1 FINALITY OF THE REPORT

1.1 Objectives and expected results

This document reports about the WP5 Task 5.2.8 Carbon footprint methodologies & estimation for the pilot cities.

The goal of the task is to integrate in the overall model a specific module to compute the carbon footprint of the cities and in particular its scope is to:

- Review existing carbon footprinting methodologies
- Establish best methodology and relevant emission factors.
- Apply footprinting methodologies to six pilot cities based on activity data from previous tasks

2 SPECIFICATIONS OF MODELLING TOOL SET

2.1 Review of existing carbon footprint methodologies

First of all, a complete review of existing carbon footprint methodologies was completed. Carbon footprint calculation methodologies usually follow the "emission inventory" or the "consumption-based" approaches. The review covered as the "emission inventory" approaches (such as WRI protocol for example¹) than input-output models approaches.

The "emission inventory" approaches usually include generating GHG emissions activities that occur inside the city/region boundary as well as outside the city/region boundary. To distinguish between these, the approaches group emissions into three categories based on where they occur: scope 1, scope 2 or scope 3 emissions. These approaches distinguish between emissions that physically occur within the city/region i.e. from sources located within the city boundary (scope 1), from those that occur from the use of electricity, steam, and/or heating/cooling supplied by grids which may or may not cross city/region boundaries (scope 2), from those that occur outside the city/region but are driven by activities taking place within the city's/region's boundaries (scope 3). Scope 1 emissions may also be termed "territorial" emissions, because they are produced solely within the territory defined by the geographic boundary.

Cities, by virtue of their size and connectivity, inevitably give rise to GHG emissions beyond their boundaries. Measuring these emissions allows cities to take a more holistic approach to tackling climate change by assessing the GHG impact of their supply chains, and identifying areas of shared responsibility for upstream and downstream GHG emissions.

The usual methodologies for city (such as WRI Protocol) includes scope 3 accounting for a limited number of emission sources, including transmission and distribution losses associated with grid-supplied energy, and waste disposal and treatment outside the city boundary and transboundary transportation.

Cities may optionally report Other Scope 3 sources associated with activity in a city-such as GHG emissions embodied in fuels, water, food and construction materials.

Consumption-based accounting is an alternative to the sector-based approach to measuring city/region emissions. This focuses on the consumption of all goods and services by residents of a city/region, and use EFs expressed as emissions for unit of good and services including all the processes (production, transport, disposal).

GHG emissions are reported by consumption category rather than the emission source categories. The consumption-based approach allocates GHG emissions to the final consumers of goods and services, rather than to the original producers of those GHG emissions. Consumption-based inventories typically use an input-output model, which links household consumption patterns and trade flows to energy use and GHG emissions, and their categories cut across those set out in the GPC. This approach is complementary to the GPC and provides a different insight into a city's/region's GHG emissions profile. At conclusion of review work

¹ WRI(2014), Global Protocol for Community-Scale Greenhouse Gas Emission Inventories. An Accounting and Reporting Standard for Cities

a best methodology has been established defining the selected approach and the activities included in scope 3 to take into consideration.

2.2 Clair city approach to carbon footprint

Clair city approach is to evaluate in an integrated way emissions inventory and carbon footprint. Future scenarios are produced for simultaneous reduction of air pollutants emission and carbon footprint.

Considering the general goals of the activities and to delimitate the efforts from other partners in data retrieval, we select scope 2 approach considering emissions that:

- physically occur within the city/region i.e. from sources located within the city boundary;
- occur from the use of electricity, steam, and/or heating/cooling supplied by grids which may or may not cross city/region boundaries.

As the project is finalized to produce strategies for the cities the carbon footprint evaluation will be conducted following an emission inventory approach similar to the approach followed in the Covenant of Mayors² and using both:

- “Standard” emission factors (emissions will be evaluated using methodologies and emission factors from 2006 IPCC Guidelines for National Greenhouse Gas Inventories³ and specific activity level); the methodology cover all the CO₂ emissions that occur due to energy consumption within the territory of the city/region, either directly due to fuel combustion within the city/region or indirectly via fuel combustion associated with electricity and heat/cold usage within their area; the standard emission factors are based on the carbon content of each fuel, like in national greenhouse gas inventories in the context of the UNFCCC and the Kyoto protocol; in the standard approach, the CO₂ emissions from the sustainable use of biomass/biofuels, as well as emissions of certified green electricity, are considered to be zero; emission are reported as:

- CO₂ only emissions, the most important greenhouse gas,
- CO₂ equivalent emissions, including calculation of the emissions of CH₄ and N₂O with emission factor from 2006 IPCC Guidelines for National Greenhouse Gas Inventories⁴ and reported as CO₂ using the Global Warming Potential (GWP) with 100 years, time horizon⁵:

$$\begin{aligned}1 \text{ Mg CO}_2 &= 1 \text{ Mg CO}_2\text{-eq} \\1 \text{ t CH}_4 &= 21 \text{ Mg CO}_2\text{-eq} \\1 \text{ t N}_2\text{O} &= 310 \text{ Mg CO}_2\text{-eq};\end{aligned}$$

- LCA (Life Cycle Assessment) emission factors, which take into consideration the overall life cycle of the energy carrier; this approach includes not only the emissions of the final combustion, but also all emissions of the supply chain; it includes

² [Covenant of Mayors \(2010\), How to develop a Sustainable Energy Action Plan \(SEAP\) – Guidebook Part II, Baseline emissions inventory](#)

³ [2006 IPCC Guidelines for National Greenhouse Gas Inventories, Volume 2 Energy](#)

⁴ [2006 IPCC Guidelines for National Greenhouse Gas Inventories, Volume 2 Energy](#)

⁵ [IPCC, 1995. Contribution of Working Group I to the Second Assessment of the Intergovernmental Panel on Climate Change](#)

emissions from exploitation, transport and processing (e.g. refinery) steps in addition to the final combustion; this hence includes also emissions that take place outside the location where the fuel is used; in this approach, the GHG emissions from the use of biomass/biofuels, as well as emissions of certified green electricity, are higher than zero; in the case of this approach, other greenhouse gases than CO₂ may play an important role, therefore the LCA approach will report emissions as CO₂ equivalent; as a default will be used the LCA emission factors given in Covenant of Mayors guidelines, based on JRC European Reference Life Cycle Database; specific national emission factors will be investigated.

Eventual local electricity production is not included in the model while district heating is included where data are available.

2.3 Carbon footprint modeling

The Carbon Footprint tool:

- evaluates emissions at most detailed administrative territorial units level;
- uses emission factors from Covenant of Mayors guidelines;
- calculates emissions as:

$$E_k = A_{ij} F_{ik}$$

where:

- A_{ij} is the indicator of the activity i in the territorial unit j
- F_{ik} is the emission factor for different Carbon footprint indicators k for activity i (expressed in grams per unit of activity);
- k is the carbon footprint indicator used: CO₂, CO_{2eq}, CO_{2eq,LCA}

2.4 Emission factors

In Table 1 standard emission factors are reported for different energy vectors while in Table 2 electricity consumptions national emission factors are reported to use for CO₂ indirect emissions from electricity consumptions. EFs from JRC⁹ are used to have a comparable set of data for all the cities.

Table 1 – CO₂ Emission Factors

CF5002M1	Final Consumptions in Other Sectors: Residential (district heating) - Natural gas

2.7 Data evaluation at domains and subdomains

Carbon footprint is evaluated at defined subdomains. When data are available only in aggregate figures (overall domain) or at national level, it is allocated to subdomains using a “proxy” variable available at subdomains.

When data are available at city/region domain, data at subdomain level is evaluated using the following equation:

$$A_i = A * P_i / \sum_i P_i$$

where: A_i and P_i are the values of variable A and proxy variable P in the subdomain i, and A is the total of variable A in the domain.

When data are available at national level, data at subdomain level is evaluated using the following equation:

$$A_i = (N * Q_d / \sum_d Q_d) * P_i / \sum_i P_i$$

where: A_i and P_i are the values of the variable A and proxy variable P in the subdomain i, Q_d is the values of the proxy variable Q in domain d, and N is the national value of proxy variable Q.

3 BASELINE RESULTS

In the following the data collection and evaluation procedures are detailed for Bristol (par. 3.1), Amsterdam (par. 3.1.2), Ljubljana (par. 3.2.2), Sosnowiec (par. 3.3.2), Liguria Region (Genoa Area) (par. 3.4.2) and Aveiro Region (par. 3.5.2).

Fuel consumptions from road traffic are evaluated in the ClairCity project, task 5.2.2 Design & development of transport module.

3.1 Bristol

3.1.1 Data retrieval and fuel consumptions evaluation

The following tables document the methodology and data used for:

- Industrial sources (Table 5)
- Residential and commercial sources (Table 6)
- Aggregate fuel consumptions data subdivision (Table 7)
- LSOA disaggregation variables (Table 8).

Table 5 – Methodology and source of data for Bristol fuel consumptions evaluation - Industrial sources

3.4.2 Carbon footprint results

In Table 20 Carbon Footprint by fuel is reported for Sosnowiec expressed as CO₂, CO₂ equivalent and CO₂ equivalent on Life Cycle.

Table 20 – Sosnowiec Carbon Footprint by Fuel (Mg)

Energy Vector	CO ₂	CO _{2eq}	CO _{2eq,LCA}
Biomass	-	477	193
Gasoil/diesel	74.085	84.868	74.285
Gasoline	30.010	37.816	30.097
LPG	772	956	772
Natural gas	103.449	122.996	103.449
Coal	424.056	444.796	426.704
Electricity	832.889	896.229	836.145
Total	1.465.262	1.588.137	1.471.644

In Figure 23 Carbon Footprint expressed as CO₂ equivalent on Life Cycle is reported by fuel and sector. The data source used reports aggregate values for industry and services fuel consumptions; in consequence also in carbon footprint the data are reported together.

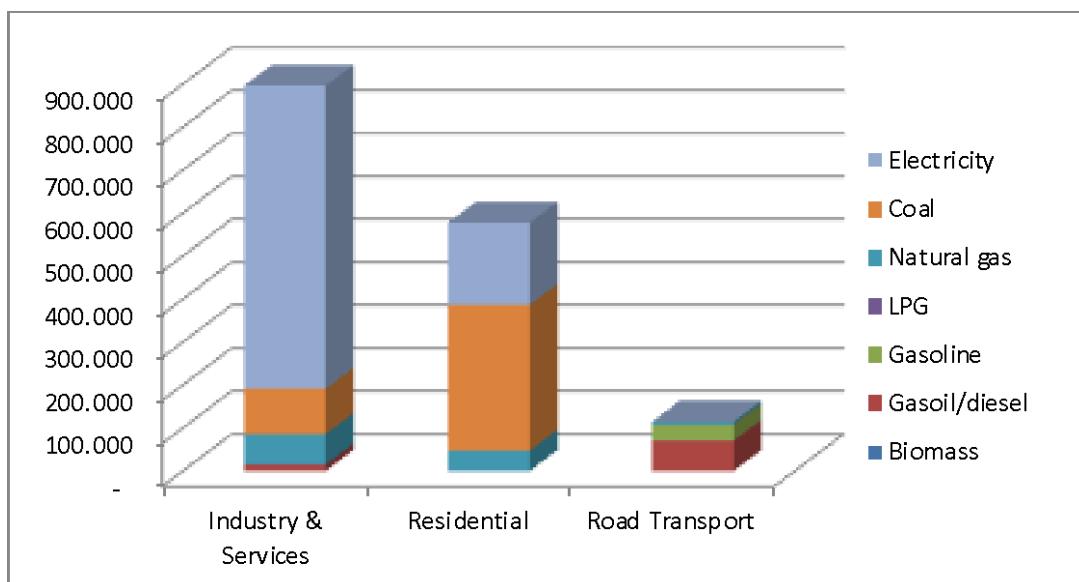

Figure 23 – Sosnowiec Carbon Footprint (Mg CO₂ equivalent on Life Cycle)

For Sosnowiec Gminas is not defined a subdivision of the territory and the maps are not reported as not relevant (the map would report only one territory).

3.5 Liguria Region (Genoa Area)

3.5.1 Data retrieval and fuel consumptions evaluation

The following tables document the methodology and data used for:

- Industrial sources (Table 21);
- Residential and commercial sources (Table 22);
- Wood statistics (Table 23);
- Residential fuel energy demand (Table 24);
- Sezione di censimento disaggregation variables (Table 25).

3.6 Aveiro Region

3.6.1 Data retrieval and fuel consumptions evaluation

The following tables document the methodology and data used for:

- Industrial sources (Table 27);
- Residential and commercial sources (Table 28);
- Freguesia disaggregation variables (Table 29).

Note that we use Freguesia subdivision at time of 2011 census.
