ABSTRACT

C-band InP vertical cavity surface emitting laser (VCSEL) exploitation can be appealing also for high-capacity transmission over hundreds of kilometres. Long-wavelength VCSELs can represent an alternative solution for the development of transmitters with reduced cost, power consumption and footprint by adopting direct modulation (DM) and single sideband (SSB) discrete multitone (DMT) modulation to achieve dense wavelength division multiplexing (WDM) granularity. Due to numerous hops between nodes inside metropolitan area networks the effect of filtering can severely impact the transmission performance. We present preliminary experimental assessments of DM VCSEL sources with multi-carrier modulation formats, for more than 50 Gb/s per-channel transmission to target a metro network including nodes, handling 25-GHz granularity.

Keywords: VCSELs, metro networks, WSS, discrete multitone transmission.

1. INTRODUCTION

Nowadays, most of the total data traffic is concentrated in less of the 5% of the geographical area, for example in the metropolitan area networks (MANs). This kind of networks need to support services such as 5G, Mobile Edge Computing, UHD TV, etc.. generating a huge IP traffic with uneven distribution along day-time. Optical transport technologies for MANs are encouraged to shift the paradigm of long-haul transmission developing agile solutions supporting a “pay-as-you-grow” evolution, to target reduced costs and possibly power consumption [1].

Innovative photonic technologies have the potentials to support the optical data transport allowing a huge transmission capacity and routing over variable distances and topologies, providing also low cost, low power consumption and reduced footprint. Different paths have been chosen to guarantee this high throughput either increasing the number of wavelength-division multiplexed (WDM) channels [2] exploiting ultra-wide band amplification (S, C and L band) or increasing the single channel data rate exploiting ultra-high speed silicon-photonics (SiPh) devices [3].

As an alternative multi-Tb/s capacity can be achieved employing massive photonic integration to develop a photonic integrated circuit (PIC) transmitter including multiple long-wavelength high-bandwidth vertical cavity surface emitting laser (VCSEL) sources and SOI multiplexers [4, 5]. VCSELs have been used for a long time in data communications [6] but, the exploitation of direct modulation (DM) with discrete multitone (DMT) modulation with single-mode devices [7, 8] combined with multi-channel coherent receivers (CO-RXs) allows to realize a compact and cost-effective sliceable bandwidth and bitrate variable transceiver (S-BVT) able to adaptively load/manipulate the spectrum, enabling multiple Tb/s capacity [9].

Long-wavelength InP VCSELs emitting in the C band, DM by multicarrier formats, such as DMT, have been in fact recently proposed with direct detection (DD) to bridge tens of km distances with more than 50 Gb/s capacities [10-12]. To target typical MAN reach distances in standard single mode fibre (SSMF) links, there is otherwise the necessity to avoid the impairments due to the cumulated chromatic dispersion (CD), which indeed can be compensated by exploiting digital signal processing (DSP) techniques enabled by coherent detection (COHD) [13]. Moreover, in order to achieve a higher spectral efficiency and target very dense WDM transmission, i.e. with 25-GHz channel spacing, single side-band (SSB) DMT modulation can be performed [14]. This helps also in improving the resilience towards filtering effects due to traversing multiple MAN nodes, based on wavelength selective switching (WSS) filters, which should be carefully considered due to the adopted fine WDM granularity [15].

In this paper we assess the performance of the above-mentioned transmitter, employing coherent detection with reduced complexity [16]. In particular we compare simulations and experimental results; we evaluate the transported capacity for single channel transmission in function of nodes number, considering the actual VCSEL chirp coefficients and frequency response and we confirm already obtained simulated results [15] demonstrating reach distances of hundreds of kms typical of MANs, maintaining a capacity per channel higher than 50 Gb/s.

2. C-BAND VCSEL-BASED S-BVT TRANSMITTER

The motivations which lead to use of a very tight filtering to obtain a DMT SSB modulated signal come from the aim to develop a multi-Tb/s S-BVT transmitter. Thanks to bit and power loading at DSP level, DMT is able to address the efficient usage of the bandwidth resource as a function of the requested capacity allowing dynamic and flexible adaptation to traffic/channel conditions [17]. SSB modulation allows on the other hand to interleave up to 4 SOI chip modules integrating multiple VCSELs in the C-band with 100-GHz channel spacing achieving an ultimate granularity of 25 GHz [1]. By targeting beyond 50-Gb/s per VCSEL rate the overall supermodule capacity can reach 8-Tb/s capacity with 4-b/s/Hz spectral efficiency in case of polarization division multiplexing (PDM) [16, 18].

2.1 Experimental set up

In order to have a preliminary assessment of the above-described multi-Tb/s transmitter we evaluated the performance of the single DM VCSEL in presence of propagation in up to 200 km SSMF with the use of a Finisar Waveshaper 4000S to mimic the presence of WSSs in the MAN, as depicted in Figure 1.

The short cavity (SC) VCSEL emits at 1533.5 nm, with 5-MHz measured linewidth. It is characterized by an E/O bandwidth of 18 GHz and preliminary measurements provided a α linewidth enhancement factor of 3.7 and κ adiabatic constant of $1.52 \cdot 10^{13}$ [15].

The DMT signal is composed by 256 sub-carriers in a 20-GHz frequency range, thus the sub-carrier spacing is 78.125 MHz; a cyclic prefix (CP) of about 2.1% of the symbol length is also added. The bias current is set at 9 mA, while the modulation depth is fixed at 450 mV in order to limit the frequency chirp insurgence and reduce the penalty due to SSB filtering. The DMT signal is generated by a MICRAM 100-GS/s digital-to-analog converter (DAC10002) with 35-GHz electrical bandwidth and 6 bits vertical resolution and it directly modulates the VCSEL with a bias current of 9 mA and a modulation depth of at 450 mV. The modulation depth is optimized in order to limit the spectrum broadening associated with the frequency chirp, reducing the penalty due to SSB and WSS-node filtering. The SSB modulation is obtained by properly detuning a standard 25-GHz spacing WSS filter, which shows a 21-GHz full width half maximum (FWHM) [19]; the frequency detuning, around 8GHz, allows to select half of the DMT dual sideband (DSB) spectrum while preserving the optical carrier, as shown in Figure 2 a).

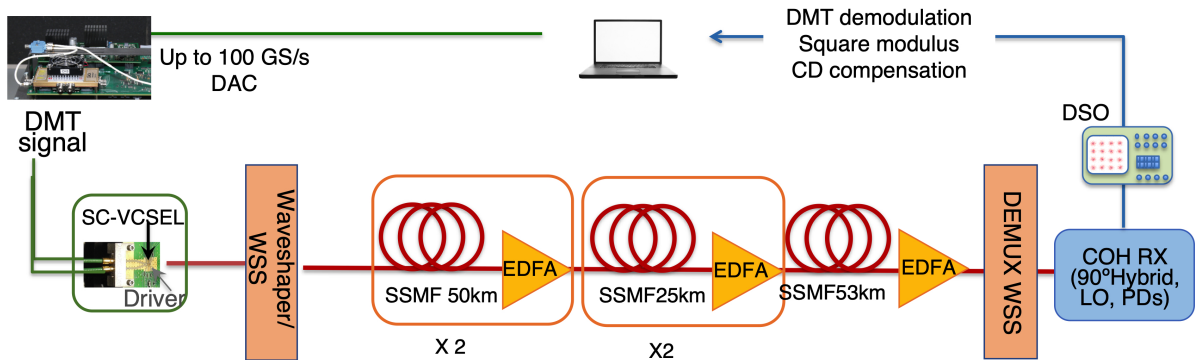

Figure 1. Experimental set up employed to perform a preliminary assessment of the VCSEL-based multi-Tb/s transmitter.

After amplification in an Erbium-doped fibre amplifier (EDFA), the generated SSB DMT signal is transmitted in the emulated MAN link, constituted by 5 SSMF spools, to bridge up to 200 km distance. The launch power is set to +1 dBm.

At the receiver side in order to target hundreds of kilometres of transmission distances, we employ digital coherent detection (COHD) which allows easy CD DSP compensation, avoiding also the VCSEL chirp interplay with CD. The chirp associated with VCSEL DM will impair transmission performance only due to the presence of filtering associated to wavelength multiplexers and demultiplexers. Actually, the received signal is detected by a Tektronix coherent receiver OM4245 with 45-GHz bandwidth; the local oscillator (LO) is a tuneable 100-kHz laser with +15.5 dBm optical power. The inphase/quadrature signals are acquired by a Tektronix real-time oscilloscope with 8-bits vertical resolution, 100-GS/s and 33-GHz electrical bandwidth respectively. Alternatively, some preliminary back to back measurements have been performed with DD obtained with a pre-amplified 50-GHz PIN photodiode (PD). After ADC conversion the signal is processed off-line. Due to DM, the transmitted signal is just intensity modulated and then a simplified coherent receiver can be used: after I and Q components recovery and CD compensation the I and Q square moduli are performed and summed up in order to obtain the originally transmitted intensity signal. This approach has the drawback to cancel the COHD advantages in terms of bit error rate (BER) as a function of signal to noise ratio (SNR) with respect to direct detection (DD), but avoids the use of phase and frequency recovery, reducing the complexity of the receiver DSP and also relaxing the

constraints on VCSEL and local oscillator (LO) linewidths [14]. The signal to noise ratio (SNR) of each sub-carrier is obtained by transmitting a probe DMT signal, mapped with uniform QPSK loading and it is used to perform Chow's algorithm, as standard bit- and power-loading procedure [20]; the target bit error rate (BER) is set to $4.6 \cdot 10^{-3}$ according with the exploitation of an advanced hard-decision forward error correction code with 7% overhead.

3. EXPERIMENTAL RESULTS

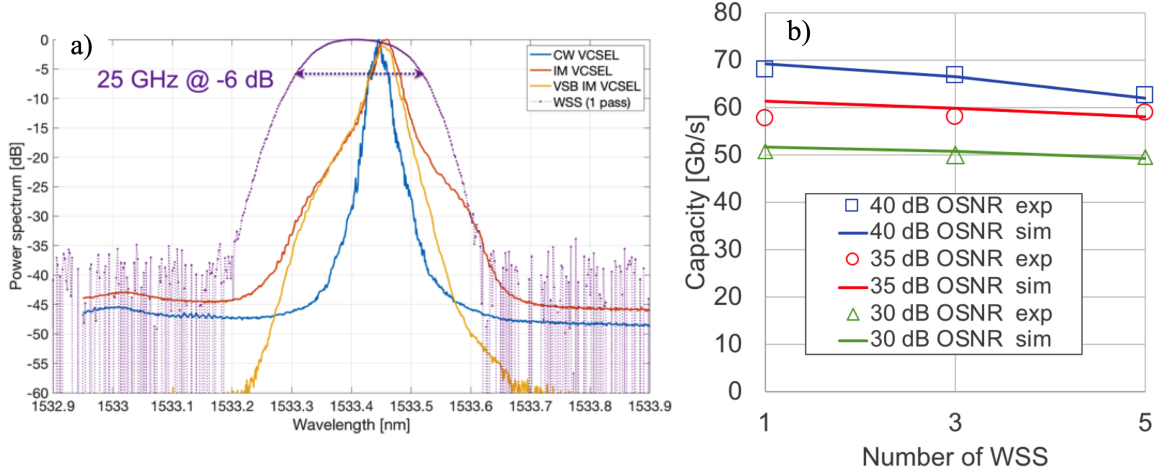

Figure 2 a) SSB DMT spectra: CW blue, DSB DMT orange, SSB DMT yellow, WSS purple. b) transmission capacities in b2b vs number of crossed WSS for: 40-dB OSNR (blue), 35-dB OSNR (red), 30-dB OSNR (green), simulations (continuous line) experimental results (open symbol).

At first we performed some preliminary back to back (b2b) measurements with DD and we compared them with simulations obtained with a transmission model including the electro/optical and chirp transfer functions of the VCSELs, the adopted receiver and featuring all experimental conditions including bias current, modulation depth, electrical device bandwidths, DACs and ADCs bit resolution, PD noise equivalent current (NEC), received powers and the measured WSS transfer function. Fig. 2b) shows the b2b measured capacities achieved for optical SNR (OSNR) ranging from 30 dB to 40 dB in function of the number of crossed WSS (open symbols); experimental results obtained by a variable optical noise loader are compared with simulations (continuous line). As expected, a slight reduction of the capacity appears for lower OSNRs, whereas the capacity barely reduces increasing the number of crossed WSS. Thanks to the steep profile of the WSS transfer function, in fact, the carrier and the single sideband optical spectrum are preserved even in case of several WSS crossings. A very good agreement is obtained between experimental results and simulations.

We then evaluated the performance of the VCSEL-based S-BVT after SSMF propagation in single-channel single-polarization conditions. Figure 3 shows the measured SSB-DMT capacities as a function of the bridged SSMF length for a launch power of +1 dBm in every span; on the right the corresponding OSNRs are also displayed. A capacity around 65 Gb/s is supported up to 100-km SSMF propagation thanks to high OSNR levels, while it decreases for 150 km and 200 km. However, a total transported capacity per polarization higher than the target 50 Gb/s can still be achieved even after 200-km propagation [21].

Finally, for 100-km and 200-km SSMF reaches we measured the performance in presence of WSS filter cascading, which can impair the directly-modulated DMT signal transmission, due to the filter narrowing effect [15]. In particular in the experiments the multiple crossing of WSS filters has been emulated by the Finisar Waveshaper filter by featuring the transfer function of the cascaded WSSes. Table I presents the percentage reduction of capacity with respect to the b2b condition (e.g. 67 Gb/s) due to propagation in 100 km and 200 km SSMF and WSSes crossing. It can be noticed that the capacity barely reduces increasing the number of crossed WSSs, allowing capacities higher than 50 Gb/s even after 200-km SSMF propagation and 6 crossed WSS-like network nodes.

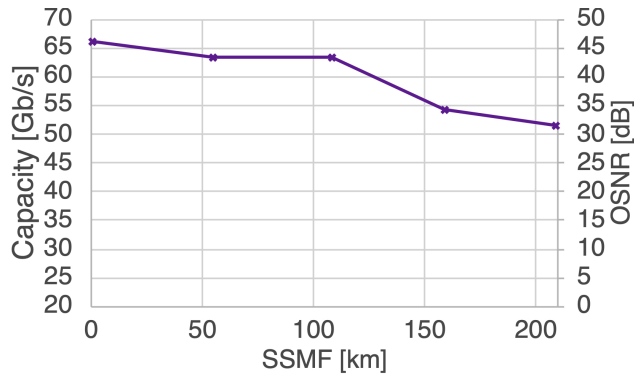

Figure 3 Measured SSB-DMT capacities as a function of the bridged SSMF length [km], on the right the corresponding OSNRs are also reported.

Table I SSB DMT percentage reduction of capacity with respect to the b2b condition due to propagation in 100 km and 200 km SSMF as a function of the number of WSSes crossing (up to 6).

Capacity percentage reduction with respect to b2b 67 Gb/s	Number of WSS	100 km SSMF	200 km SSMF
	1	6%	23%
	2	6%	24%
	4	6%	25%
	6	7%	26%

4. CONCLUSIONS

We presented preliminary experimental assessments of DM VCSEL sources with multi-carrier modulation formats, to target hundreds of kilometres transmission in SSMF with per SOP per channel capacity beyond 50 Gb/s. As multi-Tb/s transmitter modules including multiple C-band DM-VCSELs and WDM multiplexers in SOI chips can be aggregated to target a very fine WDM granularity (i.e. 25-GHz) [16], SSB DMT modulation appears one of the most promising formats to be exploited.

Indeed, the combination with simplified coherent detection allows to bridge MAN typical link distances thanks to DSP CD compensation, but due to the presence of numerous hops between nodes inside metropolitan area networks the effect of filtering has also to be taken into account. For these reasons we analysed the impact on the transmission performance of cascaded WSSes filter, remembering that a spectral broadening is induced by the chirp associated with DM.

The obtained preliminary results confirm that by means of SSB DMT direct modulation and simplified coherent detection 200-km SSMF distances can be reached also in presence of 25-GHz WSS filters with 50-Gb/s capacity per SOP, enabling 4-b/s/Hz spectral efficiency PDM S-BVT multiple modules for MAN multi-Tb/s transmission.
