Rotation and flares of M dwarfs with habitable zones accessible to TESS M. Bogner^{1,*}, B. Stelzer^{1,2} and St. Raetz¹

[1] Institut für Astronomie und Astrophysik Tübingen (IAAT) [2] INAF – Osservatorio Astronomico di Palermo [*] bogner@astro.uni-tuebingen.de

Sample

Data Analysis

- **112 M dwarfs** (spectral types K8 to M5)
- listed in TESS Habitable Zone Star Catalog (Kaltenegger+2019)
- TESS can detect planets in the full extent of the habitable zone • **TESS** mag≤11.5

• **1276** 2-min. cadence **light curves** (LCs) analyzed; example LC in Fig. 1

sample. Numbers denote M subclasses, -2 stand for K8. (Bogner et al., in prep.)

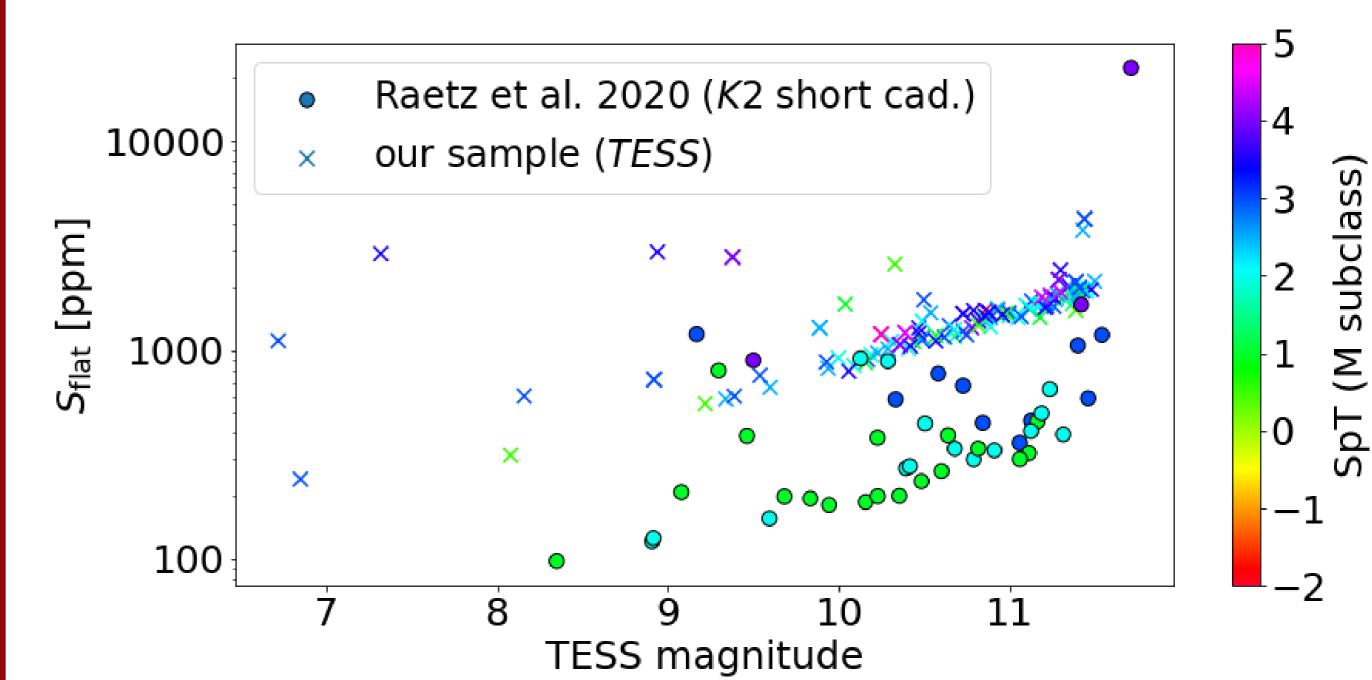

Fig. 3: Standard deviation of the flattened and cleaned LC as a function of TESS magnitude. For comparison, the values of K2 short cadence LCs from Raetz+2020 are also shown. The figure makes use of an empirical conversion between K2 and TESS magnitudes that we derived

The algorithm can be briefly summarized as follows:

For details, see Stelzer+2016

• rotation period search with 3 methods: Generalized Lomb Scargle Periodogram, autocorrelation function and sine fit

N.S

• flare detection based on flattened and cleaned LC with standard deviation $S_{\rm flat}$: A potential flare is a part of the original LC with **3 or more consecutive data points** deviating $> 3 S_{flat}$ from the LC's mean value.

and Raetz+2020

• further validation criteria (e. g. decay time > rise time)

• **contamination factor** = <u>summed up flux of contaminating stars</u> in aperture mask target flux

• energy completeness limit for flare detection determined from flare energy frequency distribution (FFD) following Hawley+2014

Analysis results

- 35 stars show flares (~31% of the sample); 2532 flares detected
- fraction of flaring stars higher for later M SpT subclasses (cf. Fig. 2)
- •12 stars (~11% of the sample) show reliable rotation periods (i. e. period search yielded consistent results for all TESS sectors of the star)
- rotational modulations with low amplitudes are hidden in the noise for **TESS LCs** due to higher standard deviation w. r. t. K2 (Fig. 3)
- 0.28 $d \leq P_{rot} \leq 3.94 d$
- 2138 flares occur on the 12 stars with reliable P_{rot} only 394 flares on others
- for most flares: **peak flare flux at inner HZ boundary** is larger than the bolometric flux hitting the top of Earth's atmosphere, i. e. (peak flare flux)/ $S_0 > 1$, cf. Fig. 4
- binned flare energy frequency distribution (FFD) for earlier SpT range (M2.5-M3.5) shifted to higher flare energies w.r.t. later SpT range (M4.5-M5) (Fig. 5)
- \rightarrow flares on later M subtype stars are less energetic

 stars with higher flare rates have higher energies of their largest flares; stars with reliable $P_{\rm rot}$ have the highest flare rates (Fig. 6)

Summary

- rotational modulation with low amplitude difficult to detect with TESS due to high standard deviation of the LCs (Fig. 3)
- atmospheres of potential exoplanets at inner HZ boundary are exposed to larger fluxes during flare events than Earth in quiescent solar state (Fig. 4)

based on ~19 000 main-sequence stars. (Bogner et al., in prep.)

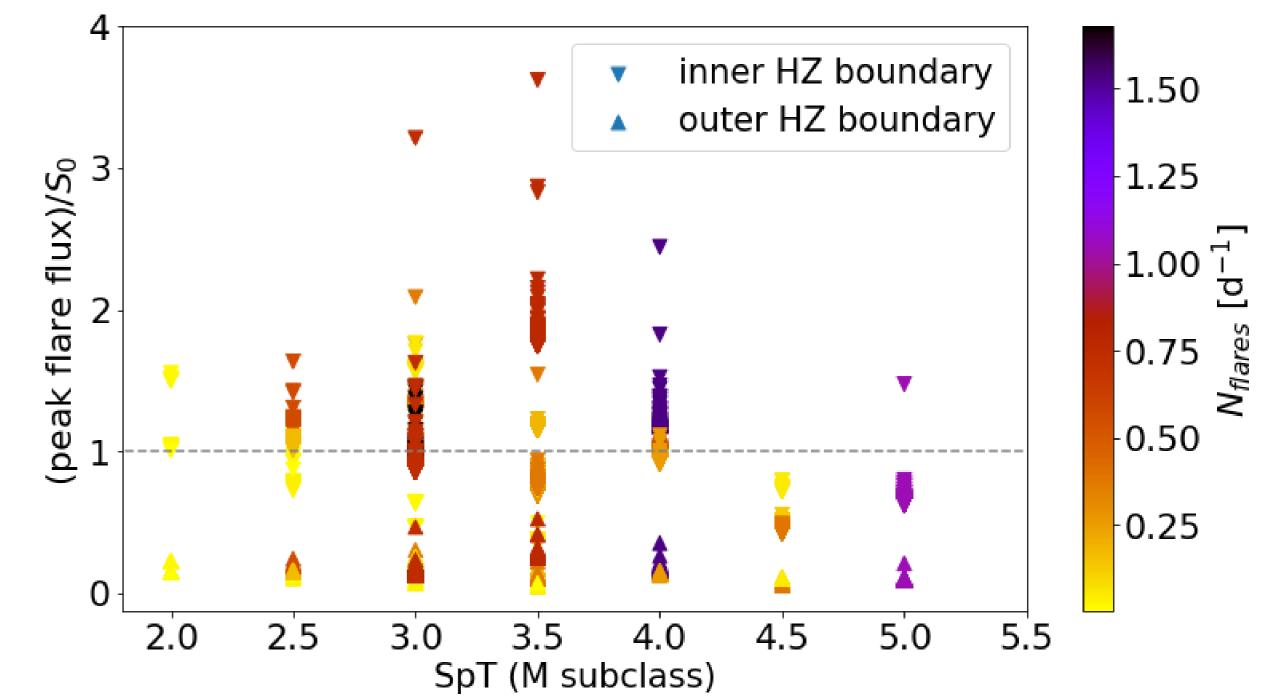

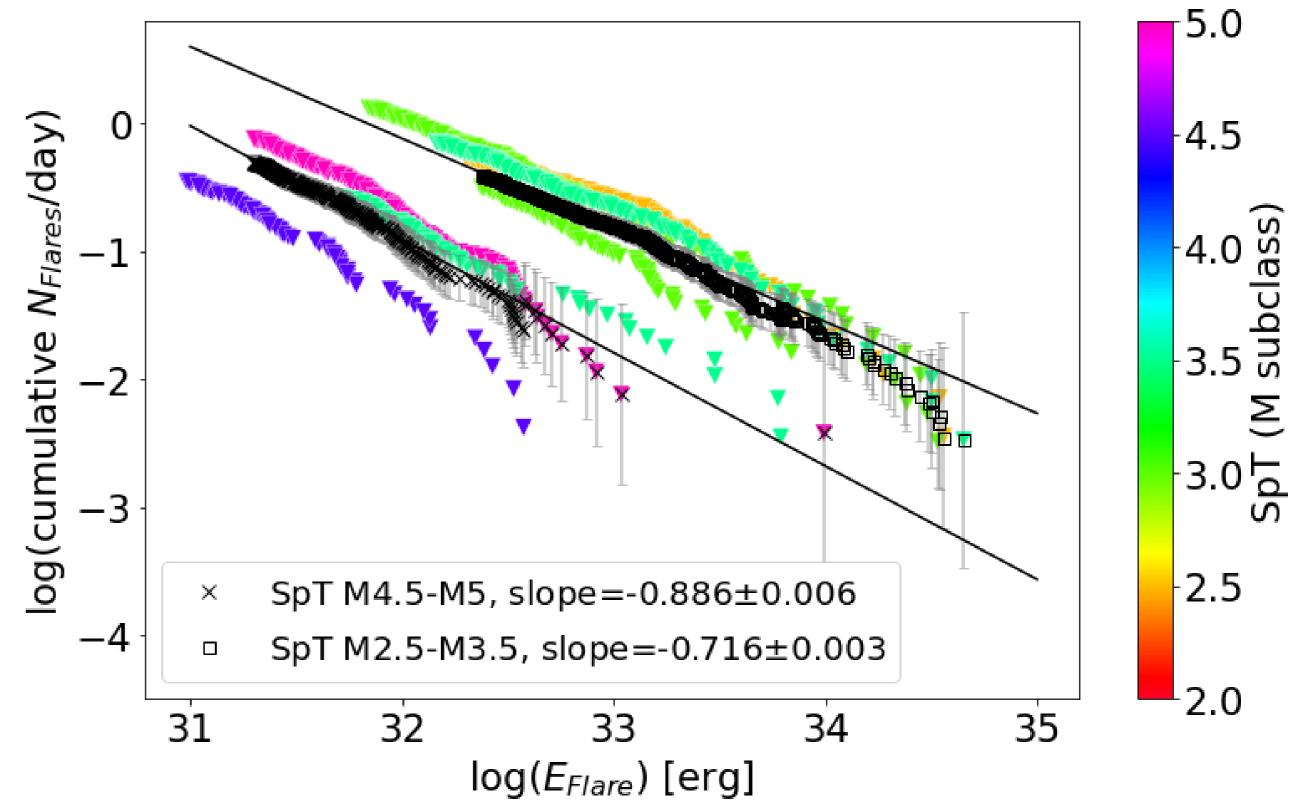

Fig. 4: Peak flare flux at the inner (Recent Venus) and outer (Early Mars) habitable zone boundary. Fluxes are normalized by the solar constant. The flare rate of each star is color-coded.

- earlier M subtype stars show flares with higher energies (Fig. 5)
- stars with reliable P_{rot} show higher flare rates; for each SpT, stars with higher flare rates also show higher energies of their largest flare (Fig. 6)

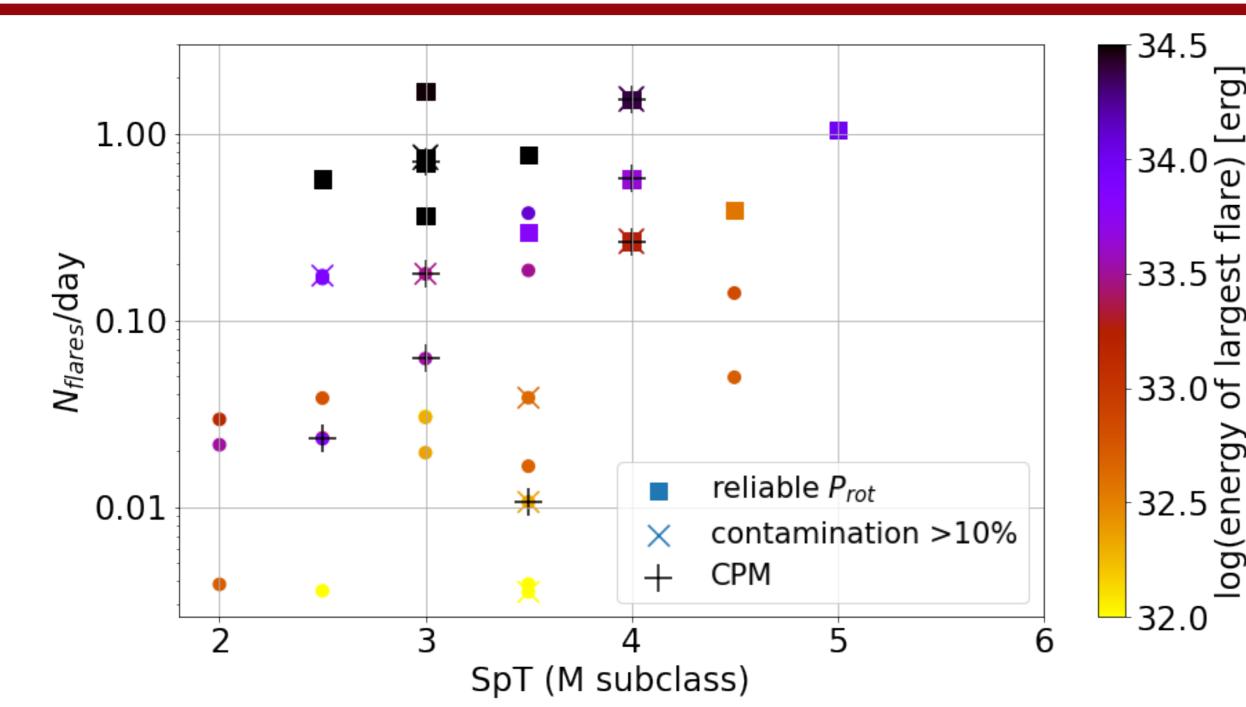

Fig. 6: Relation btw. flare rate and SpT. Stars in binaries are marked with '+', 'x' denotes those with a flux contamination >10%.

Fig. 5: FFDs of the 7 stars with reliable rotation periods that are not part of a close binary and have a flux contamination factor <10%. Only data points above the energy detection threshold are plotted. Black curves: binned FFDs in two different SpT ranges and fits. (Bogner et al., in prep.)
