Abstract

This paper introduces how to perform intersection detection of pair of static/dynamic cuboid/tetrahedron in 2D/3D by using the Fourier-Motzkin elimination method.

It includes the mathematical definition of the problem, its mathematical resolution with the Fourier-Motzkin elimination method, the resulting algorithm and its implementation in C, and its validation and qualification against the SAT algorithm. Results are commented and show that the FMB algorithm can be in average up to 4 times faster than the SAT algorithm.

Introduction

This paper introduces the FMB (Fourier-Motzkin-Baillehache) algorithm which can be used to perform intersection detection of moving and resting parallelepipeds and triangles in 2D, and cuboids and tetrahedrons in 3D.

The detection result is returned has a boolean (intersection / no intersection), and if there is intersection, a bounding box of the intersection.

The two first sections introduce how the problem can be expressed as a system of linear inequation, and its resolution using the Fourier-Motzkin method.

The algorithm of the solution and its implementation in the C programming language are detailed in the three following sections.

The three next sections introduce the unit tests, the validation and the qualification in term of relative performance of the FMB algorithm against the SAT algorithm.

Finally, the last section contains comments about the qualification results.

All the algorithms, the code, the results and this doc are available on GitHub at:

<https://github.com/BayashiPascal/FMB>

1 The problem as a system of linear inequations

1.1 Notations and definitions

- $[M]_{r,c}$ is the component at column c and row r of the matrix M
- $[V]_r$ is the r -th component of the vector \vec{V}
- the term "Frame" is used indifferently for parallelepiped, triangle, cuboid and tetrahedron.

1.2 Static case

The two Frames are represented as a vector origin and a number of component vectors equal to the dimension D of the space where live the Frames. Each vector is of dimension equal to D .

Let's call \mathbb{A} and \mathbb{B} the two Frames tested for intersection. If \mathbb{A} and \mathbb{B} are two cuboids:

$$\mathbb{A} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \vec{O}_{\mathbb{A}} + C_{\mathbb{A}} \cdot \vec{X} \end{array} \right\} \quad (1)$$

$$\mathbb{B} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \vec{O}_{\mathbb{B}} + C_{\mathbb{B}} \cdot \vec{X} \end{array} \right\} \quad (2)$$

where $\vec{O}_{\mathbb{A}}$ is the origin of \mathbb{A} and $C_{\mathbb{A}}$ is the matrix of the components of \mathbb{A} (one component per column). Idem for $\vec{O}_{\mathbb{B}}$ and $C_{\mathbb{B}}$.

If \mathbb{A} and \mathbb{B} are two tetrahedrons:

$$\mathbb{A} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ \vec{O}_{\mathbb{A}} + C_{\mathbb{A}} \cdot \vec{X} \end{array} \right\} \quad (3)$$

$$\mathbb{B} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ \vec{O}_{\mathbb{B}} + C_{\mathbb{B}} \cdot \vec{X} \end{array} \right\} \quad (4)$$

I'll assume the Frames are well formed, i.e. their components matrix is invertible. It is then possible to express \mathbb{B} in \mathbb{A} 's coordinates system, noted

as \mathbb{B}_A . If \mathbb{B} is a cuboid:

$$\mathbb{B}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ C_A^{-1} \cdot (\vec{O}_B - \vec{O}_A + C_B \cdot \vec{X}) \end{array} \right\} \quad (5)$$

If \mathbb{B} is a tetrahedron:

$$\mathbb{B}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ C_A^{-1} \cdot (\vec{O}_B - \vec{O}_A + C_B \cdot \vec{X}) \end{array} \right\} \quad (6)$$

\mathbb{A} in its own coordinates system becomes, for a cuboid:

$$\mathbb{A}_A = \left\{ \vec{X} \in [0.0, 1.0]^D \right\} \quad (7)$$

and for a tetrahedron:

$$\mathbb{A}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \end{array} \right\} \quad (8)$$

The intersection of \mathbb{A} and \mathbb{B} in \mathbb{A} 's coordinates sytem, $\mathbb{A}_A \cap \mathbb{B}_A$, can then be expressed as follow.

If \mathbb{A} and \mathbb{B} are two cuboids:

$$\mathbb{A}_A \cap \mathbb{B}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ C_A^{-1} \cdot (\vec{O}_B - \vec{O}_A + C_B \cdot \vec{X}) \in [0.0, 1.0]^D \end{array} \right\} \quad (9)$$

If \mathbb{A} is a cuboid and \mathbb{B} is a tetrahedron:

$$\mathbb{A}_A \cap \mathbb{B}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ C_A^{-1} \cdot (\vec{O}_B - \vec{O}_A + C_B \cdot \vec{X}) \in [0.0, 1.0]^D \end{array} \right\} \quad (10)$$

If \mathbb{A} is a tetrahedron and \mathbb{B} is a cuboid:

$$\mathbb{A}_A \cap \mathbb{B}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ C_A^{-1} \cdot (\vec{O}_B - \vec{O}_A + C_B \cdot \vec{X}) \in [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [C_A^{-1} \cdot (\vec{O}_B - \vec{O}_A + C_B \cdot \vec{X})]_i \leq 1.0 \end{array} \right\} \quad (11)$$

If \mathbb{A} and \mathbb{B} are two tetrahedrons:

$$\mathbb{A}_{\mathbb{A}} \cap \mathbb{B}_{\mathbb{A}} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}} + C_{\mathbb{B}} \cdot \vec{X}) \cap [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} \left[C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}} + C_{\mathbb{B}} \cdot \vec{X}) \right]_i \leq 1.0 \end{array} \right\} \quad (12)$$

These can in turn be expressed as systems of linear inequations as follow, given the two shortcuts $\vec{O}_{\mathbb{B}_{\mathbb{A}}} = C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}})$ and $C_{\mathbb{B}_{\mathbb{A}}} = C_{\mathbb{A}}^{-1} \cdot C_{\mathbb{B}}$.

If \mathbb{A} and \mathbb{B} are two cuboids:

$$\left\{ \begin{array}{l} [X]_0 \leq 1.0 \\ \dots \\ [X]_{D-1} \leq 1.0 \\ -[X]_0 \leq 0.0 \\ \dots \\ -[X]_{D-1} \leq 0.0 \\ \sum_{i=0}^{D-1} [C_{\mathbb{B}_{\mathbb{A}}}]_{0,i} \cdot [X]_i \leq 1.0 - [O_{\mathbb{B}_{\mathbb{A}}}]_0 \\ \dots \\ \sum_{i=0}^{D-1} [C_{\mathbb{B}_{\mathbb{A}}}]_{D-1,i} \cdot [X]_i \leq 1.0 - [O_{\mathbb{B}_{\mathbb{A}}}]_{D-1} \\ -\sum_{i=0}^{D-1} [C_{\mathbb{B}_{\mathbb{A}}}]_{0,i} \cdot [X]_i \leq [O_{\mathbb{B}_{\mathbb{A}}}]_0 \\ \dots \\ -\sum_{i=0}^{D-1} [C_{\mathbb{B}_{\mathbb{A}}}]_{D-1,i} \cdot [X]_i \leq [O_{\mathbb{B}_{\mathbb{A}}}]_{D-1} \end{array} \right. \quad (13)$$

If \mathbb{A} is a cuboid and \mathbb{B} is a tetrahedron:

$$\left\{ \begin{array}{l} -[X]_0 \leq 0.0 \\ \dots \\ -[X]_{D-1} \leq 0.0 \\ \sum_{i=0}^{D-1} [C_{\mathbb{B}_{\mathbb{A}}}]_{0,i} \cdot [X]_i \leq 1.0 - [O_{\mathbb{B}_{\mathbb{A}}}]_0 \\ \dots \\ \sum_{i=0}^{D-1} [C_{\mathbb{B}_{\mathbb{A}}}]_{D-1,i} \cdot [X]_i \leq 1.0 - [O_{\mathbb{B}_{\mathbb{A}}}]_{D-1} \\ -\sum_{i=0}^{D-1} [C_{\mathbb{B}_{\mathbb{A}}}]_{0,i} \cdot [X]_i \leq [O_{\mathbb{B}_{\mathbb{A}}}]_0 \\ \dots \\ -\sum_{i=0}^{D-1} [C_{\mathbb{B}_{\mathbb{A}}}]_{D-1,i} \cdot [X]_i \leq [O_{\mathbb{B}_{\mathbb{A}}}]_{D-1} \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \end{array} \right. \quad (14)$$

If \mathbb{A} is a tetrahedron and \mathbb{B} is a cuboid:

$$\left\{ \begin{array}{l} [X]_0 \leq 1.0 \\ \dots \\ [X]_{D-1} \leq 1.0 \\ -[X]_0 \leq 0.0 \\ \dots \\ -[X]_{D-1} \leq 0.0 \\ -\sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{0,i} \cdot [X]_i \leq [O_{\mathbb{B}_A}]_0 \\ \dots \\ -\sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{D-1,i} \cdot [X]_i \leq [O_{\mathbb{B}_A}]_{D-1} \\ \sum_{j=0}^{D-1} \left(\left(\sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{j,i} \right) \cdot [X]_i \right) \leq 1.0 - \sum_{j=0}^{D-1} [O_{\mathbb{B}_A}]_j \end{array} \right. \quad (15)$$

If \mathbb{A} and \mathbb{B} are two tetrahedrons:

$$\left\{ \begin{array}{l} -[X]_0 \leq 0.0 \\ \dots \\ -[X]_{D-1} \leq 0.0 \\ -\sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{0,i} \cdot [X]_i \leq [O_{\mathbb{B}_A}]_0 \\ \dots \\ -\sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{D-1,i} \cdot [X]_i \leq [O_{\mathbb{B}_A}]_{D-1} \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ \sum_{j=0}^{D-1} \left(\left(\sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{j,i} \right) \cdot [X]_i \right) \leq 1.0 - \sum_{j=0}^{D-1} [O_{\mathbb{B}_A}]_j \end{array} \right. \quad (16)$$

1.3 Dynamic case

If the frames \mathbb{A} and \mathbb{B} are moving linearly along the vectors $\vec{V}_{\mathbb{A}}$ and $\vec{V}_{\mathbb{B}}$ respectively during the interval of time $t \in [0.0, 1.0]$, the above definition of the problem is modified as follow.

If \mathbb{A} and \mathbb{B} are two cuboids:

$$\mathbb{A} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ \vec{O}_{\mathbb{A}} + C_{\mathbb{A}} \cdot \vec{X} + \vec{V}_{\mathbb{A}} \cdot t \end{array} \right\} \quad (17)$$

$$\mathbb{B} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ \vec{O}_{\mathbb{B}} + C_{\mathbb{B}} \cdot \vec{X} + \vec{V}_{\mathbb{B}} \cdot t \end{array} \right\} \quad (18)$$

where \vec{O}_A is the origin of \mathbb{A} and C_A is the matrix of the components of \mathbb{A} (one component per column). Idem for \vec{O}_B and C_B .

If \mathbb{A} and \mathbb{B} are two tetrahedrons:

$$\mathbb{A} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ \vec{O}_A + C_A \cdot \vec{X} + \vec{V}_A \cdot t \end{array} \right\} \quad (19)$$

$$\mathbb{B} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ \vec{O}_B + C_B \cdot \vec{X} + \vec{V}_B \cdot t \end{array} \right\} \quad (20)$$

If \mathbb{B} is a cuboid, \mathbb{B}_A becomes:

$$\mathbb{B}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ C_A^{-1} \cdot (\vec{O}_B - \vec{O}_A + C_B \cdot \vec{X} + (\vec{V}_B - \vec{V}_A) \cdot t) \end{array} \right\} \quad (21)$$

If \mathbb{B} is a tetrahedron, \mathbb{B}_A becomes:

$$\mathbb{B}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ C_A^{-1} \cdot (\vec{O}_B - \vec{O}_A + C_B \cdot \vec{X} + (\vec{V}_B - \vec{V}_A) \cdot t) \end{array} \right\} \quad (22)$$

\mathbb{A} in its own coordinates system has the same definition as in the static case. For a cuboid:

$$\mathbb{A}_A = \left\{ \vec{X} \in [0.0, 1.0]^D \right\} \quad (23)$$

and for a tetrahedron:

$$\mathbb{A}_A = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \end{array} \right\} \quad (24)$$

The intersection of \mathbb{A} and \mathbb{B} in \mathbb{A} 's coordinates sytem, $\mathbb{A}_A \cap \mathbb{B}_A$, can then be expressed as follow.

If \mathbb{A} and \mathbb{B} are two cuboids:

$$\mathbb{A}_{\mathbb{A}} \cap \mathbb{B}_{\mathbb{A}} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}} + C_{\mathbb{B}} \cdot \vec{X} + (\vec{V}_{\mathbb{B}} - \vec{V}_{\mathbb{A}}) \cdot t) \cap [0.0, 1.0]^D \end{array} \right\} \quad (25)$$

If \mathbb{A} is a cuboid and \mathbb{B} is a tetrahedron:

$$\mathbb{A}_{\mathbb{A}} \cap \mathbb{B}_{\mathbb{A}} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}} + C_{\mathbb{B}} \cdot \vec{X} + (\vec{V}_{\mathbb{B}} - \vec{V}_{\mathbb{A}}) \cdot t) \cap [0.0, 1.0]^D \end{array} \right\} \quad (26)$$

If \mathbb{A} is a tetrahedron and \mathbb{B} is a cuboid:

$$\mathbb{A}_{\mathbb{A}} \cap \mathbb{B}_{\mathbb{A}} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}} + C_{\mathbb{B}} \cdot \vec{X} + (\vec{V}_{\mathbb{B}} - \vec{V}_{\mathbb{A}}) \cdot t) \cap [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}} + C_{\mathbb{B}} \cdot \vec{X} + (\vec{V}_{\mathbb{B}} - \vec{V}_{\mathbb{A}}) \cdot t)]_i \leq 1.0 \end{array} \right\} \quad (27)$$

If \mathbb{A} and \mathbb{B} are two tetrahedrons:

$$\mathbb{A}_{\mathbb{A}} \cap \mathbb{B}_{\mathbb{A}} = \left\{ \begin{array}{l} \vec{X} \in [0.0, 1.0]^D \\ t \in [0.0, 1.0] \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}} + C_{\mathbb{B}} \cdot \vec{X} + (\vec{V}_{\mathbb{B}} - \vec{V}_{\mathbb{A}}) \cdot t) \cap [0.0, 1.0]^D \\ \sum_{i=0}^{D-1} [C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}} + C_{\mathbb{B}} \cdot \vec{X} + (\vec{V}_{\mathbb{B}} - \vec{V}_{\mathbb{A}}) \cdot t)]_i \leq 1.0 \end{array} \right\} \quad (28)$$

These lead to the following systems of linear inequations, given the three shortcuts $\vec{O}_{\mathbb{B}_{\mathbb{A}}} = C_{\mathbb{A}}^{-1} \cdot (\vec{O}_{\mathbb{B}} - \vec{O}_{\mathbb{A}})$, $\vec{V}_{\mathbb{B}_{\mathbb{A}}} = C_{\mathbb{A}}^{-1} \cdot (\vec{V}_{\mathbb{B}} - \vec{V}_{\mathbb{A}})$ and $C_{\mathbb{B}_{\mathbb{A}}} = C_{\mathbb{A}}^{-1} \cdot C_{\mathbb{B}}$.

If \mathbb{A} and \mathbb{B} are two cuboids:

$$\left\{ \begin{array}{l} t \leq 1.0 \\ -t \leq 0.0 \\ [X]_0 \leq 1.0 \\ \dots \\ [X]_{D-1} \leq 1.0 \\ -[X]_0 \leq 0.0 \\ \dots \\ -[X]_{D-1} \leq 0.0 \\ [V_{\mathbb{B}_A}]_0 \cdot t + \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{0,i} [X]_i \leq 1.0 - [O_{\mathbb{B}_A}]_0 \\ \dots \\ [V_{\mathbb{B}_A}]_{D-1} \cdot t + \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{D-1,i} [X]_i \leq 1.0 - [O_{\mathbb{B}_A}]_{D-1} \\ -[V_{\mathbb{B}_A}]_0 \cdot t - \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{0,i} [X]_i \leq [O_{\mathbb{B}_A}]_0 \\ \dots \\ -[V_{\mathbb{B}_A}]_{D-1} \cdot t - \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{D-1,i} [X]_i \leq [O_{\mathbb{B}_A}]_{D-1} \end{array} \right. \quad (29)$$

If \mathbb{A} is a cuboid and \mathbb{B} is a tetrahedron:

$$\left\{ \begin{array}{l} t \leq 1.0 \\ -t \leq 0.0 \\ -[X]_0 \leq 0.0 \\ \dots \\ -[X]_{D-1} \leq 0.0 \\ [V_{\mathbb{B}_A}]_0 \cdot t + \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{0,i} [X]_i \leq 1.0 - [O_{\mathbb{B}_A}]_0 \\ \dots \\ [V_{\mathbb{B}_A}]_{D-1} \cdot t + \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{D-1,i} [X]_i \leq 1.0 - [O_{\mathbb{B}_A}]_{D-1} \\ -[V_{\mathbb{B}_A}]_0 \cdot t - \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{0,i} [X]_i \leq [O_{\mathbb{B}_A}]_0 \\ \dots \\ -[V_{\mathbb{B}_A}]_{D-1} \cdot t - \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{D-1,i} [X]_i \leq [O_{\mathbb{B}_A}]_{D-1} \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \end{array} \right. \quad (30)$$

If \mathbb{A} is a tetrahedron and \mathbb{B} is a cuboid:

$$\left\{ \begin{array}{l} t \leq 1.0 \\ -t \leq 0.0 \\ [X]_0 \leq 1.0 \\ \dots \\ [X]_{D-1} \leq 1.0 \\ -[X]_0 \leq 0.0 \\ \dots \\ -[X]_{D-1} \leq 0.0 \\ -[V_{\mathbb{B}_A}]_0 \cdot t - \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{0,i} [X]_i \leq [O_{\mathbb{B}_A}]_0 \\ \dots \\ -[V_{\mathbb{B}_A}]_{D-1} \cdot t - \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{D-1,i} [X]_i \leq [O_{\mathbb{B}_A}]_{D-1} \\ \sum_{j=0}^{D-1} \left([V_{\mathbb{B}_A}]_j \cdot t + \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{j,i} [X]_i \right) \leq 1.0 - \sum_{j=0}^{D-1} [O_{\mathbb{B}_A}]_j \end{array} \right. \quad (31)$$

If \mathbb{A} and \mathbb{B} are two tetrahedrons:

$$\left\{ \begin{array}{l} t \leq 1.0 \\ -t \leq 0.0 \\ -[X]_0 \leq 0.0 \\ \dots \\ -[X]_{D-1} \leq 0.0 \\ -[V_{\mathbb{B}_A}]_0 \cdot t - \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{0,i} [X]_i \leq [O_{\mathbb{B}_A}]_0 \\ \dots \\ -[V_{\mathbb{B}_A}]_{D-1} \cdot t - \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{D-1,i} [X]_i \leq [O_{\mathbb{B}_A}]_{D-1} \\ \sum_{i=0}^{D-1} [X]_i \leq 1.0 \\ \sum_{j=0}^{D-1} \left([V_{\mathbb{B}_A}]_j \cdot t + \sum_{i=0}^{D-1} [C_{\mathbb{B}_A}]_{j,i} [X]_i \right) \leq 1.0 - \sum_{j=0}^{D-1} [O_{\mathbb{B}_A}]_j \end{array} \right. \quad (32)$$

2 Resolution of the problem by Fourier-Motzkin method

2.1 The Fourier-Motzkin elimination method

The Fourier-Motzkin elimination method has been introduced by J.J.-B. Fourier in 1827 [1], and described in the Ph.D. thesis of T.S. Motzkin in 1936 [2]. This is a generalization of the Gaussian elimination method to linear systems of inequalities. This method consists of eliminating one variable of the system and rewrite a new system accordingly. Then the elimination operation is repeated on another variable in the new system, and so on until we obtain a trivial system with only one variable. From there, a solution

for each variable can be obtained if it exists. The variable elimination is performed as follow.

Lets write the linear system \mathcal{I} of m inequalities and n variables as

$$\begin{cases} a_{11}.x_1 + a_{12}.x_2 + \cdots + a_{1n}.x_n \leq b_1 \\ a_{21}.x_1 + a_{22}.x_2 + \cdots + a_{2n}.x_n \leq b_2 \\ \vdots \\ a_{m1}.x_1 + a_{m2}.x_2 + \cdots + a_{mn}.x_n \leq b_m \end{cases} \quad (33)$$

with

$$\begin{aligned} i &\in 1, 2, \dots, m \\ j &\in 1, 2, \dots, n \\ x_i &\in \mathbb{R} \\ a_{ij} &\in \mathbb{R} \\ b_j &\in \mathbb{R} \end{aligned} \quad (34)$$

To eliminate the first variable x_1 , lets multiply each inequality by $1.0/|a_{i1}|$ where $a_{i1} \neq 0.0$. The system becomes

$$\begin{cases} x_1 + a'_{i2}.x_2 + \cdots + a'_{in}.x_n \leq b'_i & (i \in \mathcal{I}_+) \\ a_{i2}.x_2 + \cdots + a_{in}.x_n \leq b_i & (i \in \mathcal{I}_0) \\ -x_1 + a'_{i2}.x_2 + \cdots + a'_{in}.x_n \leq b'_i & (i \in \mathcal{I}_-) \end{cases} \quad (35)$$

where

$$\begin{aligned} \mathcal{I}_+ &= \{i : a_{i1} > 0.0\} \\ \mathcal{I}_0 &= \{i : a_{i1} = 0.0\} \\ \mathcal{I}_- &= \{i : a_{i1} < 0.0\} \\ a'_{ij} &= a_{ij}/|a_{i1}| \\ b'_i &= b_i/|a_{i1}| \end{aligned}$$

Then $x_1, x_2, \dots, x_n \in \mathbb{R}^n$ is a solution of \mathcal{I} if and only if

$$\begin{cases} \sum_{j=2}^n ((a'_{kj} + a'_{lj}).x_j) \leq b'_k + b'_l & (k \in \mathcal{I}_+, l \in \mathcal{I}_-) \\ \sum_{j=2}^n (a_{ij}.x_j) \leq b_i & i \in \mathcal{I}_0 \end{cases} \quad (36)$$

and

$$\max_{l \in \mathcal{I}_-} \left(\sum_{j=2}^n (a'_{lj}.x_j) - b'_l \right) \leq x_1 \leq \min_{k \in \mathcal{I}_+} \left(b'_k - \sum_{j=2}^n (a'_{kj}.x_j) \right) \quad (37)$$

The same method is then applied on this new system to eliminate the second variable x_2 , and so on until we reach the inequality

$$\max_{l \in \mathcal{I}''_{-} \dots'} (-b''_{l'} \dots') \leq x_n \leq \min_{k \in \mathcal{I}''_{+} \dots'} (b''_{k'} \dots') \quad (38)$$

If this inequality has no solution, then neither the system \mathcal{I} . If it has a solution, the minimum and maximum are the bounding values for the variable x_n . One can get a particular solution to the system \mathcal{I} by choosing a value for x_n between these bounding values, which allows to set a particular value for the variable x_{n-1} , and so on back up to x_1 .

2.2 Application of the Fourier-Motzkin method to the intersection problem

The Fourier-Motzkin method can be directly applied to the inequality systems of the previous section, to obtain the bounding box of the intersection, if the system has a solution. If the system has no solution, the method will eventually reach an inconsistent inequality, meaning there is no intersection between the two Frames.

One coordinate \vec{S} , or (\vec{S}, t) in dynamic case, within the bounds obtained by the resolution of the system is expressed in the Frame \mathbb{B} 's coordinates system. One can get the equivalent coordinates \vec{S}' , or (\vec{S}', t) , in the real world's coordinates system as follow:

$$\vec{S}' = \vec{O}_{\mathbb{B}} + C_{\mathbb{B}} \cdot \vec{S} \quad (39)$$

$$(\vec{S}', t) = \left(\vec{O}_{\mathbb{B}} + C_{\mathbb{B}} \cdot \vec{S} + \vec{V}_{\mathbb{B}} \cdot t, t \right) \quad (40)$$

Only one inconsistent inequality is sufficient to prove the absence of solution, and then the non intersection of the Frames. Thus, one shall check the inconsistency of each inequality as soon as possible during the resolution of the system to optimize the speed of the algorithm.

A sufficient condition for one inequality $\sum_i a_i X_i \leq Y$ to be inconsistent is, given that $\forall i, X_i \in [0.0, 1.0]$:

$$Y < \sum_{i \in I^-} a_i \quad (41)$$

where $I^- = \{i, a_i < 0.0\}$.

2.3 About the size of the system of linear inequations

During implementation in languages where the developer needs to manage memory itself the size of the systems (35) resulting from variable elimination

is necessary but cannot be forecasted. Instead, a maximum size can be calculated as follow.

Let's call n_- , n_+ and n_0 , each in $[0, \mathbb{N}]$, the size of, respectively, \mathcal{I}_- , \mathcal{I}_+ and \mathcal{I}_0 , and N the number of inequalities in the original system and N' the number inequalities in the resulting system. We have:

$$n_- + n_+ + n_0 = N \quad (42)$$

and

$$n_- . n_+ + n_0 = N' \quad (43)$$

Now let's define $K = N - n_0$, then we have:

$$n_- + n_+ = K \quad (44)$$

then,

$$n_- . n_+ = n_- . (K - n_-) \quad (45)$$

then,

$$n_- . n_+ = K . n_- - n_-^2 \quad (46)$$

The right part is a polynomial whose maximum is reached for $n_- = K/2$. Then,

$$n_- . n_+ \leq K^2/2 - K^2/4 \quad (47)$$

or,

$$n_- . n_+ \leq K^2/4 \quad (48)$$

and putting back the definition of K

$$n_- . n_+ \leq (N - n_0)^2/4 \quad (49)$$

which is also

$$n_- . n_+ \leq N^2/4 \quad (50)$$

From (43) we get,

$$N' \leq N^2/4 + n_0 \quad (51)$$

and finally,

$$N' \leq N^2/4 + N \quad (52)$$

The maximum number of inequations in the initial system is defined for each case (2D/3D, static/dynamic) in the previous section. This leads to the following maximum number of inequations:

	N	N'	N''	N'''
<i>2Dstatic</i>	8	24		
<i>2Ddynamic</i>	10	35	342	
<i>3Dstatic</i>	12	48	624	
<i>3Ddynamic</i>	14	63	1056	279840

However, these values are much higher than the ones encountered in the case of the systems corresponding to the intersection problem. It can be noticed that n_0 can be better estimated as the inequations corresponding to the constraints $0.0 \leq x \leq 1.0$ leads to, for N' , $n_0 \in \{D - 1, 2(D - 1)\}$ in static case and $n_0 \in \{D + 1, 2D + 1\}$ in dynamic case. Thus we can reduce N' to:

	N	N'
<i>2Dstatic</i>	8	14
<i>2Ddynamic</i>	10	16
<i>3Dstatic</i>	12	27
<i>3Ddynamic</i>	14	29

and so on for N'' and N''' . In practice, the maximum number of inequations encountered during validation were:

	N	N'	N''	N'''
<i>2Dstatic</i>	8	11		
<i>2Ddynamic</i>	10	13	21	
<i>3Dstatic</i>	12	20	55	
<i>3Ddynamic</i>	14	22	57	560

3 Algorithms of the solution

In this section I introduce the algorithms of the solution of the previous section for each case (static/dynamic and 2D/3D), and the algorithms to manipulate the structure used to represent the Frames.

Algorithms are given in pseudo code, and consequently without any optimization based on properties of one given language. One can refer to the C implementation in the following section for possible optimization in this language.

Algorithms are also given independantly from each other. Code commonalization may be possible if one plans to use several cases together, but this

is dependant of the implementation and thus left to the developer responsibility.

5 Minimal example of use

In this section I give a minimal example for each case of how to use the code given in the previous section.

5.1 2D static

```

// Include standard libraries
#include <stdlib.h>
#include <stdio.h>
#include <stdbool.h>

// Include the FMB algorithm library
#include "fmb2d.h"

// Main function
int main(int argc, char** argv) {

    // Create the two objects to be tested for intersection
    double origP2D[2] = {0.0, 0.0};
    double compP2D[2][2] = {

        {1.0, 0.0}, // First component
        {0.0, 1.0} // Second component

    };

    Frame2D P2D =
        Frame2DCreateStatic(
            FrameCuboid,
            origP2D,
            compP2D);

    double origQ2D[2] = {0.0, 0.0};
    double compQ2D[2][2] = {{1.0, 0.0}, {0.0, 1.0}};
    Frame2D Q2D =
        Frame2DCreateStatic(
            FrameCuboid,
            origQ2D,
            compQ2D);

    // Declare a variable to memorize the result of the intersection
    // detection
    AABB2D bdgBox2DLocal;

```

```

// Test for intersection between P and Q
bool isIntersecting2D =
    FMBTestIntersection2D(
        &P2D,
        &Q2D,
        &bdgBox2DLocal);

// If the two objects are intersecting
if (isIntersecting2D) {

    printf("Intersection detected in AABB ");

    // Export the local bounding box toward the real coordinates
    // system
    AABB2D bdgBox2D;
    Frame2DExportBdgBox(
        &Q2D,
        &bdgBox2DLocal,
        &bdgBox2D);

    // Clip with the AABB of 'Q2D' and 'P2D' to improve results
    for (
        int iAxis = 2;
        iAxis--;) {

6 Unit tests

In this section I introduce the code I've used to test the algorithm and its implementation. The test consists of running the algorithm on a set of cases for which the solution has been computed by hand. The code of the implementation of the SAT algorithm is given in annex (p.280)

6.1 Code

6.1.1 2D static

```

// Include standard libraries
#include <stdlib.h>
#include <stdio.h>
#include <stdbool.h>

// Include the FMB algorithm library
#include "fmb2d.h"

// Epsilon for numerical precision
#define EPSILON 0.0001

// Helper structure to pass arguments to the UnitTest function
typedef struct {

```

```

    FrameType type;
    double orig[2];
    double comp[2][2];
} Param2D;

// Unit test function
// Takes two Frame definitions, the correct answer in term of
// intersection/no intersection and the correct bounding box
// Run the FMB intersection detection algorithm on the Frames
// and check against the correct results
void UnitTest2D(
    const Param2D paramP,
    const Param2D paramQ,
    const bool correctAnswer,

All unit tests 3DTime have succeed.

```

7 Validation against SAT

In this section I introduce the code I've used to validate the algorithm and its implementation. The validation consists of running the FMB algorithm on randomly generated pairs of Frame and check that its result is equal to the one of running the SAT algorithm on the same pair of Frames. The code of the implementation of the SAT algorithm is given in annex (p.280)

7.1 Code

7.1.1 2D static

```
// Include standard libraries
#include <stdlib.h>
#include <stdio.h>
#include <stdbool.h>
#include <time.h>

// Include FMB and SAT algorithm library
#include "fmb2d.h"
#include "sat.h"

// Epsilon to detect degenerated triangles
#define EPSILON 0.1

// Range of values for the random generation of Frames
#define RANGE_AXIS 100.0

// Nb of tests of the validation
#define NB_TESTS 1000000

// Helper macro to generate random number in [0.0, 1.0]
#define rnd() (double)(rand())/(double)(RAND_MAX)

// Global variables to count nb of tests resulting in intersection
// and no intersection
unsigned long int nbInter;
unsigned long int nbNoInter;

// Helper structure to pass arguments to the Validation function
typedef struct {

    FrameType type;
    double orig[2];
    double comp[2][2];

} Param2D;

// Validation function
// Takes two Frame definition as input, run the intersection test on
// them with FMB and SAT, and check the results are identical
void ValidationOnePair2D(
    const Param2D paramP,
    const Param2D paramQ) {
```

```

// Create the two Frames
Frame2D P =
    Frame2DCreateStatic(
        paramP.type,
        paramP.orig,
        paramP.comp);

Frame2D Q =
    Frame2DCreateStatic(
        paramQ.type,

    paramQ.comp[0][2] * paramQ.comp[2][1]) +
    paramQ.comp[2][0] * (paramQ.comp[0][1] * paramQ.comp[1][2] -
    paramQ.comp[0][2] * paramQ.comp[1][1]);

// If the determinants are not null, ie the Frame are not degenerate
if (fabs(detP) > EPSILON && fabs(detQ) > EPSILON) {

    // Run the validation on the two Frames
    ValidationOnePair3DTime(
        paramP,
        paramQ);
}

}

// If we reached here it means the validation was successfull
// Print results
printf("Validation3DTime has succeed.\n");
printf("Tested %lu intersections ", nbInter);
printf("and %lu no intersections\n", nbNoInter);
}

int main(int argc, char** argv) {

    printf("==== 3D dynamic =====\n");
    Validate3DTime();

    return 0;
}

```

7.2 Results

7.2.1 Failures

Validation has failed in one case: when one or both of the frame are degenerated (at least two of there components are colinear). An example is given below for reference:

```

===== 2D static =====
Validation2D has failed
Co(-63.571705,-22.581119) x(55.239119,38.152177) y(-62.031537,-42.843548) against To(3.474294,22.751011)
x(-49.195251,84.166201) y(41.179031,-95.350316)
FMB : intersection
SAT : no intersection

```

This case can be detected and avoided prior to the intersection test by checking the determinant of the frame: degenerated frames have a null determinant. In the example above the determinant of the first frame is equal to -0.001667.

7.2.2 2D static

```

===== 2D static =====
Validation2D has succeed.
Tested 468920 intersections and 1530990 no intersections

```

7.2.3 2D dynamic

```

===== 2D dynamic =====
Validation2DTime has succeed.
Tested 743116 intersections and 1256800 no intersections

```

7.2.4 3D static

```

===== 3D static =====
Validation3D has succeed.
Tested 314980 intersections and 1685018 no intersections

```

7.2.5 3D dynamic

```
==== 3D dynamic =====  
Validation3DTime has succeed.  
Tested 523862 intersections and 1476138 no intersections
```

8 Qualification against SAT

In this section I introduce the code I've used to qualify the algorithm and its implementation. The qualification consists of running the FMB algorithm on randomly generated pairs of Frame, and check its execution time against the one of running the SAT algorithm on the same pair of Frames.

8.1 Code

8.1.1 2D static

```
// Include standard libraries  
#include <stdlib.h>  
#include <stdio.h>  
#include <stdbool.h>  
#include <time.h>  
#include <sys/time.h>  
  
// Include FMB and SAT algorithm library  
#include "fmb2d.h"  
#include "sat.h"  
  
// Epsilon to detect degenerated triangles  
#define EPSILON 0.1  
  
// Range of values for the random generation of Frames  
#define RANGE_AXIS 100.0  
  
// Nb of run  
#define NB_RUNS 9  
  
// Nb of tests per run  
#define NB_TESTS 500000  
  
// Nb of times the test is run on one pair of frame, used to  
// slow down the processus and be able to measure time  
#define NB_REPEAT_2D 1500  
  
// Helper macro to generate random number in [0.0, 1.0]  
#define rnd() (double)(rand())/(double)(RAND_MAX)  
  
// Helper structure to pass arguments to the Qualification function  
typedef struct {  
  
    FrameType type;  
    double orig[2];  
    double comp[2][2];
```

```

} Param2D;

// Type of qualification
typedef enum {
    typeQualif_all,
    typeQualif_nearCaseOnly

9 Comments about the qualification results

For the 2D static case:

- FMB is in average 1.3 times slower than SAT to detect intersection and non intersection between Tetrahedrons.
- FMB is in average 1.9 times slower than SAT to detect intersection between a Tetrahedron and a Cuboid, and 1.3 times slower to detect non intersection.
- FMB is in average 2.5 times slower than SAT to detect intersection between Cuboids, and 1.2 times slower to detect non intersection.

FMB is then in average always slower (from 2.5 times to 1.2 times) than SAT whatever the combinaison of Tetrahedron and Cuboid and the percentage of intersection.

For the 3D static case:

- FMB is in average 4.2 times faster than SAT to detect intersection between Tetrahedrons, and 1.1 times faster to detect non intersection.
- FMB is in average 2.4 times faster than SAT to detect intersection between a Tetrahedron and a Cuboid, and 1.5 times faster to detect non intersection.
- FMB is in average 1.4 times faster than SAT to detect intersection between Cuboids, and 2.0 times faster to detect non intersection.

FMB is then in average always faster (from 4.2 times to 1.1 times) than SAT whatever the combinaison of Tetrahedron and Cuboid and the percentage of intersection.

For the 2D dynamic case:

- FMB is in average 1.7 times slower than SAT to detect intersection between Tetrahedrons, and 1.5 times slower to detect non intersection.
- FMB is in average 2.2 times slower than SAT to detect intersection between a Tetrahedron and a Cuboid, and 1.5 times slower to detect non intersection.
- FMB is in average 3.1 times slower than SAT to detect intersection between Cuboids, and 1.5 times slower to detect non intersection.

FMB is then in average always slower (from 3.1 times to 1.5 times) than SAT whatever the combinaison of Tetrahedron and Cuboid and the percentage of intersection.

For the 3D dynamic case:

- FMB is in average 1.8 times faster than SAT to detect intersection between Tetrahedrons, and 1.05 times faster to detect non intersection.
- FMB is in average 1.4 times slower than SAT to detect intersection between a Tetrahedron and a Cuboid, and 1.2 times faster to detect non intersection.
- FMB is in average 2.6 times slower than SAT to detect intersection between Cuboids, and 1.4 times faster to detect non intersection.

FMB is then in average always faster (from 1.8 times to 1.05 times) than SAT for a set of Tetrahedron, and faster than SAT for a combinaison of Tetrahedrons and Cuboids containining less than around 35% of intersection, or a combinaison of Cuboids containining less than around 15% of intersection.

Overall, FMB is faster than SAT, at least if the percentage of intersecting Frames is low, for the 3D cases. But it is always slower for the 2D dynamic cases. In practice, for example in applications where the Frames represents real world objects supposedly normally not in intersection, FMB would be a

better choice than SAT for 3D applications.

In a real world collision detection system the pair of Frames would be pruned by first applying a rough but fast detection algorithm. The slower but accurate SAT and FMB algorithms would be then only applied to pairs of Frames closed together. To ensure the results stay valid on this subset of possible cases, I've also run the qualification for 2D and 3D static cases in 'near case only' mode. In this mode, only pairs of Frames whose AABBs are intersecting are used. The results are as follow.

For the 2D static near only case:

- FMB is in average 1.3 times slower than SAT to detect intersection between Tetrahedrons, and 1.4 times slower to detect non intersection.
- FMB is in average 1.9 times slower than SAT to detect intersection between a Tetrahedron and a Cuboid, and 1.4 times slower to detect non intersection.
- FMB is in average 2.5 times slower than SAT to detect intersection between Cuboids, and 1.3 times slower to detect non intersection.

There is no significant difference with the general cases.

For the 3D static near only case:

- FMB is in average 4.3 times faster than SAT to detect intersection between Tetrahedrons, and 1.1 times faster to detect non intersection.
- FMB is in average 2.4 times faster than SAT to detect intersection between a Tetrahedron and a Cuboid, and 1.5 times faster to detect non intersection.
- FMB is in average 1.4 times faster than SAT to detect intersection between Cuboids, and 2.0 times faster to detect non intersection.

There is no significant difference with the general cases.

SAT and FMB follows the same strategy: assume that the pair of Frames is in intersection and try to prove it is false by checking a list of conditions. These conditions are the difference between the two algorithms. The results of the qualification show that in average the conditions used by FMB allows to detect a non intersection faster than those of SAT.

For one given pair in intersection, all the conditions must be checked before the algorithms give their answer. The algorithm with the smallest execution time of all these conditions is then the fastest, and the results shows that this is in general SAT (the exceptions are the 3D static case and 3D dynamic case for Tetrahedrons pairs). This is shown in the results by the low variability of the ratio $\text{timeFMB}/\text{timeSAT}$ for intersecting pairs.

For one given pair not in intersection, the algorithms reply as soon as one condition is verified. This may be the first one, as it may be the last one depending on the geometry of the pair of Frames. Then, the variability of the ratio $\text{timeFMB}/\text{timeSAT}$ varies widely as shown in the results, from 50 times faster to 29 times slower, but the results shows that in general the advantage goes to the FMB algorithm (the exception is the 2D dynamic case).

In the SAT algorithm, one must perform the projection of all vertices on one axis and then check the result which is the intersection condition. Every axis comes from the geometry of the Frames and one cannot preview which one will be lead to the checked condition for a non intersecting pair. In the FMB algorithm, the conditions depends on the way the system of linear inequation is built. Then, for best performances, it must be done in such a way that inequality (41) is encountered as soon as possible. With the FMB representation, contrary to the SAT one, it is possible to do so independantly of the geometry of the pair of Frames by reordering the inequalities of the system. For example, the $X_i \leq 1.0$ inequalities must be moved down to the end of the system of the linear inequalities for better performance, as they will never lead to '(41) is true' at the first step of the Fourier-Motzkin algorithm.

Looking for other rearrangement of the inequations, I've come to the conclusion that the best possible case (in term of speed) is, when checking Frame A against Frame B, to have:

- B's origin is the nearest vertex of B relative to A's origin
- the projection of B's origin in A's coordinate system is such as components of $\overrightarrow{AB_A}$ are all positive

This the best possible case because it minimised the a_i in (41) in the initial system or during Fourier-Motzkin algorithm, which leads quickly to '(41) is true' if the Frames are not in intersection. The Frame representation is invariant of the vertex chosen as origin, so it's possible to rearrange them to try to fit the conditions above (however it's not always possible to fit both). I've checked that it effectively leads to slightly better performances by first modifying the qualification program to generate only these cases, and then by adding a rearrangement of the origins at the beginning of the FMB algorithm. Unfortunately, the cost of the origin rearrangement is heavier than its benefit. Still, I believe one may find some clever rearrangement which would lead to even better performance for the FMB algorithm.

10 Conclusion

In this paper I've introduced the FMB algorithm which solve efficiently the intersection detection problem of 2D/3D static/dynamic cuboid/tetrahedron by using the Fourier-Motzkin elimination method. All information necessary to implement and use the FMB algorithm, or reproduce the results introduced in this paper are included in this paper, and available on the GitHub repository <https://github.com/BayashiPascal/FMB/> .

Validation and qualification against the SAT algorithm prove the correctness of the results from the FMB algorithm and prove it's a valid alternative in term of performance to the SAT algorithm, especially when applied to tetrahedrons and/or in the 3D static case. It is also important to note its simplicity to implement, and the fact that the FMB algorithm returns a bounding box of the intersection, if any, while the SAT algorithm only returns a boolean answer.

Idea on direction to explore with the view to improve the FMB algorithm is given. Steps of the Fourier-Motzkin could also be easily parallelized on an appropriate architecture to improve performance. Tests of implementation with others programming languages, or on other runtime environments, or against other algorithms (such as CJK) would also be interesting to perform. Finally, while the algorithm is introduced here in 2D and 3D, its extension

to upper dimensions is straightforward.

11 Annex

11.1 Runtime environment

Results introduced in this paper have been produced by compiling and running the corresponding algorithms in the following environment:

```

11.2 SAT implementation

In this section I introduce the code of the implementation of the SAT algorithm, used to validate and qualify the FMB algorithm.

11.2.1 Header

```

#ifndef __SAT_H_
#define __SAT_H_

#include <stdbool.h>
#include <string.h>
#include "frame.h"

// ----- Functions declaration -----

// Test for intersection between 2D Frame that and 2D Frame tho
// Return true if the two Frames are intersecting, else false
bool SATTestIntersection2D(
    const Frame2D* const that,
    const Frame2D* const tho);

// Test for intersection between moving 2D Frame that and 2D
// Frame tho
// Return true if the two Frames are intersecting, else false
bool SATTestIntersection2DTime(
    const Frame2DTime* const that,
    const Frame2DTime* const tho);

// Test for intersection between 3D Frame that and 3D Frame tho
// Return true if the two Frames are intersecting, else false
bool SATTestIntersection3D(
    const Frame3D* const that,
    const Frame3D* const tho);

```

```

// Test for intersection between moving 3D Frame that and 3D
// Frame tho
// Return true if the two Frames are intersecting, else false
bool SATTestIntersection3DTime(
    const Frame3DTime* const that,
    const Frame3DTime* const tho);
#endif

```

11.2.2 Body

```

#include "sat.h"

// ----- Macros -----

#define EPSILON 0.0000001

// ----- Functions declaration -----

// Check the intersection constraint along one axis for 3D Frames
bool CheckAxis3D(
    const Frame3D* const that,
    const Frame3D* const tho,
    const double* const axis);

// Check the intersection constraint along one axis for moving 3D Frames
bool CheckAxis3DTime(
    const Frame3DTime* const that,
    const Frame3DTime* const tho,
    const double* const axis,
    const double* const relSpeed);

// ----- Functions implementation -----

// Test for intersection between 2D Frame that and 2D Frame tho
// Return true if the two Frames are intersecting, else false
bool SATTestIntersection2D(
    const Frame2D* const that,
    const Frame2D* const tho) {

    // Declare a variable to loop on Frames and commonalize code
    const Frame2D* frameEdge = that;

==8646==
==8646== TO CONTROL THIS PROCESS USING vgdb (which you probably
==8646== don't want to do, unless you know exactly what you're doing,
==8646== or are doing some strange experiment):
==8646==   /usr/lib/valgrind/../../bin/vgdb --pid=8646 ...command...
==8646==
==8646== TO DEBUG THIS PROCESS USING GDB: start GDB like this
==8646==   /path/to/gdb ./unitTests
==8646== and then give GDB the following command
==8646==   target remote | /usr/lib/valgrind/../../bin/vgdb --pid=8646
==8646== --pid is optional if only one valgrind process is running
==8646==

12 Versions of this paper

This paper has been revised has follow:

- February 5, 2020 : Original version
- April 5, 2020 : Addition of the 'near-case only' results in qualification.
- April 25, 2020 : Update of the qualification results after moving the computation of the inverse of components matrix from outside to inside the intersection detection test for a better comparison with SAT.
