1. Event definition

Definition

Diabetes mellitus (diabetes) is a group of metabolic diseases characterized by metabolic and hormonal changes in the form of hyperglycemia and defects in insulin secretion. The clinical classification of diabetes includes four classes¹:

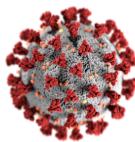

- Type 1 diabetes (results from b-cell destruction, usually leading to absolute insulin deficiency)
- Type 2 diabetes (results from a progressive insulin secretory defect on the background of insulin resistance)
- Other specific types of diabetes due to other causes, e.g., genetic defects in b-cell function, genetic defects in insulin action, diseases of the exocrine pancreas (such as cystic fibrosis), and drug- or chemical-induced (such as in the treatment of HIV/AIDS or after organ transplantation), autoimmune etiology?
- Gestational diabetes mellitus (GDM) (diabetes diagnosed during pregnancy that is not clearly overt diabetes)

Long term effects of chronic diabetic hyperglycemia are associated with long-term damage, dysfunction, and failure of different organs, especially the eyes, kidneys, nerves, heart, and blood vessels.

Clinical Criteria

Diagnosis for diabetes is based on laboratory tests. A test result diagnostic of diabetes should be repeated to rule out laboratory error, unless the diagnosis is clear on clinical grounds, i.e. patients with a hyperglycemic crisis or classic symptoms of hyperglycemia and a random plasma glucose ≥ 200 mg/dL.

- A1C $\geq 6.5\%$. The test should be performed in a laboratory using a method that is NGSP certified and standardized to the DCCT assay. Or
- Fasting plasma glucose (FPG) ≥ 126 mg/dL (7.0 mmol/L). Fasting is defined as no caloric intake for at least 8 h. Or
- Two-hour plasma glucose ≥ 200 mg/dL (11.1 mmol/L) during an oral glucose tolerance test (OGTT). The test should be performed as described by the World Health Organization, using a glucose load containing the equivalent of 75 g anhydrous glucose dissolved in water. Or
- In a patient with classic symptoms of hyperglycaemia or hyperglycaemic crisis, a random plasma glucose ≥ 200 mg/dL (11.1 mmol/L).
- In the absence of unequivocal hyperglycaemia, result should be confirmed by repeat testing.

2. Synonyms / lay terms used

Diabetes type 1, diabetes type 2, gestational diabetes mellitus (GDM), juvenile-onset diabetes, adult-onset diabetes, insulin-dependent diabetes (IDDM), non-insulin dependent diabetes (NIDDM), brittle diabetes, latent autoimmune diabetes in adults (LADA)

3. Laboratory tests done specific for event

See above. (Plasma glucose measurements.)

4. Diagnostic tests done specific for event

Not relevant

5. Drugs used specific for event treatment

Recommendations for insulin therapy for type 1 diabetes:

- Most people with type 1 diabetes should be treated with MDI (multiple dose injections) therapy (three to four injections per day of basal and prandial insulin) or insulin
- Most people with type 1 diabetes should use insulin analogues to reduce the risk of hypoglycemia.

Recommendations for insulin therapy for type 2 diabetes:

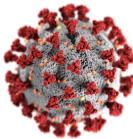

- Metformin is the preferred initial pharmacological agent for type 2 diabetes.
- If noninsulin monotherapy at maximal tolerated dose does not achieve or maintain the A1C target over 3–6 months, a second oral agent (sulfonylureas, alpha-glucosidase inhibitors, glinides, thiazolidinediones, biguanides, dipeptidyl peptidase-IV inhibitors), a glucagon-like peptide-1 (GLP-1) receptor agonist, an amylin analogue or insulin should be added.
- In newly diagnosed type 2 diabetic patients with markedly symptomatic and/or elevated blood glucose levels or A1C, insulin therapy should be considered from the outset. Due to the progressive nature of type 2 diabetes, insulin therapy is eventually indicated for many.

5. Procedures used specific for event treatment

No imaging

6. Procedures used specific for event treatment

NA

7. Setting (outpatient specialist, in-hospital, GP, emergency room) where condition will be most frequently /reliably diagnosed

Outpatient: GP or by ambulatory specialist

8. Diagnosis codes or algorithms used in different papers to extract the events in Europe/USA

>= 1 ICD-9 code: 250.01, 250.03, 250.11, 250.13, 250.21, 250.23, 250.31, 250.33, 250.41, 250.43, 250.51, 250.53, 250.61, 250.63, 250.71, 250.73, 250.81, 250.83, 250.91, or 250.93

The Sentinel review stated the following

"A literature review produced 14 articles regarding algorithms or codes to identify type I diabetes. Type I diabetes is explicitly intertwined with type II diabetes in the validation literature. Many validation studies exist that examine codes for both type I and type II diabetes, report PPVs and sensitivities ranging from 64%-98% and 73%-97%, respectively. Much less information is available when considering the distinct ICD-9 codes to distinguish between Type I and Type II diabetes, but validation studies do exist.

In a study by Bobo et al., authors validated an algorithm for identifying persons with type I diabetes within Tennessee Medicaid data, finding a PPV of 80%, sensitivity of 65% and specificity being > 99%.108 Operationally, since this study included codes for both Type I and II diabetes, the algorithm required: 1) a primary discharge diagnosis of 250 [*diabetes mellitus*], 250.0x [*diabetes mellitus without mention of complication*], 250.1x [*diabetes with ketoacidosis*], 250.2x [*diabetes with hyperosmolarity*], 250.3x [*diabetes with other coma*], or 250.9x [*diabetes with unspecified complication*]; 2) an inpatient stay with a secondary discharge diagnosis for one of these same ICD-9 codes + no diagnosis for 256.4 [*polycystic ovaries*] within 120 days of the diabetes diagnosis + a confirmatory antidiabetic prescription or an additional any-setting any-position ICD-9 code for diabetes within 120 days; or 3) an outpatient visit with a primary diagnosis for one of these same ICD-9 codes + a confirmatory antidiabetic prescription or an any-position inpatient ICD-9 code for diabetes within 120 days. In any of these three scenarios, >=1 prescription for insulin was also required within 120 days of the diabetes diagnosis, with no more than a single prescription for an oral antidiabetic drug during that interval. A single prescription for an oral agent did not serve as an exclusion criterion, because such drugs may be occasionally prescribed while awaiting the results of confirmatory testing for type I diabetes. If the aforementioned definition was not met, the individual was classified as a type II diabetic. Of note, the study population consisted solely of a small number of pediatric, adolescent, and young adult atypical antipsychotic users aged 6-24 years.

Rhodes et al. also examined a pediatric, adolescent, and young adult population, yet within the Endocrine/Diabetes or Obesity Programs at Children's Hospital in Boston, finding a PPV of 97% for Type I diabetes codes.109 To identify Type I diabetes, the algorithm required an inpatient or outpatient ICD-9 code for 250.x1 or 250.x3 which includes: 250.01 [*diabetes mellitus without mention of complication*, type one [*juvenile type*], not stated as uncontrolled], 250.03 [*diabetes*

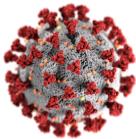

mellitus without mention of complication, type one [juvenile type], uncontrolled], 250.11 [diabetes mellitus with ketoacidosis, type one [juvenile type] not stated as uncontrolled], 250.13 [diabetes mellitus with ketoacidosis, type one [juvenile type], uncontrolled], 250.21 [diabetes mellitus with hyperosmolar coma, type one [juvenile type], not stated as uncontrolled], 250.23 [diabetes mellitus with hyperosmolar coma, type one [juvenile type], uncontrolled], 250.31 [diabetes mellitus with other coma, type one [juvenile], not stated as uncontrolled], 250.33 [diabetes mellitus with other coma, type one [juvenile], uncontrolled], 250.41 [diabetes mellitus with renal manifestations, type one [juvenile type], not stated as uncontrolled], 250.43 [diabetes mellitus with renal manifestations, type one [juvenile type], uncontrolled], 250.51 [diabetes mellitus with ophthalmic manifestations, type one [juvenile type], not stated as uncontrolled], 250.53 [diabetes mellitus with ophthalmic manifestations, type one [juvenile type], uncontrolled], 250.61 [diabetes mellitus with neurological manifestations, type one [juvenile type] not stated as uncontrolled], 250.63 [diabetes mellitus with neurological manifestations, type one [juvenile type] uncontrolled], 250.71 [diabetes mellitus with peripheral circulatory disorders, type one [juvenile type], not stated as uncontrolled], 250.73 [diabetes mellitus with peripheral circulatory disorders, type one [juvenile type], uncontrolled], 250.81 [diabetes mellitus with other specified manifestations, type one [juvenile type], not stated as uncontrolled], 250.83 [diabetes mellitus with other specified manifestations, type one [juvenile type], uncontrolled], 250.91 [diabetes mellitus with unspecified complication, type one [juvenile type], not stated as uncontrolled], or 250.93 [diabetes mellitus with unspecified complication, type one [juvenile type], uncontrolled]. This algorithm is much less complicated than the algorithm proposed by Bobo et al. and has a higher PPV, but authors did not report sensitivity or specificity.

Additionally, Klompas et al. developed algorithms for identifying individuals with type I diabetes, without regard to patient age, within Atrius Health electronic medical record data. The algorithm required ≥ 2 ICD-9 diagnoses for 250.x1 or 250.x3 (as described above), a current prescription for insulin and no prescription for an oral antidiabetic agent at any time (excluding metformin). This yielded a PPV of 81% and sensitivity of 32%. Twenty-one other candidate algorithms were presented by the authors in the manuscript. Of note, among persons meeting screening criteria for potential diabetes, algorithms that maximized sensitivity (often at the cost of PPV) included individual components such as: a prescription for insulin; no record of any oral antidiabetic drug; and no record of any oral antidiabetic drug (excluding metformin). Algorithms that maximized PPV (often at the cost of sensitivity) included individual components such as: a ratio of type I to type II ICD-9 codes >0.5 ; a ratio of type I to type II ICD-9 codes $>0.5 +$ prescription for insulin; a ratio of type I to type II ICD-9 codes $>0.5 +$ prescription for glucagon; C-peptide <0.8 ; and a prescription for urine acetone test strips. An algorithm that maximized PPV (96%) while maintaining an acceptable level of sensitivity (61%) included a requirement for a ratio of type I to type II ICD-9 codes >0.5 and no prescription for an oral antidiabetic drug (excluding metformin). The authors also developed an “optimized” algorithm, achieving a high PPV (96%) and perfect sensitivity (100%), yet this definition requires laboratory components that are not currently supported by the MSCDM (e.g., C-peptide, diabetes autoantibodies results).

In addition to the studies validating ICD-9 codes, a study by Vanderloo et al. conducted in British Columbia, reviewed both ICD-9 and ICD-10 codes. The PPV, sensitivity and specificity reported were 98%, 99% and 78%, respectively for type I diabetes. The workgroup did not recommend this algorithm, based its lumping of ICD-9 and ICD-10 codes.

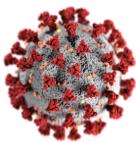

For defining the outcome of type I diabetes, the workgroup favors the algorithm proposed by Rhodes et al., which includes inpatient or outpatient ICD-9 codes 250.x1 or 250.x3, in any position. This algorithm will best identify pediatric, adolescent, and young adults with type I diabetes, and

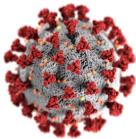

although similar to Bobo et al., the algorithm was evaluated in more persons. As a secondary algorithm, the workgroup proposes the algorithm by Klompaas et al. which includes: a ratio of type I to type II ICD-9 codes >0.5 + no prescription for an oral antidiabetic drug (excluding metformin), when researchers are interested in an adult patient population. Should requisite laboratory data be made available within the distributed database, the Klompaas et al. “optimized” algorithm should be used”.

11. Algorithm proposal

Broad algorithm:

- All concept sets: Concept sets = (Type1diabetes, diabetes_mellitus), any position, any provenance
- Index date: first occurrence of any of these concept sets

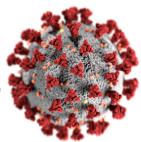

Narrow algorithm:

- Narrow codes excluding oral antidiabetic ([ATC=A10B](#))
- Index date: first occurrence of concept set
