SPORTOMICS ANALYSIS OF METABOLIC RESPONSES IN OLYMPIAN RUNNERS USING A 100M DASH RACE AS A MODEL

Magno França, A.1,2,3, Magalhães-Neto, A.M.1,4, Bachini, F.1, Cataldi, E.1, Bassini, A.1, Cameron, L.C.1

*1:LBP-UNIRIO; 2:UFU; 3: CDE; 4:UFMT (Brazil)*

Introduction The 100m dash is the fastest race in the Athletics Olympic program. This exercise requests an important ATP hydrolysis and regeneration. Due to its high intensity and short duration, followed by rest, this race is extremely useful to study the blood kinetics of some metabolites in high energetic demand. Sportomics is a field of study combining "-omics" sciences with classical biochemical analyses in order to understand sports induced systemic changes (Bassini and Cameron, 2008). Sportomics deals with real in-field athletic conditions and allows us to make personalized training adaptations based on both cellular and systemic biochemical changes. In this paper, we compare Sportomics findings during a 100m dash race to describe metabolic responses of two top-level sprinters. Methods Two world-class female athletes were evaluated during a 100m-dash training test. We collected 6 blood samples: at fasting; pre-race (T1); immediately post-race (T2); and after 2, 5, and 10 min (respectively T3, T4 and T5) recovery. For this study we analyzed nearly 40 blood parameters in order to understand the different personal responses to exercise. Results Hematocrit levels increased in response to exercise from approximately 2 or 6 % normalized at T1 for each athlete. The lactate kinetics curve was quite similar for both athletes, reaching a plateau at T2 and maintaining this level until T5. While athlete 1 had an increase in lactate concentration of ~275 % (3.9 - 14.9 mmol/L), athlete 2 was near ~800 % (1.8 - 16.0 mmol/L). Ammonia response in athlete 1 has two big slopes (T1 - T2 and T3 - T4), peaking at 130  $\mu\text{mol/L}$  (250 %) and 148  $\mu\text{mol/L}$  (315 %) decreasing to 90  $\mu\text{mol/L}$  at T5. In contrast, a single component was measured for the second athlete, with concentration at T2 (540 %; 205  $\mu\text{mol/L}$ ), maintaining a plateau from T3 to T5 around 135  $\mu\text{mol/L}$  (320 %). Blood creatinine concentration followed the same kinetics from T1 to T3 in both athletes, raising 8 - 9 %. The general response was similar in T4 and T5 as well, but

absolute values varied in athlete 1 (1.0 to 1.1 mg/dL) when compared to athlete 2 (1.4 to 1.5 mg/dL). Discussion Even though we are dealing with two elite athletes of the same team, exposed to the same training experiences and competition routines, their metabolic answers were quite different in some parameters as previously described by us (Bassini-Cameron et al., 2008). This analysis allows us to infer that the difference of metabolic responses to the exercise of both athletes is due to a bigger ATP storage in the muscle or to lower bioenergetics efficiency. ## TWELVE WEEKS OF UNCOMPLICATED RESISTANCE TRAINING INCREASES LEAN BODY MASS AND REDUCES MARKERS OF MUSCLE ATROPHY IN OLDER ADULTS

Egan, B., Crognale, D., Krause, M., Cogan, K., Newsholme, P., De Vito, G.

*UCD Institute for Sport and Health*

**Introduction** Resistance exercise is an established countermeasure to attenuate the decline in lean body mass (LBM) that occurs with aging, but the effects of resistance exercise training on markers of muscle atrophy in older adults is not well-described. The aim of the present study was to investigate the effects of twelve weeks of 'uncomplicated' resistance exercise training on LBM and markers of muscle atrophy in older adults. **Methods** Thirty-nine medically-stable, free-living older adults were randomised to either resistance exercise training (REX, n=21; age, 63.9±4.1 y; body mass index, 25.2±2.5 kg m<sup>-2</sup>) or non-training control (CON, n=18; 63.1±4.8 y; 26.7±2.9 kg m<sup>-2</sup>) for a 12 week intervention. REX consisted of three supervised exercise sessions per week, each lasting 45 minutes and consisting of uncomplicated resistance exercises predominantly in the form of bodyweight and resistance band exercises. Physical function including 10 m walking test and chair raise tests was assessed before and after the intervention. Muscle biopsies from the vastus lateralis were taken prior to commencing training and at 60 h after the final training session. Changes in transcript abundance for molecular markers of fibre type and muscle atrophy were assessed by quantitative polymerase chain reaction (qPCR). Results REX resulted in an increase in whole-body LBM (0.93±0.83 kg; p<0.001) and leg LBM (0.25±0.27 kg; p=0.001), which were unchanged in CON. Improvements in 10 m walking test and chair raise tests (reps in 30 sec and time for 5 reps) were observed in REX (all p<0.05), but not CON. Relative mRNA expression of FOXO3 was decreased (30%; p<0.05), MAFbx tended to be decreased (24%; p=0.077), and MYOD was decreased (38%; p<0.01) after REX, but myostatin was unchanged. Myosin heavy chain isoform expression was decreased for type I (40%; p<0.01) and type IIX (48%; p<0.05) and increased for type IIA (43%; p<0.001) muscle after REX. **Discussion** The present study describes a REX training intervention of bodyweight- and resistance band-based exercises for older adults, which demonstrates efficacy to increase LBM and physical function in this population. Increases in LBM coincided with reductions in markers of muscle atrophy and elevated expression of type IIX muscle fibres. Future work will explore markers of muscle protein synthesis in these samples. **Acknowledgements** This work supported by funding from Enterprise Ireland and Food for Health, Ireland. ## IMPACT OF ACE I/D POLYMORPHISM ON HEART RATE VARIABILITY AFTER 10 WEEKS OF AEROBIC TRAINING IN CHILDREN

Silva, C.C., Nakamura, F.Y., Ramos, P., Okuno, N.M., Higashi, D.T., Venancio, E.J.

*Universidade Estadual do Norte do Paraná*

**Introduction** Heart rate variability (HRV) has important cardio-protective effects and is modulated by physical training. Likewise, the renin-angiotensin system interacts with the autonomic nervous system and the angiotensin-converting enzyme (ACE) is suggested to have a genetic variability that exerts considerable influence on HRV (Thayer et al., 2003). However, no data are available regarding the genetic determinants of HRV responsiveness to training in pediatric populations. Thus, the purpose of this study was to test the impact of ACE I/D polymorphism on resting HRV after 10 weeks of physical training in pre-pubertal children. **Methods** Eighty-four children (44 male and 40 female) between 8 and 9 years old (Tanner 1) took part in this study. They were assigned to a 10-week running training program (3 times per week for 40 min per session; intensity >80% of maximal aerobic velocity). To investigate the effects of different ACE polymorphisms on HRV responses to training, the participants were assigned to three distinct groups (ID, II and DD) based on their ACE gene I/D genotype. For ACE genotyping, DNA was isolated from saliva samples and subjected to polymerase chain reaction (PCR) followed by polyacrylamide gel electrophoresis (SDS-PAGE). Resting heart rate was obtained during 10 min in a supine position (Polar RS800) and HRV was measured using spectral and time domain analysis. The groups (ID, II and DD) versus time (pre HRV x post HRV 10 weeks) comparisons were performed using two-way ANOVA with repeated measure analyses. Results Of the 84 children, 46 presented the ID genotype; 21, the II and 17, the DD. After training, all groups demonstrated enhanced HRV parameters compared to baseline. However, ACE DD homozygotes demonstrated significantly lower values (P<0.05) pre training for SDNN, RMSSD and SD1 (28.8±8.6 ms; 21.7±6.0 ms and 15.5 ± 4.3 ms) when compared with ACE ID (42.5 ± 12.8 ms; 42.5 ± 12.8 ms and 29.8 ± 11.3 ms) and ACE II (29.8 ± 11.3 ms; 29.8±11.3 ms and 29.3 ± 16.7 ms, respectively). Furthermore, the ACE DD demonstrated significantly higher (P<0.05) LF (nu) values (60.5 ± 9.8) pre training, compared to ID (54.2 ± 14.4). **Discussion** It is recognized that homozygous DD allele have higher angiotensin II levels which elicit vasoconstriction and consequently higher blood pressure and lower HRV (Thayer et al., 2003). Our results corroborated these findings and demonstrated that homozygous DD allele demonstrated significantly lower HRV with respect to their II/ID counterparts pre-training. However, independent of ACE I/D genotype, a 10 week running training program provoked improvements in vagal-related indices (RMSSD and SD1), in addition to enhancing SDNN in all the ACE I/D polymorphism groups. ## DEVELOPMENT OF THE ATHLETES RECRUITING SYSTEM IN CYCLIC SPORTS BASED ON INDIVIDUAL MORPHOFUNCTIONAL AND GENETICS PARAMETERS

Yevdaliuk, S.V.1, Melnov, S.B.2, Kruchynsky, N.G.3, Davydov, V.Y.3, Lebed, T.I.3, Kozlova, A.S.4, Shepelevich, N.V.3

*Brest regional center of sports medicine*

**INTRODUCTION** Modern approaches to the sportsmen recruitment and individualization of the training process should take into account both genetic and environmental factors contribution to the making of the world-class athlete. The aim of this study was to develop a genetic monitoring program to determine the individual profile for athletes reserve in cyclic sports. **METHODS** The study group comprised 250 swimmers, both males and females, aged 10-19. We evaluated the morpho-functional state of swimmers using morphological and functional suitability scales (Davydov V.Y. et al.). Genotyping and frequency of 5HTT, ACE, AGT, PPARA, PPARG, PPARGC1A, and TFAM polymorphisms were obtained by site-specific PCR amplification that was performed on genomic DNA isolated from buccal epithelial

cells (Akhmetov I.I.). RESULTS The morphofunctional state evaluation showed that most of the athletes had 'average' (66.7% total; 62.2% in girls; 69.7% in boys) and 'above average' morphophysiological level (21.6% total; 24.4% in girls; 21.6% in boys). 9.0% of the study group had 'below the average' level (8.9% in girls; 9.1% in boys), and only 2.7% had 'high level' (4.5%; and 1.5%). The prevalence of the following genotypes was discovered: AGT CC (77.78%±5.66% in boys; 73.17%±6.92% in girls), PPARA GG (65.38%±6.60%; 70%±7.25%) TFAM GG (59.62%±6.80%; 53.66%±7.79%), PPARD TT (58.82%±6.90%; 70%±7.25%). These genotype frequencies were significantly higher than in controls. There was also significant difference of the distribution of the ACE ID in boys (24.53%±5.91%) and girls (46.34%±7.79%), and ACE II in study group (22.64%±6.15% in boys vs. 14.63%±5.52% in girls); the frequency of the TFAM GC was also significantly higher in girls (31.71%±7.27% vs. 13.46%±4.73%). We also observed the trend in PPARD TT genotype distribution (70%±7.25% in girls vs. 58.82%±6.90% in boys). DISCUSSION Conducted anthropological examination allowed to develop the model parameters of morphological and functional parameters of the athletes. We analyzed the morphophysiological developmental level based of these characteristics and evaluated maximum potential taking into account so called 'testosterone peak'. The most promising athletes were observed in groups of 14 and 15 years (girls) and 11 and 15 years (boys). On the basis of previous studies we selected 5 candidate genes and studied a common genetic profile of the swimmers. As a result, the basic polymorphic genes set for subsequent screening study was developed. Thus, AGT C, PPARA G, PPARD T and TFAM G alleles can be considered as relevant genetic markers for swimmers. After initial screening examination of these genetic markers further molecular genetic testing for the 13 gene polymorphism will be carried out. References Akhmetov I.I. ### EPIGENETIC CHANGES WITHIN THE ADAMTS4 GENE PROMOTER MAY MODIFY RISK OF PATELLA TENDINOPATHY.

Raleigh, S., El Khoury, L., Rickaby, R., Samiric, T.

*University of Northampton*

Introduction Patellar tendinopathy (PT) is common in sports involving jumping where it represents more than 30% of knee injuries (Christian et al, 2014). Genetic factors are known to increase the risk of other tendinopathies (Raleigh and Collins, 2012) but the role of epigenetics in overuse injuries has never been described. Epigenetic modification, such as the methylation of DNA CpG sites, alters gene expression and is likely to impact on performance phenotypes (Raleigh, 2012). Indeed, DNA methylation plays an important role in disease processes and represents a promising avenue of research in tendinopathy. Accordingly, the aims of this study were to identify whether the DNA methylation status of two genes (ADAMTS4 and TIMP2) known to be involved in the tendinopathic process (Corps et al, 2008; El Khoury et al, 2013) were altered in tissue collected from those with PT compared to controls. Methods Twenty (10 PT and 10 healthy controls) male patellar tendon samples were collected for this study. The DNA methylation status of 6 ADAMTS4 and 4 TIMP2 CpG sites from within the respective promoters were determined in all samples using next generation sequencing (NGS). Data were analysed using a t-test and significance was set at  $p < 0.05$ . All procedures were approved by the relevant research ethics committees. Results There were no significant differences in mean methylation profiles for both the ADAMTS4 ( $p = 0.294$ ) and TIMP2 ( $p = 0.885$ ) gene promoter regions between PT and controls. However, a specific site within an important regulatory region of the ADAMTS4 promoter was hypermethylated in the PT group ( $p = 0.016$ ) compared to controls. Discussion This is the first study to focus on epigenetics as a possible determinant of tendinopathy. Although mean DNA methylation levels for both the ADAMTS4 and TIMP2 promoters were not altered, the hypermethylation of a single CpG site with the ADAMTS4 promoter between PT and the control groups may be functionally important. This area of the ADAMTS4 promoter is known to be important for its regulation (Thirunavukkarasu et al, 2006). Our investigation did not cover all of the CpG sites within the promoter regions studied. Ongoing work within our laboratory continues to investigate the epigenetic basis of soft tissue pathologies related to sports and physical activity. Christian RA, Rossy WH, Sherman OH. ## Mini-Orals

### MO-PM33 Neuromuscular Physiology: Fatigue

#### H-WAVE AMPLITUDE FLUCTUATION IS ASSOCIATED WITH VARIATION OF MAXIMAL VOLUNTARY MUSCLE CONTRACTION WITHIN A SUBJECT

Taki, C.I, Shiozawa, N.I, Kimura, T.T

*1: Ritsumeikan University (Japan), 2: Kobe University (Japan)*

Introduction Unexpected kinetic errors in repeated body motions always happen in competitive athletes. Even in a maximal voluntary muscle contraction (MVC) in the laboratory testing, the subject often experiences the failure of maximal effort, i.e., the fluctuation of the peak force between the MVC trials; while its detailed mechanism remains to be elucidated. A previous study (Nozaki et al., 1995) showed the time-series variation of H-wave amplitude in soleus muscle (SOL), which reflects the input-output characteristics of the  $\alpha$  motor neuron ( $\alpha$ MN) pool. These observations led us hypothesize that the fluctuation of the  $\alpha$ MN excitability influences the variation of the MVC. The aim of this study was therefore to assess effect of the variation in  $\alpha$ MN excitability on the MVC fluctuation. Methods The subjects were 11 healthy men (21-31 yrs). Surface EMG was recorded from each of the medial and lateral gastrocnemius muscles (MG and LG) and SOL. Each subject repeated 2-s isometric MVC of plantar flexors ten times with sufficient rests (>2min), while the average amplitude of three H-waves was recorded in each muscle during 2-5s before each MVC trial. For each MVC trial, the EMG RMS value (1-s window) at peak force was computed in each muscle. For each muscle, the ten MVC trials were ranked according to the greatness of the muscle's EMG RMS value, and we defined the upper and lower three MVC trials as successful and failed trials, respectively, of the muscle. The averages of EMG RMS and H-wave amplitude were calculated for the successful and failed trials for each muscle in each subject. Results and Discussion There was no significant difference between the average trial numbers which induced successful and failed trials, in each muscle (N.S.). The average of EMG RMS value in the successful trials across subjects was significantly larger than that in the failed trials, in

each muscle ( $P < 0.01$ ). Also, the average of H-wave amplitude in the successful trials was significantly larger than that in the failed trials in MG ( $P < 0.05$ ). In contrast, in the relative change of H-reflex amplitude, significant correlations among subjects were found between SOL and LG at the successful ( $r = 0.98$ ,  $P < 0.01$ ) and failed ( $r = 0.77$ ,  $P < 0.05$ ) trials, while no significant correlation was found as for MG. These results indicate that there existed the substantial variability in the motor output in each muscle between the repeated MVC trials, and, in MG, the fluctuation of muscle output was associated with that of input-output characteristics of  $\alpha$ MN. On the other hand, LG and SOL might have different mechanisms. References Nozaki D, Nakazawa K, Yamamoto Y.(1995). *Exp Brain Res*,105(3), 402-410. Contact sh0011kk@ed.ritsumei.ac.jp

### HOW MANY SETS OF SUBMAXIMAL CONSTANT-TORQUE PASSIVE STRETCH ARE NECESSARY TO REDUCE PLANTAR FLEXOR PASSIVE TENSION?

Trajano, G.S., Seitz, L.B., Nosaka, K., Blazevich, A.J.

*Edith Cowan University*

**Introduction:** Passive muscle stretching is commonly used in pre-exercise preparatory routines with the aim of decreasing muscle-tendon unit (MTU) passive tension and consequently increasing joint range of motion during physical activity and clinical rehabilitation training. It has been clearly demonstrated that passive stretch can reduce passive tension in the plantar flexors, however the majority of the studies investigating changes in passive tension after passive stretch have imposed constant-angle stretches while standard stretching practices are more similar to a submaximal constant-torque stretch design. To the best of our knowledge there is a lack of data in the literature reporting the dose-dependent response to submaximal constant-torque stretches. Thus, the purpose of the present study was to investigate the dose response of MTU passive tension to a series of submaximal constant-torque plantar flexor stretches to provide information as to the optimum stretch dose. **Methods:** Fifteen men performed four 1-min stretches with a 15-s inter-stretch rest interval after a warm-up. The stretches were performed as a constant-torque ankle stretch on an isokinetic dynamometer. The intensity of stretch was set as 90% of maximal tolerable torque measured during a maximal passive stretch in a familiarisation session. Passive torque was measured at 5°, 10° and 15° while the isokinetic dynamometer passively rotated the ankle into dorsiflexion on. A two-way repeated measures ANOVA was used to compare passive tension measured at 5°, 10° and 15° between stretches 1 - 4. **Results:** There was a significant angle  $\times$  stretch interaction effect ( $p = 0.001$ ). Post-hoc analysis revealed that passive torque was reduced by ~8% at the three angles after the first 1-min stretch. Passive torque was further reduced by 11 and 13% at 10° and 15°, respectively, after the second stretch. No further reductions were observed after the third stretch. **Discussion:** A single submaximal, constant-torque plantar flexor stretch significantly reduced passive torque at all three angles; the magnitude of this reduction is likely to be clinically/functionally relevant. However, two 1-min stretches induced a greater reduction in passive torque at the greater dorsiflexion angles, but continued stretching did not cause any additional reduction. These results suggest that there is a dose-response relationship between stretch volume and the reduction in passive tension in the plantar flexor group where two 1-min stretches seem to be optimal to reduce passive torque. Further research using different stretch intensities and durations would possibly allow for more detail to be gained with respect to the optimum dose of static stretching. ### NEUROMUSCULAR CHARACTERISTICS OF QUADRICEPS AND HAMSTRINGS MUSCLES DURING A SOCCER MATCH.

Kalema, R., Pesola, A., Finni, T.

*University of Jyväskylä*

**INTRODUCTION:** To investigate the EMG activity of quadriceps and hamstrings muscles in the first (PRE) and last 15 minutes (POST) of a soccer match and to determine the player's neuromuscular activity profile using burst analysis method during an entire match. **METHODS:** Seven professional players, 1 left-footed and 6 right-footed, playing the highest Finnish soccer league volunteered (age  $23.1 \pm 6.1$  y; height  $1.82 \pm 5.2$  m; mass  $78.4 \pm 10$  kg). EMG from left and right quadriceps (LQ, RQ) and hamstrings (LH, RH) were measured, maximal voluntary contraction (MVC) during knee extension and flexion were assessed before the match. Muscle light, moderate and vigorous activities were defined as EMG value during treadmill running at 6, 12 and 16 km/h, respectively. Muscle inactivity threshold was defined as EMG value below 2% of EMGMVC (Tikkanen et al. 2013). After artifact removal, raw EMG data were rectified and ran through a Matlab algorithm, which normalized the EMG to EMGMVC and provided the distribution of muscle inactivity and activity at different percentage of EMGMVC. Burst analysis provided average EMG (aEMG), number of bursts, duration of bursts, burst amplitude, burst rate/seconds. Wilcoxon signed rank test with significance level of  $p < 0.05^*$  was applied. **RESULTS:** Compared to PRE, aEMG in the final 15 minutes of the match showed a significant decrease for RQ (27%), RH (29%) and LH (18 %). Burst duration revealed a significant decrease of 31% for RH, 22% for LQ and increase of 29% for LH. Burst amplitude was decreased by 23% for RQ and 20% for RH. RQ burst rate decreased by 20%. Inactivity time increased by 10% for LQ and 35% for LH. RQ light activity increased by 6%. Moderate activity time decreased for RH (17%) and LH (23%). Finally, vigorous activity reduced significantly for RQ (31%), RH (37%) and LH (27%). **DISCUSSION:** For the first time, this study reports a muscle EMG activity measured during an actual soccer match. As expected, EMG activity was reduced and the players spent more time at lowest intensities compared to highest intensities in the final 15 minutes. Rahnama et al (2006), showed similar EMG results when exercising at match-like intensity. Our study revealed greater muscle activities for dominant than for non-dominant leg. While care should be taken when interpreting the EMG signal amplitude, our results give an interesting starting point for using EMG as a monitoring and measurement tool for performance evaluation and prevention of soccer injuries. **REFERENCES** 1. ### THE ETIOLOGY OF ELECTROSTIMULATION-INDUCED MUSCLE FATIGUE IS RELATED TO THE MODULATION OF STIMULATION PARAMETERS

Alain, M., Grosprêtre, S., Vilhem, C., Le Fur, Y., Bendahan, D., Gondin, J.

*Université de Bourgogne*

**Introduction:** Neuromuscular electrical stimulation (ES) applied with high frequency and wide pulse (WPHF) results in greater force loss than short-pulse-low-frequency ES protocols (CONV) (1). This greater fatigue development has been related to a higher metabolic cost per activated motor units (MUs) for high than low stimulation frequency (2). However, a reduction of the amount of solicited MUs linked to a higher stimulation frequency could also be involved (3). In the present study we combined electrophysiological and metabolic measure-

ments in order to characterize the impact of ES parameters on the etiology of muscle fatigue. Methods: Eleven healthy subjects completed both WPHF (80Hz-1ms) and CONV (20Hz-50 $\mu$ s) protocols for two testing sessions. The triceps surae muscle (TS) was electrostimulated through the tibial nerve at an intensity evoking 20% of maximal voluntary contraction (Istim) for 40 trains (6s on- 6s off). During the first session, force-frequency relation (F(Hz)) were established at Istim before and after each protocol in order to assess the contractile properties of the solicited MUs. For both protocols, a single twitch was delivered at Istim after each train. Force and electromyographic activity (EMG) of the TS were continuously recorded. M-wave EMG responses were assessed to provide an index of the amount of solicited MUs during each protocol. During the second experiment, subjects were supine with the right leg centered within a 3T magnet. Changes in concentrations of phosphocreatine (PCr) and intracellular pH were assessed during each protocol using <sup>31</sup>P-MR spectroscopy. Results: A similar decrease in force was observed for both protocols. The CONV protocol induced a force reduction at all stimulation frequencies of the F(Hz) ( $P < 0.05$ ) leading to a rightward shift of F(Hz). On the contrary, a significant reduction of the TS M-wave amplitude evoked at Istim was only observed for the WPHF protocol. This decline was positively correlated with the ES force decrease ( $R = 0.96$ ,  $P < 0.001$ ). Both changes in PCr and pH were similar for the two protocols. Discussion: We showed that the magnitude of force loss and metabolic changes were similar for both protocols. However, the etiology of the muscle fatigue was strongly related to the ES parameters. Indeed, WPHF-induced fatigue was related to changes in axonal excitability threshold leading to a lower amount of solicited MUs whereas intramuscular processes (i.e., at the cross-bridges level) are likely to be involved during CONV protocol. ### EMG RESPONSES OF POWER PRODUCER AND POWER TRANSMITTER MUSCLES DURING A FATIGUING CYCLING EXERCISE

Lee, S., Chung, W., Bishop, D., Rouffet, D.M.

*Victoria University*

Introduction In various sports, the performance produced by athletes depends on their ability to maintain high levels of power output by regulating the contribution of their muscles. Dorel et al (2009) reported that towards the end of a time-to-failure (TTF) cycling exercise, athletes may increase the EMG activity of the hip extensor muscles to compensate for the loss of force of knee extensors. The aim of this study was to determine if changes in the EMG of the lower limb muscles vary depending on their functional role (Zajac et al., 2002) during a TTF cycling exercise. Methods Ten males completed a Torque-Velocity (T-V) test followed by a TTF cycling exercise performed at 110% VO<sub>2</sub>max and stopped when power fell below 105% VO<sub>2</sub>max. Crank torque, cadence and power output were measured using SRM cranks while surface EMG signals of 7 muscles [gluteus maximus (GMAX), rectus femoris (RF), vastus lateralis and medialis (VAS), tibialis anterior (TA), soleus (SOL), and gastrocnemius (GAS)] were recorded. Results from the T-V test were used to calculate relative levels of power (Gardner et al., 2009) and EMG (Rouffet & Hautier, 2008) during two intervals of the TTF: Int5-10%, and Int95-100%. Finally, the EMG responses of the muscles were analysed by considering separately power producer muscles (PP): GMAX, RF and VAS and power transmitter muscles (PT): TA, SOL and GAS. A two-way ANOVA (time interval x muscle group) with repeated measures was used for analysing EMG responses. Results Power output fell below 105% VO<sub>2</sub>max after 193 $\pm$ 74s and was lower during Int95-100% (309 $\pm$ 52W vs. 284 $\pm$ 53W;  $p < 0.05$ ). However, no changes were observed for the relative level of power (37 $\pm$ 9% vs. 36 $\pm$ 8%;  $p = 0.13$ ) and EMG activity of the 7 muscles (30 $\pm$ 2% vs. 27 $\pm$ 3%;  $p = 0.20$ ) measured during the first and last time intervals. A muscle group\*interval effect was seen on the EMG responses: EMG activity of PP muscles increased (28 $\pm$ 7% vs. 36 $\pm$ 12%;  $p < 0.05$ ) while EMG activity of PT muscles decreased (34 $\pm$ 7% vs. 29 $\pm$ 10%;  $p < 0.05$ ) between the first and last intervals. Discussion The adjustments of the EMG of the lower limb muscles differed from those previously reported during a comparable TTF cycling exercise (Dorel et al., 2009). Our EMG results suggest the occurrence of peripheral fatigue in PP muscles (including both knee and hip extensors) with a reduction in the demand placed on the PT muscles and/or the occurrence of central fatigue in PT muscles at the end of the TTF cycling exercise. ### EFFECTS OF UPHILL WALKING AND DOWNHILL WALKING ON POSTURAL CONTROL

Werner, I., Enzinger, A., Ressel, J.

*Institute of Sport Science*

Introduction Finding risk factors for stumbles and falls is a major topic in accident prevention. Mountain hikers as well as elderly people are claimed to step precisely and to control posture to minimize risk of falling. Balance performance is impaired after fatiguing exercise (Helbostad et al., 2010). The aim of this study is to compare postural control after exercise without fatigue and to compare effects of uphill and downhill walking. Methods 12 well trained young male students (mean age 27y, SD 2y) took part in this study. Postural control was checked with MFT S3 check (Raschner et al., 2008) where participants had to keep at level a platform tilting in anterior-posterior or medial-lateral direction while standing on it. Postural control was measured before and after a 20 min walk on a treadmill (uphill – speed 3km/h, or downhill, both 20% tilt) in a cross over design. The speed of downhill walking was adapted to leg length. Every five minutes the heart rate and the mental state by a Borg-scale (6-20) were recorded. ANOVA with repeated measures was conducted, level of significance was set on 0.05. Results Heart rate was significantly higher in uphill walking while the work load was felt similar. Borg scale values (about 13) were slightly but not significantly higher for downhill walking. Balance scores in the anterior-posterior direction after walking were significantly higher (=worse) than before walking ( $F(1,11) = 6.5$ ,  $p = 0.027$ ,  $\eta^2 = 0.37$ ). There was no difference in the deterioration of balance after uphill compared to downhill walking. Balance scores in the medial-lateral direction were unaffected. Discussion Balance performance on a tilting platform was negatively affected after treadmill walking only in the anterior-posterior direction. This might be due to the deterioration of the joint position sense (Bottoni et al., 2014). In our study participants were not fatigued (Borg scale 12-14). While the control of movements in the medial-lateral direction seems to be the same over all exercises, the balance control of the platform tilting in the anterior-posterior direction demands activity of the knee and ankle muscles highly involved in walking. Because of the fact that the participants were not fatigued after the exercises further studies should focus on adaptation strategies of perceptual information for postural control. ## EFFECTS OF DIETARY NITRATE SUPPLEMENTATION ON LOW-FREQUENCY FATIGUE AND VOLUNTARY CONTRACTILE PERFORMANCE DURING FATIGUING EXERCISE

Tillin, N.A., Tyler, C.J., Floyd, K.M., Medlock, H., Giacomelli Ranzi, E., Campos De Souza, F., Manwaring, R.  
*University of Roehampton*

**Introduction** Dietary nitrate supplementation has been shown to increase skeletal-muscle force at low (<20 Hz) stimulation frequencies (Haider & Folland, 2014), which may be due to improved excitation-contraction (EC) coupling (Hernández et al., 2012). Disruption to EC coupling is thought to be a major contributing factor to reduced maximal voluntary force (MVF) during fatiguing exercise (Westerblad et al., 2000) and appears to have its greatest effect at low stimulation frequencies (low frequency fatigue; LFF). Thus, dietary nitrate supplementation may protect against LFF, and attenuate reductions in MVF during fatiguing exercise. The purpose of this study is to investigate the effects of dietary nitrate supplementation on voluntary performance and LFF during a fatiguing exercise. **Methods** 6 males visited the lab for a familiarisation, and 3 measurement trials. Trials 1 (baseline) and 2, and 2 and 3 were separated by 7 and 9 days respectively. In the 7 days before trials 2 and 3, participants consumed 2x70-ml shots per day of either nitrate-rich (0.4g/70ml) or nitrate-depleted (placebo) beetroot juice in a double blinded, counterbalanced order. In each trial participants completed a series of involuntary and voluntary isometric knee extensions at a 120° knee angle. Involuntary contractions involved 1-s tetanic contractions at 10, 20, 50, and 100 Hz at a stimulation current eliciting 50% of MVF at 100 Hz. Tetanic contractions were performed before and immediately after 60, 3-s maximal voluntary contractions (MVCs) separated by 2 s. Dependent variables included: the %Δ in peak tetanic force at each stimulation frequency from pre to post 60 MVCs; the %Δ in 20:50 Hz peak tetanic force from pre to post 60 MVCs; MVF; total impulse during the 60 MVCs, end-test force (average force of the last 6 MVCs); and fatigue index (%Δ in mean force from the first 6 to the last 6 MVCs). **Main effects of condition** (baseline, placebo, and nitrate) were determined with a one-way ANOVA. Results There was no main effect ( $P > 0.05$ ) of condition on MVF ( $677 \pm 168$  N); total impulse ( $63591 \pm 9187$  Ns); end-test force ( $229 \pm 41$  N); or fatigue index ( $56 \pm 7\%$ ) during the 60 MVCs. There was a similar decline in peak tetanic force at 10 ( $-57 \pm 11\%$ ), 20 ( $-51 \pm 14\%$ ), 50 ( $-38 \pm 14\%$ ), and 100 Hz ( $-38 \pm 14\%$ ) from pre to post 60 MVCs in all conditions ( $P > 0.05$ ). There was also a similar decrease in 20:50 Hz peak force from pre to post 60 MVCs in all conditions ( $-21 \pm 12\%$ ;  $P > 0.05$ ). **Discussion** Nitrate supplementation did not affect either voluntary contractile performance during the 60 MVCs, or LFF following the MVCs. Changes in EC coupling with nitrate supplementation may only occur in Type II muscle fibres (Hernández et al., 2012) and may have minimal influence on in-vivo whole muscle performance. ## IMPACT OF SELECTIVE PRE-FATIGUE ON QUADRICEPS SYNERGISTS ACTIVATION STRATEGY

Matkowski, B.1, Place, N.2, Lepers, R.1, Martin, A.1  
*University of Burgundy*

1: INSERM U1093, University of Burgundy (Dijon, France), 2: Institute of Sport Sciences, University of Lausanne (Lausanne, Switzerland) **Introduction** It is known that the activation strategy differs among the knee extensors, i.e. vastii vs. rectus femoris (RF), during a submaximal isometric contraction (I). This has been mainly attributed to functional anatomical differences between mono- and bi-articular muscles. The present study aimed to examine whether the activation strategy among the knee extensors was different when vastus lateralis (VL) was pre-fatigued. To do so, we compared the activation strategy, i.e. electromyographic (EMG) activity among knee extensor muscles during a sustained isometric submaximal contraction maintained until failure with or without pre-fatigue of VL. **Methods** Thirteen males participated in two experimental sessions (randomly assigned), consisting of maintaining 20% of maximal voluntary contraction torque (MVC) until task failure. For one of the session, the task was preceded (pre-fatigue) by 30 repeated submaximal fatiguing contractions of the VL muscle induced by electrical stimulation (ES; duty cycle 6.25s on - 27s off) at an intensity evoking 20% MVC. EMG activity of VL, vastus medialis (VM) and RF muscles and torque were continuously recorded. **Results** Time to task failure was significantly shorter with than without pre-fatigue ( $-23.2\%$ ,  $P < 0.001$ ). At the beginning of the contraction (first 10% of time to task failure), EMG activity did not differ between muscles with and without pre-fatigue, excepted for VM with pre-fatigue which was significantly higher (15.5, 16.3 and 16.0% MVC EMG vs. 15.5, 21.1 and 17.5% MVC EMG for VL, VM, RF muscles without vs. with pre-fatigue, respectively). For the last 10% of time to task failure, level of EMG activity of RF muscle was higher than VL and VM without pre-fatigue, whereas VM and RF were higher than VL with pre-fatigue (31.9, 33.5 and 37.5% MVC EMG vs. 31.9, 46.6 and 45.1% MVC EMG for VL, VM, RF muscles without vs. with pre-fatigue, respectively). **Discussion** We observed a different strategy among knee extensor muscle when VL was pre-fatigued. Interestingly, our results contrast with those from previous study (2) in which load sharing was not redistributed among the quadriceps muscles after selective pre fatigue of the VL muscle. These findings suggest that activation strategy of VM depends on the fatigue status of VL. **References** 1. Place N, Matkowski B, Martin A, Lepers R. (2006). *Exp Brain Res*, 174, 595-603. 2. ## CONTRIBUTION OF THE ANKLE PLANTAR FLEXORS TO POWER PRODUCTION DURING SPRINT CYCLING

D'Amico, J.M.1,2, Bobbert, M.3, Rouffet, D.M.1  
1. Victoria University 2. NeuRA 3. VU University

**Introduction** Ankle plantar flexor muscles (APFs) impact human performance during exercises such as speed skating or vertical jumping (1). During cycling, APFs transmit the power generated by knee and hip extensors to the crank (2). Interestingly, large reductions of the net ankle joint power produced by the APFs accompany reductions in crank power during sprint cycling (3). The aim of this study was to investigate the effect of a force-loss of the APFs on the ankle joint power and crank power production during sprint cycling. **Methods** Ten participants performed a 30-s maximal cycling exercise under two randomized conditions: 1) control condition (CTL) and 2) after pre-fatiguing the APF muscles (APF-). In the APF condition, a 40% reduction in APF force (isoFAPF) was induced using a series of 3-s maximal isometric contractions interspersed with 6s recovery. Pre and post cycling sprints, neuromuscular testing (NMT) was completed to measure isoFAPF, isoEMG (SOL/GAS) and resting maximal M-waves (MSOL/GAS). EMG of APFs (cycEMGSOL/GAS), ankle joint power produced by APFs (cycPAPF) and crank power (cycPcrank) were calculated for the first and last 6s of the cycling sprints. Two-way ANOVAs with repeated measures (condition\*time) were used to analyse changes in the variables extracted. **Results** Reductions in isoFAPF ( $-39 \pm 10\%$ ), isoEMGSOL ( $-46 \pm 14\%$ ), isoEMGGAS ( $-40 \pm 16\%$ ), MSOL ( $-19 \pm 15\%$ ) and MGAS ( $-12 \pm 15\%$ ) were induced prior to the cycling exercise in the APF-condition. During the last 6s of the cycling sprints, cycEMGSOL ( $29 \pm 7\%$  vs.  $16 \pm 5\%$ ), cycEMGGAS ( $37 \pm 9\%$  vs.  $28 \pm 8\%$ ), cycPAPF ( $128 \pm 49$  W vs.  $37 \pm 14$  W) and cycPcrank ( $467 \pm 132$  W vs.  $231 \pm 52$  W) were all decreased ( $p < 0.05$ ). A larger condition effect was observed during the first 6s of the sprint for cycEMGSOL ( $-9 \pm 5\%$  vs.  $-3 \pm 2\%$ ), cycEMGGAS ( $-9 \pm 7\%$  vs.  $-5 \pm 6\%$ ), cycPAPF ( $-14 \pm 20$  W vs.  $-2 \pm 8$  W) and cycPcrank ( $-29 \pm 28$  W vs.  $-14 \pm 20$  W).

vs.  $-3\pm 36W$ ). Post sprint, isoFAPF ( $-13\pm 8\%$ ), isoEMGSOL ( $-34\pm 16\%$ ), isoEMGGAS ( $-14\pm 18\%$ ) and MSOL ( $-9\pm 17\%$ ) were lower during the APF-condition. Discussion Only small reductions in both the ankle joint power produced by the APFs and the power transmitted to the crank were observed following a large force-loss in the APFs, indicating that the impact of APFs on sprint cycling performance is lower than what is observed during vertical jumping and skating. Altogether our results also show that completion of a 30-s cycling sprint does not seem to induce fatigue in the APFs, suggesting that only low levels of force need to be produced by the APFs to allow the transfer of knee and hip extensor power to the crank. #### THE AGE-PERFORMANCE RELATIONSHIP: TOWARD NEW MODELS

Berthelot, G., Marck, A., Bronikowski, A.M., Morgan, T.J., Garland Jr, T., Carter, P.A., Toussaint, J.F.

*INSEP*

The physiological traits characterizing human capacities (the ability to move, reproduce or perform tasks) change with age: performance is limited at birth, increases to a maximum, then decrease back to zero at death. Both physical and intellectual skills follow similar ontogenies [1-3]. The development of sport and chess performances during the lifetime was previously investigated at two different scales: the individual athletes' careers and the world record by age class in 25 Olympic sports and in elite chess players [3]. For all data sets, a biphasic pattern of growth and decline is described by a simple equation [1] and the two processes (growth and decline) are exponential and operate throughout the lifetime, starting at age 0. PURPOSE: Here we aim to (i) demonstrate that this biphasic behaviour is probably widespread among biological phenomena (ii) introduce a new model to estimate the characteristics of the biphasic pattern (peak value, age of death). METHODS: Performances data were gathered for human (200, 400 and 800m races,  $n=5,065$ ,  $5,013$  and  $5,080$ , respectively), greyhound (480m competitions,  $n=47,991$ ), mice (distance run on wheels during 24h,  $n=14,241$ ) [4] and *Caenorhabditis elegans* (using an experimental eletrotaxis device). Two models were adjusted to the data: the equation of Moore [1], and a new model based on a populational approach. RESULTS: A U-inversed biphasic pattern is found in both the athletic (human Olympians and elite greyhound) and non-athletic (mice, *Caenorhabditis elegans*) species. The new model describes the dynamics of performance with aging with greater accuracy compared with the initial model, based on classical goodness-of-fit indicators ( $R^2$ , rmse, AIC, BIC). CONCLUSION: The pattern is robust, whatever the type of effort and duration: free activity vs. constrained running or overall distance traveled vs. maximum speed. Our results suggest a similar age-related pattern in very different species. The description of the physiological limits shows that there is no brutal transition between the developmental and senescent periods. It thus questions the narrowed link between those two processes. 1. Moore II, D.H. A study of age group track and field records to relate age and running speed. Nature 253:264-265 (1975). 2. #### THE HERITABILITY OF AN OLYMPIC MEDAL: A POPULATION-BASED STUDY ON OLYMPIANS FROM THE GAMES OF 1896 UP TO 2012

Antero-Jacquemin, J., Saulière, G., Foulenneau, V., Toussaint, J.F.

*INSEP*

Background: Genetic and environmental factors have proved influence in sport performance. We hypothesize an inheritance component affecting the genetic and environmental interplay and thus, having a kinship with a former Olympic medalist may increase the chances of an athlete, to repeat the achievement of his/her kinship. We aimed to measure the heritability of an Olympic medal among Olympians. Methods: Cross-sectional study based on the entire population of athletes participating in the Olympics from 1896 up to 2012. Data concerning Olympics participation, medals obtained, biographies and kinship with other Olympians was collected for all Olympians ( $n = 125,051$ ). The frequencies of medals among Olympians presenting a kinship with a former Olympic medalist ( $n=1,086$ ) were compared to the frequency of Olympians presenting a kinship with Olympians non-medalist ( $n=4,575$ ) and with Olympians without a kinship in the games ( $n=119,390$ ). The pairs of studied kinships were: grandparents-granddaughter/grandson, aunt/uncle-niece/nephew, parents-offspring, siblings, dizygotic (DZ) and monozygotic (MZ) twins. The Qui-squared test was used to test whether the performance level is independent of a kinship with an Olympic medalist at 0.05 significance level. Concordance rates among twins were assessed by probandwise concordance rates, and the heritability ( $h^2$ ) variation of the phenotype genetically determined was estimated according to classical twins' studies. Results: The probability to obtain a medal related with the medals distribution in the games is 20.85%. Among Olympians with no kinship with other Olympians is 20.37% (95% CI: 20.1-20.6) and is not significantly different from Olympians with a non-medalist kinship ( $p>0.05$ ). Among Olympians presenting a kinship with a former Olympic medalist the probability to be also a medalist is: among granddaughter/son 36.84% (95% CI: 20.2-59.4,  $p > 0.05$ ); niece/nephews 44.44% (95% CI: 33.7-54.2;  $p < 0.001$ ), offspring 43.38% (95% CI: 37.4-48.6;  $p < 0.001$ ), siblings 64.8% (95% CI: 61.2-68.8;  $p < 0.001$ ); DZ twins 75.47% (95% CI: 63.3 - 86.6;  $p < 0.001$ ); MZ twins 85.71% (95% CI: 63.6 - 96.9;  $p < 0.001$ ); with significantly greater concordance between MZ than DZ ( $p = 0.01$ ) and  $h^2$  estimated at 20.48%. Conclusion: This study shows that high performance in sports is a heritable trait related with a genetic and environmental predisposition. Having a kinship with a previous Olympic medalist increases the probability of an Olympian to be also a medalist as greater is the coefficient of relatedness relying them.

## IT IS YOUR TEAMMATES NOT YOUR SCHOOLMATES THAT MATTERS: THE IMPORTANCE OF RISK POPULATION IN TALENT DEVELOPMENT STUDIES.

Rossing, N., Flattum, A., Biegel, A., Karbing, D.

*Aalborg University*

Objectives: Studies have shown that elite athletes tend to come primarily from communities with a certain population size or density depending on the sport and nation (Côté et al. 2006; Bruner et al., 2011) this being commonly referred to as the birthplace effect. Birthplace studies have traditionally compared the distribution of elite players to census statistics across community categories, the census data representing the risk population from which talents originate. Recently, it was suggested that youth players should be a more appropriate risk population also to elucidate if elite players simply come from communities with more youth players (Rossing et al., 2015). Our objective was to examine how selection of risk population affects the analysis of birthplace effect among Danish male national youth handball players (NP). Methods: The sample included 80 Danish NP ranging from below 18 years to below 21 years (U18-U21) national youth teams in 2014. Risk populations were either 35.948 registered male youth handball players or 249.289 6-12 years old children. Birthplace communities were divided into six sub-divisions by population density and odds ratio (OR) were calculated comparing the odds for being a NP with odds for being a child in each community or a registered youth player for a specific community sub-division. OR results were considered significant if 95% confidence intervals (CI) did not include 1. Results: Compared to distribution of children aged 6-12 years, NP were overrepresented in medium density communities ( $\geq 100$ -250 pop./square km) (OR(CI)) (1.68(1.04-2.73)) with no other significant results. Compared to registered youth players, NP were underrepresented in low density communities ( $\geq 50$ -100 pop./square km) (0.44(0.24-0.88)) with no other significant results. Conclusions: The choice of risk population significantly affected results of the odds ratio analysis. This indicates that the distribution of registered youth players indeed is related to the distribution of players selected for the Danish national youth teams in handball. Therefore, future studies should also include youth players as risk population. The results of this study also suggest that the structure of the talent development in the Danish handball federation seem to create good opportunities to both rural and urban talented players. ## DIFFERENCES BETWEEN BALL POSSESSION ON WHEELCHAIR-ATHLETE ACTIVITIES IN RELATION TO FIELD POSITION IN WHEELCHAIR BASKETBALL

de Witte, A., Hoozemans, M., Berger, M., van der Woude, L., Veeger, H.

*The Hague University of applied sciences*

Introduction In wheelchair basketball, athlete performance is determined by the individual capabilities of the athlete, interaction with the wheelchair in combination with the requirements of the game. There are three field positions (guard, forward and centre) and each position has specific requirements and therefore specific physical and wheelchair actions. Athletes require a wheelchair design that best meets the demands of a specific sports discipline (Vanlandewijck et al., 2001). A better understanding of wheelchair-athlete activities is required for optimization of the wheelchair. In order to find out or detect regularities and principles in the game of (wheelchair) basketball, it is necessary to investigate individual parts of game flow like ball possession (Perica et al., 2011). Therefore, the aim of this study is to determine whether differences between field positions in wheelchair-athlete activities are different between ball possession and no ball possession during wheelchair basketball matches. Methods Using video analysis, absolute and relative duration of wheelchair movements (forward, backward, rotate, standing still, brake and block) and athlete control options (0, 1 or 2 hands) were examined in 27 Dutch National players and 29 International players during entire matches. Data were analysed using repeated measures ANOVA (with/ without ball possession) with a between subjects factor (field position). Results During a game, on average 21% of the active time guard players (n=18) had ball possession, while forward players (n=24) and centre players (n=14) possessed the ball for 16 and 18%, respectively. For the activity driving forward there was a statistically interaction (p=.02). Guard players drove relatively 4% more forward with ball possession compared without ball (Total percentage (TP) driving forward: 46%) while in contrast, forward players drove 6% less forward (TP: 45%) and centre players drove 8% centre less forward (TP: 45%). Conclusion During ball possession, both guards, forwards and centers showed different wheelchair-athlete activities compared to no ball possession for the activity driving forward. These findings indicates that mobility performance can be enhanced by focusing on the specific requirements of the different field positions in wheelchair basketball, for instance by optimizing the wheelchair design and settings. ## RELATIVE AGE EFFECT AND PERFORMANCE IN YOUNG EUROPEAN FEMALE BASKETBALL CHAMPIONSHIPS

Arrieta, H., Torres-Unda, J., Gil, S.M., Irazusta, J.

*University of the Basque Country (UPV/EHU)*

Introduction An overrepresentation of relatively older participants, known as the Relative Age Effect (RAE) has been widely studied (Musch & Grondin, 2001), particularly in high-level sports (Romann & Fuchslocher, 2013). However, few studies have investigated RAE in women's basketball (Delorme & Raspaud, 2009) and no one has focused on European Female Championships. Thus, our aim was to describe the possible presence of this effect in young female elite players and national teams of U16, U18 and U20 cohorts to ascertain the underlying causes of RAE in women's basketball. Methods We analysed the following data: date of birth, height, minutes played and performance parameters of 1102 young female basketball players who took part in the European U16, U18 and U20 Female Championships. In order to avoid the possible effect of played minutes in performance parameters, all the data were normalised per minute played. To determine the performance of the teams, we also collected the classification of each national team in the championship. Results We observed a skewed distribution of the birth dates in the youngest two cohorts, with more players being born in the first quarter of the year (36%). However, this bias disappeared in the U20 championships. In addition, significant correlations were observed between relative age and certain performance related parameters such as played minutes, assists, steals and scored points (p<0.05). It is also noteworthy that the correlations were not significant when data were normalized per played minutes. Relative age was not correlated to height of the players. Regarding the classification, there were significant correlations between the classification achieved in the U20 and the relative age (p<0.005), with the teams with relatively oldest players being the best classified. Discussion Our results demonstrated that RAE is relevant in high-level female youth basketball, although differences in birth distribution were not so skewed as in male players. There was an overrepresentation of players born in the first quarter of the year in U16 and U18 championships and in the best teams of U20 championships. Trainers, coaches and youth sport authorities should consider the present findings in order to avoid unequal selections at early

ages. References Delorme, N., & Raspud, M. (2009). ### THE RELATIONSHIP BETWEEN MOTIVATION FOR PHYSICAL ACTIVITY AND LIFESTYLE IN 10- TO 12-YEAR-OLD CHILDREN IN SOUTH KOREA AND JAPAN

Ikedda, T.1, Han, N.2, Choi, T.2, Aoyagi, O.3

1 Fukuoka Prefectural University, 2 Jeju National University, 3 Fukuoka University

Introduction Children in Asia have been becoming increasingly inactive in recent years (Muller et al., 2013), and low motivation for physical activity (MPA) has been identified as a factor in the decline in their physical fitness. The objective of this study was therefore to investigate and compare countries (Korea and Japan) in terms of the relationship between MPA and lifestyle in elementary school-aged children. Methods The study participants were 985 children aged 10-12 years. The participants completed a questionnaire consisting of 41-items relating to MPA (Inomata, 1997) and lifestyle. The questionnaire elicited data pertaining to the following: afterschool lessons, play and games, study and motivation for learning (ML), and level of achievement regarding movement skills. MPA was subjected to factor analysis using the principal factor method and Promax rotation. To investigate the relationship between MPA and lifestyle, a multiple regression analysis was applied with dummy variables, thus establishing each MPA factor score as a dependent variable. Results MPA was found to involve seven factors: Self-awareness (S), Affinity with the activity (AF), Desire for achievement (Ach), Consistency with personal values (V), Activeness (Act), Competitiveness (C), and Desire to avoid failure (F). In the multiple regression analysis, the variables of the holding game machine, time of study, and gender were excluded from all formulas. The largest coefficients for each formula were as follows: gymnastics skills (.391[S], .304[Act]), high ML based on self-determination (.321[AF], .396[Ach], .284[V]), and low ML (.246[C], .330[F]). The significant (5%) regression coefficients for country were as follows: -.200[S], -.093[Act], .097[V], .090[F]. Discussion The levels of achievement pertaining to movement skills were generally higher in this study, and MPAs were higher regardless of nationality. In addition, ML pertaining to self-determination was higher in this study, as were MPAs pertaining to self-determination. Regarding those factors underlying MPA, Japanese children showed higher V and F and lower S and Act than their South Korean counterparts. These differences may be attributed to cultural differences between the two countries (Hong et al., 2009; Jang & Berry, 2011; Mochizuki & Ishida, 2009). The results revealed differences and similarities in the relationship between MPA and lifestyle in both countries, and identified areas for effective intervention in terms of increasing physical activity in children. ### "MAGNITUDE-BASED INFERENCE": A STATISTICAL REVIEW

Welsh, A.

*Australian National University*

We consider "magnitude-based inference" and its interpretation by examining in detail its use in the problem of comparing two means. We extract from the spreadsheets which are provided to users of the analysis (<http://www.sportsci.org/>) a precise description of how it is implemented. We compare the implemented version of the method with general descriptions of it and interpret the method in familiar statistical terms. We show that "magnitude-based inference" is not a progressive improvement on modern statistics. The additional probabilities introduced are not directly related to the confidence interval but rather are interpretable as p-values for two different, non-standard tests (for different null hypotheses). We also discuss sample size calculations associated with "magnitude-based inference" and show that the substantial reduction in sample sizes claimed for the method (30% of the sample size obtained from standard frequentist calculations) is not justifiable so the sample size calculations should not be used. Rather than use "magnitude-based inference", a better solution, is to use either confidence intervals or a fully Bayesian analysis.

### STUDY OF THE PERFORMANCE EVALUATION OF MASS SPORTS PUBLIC INPUT ON STRUCTURAL EQUATION MODEL ANALYSIS - BASED ON THE INVESTIGATION OF 25 PROVINCES IN CHINA

Zhang, F.B., Zhang, N.Z.

*Dalian University of Technology*

Introduction Though the 《The nationwide body-building plan》 was carried out for more than 20 years in China, there is a big gap between the need of the general public and the sports facilities, organization system, fitness guidance, constitution monitoring, etc. The performance evaluation (PE) of mass sports public input (MSPI) is important to improve the level of public sports performance and the efficiency of resource assignment. Methods Base on the literature research, Delphi method, factor analysis method and structural equation model, we built a model for the PE of MSPI. After normalization of the path coefficients of the model, we determined the coefficients of the weight (CW). The CW of the input, output, and effect to the PE of MSPI are 0.22137, 0.38550 and 0.39313, respectively. The CW of the input in mass sports and sports facilities are 0.38931 and 0.61069 respectively. The CW corresponding to mass sports activity sites, the population of daily exercise, sports clubs, and the population of social sports instructors per 10,000 people to the output are 0.29412, 0.26144, 0.27124 and 0.17320, respectively. The CW of the population of reaching the national physical standard and the quantified rate on the effect are 0.75701 and 0.24299, respectively. Results and Discussion Using the PE index system, we got the empirical analysis on the performance of the MSPI for 25 provinces in China. (1) The public input performance in 2008-2014 is extremely low in mass sports in China, only Jiangsu and Shandong provinces in good and fair level. With the growing of economy and society, the performance levels of MSPI tend to increase accordingly. (2) The difference in performance level is defined as the performance difference between different regions within the same time period. It is a measurement of performance disparities among different regions. The differences in performance indicator of Guizhou and Qinghai provinces are the biggest. And the performance difference degree of the MSPI is tending to expand further from 2008 to 2014. (3) The performance improvement indicator refers the speed and degree of performance improved at the same area in different times. In 2009-2014, 19 out of 25 provinces, the MSPI performance improved at different levels. (4) The coincident index is the ratio of performance improvement indicators and social economic development speed, which is used to analyze the

orientation relationship between the performance of public input improvement and the level of social economic development speed. There are 17 provinces in China showed a tendency of synchronous growth of the MSPI performance with the per capita GDP. The PE of the MSPI should focus on indicators of output and effect. This also enlighten us to improve the performance of MSPI, namely, to strengthen the construction of sports facilities, to cultivate social sports instructors, to encourage more people into physical activity, and elevate the physical health level of people.

### MO-PM14 Health & Fitness: Children, Team Sports

#### ACCEPTABILITY AND FEASIBILITY OF AN INTERNET-BASED INTERVENTION TO INCREASE PHYSICAL ACTIVITY AMONG ADOLESCENTS

Grieben, C., Stassen, G., Schaller, A., Frick, F., Froboese, I.

*German Sport University Cologne*

**Introduction:** The fact that most adolescents do not achieve the age-specific physical activity (PA) recommendations points out the importance of target-group specific interventions promoting PA (Roski, 2009; WHO, 2010). Current research shows that internet-based interventions, offered in addition to standard face-to-face interventions, are a promising approach to reach adolescents. However it is completely unclear whether this approach is accepted and to what extent it is used (Price et al., 2015). The aim of the study is to evaluate the acceptability and feasibility of an internet-based intervention to increase PA at school. **Methods:** The present study included five classes of 9-11th graders randomly chosen of five schools (3 high schools, 1 comprehensive school and 1 vocational school). The total sample was 119 (mean age: 14.8; boys=40%). Participants received an 8-week face-to-face intervention combined with an internet-based intervention. Acceptance and feasibility were analyzed. Acceptance was measured by a questionnaire, assessing usability, understandability, perceived benefits and perceived costs of the internet intervention. Feasibility was measured by usage of the portal (utilization rate, number of logins, consulted resources). **Results:** Response rate of the acceptability questionnaire was 64% (n=76). 84% (n=64) reported that the internet program was well understandable; the usability was accepted by 65% (n=49). 102 pupils (86%) logged in at least one time. The registered adolescents accessed the platform, with a task-completion rate of 25%. Overall login duration at the weekend was two minutes less than during the week. High school pupils used the platform weekdays significantly more often than participants attending comprehensive school ( $p \leq 0.000$ ). There are no differences in usage regarding sex and age. **Discussion:** The results show that low threshold facilities such as internet-based interventions offered in schools are accepted and feasible in regard of health promotion of adolescents. However, it is necessary to consider which functionalities of the internet platform were most frequently used and might be supportive in promoting PA (Lau et al., 2011). Furthermore we need to explore reasons for non-participation and identify strategies to increase the involvement. **References:** Lau, P. W. C., Lau, E. Y., Wong, D. P., & Ransdell, L. (2011). *Journal of Medical Internet Research*, 13(3). Price, M., Yuen, E. K., Davidson, T. M., Hubel, G. & Ruggiero, K. J. (2015). *Psychological services*. Roski, R. (2009). #### IS PHYSICAL ACTIVITY OF ADOLESCENTS AND THEIR BEST CLASSMATES ASSOCIATED? A PILOT STUDY IN LITHUANIAN, NORWEGIAN AND SWEDISH HIGH SCHOOLS

Karvelyte, V., Gruodyte-Raciene, R.

*Lithuanian sports university*

**Introduction** Boys and girls of primary school, whose best friends are physically active, have higher level of physical activity (1). The aim of this study was to investigate whether these relationships persist in adolescence. **Methods** In total, one hundred and eighty three school-children of 16 – 18 years of age from one secondary school in Kaunas (Lithuania), one secondary school in Oslo (Norway), and one secondary school in Malmö (Sweden) took part in this pilot study: from Lithuania there were 64 students (28 boys), from Norway - 60 (32 boys), and 59 students were from Sweden (33 boys). To measure their total amount of physical activity (PA) (i.e. the energy expenditure in MET-minutes/week) during the past seven days, the short form of an International Physical Activity Questionnaire (IPAQ) was used (2). The level of vigorous (VPA), moderate (MPA) and low (walking) intensity physical activities as well as the total amount of PA (ToPA) of the respondents was determined using IPAQ scoring protocol guidelines (3). **Results** Comparing high school students' physical activity according to country and sex, Lithuanian adolescent girls expend more energy in ToPA than Norwegian and Swedish girls ( $p < 0.05$ ). When ToPA is stratified into activities of different intensity, Lithuanian girls expend significantly more energy in walking than girls from Norway and Sweden, and more energy in MPA than Norwegians. In VPA the energy expenditure of Norwegian boys and girls is lower than of Lithuanian and Swedish ( $p < 0.01$ ). Statistically significant, but negative relationship between high school students' and their best classmate's levels of physical activity was found only in Swedish boys ( $r = -0.41$ ;  $p < 0.05$ ). **Conclusions** We may conclude that in adolescence the boys and girls, whose best friends are physically active, does not necessarily have higher level of physical activity as it was found in primary school. Norwegian adolescents, both boys and girls, expend significantly less energy in physical activities than their counterparts from Lithuania and Sweden. **References** 1. ## EFFECT OF THE ROTATIONAL SPEED OF THE ROPE IN A PERSON TURNING A LONG JUMP ROPE IS ON THE HEART RATE AND OXYGEN UPTAKE

Yoshida, N.1, Wada, T.1, Tamari, Y.1, Saito, T.1, Kremenik, M.J.2, Yamaguchi, H.3, Onodera, S.2

1 Graduate school, kawasaki university of medical welfare, 2 Kawasaki university of medical welfare, 3 Kibi international university

**Purpose:** Exercising with a long jump rope is standard in elementary school physical education classes in Japan. However, there is no report that investigates the physiological responses of a person turning the long jump rope during long jump rope exercise. The purpose of this study was to clarify the effect of heart rate and oxygen uptake on a person turning a long jump rope at different rotational speeds. **Methods:** Subjects were six healthy Japanese males volunteered to participate in this study. Their age, height and body weight were  $22 \pm 1$  years,  $171.7 \pm 9.3$  cm and  $65.8 \pm 6.4$  kg, respectively (mean  $\pm$  SD). All subjects signed informed consent forms prior to participation in this study. The measurement conditions were set for a jump rope at three rotational speed conditions: 70, 90 and 110 rpms. The experimental protocol called for sitting in a chair at rest for five minutes, three minutes of exercise, and five minutes in a chair resting as a recovery. The exercise chosen was to turn a jump rope for three minutes at the three conditions. A long jump rope certified by NARJ (length of rope: 10 m) was used. Measurement indexes were heart rate, oxygen uptake, blood pressure and Rating of Perceived Exertion (RPE). **Results:** 90 and 110 rpm conditions showed significant heart rate increases one minute after the three minute exercise compared with the 70 rpm condition ( $p < 0.05$ ). 110 rpm condition showed significant heart rate increases one minute after the three minute exercise condition compared with the 90 rpm condition ( $p < 0.05$ ). 90 and 110 rpm conditions showed significant oxygen uptake increases one minute after the three minute exercise compared with the 70 rpm condition ( $p < 0.05$ ). 110 rpm condition showed significant oxygen uptake increases one minute after the three minute exercise condition compared with the 90 rpm condition ( $p < 0.05$ ). 90 and 110 rpm conditions showed significant increases in RPE one minute after the three minute exercise compared with the 70 rpm condition ( $p < 0.05$ ). 110 rpm condition showed significant increases in RPE one minute after the 3 minute exercise condition compared with the 90 rpm condition ( $p < 0.05$ ). **Discussion:** Changes in heart rate and oxygen uptake by using a hand ergometer are dependent on the rotational speed. In this study, when the rotational speed of the rope went up, heart rate and oxygen uptake increased exponentially. The exercise intensity of a person turning a long jump rope is limited by the speed of the rope's rotation. **Conclusion:** Changes in heart rate and oxygen uptake by a person turning a long jump rope were dependent on the rotational speed of the rope.

## RESIDENCE AND LIFESTYLE PARAMETERS IN YOUNGSTERS

Farkas, A., Szmodis, M.

University of Physical Education, Budapest

**Introduction** The modern life style and the achievements of the civilization mostly negatively effect the physical health, causing deviations of the posture and the skeleto-muscular system, especially because of the sedentary lifestyle or the low level of physical activity. In our present study the connection, if any, between the life style parameters and the dwelling circumstances, in respect of the size of the settlements was examined. **Methods** Among the higher classes of the elementary schoolchildren a questionnaire was used to gain information on their leisure time activity, on some basic nutritional aspects and about their own health status. Altogether 195 questionnaire (girls=100, boys=95) were analyzed in five different size of settlements, namely in a village (n=40), in a little town (n=40), in a larger town (n=40), in a county town (n=37) and in the capital (n=38). Within the settlements the type of the housing was asked and categorized as housing estate (blocks), family house, and new estate. The most important information on the leisure time activity structure and about the screen-time, and basic nutrients, meals and fast-food consumption were asked. Further information of any type of musculo-skeletal or postural deviation or deformity was gathered (e.g.: flat foot). BMI also was calculated by the self-reported body dimensions and were compared to the Hungarian reference values. For comparing the subgroups Student-t test for independent samples was used on the 0,05 level of significance. **Results** By our results we can state that by the size of the settlements the screen time was clearly increasing, especially in computer time, while it was more balanced in watching TV. For the latter the average time was about one or two hours equally, daily, for the whole sample. It is hard to tell if those having more time spent with computer have also the more time hanging on TV screen, or it is alternative. In the capital where more leisure time facilities could be easily reach, both the computer and TV screen time was less. Among other leisure time activities listening to music, sporting and family time was included in the first five order. Three-quarter of the whole sample evaluated their nutrition healthy, especially because of eating a lot of fruits and vegetables and less sweets. On the other hand somewhat less than half of the children eat fast foods. Children also were grouped by having flat foot or not. More of those with flat foot lived in block houses with less possibility of the open area and had extra weight. **Discussion** Both the extra weight and the dwelling, especially living in block housing estate develop flat foot. Lifestyle and dwelling have a definitive effect on the health status. In the larger settlements the rate of the overweight children was higher. More conscious and effective training could help to follow healthier lifestyle.

## ACADEMIC ACHIEVEMENT, OBESITY AND LOW FITNESS IN JAPANESE ADOLESCENTS

Morita, N.1, Nakajima, T.2, Okita, K.3, Fukuoka, R.4, Sagawa, M.1, Yamatsu, K.5

1. Hokkaido Univ. Education, Iwamizawa, Hokkaido; 2. Hokkaido Univ. Science, Hokkaido; 3. Hokusho Univ., Hokkaido; 4. Hokkaido Univ. Education; Saga Univ., Saga

**Introduction:** It has been shown that aerobic capacity is related to reading and arithmetic ability in children and that acute exercise enhances cognitive function (1,2). Also, childhood obesity has been reported to have a negative influence on cognitive function and academic achievement (3). However, there is no reports examined the influence of physical and physiological factors such as childhood obesity and low physical fitness on academic achievement in Japanese schoolchildren. The aim of this study was to investigate whether obesity and physical fitness are related to academic achievement in Japanese first-year junior high school students (equal to 7th graders in the U.S.). **Methods:** The data of 421 students (male, n = 222; female, n = 199; age = 12.4 yrs) were analyzed. Academic achievement was assessed by the total grade points of 8 school subjects (GP8; each subject was assigned 1 to 5 points) not including physical education. Comprehensive physical fitness was evaluated by the total score of 8 fitness tests including a 20-m shuttle run. Socioeconomic and behavioral confounders including mother's education, household income and cram school utilization were used as covariates. **Results:** The GP8 of students with a body mass index (BMI) over 25 was significantly lower than that of students with a BMI under 25 or under 18 (25.3 vs. 28.7 vs. 28.7 points, respectively;  $p < 0.05$ ). Comprehensive physical fitness and 20-m shuttle run test scores were correlated with GP8 in male students ( $r = 0.35$  and  $r = 0.36$ , respectively). In female students, only the 20-m shuttle run test score was correlated with GP8 ( $r = 0.16$ ). After adjusting for the confounders, comprehensive physical fitness score was found to be a significant factor for determi-

nants of GP8 in male students ( $\beta = 0.33$ ), but not in female students. Obesity status was a factor for GP8 in female students ( $\beta = -0.22$ ), but not in male students. Conclusion: These results suggest that obesity and low physical fitness could have a negative effect on academic achievement in Japanese junior high school students. References: 1. ## ESTABLISHMENT OF MEASUREMENT SYSTEM REGARDING SIMILARITY OF MONOZYGOTIC AND DIZYGOTIC TWINS

Fujii, K.

*Aichi Institute of Technology*

Introduction Scientific verification is impossible without quantitative assessment of the similarity or dissimilarity to the curve of growth pattern of twins. In this study, this assessment was verified by applying a cross-correlation function in analyzing changes from collapsing one of the curves to examine their similarity. The minimum growth curve must be functionalized to apply a cross correlation function. Thus it is important to approximate the growth curve by the Wavelet Interpolation Method proposed by Fujii (1999). Cross correlation function can then be applied to the quantified curve by Wavelet Interpolation Method. Methods : Longitudinal growth data consisting of height, weight, sitting height, and leg length was obtained for a pair of identical and a pair of fraternal twins from age six (first year of elementary school) to age 17 (third year of high school). : A cross correlation function is used to show the similarity between two waveforms, and the cross correlation function may be evaluated by convolving one function. In this study, a cross correlation function was assumed from the velocity curve values found from differentiation using the WIM for twins' physiques. < Analytical procedure>: WIM (Wavelet Interpolation Method) was applied to longitudinal growth data consisting of height, weight, sitting height, and leg length for pairs of identical twins and pairs of fraternal twins from age six (first year of elementary school) to age 17 (third year of high school). A cross correlation function was applied to the measured developmental indicators found by WIM and the velocity curve values. Results Changes in the cross-correlation coefficient found by applying the cross-correlation function to identical and fraternal twin height growth described by WIM and collapsing one (set of) growth distance values and velocity values. With  $r = 0.9$  for identical twins and  $r = 0.8$  for fraternal twins, similarity in identical twins was found to be very high when examining changes in correlation coefficients. Similarity among identical twins was also found to be high when weight, sitting height and leg length were analyzed, with high correlation coefficients in all three. Discussion Although it is only natural for identical twins to have a high degree of similarity, there is considerable variability amongst individuals making it possible for fraternal twins to have a high degree of similarity as well. Therefore identical twins showed clearly high cross correlation function in height growth. It is noteworthy that objective assessments can be made from the coefficient even when the difference in correlation coefficient is as slight as 0.1. Identical twins also showed a high degree of similarity in other physical attributes including weight, sitting height and leg length. References Fujii K, and Matsuura Y. (1999) Analysis of the growth velocity curve for height by the Wavelet Interpolation Method in children classified by maturity rate. *Am J Hum Biol*, 11, 13-30.

#### EFFECT OF AN INTENSIVE STRENGTH TRAINING MICROCYCLE ON RESTING HEART RATE VARIABILITY

Schneider, C., Schumbera, O., Raeder, C., Wiewelhoe, T., Ferrauti, A.

*Ruhr-University Bochum*

Introduction During the last decades, measures of heart rate variability (HRV) are receiving a growing interest for assessing cardiorespiratory fitness, as well as for monitoring fatigue and recovery in response to training stress. However, HRV-research has mainly focused on endurance training regimens and on team sports environments. Accordingly, evidence-based recommendations regarding the usefulness of HRV measures in an applied strength training setting are still missing. Therefore, the aim of the study was to investigate the influence of an intensive strength training microcycle (STM) on vagally-derived HRV indices, assessed under resting conditions. Methods Fifteen resistance-trained athletes (mean $\pm$ SD, female (n=7) 25.0 $\pm$ 1.5 yrs, 167.0 $\pm$ 4.9 cm, 62.0 $\pm$ 7.0 kg; male (n=8) 24.5 $\pm$ 2.1 yrs, 179.3 $\pm$ 6.3 cm, 76.5 $\pm$ 7.4 kg) completed a 6-day STM (eleven training sessions total) consisting of high-resistance (i.e., 85% 1RM) combined with maximal eccentric (i.e., 100% 1RM) strength exercises, both for upper and lower limbs. HRV (i.e., the natural logarithm of the square root of the mean sum of the squared differences between adjacent R-R intervals, Ln rMSSD) was assessed daily upon awakening in the morning (seven minutes under supine conditions) during a 4-day baseline period, a 6-day overload STM and a 4-day recovery period. HRV was analyzed using a 4-day rolling average. The smallest worthwhile change, calculated as one-half of the coefficient of variation, was used to determine practical significance through magnitude-based inferences (chances that the true difference was higher/trivial/lower) between baseline (Pre) and recovery (Post 1, Post 2, one and four days following STM, respectively). Results Ln rMSSD displayed a continuous negative trend during STM and was most likely decreased between Pre and Post 1 (0%/1%/99%). Changes between Post 1 and Post 2 were possibly positive (65%/35%/0%) but remained likely decreased between Pre and Post 2 (0%/6%/94%). Discussion The decrements in Ln rMSSD during STM suggest alterations in cardiac autonomic balance, which were commonly associated with fatigue and may possibly detect functional overreaching in endurance athletes. The changes after the STM indicate a state of fatigue at Post 1 and a not completely recovered state at Post 2. Although, current opinions on the usefulness of HRV assessments mainly focus on endurance-based training regimens, we provided data that HRV measures may further be of high value in monitoring fatigue and recovery in strength training-induced stress. ## THE EFFECT OF FUNCTIONAL OVERREACHING ON HEART RATE VARIABILITY AND PERCEPTIONS OF TRAINING TOLERANCE

Bellenger, C.1, Karavirta, L.2, Thomson, R.1, Robertson, E.3, Davison, K.1, Buckley, J.1

1 University of South Australia, 2 Polar Electro Oy, Kempele, Finland, 3 South Australian Sports Institute, Adelaide, Australia

**Introduction:** Research suggests that weekly averages of daily heart rate variability (HRV) assessment may better predict overreaching than isolated daily measures (1,2). However, HRV has been shown to both increase and decrease in response to overreaching. This study aimed to determine whether combining assessments of training tolerance with weekly average values of resting HRV could indicate a state of functional overreaching. **Methods:** Vagal-related indices of HRV (Ln RMSSD and Ln SD1) and RR interval were recorded daily in supine (2 min) and standing (2 min) postures during 1 week of light-training (LT), 2 weeks of heavy-training (HT) and 10 days of tapering (T) in male runners/triathletes (n=15, age=35.1 ± 7.0 years, body mass=76.5 ± 8.6 kg, mean 5 km time-trial time=19:06 ± 2:10 min). RR interval, Ln RMSSD and Ln SD1 were analysed as weekly average values and as isolated values at the end of LT, HT and T. Measures of training tolerance (Daily Analysis of Life Demands for Athletes questionnaire, and perception of energy levels, fatigue and muscle soreness) were also recorded daily and analysed as weekly average values. Performance was assessed following LT, HT and T with a 5 km time-trial on a treadmill. **Results:** Time to complete 5 km increased by 21.8 ± 19.0 sec (P=0.002) following HT, and then decreased by 45.3 ± 27.4 sec (P≤0.001) following T, for an overall decrease of 23.5 ± 18.9 sec (P=0.001). Weekly average RR interval, Ln RMSSD and Ln SD1 in the standing position increased after HT in comparison to LT (P≤0.007), and remained higher than LT at T (P≤0.04), however isolated values remained unchanged. Weekly average and isolated values of RR interval, Ln RMSSD and Ln SD1 remained unchanged in the supine position. Training tolerance decreased after HT (P≤0.002) and then increased after T (P≤0.007). **Conclusion:** Vagal-related HRV indices in the standing posture increased after both HT and T in comparison to LT, demonstrating an increase in vagal modulation during both negative and positive adaptations to training. Thus, interpretation of HRV to diagnose such training adaptations is difficult in isolation, indicating the importance of measures of training tolerance to contextualise changes in HRV and allow for effective monitoring in the field. Supine measures of Ln RMSSD and Ln SD1, in addition to isolated values in both postures were not sensitive for detecting negative and positive adaptations to training. 1. Plews, DJ et al. *Int. J. ## INCREASED SATELLITE CELL PROLIFERATION WHEN CULTURED WITH POST-EXERCISE SERUM: ROLE OF TESTOSTERONE?

Luk, H.Y., Duplanty, A.A., Levitt, D.E., Budnar, R.G., McFarlin, B.K., Hill, D.W., Vingren, J.L.

University of North Texas

**Introduction** Testosterone (T) is a potent muscle growth facilitator, and long-term administration of T is positively associated with satellite cell activation and proliferation. Resistance exercise can induce a transient increase in a range of circulating biomarkers including T, but the effect of such transient increases on satellite cells (SCs) are not known. The purpose of this study was to examine the effect of the exercise-induced changes in circulating biomarkers on muscle SC proliferation. **Methods** Resistance trained young men (M; n=5; 26±3y) and women (W; n=7; 22±2y) participated in a heavy squat exercise protocol (6 sets of 10 repetitions at 80% of 1 repetition maximum). Serum was collected before exercise (PRE), and immediately (IP), 20, 40, 60, 120, and 180min after exercise and analyzed for T concentration. Muscle SC were loaded with proliferation dye and cultured with either PRE (CON) or the progression of PRE and the 6 post-exercise serums sample for 72h (EXE). SC were incubated with the 180min serum sample for the last 68.5h of the 72h incubation period. Then, SC proliferation was measured using image-based flow cytometry (Amnis FlowSight). **Results** Incubation with M's serum from EXE induced a significantly higher percent of SCs in generation (G) 5 [EXE: 17±4%; CON: 10±3%] and G6 [EXE: 3±1%; CON: 0±0%] compared to CON. Incubation with W's serum from EXE did not change proliferation compared to CON. For incubation with serum from EXE, M's samples resulted a significantly lower percentage of SCs in G1 (M: 4±4%; W: 16±3%) and G2 (M: 19±5%; W: 34±4.%) compared to W's samples, but a significantly higher percentage of SCs in G4 (M: 26±5%; W: 35±4%), G5 (M: 17±4%; W: 12±4%), and G6 (M: 3±1%; W: 0±0%). For incubation with serum from CON, M's samples resulted a significantly higher percentages of SCs (3-fold higher) in G4+G5+G6 compared to W's samples. Serum T increased significantly (p<0.05) from PRE (19±4 nmol·L<sup>-1</sup>) to IP (25±2nmol·L<sup>-1</sup>) and then gradually returned to PRE levels by 180 min (21±2 nmol·L<sup>-1</sup>) for M; no change in serum T was observed (PRE: 3±1; IP: 3±1; 180 min: 2±1 nmol·L<sup>-1</sup>) for W. Serum T concentrations were higher in M than in W at all-time points. **Discussion** When cultured with serum collected from M following heavy squat exercise SC grew at a faster rate compared to when SC were cultured with resting serum from M; this effect of exercise was not observed with serum from W. Furthermore, serum from M (CON or EXE) induced greater SC proliferation than serum from W. Given the observed gender differences in serum T at rest and in the response to exercise, and the physiological role of T, it is logical to speculate that these differences in T may underlie the observed differences in SC proliferation.

## HIGH-DOSE INHALED SALBUTAMOL DOES NOT INCREASE 10-KM TIME-TRIAL PERFORMANCE IN TRAINED CYCLISTS

Koch, S.1, Ahn, J.R.1,2, Koehle, M.S.1

1: UBC (Vancouver, Canada), 2: UWO (London, Canada)

**Introduction** Inhaled β<sub>2</sub>-agonists (IBAs) are used to prevent the transient narrowing of the airways during or following exercise, which is defined as exercise-induced bronchoconstriction (EIB). Athletes with EIB, who use IBAs tend to win a disproportionately greater percentage of the individual Olympic medals compared to athletes who do not use IBAs (Fitch, 2012). The aim of this study was to investigate if the maximum allowable daily dose of inhaled salbutamol (World Anti-Doping Agency, 2015), leads to an enhanced athletic performance in cyclists based on dose per kilogram of body weight (kg/BW). **Methods** Twenty trained, male cyclists performed two simulated 10-km time-trials on a cycle ergometer 30 min after the inhalation of either 1600µg salbutamol (APOTEX Inc., Toronto, Canada) or placebo using a crossover design. The Eucapnic Voluntary Hyperpnea (EVH) test (Anderson et al., 2001) was used to screen athletes for EIB. Eight athletes tested positive (EVH+) and 12 athletes tested negative (EVH-). Lung function, assessed by forced expiratory volume in 1 second (FEV1), was measured immediately before and 15min after drug treatment. Performance was measured by mean power output. **Results** Despite an increase in FEV1 (M(SD) = 6.4%(4.9%), p< 0.001) following salbutamol, mean power output remained unaffected, regardless of inhaled dose per kg/BW or EIB status. Mean heart rate (p = 0.01), respiratory rate (p = 0.01), minute ventilation (p = 0.03) and perceived leg fatigue (p = 0.03) were increased in the salbutamol time-trial compared to placebo. **Discussion** Even though the inhaled IBA-dose per kg/BW varied by up to 33% (17.8-23.71600µg per kg/BW), there was no ergogenic impact of supramaximal IBA treatment on a 15-minute task. The present study supports the findings by Dickinson et al. (2014) and Kalsen et al. (2014), showing no ergogenic effect of high-dose IBA

treatment on run and swim performances longer than 2min. Future research should focus on the ergogenic potential of high-dose IBAs in exercise protocols shorter than 2min at anaerobic intensities. One limitation of the study was the difficulty of blinding athletes due to the high prevalence of tachycardia and tremor. In an attempt to mitigate potential bias, the verbal encouragement during testing was standardized. . References Anderson SD, Argyros GJ, Magnussen H, Holzer K. (2001). *BJSM*, 35, 344-47. ### EFFECT OF ALTITUDE TRAINING ON MUCOSAL IMMUNITY AND SLEEP IN ELITE CROSS-COUNTRY SKIERS.

Svendsen, I., Hem, E., Tønnessen, E., Gleeson, M.

*Loughborough University*

**INTRODUCTION:** Altitude training is a key component of the training process of many of today's elite endurance athletes. However, evidence suggests that altitude training can compromise both cellular and mucosal immunity, as well as adversely affect sleep. The aim of the current study was to investigate changes in mucosal immunity and sleep in world-class endurance athletes during a training camp at moderate altitude. **METHODS:** Nine male (age  $23 \pm 3$  years,  $\dot{V}O_2\text{max}$   $81 \pm 4$  ml/kg/min) and two female (age  $23 \pm 1$  years,  $\dot{V}O_2\text{max}$   $67 \pm 2$  ml/kg/min) elite cross-country skiers volunteered written informed consent to take part in the study. Participants were all part of the Norwegian cross-country skiing team. Sleep was analysed via wristwatch actigraphy for five days at sea-level (SL) and for 10 days while living and training at 2000-3200 masl. Whole, unstimulated saliva samples were collected first thing in the morning at SL and on day 1, 3 and 10 at altitude for determination of salivary cortisol, testosterone and antimicrobial proteins (immunoglobulin-A, LL-37 and lysozyme) via ELISA. Saliva osmolality was determined by freezing point depression. Athletes logged details of every training session, both at sea-level and altitude, in a specifically designed on-line training diary. **RESULTS:** Total training volume increased by ~63% at altitude compared to SL ( $185 \pm 33$  min/day vs.  $113 \pm 20$  min/day,  $p < 0.05$ ). This was driven by an increase in low-intensity endurance training, while the volume of resistance exercise and high-intensity endurance training were significantly lower. Assumed sleep time was significantly reduced by ~11% at altitude compared to SL. Sleep efficiency was also reduced during nights 4-6 and 7-10 at altitude ( $79 \pm 5\%$  and  $81 \pm 5\%$  vs.  $85 \pm 7\%$  at SL,  $p < 0.05$ ). There were no changes in salivary cortisol and testosterone. However, when examined separately, male athletes had significantly reduced cortisol and increased testosterone:cortisol ratio on day 1 and 3 at altitude. Salivary immunoglobulin-A secretion was increased on day 3 at altitude ( $140$  [95% CI 73-230] vs. SL:  $75$  [95% CI 43-116]  $\mu\text{g}/\text{min}$ ,  $p = 0.013$ ), as was LL-37 secretion (day 3:  $6.0$  [95% CI 3.0-9.0],  $p = 0.044$ , and day 10:  $4.7$  [95% CI 2.5-6.8],  $p = 0.024$ , vs. SL:  $2.6$  [95% CI 1.6-3.6]). There were no significant changes in salivary flow rate, osmolality or lysozyme. **CONCLUSION:** With appropriately adjusted training and good nutrition, hydration and hygiene practices, it appears possible for athletes to live and train at moderate altitude without compromising immunity. On the other hand, both sleep quality and quantity are reduced. However, these reductions do not appear to be severe and could likely be compensated for by making provision for day-time naps and some modest adjustments in training and meal times to allow athletes more time in bed.

### EFFECTS OF REDUCED ARTERIAL CO<sub>2</sub> PRESSURE ON VENTILATORY AND CEREBROVASCULAR RESPONSES DURING PROLONGED EXERCISE IN THE HEAT

Tsuji, B.1,2, Honda, Y.2, Fujii, N.3, Kondo, N.1, Nishiyasu, T.2

*1 Kobe University, Japan, 2 University of Tsukuba, Japan, 3 University of Ottawa, Canada*

**INTRODUCTION** Elevated body core temperature during exercise leads to increases in ventilation (VE) independently of metabolic factors, resulting in reduced arterial PCO<sub>2</sub> (hypocapnia) (Tsuji et al., 2012). Hyperthermia also decreases cerebral blood flow (CBF), which is one of the mechanisms behind decreased exercise performance in the heat. However, the effects of hypocapnia on VE and CBF during hyperthermic exercise are not fully understood. This study thus examined how temporary restoration of hypocapnia by inhaling CO<sub>2</sub> gas affects ventilatory and cerebrovascular responses during prolonged exercise in the heat. **METHODS** Eight healthy men performed a cycle exercise at 50% of peak oxygen uptake in the heat (38°C and 50% relative humidity) until esophageal temperature (Tes) reached 39°C. When during the exercise Tes increased by 1.0°C, 1.5°C and 2.0°C, and end-tidal PCO<sub>2</sub> (PETCO<sub>2</sub>, an index of arterial PCO<sub>2</sub>) decreased below 5-min level, subjects breathed CO<sub>2</sub>-enriched air (a mixture of room air and 100% CO<sub>2</sub>) for 2-3 min to restore reductions in PETCO<sub>2</sub> to the 5-min level. **RESULTS** VE increased with rising Tes from  $54 \pm 5$  l/min at 5 min (Tes of +0.4°C) to  $68 \pm 12$  l/min at Tes of +2.0°C ( $P < 0.01$ ), while PETCO<sub>2</sub> and middle cerebral artery blood flow velocity (MCAV) decreased from  $44 \pm 1$  mmHg and  $77 \pm 20$  cm/s to  $39 \pm 2$  mmHg and  $64 \pm 9$  cm/s, respectively (both  $P < 0.038$ ). CO<sub>2</sub> inhalation restored the decreased PETCO<sub>2</sub> to the 5-min level at any Tes level (+1.0, 1.5 and 2.0°C:  $43 \pm 1$ ,  $43 \pm 2$  and  $43 \pm 2$  mmHg, respectively, all  $P > 0.31$ ). This restoration of PETCO<sub>2</sub> significantly increased VE compared to pre-inhalation at any Tes level (+1.0, 1.5 and 2.0°C:  $60 \pm 6$  vs.  $65 \pm 7$ ,  $66 \pm 10$  vs.  $76 \pm 10$  and  $68 \pm 12$  vs.  $83 \pm 18$  l/min, respectively, all  $P < 0.018$ ). The PCO<sub>2</sub> restoration also significantly restored the reduced MCAV by 47-69% (+1.0, 1.5 and 2.0°C:  $71 \pm 15$  vs.  $74 \pm 16$ ,  $67 \pm 12$  vs.  $71 \pm 13$  and  $64 \pm 9$  vs.  $69 \pm 11$  cm/s, respectively, all  $P < 0.039$ ). **DISCUSSION** It is well recognized that in normothermic condition, hypocapnia suppresses VE via central chemoreceptors. The increases in VE caused by temporary restoration of hypocapnia in this study indicate that under hyperthermic conditions during exercise, hypocapnia suppresses VE. In addition, the ~50-70% increase in MCAV by the restoration of hypocapnia indicates that hypocapnia contributes largely to reductions in MCAV. Given our previous study in which during passive heating at rest, VE was unchanged and MCAV was restored by ~30-40% by temporary restoration of hypocapnia (Fujii et al., 2008), we speculate that hypocapnic effects on ventilatory and MCAV responses during hyperthermia differs between during exercise and at rest. In conclusion, present results suggest that during prolonged exercise in the heat, 1) ventilatory response with rising core temperature is suppressed by hypocapnia and 2) hypocapnia during hyperthermia largely accounts for reductions in CBF. **REFERENCES** Tsuji B, Honda Y, Fujii N, Kondo N, Nishiyasu T (2012). *J Appl Physiol* 113, 1388-1397. ### THE RELATIONSHIP BETWEEN MUSCLE THICKNESS AND MUSCLE VOLUME: MT IS A RELIABLE INDICATOR IN ASSESSING CHANGES IN SKELETAL MUSCLE MASS OF THE LOWER LIMBS IN RESPONSE TO RESISTANCE TRAINING

Franchi, M.V., Mallinson, J., Quinlan, J.I., Taylor, T., Atherton, P.J., Greenhaff, P., Narici, M.V.

*University of Nottingham*

The assessment of skeletal muscle mass is essential for quantifying hypertrophic responses to resistive training or in clinical scenarios, as in sarcopenia or disuse-atrophy (Heymsfield et al. 2014). In the last decades Computer Tomography (CT), Magnetic Resonance Imaging (MRI) and Dual-Energy X-Ray absorptiometry (DXA) have been used mainly in clinical settings to evaluate muscle mass; yet these techniques are expensive, not easily accessible and, in the case of CT, involve ionizing radiations. Recently, the use of ultrasound has been advocated as a potential reliable tool for assessing muscle architecture and ultimately mass/growth (Narici et al. 1999; Lieber et al. 2000; Sanada et al. 2006; Takai et al. 2014). Previous studies have shown that from a single scan, muscle thickness (MT) can be used as an indicator of increase in skeletal muscle size with hypertrophy (Akagi et al. 2008). Hence the purpose of the present study was to test whether MT could be used as a surrogate of muscle cross-sectional area (CSA) or volume in a population of healthy young males ( $n=8$ , age  $24\pm 1$  yr). The study received approval by the local Ethic Committee and informed consent was obtained from all participants. Muscle volume of the quadriceps femoris (QF) and vastus lateralis (VL) muscles was assessed by MRI (1.5 Tesla Philips AchievaScanner, NL) while MT of the VL muscle was measured by ultrasound (MyLab 70, Esaote Biomedica, It) at the distal 2/3 of femur length. Measurements were taken at baseline and at 28 and 84 days of a resistive exercise training (RET) programme (5 sets of 30 maximal isokinetic contractions at 90 deg/s performed 3 times/week). Correlation between the MRI and ultrasound measurements was tested by linear regression analysis. A significant correlation was found between VL VOL and VL MT ( $r=0.83$ ,  $P<0.001$ ) when all the values of Vol and VL MT were plotted independently from the time of acquisition; when instead the value at the 3 different time points were plotted separately, at Baseline, 28 and 84 days, the respective  $r$  values were  $r=0.88$ ,  $P<0.0001$ ;  $r=0.86$ ,  $P<0.0001$ ;  $r=0.83$ ,  $P<0.0001$ ). QF Vol vs. VL MT linear relationship was also significant ( $r=0.75$ ,  $P<0.001$ ), as was VL CSA vs. VL MT ( $r=0.80$ ,  $P<0.001$ ). The present data not only support the contention that MT may be regarded as a reliable index of skeletal muscle volume and CSA, but also that ultrasound could be a useful alternative to MRI for detecting changes in muscle mass with hypertrophic responses to RET. 1- Heymsfield SB et al. *J Cachexia Sarcopenia Muscle* 2014 2- Narici MV, *J Electromyogr Kinesiol* 1999 3- Lieber & Friden, *Muscle Nerve* 2000 4- Sanada et al. *Eur J Appl Phys* 2006 5- Takai et al. *J Nutr Health Ageing* 2014 6- Akagi et al. *J Strength Cond Res* 2008

### EFFECT OF A TAILORED, 12-WEEK, MODERATE-INTENSITY, STRENGTH TRAINING PROGRAM ON INDIVIDUALS WITH AMYOTROPHIC LATERAL SCLEROSIS

Ferri, A.

*Victoria University; University of Milano-Bicocca*

Introduction Amyotrophic Lateral Sclerosis (ALS) is a fatal, rapidly-progressive, neurodegenerative disease of unknown origin, characterised by motor neuron degeneration and inexorable skeletal muscle weakness. The safe range for therapeutic exercise in individuals with ALS (iALS) has been narrowed, because of the variegated expression of the disease and the possible overuse effects on weak muscles. However, evidence supporting a beneficial role for moderate-intensity exercise in iALS is emerging (Dal Bello-Haas & Florence 2013), based on the assumption that exercise can minimise the superimposed disuse that inevitably accompanies the neurogenic atrophy caused by the disease itself. The objective of this study was to evaluate the effects of tailored, moderate-intensity, strength training on functional capacities and strength in iALS. Methods Seven iALS ( $50.9\pm 6.5$  yrs; mean $\pm$ SD; M/F: 5/2) undertook 12 weeks of resistance training at about 60% of their 1 Repetition Maximum (RM), 3 times a week. Each session started with 15 min of cycling at an intensity corresponding to 50% between baseline and the ventilatory threshold on a cyclo-ergometer. Exclusion criteria were ALSFRS  $<24$  or desaturation index  $<92\%$  during exercise. Before and at the end of the training we evaluated the 1RM for the leg extension (LE), arm curl and lateral raise exercises, and the exercise capacity (VO<sub>2</sub>peak) on a cyclo-ergometer. Participants also performed the "Timed Up and Go" test (TUG) and the "6 min walking test (6MWT)". Results Even if the post-training values were increased by 16% (VO<sub>2</sub>peak), 70% (arm curl) and 29% (arm lateral raise), these increases did not reach significance. The 1RM value for the LE also increased by 60.3% from  $39.8\pm 21.8$  to  $63.8\pm 42.9$  kg ( $p=0.07$ ). An improvement in the functional tests was noticed (9% increase in TUG and 2% increase in 6MWT), but without statistical difference. Conclusion This study showed that 12 weeks of tailored, moderate-intensity, strength training maintains strength and functional motor skills in iALS. In addition, these results indicate that exercise does not debilitate iALS. Indeed, interventions such as exercise, that maximize function, will become increasingly important in the disease treatment. Further studies with larger number of iALS are required to confirm our statements. References Dal Bello-Haas V & Florence JM. (2013). *The Cochrane Collaboration*. 1,34 Contact alesandra.ferri@unimib.it

### PCOS AND MUSCLE STRENGTH: PRELIMINARY RESULTS IN NORMAL WEIGHT WOMEN

Donà, S.1, Bacchi, E.1, Moretta, R.1, Coratella, G.2, Flamigni, S.1, Livornese, D.1, Sacco, A.P.1, Tosi, F.1, Negri, C.1, Kaufman, J.M.3, Schena, F.2, Moghetti, P.1

*University of Verona*

Polycystic ovary syndrome (PCOS) is a very common endocrinopathy in reproductive-aged women, characterized by hyperandrogenism, chronic anovulation and polycystic ovaries on ultrasound. PCOS is also frequently associated with body fat excess and insulin resistance, factors that may limit physical performance. However, androgen excess could be an advantage, in these women, in terms of increased muscle strength and performance. To date, only few studies in overweight/obese women have addressed the possibility that PCOS may be associated with changes in muscle strength, with controversial results. The aim of this study was to assess muscle strength in a sample of normal weight PCOS women (to avoid the confounder effect of excess body fat) compared with healthy controls. Eight women with PCOS and 10 age- and BMI-matched healthy controls, with a similar level of habitual physical activity, were recruited. The strength of the knee extensor muscle of the dominant leg was assessed by isokinetic dynamometry at two different rates of execution (30°/s and 120°/s) in concentric and eccentric phase, whereas muscle architectural characteristics (thickness, fascicle length and pennation angle) were analyzed by ultrasound scan of the vastus lateralis muscle. Anthropometric and metabolic features, serum total and free testosterone levels (as measured by LC-MS/MS and equilibrium dialysis) were also assessed. As expected, testosterone levels were higher in PCOS women compared with controls, while no significant differences were observed in body composition and metabolic features between PCOS and controls. The PCOS group showed greater isokinetic muscle strength in concentric phase at slow rate of execution (30°/s) (difference between groups 17%,  $p=0.04$ ), whereas borderline differences were observed at higher rates of execution. No differences in

muscle architectural characteristics were found. In conclusion, this preliminary study suggests that women with PCOS have increased muscle strength. Further research should assess whether this phenomenon may be related to the effects of hyperandrogenemia on muscle fiber expression.

#### DIVING RESPONSE DURING DRY STATIC APNOEA: COMPARISON BETWEEN ELITE MALE AND FEMALE DIVERS

Magnani, S., Mulliri, G., Sainas, G., Ghiani, G., Pinna, V., Sanna, I., Marongiu, E., Crisafulli, A., Tocco, F.

*University of Cagliari*

Introduction Elite divers (ED) are able to maintain very long apnoeas through the diving response (DR), characterized by bradycardia, reduced cardiac output (CO), blood shift and increased mean blood pressure (MBP). This scenario has been well characterised and changes in heart rate (HR), stroke volume (SV), MBP and arterial oxygen saturation (SaO<sub>2</sub>) were described several times. However little attention has been put on the possible effect of gender on DR (Tocco et al., 2012; Cherouveim et al., 2013). We focused on the gender effect on hemodynamic changes during dry static apnoea. Methods 17 ED (9-M and 8-F) were tested in three conditions: A) 3 min resting with normal breathing, B) 140 s breath-hold in air and C) 1 min recovery. SV, HR, SV/ventricular ejection time ratio (SV/VET), SV/diastolic time ratio (SV/DT) and systemic vascular resistance (SVR) were assessed through impedance cardiography. A sphygmomanometer and a fingertip pulse oximeter were applied to detect MBP and SaO<sub>2</sub>. The mean value of each variable was calculated over 5 heart beats for every 20 s. To compare subjects with different gender, data were transformed into percentage changes from A. Results HR initially increased (+20%) and after started to decline until the end of apnoea (-20%), in both groups. SV firstly decreased (-30% in M and -50% in F) then returned to condition A. As consequence during the first 40 s of condition B a drop in CO, greater in F than M (-45% vs. -20%, p<0.05) took place. A similar time course was found for SV/VET (F -45% vs. M -24%, p<0.05). SV/DT values increased in M and decreased in F (+25% vs. -25%, p<0.05) and SVR rose with a marked gender effect (F +100% vs. M +30%, p<0.001). Finally, MBP raised until the 30% of A and SaO<sub>2</sub> dropped to 5% at the end of B condition in both groups. Conclusion Results show that overall the DR was similar in M and F but we first found that DR in F was more promptness in term of CO reduction and vasoconstriction response (i.e. SVR increase). We speculate that the elevation in intrathoracic pressure, which is observed when apnoea is sustained at large lung volumes (Ferretti, 2001; Novaliija et al., 2007) could be different between genders and it could be partially explain the present results. In our opinion the effect of gender on DR is little known and deserves further researches. References Ferretti G. #### IMPORTANCE OF ANTHROPOMETRIC, HAEMODYNAMIC AND RESPIRATORY PARAMETERS TO DETERMINE PERFORMANCE DURING BREATH-HOLD DIVING

Tocco, F., Magnani, S., Mulliri, G., Melis, F., Sainas, G., Ghiani, G., Pinna, V., Sanna, I., Marongiu, E., Crisafulli, A.

*Cagliari University*

Introduction Overall, elite divers' (ED) ability to sustain very long apnoeas depends on high pulmonary volumes and diving response (DR), which through cardiac output (CO) reduction and blood shift causes an oxygen sparing effect. We evaluated the correlation among several respiratory and hemodynamic parameters, measured during dry-apnoea performed in laboratory setting, and the performances reached during real breath-hold diving competition (AIDA World Team Championship 2014). Moreover, we sought for possible gender differences (Tocco et al., 2012; Cherouveim et al., 2013). Methods Breath-hold in air (BHA) was performed by 15 ED (7-M and 8-F). Before starting tests height and body mass were measured to determine the body surface area (BSA). Forced vital capacity (FVC) was assessed by the use of computer-based spirometer. CO was assessed by means of impedance cardiography and a standard sphygmomanometer was used to detect the blood pressure (BP). Thus, systemic vascular resistance (SVR) was obtained by dividing the mean BP (calculated as diastolic BP+1/3systolic BP-diastolic BP), by CO. Data were processed by non parametric statistics (Spearman test) to evaluate their correlation with the performances obtained in static (SA) and dynamic (DA) apnoeas and during constant weight diving (CWD). Results Significant correlation was found among BSA and the SA and DA performances ( $r_2=0.67$  and  $r_2=0.73$  respectively;  $p<0.05$ ) in males only. No correlation between CWD and any of the variables collected during BHA was demonstrated. Conclusion Results addressed to the hypothesis that divers' anthropometric characteristics more than promptness in term of CO reduction and vasoconstriction response were determinant in performing SA and DA. Besides, this was found in males only and confirmed previous remarks (Ferretti et al. 2012). The results of the present investigation suggest that our pre-competition evaluation tests were of limited use to predict racing outcome. #### THE EFFECTS OF HIGH INTENSITY PHYSICAL TRAINING ON ADIPOKINES OF MEN WITH METABOLIC SYNDROME

Santos, D.L., Vargas, L.S., Farinha, J.B., Benetti, C.B.

*Federal University of Santa Maria*

Introduction Metabolic Syndrome (MS) is characterized as a grouping of metabolic risk factors and a pro-inflammatory status, related to central adiposity and insulin-resistance. The adipokines secreted by the adipose tissue have an important role in the metabolic and inflammatory complications associated to SM and obesity (Ouchi et al., 2011). It is already well known that physical exercise has an important influence on MS risk factors and inflammatory profile, especially aerobic exercises (Colombo et al., 2013). Therefore, the aim of this study was to analyze the effects of 15 weeks of anaerobic high-intensity physical exercise on adipokines of men with MS. Methods The sample included 21 men aged between 40 and 66 years, diagnosed with MS according to NCEP/ATP-III (2001) parameters. They had anthropometric measures and blood sample collected before and after 15 weeks of physical training, that consisted in a high intensity

physical exercise protocol, 3 times a week, lasting approximately 1 hour, where muscle resistance exercises were performed (60 to 80% of maximal load). The statistical analyses used Student t test and Wilcoxon Rank Test. Results A decrease in body fat percentage ( $32.51 \pm 5.02$  to  $31.90 \pm 5.15$ ,  $p < 0.05$ ) and an increase in body lean mass percentage ( $64.12 \pm 4.73$  to  $64.68 \pm 4.87$ ,  $p < 0.05$ ) were observed. The physical training also diminished resistin ( $77.8 \pm 5.56$  vs  $58.57 \pm 8.11$  ng/mL,  $p < 0.001$ ), ghrelin ( $49.47 \pm 5.7$  vs  $7.45 \pm 40.23$  pg/mL,  $p < 0.001$ ) and leptin ( $140.57 \pm 7.76$  vs  $83.9 \pm 10.94$  ng/mL,  $p < 0.001$ ) levels, and increased adiponectin levels ( $39.09 \pm 6.41$  vs  $79.14 \pm 12.98$  ng/mL,  $p < 0.001$ ). Discussion It was observed that the high intensity exercise protocol increased lean body mass and decreased body fat, which may have caused the positive changes viewed in the adipokines towards an anti-inflammatory effect, since the adipose tissue produces these proteins. There is growing evidence that exercise exerts its beneficial effects partly through alterations in the adipokine profile, that is, exercise increases secretion of anti-inflammatory adipokines and reduces proinflammatory cytokines (Golbidi; Laher, 2014). Thus, it was concluded that a high intensity exercise protocol causes decreases in the pro inflammatory metabolic proteins, leptine, ghrelin and resistin, and decreases the levels of the anti-atherogenic protein, adiponectin, therefore, is an excellent treatment and prevention for MS. ### A COMPARATIVE STUDY OF LOW VOLUME HIGH INTENSITY INTERVAL TRAINING VERSUS MODERATE INTENSITY CONTINUOUS TRAINING FOR A RECREATIONALLY ACTIVE POPULATION

Hughes, B., Murphy, C., Collins, D.K.

*Institute Of Technology Tallaght*

Introduction High intensity interval training (HIIT) protocols have been shown to be effective at inducing physiological remodeling similar to continuous moderate intensity training despite reduced time commitment and relatively small total exercise volume (Gibala et al. 2008). Critical velocity is defined as peak power output, measured in Watts, maintained over a 1-minute period. The aim of the current study was to assess the effectiveness of an exercise protocol prescribed using the critical velocity model of HIIT compared to moderate intensity continuous training (MICT) on a recreationally active population. Methods Sixteen recreationally active men ( $n=16$ , age =  $29 \pm 7$ ) were allocated to HIIT ( $n=8$ ) or MICT ( $n=8$ ) group and undertook testing pre- and post-intervention which included anthropometric and maximal oxygen uptake (graded exercise test GXT) measurements. Participants in both groups undertook 6 sessions over a 2-week period no less than 24 hours apart. The HIIT protocol consisted of 6 bouts of 20 seconds at 170% of participant's critical velocity (determined from GXT) interspersed with 100 seconds of low intensity exercise at 50 Watts. Warm up and cool down exercises gave a total time commitment of 18 minutes. Workloads elicited 80-100% of maximum heart rate (HRmax). The MICT protocol consisted of 50 minutes of 40% of participant's critical velocity (determined from GXT), workloads elicited 65-75% of HRmax. Data is communicated as mean  $\pm$  SD. A paired t-test and one-way Anova was performed to assess the relative effectiveness of the different exercise regimes. Results The results show no significant changes across anthropometric data in the HIIT group for weight ( $89.3 \pm 9.4$  vs.  $88.8 \pm 8.9$  kg), BMI ( $28.5 \pm 3.7$  vs.  $28.3 \pm 3.5$ ) or body fat percentage (BF%) ( $24.2 \pm 8.9$  vs.  $24.0 \pm 4.8\%$ ). The MICT group showed a statistically significant change in weight ( $81.9 \pm 6.1$  vs.  $80.9 \pm 6.1$  kg;  $p=0.001$ ) and BMI ( $26 \pm 2.3$  vs.  $25.6 \pm 2.4$ ;  $p=0.023$ ), no substantive difference in BF% ( $20.1 \pm 4.0$  vs.  $20.2 \pm 4.4\%$ ) pre and post-intervention were observed. Statistically significant improvements in the  $VO_{2peak}$  for both HIIT ( $39 \pm 5.5$  vs.  $43 \pm 7.5$  ml.kg<sup>-1</sup>.min<sup>-1</sup>;  $p=0.04$ ) and MICT ( $44 \pm 5.5$  vs.  $47 \pm 7.5$  ml.kg<sup>-1</sup>.min<sup>-1</sup>;  $p=0.024$ ) groups were observed. The time to exhaustion (TTE) of the HIIT group ( $28 \pm 3.7$  vs.  $30 \pm 3.1$  mins;  $p=0.05$ ) showed a statistically significant improvement unlike the MICT group ( $27 \pm 3.7$  vs.  $28 \pm 3.9$  mins) who displayed only a modest improvement within the error limit. Discussion These findings provide a comparative insight into the relative merits of HIIT and MICT exercise regimes on a recreationally active population. While the HIIT group showed no significant improvements in weight, BMI or body fat composition, the improvements in  $VO_{2peak}$  and TTE indicate that HIIT offers a effective alternative to MICT for improving cardiorespiratory fitness. The marked decrease in time required for HIIT suggest that it could provide a attractive alternative to MICT when time is a limiting factor to exercise. ### PGC-1 $\alpha$ GENE EXPRESSION INDUCED BY INTERVAL EXERCISE AT LACTATE THRESHOLD

Ryo, A., Yasuki, H., Akira, K., Hiroaki, T.

*Fukuoka university*

Introduction Peroxisome proliferator-activated receptor gamma co-activator-1 alpha (PGC-1 $\alpha$ ) plays a key role as an activator of mitochondrial biogenesis. So, study of exercise protocol to induce the expression of PGC-1 $\alpha$  is important. Previous study demonstrated that PGC-1 $\alpha$  mRNA was increased by continuous exercise at intensity above the Lactate Threshold (Tobina et al., 2011). However little is known about the effect of interval exercise at lactate threshold intensity on PGC-1 $\alpha$  mRNA expression. Since lactate threshold intensity interval exercise is safe, practical and well tolerated by untrained individuals, it is important to determine whether lactate threshold intensity interval exercise induces PGC-1 $\alpha$  gene expression. Therefore, the purpose of this study is to examine whether lactate threshold intensity interval exercise induces PGC-1 $\alpha$  gene expression. Method Nine healthy subjects ( $28.6 \pm 14.1$  years,  $168.2 \pm 8.1$  cm,  $63.2 \pm 8.2$  kg,  $22.3 \pm 1.9$  kg m<sup>-2</sup>), Prior to this experiment, it was performed using a treadmill exercise test to determine the lactate threshold. They performed interval exercise at lactate threshold intensity. They repeated 40 jogging-walking sets on treadmill (jogging of 1min, and walking of 30sec). Muscle biopsy was taken from the vastus lateralis muscle under local anaesthesia before, and 3 hours after exercise. Blood lactate was measured before and after exercise. RPE was recorded every 10 sets were completed. Result PGC-1 $\alpha$  mRNA was increased 3 hours after exercise ( $2.78 \pm 1.80$  - fold,  $p < 0.05$ , respectively). Blood lactate was unchanged after exercise ( $1.2 \pm 0.5$  to  $1.3 \pm 0.5$ ,  $p = 0.09$ ). RPE was unchanged during exercise (10set :  $12 \pm 1$ , 20set :  $12 \pm 1$ , 30set :  $12 \pm 1$ , 40set :  $12 \pm 1$ ). These results indicate that PGC-1 $\alpha$  mRNA expression was induced by lactate threshold intensity interval exercise without elevation of blood lactate and RPE. Conclusions Lactate threshold intensity interval exercise can induce PGC-1 $\alpha$  mRNA expression. ## LARGER BETA SYNCHRONIZATION IN ELDERLY SUGGESTS BRAIN-RELATED ADAPTATIONS IN SELECTIVE INHIBITORY PROCESSES

Barral, J.I., Thut, G.2, Deiber, M.P.3,4, Sallard, E.1

*Institute of Sport Sciences*

1: GRISSUL (Lausanne, Switzerland), 2: Institute of Neuroscience and Psychology (Glasgow, United-Kingdom), 3: INSERM (La Tronche, France), 4: Clinical Neurophysiology and Neuroimaging Unit (Geneva, Switzerland). Introduction Recently, we distinguished concomitant post-movement beta synchronization (PMBS) related to sensory reafference and active inhibitory processes (respectively over the left and right hemispheres) after a selective stop of the left hand in young adults (Sallard et al., 2014). In elderly, the modulations of PMBS in relation to these two processes have not been investigated yet. Here, we compare the spatio-temporal brain modulations in a selective motor inhibition task between old and young adults. Methods Seventeen young ( $25 \pm 3$  years) and 13 old ( $67 \pm 4$  years) adults participated to the study. For each trial, the participants started with a simultaneous bimanual (BM) index fingers' tapping (2 Hz). At a first visual signal, they had either to prepare to selectively stop the left index while continuing the tapping with the right index (SWIT condition), or to maintain the BM tapping. They executed the required action after the imperative auditory stimulus. A time-frequency analysis was performed on each trial (epoch of interest:  $-2500/+2500$  ms time-locked on the imperative stimulus). The PMBS measures were obtained by averaging the energy across the beta band (14-30 Hz). We focused on the SWIT condition and compare time-frequency signals between young and old groups. In addition, we estimated electric sources using a distributed linear inverse solution based on a local autoregressive average (LAURA) regularization approach. Results Behavioral results showed that old adults significantly increase inter-tap variability and error rates at the switching. The EEG analyses revealed larger PMBS amplitude in the old compared to the young group from 1400 to 2500 ms after the imperative stimulus onset. Source estimation analyses showed larger PMBS amplitude within the bilateral frontal and parietal cortices in old adults. Solution points with maximal differences localized these effects within the left superior parietal lobule, left superior frontal gyrus and left precuneus. Discussion Our findings show 1) that the old participants encounter difficulties in selectively stop one hand while stabilizing the tapping of the other and 2) a larger fronto-parietal network in the elderly to perform the selective inhibition task. The late occurrence of that additional recruitment of brain areas might help the elderly to actively maintain the inhibition of the left hand and to prevent its re-initiation. These brain-related adaptations are discussed in terms of dedifferentiation/compensation processes. References Sallard E, Tallet J, Thut G, Deiber M-P, Barral J (2014). ## BLUNTED ANGIOGENESIS AND HYPERTROPHY ARE ASSOCIATED WITH INCREASED FATIGUE RESISTANCE AND UNCHANGED AEROBIC CAPACITY IN OLD OVERLOADED MOUSE MUSCLE

Ballak, S.B., Jaspers, R.T., Busé-Pot, T., Harding, P.J., Yap, M.H., Deldicque, L., de Haan, A., Degens, H.

*MMU Manchester*

Background: The hypertrophic response in old mouse and human muscle is attenuated (Ballak et al., 2015; Slivka et al., 2008). We hypothesise that 1. this is partly due to a reduced capillarisation and angiogenesis, which is 2. accompanied with a reduced oxidative capacity and fatigue resistance in old control and overloaded muscles, that 3. can be rescued by the anti-inflammatory anti-oxidant resveratrol. Methods: To investigate this, the hypertrophic response, capillarisation, oxidative capacity and fatigue resistance of m. plantaris were compared in adult 9- and 25-month-old non-treated and 25-month-old resveratrol-treated mice. Results: Capillarisation was not significantly affected by age. Overload increased the local capillary to fibre ratio more in adult than old muscle ( $P < 0.05$ ), indicating attenuated angiogenesis in old muscles. Although muscles of old mice had a higher succinate dehydrogenase (SDH) activity ( $P < 0.05$ ) and a slower fibre type profile ( $P < 0.05$ ), the isometric fatigue resistance was similar in 9- and 25-month-old mice. In both age-groups, the fatigue resistance was increased to the same extent after overload ( $P < 0.01$ ), despite unaltered SDH activity and attenuated angiogenesis. Interestingly, the SDH activity for a given fibre size was higher in overloaded than control muscles. Resveratrol supplementation had no significant effect on hypertrophy, capillarisation, or fatigue resistance. Conclusion: The attenuated angiogenesis during overload may contribute to the attenuated hypertrophic response in old age. Neither was rescued with resveratrol. The dissociation between changes in SDH activity and fatigue resistance with age and overload suggests that other factors than oxidative capacity and capillarisation are the prime determinants of fatigability determined in our test. s.b.ballak@vu.nl References: Ballak, S.B., Jaspers, R.T., Deldicque, L., Chalil, S., Peters, E.L., de Haan, A. and Degens, H., 2015. ## A COMPARISON OF ELASTIC BAND-BASED HIGH-SPEED POWER TRAINING AND TRADITIONAL LOW-SPEED STRENGTH TRAINING ON COGNITIVE FUNCTION, PHYSICAL PERFORMANCE AND MUSCLE STRENGTH IN OLDER WOMEN WITH MILD COGNIT

Yoon, D.H., Kim, H.J., Kang, D.H., Kim, J.S., Son, J.S., Song, W.

*SEOUL NATIONAL UNIVERSITY*

1. Introduction It is known that exercise increases muscular strength and functional ability. Particularly for older adults, one of the important roles of exercise is improving cognitive function. Many studies demonstrated the effect of various exercise, the effect of resistance training that had been emphasized to maintain and improve cognitive function among elderly. In this study, after the 12 weeks of HSPT with elastic band training, cognitive function, body composition, muscular strength, functional ability of older adults with MCI were measured to demonstrate the effectiveness of elastic band-based HSPT. 2. Method Fifty eight women aged over 65 years were recruited from silver academy college of Y church in Seoul, and only thirty participants met our criteria. Participants were randomly assigned into an elastic band-based high-speed power training (HSPT) group ( $n = 14$ , age =  $75.0 \pm 0.9$  y), a low-speed strength training (LSST) group ( $n = 9$ , age =  $76.0 \pm 1.3$  y), and a control group (balance and tone,  $n = 7$ , age =  $78.0 \pm 1.0$  y). Twelve weeks of one hour exercise program was provide twice a week for HSPT group, LSST group and CON group conducted balance and tone exercise for 12 weeks. 3. Results The result show significant increase in change rate of cognitive function, physical function, and muscle strength. For cognitive function, change rate of Mini Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA) showed significant increase in both HSPT and LSST compared to control group (MMSE: HSPT vs CON, 20.94 % vs -5.11 %,  $p < 0.05$ ; LSST vs CON, 13.83 % vs -5.11 %,  $p < 0.05$ , MoCA: HSPT vs CON, 30.40 % vs -2.70 %,  $p < 0.05$ ; LSST vs CON, 8.18 % vs -2.70 %,  $p < 0.05$ ). For the physical functions, change rate of SPPB scores increased significantly in HSPT and LSST compared to control group as well (HSPT vs CON, 48.74 % vs 9.37 %,  $p < 0.05$ ; MoCA: HSPT vs CON,

17.56 % vs 9.37 %,  $p < 0.05$ ). 4. Discussion In 12 weeks of elastic band-based training, HSPT showed a great improvement in older adults with MCI than LSST as similar to the results of previous studies (Henwood et al., 2008; Sayers and Gibson, 2010; Wallerstein et al., 2012) although both trainings were effective in improving cognitive function, physical function and muscle strength. Taken together, elastic band-based HSPT is more efficient and safer way to treat older adults with MCI than LSST. 5. Reference Henwood, T.R., Riek, S., Taaffe, D.R., 2008. ## Mini-Orals

### MO-PM20 Physiology: Muscle damage, Hypoxia

#### EFFECT OF 3 WEEKS COMBINED 'LIVE HIGH-TRAIN LOW' EXPOSURE WITH HEAT INTERVAL TRAINING IN TRAINED RUNNERS

McCleave, E.1,2, Slattery, K.M.2, Duffield, R.1, Saunders, P.3,4, Sharma, A.P.3, Garvican, L.3,4, Coutts, A.J.1

1: UTS (Sydney, Australia), 2: NSWIS (Sydney, Australia), 3: AIS (Canberra, Australia), 4: University of Canberra (Canberra, Australia).

**Introduction** Recent research has shown promising physiological and performance effects of living at altitude and training in the heat during short-term training camps in team sport athletes (Buchheit et al., 2013). Currently, no studies have confirmed these findings or extended this research to well-trained endurance athletes. The present study examined the performance and physiological adaptations to 21 days of high-intensity interval training in normobaric hypoxia 'live high-train low' (LHTL,  $\geq 12$  h/day at 3000m) combined with a hot environment (32°C, 55% RH), compared to training in a hot environment only or temperate conditions (14°C, 55% RH). **Methods** Twenty seven well-trained middle-distance runners (mean  $\pm$ SD; age 29.8  $\pm$ 6.9 y,  $\text{VO}_2\text{peak}$  64.2  $\pm$ 7.7 ml/kg/min) completed three weeks (12 sessions) of interval training in a matched group experimental design. Participants were assigned to one of three conditions: LHTL plus heat training (LHTL+HOT; n=10), heat training only (HOT; n=9) or living and training in temperate conditions (Control; n=8). Following the exposure period, all participants completed 3 weeks taper in temperate conditions. A 3-km time trial was completed prior to, immediately following the exposure period, and after the 3 weeks taper. Haemoglobin mass (Hbmass), and a heat response test (45min run at 65% $\dot{V}\text{O}_2\text{peak}$  + 30min seated rest; 32°C, 55%RH) were measured pre, immediately post, and one and three weeks into the taper. **Results** There were no differences in performance between any groups immediately following the 3 week exposure; however, performance improved in the HOT group (mean  $\pm$ 90%CL; -3.3 $\pm$ 1.3%) following the 3 week taper. Conversely, there were no taper-induced changes in performance in either the LHTL+HOT (-0.6 $\pm$ 1.4%) or Control (-0.2 $\pm$ 0.9%) groups. Hbmass increased during 3 week exposure period in LHTL+HOT (3.8 $\pm$ 1.8%) and remained elevated during the following 3 weeks. During the heat response test, heart rate was reduced during both exercise (-6.7 $\pm$ 1.7%) and recovery (-5.5 $\pm$ 2.1%) in the HOT group immediately following the exposure period, but returned to baseline by the end of the 3 week taper. **Discussion** Three weeks of interval training in the heat improved 3km run time-trial performance. The addition of LHTL to the heat training enhanced haematological adaptations, but did not improve 3km time-trial performance. The lack of performance improvement contrasts with findings by Buchheit et al. (2013), though these team sport athletes were of lower starting training status than the present athletes. Future studies should examine the factors that might determine physiological and performance adaptations to training camps in heat and/or hypoxic conditions. **References** Buchheit M, et al (2013) *Br J Sports Med* 47 Suppl 1: p. 159-69. #### METABOLIC RESPONSES TO ACUTE HYPOXIA AND MODERATE INTENSITY NORMOXIC EXERCISE IN HUMANS

Duncan, B.1, Richardson, A.J.1, Watt, P.1

University of Brighton

1. Centre for Sport Exercise Science and Medicine. University of Brighton, UK. **Introduction:** Acute exposure to hypoxic conditions at rest can alter metabolism and fuel oxidation in humans. Specifically increases in metabolic rate and greater fat oxidation immediately post exposure has been reported (Workman & Basset, 2012). These findings highlight hypoxic induced alterations that may have important implications for weight loss strategies. The primary aims of this investigation were to; characterise the metabolic response of an acute hypoxic exposure at rest following the ingestion of a high lipid drink, and to; assess the response of an acute hypoxic exposure at rest coupled with a post exposure moderate intensity exercise bout in normoxic conditions. **Methods:** Eight individuals (7 males, 1 female; age, 22  $\pm$  5 yr; BMI 24  $\pm$  4 kg/m<sup>2</sup>) participated in all trials. Participants consumed a high lipid drink prior to 60 minutes of normoxic (NORM) or hypoxic (HYP) rest on separate occasions. Following the rest period participants undertook 60 minutes of moderate intensity cycling exercise at 60% heart rate reserve in normoxic conditions (NORM EX & HYP EX). Measures of metabolic rate, fuel oxidation and blood lipid measures were assessed for a period of 240 minutes. A control trial (CON) was undertaken during which participants consumed a high lipid drink and rested for 240 minutes in normoxic conditions. **Results:** Acute hypoxic exposure induced significant increases in energy expenditure (+ 22  $\pm$  11 kcal.hr<sup>-1</sup>) ( $p \leq 0.05$ ) and CHO oxidation (+ 0.17g.min<sup>-1</sup>) ( $p \leq 0.05$ ) compared to normoxia during 60 minutes of rest. Pre exercise hypoxic rest did not alter metabolic rate (7.01  $\pm$  3.61 & 8.2  $\pm$  3.03 kcal.min<sup>-1</sup>) and fuel oxidation (0.99  $\pm$  0.57 g.min<sup>-1</sup> & 1.01  $\pm$  0.72 g.min<sup>-1</sup>) during moderate intensity exercise in normoxic conditions compared to rest in normoxia prior to exercise. Measures of free fatty acids (+ 0.18  $\pm$  0.06 mmol/L & +0.27  $\pm$  0.19 mmol/L) and triglycerides (+ 0.11  $\pm$  0.20 mg.dL<sup>-1</sup> & +0.10  $\pm$  0.18 mg.dL<sup>-1</sup>) increased over time in NORM EX and HYP EX ( $p \leq 0.05$ ) yet did not differ between conditions ( $p > 0.05$ ) throughout the experiment. **Conclusions:** An acute hypoxic exposure was sufficient in inducing increases in metabolic rate through greater CHO oxidation at rest. The consumption of a high lipid meal prior to exposure did not alter this hypoxic induced effect. Greater fat oxidation and increased metabolic rate following an acute hypoxic exposure did not occur during moderate intensity exercise as it has been shown to do during post hypoxic rest (Workman & Basset, 2012) most likely due to the intensity of exercise and length of hypoxic exposure. Email: bd27@uni.brighton.ac.uk **References:** Workman, C., & Basset, F. a. (2012). Post-metabolic response to passive normobaric hypoxic exposure in sedentary overweight males: a pilot study. *Nutrition & Metabolism*, 9(1), 103.

## THE RELATIONSHIP BETWEEN CHANGES IN BRACHIAL-ANKLE PULSE WAVE VELOCITY AND BLOOD PRESSURE AFTER SHORT-TERM HYPOBARIC HYPOXIC TRAINING

Ogita, F.1, Yotani, K.1, Taguchi, N.1, Tamaki, H.2

1:National Institute of Fitness and Sports (Kanoya, JAPAN), 2:Niigata University of Health and Welfare (Niigata, JAPAN)

**Introduction** Recently, we have observed that hypobaric hypoxic exercise could induce more beneficial vasculature adaptations, such as a decrease in brachial-ankle pulse wave velocity (baPWV), which is an index of arterial stiffness, and in blood pressure especially during exercise within relatively short training period even in healthy young subjects (Ogita 2011, 2013). Furthermore, it seems that there are large individual differences in changes in these variables induced by training. However, it has not been clarified what influences on the individual differences. Therefore, present study aimed to examine whether the changes in baPWV after short-term hypobaric hypoxic training are related to initial (pre-training) level, and also are associated with the changes in blood pressure at rest. **Methods** The subjects were 41 healthy male adults (22±2 yrs). They had a 30 min aquatic exercise at the intensity of around 50%VO<sub>2</sub>max for 5 consecutive days or 4 of 5 days under hypobaric hypoxic conditions corresponding to 2000m above sea level. Before and after the training, systolic (SBP), diastolic (DBP) and mean blood pressure (MBP) at rest and baPWV were determined. All post-training tests were accomplished over 2nd to 3rd day after their last exercise session. **Results** After the training, baPWV significantly decreased, which means that arterial stiffness improves within relatively short period (5 days). A negative correlation was found between baPWV at baseline and changes in baPWV after the training. Also, SBP, DBP and MBP at baseline were significantly correlated to baPWV, respectively. However, all of SBP, DBP, and MBP showed a tendency to decrease, but it was not statistically significant. Consequently, no significant correlations were found between changes in baPWV and blood pressure at baseline or changes in blood pressure (i.e. all of SBP, DBP, and MBP). **Discussion/Conclusion** These findings suggest that short-term hypobaric hypoxic training improves baPWV as an index of arterial stiffness and that changes in baPWV after the training depends on baPWV at baseline in healthy men, but are not related to resting blood pressure at baseline or to changes in blood pressure after the training. **Reference** Ogita, F., Kurobe, Z., Huang, G., Ozawa, A., Nagira, M., Nishiwaki, T., Tanaka, H., Tamaki, H., Takekura. ## REACTIVE OXYGEN SPECIES AND DNA INTEGRITY IN SOME IRAQ ATHLETICS FEMALE

Fathi, R., Ali, P.

Baghdad University College of Physical Education

Do notEffect of physical exercises on human health depends on the time and the hardness of the exercises. This effect could improve the health of the athletics by decreasing the risk of mortality, and increase the fitness compared to no fitness for low exercise practicing. During the exercises, the metabolism rate increases greatly, as quantified by oxygen consumption and heat production, which enhanced generation of reactive oxygen species (ROS). ROS describe both oxygen-centered free radical, and reactive non-radical derivatives oxygen. To overcome the misunderstanding on the role of ROS on cell damaging, we studied the effect of exercises on the integrity of the DNA of female from the Iraqi team for bicycles. The studied (12) subjects were divided to two groups, Group one (6 female) from Iraqi team for bicycle, group two (6 female) un-athletics as control with mean age ( 22.5 ±1.48) for both groups, The two group were sex and age matched. DNA samples were extracted from the blood of the both groups by using mini-prep kit (Promega), while Malodialdehyde levels were measured by using colorimetric method. Results revealed an effect of ROS on the integrity of the DNA associated with an insignificant increment of Malodialdehyde levels in the athletic group as compared to control. As a conclusion, to decrease the effect of ROS on the integrity of DNA the time and the hardness of the exercises must be set carefully and there nutrition must be healthy. insert authors here

## MAXIMAL LACTATE STEADY STATE DURING STEP TESTING IN NORMOXIA AND ACUTE NORMOBARIC HYPOXIA

Fisch, M., Platen, P.

Ruhr University Bochum

**Introduction:** The step test (ST) is frequently applied in performance diagnosis and might be used for testing during mountaineering. Further, analysis of blood lactate (La) during exercise, the determination of the maximal lactate steady state concentration (MLSS) and the corresponding workload at defined La concentrations (like 4-mmol/l) (Heck et al. 1985) are widely used since many years. MLSS, however, has not been determined during ST in normoxia (NN) and hypoxia so far. The aims of this study were 1) to determine MLSS during several constant load step tests in NN and in two hypoxic conditions (15%O<sub>2</sub> and 17%O<sub>2</sub>, respectively (NH15, NH17)), and 2) to analyse the validity of the determination of the corresponding work load (step frequency (SF)) at MLSS (SF-MLSS) from one single incremental ST at NN and altitude. **Methods:** 12 subjects (4f, 8m, 22.5±2.6yrs, 172.0±10.9cm, 69.1±12.2kg) performed an incremental ST (SF: 66, 84, 102, 114, 132, 144 bpm, 5 min duration/SF, 1 min rest between SFs) until exhaustion in NN, NH17, and NH15, respectively, with determination of La at the end of each SF. Thereafter, n=3 to 5 30-minute constant-load ST for the determination of MLSS and the corresponding SF-MLSS were performed at each altitude, starting with the respective SF corresponding to 4 mmol/l La concentration during incremental step test and then either increasing or reducing workload of each 30-min constant-load test by 3 bpm until MLSS was clearly defined (e.g.: La did not increase any more than 1 mmol/l during the last 20 min). Parameters included maximum values of SF (SFmax), La (Lamax), heart rate (HRmax), V'O<sub>2</sub>peak, and RERmax and the respective values at MLSS. **Results:** SFmax, Lamax, V'O<sub>2</sub>peak, Hfmax and RERmax did not differ between NN, NH17 and NH15 (data not shown). MLSS was significantly higher in NH15 compared to NH17 and NN (MLSS: NN: 3.63±0.94; NH17: 4.06±0.85; NH15: 5.01±1.06 [mmol/l]). SF-MLSS was significantly reduced in NH15 compared to NH17 and NN (SF-MLSS: NN: 110.3±12.1; NH17: 107.6±13.5; NH15: 102.2±11.5 [bpm]). HR-MLSS, VO<sub>2</sub>-MLSS, and RER-MLSS were unaffected by altitude (data not shown). Step frequency at MLSS determined by constant-load stepping correlated significantly with step frequency corresponding to 4 mmol/l lactate concentration during incremental step test at both altitude conditions, but not at NN (NN: r=0.32, NH17: r=0.82, NH15: r=0.79). **Discussion:** MLSS might be determined by means of incremental ST at moderate to high altitude, and ST might be used for performance diagnosis under field conditions in the mountains. Alterations in La metabolism at altitude, however, have to be taken into account. **References:** Heck, H.; Mader, A.; Hess, G.; Mücke, S.; Müller, R.; Hollmann, W. (1985): Justification of the 4-mmol/l lactate threshold. Int J Sports Med 6 (3), S. 117–130.

**NO EFFECT OF DIETARY NITRATE ON THE HUMAN DIVING RESPONSE IN DRY AND WET APNEAS**

Johansson, H.1, Engan, H.K.1,2, Melin, M.1, Patrician, A.1, Lodin-Sundström, A.1, Schagatay, E.1,3

1:Environmental Physiology Group, Mid Sweden University, Sweden. 2:LHL-Klinikkene Røros, LHL Health, Norway. 3: Swedish Winter Sports Research Centre, Mid Sweden University, Sweden.

**Introduction** Ingestion of dietary nitrate has been shown to increase dry apnea duration (Engan et al., 2012; Collofello et al., 2014) and reduce arterial oxygen saturation (SaO<sub>2</sub>) during fixed duration apneas, but conflicting results have been presented with wet apneas (Schiffer et al., 2014) and the underlying mechanisms have not been identified. Dietary nitrate might influence the oxygen conserving diving response. The aim of this study was to determine the effect of dietary nitrate on the diving response during apnea and simulated diving by facial immersion (wet apneas; WA). **Methods** Five men and three women aged 27 (9.5) years consumed on separate days either concentrated beetroot (BR; 5 mmol NO<sub>3</sub><sup>-</sup>) or placebo (P; 0.03 mmol NO<sub>3</sub><sup>-</sup>) juice ~2.5 hours before tests in a weighted order. Subjects performed apneas (A) and apneas with face immersion in 15 °C water (WA), of equal duration during prone rest. HR, SaO<sub>2</sub>, skin blood flow and mean arterial blood pressure were measured continuously across the tests. Results Baseline HR (BR: 71±17 bpm and PL at 74±15 bpm; NS) and skin blood flow (BR: 5.6±5.9 p.u and PL at 5.0±5.1 p.u) were similar between BR and PL (NS), while MAP was reduced with BR at 72±11 mmHg compared to PL at 98±5 mmHg (P<0.05). During A and WA, the HR reduction from baseline, characterizing the diving response, was present with both BR and PL. The HR reduction tended to be enhanced with WA in both BR and PL conditions. The magnitude of the HR reduction during A compared to WA was not different between BR and PL (p=0.58). Skin blood flow was reduced in a similar way during A and WA in both BR and PL conditions. The SaO<sub>2</sub> reduction from baseline tended to be less pronounced with WA compared to A in BR (1.3±2.0 %; P= 0.08) while it was not different between WA and A in PL (0.49±2.0 %; P=0.48). The magnitude of SaO<sub>2</sub> reduction during A compared to WA was not different between BR and PL (P=0.36). **Conclusion** BR has no effect on the oxygen conserving diving response in dry or wet apneas. Such an effect can thus not explain the conflicting results concerning arterial oxygen saturation and apneic duration in previous studies. **References** Collofello B., et al. 2014. **Mini-Orals****MO-PM22 Physiology: Cardiovascular physiology****EFFECT OF AGE ON BLOOD FLOW KINETICS DURING PLANTAR FLEXION EXERCISE**

Askew, C.D., Druce, P., Meneses, A., Russell, F.D.

*University of the Sunshine Coast*

**Introduction** The increase in leg blood flow during exercise is attenuated in older adults, particularly at a given relative intensity. At absolute exercise intensities, the ageing effect is less evident with no apparent difference in steady state blood flow (I). The extent to which ageing influences blood flow kinetics during exercise is unclear. Therefore, the aim of this study was to compare the magnitude and kinetic parameters of the leg blood flow response, between younger and older adults, during plantar flexion exercise at the same absolute intensity. **Methods** Younger (Y: age 25±3 y, n=11) and older (O: age 68±5 y, n=11) participants underwent measures of supine resting leg blood flow and post-occlusive reactive hyperaemia using venous occlusion plethysmography (VOP). Participants then completed 2 x 5min bouts of intermittent plantar flexion exercise, 7 days apart, with their dominant leg while seated in an isometric dynamometer. Each bout included 60 contractions that were 2s and separated by 3s rest. Contraction intensity was 500N. Mean arterial blood pressure (MAP) was monitored at the finger. Leg blood flow was measured during the rest periods following each contraction using VOP, which required a thigh cuff (30mmHg) to be maintained throughout each bout. Blood flow data for the two trials were averaged and fitted to a triphasic model to determine the kinetic parameters of the exercise response. Results There were no differences between age groups for resting leg blood flow (O: 3.54±1.65; Y: 2.78±0.72 ml/100ml/min) or reactive hyperaemia (O: 15.05±8.21; Y: 17.03±5.37 ml/100ml/min). MAP was higher in older (98±10) compared with younger participants (80±6 mmHg) at rest, and throughout exercise. Blood flow magnitude (~45 ml/100ml/min) was not different between groups during exercise. Amplitude of the first phase of the exercise blood flow response tended to be smaller in the older (22.08±7.06) compared with younger group (29.03±9.99 ml/100ml/min, p=0.08); second phase amplitude was larger in older (15.91±5.25) than in younger (9.40±4.83 ml/100ml/min, p=0.008); and there tended to be a larger third (slow) phase amplitude in older (12.62±2.85) than in younger participants (5.13±2.84 ml/100ml/min, p=0.13). Time-delays and rate constants for each phase were not different between age groups. **Conclusion** Despite there being no difference in the magnitude of the rise in blood flow during exercise at a given absolute intensity, the kinetics of the blood flow response tended to be slower in older adults, with a smaller initial rise in blood flow (non-sig) at the onset of exercise that was offset by larger later-phase amplitudes. **Reference:** 1. **THE EFFECTS OF CONTINUOUS AND INTERVAL AEROBIC EXERCISE ON BLOOD PRESSURE**

Hoseinzadeh Gonabadi, A., Maghamnia, Z., Daryanoush, F.

*Sama Technical and Vocational Training College, Azad University, Shiraz Branch*

**Introduction** Exercise and physical activity are one of the non-drug methods which are effective on the reduction of the blood pressure. The present study was aimed to compare the effect of continuous and interval aerobic exercise on blood pressure in hypertensive middle-aged women. **Methods** Twenty hypertensive women volunteered to participate in this quasi-experimental study. Having filled the questionnaire, the subjects were randomly divided into two groups of continuous aerobic exercise (n=10, age: 58.1, ±1.94, wt: 72.93±3.56) and interval aerobic exercise (n=10, age: 56.4±2.5, wt:70±5.39). The continuous aerobic exercise group performed aerobic exercise training at the intensity of 60% of their maximum heart rate. The interval aerobic exercise group performed its variable-intensity activities including 2 minutes of cycling with the intensity of 50% and 1 minute with the intensity of 70% of their maximum heart rate. Heart rate and systolic and diastolic blood pressure were measured before and after the training every 30 minutes for 10 hours. **Results** The

results of the study revealed that one session of continuous and interval aerobic exercise has no significant effect on the mean arterial blood pressure (MAP) of middle-aged women. Discussion Although one session of continuous and interval aerobic exercise had no significant effect on the mean arterial blood pressure (MAP) of middle-aged women, the decrease of mean arterial pressure lasted for 10 hours and the reduction was more in the continuous aerobic exercise group. This shows that the aerobic exercise especially the continuous one helps reduce blood pressure of hypertensive patients for some hours following the exercise. References Rahimian, Z., R. Hosseini, J. ## ASSESSMENT OF CARDIOVASCULAR ADJUSTMENTS DURING MOTORCYCLE RIDING

Pinna, V., Sanna, I., Mulliri, G., Roberto, S., Olla, S., Milia, R., Crisafulli, A.

*University of Cagliari*

Introduction Hemodynamic parameters, such as Cardiac Output (CO) and Stroke Volume (SV), have never been studied in motorcycle racing. This because the measurement of these variables is hampered by difficulties related to the particular environment of motorcycle performance, which can be considered an extreme condition. Moreover, these parameters need the availability of a non-invasive and reliable portable cardiovascular measurement systems. Indeed, the only data available are about Heart Rate (HR), which increases to 90-95% of maximum, despite the supposed low energy requirements of motorcycle riding (Kontinen T. et al. 2007; D'Artibale E. et al. 2007). The aim of this study was to measure hemodynamics of enduro- motorcycling pilots during real motorcycle race by means of portable impedance cardiograph. Methods Seven male elite motorcycle riders performing regional and national competitions on enduro motorcycles were studied. Hemodynamics was assessed by means of a portable impedance cardiograph (New Core, 2C Technologies Inc., Cagliari, Italy, Tocco et al. 2013). Data were collected at rest, throughout 10 minutes of motorcycle race at maximum speed possible. Results The comparison between rest and exercise showed a significant increase in hemodynamic parameters. In detail, increments in both HR ( $159.8 \pm 6.2$  vs  $94.8 \pm 14.8$  at rest,  $p < 0.05$ ) and SV ( $79.2 \pm 16.8$  vs  $62.1 \pm 10.1$  at rest  $p < 0.05$ ) were observed, thereby leading to a CO elevation ( $12.7 \pm 2.9$  L/min vs  $5.8 \pm 1.02$  L/min at rest,  $p < 0.05$ ). Conclusions Data obtained show that enduro motorcycle riding leads to significant increments in both HR and SV. While the former fact was already known, the latter is a new finding of the present investigation. The significant SV response can be the consequence of a substantial increase in cardiac contractility which can be ascribed to a sympathetic activation, as testified by the contemporary increase in HR. It is possible to speculate that the heavy muscular work of the upper and lower limbs activates the exercise pressor reflex, thereby causing sympathetic activation. ## EFFECTS OF MENSTRUAL CYCLE PHASE ON THE DYNAMICS OF CARDIOVASCULAR CONTROL DURING AN INCREMENTAL STRESS-TEST TO VOLITIONAL EXHAUSTION

Merzbach, V.1, Scruton, A.1, Barnes, R.2, Baker, J.1, Johnstone, J.1, Gordon, D.1

*1Anglia Ruskin University, 2University of Cambridge*

Introduction During incremental exercise to  $VO_{2max}$ ,  $O_2$  delivery is expressed through cardiac output (Q), (a function of stroke volume (SV) and heart rate (HR)) and capacity to extract oxygen at the muscle,  $a-vO_{2dif}$ .  $VO_{2max}$  is associated with the attainment of  $Q_{max}$  and  $a-vO_{2difmax}$ , yet SV response is less clear. How SV responds in female participants is unclear, with limited data reflecting menstrual function and cardiovascular control. Therefore the purpose of this study was to examine the effects of menstrual cycle phase on cardiovascular control during a  $VO_{2max}$  test. Method 15 physically active participants of which  $n=9$  formed the non-oral contraceptive group (n-OC) (age  $20.6 \pm 1.6$ yr, height  $169.9 \pm 6.4$ cm, mass  $68.7 \pm 7.9$ kg) who displayed regular menstrual function. Remaining 6 participants formed the oral-contraceptive control group (OC) (age  $21.7$ yr  $\pm 2.1$ , height  $168.1 \pm 6.8$ cm, mass  $61.6 \pm 6.8$ kg). All reported to the laboratory on 5 separate occasions for the determination of  $VO_{2max}$ . All trials completed on an electronically braked cycle ergometer (60-80 rpm) with work-rate increasing by  $0.42$  W/s. Cardiovascular responses were recorded using impedance cardiography with parameter variations analysed and compared with those measured during the calibration procedure. Four of the visits corresponded to menstruation (MEN), mid-follicular (mFOL), mid-luteal (mLUT) and immediately pre-menstrual (pMEN), with the 5th a familiarization trial. For OC, all trials were completed according to a pseudo menstrual cycle. Also recorded for the n-OC were progesterone and  $17\beta$ -oestradiol. Results Significant differences were found for Q between OC and n-OC during MEN at 30% ( $P=0.047$ ), 70% ( $P=0.048$ ) and 100%  $VO_{2max}$  ( $P=0.036$ ), with a significant difference also observed for  $Q_{max}$  ( $P=0.01$ ) between OC ( $16.5 \pm 1.5$  l/min) and n-OC ( $20.3 \pm 3.3$  l/min). Additionally significant differences were identified during MEN for  $a-vO_{2dif}$  between OC and n-OC at 100%  $VO_{2max}$  ( $P=0.04$ ), with a further significant difference observed for  $a-vO_{2difmax}$  for OC ( $0.16 \pm 0.02$ ml) and n-OC ( $0.13 \pm 0.01$ ml) and  $SV_{max}$  OC ( $96.7 \pm 11.2$ ml), n-OC ( $116.3 \pm 19.7$ ml) ( $P=0.03$ ). Discussion Irrespective of phase both n-OC and OC exhibited typical responses for both SV and  $a-vO_{2dif}$  levelling out at 40% and 80%  $VO_{2max}$  respectively. Lack of difference between groups and phases for SV, Q and  $a-vO_{2dif}$  suggests that although oestrogen is implicated in cardio-protection it does not affect cardiovascular control. The significant difference in MEN for Q and  $a-vO_{2dif}$  deserves further investigation and may be associated with blood volume. viviane.merzbach@anglia.ac.uk

## EFFECT OF LIFESTYLE MODIFICATION ON PULSE PRESSURE AMPLIFICATION IN OVERWEIGHT AND OBESE MEN

Yoshikawa, T.1, Zempo-miyaki, A.2, Kumagai, H.1, Tsujimoto, T.1, So, R.1, Tanaka, K.1, Maeda, S.1

*1: University of Tsukuba (Ibaraki, Japan), 2: Ryutsu Keizai University (Ibaraki, Japan)*

Introduction: Recently, it has been demonstrated that central to peripheral pulse pressure amplification (PPA) is more relevant for predicting cardiovascular disease than the traditional risk factors (i.e., blood pressure) (Benetos et al., 2010). In obese individuals, PPA is low as compared with age-matched normal weight counterparts (Pierce et al., 2013). However, it is unclear that the effect of lifestyle modification on PPA in overweight and obese individuals. The purpose of this study was to investigate whether lifestyle modification increases PPA in

overweight and obese men. Methods: Thirty-three overweight and obese men (age:  $51 \pm 1$  years, BMI:  $28.5 \pm 0.3$  kg/m<sup>2</sup>) completed a 12-week lifestyle modification program, combining regular aerobic exercise and dietary modification. Before and after the program, we measured anthropometric variables, aortic and femoral pulse pressure and PPA. PPA was calculated as percentage ratio of the femoral pulse pressure to the aortic pulse pressure. Results: The 12-week lifestyle modification led to marked weight loss (from  $82 \pm 1$  to  $70 \pm 1$  kg,  $P < 0.001$ ). After the program, aortic pulse pressure decreased significantly (from  $43 \pm 1$  to  $39 \pm 1$  mmHg,  $P = 0.001$ ), while femoral pulse pressure remained unchanged (from  $49 \pm 1$  to  $46 \pm 1$  mmHg,  $P = 0.060$ ). PPA significantly increased after the program (from  $115 \pm 2$  to  $120 \pm 1$  %,  $P < 0.001$ ). There was no significant correlation between changes in weight and those in PPA ( $r_s = 0.026$ ,  $P = 0.886$ ). Discussion: We demonstrated for the first time that the 12-week lifestyle modification increases PPA in overweight and obese men. Although lifestyle modification caused marked weight loss (approximately 15 %), changes in weight did not correlate with those in PPA, indicating that weight loss is not a direct mechanism underlying lifestyle modification-induced increases in PPA. Further investigations are needed to clarify the mechanisms underlying lifestyle modification-induced increases in PPA in overweight and obese men. References: Benetos A, Thomas F, Joly L, et al. ## HEART RATE VARIABILITY: CONVENIENCE, MEASUREMENTS AND MONITORING. REVIEW ARTICLE

Gene-Sanahuja, P.

*Catalonian High Performance Rowing Center, Banyoles, Spain.*

Heart Rate Variability: convenience, measurements and monitoring a review. Pol Gene-Sanahuja1. 1Catalonian High Performance Rowing Center, Banyoles, Spain. Autonomous Nervous System (ANS) balances actions of the sympathetic nervous system (SNS) and parasympathetic nervous system (PNS). At vagal state, stimulations are provided through the SNP, while in an anxiety stress or active state, the stimulation of the SNS is higher1. Increasing SNS or diminished PNS results in cardio-acceleration, conversely, lower SNS or higher PNS activity causes cardio-deceleration2, the connexion of both, controls the heart rate (HR)3. Scheduled exercise induces stress to athlete with an over-reaching response after an appropriate recovery providing gains in performance, as described by the super-compensatory theory4. Consequently the use of heart rate variability (HRV) to indirectly detect ANS status in response to training is in continues to grow5,6 evaluating training efficacy, recovery status, load impact, over training and illness or injury7. A growing body of evidence supports the utility of HRV's as good instrument to predict physical performance in athletes, further changes in vagal-derived indices of HRV have been suggested to indicate negative and positive adaptations to endurance training regimens5,6. Consequently, some parameters have been studied from unsatisfactory recovery procedure and fitness performance, giving an individualized recovery-stress index to athletes. HR monitors, specifically designed systems or smart phone applications give an easier way to assess HRV collecting beat-by-beat time, known as RR interval. So far, spectral and time interpretations were used to assess ANS responses7, but a main reliable value still undefined, the aim of this review was to define which are the more important HRV parameters and how to monitor them in the sport specific field using new technology instruments. #### MODERATE EXERCISE IMPROVES COGNITIVE FUNCTION EVEN UNDER SEVERE HYPOXIA

Komiyama, T.1, Katayama, K.2, Ito, Y.2, Sudo, M.3, Ishida, K.2, Higaki, Y.1, Ando, S.4

1: Fukuoka Univ. (Fukuoka, Japan), 2: Nagoya Univ. (Nagoya, Japan) 3: Meiji Yasuda Life Foundation of Health and Welfare. (Tokyo, Japan) 4: The University of Electro-Communications. (Tokyo, Japan)

Introduction It is well known that acute moderate exercise improves cognitive function. Recently, we demonstrated that moderate exercise improved cognitive function under moderate hypoxia (FIO<sub>2</sub>: 0.15) (Komiyama et al., 2015). In contrast, severe hypoxia obviously produces physiological disorders because of reduction in available oxygen. Hence, severe hypoxia may impair cognitive function. However, it is unclear how moderate exercise affects cognitive function under severe hypoxia. The purpose of this study was to determine the effects of acute exercise under severe hypoxia on cognitive function. Methods Eight subjects completed two trials under either normoxia or severe hypoxia (FIO<sub>2</sub>: 0.12~0.13) on a different days. They undertook preliminary test to assess peak oxygen uptake (VO<sub>2peak</sub>) by a cycle ergometer under both normoxia and hypoxia, respectively. At the beginning of the experiment, the subjects performed the cognitive task at rest. Then, after a 5 min warm-up (30%VO<sub>2peak</sub>), they cycled the ergometer at moderate intensity (50%VO<sub>2peak</sub>) for 15 min. Cognitive tasks were started 5 min after the start of exercise at moderate intensity. Cognitive task consisted of Spatial Delayed Response task and GO/NOGO task, which required working memory and executive function. Cognitive performance was assessed by speed of response (reaction time) and accuracy. Cerebral oxygenation was assessed by near infrared spectroscopy. Pulse oximetry saturation (SpO<sub>2</sub>) and cerebral oxygenation were monitored throughout the experiment. Results SpO<sub>2</sub> and cerebral oxygenation were significantly lower under hypoxia than normoxia ( $p < 0.01$ ). Moreover, exercise significantly decreased SpO<sub>2</sub> and cerebral oxygenation under hypoxia relative to normoxia ( $p < 0.01$ ). However, reaction time in the cognitive task decreased during exercise as compared with rest under both conditions ( $p < 0.01$ ). The degree of decrease in reaction time was not different between normoxia and hypoxia. Neither exercise nor hypoxia altered the accuracy in the cognitive task. Discussion Severe hypoxia substantially induced lower available oxygen during exercise than normoxia. Nevertheless, cognitive function improved during exercise relative to rest under hypoxia as well as normoxia. Thus, acute moderate exercise has the beneficial effect on cognitive function even if decreased oxygen availability in the brain. We conclude that moderate exercise improves cognitive function even under severe hypoxia. References Komiyama T, Sudo M, Higaki Y, Kiyonaga A, Tanaka H, Ando S. **TOTAL PEPTIDE YY CONCENTRATIONS FOLLOWING SHORT TERM CONSUMPTION OF VEGETARIAN DIETS**

Silalertdetkul, S., Pholpramool, C.

*Srinakharinwirot University*

Introduction Body fat, cholesterol and oxidative stress decrease following long term of vegetarian diets (Kim et al., 2012). Circulating of leptin concentrations in non-vegetarians were higher than vegetarians (Ambrosziewicz et al., 2004). However, the impact of vegetarian intake on appetite is still unclear whether short-term consumption of vegetarian diets has impact on satiety hormone like peptide YY (PYY) concentrations. Therefore, the objective of this study was to investigate the effect vegetarian diets on total PYY concentrations. Methods Fifteen males age between 19 and 21 years participated in this study, which had been approved by the local ethics committees (body mass index,  $23 \pm 2$  kg/m<sup>2</sup>; percent body fat,  $12 \pm 4$  %; percent fat free mass,  $88 \pm 4$  %; resting heart rate,  $62 \pm 11$  beat/min; systolic /diastolic blood pressure,  $122 \pm 7/68 \pm 9$  mmHg; maximum oxygen consumption,  $58 \pm 7$  ml/kg/min: mean  $\pm$  SD). This is a randomized cross-over design with two main trials separated by at least 14 days. Participants were asked to consumption either normal or vegetarian diets for ten days. Subjective feeling of hunger and fullness were measured before and after either normal or vegetarian diets. Fasting total PYY, glucose and lipid profile concentrations were assessed at the same period of time. The data were analyzed using two way repeated measures ANOVA and paired t-test. Results There was no change in circulating plasma total PYY, glucose, high density lipoprotein concentrations, body weight, body fat and subjective feeling of hunger and fullness following consumption of vegetarian diets. However, cholesterol (before:  $178 \pm 27$ ; after:  $154 \pm 28$  mg/dL,  $P = 0.04$ ) and low density lipoprotein (before:  $119 \pm 21$ ; after:  $100 \pm 24$  mg/dL,  $P = 0.02$ ) were decreased significantly following consumption of vegetarian diet. Discussion Consumption of vegetarian diet for ten days induced decreased in cholesterol and low density lipoprotein but there was no impact on total PYY and subjective feeling of hunger and fullness. **FAECAL CALPROTECTIN RESPONSES TO MODERATE INTENSITY EXERCISE; PILOT OBSERVATIONS.**

Hamzah, N., Chester, N.I, Scott, M.I, Doran, D.A.I

*Liverpool John Moores University*

Introduction Exercise is associated with a loss of gastrointestinal (GI) epithelial barrier integrity. Recently calprotectin, a 36-Kda cytosolic protein marker of GI inflammation has been postulated as a putative biomarker of exercise related perturbations in GI function (van Wijck et al. 2012). The aim of this study was to examine the effect of a single bout of exercise relative to rest upon faecal calprotectin (FC) expression. Methods Four healthy males (Age  $20.5 \pm 0.5$  yr; Weight  $72.6 \pm 11.2$  kg; VO<sub>2</sub> max  $4.03 \pm 0.49$  l/min) undertook a counter balanced repeated measures design of 50 minutes of rest (Control) or steady state running (~70% VO<sub>2</sub> max). Subjects were monitored for HR, core temp, RPE, and GI discomfort. Faecal samples were collected as the first void prior to and after each experimental protocol and stored at  $-80^{\circ}\text{C}$  until analysis via a quantitative rapid assay test (Bühlmann QUANTUM BLUE®). Results Physiological responses for HR, RPE, core temp, GI symptoms were increased during exercise relative to rest ( $P < 0.05$ ). Following exercise a reduction in FC was observed pre to post exercise ( $127.8 \pm 102.7$   $\mu\text{g/g}$  vs  $85.3 \pm 56.1$   $\mu\text{g/g}$ ;  $P > 0.05$ ). Conversely, during the rest protocol FC increased pre to post protocol completion ( $81.3 \pm 9.3$   $\mu\text{g/g}$  to  $117.7 \pm 11.5$   $\mu\text{g/g}$ ;  $P > 0.05$ ). Discussion FC is a neutrophil degranulation protein clinically associated with GI inflammation. Whilst detectable in faeces and plasma no reports of FC responses exist. Previous literature indicates significant elevations in plasma calprotectin after moderate intensity exercise. However, when measured in faecal samples, a reduction in calprotectin occurred after exercise. Intriguingly following the resting protocol, we observed increased FC concentrations. These observation may relate to the compartment from which calprotectin was sampled i.e. plasma vs faecal. Calprotectin is released from skeletal muscle; as such its elevation in plasma may not be attributable to GI inflammation alone. FC may thus present a more GI specific marker of inflammation although present data suggest it may be highly variable reflecting that seen in clinical populations (Lasson et al., 2015). This FC variability is perhaps due to the time gap (>8-12hrs) between protocol completion and faecal voiding. In conclusion, the utility of FC as a biomarker of exercise mediated gut inflammation remains to be fully elucidated. van Wijck, K. et al., (2012). *AJP: Gastrointestinal and Liver Physiology*, 303 (2), G155–G168. **CARDIORESPIRATORY RESPONSES AND PEDAL FORCE DURING ONE-LEGGED EXERCISE WITH A TANDEM-BICYCLE ERGOMETER**

Onodera, S.1, Saito, T.1, Hayashi, S.2, Murata, M.3, Nishimura, K.4, Yoshioka, A.5, Katayama, K.6, Ogita, F.7

*1Kawasaki University of Medical Welfare, 2Fukuyama Heisei University, 3Graduate School, Kawasaki University of Medical Welfare, 4Hirashima Institute of Technology, 5Okayama University, 6Nagoya Univers*

Purpose: The tandem-bicycle ergometer, which we recently developed has new characteristics, a swing joint with one load and a pist type. We have reported that the tandem-bicycle ergometer is a suitable apparatus to give an equal load to two subjects from sub-maximal exercise to exhaustion, which was evaluated by cardiorespiratory responses (Onodera S. et al., ECSS 2012, 2013). Even if the peak oxygen uptake of a pair is different by up to 10%, the values of peak oxygen uptake obtained during single bicycle ergometer exercise, in front or rear saddle trial during tandem bicycling ergometer exercise were not significantly different (Onodera S. et al., ECSS 2014). The purpose of this study was to investigate a comparison of cardiorespiratory responses and pedal force between front and rear saddle trial during a tandem-bicycle ergometer exercise. Methods: Six Japanese healthy young males volunteered to participate in this study. Their age, height, weight, and peak oxygen uptake were  $20.2 \pm 0.4$  years,  $170.0 \pm 5.9$  cm,  $62.2 \pm 3.0$  kg and  $49.0 \pm 2.2$  ml/kg/min (mean  $\pm$  SD). All subjects signed informed consent forms prior to participation in this study. The subjects were divided into three pairs matching for peak oxygen uptake. The subjects performed one-legged exercise with tandem-bicycle ergometer four times (for both the right-leg in front (RF) and left-leg in rear saddles (LR), for both the left-leg in front (LF) and right-leg in rear saddles (RR)). Each condition was randomly selected. The exercise was done for ten minutes (Pedal rate; 60rpm, load; 2.0 kp). We measured heart rate, oxygen uptake and pedal force. Results and Discussion: Mean values of heart rate, oxygen uptake and pedal force were  $105.8 \pm 21.8$  bpm,  $15.3 \pm 4.2$  ml/kg/min and  $163.1 \pm 40.4$  N (RF),  $106.5 \pm 22.1$  bpm,  $16.0 \pm 3.3$  ml/kg/min and  $160.7 \pm 40.5$  N (RR),  $113.3 \pm 23.1$  bpm,  $18.7 \pm 5.1$  ml/kg/min and  $175.1 \pm 34.1$  N (LF),  $113.8 \pm 24.3$  bpm,  $18.4 \pm 3.7$  ml/kg/min and  $178.0 \pm 37.7$  N (LR), respectively. No significant differences were found in heart rate, oxygen uptake and pedal force between the RF and RR, LF and LR conditions. These results suggest that physiological responses and pedal force during one-legged exercise with tandem-bicycle ergometer are at comparable levels between the

front and rear saddle trial. [The Ministry of Education, Culture, Sports, Science and Technology, Grant-in-Aid for Scientific Research (24500686)]

### **CAN WE IMPROVE MORNING QUADRICEPS MAXIMAL VOLUNTARY CONTRACTION FORCE BY BRIGHT LIGHT ADMINISTERED THE DAY BEFORE, DAWN SIMULATION ON THE DAY OF TESTING OR A COMBINATION OF BOTH?**

Edwards, B.J., Hall, E.C.R., Bowden-Davies, K.A., Dugdale, M., Knight, J.C., McGuire, S., Rama, J.J., Pullinger, S.A., Ab Malik, Z., Robertson, C.A., Erskine, R.M., Burniston, J.G., Waterhouse, J.M.

*Liverpool John Moores University*

Humans are biologically weaker in the morning than the evening; heats for major sporting competitions are sometimes scheduled in the morning. Therefore, we investigated potential methods to improve morning muscle performance by either, exposing subjects to 1) morning exogenous dawn simulation on the day of testing (DS); 2) bright light administered the day before (BL), or 3) a combination of both dawn simulation and bright light conditions (BL+DS). Ten active males (mean±SD: age, 25.5±1.9 yrs; body mass, 71.0±6.7 kg; height, 1.8±0.1 m) volunteered and were familiarized before completing six sessions counterbalanced in order of administration (separated by 48 h): control morning (M, 07:30 h) and evening (E, 17:30 h) sessions followed by 3 further sessions at 07:30 h preceded by either a morning exogenous dawn simulation on the day of testing from 05:30 to 06:00 h (DS); bright light administered the day before (1 h at 07:00 h, BL), or a combination of both dawn simulation and bright light conditions (BL+DS). Each trial involved a resting phase, 5-min cycling at 150 W, then four measures of maximal voluntary contraction (MVC) with twitch-interpolation technique on an isometric ergometer. Rectal and muscle (T<sub>rec</sub> and T<sub>m</sub>) temperatures, ratings of perceived exertion (RPE), thermal comfort (TC) and perceived effort (PE) were measured at rest, following warm-up, before or after the MVC efforts. Resting values for perceived onset of mood state was measured. Data were analysed by GLM with repeated measures. T<sub>rec</sub> and T<sub>m</sub> values were higher in the evening than the other conditions (~0.5 and 0.6°C respectively; P<0.05). M values for T<sub>rec</sub> and T<sub>m</sub> were no different than the other morning conditions (P>0.05). T<sub>rec</sub> and T<sub>m</sub> values increased from rest, post warm-up and until the MVC were completed. There was no interaction between condition and time, such that the profiles increased in the same manner over time for each condition. The subjects' ratings of TC, RPE and PE was no different between conditions (P>0.05). There was a significant effect of time such that TC and RPE increased from rest to post MVC, however there was no interaction. E condition resting calm, happy and vigour 'mood' scores were higher than any other condition. All conditions showed higher isometric peak force for knee extension compared to that of a morning control condition (range of 10.5-17.8 % or 70.2-118.3 Nm<sup>-1</sup> respectively; P<0.05). However, there was no statistical difference between experimental and E condition such that all experimental conditions showed the possibility to potentially offset the daily variation in muscle strength and this has implications for athletes who are competing in the morning. The reason for this improvement however, is still unclear. Further research utilising these 'lighting' conditions but with a direct measure of sporting performance such as a self-paced cycling time-trial is warranted.

### **THE EFFECT OF PROLONGED EXERCISE ON BRAIN ACTIVITY MOOD AN EFFORT**

Wollseiffen, P.1, Solomon, C.2, Martin, L.A.2, Kerherve, H.2, Klein, T.1,2, Schneider, S.1,2

*1 Institute of Movement and Neurosciences, German Sport University Cologne, Germany 2 Faculty of Science, Health, Education and Engineering at the University of the Sunshine Coast, QLD, Australia*

**INTRODUCTION** Long duration exercise has been linked with the psychological model of Flow. Flow describes a mental state, during which a person is fully immersed in the process of an action. It is expected that the Flow experience is going along with specific changes in cortical activity, especially a transient hypofrontality which has recently been connected with an increase in cognitive performance post exercise. Nevertheless data on neuro-affective and neuro-cognitive effects during prolonged exercise are rare. **METHODS** Within this study cognitive performance as well as mental state, flow experience and brain cortical activity were assessed several times before, during and after a six hour run in eleven ultra marathon runners (six female, five male). **RESULTS** Results indicate a decrease of cortical activity (beta-activity) in the frontal cortex, whereas no changes could be obtained for global beta, nor frontal or global alpha-activity. Perceived physical relaxation and flow state increased significantly after one hour of running but decreased during the following five hours state. Perceived physical state and motivational state remained stable during the first hour of running but then decreased significantly. Cognitive performance as well as underlying neurophysiological events (recorded as event related potentials) remained stable across the six hours run. Except the fact that women reported significant higher levels of Flow no further gender effects were noticeable. **DISCUSSION** Following the theory of a transient hypofrontality, a clear and significant decrease in frontal cortex activity was noticeable. Interestingly this had no effect on cognitive performance. The fact that self reported Flow experience increased just during the first hour of running followed by a dramatic decrease let us assume that changes in cortical activity and the experience of flow are not linked as previously supposed. **CONTACT** p.wollseiffen@dshs-koeln.de

### **THE EFFECT OF MATCH-RELATED PHYSICAL EXERTION ON REACTIVE AGILITY IN RUGBY LEAGUE PLAYERS**

Minova, D.1, Duncan, M.1, Lyons, M.2, Hankey, J.1

*1: Coventry University (UK), 2: University of Limerick (Ireland)*

**Introduction** Previous research in Rugby League has reported reductions in agility following game-specific exercise. A fundamental component of agility is decision-making as players are required to execute a quick change of direction in response to unpredictable stimuli (Serpell et al., 2010). Few studies however, have considered this decision-making stimulus. Considering that the high physiological demands of Rugby League force players to compete under high levels of physical exertion, the aim of this study was to examine the impact of an 80-minute match simulation protocol on reactive agility accounting for player's fitness level. **Methods** Twelve Rugby League players (mean ± SD, age 23 ± 3 years, height 1.8 ± 0.1m, body mass 87.7 ± 11.5 kg) participated in this study following ethical approval and informed consent. Players initially undertook measurements of anthropometry and fitness testing including an assessment of aerobic capacity (20m Multi-stage Fitness Test). During the follow-up testing session, players were asked to perform an 80-minute match simulation protocol (Sykes et al., 2013). Three trials of the repeated Reactive Agility Test (rRAT; Jordan et al., 2013) were performed at six time points throughout the simulation protocol. Reactive agility was measured as the combined total of decision-making and sprint time. **Results** Decision-making time, sprint time and total time were assessed using a two-way ANOVA with repeated measures (time point [6] x trial [3]) to assess differences over time and between trials. A significant main effect of trial on decision-making time was reported (P = 0.033). Post-hoc analysis using the Least Significant Difference (LSD) correction revealed that the time taken to complete the first trial of each rRAT was significantly higher than the time taken to complete the third trial (P = 0.027) across the six time points. Using individual

body fat percentage and fitness level as separate covariates, no significant interactions were reported. There were also no significant main effects of physical exertion on sprint time and total time. Discussion Match-related physical exertion did not have an effect on reactive agility across the 6 match periods in contrast with the results reported by Gabbett (2008). The current findings that decision-making time was higher in the first trial compared to the third trial across the 6 periods may suggest that, rather than a cumulative effect, there is only an acute effect of match-related exertion on decision-making in Rugby League. ### THE INFLUENCE OF UNILATERAL AND BILATERAL LOAD CARRIAGE ON GAIT AND STATIC POSTURE OF YOUNG HEALTHY MALES

Inoue, Y.

*Osaka Institute of Technology*

Introduction Little research has been done to examine the influence of heavy load on the youth posture and gait. The purpose of this study is to examine the influence of unilateral and bilateral load carriage on gait pattern and static posture. Methods Fifteen healthy male college students (age  $20 \pm 2$  years, body mass  $60.1 \pm 8.1$  kg) were participated in the first and the second experiments. Three carrying loads, 0%, 10% and 20% of body weight, were used as three load conditions (0%BW, 10%BW, 20%BW). The participants carried loads with two-strap backpack in the first experiment and carried load with one-strap backpack over each shoulder in the second experiment. Each participant was required to keep static posture on the plate-type pressure sensor (Footscan 2D plate, RS International) during 30 seconds on each condition to measure the contact pressure and the center of pressure (COP). The static posture was recorded by a video camera with 200Hz in filming rate. Then, each participant walked ten steps at their natural cadence on the plate-type pressure sensor. One pair of plantar pressure of the fourth and the fifth steps was measured with a sampling rate of 300Hz. Results The sum of plantar pressure and the contact time during gait increased most on the 20%BW, and then on the 10%BW in the first and second experiments. The main effects of loads were statistically significant at contact time, but the main effects of bilateral difference were not. The contact pressure of static posture increased more as the loads became heavier. The main effects of bilateral difference and loads were significant at contact pressure in both the experiments. The interaction effects were also statistically significant in the second experiment. The trajectory length of COP tended to be longest on the 20%BW. Furthermore, when the participant carried load over the left shoulder, the left shoulder was higher than right one and vice versa. Discussion The experiments showed that the contact time during gait was longer as the loads increased. Our results were similar to the results of Ghori et al. (1985), Choi et al. (2007) and Ozgul et al. (2011). It was suggested that when the loads increased, it took more contact time to stabilize gait. However, the bilateral difference of the contact time was not significant even when the participant carried unilateral loads. It was suggested that the contact time was so short that unilateral loads had little influence. In contrast, the significant bilateral differences were the contact pressure and the position of shoulders in static posture. These results showed that the unilateral loads were more affected in keeping static posture than walking. References Ghori G.M.U, Luckwill R.G. (1985). ### HEART RATE VARIABILITY DURING SLEEP IN WORLD CLASS ALPINE SKIERS: BEAT TO BEAT VARIABILITY DURING DIFFERENT STATES OF CONSCIOUSNESS

Herzig, D., Testorelli, M., Schäfer, D., Erlacher, D., Achermann, P., Eser, P., Wilhelm, M.

*University Hospital Bern*

Background/Aim: High sleep quality is essential for recovery and performance in athletes. Slow-wave sleep (SWS) is characterized by a high delta wave power of the electroencephalogram (EEG) and is an indicator of sleep quality and depth. The aim of this study was 1) to verify the relationship between cortical and the autonomic nervous system (ANS) activity by means of heart rate variability (HRV) in elite athletes, and 2) to compare HRV parameters during different states of consciousness such as wake, SWS and non-SWS. Methods: Eleven world cup level alpine skiers (age  $25.9 \pm 2.7$  y) were recruited. In each athlete, RR-intervals were monitored by ECG and delta-wave activity by 1-channel EEG during four nights' sleep as well as after awakening. Power spectral density of the EEG was calculated and the delta frequency (DF) band (1-4.5 Hz) of 30-s segments was further analyzed. A moving median filter (120 s) was applied to DF. Correlation coefficients of the RR-intervals (Poincaré plots; rRR) of consecutive 30 s were determined for the whole night. Correlations between DF and rRR time series were calculated. SWS phases were defined when DF was above 30 % of the night's maximum value for at least 10 min. For each SWS phase, a 4 min segment was placed at the segment's center and mean HRV values of all identified SWS phases were calculated. Non-SWS phases were defined for all phases with DF values below 15% of the night's maximum (comprises light sleep, REM sleep and waking). In the morning, a 4 min segment in supine position with controlled breathing was analyzed. Mean RR interval, root mean squared differences of successive RR intervals (RMSSD) and RMSSD adjusted for RR (RMSSD/RR) were calculated for the three states. HRV parameters of the three states were compared (paired Wilcoxon signed-rank tests). Results: Data of 15 nights (between 1- 4 nights per athlete) were of sufficient quality to be included in analysis. Mean correlation between DF and rRR was  $-0.49 \pm 0.2$  (range -0.3 to -0.7). In SWS RMSSD/RR was lower than in non-SWS ( $P = 0.046$ ), while a trend for longer RR intervals ( $P = 0.075$ ) was observed. No differences between parameters of SWS and wakefulness in supine position were observed. Conclusions: A close relationship between HRV and cortical activity was present in elite athletes. Contrary to previous studies in non-athletes, RMSSD/RR in SWS was reduced compared to non-SWS, possibly due to a saturation of HRV in athletes.

### EFFECTS OF GRADUATED COMPRESSION STOCKINGS ON SKIN TEMPERATURE IN RUNNING

Gil-Calvo, M.1, Priego, J.I.1,2, Giménez, J.V.1, Lucas-Cuevas, A.1, Aparicio, I.1, Cibrián, R.M.2, Salvador, R.2, Pérez-Soriano, P.1

*University of Valencia*

Introduction The effect of Graduated Compression Stockings (GCS) on skin temperature after running remains unknown. The aim of the study was to evaluate the effect of running with GCS on the variation of the skin temperature of the lower limb. Methods In this study participated 44 runners: 29 males and 15 females (age  $[28.6 (4.3)]$  years), weight  $[66.3 (14.7)]$  kg], height  $[1.69 (0.7)]$  m], weekly running  $[36.6$

(14.7) km/week]. Runners performed 3 tests. First test consisted in run 5 minutes in the shortest time possible to know their maximal aerobic speed (MAS) in order to individualize their laboratory tests. Then they carried out 2 laboratory tests (one with GCS and another without GCS) in which they ran for 30 minutes: 10 minutes at a comfortable speed to warm up and 20 minutes at 75% of their MAS. 12 regions of interest (ROI's) of the lower limb was measured using an infrared thermography camera (FLIR E60, FLIR, Belgium) in 2 different moments: 1) before running after 10 minutes of acclimatization; 2) after running. Temperature variation was compared before and after the running test. Differences between GCS test and the test without GCS in the ROI's were analyzed with a repeated-measures ANOVA ( $p < 0.05$ ). Results Wearing GCS presented a greater temperature increment than the test without GCS ( $p = 0.002$ , 95% CI [0.11 - 0.45°C]). The main differences were observed in the vastus lateralis ( $p = 0.04$ , 95% CI [0.01 - 0.52°C]), abductor ( $p = 0.04$ , 95% CI [0.01 - 0.48°C]), ankle anterior ( $p = 0.003$ , 95% CI [0.21 - 0.91°C]), tibialis anterior ( $p < 0.001$ , 95% CI [0.34 - 0.83°C]), semitendinosus ( $p = 0.04$ , 95% CI [0.01 - 0.48°C]) and gastrocnemius ( $p = 0.02$ , 95% CI [0.04 - 0.46°C]). Discussion The present study explored the effect of running with GCS on skin temperature of the lower limb before and after running. The main finding was the greater variation of skin temperature wearing GCS. On the one hand, this greater variation could be due to the insulating effect produced by the textile which reduced the effectiveness of the sweat evaporation (Sperlich et al. 2013). On the other hand, the increase in the temperature variation in the body regions that were not in contact with the garment could be explained by the greater blood perfusion generated by the compression of the GCS (Ali et al. 2010). Nevertheless, this higher variation of the skin temperature did not exceed 33°C in any ROI which is considered as a limitation of the aerobic performance (Sawka et al., 2012). In conclusion, running with GCS produced a greater variation of the skin temperature that may be explained by the textile insulation and the higher blood perfusion. #### IDENTIFY FACTORS INFLUENCING THE PROCESS OF SOCIALIZATION THROUGH SPORT

Yektayar, M.

*Islamic Azad University Sanandaj branch*

Identify Factors Influencing the Process of Socialization through Sport Abstract Research showed that participation in sport decrease antisocial behaviors and increase sociomoral behavioral in athletes (Rutten et al,2007).Van Bottenburg and Schuyt (1996) contend that sporting activity fosters the development of important virtues, such as team spirit and social responsibility (Van Bottenburg, Schuyt,1996).Coakley (1984)emphasized that sporting activity stimulates social-cognitive competences, such as role-taking ability, as athletes must constantly anticipate their opponents' actions or moves (Coakley,1984). While role-taking ability is a necessary condition for growth in moral reasoning, virtuous dispositions like self-control or perseverance could be important for the translation of moral reasoning into moral behavior (Matsuba and Walker,1998). The aim of this study was to identify factors influencing the process of socialization through sport. Method: Total 270 athletes were selected randomly as sample. Face and content – related validity of questionnaire improved by experts and reliability of questionnaire obtained  $r = 0.88$  in a pilot study. Factor analysis method was used to identify factors. LISREL software was used to determine the factor loadings. Result: The results revealed seven major factor priorities are family with factor loading 0.786, Competence with factor loading 0.739, strengthens human values 0.745, peers 0.615, and expands human communication with factor loading 0.656; efficiency and Adequacy with factor loading 0.756 as well as coaches with factor loading 0.616 are factors which play a major role in the socialization through sport. Conclusion: Socialization process can easily be achieved through participation in sports activities. It is one of the most important components of growth and one of the most fundamental aspects of the personality. In this process social values is preferred to individual values, all people are trying to achieve a common goal.Family and peers are important in socialization through sport Exercise helps everyone do their role well in the society. #### SPORT VS. SCHOOL: CONCILIATION STRATEGIES OF YOUNG ATHLETES BENEFIT FROM ATHLETE SCHOLARSHIP PROGRAM IN BRAZIL

Silva, A., Soares, A., Melo, L., Costa, F., Silva, M.

*National Institute for Deaf Education*

The formation of high-level athletes competes with the student life of young people around the world. With the completion of major sporting events in Brazil, the condition maintenance programs of athletes became part of the national political agenda, including young students that, with his family, establish conciliation strategies between the times of sports training and education. In this paper, we analyze the group benefited by the Student Athlete Scholarship Program of the Ministry of Sport growth acceleration program, which matches young 245 athletes, between 14 and 20 years old, who work in several Olympic and Paralympic sports. The sample submitted to the questionnaire was comprised of 165 athletes, the data recorded in the SPSS for Windows, and treated from a statistical analysis descriptive and multivariate analysis. The next step was interviews with 20 young athletes who allowed deepen unanswered questions by quantitative data. We use the thematic content analysis for the treatment of textualities written and spoken, that were organized in the software WebQda. Of the twenty respondents, thirteen assumed the difficulty of reconciliation, but not its impossibility. One athlete declares it is impossible to reconcile because of the tiredness of the routine training/school. About the career in the sport the goal is to participate in the world championship of each modality and of the Olympic Games and, as they reach sports success, the greater the chances of shift away from education. The twenty respondents intend to follow through with the studies, because they understand that the sports life is short and the school provides the credentials required by the labour market. We note that the criteria for obtaining results for conquer the scholarship can cause a reverse effect to the goal of the program (keep the young in school), because the athlete leaves the background studies to maintain their results and, and by consequence, the scholarship. Another problem is the lack of interaction

between school systems and Brazilian sports system, leaving the young athlete with the responsibility of reconciling its formation. CHRISTENSEN, Mette Krogh; SØRENSEN, Jan Kahr, "Sport or school? ### SELECTION IN NORWEGIAN MALE SOCCER: FROM THE U-15 NATIONAL TEAM TO THE A-NATIONAL TEAM

Welde, B., Rafoss, K.

*North-Traendelag University College; UiT- The Arctic University of Norway*

**Introduction:** The Norwegian Soccer Association has the oldest, most extensive and most systematically selection structure to be found within Norwegian sports. Those that are considered to be the most talented players are selected out in a series of steps, including zone, district, pre-youth national teams and national team. However, selecting at young age may hold the problem of ignoring potentially talented and perhaps late maturing players. **Purpose:** Examine 1) to what extent male soccer players selected for the U-15 national team experienced the event of playing for the A-national team; 2) if being selected for the U-15 national team influences career length. **Methods:** Altogether 563 male, Norwegian soccer players, selected for the U-15 national team in the years 1982-2003 and the A-national team in the years 1998-2011, were included in this study. Career length was defined as the number of appearances at the A-national team and was evaluated by a linear regression model including only those who had appeared at the A-national team. Cox regression analysis, including those players who had been selected to the U-15 national team, was applied to evaluate time to event. Time to event was defined as time elapsed from the first U-15 national appearance to the first A-national appearance. **Results:** Of the players that had been selected for the U-15 national team, 7.8% did experience the event. For time to event, Cox regression showed that the number of appearances at the U-15 national team as well as playing for several pre-youth national teams, were not as important as being selected to the U-21 national team ( $BEXP = 35.7, p < 0.001$ ). Of the players that actually appeared at the A-national team, 75% had formerly participated at the U-21 national team. Of these, 75% were not selected to the U-15 national team when they were at that age. Previously being selected to the U-21 national team significantly predicted the number of A-national team appearances ( $BUNSTD = 13.3, p = 0.006$ ); being a former U-15 national player was not significant ( $BUNSTD = -4.7, p = 0.34$ ). **Conclusion:** Our data indicate a weak relationship between selection to the U-15 national team and later selection to the A-national team, as well as career length, while the association between selection to the U-21 national team and future A-national team appearances appear to be stronger. This may indicate an inaccuracy in selecting early in the youth when the goal is to pick out athletes for successful performance at adulthood. Further analyses and studies should investigate the potential effect of time of birth in the selection year, as this may confound the selection process.

### THE IMPACT OF STUDENTS RECREATION CENTER ON SOCIAL BELONGING AND RETENTION

Zarei, A.1, Zarei, N.2, Chamanpira, M.3

*1: Islamic Azad University, Central Tehran Branch (Tehran, Iran ), 2: University of Tehran (Tehran, Iran ), 3: Allame tabatabaee University (Tehran, Iran )*

**THE IMPACT OF STUDENTS RECREATION CENTER ON SOCIAL BELONGING AND RETENTION** **Introduction** The opportunity to socialize with other ones can be considered as a vivid and inherent characteristic in recreational activities which is more obvious in intramural activities. These intramural programs prepare suitable and important conditions for students to socialize. These relationships can lead to significant improvement of social skills and belonging sense and coordination with university, it can even rise the rate of retention among the students who participate in these activities continuously [3]. The purpose of this study was to assess the relation of student recreation center use on feelings of social belongings and retention at 8th district of Islamic Azad University. **Methods** Descriptive and inferential or Pearson correlation statistics were used to analyze research findings. **Results** Findings showed that students who used student recreation centers enhanced their sense of belonging to the university, however male students preferred high interaction with peers. The correlation results indicated that the number of times a student works out at the student recreation center influences the way in which they interact with new people, relates to his or her perceived self-confidence and leadership abilities, and improved their perceived ability to manage time. **Discussion** In this study it was found that by increasing the number of students trained in these centers get more confident. There are significant, and previous research has often been limited to a specific group of students, but the results of the present studies [1, 2, and 5] found that as many students in recreational activities or sports participate as a way to increase social interaction by interaction with the students is to be consistent. Also research [6, 4], which showed that the recreational sports community is a place where students can communicate with their peers to provide, without regard to whether to participate or not and also, increasing conscious leadership ability, the students stay at recreational areas and other areas interested. Improving Time Management among students, as another important factor, this paved the way for a stay at the University and has been followed by improvements in education. **References** [1] Artlinger, L., Clapham, L., Hunt, C., Meigs, M., Milord, N., Sampson, B., & Forrester, S.A.(2006). *NASPA Journal*, 43(1), 69-86. ### INSIGHTS FROM THE "LLP FACILITATING HIGHER EDUCATION FOR ATHLETES – WINNER EDUCATION MODEL" PROJECT: PRELIMINARY FINDINGS ON ITALIAN STUDENT-ATHLETES' PERCEPTIONS ON DUAL CAREER OUTCOMES AND SERVICES

Guidotti, F., Capranica, L.

*University of Rome Foro Italico*

**Introduction** Dual career (i.e., the combination of sport and education) has become a crucial issue in the European Commission (EC) strategies for sport (EC, 2012). In this framework, the LLP WINNER EDUCATION MODEL intends to structure an appropriate education model for dual career students (<http://www.winner-project.eu/>). Therefore, the aim of this study was to investigate student-athletes' opinions regarding: i) their sport and academic career outcomes; and ii) available dual career services and possible implementations. **Methods** Using the focus group method (Kitzinger, 1994), a 36-item semi-structured questionnaire was created during a project meeting. The English version of the instrument was back translated (Su and Parham, 2002) to achieve a valid Italian version. Participants were required

to respond on-line to closed-ended items (5-point Likert-type agreement scale) and to provide additional open comments. Descriptive statistics was used to analyse collected responses. Results Thirty-four respondents (gender: 50% male, 50% female; age: 24.6±3.5yrs; type of sport: 71% individual, 29% team; competition level: 56% national, 44% international) declared to be satisfied with their educational path (3.9±1.0pts), to be able to meet the academic requirements (3.4±1.2pts), perceiving that the university provides them a good education (3.0±1.0pts) for their future professional opportunities (3.3±0.9pts). Nevertheless, the dual career was perceived highly demanding (3.6±1.0 pts) in absence of academic (2.5±1.4pts) and sport (2.0±1.3pts) policies. However, student-athletes were able to manage both academic (3.5±1.0pts) and sport (3.9±0.8pts) careers. Furthermore, the sport staff was perceived more sensible (3.4±1.3pts) and available for a flexible path (2.7±1.4pts) compared to teachers (2.1±1.2pts and 1.7±1.0pts, respectively), whereas family and peers were considered highly supportive (4.2±1.0pts). Finally, the need for a flexible academic path (i.e., class attendance and exam schedule), the recognition of the student-athlete status, e-learning provisions, an effective dialogue with teachers, and a higher cooperation between sport and academic organizations emerged. Discussion Findings confirm the importance to guarantee proper services to Italian elite student-athletes. Further cross-national comparisons are needed to structure an appropriate dual career education model in Europe. References European Commission (2012). EU Guidelines on Dual Careers of Athletes. ## A STUDY ON THE PREVENTION POLICY ESTABLISHMENT FOR SCHOOL SAFETY INCIDENTS IN KOREA

Nam, Y.

*Duksung Women's University*

Introduction: School safety incidents, occurring during educational activities, are any accidents that damage lives or the bodies of students, faculty and staff members, or educational activity participants, and diseases of those directly caused by works belonging to the management and supervision of the principal such as school lunches and etc. The purpose of this study is to establish the concept of the school safety incident and also its prevention policy by statistically analyzing the existing data of school safety incidents (Lee, 2011). Methods: Domestic and international literature, including various reports and academic research papers, related to school safety incidents were surveyed to analyze the current status of existing school safety incidents. The current status such as frequency of occurrence and major causal analysis of school safety incidents was analyzed by applying the cross-analysis out of statistical analysis techniques on 105,323 cases of school safety incidents of FY2013. In-depth interview was carried out. First, a qualitative analysis of the various conditions and circumstances was performed on experienced people and witnesses of school safety incidents. Second, in-depth interview was performed three times on three security professionals. The survey was conducted by FGI (Focus Group Interview). The ideas on the prevention policy were brought out by expert meeting. Results: School accidents were occurred most frequently in class for kindergarten (44.4%), in physical education class and lunch time (47.8%) for elementary school, in physical education class for middle school (34.8%) and high school (31.1%). School safety incidents were most frequently occurred at the class rooms for kindergarten (49.7%) and at the playgrounds for elementary school (36.5%), middle school (46.1%), and high school (48.0%). While the most injured part of students was head for the kindergarten (43.3%) and elementary school (36.5%), it was foot for middle school (21.6%) and high school (29.1%). Discussion: In this study, the concept of school safety incidents was classified into life safety, school violence, road safety, disaster safety. Prevention policy proposals for school safety incidents consist of (i) execution of the project on improved School Safety Awareness: reestablishment of the scope and content of school safety, construction of School Safety Information system, safety management of school bus in school education, operational management, and training activities., (ii) improvement of School Safety Physical Environment: safety management of school facilities, access control of outsiders, operations management of school CCTV's, improvement of environmental management for around schools, improvement of school violence-related systems, (iii) reestablishment of School Safety organization • system: reestablishment of management organization for School campus safety, installation and management of Experience comprehensive school safety, stable financing for school safety, legislation of comprehensive school safety law.

#### SPORT TOURISM IN KOSOVO – THE IMPACT OF HIKING

Berisha, V.

*University Of Prishtina*

Sport Tourism is one important and growing part of the total Tourism-industry around the world. This study concentrates on Sport Tourism in Kosovo, Studying Hiking as a specific phenomenon within the field of Sport Tourism. I analyze the Sport Tourism sector from a macro-, meso-, and micro level and my study are among the first studies within this field in Kosovo. The aim of this study is to analyze and understand the possibilities for sport tourism in Kosovo and I use hiking as a case to explore and explain this the entire research is based on the empirical research and has provided data from locally Kosovo. Since there was no empirical data made there, it was very tough to find and based in very little research that was done previously in Kosovo. In Kosovo until now there are no significant academic researches made regarding tourism and sport Tourism. There are number of institutions which provide information regarding the tourism, and Sport Tourism, but the major problem remain on the accuracy of this data's, since they are coming from different sources and very often influenced from daily politics aspect. Since the policy of government has been focus in other direction of investment I do believe that my research will increase the awareness to Kosovo institutions, that maybe in future the investment will change direction in Sport Tourism and Hiking. This study tends to explore this phenomenon and to try to create a better knowledge within this area related to Kosovo. And because of this I have used the exploratory research approach. Hopefully Sport Tourism in nearest future can have a good impact to increase the Kosovo economy. The aim of this research is to analyze sport tourism and Hiking in Kosovo. This thesis uses qualitative research techniques, mainly in-depth interview. In addition, the reflective practice technique was used because the author of the thesis has been involved in implementing the Hiking guides around Kosovo.

## INVESTIGATION THE BARRIERS REVENUE FROM SPORTS TOURISTS

Hemati, J.1, Eslami, S.2

*Department of sport, Behbahan Branch, Islamic Azad University, Behbahan, Iran 2: PNU (University of Payame Noor)*

Do not insert authors here Introduction Tourism is a commercial activity. Major corporations such as airlines and major hotel chains have an interest in fostering niche tourism markets such as sport tourism. Sporting events as a major tourist attraction and development capabilities in research have been underlined. Features and capabilities as a critical component of the tourist destinations in the business of hosting sporting events emphasize with the researchers Methods The method of this study was descriptive survey with the practical purpose. The statistical population was include all persons who had at least one book or two scientific papers in areas related to employment and tourism and the administrative experts in the field of employment and tourism, with at least a bachelor's degree, who are at least 10 years of experience. Samples were selected through stratified random sampling. The measurement tool in this research was researcher- designed questioner. The final questionnaire's face validity was approved by experts. To determine the content validity were used exploratory and confirmatory factor analysis. Cronbach s Alfa coefficient was calculated 0/90. Structural equation models (SEM) were investigated to access variables observed effects on the latent variables and confirm the conceptual model. Results Friedman test showed significant differences between the various obstacles revenue( $X^2= 652.616$ ,  $p= 0.001$ ). The results showed that the various obstacles, the low level of tour leader in In implementing Tour was First rank, The low number of major events was second rank and Lack of proper marketing in attracting tourists with high incomes was third rank(mean rank 1= 7.28, mean rank 2=6.62& mean rank 3= 6.17) Discussion The tour leader must be increase the information about manage behaviours with tourists. Sport is both a community activity and a major part of the entertainment industry. At the local level, it is a social activity run primarily by volunteers, and is very much not-for-profit. At its highest levels of performance, it is a multi-million dollar industry. Sporting events as a major tourist attraction and development capabilities in research have been underlined (Solberg, Preuss, 2007; Icoz et al., 2010). Features and capabilities as a critical component of the tourist destinations in the business of hosting sporting events emphasize with the researchers (Emery, 2010). ## ORAL PRESENTATION

Plested-Alvarez, M.C., Díaz-Valencia, A.L.

*GITT, University of Antioquia*

We carry out a documentary research to determinate key aspects for this study e.g. Hublot, Nike, Adidas, Falcao, Cristiano Ronaldo, James Rodriguez. Situations concerning show business, marketing and big money as pressure to the sport people result in a kind of harassment in sport. The terminological methods and the analysis done, allowed the elaboration of a conceptual map (Plested, M.C., Giraldo, B.S., 2001) and showed general behavior concepts taken from specific cases, which will be discussed. It's necessary to deep into the analytical reflections to take socio-educational measures as analysis against these marketing behaviors e.g. "The private franchise ownerships" as in USA sport. We propose outreach activities at national and international committees to search for a new agreement about this social reality. A qualitative methodology to analyze sociologically statements regarding their origins, and also a conceptual analysis to different contexts was applied. A qualitative methodology concerned to terminologically analyze the statements (Budín, 1998) under the concept of 'representative virtual psychological space of each implicated' (Sánchez Medina, G. 1987) in conjunction to the world image permitted to confirm some business and marketing, as a social case study "Professional sports may be one of the most misunderstood occupations in the world. The public sees the mansions, the bling, and the fancy cars. What it doesn't feel is the insecurity of a profession that averages just two and a half to four seasons before someone younger, faster or stronger comes along. It doesn't see the scam artists who suck away salaries and it doesn't see the egotism and sense of entitlement that can lead a ... to believe that the rules that govern society do not apply to them" as said in Scandals of the decade. It is necessary to change some commercial and marketing parameters taking into account the cultural, social environments and also the staff of each of those sportspersons. After tracing the life details of sportspersons, it was systematically found that the specific staff was part of the scene, working under his or her instructions. Some of the specific teaching parameters in sport need to face up some universals to improve or understand the situation. We concluded that in some cases sport marketing is conceptualized through actions which actually place sport people as market objects. Unfortunately, it seems that this is a fixed parameter of those who call themselves 'members of a civilized sport culture'. We propose some cultural and pedagogical sportive ways to minimize it. ## THE IMPACT OF DEVELOPING SUSTAINABLE FACILITIES ON LOCAL SPORTS PARTICIPATION: THE ITALIAN CASE

Masoni, I.

*Università di Pisa*

The aim of this paper is to analyze how recent initiatives to build or develop sustainable sports facilities have influenced local sports participation in Italy. Past statistical analyses show that Italian infrastructures are frequently old and impracticable, and that there is a significant difference between northern and southern regions (in terms of both number and quality of infrastructures). Furthermore, previous studies have highlighted a lack of variety in the sports facility supply. This has led to low levels of sports participation for several reasons: for example, high prices, inflexible opening times and long distance from the place of residence. Against this background, Italian institutions recently adopted several measures to enhance the sustainability of local sports facilities. Most of these measures are improvements of preexisting structures, such as removal of architectural barriers or increases in efficiency. In other cases, governments have even built new sports facilities for free sports activity (for example, outdoor gym or cycle routes). By concentrating on a dozen of specific measures, the paper starts from analyzing the differences between renovating existing facilities and building new infrastructures. The paper will then focus on the effects of these interventions with respect to: (1) the number of people who practice sports activities; (2) the categories of people who practice sports activities (for example, on the basis of age, type of job, revenue, etc.); (3) variation in the supply of sports facilities.

**BRAND CULTIVATION AND DEVELOPMENT STRATEGIES IN THE POPULARIZATION OF CHINA'S TRADITIONAL TAI CHI**

Zhou, W., Zhou, J., Wang, H.

*China university of petroleum*

**Introduction** The thesis analyzes the orientation of cultural brand of Tai Chi from its product dimension, competition dimension, audience dimension and strategic level through application of the research methodology of documentation, expert interviews and synthetic analysis and on the basis of discussion of the concept, significance and entitlement of Tai Chi cultural brand. Meanwhile, the thesis advocates enhancement of Tai Chi cultural industry via all-in fitness and diversified security system and proposes references to its cultivation and development strategies. The research findings aim to enrich the content and cultural value of Tai Chi theoretical system and eventually to serve the popularization of China's traditional culture as well as the construction of sports strength. **Methods** The analyses are based on documentation, expert interviews, and logicalization. **Results** Tai Chi, the general term for Tai Chi techniques and relevant cultural theories, is the precious Chinese cultural heritage and the perfect integration of Tai Chi boxing and traditional culture. It is endowed with the essential spirit and value orientation of Chinese traditional culture, which is characterized with the Chinese ancient philosophical outlook of integrity of Man and Nature and the unity of Body and Mind, as well as the combination of body care and body fitness under influence of specific Chinese outlook on life and exercise. As a result, Chinese Tai Chi exerts appeal, assimilation and integration on a variety of sports cultures throughout the world. It is of great significance to innovate, enhance and popularize the cultural brand of Tai Chi for the purpose of global cultural exchanges of Tai Chi. **Discussion** The thesis analyzes the orientation of cultural brand of Tai Chi from its product dimension, competition dimension, audience dimension and strategic level, advocates enhancement of Tai Chi cultural industry via all-in fitness and diversified security system and proposes references to its cultivation and development strategies. The research findings aim to enrich the content and cultural value of Tai Chi theoretical system and eventually to serve the popularization of China's traditional culture as well as the construction of sports strength. It is anticipated that more institutes devoted to Tai Chi popularization will step on an industrialized and globalized path to make further progress in developing this cultural brand by resorting to scientific, innovative and inclusive development. **References** [1] LUO Wei-min, GUO Yu-cheng. **Mini-Orals****MO-PM26 Rehabilitation and Physiotherapy: Orthopedic rehabilitation****INTRA- AND INTER-RATER RELIABILITY OF STANDING HIP FLEXION STRENGTH AND SUPINE LUMBO-PELVIC CONTROL IN PATIENTS WITH LONGSTANDING HIP AND GROIN PAIN.**

Pålsson, A., Nordqvist, J., Persson, J., Ageberg, E.

*Department of Health Sciences*

**Background:** Longstanding hip groin pain (LHGP) is a common problem among athletes. Reduced isometric hip flexion strength in a sitting position has been observed in patients with LHGP. However, the sitting test position does not resemble any functional activity. Poor lumbo-pelvic control (LPC) has been suggested to contribute to the development of LHGP. Double leg lowering test (DLLT), i.e., a person's ability to stabilize the pelvis when the legs are actively lowered from 90° hip flexion in a supine position, has shown to be a valid test for LPC. Limitations of this test are that it provides an indirect measurement of pelvic movement and has limited accuracy. **Aim:** To assess inter- and intra-rater reliability of a novel test of standing isometric hip flexion and a modified double leg lowering test for assessing LPC. **Method:** Isometric hip flexion (N) was tested in a standing, and thus more functional position, using a fixated hand held dynamometer (Standing Isometric Hip Flexion, SIHF). An iPod-based tilt sensor attached to the pelvis was used to provide a direct measure of pelvic tilt and a digital inclinometer attached to the thigh was used to give a more accurate degree of maximal active leg extension during the DLLT (modified DLLT, mDLLT). A starting position of 70° hip flexion was chosen to avoid the posterior pelvic tilt effect due to any hamstring tightness. The maximal hip extension (°) was measured when the pelvis reached 10° anterior tilt. The SIHF and the mDLLT were tested by two assessors independently on two separate occasions, three to seven days apart. Ten persons with LHGP and ten age- and gender-matched healthy controls participated and were analyzed as one group and as two separate groups. The intra-class correlation coefficient (ICC) was calculated for relative reliability, and the standard error of measurement in per cent (SEM %) and the minimal detectable change in per cent (MDC %) for absolute reliability. **Results:** Inter- and intra-rater reliability, for both assessors and both occasions, showed ICC values of 0.923-0.964, SEM% of 7.5-10.7% and MDC% of 20.8-29.7% for the SIHF and ICC values of 0.780-0.946, SEM% of 6.8-15.7%, and MDC% of 23.9-44.1% for the mDLLT. **Conclusions:** The ICC and SEM% indicate that the SIHF has good inter- and intra-rater reliability at the group level for patients with LHGP and healthy controls. A change of 20-30% is required to be considered a true change for an individual. The mDLLT showed acceptable inter- and intra-rater reliability at the group level for both groups. A change of 24-44% is required to be considered a true change for an individual. These tests may be used in further studies to assess hip flexion strength and LPC in patients with LHGP.

**RETURN TO PLAY AFTER ACHILLES TENDON RUPTURE IN ELITE SOCCER PLAYER: A CASE REPORT**

Fanchini, M.1,2, Combi, F.1, Benazzo, F.3, Impellizzeri, F.M.4, Bizzini, M.4

1: *Fc Internazionale (Italy)*, 2: *University of Verona (Italy)*, 3: *Orthopedic Clinic University of Pavia, IRCCS San Matteo (Italy)*, 4: *F-MARC, Schulthess Clinic, Zurich (Switzerland)*

**Introduction** Rehabilitation after Achilles tendon rupture is well documented in the literature, however there is lack of studies on the return to play (RTP) issue in soccer (Bizzini et al. 2014). The aim of this case report is to describe the RTP after Achilles tendon surgery. **Methods** A 39-years-old elite (Serie-A) soccer player (height 178 cm, weight 75 kg) suffered of Achilles tendon rupture during competition. After surgery, a functional rehabilitation approach was adopted and after 15 weeks, the RTP phase started. Strength was maintained as in previous phases and specific on-field activities gradually introduced. Isokinetic test (Cybex Norm), ability to perform single heel-raises (5x25

bouts) (Saxena et al. 2011) and training loads (TLs) were considered as criteria to RTP. TLs were collected during field activity with Global positioning system (GPS). Total, moderate and high intensity running distances (TD, MIR, HIR), heart rate monitoring (HR) and training duration (min) considered as outcomes. Mean TLs for RTP and for every week were collected and standardized mean differences (ES) calculated to compare TLs to pre-injury values. Results The lay-off time was lower compared to previous study (119 vs. 161 days) (Gajhede-Knudsen et al. 2013). The injured vs. un-injured side showed lower concentric peak torques at 15, 30, 60°/s after 6 and 9 months (-21, -24, -19% and -23, -9, -8%). The single heel-raises ability was reached at week 23. The TLs between average RTP and pre-injury, were similar for HIR (ES 0.1), lower for HR (ES -0.3) and min (ES -0.9), higher for TD (ES 0.6) and MIR (ES 1.9). TD/min was found higher in RTP vs. Matches (ES 1.7). During weeks 16-18, the TD, HIR, HR, min showed lower and MIR higher values vs. pre-injury. During weeks 19-21, TD, HIR, HR, min showed higher and MIR lower values vs. pre-injury. In week 22-25 all indicators were lower except HIR (higher) vs. pre-injury. Discussion The present case report suggested the use of a multifactorial approach in RTP. Strength and single heel-raises ability are criteria to RTP. The on-field activities should simulate the sport patterns and TLs should be monitored. The case presented showed that the ability to cope with the demands coming from the field should be considered another important criteria to RTP. References Bizzini, M. and H. J. Silvers (2014). ## LOWER LIMB MUSCLE WEAKNESS IN PATIENTS WITH SYMPTOMATIC HIP OSTEOARTHRITIS

Friesenbichler, B., Casartelli, N.C., Item, J.F., Wellauer, V., Maffiuletti, N.A.

*Schulthess Clinic*

**Introduction** Lower limb muscle weakness may result in a loss of independence in activities of daily living in the elderly (Rantanen et al., 2002). Patients suffering from hip osteoarthritis (OA) and concomitant hip pain may experience muscle weakness in the involved limb and thus the aim of this study was to investigate the deficits in maximal and explosive strength for different lower limb muscles in patients with symptomatic hip OA. **Methods** Twenty patients (65±5 yrs, 174±8 cm, 77±14 kg, 9 women) scheduled for unilateral total hip arthroplasty due to primary hip OA were tested. Hip abduction and adduction as well as hip, knee and ankle flexion and extension maximum voluntary contraction (MVC) strength and rate of force development (RFD50; as the rate of force developed 50 ms after contraction onset) were evaluated in isometric conditions for both the involved and the uninvolved limb. Lower limb muscle mass was estimated using bioimpedance analysis. Data between the involved and uninvolved limbs were compared using paired t-tests ( $\alpha = 0.05$ ). **Results** Compared to the uninvolved limb, MVC strength of the involved limb was significantly lower for hip flexion (-16%), hip extension (-13%), hip abduction (-9%) and knee extension (-11%). RFD50 was significantly lower for hip flexion (-32%), knee flexion (-27%) and knee extension (-24%). MVC strength and RFD50 for ankle flexion and extension did not differ significantly between the involved and uninvolved limb. Lower limb muscle mass was lower in the involved limb (-6%). **Discussion** Patients with symptomatic hip OA displayed considerable weakness for different hip and knee muscle groups, while no ankle muscle weakness was detected. Muscle weakness may partly be explained by the lower muscle mass, but interestingly, MVC strength and RFD50 deficits did not always correspond. For example, knee flexion MVC strength was not affected by OA while RFD50 was considerably impaired (-27%), suggesting that the neural drive to the muscles crossing the knee joint may also be affected by hip OA (Aagaard et al., 2002). The observed unilateral hip and knee muscle weakness may put patients with hip OA at high risk of becoming dependent in activities of daily living. These results emphasize the importance of preventive strength training for hip OA patients, predominantly for muscles crossing the hip and knee joints. **References** Aagaard P, Simonsen EB, Andersen JL, Magnusson P, Dyhre-Poulsen P. ## EFFECT OF LOW-INTENSITY PULSED ULTRASOUND ON SKELETAL MUSCLE CROSS-SECTIONAL AREA AFTER CARDIO-TOXIN-INDUCED DAMAGE IN A MOUSE MODEL

Nakamura, A.1, Sakamoto, M.2, Moriya, C.2, Matsunaga, A.1,2

1: *Kitasato University Graduate School (Sagamihara, Japan)*, 2: *Kitasato University (Sagamihara, Japan)*

**INTRODUCTION** Low-intensity pulsed ultrasound (LIPUS) is a treatment used to promote wound healing. Although several studies have reported the effects of LIPUS on bone, tendon, and ligament injuries, little is known about its effects on skeletal muscle injury (Rantanen et al., 1999, Nagata et al., 2013). Since collagen content in skeletal muscle is lower than in bone and ligaments, less ultrasound energy is absorbed by skeletal muscle. We previously studied the effects of LIPUS with high energy on skeletal muscle regeneration in a mouse model at 7 days after injury and found no significant difference in mean cross-sectional area (CSA) of skeletal muscle. We hypothesize that a significant difference would be observed with muscle fibers that are more mature. **METHODS** Female ICR mice (12-week-old) were divided into muscle injury (non-US, N=20) and LIPUS exposure (US, N=22) groups. To induce muscle injury, a cardiotoxin was injected into the left tibialis anterior (TA) muscle. LIPUS was initiated 2 hours after injury to the left TA muscle and applied once daily thereafter until 6 days after injury. LIPUS was performed 10 min/day, at a frequency of 3 MHz, intensity of 0.5 W/cm<sup>2</sup>, and 50% duty cycle. The non-US group received sham LIPUS. TA muscles were excised 7 and 14 days after injury, frozen sections were prepared and reacted with anti-desmin antibody, and CSA was measured. Sections prepared 14 days after injury were reacted with anti-embryo-type myosin heavy chain (MHCemb). Results were analyzed using the unpaired t-test or chi-square test, with statistical significance set at p<0.05. **RESULTS** MHCemb-positive cells were not detected at 14 days after injury in either group. No significant group-dependent differences in mean CSA were observed at both 7 and 14 days after injury (7D, 674.9±149.2 μm<sup>2</sup> and 789.5±185.2 μm<sup>2</sup>; 14D, 1194.0±248.6 μm<sup>2</sup> and 1281.4±283.8 μm<sup>2</sup> in the non-US and US groups, respectively). However, the CSA distribution revealed a significantly higher number of myofibers with CSA>1000 μm<sup>2</sup> in the US group relative to that in the non-US group at both 7 and 14 days after injury (p<0.05). **DISCUSSION** The number of larger myofibers was significantly higher in the US group than in the non-US group at both 7 and 14 days after injury. However, even when skeletal muscle fibers were mature, no significant difference in mean CSA between the non-US and US groups was observed. Under condition in the present study, these results suggest that LIPUS likely does not promote skeletal muscle regeneration. **REFERENCES** Rantanen J, et al. (1999). *Am J Sports Med* 27, 54-59. **ERROR-REDUCED OBJECT CONTROL SKILLS TRAINING: FROM RESEARCH TO PRACTICE**

Capio, C.M.1, Eguia, K.F.2, van der Kamp, J.3, Masters, R.S.W.4

*1:University of Hong Kong (Hong Kong), 2:TherapyWorks (Philippines), 3:VU University Amsterdam (Netherlands), 4:University of Waikato (New Zealand)*

**Introduction** Children with intellectual disability (ID) display proficiency deficits in object control skills (Westendorp et al. 2011), which should be ameliorated by training. Recent research showed that reducing errors during practice improved the object control skill of throwing in children with ID (Capio et al. 2013). This paper presents how such research finding was evolved into clinically viable training programs that practitioners implement, pushing evidence-based practice. **Methods** Using a mixed-methods design, error-reduced learning was applied in a clinic-situated object control skills training program for children with ID. First, a focus-group discussion (FGD) with 5 physiotherapists of children with ID explored current approaches in movement skills training. Second, 12 children with ID (mean age = 8.5±.79 years) were allocated into one of two groups: training or waiting-control. The training group practiced 5 object control skills (strike, dribble, throw, catch, kick) over 8 weekly sessions. In each session, task difficulty was manipulated to suppress practice errors. The control group had a waiting period of 8 weeks, and received training after the post-test. Object control skill components of the Test of Gross Motor Development-2 (TGMD-2; Ulrich, 2000) were used for pre- and post-test. Third, a process evaluation examined physiotherapists' clinical notes during the program. **Results** The FGD showed that therapists typically train children with ID using graded verbal instructions and physical demonstrations. In part two of the study, non-parametric tests comparing TGMD-2 scores of training and control groups showed: (1) no group differences at pre-test in overall object control and individual skill components (all  $p > .05$ ) and (2) the training group scored significantly higher than the control group at post-test in overall object control ( $p = .002$ ) and in 5/6 skill components ( $p = .026-.002$ ). Finally, the process evaluation showed that to apply error-reduced approach, therapists used (1) small group training, (2) continuous assessment and (3) individualised progression. **Discussion** This study brings evidence from experimental research to clinical practice of physiotherapists. Analysis of multiple data sources shows how error-reduced learning may be implemented in a clinical setting, resulting in improved object control skills of children with ID. Moreover, process evaluation has identified guiding principles to support practitioners in implementing the error-reduced approach in training movement skills of children with disability. Further research is warranted to examine related outcomes such as functional independence and play patterns. **References** Capio CM, et al. (2013). *J Intellect Disabil Res*, 57(4), 295-305. **PREDICTORS OF ONSET OF MOBILITY DIFFICULTY IN AMBULATORY PATIENTS UNDERGOING MAINTENANCE HEMODIALYSIS**

Ishikawa, R., Matsunaga, A., Abe, Y., Yoneki, K., Harada, M., Watanabe, T., Miyako, Y., Shigeta, K.

*Kitasato university*

**INTRODUCTION** Difficulty in activities of daily living is more likely to contribute to decreased habitual physical activity. Recent cross-sectional studies have demonstrated that decreased physical activity is independently associated with adverse clinical events and mortality in patients undergoing hemodialysis (HD) (O'Hare AM, et al., 2003, Matsuzawa R, et al., 2012). However, determinants of difficulty in activities in HD patients are unknown. The present study aimed to identify predictors associated with onset of mobility difficulty in ambulatory HD patients. **METHODS** This prospective and longitudinal study followed Japanese outpatients undergoing maintenance hemodialysis three times a week at the Hemodialysis Center from October 2006 to December 2014 for a 12-month period. Patients who had reported difficulty in walking at baseline, and were hospitalized during the study period due to adverse clinical events were excluded. Age, sex, body mass index, hemodialysis duration, primary cause of end-stage renal disease, blood hemoglobin, and serum albumin concentration were obtained from clinical records. The presence of comorbidities (i.e., diabetes mellitus, cardiac disease, cerebrovascular disease, and orthopedic abnormality) were also assessed based on clinical records at baseline. Moreover, leg strength and functional reach were measured to assess motor function at baseline. Patients were asked to identify whether they had difficulty in walking 1 km based on a 5-point Likert scale (inability, severe difficulty, moderate difficulty, mild difficulty, and ease) both at baseline and endpoint, and diagnosed with new onset of difficulty if they reported mild to severe difficulty in walking at endpoint. Multivariate logistic regression analyses adjusted for baseline clinical variables were performed to identify predictors associated with new onset of difficulty in walking after one year. **RESULTS** A total of 74 eligible Japanese outpatients (mean age, 65.2±8.2; male, 50.0%) were analyzed in the study. 37 HD patients (50.0%) newly had difficulty in walking 1 km at the endpoint. Adjusted multivariate logistic regression analyses revealed a significant association between new onset of difficulty in walking and leg strength (odds ratio [OR], 0.92; 95% confidence interval [CI], 0.88-0.96;  $P < 0.01$ ), functional reach (OR, 0.86; 95% CI, 0.76-0.96;  $P < 0.05$ ) and presence of orthopedic abnormality (OR, 3.36; 95% CI, 1.01-11.17;  $P < 0.05$ ). **CONCLUSION** Decreased motor function is closely and independently associated with an onset of mobility difficulty in HD patients. **REFERENCES** O'Hare AM, et al. **EXERCISE INTENSITY DOES NOT AFFECT POST-RESISTANCE EXERCISE HYPOTENSION IN TREATED HYPERTENSIVE ELDERLY FEMALES**

Rodriguez, D.

*São Judas Tadeu University*

**INTRODUCTION:** Hypertension affects over 50% of the elderly population; therefore it is extremely important to search strategies for prevention and treatment of this disease. Resistance exercise (RE) has been recommended for this population, however, the cardiovascular behavior during and after its end is not completely elucidated. **OBJECTIVE:** To verify the influence of training intensity on post-resistance exercise hypotension (PREH) in treated hypertensive elderly women. **METHODS:** Twenty sedentary treated hypertensive women ( $n = 20$ ; 65 ± 3 years; BMI 30 ± 5 Kg/m<sup>2</sup>; MBP 94 ± 6 mmHg; HR 80 ± 12 bpm) performed two experimental RE sessions (40% and 80% OF 1-MVC) composed by 5 exercises (3 sets; 10-12 reps). Blood pressure (BP) was monitored before (20 min) and after (60 min) the RE sessions. Two-way repeated measures analysis of variance test (ANOVA) (SPSS 14.0 for Windows; SPSS Inc., Chicago, IL, USA) was applied followed by Kruskal-Wallis or Bonferroni's post-hoc test when appropriate.  $P < 0.05$  was accepted as statistically significant. **RESULTS:** Both training intensities caused PREH during the whole period observed, however, no statistical difference was found in SBP (40%: -12 ± 3 mmHg; 80%: -13 ± 2 mmHg), DBP (40%: -6 ± 2 mmHg; 80%: -4 ± 3 mmHg) and MBP (40%: -10 ± 4 mmHg; 80%: -8 ± 3 mmHg). **CONCLUSION:** Our data showed that RE is capable of producing PREH in treated hypertensive elderly women, nevertheless training intensity seems not to influence its magnitude or duration. **REFERENCES:** Chen CY, Bonham AC. ### POSTURAL CONTROL DURING STAR EXCURSION BALANCE TEST

Karagiannakis, D., Iatridou, K., Athanasopoulos, S., Mandalidis, D.

*National and Kapodestrian University of Athens*

Postural control during Star Excursion Balance Test Introduction The Star Excursion Balance Test (SEBT) has been used by several authors in the assessment of dynamic balance and lower limb rehabilitation (Plisky et al., 2006; Earl and Hertel, 2001). The aim of the present study was to examine postural control during execution of SEBT by means of body sway and EMG activity of the foot and ankle stabilizers. Methods Eighteen healthy, physically active participants (9 men, 9 women) 27.6 +/- 4.5 years of age, 172.2 +/- 8.2 cm height and 67.1 +/- 13.6 kg body weight, volunteered for the study. The SEBT was performed as described by Robinson and Gribble (2008) with each participant standing on the supportive leg. Postural sway was determined based on the anteroposterior deviation (APd) and mediolateral deviation (MLd) of the center of pressure using a foot pressure platform. The EMG activity of tibialis anterior (TA), peroneus brevis (PB), medial gastrocnemius (GM) and lateral gastrocnemius (GL) was recorded simultaneously during the test and reported as a percentage of each muscle's maximum voluntary contraction (%MVC). Both postural sway and EMG activity was recorded during three attempts of 10-sec each that performed in every direction. Results Our findings revealed that APd was significant greater compared to MLd (13.5 +/- 3.9 mm vs. 7.2 +/- 0.9 mm) regardless of direction ( $p < 0.001$ ). The A, AM and AL directions demonstrated greater APd compared to all other directions (with variable levels of statistical significance). However, the differences between directions with regard to MLd were not significant. The EMG activity of TA was significantly greater (40.7 +/- 13.6 %MVC) compared to PB (24.4 +/- 9.3 %MVC), GL (20.5 +/- 12.7 %MVC) and GM (12.6 +/- 6.5 %MVC) regardless of direction ( $p < 0.001$ ). However, TA and PB EMG activity was less in the A, AM and AL direction compared to the other directions (with variable levels of statistical significance). Discussion The findings of the present study suggest that the human body during SEBT is swayed primarily in anteroposterior direction and postural control is ensured, at least as far as the ankle and foot dynamic stability is concerned, by the activation of TA and PB. The direction-dependent differences, with regard to APd, could be justified by the differences in the EMG activity of TA and PB. The higher APd in A, AM and AL directions compared to ML and P directions may be explained by the lower EMG activation recorded by the TA and PB muscles. Conversely, the greater activation of TA and PB in ML and P directions may enhance postural control, resulting in lower APd in these directions. #### EFFECTS OF INTERVAL EXERCISE TRAINING ON BLOOD PRESSURE AND ENDOTHELIAL FUNCTION IN PRE- AND HYPERTENSIVE PATIENTS

Park, J.J.1, Jo, E.A.1, Cho, K.I.2, Im, D.S.3

*1 Pusan National University, 2 Kosin University, 3 Korea University*

Background: Recently, several studies have shown that interval exercise training (IT) is superior to continuous aerobic exercise (CE) for improvement on endothelial function in hypertensive patients. However, little is known about its effects on changes in blood pressure, especially in hypertensive patients. Purpose: To compare the effects of IT and CE on changes in blood pressure reduction and endothelial function in pre- and hypertensive patients. Methods: Seventeen pre- and hypertensive patients, aged 52.1±7.6, participated in this study, tapered off their medications, if necessary, and were randomized to either IT (n=9) or CE (n=8) group. IT was composed of 5 sets of 3 min exercise at 80% HRR, and each interval was separated by 3 min recovery at 40% HRR. CE was composed of 35 min exercise at 60% HRR. Both groups were designed to use same energy expenditure, and performed exercise 5 days per week for 4 weeks. Endothelial function was determined by assessing endothelial progenitor cells (EPCs) using flow cytometry and flow mediated dilation (FMD) using ultrasonography. Arterial stiffness was measured by pulse wave velocity (PWV). Systolic blood pressure (SBP) and diastolic blood pressure (DBP) were measured at rest and during exercise at 60% HRR by using automatic blood pressure monitor. Results: At rest, SBP was significantly decreased in IT ( $p < 0.01$ ) and CE ( $p < 0.05$ ), and DBP was significantly decreased in IT ( $p < 0.001$ ), but not in CE. During exercise, SBP was significantly decreased in CE ( $p < 0.05$ ), but not in IT, and DBP was significantly decreased in IT ( $p < 0.01$ ), but not in CE. FMD and EPCs were significantly improved in IT ( $p < 0.01$  and  $p < 0.05$ , respectively), but not in CE. There were significantly different changes in DBP during exercise and EPCs between groups ( $p < 0.05$ ). However, PWV was not changed in both groups. Conclusion: The results of this study suggest that IT and CE equally have beneficial effects on blood pressure reduction at rest and during exercise. However, IT may improve endothelial function greater than CE. Therefore, IT could be a better exercise program than CE for pre- and hypertensive patients. Contact e-mail: jiparkpnu@pusan.ac.kr

#### THE EFFECT OF HIGH-INTENSITY INTERVAL EXERCISE AND RESISTANCE EXERCISE ON BLOOD PRESSURE IN NON-OBESE ADULTS\*

Shi, Q.

*Macao Polytechnic Institute*

Shi, Q.1, Kong, Z.2, Lin, H.3, Tong, T.4, Leong, K1, Nie, J.1:1 MPI (Macao, China). 2: UMAC (Macao, China). 3: LNU (Dalian, China). 4: HKBU (Hong Kong, China). Introduction Current recommendations for blood pressure (BP) control involve performing prolonged endurance and resistance exercise. However, the general population fails to follow such regimes due to lack of time. Therefore, it is very important to develop time-efficient exercise intervention strategies. A growing body of evidence demonstrates that minimal volume of high-intensity interval training and resistance training can serve as effective alternates to traditional time-consuming training, inducing similar or even superior physiological adaptations (Babraj et al., 2009). However, limited information is available regarding the impact of minimal vol-

ume exercise on BP. The study aimed to analyze BP responses in non-obese adults following minimal volume high-intensity interval exercise (HIE) and resistance exercise (RES). Methods Twelve non-obese adults (age: 24.3±2.3 years; BMI: 20.8±1.7) underwent: (1) HIE: all-out cycling exercise 30 sec × 4, interspersed with 4 min of rest; (2) RES: a circuit of nine resistance exercise involved the large muscle groups with ten repetitions, interval with 1 min of rest; and (3) CON: a control session of no exercise. Systolic (SBP), diastolic (DBP) and mean arterial (MAP) were measured by ambulatory blood pressure monitoring (ABPM) over a 15 hrs period following exercises and CON, including daytime and nighttime. Results Compared with CON, only RES elicited post-exercise DBP (CON vs. RES: 72±11 vs. 68±12 mmHg) and MAP (CON vs. RES: 94±11 vs. 91±12 mmHg) reduction that lasted 40 min after exercise (P<0.05). Also, the mean SBP (CON vs. RES: 114±8 vs. 117±7 mmHg), DBP (59±4 vs. 56±4 mmHg) and MAP (77±4 vs. 74±4 mmHg) during sleep were lower following RES (P < 0.05). Discussion Though hypertension is the most common chronic condition in more than 40 yr olds, preventing the induction of hypertension in 20-40 yr olds is as important as treating the later stages of the disease. The results of the present study demonstrate that, compared with no exercise and HIE, minimal volume RES (total exercise period of 14 min) was effective in promoting hypotension effects in BP in normotensive adults, as measured by ABPM. It is known that responses to physical training are the result of cumulative acute effects over time (Thompson et al., 2001). Therefore, the current findings led the authors to speculate that minimal volume resistance exercise involved the large muscle groups may represent a time-efficient tool for hypertension prevention in young subjects. \*The study was supported by a research grant from Macao Polytechnic Institute (RP/ESE FD-02/2012). ### PREVALENCE AND CHARACTERISTICS OF EARLY REPOLARIZATION IN MACAO AMATEUR MALE ATHLETES' ELECTRO-CARDIOGRAM \*

Nie, J.

*Macao Polytechnic Institute*

Nie, J.1, Kong, Z.2, Lin, H.3, Tong, T.4, Wang, K. 1, Shi, Q.1 1: MPI (Macao, China). 2: UMAC (Macao, China). 3: LNUU (Dalian, China). 4: HKBU (Hong Kong, China). Introduction Early repolarization (ER), defined as QRS slurring and/or a J-wave on the electrocardiogram (ECG) is found in over 5% of the general European population, and more frequent in athletes. It has long been considered as a normal variant and even an ECG marker of good health (Tikkanen et al., 2009). However, this view was recently challenged by some large population studies demonstrated that ER was associated with reduced overall survival and an increased risk for arrhythmic death (Tikkanen et al., 2009). The purpose of this study was to assess the prevalence and characteristics of ER in Macao amateur male athletes. Methods The 12 lead ECGs recorded in digital form of 106 Macao amateur male athletes (age: 24.0±5.6 years), of Chinese Han ethnicity, with a normal cardiovascular physical examination and without family and personal history of heart disease, were analyzed. In this study, there were 5 different definitions of ECG abnormalities (Type 1-5), which are currently being associated with so called early repolarization. Types 1, 3 and 5 all have an elevated ST amplitude>0.1 mV with or without a notch or slur while Types 2 and 4 have the peak of a notch or onset of a slur>0.1 mV but without ST elevation (Macfarlane et al., 2013). Results Overall, 84.9% of the population studied had one or other form of "early repolarization" defined as one of the five patterns illustrated with the inclusion of ST elevation. Specifically, the prevalence in Type 1-5 was 25.5%, 21.7%, 5.7%, 9.4% and 83.0%, respectively. Discussion Few trials have compared origin of individuals exhibiting ER. To our knowledge, this study is the first to evaluate the prevalence of ER pattern in a athlete population of Chinese Han ethnicity. Macfarlane et al. (2013) in a study of 859 ECGs recorded in Caucasians found that 35% had any form of ER 35% if ST elevation is not considered part of the definition, and 3.3% with the inclusion of ST elevation. These data are far lower than those obtained in our study, particularly in relation to ST elevation. Thus, the associations between ER and cardiac structure and function is worthy of further enquiry. Further, longitudinal investigation is warranted into the long-term significances of different type of ER. \*The study was supported by a research grant from Macao Polytechnic Institute (RP/ESEFD-01/2012). ### EFFECT OF MUSIC TYPE ON HEART RATE VARIABILITY DURING RECOVERY FROM MODERATE INTENSE EXERCISE

Liang, I.J., Lee, P.Y., Liao, C.J., Lin, H.T.

*Kaohsiung Medical University*

Introduction Listening to music not only makes people feel delighted but helps them release their pressure. Previous studies have shown that music can affect the human automatic nervous system and lead to decreased blood pressure and heart rate (Yamasaki et al., 2012). Therefore, the purpose of this study was to discuss the effect of music type on the heart rate variability (HRV) during recovery after engaging in cycling exercise Methods Twelve healthy male college students aged 19.7±0.7 years old were recruited in this study. Every subject participated in three testing conditions randomly including listening Latin, classic and without music after cycling exercise. Cycling intensity was set at resistance of 120W and cycling speed must maintain at 60 rpm for 15 minutes. After exercise, subjects walked on the treadmill at constant speed of 3 km/h and listened the music at the same time. The heart rate was detected at the time 1, 3, 5, 10, 15 minutes after exercise and HRV were analyzed every five minutes after exercise. Results The results showed that the high frequency (HF) of HRV is higher when listening Latin music during recovery especially during 10-15 minutes after exercise reached significant than without music. Moreover, the heart rate decreased rate also faster when listening Latin music than without music 15 minutes after exercise. Discussion Previous study indicated that HF component of HRV could represent the stimulation of the parasympathetic nervous system (Hayano et al., 1991). The results in this study showed that HF of HRV is significantly higher when listening Latin after exercise than without music, which may represent listening Latin music could activate Parasympathetic nerves more after exercise. In addition, this study also found that the heart rate recovered when listening Latin was faster than without music. Listening Latin music could stimulate parasympathetic nervous system and could recover the heart rate quickly after moderate exercise. ## EXERCISE PERFORMANCE IMPAIRMENT IN AN ELITE ENDURANCE ATHLETE AND HORMONAL CONTRACEPTIVE: IS THERE A LINK? CASE REPORT

Heinicke, K.1, Wolfarth, B.2,3

1: University of Bayreuth, 2: TU Munich, 3: Humboldt University, Charité University School of Medicine, Berlin

**Introduction** There is a cumulative number of anecdotal cases of a decline in performance in elite female athletes who use hormonal contraceptives (HC), (1). Given the widespread use of HC in athletes with an estimated similar prevalence as in the general population a potential effect on exercise performance is of particular relevance (2). The purpose of this single case study is to raise awareness regarding the possible impact of HC on exercise performance and health. **Methods and Results** A 23-yr-old female highly trained endurance biathlete (VO<sub>2</sub>max 62.0 ml.kg<sup>-1</sup>.min<sup>-1</sup>, BMI 19.5 kg/m<sup>2</sup>, whole-body fat 12.6 %) complained about a severe decline in exercise performance over a period of 5 months after the athlete had begun to use a low dose vaginal NuvaRing HC. Two to three months after first taking HC she reported chronic fatigue and being unable to train within her normal exercise capacity. Resting heart rate (HR) was increased from her normal value avg. 44 to 62 bpm and blood pressure was increased from avg. 105/70 to 142/85 mmHg. Values of the active orthostatic HR-test (H. Rusko) were increased for the 90-120th sec after standing up from 75 to 109 bpm. She was incapable of achieving an adequate race performance (max. HR 175 bpm compared with her norm of 185 bpm). The athlete experienced extreme dizziness, vertigo, tunnel vision during racing and visual problems while target shooting. She reported repeated sudden sweating and hot flashes induced by high intensity exercise. After differential diagnosis including cardiac dysfunction, electrolyte imbalance, iron deficiency and thyroid gland disorder the athlete was advised to discontinue HC. Subsequently symptoms disappeared within 2 months. **Discussion** The athlete, while using HC, was diagnosed with circulatory dysregulation and impaired exercise performance, which resolved upon HC discontinuation thus supporting evidence from the literature of HC to have serious implications on performance in training and competition. Reported potential effects are e.g. a 5-13 % reduction in VO<sub>2</sub>max (2), increased core body temperature and change in sympathetic control of blood pressure (3). Because there is no awareness of a possible coherence and considering that the smallest worthwhile change in elite athletes performance decides over winning a competition, it is most important to advise athletes on potential adverse effects of HC on exercise performance. **References** (1) Little C (cited 2011 Aug 17). ## EFFECT OF MUSIC TYPE IN LACTATE CLEARANCE AND CARDIOPULMONARY SYSTEM AFTER MODERATE INTENSE EXERCISE

Lee, P.Y., Liao, C.J., Lin, H.T.

*Kaohsiung Medical University*

**Introduction** Previous studies assessing the recovery from high-intensity exercise demonstrated that active recovery was more efficient than the passive one, for removal of lactate from the blood and for restoring exercise capacity. The research found that the motivational music during recovery could increase lactate clearance after exercise. However, this research did not control the steps rate, so that removal of lactate may not only vary from music (Eliakim et al., 2012). Our purpose was to investigate how Latin and classical music affect cardiopulmonary function and lactate clearance under fixed step rate after moderate exercise. **Methods** Twelve healthy male college students aged 19.7±0.7 years old were recruited in this study. Every subject participated in three testing conditions randomly including listening Latin, classic and without music after cycling exercise. Cycling intensity was set at resistance of 120W and cycling speed must maintain at 60 rpm for 15 minutes. After exercise, subjects walked on the treadmill at constant speed of 3 km/h and listened the music at the same time. The VO<sub>2</sub>, VCO<sub>2</sub>, R, RF, RPE, and Lactate intensity were detected at the time 1, 3, 5, 10, 15 minutes after exercise. **Results** The results found that there is no significance difference in VO<sub>2</sub>, VCO<sub>2</sub>, R, RF and RPE between three conditions during recovery. With regard to Heart recovered rate in 15 minutes, Latin was significantly faster than without music. Besides, lactate clearance in 3-15 minutes is significantly faster with Latin music than without music. **Discussion** Previous study showed that relaxing music could not help heart rate recovery after exercise (Tan et al., 2014). However, this study found that listening Latin after exercise let the heart rate recover more quickly than without music that may represent different music type have different effect in cardiovascular function after exercise. Moreover, Latin music also could help lactate clearance more rapidly. The previous research demonstrated that listening to the motivational music got more steps which benefited the lactate clearance (Eliakim, 2013). This study proved that, even at the same steps rate, listening Latin music still could have faster lactate clearance and heart rate recovery. This study shows that listening Latin after exercise could help cardiovascular system recovery. **References** Eliakim M, Bodner E, Eliakim A, Nemet D, Meckel Y. ## PHYSICAL ACTIVITY AND GESTATIONAL WEIGHT GAIN, POSTPARTUM WEIGHT RETENTION AND INFANT'S BIRTH WEIGHT AMONG WOMEN AT RISK OF GESTATIONAL DIABETES

Leppänen, M.

*University of Jyväskylä*

**Introduction** Regular physical activity during pregnancy is recommended for all healthy women during pregnancy and postpartum due to its marked benefits for the mother and the fetus. Physical activity may, for example, be effective in reducing excessive gestational weight gain (GWG), which is associated with short- and long-term health problems such as mother's higher postpartum weight retention (PPWR) and infant's higher birth weight (BW). To prevent this, health care professionals need information about the associations of physical activity with lower GWG, PPWR and infant's BW in this specific target group. The aim of this study was to examine the association of pre-pregnancy leisure-time physical activity (PreLTPA) and changes in LTPA during pregnancy (ChalTPA) with GWG, PPWR (at 8-10 weeks' postpartum) and infant's BW in Finnish women at risk of gestational diabetes. **Methods** The cohort study consisted of 399 pregnant women. Assessment of LTPA was based on self-report at 8-12 (recall on PreLTPA), 26-28 and 36-37 weeks' gestation, and was divided into two domains: 1) LTPA excluding domestic activities, and 2) LTPA including domestic activities. Data on GWG, PPWR, and infant's BW were based on measurements except the self-reported pre-pregnancy weight. Linear regression was used to assess associations between LTPA with and without domestic activities with GWG, PPWR and infant's BW. **Results** The women with 61-180 of light- or 61-120 weekly minutes of moderate-intensity PreLTPA excluding domestic activities had lower GWG (adjusted coeff. -1.43, 95% CI -2.81 to -0.06; adjusted coeff. -1.53, 95% CI -2.94 to -0.12) in comparison with less active women. Similar association was discovered between 61-120 weekly minutes of moderate-intensity PreLTPA excluding domestic activities and lower PPWR (adjusted coeff. -2.08, 95% CI -3.91 to -0.25). More

than 90 weekly minutes of vigorous-intensity PreLTPA including domestic activities were associated with lower infant's BW (adjusted coeff. -140.8, 95% CI -262 to -19.6). In ChalTPA statistically significant associations were not found. Discussion More than one hour of light- or moderate-intensity PreLTPA excluding domestic activities associated with lower GWG and PPWR, whereas more than one hour of vigorous-intensity PreLTPA including domestic activities associated with lower infant's BW. The findings suggest that pre-pregnancy physical activity should be promoted in order to reduce excessive GWG, PPWR and infant's BW.

#### OXIDANT/ANTIOXIDANT MARKERS IN FEMALE SOCCER PLAYERS WITH AND WITHOUT PREMENSTRUAL SYNDROME

Foster, R.1, Vaisberg, M.1, Bachi, A.L.L.1,2, Santos, J.M.B.1, Martins, M.1, Luna Jr, L.A.1, Katekaru, C.M.1, Araujo, M.P.1, Parmigiano, T.R.1, Bella, Z.I.K.J.1

1:UNIFESP; 2:UNICSUL

**Introduction** In a study of David et al (2009), it was shown that PMS affect the performance of female athletes. PMS is defined as a group of physical and behavioral changes starting during the luteal phase and ending during menstruation (Usman et al, 2008). It is also known that intense physical activity is closely associated with the development of oxidative stress (Cooper et al, 2002). It's noteworthy the lack of studies in the literature relating the production of free radicals in female athletes with PMS. The aim of this study was to evaluate oxidant/antioxidant markers in female soccer players with and without PMS in 4 moments: before (pre) and after (post) the game and in the two phases of the menstrual cycle: follicular and luteal. **Methods** Fifty-two eumenorrheic soccer players were evaluated (age :19.8±4.7). The PMS and phases of the menstrual cycle were determinate by monitoring for 3 consecutive months. Evaluation of oxidized Low Density Lipoprotein (oxLDL), Human Anti Oxidized Low Density Lipoprotein antibody (anti-oxLDL), Total Antioxidant Status (TAS) and Peroxide were performed in urine and quantified by ELISA method. The study protocol was approved by UNIFESP Research Ethics Committee (No.1604/10). For data analysis we used ANOVA and Pearson correlation with significance level of 5%. **Results** We were able to show an increase of oxLDL ( $p<0,005$ ) post game in luteal phase, TAS ( $p=0,008$ ) and peroxide ( $p<0,005$ ) post game in follicular phase only in the group without PMS. The correlation analysis revealed a positive correlation between oxLDL and TAS post game in follicular ( $p<0,005$ ) and luteal ( $p=0,03$ ) phases only in PMS group. In addition there was a positive correlation between oxLDL and anti-oxLDL post game in follicular phase ( $p=0,01$ ) only in PMS group. **Discussion** The findings of our study suggest that mechanism controlling the production of free radicals is expressed differently in the group with PMS. Hormonal fluctuations and neurotransmitters that act in PMS may have influence on oxidative stress. We emphasize the importance of detection and monitoring PMS in female athletes as a tool to improve performance and protect athletes' health. **References** David AM et al. #### GENDER DIFFERENCES IN KNEE ABDUCTION DURING WEIGHT-BEARING ACTIVITIES: A SYSTEMATIC REVIEW AND META-ANALYSIS

Cronström, A., Creaby, M.W., Älmqvist, J., Ageberg, E.

Department of Health Sciences, Lund University, Lund, Sweden, School of Exercise Science Australian Catholic University, Brisbane, Australia

**Background** Women are reported to have a higher prevalence of patellofemoral pain syndrome (PFPS) and anterior cruciate ligament (ACL) injury than men. Increased knee abduction during weight-bearing activity is suggested to be a contributing factor, but results from different studies are inconclusive. **Objective** The aim was to systematically review gender-differences in knee abduction during weight-bearing activities in individuals with or without knee injury. **Data sources** A systematic review and meta-analysis were conducted according to the PRISMA guidelines. A search in the databases Medline (PubMed), CINAHL and EMBASE (OVID) was performed in December 2014. **Study selection** Inclusion criteria: Studies including weight-bearing lower extremity functional tasks and 1) investigating gender differences in knee abduction/knee medial to foot position, 2) including healthy men and women and/or those with ACL injury or PFPS, and 3) assessing knee abduction in degrees in either a two-dimensional or three-dimensional motion analysis system, and/or medio-lateral knee position by visual observation. **Data extraction** Study year, type of subjects (healthy, ACL injury or PFPS), number of participant, gender, outcome measure (knee abduction in degrees or visual observation), time point for the assessment (initial contact, peak knee abduction or knee abduction excursion), functional task and effect size were extracted from the studies. **Synthesis of results** Meta-analyses were performed on three studies for patients with knee injury and on 51 studies for healthy individuals. Females with knee injury had increased peak knee abduction compared to their male counterparts (Std diff in mean; -1.16, SE; 0.18, 95%CI; -1.52 to -1.80). In healthy individuals, women performed weight-bearing tasks with increased knee abduction throughout the movement (initial contact; Std diff in mean; -0.65, SE; 0.15, 95%CI; -1.43 to -0.36, peak knee abduction; Std diff; -0.82, SE; 0.12, 95%CI; -1.06 to -0.58 and knee abduction excursion; Std diff; 0.72, SE; 0.17, 95% CI; -1.05 to -0.40). Subgroup analyses for weight-bearing tasks revealed that jump landings, cutting and running were best at discriminating between men and women, whereas there were no gender-differences for drop jump or single-leg squat. **Conclusion** Increased knee abduction during weight-bearing activity is more common in women than in men. Thus, this may be a contributing factor to the gender-difference in knee injuries.

#### THE EFFECT OF ORAL CONTRACEPTIVES ON ATHLETIC PERFORMANCE IN FEMALE ATHLETES.

Nakamura, M., Eguchi, K., Ogura-Nose, S.

Japan Institute of Sports Sciences

**[Introduction]** In Japan, the use of oral contraceptives (OC) in female athletes is low (2%)(Ogura-Nose et al., 2014). The prevalence of dysmenorrhea and premenstrual syndrome (PMS) in elite female athletes in Japan are 25.6 % and 70.3% respectively (Ogura-Nose et al., 2014). The use of OC is necessary as treatment for PMS and menstrual cycle control in addition to dysmenorrhea. However, the effect of

OC on athletic performance is unclear. The purpose of this study was to examine the effect of OC on endurance performance. [Method] Eight female athletes were recruited. All subjects were examined during the menstrual (M) phase, follicular (F) phase, ovulatory (OV) phase, and luteal (L) phase. In addition all subjects were examined during the OC phase (days 10-20 of their OC use) and withdrawal-bleeding (W) phase (days 2-5 post OC phase). Subjects were enrolled randomly during different phases in the menstrual cycle to prevent examiner bias. Phase of the menstrual cycle was confirmed by plasma estrogen and progesterone levels. After natural menstrual cycle tests, all subjects began taking OC. A monophasic oral contraceptives with ultra low-dose (ethinylestradiol: 0.02mg, norethisterone: 1mg) was used. The same measurements were taken once two months after taking OC and during W phase. Post-exercise cardiovascular reactivation test, lactate curve test, and VO<sub>2</sub>max tests were performed during all phases. All parameters were first analyzed by one-way analysis of variance for repeated measurements. All data are presented as means  $\pm$  SD, and a P value of  $< 0.05$  was considered statistically significant. The change in individual measurements due to taking OC was compared using typical error (TE)(Hopkins, 2000). [Results] No changes in resting indexes or endurance performance tests during all phases (among natural cycle, OC phase, and W phase) were observed. Thus, no effect was observed on a natural period. In addition, taking OC did not affect resting indexes or endurance performance. However, when focusing on individual differences, the possibility of increased VO<sub>2</sub>max of for athlete A existed (TE=1.8) in both the W phase (4.2) and L phase (3.7) compared with the F phase. On the other hand, in the case of athlete B, the possibility of decreased VO<sub>2</sub>max existed (TE=1.4) in the L phase (-1.7), the OC phase (-3.1), and W phase (-1.6) compared with the F phase. [Summary] These results suggest that endurance performance did not change during the natural menstrual cycle. As for the effect of taking OC on endurance performance, it is possible that a difference was not recognized because there are great differences between individuals. Therefore, when considering the effect of OC on endurance performance, it is important to consider individual differences.

### CROSSFIT INJURIES – A DESCRIPTIVE SURVEY-BASED RETROSPECTIVE STUDY

Larsen, C., Grosen, K., Nielsen, R.O., Pfeiffer-Jensen, M.

*Aarhus University Hospital*

**Introduction** CrossFit is a combined strength and conditioning fitness program with varied movements performed at a high intensity. Although CrossFit have attained a reputation of being associated with considerable injury risk, only few studies have examined the prevalence of CrossFit-related injuries (Hak PT et al., 2013 & Weisenthal BM et al., 2014). The aim of the present study was to determine the prevalence, the anatomical location and types of injuries in Danish CrossFit athletes. **Material and methods** In November 2014, an email was sent to all members of a local Danish CrossFit gym asking them to complete an online-based, study-specific survey. Participants were asked to self-report current CrossFit-related injuries, including questions on type, location, duration, and characteristics of CrossFit-related injuries. In addition, participants were asked to report time to recovery (number of missed training days), absence from work due to injury, and medical attention. This approach corresponds to the first step in the sequence of prevention, where the extent of the injuries must be identified and described (van Mechelen W et al., 1992). **Results** In total, 930 (29% females) of 1,423 members completed the online survey corresponding to a response rate of 65%. The median age was 26 (IQR: 24-32). At time of data collection, the overall injury prevalence was estimated at 13% (95% CI: 10.8 to 15.3), with 18 participants reporting multiple injuries. Current injuries were most frequently located to the shoulders (n=48, 34.3%) followed by knees (n=26, 18.6%) and lower back (n=16, 11.4%). **Conclusion** To the best of our knowledge, this is the largest study on CrossFit-related injuries. An overall injury prevalence was estimated at 13%, with shoulders, knees and lower back being the most common anatomical locations of injury. Our findings are in concordance with initial studies of CrossFit-related injuries. These findings also call for larger, prospective studies using a standardized survey to examine in detail the identified injury patterns, with the end goal being development of injury prevention strategies. This would also enable comparison of CrossFit-related injuries across studies and sports. **References** Hak PT et al. (2013). *J Strength Cond Res*. Epub ahead of print, Weisenthal BM et al. (2014). *The Orthopaedic Journal of Sports Medicine*, 2(4), 2325967114531177. van Mechelen W et al. (1992). *Sports Med*, 14:82-99. Contact christian.larsen@rm.dk

### THE DIFFERENCES OF SHOULDER ROTATION AGONIST/ANTAGONIST TORQUE RATIO BETWEEN BASEBALL PLAYERS AND NON-PLAYERS IN DIFFERENT TESTING VELOCITIES AT VARIOUS JOINT POSITION

Lin, S.

*Kaohsiung Medical University*

**Introduction** Baseball players have to sustain large loading in shoulder and require strong muscles co-contraction to keep joint stability. The agonist/antagonist strength ratio is one of the indicators to evaluate the joint stability condition in different group. Moreover, the rotational velocity and joint angle are the factors could affect muscle strength that may also change the ratio. The purpose of this study was to investigate the difference the rotational agonist/antagonist strength ratio between baseball players and untrained subjects in different shoulder abduction angle at various rotational velocities(Stodden, Fleisig et al. 2005). **Methods** Nine subjects including five baseball players who played for their university and four university students, aged 20-23, without any upper limb injuries were recruited in the study. In the isokinetic shoulder internal and external rotation concentric strength test, the joint strength was measured by the dynamometer system (System 3, Biodex Medical Systems, USA) in the rotational velocity 60°/sec, 120°/sec and 210°/sec at shoulder abduction 45°, 70° and 90°(Manske, Tajchman et al. 2004). **Results** The internal rotation peak torque of the subjects showed significant differences in different position, and baseball players had larger strength, moreover, the position had interaction with group ( $p < 0.05$ ). The peak external rotation torque also could find significant differences in different positions, rotational velocities ( $p < 0.001$ ), and baseball players also have larger external rotation strength ( $p = 0.023$ ). The ratio of internal/external rotation peak torque had significant differences in different testing velocities and groups ( $p < 0.001$ ). **Discussion** This study found that the joint position and rotational velocities did affect the shoulder rotational strength. However, the rotational velocity had little effect in internal rotation strength, that may result from throwing motion is a common exercise during daily activity, the subjects adapted different throwing velocities(Mulligan, Biddington et al. 2004). We also found that the ratio of internal/external rotation strength was also different at different velocities, higher velocity had higher ratio, that may show the change of internal rotator strength with velocities increase did not the same with external rotators. The shoulder joint have different stability condition at different rotational velocities. Moreover, the ratio was also different in the group. In order to prevent injury, the baseball players have different muscles power to keep joint stability. This information could provide the athletes trainers, coaches, and players for better design muscle strengthening program for prevent injury.

**PREVENTION OF ANTERIOR CRUCIATE LIGAMENT INJURIES IN COMPETITIVE ALPINE SKIERS**

Westin, M.

*Karolinska Institutet*

**INTRODUCTION.** There is a high risk for alpine ski students to sustain an injury during their education at a Swedish Ski High School. Westin et al (2012) reported that the knee was the most common localization of an injury in both male and female skiers. Furthermore, both genders were more likely to sustain injuries to their left than to their right leg. Anterior cruciate ligament (ACL) injury was found to be one of the most severe injuries in elite alpine ski students. An ACL injury often forces the skier to stop skiing for several months. Moreover, an ACL injury often leads to multiple problems from a physiological, psychological, social and economical point of view. Therefore, ACL injury prevention is important and to the best of our knowledge no earlier study on ACL injury prevention has been performed in competitive alpine skiers. **METHOD.** This study represents the fourth step of van Mechelen's "Sequence of prevention" (van Mechelen et al, 1992). The implementation of preventive strategies has been preceded by an injury profile identifying both intrinsic and extrinsic risk factors in competitive alpine skiers. All alpine skiers studying at a Swedish Ski High School between 2011 and 2013 represented an intervention group, while alpine skiers who studied at a Swedish Ski High School between 2006 and 2010 served as controls. Based on injury mechanism and risk factors a professional video film was developed trying to reduce severe knee injuries in alpine skiers. The intervention group watched this film during two seasons. In September 2011 all ski coaches were taught how to implement prevention strategies using different exercises. During the first year the alpine ski students watched the film 1-10 times. Regular contacts (phone calls and e-mails) were continuously performed with each school. At the end of the first season all schools were visited by the principal test leader (MW) to check injury recordings and how they performed the exercises for possible knee injury prevention. A questionnaire was used for checking compliance of the performance of these exercises. At the end of the second season a meeting with the ski coaches was held in order to verify the data collected during these years. **RESULTS.** To be presented at the conference **DISCUSSION AND CONCLUSIONS.** To be given at the conference not insert authors here

**THE LONG-TERM USE OF LONG ACTING  $\beta_2$ -AGONISTS IMPROVES SPRINT AND STRENGTH PERFORMANCE.**

Merlini, M.

*University of Kent*

**The Long-Term Use of Long Acting  $\beta_2$ -Agonists Improves Sprint and Strength Performance.** Background: Long-acting  $\beta_2$ -Agonists can be used on a daily basis by athletes to protect against bronchoconstriction; therefore athletes prescribed with long-acting  $\beta_2$ -Agonists take this on a daily basis for a prolonged period of the time. Limited data is available regarding the ergogenic effects of long acting inhaled  $\beta_2$ -agonists. It is unknown whether the long-term use of long acting  $\beta_2$ -Agonists improves sprint and power performance. Purpose: To investigate the impact of inhaling 100  $\mu$ g of salmeterol (SAL) or 12  $\mu$ g of formoterol (FOR) twice daily over a 10 week period on 30 m Sprint Performance and 1RM Leg Press in competitively active male athletes. Methods: 21 male non-asthmatic competitively active participants were recruited (mean  $\pm$  SD; age  $28 \pm 5.5$  years; weight  $72.1 \pm 10.5$  Kg; height  $164.7 \pm 7.1$  cm). In a randomised single blind design participants were asked to inhale doses of either 100  $\mu$ g of salmeterol (SAL), 12  $\mu$ g of formoterol (FOR) or placebo twice daily over a 10 week period. Over the course of the 10 weeks period participants attended 37.5 hours of resistance training split into 30 sessions. All the training sessions were supervised by a personal trainer who recorded the weight lifted during each session. Participants performed a 30 m sprint and 1RM Leg Press at baseline, 5 weeks and 10 weeks. 3 x 3 Repeated measures ANOVA was used to investigate the changes in sprint performance and 1RM Leg Press. Results: Over the course of the 10 week training programme 30 m sprint time improved significantly in both SAL and FOR groups when compared with PLA (-0.61s and -0.44s) ( $p < 0.001$ ). Over the 10 weeks period improvements in 30 m sprint performance did not differ between SAL and FOR. Significant improvements in sprint performance were observed in SAL and FOR from baseline to the 5 weeks mid-test assessment when compared to PLA (-0.38s; 0.56s) ( $p < 0.01$ ). No significant improvements in 30 m sprint time were observed between SAL, FOR and PLA in the last 5 weeks of training. Over the 10 week training period 1RM significantly improved ( $p = 0.047$ ) in SAL ( $179.63 \pm 35.52$  kg) and FOR ( $133.79 \pm 77.5$  kg) when compared to PLA ( $101 \pm 78.94$  kg). Discussion: This study is the first to demonstrate 10 weeks of inhaling either SAL or FOR results in a significant improvement in 30 m sprint and 1RM Leg Press. Future research is required to investigate whether the mechanism for the improvement in 30 m sprint and Leg Press is as a result of improved muscle function or central control. The findings would suggest WADA may consider re-introducing the requirement for therapeutic use exemption certificates for athletes requesting to use SAL and FOR during training and competition.

**BALANCING THE IMBALANCE OF STROKE SURVIVORS WITH BACKWARD SLOPE WALKING ON DIFFERENTIAL TREADMILL GRADIENTS**

Agbonlahor, E.

*university of benin, benin city, nigeria*

**ABSTRACT** The purpose of this study was to balance the imbalance of stroke survivors by using backward slope walking on differential treadmill gradients to challenge the cardiovascular and neuro-muscular systems and by synthesizing an analysis of lower limb biomechanics during this task. Thus, a total of thirty (30) stroke survivors randomly drawn participated in this study. Balance and co-ordination were tested in relation to backward slope walking on differential treadmill gradients (0, 5 and 10). Analysis of covariance was used to test the hypotheses at 0.01 level of significance. The F-values of 68.80\* and 33.32\* for balance and coordination were respectively found to be statistically significant at 0.01. Turkey HSD was used to determine the source of the significant difference among the groups. It was discovered that there was a significant difference at 10 gradient compared to 5 and 0 gradients ( $10 > 5 > 0$ ) in the balance and co-ordination of the participants. It was therefore recommended that backward slope walking should be used as an additional component in intervention/rehabilitation programme to provide cardiovascular fitness, balance control/proprioception by increasing the amount of blood pump at each stroke and the efficiency of the heart of stroke survivors.

## BMC AND BMD OF MIDDLE-AND OLD-AGED MALES UNDERGOING SHUTTLECOCK KICKING WITH DIFFERENT STYLES AND DURATIONS

Ding, H.

*Guangzhou Institute of Physical Education*

Objective: Kicking shuttlecock is a popular traditional sport in china, the purpose of this study is to compare and explore the BMC and BMD of middle-and old-aged males who underwent shuttlecock kicking with different styles duration. Methods: Twenty seven subjects, aged 40-60 years of kicking shuttlecock 5times a week,2 hours per time, were selected ,and divided into following groups according to their kicking styles leg and durations: group I : kicking with double legs for 3 to 12 years (n =13),group II : kicking with single leg for 1 to 3 years(n =14),and control group: rarely kicking(n =16).The BMC and BMD of skull, thoracic vertebrae, lumbar vertebrae, pelvis, non-dominant arm, dominant arm, left ribs, right ribs, non-dominant leg and dominant leg were analyzed by dual-energy X-ray absorptiometry (EDXA) and their differences were compared among the three groups. Results: BMC and BMD in 10 parts of body in groups I and II were significantly higher than that in control group( $P < 0.05$ ,  $P < 0.01$ ); BMC and BMD of legs, non-dominant leg and pelvis in group II were significantly higher than in control group( $P < 0.05$ ,  $P < 0.01$ ). BMC in all tested parts except right ribs, and BMD in all 10 tested parts in group I were significantly higher than that in control group( $P < 0.05$ ,  $P < 0.01$ ).The BMD of non-dominant leg in group II was significantly higher than in group I ( $P < 0.01$ ). Conclusion: Long-term shuttlecock kicking for middle-and old-aged individuals revealed a greater acquisition of BMC and BMD in almost the whole body. Prolonged kicking duration could cause more acquisition of BMC and BMD, especially in the legs and pelvis. Long-term single-legged kicking seemed to be resulted in unbalanced BMD development of legs.

#### QUANTITATIVE, MULTISCALE PROFILING OF MOTION AND ACTIVITY IN CHILDREN

Clark, C., Barnes, C., Summers, H., Stratton, G.

*Swansea University*

Introduction The de facto standard for objectively measuring physical activity is accelerometry, through devices such as the ActiGraph. However, commercially available accelerometers deliver manufacturer-dependent output values (counts) that are computed by obscure and proprietary signal processing techniques (van Hees et al, 2012) and only provide basic quantification of time averaged activity. It is evident that for a comprehensive analysis of both the level of a child's activity and the mechanics of motion that determine it, detailed quantitative measures are required across time scales (Mannini et al, 2013). This can be achieved by using automated signal analysis of millisecond resolution acceleration data to report on exercise 'quality' through gait analysis together with data integration across longer timescales (minutes to days) to assess the 'quantity' of activity, i.e. duration, variation and intensity, previously unreported in the literature. The aim of this study was to use a multi-time scale analysis to implement a novel approach to the profiling of activity and motion in children and to use this data for cluster based stratification of the cohort. Methods Eighty children (9-11y) volunteered to take part in this study and performed the 20m multistage fitness test (MSFT) whilst wearing a custom made, ankle worn Micro Electro Mechanical System (MEMS) device. Raw tri-axial acceleration traces from the device were used to derive various measures that describe both quantity and quality of motion. These included activity, duration and intensity, the spectral purity of the frequency content of the motion as well as key force characteristics of the gait trace. Results Preliminary data analysis confirmed that the quantity (5-20 minute profiles) and quality (50-500 ms profiles) characteristics were robustly and accurately assessed using the stored acceleration data. Profiling of the cohort using mean and coefficient of variation statistics for each of the quantifiers identified the stride to stride variability in the individual motion as well as the population heterogeneity that describes all of the children. Discussion Automated, quantitative profiling has allowed data from a cohort of children to be grouped together based on their similarity, enabling large amounts of data to be processed and allowing greater insight into both the quality and quantity of movement hitherto unavailable in the literature. #### CRITERION VALIDITY AND RELIABILITY OF REAL-TIME GPS FOR THE MEASUREMENT OF TEAM SPORT ACTIVITY

Minett, G., Cooper, C.

*Queensland University of Technology*

Introduction Global positioning system (GPS) technology has become an increasingly utilised means of quantifying movement patterns and athletic workloads in elite team sports. Traditionally restricted by post-session (PS) download and analyses, commercial GPS systems now offer real-time (RT) monitoring capabilities. In combination with other integrated technologies (e.g. accelerometers and heart rate monitors), RT GPS technology provide immediate feedback that may be used to decisions relating to athletic performance. Despite widespread use, the validity and reliability of commercially available RT GPS systems remain unclear. This study aimed to examine the criterion validity of RT GPS against a known distance and to examine differences between RT and PS download GPS data during simulated team sport activity. Methods Three team sport athletes completed repetitions (n=300) of a 60s, 128.5m exercise circuit involving bouts of stationary, walking, jogging, running and sprinting activity designed to reflect the movement demands of team sports (Bishop et al., 2001). During exercise, participants wore a heart rate monitor and five 15Hz GPS units (SPI HPU, GPSports, Canberra, Australia) within a customised harness. A portable wireless transceiver was positioned within a clear 50m range of the participants to allow live GPS transmission. All data were recorded using the associated commercial software packages, with output settings for speed, distance, heart rate and impacts of the PS download software modified to match those provided by the RT software. Results Significant differences were observed between RT and PS download GPS measures for total distance, peak speed, mean heart rate and total impacts ( $P < 0.02$ ;  $d = 0.23-0.88$ ). Notably, RT and PS download GPS underreported a known distance by  $2.7 \pm 7.3\%$  and  $1.6 \pm 8.4\%$ , respectively. Although variation in total distance between the analysis methods were similar ( $CV = 5.80\%$  vs.  $5.76\%$ ), variability of distance in designated speed zones were higher

using real-time methods (<14.4km.h<sup>-1</sup>: CV=16.0% vs. 7.57%; >14.4km.h<sup>-1</sup>: CV=22.3% vs. 8.95%). Strong positive intraclass correlations were apparent between methods for measures of peak speed, heart rate and impacts ( $r=0.74-0.97$ ;  $P<0.05$ ). Discussion These data highlight marked differences in the measurement of simulated team sport activity between RT and PS download GPS analyses. While the measurement accuracy of RT GPS measures of total distance is acceptable, the variance in speed zone classifications in comparison with PS download analysis is high. Practitioners should be cautioned about using RT and PS download methods interchangeably and be aware of this error when monitoring GPS data live. ### **RUNNING ECONOMY CORRELATES WITH HORIZONTAL ACCELERATIONS OF THE HIP**

Franch, J., Larsen, R.G., Poulsen, M.K.

*Aalborg University*

**Introduction** A standardized method of comparing efficiency of running at different velocities is running economy (RE), measured as oxygen uptake per kg bodyweight in relation to running velocity. RE have been examined during treadmill and level path running showing considerable variation, app. ranging 170-240 ml O<sub>2</sub>/kg/km (1,2). Uniaxial accelerometry (vertical accelerations) is widely used for quantifying energy expenditure (EE) during activities of daily living. The accelerometer is most often positioned close to the body's center of mass, at the hip. While hip accelerometer counts correlate with EE at walking and very low running velocities < 10 km/h (3), counts do not to correlate with EE at low to high running velocities (4). The aim of this study was to investigate variation in RE during treadmill running using tri axial accelerometry. **Methods** Twelve male subjects, age 27.4 ± 8.5 yr, weight 69.8 ± 7.1 kg, height 178.7 ± 7.1 cm (mean ± SD) participated. All subjects were familiarized with treadmill running. Subjects performed six submaximal running velocities at 8.0, 10.0, 12.0, 14.0, 16.0 and 18.0 km/hr. Each exercise period was 4 min separated by 30 sec rest. Pulmonary VO<sub>2</sub> and VCO<sub>2</sub> were measured using Oxycon Pro (Jaeger, CareFusion). Accelerometer counts were measured at the subjects' right hip with triaxial accelerometers (GT3X, ActiGraph). **Results** Running economy at all sub-maximal velocities averaged 209.3±1.6 ml O<sub>2</sub>/kg/km (mean ± SE) and showed a curve linear relationship with increasing treadmill velocity ( $r=0.54$ ,  $p<0.001$ ) and an average optimum running economy of 202.3 ml O<sub>2</sub>/kg/km at 14.7 km/h. Accelerometer counts for all velocities averaged 8623±143, 3216±127 and 1293±103 counts pr. min (mean ± SE) in the vertical, horizontal and mediolateral axis, respectively. RE showed a significant linear correlation with hip horizontal acceleration counts ( $r=0.40$ ,  $p<0.001$ ). Higher counts were associated with superior RE. In contrast, vertical, mediolateral or vector magnitude counts were not correlated with RE. **Discussion** We report that high counts in horizontal hip accelerations are related to superior RE. Our data cannot entirely explain the variations observed in RE, although horizontal counts quantify accelerations occurring in the running direction. As high intensity interval training and strength training are known to improve RE (5), future investigations should therefore examine the effect of training interventions on hip accelerations in combination with leg accelerations. **References** 1. ### **CONCURRENT VALIDITY OF A FOOT MOUNTED IMU TO ESTIMATE STRIDE LENGTH IN RUNNING**

Brahms, C.M.1, Zhao, Y.2, Barden, J.M.1, Gerhard, D.2

*University of Regina*

**INTRODUCTION:** In recent years, several studies have tried to estimate stride length (SL) using body-mounted IMUs and reported promising results [1-4]. However, many studies have only focused on estimating SL for walking [3,4] and, to the best of our knowledge, no study has explicitly investigated the concurrent validity of a single foot-mounted IMU to estimate SL for running. Therefore, the purpose of this study was to determine whether a foot-mounted IMU could provide valid estimates for SL during distance running. It was hypothesized that SL as calculated by the sensor would display high to excellent levels of agreement with a 3D motion capture system criterion. **METHODS:** 11 young, healthy adults (4 female, 7 male) were recruited for this study. Participants were equipped with 3 reflective markers and a foot-mounted 9-DOF IMU (Xsens, MTw) on their right foot and subsequently performed 20 individual 10m runs in which they were tracked by a 6-camera 3D system (Vicon, T-Series). In order to identify the beginning and end of each trial, participants were asked to stand still for 5 sec before and after each run. A running-specific ZUPT-algorithm written in MATLAB was used to calculate SL with the IMU. **RESULTS:** A total of 331 strides were collected and included in the analysis. The analytical procedures successfully identified all of the steps that were recorded by the camera system. Statistical analysis revealed excellent levels of absolute agreement (ICC(3,1) = 0.955) between the two methods (Camera vs. IMU). The upper and lower bounds of the 95% confidence interval were 0.927 and 0.970, respectively. The mean absolute error of the sensor-based method was 1.8% (0.05m). **DISCUSSION:** The results show that SL for running can be accurately estimated with a single foot-mounted IMU in a controlled laboratory setting. However, it was noted that the accuracy varied between participants. It is likely that individual variations of running technique, such as foot strike patterns and ground contact time affect the accuracy of the sensor-based SL algorithm. Future research should focus on investigating whether similar accuracy can be achieved during prolonged overground running and for different populations and conditions. **REFERENCES:** [1] Angermann M, Robertson P, Kemptner T, Khider M (2010). *International Conference on Indoor Positioning and Indoor Navigation*, p.1-6. ### **QUANTIFICATION OF HIGH RUNNING VELOCITY USING A SOCCER MOTION CAMERA TRACING SYSTEM**

Enright, K., Dallaway, N., Daley, T., Li, F.X.

*Liverpool Hope*

**Introduction** Professional soccer clubs utilise semi-automated 'motion camera tracking systems' (MCTS) to track player's movements in competitive matches. This information is then used to inform the coaching process (Wright et al. 2014). The accuracy of MCTS have previously been validated using timing gate technology (TGT) (Di Salvo et al., 2006). This initial study demonstrated strong correlations of average speeds ( $r = 0.999$ ). However, the investigators did not measure total sprint distance or the number of entries into the 'sprint zone' (> 7m.s<sup>-1</sup>). Therefore, the aim of this study was to establish the accuracy of a widely used MCTS at detecting entries into the sprint zone. **Methods** Fourteen amateur soccer players were instructed to complete 4 maximal 30-meter sprints from a standing start (52 runs in total). Sprint speeds were recorded simultaneously using TGT (Brower timing Systems, Utah, USA) and a MCTS (Prozone @, Leeds, UK).

Timing gates were placed at 5m intervals across the running area from 10-30m. Each running time was recorded for further analysis. Results The MCTS recorded 39 entries into the 'sprint zone' and TGT recorded 22. A chi-square test was performed and no relationship was found between a confirmed sprint (TGT) and sprint detection by MCTS,  $X^2(1, N = 40) = .84, p = .58$ . The average Vpeak for TGT was  $7.11 \pm 0.68$  m.s<sup>-1</sup> ( $M \pm SD$ ) and  $8.04 \pm 0.63$  m.s<sup>-1</sup> for MCTS. Vpeak was moderately correlated between the 2 systems,  $r(40) = .63, p < .01$ . The total sprint distance recorded by MCTS was 553m but 109m was not confirmed by TGT. The average sprint distance from MCTS when not confirmed by TGT is  $7.77m \pm 3.41$ , and average TGT Vpeak  $5.05 \pm 0.36$  m.s<sup>-1</sup>. In contrast the average sprint distance from MCTS when confirmed by TG is  $18.5m \pm 8.58$ , and average TGT Vpeak  $6.02 \pm 0.59$  m.s<sup>-1</sup>. Discussion The results suggest that this MCTS is not accurate at detecting high velocity movements. Considering that movement at higher speeds may influence the recovery process following competition (Nedelec et al. 2014) this observation may have implications for applied practitioners who prescribe recovery protocols following match-play. Further research is required to validate the findings from this study using a larger sample size. References: Di Salvo et al. ### A NOVEL WIRELESS ELECTRONIC DEVICE TO DIRECTLY MONITOR TV VIEWING TIME

Alahmadi, M.A.

*King Saud University*

Television (TV) viewing time is the most predominant sedentary behavior and associates with a number of cardiovascular risk factors such as the metabolic syndrome, obesity, and abnormal glucose metabolism. Few measurement tools, such as direct observation and videotaping, have been utilized to objectively monitor TV viewing time. Unfortunately, these measurements have shortcomings as they invade the personal privacy and are impractical in large-scale research studies. Thus, there is a need for alternative objective measures. The main aim of this study was to design an electronic device to objectively monitor TV viewing time in children. Eight children (mean  $\pm$  SD, age,  $10.7 \pm 2.1$  years; body mass,  $35.7 \pm 17$  kg; height,  $137.4 \pm 12.3$  cm) participated in this study. TV viewing time was directly measured for two consecutive days by a novel wireless electronic device, using Radio-frequency identification (RFID) technology which is connected to a main electronic board that is designed to measure TV viewing time in minutes. The preliminary results show that the average TV viewing time of children was  $99 \pm 75$  min/day. It is concluded that the current research is expected to produce a novel wireless electronic tool that can monitor TV viewing without intrusion to the personal privacy and can be widely used as an objective method of assessing TV viewing time.

### VALIDITY OF THE WAHOO KICKR POWER TRAINER AND RELIABILITY OF A 4 KM CYCLE TIME TRIAL

Zadow, E.K., Fell, J.W., Smith, S.T., Shing, C.M.

*University of Tasmania*

Purpose: To assess the validity of power output of the Wahoo KICKR Power Trainer using a dynamic calibration rig and the reliability of a 4 km cycle time trial (TT) when completed on the Wahoo KICKR Power Trainer. Methods: The Wahoo KICKR power output was compared to a dynamic calibration rig over power outputs of 100-600 W at cadences of 80, 90 and 100 rpm. To assess the reliability of a 4 km TT, twelve trained male cyclists (mean  $\pm$  SD; age:  $34.0 \pm 6.5$  years, height:  $178.4 \pm 6.2$  cm, body mass:  $76.8 \pm 9.6$  kg) completed three 4 km TTs on the Wahoo KICKR Power Trainer, each separated by a minimum of two and a maximum of three days. Mean power (W), cadence (rpm:  $n = 11$ ), speed (km.h<sup>-1</sup>), heart rate (bpm) and total time (s) were recorded for each TT while ratings of effort (0-10) were collected immediately upon TT completion with sessional ratings of perceived exertion (6-20) collected 10 mins post each TT. Results: Bland - Altman analysis demonstrated a bias of -0.8% (95% Limits of Agreement: -5.6 - 4.0%) across all three cadences for the Wahoo KICKR Power Trainer when compared with the dynamic calibration rig. Intraclass correlation (ICC) determined reliability with the average ICCs between TTs (2 to 1, 3 to 2 and 3 to 1) nearly perfect for power 0.95 (95%CI 0.89-0.98) and heart rate 0.93 (95%CI 0.85- 0.98) while the ICC was moderate for speed 0.70 (95%CI 0.46- 0.88) and total time 0.75 (95%CI 0.53-0.90) with a high ICC for cadence 0.80 (95 %CI 0.60- 0.92). Coefficient of variation was 2.9%, 4.5%, 3.7%, 1.5% and 3.6% for power, cadence, speed, heart rate and total time, respectively. Conclusion: When compared to a dynamic calibration rig, the Wahoo KICKR Power Trainer displays a small mean bias across power outputs of 100-600 W. When completed on the Wahoo KICKR Power Trainer, a 4 km TT in trained cyclists is highly reproducible for power with a sensitivity to detect a smallest worthwhile change in power output of 1.5%.

### MO-PM34 Neuromuscular Physiology: Coordination

#### BILATERAL DEFICIT: CONTRIBUTION OF POSTURAL ADJUSTMENTS TO TORQUE PRODUCTION

Simoneau-Buessinger, E., Leteneur, S., Toumi, A., Dessurme, A., Gabrielli, F., Barbier, F., Jakobi, J.M.

*Université de Valenciennes et du Hainaut Cambresis*

Introduction During maximal contractions, the sum of forces exerted by homonymous muscles unilaterally is typically higher than the sum of forces exerted by the same muscles bilaterally. However, the underlying mechanism(s) of this phenomenon, which is known as the bilateral deficit, remain equivocal (Jakobi & Chilibeck 2001). One potential factor that has received minimal attention is the contribution of postural muscles and positional adjustments to bilateral and unilateral force production. The purpose of this study was to evaluate the plantar-flexors in one common position in an innovative ergometer that permitted the influence of torque from postural adjustments to be adapted. Methods Twenty healthy adult males performed unilateral and bilateral maximal voluntary isometric plantar-flexion contractions. Torques at the ankles were assessed with a custom designed ergometer that allowed the participant to be identically positioned between setups where torque generated from postural adjustments were included within the net ankle torque (locked-unit) or independent of the ankle (open-unit). Electromyographic activity was recorded from the soleus, gastrocnemius medialis, gastrocnemius lateralis and tibialis anterior muscles of both legs. Results While there was a significant bilateral deficit in the locked-unit ( $p=0.01$ ), it was not evident in the open-unit ( $p=0.07$ ). In the locked-unit, unilateral torque was greater than in the open-unit ( $p<0.001$ ) and this was due to an

additional torque from the body since the electromyographic activity of the agonist muscles did not differ between the two setups ( $p>0.05$ ). Discussion This study revealed that postural adjustments directly influence isometric torque production in unilateral and bilateral contractions and this contributes to observations of the bilateral deficit. The present data demonstrated that postural adjustments contribute substantially to torque and that when these adjustments are contained within a measure of plantar-flexion the bilateral deficit is recorded. However, when force is localized to the ankle joint bilateral and unilateral forces were similar. The vast majority of the literature on the bilateral deficit has clearly speculated and attempted to study a neural phenomenon. These data indicate that further exploration into the bilateral deficit needs to account for postural adjustments in the measurements of torque. References Jakobi JM, Chilibeck PD. (2001). *Can J Appl Physiol*, 26, 12–33. Contact emilie.simoneau@univ-valenciennes.fr

### INVESTIGATION OF MOTOR UNIT SHORT-TERM SYNCHRONIZATION IN STERNOCLEIDOMASTOID MUSCLES

Bo Cing, Y., Chia-Chi, Y., Tzu-Han, C., Fong-Chin, S., Lan-Yuen, G.

*Kaohsiung Medical University, National Cheng-Kung University*

Motor units are the fundamentally functional units of the neuromuscular systems, the recruitment or derecruitment of the motor units and the pattern of the discharge rates of the active motor units have been proven to modulate the forced production of the neuromuscular systems (1). Along with these basic electrophysiological properties, the motor unit short-term synchronization, which stands for an above-chance tendency for near-simultaneous discharges between pairs of motor units, also plays a pivotal role in regulating the mechanical output of the neuromuscular systems (2). This study, aimed to investigate the properties of the motor unit short-term synchronization to characterize the neuromuscular control strategies in the sternocleidomastoid muscles for healthy individuals. The surface electrophysiological signals of the bilateral sternal heads of the sternocleidomastoid muscles were detected at 25% of the maximum voluntary contraction during cervical isometric flexion in twelve healthy individuals (mean age:  $27.5\pm 6.2$  years) and then decomposed into individual motor unit action potential trains. Subsequently, the strength of the short-term synchronization index (Sync Index) of each motor units pair were determined by computing the percentage of the significantly synchronous firings occurring within  $\pm 6$ ms of zero time latency normalized to the number of firing instances of the reference motor unit. In the results, a total of 479 motor units and 2,193 motor units pairs was identified and averages of 1.52%, 3.14%, 3.78%, 4.68%, 6.63% and 5.40% of all the firings were short-term synchronized for all identified motor units pairs with mean recruitment thresholds of 0%~5%, 5%~10%, 10%~15%, 15%~20%, 20%~25% and more than 25% MVC, respectively. Significant dependence of short-term synchronization on the mean recruitment threshold in each identified motor units pair was documented in healthy individuals ( $\text{Sync Index} = 0.17 * \text{Threshold} + 1.60$ ,  $R^2 = 0.811$ ,  $p < 0.01$ ). These present results agreed with previous observations of greater strength of short-term synchronization for the motor units pairs with high-mean recruitment thresholds as compared to those with low-mean recruitment thresholds (3, 4). It is concluded that motor unit short-term synchronization serves as a deliberate strategy for neuromuscular activation attempting to produce efficient mechanical output of the sternocleidomastoid muscles in healthy individuals. 1. ### REACTION TIME IN UPPER EXTREMITIES FOLLOW A PROXIMAL-DISTAL GRADIENT THAT MIGHT BE LINKED TO NEUROPHYSIOLOGICAL DIFFERENCES

Aune, M.A., Djuvsland, A., Aune, T.K.

*Nord Trøndelag University College*

Introduction Reaction time (RT) is the interval between presentation of a stimulus and the response to it (Oxedine, 1968; Schmidt & Lee, 2014), and a short RT is important for coping with challenging events and perturbations in everyday life. RT depends on properties of the neuromuscular system (Guyton & Hall, 2011). The neuromuscular system for proximal and distal effectors have several neurophysiological differences that might influence RT. Such differences is documented for the corticospinal pathways, number of synapses, latency time, size and length of axons from motor cortex to the innervated muscles and nerve conduction velocity (Bear, Connors & Paradiso, 2006; Brodal, 2004; Kolb & Wishaw, 2009). Based on these morphological differences the purpose of this study was to explore eventually functional differences in RT for effectors in the upper extremities. Method 12 sport science students were recruited to perform a simple RT-task. The subjects had to press a button as quickly as possible after a presentation of a light stimulus. The task consisted of a constrained single joint isometric contraction (pressing the button) by randomized single-joint extension of shoulder, elbow, wrist and index finger. Results The results showed a proximal-distal gradient in RT with a significant joint effect for shoulder, elbow, wrist and index finger. Shoulder had the lowest RT (mean  $22.699\text{ms} \pm 1.753$ ), followed by elbow (mean  $23.811\text{ms} \pm 1.756$ ), wrist (mean  $24.704\text{ms} \pm 3.412$ ) and index finger (mean  $30.256\text{ms} \pm 3.907$ ). Discussion The observed proximal-distal gradient in RT for upper extremities favored proximal compared to distal effectors. The relatively low RT for proximal effectors might be explained by higher nerve conduction speed because of big sized axons and higher action potential frequency in addition to shorter neural pathway from M1 to the activated muscles. This in spite of distal effectors monosynaptic projections, lower latency time and lower threshold for action potentials. In conclusion, the neurophysiological differences between for proximal and distal joints in sum cause a proximal-to-distal gradient for RT. References Bear, MF., Connors, BW., Paradiso. MA. ### CORTICOSPINAL EXCITABILITY AND INTERHEMISPHERIC INHIBITION

Gueugneau, N., Grosprêtre, S., Lepers, R.

*Université de Bourgogne*

CORTICOSPINAL EXCITABILITY AND INTERHEMISPHERIC INHIBITION ASSOCIATED WITH WIDE-PULSE HIGH-FREQUENCY NEUROMUSCULAR STIMULATIONS Nicolas Gueugneau, Sidney Grosprêtre, Romuald Lepers INSERM-U1093 (Dijon, France) ngueugneau@netcourrier.com INTRODUCTION Neuromuscular electrical stimulations (NMES) with wide-pulse-high-frequency (WPHF) induce muscle contractions partly originating from a central pathway (1). Yet, while this type of NMES is known to modulate spinal excitability, the precise contribution of supraspinal circuits of motor control remains to be determined (2). Here, we aimed at evaluating the effect of an acute upper-arm WPHF

NMES training on both spinal and cortical excitability. Particularly, we evaluated spinal excitability (through H-wave), and cortical and transcallosal excitability, as assessed by motor evoked potentials (MEPs) and interhemispheric inhibition (IHI) respectively. METHOD Ten healthy subjects underwent a single WPHF NMES session consisting of 60 stimulation trains (100Hz with 1ms pulse width evoking 15% of MVC, 5s on / 5s off) of the right Flexor Carpi Radialis (FCR). The following parameters were recorded from the right and left FCR before and after the NMES protocol: MVC torque (wrist flexion), H reflex (Hs), M wave (Ms), MEPs amplitudes, and IHI from right to left motor cortex. Wrist force (torque time integral), right and left Hs were also monitored throughout the protocol. RESULTS The NMES session did not produce any significant change of the MVC, Ms and MEPs bilaterally ( $P > 0.05$ ). However, right Hs/Ms was strongly decreased (-50%,  $P < 0.05$ ) and right to left IHI was significantly increased (+15%,  $P < 0.05$ ) after the protocol. Interestingly, online monitoring of the wrist force and Hs of the right FCR shown that they abruptly drop after the very first contractions (-40%, of their pre-test values during the 5 first contractions) and then slowly decreased until reach their post-test values. DISCUSSION We showed that an acute session of WPHF NMES applied to the right upper limb did not produce any change of the MVC. However, spinal excitability was strongly decreased during the protocol as we shown an abrupt drop of the right Hs. Interestingly, while cortical excitability was not significantly modulated, it seem that the NMES session had an influence on transcallosal excitability, as we showed an increased of IHI after the protocol (to a comparable extent to what is observed after voluntary contractions (3)). It can be concluded that WPHF NMES involve mechanisms located at spinal and supraspinal levels. REFERENCES (1) Collins DF & al., *J Physiol* 2002; 538: 289–301. ### DIFFERENCE BETWEEN MECHANOMYOGRAPHIC AND ELECTROMYOGRAPHIC RESPONSES TO ISOMETRIC CONTRACTIONS OF BICEPS BRACHII AT DIFFERENT ELBOW JOINT ANGLES

Shima, N.1, Murayama, M.2, Inami, T.3, Nosaka, K.4

1:Tokai-Gakuen University (Japan), 2:Keio University (Japan), 3:Waseda University (Japan), 4:Edith Cowan University (Australia)

Introduction A previous study reported that biceps brachii electromyogram (EMG) amplitude linearly increased with increasing in contraction intensity, but this was not the case for mechnomyogram (MMG) [1]. The amplitude of MMG represents low-frequency oscillations of active muscle fibres [2], thus MMG may be affected by muscle stiffness that is determined by the number of attached cross-bridges. It was hypothesised that EMG would not be affected by muscle length changes, but MMG would be. The present study investigated the effect of muscle length modulated by the elbow joint angle on MMG and EMG of biceps brachii during isometric contractions at different intensities. Methods Fifteen men (24-33y) performed isometric contractions of the elbow flexors at 15, 30, 45, 60 75, and 90% of their maximal voluntary contraction (MVC) strength at the elbow joint angle of 90°, 60° and 30° (0°=full extension), in this order. Surface bipolar EMG electrodes were placed at the mid-belly of the biceps brachii, and an accelerometer to record MMG was placed in between the electrodes. Torque, MMG, and EMG signals were recorded to a computer at a sampling rate of 2 kHz, and root-mean-square (RMS) of the MMG and EMG signals was calculated for 0.5 s when the target force was achieved, and normalised by RMS during MVC. A two-way repeated-measures ANOVA was used to compare between MMG and EMG for changes in RMS amplitude over the intensities for each joint angle. When a significant main or interaction effect was found, a Tukey post-hoc test was followed. Results MVC strength was greater ( $P < 0.05$ ) at 90° followed by 60° (87% of that at 90°) then 30° (68%). For all elbow joint angles, RMS of EMG linearly increased with increasing the intensity from 15% to 75% (30°, 60°) or 90% (90°), and no significant difference was found for the magnitude of the change between the angles. RMS of MMG at 90° also linearly increased with increasing the intensity from 15% to 90% ( $P < 0.05$ ) in a similar way to that of EMG. However, at 60° and 30° the increases in RMS were greater for MMG than EMG ( $P < 0.05$ ) from 30% to 60%, but no further increases in MMG were evident after 60% MVC at 60° and 45% MVC at 30°. Discussion These results supported the hypothesis, showing that muscle length change did not affect EMG but affected MMG. It may be that no further increases in RMS of MMG after the moderate intensity at 30° and 60° indicate no further increases in muscle fibre oscillations, because of longer muscle fibre length at these angles than 90°. ### SHORT-TERM LOW-LOAD BLOOD FLOW RESTRICTED EXERCISE IMPROVES MECHANICAL MUSCLE FUNCTION AND NEUROMUSCULAR ACTIVATION

Nielsen, J.L.1, Frandsen, U.1, Simonsen, C.1, Nielsen, M.1, Aagaard, P.1

University of Southern Denmark

Introduction In the last decade low load blood flow restricted (BFR) exercise has been established as a low load alternative to increase maximal muscle strength (MVC) and muscle mass in human subjects (Kubo et al. 2006; Nielsen et al. 2012). Recently, we showed a marked rapid increase in myofiber cross sectional area (CSA) after 5 days of BFR training (Nielsen et al. 2012). However, it remains unknown if such early increase in myofiber CSA is translated into functional strength gains or mainly reflects transient cellular fluid accumulation. Therefore, the aim of this study was to investigate whether short-term (5 days) BFR exercise intervention leads to enhanced mechanical skeletal muscle function. Methods Ten healthy male subjects performed 5 consecutive days (7 sessions) of knee extension exercise with partial blood flow restriction. Four sets of unilateral knee extensions were performed to concentric failure using low muscle loadings (20% 1RM). Lower limb blood flow restriction was achieved using a pneumatic cuff (Zimmer, US) inflated to 100 mmHg, which was released upon cessation of the fourth set. Mechanical muscle function and neuromuscular activation were evaluated before and after the 5-days intervention period using maximal isometric knee extensor dynamometry (MVC) and interpolated twitch analysis, respectively. Results MVC increased 3.0% from Pre ( $324.6 \pm 69.9$  Nm) to Post intervention ( $334.6 \pm 59.1$  Nm) ( $P < 0.05$ ) ( $P < 0.05$ ). Similarly, neuromuscular activation increased 1.8% from Pre ( $94.4 \pm 2.5$  %) to Post ( $96.1 \pm 1.9$  %) ( $P < 0.05$ ). Discussion In the present study MVC increased (~3 %) after just 5 days (7 sessions) of low-load BFR exercise, which was accompanied by comparable gains in neuromuscular activation (~2 %). Thus, the marked increases in myofiber CSA (~38 %) previously observed using a similar time course and exercise regime (Nielsen et al. 2012) might be accompanied by quantitative and/or qualitative gains in contractile acto-myosin properties, although the present increase in MVC could also be related to increased neuromuscular activation. In contrast, neuromuscular activation remained unchanged after 12 weeks of BFR training (Kubo et al. 2006), while no previous study has reported detectable neural adaptations with BFR exercise. These divergent observations may be related to differences in training protocols, as repetitions were performed to failure in the present study (vs. using a preset number of repetitions), potentially resulting in sEMG values  $\geq 100$  % of maximal isometric sEMG (Wernbom et al. 2006) that may represent a significant stimulus for neural adaptation. ### NEUROMUSCULAR RESPONSE OF THE LOWER LIMB DURING GROSS MOTOR TASKS

Furlong, L.A.M.<sup>1,2</sup>, Kong, P.W.<sup>3</sup>, Pain, M.T.G.<sup>1</sup>

*Loughborough University*

1. School of Sport, Exercise and Health Sciences, Loughborough University, United Kingdom 2. Institute for Sports Research, Nanyang Technological University, Singapore, 3. National Institute of Education, Nanyang Technological University, Singapore. **INTRODUCTION:** Neuromuscular (NM) response during simple reaction time tasks requiring co ordination of large muscles is less well understood than during simple tasks with small muscles. In athletic actions the former are required and given the marked differences in the neuromuscular system between the two scenarios differences in reaction time between them may be meaningful. The aim of this study was to investigate temporal characteristics of the lower limb NM response during weight-bearing (WB) and non-weight-bearing (NWB) simple reaction kicking and plantarflexion tasks. **METHODS:** Following ethical approval, 16 healthy males ( $23.5 \pm 1.0$  years) performed 10 trials of plantarflexion and kicking as quickly as possible following visual stimulus from WB and NWB start positions. Wireless surface EMG electrodes with tri-axial accelerometers (2000 Hz, Trigno, Delsys Inc., Natick, MA., USA) were attached to biceps femoris, rectus femoris, vastus lateralis and medialis, gastrocnemius lateralis and medialis and tibialis anterior of the preferred kicking leg. Time difference between onset of stimulus and initiation of first muscle activation (pre-motor time, PMT), initiation of primary agonist muscle (PA) and initial acceleration (movement time, MT) were determined for each trial. Between-task and between-condition differences were determined using paired t-tests (statistical significance:  $p < 0.05$ ) and Cohen's Dz (moderate effect  $> 0.6$ , large effect  $> 1.2$ ). **RESULTS:** Average PMT, PA and MT were 171, 197 and 224 ms (NWB kicking), 163, 255 and 255 ms (WB kicking), 188, 197 and 229 (NWB PF) and 192, 242 and 254 (WB PF). All differences were moderate/large. Differences between WB and NWB PA during kicking (197 vs. 255 ms) and plantarflexion (197 vs. 242 ms), and PMT in WB kicking and plantarflexion (163 vs. 192 ms) were statistically significant. Muscle used to determine PMT varied with subject, task and condition but gastrocnemius medialis was used most frequently across all trials. **DISCUSSION:** Increased PMT during WB plantarflexion compared to kicking may be due to preferential selection of muscles for initial stabilisation with longer response times, in particular the antagonistic tibialis anterior. Increased PMT is associated with decreased ability to respond to perturbation. A need for stabilisation prior to completion of WB test tasks may explain shorter PA during NWB tasks. Results support the large capacity and individual nature of neuromuscular system adaptation to altered task demands, but further work is required to fully investigate these capacities. **CONTACT:** L.A.M.Furlong@lboro.ac.uk

### SPECTRAL EMG CHANGES OF THE SUPERIMPOSED M WAVE DURING ISOMETRIC VOLUNTARY CONTRACTIONS OF INCREASING INTENSITY

Rodriguez-Falces, J.

*Public University of Navarra*

**Objective:** We examined the power spectral changes of the compound muscle action potential (M wave) evoked during isometric contractions of increasing strength. **Methods:** Surface electromyography (sEMG) of the vastus lateralis and medialis was recorded from 20 volunteers who performed 4-s step-wise isometric contractions of different intensities. A maximal M wave was elicited by a single stimulus to the femoral nerve and superimposed on the voluntary contractions. The spectral characteristics ( $F_{mean}$  and  $F_{median}$ ) of sEMG and M-wave signals were calculated. **Results:** M-wave spectral indicators increased systematically with contraction intensity up to 60% MVC, and then levelled off at higher forces. Over the 10-60% MVC range, the increase in spectral indicators was 3 times higher for M waves (36%) than for sEMG (12%). **Conclusions:** The consistent increase in M-wave spectral characteristics with force is due to the fact that the number of motor units recruited by the superimposed supramaximal stimulus is approximately stable.

### EFFECT OF WEIGHT BEARING ON TOE FLEXOR STRENGTH AND FOOT ARCH HEIGHT

Fukuoka, R.<sup>1</sup>, Morita, N.<sup>2</sup>, Kurihara, T.<sup>3</sup>, Yamauch, J.<sup>4</sup>

*1.Grad. Sch. Medicine, Hokkaido Univ, JAPAN 2.Hokkaido Univ. Education, JAPAN 3.Ritsumeikan Univ, JAPAN 4.Tokyo Metropolitan Univ, JAPAN*

**[Introduction]** Toe flexor strength (TFS) is associated with the cross-sectional area of foot intrinsic muscles (Kurihara et al., 2014) and physical performances of the lower limbs in children (Morita et al., 2015) and adolescents (Otsuka et al., in press), but not with the foot arch height (FAH; Morita et al., 2015). Kelly et al. (2014) shows that with increasing load perpendicular on the foot, FAH decreases and activities of electromyography of the intrinsic foot muscles increase; however, it is still unclear whether changes in FAH with increasing loading affect TFS. The aims of this study were to investigate the effects of weight bearing on TFS and how changes in FAH were related to TFS. **[Methods]** Twelve healthy college-students participated, and their TFS and FAH were measured with 5 weight bearing conditions (0, 20, 40, 60, and 80 kg) in the sitting position. Weight plates were borne on the distal end of thigh and the vertical ground reaction force on the foot was recorded during TFS measuring. FAH was assessed as distance between the navicular tuberosity of the foot and the floor. **[Results]** TFS increased with increasing load, while FAH lowered with increasing load. There were significant correlations between changes of TFS and changes of FAH after weight bearing ( $r = -0.333$ ,  $p < 0.05$ ). **[Conclusion]** Our results suggest that weight bearing on the foot could enhance TFS that might be due to the decrease in the foot arch height with the stretching of the plantar muscles. **References:** Morita N, Yamauchi J, Kurihara T, Fukuoka R, Otsuka M, Okuda T, Ishizawa N, Nakajima T, Nakamichi R, Matsuno S, Kamiie S, Shide N, Kambayashi I, Shinkaiya H. #### COMPARATIVE OF RACE STRATEGIES VERSUS OPTIMAL STRATEGIES IN 2000 M ROWING

Rachnavy, P.

*suranaree university of technology*

**Introduction** To be successful in rowing competition need a good strategy. Pacing strategic is one of a key factor for rowing competition. It is influencing in energy expenditure and the development of fatigue. Therefore, the aim of this study was to compare optimal strategy with race strategies of Thailand women double scull team. **Methods** A numerical program of rowing has been developed to simulate and optimization rowing strategy which relates the energy production and spent during the race. The simulations in this study are performed by solving equations of motion. The forces acting on the rower and boat are considered. By vary the power output will result in fastest strategy. Then the optimal strategy profile were compared with the race profile. **Results** The results are clearly showing that optimal pacing strategies are more beneficial to performance than race strategy. Optimal strategy achieved better finishing times than race strategy. It have lower variation of boat speed during the race. **Discussion** The studies in this paper has demonstrated the influence of pacing strategy on performance. It is suggested that psychological factors influenced for decision making by rowers in competitive event. They believe that when they leading the race from the start it is easier to control the race and get some psychological advantage. However it is not an idea for good energy expenditure and developing of fatigue. The results of this study are significance to rowers, coaches and sport scientists, for training and racing. **References** Muehlbauer T, Schindler T, Widmer A. (2010) *Eur J Sport Sci*, 5, 291–296. #### STRUCTURAL EQUATION MODELS OF MORPHOLOGICAL SPRINT MOTION FOR ELEMENTARY SCHOOL CHILDREN

Kokudo, S.

*Kobe University*

The purpose of this study was to establish morphological models of the sprint in order to develop some effective methods for teaching the sprint in the physical education class. **Methods** The two types morphological models of the sprint motion, circular model and infinity model, were drawn applying cause and effect diagram or fishbone diagram, one of the quality control tools. These models were covered the descriptive checkpoints of previous studies. The circular model composed 3 major motions; ground catching, driving, and swing action. The infinity models were composed ground catching, scissors and release, on which scissors positioned center and other 2 motions formed infinity shape. These motions were constructed 36 morphological observation points. Every morphological observation was categorized into 2-3 levels respectively. Intermediate sprint forms (25-35m of 50m sprint) of 189 3rd and 4th-grade elementary school children were recorded by digital video cameras. Their forms were played in slow motion or frame-by-frame, and an investigator evaluated the checkpoints. **Structural equation modeling (SEM)** was applied for both circular and infinity models based on the two hypothesized causal models. **Results and Discussion** The major motions of sprint of both circular and infinity models were constructed from 5 motions: swing of free leg, the catching preparation, ground-catching motion, drive motion and push motion including 13 checkpoints. The circular model was better than infinity models; the fitting indices were chi-square=114.91 (df=98,  $P<0.05$ ), RMR=0.044, GFI=0.906, AGFI=0.856 and RMSEA=0.070 on the circular model, and chi-square=140.75(df=59,  $P<0.05$ ), RMR=0.039, GFI=0.885 AGFI=0.822 and RMSEA=0.086 on the infinity model. The model was easy to understand the casual relationship of time-followed sprint motions. The viewpoints related to scissors motion should be developed because the motion on the infinity model was assumed the one of the important concept for sprint motion. Arm pumping action and 10-meter running time were added on the circle model: the fitting indices were chi-square=170.93 (df=26,  $P>0.05$ ), RMR=0.064, GFI=0.886, AGFI=0.842 and RMSEA=0.063. The arm pumping action was only affected to ground-catching motion. The other arm motions such as arm front position or back position and body axis construction motion were not contributed to the final model. The drive motion strongly influenced running time (causal coefficient = -0.88). **Conclusions** Sprint motion was able to evaluate with circular model of leg motions. The model. **Criterion-related validity** was investigated on the circular model. This work was supported by Grant-in-Aid for Scientific Research(C), (24500697) Japan. #### SWIMMER TRACKING BY SINGLE HIGH-DEFINITION CAMERA

Minato, Y., Kitahara, I., Kameda, Y., Ohta, Y.

*University of Tsukuba*

**INTRODUCTION** Zoom video of Swimmers is useful for coaching and reviewing. Location of a swimmer along a swimming lane is necessary to produce his/her zoom video automatically. There are some approaches to estimate location of a swimmer by setting multiple cameras with computer vision method on a pool such as [1], but these approaches are not practically available in regular pools. We propose swimmer tracking method that utilizes single 4K camera with a resolution of 3840 pixels by 2160 pixels. **METHOD** We assume the camera is set at the higher position in audience seats so that it can cover whole water surface of the pool. Our proposed procedure has four steps; lens distortion correction, rectification of the pool area, extraction of swimmer region, and model fitting to finally estimate the position of a swimmer. First two steps are implemented by geometric operation in computer vision approach[2]. A rectangular shape region that corresponds to one lane is passed to the extraction step of swimmer region. Background subtractor[3] is applied to detect swimmer region. Detected region is integrated along the vertical axis of the swimming lane. As a result, image feature function  $f(p, t)$  is obtained where  $p$  is the distance along the swimming path from the start, and  $t$  is the time with resolution of frame per second. We prepare a swimmer model  $s(p)$  that describes the distribution of image feature over swimming path direction. By searching the most fitted position  $p$  with the model  $s(p)$  over  $f(p,t)$  at time  $t$ , we obtain the swimmer location  $p$  at time  $t$ . **RESULTS AND DISCUSSION** We have applied the proposed method for a real swimming game to verify the performance. Reference location of swimmers was manually given by checking the original 4K video. We have verified the performance of the proposed method for surface swimming section because our current swimmer model  $s(p)$  is designed to describe swimming actions near water surface. Underwater section and turn section are left for our future work. The averaged errors of location estimation for surface section are; breaststroke:20cm, backstroke:20cm, freestyle:50cm, butterfly:30cm. Note that we eliminated a section where strong disturbance from large video screen could be found. **REFERENCE** [1] E. Pogalin et al, "Video-based Training Registration for Swimmers. *Int. J. Computer Science in Sport*, vol.6, ed.1, pp.4-17, 2007. [2]

### SUCCESS IN ELITE JUNIOR TENNIS: THE SHORT STORY

Klaus, A.1, Bradshaw, R.3, Young, W.3, O'Brien, B.3, Zois, J.2

<sup>1</sup>Humboldt University of Berlin, Berlin <sup>2</sup>Victoria University, Melbourne <sup>3</sup>Federation University Australia, Ballarat

Introduction Point duration in competitive tennis is becoming shorter thus placing a greater emphasis on the first strokes of each point. Therefore, the aim of this study was to analyse the point profile of short rallies in elite junior tennis. Methods We investigated stroke type, point outcome and stroke position during ten randomly selected sets of competition (State Championships on hard court). All participants (n=8) were right handed and male tennis player of the age group 14 and under. Descriptive measures included the general point profile considering performance of the first three strokes of each point: service, return-of-serve (return) and first groundstroke of the service player (first-shot). Results Almost half of all rallies (49.0%), which are characterized by a short duration (5.81 sec SD  $\pm$  6.41), completed concluding 1-3 strokes (overall mean: 4.8 strokes per rally; SD  $\pm$ 3.7; median: 4) as a consequence of an error (82.8% compared to 17.2% winners;  $p < 0.001$ ). A large percentage of errors were made via the return and first-shot (44.8% and 38.0%;  $p < 0.001$ , respectively). In comparison to net game specific stroke types (e.g. volley; 3.5%) a more frequent utilization of groundstrokes (33.4%), and service and return (40.7%) was observed. The performance of the first-serve is characterized by an 'in-percentage' of 54.6% and an improved chance of winning the point (for the server) following a 1st serve (55.9%;  $p < 0.001$ ) compared to a 2nd serve (49.9%). The 2nd serve return was reliant on the forehand compared to backhand return (65.7%;  $p < 0.001$ ), as was the first-shot to forehand groundstroke compared to other strokes (56.8%;  $p < 0.001$ ). The majority of stroke positions for first-shot winners were located in the central zone of the court (52.2%;  $p < 0.01$ ). Discussion Contrasting to professional tennis players, juniors produce more 1st serve errors and win fewer points directly via the serve. Success in junior tennis relies in minimizing errors within short rallies specifically on the return and first-shot of the server. Developing a court position which enables optimal use of the forehand groundstroke following the 1st serve also seems to be of high tactical importance. Coaches of elite junior tennis players should focus on strategies to optimize court position following the serve, and service/return percentage within short rallies to optimize success rate in junior tennis. To achieve this, the server should utilize the serve as a 'set-up' tool, dictating the direction of the returners return of serve within the central zones of the court. Additionally, short point duration and less number of strokes underline the demand for game-specific physical and tactical practice for junior tennis player. ### DIGITAL ZOOM VIDEO OF SWIMMERS BY HIGH-DEFINITION CAMERA

Kameda, Y., Kitahara, I., Ohta, Y., Yoshimi, J., Ishikura, K., Takagi, H.

University of Tsukuba

INTRODUCTION Swimming video in fine resolution could be helpful for swimmers to review their races. However, conventional manual tracking by a zoom camera on a tripod can produce only one video for single swimmer at a time. We propose a new video production approach that can produce multiple zoom videos for each swimmer in a race. 4K camera with the resolution of 3840 pixels by 2160 pixels is used for capturing source video. Note that a swimmer registration method is also developed for this approach but it is beyond the scope of this article. METHOD The 4K camera is set to cover the whole water surface of a pool. Usually we set the camera in the middle of the longer side of the pool at higher elevation of audience seats. The 4K race video is marked with a starting signal of a race. The video is then geometrically undistorted in order to remove the artifact of lens distortion. Since the water surface can be recognized as a plane, homography projection can be applied so that we can obtain a pool region in rectangle shape. Four corners of the pool should be manually given before we start the process. Since the video process of undistortion and homography projection does not high computation cost, it could be processed within a couple of minutes for a race. Both the perspective video (original video) and the squared video are utilized to produce the final digital zoom video of each swimmer in each lane. The perspective video is good for providing natural zoom view of swimming while the squared video has the advantage of clearly showing the location along a swimming lane. In order to help reviewing process, virtual lines are imposed on water surface at every five meters in both perspective video and the squared video. IMPLEMENTATION AND DISCUSSION Our preliminary system has been implemented on a laptop computer with Intel-i7. OpenCV is used for video conversion part. When we align the longer side of 4K image with the longer side of the pool, the upper limit of the resolution is 1.3 cm/pixel. It is about 5 cm/pixel in practical camera set-up. The final video can contain a couple of zoom video in any layout. After we have interviewed swimming coaches, we have adopted two perspective zoom video in different zoom parameter and one squared video which covers whole lane in the aspect of 100:5 (50 meters by 2.5 meters). We adopt the resolution of 1920 pixels by 1080 pixels in MP4 format because it could be played in major popular devices. We have got comments from swimming coaches who tell more resolution is needed when they see the final video in large display. We are planning to utilize multiple 4K cameras to archive higher resolution. CONTACT [kameda@iit.tsukuba.ac.jp](mailto:kameda@iit.tsukuba.ac.jp)

### PERFORMANCE TIME DIFFERENTIALS OF ELITE ALPINE SKIERS

Spencer, M.1, Gilgien, M.1, Haugen, P.1, Reid, R.2

1: Norwegian School of Sports Sciences, Oslo, Norway; 2: Norwegian Ski Federation, Oslo, Norway

PERFORMANCE TIME DIFFERENTIALS OF ELITE ALPINE SKIERS Introduction The difference between winning an alpine ski World Cup race and missing the podium may be a fraction of a second. To date, there is limited information documenting the performance time differentials of elite skiers. The aim of this study was to provide a detailed analysis of the time differentials in the downhill (DH) and super-G (SG) disciplines. Methods Official race times and course information for men's and women's DH and SG World Cup competitions from seasons 2001-2013 were downloaded from [fis-ski.com](http://fis-ski.com). In analyses of the top 30 athletes from each race there were 66 to 103 races in total. Performance time differentials for each fifth place (i.e., 1 to 5, 6 to 10... 26 to 30) were documented for each race. Comparisons between DH and SG, sexes and periods (seasons 2001-2006 vs 2007-2013) were analyzed. The percentage likelihood of difference between comparisons was calculated and considered meaningful for likely (>75%), very likely (>99%), or almost certainly (>99.5%) (Hopkins et al., 2009). Results There were likely to most certainly time differentials between place 1 to 5 for DH and SG for both sexes (mean  $\pm$  SD; men: 0.63  $\pm$  0.28, 0.52  $\pm$  0.23 s; women: 0.64  $\pm$  0.28, 0.57  $\pm$  0.25 s; respectively) versus all other place categories (range; men: 0.33-0.39, 0.32-0.35 s; women: 0.32-0.38, 0.31-0.35 s). When comparing the early seasons to the later seasons, mostly trivial differences were

evident for both disciplines and sexes. Discussion The greater time differentials for place 1 to 5, when compared to the other place categories, highlights the dominance of these very elite skiers. This may be due to a combination of individual variation, superior fitness, technique, psychology or coaching and technical support. Comparable findings were reported in sprint prologue races of elite cross-country skiers (Spencer et al., 2013), suggesting that this effect may not be sport specific. The lack of meaningful differences between season periods suggests that the competition depth has remained stable over the seasons investigated. ### PHYSIOLOGICAL RESPONSES AND PHYSICAL ACTIVITY IN SMALL-SIDED GAMES FOR COLLEGIATE SOCCER PLAYERS

Takai, Y., Horio, K., Kai, T., Aoki, T.

*National Institute of Fitness and Sports in Kanoya*

Purpose: Small-sided games (SSGs) are often used as part of training in soccer, regardless of playing level and age. There are many earlier findings concerning SSGs in professional and semi-professional soccer player (e.g. Owen et al., 2012; Casamichana et al., 2014), but less information is about SSGs in collegiate soccer players. The purpose of this study was to clarify the difference in physiological responses and physical activity of SSGs in collegiate soccer players. Methods: Twelve collegiate male soccer players conducted SSGs (3 sets × 4 min with interval of 4 min passive recovery, 40 × 30m) in 5 conditions; 3-a-side SSG (150 m<sup>2</sup>, pitch area per player), 4-a-side SSG (120 m<sup>2</sup>), 5-a-side SSG (100 m<sup>2</sup>), and 4-a-side with a free player (109 m<sup>2</sup>), SSG with less than 2 ball touches (120 m<sup>2</sup>). The players were randomly assigned in two teams, and measured during each SSG. All games were played on an outdoor grass field and included in two goalkeepers. The activity of player was determined by using global positioning system (15 Hz) in the SSGs. The total distance covered and the distance covered of the following velocity zone (<1.7, 1.7-3.3, 3.3-5.0, and >5.0 m/s) were calculated from the obtained two-dimensional position coordinate data. The high-intensity running distance covered was defined as the distance covered over 5.0 m/s. Heart rate was continuously monitored during the SSGs. Maximal heart rate (HRmax) was determined using the Yo-Yo Intermittent Recovery Test Level 1. The mean heart rate during the SSG was divided into HRmax (% HRmax). Results: The total distance covered in the 3-a-side SSG (1771 m) was higher than the other SSGs (1589-1648 m). High-intensity running distance covered (148 m), mean heart rate (169 bpm) and % HRmax (88% HRmax) in the 3-a-side SSG were higher than the other SSGs (67-148 m, 154-161 bpm, 80-84% HRmax), except for the 4-a-side SSG (100 m, 163 bpm, 84% HRmax). There were no effects of ball touch restriction and a free player in the distance covered, mean heart rate and % HRmax. Mean heart rate and % HRmax during warm up did not significantly differ among the conditions. The score of Yo-Yo IR1 was positively related to the total distance covered in the 3-a-side SSG ( $r = 0.58$ ), and the distance covered over 5.0 m/s in the 4-a-side with a free player ( $r = 0.62$ ). Conclusion: The current results that, within same pitch size, physiological response and physical activity of SSG depends on pitch area per players in collegiate soccer players, regardless of ball touch restriction and a free player. ### EFFECT OF PLAYING LEVEL ON MATCH-PLAY ACTIVITY PROFILE IN COLLEGIATE SOCCER

Horio, K., Takai, Y., Aoki, T., Kai, T., Yamamoto, M.

*National Institute of Fitness & Sports in Kanoya*

Purpose: Elite soccer players have a greater the amount of high-intensity running in a competitive match than mature players (Mohr et al., 2003). Furthermore, the amount of high-intensity running differ among positions (Di Salvo et al., 2006). However, whether the earlier findings can be applied to collegiate soccer players within same team is still remained. The purpose of this study was to examine the effects of playing level and position on match-play activity profile in collegiate soccer players within same team. Methods: Collegiate soccer players participated in this study, and were divided into regular group and non-regular group, excluded in goalkeeper. All games were played on an outdoor grass field. The match-play activity was determined by using global positioning system (15 Hz) in their official and practice matches (90 min/match). The total distance covered and the distance covered of the following velocity zone (<1.7, 1.7-3.3, 3.3-5.0, 5.0-6.7, 6.7-8.3, and >8.3 m/s) were calculated from the obtained two-dimensional position coordinate data, respectively. The distance covered (m) was divided into pitch size (m<sup>2</sup>) because the pitch size differed among matches. The distance covered over 5.0 m/s was divided into the total distance covered. Results: The total distance covered per pitch size was higher in non-regular group than in regular group, except for side midfielder. The distance covered over 5.0 m/s in the regular group was higher than that in the non-regular group for central midfielder and side defender. The significant differences in total distance covered, distances covered over 5.0 m/s and over 6.7 m/s were found among positions in the regular group. There were less significant differences in the corresponding variables in the non-regular group. The percentage of distance covered over 5.0 m/s to total distance covered in the regular group ( $10.4 \pm 1.5\%$  for central midfielder, and  $13.0 \pm 1.7\%$  for side defender) was higher than that in non-regular group ( $6.4 \pm 1.5\%$ , and  $9.0 \pm 2.9\%$ ). Conclusion: The current findings indicate that, even within same team, regular players of central midfielder and side defender can perform more high-intensity running than non-regular players of the corresponding positions in a match. **IS-PM09 PERFORMANCE AND TRAINING OF THE TOP-ATHLETE \*****THE EFFECT OF INTENSIFIED TRAINING; TRAINING OF THE TOP-CLASS OARSMAN**

Christensen, P.

*University of Copenhagen, Team Danmark*

Olympic level rowing is performed over a 2000-m distance lasting ~5.5 - 7 min depending on water and weather conditions. Such an effort relies mainly on aerobic metabolism, but the capacity for potassium (K<sup>+</sup>) and hydrogen (H<sup>+</sup>) ion transport and anaerobic power for starts and sprints are also considered as important. High intensity training in rowing can be defined as intensities between race pace and maximal intensity. Race pace training is performed with a mean power of ~450 and ~500 W for international level Danish male light-weight (LW, < 72.5 kg) and open-weight (OW) rowers, respectively, which can be sustained for ~3-6 min eliciting values close to VO<sub>2</sub>-max. In maximal sprints average power for a 15-s effort is ~800 W for LW and ~1000 W for OW. In trained subjects, race-pace intensity training (3-6 min intervals) appears to improve mainly VO<sub>2</sub>-max, in particular with block periodization (1). Oxidative enzymes are often unchanged, however specific adaptations have been found in high order motor units (2) which are likely taxed in maximal rowing. Moreover, oxidative enzymatic adaptations may be augmented when performing such training on low glycogen levels (3) but the functional significance of this with regards to performance at high intensity is unknown. Little is known with regards to effects on ion transporters and angiogenesis. Repeated sprint training (eg. 30-s intervals) appears to have minor effect on VO<sub>2</sub>-max, angiogenesis and oxidative enzymes, whereas an increase in the content of H<sup>+</sup> and K<sup>+</sup> transporters has been observed (4,5). Taken together, race-pace and repeated sprint training appear to act through distinct mechanisms and are considered important for performance. Yet, a small part (<5%) of the total training volume from January to end of August (world championships) is performed at these intensities in Danish elite rowers. However, the demand for recovery and mental and technical aspects are important factors that the experienced coach needs to balance in the training plan. In turn, low intensity training (6) and accumulated training volume (7) appear to elicit the strongest angiogenic stimuli which may be important for exchange of metabolites and oxygen during intense exercise (8). Training slightly below race-pace intensity also stimulates the cardio-vascular system and muscular adaptations with Danish elite rowers undertaking significant parts (>10%) of training at such intensity during the season. 1. **IS-PM13 SKELETAL MUSCLE LIPOTOXICITY; SHOULD WE BE INTERESTED?****SKELETAL MUSCLE LIPOTOXICITY: WHAT IS IT AND WHAT DOES IT DO?**

Schrauwen, P.

*Maastricht University*

Skeletal muscle plays an important role in the regulation of glucose homeostasis as it is responsible for ~ 80% of postprandial glucose uptake. In obesity, excessive fatty acids not only accumulate in adipose tissue but also in liver, heart and the muscle. In skeletal muscle, fat accumulation inside the muscle cell is associated with the development of insulin resistance and mitochondrial dysfunction, often referred to as lipotoxicity. Remarkably, however, endurance trained athletes are also characterized by elevated levels of intramyocellular lipids despite being very insulin sensitive. This so-called 'athletes paradox' has been explained by differences in the content of fatty acid intermediates that could interfere with insulin signaling between obese subjects and endurance trained athletes, but recent data questions this explanation. Recently, evidence is starting to accumulate that lipid droplet dynamics may play an important role in determining the lipotoxic effects of intramyocellular lipids. Thus, in muscle fatty acids are stored in lipid droplets that are surrounded by a large number of so-called lipid droplet coating proteins called perilipins. Overexpressing perilipin-2 or -5, the most abundant muscle PLINs - prevent the development of lipid-induced insulin resistance. Interestingly, PLIN content is increased in endurance trained athletes and under the transcriptional control of PGC1 $\alpha$ , a transcription co-activator involved in mitochondrial biogenesis. These data point towards a concerted regulation of mitochondrial and lipid droplet biogenesis, which may be disturbed in type 2 diabetes.

**'THE EFFECTS OF EXERCISE TRAINING ON SKELETAL MUSCLE LIPIDS'**

Goodpaster, B.

*Translational Research Institute for Metabolism and Diabetes*

Session-ID: IS-PM13 'Skeletal muscle lipotoxicity: should we be interested?' Date: 25.06.2015 Intramyocellular lipid (IMCL) is predominantly stored as intramuscular triglyceride (IMTG) in lipid droplets. Excess IMTG storage and/or decreased utilization was initially implicated in muscle insulin resistance (IR) in obesity, aging and type 2 diabetes. Exercise training, however, can promote enhanced storage and utilization of IMTG. Thus it has become apparent that IMTG do not actually cause IR, but rather, an excess accumulation of other lipid moieties such as long chain acyl CoA's, ceramides, and diacylglycerol are the more likely culprits. The aim of this presentation is to review current knowledge of IMCL-mediated IR and to cover emerging and important areas of investigation, including myocellular lipid transport and lipid droplet protein metabolism. We also identify several crucial questions that remain unanswered. For example, it is not yet clear which specific DAG and ceramide species, and from which subcellular location, may mediate IR in human muscle. Also, the evolving

nature of “mitochondrial dysfunction” in IR is discussed. Targeted, quantitative lipidomics coupled with novel model systems and clinical investigations in humans will better define the underlying mechanisms for pathological IMCL accumulation and IR.

### EFFECTS OF SKELETAL MUSCLE LIPOTOXICITY ON MUSCLE PROTEIN SYNTHESIS: IMPLICATIONS FOR ATHLETIC AND AGEING POPULATIONS

Guillet, C.

*University of Auvergne*

Ectopic lipid accumulation in skeletal muscle is linked to reduced insulin sensitivity in various groups of subjects. The increased lipid content within muscle in older people is independently associated with insulin resistance. Physical exercise improves muscle lipid infiltration and insulin resistance in postmenopausal women. Beside the consequence of muscle fat accumulation on insulin sensitivity, some evidences clearly show that high fat feeding in young mice influences the ability of muscle to hypertrophy in response to anabolic stimuli (Anderson, 2008). In addition, muscle fat accumulation in older people is associated with poorer strength and poor physical performance and subsequent disability. A negative relationship has been highlighted between body fat mass and muscle protein synthesis in young and elderly people (Guillet, 2009; Katsanos, 2011). These observations suggest that an increase in adipose or ectopic fat mass may affect protein kinetics within skeletal muscle. Recent data have clearly shown that intra-muscular lipid deposition during aging affects protein synthesis via impairment in the regulation of a specific factor of intracellular signaling pathway of insulin: eIF2- $\alpha$  (Tardif, 2014). This effect has also been demonstrated in adult rats in which lipid accumulation in muscles during prolonged obesity is deleterious for amino acid incorporation in skeletal muscle proteins (Masgrau, 2012). In vitro and in vivo data have shown that the deleterious effect of intra-muscular fat accumulation on muscle protein synthesis might be due to a specific reactive lipid species. Indeed the accumulation of ceramides within muscle is linked with the reduction of muscle protein synthesis and the hyperphosphorylation of eIF2- $\alpha$  (Tardif, 2014). The effect of muscle lipotoxicity on muscle protein synthesis could also be due to an indirect effect through the modulation of insulin sensitivity and inflammation by the nature of lipids ingested. For instance, in old rats fed a high-fat oleate-enriched diet, insulin sensitivity and inflammation are improved and concomitantly skeletal muscle protein synthesis is enhanced (Tardif, 2011). Recent data provide strong arguments for the involvement of muscle lipotoxicity in reduction of muscle protein synthesis during ageing. This process may contribute to the loss of muscle mass and function observed in elderly people, defined as “sarcopenia”. References: Anderson SR, et al. (2008). *Metabolism*, 57, 347–354. ### OP-BN16 Coaching: Mixed session II

#### WHO ARE THE PARENTS? A STUDY OF THE PARENTAL BACKGROUND OF CHILDREN AGE 13-14 INCLUDED IN THE FIRST TALENT PROCESS STEPS IN SOCCER AND ATHLETICS IN SOUTHERN SWEDEN.

Hafsteinsson Östenberg, A., Linnér, S., Strömberg, C., Fahlström, P.G.

*Sport Science*

Who are the parents? A study of the parental background of children age 13-14 included in the first talent process steps in soccer and athletics in southern Sweden. Introduction Literature including talent development is usually concentrated on physical performance in sports (Ericsson et al., 1993, Brown et al., 2001). Also different cultural aspects, i.e. the importance of the coach and parents have been studied (Coté, 1999; Kay, 2003). However, research of the importance of the parents is limited. This study has its theoretical view of origin in Bourdieu (1978) who relates to habitus and social capital and the purpose was to study family background and family support among the athletes/players who were included in the first talent process in athletics and soccer in southern Sweden. Methods Participants were parents to children (age 13-14) participating in athletics (qualified) and soccer (chosen by the federation). Data was collected using inquire that was sent out by mail to all parents of the participating children and data was processed using SPSS. Results A total of 419 (48%) families (292 soccer/127 athletics) answered the questionnaire. Of the parents, 95% were real estate owners and worked full time, 38% and 68% of the parents of soccer player and athletics respectively had a university degree and 90% had very good grades in physical education in high school. 87% of the parents had participated in sports during their childhood. It was important to men, especially soccer parents, that their child was successful in sports. 95% were very interested in and 96% were engaged in their child's sport. 77% of the men and 50% of the women considered themselves being knowledgeable in their child's sport and 50% thought it was important for the child. Approximately 75% gave their children advice during training and game/competition, 35% encouraged extra practice and 80% drove their children to practice and games/competitions. Discussion The results of this study are in accordance with earlier research and show the importance of the family in youth talent development processes. The results raise questions if family background, socioeconomic status and commitment of parents are to be seen as a direct prerequisite for children's sporting activities and performance development? The results also raise questions about who is included in a talent development process. References Bourdieu P. (1978) *Social Science Information*, 17(6) 819-840. Brown, Jim. #### PREDICTION OF PERFORMANCE IN MONOFIN SWIMMING WITH THE DYNAMOMETER. A PILOT STUDY

Rozi, G.

*NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS*

Introduction Strength measuring is a necessary source of information in training procedure (Marinho & Orival, 2002). The ability of muscles to contract and so produce the greatest force in the shortest possible time is called explosiveness (Dopsaj, 2004). The aim of this study is to define a mathematical model for sprint fin swimmers (50 and 100 m swimming with monofin) to be used in predicting performance results, based on the indicators that assess explosiveness, which is diagnosed for different muscle groups. Methods In the re-

search 8 fin swimming athletes participated, aged  $17 \pm 0.4$  years, height  $176 \pm 5$  cm and weight  $72 \pm 5$  kg. The participants swam in two different days 50m and 100m with a snorkel and monofin on the surface of the water with maximum intensity. In next two days maximum pulling force of legs and of ankle extensors were measured in the gym with a tensiometric dynamometer. For the analysis of the results, multiple regression analysis was applied with the statistical program SPSS 22. Results The results showed that average maximum pulling force for legs was  $1302,62 \pm 696,05$  N, average maximum pulling force for ankles extensors was  $2689,14 \pm 617,13$  N. The analysis of the results showed that for 50m with monofin, none of the two variables are good predictors. On the other hand, the maximum force of legs is best predictor for the performance of 100m with monofin. The two variables explained the 43,9% of the variance of 100m performance time with monofin (Sig. .043). The pulling force of leg has a positive correlation with performance time in 100m and is the best predictor for the dependent variable- time in 100m. Discussion This research showed that there are specific parameters that can predict performance in monofin swimming. Using the model that occurs from the analysis, a trainer can create the actual competitive fitness level for each swimmer for 100m. Furthermore, such a procedure that controls the swimmer's fitness level on land enables more accurate management of the training process. Other physiological, biomechanical and parameters of strength, should be studied in order to create a better predictive model for monofin swimming. ## SPECIALISING OR SAMPLING - CAREERS PATHWAYS IN SWEDISH ELITE SPORTS

Fahlstrom, P.G., Gerrevall, P., Glemne, M., Linnér, S.

*Linnaeus University*

Introduction The sport talent discourse is dominated by the controversy regarding early specialization or sporting diversification and sampling (Cote & Fraser-Thomas, 2007 and Bridge & Toms, 2012). The main purpose of the project was to study Swedish top athletes and describe the pathways to national top level in sports and the athletes' perception of this process. More specifically the project studied socio-economic background, families sporting background, sports debut age, age of specialisation and investing in sports. Method Questionnaires were distributed to 349 national team athletes from 39 different sport federations. 328 athletes, 195 females and 133 males, returned the questionnaires, an answering rate of 93,8%. The average age was 25 years. 62% were involved in individual sports. They were all nations team athletes and 69% of them had received special elite support as potential medal winners at World Cups and Olympic games. Results The study showed the strong family influence on the sport activities. The national team athletes typically came from sport families, their parents had own sport experiences often from a high level within the same sport as the children. The parents often were engaged as coaches, committee delegates, board members etc. The study identified several different paths to the national team. The career steps from early involvement to top level performances are varying and individual. Beside the two dominating paths the results showed different nuances and individual pathways including early sport choice but with early or late specialization as well as later sport choice with or without sampling periods. These results are corresponding with other recent studies (see for example Storm et al 2012). Discussion The findings in this study indicate that the talent programs and talent identification systems have to be more flexible to match the different individual pathways to elite level. The standardized talent programs and the traditional talent "stairways" are discussed since they run the risk of missing talents who don't seem to fit expected sport activity patterns. ## PREDICTING SPECIFIC PERFORMANCE VIA CRITICAL VELOCITY AND MODIFIED-WINGATE TEST IN KAYAK ATHLETES

Lee, T.T., Lee, M.M., Chien, L.H., Li, T.L.

*Graduate Institute of Athletics and Coaching Science, National Taiwan Sport University*

Introduction The canoe/kayak athletes' performance appears to be affected by both aerobic capacity and anaerobic power. However the equipment of VO<sub>2</sub>max test is expensive and the measurement is time consuming. The critical velocity (CV) model and Wingate test offer a convenient method to examine exercise capacity in athletes. The aims of this study are to develop a model to estimate kayak athletes' aerobic and anaerobic capacities and to predict the performance of flat water sprint kayaking by CV and a modified-Wingate test on kayak ergometry. Methods Fifteen male junior kayak athletes (age  $15.6 \pm 2.9$  years old; height  $170.6 \pm 5.5$  cm; body mass  $65.3 \pm 8.5$  kg; body fat  $16.9 \pm 4.8$  %) were volunteered to participate in the study. Participants were asked to complete four experimental trials including a kayak ergometry CV tests modified according to Kendall et al. (2011) at 200-m, 500-m, 1000-m and 2000-m, a kayak ergometry modified-Wingate 30s sprint test, and a 200-m and a 1000-m open water kayaking sprint tests. Performance times, heart rate and blood lactate responses were recorded in every trial. Results The average results of ergometry CV test and modified-Wingate test were  $3.14 \pm 0.21$  m/s in CV and  $351.9 \pm 93.5$  W,  $15.9 \pm 4.9$  kW,  $281.8 \pm 62.5$  W,  $226.9 \pm 53.0$  W and  $254.5 \pm 58.2$  W in Ppeak, AnC, Pmax, Pmin and Pmean respectively. The 1000-m open water kayaking time ( $284.2 \pm 26.7$  s) was significantly correlated to the CV ( $r = -.900$ ), the ergometry 1000-m paddling test ( $r = .898$ ), and the modified-Wingate test ( $r = .805$ ). The best regression formula of predicting the 1000-m open water kayaking time was  $Y = 642.06 - 113.9 \times CV$  ( $R^2 = .810$ ,  $p = .000$ ). The 200-m open water kayaking time ( $40.6 \pm 4.7$  s) was significantly correlated to the CV ( $r = .814$ ), the ergometry 200-m paddling test ( $r = .592$ ), and the modified-Wingate test ( $r = .930$ ). The best regression formula of predicting the 200-m open water kayaking was  $Y = 69.957 - 0.093 \times Pmin + 0.058 \times Pmean - 0.001 \times AnC + 0.012 \times Pmax$  ( $R^2 = .865$ ,  $p = .000$ ). Discussion The main findings of this study suggest that the CV is a better indicator of predicting a 1000-m open water kayaking performance than modified-Wingate test because the CV was highly related to VO<sub>2</sub>max and lactate threshold positively (Clarke et al., 2014; Clark et al., 2013; Kendall et al., 2011). Whereas, the modified-Wingate test is a better indicator to predict a 200-m open water kayaking performance than the CV since the shorter distance kayaking depends on more anaerobic metabolism. ### OP-PM13 Physiology: Endurance

#### ALMOST PERFECT CORRELATION BETWEEN HEMOGLOBIN MASS, MAXIMAL O<sub>2</sub>-UPTAKE AND LEAN BODY MASS IN 13 YEARS OLD BOYS AND GIRLS

Landgraff, H., Hallén, J.

*Norwegian School of Sport Sciences*

**INTRODUCTION:** It has been suggested that lean body mass (LBM) is a more appropriate anthropometrical reference for the hemoglobin mass (Hb-mass) than body weight (Schumacher, Ahlgrim & Pottgiesser, 2008). This conclusion was based on measurements on a homogenous endurance trained male athletic population. Whether these findings can be transferred to other groups such as females or children is unknown. Our study aimed to investigate if there is an association between LBM and changes in Hb-mass in a group of 13 years old Norwegian cross country skiers of both sexes. **METHODS:** Sixty-six Norwegian children (boys n=44, age 13.4 ± 0.2 and girls n=22, age 13.4 ± 0.2) were recruited from cross-country ski clubs. Hb-mass was determined using the optimized CO rebreathing method. VO<sub>2</sub>max was measured directly while running to exhaustion on a motor driven treadmill. Body composition was determined by InBody 720 bioelectrical impedance analysis. Correlations between variables were assessed by Pearson's product-moment correlation and correlation coefficients were classified as small (0.1≤r<0.3), moderate (0.3≤r<0.5), high (0.5≤r<0.7), very high (0.7≤r<0.9) and almost perfect (r≥0.9) (Hopkins, 2000). **RESULTS:** VO<sub>2</sub>max and Hb-mass were almost perfectly correlated in boys (r=0.90; p<0.01) and very highly correlated in girls (r=0.82, p<0.01). The correlations between Hb-mass and body weight were very high in both boys (r=0.87, p<0.01) and girls (r=0.77, p<0.01). Similarly, the correlations between Hb-mass and LBM were almost perfect in boys (r=0.91, p<0.01) and very high in girls (r=0.86, p<0.01). The correlations between VO<sub>2</sub>max and body weight were very high in boys (r=0.85, p<0.01) and high in girls (r=0.67, p<0.01) and the correlations between VO<sub>2</sub>max and LBM were almost perfect in boys (r=0.90, p<0.01) and very high in girls (r=0.80, p<0.01). **DISCUSSION:** It has previously been shown that VO<sub>2</sub>max and Hb-mass relative to body weight are highly associated (Eastwood et al., 2009). This is also the case in the present study (data not shown). However, the present study shows that both VO<sub>2</sub>max and Hb-mass are almost perfectly associated to LBM. This indicates that relative VO<sub>2</sub>max and Hb-mass are negatively associated with the body fat percentage. **REFERENCES:** Schumacher YO, Ahlgrim C, Pottgiesser T. *J Sports Med Phys Fitness*. 2008 Dec;48(4):509-14. #### THE CORRELATION BETWEEN ONE YEAR CHANGE IN MAXIMAL OXYGEN CONSUMPTION, HEMOGLOBIN MASS, MUSCLE MASS AND BODY WEIGHT IN 12-13 YEARS CHILDREN

Riiser, A.1, Hege Wilson Landgraff, H.W.2, Hallén, J.2

*1 Sogn og Fjordane University College, 2 Norwegian School of Sport Sciences*

**Introduction** Maximal oxygen consumption (VO<sub>2</sub>-max) has been shown to be associated with hemoglobin mass (Hb-mass) in children as well as adults. The present study aims at investigating correlations between change scores over one year of VO<sub>2</sub>-max and Hb-mass in 12-13 years old schoolchildren. Secondly we aimed to examine if the change scores in VO<sub>2</sub>-max and Hb-mass are associated with increases in muscle mass or body weight. **Methods** In schoolchildren VO<sub>2</sub>-max was measured directly while running to exhaustion on a motor driven treadmill. Hb-mass was measured by the optimized CO-rebreathing method and muscle mass and body weight was assessed by InBody 720. The same children were tested twice one year apart at age 12.5 (SD 0.2) and 13.5 (0.2). Valid data both years were obtained from 25-30 children. Correlations between change scores of the different variables were assessed by Pearson's product-moment correlation and correlation coefficients were classified as small (0.1≤r<0.3), moderate (0.3≤r<0.5), high (0.5≤r<0.7), very high (0.7≤r<0.9) and almost perfect (r≥0.9) (Hopkins, 2000). **Results** Change in VO<sub>2</sub>-max was very highly associated with change in Hb-mass (r=0.71; p<0.001). Change in VO<sub>2</sub>-max was also very highly associated with change in muscle mass (r=0.74; p<0.001), but only moderately associated with body weight (r=0.39; p=0.031). Likewise, change in Hb-mass was very highly associated with change in muscle mass (r=0.76; p=0.001), but only moderately associated with change in body weight (r=0.40; p<0.024). **Discussion** It has previously been shown a high correlation between VO<sub>2</sub>-max and Hb-mass, both in adults and children. This study adds to this by showing that also change scores of these variables over one year are very highly correlated in children. Furthermore, the data indicate that changes in both variables are more connected to change in muscle mass than change in body weight. **References** Hopkins, W. G. A scale of magnitudes for effect statistics. In: *A New View of Statistics*. Internet Society for Sport Science 2000: <http://www.sportsci.org/resource/stats/>.

#### MUSCLE RESPONSE TO COMBINED SPEED ENDURANCE AND ENDURANCE EXERCISE

Skovgaard, C., Pilegaard, H., Bangsbo, J.

*University of Copenhagen*

**Introduction** The aim of the present study was to investigate the mRNA response of human skeletal muscle to speed endurance exercise, endurance exercise and the combination of the two types of exercise. **Methods** Seventeen moderately trained subjects with an average age, height, weight and maximum oxygen uptake (VO<sub>2</sub>-max) of 23.6±1.0 (mean±SE) years, 183.4±1.4 cm, 75.5±1.5 kg and 57.2±0.9 ml O<sub>2</sub>/min/kg, respectively, took part in the study. Subjects completed three protocols (S; S+E; E) in a randomized crossover design with a minimum of 7 days between trials. S consisted of 6\*30-s all-out cycle sprint intervals (resistance: 56.6±1.2 N) separated by 3 min of rest with total work being 148±4 kJ. E consisted of 60 min of cycling with a power output of 156±5 W (60% VO<sub>2</sub>-max) corresponding to a total work of 188±6 kJ. S+E was performed as S followed by E after a 3-min break with total work being 334±8 kJ. A biopsy was taken from m. vastus lateralis at rest, before exercise (all trials), at the end of exercise (S+E and E) as well as 1h, 2h (all trials) and 3h (S only) after each exercise bout. **Results** In S, muscle PGC-1α mRNA was 7- and 5-fold higher (p<0.05) 2 and 3h after exercise (ae), respectively, 4- and 8-fold higher (p<0.05) 1 and 2 h ae in S+E, respectively, and 4-fold higher (p<0.05) 2h ae in E compared to rest, with the level after S+E being higher (p<0.05) compared to E (1 and 2h ae) and S (3h ae). In S, muscle hexokinase II mRNA was ~2 fold higher (p<0.05) 2 and 3h after compared to before exercise. Only in S+E, muscle HO-1 mRNA was higher (p<0.05) 0, 1 and 2h ae compared to rest. Elevated (p<0.05) muscle MRF-4 mRNA was found at the end of exercise in S+E and 2h ae in S+E and E. Lowered (p<0.05) level of myostatin was

observed in S+E 1 and 2 h ae. Discussion Combined speed endurance and endurance exercise lead to larger increases in PGC-1 $\alpha$  mRNA compared to speed endurance and endurance exercise performed separately, suggesting that speed endurance exercise reinforce the mitochondrial biogenesis effect of endurance exercise. Only combined speed endurance and endurance exercise elicited higher levels of HO-1 mRNA, which may be due to the higher oxidative stress associated with the larger total work performed compared to the protocols carried out separately. Lower levels of myostatin mRNA was found only with combined speed endurance and endurance exercise whereas higher levels of MRF-4 mRNA was found with combined speed endurance and endurance exercise and only endurance exercise, suggesting a significant effect of endurance exercise on myogenic regulators. Only speed endurance exercise elicited changes in hexokinase II mRNA but not when endurance exercise was added, suggesting that endurance exercise blunted the effect of speed endurance exercise. ### COGNITIVE ACTIVITY AND CEREBRAL OXYGENATION DURING A 20-KM CYCLING TIME TRIAL

McCarron, J., Smith, M.F.

*University of West England at Hartpury College*

Introduction Maintenance of cerebral oxygenation (O<sub>2</sub>Hb) within a stable range during endurance exercise is thought to contribute to successful performance (Nielsen & Seifert, 2011). This may be due to the importance of cognitive processes inherent within the ability to regulate pace (Renfree et al., 2013). Yet cognitive function has been suggested to be impaired during high intensity exercise (Dietrich & Audiffren, 2011). Using a dual-task paradigm this study explored the phenomenon of pacing through evaluating the impact of increased cognitive load at different stages of a cycling time trial (TT) on cerebral O<sub>2</sub>Hb, pacing and time to completion. Methods Twelve well-trained cyclists (31  $\pm$  9 yrs, PPO 352  $\pm$  29 W, VO<sub>2</sub>peak 57  $\pm$  6 ml·kg<sup>-1</sup>·min<sup>-1</sup>) performed, in a randomised order, 4 simulated 20-km cycling TTs on separate occasions. These included a control simulated 20-km TT (TTCO) and 3 experimental conditions in which participants concurrently performed an executive cognitive task for the duration of the 1st half (TT1stHCL), the 2nd half (TT2ndHCL) and the whole duration of the TT (TTFullCL). Cerebral O<sub>2</sub>Hb was assessed at the dorsolateral prefrontal cortex (dLPFC). Blood lactate (BLa), effort (TEA), exertion (P-RPE) and affect (FS) were measured. Results Completion time during TTCO (2122s  $\pm$  378) compared to all experimental conditions was significantly faster; TT1stHCL (2257s  $\pm$  382; p<0.01, partial  $\eta^2$ =0.93); TT2ndHCL (2205s  $\pm$  407; p<0.01, partial  $\eta^2$  =0.64); TTFullCL (2307s  $\pm$  411; p<0.01, partial  $\eta^2$ =0.79). Mean cerebral O<sub>2</sub>Hb increased in all conditions but did not change between conditions. Pacing profile was not different between TTCO and TTFullCL. Mean values of BLa, TEA, P-RPE and FS were not different between conditions, even though mean PPO was lower in experimental conditions. Cognitive performance was impaired in all conditions. Discussion Increased cognitive load has a detrimental impact upon endurance cycling performance. Upon an initial increase there was a plateau, then decline, in cerebral O<sub>2</sub>Hb during the cycling TT which was not affected by experimental conditions. This suggests a ceiling in O<sub>2</sub>Hb delivery to the dLPFC during endurance exercise performance. Thus, increased cognitive load led to a greater competition of dLPFC O<sub>2</sub>Hb delivery. For a given level of power output, TEA, P-RPE and FS increased in the experimental conditions. Therefore increased cognitive load carries an effortful cost that during self-paced endurance exercise may curtail the selected level of exercise intensity. During competition athletes should aim to reduce the cognitive load associated with pacing strategies. References Nielsen HB, Seifert T. (2011). *J Appl Physiol*, 110 (1):292. ### COMPARISON BETWEEN PERPOT SIMULATED AND LACTATE BASED ANAEROBIC THRESHOLD IN HANDBALL PLAYERS

Endler, S., Hoffmann, S., Pfeiffer, M.

*Johannes Gutenberg University*

Introduction A main challenge for sport scientists and coaches is an individual intensity specification as exercise prescription for athletes (Hofmann and Tschakert, 2011). Ideally, in endurance sports percentages of the heart rate at maximal lactate steady state (MLSS) are used. Since the late 1970s, MLSS is approximated by several anaerobic thresholds based on lactate extraction during graded incremental tests. These invasive methods are expensive and laborious. Thus, scientists are looking for non-invasive methods to approximate these thresholds. Our new approach uses the sports computer science Performance Potential model (PerPot) for the determination (Perl, 2004). PerPot models a delayed heart rate progress related to a speed progress. The individual delays are determined using heart rate and speed progress during a graded incremental test. Our survey compares PerPot simulated and lactate based thresholds in handball players. Methods 15 male handball players performed a sports medicine diagnostic. Therefore, a graded incremental test (step duration 3 Min., initial workload 6 km/h and step incremental 2 km/h) with lactate extraction and continuous heart rate recording was performed on a treadmill. Lactate measurement was used for determination of four established lactate based anaerobic thresholds. Speed and heart rate processes were used for PerPot determination of the threshold. Results Both, Pearson correlations (.883 - .895) and intra-class correlation (.894 - .932) show high correlations between lactate based and PerPot simulated thresholds. Discussion Using anaerobic threshold for exercise prescription is the ideal case. However, anaerobic threshold changes because of training induced adaptations. Therefore determination should be repeated periodically. In practical, difficult invasive determination in laboratory and high cost leads to no repetition. Other non-invasive methods like Conconi could not achieve the desired precision (Carey et al., 2008). Our new non-invasive approach PerPot shows high correlations compared to lactate based thresholds. Besides low costs, another advantage is the easy portability of results to field, because graded incremental tests are not linked to laboratory anymore. It is therefore an ideal addition to sports medicine diagnostics. References Hofmann P., Tschakert G. (2011). ### LABORATORY PERFORMANCE PREDICTORS FOR MULTI-STAGE MOUNTAIN BIKE EVENTS

Engelbrecht, L., Greeff, M., Terblanche, E.

*Stellenbosch University, South Africa*

Introduction Mountain biking is one of the most rapid growing sports in the world with the number of multi-stage events increasing each year. A recurring question for exercise physiologists, coaches and athletes is whether laboratory measurements can predict field performance, as is the case for road cycling (Bentley et al., 2001). Performance predictors and exercise intensity profiling are thus valuable tools

for cyclists and coaches to optimize program design and event preparation (Lamberts, 2014). Methods 25 well-trained cyclists (22-56 years of age) performed a maximal aerobic capacity incremented exercise test eight weeks prior to participating in an 8-day multi-stage mountain bike event. Blood lactate measurements were taken during the incremental test to determine the lactate threshold (LT) and the 4 mmol/L lactate threshold (OBLA). Overall race time and final race classification were selected as dependent variables and the best subsets regression analysis was used to identify specific predictors from the physiological and performance variables obtained during the laboratory assessment. The best subset models were identified as those with the highest R<sup>2</sup> values and significance level less than 0.05. Results Absolute PO at OBLA ( $p = 0.01$ ) and relative PO at OBLA ( $p = 0.02$ ) were significant predictors for final event time and accounted for ~71% of the total race time. Statistically significant predictors for the cyclists' general classification were relative PPO ( $p = 0.02$ ) and relative maximal aerobic capacity ( $p = 0.048$ ), explaining 56% of the variance in general classification. Discussion The main finding of this study was that the laboratory variables were better at predicting total race time than general classification during a multi-stage MTB race. Similarly to road cycling, absolute and relative PO is important components of MTB performance and can be used as performance predictors for multi-stage MTB events. This is also in accordance with Impellizzeri et al. (2005), who reported strong correlations between absolute ( $r = -0.76$ ) and especially relative ( $r = -0.89$ ) PO at OBLA and total race time during a cross-country event. A maximal aerobic test combined with OBLA is therefore an effective laboratory assessment to measure in-field performance predictors. ### IS-BN05 PERFORMING WHEN GETTING OLDER: ALTERATIONS AND PLASTICITY OF THE AGEING NEUROMUSCULAR SYSTEM

---

#### BRAIN FUNCTION AND MOTOR PERFORMANCE IN OLDER ADULTS

Swinnen, S.

*KU Leuven*

When older adults perform cognitive or motor tasks, they often show increased activation as compared to young adults. However, the mechanisms underlying these age-related changes in brain activation are still unclear. Changes in brain structure, in concentration of neurochemicals, and brain connectivity alterations may possibly contribute to this effect. Furthermore, it remains to be clarified whether this increased activation is associated with higher performance levels (compensatory mechanism) or whether it is a mere expression of neural irradiation (dedifferentiation) within the older adults' group. Reporting about several functional magnetic resonance imaging (fMRI) studies, we will address the following issues related to overactivation in older adults. First, we will document age-related activation increases during the production of motor coordination tasks and demonstrate that older adults exhibit increased cognitive control of action. Second, we will address evidence for compensatory recruitment by demonstrating that older adults who show higher activation levels as compared to those who do not, also exhibit higher motor performance levels (i.e., evidence for compensatory brain activation). Third, we will discuss whether these higher activation levels in older adults impose restrictions on modulation of brain activity as a function of increasing task difficulty. Finally, we will look into neuroplasticity during motor task learning in older adults and address the question whether training-induced plasticity allows the older adults to reduce these increased activation levels as compared to young adults.

#### AGE-RELATED NEUROMUSCULAR ADAPTATIONS

Baudry, S.

*Université Libre de Bruxelles*

Motor performance decreases with ageing, reflecting dysfunctions of the central and peripheral nervous systems, and the muscular system. The word sarcopenia has been used for a long time to describe the loss of muscle mass and associated motor functions in elderly adults. Nonetheless, the reorganisation of motor units (development of "giant" motor units), associated with other neural changes should also be considered when the functional alterations associated with senescence is evoked. Indeed, age-specific neural adaptations and modulation of corticospinal and spinal inputs converging onto motor neurone pool during various motor tasks have been documented. Nonetheless, although most of these changes would be considered as alterations, the ageing neuromuscular system also demonstrates increased functions such as greater relative fatigue resistance at submaximal force level. As a consequence, a better understanding of the age-related alterations in motor functions requires questioning the impact of neuromuscular changes occurring with ageing. The purpose of this symposium is to summarize the scientific knowledge related to age-related alterations in neuromuscular functions and their possible consequences on motor performance.

#### INFLUENCE OF MUSCLE STRENGTH ON PHYSICAL FUNCTION OF MEN AND WOMEN WITH AGE

Jakobi, J.

*University of British Columbia*

Exercise is the known most powerful intervention for the prevention of disease, the promotion of health, and for slowing age-associated physical and functional decline. Yet, present-day older adults are actually less physically active and are diagnosed with more chronic disease and disability than previous generations. Daily physical activity may not be enough to meet the health needs of society's current older adults, thus requiring planned exercise programmes to keep the ageing population healthy. This talk will summarize current evidence for plasticity in the neuromuscular system and the role of physical strength in sex-differences of functional aging. Long-term electromyography (EMG) recorded during daily life and laboratory-based functional tasks of steadiness will be discussed relative to differential changes in muscle strength, single fibre length and tendon stiffness between men and women with aging. Although exploration is in its infancy, it appears that women experience earlier onset of neuromuscular weakness and this contributes to earlier onset of declines in physical function. This symposium will be of interest to scientists, exercise leaders and health educators wanting to gain current

knowledge on the interrelationship between muscle strength and elasticity relative to sex-related differences in functional decline with age.

## Invited symposia

### IS-BN07 INTEGRATIVE APPROACH OF MUSCLE FATIGUE IN 2015 - SPONSORED BY THE PHYSIOLOGICAL SOCIETY

---

#### MUSCLE FATIGUE: THE NEED FOR A TRANSLATIONAL APPROACH

Place, N.

*University of Lausanne*

The origin of the exercise-induced impaired muscle performance is a subject of debate in the scientific community. Whereas some studies indicate that failure proximal to the neuromuscular junction ("central fatigue") explains much of the impairment in muscle function, others show that processes distal to the neuromuscular junction ("peripheral fatigue") are of great importance. This talk will present the tools used to study neuromuscular adaptations in humans and will use examples from the literature to illustrate the task dependency of muscle fatigue (1). It will also be emphasized that the mechanisms underlying muscle fatigue may also depend on the criteria used as indexes of fatigue (e.g. time to task failure vs. reduction in maximal voluntary contraction force) (2). Finally, the presentation will discuss the usefulness of combining animal and human approaches (intact single muscle fibres vs. exercising humans) to get a better understanding of muscle fatigue processes (3). It will be shown that this kind of approach can be useful to get insights into the methods used to study muscle fatigue, such as the twitch interpolation technique widely used for central fatigue assessment (4). #### MUSCLE FATIGUE: THE CONTRIBUTION OF MOTONEURONAL FACTORS

Gandevia, S.C., Taylor, J.L.

*Neuroscience Research Australia*

Key determinants of the force produced by a muscle's contraction are the voluntary firing of its motoneurons and the force generated by the muscle fibres innervated by the motoneurons. Fatigue develops when muscle fibres are driven for long periods or at high rates (i.e. maximal force-generating capacity declines). In healthy limb muscles much of this occurs due to processes distal to the neuromuscular junction (i.e. peripheral fatigue) (1). However, central processes also limit force in voluntary contractions (2). In many exercise situations there is 'supraspinal' fatigue (i.e. a failure to generate sufficient output from the motor cortex). Much evidence indicates that when voluntary force declines, motoneuron firing rates are not sustained at sufficiently high rates or motoneurons stop firing altogether. The presence of supraspinal fatigue has been documented with cortical stimulation in many tasks. While this shows that cortical and motoneuronal output are both suboptimal, the mechanisms are not straightforward. Recent work using techniques to silence motoneurons transiently has highlighted novel processes that reduce 'gain' at the motoneuron during voluntary contractions (e.g. 3) while other studies using antidromic activation have revealed that strong voluntary contractions produce an activity-dependent reduction in motoneuron excitability measured as the capacity to produce a recurrent discharge (e.g. 4). Such processes will accompany muscle fatigue and increase the voluntary synaptic input needed to generate motoneuron output. 1 Allen DG, Lamb GD, Westerblad H 2008 Physiol Rev 88: 287-332 2 Gandevia SC 2001 Physiol Rev 81: 1725-89 3 McNeil CJ, Martin PG, Gandevia SC, Taylor JL 2009 J Physiol 587: 5601-12 4 Khan SL, Giesebrecht S, Gandevia SC, Taylor 2012 J Physiol 590: 4957-69

#### MUSCLE FATIGUE: THE POTENTIAL CONTRIBUTION OF MUSCULAR FACTORS

Westerblad, H.

*Karolinska Institutet, Stockholm*

The ability to contract becomes impaired when muscles are driven for long periods or at high rates, i.e. fatigue develops. The impaired contractile function in fatigue is to a large, but variable, extent due to factors within the muscle fibres, i.e. peripheral fatigue (1). Fatigue-induced impairments in muscle fibres initially affect myofibrillar function, causing reduced cross-bridge force production and decreased Ca<sup>2+</sup> sensitivity. Subsequently when fibres start to reach exhaustion, force is further reduced due to decreased Ca<sup>2+</sup> release from the sarcoplasmic reticulum (SR). Interestingly, fatigue can induce long-lasting decreases in myofibrillar Ca<sup>2+</sup> sensitivity and/or SR Ca<sup>2+</sup> release. The relative extent of these two force-depressing mechanisms depends on the cellular handling of reactive oxygen/nitrogen species (ROS/RNS)(2). ROS/RNS also seem to have key roles in the fine-tuned balance between positive effects of endurance training vs. detrimental effects observed with overtraining (3). The proposed presentation will summarise mechanisms underlying the acute and prolonged fatigue-induced impairments and their relation to training-overtraining. REFERENCES 1. ### IS-SH10 URBAN SPORT LANDSCAPES

#### 'GLOCAL' URBANISATION – SPORT'S POWER OF POSITION

Westerbeek, H.

VICTORIA UNIVERSITY

The sporting industry has never been more global, in an era during which the perceived value of the few hallmark sporting events that reach out to the whole planet cannot be overstated. Ironically in that context of global expansion, sport is increasingly argued to remain a product that is best locally consumed. As a product that is universally understood in regard to its rules, but locally produced (other than cyber-sport) in context of culture and physical surroundings, it offers tremendous scope to draw in the global in order to sell the local. This glocalisation can be explored from a number of perspectives. An interesting starting point is the increasingly prominent place of the city as a means to position nations, nationalities, cultures, and corporate capacity. In this presentation we explore the various angles that city and brand marketeers can take in their efforts using sport activities, sport identities, sport facilities, and sport performance to promote and position their brand and destination. Some initial findings from the Global Sport Impact project will be presented. References Allen D, Knott, B, Swart, K. (2013). *the International Journal of the History of Sport*, 30(16), 1994-2006. #### ACTIVATING AND INCLUDING DOGMA ARCHITECTURE IN URBAN SPACE

Kural, R.

*Schools of Architecture, Design and Conversation*

Introduction In 2012 conducted Centre for Sports and Architecture, Denmark, a major intervention project in a socially deprived area, Haraldsgade. Three installations were designed to generate physical activity among groups usually excluded from urban space: Girls, women, young children, seniors and people of different ethnic origin. The starting point was to obtain new knowledge about whether physical environments can help to promote the physical and spontaneous activity in the public sphere. The hypothesis was that the design of urban space can influence people to be more physically active in everyday life while increasing their joy of living and quality of life. On this basis, we constructed the installations in three remaining areas, three street corners, so they did not take up space in the already dense neighborhood. Methods The design work was done in relation to seven value concepts. The concepts derived from scientific studies, and - where they do not exist - from guidelines, manuals and programs from practice. (3). The value concepts were: 1. visibility, 2. availability, 3. security, 4. shelter, 5. spectators, 6. identity and 7. aesthetics. Observational studies: in 16 days in spring and autumn 2012, eight students conducted 2 x 768 observations of 15 minutes. On a plan of the area they signed in the gender of those who used the facilities, what they did, their age, activity level and position in space. During the observation period, more than 7000 people used the installations. Results and discussion The results showed that a broad section of the neighborhood's very complex population across age, gender, race, creed and origin, had used them - though not senior citizens (1). Similar studies show that when urban spaces are open spaces for activity, they are often taken over by boys and men, while girls and women are looking to the periphery, which the activities can be observed (2). The same was true with the installation, seven swings, designed for girls and women. The observations showed that on this installation it was teenage girls and women who seized the social and spatial control. Referencer (1) Center for Idræt og Arkitektur. #### PLANNING FOR ACTIVITY – LINKING PHYSICAL ACTIVITY TRENDS AND URBAN DEVELOPMENT TRENDS

Book, K.

*Malmö University*

This presentation takes as point of departure a number of physical activity and sporting trends in Sweden, but also other Western World countries. The trends highlighted, are of an everyday and non-elite character and include among others: Decreased interest in organized sport activities, increased interest in flexible, individual and self-organized activities as well as activities provided by commercial actors, the rise of 'new' activities like parkour and lifestyle sports and a growing activity segregation. A common feature of these activities is a need for other (urban) environments than ordinary sports facilities. This paper analyses the new physical activity trends in the light of urban development and planning, using research results and examples from different cities. The presentation has a conceptual and comprehensive character using results mainly from three research projects conducted by Karin Book: -The role of sport in urban planning: This project deals with the perception of sport and its role and place in urban planning in Sweden. The starting point of this project is on the one hand the changing conditions for planning including for instance increased focus on densification and infill strategies as well as new solutions for integration of different functions. And, on the other hand it is the changing conditions for the sports movement and how sport is carried out. -Motions in the city. Physical Activity and Mobility in a Segregated City: This project deals with the activity level and geographical/territorial range in connection to physical activity among adolescents in three residential areas with different spatial and socio-economic characteristics in Malmö, Sweden. Moreover, the project deals with the planning of different types of physical-activity places in ordinary, everyday environments, in which many adolescents spend their leisure time. -Running out of time? Strategies and perceptions in connection to physical activity: This project concerns perspectives on time use and perception and strategies for physical activity with basis in the following research question: how, when and where do employed people (in Sweden), age 30-50, find time and space for physical activities? This project highlights both exercise trends among the adult population and the role of the spatial context. These projects are connected under the heading of planning for activity.

### IS-SH08 CHILDRENS RIGHTS IN SPORT

---

#### CHILDREN'S RIGHTS VS. ELITE SPORT DEVELOPMENT

Donnelly, P.

*University of Toronto*

Several commentators have pointed out that some 16 to 18 Articles of the UN Convention on the Rights of the Child are routinely or occasionally violated by those involved in the training of talented child athletes. The current structures of organized sports in many countries – authoritarian, control-based coaching; instrumentalization of the athlete's body; and a single-minded focus on sport development at the expense of social and educational development – are behind these violations of children's rights. Given that it is appropriate to nurture and develop talented children in any area their talent, and given that it is crucial to honour the rights of children, this (proposed) paper asks whether it is possible to encourage talent development in children with evident sports skills while also ensuring the protection and development of the whole child. The paper will also explore, in a preliminary way, the conflicted role of parents in nurturing the development of talented children, particularly the dilemma between ambition and protectiveness.

#### CHILDRENS RIGHTS IN SPORT - A SWEDISH PERSPECTIVE

Redelius, K.

*The Swedish School of Sport and Health Sciences*

**Introduction** In an attempt to ensure a more child centered approach, the Swedish Government decided in 2009 that if sports clubs were to receive state funding for children's sports the adoption of a child's perspective was essential. This means that sports coaches have to follow the United Nation's Convention on the Rights of the Child. However, being a sports coach for children is a complex and responsible task and often involves balancing various stakeholders' quests for sporting performance and results. In many ways, coaching children can be described as a tension between doing what is necessary in order to succeed and doing what is best for the child. Although many countries have adopted similar policies in order to protect children who are engaged in sport, there are few studies about what this means in practice. **Aim** The aim of the study presented was to investigate Swedish sports coaches' ideas and understandings of what a children's rights' perspective means in the sporting context. A starting point is the inherent strain, especially in youth sports, between conflicting discourses about competition and health. Central questions are: 1) What rights do children have in sport according to coaches? 2) How are these rights honoured in the sporting practice? And 3) How do coaches handle conflicting ideas about what is best for the sporting child? **Method** The empirical material draws on data collected through questionnaires and in-depth interviews. There were 160 coaches (111 men and 49 women) from 29 different sport federations who responded to the questionnaire. Moreover, 12 coaches (7 men and 5 women) from both individual and team sports were interviewed. All the coaches worked voluntarily for their club. Some were beginners and some had over 30 years of experience of being a coach. On the average they had coached children's sport for six years. The results from the questionnaire were analysed using Statistical Package for the Social Sciences, version 19. A content analysis of the responses from the interviews was conducted, from which emerged identifying patterns or descriptive findings concerning the coaches' perceptions of child rights. These were then assigned to different categories. **Results** The results show that coaches have limited knowledge and poor understanding of what a child right's perspective means and how it can be exercised in the sporting practice. In order for children to engage in healthy lifestyles beyond school and sustain this involvement over time, it is important to enhance coaches' awareness about children's rights in sport.

### OP-PM21 Physiology: Respiration

---

#### BREATH-BY-BREATH GAS EXCHANGE AT ALVEOLAR LEVEL: AN ALTERNATIVE IDENTIFICATION OF START AND END-POINTS OF THE RESPIRATORY CYCLE

Francescato, M., Cettolo, V.

*University of Udine*

**INTRODUCTION** Computation of the gas exchange on a breath-by-breath (BbB) basis is traditionally performed assuming that the respiratory cycle starts at the onset of inspiration and ends when expiratory flow had entirely or largely ceased (Auchincloss et al. 1966). Whenever the gas exchange is to be estimated at alveolar level, a correction for the changes in the pulmonary gas stores is also required, which implies the knowledge of the alveolar volume at the start of the breath. Grønlund (1984) circumvented this problem by proposing a new timing of the respiratory cycle, where the start and end points have equal expiratory gas fractions, despite several different time intervals are associated with the same cycle. An alternative timing of the respiratory cycle, which halves the number of time intervals associated with each breath, is here described and evaluated in comparison to the algorithm proposed by Grønlund (1984). **THEORY** The start and end points of each respiratory cycle can be identified as the times in successive breaths where identical ratios between O<sub>2</sub> (or CO<sub>2</sub>) and N<sub>2</sub> fractions (i.e. FO<sub>2</sub>/FN<sub>2</sub> or FCO<sub>2</sub>/FN<sub>2</sub> ratios) are observed towards the end of the expiration. This alternative timing of the respiratory cycle continues circumventing the need to know the alveolar volume at the start of the breath while resulting in only two time intervals for each breath: one for O<sub>2</sub> uptake and one for CO<sub>2</sub> release. **METHODS** Oxygen and carbon dioxide fractions, and ventilatory flow at the mouth were continuously recorded in 20 subjects (11 M; 9 F) over 6 min at rest and during a cycloergometer exercise including 4 increasing intensities (0.6, 0.9, 1.1, and 1.4 W/kg body mass) lasting 6 min each. Computerised procedures were developed in C language to implement the two algorithms at stake, using as far as possible the same routines, allowing us to compute alveolar BbB oxygen uptakes from the gas and flow traces applying both Grønlund's and the new method. **RESULTS** We analysed 14257 breaths, with an average breath frequency of 21.6±5.3 breaths/min among subjects. The data obtained with the two methods were close to the identity line (average slope 0.998±0.004; R>0.994; n>334 in all subjects). Average difference between the O<sub>2</sub> uptake data obtained by the two

methods amounted to  $-0.27 \pm 1.29$  mL/min, while the standard deviation of the differences was  $11.5 \pm 4.6$  mL/min. The relative percentage difference was independent from the O<sub>2</sub> uptake and showed an average bias among subjects close to zero ( $-0.06 \pm 0.15\%$ ). CONCLUSIONS The ratio FO<sub>2</sub>/FN<sub>2</sub> (or FCO<sub>2</sub>/FN<sub>2</sub>) amplified the signal changes as compared to the simple gas fractions, making the identification of the start and end times of the breaths more robust. The alternative timing of the respiratory cycle provided congruent O<sub>2</sub> uptake data without introducing systematic errors. ### THE EXCESS VO<sub>2</sub> AND THE SLOW COMPONENT OF OXYGEN UPTAKE KINETICS

Oueslati, F., Tabka, Z., Ahmaidi, S.

APERÉ (EA-3300), University of Picardie Jules Verne, Amiens, France.

1: APERÉ (Amiens, France), 2: UR12ES06 (Sousse, Tunisia) Introduction During incremental exercise, it is generally believed that VO<sub>2</sub> increases proportionally to power output (PO). However, above the anaerobic ventilatory threshold (VT), it has been shown that the VO<sub>2</sub>/PO increases non-linearly characterizing the excess of VO<sub>2</sub> ( $\Delta$ VO<sub>2</sub>). During a constant high exercise intensity (CE), the VO<sub>2</sub> shows a continuous increase until the end of the exercise, the slow component of VO<sub>2</sub> (A2VO<sub>2</sub>). The explanations given to the both phenomenon are usually attributed even to an increase in work of respiratory and/or locomotor muscles (Zoladz & Korzeniewski 2001). Therefore, the aim of this investigation was to study (i) the relationship between  $\Delta$ VO<sub>2</sub> and A2VO<sub>2</sub>, (ii) the impact of each exercise on the respiratory muscles strength (iii) the muscular slow component of VO<sub>2</sub> (A2HHb) assessed from HHb kinetic in vastus lateralis using NIRS, and their relationship with A2VO<sub>2</sub>. Methods Fourteen male cyclists performed a maximal incremental exercise (MIE) and CE at 85% of VO<sub>2</sub>max on a cycle ergometer with measurement of maximal inspiratory (MIP) and expiratory (MEP) pressure before and after each exercise.  $\Delta$ VO<sub>2</sub> corresponds to the difference between VO<sub>2</sub>max observed and VO<sub>2</sub>max expected at maximal aerobic power using the linear relationship between VO<sub>2</sub> and PO below the VT ( $VO_2 = a \times PO + b$ ) during MIE. The slow component of HHb (A2HHb) and the A2VO<sub>2</sub> correspond to the difference between their values at 3' and the end of CE. Results Results show that A2HHb was related to A2VO<sub>2</sub> ( $r=0.7$ ;  $p<0.01$ ). However, no relationship was observed between A2VO<sub>2</sub> and  $\Delta$ VO<sub>2</sub>. MIP and MEP respectively decrease by 5.2% and 11.5% ( $p<0.01$ ) after MIE, and by 19.5% and 17.6% ( $p<0.05$ ) after CE. These decline observed after CE was related to the A2VO<sub>2</sub> (MIP,  $r=0.7$  and MEP,  $r=0.5$ ;  $p<0.05$ ). Discussion The main finding of the current study highlighted the absence of relationship between the A2VO<sub>2</sub> and  $\Delta$ VO<sub>2</sub>. Although the implications of respiratory and peripheral muscles are valid for both phenomenon, but differently. The decline of MIP and MEP are greater after CE than MIE showing that the involvement of respiratory muscles is deferent. In addition, above VT fast twitch fibers (IIa) are recruited during MIE, and consume more O<sub>2</sub> than slow twitch (Krustrup et al., 2008). However, Zoladz et al. (2008) reported that the progressive recruitment of muscle fibers is not necessary for the A2VO<sub>2</sub>, which may be caused by the metabolic factors that induce muscle fatigue and, as a consequence, reduce the efficiency of muscle contractions. Results indicate that VO<sub>2</sub> kinetic reflect the change of deoxyhemoglobin in vastus lateralis during a CE. ### OVERESTIMATE OF RELATIVE AEROBIC CONTRIBUTIONS WITH MAXIMAL ACCUMULATED OXYGEN DEFICIT IN ADOLESCENT FEMALE KAYAKERS

Li, Y., Wu, Y., Niessen, M., Hartmann, U.

Shanghai University of Sport

Introduction Previous investigators have demonstrated a variety of values of relative aerobic contributions (WAER%) in Olympic kayaking (e.g. 29-40% in 200m, and 57-69% in 500m). The methods utilized to calculate the energy contributions may be one cause of these different values. The aim of this study was to compare the WAER% calculated with two different methods in simulated 200m and 500m kayak racing. Methods Eleven adolescent female kayakers ( $14 \pm 1$  yrs,  $172 \pm 4$  cm,  $65.4 \pm 4.2$  kg,  $42.6 \pm 4.9$  mL $\cdot$ min $^{-1}$  $\cdot$ kg $^{-1}$ ) volunteered to participate in this study. The kayakers performed an incremental test and two time trials on a kayak ergometer (Dansprint, Denmark) on separate days, with at least 24-h rest in between. The incremental test consisted of four to six 5-min steps with 1 min interruption in between, starting from 40 watts with an incremental of 15 watts. The two time trials lasted 40s and 120s to simulate the 200m and 500m racing, respectively. A portable spirometric system (MetaMax 3B, Germany) was utilized to measure the gas metabolism throughout all the tests. 20  $\mu$ L was taken after each step in the incremental test, and before and after the time trials, and was later assessed with a lactate analyzer (Biosen S\_line, Germany). Two methods were utilized to calculate the energy contributions during the time trials. The first was the maximal accumulated oxygen deficit (MAOD) (Medbo et al. 1988). The second was based on the fast component of oxygen debt after the exercise (Pcr-La-O<sub>2</sub>) (Beneke et al. 2002). The WAER% between the two methods was compared using two-tail paired t-tests. A type-I error rate was set at 0.05. Results MAOD induced higher WAER% than Pcr-La-O<sub>2</sub> during the 40s ( $36.1 \pm 3.7\%$  vs.  $30.6 \pm 3.5\%$ ) and 120s ( $60.7 \pm 12.2\%$  vs.  $57.5 \pm 4.5\%$ ) time trials, and the difference in the 40s time trial was significant ( $p<0.05$ ). Discussion The primary findings in this study were the overestimate of WAER% with MAOD compared with that with Pcr-La-O<sub>2</sub> in kayaking time trials, especially when the intensity was higher (i.e. 40s). This was consistent with our previous literature review (Li et al. 2014) and other challenges for MAOD (Bansbo 1992). Although MAOD is the most popular method in calculating energy contributions in exercise/sports (Li et al. 2014), the theoretical basis of MAOD has some limitations, including the linear correlation between the intensity and VO<sub>2</sub> and the ignorance of the anaerobic energy contribution during exercises under a sub-maximal intensity (35-90% of VO<sub>2</sub>max). These limitations might lead to an underestimate of the anaerobic energy contribution, and then an overestimate of WAER%. However, it is still open for research to investigate which method provides a value closer to the nature. References BANGSBO, J. (1992). *J Appl Physiol*, 73(3), 1207-1209. Beneke et al. ### ACUTE INSPIRATORY LOADING DOES NOT IMPROVE 2.4 KM TIME-TRIAL PERFORMANCE WITH A 25 KG THORACIC LOAD

Faghy, M., Brown, P.I.

University of Derby

Purpose: The addition of an inspiratory muscle warm-up (IMWU) to active warm up (AWU) has demonstrated increases in performance on maximal exercise tasks. This is attributed to the priming of the respiratory musculature prior to exercise attenuating exertional dysp-

noea, lactate accumulation and respiratory muscle fatigue. To date, these observations have been made in sporting activities; however, when wearing a backpack such as in physically demanding occupations. Wearing such loads alters breathing mechanics, replaces a volume limitation upon the thoracic cavity, heightens the work of breathing and leads to premature fatigue of the inspiratory muscles group; ultimately impairing whole body performance. Therefore, it is attractive to suggest that acute inspiratory loading could improve performance in this exercise mode; however this remains unknown. Methods: Participants (n= 9) performed five 2.4km time-trials with a 25kg thoracic load in a backpack on separate days preceded by either 1) IMWU, 2) AWU, 3) placebo IMWU (PLA), 4) AWU followed by IMWU and 5) AWU followed by PLA. IMWU comprised two sets of 30 inspiratory efforts against a pressure threshold load of 40% of maximal inspiratory pressure (PIMAX) measured prior to each trial. PLA trials comprised five min quiet breathing against a sham device with no resistance. No resistance was favoured of smaller resistances to negate increased diaphragm excitability, observed when using lower resistances. AWU comprised 10min unloaded exercise at lactate turn point ( $10.33 \pm 1.58 \text{ km}\cdot\text{h}^{-1}$ ). All AWU components were conducted prior to IMWU and PLA. Results: Time-trial performance was similar between all trials (IMWU:  $14.32 \pm 1.34 \text{ min}$ , AWU:  $14.40 \pm 2.28 \text{ min}$ , PLA:  $14.77 \pm 1.92 \text{ min}$ , IMWU+AWU:  $14.14 \pm 1.74 \text{ min}$  and PLA+AWU:  $14.68 \pm 2.15 \text{ min}$ ;  $P > 0.05$ ) although performance for IMWU and AWU+IMWU were quicker than PLA trials this was not statistically significant ( $P > 0.05$ ). All respiratory, ventilatory, physiological and perceptual responses were also similar between trials. Conclusions: The addition of a specific IMWU to an existing AWU did not increase performance during a 2.4km time-trial when wearing a 25kg backpack; we suggest that AWU consisting of moderate intensity exercise for 10 min was sufficient in preparing the inspiratory musculature for high-intensity exercise with thoracic loading, without the need for specific priming of inspiratory muscles.

### MODELING INTERMITTENT CYCLING PERFORMANCE IN HYPOXIA USING THE CRITICAL POWER CONCEPT

Townsend, N., Shearman, S., Skiba, P., Dwyer, D.

*Aspetar Orthopaedic and Sports Medicine Hospital*

Purpose: Recently, a novel model derived from the critical power (CP) concept was developed to determine  $W'$  balance ( $W'$ BAL) during variable intensity exercise. The purpose of this study was to investigate the effect of hypoxia on the efficacy of the  $W'$ BAL model during high-intensity intermittent exercise. Methods: Eleven trained, male cyclists (mean $\pm$ SD; age  $27 \pm 6.6$  years,  $\text{VO}_2\text{peak}$   $4.79 \pm 0.56$ ) completed a maximal incremental ramp test and a 3 min "all out" test to determine end power (EP) and work performed above EP ( $W'$ EP). On another day an intermittent test to task failure was performed. All procedures were performed in normoxia (NORM) and hypoxia (HYPO;  $\text{FiO}_2 = 0.155$ ). The experimental condition was single-blinded, randomized and counter-balanced, and the  $W'$ BAL model was used to calculate the minimum  $W'$  ( $W'$ BALmin) achieved during the intermittent test.  $W'$ BALmin in HYPO was also calculated using model parameters derived in NORM (N+H). Results: In HYPO there was a significant decline in  $\text{VO}_2\text{peak}$  ( $4.79 \pm 0.56$  vs  $3.93 \pm 0.47 \text{ L/min}$ ;  $P < 0.001$ ) and EP ( $353 \pm 46$  vs  $319 \pm 49 \text{ W}$ ;  $P < 0.001$ ), whereas no change occurred for  $W'$ EP ( $12.6 \pm 4.1$  vs  $13.3 \pm 5.3 \text{ kJ}$ ;  $P = 0.34$ ; NORM vs HYPO). The change in  $\text{VO}_2\text{peak}$  was significantly correlated with the change in EP ( $r = 0.72$ ;  $P < 0.05$ ). There was no difference between NORM and HYPO for  $W'$ BALmin ( $1.7 \pm 0.9 \text{ kJ}$  vs  $1.3 \pm 0.8 \text{ kJ}$ ). The N+H analysis revealed a gross overestimation of  $W'$ BALmin ( $8.3 \pm 3.2 \text{ kJ}$ ) and compared with HYPO ( $P < 0.001$ ). Conclusion: The  $W'$ BAL model behaves similarly in hypoxic conditions equivalent to  $\sim 2450 \text{ m}$  as previously reported for normoxia, but only when the model parameters (CP and  $W'$ ) are determined under the same environmental conditions. The practical application of the  $W'$ BAL model for altitude training and performance monitoring requires CP and  $W'$  to be measured at altitude.

## Oral presentations

### OP-BN04 Running

#### THE INTERACTION BETWEEN NEUROMUSCULAR RESPONSES AND INITIAL LOADING RATE IN ELITE KENYAN RUNNERS

Tam, N., Tucker, R., Coetzee, D.R., Noakes, T.D., Santos-Concejero, J.

*University of Cape Town*

Introduction: Loading rate has been proposed to be a risk factor for stress fracture when running. Previous research has suggested that muscle activation strategies and resultant kinematics prior to initial ground contact influence loading rate<sup>1,2</sup>. Studying various trained groups may provide insight into the muscle activation strategies related to modifying the loading rate and running injury risk factors. Methods: Fourteen elite Kenyan ( $24 \pm 4.1$  years &  $28.7 \pm 0.4 \text{ min}$  10-km race time) participated in this study. Ground contact forces (AMTI Watertown, USA) and electromyography (Noraxon, Arizona, USA) of medial and lateral gastrocnemii, peroneus longus, tibialis anterior, rectus and biceps femoris and gluteus medius muscles were measured at 12 km/h (warm-up) and 20 km/h (race pace) in both shod and barefoot conditions. Results: Condition differences were found between all muscles during pre-activation except peroneus longus and rectus femoris. Ground contact condition differences were found in lateral gastrocnemius, tibialis anterior, biceps femoris and gluteus medius. Differences in activity related to running speed in the Kenyan runners were only found in the medial gastrocnemius. Increased lateral gastrocnemius activity during stance were positively associated with initial loading rate at all running speeds Discussion: These findings suggest that elite Kenyan runners will indeed respond differently between both barefoot and shod conditions. Further that the medial gastrocnemius pre-activity appears to be influenced by running speed that may also suggest it is not as active during slow running. The relationships found implicate that high initial loading rates are related to lateral gastrocnemius activity, which may indicate a stabilizing role in weight transfer.

#### BIOMECHANICAL 3D FIELD MEASUREMENTS OF TRAIL RUNNERS

Swarén, M., Born, D., Stöggl, T., Björklund, G.

1: Swedish Winter Sports Research Centre, MidSweden University, Östersund, Sweden 2: Royal Institute of Technology, Mechanics Dept, Stockholm Sweden 3: University of Würzburg, Experimental and Integrat

Introduction: Trail running, where you run on dirt roads, single tracks, rocks and in the mountains has increased in popularity during the last few years. Compared to flat running, trail running is more technical challenging as the running takes place over rocks, roots as well as firm gravel roads or slippery tracks in the forest. Also, trail running often includes very steep uphill and downhill sections where it is too steep to run for most runners. The difference between track running and trail running is therefore significant and it is likely that biome-

chanical and physiological characteristics are different in specialized track runners compared to specialized trail runners. Hence, the purpose of the present study was to investigate the biomechanical and physiological characteristics for specialized trail runners compared to track runners, while running a typical trail running track. Method: Nine professional runners (3 women and 6 men) were recruited to the study. First, the runners performed an incremental lab test to determine running economy and VO<sub>2</sub>max. Thereafter, the group was divided into trail running specialists and track runners (5 trail runners and 4 flat runners). Second, all runners were equipped with 16 Inertial Measurements Units, IMU (MyoMotion, Noraxon Inc., Scottsdale, AZ, USA) and pressure insoles (MotiCon GmbH, Munich, Germany). Kinematic data was collected at 200 Hz and pressure data at 50 Hz. Each subject performed a 10-15 min long warm up before the data collection. The track consisted of two laps on a 3.5 km long technical loop which included a total vertical climb of 850 m. Ten continuing running cycles were analyzed during running on flat single track, moderate downhill and steep downhill. The subjects had one minute of rest between the two laps where all systems were checked and adjusted if necessary. Results: The trail running specialist showed a trend to complete the two runs on average 59.3 s faster than the track runners as well as losing less time between the two runs compared to the track runners (54.0 s vs. 100.3 s. respectively). Step frequency and ground contact time were significantly higher during steep downhill running compared to flat- and moderate downhill running ( $p < 0.001$ ). Steep downhill running generated lower peak forces than flat running ( $p < 0.05$ ). No differences in step kinetics were observed between flat- and moderate downhill running. A trend to increased hip and knee flexion was observed in the trail running specialists compared to the flat runners. Discussion: The present study showed clear differences in step kinetics when running in undulating terrain. Experienced trail runners completed the two laps on average 59.3 s. faster, even though all subjects have comparable VO<sub>2</sub>max (53±3 mL/kg/min for women and 65±5 mL/kg/min for men). Trail runners showed better ability to adapt to the surface and the kinematic data show increased joint flexion in the lower joints which is considered to decrease leg stiffness and contribute to "Groucho" running.

### INFLUENCE OF SHOE TYPE AND FATIGUE ON RUNNING STYLE

Mann, R.1,2, Malisoux, L.1, Urhausen, A.1,3, Statham, A.4, Meijer, K.2, Theisen, D.1

1. Luxembourg Institute of Health, 2. NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht University, The Netherlands, 3. Sports Clinic, Centre Hospitalier de Luxembourg, 4. ATOGEAR, E

Introduction It is thought that a minimalistic running shoe (MIN) will encourage a forefoot strike pattern, thereby reducing external loading rates applied to the body [1]. It is unclear whether first-time use of such shoes will induce an acute change in running style. In addition, the effect of musculoskeletal fatigue on the running style is not clearly understood, and research until now has yielded conflicting findings. We aimed to study the effect of first time MIN use and fatigue after a prolonged running bout and any interaction on running style. Methods We used a pressure-sensitive insole device to measure the strike index (point of contact on the footsole with the ground, expressed as a percentage of total sole length) and spatiotemporal parameters of running. 26 recreational runners were tested using conventional (CONV) and MIN shoes before and after a prolonged running bout (~20% of habitual session duration) on a treadmill at their preferred running speed. The coefficient of variation was calculated and detrended fluctuation analysis performed to determine stride-to-stride variability and correlative patterns, respectively. Results No significant differences were found for strike index between CONV [25.7±14.6% (unfatigued) and 23.1±11.1% (fatigued)] and MIN [28.9±19.1% (unfatigued) and 26.7±17.6% (fatigued)]. Similarly, no spatiotemporal parameter differences were observed between shoe types or fatigue states. Stride-to-stride variability and correlative patterns did not differ significantly between shoe type or fatigue states. However, there was an overall trend towards less correlation between strides when using CONV ( $p = 0.075$ ). The interaction between the conditions was not significant. Discussion The non-significant differences observed between the shoe types suggest that recreational runners do not naturally adapt their running style with first-time MIN use. The trend towards less correlation in strike index between strides with CONV shoe use could suggest that runners are more comfortable making changes in their strike pattern, possibly due to the added overall cushioning and familiarity of this shoe type. Our runners were able to maintain their running style despite the fatiguing effect of the prolonged running bout. References 1. Rixe JA, Gallo RA, Silvis ML. The barefoot debate: can minimalist shoes reduce running-related injuries? *Curr Sports Med Rep.* 2012;11(3):160-5.

### RUNNING BAREFOOT INDUCES LOWER VERTICAL DISPLACEMENT COMPARED TO SHOD CONDITION

Ekizos, A., Santuz, A., Arampatzis, A.

Humboldt-Universität zu Berlin

Introduction Barefoot running was prominent for millions of years until modern shod running. Several studies reported that barefoot running is more economical (2 to 6%) compared to shod running (Hanson et al. 2011; Perl et al. 2012). We hypothesized that a lower vertical displacement per unit of distance traveled while running would be a possible mechanism that may explain the lower energy cost in the barefoot condition. Therefore, we investigated the differences in the vertical and medio-lateral displacement for a long time interval (i.e. two minutes) between barefoot and shod running. Methods Twenty one participants performed randomly two minutes long barefoot and shod running trials (two of each), at their preferred velocities on a treadmill. Vertical ground reaction forces were measured using a pressure plate (Zebris FDM), integrated in the treadmill. Further using six cameras of the Simi Motion system (190 Hz) we measured the 3D coordinates of 11 reflective markers positioned on the back of the participants. The displacements of the spine and the scapula were identified and analysed separately. The vertical spine (VSp), vertical scapula (VSc), medio-lateral spine (MLSp) and medio-lateral scapula (MLSc) displacements have been extracted from the 3D coordinates of the 11 markers. Results Lower displacements ( $p < 0.05$ ) were documented in the barefoot condition on VSp, VSc and MLSp but not in MLSc ( $p > 0.05$ ). The differences to the shod condition were 4.4%, 3.4% and 6% for VSp, VSc and MLSp respectively. Foot strike patterns changed significantly ( $p < 0.05$ ) towards the front of the foot and cadence increased ( $p < 0.05$ ) by ~2.5% in barefoot condition. The integral of ground reaction forces over time decreased significantly ( $p < 0.05$ ) by ~9.8% when barefoot. We found a decreased total contact time (~4.9%) and an increased total flight time (~20.0%) in the barefoot compared to the shod condition. Discussion We found a lower vertical displacement on VSp and VSc at the same running velocity in the barefoot compared to the shod condition supporting our hypothesis. The lower vertical displacement resulted from the lower vertical impulses of the ground reaction force in the barefoot condition. The lower vertical displacement during barefoot running might be an important mechanism affecting the energy cost of running. References Hanson N.J., Berg K., Deka P., Meendering J.R., Ryan C. **EFFECTS OF MENTHOL IN STOCKINGS ON SKIN TEMPERATURE AND THERMAL PERCEPTION DURING RUNNING**

Aparicio, I.1,2, Priego, J.I.1, Giménez, J.V.1, Lucas-Cuevas, A.G.1, Sellés, O.1, Llana, S.1

*University of Valencia*

**INTRODUCTION** The use of menthol in sport garments has been observed to improve thermal comfort in sports (Gillis et al., 2010). The aim of the study was to analyze the effect of menthol, applied in stockings by padding, on skin temperature and thermal perception before, during and after running. **METHODS** 10 male runners (age [28 ± 5 years], weight [66 ± 5 kg], height [174 ± 6 cm], and weekly mileage [37 ± 12 km/week]) participated in the study. Runners carried out 2 laboratory tests (normal stockings [NORMAL] and stockings with menthol [COLD]). Menthol was applied by padding (AITEX- Textile Research Institute) in a concentration of 7% Menthol, 3% PVP, 35% ethanol, 55% water. The order of the tests was randomized. At each test participants ran for 10 minutes at 10 km/h followed by 10 minutes at 12 km/h. All tests were carried out in a moderate indoor environment: 22.2 ± 0.7°C and 36.7 ± 9.5% relative humidity. Skin temperature of eight regions of interest on the lower limb was measured using infrared thermography before running (after 10 minutes of adaptation at room temperature) and immediately after the running test. Temperature variation between both measurements was assessed. Perception of temperature and thermal comfort were measured using a 15-cm visual analogue scale before, during and after running. Differences between NORMAL and COLD test were analyzed with a repeated-measures ANOVA. **RESULTS** No differences were observed between conditions in temperature variation and thermal comfort ( $p>0.9$ ). Temperature variation in both conditions was 0.5±0.3°C and thermal comfort of COLD condition was 10.3±2.5 cm, 9.5±2.3 cm, and 9.7±3.1 cm before, during and after running, respectively. Thermal comfort of the NORMAL condition was 8.5±2.0 cm (before), 7.9±2.8 cm (during) and 9.3±2.5 cm (after). Before running, no differences between both conditions were observed in temperature perception ( $p=0.9$ ), but COLD condition was perceived cooler than NORMAL condition during running (COLD vs NORMAL: 5.7±3.4 vs 10.0±1.1 cm,  $p=0.03$ ) and after running (4.7±2.8 vs 8.8±1.7 cm,  $p=0.04$ ). **DISCUSSION** Skin temperature did not vary across conditions (COLD and NORMAL). Also, no differences in perception of thermal comfort were observed between stockings. These results may imply that the use of stockings with menthol do not influence skin temperature and comfort in a moderate environment. Similar results have been observed in warm and humid conditions (Barwood et al, 2014). However, athletes perceived a lower skin temperature with the use of the menthol stockings, so it could be beneficial for comfort during exercise in a warm environment. In conclusion, running in a moderate environment while wearing stockings with menthol was perceived cooler for runners without compromising their skin temperature or perception of comfort. **REFERENCES** Gillis DJ, House JR., Tipton MJ. **Oral presentations****OP-PM40 Training & Testing: Strength I****EFFECTS OF VARIOUS WARM-UP MODELS ON 1 RM LEG PRESS PERFORMANCE IN COLLEGIATE ROWERS**

Akca, F., Aras, D.

*Ankara university, Faculty of Sport Sciences*

**INTRODUCTION** Strength was proved to be one of the limiting factors of rowing performance. Significant relationships between 1RM leg press and rowing performance were demonstrated (Akca, 2014). Determining the leg press 1 RM precisely as possible is crucial to optimize the training plan of rowers individually. The warm-up procedure is a critical factor which effect the precision of the 1RM tests (Bishop, 2003). Thus; the aim of this study was to compare leg press 1 RM performance after different warm-up protocols. **METHODS** In a randomized crossover fashion, 1 RM leg press performance were measured in 4 different occasions after different warm-ups using rowing ergometer. The combinations were as follows: 1.Constant Low Intensity (CLI): 15 minutes at the power output that corresponds to 40% of VO2Max. 2. Low Frequency Intermittent (LFI): 13 minutes at the power output that corresponds to 40% of VO2Max and two 15 seconds sprints with the intensity of 170% of the power output at VO2Max during the last 2 minutes. 3. Moderate Frequency Intermittent (MFI): 10 minutes at the power output that corresponds to 40% of VO2Max and five 15 seconds sprints with the intensity of 170% of the power output at VO2Max during the last 5 minutes. 4. High Frequency Intermittent (HFI): 5 minutes at the power output that corresponds to 40% of VO2Max and ten times 15 seconds sprints with the intensity of 170% of the power output at VO2Max during the beginning of every min. in the last 10 min. Intermittent sprints during protocols separated by 45 seconds of recovery at 40% of VO2Max. After general warm-up, subjects performed standardized specific warm-up protocol. HR, RPE and Lactate were measured before and after each warm-up. Mixed linear analysis was employed for statistical analysis, warm-up conditions were set as fixed factor while participants as a random factor. **RESULTS** 1RM leg press performance was found significantly better (aprox. 4%) after LFI protocol compared with others. **DISCUSSION** The performance improvement compared with other protocols after using LFI warm-up may be considered small (aprox. 4%); however, the improvements about 3-4% is similar to those observed in response to a long term strength training (Kraemer, 1997). Thus, the results of the present study are important for both practical and research environments. **REFERENCES** Akca F. **DO CLUSTER-TYPE REGIMENS OFFER A SUPERIOR ALTERNATIVE TO TRADITIONAL RESISTANCE TRAINING METHODS WHEN THE GOAL IS MAXIMAL STRENGTH DEVELOPMENT?**

Nicholson, G., Ispoglou, T., Bissas, A.

*Leeds Beckett University*

**Introduction** It is widely believed that 'strength-type' (STR) resistance training (RT) is a more effective way of improving maximal strength than 'hypertrophy-type' RT (HYP) however, research comparing these training methods is far from unequivocal (Nicholson et al., 2014). Furthermore, cluster training (CL) challenges the traditional way in which strength training sessions are designed although there is a paucity of research into this approach. Our main objective was to compare the adaptations resulting from STR, HYP and CL training over a

6 week period involving the back squat. Methods 46 trained males (age:  $21.8 \pm 2.6$  years; height:  $178.0 \pm 6.3$ cm; mass:  $81.1 \pm 8.8$ kg) were matched according to one repetition maximum [1RM] strength before being randomly assigned to one of 4 groups: a) STR: 4x6 reps, 85% 1RM, 900s total rest; b) HYP: 5x10 reps, 70% 1RM, 360s total rest; c) CL-1 4x6 reps, 85% 1RM, 1400s total rest; d) CL-2: 4x6 reps, 90% 1RM, 1400s total rest. Physiological and mechanical variables were measured before, during and after the workouts to investigate the acute training stimulus whilst similar techniques were employed before, during and after a 6 week intervention (2 sessions per week) to investigate the training effects. The findings were analysed using a two-way mixed ANOVA with significance set at  $p < 0.05$ . Results From an acute perspective, the STR and HYP workouts resulted in significantly greater reductions in repetition quality than the CL workouts ( $p < 0.05$ ). Furthermore, the STR and HYP workouts showed significant post-exercise elevations in blood lactate concentration ( $p < 0.001$ ). In terms of chronic responses, all four groups elicited significant increases (8-13%;  $p < 0.001$ ) in 1RM strength after training; however, the 1RM improvements were significantly greater for the STR ( $12.1 \pm 2.8\%$ ;  $p < 0.05$ ) and CL-2 ( $13.2 \pm 2.2\%$ ;  $p < 0.001$ ) groups than the HYP group ( $8.1 \pm 2.5\%$ ). Increases in isometric peak force, rate of force development, muscle activity and jump height were not significantly different between groups. Discussion The STR and CL-2 regimens represented the most favourable means of improving maximal strength. The effectiveness of the STR and CL-2 regimens underlines the importance of longer time under tension and greater impulse generation for strength development but does not support the importance of higher velocities which are often used to signify repetition quality. The findings highlight that CL regimens can offer similar performance enhancements to STR regimens so the decision as to which approach should be used lies with coaches. ### NEUROMUSCULAR ADAPTATIONS TO SHORT-TERM RESISTANCE TRAINING WITH LINEAR AND DAILY UNDULATING PERIODIZATION IN ADOLESCENT ELITE JUDOKA

Pelzer, T., Ullrich, B., Oliveira, S.R.S., Holzinger, S., Pfeiffer, M.

*Olympic Training and Testing Center Bad Kreuznach*

Introduction Few studies have assessed neuromuscular adaptations and strength outcomes after short-term strength training periods in adolescent athletes (Blazevich et al., 2003). Furthermore, the influence of different periodization models on temporal changes of neuromuscular parameters during short-term training periods remains unclear. This work examined the temporal changes of muscle architecture, neural drive, and maximal upper- and lower body strength after two short-term strength training mesocycles with either linear or daily undulating periodization in adolescent judoka. Methods Eleven adolescent elite judoka (14.8 years, 5 males and 6 females) performed two 4-week strength training mesocycles (each with 12 training sessions) with either linear (LP) or daily undulating (DUP) periodization separated by a 7-week washout period (no training and competition). Training was performed as dynamic lifting and lowering of weights using squats, knee flexion curl, clean & jerk, snatch, bench press, barbell bench pull, and lat-pull down. The mesocycles were equated for intensity zones (50-90% of 1RM) that addressed the optimization of strength, power or velocity and the number of repetitions. Laboratory and 1RM testing were carried out at five different occasions: two times during the baseline (T1, T2), after the LP-mesocycle (T3), after the washout period (T4), and after the DUP-mesocycle (T5). At each testing occasion, isometric knee extensor and knee flexor MVC, EMG-estimated neural drive of the M. quadriceps femoris (QF), vastus lateralis (VL) muscle architecture, and 1RM values of all training exercises were measured. ANOVA with repeated measures was performed to analyze the temporal changes for all absolute study outcomes. Wilcoxon-comparisons were used to analyze the percentage changes for each outcome between the two mesocycles. Results Moderate ( $\Delta$  5.5- 13.5%), but significant ( $P < 0.05$ ) gains in knee extensor MVC, 1RM values, and VL-muscle architecture occurred during both mesocycles. Importantly, no significant differences for the percentage changes of any outcome were found between the LP- and DUP mesocycles. Discussion For strength training experienced adolescent judoka, both linear and daily undulating periodization were equally adept in improving VL-muscle architecture, QF-neural drive, and maximum upper-and lower body strength during two 4-week strength training mesocycles. These findings question the influence of stimuli-periodization during short-term training periods. References Blazevich, A.J. (2003). *Medicine & Science in Sports & Exercise*, 35, 2013-2022.

### EFFECTS OF DIFFERENT SPLIT TRAINING ROUTINES ON ACUTE NEUROMUSCULAR PERFORMANCE OF ELBOW FLEXORS IN TRAINED MEN

Ferreira-Junior, J.B.1,2, Castanheira, R.P.M.2, Martorelli, S.2, Sampaio, S.R.S.2, Pereira, M.C.2, Rocha-Junior, V.2, Bottaro, M.2

*1.Federal Institute of Sudeste of Minas Gerais and 2.University of Brasília*

Introduction Split resistance training routine has been recommended for intermediate and advanced resistance trained subjects in order to allow appropriate muscle recovery and maximize training volume within a training session (ACSM, 2009). A synergist muscle arrangement are usually recommended for split training routines (Monteiro et al., 2009). However, the performance of single-joint exercise (i.e. arm curl) could be affected by the prior multi-joint exercise (i.e. seated row) during a synergist split training routine session. Moreover, controlled studies on the effects of split training arrangement on neuromuscular performance are lacking. Therefore, the aim of this study was to investigate the effects of different split training routines (synergists vs. non-synergists) on training performance of elbow flexors in trained men. Methods Eighteen trained men ( $23 \pm 3$  years) randomly performed three training routines separated by 7 days: 1) Synergist routine (SN): 6 sets of 10 maximum repetitions (RM) at supinated row machine followed by 4 sets of 10RM of elbow flexors on isokinetic dynamometer, 2) Non-synergist routine (NS): 6 sets of 10RM of bench press on smith machine followed by 4 sets of 10RM of elbow flexors on isokinetic dynamometer, and 3) Control (CO): 4 sets of 10RM of elbow flexors on isokinetic dynamometer. The rest interval between sets was 2 min. Elbow flexors mean torque (MT), total work (TW) and the amplitude of electromyography signal (EMG) were measured during elbow flexors isokinetic exercise. Results MT were significantly lower during SN and NS routines when compared to CO routine (3.6 and 6.4%, respectively) ( $p < 0.05$ ). MT were also 2.8% higher in NS than SN routine ( $p < 0.05$ ). Moreover, TW were higher in CO routine compared to SN and NS routines (10.3 and 5.5%, respectively). TW were 5.0% greater in NS than SN routines. Additionally, EMG did not differ among split training routines ( $p > 0.05$ ). Discussion The main finding of the present study was that training performance and volume of the elbow flexors exercise was impaired when the split training arrangement was composed by synergist exercises. Considering that EMG was not different among split training routines, the impaired training performance of the elbow flexors observed during SN split training may be due to peripheral changes such as impaired excitation-contraction coupling, shift of  $Na^+$  and  $K^+$  concentration in intracellular and extracellular fluids reductions in  $Ca^{2+}$  release (Gentil et al., 2007). In conclusion, if one wants to maximize the neuromuscular performance using a split training routine, a non-synergist session (i.e. chest exercise before elbow flexors exercise) is recommended for trained subjects. ### **LOW-INTENSITY RESISTANCE TRAINING WITH SLOW MOVEMENT AND TONIC FORCE GENERATION INCREASES MUSCLE SIZE AND STRENGTH BUT NOT POWER**

Maeo, S., Usui, S., Tayashiki, K., Nakatani, M., Kanehisa, H.

*National Institute of Fitness and Sports in Kanoya*

**Introduction** Low-intensity resistance training with slow movement and tonic force generation (LST) has been shown to be effective in increasing muscle size and strength (Tanimoto and Ishii 2006). However, it is unknown whether LST increases power output during fast movements, which plays substantial roles in various physical activities. We tested our hypothesis that LST would increase muscle size and strength but not necessarily power during fast movements due to task-specific adaptation to the training modality. **Methods** Sixteen young men were assigned to LST [50% one repetition maximum (1RM) load, 3 s lowering and 3 s lifting without relaxing phase, 10 reps; n = 9] or low-intensity normal speed (LN: 50% 1RM load, 1 s for lowering and 1 s lifting with 1 s relaxing phase, 10 reps; n = 7) group. Both groups underwent a parallel squat training program 3 sets/day, 3 days/week, for 8 weeks by the assigned methods. Before and after the training, the following variables were measured; muscle thickness of quadriceps femoris (30%, 50%, and 70% of the femur for rectus femoris and vastus intermedius, 50% for vastus lateralis and vastus medialis), isometric torque during maximal voluntary hip extension and knee extension, 1RM of squat, maximal lifting power from squatting position (load: body mass), maximal leg extension power (0.8 m/s), and vertical and counter-movement jump height. **Results** After the training, LN showed no changes in all variables. In LST, significant increases were found in the muscle thickness of rectus femoris (+7%) and vastus intermedius (+14%) at 70% of the femur, isometric torque during hip extension (+15%), and 1RM of squat (+9%), but there were no changes in lifting power, leg extension power, and vertical and counter-movement jump height. **Discussion** Significant increases in muscle size and strength in LST but not in LN would be due to longer time under tension and greater metabolic stress in LST than LN (Tanimoto and Ishii 2006). The reason why significant increases in muscle thickness were found only at 70% of rectus femoris and vastus intermedius may be explained by inter- and inner-muscle difference in activation level during exercise (Wakahara et al. 2013). Regarding no changes in maximal power, Tanimoto et al. (2009) reported that 13-weeks LST changed muscle activation pattern during force production to be tonic, which may have negative influence on power production. These findings together with the current results suggest that LST can increase muscle size and strength, but has little effect on power production during fast movements. **References** Tanimoto M et al. ### **ACUTE EFFECTS OF SELF MYOFASCIAL RELEASE ON SINGLE LEG STABILITY AND VERTICAL JUMP: A PILOT STUDY**

Russo, L.1,3, Benis, R.2,3

*University of L'Aquila; University of Milan; ATS Trainer*

**Introduction:** Self myofascial release (SMR) with foam roller is very popular among athletes and trainers. Practitioners use it before the training session because it is documented that SMR increases the articular ROM but does not affect neuromuscular characteristics (Healey et al., 2014; MacDonald et al., 2015). Previous studies did not use an SMR protocol on all the lower limb muscles as often happens during the field practice. The aim of the study is to measure the acute effects of a whole lower limb SMR protocol on single leg stability and vertical jump performance. **Methods:** Eighteen young and sporty people (10 male and 8 female: 24.5±4.5 y-o; 167.2±9.4 cm; 62.1±10.3 kg) were involved in a single session protocol consisting of: brief warm up, CMJ test, single leg stability test, 20 minute of lower limb SMR procedure, CMJ test, single leg stability test. CMJ and single leg stability tests were performed respectively by 10 and 18 people. The SMR protocol lasted 60' for each of the following muscular districts: plantar fascia, calves, tibialis anterior, peroneals, hamstring, quadriceps, gluteus, adductors, tensor fasciae latae of both legs. CMJ performance was measured by using a Bosco's conductive device (TT Sport, San Marino Republic). Single leg stability was measured both in Open Eyes condition (OE) and in Closed Eyes condition (CE) by using a FreeMed 40x40 platform (Sensor Medica, Italy). A Student's T-Test was used to assess the difference pre-post SMR protocol. Statistical significance was set at p<0.05. **Results:** CMJ showed a 7% significant decrease (p=0.010) between pre (35.5±9.4 cm) and post (33±8 cm) SMR protocol. Single leg stability did not show any significant difference for the right leg both in OE and in CE condition, while showed just a little significant difference (p=0.041) for the left leg in OE condition for the anterior-posterior movement. **Discussion:** The study shows how a longer SMR protocol on all muscles of the lower limb does not alter the stability in OE and CE condition, but it can affect the vertical jump performance, maybe for a prolonged lying on the ground position, as well as static stretching. It is very important for trainers and athletes to take this result into consideration in programming the warm up session. This pilot study will be implemented with other future tests but it is recommended to insert a brief neuromuscular activation after the SMR procedures to avoid any lowering in explosive movements. **References:** Healey KC et al. #### **OPTIMIZED BODY COMPOSITION FOLLOWING COMBINED ENDURANCE AND STRENGTH TRAINING ON ALTERNATING DAYS COMPARED TO SAME-SESSION COMBINED TRAINING IN MEN**

Eklund, D.1, Häkkinen, A.2, Schumann, M.1, Balandic, M.1, Nyman, K.3, Häkkinen, K.1

*1, 2: University of Jyväskylä, Jyväskylä, Finland, 3: Central Hospital of Central Finland, Jyväskylä, Finland*

**Introduction** Our previous study has shown that strength (S) and endurance (E) performance increase to a similar extent when S and E are performed on alternating days or consecutively in the same training session with different orders (1). However, split exercise sessions may result in increased EPOC (2) and, thus, changes in body composition following combined training on alternating days may differ from changes following S and E training performed in the same-session. Thus, the purpose was to compare adaptations in body composition during S and E training performed either on alternating days or in the same training session in men. **Methods** Physically active men were

assigned to an alternating-day (AD, n=21, BMI 25±3 kg/m<sup>2</sup>, 29±6yrs) or a same-session training group with E preceding S (ES, n=17, BMI 25±3 kg/m<sup>2</sup>, 30±6 yrs) or vice versa (SE n=18, BMI 24±2kg/m<sup>2</sup>, 30±4 yrs). Training volume was matched in all groups. Training was performed for 24 wks with a frequency of 2-3 weekly sessions of both E and S in AD and 2-3 weekly combined sessions in ES and SE. S-training focused on leg muscles (but also included upper body and trunk exercises) with loads of 70-95% of 1RM. E training consisted of steady-state and interval cycling of progressively increasing intensity and duration. Total body lean (TBL) and fat mass (TBF) were assessed by DXA. Dynamic leg press 1 RM and peak workload (Watts, Wmax) during a maximal incremental cycling test were measured. Subjects were asked to maintain their regular dietary intake. Results TBL increased similarly in all training groups (AD 4±3% p=0.011, ES 3±3% p=0.001, SE 3±2% p<0.001), while significant decreases in TBF were observed in AD only (-14±15%, p<0.001). A significant increase in bodyweight was observed in SE only (2±4%, p=0.05). All groups similarly improved 1 RM (AD 13±7%, ES 12±9%, SE 17±12%, all p<0.001) and Wmax (AD 21±11%, ES 13±9%, SE 16±7%, all p<0.001). Discussion This study showed that combined S and E training performed on alternating days is similarly effective in increasing TBL, when compared to same-session combined training. However, splitting S and E onto alternating days led to significant reductions in TBF, indicating that AD training may be more beneficial for simultaneously improving both body composition and performance compared to ES or SE. These findings suggest that healthy individuals can increase TBL following either training mode, while differences may be observed in reductions of TBF. References 1. Eklund et al. 2015 IJSM, 2. ### EFFECTS OF HIGH INTENSITY INTERVAL TRAINING AND STRENGTH TRAINING ON CARDIOVASCULAR RISK FACTORS IN WOMEN WITH POLYCYSTIC OVARY SYNDROME: A RANDOMIZED, CONTROLLED TRIAL

Almenning, I., Rieber-Mohn, A., Garnæs, K.K., Lundgren, K.M., Lovik, T.S., Moholdt, T.

*Norwegian University of Science and Technology*

Introduction Polycystic ovary syndrome (PCOS) is the most common endocrine disorder of reproductive-age women and a leading cause of infertility, affecting up to 20%. PCOS is also recognized as a metabolic disorder with increased prevalence of insulin resistance, dyslipidemia (Kim and Choi, 2013), and low-grade inflammation (Repaci et al, 2011). Further, endothelial function is found to be compromised in PCOS (Sprung et al, 2013). Taken together, this suggests that women with PCOS are at increased risk of cardiovascular disease. Our primary aim was to study effects of high intensity interval training (HIT) and strength training (ST) on cardiovascular risk factors in women with PCOS. Methods Thirty-one women with PCOS were randomized to: HIT (n=10), ST (n=11) three times/week for ten weeks, or a control group (n=10). We measured maximum oxygen uptake, endothelial function (flow-mediated dilation of the brachial artery), resting heart rate, and blood pressure. In blood, we assessed: reproduction-related hormones, homocysteine, high sensitivity CRP, glucose, insulin, adiponectin and leptin. We used Bonferroni-adjusted covariance analysis with baseline values as covariate and group as fixed factor to assess differences between groups. Results Maximum oxygen uptake improved only after HIT, by 3.7 ml/min/kg, (95 % confidence interval (CI) 2.62, 4.83), with significant between-group difference (p<0.01). After HIT, high-density lipoprotein cholesterol increased by 0.2 (95% CI, 0.02, 0.5) mmol/L, with between group difference (p = 0.04). Endothelial function increased significantly after HIT, by 2.0 (95% CI, 0.1, 4.0) %, between-group difference (p = 0.08). There was a trend towards decreased resting heart rate after HIT, by -4.6 (95% CI, -9.6, 0.5) beats/min. There were no significant changes in blood pressure, homocysteine, high-sensitivity C-reactive protein, adiponectin or leptin in any group. Body weight did not change. Discussion HIT, but not ST, for ten weeks improved some cardiovascular risk factors in women with PCOS, without change in body weight. HIT was well tolerated with good adherence to exercise in these women. To our knowledge, this is the first study finding increased HDL cholesterol after exercise training in PCOS. There is little prior evidence of effects of exercise cytokines in this population and our study indicate that adiponectin and leptin levels do not change after ten weeks of exercise in PCOS. ### SIX WEEKS OF HIT INCREASES VO<sub>2</sub>MAX AND DECREASES VISCERAL FAT CONTENT IN ELDERLY

Dideriksen, S., Abildskov, C., Søgaard, D., Dehlbæk, M.S., Dela, F., Helge, J.W.

*Exercise laboratory*

Introduction High intensity training (HIT) improves aerobic capacity (VO<sub>2</sub>max) and decreases visceral fat content in overweight sedentary young individuals (Trapp et al, 2008; Gillen et al, 2013). The effect of HIT in overweight sedentary elderly has not yet been investigated and it is uncertain whether HIT can be tolerated by this group. The aim of this study was to investigate 6 weeks of HIT as an alternative training method for elderly individuals and the effect on VO<sub>2</sub>max and visceral fat content. Our hypothesis was that HIT can be applied to elderly individuals and lead to an increase in VO<sub>2</sub>max and a decrease in visceral fat content. Methods Seventeen healthy but overweight sedentary subjects (8 M/9 F, 62±1 years, BMI: 31±0.8 kg/m<sup>2</sup>) completed 6 weeks of supervised HIT, 3 days/week. Their training consisted of 5 x 60 s cycling at 137±4 % of maximal work load interspersed with 90 s recovery. Before and after the 6 weeks of HIT aerobic capacity was measured with an incremental VO<sub>2</sub>max test to exhaustion on a cycling ergometer and body composition by dual-energy X-ray absorptiometry (DXA) (GE Luna iDXA, Madison, WI, USA). Visceral fat content was calculated by an algorithm from the DXA data. Results 6 weeks of HIT increased (P<0.003) VO<sub>2</sub>max from 2.3±0.1 l/min to 2.5 ±0.2 l/min. Visceral fat content decreased (P<0.031) by 5.4±2.6 %. DXA scan data showed a decrease (P<0.04) in total body fat percentage (1.9±0.8 %) including a decrease in android (P<0.05) and gynoid (P<0.003) fat percentage (2.7±1.1 % and 3.3±0.9 %, respectively). Total body mass (pre: 89.6±2.8 kg, post: 89.0±2.9 kg, P=0.235), total lean body mass (LBM) (pre: 51.9±2.6 kg, post: 52.2±2.6 kg, P=0.31) and leg LBM (pre: 18.4±0.9 kg, post: 18.5±0.9 kg, P=0.44) were not different after training. Discussion This study demonstrates that elderly individuals can tolerate and complete 6 weeks of HIT. The training increased VO<sub>2</sub>max, and decreased visceral fat content and total fat percentage including android and gynoid fat percentage. These findings extend and support previous studies reporting an improved VO<sub>2</sub>max and body composition in young sedentary males and females in response to HIT. We did not find an overall increase in leg LBM, but in the male subjects the leg LBM, was increased (P<0.02), which indicates a possible gender specific difference in the response to HIT. In conclusion, HIT is a possible training method to improve VO<sub>2</sub>max and body composition in sedentary elderly subjects. Further studies are necessary to elucidate the mechanisms responsible to adaptations to HIT in elderly individuals. References Gillen JB, Percival ME, Ludzki A, Tarnopolsky MA, Gibala MJ. ### **REDUCING SITTING TIME THROUGH STRUCTURED EDUCATION: SUGGESTED INTERVENTION IMPROVEMENTS IDENTIFIED BY PARTICIPANTS AND WORKSHOP LEADERS IN PROJECT STAND**

Biddle, S.

*Victoria University*

**Introduction.** Substantial portions of the day are spent sitting and this has been shown to have deleterious effects, particularly for cardio-metabolic health. Project STAND was a 12m RCT using structured education to reduce sitting. Results were mixed, but with some indication of small positive intervention effects. **Methods.** Participants taking part in STAND were younger adults at risk of diabetes. They were invited to attend a 3-h structured education workshop on sedentary behaviour and diabetes. They were interviewed 6 weeks after the workshop (n=45) and at the conclusion of the 12 month trial (n=10), as were two workshop leaders. We probed for data on intervention improvements to the overall trial. **Results.** Themes from participants included educational outcomes, motivational outcomes, and use of a self-monitoring tool provided. Participants felt that the workshop provided highly useful information and dispelled many myths. The periodic testing that was performed during the RCT was used by participants as motivation for behaviour change. Views on a self-monitoring device were mixed. The workshop leaders also highlighted the educational benefits but questioned some minor elements concerning some educational tasks and resources used. Feeding back individual ActivPal data was seen very positively, but views on the self-monitoring tool were mixed. **Conclusion.** The structured education workshops were viewed favourably by both leaders and participants. Better self-monitoring of sedentary behaviour is required for greater likelihood of behaviour change.

### **IDENTIFYING THE HEALTH PROMOTION NEEDS OF WHITE COLLARS TO SUPPORT BY INFORMATION AND COMMUNICATION TECHNOLOGIES**

Kuru, H., Ince, M.L.

*Middle East Technical University*

**Introduction** The aim of this study was to identify the exercise stages of change (Contemplation, Preparation, Action & Maintenance) based health promotion coaching needs of white collars (college graduated employees) to provide online coaching support by information and communication technologies (ICT- communication device or application, encompassing: radio, television, cellular phones, computer and network hardware and software, as well as the various services and applications associated with them, such as mobile applications). **Methods** Participants were 40 college graduate employees (20 women & 20 men) working on a full time job at least five days a week. Mean age of participants was 30.1 years (SD = 3.3). Participants' exercise stages of change was identified by using Physical Activity Stages of Change Questionnaire (Marcus & Lewis, 2003). Moreover, an interview was conducted with each of them. During the interview, participants firstly ranked six cards (persona cards) that were depicting one of the six health promoting behaviors including Health Responsibility, Exercise, Nutrition, Social, Life Appreciation and Stress Management Support by their perceived needs from most to least important. Then, participants were asked three questions; 1) rationale behind their rankings, 2) examples of problems that they faced about each support dimension, and 3) ICT-based solutions for each problem. Quantitative data was analyzed by descriptive statistics and Kruskal-Wallis test ( $p < .05$ ). Interview data was analyzed by content analysis method. **Results** Findings indicated that ICT supported health promotion coaching needs of college graduated employees differed in terms of exercise stages of change ( $p < .05$ ). Kruskal-Wallis test results were significant for Stress Management Support,  $H(3) = 7.82, p < .05$ . According to pairwise multiple comparisons, Preparation stage participants' perceived needs on Stress Management Support were significantly higher than Contemplation stage participants' perceived needs. In addition, persona card rankings' differed in each stage. Contemplation stage participants ranked Health Responsibility Support; Preparation and Maintenance stage participants ranked Nutrition Behavior Support; and Action stage participants ranked Exercise Support as their most important health promotion coaching needs. Furthermore, interview findings supported the ranking differences by exercise stages of the participants. **Discussion** ICT supported health promotion coaching needs of college graduate employees differed by their exercise stages of change. Current study provides evidence about the college graduate employees expectations from ICT supported health promotion coaching systems in terms of exercise stages of change. Future ICT based health promotion coaching systems should consider the college graduate employees' exercise stages of change to meet the specific perceived needs of this group. **References** Marcus, B. ### **OP-SH06 Psychology (Self-determination)**

#### **EXAMINING PATTERNS OF CHANGE IN SELF-DETERMINED EXERCISE MOTIVATION USING LATENT GROWTH CURVE MODELS.**

Weman-Josefsson, A.K., Lindwall, M., Ivarsson, A.

*Halmstad University*

Few previous studies have targeted how self-determined motivation changes within persons across shorter periods of time (e.g., weeks). Latent growth curve models allow study of within-person change and between-person differences in within-person change over time. The purpose of the study was to study within-person change and between-person differences in change in exercise and motivation in a sample of 2797 exercisers in a natural course of events (i.e. no intervention) over a period of eight weeks. Motivational variables related to self-determination theory were measured by the Basic Psychological Needs in Exercise Scale (BPNES) and the Behavioral Regulation in Exercise Questionnaire-2 (BREQ-2) and Godin Leisure-Time Exercise Questionnaire (GLTEQ) was used to assess self-reported exercise level and intensity. The data was analyzed by latent growth curve models in Mplus. The results show significant increase in the average change (mean slope) of psychological need satisfaction whereas there was significant decrease in amotivation. Furthermore, the slopes of variance were significant for all variables except for autonomy, competence and intrinsic motivation, indicating a pattern of heterogeneity in terms of within-person change. No significant changes were detected in exercise level or intensity (METS). The results will be used as reference data in a future intervention study aiming to enhance self-determined exercise motivation in a comparable population.

## EFFECTS OF A SELF-DETERMINATION THEORY-BASED INTERVENTION AT THE ORGANIZATIONAL LEVEL IN SWEDISH SPORT CLUBS

Stenling, A., Tafvelin, S.

*Umeå University*

Introduction Self-determination theory (SDT) provides a useful framework for understanding and explaining motivational processes in sport and exercise settings. It is proposed within SDT that when the social environment support peoples' basic needs of autonomy, competence, and relatedness they become autonomously motivated, increase their well-being, and perform better (Deci & Ryan, 2012). Intervention studies using SDT as theoretical framework have successfully been conducted in exercise, health, and school settings (Su & Reeve, 2011). Few studies, however, have used SDT to understand these motivational processes at the organizational level in sport clubs. Therefore, the purpose of the present study was to examine effects of an intervention aimed at increasing need support from the organizational level in Swedish sport clubs. Method Leaders (N = 152) at the organizational level in 38 Swedish sport clubs participated in a one-week education programme that focused on how these sport clubs could incorporate need supportive strategies for human resource management, goal-setting, and organization. Participants responded to questionnaires about perceived autonomy support from the club, basic need satisfaction, and readiness for change before and after the one-week education programme. The participants also responded to questions about their understanding of the content in the education programme and the perceived usefulness of the content. Results Data have been collected and we will present results from the pre- and post-measures of the short-term learning effects (1 week) and various predictors of these short-term effects, such as perceived autonomy support from the club, basic need satisfaction, and readiness for change. Data will be analyzed with longitudinal multilevel modeling to separate effects at the between- and within-person level. Discussion From a theoretical perspective this study can highlight the usefulness of integrating SDT with the transfer of training literature (cf. Blume, Ford, Baldwin, & Huang, 2010). The results can also show the utility of SDT-based organizational-level interventions in sport clubs. References Blume, B. D., Ford, J. K., Baldwin, T. T., & Huang, J. L. (2010). ## SELF-DETERMINATION IN EXERCISE INTERVENTIONS: IMPACT ON FITNESS AND BODY COMPOSITION

Thøgersen-Ntoumani, C.1, Shepherd, S.O.2, Wagenmakers, A.J.M.2, Shaw, C.S.3

*1: Curtin University (Perth, Australia), 2: Liverpool JM University (Liverpool, UK), 3: Deakin University (Melbourne, Australia)*

Objective: To examine the motivational process through which increases in aerobic capacity and decreases in total body fat and abdominal fat are achieved during High Intensity Intermittent Training (HIT) and Moderate Intensity Continuous Training (MICT) interventions. Methods: Eighty-seven physically inactive adults (65% female; age= 42 ± 12, BMI = 27.67 ± 4.99 kg/m<sup>2</sup>) took part in a 10-week randomized intervention testing group-based HIT (repeated sprints of 15-60 s interspersed with periods of recovery cycling ≤ 25 mins/session, 3 sessions.wk<sup>-1</sup>) or Moderate Intensity Continuous Training (MICT; cycling at constant workload of ~65% VO<sub>2</sub>max, 30-45 min.session<sup>-1</sup>, 5 sessions.wk<sup>-1</sup>). Assessments of aerobic capacity (VO<sub>2</sub>max), total body fat and abdominal fat were made pre- and post-intervention. Self-determined motivation was assessed mid-intervention and class attendance was monitored throughout. Analyses controlled for treatment arm and baseline values, and path analysis (using EQS 6.2) was employed. Results: Above and beyond baseline levels of VO<sub>2</sub>max, total body fat and abdominal fat, as well as treatment arm, intrinsic motivation during the intervention and overall adherence predicted higher levels of VO<sub>2</sub>max and lower levels of total and abdominal fat at the end of the study. Conclusions: Participants in both HIT and MICT interventions may experience greater gains in fitness and body composition if intrinsic motivation can be fostered during the intervention.

## POTENTIAL UTILITY OF MESSAGE-FRAMING IN ENHANCING SPORT PERFORMANCE

Chew, W.C.E., Kee, Y.H.

*Nanyang Technological University*

Introduction In competitive sports, it is common to see coaches give short and motivational instructions to help athletes enhance performance. One key issue is whether such well-intended pre-game or in-game message is more detrimental than helpful to the athlete given the situation that the athlete is facing. To better understand the consequence of pep-talk messages prior to critical situations in sports, we aimed to test the applicability of the regulatory fit theory through an experimental study involving the manipulation of game situation and coaching message in predicting speed and accuracy of performance. Method Using a computer-simulated game of table tennis, we experimentally manipulated the game such that the participant will be momentarily induced with a prevention- or promotion-focus as they reached a critical game situation. A vigilant- or eager-framed coaching message was then presented depending on the experimental condition that the participant was randomly assigned to. A match between the coaching message (e.g., vigilant) and the induced regulatory-focus (e.g., prevention focus) creates a condition of fit (e.g., prevention fit). The 2 situation (prevention-focus or promotion-focus) x 2 message (vigilant-framed or eager-framed) experimental design allowed us to test the effects of regulatory fit or non-fit (situation x message interaction) on performance. Participants' performances were assessed by time taken to, and accuracy in, clicking on the ball with the mouse pointer. Factorial ANOVA were conducted to test the hypotheses. Result There was significant interaction effect between situation and message on accuracy,  $F(1, 156) = 6.138, p = .014, \text{partial } \eta^2 = .038$ , and a non-significant interaction for time,  $F(1, 156) = .035, p = .851$ . Simple effects analysis to investigate the nature of the interaction effect for accuracy showed that there was no significant difference in accuracy between vigilant ( $M = 3.119$ ) and eager ( $M = 2.969$ ) messages when these messages were presented at promotion-focus situation,  $p = .539$ , but there was a very significant difference ( $p = .004$ ) when they (vigilant,  $M = 2.656$ ; eager,  $M = 3.359$ ) were presented at prevention-focus situation. Discussion In accordance with the regulatory fit theory (Higgins, 2000) and as expected, both prevention- and promotion-fit conditions were linked to higher accuracy compared to their corresponding non-fit conditions, albeit that the difference in accuracy between fit and non-fit was non-significant in the promotion condition. The findings suggest the utility of appropriately framed messages in enhancing performance. The use of vigilant-framed (non-loss) message seems to have a salutary effect on accuracy in performance. ### OP-SH22 Sociology (Sport Science in ECSS)

#### SPORT SCIENCE IN EUROPE: AN OVERVIEW OF ITS CURRENT SITUATION AND ITS EVOLUTION SINCE TWENTY YEARS

Camy, J.

*University of Claude Bernard Lyon*

The purpose is to present the first results of a research project run by a group of European researchers on "Sport Science in Europe". This presentation is mostly based on the treatment of the information contained in the ECSS meta-database (European Database of Sport Science (EDSS) powered by Sportools GmbH.) gathering key information on the 23000 abstracts presented during the 19 ECSS Congresses. The theoretical framework, inspired by the "sociology of scientific knowledge" and the "science studies", considers that scientific activities are run within specific social, cultural, political and economic contexts which influence them. We will present our results following three main categories of questions: 1) What is the "structure of the field of sport science"? Which topics are there and what is their relative importance? The structure of the field of sport science as it is produced within ECSS, reflects the internal debates on its identity and the way they are related to the position of sport science in the entire academic field. The main "tensions" are between a position as close as possible from well established scientific disciplines (basic and sport applied) and a position oriented towards specific professionally led knowledge with some other subcategories of positions. 2) What are the institutions in Europe playing a key role in the sport science production process? The landscape we have just described is mostly supported by sport science research and education institutions, themselves part of an academic environment in different European countries. We will examine which are the key actors in the field of sport science and in which way they contribute to the internal debates presented above. 3) How do sport scientists work in that production process? The key producers of sport science remain sport scientists. Taking care of the limitations of our sources of information, we will examine how they construct their scientific environment. In particular we will see with which other scientists they collaborate at local, national and international level and into which formal and informal networks they operate. We will see also which relations they have with other sport and physical activities stake holders. #### THE ACADEMISATION OF SPORT IN SWEDEN

Wirén Aakesson, J.

*Institution of Sport Sciences*

Introduction In recent years, sport has undergone a remarkable academisation process in Sweden. Since the 1970s a broad field of sport research has been established within which scientific knowledge is being produced. A series of higher educations in the area has formed since the new millennia - through which scientific knowledge is mediated to students. In addition, the demand for labor in the sports labor market has increased in recent decades – and the demand for academic background is not unusual. This study deals with the sport academisation process. The purpose is to extend knowledge and understanding of higher sport science education and its relationship to sport research, and the sport labor market. The research questions are: What knowledge is produced within sport research, what knowledge is mediated through higher sport education, and what knowledge is demanded in the sport labor market? How does the production, mediation and demand for scientific knowledge relate to each other? Do they differ and if so in what ways and why? The study has two main theoretical perspectives. The first is Academisation (Dellgran & Hojer 2000) – which concerns how a field of general knowledge develops into a field of scientific knowledge. The second is Institutionalization – which is used to study how sport as an academic area has become structured in Sweden (Powell & DiMaggio 1991). Methods The empirical material mainly consists of various documents, such as: dissertations, journal articles, educational curriculums, job listings, and various statistical materials. The documents have been analyzed quantitatively as well as qualitatively, through content analysis. Results The study shows that there are discrepancies between produced, mediated and demanded knowledge. The largest proportion of research has been produced within fields that are closely connected to PE-teacher educations. At the same time, almost half of the educations are within Sport Management – an area where there is very little research being conducted in Sweden. Although there is a large demand for labor in the sport labor market, the employment opportunities mainly consist of temporary part-time employments. The demand for scientific knowledge also varies between different professional roles. For some professions, an academic background is essential, for others it has less importance. Discussion Sport research, higher sport education and the sport labor market has its own distinct histories and institutions, and therefor reproduces different ideas, ideals and logics. The three arenas are partly separate and have their own distinct characteristics, but are also interwoven in specific ways. References Dellgran, Peter & Hojer, Staffan (2000). *Knowledge-formation, Academisation and Professionalization in social work* (transl.). Diss. Gothenburg: Univ. Powell, Walter W. & DiMaggio, Paul J. (ed.) (1991). *The new institutionalism in organizational analysis*. Chicago: University of Chicago Press

#### CONTENT LEXICAL ANALYSIS ON INTERDISCIPLINARITY IN SPORT SCIENCES

Fargier, P., Massarelli, R.

*Université de Lyon, Université Claude Bernard Lyon 1, Centre de Recherche et d'Innovation sur le Sport (CRIS, EA 647), 69622 Villeurbanne cedex, France*

Interdisciplinary research in Sport Sciences is a challenge, a fortiori when one aspires to more than basic multidisciplinary (i.e. the distinct studies of a given objet by several scientific disciplines). While calling to the coverage of societal questions (e.g. health status of the populations) several sponsors invite researchers to go beyond such perspectives. Moreover, some researchers from different domains tend to collaborate with the aim to develop a unitary approach of a given object (e.g. collaborations between psychologists and neuroscientists in the study of motor control). Some attempts to produce more transversal conceptual frameworks may also be noticed (e.g. the courses

of action approach). From such standpoint the present study examined the conceptions of interdisciplinarity among European senior researchers in Sport sciences. The interviews of a sample of such researchers chosen for their affinity with interdisciplinarity (50% of them specialized in Social sciences and humanities and 50% specialized in Life sciences) have been analyzed with the support of Alceste plus© software. The results of the lexical analysis allowed a categorical analysis resulting in the determination of the reference worlds of the speeches, thus to the sense of the lexical categories. A preliminary study (8 interviews, 28 775 forms, 874 lexems and 702 elementary unities of context) led to hierarchical descendent classifications allowing the determination of 7 lexical categories. The subsequent categorical analysis led to the determination of 3 reference worlds underlining: 1) the development of methods applicable to several objects of study and scientific areas; 2) the appeal to methods of a specific domain to direct and/or validate the analysis of data gathered via methods and tools of another scientific domain; 3) a reflection on the institutional and managerial conditions favorable to interdisciplinary research (notably relative to the academic world and to the industry) and on the direction of the corresponding research projects (to reduce the gaps between the ecology of a social domain of activity and the scientific reductionism and/or the study of an epiphenomenon vs. the study of a corresponding underlying process). A content analysis of EDSS abstracts relative to PE (produced from 1996 to 2014) will be shortly realized as a complement to the interviews with the purpose to produce the state of the art on interdisciplinarity and of its possible variations compared with the reflection on interdisciplinarity in Sport sciences among senior researchers.

### THE FANS CAN: A SWEDISH CASE STUDY

Radmann, A., Hedenborg, S.

*Malmö University*

Background: The technological development of media has changed ways of communication among fans. Fans can present themselves and their activities in a perspective they chose instead of relying on official club information or newspapers not seldom presenting fans as a problem rather than as a resource. In that way the new mediated experience allows for a broader audience to move from mere spectator to participant (cultural citizenship), and for the empowerment of fans. These experiences can be used to question who is the righteous member of a football club or carrier of the football culture. The project will map out and analyse these activities. In addition, the notion of new media technologies as enabling fans will be critically examined. It is possible that despite the growing membership action on the internet sites, the real power of the football clubs is still in the hands of the club board and the owners. Furthermore, not all groups (in relation to gender and social class for example) have equal access to new media technologies. Furthermore the question of how the football club should be organized is of importance. Not the least, the question of the influence of commercialization on a membership organization or the democratic process. This is, however, not isolated to fandom cultures. It is an important question for societal change over-all as a pivotal question is: who is to decide to what extent market forces are to influence the society? A gender perspective will be used.

### OP-PM64 Nutrition: Amino acids and proteins

#### TWENTY-FOUR WEEKS OF $\beta$ -ALANINE SUPPLEMENTATION DOES NOT AFFECT CLINICAL MARKERS OF HEALTH: PRELIMINARY FINDINGS

Saunders, B.1, Painelli, V.S.1, Silva, V.E.1, Silva, R.1, Sale, C.2, Harris, R.C.3, Artioli, G.G.1, Gualano, B.1

*1University of Sao Paulo, Brazil. 2Nottingham Trent University, UK. 3Junipa Ltd, UK.*

Introduction:  $\beta$ -alanine is a popular ergogenic aid used by athletes worldwide; 61% of around 600 Australian team sports players reported taking the supplement (Kelly et al., 2013). There is currently no evidence on the safety of long-term supplementation and its effects on health parameters. Aim: To investigate the effects of chronic  $\beta$ -alanine supplementation on markers of health. Methods: Sixteen healthy male participants (age  $27 \pm 4$  y; height  $1.73 \pm 0.10$  m; body mass  $78.9 \pm 11.7$  kg) were supplemented with 6.4 g/day of sustained release  $\beta$ -alanine (N=11; CarnoSynTM, NAI, USA) or placebo (N=5; maltodextrin, NAI, USA) over a 24-week period. Resting venous blood samples were taken in the supine position every 4 weeks and analysed for markers of renal, hepatic and muscle function (aspartate transaminase; alanine aminotransferase; alkaline phosphatase; lactate dehydrogenase; albumin; globulin; creatinine; estimated glomerular filtration rate and creatine kinase). Data were analysed using mixed model ANOVA. Results: The present results are from a larger investigation that is currently ongoing. There were no self-reported side effects in these participants throughout the study. There was no effect of treatment, time or any interaction effects on any blood marker (all  $P > 0.05$ ) except alkaline phosphatase, which had a significant interaction effect ( $P = 0.006$ ). Post-hoc analysis revealed a difference only within the placebo group between weeks 4 and 12. Importantly, mean and individual analysis of data revealed blood parameters remained within normal range and did not significantly change across time with  $\beta$ -alanine supplementation. Conclusions: Twenty-four weeks of  $\beta$ -alanine supplementation at 6.4 g/day did not adversely affect clinical markers of renal, hepatic or muscle function in these healthy participants. These results have important implications for athletes who are likely to supplement with  $\beta$ -alanine for extended periods of time. Future analysis of muscle taurine will further contribute to the safety profile of long-term  $\beta$ -alanine supplementation. References: Kelly, V. G., Jenkins, D. G., Leveritt, M. D., Brennan, C. T., & Slater, G. J. (2013). Evaluation of the prevalence, knowledge and attitudes relating to  $\beta$ -alanine use among athletes. *British journal of sports medicine*, 47(17), e4-e4. ### AMELIORATING EFFECT OF BRANCHED-CHAIN AMINO ACIDS SUPPLEMENTATION ON MARATHON-INDUCED MUSCLE DAMAGE, INFLAMMATION AND MUSCLE SORENESS

Ishikura, K.I, Komine, S.I, Ra, S.G.I, Miyazaki, T.2, Miyakawa, S.I, Ohmori, H.I

*University of Tsukuba*

**Introduction** Several laboratory studies reported that Branched-Chain Amino Acids (BCAA) attenuated eccentric exercise induced delayed-onset-muscle-soreness (DOMS) and muscle damage (Shimomura et al., 2010). Immediate-onset muscle soreness (IOMS) is frequently observed in exercise involving running, particularly in long distance running, such as the marathon event, with onset sometimes even occurring during exercise. Although, in our preliminary study, BCAA ingestion improved systemic fatigue and IOMS after a full-marathon (Ishikura et al., 2014), its effectiveness on muscle damage and inflammation induced by long distance running is unknown. This study investigated, in a randomized, placebo-controlled, and double-blind manner supplemented, the inhibitive effect of BCAA ingestion on marathon-induced muscle damage and inflammation in non-professional full-marathon runner. **Methods** Subjects were 36 non-professional runners participating in a full-marathon race. They received either 3.2g of BCAA or placebo 3 times a day, from the day before to three days after the event. Serum creatine kinase (CK), aldolase, glutamic-oxalocetic transaminase (GOT), lactate dehydrogenase (LDH), C-reactive protein (CRP) were measured as well as systemic fatigue and muscle soreness, before, immediately after, and 1 to 4 days after the event. Systemic fatigue and soreness in seven muscle regions were evaluated using a numeric rating scale. **Results** Since the increase in score peaked at immediately after the marathon, IOMS was observed in all examined muscle regions. Measured biochemical markers peaked at 1 day after the event. BCAA ingestion was observed to significantly decrease IOMS in the anterior thigh and buttock areas. In addition, BCAA ingestion significantly inhibited the serum CK, GOT, and CRP concentrations induced by the marathon. **Discussion** This study revealed that the effectiveness of BCAA ingestion on reducing muscle damage, inflammation, and IOMS after the running of a full marathon as well as eccentric exercise induced muscle damage and DOMS. On the basis of this result, it is proposed that BCAA supplements can be administered to ameliorate muscle damage, inflammation, and muscle soreness induced by various types of exercise. **References** Shimomura Y, Inaguma A, Watanabe S, Yamamoto Y, Muramatsu Y, Bajotto G, Sato J, Shimomura N, Kobayashi H, and Mawatari K. ### METABOLIC CONSEQUENCES OF B-ALANINE SUPPLEMENTATION DURING SUPRAMAXIMAL CYCLING AND 4000-M TIME TRIAL PERFORMANCE IN HIGHLY-TRAINED CYCLISTS

Bellinger, P., Minahan, C.

*Griffith University, School of Allied Health Sciences, Gold Coast 4222, Queensland, Australia*

**INTRODUCTION:**  $\beta$ -alanine supplementation may enhance short-duration, high-intensity exercise performance. Nonetheless, several questions remain unanswered regarding the effects of  $\beta$ -alanine supplementation on energy provision, acidosis, and metabolite accumulation. The present study examined changes in the contribution of the aerobic and anaerobic energy systems during a 4000-m cycling TT, as well as the resultant acidosis and metabolite accumulation during supramaximal cycling before and after  $\beta$ -alanine supplementation. **METHODS:** Sixteen highly-trained cyclists ( $n = 2$  women;  $\text{VO}_2\text{max} = 66.6 \pm 10.4 \text{ mL} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ ) were administered 6.4 g of  $\beta$ -alanine or placebo daily for 4 wk. Subjects performed a supramaximal cycling bout to exhaustion (equivalent to 120%  $\text{VO}_2\text{max}$  determined at 0 wk) before (Exh0wk) and immediately after (Exh4wk) the 4-wk supplementation period as well as an additional test identical in duration and power output to Exh0wk (Match4wk). Anaerobic capacity and blood pH, lactate and bicarbonate concentrations were measured pre-, immediately post-, and 5 min post-exercise. Subjects also performed a 4000-m cycling TT before and after supplementation with anaerobic and aerobic attributable power output estimated from the gross efficiency method (Serresse, 1988; Noordhoff, 2011). Absolute changes in performance and physiological variables were compared using a two-way ANOVA and magnitude-based inferences were calculated for each variable (Hopkins, 2007). **RESULTS:**  $\beta$ -alanine supplementation elicited significant increases in time to exhaustion ( $18.4 \pm 1.5$  s;  $p = 0.029$ ) and anaerobic capacity ( $2.0 \pm 1.2 \text{ mL} \cdot \text{kg}^{-1}$ ;  $p = 0.0043$ ) in Exh4wk compared to Exh0wk. Furthermore,  $\beta$ -alanine supplementation resulted in a possibly beneficial attenuation in the decrease in blood pH immediately post-exercise ( $0.039 \pm 0.056$  units; 48% likelihood;  $p = 0.087$ ) and 5 minutes post-exercise ( $0.032 \pm 0.047$  units; 33% likelihood;  $p = 0.098$ ) in Match4wk compared to Exh0wk. Performance time in the 4000-m TT was likely to be beneficial following  $\beta$ -alanine supplementation ( $-7.9 \pm 10.1$  s; 93% likelihood;  $p = 0.063$ ) and the mean anaerobic power output was possibly likely to be greater ( $14.2 \pm 23.8$  W; 70% likelihood;  $p = 0.134$ ). **DISCUSSION:** These results suggest that  $\beta$ -alanine supplementation is beneficial to cycling performance in highly trained cyclists, presumably by elevating carnosine content, and providing a practically meaningful attenuation in the reduction in blood pH. Furthermore,  $\beta$ -alanine supplementation increased anaerobic capacity which was also reflected by a meaningful increase in the anaerobic attributable power output during a 4000-m cycling TT, resulting in an enhanced overall performance. **REFERENCES:** Serresse O, Lortie G, Bouchard C, Boulay M. ### DIETARY PROTEIN INTAKE AND DISTRIBUTION OF ELITE AUSTRALIAN TEAM-BASED SPORT ATHLETES

Devlin, B., Belski, R.

*La Trobe University*

**Introduction** The physical demands placed on elite athletes require optimal dietary intake to maximise performance, facilitate adaptations, assist in recovery and prevent illness and injury. Dietary protein ingestion, in particular, plays an important role in muscle synthesis and recovery. Both the consumption of high quality protein immediately following exercise, and the exercise bout itself can stimulate the muscle protein synthetic response, for up to 24 hours. Therefore, current sport nutrition guidelines highlight the importance of timing and distribution of total dietary protein intake to optimise adaptations. Yet, there is minimal research reporting dietary protein intake patterns of elite male team-based sport athletes. **Objective** To explore and gain insight into the current dietary intake practices, specifically protein distribution, of elite male team-based sport athletes. **Methods** Thirty nine elite male Australian football (AF) athletes ( $23.1 \pm 2.6$  yrs,  $88.1 \pm 8.2$  kg) and twenty five elite male soccer athletes ( $25.3 \pm 5.4$  yrs,  $75.6 \pm 6.5$  kg) participated in the study. Dietary intake data was obtained via 3-day food records and 24-hour dietary recalls during the 2013 and 2014 pre-season periods for AF and soccer respectively. Average reported total daily energy and macronutrient intake, as well as meal and snack intake was analysed. Meals and snacks were defined according to timing of intake over a 24 hour period. Subgroups based on years at elite level and self-reported weight goals were created for analysis. **Results** Average total reported energy and protein intake was  $13.6 \pm 3.1$  MJ,  $196.0 \pm 57.0$  g

( $2.2 \pm 0.6$ g/kg) and  $9.4 \pm 2.3$ MJ,  $140.4 \pm 35.1$ g( $1.9 \pm 0.5$ g/kg) for AF and soccer athletes respectively. Soccer and AF athletes reported 4.5 eating occasions (3 meals, 1.5 snacks) and 5.1 eating occasions (3 meals, 2.1 snacks) per day, respectively. Protein intake was skewed towards the evening meal for all athletes. The majority of protein was consumed at main meals (86% and 89% of total protein, Breakfast:  $35.8 \pm 22.3$ g,  $18.3 \pm 8.9$ g; Lunch:  $56.9 \pm 25.5$ g,  $48.2 \pm 20.9$ g; Dinner:  $76.2 \pm 23.5$ g,  $58.0 \pm 29.0$ g; AF and soccer athletes respectively). Snacks contributed little to total protein intake but AF athletes consumed significantly more protein at the evening snack ( $10.3 \pm 13.6$ g,  $1.4 \pm 2.7$ g;  $p < 0.05$ ). Discussion This is the first study reporting protein intake patterns of elite Australian male team-based sport athletes. There is ongoing debate in the literature regarding ideal protein intake recommendations for athletes, despite a lack of research reporting the current dietary intake practices. Elite athletes appear to be meeting total protein intake recommendations however could further increase training adaptations and potentially improve performance if distribution of protein intake was optimised. ### EFFECT OF WHEY PROTEIN HYDROLYSATE ON ADAPTATION TO ENDURANCE TRAINING IN WELL-TRAINED RUNNERS

Hansen, M., Sondergaard, L., Rokkedahl, T.L., Christensen, B., Bangsbo, J., Brandt, N., Ortenblad, N., Madsen, K.  
Aarhus University

INTRODUCTION: Long distance endurance athletes wish to enhance fat oxidative capacity to delay the emptying of the glycogen stores. Training with low carbohydrate availability seems to enhance enzymatic adaptations, whereas the influence of a timed protein intake on adaptation to endurance training is not clarified. PURPOSE: To study the effect of intake of whey protein hydrolysate (WB) before and after each exercise session compared to isocaloric control on mitochondrial adaptation to six weeks endurance training in well-trained runners. METHODS: 24 well-trained endurance runners (Age  $30 \pm 9$  yrs,  $VO_{2max}$   $61 \pm 4$  ml  $O_2$  min<sup>-1</sup> kg<sup>-1</sup>) participated in a block randomized controlled intervention trial including a six weeks running program. Half of the runners ingested WB before ( $0.3$  g kg<sup>-1</sup>) and WB+carbohydrate ( $0.3$  g protein kg<sup>-1</sup> +  $1$  g carbohydrate kg<sup>-1</sup>) after each exercise session (PRO). The others ingested isocaloric carbohydrate before and after exercise (CAR). Muscle biopsies were obtained before and after the first training session. Before and two days after the intervention period post-absorptive muscle biopsies were obtained and  $VO_{2max}$  and 6k performance were tested. Daily protein intake excluding intervention beverages was not different between groups. RESULTS: Western blot analysis showed group difference in adaptations in Cyt C (PRO  $19 \pm 8\%$ , CAR  $-17 \pm 13\%$ ,  $p < 0.05$ ). Tendencies towards similar adaption pattern were observed for other mitochondrial targets (VDAC, HSP60, PHB1, SDHA; intervention interaction  $p < 0.1$ ). mRNA expression of mitochondrial PGC1- $\alpha$  was acutely enhanced after the first running session (0hr post-exercise  $339 \pm 27\%$  and 2 hr post-exercise  $651 \pm 25\%$ ,  $p < 0.01$ ), but not influenced by intervention beverages. Improvements were observed in 6k-run performance test ( $25 \pm 1$  sec,  $p < 0.01$ ) and  $VO_{2max}$  ( $0.07 \pm 0.01$  L  $O_2$ /min,  $p < 0.05$ ) compared to baseline, but no intervention interaction was observed CONCLUSION: Intake of whey protein seems to have a positive influence on mitochondrial adaptations in well-trained runners and might be beneficial for performance in a longer time perspective.

### OP-PM30 Sports Medicine & Orthopedics: Physiotherapy I

#### EFFECTIVENESS OF EXERCISE THERAPY IN TREATMENT OF PATELLOFEMORAL PAIN SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

Clijisen, R., Fuchs, J., Taeymans, J.

1. University of Applied Sciences and Arts of Southern Switzerland, Department of Business Economics, Health and Social Care, Landquart, Switzerland.

Introduction This systematic review and meta-analysis was accomplished to determine whether exercise therapy is an effective intervention to reduce pain and patient reported measures of activity limitations and participation restrictions (PRMALP) in patients with patellofemoral pain. Methods Randomized controlled trials in English and German language, published in Medline, PEDro and Cochrane databases were searched. Eligibility was assessed in two stages. The methodological quality of the studies was rated using the PEDro scale. Data were pooled using random-effects meta-analysis allowing for variability among studies. For clinical use, overall estimates were re-expressed in the original VAS scores. Significance was set at 5%. Results Fifteen studies with a total of 748 participants were included and pooled for a meta-analysis. Six studies compared the effect of exercise therapy with a control group neither receiving exercise therapy nor another intervention. Four studies compared the effect of exercise therapy versus additive therapy while five papers compared different exercise interventions. In both comparisons exercise therapy resulted in strong pain reduction and improvement of PRMALP effects. Significant short-term effects ( $\leq 12$  weeks) of exercise therapy were found for pain and PRMALP while long-term effects ( $\geq 26$  weeks) were observed for PRMALP only. Conclusion This meta-analysis presents evidence that exercise therapy has a strong pain reducing effect and decreases PRMALP in patients with patellofemoral pain. However, the question, which exercise modality yields the strongest reducing effect on pain and PRMALP, remains unrevealed. The 15 studies included in this analysis were of variable quality. Large, high quality RCTs are needed to further the evaluation of the possible effects of different exercise therapy modalities on patellofemoral pain. References Clijisen R, Fuchs J, Taeymans J. #### EFFECTS OF BRANCHED-CHAIN AMINO ACIDS SUPPLEMENTATION ON CHANGES IN KNEE EXTENSOR MUSCLES FUNCTION AND ENERGETIC METABOLISM RESULTING FROM EXERCISE-INDUCED MUSCLE DAMAGE

Fouré, A.1, Nosaka, K.2, Gastaldi, M.3,4, Mattei, J.P.1,5, Boudinet, H.4, Guye, M.1,4, Vilmen, C.1, Le Fur, Y.1, Bendahan, D.1, Gondin, J.1

1.AMU, CNRS, (Marseille, France), 2.ECU (Joondalup, Australia), 3.AMU, INSERM, INRA (Marseille, FR), 4.APHM, La Timone Hospital (Marseille, FR), 5.APHM, Sainte Marguerite Hospital (Marseille, FR)

Introduction Branched-chain amino acids (BCAAs) promote muscle-protein synthesis, reduce protein oxidation (Wang and Proud, 2006) and have positive effects on mitochondrial biogenesis and reactive oxygen species scavenging (D'Antona et al., 2010). The purpose of the study was to determine whether these might be translated at the level of changes in force capacity (MVC), muscle soreness (DOMS) and

muscle energetics resulting from severe muscle damage (Fouré et al., 2015). Methods Young healthy men were randomly assigned to a group supplemented with BCAAs (n=13) - leucine, isoleucine and valine (2:1:1, 100 mg/kg) - or placebo (n=13). Supplementations were taken by each subject: three times the day of the damaging exercise and once daily on the four recovery days after exercise-induced muscle damage (EIMD). The damaging exercise consisted of 40 isometric electrically evoked knee extensions (100 Hz, duty cycle: 12.5%) with joint angle fixed at 100° (0° = full extension). MVC and DOMS of the knee extensors were assessed before, two (D2) and four (D4) days after EIMD. Metabolic variables including concentrations of phosphocreatine (PCr), inorganic phosphate (Pi) and pH were measured during a standardized rest-exercise-recovery protocol using <sup>31</sup>P spectroscopy before, and D2 and D4. Results EIMD led to both a similar decrease in MVC (-24% at D2 and -21% at D4) and increase in DOMS in the two groups. In addition, we found a similar increase in resting [Pi] (+42% at D2 and +34% at D4), resting cellular acidosis (-0.04 pH unit at D2 and -0.03 pH unit at D4) and a slower PCr recovery rate (-18% at D2 and -24% at D4). Discussion These results showed no effect of BCAAs supplementation on decreased MVC and increased DOMS whereas with a similar BCAAs intake, previous studies did (e.g., Howatson et al., 2012). The large extent of muscle damage induced in the study might have limited the potential benefits associated to BCAAs supplementation on changes in MVC, muscle soreness and energetic metabolism after EIMD. A 100 mg/kg BCAAs supplementation was unsuitable to attenuate metabolic and functional alterations resulting from severe muscle damage. References D'Antona G., Ragni M., Cardile A. et al. ### TRAINING AND DE-TRAINING EFFECTS : SIX-MONTH FOLLOW-UP OF A 3-MONTH RESISTANCE EXERCISE PROGRAM IN THE MILD DEMENTED ELDERLY

Lin, P.

*Chang Gung University*

Background and Purpose: The fastest growing age segment of population worldwide is the 'elderly' (65 years and older), a high-risk group for developing dementia. Evidence showed resistance training may potentially improve neuronal and thus cognitive functions. Therefore, the main purpose of this study is to investigate the effects of resistance training on cognitive function and muscle strength. Method: Forty mild dementia elderly were randomly assigned to two groups: resistance training (RT, N= 22) and control group (CG, N=18). The inclusion criteria: (1) community-dwelling elderly aged  $\geq 65$ , (2) CDR score: 0.5 or 1 (3) having no functional disabilities that would restrict for exercise participation. The hydraulic resistance exercise (HRE) equipments were used 40 minutes/session, twice weekly for resistance training. CG maintained their regular daily activities. Outcome measures included cognitive ability screening instrument (CASI) and muscle strength (grip strength (GS), knee extension (KE), 30sec chair stand(CS) and 30sec arm curl(ACI)). Independent t-test was used to compare baseline demographic variables. Repeated measure ANOVA was used to compare the group and time effects. Wilcoxon signed rank test by using the mean differences of pre-post-test was analyzed. Result: There were no significant differences of baseline data among 2 groups except for the CASI (t=2.029, p=0.049) and GS (t=3.127, p=0.003). The results showed significant interaction in KE (F=38.000, p=0.017) and ANML in CASI (F=5.821, p=0.021), significant group effect in CASI (F=8.900, p=0.005), KE (F=10.289, p=0.003), GS (F=13.216, p=0.001), CS (F=8.133, p=0.007), STM (F=14.646, p=0.000), ATTN (F=8.497, p=0.006), MENMA (F=4.937, p=0.032) and LANG (F=4.592, p=0.039), significant time effect in GS (F=4.510, p=0.04), CS (F=8.590, p=0.006), and STM (F=10.270, p=0.003). Wilcoxon test revealed significant training effect of KE in RT compared with CG group (z= -2.528, p=0.011). The CASI (z= -2.112, p=0.035) and STM (z= -2.605, p=0.009) of RT showed significantly improve post-training, while, the CS (z= -2.365, p=0.018) in CG decreased significantly after 3 months. Conclusion: Mild dementia elderly people undergo 3-month resistance training showed significant improvements in cognitive function, lower extremity muscle strength and some physical functions, however, only muscle strength reached group difference. Besides, the effects attenuated especially in the control group at 6-month after intervention.

### ECCENTRIC-OVERLOAD RESISTANCE EXERCISE USING FLYWHEEL IMPROVES COGNITIVE FUNCTION AND INCREASES MUSCLE SIZE, POWER AND PERFORMANCE IN STROKE VICTIMS

Fernandez-Gonzalo, R.1, Fernandez-Gonzalo, S.2, Turon, M.2, Jodar, M.2, Prieto, C.2, Rubio, M.2, Tesch, P.A.1, Garcia-Carreira, M.C.2

1: Karolinska Institutet (Stockholm, Sweden), 2: Tauli Hospital (Sabadell, Spain)

Introduction To combat neuromuscular dysfunction following stroke, resistance exercise (RE) including high-force muscle actions, has shown efficacy. Compromised physical abilities consequent to stroke, are typically accompanied by impairment of multiple cognitive functions. Investigations have disclosed positive impacts of RE on different cognitive domains (Cassilhas et al. 2007). Further, eccentric (ECC) muscle actions, critical in evoking skeletal muscle adaptations, induced greater cortical activities and involved more functional regions of the brain, than concentric actions (Fang et al. 2004). The current study explored the effects of 12-week ECC-overload flywheel RE training of the paretic limb of chronic stroke patients, on muscle and cognitive functions. The study design allowed for examining the relationship between adaptations of skeletal muscle and cognitive functions. Methods Thirty-two stroke patients were randomly assigned to a training group (TG) performing ECC-overload flywheel RE (12 weeks; 2 times/week; 4 sets of 7 maximal repetitions; total contractile activity time < 2 min per session) or a control group (CG) that followed their prescribed daily routines. Cognitive function, m. quadriceps femoris (QF) volume and cross sectional area (CSA), and maximal force and power were assessed before and after the training period in both TG and CG. Results TG improved power in the affected, trained (48%; P<0.0005) and the non-affected, untrained leg (28%; P=0.006). QF muscle volume and CSA of the affected leg increased by 9% (P<0.0005). Executive functions (working memory and verbal fluency tasks) and speed of information processing improved in the TG (P<0.04) after the intervention. Significant correlations were found between QF volume and CSA gains on one hand, and verbal fluency improvements (P=0.01-0.014; R=0.49-0.64). There were no changes in CG. Discussion In supporting our recent findings (Fernandez-Gonzalo et al. 2014), the current data suggest flywheel RE using ECC-overload offers an efficient and very powerful tool to improve neuromuscular function and performance, accompanied by marked muscle hypertrophy in chronic stroke patients. The most novel finding of this study however, was the parallel improvement in several cognitive functions. Indeed, correlation analysis inferred there is significant crosstalk between certain brain domains and skeletal muscle. These important adaptations occurred after only 24 exercise sessions, with less than 4 min per week dedicated to muscle contractile activity. ## INCREASED EXERCISE INTENSITY DURING INTERVAL ROBOT-ASSISTED GAIT THERAPY IN SPINAL CORD INJURED PERSONS

Gerrits, K., van Hezel, S., Greidanus, M., Bannwart, V., Janssen, T.

*Research Institute MOVE, VU University Amsterdam*

Background: Exercise intensity (in terms of cardiometabolic load) is relatively low during current 30-min continuous Robot Assisted Gait Therapy (RAGT)(1). This may in part limit the effectiveness of RAGT induced gait improvement in individuals with incomplete spinal cord injury (iSCI). Exercise intensity may be increased by applying interval exercise with high intensity exercise bouts. Objective: To determine if high intensity interval RAGT is feasible and to evaluate if muscle activity and cardiometabolic load are higher than during continuous exercise. Subjects: Nine subjects with iSCI (ASIA impairment scale C or D). Methods: All subjects performed a 30-minute interval exercise and a 30-minute continuous exercise in the Lokomat. During both sessions EMG activity of the lower-limb muscles and different cardiorespiratory responses (%HRR, VO<sub>2</sub>, VCO<sub>2</sub>, VE and RER) were obtained. Furthermore, all patients filled out the Borg-scale for rate of perceived exertion (RPE) and a self-developed questionnaire about their experiences with both sessions. Results: All subjects successfully completed the interval exercise on the Lokomat. Both the muscle activity and the cardiorespiratory responses were increased during the interval exercise compared to the continuous exercise, although for the muscle activity this difference was not significant. During the interval exercise, subjects' average %HRR was more than 15% higher than during the continuous exercise (33.6% vs. 18.0%). Besides, during the interval exercise subjects exercised almost half of the time (48%) above levels of aerobic exercise (>30% HRR), while this percentage was only 8% during the continuous exercise. In addition, the RPE was significantly higher after the interval session (mean 12.8 (1.3)) than during the interval session (mean 10.9 (1.7)). Nevertheless, 78% of the subjects preferred the interval session over the continuous session. Conclusion: Persons with iSCI can perform a high intensity interval RAGT. Besides, this study clearly demonstrates that the cardiometabolic load during this interval exercise is higher than during a continuous exercise. In addition, the cardiometabolic load during the interval exercise was high enough to reach levels of aerobic exercise, which may lead to an increased exercise capacity. Future research should clarify whether this type of RAGT exercise is effective in regaining walking ability for persons with iSCI. 1. F. Hoekstra et al. Effect of robotic gait training on cardiorespiratory system in incomplete spinal cord injury, *J. Rehabil Res Dev*, 50(10) pp. 1411-1422, 2013.

## THE IMPACT OF SIMVASTATIN ON INSULIN SENSITIVITY IN PATIENTS WITH AND WITHOUT MYALGIA

Torp, M., Kuhlman, A.B., Morville, T., Dohlmann, T., Sahl, R., Asping, M., Helge, J.W., Dela, F.

*University of Copenhagen*

Introduction Simvastatin is a commonly prescribed cholesterol-lowering drug used to reduce the risk of cardiovascular disease. Despite the beneficial effects of simvastatin, adverse effects such as myalgia, muscle cramps, and fatigue have frequently been reported (1). Occurrence of the aforementioned adverse effects may inhibit a physically active lifestyle, which may further maintain or potentially worsen an already unhealthy way of living. The aim of this study is to investigate if insulin sensitivity is affected in subjects with or without simvastatin-associated myalgia. We hypothesize that subjects with myalgia, not without, have impaired insulin sensitivity, as shown in the study from Mallinson et al. (2), where subjects with myalgia had impaired insulin sensitivity compared to healthy non-statin users. Methods We will include 60 subjects with normal glucose tolerance undergoing treatment with simvastatin to participate in three separate trial days. The study is presently ongoing and 16 subjects have been completed. The subjects were divided into two groups based on the presence or absence of self-reported myalgia assessed by VAS-score. DXA-scan was used to measure body composition. Whole body stimulated glucose uptake was assessed by the hyperinsulinemic euglycemic clamp technique. A constant insulin infusion was administered intravenously over 2 hours with a concentration of 80 mU/m<sup>2</sup>/min and IV glucose was given at variable rates to keep the blood sugar at a constant level of 5.6 mM. Maximal whole body stimulated glucose uptake was calculated as the average glucose infusion rate during the last 30 min. Results 9 subjects with myalgia (5 M/4 F; age 61 +/- 2 years; weight 91 +/- 8 kg; BMI 30 +/- 2; fat % 38 +/- 4; FFM 56 +/- 4 kg; VAS 4.6 +/- 0.9) and 7 without myalgia (5 M/2 F; age 58 +/- 3 years; weight 86 +/- 8 kg; BMI 28 +/- 2; fat % 31 +/- 3; FFM 60 +/- 5 kg; VAS 0.1 +/- 0.1) have completed the study. GIR values were similar, 11 +/- 1 and 13 +/- 1 mg/min/kg FFM, in the group with and without myalgia, respectively. By using FFM instead of body weight, we corrected for the differing body compositions between the male and female subjects, but GIR values per body weight were also similar. Discussion At this point, our results do not demonstrate any statistically significant differences in insulin sensitivity between the group with simvastatin-associated myalgia and the group without. Apart from the VAS-scores, groups were comparable for all parameters measured. Additional subjects are needed in order to draw any final conclusions. References (1) Franc S et al. ### OP-PM10 Physiology: Age II

#### EFFECT OF HIGH INTENSITY TRAINING AND ISOINERTIAL TRAINING ON INTERMUSCULAR ADIPOSE TISSUE IN OLDER ADULTS.

Bruseghini, P.1, Tam, E.1, Calabria, E.1, Pogliaghi, S.1, Rossi, A.1, Capelli, C.1,2

*1: University of Verona (Verona, Italy); 2: NCCS (Oslo, Norway)*

Introduction Recent findings suggest that, in elderly, Intermuscular Adipose Tissue (IMAT) may be associated with inactivity and that exercise training may be able to mitigate the content of IMAT (Murphy et al., 2012; Santanasto et al., 2011). The purpose was to determine how IMAT can be influenced by exercise and if a greater reduction in IMAT occurs with concurrent aerobic High Intensity Training (HIT) and Isoinertial Resistance Training (IRT). Methods 12 moderately active older adults (age: 69.4±4.3 yy; weight: 78.5±10.5 kg; height: 171.2±5.3 cm; BMI: 22.9±2.7 kg/m<sup>2</sup>; V<sub>O</sub>2max: 29.5±4.1 mL/kg/min) were exposed to 8 weeks of: i) HIT training with 7 two-minute cycling repetitions at 90% of V<sub>O</sub>2max, 3 times/week and, after 4 months, ii) IRT performed with an isoinertial leg press (YoYo Technology AB) comprised 4x7 maximal concentric-eccentric knee extensions, 3 time/week. MRI of the mid-thigh was examined to determine changes in muscle composition (Cross Sectional Area (CSA) and IMAT) after exercise intervention using SliceOmatic image analysis software (Rossi et al., 2010). IMAT was defined as adipose tissue area visible between quadriceps muscle groups. Results Quadriceps CSA increased

significantly after HIT and after IRT by 6% ( $P<0.05$ ) and 7% ( $P<0.05$ ) respectively. IMAT decreased after HIT and IRT by 31% ( $P<0.05$ ) and 41% ( $P<0.05$ ) respectively. Net thigh lean mass increased significantly after both training by 10% ( $P<0.05$ ). Discussion Our data, in contrast with Jacobs (2014) and Goodpaster (2008) but in agreement with other previous studies (Murphy et al., 2012; Santanasto et al., 2011), show that IMAT decrease after a 8 weeks exercise intervention in older adults both after HIT and IRT. Preliminary data show that exercise training performed at high intensity in older adults may contrast skeletal muscle fat infiltration. Our study is non-randomized, not-counterbalanced and limited by small sample size: additional studies are needed to determine the most effective exercise (type, intensity, modalities) able to decrease IMAT and how this decrease may positively affect health in elderly. ### **BLOCKING ANGIOTENSIN II TO IMPROVE THE ACUTE MUSCLE RESPONSE TO EXERCISE IN ELDERLY MEN**

Heisterberg, M.F., Andersen, J.L., Schjerling, P., Bülow, J., Kjær, M., Mackey, A.L.

*Bispebjerg Hospital and University of Copenhagen*

Title Blocking angiotensin II to improve the acute muscle response to exercise in elderly men Introduction The molecular mechanisms behind sarcopenia are largely unknown. Satellite cells (SC) are important for the plasticity and regenerative capacity of skeletal muscle and the decline in SC function with age is associated with increased Transforming Growth Factor-beta (TGF-beta) signalling [1]. Blocking Angiotensin II (AngII) in sarcopenic mice has been reported to downregulate TGF-beta and upregulate Insulin-like Growth Factor-1 (IGF-1) signalling in remodelling skeletal muscle [2], suggesting that blocking AngII could enhance muscle adaptation to loading. This has not previously been investigated in human skeletal muscles. The aim of this study was to investigate the effect of blocking AngII on the acute response of muscle to exercise in elderly men. Methods 26 elderly healthy men (+64 years) were recruited and assigned to an AngII blocker (Losartan) or Placebo group using stratified randomization according to age, BMI and ACE genotype. Losartan (100mg/day) or placebo was consumed for 18 days. Participants performed one bout of heavy one-legged resistance exercises, consisting of 5x12 repetitions of concentric work (70% of 1RM) and 4x6 repetitions of eccentric work (110% of 1RM). Six muscle biopsies were obtained from each subject from the Vastus Lateralis muscles: before (baseline) and after one week of treatment with Losartan, and after exercise at 4 hours and on days 1, 4 and 7. Blood pressure and blood samples were collected at the same six time points. Biopsies were sectioned and stained for Pax7, type I myosin and laminin for enumeration of SC associated with type I and type II fibres. mRNA levels of Tenascin-C, TGF-beta, IGF-1, and Collagen I were determined by real time PCR. Data were analysed by 1 or 2 way repeated measures ANOVA. Results There was no significant effect of Losartan on the SC response to exercise, but a main effect of time for SC per type I fibre was found, with increases on days 4 and 7 after exercise. No significant effect of Losartan was found for gene expression levels of Tenascin-C, TGF-beta, IGF-1, or Collagen I. Losartan treatment resulted in a small drop in diastolic blood pressure. Discussion Contrary to our hypothesis we did not find any effect of Losartan on the muscle response to acute exercise. However, it is possible that treatment and exercise over a longer period of time are required in order to be able to detect an effect. A study is currently underway to investigate this. References 1. ### **MATTERS OF FIBRE SIZE AND MYONUCLEAR DOMAIN; DOES SIZE MATTER MORE THAN AGE?**

Karlsen, A., Couppé, C., Andersen, J.L., Mikkelsen, U.R., Nielsen, R.H., Magnusson, P., Kjær, M., Mackey, A.L.

*University of Copenhagen, Denmark*

Introduction The relationship between skeletal muscle fibre size and myonuclear content is poorly understood, and may be influenced by ageing and life-long endurance exercise. Data from muscle biopsy cross-sections are typically reported as biopsy means, overlooking the great variability in fibre size (Mackey et al, 2014) and potentially the size-specific changes with age (Brack et al. 2005). The aim of this study was to gain more insight in the relationship between fibre size and myonuclei in a group of master athletes, age-matched controls and younger counterparts. Methods 49 subjects were recruited into 4 groups as young/old and endurance trained/untrained. A biopsy was obtained from the vastus lateralis muscle of each individual, sectioned and stained by immunohistochemistry for determination of fibre area and the number of myonuclei per fibre (MN/F). Myonuclear domain (MND) was calculated from these data. The MN/F and MND data were divided into clusters according to different ranges in fibre size: 3 large 2000  $\mu\text{m}^2$  clusters, and 20 small 500  $\mu\text{m}^2$  clusters. Clusters were analyzed by a 1-way ANOVA. Results The 2000  $\mu\text{m}^2$  analysis revealed that in fibres of comparable size there were no differences in MN/F or MND between the 4 groups. Therefore the groups were pooled, revealing a greater MN/F and a larger MND in medium vs. small fibres, but also in large vs. medium fibres. The 500  $\mu\text{m}^2$  analysis indicated a strong linear relationship between MN/F and fibre area. MND was non-linearly related to fibre area, with a markedly smaller domain in fibres <3000  $\mu\text{m}^2$ . A larger proportion of type II fibres <3000  $\mu\text{m}^2$  was observed in the old. Discussion In contrast to (Brack et al. 2005) we did not observe age-related differences in MN/F in fibres of similar size, and there was no effect of life-long endurance training on myonuclear content. The strong linear relationship between fibre size and MN/F indicate that changes in fibre size are followed by changes in myonuclear content (or the other way around). The MND findings suggest that age-related reductions in MND could be explained by a larger proportion of small fibres, and highlight the usefulness of fibre size-based clusters in gaining mechanistic insight into the relationship between skeletal muscle fibre size and myonuclear content. ### **NO RESISTANCE EXERCISE INDUCED MUSCLE PROTEIN SYNTHESIS RESPONSE IN ELDERLY MEN AS COMPARED TO YOUNG**

Reitelseder, S., Bülow, J., Holm, L.

*Institute of Sports Medicine Copenhagen and Center for Healthy Aging, University of Copenhagen*

Introduction Young and elderly do not seem to have different basal muscle protein synthesis (MPS) rates (Volpi et al., 2001), however, elderly has shown diminished MPS responses to both exercise (Kumar et al., 2009) and essential amino acid feeding (Cuthbertson et al.,

2005). Therefore, the underlying mechanisms for age-related muscle loss may be reduced sensitivity to exercise and feeding. We hypothesized that a more severe exercise program might enhance exercise-related MPS sensitivity in elderly. Aim of this study was to measure MPS at normal and following a 4-d severe heavy resistance exercise program in groups of young and elderly men. Methods 8 young ( $23 \pm 1$  y (mean  $\pm$  SE),  $24.1 \pm 0.9$  kg/m<sup>2</sup> BMI) and 8 elderly ( $70 \pm 1$  y,  $26.1 \pm 0.8$  kg/m<sup>2</sup> BMI) men were recruited and underwent a 4-d unilateral heavy resistance exercise program. Exercise consisted of leg press and leg extension, each 3–4 sets at 8–10 RM, and was performed every day in 4 days. Muscle biopsies were taken from vastus lateralis in the normal and exercised legs at day 2 prior to exercise and again following exercise and a 4-h flood primed, continuous infusion of L-[ring-<sup>13</sup>C<sub>6</sub>]phenylalanine at day 4 to measure and calculate normal and exercise myofibrillar fractional synthesis rates (FSR). Blood samples were collected during the infusion trial at 1 h intervals. Results Myofibrillar FSR were in the normal and exercised state  $0.039 \pm 0.003$  %/h and  $0.057 \pm 0.003$  %/h in young, and  $0.044 \pm 0.004$  %/h and  $0.048 \pm 0.002$  %/h in elderly. 2-way ANOVA (state repeated, group non-repeated) revealed a significant interaction ( $P = 0.039$ ). Student Newman-Keuls post hoc test showed no difference in normal FSR between young and elderly, but only young had increased FSR in the exercised muscle ( $P < 0.001$ ). Discussion Young and elderly men have equal normal myofibrillar protein synthesis rates, but the elevated response to 4 heavy resistance exercise bouts on 4 consecutive days is only manifest in the young individuals. Therefore, it can be concluded that a 4-d severe heavy resistance exercise program is not capable of inducing an anabolic response in elderly men, at least in the overnight fasted state. ### EFFECTS OF EXERCISE ON HAEMATOLOGICAL CHANGES OF ELDERLY PERSONS

Uba Chupel, M., Furtado, G., Pedrosa, A.F., Rieping, T., Souza, N., Direito, F., Silva, J., Ferreira, J.P.L., Teixeira, A.M.  
*Universidade de Coimbra*

Introduction Hematopoietic modulation can become unstable with aging. The data provided by the complete blood count (CBC) in this case are essential within the investigation of hematologic diseases. The diversity of information that the CBC can provide makes this one of the most requested subsidiary examination in clinical and surgical practices. Peripheral blood alterations in aging include discrete and isolated elevations in the erythrocyte sedimentation rate, mild lymphocytopenia without clinical and laboratory manifestations, and decreased mean hemoglobin and hematocrit concentrations (Sgnaolin et al. 2013). However, little is known about the effects of an exercise program on quantitative and morphological variation of elements in the blood, especially in elderly individuals. The aim of this study was to verify hematologic changes in elderly women due to the practice of two different exercise programs in a period of 28 weeks. Methods Fifty-four ( $n=54$ ) elderly women divided in three groups designated Aerobic/Walking Exercise (AWE,  $n=21$ ), Yoga/Flexibility (YF,  $n=24$ ) and Control Group (CG,  $n=9$ ) had a CBC done before (M1) and after (M2) a period of 28 weeks. During this period the AWE and YF programs were implemented and the subjects exercised 2–3 times per week, at low/moderate intensity. Results The analyses of leucocytes, red cells indices and platelet series in blood demonstrated that there are no significant differences ( $p > 0.05$ ) in the variables of the CBC when the two moments of the collection data were compared. However, a slight decrease occurred in the average values for white blood cells counts in the CG. Discussion There were no significant changes in any variables of the CBC for the groups that performed the exercise programs. The main changes occurred in the CG, where a decrease in the number of leukocytes was observed after the seven months. Previous evidence has shown that immune system maintenance is expected with the regular practice of physical exercises (Simpson et al. 2012), which corroborates the results of this research. Aging-associated changes in monocyte and macrophage function have been recognized as major contributors to dysregulation of the immune system in a variety of disease processes (Desai et al. 2010). In our study, we saw that decreases in monocyte counts occurred with more incidence in sedentary CG than in those that participated in the low/moderate intensity exercise programs. ### ANABOLIC EFFECTS OF LIGHT LOAD RESISTANCE EXERCISE AND DISTRIBUTION OF PROTEIN INTAKE IN ELDERLY – WITH EMPHASIS ON MUSCLE PROTEIN SYNTHESIS REGULATION AND AMINO ACID TRANSPORTERS

Agergaard, J., Bülow, J., Jensen, J.K., Reitelseder, S., Schjerling, P., Drummond, M.J., Holm, L.  
*Bispebjerg Hospital*

Introduction The present study investigated whether well-tolerable light-load resistance exercise (LL-RE) affects skeletal muscle fractional synthetic rate (FSR) and anabolic intracellular signalling as a way to counteract anabolic resistance and age related loss of muscle mass. Furthermore, we explored whether LL-RE affected post-prandial amino acid transporter (AAT) expression in ageing skeletal muscle, thus altering amino acid sensing. Methods Untrained healthy men (age: +65 years) were subjected to 13 hours of supine rest with infusion of a stable amino acid tracer (ring-<sup>13</sup>C<sub>6</sub>-phenylalanine). After 2½ hours of rest, unilateral LL-RE was conducted (leg extensions; 10 sets, 36 repetitions) at 16% 1RM. Hereafter, the subjects were randomised to oral intake of 700 mg/kg fat-free mass (~40g) whey-protein either as hourly drinks (~4g per drink) (PULSE,  $n=10$ ) or two boluses (~28g at 0h and ~12g at 7h) (BOLUS,  $n=10$ ) or isocaloric maltodextrin (~4g/hour) (Placebo,  $n=10$ ). Quadriceps muscle biopsies were taken at 0, 3, 7 and 10 hours post-exercise from both the resting and exercised leg. Myofibrillar-FSR, activity through mTORC1-signalling cascade and membrane-associated protein expression of select AATs involved in mTORC1 activation were analysed from the biopsies. Results LL-RE increased myofibrillar-FSR compared to the resting leg in all groups. p-AKT (T308) expression increased in the exercise leg immediately after exercise, which in the Placebo-group persisted throughout the post-exercise period, reflecting plasma insulin levels. p-4E-BP1 (T37/46) increased throughout the post-exercise period in the exercised leg in Placebo and BOLUS group and peaked at 7h. p-eEF2 (T56) decreased in response to LL-RE in all three groups. An increase in AAT expression was only observed when LL-RE was followed by whey-protein intake and reflected changes in plasma amino acid concentrations. Specifically, LAT1 and PAT1 expression increased in PULSE and PAT1 expression increased in BOLUS. Conclusion Resistance exercise at only 16% 1RM increased myofibrillar-FSR, irrespective of nutrient type and feeding pattern, which indicate an anabolic effect of LL-RE in elderly. This finding was supported by increased signalling for translation initiation and translation elongation in response to LL-RE. The Placebo group had a greater signalling through AKT, whereas LL-RE increased membrane-associated AAT protein expression in whey-protein groups (PULSE and BOLUS), making the muscles more susceptible to amino acids and increasing the potential for mTORC1-signalling.

#### THE EFFECT OF COLD-WATER IMMERSION ON THE CHANGE IN SKELETAL MUSCLE NA<sup>+</sup>-K<sup>+</sup>-ATPASE GENES FOLLOWING INTENSE INTERMITTENT EXERCISE IN HUMANS

Christiansen, D., Broatch, J.R., Bishop, D.J.

*Institute of Sport, Exercise and Active Living, Victoria University*

Introduction The Na<sup>+</sup>-K<sup>+</sup>-ATPase (NKA) is known as a key regulatory protein influencing skeletal muscle function, and its adaptability at both the gene and protein level appears of functional relevance to intense, human exercise performance [1, 2]. Developing strategies to augment the muscular adaptations specific to the NKA genes would therefore seem of interest. Research suggests that NKA genes may be augmented by cellular hypoxia and the subsequent creation of reactive oxygen species [3, 4] and hyperoxia [5]. Given the potential of cold-water immersion to promote these cellular stressors [6], we therefore evaluated the hypothesis that CWI could amplify the induction of NKA genes in human skeletal muscle in response to a single session of intense intermittent exercise. Methods Nineteen males with an age and VO<sub>2</sub>peak (mean ± SD) of 24 ± 6 years and 46.5 ± 8.1 mL·kg<sup>-1</sup>·min<sup>-1</sup>, respectively, completed an intense interval exercise session consisting of four 30-s 'all-out' efforts on a cycle ergometer, which was followed by one of two 15-min recovery interventions: cold-water immersion (CWI, n = 9; 10.3 ± 0.2°C) or rest at room temperature (CON, n = 10; 23.0 ± 0.1°C). Muscle were sampled at rest before exercise, and immediately and 3-h post recovery, in order to compare the changes in NKA genes following CON and CWI. Results At 3-h post recovery, the relative mRNA expression of the NKA catalytic α1 and structural β3 isoforms was increased (P<0.05) in both groups (CON: ~1.5- and ~2.1-fold, ES = 0.6 and 1.2; CWI: ~1.9- and ~2.8-fold, ES = 0.8 and 1.6, respectively), with the rise in β3 mRNA being of greater magnitude in the CWI group compared to CON (P<0.05). No changes in α1 and β3 mRNA occurred at any other time points relative to before exercise. The mRNA expression of the remaining isoforms remained unchanged in both groups following the exercise session. Discussion This study is the first to demonstrate that CWI can enhance the induction of the Na<sup>+</sup>-K<sup>+</sup>-ATPase β3 gene in human skeletal muscle in response to a one-off intense interval exercise session. These data provide a basis for studying the structural and functional adaptations associated with muscle ion transport, as well as possible performance alterations, following a period of post-exercise CWI. #### HIGH-INTENSITY EXERCISE, LACTATE SHUTTLE THEORY AND TUMOUR METABOLISM – A THEORETICAL APPROACH

Hofmann, P.

*University of Graz*

Strategies to disrupt pH control were widely suggested to be effective to positively influence aggressive glycolytic tumours (7). Evidence was provided for aerobic exercise training to modulate several host- and tumour-related pathways (6). It was suggested "... that exercise may do more than decrease symptoms and improve quality of life for cancer patients" (1) but the optimum amount of intensity and duration is still unknown. According to the lactate shuttle theory three phases of metabolism can be determined (2). These three distinct metabolic patterns allow prescribing defined workloads such as low (LO), moderate (MO) or high exercise (HI) with either lactate consuming or lactate producing conditions (5). As manipulating the tumour acidification may be a cancer treatment strategy at least to improve therapy resistance (7) exercise prescription may be crucial. Contrary to the mainly prescribed MO intensity for cancer patients, two main intensity domains are suggested to be relevant with respect to tumour metabolism, tumour-host interaction and host stability namely LO and HI exercise. LO is set below the first lactate (La) turn point indicated by whole body La oxidation rate exceeding the local La production rate (= reduction of elevated systemic blood La concentration) and HI is set above the second La turn point inducing a high systemic La acidosis which in turn inhibits glycolytic La production within every cell relying on anaerobic glycolysis (5). We recently showed in healthy subjects that the elevations of La by means of all out hand crank exercise reduced net-La increase in a subsequent HI anaerobic leg exercise by 50% (4). The functionality of these principles was shown for LO (9) and HI (3) exercise in tumour models. LO resulted in decreased tumour angiogenesis, an increase in oxygenation, reduced La concentration in the tumour micro-environment and a normalization of pH in tumour-bearing host. HI anaerobic exercise was shown to decrease tumour growth, cancer cachexia and increased innate and adaptive immune function in rats. Effects of exercise on cancer progression, and metastasis in a murine prostate cancer model were tumour vascularisation and a shift towards suppressed metastasis (6). Episodic, transient systemic acidosis was suggested to delay the evolution of the malignant phenotype (8). A multi-modal approach combining LO and HI components is therefore suggested to be an optimal model. Conclusion LO and HI exercise were shown to be effective to influence tumour growth and the tumour-host interaction but studies in eligible patients on the direct influence on tumour metabolism as well as tumour-host interaction of defined exercise intensities and modes are needed. #### HIGH INTENSITY INTERVAL TRAINING ATTENUATES INSULIN RESISTANCE INDUCED BY SLEEP DEPRIVATION

Souza, J., Dáttilo, M., de Mello, M.T., Antunes, H.K.M.

*Federal University of São Paulo*

Introduction Several studies have shown that sleep deprivation promotes negative influences on carbohydrate metabolism resulting in insulin resistance and increases risk of type 2 diabetes mellitus. On the other hand, physical exercise has been considered as a non-pharmacological strategy to glycemic control. Thus, the aim of this study was to analyze the effects of high intensity interval training (HIIT) on the blood glucose, insulin and free fatty acids (FFA) concentrations. Methods Eleven male volunteers, young and healthy were submitted to four conditions: Regular Sleep (RS), Sleep Deprivation (SD), HIIT + Regular Sleep (HIIT+RS) and HIIT + Sleep Deprivation (HIIT+SD). HIIT protocol consisted of 6 training sessions in two weeks, and after this period the volunteers slept normally or were deprived of sleep for 24 consecutive hours in a cross-over type design. We evaluated the concentrations of FFA in the blood and the insulin sensitivity was evalu-

ated by Oral Tolerance Glucose Test (OGTT) (NCT02125656). Results The area under the curve of glucose was 83% higher in SD condition when compared to RS condition (RS =  $360.7 \pm 62.2$ ; SD =  $432.2 \pm 87.6$ ; HIIT+RS =  $403.1 \pm 69.9$ ; HIIT+SD =  $377.1 \pm 46.5$ ) and the area under the curve of insulin was 60% higher when compared to the other conditions (RS =  $83.9 \pm 44.7$ ; SD =  $134.6 \pm 61.1$ ; HIIT+RS =  $79.0 \pm 27.3$ ; HIIT+SD =  $81.4 \pm 32.9$ ). Furthermore, FFA was 187% higher in SD condition when compared to RS condition (RS =  $280.7 \pm 100.8$   $\mu\text{mol/L}$ ; SD =  $525.6 \pm 235.0$   $\mu\text{mol/L}$ ; HIIT+RS =  $389.2 \pm 202.23$   $\mu\text{mol/L}$ ; HIIT+SD =  $425.7 \pm 194.4$   $\mu\text{mol/L}$ ). Discussion Sleep deprivation was able to increase the area under the curve of glucose and insulin, confirming the literature data showing that sleep debt has a negative impact on carbohydrate metabolism (Klingenberg et al, 2013). Insulin resistance can be explained by the increase of FFA in the bloodstream, resulting in an impairment in insulin signaling (Boucher et al., 2015). However, when the volunteers practiced previously HIIT sleep deprivation, the exercise proved to be a beneficial strategy for glycemic control. The HIIT is able to enhance expression of GLUT4 and AMPK (Gibala et al., 2009), increase mitochondrial biogenesis and the oxidation of FFA (Burgomaster et al., 2008), minimizing the insulin resistance observed in sleep deprivation. ## EFFECTS OF AGE AND SEX ON THE MECHANICAL CHARACTERISTICS OF THE KNEE JOINT EXTENSORS

Wu, R.1, Delahunt, E.1, Ditroilo, M.3, Lowery, M.2, De Vito, G.1

*Institute for Sport and Health*

1: Institute for Sport and Health, University College Dublin, Ireland, 2: School of Electrical, Electronic and Communications Engineering, University College Dublin, Ireland, 3: Department of Sport, Health and Exercise Science, University of Hull, United Kingdom Introduction Age-related decreases in muscle strength can be explained to a great extent by changes in the mechanical characteristics of the musculoskeletal system. Other "mechanical factors" such as muscle architecture (MA) and tissues stiffness significantly contribute to force generation and transmission. Experimental evidence has shown that these properties exhibit considerable plasticity, undergoing changes with aging. Therefore, the aim of this study was to compare and contrast the mechanical properties of the knee extensor musculature in young (Y) and older (O) males and females. Methods 22 Y (11 Females, 23.9+3.4 years; 11 Males, 24.3+4.2 years) and 20 O (9 Females, 66.3+4.4 years; 11 Males, 66.9+3.5 years) subjects participated. MA parameters of vastus lateralis (VL) were obtained by ultrasonography. Knee-extensor maximum voluntary isometric contraction (MVIC) was measured on a leg-extension dynamometer. Muscle stiffness (MS) of the VL was obtained by myotonometry (relaxed and at 20% MVIC) whilst musculo-articular stiffness (MAS) was evaluated via the free-oscillation technique (at 20% MVIC). Results Males were characterized by a larger decline in MVIC (42.94%) compared to O females (30.27%) with main effects observed for age (Y=239.5+90.6, O=150.3+49.0Nm; P<.001) and sex (Males=234.2+90.4, Females=156.2+54.0 Nm; P<.001). Concerning VL thickness main effects were observed for age (Y=22.8+3.2, O=19.5+2.0mm, P<.001) and sex (Males=22.3+3.4, Females=20.1+2.4mm; P<.01). For VL fascicle length there was a main effect for age (Y=104.8+12.1, O=89.8+10.5mm, P<.001). Regarding VL pennation angle there was a main effect for sex (Males=13.5+2.7, Females=11.0+1.8°, P<.001). MS relaxed demonstrated a main effect for age (Y=379.8+36.2, O=342.5+36.4N/m; P<.001) and sex (Males=377.7+35.3, Females=344.9+39.6N/m; P<.01). MS contracted was characterized by a significant main effect for sex (Males=479.0+46.3 Females=410.3+63.6N/m; P<.001). For MAS a significant main effect was observed for age (Y=977.6+435.0, O=551.4+191.2N/m; P<.001) and sex (Males=898.8+437.9, Females=638.1+310.6N/m; P<.01). Discussion The main finding of this study is that there is a significant age-related decrease in the mechanical properties of the knee joint extensor musculature in both males and females, with a more evident reduction observed in males. Overall, our results suggest that age-related changes in the mechanical characteristics of knee extensors impair the execution of motor tasks in both sexes with a more pronounced effect in males. rui.wu.1@ucdconnect.ie

## EXERCISE INDUCED BRONCHOCONSTRICTION IN CHILDREN WITHOUT ASTHMA

Westergren, T.1, Lødrup Carlsen, K.C.2,3, Mowinkel, P.2, Håland, G.2, Fegran, L.1, Berntsen, S.1, Carlsen, K.H.2,3,4

*1.University of Agder. 2.Department of Paediatrics, Oslo University Hospital. 3.Faculty of Medicine, University of Oslo. 4.Norwegian School of Sport Sciences.*

Introduction Exercise induced bronchoconstriction (EIB) is common in asthma and may be associated with inactivity and overweight. EIB may, however, also be prevalent in non-asthmatic children. We aimed to investigate whether EIB was associated with baseline lung function, overweight or self-reported physical activity (PA) in non-allergic, non-asthmatic children. Methods The present study included 432 children from the Environment and Childhood Asthma birth cohort study (mean age 10.7, 46% boys) who had no doctor's diagnosis of asthma, no self-reported wheeze during the last 12 months, no use of asthma medications and negative skin prick test for allergy. Lung function (forced expiratory flow at 1 second (FEV1), forced expiratory flow at 25-75% of FEV1 (FEF25-75), forced vital capacity (FVC), and FEV1/FVC) were measured and calculated according to international standards. Overweight were defined according to age and gender adjusted body mass index according to Cole et al (2000). All completed a standardized EIB challenge test, regarded positive with a fall in FEV1 of at least 10 percent, and a questionnaire regarding physical activity and participating in sports. Results were compared using Chi-square tests for categorical and independent t-tests for continuous variables. Multivariate associations were analyzed in a logistic regression model, removing the least significant variable stepwise until only significant variables remained. Results Fifty-seven children (13%) had a positive EIB-test. Mean baseline FEV1 were 98 ( $\pm 9$ ), mean body mass was 38 ( $\pm 8$ ) kg and height 145 ( $\pm 7$ ) cm, and mean hours/week participating in sports were 2.13 ( $\pm 1.54$ ). Lung function was similar in children with and without EIB. Children with compared to without EIB were significantly more often overweight (25% vs. 12%,  $p=0.01$ ), and spent significantly less time in sports (mean hours 1.71, (95% confidence interval (CI); 1.37, 2.06) /week vs. 2.19, (2.11, 2.35),  $p=0.03$ ). In final multivariate analysis adjusted for gender, overweight children were more likely to have a positive EIB (Odds ratio; 2.47, (95% CI 1.24, 4.92)) whereas children doing one or more hour sports/week were less likely (0.80 (0.65, 0.98)) to have EIB. There was no significant interaction between overweight and hours participating in sports. Discussion Exercise induced bronchoconstriction that was relatively common in non-asthmatic subjects, was associated with being overweight as well as spending less time in sports than subjects without EIB. This suggests that EIB may be a barrier not only to PA but to participation at possibly lower intensity, also in children without recognized asthma. References Cole, T. J., Bellizzi, M. C., Flegal, K. M., & Dietz, W. H. (2000). Establishing a standard definition for child overweight and obesity worldwide: international survey. *British Medical Journal*, 1240-1243. ## EXERCISE EFFICIENCY IS INCREASED WITH AGE BUT NEITHER DETERMINED BY FIBRE-TYPE DISTRIBUTION, MITOCHONDRIAL FUNCTION NOR CITRATE SYNTHASE ACTIVITY

Gehrig, S.M.1,2, Aguayo, D.3, Jacobs, R.A.1, Lundby-Meinild, A.K.2, Auer, M.4, Jung, H.H.4, Toigo, M.3, Lundby, C.1,2  
*University of Zurich (1,2,4,5), ETH Zurich (3)*

Whether exercise efficiency (EE) is increased with age is a matter of debate and hence also the potential mechanisms that may facilitate this remain disputed. Accordingly, the purpose of this study was to determine if EE is altered in aged humans and to test whether changes can be related to skeletal muscle properties. Peak oxygen uptake (VO<sub>2peak</sub>) and EE were assessed with an incremental cycling test in 11 young (YNG, 27 ± 4 yrs) and 13 old (OLD, 65 ± 4 yrs) individuals. With the intent to reduce the possible confounding factor of training status, VO<sub>2peak</sub> of OLD were adjusted for age by subtracting 4 ml/kg/min per decade (Wilson and Tanaka, 2000) and subsequently matched to YNG. EE was calculated as the mean ratio of work and energy expenditure at ~50, 60, 70 % VO<sub>2peak</sub> (on the basis of Coyle et al., 1992). Skeletal muscle biopsies were obtained from the m. vastus lateralis for the evaluation of muscle fibre-type distribution (% slow-twitch, ST; % fast-twitch, FT), citrate synthase (CS) activity as a marker of mitochondrial content, maximal mitochondrial respiratory capacity (OXPHOS) and mitochondrial efficiency (MitEFF). EE was higher in OLD vs. YNG (16.7 ± 1.5 vs. 14 ± 2.4 %, P < 0.01). There was no effect of age on % ST and FT (60.2 ± 11.9 vs. 53.4 ± 10.9 %, P = 0.161; 39.8 ± 11.9 vs. 46.6 ± 10.9 %, P = 0.162) or on CS activity (168.3 ± 32.6 vs. 144.8 ± 25.7 μmol/ml/min, P = 0.066). OXPHOS, OXPHOS per CS activity, MitEFF and MitEFF per CS did not differ between OLD and YNG (93.5 ± 16.7 vs. 91 ± 12.7 pmol O<sub>2</sub>/mg/s, P = 0.690; 56.6 ± 10 vs. 65.2 ± 17.2 %, P = 0.135; 35.7 ± 4.2 vs. 36.6 ± 8.6 %, P = 0.749; 22 ± 5 vs. 25.8 ± 6.5 %, P = 0.117). Neither of the tested variables correlated to EE. EE was higher in OLD vs. YNG at comparable fitness levels, which extends previous findings by accounting for the age-dependent decrease in VO<sub>2peak</sub>. Furthermore, EE was higher in OLD vs. YNG after controlling for % ST, FT, CS activity, OXPHOS or MitEFF. Accordingly, these findings suggest that with older age the energetic needs are met with a smaller perturbation of intracellular metabolism. Coyle EF., Sidossis LS., Horowitz JF., Beltz JD. ### OP-PM68 Adapted Physical Activity: Physical disabilities

#### SPORT PARTICIPATION OF DISABLED CHILDREN IN KOSOVO

Begaj, E.

*University of Prishtina*

This research titled sport participation of disabled children in Kosovo presents results from a study performed with young people with disability and from an interview with a sport physical education teacher who works with those children. Being concerned with these children experiences of sport and participation in sport this research investigated the barriers that these children experience to participation in sport. The aim of this research was to help Ministry of Youth, Culture and Sport, teachers and others to make better investment in sport for people with disabilities. The accessibility of public facilities for people with disabilities in Kosovo is nearly impossible not just in sports facilities but also accessing on the roads, in coffee bars, restaurants and public transportation. This study has been done with a mixed research paradigm. The combination of quantitative and qualitative methods. The literature review has been performed with the focus of a wide range of literature for sport and disabled people and especially about participation in sport. In the current study have been used three methods to collect data: questionnaires that were completed by children, individual interview with physical education teacher, and observations that were done in the classrooms. This study has gathered and analyzed evidence relating to pupils and physical education teacher's views pupils' participation in sport. This study has produced clear evidence that the main barriers for not participating in sport is the low economical condition of our country, low economical condition of the families, lack of facilities, society and support of institutions.

#### THE PROGRESSION OF SPRINT PERFORMANCES IN BLADE RUNNERS

Terblanche, E., Ferreira, S., Grobler, L.

*Stellenbosch University*

**INTRODUCTION** Similarly to able-bodied sport, technological advances in sporting equipment is also evident in sport for athletes with disabilities. One of the prominent developments involves the running specific prosthesis (RSP) used by athletes with lower limb amputations. For these athletes, the RSP not only affects his/her performance, but essentially enables the athlete to run. It is reasonable to think that RSP's had similar ergogenic effects on Paralympic sprinters than technical swimsuits on Olympic swimmers, albeit not necessarily to the same extent. The purpose of this study was to investigate the performance changes in athletes with lower limb amputations since 1992 to assess whether the developments in RSP technology is evident in sprinting performances. **METHODS** Results for the Olympic and Paralympic Games from 1992 to 2012 for sprint athletes in the T12, T13, T37, T42 and T44 classes were gathered from two websites(1, 2). Athletes' performances in the Olympic Games were included as reference points to assist in the interpretation of changes in the T42 and T44 performances. The descriptive statistics (means, standard deviations and percent change) were calculated from the race times. Competition density (CD) was calculated to illustrate the competitiveness of each event. High values indicate that competitors completed the race close together and vice versa. **RESULTS** The greatest performance increases were seen in athletes with lower limb amputations (T42 = 26%, T44 = 14%). These performance improvements were greater than for Olympic athletes (< 3%), as well as Paralympic athletes with visual impairments and cerebral palsy (< 10%). In both the 100m and 200m the Olympic results were most dense (23.90 and 9.29 competitors.s-1), respectively, whereas the T42 class was the least dense in both events (100m = 4.53 competitors.s-1; 200m = 1.93 competitors.s-1). **DISCUSSION** The performance trends for Paralympic athletes with lower limb amputations suggest that RSP technology almost certainly played a significant role in the advancement of their performances until 2012. A further indication of the importance of RSP technology in the performances of these athletes is that athletes who are more dependent on RSPs for locomotion (i.e. athletes with above knee amputations) showed the largest improvements in performance, as well as greater variation among athletes in a race. For athletes to remain competitive, they will not only need access to the latest RSP technology, but they will also need the scientific backup to match him/her with the most appropriate RSPs for the specific event. **REFERENCES** 1. ## ELITE ICE SLEDGE HOCKEY PLAYERS DO NOT DIFFER FROM ABLE-BODIED CROSS-COUNTRY SKIERS IN EXERCISE EFFICIENCY

Baumgart, J.K., Brurok, B., Sandbakk, Ø.

*Norwegian University of Science and Technology*

**Introduction:** Exercise efficiency (EE), which is the ratio of work rate (WR) generated to the energy expended, is a key factor for aerobic endurance performance. EE is, therefore, suggested to be of importance in ice sledge hockey, where most of the game is spent upper-body poling at submaximal intensities, as well as in cross-country skiing, where comparable upper-body poling is executed at high continuous aerobic endurance levels. Although the training of both groups comprises large amounts of poling-specific upper-body endurance exercise, it remains unclear if the disabilities of the ice sledge hockey players (ISH) affect EE. Therefore, the purpose of this study was to investigate possible differences in EE between elite ISH and cross-country skiers (XC). **Methods:** 9 male elite ISH (training/year: 550±126.5hrs) and 13 male elite able-bodied XC (training/year: 612±37hrs) of similar age and weight performed 3x4-min submaximal stages of upper-body poling on a modified Concept2 ski ergometer, while sitting in an ice sledge hockey seat. Additionally, peak aerobic capacity (VO<sub>2</sub>peak) was determined from a 3-min all-out test in the same exercise mode. The 3 submaximal stages corresponded to a %VO<sub>2</sub>peak of approximately 55 (SUB1), 65 (SUB2) and 80% (SUB3). A steady state WR was maintained throughout each stage and recorded by the ergometer's internal software. The metabolic rate (MR) was calculated as the energetic equivalent of the mean VO<sub>2</sub> during 60-s (L·min<sup>-1</sup>) and the corresponding respiratory exchange ratio. Linear regression analyses were performed to identify the WR-MR relationship for ISH and XC. To test for differences in the inclines of the two regression lines an ANCOVA was performed. **Results:** The mean WR for ISH and XC was 40±11 and 68±8W at SUB1, 54±14 and 92±12W at SUB2 and 72±22 and 119±21W at SUB3, respectively. The corresponding MR values were 428±72 and 629±106 at SUB1, 530±78 and 792±154 at SUB2, and 683±215 and 997±187 at SUB3. The VO<sub>2</sub>peak differed significantly between ISH (2.5±0.5L·min<sup>-1</sup>) and XC (3.6±0.8L·min<sup>-1</sup>) (p=0.001). The regression lines identified for ISH (y=131+7.5x, R<sup>2</sup>=0.80) and XC (y=108+7.5x, R<sup>2</sup>=0.80) did not significantly differ (p=0.991). **Conclusion:** EE in upper-body poling was not different between ISH and XC and, therefore, not significantly influenced by the disabilities in our ISH sample. The current data indicates that the higher work rates produced by XC are related to the higher VO<sub>2</sub>peak instead. The difference in VO<sub>2</sub>peak may be attributed to the varying sport-specific demands and, more importantly, to the possibility of the XC skiers to regularly execute whole-body endurance exercise.

## HOW CAN SPORT CLUBS FOR NON-DISABLED YOUTH INCLUDE CHILDREN AND ADOLESCENT WITH DISABILITIES?

Jerlinder, K.1, Geidne, S.2

1: *University of Gävle (Gävle, Sweden)*, 2: *Örebro University (Örebro, Sweden)*

**Introduction** Young people with disabilities participate in sports to a lesser extent than other adolescents [1]. That physical activity has positive effects on children and adolescents, such as reduced risk of diabetes, overweight and obesity, anxiety and depression are understood [2]. The positive effects of participation in organized sport and physical activity are at least as great for children and young people with disabilities as children and young people without disabilities. One of the most important tasks of various actors is to find ways to increase physical activity and the health of children and youth with disabilities. Sports clubs are identified as potential and attractive environments for physical activity, but also for social and mental health [3]. The reasons why children and young people with disabilities participate to a lower extent in organized sport is complex and barriers can be deriving from many different levels. However, barriers have been studied more than what can facilitate participation in organized sport [4]. Therefore the aim of this study is to present the first results from a systematic international and scientific literature review of how sport clubs for non-disabled youth can include children and adolescents with disabilities in their activities. **Method** Articles (with inclusion criteria of studies focusing on children and adolescents, disability, physical activity, engagement in organized sports, inclusive sport settings) from a 20 years period were selected. Studies with topics that concerned physical education, medical, physical activity without an organized sport agenda, elite sport or equipment issues were excluded. **Results** The results will focus on which type of sport, target group and countries the examples are from, but foremost on how sport clubs for non-disabled youth actually do to include children and adolescents with disabilities in their activities. **Discussion** It is essential to establish a knowledge base for as well methods for inclusion in everyday activity, as effective interventions towards the target group at hand. If more children and youth with disabilities participate in organized sports several positive health benefits can be achieved. **References** [1] Ungdomsstyrelsen, Levnadsvillkor för unga med funktionsnedsättning, FOKUS12, Stockholm. ### OP-PM56 Health & Fitness: Endurance

#### POSTURAL CONTROL AFTER ENDURANCE EXERCISES AT DISTINCT INTENSITIES

Fischer, H., Beneke, R.

*Philipps University Marburg - Germany*

**Introduction** Endurance exercise can affect postural sway. Fatiguing incremental exercise increases postural sway. However, results about effects of different levels of exercise intensity in particular related to measures of energy metabolism are inconsistent and rare (Paillard 2012). Additionally, diversity of methods used to evaluate postural sway limits comparability. Purpose of this study was to investigate effects of cycling exercises at three distinct intensity domains as indicated by metabolic conditions on postural sway in bipedal stance without and with visual deprivation. **Methods** 23 regularly physically active participants (10 males, 13 females; 23.7±1.6 yr; 177±9 cm; 74±12 kg) performed an exhausting incremental cycle ergometer test followed by four 20 min constant load tests at exercise intensi-

ties corresponding to 2, 3, 4 and 5 mmol/l blood lactate concentration (BLC) of the incremental test in randomised order. The exhausting incremental test, the lowest completed 20 min constant exercise at which the BLC showed no steady state by increasing until test termination (severe), and the 2 mmol/l intensity test showing a constant steady state BLC response after some variability during the initial 10 min (moderate) were taken for analysis (Bencke 2003). Postural sway in terms of the 95% ellipse area of center of pressure (CoP-area) was measured immediately before (pre) and 1 min after (post) each exercise for 30 sec in barefooted bipedal stance (bi) with eyes open (eo) and closed (ec). Results CoP-area shows main effects for pre-post in both bipedal stances (bieo: pre  $1.30 \pm 0.70 \text{ cm}^2$ , post  $2.05 \pm 1.51 \text{ cm}^2$ ;  $p \leq 0.001$ ; biee: pre  $1.26 \pm 0.61 \text{ cm}^2$ , post  $1.80 \pm 1.43 \text{ cm}^2$ ;  $p \leq 0.001$ ), interaction effects with energy metabolism (bieo  $p \leq 0.05$ ; biee  $p \leq 0.01$ ) and a main effect of energy metabolism in bieo ( $p \leq 0.05$ ). Exhausting exercise increased CoP-area of both stances (bieo: pre:  $1.31 \pm 0.69 \text{ cm}^2$ , post:  $2.67 \pm 1.34 \text{ cm}^2$ ;  $p \leq 0.001$ ; biee: pre:  $1.21 \pm 0.58 \text{ cm}^2$ , post:  $2.30 \pm 1.95 \text{ cm}^2$ ;  $p \leq 0.01$ ), whilst severe exercise increased CoP-area in biee (pre  $1.06 \pm 0.40 \text{ cm}^2$ ; post  $1.73 \pm 1.33 \text{ cm}^2$ ;  $p \leq 0.05$ ) only. Moderate exercise had no effect on postural sway. Conclusion Exhaustive exercise increased postural sway irrespective of visual input. Visual control seems to be required for preventing increase in postural sway after non-exhaustive effort of 20 min duration in the severe intensity domain, but not after moderate exercise of similar duration. Endurance exercise in the severe, but not in the moderate exercise domain seems to challenge postural control requiring unimpaired sensory input. References Bencke R (2003). ### OXIDATIVE STRESS AND RUNNING ECONOMY

Santos, J.M.B.1, Luna Jr, L.A.1, Foster, R.1, Estevam, V.1, Sá, M.1, Amirato, G.R.1, Pagani, L.G.1, Bachi, A.L.L.1,2, Vaisberg, M.1  
1: Universidade Federal de São Paulo; 2: Universidade Cruzeiro do Sul. São Paulo, Brazil, 2: Universidade Cruzeiro do Sul. São Paulo, Brazil

Introduction Running economy is defined as the oxygen consumption necessary to run at a given determined speed and express the relation between energetic cost and work done. In a previous paper of our group we have demonstrated that less inflamed athletes showed increased running economy. It's well demonstrated that inflammation and oxidative stress are closely related. In this research we observed mechanisms of oxidative control during and soon after a marathon, and possible relation to running economy. Results Immediately after the race, levels of oxidized LDL (oxLDL) and total antioxidants complex (TAC) showed a significant decrease compared to baseline levels. Pearson's correlation analysis between running economy and TAC in the time 72 h after the marathon, that although not statistically significant ( $p=0.08$ ,  $r = 0.37$ ). Discussion This finding suggests that antioxidant molecules represented by TAC could buffer oxidative stress, preventing an increase of oxLDL. Seventy-two hours after the race, levels of oxLDL and TAC showed a tendency to return to the basal values. Conclusion The correlation between running economy and TAC suggests that athletes with lower values of running economy have greater necessity to use antioxidant mechanisms, in order to avoid a state of oxidative stress. ### ACUTE PHYSIOLOGICAL DIFFERENCES BETWEEN CYCLING AND RUNNING AT MATCHED OXYGEN UPTAKES

Abrantes, C.1, Machado, I.1, Sousa, N.1

1: Research Center for Sport, Health and Human Development (CIDESD), University of Trás-os-Montes and Alto Douro, Vila Real, Portugal

Introduction It is presumed that running compared to cycling exercise, promotes higher rates of oxygen uptake and energy expenditure in submaximal and maximal exercise intensities. Previous research was carried using one maximal protocol or a submaximal intensity to compare these exercise modes. The purpose of this study was to determine the differences in acute physiological responses of exercising in cycling and running at matched rates of oxygen uptake (from low-to-high intensities). Methods The sample comprised twenty voluntary male participants (age= $22.5 \pm 1.8$  years; height= $177.7 \pm 7.0$  cm; body mass= $72.6 \pm 7.9$  kg; fat mass= $7.87 \pm 1.3$  %) that performed five submaximal 8 min exercise bouts, interspersed with a 10 min period of passive recovery. Exercise intensity in the treadmill running was 10, 12, 14, 15 and 16 km/h (0% gradient), and in the cycle ergometer was 80, 120, 160, 180 and 200 W (65-70rpm). The following variables were measured using standardised protocols: oxygen uptake ( $\text{VO}_2$ ), ventilation, heart rate (HR), respiratory exchange ratio (RER), rate pressure product (RPP), blood glucose, systolic and diastolic blood pressure (SBP, DBP, respectively), body temperature (Temp), blood lactate and perceived exertion (RPE). To enable comparisons between the two exercise modes at matched oxygen uptakes, the results were forecasted for .5, 1, 2, 3, 4, 5 and 6 L/min of oxygen uptake, using intercepts and slopes obtained contrasting gathered data with their  $100 \cdot \text{LN}$ . The statistical comparisons between modes were carried via standardized mean differences and non-clinical magnitude-based inferences (Hopkins, Marshall, Batterham, & Hanin, 2009). Results The results obtained showed no differences between exercise modes in blood glucose, SBP, DBP, RER, RPP and Temp. Blood lactate, HR and RPE were significantly higher in cycling to forecasted oxygen uptakes above 4 L/min. Ventilation was higher in cycling for  $\text{VO}_2$  above 3 L/min. These differences ranged from moderate to high. Discussion Running or cycling at lower oxygen uptakes did not promote different acute physiological responses. However, at higher intensities the metabolic and perceptual acute responses were consistently higher, probably due to the lower muscle mass quantity and the cycling specific muscle contraction pattern. The blood lactate, HR and also RPE responses were likely dependent upon intensities near or above the anaerobic threshold. Exercise prescription should account for these dose-response mode effects, especially at higher intensities. References Hopkins, W. G., Marshall, S. W., Batterham, A. M., & Hanin, J. (2009). Progressive Statistics for Studies in Sports Medicine and Exercise Science. *Medicine and Science in Sports and Exercise*, 41(1), 3-12.

### THE ASSOCIATION BETWEEN DAILY STEPS AND HEALTH: A Pedometer-Based, Cross-Sectional Study in an Employed South African Population

Pillay, J.D.

Durban University of Technology

Background: Walking is recognised as an easily accessible mode of physical activity and is therefore supported as a strategy to promote health and well-being. To complement walking, pedometers have been identified as a useful tool for monitoring ambulatory physical activity, typically measuring total steps/day. There is, however, little information concerning dose-response for health outcomes in relation to intensity or duration of sustained steps. We aimed to examine this relationship, among employed adults. Methods: A convenience

sample, recruited from work-site health risk screening (N=312, 37±9yrs), wore a pedometer for at least three consecutive days. Steps were classified as "aerobic" ( $\geq 100$  steps/minute and  $\geq 10$  consecutive minutes) or "non-aerobic" ( $< 100$  steps/minute and/or  $< 10$  consecutive minutes). The data were sub-grouped according to intensity-based categories i.e. "no aerobic activity", "low aerobic activity" (1-20 minutes/day of aerobic activity) and "high aerobic activity" ( $\geq 21$  minutes/day of aerobic activity), with the latter used as a proxy for current PA guidelines (150-minutes of moderate-intensity PA per week). Health outcomes included blood pressure, body mass index, percentage body fat, waist circumference, blood cholesterol and blood glucose. Analysis of covariance, adjusting for age, gender and total steps/day were used to compare groups according to volume and intensity-based steps categories. Results: Average steps/day were  $6,574 \pm 3,541$ ; total steps/day were inversely associated with most health outcomes in the expected direction ( $p < 0.05$ ). The "no aerobic activity" group was significantly different from the "low aerobic activity" and "high aerobic activity" in percentage body fat and diastolic blood pressure only ( $P < 0.05$ ). Conclusion: The study provides a presentation of cross-sectional pedometer data that relate to a combination of intensity and volume-based steps/day and its relationship to current guidelines. The integration of volume, intensity and duration of ambulatory physical activity in pedometer-based messages is of emerging relevance.

### ICYCLE MESSENGERS: ANTHROPOMETRIC CHARACTERISTIC AND PERFORMANCE

Casonato, S., Tellan, F.

*university of milan*

**INTRO** Bicycle messengers are people who work for courier companies delivering items by bicycle. These Couriers are most often found in the central business districts of metropolitan areas. Courier companies use bike messengers because bicycle travel is less subject to unexpected holdups in city traffic jams, and is not deterred by parking limitations, fees or fines in high density development that can hinder or prevent delivery by motor vehicle, thereby offering a predictable delivery time. There are few studies which outlines the characteristics of this population. **METHODS:** This study analyzes the anthropometric and performance characteristics of 9 male bike messengers (30±6 years old). We took anthropometric measurements on each subject. These included height ( $1,75 \pm 0,02$ m), weight ( $67,6 \pm 4,3$ kg), body composition ( $15,2 \pm 2,3\%$  body fat), Body Mass Index ( $22 \pm 1,4$ ). An incremental VO<sub>2</sub>max Test ( $75 + 25$  W/min) has been performed by each subject. Ventilatory Threshold (VT) and relative power at this level have been calculated. Further measurements were collected during their working day using Cycleops Joule GPS® heart rate monitor in order to evaluate the metabolic cost of their working shift. **RESULTS:** Vo<sub>2</sub>max  $61,0 \pm 4,2$  ml/kg/min(-1) and Power Output at VT  $4,36 \pm 0,4$  W/Kg values were similar to those reported in literature for amateur cyclists. During an hour working shift, the average EE was  $361 \pm 92$  kcal/h; GPS-related data show an average of  $22,5 \pm 5,4$  kms, elevation gain of  $99,6 \pm 44,5$  m and speed of  $7,4 \pm 1,5$  km/h. **CONCLUSION:** Urban bicycle messengers are a workforce characterized by higher physiological values than standard workers'. Their EE is greater than other employees and, according to their vo<sub>2</sub>max, is strongly related to their body composition. Most of the time is spent in fat burning zones (below 65% of Vo<sub>2</sub>Max). Moreover, the heart rate pattern is highly variable during the shift, according to the type of delivery and urban track. Further investigations must be developed to unveil this new workers population. **REFERENCES** 1: Bernmark E, Wiktorin C, Svartengren M, Lewné M, Aberg S. ### OP-SH23 Sociology/Sport management

#### HUMAN RESOURCES IN GERMAN SPORTS ORGANIZATIONS: STRUCTURES, SYSTEMS, DEVELOPMENTS

Werkmann, M.

*Johannes Gutenberg University Mainz*

The associations and organizations of German organized sports are usually characterized – like all other non-profit-organizations – by voluntary work of their members. However, in times of increasing professionalization and commercialization of sport many tasks, obligations and responsibilities can't be covered only by volunteers anymore (Thiel, Meier & Cachay, 2006, p. 9). Already in 2012 one third of German sports associations and organizations had employed professional workers (cf. Breuer, 2013, p. 337). Especially in larger non-profit-organizations in German sports an increasing number of professional employees and a corresponding adjustment of their responsibilities and decision-making competences can be found. For a long-term understanding and explanation of these process changes, competence shifts etc., it is firstly necessary to collect empirically proved data of the current personnel structures and systems of the sports organizations to derive possible future developments. The German research community in sports science has dealt with the personnel in organized sports for a long time and from various analytical perspectives (cf. e.g. Winkler & Karhausen, 1985; Schütte, 1999; Cachay, Thiel & Meier, 2001; Wagner, 2008; Thiel & Meier, 2009). Scientific studies focusing exclusively on the professional employees, their current numbers, structures and systems on the highest level of sports organizations in Germany are lacking so far. For the exploration of this desideratum an empirical study with focus only on the professional staff in German sports organizations was carried out. Therefore, the German Olympic Sports Confederation (DOSB) and its 98 member organizations are questioned in a standardized online-survey in spring 2014. With a response rate of almost 72% the study provides, for the first time, meaningful results of the total number of employees of the sports organizations as well as the number of executives on the different hierarchy levels and their distribution of the separate working areas. Moreover, the data provides information about the processes of personnel recruitment and the implemented or planned measures of strategic human resources development. In addition to the presentation of the empirical study the lecture also contains a future-oriented view to the personnel development of organized sports in Germany. The change processes in the personnel structure as well as their reasons and consequences will be examined and scrutinized critically, inter alia, on the basis of the recent amendment of the DOSB (cf. Kosok, 2014; Kuske, 2014; Seubert, 2014; Deutscher Olympischer Sportbund, 2014).

## MONITORING AND EVALUATION AS STRATEGIC TOOL FOR PROGRAMME EFFECTIVENESS

Hollander, W.

*University of Johannesburg*

The absence of an overarching organizational and programme effectiveness theory impacts directly on the identification of success indicators for monitoring and evaluation purposes. Influential models of organizational and programme effectiveness in the sport sector underpin approaches of programme resourcing, processes and goal attainment from which indicators for monitoring and evaluation purposes could be identified and formulated. A synthesis of such theoretical approaches ensures that the various strengths and weaknesses of each not only complement the other in the management of the programme, but also inform indicator identification as well as the process for monitoring and evaluation. The internationally developed and advocated Nike Designed to Move Framework for Action identified seven distinguishable filters (indicators) that focuses on input, process and output that are not only provided for programme design, management and delivery, but also for monitoring and evaluation purposes. The aim of the study was to monitor and evaluate the programme management and delivery of the Butterflies programme in Alexandra Township in the Greater Johannesburg against the seven filters or indicators as proposed by the Designed to Move Framework developed by Nike. A Participatory Action Research (PAR) approach was followed utilizing the S.DIAT (Sport in Development Impact Assessment Tool), with a pre- post design. Mixed methods allowed for quantitative and qualitative data capturing which comprised of attendance and activity registers completed by coaches, questionnaires completed by coaches and primary school participants, interviews with school representatives and focus groups with coaches and participants. Observations of facilities and practice sessions were also made during the research visits. Findings show that the learners' attendance of training sessions was relatively high with a low average dropout rate. Relatively more girls than boys attended the programme across the schools with an age spread of between 8 and 13 years of which most being between the ages of 8 and 10 years. Narratives demonstrate a high level of fun from all participants, with an observed change from 'wanting to compete' or 'develop talent' to 'having fun' and 'playing with friends' over time. In addition most participants were highly satisfied with the quality of sessions, although boys expressed a need for 'more technical knowledge'.

## PUBLIC VIEWING EVENT VISITORS AND THEIR CONTRIBUTION TO ECONOMIC AND TOURISM IMPACT – EVIDENCE FROM BERLIN DURING THE WORLD CUP 2014 IN BRAZIL

Mielke, G.

*HWTK-University of Applied Sciences*

**Introduction** The analysis of the economic impact of sporting mega-events is always a very controversial debate amongst economists. Hosting events can cause positive effects regarding tourism and economic impacts. The demand from tourists can subsidize the production of goods and services, by the advantages of economics of scale. Events are considered as an important tool for the destination marketing (event signaling). This study analyzes the economic and tourism impact of sport events, paying special attention to a relatively new phenomenon, public viewing events, which take part away from the hosting cities of the real sporting event. Therefore, the aim of the study was to identify event legacies for Berlin caused by event visitor's expenditures. Theoretical roots to ascertain consumption patterns draw back to the study from Preuss, Kurscheidt and Schuette (2009), Preuss (2007) and Gratton, Dobson and Shibli (2000). Methods Data was conducted with a questionnaire. The survey was conducted personally and consists of 150 variables collected at public viewing events in Berlin (n = 880). The research design was based on the very similar surveys done at the FIFA World Cup 2006 and 2010. The analysis of data based on total consumption of the event visitors and the released economic effects to the city of Berlin. Results The presentation will focus on the public viewing visitor's consumption at public viewing events in Berlin during the FIFA World Cup 2014. It will show the visitor's consumption as a significant contribution to the economic success for the city of Berlin. Furthermore, the study gives an overview about the most important socio-demographic data of public viewing event visitors. Finally the presentation shows overall economic impact of public viewing events 2014 caused by its visitors. Discussion It is fact, that different events have different effects for the host cities (Kurscheidt, 2009; Hall, 1992). It will become clear, that all events has different visitors consuming different as well as that is not possible to predict event-legacies without any information on the consumption and other data of visitors. Therefore, a prediction of any economic impact for future events should be done with great care. References Gratton, C., Dobson, N. & Shibli, S. (2000). ## THE ONLINE MARKETING TOOLS USED BY HUNGARIAN FIRST DIVISION FOOTBALL CLUBS

Kajos, A., Prisztóka, G.

*University of Pécs - Faculty of Sciences - Institute of Sport Science and Physical Education*

**Introduction** We often here the phrase, that if you, your institution, your firm, your product etc. is not "on the internet" that it does not exist. This sentence is really hard to den in a world where the average internet penetration in Europe is over 70%, and a community called Facebook has over 890 million active daily users – and the number of monthly users exceeds 1, 39 billion – and where 280 million people send over 500 million tweets daily. Sport teams in Hungary still barely use online marketing tools. Since the teams' main income source is from government funding – i.e. through the income tax regulation system – the teams are not forced to use similar marketing tools as in other countries which also stands for online marketing tools as well. Current study investigates the online marketing tools used by Football teams playing in the Hungarian 1st Division (N=16). While the two main online marketing tools used by Hungarian sport teams and individuals are websites and Facebook pages, we intend to concentrate the content of these two marketing communication tools. Other online tools will be taken into consideration if this pilot study shows their significance. Research Questions RQ1: What types of online marketing tools 1st Division Football clubs use in General? RQ2: What types of communication tools (e.g., status update, video, links) are most frequently used on the teams' website? RQ3: How often the team shares information through its website and their Facebook site. RQ4: What types of communication tools (e.g., status update, video, link) are most frequently used on their website and Facebook site? RQ5: What types of information the 1st Division Football clubs shares on their website? RQ6: What types of information the 1st Division Football clubs shares on their Facebook page? RQ7: What are the factors differentiates the clubs from each other (city size, number of followers, region inside the country, other demographic factors) RQ8: How the followers of the teams Facebook page responds to differ-

ent types of contents? Methodology For answering RQ1, we search through the website of each clubs looking for links to other online marketing tools. In the cases of RQ2 to RQ8 we use content analysis methods. The coding of the categories and variables will done later in accordance of the content of the. The website and Facebook page will be followed for two consecutive weeks in March (the start of the spring season) and May. Expected Results While our research is just in the preparatory phase, we can just assume the predicted future results. We predict, that Football teams playing in the Hungarian 1st Division are not using online marketing tools as frequent and as effective as other western or eastern European teams playing in the similar Division of their country. Also the frequency and the following of the information will be lower as well. We believe that this is because of the governmental funding and the lack knowledge in online marketing.

### EFFECTIVENESS OF PROFESSIONAL HANDBALL CLUBS

Baráth, K., Géczi, G.

*University of Physical Education, Doctoral School*

Introduction In European handball most of the professional handball clubs are still operating as non-profit sport organization, however, they have a lot of profit-orientated issue as well. Today sports organizations are becoming more business-like (Gammelsæter, 2010) hence it is really important for the handball clubs to adapt to the more professional and commercialized sports world. Stakeholders and other agencies have interest in doing business within sports clubs (Smart, 2007), thus it is essential how sport results are realized besides different institutional logics, economic and organizational efficiency affected by commercialization. Different European professional handball clubs are influenced by globalization and commercialization in a different way. Even if clubs are non-profit sports organizations or operated by different kind of companies they may have mixed funding, operating system, and still not commercialized completely. "Commercial" is frequently translated as "for-profit" or "concerned with making money" (Westerbeek & Smith, 2003), but beside the background of frequent overspending and low profitability of European commercialized sport clubs, they are more likely moving from non-profit to "not-profit" form than to for-profit (Gammelsæter, 2010). The aim of this paper is to give a descriptive analyzes of globalization's and commercialization's effects on professional handball club management, organizational performance in Denmark, Hungary and Sweden, three powerhouses in European handball, in addition to determine the factors of high-level professional handball clubs' effectiveness (by cultural, organizational context; by professional and economic results). Methods The used methods were qualitative and quantitative to analyse the aspect of handball clubs and leagues. On the one hand in-depths interviews of the qualitative perspective were important to understand processes of the clubs and to describe the handball clubs' culture in question. On the other hand we used Data Envelopment Analysis (DEA) in order to define frontier efficiency in the selected countries, in addition to define the most efficient and interesting clubs for further selection and measurement. Results Essential difference were found between the clubs' efficiency, in addition similarities were found between the handball clubs' culture and institutional logics in the selected countries. ### OP-SH16 Physical Education & Pedagogics II

#### HUMAN PRACTISING IN PHYSICAL EDUCATION

Larsson, H.

*The Swedish School of Sport and Health Sciences*

'Learning and knowing' is a prominent theme in research on the school subject physical education (PE). In Sweden, this research goes hand in hand with debates around what learning and knowing could be about both in PE (Nyberg & Larsson, 2014; Quennerstedt & Larsson, 2015) and in PE teacher education (Backman & Larsson, 2014). In an attempt to broaden the scope concerning learning and knowing in PE practice, I will explore an alternative approach to the theme, namely human practising. My ambition is to outline the concept of practising (in Swedish: övning, att öva) as an analytical tool for exploring learning and knowing in PE. My overarching aim is hopefully to contribute to the discussion about the aim of PE in schools, what students are to learn (or know), i.e. what they might be practising during PE practice. In his book *You must change your life!*, German philosopher Peter Sloterdijk maintains that human beings are practising animals (Sloterdijk, 2013). In fact, "humans are beings that cannot not practise" (Sloterdijk, 2013, p. 407). Practising should not be confused with merely doing an activity or training a specific capacity of the organism. Rather, it means "any operation that provides or improves the actor's qualification for the next performance of the same operation, whether it is declared as practise or not" (Sloterdijk, 2013, p. 4). In short, human practising involves agency, effort, repetition and vertical tension between better or worse. Further, it always has a background, involves apprenticeship and is related to self-perfection. Even if practising appears to be a most obvious and basic aspect of human movement (humans need to practise even the most basic things such as standing, walking, running, etc.), it has hardly received any attention in the philosophy of sport and accounts of human activity in general. There can be many reasons for this. One could be that the precise nouns and verbs that describe this phenomenon in German (Übung/üben) and Scandinavian languages (öva, övning) easily lose their meaning when translated into the English noun practice or verb practise. This may have confused the active human activity of 'being practising' with merely taking part in social practices. In the presentation, I will use the concept human practising as outlined above in an analysis of some video excerpts from a previous project called "Physical education and health – a subject for learning?" ## INCLUSION WITHIN SWEDISH PHYSICAL EDUCATION? PROBLEMATIZING THE 'TEXT' SURROUNDING PHYSICAL EDUCATION AND THE EXPERIENCES OF IMMIGRANT YOUTH

Knez, K., Ekberg, J., Ericsson, I., Londos, M.

*Malmö University*

Introduction: Sweden has a relatively long history of immigration, despite recent local media rhetoric that would assume otherwise. Interestingly, Swedish government based data suggests that young people from an 'immigrant' background are less likely to be represented among the top 'scoring' students within physical education, and more likely to be over-represented among the lower 'scoring' students. Whilst such data can be problematic and reductive in nature, it also raises important questions surrounding the implementation of democratic practices within physical education in Sweden, which self identifies as a country that has a long and established history of inclusiveness and equality across all sectors of society. Aim: The aim of this presentation is to look beyond government-based statistics and to problematize the 'text', based on policy documents and academic literature within physical education and the experiences of immigrant youth surrounding physical education practice, with a focus on the Swedish context. Methodology: Postcolonialism provides a useful framework to 'borrow' from, through which to consider how Eurocentric ways of knowing have shaped the historical developments, curriculum documents and current (dominant) pedagogical practices within physical education. This will allow us to problematize the physical education experiences of immigrant youth as presented through government statistics. Discussion and Conclusion: While research has shown that Swedish curriculum has a strong focus on movement and physical activity participation, and that it is less competitive and performance based when compared to other countries, there still remains a discrepancy between policy and practice. Swedish based research continues to highlight a tendency for 'masculine' (and we would add 'western') ball based team sports to dominate physical education lessons. Furthermore, while the physical education experiences of young immigrants is considered within contemporary research, a dearth of literature remains that actually explores the meaning and place of physical activity and physical education in the lives of young immigrants, from the young people themselves. In a country that strives for equality across society, gender perspectives continue to dominate, and while important, it must be acknowledged that not all 'males' and 'females' experience their gender in the same way. It is through exploring and questioning dominant practices within physical education that allow for a more complex understanding of the experiences of young immigrants in physical education. This line of questioning opens up spaces for new possibilities and avenues through which to move towards a more sustainable democratic physical education for the future.

## DEVELOPMENT OF QUALITY PHYSICAL EDUCATION IN ASIAN SCHOOL – PERCEPTION AND ACHIEVEMENT

Ho, W.

*University of Macau*

Do not insert authors here Introduction The conference of UNESCO on the twenty-first of November 1978 in Paris adopted the International Charter on Physical Education with the purpose to place the teaching of physical education in school as the service of human progress due to its intrinsic value in education, social life and health development. Governments, competent non-governmental organizations, educators, families and individuals were urged to disseminate it and to put it into practice. It was almost thirty-five years after the implementation of the Charter and physical education experienced the gradual transformation from sport as a recreation into a formal subject in learning. For many countries, physical education is already the norm for practice in school education with equal academic status like the study of language, science, mathematics, arts, health and social studies. This specific nature yielded the interest to investigate its current status and conditions of work when there is a trend to call for quality improvement for education in school (Hardman, 2008, 2013). Methods This paper shared the research work on Quality Physical Education from 2011 to 2013. 10 Asian cities coming from High, Upper Middle and Lower Middle Income Groups were involved in the survey. Questionnaires were sent to physical education and sport professional with request to answer questions on three perspectives of "status and role of physical education", "educational elements" and "development of supportive features" and a return of N=782 were collected. Descriptive statistics, table means, pairwise mean comparison between cities and Post-Hoc Scheefe's test were used to present the observation. Results Data indicated a consistent pattern of high agreement on status and role, educational elements and supportive features but exhibited with cautious when questions were asked on the achievement of educational elements and supportive features. Regarding to the general trend of development for physical education, Lower Middle Income Group did not indicate "poor" performance when compared with the High and Upper Middle Income Groups. Discussion There is a common agreement on the provision of physical education in school. This common agreement seems to be universal and serves as fundamental principles in the improving works of physical education. Yet, it is essential to recognize the fact that quality support and educational development for physical education are necessary but not pre-requisite criteria for success. ## STUDENTS' MOTIVATION TOWARDS PHYSICAL EDUCATION: INDIVIDUAL, CLASS-LEVEL AND TEACHER-LEVEL FACTORS

Speleers, L., De Meyer, J., Haerens, L.

*University college Ghent*

Introduction As autonomous motivation (Deci & Ryan, 2000) leads to positive outcomes (Haerens et al., 2010), the main aim of this paper is to investigate the relationships between teacher-level factors, class-level factors and individual characteristics and students' motivation for PE. Methods Participants of this quantitative research were 1156 Flemish secondary school students. To define the type of motivation, the students filled in the BRPEQC (Aelterman et al, 2012). Teacher behaviour was measured by the TASCQ; individual and class-related factors were also measured through questionnaires. Results/Findings Individual factors explain most of the variance as well for autonomous motivation (86,21%), controlled motivation (93,65%) as for amotivation (92,97%). On the individual level, girls ( $\beta = -0.611$ ) and older teenagers ( $\beta = -0.082$ ) are less autonomous motivated. On the class level, pupils from vocational schools ( $\beta = 0.236$ ) are more amotivated, as well as pupils who emphasize the importance of the infrastructure ( $\beta = 0.062$ ), the topic ( $\beta = 0.117$ ) and the atmosphere in the class ( $\beta = 0.066$ ). On the teacher-level, pupil who perceive need support ( $\beta = 0.594$ ) are more autonomous motivated. Conclusion Differences in motivation towards physical education between students are more exhaustive than differences between classes or teachers. The importance of considering individual, class-level and teacher-level factors when explaining variance in motivation for PE is clearly exposed. This can give important guidelines to teachers and authorities. Discussion The importance of considering individual, class-level and teacher-level factors when explaining variance in motivation for PE is clearly exposed. Anyhow, we need to emphasize that these results

do not explain causalities or outcomes towards motivation. Contact lise.speleers@hogent.be

## INCLUSIVE PHYSICAL EDUCATION, WITH A FOCUS ON AUTONOMY, COMPETENCE AND RELATEDNESS

Rostboell, S., Oestergaard, C., Mouritzen, P., Hinrichsen, L., Piaster, T., Gade, K.

*Metropolitan University College*

In Denmark, a considerable percentage of children, e.g. girls with a migrant background, do not participate in physical activities, PA and are marginalized in physical education, PE lessons. Evaluation of PE in Danish schools shows that the causes of the pupils demotivation are lack of study plan, lack of participation and too much focus on competitive sports (Danmarks Evalueringsinstitut 2004, Von Seelen 2012). A school reform is currently being implemented in Denmark. The intention is to improve inclusive education and to enhance the academic standards for all pupils in the public schools. This study investigates girls' motivation for physical education. On the basis of the empirical findings, our study suggests a didactics, which enhances the pupils' activity rates and improve their participation in PE. The data analysis is inspired by Self Determination Theory, which is a motivational theory, containing three main categories: autonomy, competence and relatedness. Methods: The study focuses on the 6th and 7th grade and specifically on girls. The data consist of observations in 8 classes at two schools in socio-economic underprivileged areas and two schools in socio-economic privileged areas and focus group interviews, combined with in-depth interviews with 16 selected girls before and after a 7 weeks intervention in so called Inclusive PE. Results: The findings showed that the three categories from the Self Determination Theory are suitable for investigating motivation for PE. Significant in the study was the girls' feeling of the boys' dominance in PE in the ordinary PE lessons also in a Danish context. The interventions in inclusive PE in the classes focusing on 'autonomy', 'competence' and 'relatedness', showed that it increased the girls' motivation for PE, especially in the classes where the girls had a good relationship with the teacher. Furthermore, it was clear that the girls felt best in an environment characterized by helpfulness, cooperation and work in smaller groups. In the interviews, the girls pointed out the importance of knowing the goals of the teaching, variation in the activities and achieving specific skills. Discussion: A review of studies in PE using SDT conclude that it is not the content that matters for the children's feeling of motivation but the methods used and the teachers' way of giving response to the pupils (Berghe 2014). The present study reaches the same conclusion, but goes further in the suggestion of an inclusive didactics in PE focusing on all three categories in SDT. References Berghe, L. V. D., et al. ## FORMATION PROCESS OF STUDENTS' PERCEPTIONS OF PHYSICAL EDUCATION

Nakazawa, K.1, Nishihara, Y.2

1:UA, 2:NUHW

Introduction The basic goal of all health and physical education courses is to develop cognitive and social skills relative to the body and the overall self. Therefore, in designing such a class, great importance needs to be placed on teaching material selection and unit sequence. Furthermore, students' perceptions of such classes have gradually been recognized as important. The present study analyzes the processes by which students form such perceptions. Methods Subjects were freshmen (N = 126) enrolled in a university general physical education course. The course unit order was arranged thus: badminton, volleyball, and basketball. We asked the subjects to record simple notes after every class. At the end of the course, the students were allowed to refer to these notes to describe their thoughts, which were broken down into four categories: one per course unit and one labeled "throughout the whole course." We analyzed the documented responses via text mining. First, we examined the 20 most frequent words and identified 11 common to all four sections. Second, from a physical education perspective, we created eight codes similar to the most common words: 'educational materials,' 'collective cohesion,' 'play skill,' 'game,' 'interaction,' 'others,' 'self,' and 'positive emotion.' Third, we compared the frequency of codes across sections. Data were analyzed through cross tabulation and chi-squared tests. Results The frequency of 'education materials' ( $\chi^2 = 37.6$ ,  $p < .001$ ), 'collective cohesion' ( $\chi^2 = 18.7$ ,  $p < .001$ ), 'play skill' ( $\chi^2 = 6.5$ ,  $p < .005$ ), 'interaction' ( $\chi^2 = 11.6$ ,  $p < .001$ ), and 'others' ( $\chi^2 = 7.1$ ,  $p < .001$ ) significantly differed between the badminton and volleyball sections. The frequency of 'education materials' ( $\chi^2 = 32.0$ ,  $p < .001$ ), 'collective cohesion' ( $\chi^2 = 10.0$ ,  $p < .001$ ), 'play skill' ( $\chi^2 = 25.4$ ,  $p < .001$ ) differed between the badminton and basketball sections. The frequency of 'play skill' ( $\chi^2 = 5.9$ ,  $p < .005$ ), 'interaction' ( $\chi^2 = 15.4$ ,  $p < .001$ ), 'others' ( $\chi^2 = 5.8$ ,  $p < .005$ ) significantly differed between the volleyball and basketball sections. Discussion Eleven common elements were found between the segments that represented the students' reflection processes. For the volleyball course especially, enhanced team interactions had a significant effect on collective cohesion. Interaction was shown to be the foundation for effective play skill development. The 'positive emotion' identified in the overall evaluation of the course appeared to be in response to the unfolding of the overall teaching process. References Gallagher, J. (1994). #### IMPROVED CAPILLARY ULTRASTRUCTURE AFTER EXERCISE TRAINING IN PATIENTS WITH ESSENTIAL HYPERTENSION

Gliemann, L.1, Buess, R.2, Nyberg, M.1, Hoppeler, H.2, Odriozola, A.2, Thaning, P.3, Hellsten, Y.1, Baum, O.2, Mortensen, S.P.4

*University of Copenhagen*

1: NEXS (University of Copenhagen, Denmark), 2: Institute of Anatomy (University of Bern, Switzerland), 3: CMRC (Copenhagen, Denmark), 4: Department of Cardiovascular and Renal Research (University of Southern Denmark, Denmark) Introduction Essential hypertension is a major cardiovascular risk factor affecting approximately 1 billion people worldwide. The pathogenesis of essential hypertension is multifactorial and includes capillary rarefaction in various tissues, which may ultimately limit tissue oxygenation. However, little is known about skeletal muscle capillarization and capillary ultrastructure in essential hypertension and how this is affected by exercise training in man. Methods To investigate skeletal muscle angiogenesis and capillary ultrastructure in essential hypertension, muscle biopsies were obtained from m. vastus lateralis in essential hypertensive patients ( $183 \pm 7/101 \pm 5$  mmHg;  $n=10$ ) and normotensive controls ( $142 \pm 5/74 \pm 3$  mmHg;  $n=11$ ) before and after 8 weeks of aerobic exercise training. Morphometry was performed after transmission electron microscopy and protein levels of several angioregulatory factors were determined. Results At baseline, capillary density and capillary-fiber-ratio were not different between the two groups. However, hypertensive patients had 9% lower capillary area ( $12.7 \pm 0.4$  vs.  $13.9 \pm 0.2 \mu\text{m}^2$ ) and tended to have thicker capillary basement membranes ( $399 \pm 16$  vs.  $358 \pm 13$  nm;  $P=0.094$ ) than controls. Protein expression of vascular endothelial growth factor (VEGF), VEGF receptor-2 and thrombospondin-1 were similar in normo- and hypertensive subjects but tissue inhibitor of matrix metalloproteinase was 69% lower in the hypertensive group. After training, angiogenesis was evident by 15% increased capillary-to-fiber ratio in the hypertensive patients only. Capillary area and capillary lumen area were increased by 7% and 15% in the hypertensive patients whereas capillary basement membrane thickness was decreased by 17%. VEGF expression after training was increased in both groups whereas VEGF receptor-2 was decreased by 25% in the hypertensive patients. Discussion Essential hypertension is associated with decreased lumen area and a tendency for increased basement membrane thickening in capillaries of skeletal muscle. Exercise training appears to improve the diffusion conditions in essential hypertension by altering capillary structure as well as capillary number. These data adds to the understanding of the pathogenesis of essential hypertension at the microvascular level and suggest that, in pathological conditions where capillary ultrastructure is affected, exercise training could be a novel therapeutic intervention for normalizing capillary morphology in hypertension. Contact gliemann@nexs.ku.dk

#### RESPONSES TO AN ISOMETRIC LEG-EXERCISE TEST PREDICTS SEX-SPECIFIC TRAINING-INDUCED REDUCTIONS IN RESTING BLOOD PRESSURE AFTER ISOMETRIC LEG TRAINING

Baross, A.1, Milne, K.2, McGowan, C.2, Swaine, I.3

*1: Sport and Exercise Science, UON (UK), 2: Department of Kinesiology, University of Windsor, (Canada), 3: Sport and Exercise Science, CCCU (UK)*

Introduction Isometric training, using either isometric handgrip (IHG) or isometric bilateral-leg (IBL) protocols, is an effective method of lowering resting systolic blood pressure (SBPrest). However, the reductions in SBPrest seen after training vary widely between individuals. Predicting likely training-induced reductions in SBPrest could make it possible to optimise the effects of the training in all participants. It is known that post-IHG training reductions in SBPrest can be predicted by SBP responses to a 2 minute IHG task in both hypertensive and older normotensives (Millar et al., 2009; Badrov et al., 2013). However, the predictability of such a test in younger individuals and when using a comparable IBL task, has not been established. Furthermore, it is not known whether these simple isometric tests can predict reductions in ambulatory SBP (mean 24-hour, SBPamb) as well as SBPrest. Therefore, the purpose of this study was to determine whether an IBL test can be used to predict training-induced reductions in SBPrest and SBPamb following 10 weeks of IBL training in young men and women. Methods Resting and ambulatory BP (SBPrest and SBPamb) were measured prior to and following 10 weeks of IBL training using an isokinetic dynamometer (4, 2-minute contractions at 20% MVC with 2 minute rest periods, 3/week) in 20 normotensive individuals (10 men, age= $21 \pm 4$  years; 10 women, age= $23 \pm 5$  years). SBP responses to the IBL test (single 2-minute period of IBL exercise) was derived by calculating the difference between peak SBP and mean baseline SBPrest. Pearson's product moment correlation coefficient was used to assess the relationship between the blood pressure responses to a short 2-minute IBL test and the magnitude of the reductions in SBPrest and SBPamb after IBL training. Results There were significant reductions in men and women's SBPrest ( $7.0 \pm 4.8$  mmHg,  $p=0.0001$  &  $5.7 \pm 4.1$  mmHg,  $p=0.001$ ) and SBPamb ( $4.0 \pm 1.9$  mmHg,  $p=0.011$  &  $6.1 \pm 4.1$  mmHg,  $p=0.0001$ ) following training. These changes in SBPrest were strongly correlated with pre-training SBP response to the IBL test in both men ( $r=-0.83$ ,  $p=0.003$ ,  $SEE=3.03$ ) and women ( $r=-0.81$ ,  $p=0.004$ ,  $SEE=2.56$ ). However, the magnitude of the reductions in SBPamb were not correlated with SBP response to the IBL test (men,  $r=-0.44$ ,  $p=0.199$ ,  $SEE=1.76$ ; women,  $r=-0.23$ ,  $p=0.517$ ,  $SEE=6.01$ ). Discussion These results support previous research which has identified that IBL training is an effective tool for lowering both resting and ambulatory BP. Furthermore, a simple isometric exercise test can be used as a tool to predict reductions in resting SBP, but not ambulatory SBP, after IBL training in both men and women. This test could be used to optimise the effects of this type of training in a wider range of participants, perhaps through modification of the training, to suit the anticipated effects in different individuals. #### THE MECHANISM OF EXERCISE LIMITATION IN ILIOFEMORAL VEIN OBSTRUCTION POST-DVT

Reuveny, R., Segel, J.M., Luboshitz, J., Shlomi, D., Ben-Dov, I.

*Pulmonary Institute & The Israeli National Hemophilia Center, Sheba Medical Center, Tel-HaShomer, and the Department of Physical Therapy, University of Haifa*

Hypothesis and Aim: In a previous study, we showed that iliofemoral Vein Obstruction after deep vein thrombosis (DVT) resulted in reduced lower limb exercise capacity. In this study, we investigated the mechanism involved in reduced exercise capacity in post-DVT patients. Methods: Upper and lower exercise capacity were assessed by bimodality incremental symptom-limited cardiopulmonary exercise testing using leg or arm cycle ergometers. Subjects were 7 post-DVT patients with residual iliofemoral vein obstruction; controls

were 8 healthy volunteers. Leg vein obstruction was modelled by application of cuff tourniquets, inflated to 30mmHg, to the thighs of healthy controls. Results were median (range). Results: The ratio between upper and lower limb  $\dot{V}O_2$  peak was elevated in the post-DVT group, 1.14 (0.77-1.43) versus 0.71 (0.60-1.00) in controls ( $p < 0.003$ ), indicating that in post-DVT lower body exercise capacity is reduced while upper body exercise capacity is preserved.  $\dot{V}CO_2/WR$  slope was higher in the healthy group - median 13.6 ml/watt/min (range: 12.9-16.3) than in the post-DVT group - median 12 ml/watt/min (range: 7.1-15.5) ( $p = 0.029$ ), with no difference in  $\dot{V}O_2/WR$  slope. In controls, bilateral leg vein obstruction by application of tourniquets reduced peak  $\dot{V}O_2$  in leg exercise to 73% predicted (55-106%) vs 89% (77-130%) in the standard test,  $p < 0.05$ .  $\dot{V}CO_2/WR$  slope was higher in the standard test -13.6 ml/watt/min (range: 12.9-16.3) than the 2-tourniquet test - median 12.1 (range: 10.9-14.7),  $p = 0.036$ . The decrease of  $\dot{V}CO_2$  from peak exercise to 1' recovery was faster in the standard test - median 847 ml/min (range: 570-1479) compared to 680 (147-909) in the two tourniquet test ( $p < 0.025$ ) Conclusions: The comparison of exercise capacity in arm versus leg exercise suggests that reduced exercise capacity in post-DVT patients with venous obstruction may be caused by reduced venous return to the heart due to venous pooling. In post-DVT patients and in the experimental venous obstruction (thigh tourniquet) healthy control group, the slower  $\dot{V}CO_2$  kinetic in recovery and the reduced  $\dot{V}CO_2/WR$  slope may suggest a sluggish removal of  $CO_2$  from exercise muscle. This may result in an increase in localized acidosis in the muscles that may contribute to exercise limitation in post-DVT patients. These mechanisms may contribute to the pathophysiology of the reduced exercise capacity in post-DVT patients with venous obstruction.

### **BREAKING UP PROLONGED SITTING TIME WITH LIGHT INTENSITY PHYSICAL ACTIVITY BREAKS DOES NOT IMPACT BRACHIAL ARTERY ENDOTHELIAL FUNCTION**

Hopkins, N., Jones, H.

*Liverpool John Moores University*

Background: Prolonged periods of uninterrupted sitting cause an acute reduction in endothelial function [1]. Similarly, endothelial function is reduced following ingestion of a high fat meal (HFM) [2]. The cumulative effects of these behaviours is such that a significant proportion of life may be spent in a state of endothelial impairment. Recent evidence suggests regular light intensity physical activity (LPA) can offset the decline in endothelial function associated with prolonged sitting, however the effects of LPA breaks on postprandial sitting is unknown. The aim of the current study was to investigate the impact of regular LPA breaks from sitting on endothelial function, following ingestion of a HFM. Study Design and methods: Fifteen young, healthy males (21±1yrs, BMI 24±3 kg/m<sup>2</sup>) participated in a three-trial repeated measures experiment. In each trial participants ingested a HFM (1000kcal, 52g fat), followed by 30 minutes of seated rest. Participants then undertook, in a randomised order on different days, 4 hours of: continuous sitting; continuous standing; or sitting with 2-min bout of self-selected, light intensity treadmill walking (5.1±0.4 km•h<sup>-1</sup>) every 30-min. Brachial artery endothelial function was assessed via flow mediated dilation (FMD) prior to HFM (PRE), 30-min after consumption of HFM (POST1), after completion of 2-hrs of the trial (POST2hr), and on completion of the 4 hour trial (POST4hr). Data were analysed using mixed linear modelling and are presented as mean±SD. Results: There was no change in FMD over time (PRE: 7.36±0.91%, POST1: 7.73±0.69%, POST2hr: 6.99±0.24%, POST4hr: 7.02±0.64%,  $P = 0.338$ ), or in response to the trials ( $P = 0.240$ ). Furthermore no interaction between condition and time were evident for FMD ( $P = 0.379$ ). Discussion: A period of 4 hours continuous sitting, following a HFM had no effect on brachial artery endothelial function in young, healthy males. Interrupting post prandial continuous sitting with regular, light activity breaks had no additional effects on brachial artery endothelial function. Recent findings [1] indicate that femoral artery FMD is attenuated after acute, prolonged sitting, our data implies that these negative vascular effects may not be present systemically. 1. ### **EFFECT OF INFLAMMATION AND VITAMIN D ON HANDGRIP STRENGTH IN NON-INSTITUTIONALIZED OLDER ADULTS.**

Camões, M.

*School of Sports and Leisure, Polytechnic Institute of Viana do Castelo, Portugal*

Introduction: Inflammation has been suggested to affect skeletal muscle metabolism and low levels of 25-hydroxyvitamin D (25(OH)D) are commonly associated with impaired muscle strength. We investigated the associations of high-sensitivity C-reactive protein (hs-CRP), as an indicator of acute inflammation, and serum 25(OH)D levels with maximal isometric handgrip strength, in non-institutionalized older adults. Methods: Study conducted among a sub-sample of 91 non-institutionalized older adults (77% female; aged 70-94 years), randomly recruited from a total sample of 1338 subjects from Viana do Castelo region, north of Portugal. Handgrip strength was measured using a hydraulic hand dynamometer (SH5001, SAEHAN Corporation), according to the American Society of Hand Therapists (Fess EE., 1992). Hs-CRP was measured with immunoturbidimetric assay and 25(OH)D serum levels were determined by immunochemiluminescent assay in the end of the summer season (October-November 2014). Generalized linear models were used to analyse the independent associations of hs-CRP and 25(OH)D, with handgrip muscle strength (Kg). Results: After adjustment for age, gender and BMI, high hs-CRP was an independent predictor of lower levels of grip strength (right hand:  $\beta$  (95%CI)=-0.31 (-0.55; -0.07); left hand (95%CI):  $\beta$ =-0.30 (-0.53; -0.07)). In the opposite way, 25(OH)D levels were positively associated with higher levels of muscle strength (right hand:  $\beta$ (95%CI)=0.16 (0.06-0.10); left hand:  $\beta$  (95%CI)= 0.15 (0.06-0.25)). Additionally, we found a high prevalence of vitamin D deficiency and insufficiency (78% deficient: <20ng/ml; 96% insufficient: <30ng/ml), although samples were obtained in the end of the summer season. Conclusions: Our data demonstrate the independent association between inflammation and handgrip strength in non-institutionalized older adults. If not corrected, reduced strength may have implications in the functional status, morbidity and mortality risk. Also, the high prevalence of vitamin D insufficiency and deficiency, even in the post-summer season, and its associations with poor muscle strength, suggests the need to implement strategies to normalize vitamin D levels among these individuals. Acknowledgments: This study was supported by Fundação para a Ciência e a Tecnologia [Ref.: PTDC/DTP-DES/0209/2012].

#### EFFECTS OF BODY POSITION ON FORCE EXERTED DURING SUSPENSION TRAINING

Cortis, C.1, Varalda, C.2, Ferrari, M.2, Di Cecio, F.1, Cacchiani, M.1, Fusco, A.1, Giancotti, G.F.1, Capranica, L.3

1 University of Cassino e Lazio Meridionale, Italy; 2 Italian Weightlifting Federation FIPE, Rome, Italy; 3 University of Rome Foro Italico, Italy

Introduction Suspension training (ST) has become a popular form of bodyweight resistance training, eliciting higher muscle activations with respect to traditional exercises due to muscle activity used to maintain body stability and balance (McGill et al 2014; Snarr et al 2014). The load applied on upper and lower body can be modified by moving the center of mass outside of the base of support by changes in straps length and/or feet placement. Therefore, the aim of this study is to evaluate the effects of different body positions on force exerted on upper and lower body during a static push-up position performed on a ST device. Methods After giving his informed consent of participation, a highly experienced (i.e., 5 years) ST instructor (age 48years; height 186cm; weight 78kg) performed 12 isometric (upper limbs extended and flexed at 90°) push-up positions with different straps lengths according to the individual body height (SL%). A force plate (Twin Plates Globus, Treviso, Italy) and a piezoelectric force transducer (ISO Control Globus, Treviso, Italy) were used to evaluate the ground force (LBF) and that applied to ST (AinS Suspension Training System FIPE, Rome, Italy) device (UBF), respectively. Video recordings were analyzed to verify body alignment and to calculate body inclination (BI). Pearson correlation ascertained the relationship ( $p < 0.05$ ) between BI, SL%, LBF, UBF and total force (TF=LBF+UBF). Results Regardless of upper limbs position, high correlations ( $p < 0.0001$ ) between variables emerged. UBF (mean=41.7±10.5kg, range=20.0-53.9kg) was highly related to LBF ( $r = -0.996$ ; mean=49.1±7.1kg, range=40.6-64.0kg), BI ( $r = -0.980$ ; mean=31.6±14.2°, range=17.0-62.9°), and SL% ( $r = 0.907$ ; mean=146.4±25.0%, range=100-163%). LBF and TF (mean=90.8±3.5kg, range=84.0-95.8kg) were highly related to BI (LBF:  $r = 0.983$ ; TF:  $r = -0.952$ ) and SL% (LBF:  $r = -0.901$ ; TF:  $r = 0.897$ ). Discussion Body position is highly related with increased load on upper body. In particular, TF tends to increase towards horizontal positions, substantiating a greater muscle activation to maintain body stability (McGill et al 2014). Therefore, body position should be modified during ST to guarantee load progression and effects on strength gain comparable to traditional resistance training (Matè-Munoz et al 2014; Janot et al 2013). #### IS THE MUSCLE LAB FORCE-VELOCITY LINEAR ENCODER ABLE TO DETECT DIURNAL VARIATION IN MUSCLE FORCE OUTPUT?

Robertson, C., Robinson, W., Smith, M., Burniston, J., Atkinson, G., Waterhouse, J., Edwards, B.J.

University of Bolton

Humans are biologically weaker in the morning than the evening whilst there is convincing evidence to support both time-of-day variation of muscle force output using isokinetic and isometric methods. It is yet to be established for complex multi-joint methods used in applied practice. Therefore, the aim of this study was to assess whether the Muscle Lab force-velocity linear encoder (Ergotest version 4010, Norway), would be able to detect diurnal variation in multi-joint muscle force output. Thirty strength trained males (mean±SD: age 21.7±1.4yrs; body mass 80.5±4.5kg; height 1.8±0.1m) volunteered and were familiarized (where 1 RM was tested to ensure that the planned working loads would be well within each participant's physical ability) before completing 2 sessions at 09:00 and 17:00h (separated by 72h) counterbalanced in order of administration. Each trial involved a resting phase, 5-min cycling at 150W, then the participants performed either back squat or bench press (or vice versa) in a randomised order. Three lifts at each exercise were completed against progressively increasing loads (back squat: 20, 40 and 60kg; bench press: 30, 50 and 70kg), with 5-min rest between each lift. For back squat, the linear encoder was attached to an Eleiko Olympic bar (20kg) which was set upon rests within a standard squat rack so that the participant had a 90° knee flexion position. From this position, the participant was instructed to drive the bar upwards as forcefully as possible; the value recorded during the test was for the concentric phase of the action only. The Muscle Lab system measured both the average force produced, the peak velocity and time-to-peak velocity for each individual lift. For the bench press, the bar was set so that it rested just above (~2.5cm) the participant's chest and, again, the instruction given was to push against the bar as forcefully as possible. Rectal temperatures, ratings of perceived exertion, thermal comfort and perceived effort were measured at rest, following warm-up and after the efforts. Data were analysed by GLM with repeated measures. Trec, values were higher in the evening than the morning (~0.61°C;  $P < 0.05$ ). Bench press and back squat first and last load values showed a time of day effect with average force, peak velocity being higher in the evening and time to peak velocity lower in the evening respectively (2.2, 10.5 and 8.9%, respectively). The subjects' ratings of 'thermal comfort', 'rating of perceived exertion' and 'effort' was no different between conditions ( $P > 0.05$ ). The main finding of this study was that the Muscle Lab linear encoder is capable of detecting a daily variation of muscle force output when used with multi-joint exercises (back squat and bench press) which better resemble athletic performance. This means that the results provide more immediate translation to muscle force output both in the development of athletic ability and in their application to the demands of sport.

#### COLD WATER IMMERSION ATTENUATES PERFORMANCE INCREASES AND PROMOTES FAT LOSS FOLLOWING RESISTANCE TRAINING

Petersen, A., Broatch, J., Argus, C., Polman, R., Halson, S., Bishop, D.

Victoria University

Recently, a large body of research has focused on modalities designed to hasten the recovery process, with one of the most common techniques being cold water immersion (CWI). Several studies have shown beneficial effects of CWI on recovery following a single exercise bout, however the effects of repeated CWI exposure on adaptations to exercise training are unclear. We therefore investigated the effects of CWI on body composition and performance adaptations to a resistance training program. Sixteen non-resistance trained males completed a resistance training program 3d/wk for 7 weeks. Participants were randomly allocated to CWI (10°C water) or CON (23°C room air) recovery interventions for 15 minutes, which they performed immediately following each workout. CON and CWI groups were matched for age (mean±S.D. 25.0±4.9, 20.9±3.4 years), body mass (89.2±22.7, 81.0±11.4 kg), height (1.84±0.06, 1.80±0.08 m), and chest press one-repetition maximum (1RM, 79.5±17.2, 75.6±16.0 kg). Body composition (DXA), strength (chest press and leg press 1RM), and peak force (counter-movement jump, squat jump, explosive push-up) were measured pre- and post-training. Thigh muscle temperature

was measured during the recovery intervention via an indwelling needle probe inserted 3 cm below the skin. During the recovery intervention muscle temperature decreased by  $2.48 \pm 1.30^\circ\text{C}$  in CWI and  $0.51 \pm 0.19^\circ\text{C}$  in CON ( $p < 0.05$ ). Peak force during a squat jump or explosive push-up did not change as a result of training. CWI had no effect on training induced increases in whole body lean mass, chest press 1RM, or leg press 1RM, however CWI prevented the training induced increase in peak force during a counter-movement jump (CON  $98 \pm 102$  N,  $p < 0.05$ ; CWI  $-62 \pm 103$  N,  $p = 0.13$ ). CWI also caused a decrease in whole body fat mass ( $-12.4 \pm 8.6\%$ ,  $p < 0.05$ ) whereas there was no reduction in CON ( $-4.1 \pm 10.6\%$ ,  $p = 0.10$ ). These results suggest that repeated CWI attenuates some performance adaptations to resistance training, but also causes favourable decreases in fat mass.

### **HEAVY "HYPERTROPHIC" RESISTANCE TRAINING DOES NOT INDUCE IMPROVEMENTS IN RAPID FORCE PRODUCTION IN HEALTHY OLDER MEN**

Walker, S.

*University of Jyväskylä*

**INTRODUCTION** Improving both maximum and rapid force production, as well as increasing muscle mass from the same training program is an attractive model for older adults to counteract the age-related decline in muscle function and size. However, it is unclear whether improved muscle activation during maximum force production (Walker & Häkkinen 2014) will transfer to improved rapid force production. The present study was carried out to determine whether it is possible to use hypertrophic resistance training alone to improve both maximum and rapid force production in untrained older men. **METHODS** Older men (60-72 yr) performed 20 weeks of "hypertrophic" resistance training twice weekly ( $n = 27$ ) or acted as a non-training control ( $n = 11$ ). Training consisted of 2-4 sets per exercise and 8-14 repetitions per set with 1-2 min inter-set rest. Lifting tempo was 2s concentric and 2s eccentric contractions. Maximum dynamic (1RM) and isometric leg press force, as well as isometric force over 0-100ms and maximum concentric power (using 50%1RM) was measured pre- and post-intervention. Surface electromyogram of the vastus lateralis (VL) and medialis (VM) muscles assessed muscle activity during these tests. Panoramic ultrasound assessed VL muscle cross-sectional area (CSA). **RESULTS** The intervention group increased their maximum isometric and dynamic force production and the changes were significantly different to control (isometric:  $12 \pm 16$  vs.  $1 \pm 9\%$ ; dynamic:  $21 \pm 12$  vs.  $2 \pm 4\%$ ). No within- or between-group differences were observed in rapid isometric force or concentric power. Increases in maximal muscle activity were greater in the intervention group than control during maximum force production only. Muscle activity during rapid force or concentric power tests did not change. Relative increases in VL CSA trended to be statistically greater in the intervention group ( $10 \pm 8$  vs.  $3 \pm 6\%$ ,  $P = 0.06$ ). **DISCUSSION** Although the present training program improved maximum force production accompanied by increased maximal muscle activity and VL CSA, the gains did not transfer over to rapid force production or muscle activity. These results support training-specific adaptations and that the intention to perform fast contractions may be critical to improve rapid force production (Behm & Sale 1993). This study provides important information for training of older individuals and it is recommended to incorporate rapid force contractions (Häkkinen et al. 1998) into training programs for this population. **REFERENCES** Behm DG, Sale DG. ### **COMBINED PLYOMETRIC AND STRENGTH TRAINING IS SUPERIOR TO ONLY STRENGTH TRAINING ON ON-ICE SPRINT PERFORMANCE, IN NORWEGIAN U18 AND U20 ICE HOCKEY PLAYERS.**

Dæhlin, T.E., Haugen, O.C., Haugerud, S., Raastad, T., Rønnestad, B.R.

*Lillehammer University College*

**Background:** Ice hockey is a sport characterized by short and frequent maximal sprints, intermitted by full stops (Montgomery, 1988, Twist and Rhodes, 1993). Due to a long season, ways to optimize on-ice sprint performance with the use of off-ice training has become an attractive field of research. Indeed, the use of plyometric exercises to improve on-ice qualities in ice hockey players has been suggested (Behm et al., 2005, Farlinger et al., 2007), but the effect of plyometric training on on-ice sprint performance is yet to be investigated. **Purpose:** The purpose of this study was to investigate whether combined plyometric and traditional strength training have a positive effect on ice hockey players' on-ice sprinting performance, when compared to traditional strength training alone. **Methods:** 16 subjects were randomly assigned to two groups. Both groups completed 5 traditional strength-training sessions per week for 8 weeks. In addition the intervention group preceded 3 of the sessions with plyometric exercises (PLY+ST), while the control group succeeded the same 3 sessions with core/stability exercises (ST). Tests of 10- and 35 meter on-ice sprint, horizontal jumping performance, 1RM squat, skating multistage aerobic test (SMAT), maximal oxygen consumption,  $10 \times 35$  sec cycling sprints and dual x-ray energy absorptometry (DEXA) was conducted before and after the intervention to assess within-group and between-group differences. **Results:** 1RM squat, fat free mass and body mass increased significantly in both groups, while maximal oxygen consumption decreased significantly in both groups ( $p < 0.05$ ). In addition, PLY+ST improved their 10 meter on-ice sprint,  $3 \times$  broad jump and  $10 \times 35$  sec cycling sprint performance significantly, while ST improved their SMAT result significantly. Significant between-group difference was only found in 10-meter on-ice sprint performance ( $p < 0.025$ ; Cohen's  $d = 1.11$ ). **Conclusion:** Combining plyometric and traditional resistance training seems to have a greater positive effect on 10-meter on-ice sprint performance than traditional resistance training alone. **BEHM, D. ### **EFFECTS OF RESISTANCE TRAINING WITH NONLINEAR PERIODIZATION ON CYTOKINES AND INSULIN RESISTANCE IN MEN WHO ARE MIDDLE-AGED AND OBESE**

Nikseresht, M.

*Ilam Branch, Islamic Azad University, Ilam, Iran*

**Introduction** The study examined the effects of 3 months of the nonlinear resistance training (NRT) on serum levels of interleukin-6 (IL-6), IL-10, IL-17A, IL-20, insulin resistance, aerobic capacity and body composition in men who are middle-aged and obese. An additional aim was to determine possible associations between training-induced alterations of these cytokines and alterations of insulin resistance, aerobic capacity and body composition. **Methods** Obese men first were matched by aerobic capacity, age and percentage body fat and

then randomly assigned to NRT (n = 12) and control (CON, n = 10) groups. An age and physical activity matched control group of lean men (n = 11) were also recruited for baseline comparison. The NRT consisted of 40-65 minutes of weight training at different intensities with flexible periodization, 3 weekly sessions for 3 months (Nikseresht et al., 2014). Measures of serum cytokines, insulin resistance, body composition and aerobic capacity were obtained before and after the 12 weeks. Results At baseline, obese participants had significantly lower IL-20 and higher IL-10 than lean participants (P = 0.007 and P = 0.02, respectively), and there were negative correlations between IL-20 and each of body weight, percentage body fat, fat mass and waist circumference, but positive correlations between IL-10 and these variables (P < 0.05). Also, there were inverse correlations between insulin resistance and each of IL-10 and IL-20 at baseline (P < 0.05). After training, aerobic capacity increased significantly in NRT compared with CON (P = 0.001), which was accompanied by significant reductions in percentage body fat, waist circumference, fat mass, insulin and insulin resistance (P < 0.05). Serum IL-6 and IL-17A concentrations did not change significantly in response to training (P > 0.05), but IL-10 and IL-20 were significantly increased in the NRT when compared to the baseline level (P < 0.05). After training, changes in IL-20 concentration was negatively correlated with alterations in waist circumference (r = -0.69, P = 0.02), whereas increment in IL-10 after NRT was independent of changes in the anthropometry variables. Discussion According to this findings, it seems that the obesity induces are main factors for regulation of IL-10 and IL-20 levels. Also, the lack of significant differences for IL-6 and IL-17A between the obese and lean subjects might be due to the similar status in general health and aerobic capacity. The inverse relationship between insulin resistance and both IL-10 and IL-20 levels suggests a similar regulating role for these two cytokines. Thus, elevated IL-10 and IL-20 in men who are obese may have a compensatory role the underlying inflammation of obesity. Also, regarding the inverse relationship between IL-20 and waist circumference, it can be proposed that increased IL-20 is a positive adaptation with a likely protective role against atherosclerosis and insulin resistance. ### OP-PM24 Physiology: Hormonal biology & Gender

#### RESPONSES OF CARDIAC AUTONOMIC NERVOUS ACTIVITY, STRESS HORMONES AND PROFILE OF MOOD STATE ON DIFFERENT TRAINING PERIODS OF ELITE CROSS-COUNTRY SKIERS

Schäfer, D.1, Solberg, E.E.2, Gjerdalen, G.F.3, Herzig, D.1, Trachsel, L.1, Noack, P.4, Eser, P.1, Saner, H.1, Wilhelm, M.1

1: Preventive Cardiology and Sports Medicine, Inselspital 2: Diakonhjemmet Sykehus 3: Section of Vascular Investigations, Oslo University Hospital; Bjorknes College, 4: Swiss Olympic Medical Base

Introduction Measuring stress in athletes is important in order to improve performance and prevent overtraining. Currently, several markers are used to monitor athletes' stress condition, but none of them have been accepted for general use. We aimed to investigate the effect of various training periods (TPs) of a cross-country skiing season on cardiac autonomic nervous activity measured by heart rate variability (HRV), stress hormones and profile of mood state (POMS) and to assess correlations between these stress markers. Methods Participants were tested during 4 different TPs of a one-year cross-country skiing season (after recovery period (RP), at the end of preparation period 1 (P1), at the end of preparation period 2 (P2) and during competition period (CP)). Urine and saliva samples were collected in the morning after waking up. Afterwards, athletes went to the lab to measure HRV in supine position and after orthostatic challenge and to answer the POMS questionnaire. Urine was analysed for adrenaline and noradrenaline concentration while saliva was analysed for cortisol and testosterone concentration. Time-domain HRV parameters were calculated. The German short-version of the POMS was used in the Swiss athletes. Time effects were analysed using repeated measures ANOVA or Friedman tests, as appropriate. Chi-square tests were used to evaluate the association in changes of the measured parameters between TPs. Results Female (n=13, 27.31±2.50 years, VO<sub>2</sub>max 62.31±5.50 ml·kg<sup>-1</sup>·min<sup>-1</sup>) and male (n=18, 22.89±4.61 years, VO<sub>2</sub>max 75.63±6.34 ml·kg<sup>-1</sup>·min<sup>-1</sup>) elite cross-country skiers from Norway (n= 14) and Switzerland (n=17) were included. HRV parameters as well as salivary cortisol and testosterone did not change between different TPs. Of the catecholamines, only adrenaline showed a significant change over time (p<0.05), with significant differences between the RP and CP [median (interquartile range): 9(34) vs. 5 (6) nmol/l and P1 and CP 17 (35) vs. 5 (6) nmol/l. There were no consistent associations between HRV parameters and catecholamines, cortisol and testosterone over the various TPs. Discussion The time pattern of adrenaline was unexpected and may be coincidental. Our results indicate that elite cross-country skiers did not experience periods of higher stress during a whole season. Moreover, we have not found any associations between HRV and cortisol, testosterone, catecholamines and the German version of the POMS.

#### THE EFFECTS OF MENSTRUAL CYCLE PHASE ON THE INCIDENCE OF PLATEAU AT VO<sub>2</sub>MAX

Gordon, D.1, Scruton, A.1, Barnes, R.2, Baker, J.1, Merzbach, V.1

1Anglia Ruskin University UK 2University of Cambridge UK

Introduction The primary determinant of a maximal effort during a VO<sub>2</sub>max, is the manifestation of a plateau in VO<sub>2</sub> despite a continued increase in exercise intensity. Wide variations are reported in incidence with size and availability of the finite anaerobic capacity (AnC) proposed as the discriminating factor between responders and non-responders. A potential confounding variable in plateau generation in female participants are the metabolic and hormonal fluctuations associated with the menstrual cycle. Therefore the purpose of this study was to assess the incidence of plateau at VO<sub>2</sub>max during the stages of the menstrual cycle in a group of physically active participants. Methods 16 physically active participants, n=10 formed the non-oral contraceptive group (n-OC) (age 20.6 ± 1.6 yrs, height 169.9 ± 6.4cm, mass 68.7 ± 7.9kg) displaying regular menstrual function. Remaining 6 participants formed the oral-contraceptive control group (OC) (age 21.7yrs ± 2.16, height 168.1cm ± 6.8cm, mass 61.6kg ± 6.8kg). All reported to the laboratory on 5 separate occasions for the determination of VO<sub>2</sub>max. All trials completed on an electronically braked cycle ergometer (60-80 rpm), work-rate increasing by 0.42 W/s, plateau responses were determined using the criteria of ΔVO<sub>2</sub> <1.5 ml/kg/min. Four of the visits corresponded to menstruation (MEN), mid-follicular (mFOL), mid-luteal (mLUT) and pre-menstrual (pMEN), with the 5th a familiarization trial. OC trials were completed according to a pseudo menstrual cycle. Also recorded for the n-OC were progesterone and 17β-oestradiol. Results The ΔVO<sub>2</sub> (ml/kg/min) during the final 60 s of the incremental test for the n-OC were 0.86 ± 0.72, 1.62 ± 1.48, 1.19 ± 1.24 and 1.39 ± 1.09 for MEN, mFOL, mLUT and pMEN respectively. For the OC group the ΔVO<sub>2</sub> response for the pseudo phases were 1.46 ± 1.52 (MEN), 2.68 ± 0.28 (mFOL), 3.07 ± 1.09 (mLUT) and 2.95 ± 0.84 (pMEN). Non-significant differences were observed between phases within OC and n-OC (p > 0.05). Signifi-

cant differences witnessed for number of plateau responders between OC and n-OC for MEN, mLUT and pMEN ( $p < 0.0001$ ). Non-significant differences observed between groups and phase for VO<sub>2</sub>max, GET exercise time to exhaustion and HRmax ( $p > 0.05$ ). Discussion Data suggest the plateau in VO<sub>2</sub> during a VO<sub>2</sub>max is not affected by the phase of the menstrual cycle, of note was the significant impact on plateau response in the OC group. This is in agreement with previous work suggesting maintenance of the female sex-hormones may spare carbohydrate availability by promoting FFA metabolism reducing the availability of energy from substrate level glycolysis. ### COMPARISON BETWEEN MUSCLE ACTIVITY AND BLADDER MOVEMENT DURING VAGINAL PRESSURE CHANGE IN PAROUS WOMEN

Kim, H.

*Kyungnam University*

(Abstract) This study was conducted to compare the activity of the abdominal and adductor muscles with the bladder base movement using transabdominal ultrasound during pelvic floor contraction between subjects who had given birth and who had not, and between subjects in various age groups. The subjects comprised 50 female adults. Classified according to the frequency of their maternal delivery and age, 17 subjects were nonparous women in their 20s and 30s (Group 1); 16 subjects were parous women in their 20s and 30s (Group 2); 17 subjects were parous women in their 40s and 50s (Group 3). All the childbirths of the parous women were vaginal deliveries. For the measurement of the contraction of the pelvic floor muscle, a vaginal pressure probe was inserted into the vagina, and the measurement was performed three times: at 10mmH<sub>2</sub>O, at 20mmH<sub>2</sub>O, and at maximum contraction. The muscle activities of the rectus abdominal muscle, external oblique abdominal muscle, internal oblique abdominal muscle, and adductor magnus muscle were measured using an electromyography. The change in the movement of the bladder base was measured using an ultrasonography. Statistical analysis of the data was performed using SPSS version 18.0. The intraclass correlation coefficient (ICC) was used to determine the reliability between the examiner. A One-way ANOVA were used to assess the statistical significance of maximum vaginal pressure between groups. A two-way repeated ANOVA was performed using the mean measurement for each task to assess for interaction between groups. Followed by the post hoc Least Square Difference (LSD). P-values < 0.05 were considered statistically significant. The study results showed that the ratios of the bladder base distance and muscle activity increased with the increase in vaginal pressure in all the three groups, but the differences among the groups were not significant. The maximum vaginal contractility was significantly higher in the non-parous women in their 20s-30s than in the parous women in their 20s-30s and 40s-50s. This indicates that parity weakens the pelvic floor muscle, resulting in vaginal contraction. The increase in the vaginal pressure of the pelvic floor muscle increased the movement of the bladder base along with the increase of the abdominal and adductor muscles' activities. Giving birth changes the body of women in many ways, especially in terms of vaginal contraction. The results of this study, however, did not show any significant difference between the results of the parous women in their 20s-30s and those in their 40s-50s. Contraction of the pelvic floor muscle was induced in this study, which resulted in the contraction as well of the surrounding muscles.

### GUIDELINES TO CLASSIFY FEMALE SUBJECT GROUPS IN SPORT SCIENCE RESEARCH

Decroix, L., De Pauw, K., Foster, K., Meeusen, R.

*Vrije Universiteit Brussel*

Aim: The purpose of this paper is to systematically review current available literature regarding female subject groups in sport science in order to outline the terminology and performance indicators. Ultimately, we aim to formulate guidelines to classify female subject groups in sport science research. Furthermore, this classification system for female subject groups will be compared with the classification system for male subject groups. Methods: A database of 82 papers which described female subject groups contains information on pre-experimental maximal cycle-protocol designs, terminology, biometrical and physiological parameters, and cycling experience of female subject groups. Subject groups were divided into distinct "performance levels", according to the nomenclature. Body mass, body mass index, relative and absolute values of maximal oxygen consumption (VO<sub>2</sub>max), peak power output (PPO), and training status and history were compared between the performance levels, and between female and male performance levels using one-way ANOVA and Bonferroni post hoc test. Results: Four female performance levels were defined, representing untrained, regularly trained, well-trained and professional female subject groups. Absolute and relative values of VO<sub>2</sub>max and PPO significantly increased with the level of performance ( $p < 0.01$ ). For each performance level, significant differences were observed in absolute and relative VO<sub>2</sub>max and PPO between male and female subject groups. We propose a standardized pre-experimental test protocol for female subject groups, with an initial workload of 50W, a step increase of 25W and a step duration of 3 minutes. Relative VO<sub>2</sub>max is the most cited parameter for female subject groups and is proposed as the principal parameter to classify the female subject groups. Conclusion: This systematic review shows the large variety in the description of female subject groups in the existing literature. We propose a standardized pre-experimental testing protocol and guidelines to classify female subject groups into 4 performance levels, based on (1) relative VO<sub>2</sub>max, (2) relative PPO and (3) additional information regarding training status, absolute VO<sub>2</sub>max and absolute PPO.

### SERUM ZINC IS ASSOCIATED WITH PLASMA LEPTIN AND CU-ZN SOD IN ELITE MALE BASKETBALL ATHLETES

Zhao, J., Fan, B., Wu, Z., Xu, M., Luo, Y.

*China Institute of Sport Science*

Introduction Leptin, which is considered as one of the most important hormones secreted by adipose tissue (Singh et al., 2012), has been demonstrated to be vital not only in the regulation of appetite and energy balance, but also in neuroendocrine and immune functions. This paper investigates the relationship between plasma trace element and plasma leptin, as well as percent fat mass, in 16 male basketball athletes. Methods Sixteen senior elite basketball athletes participated in this study. Blood samples were obtained before intensive training and 24 h after intensive training to measure plasma zinc (Zn), copper (Cu), calcium (Ca), magnesium (Mg), iron (Fe), and leptin levels. High-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL), triglyceride (TG), total and cholesterol (TC) levels were determined using commercially available kits for humans. Results Subjects presented similar values in terms of age ( $21.1 \pm 2.2$  years old), body mass index ( $23.9 \pm 2.00$  kg/m<sup>2</sup>), percent body fat ( $14.40 \pm 1.52\%$ ), plasma hemoglobin ( $150.1 \pm 9.4$  g/L), plasma Zn ( $17.47 \pm 1.28$  μmol/L), plasma Cu ( $13.42 \pm 1.40$  μmol/L), plasma Ca ( $2.41 \pm 0.14$  mmol/L), and plasma Mg ( $0.96 \pm 0.02$  mmol/L). Plasma Zn correlated positively with plasma leptin ( $r = 0.746$ ,  $P < 0.01$ ), Cu-Zn SOD ( $r = 0.827$ ,  $P < 0.01$ ), and negatively with percent fat mass ( $r = -0.598$ ,  $P < 0.05$ ) under no-training conditions. Meanwhile, plasma Cu, Ca, Mg, and Fe did not correlate with plasma leptin or percent fat mass ( $P$

>0.05). Discussion In this study, a strong positive association was found between plasma leptin levels and percent body fat levels. Previous observations relating plasma leptin to body fat percentage and body fat mass in elite volleyball trained players are partially consistent with our results (Leal-Cerro et al., 1998). Other studies observed that plasma leptin concentrations did not correlate with BMI, nor with fat percentage in professional rugby players (Magni et al., 2010). Therefore, the precise factors relevant to the determination of adipokine levels should be further investigated. As Zn acts as an inducer of metallothionein and is an integral metal of Cu/Zn-SOD, it is an antioxidant that reduces the formation of free radicals (Prasad et al., 2009). In this study, we found that plasma Zn correlated positively with Cu-Zn SOD ( $r = 0.827$ ,  $P < 0.01$ ). This result suggested that Zn is an antioxidant agent and decreases reactive oxygen species, is required for Cu-Zn SOD activity, in the Chinese men's basketball athletes. Depending on these results, we hypothesized that the activation of many zinc-dependent enzymes can become affected because of zinc deficiency in the elite men's athletes. In conclusion, plasma Zn may be involved in the regulation of plasma leptin and may serve as a lipid-mobilizing factor in Chinese men's basketball athletes.

### LONGITUDINAL ANALYSIS OF RENAL FUNCTION IN KIDNEY TRANSPLANTED SPORTSMEN

Totti, V., Roi, G.S., Mosconi, G., Di Michele, R., Trerotola, M., Nanni Costa, A.

*National Association of Hemodialysis, Dialysis and Transplantation*

Introduction Studies have shown that exercise only transiently alter the parameters of renal function in healthy subjects (1). However, no studies have longitudinally evaluated the effects of sport on renal function of kidney transplant recipients (KTR). In this study we analyzed longitudinally some indicators of renal function in KTR who regularly practice competitive sport with the aim to evaluate if they showed adverse effects. Methods Blood and urine test reports of 16 male KTR (mean±SD age 51±10 yrs), competing in different sport activities (climbing, cycling, swimming, tennis, track and field, and volleyball) were repeatedly collected across a five-year period. The effect of time (months after transplant) on selected blood chemistry and urine parameters was assessed using linear mixed models with random intercept on individual subjects. KTR were assuming regular immunosuppressive therapy. Weekly training sessions were recorded. Results The number of weekly training sessions was superimposable over the five years (2.9±0.7 sessions/week, 2.2±1.0 hours/session). The intercepts of haemoglobin (13.16 g/dL) and haematocrit (40.4 %) were slightly lower than the normal reference values, but these parameters did not show a significant effect of time. Urea (intercept: 49.6 mg/dL) was within the range of normality at time of transplant, and did not significantly change over time. Creatinine (intercept: 1.91 mg/dL) showed values above the normal reference values at the transplant time, but significantly decreased of -0.0037 mg/dL ( $p < 0.05$ ) per month (about 0.044 mg/dL) after transplantation, thus returning towards the range of normal values. Uric acid (intercept: 7.0 mg/dL) and urine specific gravity (intercept: 1012) were within the normal reference values and remained essentially stable over time. Discussion KTR can resume sports activities showing an overall good renal function in the five years follow up, remaining within the normal reference values. During this period, regular weekly training can be carried out with normal parameters of renal function. References 1. Bellinghieri G, Savica V, Santoro D. ### OP-BN11 Skill acquisition

#### DEVELOPMENT OF A NOVEL SKILL ADAPTABILITY TEST FOR TALENT IDENTIFICATION IN TENNIS

Potter, A., Berry, J., Zois, J.

*Victoria University*

Introduction In any given sport or skill context, individuals must adapt to, and perform within a unique set of constraints which include the task, the environment and the performer's own unique characteristics (Newell, 1986). Two novel tests, a throwing and rebound task and an object striking and rebound task were created to assess the movement and skill adaptability of junior participants. The aim of this research was to establish the validity and reliability of these new tests. Methods Construct validity was assessed by comparing skilled junior athletes to a less-skilled cohort. Content validity was established via criterion-based coach rankings of athlete adaptability compared to test results. Expert tennis coaches and sport scientists provided evaluations of the tests to confirm face validity. Reliability was measured via test-retest over 3 occasions, each separated by 7-days. Results Construct validity revealed a significant effect for group with the junior athletes' superior in both tests. A Pearson's  $r$  and ICC were used to analyse content validity and reliability respectively, with both returning strong correlations. The statistical results were supplemented with the expert coaches and sport scientists confirming a high level of face validity. Discussion Current methods of talent identification (TID) in tennis are predominantly based on rankings and results despite research showing that there is no association between performances at younger ages and senior success (Brouwers, De Bosscher, & Sotiriadou, 2012). The development of skills that are essential for senior success should be the focus rather than 'winning now' (Vaeyens, Lenoir, Williams, & Philippaerts, 2008). This novel approach to TID recognises juniors that display a relatively high level of adaptable skill and movement motor skills. Adaptability has the potential to broaden the junior talent pool within tennis, as well as extending to all sports that require dynamic and time constrained perception-action, therefore it is an imperative tool for future TID programs. #### INTERMANUAL TRANSFER MECHANISMS OF FORCE FIELD ADAPTATION

Stockinger, C., Thüerer, B., Focke, A., Stein, T.

*Karlsruhe Institute of Technology (Karlsruhe, Germany)*

Introduction: Intermanual transfer, i.e. generalization of a motor skill across hands, is a well-accepted phenomenon. Yet, there are open questions regarding direction and magnitude of this transfer (Criscimanga-Hemminger et al., 2003; Joiner et al., 2013). Moreover, it is

unclear whether consolidation affects this transfer. Thus, the aim of this study was to investigate intermanual transfer mechanisms in a force field adaptation task with respect to direction and magnitude as well as the influence of consolidation on the transfer. Methods: 48 right-handed subjects (18-29 yrs) performed a force field adaptation task. Thereby, subjects made 2d point-to-point reaching movements at a robotic manipulandum (Shadmehr & Mussa-Ivaldi, 1994). Following familiarization and baseline measurement of both hands, subjects performed a training block (168 trials) in which they adapted their reaching movements to a force field. Afterwards, they were tested for transfer to the untrained hand. To evaluate both transfer directions, half of the subjects trained with the left (right) hand and were tested on the right (left) hand (indicated by LR and RL). To examine effects of consolidation, half of the subjects were tested for transfer 24h after training (LRc, RLc groups), whereas the other half was tested immediately after training (LRi, RLi groups). Subjects were randomly assigned to the four groups. To gauge motor performance and transfer, we used error clamp trials (Joiner et al., 2013). This allowed measurement of forces that subjects predictively generated to counteract the force field (excluding feedback mechanisms). Results: All subjects showed significant adaptation during training ( $p < .001$ ). This did not differ between hands ( $p = .086$ ). Immediately after training, the LRi ( $p = .001$ ) and RLi group ( $p = .006$ ) showed significant transfer to the untrained hand of 24% and 18%, respectively. Following consolidation period, only the LRc group showed significant transfer of 13% (LRc:  $p = .001$ ; RLc:  $p = .592$ ). Discussion: Our study is the first revealing bidirectional, though asymmetrical, intermanual transfer in a force field adaptation task. This finding contradicts former research reporting only dominant to non-dominant hand transfer (e.g. Criscimagna-Hemminger et al., 2003). Moreover, intermanual transfer seems to be a temporarily decreasing phenomenon that does not benefit from consolidation. The found bidirectional transfer might be attributed to the formation of a central internal representation (e.g. cerebellum) or interhemispheric transfer (e.g. via corpus callosum) of motor memory (Ruddy & Carson, 2013).
