

The Klein-Gordon Equation, $\exp(i \text{ Action})$ [Propagator] and Fluctuations Part II

Francesco R. Ruggeri Hanwell, N.B. April 22, 2021

In a previous note (Part 1), we argued that for both a relativistic and nonrelativistic free particle Lagrangian, $i\hbar d/dT \exp(i \text{ Action}) = E \exp(i \text{ Action})$ and $-i\hbar d/dX \exp(i \text{ Action}) = p \exp(i \text{ Action})$ where $\text{velocity} = X/T$. We further argued that these results allow one to convert an energy conservation equation (or even a Dirac type equation) in E and p into a differential equation in terms of d/dT and d/dX . Thus, d/dT and d/dX seem to represent fluctuations because $\text{velocity} = X/T = \text{constant}$ is not imposed. For the case of a free particle with no velocity related potential such as $vA(x)$, we argued $\text{Action} = L(v) T$ as v is constant. Furthermore, $L(v)$ so d/dt and d/dx both make use of dL/dv . In this note, we consider the presence of a magnetic vector potential term $vA(x)$, but no electric field so the particle does not accelerate.

Action in terms of T and X

In a previous note, we argued that the relativistic action $\text{Integral dt } L(v) = T \sqrt{1-vv} m_0$ and the nonrelativistic $T \cdot \frac{1}{2} m v^2$ could be written with $v = X/T$. As a next step, we argued that one may introduce fluctuations into $\exp(i \text{ Action})$ (introduced by P. Dirac) through d/dX and d/dT . These are related to p and E i.e.

$$i \hbar d/dT \exp(i \text{ Action}) = E \exp(i \text{ Action}) \quad \text{and} \quad -i \hbar d/dX \exp(i \text{ Action}) = p \exp(i \text{ Action}) \quad ((1))$$

For the relativistic case, $E = m_0 / \sqrt{1-vv}$ and $p = m_0 v / \sqrt{1-vv}$ and for the nonrelativistic, $E = \frac{1}{2} m_0 v^2$ and $p = m_0 v$.

Thus, one may take a classical equation containing p and E and replace these with $-i\hbar d/dx \exp(i \text{ Action})$ and $i\hbar d/dt \exp(i \text{ Action})$, thus obtaining the Klein-Gordon and Schrodinger equations i.e. fluctuation differential equations which conserve classical energy on average.

In this note, we consider the case of an extra $vA(x)$ potential due to a magnetic vector potential which does not accelerate the particle.

Case of a Magnetic Vector Potential (Non-relativistic case)

For the addition of a magnetic vector potential, the nonrelativistic Lagrangian is:

$$L = \frac{1}{2} m v^2 + vA(x) \quad \text{and} \quad \text{Action} = T \cdot \frac{1}{2} m v^2 + \text{Integral } dx \cdot \frac{1}{dt} A(x) \quad dt \quad ((2))$$

The integral on the RHS of ((2)) may be converted into:

$$\text{Integral } (0, X) dx \cdot A(x) \quad ((3))$$

Thus, a fluctuation in X independent of T changes the integration bound of the integral.

The result is:

$$\exp(i \text{ Action}) = \exp\{i [.5mvvT + \text{Integral} (0,X) dx_1 A(x_1)]\} \quad ((4))$$

This may be varied with respect to T and X independently which suggests a fluctuation because $v = X/T = \text{constant}$ is not imposed. For the case of $i d/dT$, one has again:

$$i d/dt \exp(i \text{ Action}) = .5mvv \exp(i \text{ Action}) \quad ((5a)) \text{ as in the absence of a magnetic vector potential}$$

$$-i d/dX \exp(i \text{ Action}) = \exp(i \text{ Action}) \{ mv + A(x) \} \quad ((5b))$$

In order to link ((5a)) and ((5b)) one may use the classical conservation of energy equation because the particle is not accelerated:

$$E = mvv/2 \text{ or } i d/dt \exp(i \text{ Action}) = 1/2m \{ p-A(x) \} \{ p-A(x) \} \text{ where } p = -i d/dX \quad ((6))$$

This is the standard result, although reached using d/dX and d/dT variation.

One may note that ((5a)) and ((5b)) are equivalent to $\exp(i \text{ action})$ being replaced by:

$$\exp(ipx - iEt) \quad ((7))$$

Here p (which is a number) is not mv, but rather $mv + \text{Integral} (0,X) dx_1 A(x_1)$

In the case of an accelerating potential, one may consider a momentum distribution, i.e.

$$W(x,t) = \exp(-iEt) \text{ Sum over } p a(p) \exp(ipx) \quad ((8))$$

Energy conservation is still retained in ((6)) i.e.

$$i d/dt \exp(-iEt) W(x) = 1/2m \{ p-A(x) \} \{ p-A(x) \} W(x) + V(x) W(x) \text{ where } V(x) \text{ may be } e \text{ Phi}(x) \text{ the electric potential.} \quad ((9))$$

Conclusion

In conclusion, we extend the ideas of replacing $v = \text{velocity}$ with X/T in a free particle relativistic or nonrelativistic Lagrangian, and computing $i d/dT \exp(i \text{ Action})$ and $-i d/dX \exp(i \text{ Action})$ for the case of a magnetic vector potential $vA(x)$. We find that the approach yields the usual $p = mv + A(x)$ and: $i d/dt \exp(i \text{ Action}) = .5mvv \exp(i \text{ Action})$ and $-i d/dx \exp(i \text{ Action}) = p \exp(i \text{ Action})$. Using a conservation of energy equation for the nonaccelerating particle gives:

$i\hbar \frac{d}{dt} \exp(i \text{Action}) = \frac{1}{2m} [p-A][p-A] \exp(i \text{Action})$ where $p = -i\hbar \frac{d}{dx}$. $\exp(i \text{Action})$ is equivalent in this case to $\exp(ipx - iEt)$ where $p = mv + \int_0^x A(x_1) dx_1$. For the case of a potential which accelerates the particle, we argue it is stochastic i.e. $V(x) = \sum_k V_k \exp(ikx)$. This leads to a momentum distribution $W(x) = \sum_p a(p) \exp(ipx)$. Thus, one has:

$$i\hbar \frac{d}{dt} W(x) \exp(-iEt) = \frac{1}{2m} [p-A][p-A] W(x) + V(x) W(x)$$
