InnoRenew CoE is funded by the European Commission under Horizon 2020, the EU Framework Programme for Research and Innovation (H2020 WIDESPREAD-2-Teaming #739574), and by investment funding from the Republic of Slovenia and the European Regional Development Fund.

KEYNOTE ADDRESS

LISANNE HAVINGA, MSc. PHD

Assistant Professor Building Performance and Principal Scientist System Integration, Technische Universiteit Eindhoven

Lianne Havinga is Assistant Professor at the Building Performance group at Eindhoven University of Technology (TU/e) in the Netherlands. She is also Principal Scientist System Integration of the Eindhoven Institute for Renewable Energy Systems, and part of the management team of the institute. She received her Ph.D. in 2019 from TU/e, titled 'Advancing Post-War Housing: Integrating Heritage Impact, Environmental Impact, Hygrothermal Risk and Costs in Renovation Design Decisions'. Her research focuses on developing

modeling and simulation strategies to support decision-making in the energy transition of the built environment. Core topics include the optimization of renovation decisions using parametric exploration of housing variations, user behavior and renovation solutions. A holistic assessment of environmental impact, incorporating life cycle assessment and circularity, is a priority in her work. Lastly, she focuses on setting up interdisciplinary collaborations to develop multi-scale, multi-carrier, dynamic models that support system integration and decision-making across scale levels (technology-building-neighborhood-city-region-country) and sectors (mobility, industry, built environment). The evaluation of innovative technologies and their potential in addressing the key challenges of the energy transition is a priority.

In recent years, she's contributed to the development of the Climate Agreement of the Netherlands by developing 'the Renovation Accelerator', a subsidy program that was recently launched, aiming to accelerate the large-scale renovation of the housing stock. In this context, she's been an advisor and led research projects for multiple governmental organizations in the Netherlands. In addition to working for governmental organizations, she has built consortia with a wide variety of industry partners. Although she only recently was awarded her PhD thesis, she has already developed a substantial track record of publications and is already building teams of PDEngs, PhD's and postdocs on the topics 1) circularity/LCA, 2) sustainable renovation, 3) urban energy transition. She has been guest-editor for Renewable and Sustainable Energy Reviews and has authored publications for journals such as Building and Environment, Renewable and Sustainable Energy Reviews, Energy and Buildings and Journal of Cultural Heritage. She is a frequent reviewer for these and more academic journals and has been a member of several scientific committees of international conferences. She was chief editor (together with Emanuele Naboni) of the book publication 'Regenerative Design in Digital Practice.'

10. 6. 2021

8:30 | **ZOOM OPEN**

9:00 | **OPENING**

Dr Michael Burnard, InnoRenew CoE
Deputy Director

9:05-9:35 | **KEYNOTE**

Lisanne Havinga, Assistant Professor,

Engineering and Design

Experimental investigations of innovative seismic-resistant CLT connections

The behaviour of cross-laminated timber (CLT) buildings during earthquakes depends mainly on the behaviour of the connections between adjacent panels. If the connections between the panels are strong enough, these structures can achieve damage-free performance even during strong earthquakes. However, amplified seismic accelerations associated with rigid connections may result in occupant's injury and contents damage which is not acceptable in terms of serviceability. To improve the ductile behaviour of CLT buildings, several solutions of dissipative connections have been proposed in recent years, mainly by modifying conventional mechanical connections.

The main aim of the contribution is to present three different concepts of CLT connections examined in terms of their cyclic response:

1) Connections with flexible polyurethane-based adhesives. The main idea of the proposed solution is to dissipate seismic energy through the adhesive joints between timber elements. A flexible adhesive could be employed at the vertical joints between adjacent panels or at the interface of glued-in rods which can be used to connect various elements (e.g. foundations and walls).

2) Weakened dowel-type fasteners. The concept of the solution is to weaken the dowels at the pre-determined locations and thus provide a controlled ductile response of the connections. Such connection could be used at different locations, e.g. as foundation-to-wall or wall-to-wall connection.

3) Steel angle brackets with PUR isolation. The isolated angle brackets have already been previously developed (by companies Getzner and Pitzl) to reduce vibration and improve sound isolation of buildings. The cyclic response of angle bracket connections was investigated and based on the results some improvements were given for the use of connections in seismic areas.

Keywords: cross-laminated timber (CLT), connections, cyclic tests, polyurethane, flexible adhesive, isolation

ACKNOWLEDGEMENT

The authors gratefully acknowledge the European Cooperation in Science and Technology for funding the InnoRenew CoE project [grant agreement #739574] under the H2020 Spreading Excellence and Widening Participation Horizon2020 Widespread-Teaming program, and Slovenian research program P2-0273; ARRS.
