Online Appendix D Explaining regional richness patterns
page: 1

## Supplementary Material

Online Appendix D. Tables D1-D14.

Time explains regional richness patterns within clades more often than diversification rates or area

Table D1. Results of Shapiro-Wilks tests for normality for the distribution of species richness among regions for each of the 15 clades. Both raw species richness and ln-transformed species richness were tested. Results in boldface indicate that normality was rejected. For the four clades in which normality was rejected for both raw and ln-richness, we also performed Spearman rank correlation tests (table D12).

Table D2. Regression analyses of relationships between raw species richness of regions and four independent variables. AFC $=$ age of first colonization; $\mathrm{SAC}=$ summed ages of colonization events; $\mathrm{NCE}=$ number of colonization events per region; NDR = mean net diversification rate. Results in boldface indicated the variable with the lowest AIC (Akaike information criterion). "Null" indicates cases in which regression analysis failed.

Table D4. Regression analyses of relationships between species richness (raw and ln-transformed) of regions and four independent variables, for the two less complete datasets. Independent variables are: $\mathrm{AFC}=$ age of first colonization; $\mathrm{SAC}=$ summed ages of colonization events; $\mathrm{NCE}=$ number of colonization events per region; $\mathrm{NDR}=$ mean net diversification rate. Results in boldface indicate the model with the lowest AIC (Akaike information criterion).

Table D5. Multiple regression analyses of relationships between raw species richness and time, number of colonization events, and diversification rates. $\mathrm{AFC}=$ age of first colonization; $\mathrm{SAC}=$ summed ages of colonization; $\mathrm{NCE}=$ number of colonization events; NDR $=$ net diversification rates. Results in boldface indicate the model with the lowest AIC (Akaike information criterion). Multiple regression analyses were only applied to some studies and only to some variables (depending on the results of the pairwise analyses, see Methods).

Table D7. Contributions of each independent variable to the multiple regression models of raw species richness. Only the best-fitting multiple regression model for raw richness for each clade is shown. Only clades for which multiple regression analyses were performed are shown. Note that the multiple regression model is not necessarily the best-fitting model for each dataset. The overall best-fitting model for each clade (including single vs. multiple regression models and raw vs. ln-transformed richness) is shown in Table 2. SPRC = standardized partial regression coefficients, showing how much of the adjusted $r^{2}$ of the best-fitting model is explained by each variable (when the other variables are held constant). AFC $=$ age of first colonization; $\mathrm{SAC}=$ summed ages of colonization; $\mathrm{NCE}=$ number of colonization events; $\mathrm{NDR}=$ net diversification rates.

Table D9. Relationships between variables among clades. Clade age, total species richness of the clade, completeness of the taxon sampling in the phylogeny, and the number of regions per study are given in table 1 . The variance in species richness among regions that is explained by time (AFC or SAC) is taken directly from table 2 for those clades in which AFC or SAC is the only variable in the best-fitting model. For those five clades in which other variables are included in the best model besides time, we multiplied the standardized partial regression coefficient for the time-related variable (table 3) by the overall percentage of the variance explained by the best model (table 2) to obtain the amount of variance explained by time. The specific values obtained were 0.491 (Vitales et al. 2014), 0.419 (Ludt et al. 2015), 0.486 (Mariguela et al. 2016), 0.234 (Beckman and Witt 2015), and 0.516 (Buckner et al. 2015). For mean area of regions, we estimated the mean area of all of the regions in each study, and then $\log 10$ transformed the mean. Values for area are given in appendix C.

| Independent variable | Dependent variable | $r^{2}$ | $P$ |
| :--- | :--- | :--- | :--- |
| clade age | richness | 0.189 | 0.1052 |
| richness | completeness | 0.193 | 0.1014 |
| richness | variance explained by time | 0.536 | 0.0019 |
| completeness | variance explained by time | 0.168 | 0.1290 |
| clade age | variance explained by time | 0.399 | 0.0115 |
| mean area of regions | variance explained by time | 0.162 | 0.1367 |
| number of regions | variance explained by time | 0.151 | 0.1520 |

Table D10. Testing the impacts of richness, clade age, taxon sampling, and global distributions on the overall results. We used unpaired t-tests to evaluate whether those clades in which richness patterns were explained primarily by time (i.e. best-fitting model includes only time-related variables AFC or SAC: 10 of 15 clades; table 2) tended to be older, more species rich, or more completely sampled (data in table 1). We also tested whether the geographic scope of the study (global vs. not; table 1) was associated with differences in clade age, species richness, taxon sampling, and the amount of variance in richness explained by time (see table D9).

| Best model includes only time |  |  |  |
| :--- | :--- | :--- | :--- |
| Species richness <br> Only time mean $=82.30$ <br> Clade age $(\mathrm{ma})$ | Not mean $=21.00$ | Mean difference $=-61.300$ | $P=0.0404$ |
| Only time mean $=60.16$ <br> Taxon sampling (percent) <br> Only time mean $=84.88$ | Not mean $=9.40$ | Mean difference $=-50.760$ | $P=0.0065$ |
|  | Mean difference $=-7.080$ | $P=0.2571$ |  |
| Global distribution $=91.96$ |  |  |  |
| Richness (species) <br> Global mean $=82.00$ | Not global mean $=48.44$ | Mean difference $=33.556$ | $P=0.2711$ |
| Clade age $($ Ma) | Mean difference $=32.517$ | $P=0.0967$ |  |
| Global mean $=62.75$ <br> Taxon sampling (percent) <br> Global mean $=88.250$ | Not mean $=86.567$ | Mean difference $=1.683$ | $P=0.7846$ |
| Variance explained by time <br> Global mean $=0.855$ | Not mean $=0.642$ | Mean difference $=0.213$ | $P=0.1110$ |

Table D11. Regression analyses of relationships between the four independent variables. AFC = age of first colonization; SAC $=$ summed ages of colonization events; $\mathrm{NCE}=$ number of colonization events per region; $\mathrm{NDR}=$ net diversification rate .
"Null" indicates that the analysis failed for that pair of variables.

Table D12. Spearman's rank correlation analyses of relationships between $\ln$-transformed species richness of regions and four independent variables. $\mathrm{AFC}=$ age of first colonization; $\mathrm{SAC}=$ summed ages of colonization events; $\mathrm{NCE}=$ number of colonization events per region; $\mathrm{NDR}=$ mean net diversification rate. Compare to the results based on least-squares regression in table 2. For Bengston et al. (2015), the non-parametric results here confirm that AFC shows the strongest correlation with richness. For Ludt et al. (2015), the results confirm that richness is correlated most strongly with NDR (but also shows a high correlation with time). For Tolley et al. (2013) the non-parametric results differ somewhat, suggesting a stronger correlation with NDR than with AFC (but also showing a high correlation with time), whereas the regression results show a strong relationship with AFC alone. For Metallinou et al. (2015), the non-parametric results also differ somewhat showing stronger correlations between NCE and NDR than with AFC or SAC alone, whereas the parametric regression results show the strongest relationship with SAC and weaker relationships with all other variables.

Table D13. Regression analyses of relationships between species richness of regions and net diversification rates (NDR) based on mean rates across colonization events. In the main analyses, NDR is weighted based on the number of species associated with each colonization event. Significant relationships are boldfaced. Compare to tables D2 and D3. Overall, relationships that were significant using weighted NDR were also significant using unweighted NDR, whereas relationships that were not significant using weighted NDR were also not significant using unweighted NDR. Nevertheless, we strongly prefer use of weighted NDR (see Methods).
