Molecular glue compounds induce protein-protein interactions that, in the context of a ubiquitin ligase, lead to protein degradation.[1] Unlike traditional enzyme inhibitors, such molecular glue degraders act sub-stoichiometrically to catalyse rapid depletion of previously inaccessible targets.[2] They are clinically effective and highly sought-after, but have thus far only been discovered serendipitously. Through systematic mining of databases for correlations between the cytotoxicity of 4,518 clinical and pre-clinical small molecules and E3 ligase expression levels across hundreds of human cancer cell lines,[3–5] we identified CR8, a cyclin-dependent kinase (CDK) inhibitor,[6] as a compound that acts as a molecular glue degrader. A solvent-exposed pyridyl moiety of CR8, in its CDK-bound form, induces CDK12-cyclin K complex formation with DDB1, the CUL4 adaptor protein, bypassing the requirement for a substrate receptor and presenting cyclin K (cycK) for ubiquitination and degradation. Our studies demonstrate that chemical alteration of surface-exposed moieties can confer gain-of-function glue properties to an inhibitor, and we propose this as a broader strategy to turn target binders into molecular glues.

49 Molecular glues are a class of small molecule drugs that induce or stabilise protein-protein

50 interactions[1]. In the context of a ubiquitin ligase, drug-induced interactions can lead to protein

51 degradation, which is an emerging strategy for the inactivation of therapeutic targets intractable

52 by conventional pharmacological means[2]. Known molecular glue degraders bind to substrate

53 receptors of E3 ubiquitin ligases and recruit target proteins for their ubiquitination and

54 subsequent degradation by the proteasome.

55 Thalidomide analogues and aryl sulphonamides are two classes of drugs that act as molecular

56 glue degraders. Widely used in the clinic, thalidomide analogues have proven to be an effective

57 treatment for multiple myeloma, other B cell malignancies, and myelodysplastic syndrome

58 with a deletion in chromosome 5q[7]. Thalidomide analogues recruit zinc-finger transcription

59 factors and other targets to CRBN[8–11], the substrate receptor of the cullin-RING E3 ubiquitin

60 ligase CUL4A/B-RBX1-DDB1-CRBN (CRL4^{CRBN})[12]. Similarly, aryl sulphonamides degrade

61 the essential RNA-binding protein RBM39 by engaging DCAF15, the substrate receptor of the

62 CRL4^{DCAF15} E3 ubiquitin ligase[13–15]. In these examples, the degraders are not dependent on a

63 ligandable pocket on the target protein, but instead leverage complementary protein-protein

64 interfaces between the receptor and the target. By reprogramming ubiquitin ligase selectivity,

65 these molecules divert the ligase to drive multiple rounds of target ubiquitination in a catalytic

66 manner[16]. Such compounds can thus circumvent limitations of classical inhibitors, expanding

67 the repertoire of "druggable" proteins. Although highly sought-after, molecular glue degraders

68 have only been found serendipitously, and there are currently limited strategies available for

69 identifying or designing such compounds.

CR8 induces proteasomal cycK degradation

To identify small molecules that mediate protein degradation through an E3 ubiquitin ligase, we correlated drug sensitivity data for 4,518 clinical and pre-clinical drugs tested against 578 cancer cell lines[3,4] with the mRNA expression levels for 499 E3 ligase components[5] (**Extended Data Fig. 1a**). *DCAF15* gene expression correlated with indisulam and tasisulam toxicity, consistent with its known function as a degrader of the essential protein RBM39 by the CRL4[DCAF15] E3 ubiquitin ligase, thus demonstrating the potential of the approach (**Extended Data Fig. 1b, c).** We sought to validate the high-scoring ligase-drug correlations by examining whether CRISPR-mediated inactivation of the identified E3 ligase component would rescue the respective drug-induced toxicity (**Extended Data Fig. 1d**). These experiments confirmed that sgRNAs targeting *DCAF15* confer resistance to indisulam and tasisulam. In addition, we observed a correlation between cytotoxicity of the CDK-inhibitor *R*-CR8[6] and mRNA expression levels of the CUL4 adaptor DDB1 (**Fig. 1a and Extended Data Fig. 1e)**. Consistently, sgRNAs targeting *DDB1* conferred resistance to *R*-CR8 **(Fig. 1b)**.

As DDB1-dependent cytotoxicity of *R*-CR8 implicated ubiquitin ligase-mediated degradation of one or more essential proteins, we performed quantitative proteome-wide mass spectrometry to evaluate protein abundance following compound treatment. Of the >8,000 quantified proteins, cycK was the only protein that consistently showed decreased abundance following *R*-CR8 addition (**Fig. 1c, Extended Data Fig. 1f, g**). As expected, *R*-CR8 did not alter cycK mRNA levels (**Extended Data Fig. 1h)** and compound-induced cycK degradation could be rescued by inhibition of the E1 ubiquitin-activating enzyme (MLN7243), cullin neddylation (MLN4924) and the proteasome (MG132) (**Fig. 1d**). Together, these results suggest that *R*-CR8 triggers rapid proteasomal degradation of cycK (**Fig. 1e**) through the activity of a DDB1-containing cullin-RING ubiquitin ligase.

To dissect the molecular machinery required for *R*-CR8 toxicity, we performed genome-wide and E3 ubiquitin ligase-focused CRISPR-Cas9 resistance screens (**Fig. 1f, Extended Data Fig. 2a, b**). SgRNAs targeting *DDB1*, *CUL4B*, *RBX1*, the cullin-RING activator *NEDD8*, and the NEDD8-activating enzyme (*NAE1/UBA3*) were significantly enriched in the *R*-CR8-resistant cell population. As all of these proteins are required for CRL activity, our results provide genetic evidence for the involvement of a functional CUL4-RBX1-DDB1 ubiquitin ligase complex in mediating *R*-CR8 cytotoxicity.

Thus far, all known cullin-RING ligases engage their substrates through specific substrate receptors, and DDB1 serves as an adaptor protein able to bind over 20 such receptors (also known as DDB1-CUL4-associated-factors, DCAFs)[17,18] to recruit them to the CUL4-RBX1

ligase core. As no DCAF was identified in our viability screens, we constructed a fluorescent reporter of cycK stability (**Extended Data Fig. 2c**), in which *R*-CR8-mediated degradation of endogenous cycK could be recapitulated with a cycK$_{eGFP}$ fusion protein (**Fig. 1d, e, Extended Data Fig. 2d-f**). Using the stability reporter, in which the extent of degradation can be determined by measuring cycK$_{eGFP}$ levels normalised to mCherry expression, we found that *S*- and *R*-CR8 facilitated cycK$_{eGFP}$ degradation to the same extent (**Extended Data Fig. 2g**; henceforth, CR8 refers to *R*-CR8). We then performed a genome-wide CRISPR-Cas9 screen for genes involved in cycK reporter stability and validated the involvement of DDB1 in CR8-mediated cycK degradation (**Fig. 1g, Extended Data Fig. 2h),** but not in compound-independent cycK degradation (**Extended Data Fig. 2i**). In addition, we identified cyclin-dependent kinase 12 (CDK12), which is a known target of CR8[19] and whose activity depends on the interaction with cycK[20], as a crucial component for CR8-induced cycK$_{eGFP}$ destabilisation (**Fig. 1g, Extended Data Fig. 2h-k**).

As neither the cycK$_{eGFP}$ stability reporter screen nor the CR8 resistance screen identified a substrate receptor, we performed additional CRISPR screens targeting 29 genes encoding known DCAFs or DCAF-like candidate proteins in four different cell lines. While sgRNAs targeting the previously identified components of the CUL4-RBX1-DDB1 complex consistently caused resistance to CR8, a DCAF substrate receptor could not be identified (**Extended Data Fig. 3**).

CR8 directs CDK12 to CRL4 core component

Since none of our genetic screens highlighted a DCAF required for cycK degradation, we tested whether CR8-engaged CDK12-cycK directly binds one of the CUL4-RBX1-DDB1 ligase components in the absence of a substrate receptor. We therefore performed *in vitro* co-immunoprecipitation experiments using recombinantly purified proteins. The kinase domain of CDK12 (CDK12$^{713-1052}$) bound to cycK$^{1-267}$ did not markedly enrich DDB1 over the bead binding control in the absence of CR8, whereas equimolar amounts of the compound led to stoichiometric complex formation (**Fig. 2a**). DDB1 β-propeller domains A (BPA) and C (BPC)[17], which are otherwise involved in DCAF binding, were sufficient for drug-induced CDK12-cycK recruitment. DDB1 β-propeller B (BPB), which binds CUL4 and is not involved in DCAF binding, was dispensable for the interaction (**Fig. 2a**). *In vitro* ubiquitination assays confirmed that the CUL4A-RBX1-DDB1 ligase core alone is sufficient to drive robust cycK ubiquitination (**Fig. 2b**). Quantification of the interaction showed that CR8 stimulated binding

137   between CDK12-cycK and DDB1 in the range of 100-500 nM depending on the experimental

138   setup (**Fig. 2c, Extended Data Fig. 4**). While weak CDK12-cycK-DDB1 interaction was still

139   detectable in the absence of the compound *in vitro*, CR8 strengthened complex formation 500-

140   to 1000-fold as estimated by isothermal titration calorimetry (ITC) (**Extended Data Fig. 4f-**

141   **k**). Thus, our data indicate that CR8-engaged CDK12-cycK is recruited to the CUL4-RBX1-

142   DDB1 ligase core through DDB1, and the compound tightens the complex sufficiently to drive

143   CR8-induced cycK degradation in the absence of a canonical DCAF substrate receptor.

144   We then crystallised CDK12$^{713-1052}$-cycK$^{1-267}$ bound to CR8 and DDB1$^{\Delta BPB}$ and determined the

145   3.5 Å resolution structure of this complex (**Fig. 2d**, **Extended Data Table 1**). In the structure,

146   CDK12 forms extensive protein-protein interactions (~2100 Å^2) with DDB1. CR8 binds the

147   active site of CDK12 and bridges the CDK12-DDB1 interface, while cycK binds CDK12 on

148   the opposite site and does not contact DDB1. The N- and C-lobes of CDK12 are proximal to

149   DDB1 residues located in a loop of the BPA domain (amino acid (aa) 111-114), BPC-helix 2

150   (aa 986-990), and a loop in the C-terminal domain (aa 1078-1081) that are otherwise involved

151   in DCAF binding (**Extended Data Fig. 5**). In addition, the C-terminal extension of CDK12

152   binds the cleft between the DDB1 domains BPA and BPC, a hallmark binding site of DDB1-

153   DCAF interactions (**Extended Data Fig. 5a-d, i**). The density for this region could only be

154   tentatively assigned, likely due to the presence of multiple conformations, but the CDK12 C-

155   terminal tail clearly engages with DDB1 and assumes a conformation different from those seen

156   in isolated CDK12-cycK structures (**Extended Data Fig. 6a, b, d**)[19,21]. Structure-guided

157   mutational analyses combined with time-resolved fluorescence resonance energy transfer (TR-

158   FRET) assays were used to assess the contribution of these interactions to CR8-dependent

159   CDK12-DDB1 complex formation (**Fig. 2e, Extended Data Fig. 5e**). Taken together, our data

160   demonstrates that CDK12 assumes the role of a glue-induced substrate receptor and places

161   cycK in a position typically occupied by CRL4 substrates (**Fig. 2f**). This renders CDK12-cycK

162   binding to DDB1 mutually exclusive with that of DCAFs and provides a structural framework

163   for why a canonical substrate receptor is dispensable for cycK ubiquitination.

164

165   **CDK12-DDB1 interface imparts selectivity**

166   CR8 is a pleiotropic CDK inhibitor reported to bind CDK1/2/3/5/7/9/12[6,19], yet in cells we

167   observed selective cycK destabilization in the presence of the drug. As cycK is reported to

168   associate with CDK9, CDK12, and CDK13[19], we tested whether the other cycK-dependent

169   kinases are also recruited to DDB1. The closely related CDK13 (90.8 % sequence identity),

170   but not the more divergent CDK9 (45.5 % sequence identity) (**Extended Data Fig. 7a-c**), was

recruited to DDB1 in the presence of CR8, albeit with a lower binding affinity (**Extended Data Fig. 7d-f**). Analogously, less productive *in vitro* cycK ubiquitination was observed for CDK13 compared to CDK12 (**Extended Data Fig. 7g**). The key difference between CDK9 and CDK12/13 primary sequence lies in the C-terminal extension (**Extended Data Fig. 7a, b**), which in our structure nestles up against DDB1 BPA and BPC propellers (**Fig. 2d, Extended Data Fig. 5i**). Mutations in, or truncation of, the CDK12 C-terminal extension (**Extended Data Fig. 5c**) abolished basal binding between CDK12 and DDB1, whereas complex formation could still be facilitated by CR8 to a varying extent (**Extended Data Fig. 7h, i**). Hence, our data show that the pan-selective CDK inhibitor CR8 induces specific protein-protein interactions between CDK12/13 and DDB1 and suggest that the C-terminal extension, while contributing to binding, is not essential for drug-dependent kinase recruitment.

CR8 phenylpyridine confers glue activity

CR8 occupies the ATP binding pocket of CDK12 and forms discrete contacts with residues in the BPC domain of DDB1 (~150 $Å^2$) through its hydrophobic phenylpyridine ring system (**Fig. 3a, b**). Mutation of DDB1 residues Ile909, Arg928, and Arg947 each diminished drug-induced recruitment of the kinase (**Extended Data Fig. 5f**), highlighting the contribution of the phenylpyridine moiety to complex formation. To evaluate the structure-activity relationship underlying the gain-of-function activity of CR8, we probed other CDK inhibitors for their ability to drive complex formation between DDB1 and CDK12. DRF053[22], a CR8-related inhibitor that carries a differently linked phenylpyridine ring system (**Fig. 3a, c**), induced binding with two-fold lower affinity than CR8 (**Extended Data Fig. 8a**). Roscovitine[23], the parent compound of CR8 that lacks the 2-pyridyl substituent but retains the phenyl ring proximal to Arg928 (**Fig. 3a, c**), also facilitated complex formation, albeit with a three-fold lower apparent affinity (**Extended Data Fig. 8a**). The affinity rank-order observed in our TR-FRET assay correlated with the degree of cycK ubiquitination *in vitro*, in which DRF053 and roscovitine showed less processive ubiquitination (**Fig. 3d**). As neither DRF053 nor roscovitine induced degradation of the cycK$_{eGFP}$ reporter in cells (**Fig. 3e**), our results demonstrate that the presence and correct orientation of the 2-pyridyl on the surface of CDK12 confer the gain-of-function activity of CR8 leading to cycK degradation.

To probe whether any ligand could in principle drive the interaction of CDK12 with DDB1, we tested the endogenous CDK nucleotide cofactor ATP for its ability to promote complex formation. ATP neither facilitated nor abrogated the interaction over basal binding observed in

204 the presence of DMSO (**Extended Data Fig. 6c**), suggesting that although the nucleotide-
205 bound conformation of CDK12 seems incompatible with approaching DDB1 (**Extended Data**
206 **Fig. 6b**), its C-terminal extension is free to adopt multiple conformations[21]. THZ531[24], a bulky
207 covalent CDK12/13 inhibitor predicted to clash with DDB1 (**Extended Data Fig. 6d-f**), locks
208 the CDK12 C-terminal extension in a conformation incompatible with DDB1 recruitment
209 (**Extended Data Fig. 6d**). Consistently, THZ531 further decreased the TR-FRET signal and
210 diminished cycK ubiquitination *in vitro* below DMSO control levels (**Fig. 3d, Extended Data**
211 **Fig. 6c, f)**[24]. Flavopiridol[25], a natural product-derived inhibitor structurally distinct from CR8
212 (**Fig. 3a, c**), also stimulated the binding of CDK12-cycK to DDB1 (**Extended Data Fig. 8a**).
213 While flavopiridol gave rise to moderate cycK ubiquitination *in vitro* (**Fig. 3d**), it failed to
214 degrade cycK in cells (**Fig. 3e**). Our results thus show that the DDB1-compound interactions
215 display significant plasticity and that structurally diverse surface-exposed moieties in CR8,
216 DRF053, roscovitine and flavopiridol can facilitate CDK12-cycK recruitment. Small
217 differences in their ability to stabilise the DDB1-CDK12 complex translate, in an almost binary
218 fashion, into cellular degradation of cycK or lack thereof. This behaviour is reminiscent of
219 CRL4[CRBN] and thalidomide analogues[11,26], where an apparent affinity threshold must be
220 overcome to drive drug-induced target degradation.
221
CycK degradation adds to CR8 toxicity
223 Finally, to delineate the contribution of CRL4-mediated cycK degradation to CR8 cytotoxicity
224 over non-degradative CDK inhibition, we compared compound toxicity in wild-type
225 HEK293T$_{Cas9}$ cells to cells that were pre-treated with MLN4924 (NEDD8-activating enzyme
226 inhibitor), genetically-depleted for DDB1, or subject to DCAF overexpression. Global
227 inhibition of CRL activity by MLN4924 had only minor effects on cell viability (**Extended**
228 **Data Fig. 9a**), but resulted in decreased sensitivity to CR8 (**Extended Data Fig. 9b**), showing
229 that CRL neddylation significantly contributes to CR8 toxicity. Overexpression of the substrate
230 receptor CRBN also affected sensitivity to CR8 and decreased cycK degradation (**Extended**
231 **Data Fig. 9c-g)**, presumably by reducing the free pool of DDB1. As expected, CR8-induced
232 endogenous cycK degradation was dependent on DDB1 (**Fig. 3f)** and, consistently, we found
233 that cytotoxicity of CR8, but not that of the other CDK inhibitors, was ten-fold lower in cells
234 depleted for DDB1 (**Fig. 3g, Extended Data Fig. 9h**). Together, the data demonstrate that the
235 CRL4-dependent gain-of-function glue degrader activity of CR8 strongly contributes to its
236 cellular potency and provides an additional layer of ortholog-specific CDK inactivation
237 through cycK degradation.

238　Kinase inhibitors have long been suspected to have a degradation component to their mode of

239　action[27,28], and our work provides the first characterization and structural dissection of how a

240　kinase inhibitor scaffold acquires degrader properties. Molecular glue degraders have thus far

241　only been shown to engage substrate-recruiting E3 ligase modules. CDK12 is not a constitutive

242　E3 ligase component, but rather serves as a drug-induced substrate receptor, linking DDB1 to

243　the ubiquitination target. CR8 thus bypasses the requirement for a canonical DCAF and instead

244　hijacks the essential adaptor protein DDB1. Although cycK is the primary ubiquitination target,

245　CDK12 may become subject to autoubiquitination upon prolonged compound exposure similar

246　to canonical DCAFs[29,30].

247　While previously reported molecular glue degraders engage a ligandable pocket on the ligase

248　to recruit target proteins, CR8 instead binds the active site of CDK12 and does not rely on an

249　independent ligand binding site on DDB1 (**Extended Data Fig. 4h**). This suggests that the

250　repertoire of targets and ubiquitin ligases accessible to targeted protein degradation can be

251　expanded by target-binding small molecules that induce *de novo* contacts with a ligase or

252　strengthen existing weak protein-protein interactions. Kinase inhibitors in particular often

253　show poor selectivity and small molecule-induced kinase inactivation that leverages

254　complementary protein-protein interfaces offers a path towards improved drug selectivity,

255　which might, for example, facilitate selective inactivation of CDK12, an emerging therapeutic

256　target[31].

257　The gain-of-function glue degrader activity of CR8 is attributed to a 2-pyridyl moiety exposed

258　on the kinase surface. Surface-exposed single residue mutations have been shown to promote

259　the formation of higher-order protein complexes, as the haemoglobin Glu to Val mutation, for

260　example, induces polymerization in sickle cell anaemia[32]. Accordingly, single residue

261　mutations designed to increase surface hydrophobicity give rise to ordered protein

262　assemblies[33]. Bound compounds, such as enzyme inhibitors, can in principle mimic such amino

263　acid changes with dramatic effects on the protein interaction landscape, suggesting that

264　compound-induced protein-protein interactions may be more common than previously

265　recognised. Taken together, our results suggest that modifications of surface-exposed regions

266　in target-bound small molecules offer a rational strategy to develop molecular glue degraders

267　for a given protein target.

Methods

Mammalian cell culture

The human HEK293T cell lines were provided by the Genetic Perturbation Platform, Broad Institute and K562$_{Cas9}$, THP1$_{Cas9}$, P31FUJ$_{Cas9}$ cell lines were provided by Zuzana Tothova (Broad Institute), MOLT-4 were purchased from ATCC and HEK293T$_{Cas9}$[26] and MM1S$_{Cas9}$[34] were previously published. HEK293T cells were cultured in DMEM (Gibco) and all other cell lines in RPMI (Gibco), with 10% FBS (Invitrogen), glutamine (Invitrogen) and penicillin–streptomycin (Invitrogen) at 37 °C and 5% CO_2.

Compounds

R-CR8 (3605) was obtained from Tocris, *S*-CR8 (ALX-270-509-M005), flavopiridol (ALX-430-161-M005) from Enzo Life Sciences, roscovitine (HY-30237), THZ531 (HY-103618), LDC00067 (HY-15878) from MedChem Express and DRF053 (D6946) from Sigma.

Antibodies

The following antibodies were used in this study: anti-cycK (Bethyl Laboratories, A301-939A for full length cycK), anti-cycK (abcam, ab251652, for cycK$^{1-267}$), anti-beta-actin (Cell Signaling, #3700), anti-CRBN (Sigma prestige, HPA045910), anti-mouse 800CW (LI-COR Biosciences, 926-32211), anti-rabbit 680LT (LI-COR Biosciences, 925-68021), anti-rabbit IgG antibodies (abcam, ab6721).

Reporter vectors

The following reporter were used in this study: Artichoke (SFFV.BsmBICloneSite-17aaRigidLinker-eGFP.IRES.mCherry.cppt.EF1α.PuroR, Addgene #73320 for Genome wide screen and validation experiments), Cilantro 2 (PGK.BsmBICloneSite-10aaFlexibleLinker-eGFP.IRES.mCherry. cppt.EF1α.PuroR, Addgene #74450 for degradation kinetics), sgBFP (sgRNA.SFFV.tBFP, for Validation of drug-E3 ligase pairs), sgRFP657, (sgRNA.EFS.RFP657 for Validation of drug-E3 ligase pairs), sgPuro, (pXPR003, Addgene #52963, for drug sensitivity assays).

Oligos

List of all oligonucleotides used in this study can be found in Supplementary Oligo Table 1.

Bioinformatic screen

We computed Pearson correlations of viability of PRISM repurposing compounds in 8 doses and 578 cell lines[4] with gene expression (GE) and copy number variation (CN) of all detectable protein-coding genes of matched cell lines from The Cancer Cell Line Encyclopedia (CCLE)[5]. Z score was computed for each pair of compounds, dose viability, and genomic feature (GE or CN) across all cell lines. For each compound-genomic feature pair, the most extreme correlations are ranked from negative to positive. To focus on novel compound-gene relationships, we restricted genes to a curated list of 499 E3 ligase components and compounds that are not one of "EGFR inhibitor", "RAF inhibitor" or "MDM inhibitor" based on PRISM repurposing annotation[5]. Hit compounds were selected if either the Z score was less than -6 or ranked in the top 15 with Z score less than -4. The resulting list of 158 E3 gene-compound pairs was further curated and shortened manually to 96 E3 gene-compound pairs, which included 95 unique E3 ligases and 85 unique compounds.

Cloning and lentiviral packaging of sgRNAs targeting 95 E3 ligases

sgRNAs targeting E3 ligases were selected from the human Brunello CRISPR library[35]. 170 oligo pairs (IDT) targeting 95 E3 ligases were annealed and cloned into the sgRNA.SFFV.tBFP (Guide ID A) or sgRNA.EFS.RFP657 (Guide ID B) fluorescent vectors in a 96-well format using previously published protocols[36]. Briefly, vectors were linearized with BsmBI (New England Biolabs) and gel purified with the Spin Miniprep Kit (Qiagen). Annealed oligos were phosphorylated with T4 Polynucleotide Kinase (New England Biolabs) and ligated into the linearized and purified vector backbones with T4 DNA Ligase (New England Biolabs). Constructs were transformed into XL10-Gold ultracompetent *Escherichia coli* (Stratagene/Agilent Technologies), plasmids were purified using MiniPrep Kit (Qiagen), and guide sequence confirmed by Sanger sequencing. For validation of the primary screen, virus was produced in a 96-well format. Briefly, 11,000 HEK293T cells were seeded per well in 100 μL DMEM medium supplemented with 10% FBS and Penicillin-Streptomycin-Glutamine. The next day a Packaging Mix was prepared in a 96-well plate consisting of 500 ng psPAX2, 50 ng pVSV-G and 17 ng sgRNA backbone in 5 μL OptiMem (Invitrogen) and incubated for 5 minutes at room temperature. This mix was combined with 0.1 μL TransIT-LT1 (Mirus) in 5 μL of OptiMem, incubated for 30 minutes at room temperature, and then applied to cells. Two days post-transfection, dead cells were removed by centrifugation and lentivirus containing medium was collected stored at -80°C prior to use.

Validation of drug-E3 ligase pairs from the bioinformatic screen

K562$_{Cas9}$, OVK16$_{Cas9}$, A564$_{Cas9}$, ES2$_{Cas9}$ and MOLM13$_{Cas9}$ cell lines were individually transduced with 192 sgRNAs targeting 95 E3 ligases in a 96-well plate format. 3000 cells/well were plated in 100 µL RPMI supplemented with 10% FCS and Penicillin-Streptomycin-Glutamine and 30µL/well of virus supernatant was added. 24 hours post infection the medium was changed. After three days, the percentage of sgRNA transduced cells was determined by flow cytometry. If more than 60% of cells were transduced, un-transduced cells were added to bring the level below 60%. Eight days post-infection cell density was measured and adjusted to 1.5 x 10^5 cells/mL with RPMI. For treatment, 50 µL of sgRNA transduced cells were seeded into each well of a 384 well plate with pre-plated DMSO or cognate drug in three concentrations (0.1 µM, 1 µM, 10 µM) with Agilent BRAVO Automated Liquid Handling Platform. Plates were sealed with White Rayon adhesive sealing tape (Thermo Fisher Scientific) and grown for three days. Adherent cell lines were trypsinised and re-suspended in 50 µL of RPMI with Matrix WellMate (Thermo Scientific). Suspension cells were directly subjected to analysis. 10 µL of cell suspension was subjected to the flow analysis with FACSCanto equipped with High Throughput Sampler (BD Bioscience). The percentage of sgRNA transduced cells in the drug treatment wells was normalised to the DMSO control. Wells with fluorescent drug and samples with less than 120 viable cells events or less than 6% fluorescent cells were removed from analysis. All E3-drug pairs were ranked based on the number of experimental conditions (cell line and drug dose) with more than 50% of sgRNA transduced cells in drug treatment wells in comparison to corresponding DMSO control.

Validation of DDB1 resistance phenotype

For validation experiments, virus was produced in a 6-well plate format, as described above with the following adjustments: 2.5 x 10^5 HEK293T cells/well in 2 mL DMEM medium, 3 µL/well of TransIT-LT1, 15 µL/well of OPTI-MEM, 500 ng/well of the desired plasmid, 500 ng/well psPAX2, and 50 ng/well pVSV-G in 32.5 µL/well OPTI-MEM. After collecting the virus, 10 x 10^3 HEK293T$_{Cas9}$ cells in 100 µL DMEM medium were transduced with 10 µL of virus supernatant. The transduced HEK293T$_{Cas9}$ cells were then mixed with untransduced control cells at a 1:9 ratio. Nine days after sgRNA transduction, cells were treated for 3 days with DMSO or 1 µM CR8 and analysed by flow cytometry to determine the percentage of BFP$^+$ cells. sgRNAs targeting DDB1 provide partial depletion of DDB1 (50% DDB1 alleles modified, reducing DDB1 levels by roughly 50%), which suggests selection towards heterozygous or hypomorphic clones.

494

Whole proteome quantification using tandem mass tag mass spectrometry

10×10^6 Molt-4 cells were treated with DMSO (triplicate) or 1 µM CR8 (single replicate) for 1 or 5 hours and later were harvested by centrifugation. Samples were processed, measured and analysed as described before[37]. Data are available in the PRIDE repository (PXD016187 and PXD016188).

500

Quantitative PCR

HEK293T$_{Cas9}$ cells were treated with DMSO or 1 µM CR8 for 2 hours, collected by centrifugation, washed with PBS, and snap-frozen at -80°C. mRNA was isolated using a QIAGEN RNA kit (Qiagen, 74106). For cDNA synthesis, total RNA was reverse transcribed using a High-Capacity cDNA Reverse Transcription Kit (Thermo Fischer) before qPCR analysis with TaqMan Fast Advanced Master Mix (ThermoFisher Scientific, 4444557) for CCNK (TaqMan, Hs00171095_m1, Life Technologies) and GAPDH (TaqMan, Hs02758991_g1). Reactions were run and analysed on a CFX96 Real Time system (Bio-Rad).

509

Immunoblots for whole protein lysate

Cells were washed with phosphate buffered saline (PBS) and lysed (150 mM NaCl, 50 mM Tris (pH 7.5), 1% NP-40, 1% glycerol, 1x Halt Cocktail protease and phosphatase inhibitors) for 20 minutes on ice. The insoluble fraction was removed by centrifugation, protein concentration was quantified using a BCA protein assay kit (Pierce), and equal amount of lysate was run on SDS-PAGE 4-12% Bis-Tris Protein Gels (NuPAGE, Thermo Fisher) and subsequently transferred to nitrocellulose membrane with Trans-Blot Turbo System (BIO-RAD). Membranes were blocked in Odyssey Blocking Buffer/PBS (LI-COR Biosciences) and incubated with primary antibodies overnight at 4°C. The membranes were then washed in TBS-T, incubated for 1 hour with secondary IRDye-conjugated antibodies (LI-COR Biosciences), and washed three times in TBS-T for 5 minutes prior to Near-Infrared Western blot detection on an Odyssey Imaging System (LI-COR Biosciences).

522

CycK stability reporter analysis

HEK293T$_{Cas9}$ expressing the cycK$_{eGFP}$ degradation reporter were transduced with experimental sgRNAs. Nine days after infection the cells were dosed for 2 hours with DMSO or 1 µM CR8 and fluorescent signal quantified by flow cytometry (CytoFLEX, Beckman or LSR Fortessa flow cytometer BD Biosciences). Using FlowJo (flow cytometry analysis software, BD), the

geometric mean of eGFP and mCherry fluorescent signal for round and mCherry positive cells was calculated. The ratio of eGFP to mCherry was normalised to the average of three DMSO-treated controls.

Genome wide CRISPR – CR8 resistance screen

5% (v/v) of the human genome-wide CRISPR-KO Brunello library with 0.4 µL Polybrene/mL (stock of 8 mg/mL) was added to 1.5×10^8 HEK293T$_{Cas9}$ in 75 mL of medium and transduced (2400 rpm, 2 hours, 37°C). 24h after infection sgRNA transduced cells were selected with 2 µg/mL of Puromycin for two days. On the ninth day post-infection, cells were treated with either DMSO (n=1) or 1 µM CR8 (n=1) and cultured for an additional 3 days. Resistant live cells were selected by gently washing away detached dead cells from the medium. Cell pellets were resuspended in multiple direct lysis buffer reactions (1 mM CaCl$_2$, 3 mM MgCl$_2$, 1 mM EDTA, 1% Triton X-100, Tris pH 7.5 - with freshly supplemented 0.2 mg/mL Proteinase) with 1×10^6 cells per 100 µL reaction. The sgRNA sequence was amplified in a first PCR reaction with eight staggered forward primers. 20 µL of direct lysed cells was mixed with 0.04U Titanium Taq (Takara Bio 639210), 0.5 x Titanium Taq buffer, 800 µM dNTP mix, 200 nM SBS3-Stagger-pXPR003 forward primer, 200 nM SBS12-pXPR003 reverse primer in a 50 µL reaction (cycles: 5 minutes at 94°C, 15 x (30 sec at 94°C, 15 sec at 58°C, 30 sec at 72°C), 2 minutes at 72°C). 2 µL of the first PCR reaction was used as the template for 15 cycles of the second PCR, where Illumina adapters and barcodes were added (0.04U Titanium Taq, 1 x Titanium Taq buffer, 800 µM dNTP mix, 200 nM P5-SBS3 forward primer, 200 nM P7-barcode-SBS12 reverse primer). An equal amount of all samples was pooled and subjected to preparative agarose electrophoresis followed by gel purification (Qiagen). Eluted DNA was further purified by NaOAc and isopropanol precipitation. Amplified sgRNAs were quantified using Illumina NextSeq platform (Genomics Platform, Broad Institute). Read counts for all guides targeting the same gene were used to generate p-values. Hits enriched in resistance population with False Discovery Rate (FDR) < 0.05 and enriched > 5-fold, are labelled on the plot (Fig. 1f)[38].

BISON CRISPR – CR8 resistance screen

The BISON CRISPR library targets 713 E1, E2, and E3 ubiquitin ligases, deubiquitinases, and control genes and contains 2,852 guide RNAs. It was cloned into the pXPR003 as previously described[35] by the Broad Institute Genome Perturbation Platform (GPP). The virus for the library was produced in a T-175 flask format, as described above with the following

562 adjustments: 1.8×10^7 HEK293T cells in 25 mL complete DMEM medium, 244 µL of TransIT-

563 LT1, 5 mL of OPTI-MEM, 32 µg of library, 40 µg psPAX2, and 4 µg pVSV-G in 1 mL OPTI-

564 MEM. 10% (v/v) of BISON CRISPR library was added to 6×10^6 HEK293T$_{Cas9}$ cells in

565 triplicates and transduced. Samples (n=3) were processed as describe above for the genome

566 wide resistance screen.

567

Genome wide CRISPR – cycK stability reporter screen

569 A single clone of cycK$_{eGFP}$ HEK293T$_{Cas9}$ was transduced with the genome wide Brunello

570 library as described above with the following modification: 4.5×10^8 cycK$_{eGFP}$ HEK293T$_{Cas9}$

571 cells in 225 mL of medium. Nine days later cells were treated with CR8 (n=3) or DMSO (n=3)

572 for at least 2 hours and the cycK stable population was separated using fluorescence activated

573 cell sorting. Four populations were collected (top 5%, top 5-15%, lowest 5-15% and lowest

574 5%) based on the cycK$_{eGFP}$ to mCherry mean fluorescent intensity (MFI) ratio on MA900 Cell

575 Sorter (Sony). Sorted cells were harvested by centrifugation and subjected to direct lysis as

576 described above. The screen was analysed as described below by comparing stable populations

577 (top 5% eGFP/mCherry expression) to unstable populations (lowest 15% eGFP/mCherry

578 expression). Hits enriched in cycK stable population with FDR < 0.05 are labelled on the plot

579 (Fig. 1g).

580

Pooled CRISPR screen data analysis

582 The data analysis pipeline comprised the following steps: (1) Each sample was normalised to

583 the total number of reads. (2) For each guide, the ratio of reads in the stable vs. unstable sorted

584 gate was calculated, and sgRNAs were ranked. (3) The ranks for each guide were summed for

585 all replicates. (3) The gene rank was determined as the median rank of the four guides targeting

586 it. (4) P-values were calculated by simulating a distribution with guide RNAs that had

587 randomly assigned ranks over 100 iterations. R scripts can be found in the Supplementary

588 Information.

589

DCAF arrayed screen

591 An arrayed DCAF library (targeting DCAFs substrate receptors, DCAF-like and control genes)

592 was constructed as described above with the appropriate oligos (Supplementary Oligo Table

593 1). K562$_{Cas9}$, P31FUJ$_{Cas9}$, THP1$_{Cas9}$ and MM1S$_{Cas9}$ were individually transduced and treated

594 with DMSO or 1 µM CR8 (K562$_{Cas9}$, P31FUJ$_{Cas9}$, THP1$_{Cas9}$) or 0.1 µM CR8 (MM1S$_{Cas9}$). The

595 analysis was performed as described above for validation of DDB1 resistance phenotype.

Protein purification

Human wild-type and mutant versions of DDB1 (Uniprot entry Q16531), CDK12 (Q9NYV4, K965R) and CCNK (O75909) were subcloned into pAC-derived vectors[39] and recombinant proteins were expressed as N-terminal His$_6$, His$_6$-Spy, StrepII or StrepII-Avi fusions in *Trichoplusia ni* High Five insect cells using the baculovirus expression system (Invitrogen)[40]. Wild-type or mutant forms of full-length or beta-propeller B domain deletion (ΔBPB: aa 396-705 deleted) constructs of His$_6$-DDB1 and StrepII-Avi-DDB1 were purified as previously described for DDB1-DCAF complexes[12]. High Five insect cells co-expressing truncated versions of wild-type or mutant His$_6$-CDK12 (aa 713-1052 or 713-1032) and His$_6$- or His$_6$-Spy-tagged cycK (aa 1-267) were lysed by sonication in 50 mM Tris-HCl (pH 8.0), 500 mM NaCl, 10% (v/v) glycerol, 10 mM MgCl$_2$, 10 mM imidazole, 0.25 mM tris(2-carboxyethyl)phosphine (TCEP), 0.1% (v/v) Triton X-100, 1 mM phenylmethylsulfonylfluoride (PMSF), and 1 x protease inhibitor cocktail (Sigma). Following ultracentrifugation, the soluble fraction was passed over HIS-Select Ni^{2+} affinity resin (Sigma), washed with 50 mM Tris-HCl (pH 8.0), 1 M NaCl, 10% (v/v) glycerol, 0.25 mM TCEP, 10 mM imidazole and eluted in 50 mM Tris-HCl (pH 8.0), 200 mM NaCl, 10% (v/v) glycerol, 0.25 mM TCEP, 250 mM imidazole. When necessary, affinity tags were removed by overnight TEV protease treatment. In case of HIS-Select Ni^{2+} affinity purified CDK12-cycK that was not subjected to TEV cleavage, the pH of the eluate was adjusted to 6.8 before ion exchange chromatography. StrepII-tagged versions of CDK12-cycK were affinity purified using Strep-Tactin Sepharose (IBA) omitting imidazole in lysis, wash and elution buffers, supplementing the elution buffer with 2.5 mM desthiobiotin (IBA GmbH), and using 50 mM Tris-HCl (pH 6.8) throughout.

For ion exchange chromatography, affinity purified proteins were diluted in a 1:1 ratio with buffer *A* (50 mM Tris-HCl (pH 6.8), 10 mM NaCl, 2.5% (v/v) glycerol, 0.25 mM TCEP) and passed over an 8 mL Poros 50HQ column. The flow through was again diluted in a 1:1 ratio with buffer *A* and passed over an 8 mL Poros 50HS column. Bound proteins were eluted by a linear salt gradient mixing buffer *A* and buffer *B* (50 mM Tris-HCl (pH 6.8), 1 M NaCl, 2.5% (v/v) glycerol, 0.25 mM TCEP) over 15 column volumes to a final ratio of 80% buffer *B*. Poros 50HS peak fractions containing the CDK12-cycK complex were concentrated and subjected to size exclusion chromatography in 50 mM HEPES (pH 7.4), 200 mM NaCl, 2.5% (v/v) glycerol and 0.25 mM TCEP. The concentrated proteins were flash frozen in liquid nitrogen and stored at -80°C.

Co-immunoprecipitation assay

The purified His$_6$-CDK12/StrepII-cycK complex was mixed with equimolar concentrations of full-length His$_6$-DDB1 or TEV-cleaved DDB1$^{\Delta BPB}$ (5 μM) in the presence 5 μM R-CR8 or DMSO in IP buffer (50 mM HEPES (pH 7.4), 200 mM NaCl, 0.25 mM TCEP, 0.05% (v/v) Tween-20) containing 1 mg/mL bovine serum albumin. The solution was added to Strep-Tactin MacroPrep beads (IBA GmbH) preequilibrated in IP buffer and incubated for 1 hour at 4°C on an end-over-end shaker. The beads were extensively washed with IP buffer, and the bound protein was eluted with IP buffer containing 2.5 mM desthiobiotin for 1 hour at 4°C on an end-over-end shaker. Eluted proteins were separated by SDS-PAGE stained with Coomassie Brilliant Blue.

Crystallization and data collection

The protein solution for crystallization contained 70 μM TEV-cleaved DDB1$^{\Delta BPB}$, 80 μM R-CR8 and 80 μM TEV-cleaved CDK12-cycK in 50 mM HEPES (pH 7.4), 200 mM NaCl, 0.25 mM TCEP. Crystals were grown by vapour diffusion in drops containing 1 μL DDB1$^{\Delta BPB}$-R-CR8-CDK12$^{713-1052}$-cycK$^{1-267}$ complex solution mixed with 1 μL of reservoir solution containing 0.9 M ammonium citrate tribasic (pH 7.0) in two-well format sitting drop crystallization plates (Swissci). Plates were incubated at 19°C and crystals appeared 5-13 days after setup. Crystals were flash cooled in liquid nitrogen in reservoir solution supplemented with 25% (v/v) glycerol as a cryoprotectant prior to data collection. Diffraction data were collected at the Swiss Light Source (beamline PXI) with an Eiger 16M detector (Dectris) at a wavelength of 1 Å and a crystal cooled to 100 K. Data were processed with *DIALS*, scaled with *AIMLESS* supported by other programs of the CCP4 suite[41], and converted to structure factor amplitudes with *STARANISO*[42], applying a locally weighted $CC_{1/2} = 0.3$ resolution cutoff.

Structure determination and model building

The DDB1$^{\Delta BPB}$–R-CR8-CDK12$^{713-1052}$-cycK$^{1-267}$ complex formed crystals belonging space group $P3_121$, with three complexes in the crystallographic asymmetric unit (ASU). Their structure was determined using molecular replacement (MR) in *PHASER*[43] with a search model derived from PDB entry 6H0F for DDB1$^{\Delta BPB}$, and PDB entry 4NST for CDK12-cycK. The initial model was improved by iterative cycles of building with *COOT*[44], and refinement using *phenix.refine*[45] or *autoBUSTER*[46], with ligand restraints generated using *eLBOW* through *phenix.ready_set*[47]. The final model was produced by refinement with *autoBUSTER*. Analysis with *MOLPROBITY*[48]. indicates that 93.9% of the residues in final model are in favourable

664 regions of the Ramachandran plot, with 0.6% outliers. Data processing and refinement statistics

665 are in Extended Data Table 1. Interface analysis was performed using PISA[49].

666

667 **Biotinylation of DDB1**

668 Purified full-length StrepII-Avi-DDB1 was biotinylated *in vitro* at a concentration of 8 μM by

669 incubation with final concentrations of 2.5 μM BirA enzyme and 0.2 mM D-biotin in 50 mM

670 HEPES (pH 7.4), 200 mM NaCl, 10 mM $MgCl_2$, 0.25 mM TCEP and 20 mM ATP. The

671 reaction was incubated for 1 hour at room temperature and stored at 4°C for 14-16 hours.

672 Biotinylated DDB1 (biotinDDB1) was purified by gel filtration chromatography and stored at -

673 80°C (~20 μM).

674

675 **Time-resolved fluorescence resonance energy transfer (TR-FRET)**

676 Increasing concentrations of Alexa488-SpyCatcher-labelled[26] His$_6$-Spy-cycK/His$_6$-CDK12

677 (Alexa488cycK-CDK12) were added to a mixture of biotinylated DDB1 (biotinDDB1) at 50 nM,

678 terbium-coupled streptavidin at 4 nM (Invitrogen) and kinase inhibitors at 10 μM (final

679 concentrations) in 384-well microplates (Greiner, 784076) in a buffer containing 50 mM Tris

680 (pH 7.5), 150 mM NaCl, 0.1% pluronic acid and 0.5% DMSO (see also figure legends). CR8

681 titrations were carried out by adding increasing concentrations CR8 (0-25 μM) into premixed

682 500 μM Alexa488cycK-CDK12, 50 nM biotinDDB1, and 4 nM terbium-coupled streptavidin.

683 Before TR-FRET measurements, reactions were incubated for 15 minutes at room temperature.

684 After excitation of terbium (Tb) fluorescence at 337 nm, emissions at 490 nm (Tb) and 520 nm

685 (Alexa488) were measured with a 70 μs delay to reduce background fluorescence and the

686 reactions were followed by recording 60 data points of each well over 1 hours using a

687 PHERAstar FS microplate reader (BMG Labtech). The TR-FRET signal of each data point was

688 extracted by calculating the 520:490 nm ratio. Data were analysed with *Prism* 7 (GraphPad)

689 assuming equimolar binding of biotinDDB1 to Alexa488cycK-CDK12 using the equations

690 described previously[8].

691

692 Counter-titrations with unlabelled proteins were carried out by mixing 500 μM Alexa488cycK-

693 CDK12 with 50 nM biotinDDB1 in the presence of 4 nM terbium-coupled streptavidin and 1 μM

694 compound for DDB1 titrations or 12.5 μM compound for CDK12 titrations. After incubation

695 for 15 minutes at room temperature, increasing amounts of unlabelled cycK-CDK12 or DDB1

696 (0-10 μM) were added to the preassembled Alexa488cycK-CDK12/biotinDDB1 complexes in a 1:1

697 volume ratio and incubated for 15 minutes at room temperature. TR-FRET data were acquired

as described above. The 520/490 nm ratios were plotted to calculate the half maximal inhibitory concentrations (IC_{50}) assuming a single binding site using *Prism* 7 (GraphPad). IC_{50} values were converted to the respective K_i values as described previously[50]. Three technical replicates were carried out per experiment.

DDB1-CUL4-RBX1 reconstitution and *in vitro* CUL4 neddylation

In vitro CRL4 reconstitution and CUL4 neddylation were performed as described[11]. His_6-CUL4A/His_6-RBX1 at 3.5 µM was incubated with His_6-DDB1 at 3 µM in a reaction mixture containing 3.8 µM NEDD8, 50 nM NAE1/UBA3 (E1), 30 nM UBC12 (E2), 1 mM ATP, 50 mM Tris (pH 7.5), 100 mM NaCl, 2.5 mM $MgCl_2$, 0.5 mM DTT and 5% (v/v) glycerol for 1.5 hours at room temperature. Neddylated and gel filtration-purified DDB1-CUL4-RBX1 ($_{N8}$DDB1-CUL4-RBX1) was concentrated to 7.6 µM, flash frozen and stored at -80°C.

In-vitro ubiquitination assays

In vitro ubiquitination was performed by mixing $_{N8}$DDB1-CUL4-RBX1 at 70 nM with a reaction mixture containing kinase inhibitors at 2 µM, CDK12-cycK at 500 nM, E1 (UBA1, BostonBiochem) at 50 nM, E2 (UBCH5a, BostonBiochem) at 1 µM, and ubiquitin at 20 µM. Reactions were carried out in 50 mM Tris (pH 7.5), 150 mM NaCl, 5 mM $MgCl_2$, 0.2 mM $CaCl_2$, 1 mM ATP, 0.1% Triton X-100 and 0.1 mg/mL BSA, incubated for 0-30 minutes at 30°C and analysed by western blot using anti-cycK and anti-rabbit IgG antibodies. Blots were scanned on an Amersham 600 CCD-based imaging system (GE Life Sciences).

Isothermal titration calorimetry (ITC)

ITC experiments were performed at 25°C on a VP-ITC isothermal titration calorimeter (Microcal Inc.). Purified and TEV-cleaved CDK12-cycK and DDB1$^{\Delta BPB}$ were exhaustively dialysed in 50 mM HEPES (pH 7.4), 150 mM NaCl, 0.25 mM TCEP, 0.5% DMSO and loaded into the sample cell at a final concentration of 10-50 µM. Kinase inhibitors (CR8 or roscovitine) were diluted from a 100 mM DMSO stock solution to 100-500 µM in buffer containing 50 mM HEPES (pH 7.4), 150 mM NaCl, 0.25 mM TCEP. The final DMSO concentration was 0.5%. Titrations with 100-500 µM compound were performed typically through about 30 injections of 6-10 µL at 210 second intervals from a 300 µL syringe rotating at 300 rpm. An initial injection of the ligand (4 µL) was made and discarded during data analysis. For probing DDB1-CDK12-cycK complex formation, DDB1$^{\Delta BPB}$ (100 µM, in the syringe) was titrated into the cell containing CDK12-cycK (10 µM) or CDK12-cycK (10 µM) pre-incubated with CR8 (30 µM).

732   The heat change accompanying the titration was recorded as differential power by the
733   instrument and determined by integration of the peak obtained. Titrations of ligand to buffer
734   only and buffer into protein were performed to allow baseline corrections. The heat change
735   was fitted using nonlinear least-squares minimization to obtain the dissociation constants, K_d,
736   the enthalpy of binding, ΔH, and the stoichiometry, n. Between one and three replicates were
737   performed per titration.

738

739   **Bioluminescence Resonance Energy Transfer (BRET) analyses**

740   Bioluminescence resonance energy transfer (BRET) experiments were using a NanoBRET PPI

741   starter kit (Promega N1821) according to the manufacturer's instructions and as previously

742   described[51].

743

744   **Drug sensitivity assays**

745   HEK293T$_{Cas9}$ cells were resuspended at 0.15×10^6 per mL and plated on a 384 well plate with

746   50 µl per well and MLN4924, MLN7243 or MG132 with or without CR8 serially diluted with

747   D300e Digital Dispenser (Tecan Inc.).

748

749   HEK293T$_{Cas9}$ cells (0.625×10^6 cells/6 well plate format) were seeded the day before

750   transfection. The following day, 2.5 ug of pRSF91-GFP or pRSF91-CRBN[9] plasmid DNA was

751   mixed with 250 µl OptiMem and 7.5 µl TransIT-LT1 (Mirus Bio) according to manufacture

752   protocol. 48 hours post transfection cells were resuspended at 0.15×10^6 cells /mL and plated

753   on a 384 well plate with 50 µl per well.

754

755   HEK293T$_{Cas9}$ cells were transduced with sgRNAs targeting either DDB1 or Luciferase in

756   pXPR003 backbone (GPP) (Supplementary Oligo Table 1). After nine days of puromycin

757   selection, cells were re-plated into a 96-well format with 2×10^4 cells per well and CR8 and

758   Roscovitine were serially diluted with D300e Digital Dispenser (Tecan Inc.).

759

760   After 3 days of drug exposure, cell viability was assessed using the CellTiter-Glo luminescent

761   assay (Promega, #G7572) on an EnVision Multilabel Plate Reader (Perkin Elmer) or

762   CLARIOstar Plus, MARS 3.4 (BMG LabTech). Cell viabilities were calculated relative to

763   DMSO controls.

764

765   **CycK stability reporter analysis with CRBN overexpression**

766 HEK293T$_{Cas9}$ cells expressing the cycK$_{eGFP}$ degradation reporter were transiently transfected

767 with pLX307-Luc or pLX307-CRBN (for flow experiment) as described above and 48 hours

768 post infection treated with CR8 for 2 hours and analysed by flow cytometry.

Extended Data Figure 4 | Characterization of DDB1-CDK12-cycK complex formation.
a, Schematic of the TR-FRET setup. Positions of the FRET donor (terbium-streptavidin (Tb)) and acceptor ($_{Alexa488}$SpyCatcher (A)) are indicated in the structural model. **b**, Titration of CDK12-$_{Alexa488}$cycK (0-3.75 μM) to 50 nM $_{terbium}$DDB1 and 5 μM CR8 or DMSO (n=3). **c**, Counter-titration of unlabelled wild-type CDK12-cycK (0-10 μM) to 50 nM $_{terbium}$DDB1, 500 nM CDK12-$_{Alexa488}$cycK and

947 12.5 µM CR8 (n=3). **d**, Counter-titration of unlabelled wild-type DDB1 (0-10 µM) to 50 nM
948 $_{terbium}$DDB1, 500 nM CDK12-$_{Alexa488}$cycK and 1 µM CR8 (n=3). **e**, Titration of CDK12(R965K)-
949 $_{Alexa488}$cycK (wild-type sequence of canonical isoform of CDK12; 0-3.75 µM) to 50 nM $_{terbium}$DDB1 and
950 5 µM CR8 or DMSO (n=3). The CDK12 K965R variant, which was used throughout our *in vitro* studies
951 (see Methods), shows a binding affinity indistinguishable from that of wild-type CDK12 (residue distal
952 from the interface with DDB1 and cycK). **f**, Isothermal titration calorimetry (ITC) experiment (n=2,
953 additional replicates for this and following panels are provided in Supplementary ITC Data).
954 Specifications of the titration are given in the panel. Asterisk marking the approximate $K_{apparent}$ value
955 denotes that the binding affinity was too high to allow confident fitting of the binding curve. **g**, ITC
956 experiment as in **f** (n=2). **h**, ITC experiment as in **f** (n=1). **i**, ITC experiment as in **f** (n=3). **j**, ITC
957 experiment as in **f** (n=3). **k**, ITC experiment as in **f** (n=1).
958
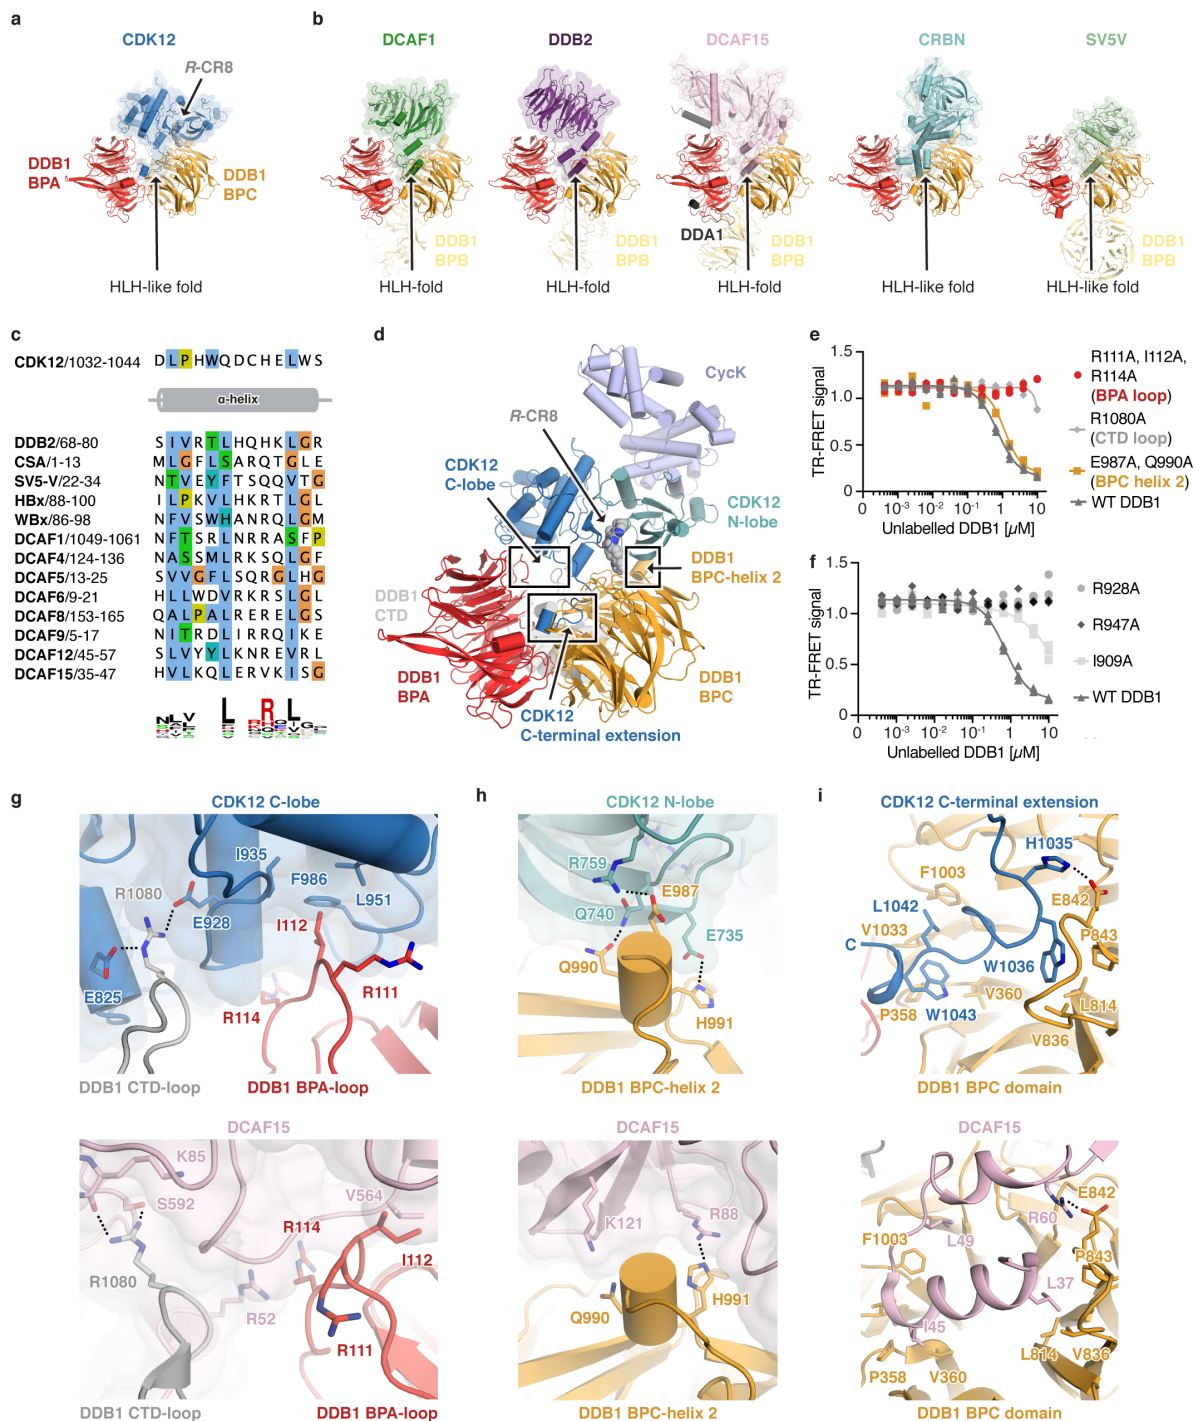

Extended Data Figure 5 | CDK12 contacts on DDB1 otherwise implicated in DCAF binding.
**a**, Structure of the CDK12-*R*-CR8-DDB1$^{\Delta BPB}$ complex. The CDK12 C-terminal domain binds a cleft between the DDB1 BPA and BPC domains (arrow) and adopts an helix-loop-helix (HLH)-like fold. **b**, Diverse DCAFs bind DDB1 through HLH- or HLH-like folds. **c**, Sequence alignment of identically positioned helices of different HLH-domains. **d**, Overview of protein-protein interaction hotspots. **e**, Counter-titration of unlabelled wild-type or mutant DDB1 (0-10 µM) into pre-assembled $_{terbium}$DDB1-CR8-CDK12-$_{Alexa488}$cycK complex (n=3). **f**, Counter titration of unlabelled wild-type or mutant DDB1 (0-10 µM) into pre-assembled $_{terbium}$DDB1-CR8-CDK12-$_{Alexa488}$cycK complex (n=3). **g-i**, Close-up of DDB1 residues contacted by CDK12 (top) that are also otherwise involved in DCAF binding (bottom).
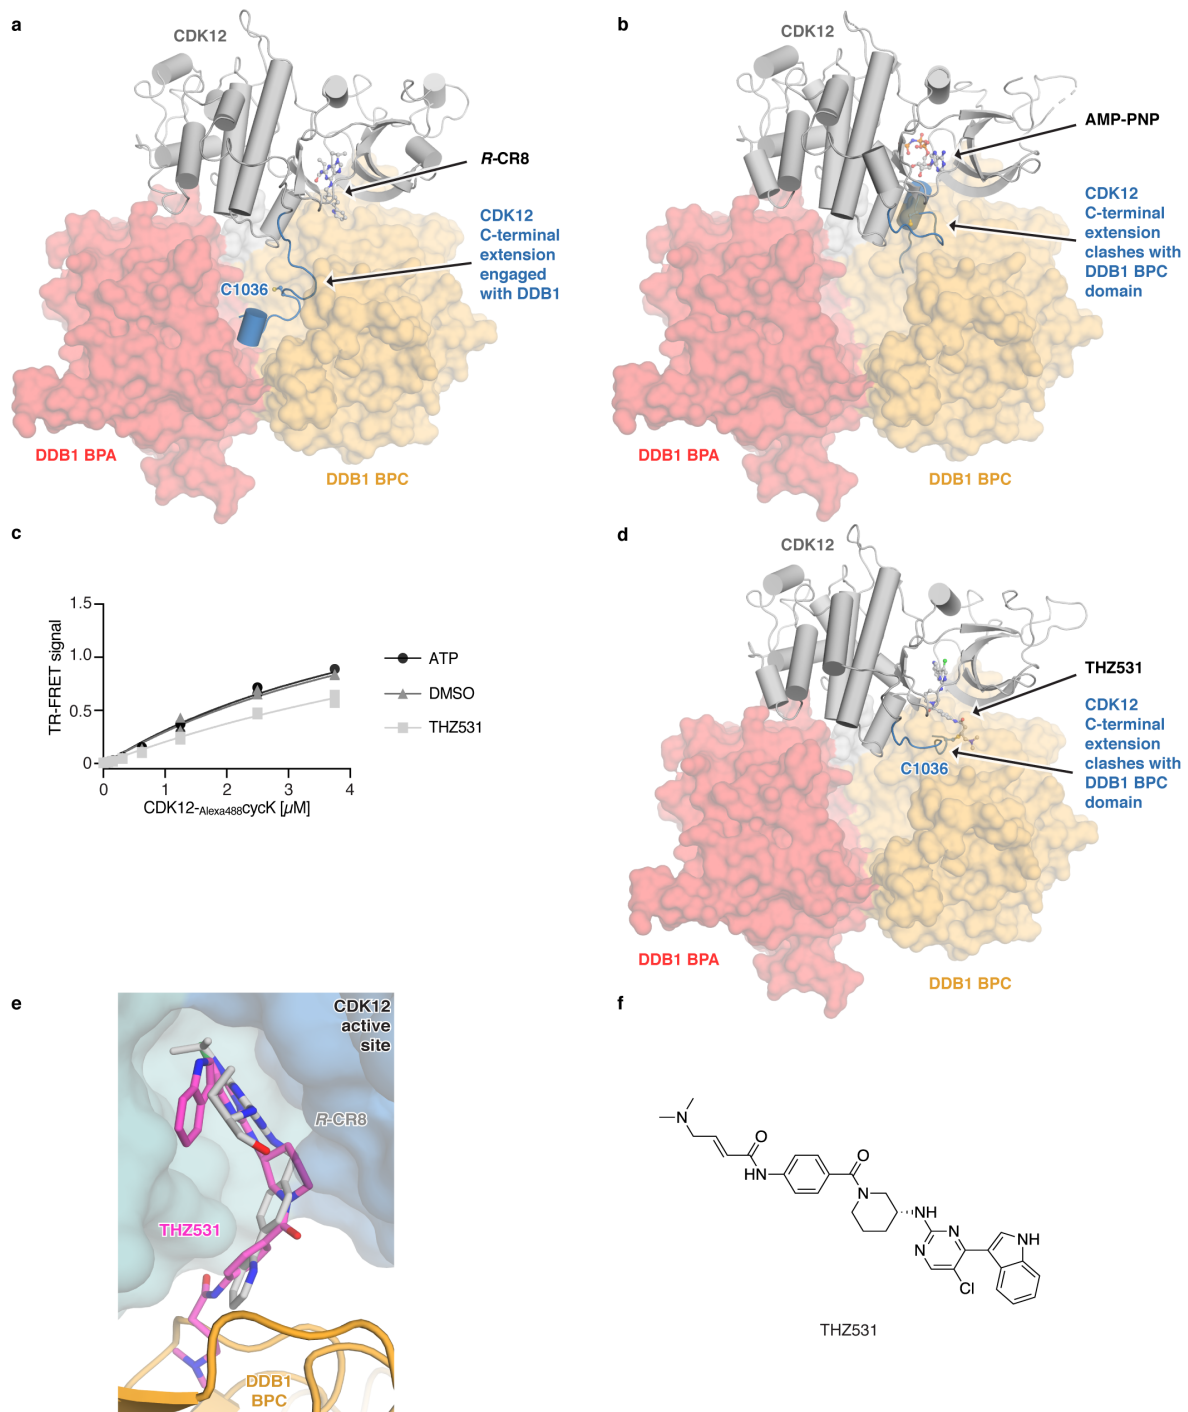

972
973 **Extended Data Figure 6 | CDK12 C-terminal extension adopts different conformations.**
974 **a**, Conformation of the C-terminal extension in the structure of the CDK12-CR8-DDB1$^{\Delta BPB}$ complex.
975 **b**, Structure of CDK12 bound to AMP-PNP (PDB entry 4CXA) superimposed onto CDK12 in the
976 CDK12-CR8-DDB1$^{\Delta BPB}$ complex. **c**, Titration of CDK12-$_{Alexa488}$cycK (0-3.75 μM) to 50 nM
977 $_{terbium}$DDB1 in the presence of 5 μM THZ531, ATP or DMSO (n=3). **d**, Structure of CDK12 bound to
978 THZ531 (PDB entry 5ACB) superimposed onto CDK12 in the CDK12-CR8-DDB1$^{\Delta BPB}$ complex. **e**,
979 THZ531 binding pose in the active site of CDK12 as in d. **f**, Chemical structure of THZ531.
980
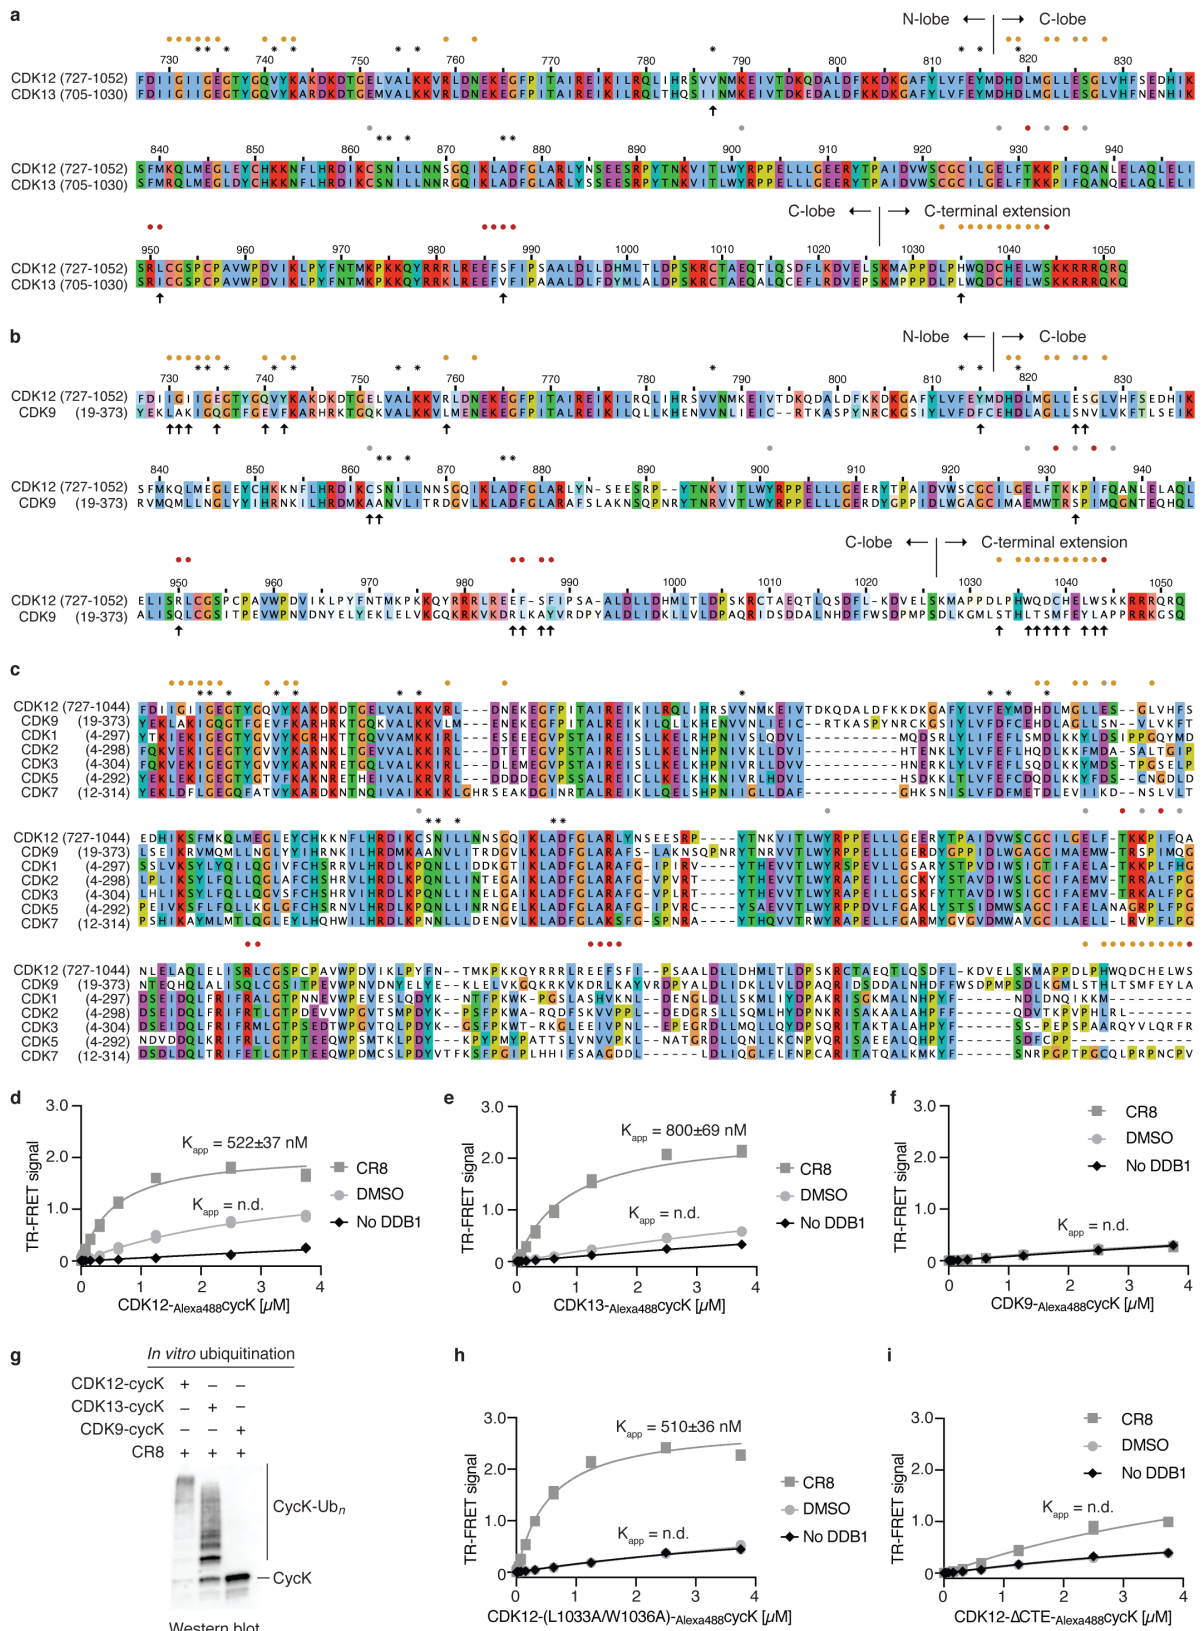

981
982 **Extended Data Figure 7 | Differences between CDK12 and other CDKs highlight residues**
983 **involved in CR8-induced DDB1 recruitment.**
984 **a**, Sequence alignment of CDK12 and CDK13. In this and later panels asterisks denote contacts with
985 CR8 and circles indicate contacts with DDB1 (coloured according to DDB1 domains, see Fig. 2).
986 Arrows mark differences at the DDB1-CR8-CDK interface. **b**, Sequence alignment of CDK12 and
987 CDK9. **c**, Multiple sequence alignment of different human CDKs. **d**, Titration of CDK12-Alexa488cycK

42

988 (0-3.75 µM) to 50 nM $_{terbium}$DDB1 and 5 µM CR8 or DMSO (n=3). No DDB1 only contains
989 streptavidin-terbium and shows concentration-dependent fluorophore effects. **e**, Titration of CDK13-
990 $_{Alexa488}$cycK (0-3.75 µM) to 50 nM $_{terbium}$DDB1 and 5 µM CR8 or DMSO (n=3). **f**, Titration of CDK9-
991 $_{Alexa488}$cycK (0-3.75 µM) to 50 nM $_{terbium}$DDB1 and 5 µM CR8 or DMSO (n=3). **g**, RBX1$_{N8}$CUL4-DDB1
992 *in vitro* ubiquitination of cycK bound to CDK12, CDK13 or CDK9 (n=2). **h**, Titration of CDK12-
993 $_{Alexa488}$cycK (CDK12 mutant (L1033A, W1036A); 0-3.75 µM) to 50 nM $_{terbium}$DDB1 and 5 µM CR8 or
994 DMSO (n=3). **i**, Titration of CDK12-$_{Alexa488}$cycK (CDK12 tail truncation (713-1032); 0-3.75 µM) to 50
995 nM $_{terbium}$DDB1 and 5 µM CR8 or DMSO (n=3).
996

a, Titration of CDK12-$_{Alexa488}$cycK into $_{terbium}$DDB1 in the presence of 10 µM compound (n=3). **b**,
NanoBRET of HEK293T cells transfected with $_{NanoLuc}$CDK12$^{713-1052}$ and $_{HaloTag}$DDB1$^{\Delta BPB}$ constructs and
treated with compound for 2 hours. Bars represent the mean (n=3). **c**, Flow analysis of CycK$_{eGFP}$
degradation in HEK293T$_{Cas9}$ cells treated with 1 µM CR8 and competitive CDK inhibitor (n=3).

Extended Data Figure 9 | Cytotoxicity of CR8 analogues does not depend on CRL4 components.
a, Drug sensitivity of HEK293T$_{Cas9}$ cells exposed to inhibitors for 3 days (n=3). **b**, Drug sensitivity of HEK293T$_{Cas9}$ cells exposed to 100 nM MLN4924 or DMSO in combination with the indicated compound for 3 days (n=3). **c,** Immunoblots of HEK293T$_{Cas9}$ cells transfected with control (pRSF91-GFP) or CRBN overexpression vectors (pRSF91-CRBN) (n=2). **d**, Immunoblots of HEK293T$_{Cas9}$ cells expressing pRSF91-GFP or pRSF91-CRBN and exposed to CR8 for 3 days (n=2). **e,** Drug sensitivity of HEK293T$_{Cas9}$ cells expressing pRSF91-GFP or pRSF91-CRBN and exposed to CR8 for 3 days (n=3). **f**, Immunoblots of HEK293T$_{Cas9}$ cells transfected with control (pLX307-Luc) or CRBN overexpression

44

1013 vectors (pLX307-CRBN) (n=2). **g**, Flow analysis of CycK$_{eGFP}$ degradation in HEK293T$_{Cas9}$ cells
1014 expressing pLX307-Luc or pLX307-CRBN and treated with CR8 for 2 hours (n=3). **h**, Drug sensitivity
1015 of HEK293T$_{Cas9}$ cells expressing sgRNAs targeting DDB1 or Luc and exposed to inhibitor for 3 days
1016 (n=3).
