Abstract

The paper presents the results of incubation and the quality of day-old chicks hatched from eggs of different weight. Total of 450 broiler breeder eggs was divided into 3 equal groups of 150 eggs, according to their weight (S group, 50.0±2.5 g; M group, 55.0 ± 2.5 g; L group 65.0 ± 2.5 g). Following parameters were measured: egg weight loss after 18 days of incubation (%); fertility of eggs (%); hatchability of incubated and fertilized eggs (%); total, early and late embryonic mortality (%); weight (g), length (cm) and yield of day-old chicks (%). Descriptive statistics method was used for data processing, and differences between the groups were tested by using of analysis of variance. The average weight of the eggs in groups of S, L and M was 55.02; 59.66 and 64.98 g, respectively, and significantly differed between groups (p<0.01). Average egg weight loss was 10.56; 10.25 and 10.22%, and without significant difference between groups. Hatchability of fertilized eggs was 93.8; 93.1 and 93.2%, respectively, and hatchability of all eggs was 91.3; 90.0 and 92.0%, respectively. Total embryo mortality in groups S, M and L was 6.2; 6.9 and 6.8%, respectively, with 4.1; 2.8 and 4.1% of early and 2.1, 4.1 and 2.7% of late mortality. Hatchability and embryonic mortality were not significantly influenced by eggs weight. The average weight of day-old chicks in S, M and L group was 37.80; 41.02 and 44.65 g, respectively, and the length of chicken was 17.68; 18.01 and 18.06 cm, respectively. The weight and length of chickens were significantly influenced by eggs weight (p <0.01). On the basis of these data it can be concluded that all analyzed groups had satisfactory results of incubation, as well as the weight and length of day-old chicks were significantly influenced by eggs' weight.

Keywords: *egg weight, incubation results, day-old chick quality.*

Introduction

Hatchability and day-old chick quality are main production parameters of hatchery, primarily used as proficiency indicator of hatchery management, but also as indicator of management at broiler breeder farm (Decuypere *et al*., 2007; Tullet, 2009; Bergoug *et al*., 2013). Day-old chicks of good quality are starting point for achievement of high productivity standards in broiler meat production (Willemsen *et al*., 2008). Relationship between hatchability or quality of day-old chicken and weight of hatching eggs was subject of many studies, and obtained results showed presence of strong relationships. Iqbal *et al*. (2016) demonstrated influence of egg weight on fertility, but Ramaphala and Mbajiorgu (2013) and Ulmer-Franco *et al*. (2010) did not confirmed these findings. Hatchability of all and fertilized eggs in study of Iqbal *et al*. (2016) and DeWitt *et al.* (2004) was influenced by egg weight, while it was not confirmed in studies of Gahri *et al*. (2015) and Ramaphala and Mbajiorgu (2013). Egg weight loss, according to Iqbal *et al*. (2016) and Kumpula (2004), depends on egg weight. Increased total embryonic mortality in larger eggs was revealed in several studies (Ramaphala and

Mbajiorgu, 2013; Terčič and Smerdu, 2014; Iqbal *et al*., 2016). Increased late mortality in large eggs was observed by Ulmer-Franco *et al*. (2010) and Gahri *et et al*., (2015), but Jaiswal *et al*. (2016) observed it in smaller eggs. Day-old chick quality can be estimated by using different methods, including measuring of chick weight and length (İpek and Sözcü, 2013). Influence of egg weight on chick weight and length was confirmed by numerous authors (Kumpula, 2004; Ramaphala and Mbajiorgu, 2013; Iqbal *et al*., 2016). Chick length, according to Mukhtar *et al*. (2013), is the best indicator of pre-incubation and incubation conditions. Willemsen *et al*. (2008) found that day-old chick weight is the second indicator of fattening performances after seven day old chick weight, while day-old chick length had low predictive value.
The objective of this study was to investigate hatchability and selected quality parameters of day-old chicken hatched from eggs with different weights.

Materials and Methods

Total of 450 broiler hatching eggs, originated from 34 week old broiler parent flock Cobb 500 exploited in 2015 in commercial farm in north part of Republic of Srpska, was used in this study. All egg was laid on the same day, and after arrival in storage room of hatchery were individually marked and distributed in one of three groups according to weight: small - S (55±2.5 g), medium - M (60±2.5 g) or large - L (65±2.5 g). Eggs were stored four days at adequate conditions (air temperature 19±1°C, relative humidity 60±5%) prior incubation. Disinfection, pre-warming and incubation of eggs were identical for all groups. Egg weight was individually measured by technical scale (0.01 g) before incubation and at transferring eggs from setter to hatcher (day 18 of incubation). Egg weight loss was calculated according equations given by Tullet (2009). Analysis of all non-hatched eggs was performed after incubation in order to determine number of fertilized and unfertilized eggs and number of hatched chicken. These data was used for calculation of egg fertility, hatchability of all and fertilized eggs, according to equations given by Hesna Sahin *et al*. (2009). Number of embryos died in the first, second and third week of incubation was used for calculation of total, early, middle, and late embryonic mortality according to equations given by Alasahan and Copur (2016). Measurement of chick length, determined as length from tip of beak to root of middle nail of right foot, was performed according to Willemsen *et al*. (2008). Chick yield was calculated based on day-old chick weight and fresh egg weight according to equation given by Tullet (2009). Statistical analysis of obtained data was performed by ANOVA and mean differences were tested by Tukey test at significance level $p<0.05$.

Results and Discussion

Results of egg weight loss are showed in table 1.

Table 1. Egg weight loss (mean ± SE) after 18 days of incubation

Egg weight group	Fresh egg weight (g)	Egg weight after 18 days of incubation (g)	Egg weight loss	
			(g)	(%)
S	55.02 ± 0.11^{c}	49.21 ± 0.11^{c}	5.81 ± 0.08^{c}	10.56 ± 0.15
M	59.66 ± 0.11^{b}	53.55 ± 0.12^{b}	6.12 ± 0.07^{b}	10.25 ± 0.11
L	64.98 ± 0.17^{a}	58.34 ± 0.18^{a}	6.64 ± 0.10^{a}	10.22 ± 0.15

^{abc} – Values indicated with different superscript in the same column are statistically different ($p<0.01$)

Egg weight loss was significantly ($p<0.01$) different among groups, and the highest egg loss was in group L (6.64 g), and the lowest in group S (5.81 g). This parameter, expressed as relative value, was not significantly different ($p>0.05$) among groups, but the highest egg loss was recorded in group S (10.56%), and the lowest in group L (10.22%). Optimal egg weight loss is 11.5% (Tullet, 2009), but its value depends on egg surface to volume ratio (Ulmer-Franco *et al.*, 2010). According to results of Iqbal *et al*. (2016) weight loss of Hubbard Classic strain eggs in three weight groups (60.05; 65.03 and 70.03 g in average, respectively) was lower ($p<0.05$) in large eggs (10.62%) compared with medium (11.12%) and small eggs (11.32%). Egg weight loss of Ross 308 eggs, according to Gahri *et al*. (2015), was lower (11.63%) in large (52.6-55.7 g) compared with egg loss (12.56%) of small eggs (52.6-55.7 g). Also, lower weight loss (11.24%) in large Anak broiler eggs (in average 60 g) has obtained by Abiola *et al*. (2008). Jaiswal *et al*. (2016) divided CARI-BRO Vishal broiler eggs in three weight groups (small <49; medium 50-59 and large 60-69 g) and found higher ($p<0.05$) weight loss in small eggs (13.09%) in relation on medium (8.34%) and large eggs (10.0%).

Parameters of hatchability according to egg weights are showed in table 2.

Table 2. Apparent fertility and hatchability parameters of egg weight groups

Egg weight group	Apparent egg fertility (%)	Hatchability of fertile eggs (%)	Hatchability of total eggs (%)
S	97.3	93.8	91.3
M	96.7	93.1	90.0
L	98.7	93.2	92.0

Apparent fertility in groups S, M and L was 97.3; 96.7 and 98.7%, respectively; and was not statistically different ($p>0.05$). Gahri *et al*. (2015) also not conformed difference in fertility of Ross 308 eggs categorized as small (52.6-55.7 g), medium (57.2-60.2 g) and large (61.7-64.7 g), and the following values were determined: 91.5; 93.0 and 94.7%, respectively. Also, fertility of eggs categorized in three groups (small 53.0, medium 57.0 and large 61.0 g in average) in study of Kumpula (2004) was 94.0; 91.5 and 93.6%, respectively, and was not different ($p>0.05$). Contrary to this, in study of Iqbal *et al*. (2016), three Hubbard Classic eggs weight groups (60.05; 65.03 and 70.03 g in average, respectively) had different ($p<0.001$) fertility (96.67; 93.33 and 90.33%, respectively).

Hatchability of fertilized eggs in this study was 93.8; 93.1 and 93.2% in S, M i L groups, respectively, while hatchability of all eggs was 91.3; 90.0 and 92.0%, respectively. These values were not influenced by egg weight ($p>0.05$). Hatchability of all eggs in study of Gahri *et al*. (2015), grouped as small (52.6-55.7 g), medium (57.2-60.2 g) and large (61.7-64.7 g), was also not influenced by egg weight (83.3; 84.0 and 80.7%, respectively), as well as hatchability of fertilized eggs (83.7; 86.4 and 83.8%, respectively). Kumpula (2004) reported insignificant differences in values of hatchability of all (85.5; 82.3 and 82.2%) and fertilized eggs (91.0; 89.9 and 87.9%) in three weight groups (small: 53.0 g; medium: 57.0 and large: 61.0 g in average, respectively). Differences in hatchability of Cobb 500 eggs with different weight (<49; 50-59 and 60-69 g), used in study of Ramaphala and Mbajiorgu (2013), were insignificant (92.43; 90.89 and 90.92%, respectively). Iqbal *et al*. (2016) found that hatchability of all and fertilized eggs in three weight groups (60.05; 65.03 and 70.03 g in average) was different ($p<0.001$), and had following values: 89.67; 83.67 and 78.33%, respectively and 92.74; 89.64 and 86.72%, respectively. Terčič and Smerdu (2014) reported lower ($p<0.05$) hatchability (76.72%) in large eggs (>63 g), and highest hatchability (82.4%) in medium eggs (53-63 g). However, hatchability of large (60-69 g) Caribro Vishal broiler eggs (80.2%) was higher ($p<0.05$) in relation on small (<49 g) and medium eggs (50-59 g) with 66.0% and 74.4%, respectively (Jaiswal *et al*., 2016). Higher ($p<0.05$) hatchability (96.7%) of medium eggs (50 g in average) compared with hatchability (82.8%) of large eggs (60 g in average) was found by Abiola *et al*. (2008).

Parameters of embryonic mortality of egg weight groups are showed in table 3.

Table 3. Parameters of embryonic mortality of egg weight groups

Egg weight group	Total embryonic mortality		Early embryonic mortality		Middle embryonic mortality		Late embryonic mortality	
	n	%	n	%	n	%	n	%
S	9	6.2	6	4.1	0	0	3	2.2
M	10	6.9	4	2.8	0	0	6	4.1
L	10	6.8	6	4.1	0	0	4	2.7

The highest total embryonic mortality was in group M (6.9%), followed by mortality in groups L (6.8%) and S (6.2%). Early embryonic mortality in groups S and L was 4.1%, and it was relatively higher from mortality in group M (2.8%). Late embryonic mortality in group M (4.1%) was relatively higher than mortality in groups L (2.7%) and S (2.2%). Middle embryonic mortality was not found in all groups. Values of all parameters of embryonic mortalities were not statistically different among groups ($p>0.05$). According to Kumpula (2004) values of early and middle mortality were not different in eggs of two commercial broiler strain divided in three weight groups (small - 53.0, medium - 57.0 and large - 61.0 g in average), and had following values: 5.6; 5.0; 5.5%, respectively; and 0.5; 0.6; 0.1%, respectively. However, late mortality was higher ($p<0.05$) in large (6.1%) compared with medium (4.3%) and small eggs (1.8%). Iqbal *et al*. (2016) found that early mortality in three egg weight groups (60.05; 65.03 and 70.03 g in average) was the lowest ($p<0.01$) in small (2.0%) then in medium (2.8%) and large eggs (3.3%), while early (1.33) and late (1.67%) mortality of small eggs was lower ($p<0.01$) then in large eggs (2.3 and 3.0%, respectively). Early mortality, according to Gahri *et al*. (2015), in three groups (small: 52.6-55.7; medium 57.2-60.2 and large 61.7-64.7 g) was 3.95; 2.96 and 4.68%, respectively, and was lower ($p<0.05$) in medium eggs; middle mortality (0.67; 0.69 and 0.67%, respectively) was not different among groups ($p>0.05$), but late mortality was higher ($p<0.05$) in large (6.38%) then in small (2.85%) and medium eggs (3.63%). Terčič and Smerdu (2014), found higher ($p<0.05$) total mortality (19.72%) in large eggs (>63 g), compared with 14.58% in medium (53-63 g) and 8.05% in small eggs (<53 g). However, Jaiswal *et al*. (2016) found higher ($p<0.05$) total embryonic mortality (15.3%) in egg weighted less than 49 g compared with 10.56% of medium (50-59 g) and 6.13% of large eggs (60-69 g).

Parameters of day-old chick quality hatched from eggs with different weight are showed in table 4.

Table 4. Quality parameters of day-old chickens (mean ± SE)

Egg weight group	Chick weight (g)	Chick length (cm)	Chick yield (%)
S	37.81 ± 0.16^{a}	17.68 ± 0.04^{a}	68.71 ± 0.12
M	41.02 ± 0.13^{b}	18.01 ± 0.05^{b}	68.75 ± 0.11
L	44.65 ± 0.19^{c}	18.06 ± 0.05^{b}	68.71 ± 0.14

^{abc}– Values indicated with different superscript in the same column are statistically different ($p<0.01$)

Average chick weight was significantly different among groups ($p<0.01$). It was the highest in group L (44.65 g), and followed by groups M (41.02 g) and L (37.81 g). Average chick length had similar trend, and it was higher ($p<0.05$) in groups L (18.06 cm) and M (18.01 cm) in comparison with group S (17.68 cm). Chick yield in groups S and L was equal (68.71%), while in group M was slightly higher (68.75%), and was not different ($p>0.05$). Influence of egg weight on chick weight was also confirmed by Ramaphala and Mbajiorgu (2013), who incubated Cobb 500 eggs in three weight groups (<49; 50-59 and 60-69 g), and reported consequently different ($p<0.05$) day-old chick weights (42.33; 44.13 and 49.01 g, respectively). Terčič and Smerdu (2014) found different ($p<0.05$) values of chick weight (34.69; 40.16 and 45.15 g, respectively) hatched from three weight group eggs (<53; 53-63 and >63 g). Kumpula (2004) categorized eggs as small, medium and large (53.0, 61.0 and 67.0 g in average) and determined different ($p<0.05$) chick weights (36.9; 40.0 and 43.1 g, respectively). Iqbal *et al*. (2016) confirmed influence ($p<0.05$) of egg weight (three weight groups with 60.05; 65.03 and 70.03 g in average) on length of male (18.99; 19.60 and 19.72 cm, respectively) and female chicken (18.98; 19.37 and 19.55 cm, respectively). Kumpula (2004) found influence of egg weight on chick length, whereas chicken hatched from small, medium and large egg (53.0, 61.0 and 57.0 g, respectively) had different lengths (18.1; 18.0 and 18.4 cm, respectively). Optimal chick yield in stored eggs is 67.5% (Tullet, 2009). Iqbal *et al*. (2016) did not found influence of egg weight (three groups with 60.05; 65.03 and 70.03 g in average) on chick yield of male (68.59; 68.43 and 67.99%, respectively) and female chicken (66.48; 66.38 and 67.66%, respectively). Kumpula (2004) found difference ($p<0.05$) in chick yield among chicken hatched from different egg weight groups, so small, medium and large eggs (53.0; 61.0 and 57.0 in average, respectively) had following chick yields 70.4; 71.3 and 71.9%, respectively.

Conclusion

On the obtained results in this study it can be concluded that hatching eggs in three studied weight categories had relatively similar results in view of fertility and hatchability. Chick weight and length was different among three egg weight groups, i.e. higher parameter values have chicken hatched from larger eggs, while chick yield was not different among analyzed egg weight groups.

Abstract

The aim of the study was to investigate the influence of two storage lengths and three egg positions during storage on following incubation results of broiler hatching eggs: egg weight loss; hatchability of incubated and fertilized eggs; total, early, medium and late embryonic mortality. Study was performed in commercial hatchery in north part of Republic of Srpska during 2015. A total of 1050 eggs originated from 32 weeks old parent flock Cobb 500 were divided into six equal experimental groups, depending on the length (7 or 10 days) and the egg position during storage (normal - the large end up; horizontal - eggs in horizontal long axis; inverted - the large end down) and one control group (4 days of storage in normal position). Data processing was performed by using the analysis of variance with *post hoc* test at a significance level of $p<0.05$. Hatchability of fertilized eggs, total and early embryonic mortality were significantly influenced by the length of storage ($p<0.05$). The influence of the egg position on examined parameters of incubation was not significant. Based on these results, it can be concluded that the length of egg storage has a significant influence on the hatchability, while the egg position in the examined storage periods had no influence on the parameters examined in this study.

Keywords: *hatching egg, storage length, egg position, incubation*

Introduction

Storage of hatching eggs are almost necessary segment in production cycle of broiler day-old chicken, and it is used to synchronize capacity of hatcheries with egg production on breeder farm on the one, and demand for day-old chicken on market, on the other side. In commercial conditions of production hatching egg are stored at least two times, primarily at broiler breeder farm, and then at hatchery before incubation. Storage length significantly effects hatchability of broiler hatching eggs in field circumstances (Yassin *et al.*, 2008), therefore it is recommended to storage eggs maximally 3 or 4 days (Meijerhof, 1992). Hatching eggs should be stored in vertical position with blunt end up, and then incubated in the same position (Milošević and Perić, 2011). Deleterious influence of extended storage on hatchability and chick quality could be limited by different procedures, with aim to preserve embryo vitality and albumen quality, as crucial factors for achieving satisfactory incubation results (Reijrink *et al*., 2008). Alternative egg storage positions, as method of hatchability preservation, were investigated by Proudfoot (1967), who determined that egg storage up to 14 days in inverted position had beneficial effect on hatchability, but that effect was deleterious when storage lasted more than 14 days. Tiwary and Maeda (2005) reported better hatchability of layer hatching eggs stored 14 and 21 days in inverted position compared with normal position, whereas hatchability of eggs stored 7 days was nearly equal in these two

positions. Beneficial effect of inverted egg position on hatchability compared to normal position was confirmed by Elibol and Brake (2008) after 14 days of storage of broiler hatching eggs, as well as Lima *et al.* (2012) and Schulte-Drüggelte (2011) after 14 and 20 days of storage of layer hatching eggs, respectively. Slightly different hatchability of White Rock breed eggs stored in different positions was reported by Oluyemi and George (1972), who found that eggs stored in inverted position had slightly better hatchability compared to eggs stored in horizontal and normal position. On the other side, incubation results of layer hatching eggs stored 5 days in inverted position were lower compared with those stored in normal position (Salahi *et al.*, 2012), primarily due to decreased hatchability and increased late embryonic mortality. According to Kgwatalala *et al.* (2015), Tswana breed eggs stored 10 and 15 days in horizontal position had higher hatchability compared with eggs stored in normal and inverted position, while hatchability of eggs stored up to 5 days was not related to storage positions.
The aim of this study was to investigate the effect of two storage length (7 or 10 days) and three egg position during storage (normal, horizontal or inverted) on incubation results of broiler hatching eggs (egg weight loss; hatchability of all eggs; hatchability of fertilized eggs; total, early, intermediate and late embryonic mortality).

Materials and Methods

Total of 1050 broiler hatching eggs, laid by 33 week old broiler breeder flock Cobb 500 raised in 2015 on commercial farm located in the north part of Republic of Srpska, were used in study. All eggs were laid and collected on the same day, and transferred to hatchery, where eggs were individually marked, placed in carton boards and stored at adequately managed storage room conditions (air temperature 19±1°C; relative air humidity 65±5%) until incubation. Eggs were divided in seven equal groups, six experimental (n=150 eggs each) according to two storage lengths (7 or 10 days) and three egg storage positions (normal egg position – the blunt end up, horizontal egg position – egg laid in horizontal long axis and inverted egg position – the blunt end down) and one control (4 days of storage in normal position). Conditions of fumigation, pre-warming and incubation of eggs followed standard technology in commercial hatchery, thus all groups in study had identical pre-incubation and incubation procedures. Egg weight was individually determined two times, before setting in incubator and at transferring eggs in hatcher (day 18th of incubation) by technical scale (0.01 g), and obtained data were used for calculation of egg weight loss according to equation given by Salahi *et al*. (2012). At the end of incubation all vital chicken were counted, and all non-hatched eggs were broken in order to determine number of unfertilized eggs and embryos died in the first (early), second (intermediate) and third week of incubation (late embryonic mortality). On the basis of this data the following parameters were calculated, according to equations given by Alasahan and Copur (2016): egg fertility, hatchability of all and fertilized eggs, total, early, intermediate and late embryonic mortality. Results are presented in tables, and statistical analysis of data was performed using ANOVA with Tukey *post hoc* tests at 5% significance level.

Results and Discussion

Results of egg weight loss and hatchability of examined eggs are presented in table 1.

Table 1. Weight loss and hatchability parameters of eggs stored in three different positions

Egg storage (days)	4	7			10		
Egg position	Nor	Nor	Hor	Inv	Nor	Hor	Inv
Egg weight at set (g)	60,22	60.17	60.31	59.81	59.90	59.70	59.61
Egg weight loss (g)	6.48	6.85	6.84	6.85	6.39	6.31	6.45
Egg weight loss (%)	10.76	11.38	11.35	11.45	10.67	10.57	10.82
Apparent fertility (%)	97.3	98.0	98.0	98.0	98.0	97.3	98.0
Hatchability of fertile eggs (%)	93.8[a]	96.6[a]	90.5[a]	93.2[a]	83.7[b]	87.7[b]	85.0[b]
Hatchability of set eggs (%)	91.3[a]	94.7[a]	88.7[a]	91.3[a]	82.0[b]	85.3[b]	83.3[b]

Nor – normal; Hor – horizontal; Inv – inverted egg position
[abc] – means with different superscripts in the same row are significantly different ($p<0.05$)

Average weight loss in normal, horizontal, and inverted position group after 7 day of storage was 6.85 g (11.38%); 6.84 g (11.35%) and 6.85 g (11.45%), respectively. After 10 days of storage average weight loss was 6.39 g (10.67%), 6.31 g (10.57%) and 6.45 g (10.82%), respectively. Egg weight loss, according to egg storage, was relatively higher after 7 days of storage. Salahi *et al*. (2012) didn't find difference in egg weight loss between eggs stored 4-5 days in normal (14.1%) or inverted position (13.4%), while Terčič and Pestotnik (2016) found difference ($p<0.05$) in weight loss of eggs stored in different intervals from 0 to 15 days in normal (11.03%) or inverted position (11.37%). Egg weight loss in interval between 6.5 and 14.0%, according to Molenaar *et al.* (2010), has no detrimental effect on hatchability, whose value depends on egg shell quality and pressure difference between egg and its surrounding.

Fertility of eggs stored for 7 days was 98.0% in all groups, while its value after 10 days of storage was 98.0% in normal and inverted group and 97.3% in horizontal group. Fertility, as complex trait, is influenced by numerous genetic and non-genetic factors, particularly by flock management, regarding nutrition, environmental conditions and cock: hen ratio, along with breeders age (King'ori, 2011).

Hatchability of fertilized eggs stored for 7 days was the highest in normal position group (96.6%), followed by inverted (93.2%) and horizontal group (90.5%), while storage for 10 days resulted in higher hatchability in horizontal group (87.7%) compared with inverted (85.0%) and normal position group (83.7%). Hatchability of all eggs in stored groups had the same pattern as hatchability of fertilized eggs in normal, horizontal and inverted position groups and was 94.7, 88.7 and 91.3% after 7 days, respectively, and 82.0, 85.3 and 83.3% after 10 days, respectively. Hatchability of all groups stored for 10 days was generally lower ($p<0.05$) compared with groups stored for 7 days and control group. Hatchability of groups stored in alternative positions had inconsistent respond, as hatchability was relatively lower in groups stored 7 days while it was relatively higher in groups stored 10 days. Elibol and Brake (2008) also found beneficial influence of inverted position on hatchability of fertilized broiler hatching eggs after 14 days of storage (57.8% vs. 49.4%), but also after only 3 day of storage (83.2% vs. 82.5%). Lima *et al*. (2012) reported higher hatchability of in inverted layer breeder eggs (92.3%) compared with normal position (90.3%) after 7 days of storage and confirmed their findings after 14 days of storage (81.54% vs. 67,7%). Relatively higher hatchability of eggs stored up to 15 days in inverted position compared with normal position was found by Terčič and Pestotnik (2016). Similar results were obtained by Tiwary and Maeda (2005), as hatchability of layer hatching eggs stored in inverted position (80.9%) for 7 days was higher compared with eggs stored in normal position (76.5%), and it was also confirmed after 14 days of storage (66.7% vs. 56.1%). Kgwatalala *et al*. (2015) found relatively higher hatchability of eggs stored 6-10 days in both inverted (67.5%) and horizontal position (60.0%) compared to eggs stored in normal position (45.0%), which was also conformed by hatchability of fertilized eggs (84.38; 83.22 and 62.14%, respectively). Contrary to this, Salahi *et al*. (2012) showed that hatchability of layer breeder eggs was lower when they were stored 4-5 days in inverted (67.6%) opposed to normal position (71.9%).

Embryonic mortality of eggs obtained in study is presented in table 2.

Table 2. Embryonic mortality of eggs stored in three different positions

Egg storage (days)	4	7			10		
Egg position	Nor	Nor	Hor	Inv	Nor	Hor	Inv
Total embryonic mortality (%)	6.1^{b}	3.4^{b}	9.5^{b}	6.8^{b}	16.3^{a}	12.3^{a}	15.0^{a}
Early embryonic mortality (%)	3.4^{b}	3.4^{b}	5.4^{b}	3.4^{b}	10.9^{a}	8.9^{a}	9.5^{a}
Intermediate embryonic mortality (%)	0.0	0.0	1.4	2.0	1.4	0.7	0.7
Late embryonic mortality (%)	2.7	0.0	2.7	1.4	4.1	2.7	4.8

Nor – normal; Hor – horizontal; Inv – inverted egg position.
^{abc} – means with different superscripts in the same row are significantly different ($p<0.05$)

Total embryonic mortality after 7 days of storage was the highest in horizontal group (9.5%), and then in inverted group (6.8%) and normal (3.4%), whereas its value after 10 days of storage was the highest in normal group (16.3%), followed by inverted (15.0%) and horizontal group (12.3%). Early embryonic mortality after 7 days of storage was the highest in horizontal group (5.4%) and identical (3.4%) in normal and inverted position group. Increased values of this parameter were detected after storage of 10 days with higher values in normal group (10.9%) compared with inverted (9.5%) and horizontal group (8.9%). Intermediate embryonic mortality after 7 days of storage in normal position was not found, while in inverted and horizontal group was 2.0 and 1.4%, respectively. This parameter after 10 days of storage was 0.7% in horizontal and inverted groups, while in normal group was 1.4%. Late embryonic mortality after 7 days of storage was not found in eggs stored in normal position; in horizontal and inverted group was 2.7% and 1.4%, respectively. Inverted, normal and horizontal groups, regarding this parameter after 10 days of storage, had values 4.8, 4.1 and 2.7%, respectively. Total embryonic mortality in study of Terčič and Pestotnik (2016) was not different between eggs stored up to 15 days in normal (13.6%) and inverted position (11.3%). Tiwary and Maeda (2005) reported that total mortality after 7 days of storage in normal and inverted position was 23.5 vs. 19.0%, and the same parameter after 14 days of storage was 43.8 vs. 33.3%, respectively. Lima *et al*. (2012) found that early mortality was 3.7 vs. 1.7% ($p>0.05$), and late mortality was 5.3% vs. 3.4% ($p<0.05$) after 7 days of storage of layer breeder eggs in normal and inverted position. Early and late mortality after 14 days of storage in normal and inverted position was 20.1 vs. 9.1% ($p>0.05$) and 5.8 vs. 5.4% ($p>0.05$), respectively. Elibol and Brake (2008) reported that inverted positioned egg compared with normal had lower ($p<0.05$) early and late mortality after 3 (9.5 vs. 8.9%; 4.3 vs. 3.8%, respectively) and 14 days of storage (30.2 vs. 26.7%; 15.4 vs. 10.9%, respectively). Blastoderm in inverted stored eggs is in position which probably decrease possibility of malposition or adhesion to egg membrane (Proudfoot, 1969), and assures better hydration of embryo, which in total results with higher hatchability percentage after storage as consequence of reduced early and late embryonic mortality (Reijrink, 2009, 2013), whereas egg quality is comparable with quality of normal stored eggs (Proudfoot, 1973).

Conclusion

According to obtained results it can be concluded that storage of broiler hatching eggs longer than 7 day had deleterious influence on hatchability, mainly as consequence of increased embryonic mortality in the first week of incubation. Influence of egg position during 7 and 10 days of storage was not clearly demonstrated on studied parameters of incubation.

Abstract

The study was carried out to compare the carcass characteristics and meat chemical composition in two lines of slow growing male chickens - La Belle (LB) and Bresse (BB), and their crosses (♂LB x ♀BB, ♂BB x ♀LB). All the birds were reared indoors in the same conditions and at the age of 12 weeks, 6 chickens of each line were selected for slaughter. One-way ANOVA was performed to assess the differences in the carcass and meat quality among lines. The results showed that crossing of LB and BB lines affected the live weight and the weight of the eviscerated carcass (P<0.001), edible by-products - neck and giblets (P<0.05), and non edible parts (P<0.01). The highest values of these parameters were observed in ♂BB x ♀LB birds. This crossbred line had the highest weight of back and wings, while the lowest weight of thighs was observed in BB chickens. Furthermore, ♂LB x ♀BB birds tended to have higher dressing percentage (P=0.08), but the lowest content of edible by-products among all lines (P<0.05). Crossing also influenced the chemical composition of the breast (P<0.001), leading to higher protein but lower moisture content in both crosses. In thighs the content of lipids and protein differed significantly between the crossbred lines as ♂BB x ♀LB had higher lipid but lower protein when compared to the ♂LB x ♀BB chickens (P<0.05) The ash had the highest content in breast of BB birds and the thighs of LB and ♂LB x ♀BB chickens.

Keywords: *Slow growing chickens, Pure lines, Crossbred lines, Carcass traits, Meat quality*

Introduction

The increasing demands of the consumers for high quality and more variety of poultry meat products draws greater attention to the indigenous lines. They appeared to be more resistant to pathogens and environmental stressors (Rizzi and Chiericato, 2010) and have some distinct features suitable for a niche market serving consumers who prefer chicken meat different from that of the commercial broilers (Zhao et al., 2012). The consumption of meat products from local chickens has increased despite their relatively high prices (Yang and Jiang, 2005). La Belle is an indigenous Bulgarian line, and the old French breed Bresse has been recently imported to the country. While the latter has initiated specific production of famous high quality products in France, few studies about the meat properties of La Belle exist (Popova, 2016 a, b). Both breeds are characterized by slower growth (Baéza et al., 2009; Popova, 2016a). Carcass composition and quality are important from economic point of view since they indicate the efficiency of the meat production. According to Shahin and Abd Elazeem (2005) a superior carcass should have maximum proportion of muscle, minimum proportion of bone and optimum proportion of fat, and also must contain high proportion of most valuable muscles that is, breast and thighs. Crossing of the pure lines is a way to manipulate various productive traits in the poultry (Amin et al., 2013), to improve the carcass composition and meat quality through expected heterotic effect in the generation (Keambou et al., 2010) which is stronger the more the parent lines are genetically distant (Wilham and Pollak, 1985). Hence, the aim of the study was to compare the carcass characteristics and meat chemical composition in two lines of slow-growing chickens - La Belle and Bresse, and their crosses.

Materials and methods

Experimental animals, slaughtering and sampling

The trial was carried out in the experimental poultry farm of the Institute of Animal Science – Kostinbrod, Bulgaria with a total of 160 Labelle (LB) and 107 Bresse (BB) obtained from the parent stock of the Institute as well as their crosses (♂LBx♀BB, n=54; ♂BB x♀LB, n=52). The 1-day-old chickens were placed in a deep litter facility with a stocking density of 14 birds m^2 in separate pens in the same poultry house. All the birds were fed *ad libitum* starter (ME- 3147 kcal/kg; protein content-20.15%) and finisher (ME -3105 kcal/kg, protein content-17.77%). Water was provided *ad libitum* with a nipple waterer. The lighting regime was 15 h of light and 9 h of darkness, andthe temperature ranged between 20 and 24◦C. At the age of 12 weeks, 6 male birds of each line were selected for slaughter based on the average live weight. After stunning, decapitationand bleeding, the carcasses were plucked, eviscerated, their feet removed,the edible by-products (neck, liver, gizzard, heart and spleen) were weighed and their content was calculated as percentage of the live weight. Hot carcass weight was registered and dressing percentage was calculated. The carcasses were then stored at 4◦C for 24 h and weighed again. Further the internal fat was removed from the carcasses and theywere separated into breast, thigh, back and wings. The weight of the parts and the internal fat was recorded. The skin and bones from the breast and thighs were removed to obtain the muscles and they were weighed. The content of the separated parts, muscles and internal fat was calculated as percentage of the cold eviscerated carcass weight. The muscles were minced and frozen at -20◦C until further analysis of the chemical composition of the meat.

Analysis of the chemical composition

The breast and thigh meat was analysed for lipid, protein, moisture and ash content following the AOAC 2004 Official method of analysis.

Statistical analysis

Data were evaluated through one way ANOVA to determine the differences between the lines in regard to the examined traits.Further, whenever appropriate, Tukey's post hoc test ($P<0.05$) was applied to compare the means between the different genotypes. Statistical analysis was performed using JMP v. 7 software package (JMP Version 7, SAS Institute Inc. Cary, NC).

Results and discussion

Carcass analysis

Carcass composition of the pure and crossbred lines is presented on Table 1. Since the experimental birds were all reared under the same conditions and slaughtered at the same age, the discrepancies in the carcass traits among the lines and their crosses could indicate effect of the line.

Significance of the factor Line: *P<0.05; **P<0.01; ***P<0.001; Values connected with different letters are significantly different (P<0.05)

The four groups differed in their live weight (P<0.001) as the highest was recorded in ♂BB x♀ LB. The same was observed for the hot and cold weight of the eviscerated carcass (P<0.001). Significant difference (P<0.01) was found in the weight of unedible parts (feet and intestines), which was determined by the highest content of feet in ♂BB x♀LB and the tendency for the highest weight of the intestines in this cross. Further, the content of the edible parts (neck and giblets)also varied among the four lines (P<0.05). This was due to the significant differences in the content of liver and gizzard between the groups. When compared to the others, ♂BB x♀LB chickens had higher weight of the liver, while the other cross exhibited the lowest weight of this internal organ. In regard tothe gizzard content, the higher was observed in ♂BB x♀LB and the pure Bresse birds, while the lowest weight was again recorded in the chickens of ♂LBx♀BB crossbred line. The internal fat tended to be higher in ♂BB x ♀LB birds (P=0.08). This corresponded to the highest weight of the liver and suggests increased rate of lipogenesis. Also the high weight of the liver in the ♂BB x ♀LB corresponded to highest live weight of this birds when compared to the other three lines. Similar relationship has been documented by Iman Rahayu et al. (2008) when comparing two genotypes of birds. Since different growth rates have been registered in the

four groups (unpublished data), it could be suggested that some of the internal organs have undergone modifications in their size to accommodate these discrepancies.
The weight of the breast did not differ between the four lines, however, the thighs both with skin and bones, and pure muscle, were significantly affected by the genotype. The weight of the thighs was the lowest in the BB chickens, while the other three lines showed close values of this parameter. The weight of the back and the wings also differed significantly between the groups (P<0.05). Both parts had the highest values of the weight in the ♂BB x♀LB birds, while the lowest were recorded in the BB line.Additionally ♂LBx♀BB also showed low values of the weight of the wings when compared to the other lines.
The birds from ♂LB x♀BB crossbred line tended to have higher dressing percentage (P=0.08) when compared to the other lines, while the lowest value of this trait was registered in the pure Bresseline. The opposite, however, was found in regard to the percentage of the edible organs and neck (P<0.05). This corresponded to the data about the absolute weight of thegiblets, presented above. In addition, the lowest dressing percentage in the Bresse birds coincided with their lowest weight of the eviscerated carcass before and after cooling and storage at 4°C, determined by the low content of thighs, back and wings found in this line, compared to the others.On the other hand, the highest dressing percentagerecorded in ♂LB x♀BB is associated with the lowest weigh of the giblets in these birds.
The meat part whose percentage was influenced by the difference in the line were thighs with bone and skin. Its values were the highest in LB birds, while in ♂BB x♀LB it was the lowest. On the other hand, the percentage of wings also tended to differ between the groups, being the highest in LB and BB, and the lowest in ♂LBx♀BB (P=0.05).The results for the superiority of the crossbred over the pure lines, mainly over the BB chickens, concerning the content of thighs, back and wings that was observed in this study could suggest certain heterotic effect in regard to these traits, influenced to a stronger extent by the mother lines (Liu et al., 1995).

Chemical composition of the meat
The chemical composition of breast and thigh meat is presented in Table 2.

Significance of the factor Line *P<0.05; ***P<0.001; Values connected with different letters are significantly different (P<0.05)

The line had no significant influence on the content of the intramuscular lipids in breast, while in the thigh it affected this parameter (P<0.05), as the differences existed between the two crosses. When compared to all, the chickens of ♂BB x♀LB crossbred line had the highest lipid content while the ♂LB x ♀BB birds had the lowest. The intramuscular lipid content is important since it is closely associated with the sensory perception of meat, but also with its tenderness and juiceness (Van Laak et al., 2001). In a previous study with La Belle and White Plymouth Rock chickens slaughtered at two different ages (Popova et al., 2016a) we did not find effect of the line on the lipid content in breast and thigh meat. Similarly, Yin et al. (2013) did not find any difference in the lipid content in breast in two lines and their hybrids. On the other hand, Jaturasitha et al. (2008) comparing chickens of Bresse, Rhode Island Red and two indigenous Thai breeds reported that the intramuscular lipid content varied significantly between breeds. In the same study, the lipid content in the breast and thigh meat of Bresse chickens was 0.76% and 4.21%, respectively for birds slaughtered at 16 weeks of age. These values are lower than the reported here for the 12 weeks old birds.

Significant differences in protein content were found between the lines in both breast ($P<0.001$) and thigh meat ($P<0.05$). The birds from both crossbred lines had higher protein than the pure LB and BB chickens. In thigh, the protein content followed the similar pattern as in the lipids, as significant differences were detected between the two crosses.♂LB x ♀BB had the higher protein content, while ♂BB x♀LB displayed lower value of this parameter. The protein content determined in our experiment is within the range found in other studies (Mikulski et al., 2011; Guan et al., 2013).The increase in the protein content in the breast of ♂LB x ♀BB and ♂BB x♀LB and at the same time the lack of changes in the lipids indicated the positive influence of the crossing between the two pure lines in regards to the dietetic value of the meat. Crossing between two lines (Arbor Acres and WL) affected the protein and lipid content in meatas observed by Liu and Niu (2008). The highest values of protein and lowest of lipid content was achieved in WL, while the opposite was observed in Arbor Acres. F1 was reported to have intermediate characteristics. The higher protein content in breast of the crossbred lines was associated with significantly lower moisture ($P<0.001$), while in the thighs no effect of the line was observed in regard to this parameter. The moisture content and respectively the dry matter of the meat are important traits since the higher dry matter content is positively related to nutritional quality of the meat. Of both pure lines, the higher moisture content in breast was determined in BB, while no difference was found between the two crosses. In this study, the moisture content was in the range of 70.57-72.92% in breast and 71.77-72.29% in thighs. Sarsenbek et al. (2013) determined moisture content of 72-93-75.16% in indigenous breed and 74.43-76.03 % in commercial broiler chicken. Ash content in breast also differed significantly among the lines ($P<0.001$), the highest being observed in BB birds, when compared to the others. Although affected by the genotype of the birds ($P<0.001$), the ash content in thigh did not follow the trend observed in the breast meat. The birds form LB line and the cross ♂LB x ♀BB had higher ash content when compared to the BB and♂BB x♀LB chickens.

Conclusions

The crossing of the two lines – LB and BB was associated with significant and positive effect on both carcass traits and chemical composition of the meat. The crossbred line where BB was used as sire line displayed the highest live weight, and weight of the eviscerated carcass, as well as the highest content of edible organs and non edible parts. The same cross had also highest weight of the thighs, back and wings. On the other hands using LB as sire line led to the highest dressing percentage, but the lowest percentage of the edible organs among all lines. The crossing of the pure lines influenced positively the chemical composition of the breast leading to higher protein and lower moisture content in both crosses. In thighs, however, the content of lipids and protein differed significantly between the crossbred lines as ♂BB x♀LB had higher lipid but lower protein. The ash had the highest content in breast of

BB birds, as well as in thethighs of LB and ♂LB x ♀BB. The findings of the study show the potential benefits of the crossing to improve the carcass traits of indigenous linesand their meat quality.

Abstract

The golden jackal was autochthonous in Hungary until the 1970s when it became extinct because of extensive persecution and habitat loss. During the 1990s, it appeared again in the southwestern part of the country. Initially, the species was invisible, because of its small population size and hiding lifestyle. Afterwards, the population began to expand and game managers mention the species as a pest, time and again. On the other hand, ecologists welcome the jackals as a new element of ecosystem, which increases the biodiversity and improves the ecosystem services. In our study, we attempted to lighten different ecological aspects of this enigmatic species. In order to attain our objectives, we investigated the effect of jackals on the epidemiology of a micro- and a macroparasite. We hypothesized that the species, through improvement of ecosystem services, favour the trend in tuberculosis epidemic sustained by wild ungulates; on the other hand, as a canid, golden jackal could pose a risk of echinococcosis. Comparing the prevalence of suspect tuberculosis lesions on jackal habitats with adjacent sites, we found a significant difference (11.9% on jackal sites and 32.1% on adjacent area). On the other hand, prevalence of echinococcosis in golden jackal was 15.4%, while mean intensity was 288.83. Summarizing these results, we concluded that the presence of this carnivore is beneficial to the trend of tuberculosis endemic; notwithstanding, the species seemed to be a reservoir of *Echinococcus* spp. on areas, where its population gets dense. Our investigation highlighted the complex effect of a change in an ecosystem.

Keywords: *Golden jackal, tuberculosis, Echinococcus spp, biodiversity, multidisciplinary approach.*

Introduction

The golden jackal (Canis aureus) is one of the most widely distributed canid species in Eurasia (Arnold et al., 2012). The species has been residing in Europe since the Holocene, though until the beginning of the last century, its number remained low and its presence was limited to the Mediterranean and Black sea coastal regions (Krofel et al., 2016). The role of the species is controversial. As a predator, it contributes to ecosystem services and improvement of biodiversity (Krofel et al., 2016). Nevertheless, game managers and livestock farmers consider the jackals to be harmful (Arnold et al., 2012; Markov, 2012). Some studies call the attention to the potential risk of disease spread might be caused by these mesopredators (Ćirović et al., 2014; Markov, 2012., Rutkowski et al., 2015). In Hungary, the golden jackal was autochthonous until the 1970s when it became extinct because of extensive persecution and habitat loss. During the 1990s, it appeared again in the southwestern part of the country (Arnold et al., 2012). Initially, the species was invisible, because of its small population size and hiding lifestyle. Afterwards, the population began to expand and game managers mention the species as a pest, time and again. On the other hand, ecologists welcome the jackals as a new element of ecosystem, which increases the biodiversity and improves the ecosystem services. In our study, we attempted to lighten different ecological-epidemiological aspects of this enigmatic species. This made an opportunity for us to demonstrate the advantage of considering ecological viewpoints during the investigation of an epidemiological problem. In order to attain our objectives, we investigated the effect of jackals on the epidemiology of a micro- and a macroparasite. We hypothesized that the species, through improvement of ecosystem services, favour the trend in tuberculosis epidemic sustained by wild ungulates; on the other hand, as a canid, golden jackal might pose a risk of echinococcosis. For confirmation of our hypothesis, we carried out a complex survey in a special jackal habitat and in its surrounding environment. During the survey, we investigated trends of tuberculosis among wild boars *(Sus scrofa)* and echinococcus infection among golden jackals. The results of the two habitat types were compared to assess the epidemiological effects of jackals.

Materials and methods

The study area was the south-western part of Hungary, where population of golden jackal has a great expansion. The two types of habitat, we studied, are markedly different. The jackal habitat is an extended sandy lowland with plenty of moors and fishponds: Inner-Somogy with the village Lábod, (GPS 46.204568, 17.463420) in the centre. The adjacent area, where the presence of golden jackals is sporadic, is the Zselic Landscape Protection Area, with the village Bőszénfa (GPS 46.23633, 17.85200) in the centre. This area is mostly hilly, highly forest-covered area with agricultural lands in the peripheral parts.During our study we examined the prevalence of suspect tuberculosis lesions (sTBL) in wild boars' submandibular lymph nodes (smLN) and prevalence and mean intensity of Echinococcus spp. infection in the golden jackal. Post-mortem examination of wild boars' smLN was performed in the field, during evisceration of the hunter-harvested bodies. Based on previous experiences that macroscopic evaluation of these organs is a suitable tool for monitoring bTB infection in wild boar populations; we limited our investigation to smLN (Csivincsik et al., 2015). The smLNs were examined *in situ*, by slicing it into 2 mm sections. Every purulent, caseous and calcified process was evaluated as suspect bTB lesions (sTBL). Data were collected during drive hunting events, when wild boars were shot without any special selection for age, gender or health status; therefore, randomness was assured by different skills of the hunters. Findings of post-mortem examination were collected into written notes; nevertheless, characteristic visible lesions were photographed. The apparent prevalence of sTBL was calculated separately for the jackal habitats and the adjacent areas. Data of the two sites were compared by Chi-square test with R Statistics software version 3.3.2 (2016-10-31). During the study, we collected small intestines from golden jackals in order to determine the level of *Echinococcus* spp. infection. Most of the samples derived from the jackal site and the others from the adjacent area. The organs were collected from hunting events in all year round. After necropsy, each organ was placed separately into a plastic bag. For safety reasons, the intestinal tract was frozen at −80 ◦C for 7 days before examination. After melting (at room temperature), the guts were opened and the content and intestinal mucosa was collected (Eckert et al. 2001). The samples were examined by sedimentation method. For morphological identification, we used Sréter's et al. (2003) work. The method was based on the number of proglottids, the length of worms and the terminal proglottid and the uterus morphology. In this survey, the nomenclature we followed was detailed by Bush et al. (1997).

For descriptive statistical analysis we calculated the prevalence and mean intensity using the Quantitative Parasitology 3.0 software (Rózsa et al. 2000) with 95% confidence interval (CI 95%).

Results

In this study, we examined altogether 49 small intestines. Six of the 42 animals, shot in the jackal site, were infected by *Echinococcus* spp., while none of the seven ones, derived from the adjacent area, proved to be infected. Thus the calculated prevalence and mean intensity proved 15,4 % (CI95% = 6.41–28.36 %) and 288.83 (CI95% = 12.05–1107.67), respectively. The wide range of confidence interval of mean intensity is owing to a heavily infected animal which carried 1648 *Echinococcus* specimen.After the species identification we concluded that all of the worms proved *Echinococcus multilocularis*. The results of the complex survey are summarized in Table 1.

Table 1 Prevalence of suspect tuberculosis lesions (sTBL) in wild boars and Echinococcus multilocularis in golden jackal within the jackal habitat and outside it

	Jackal habitat	Adjacent area	P-value
Prevalence of sTBL in wild boars	10.9% (N=92)	32.1% (N=215)	0.01>
Prevalence of *E. multilocularis* in golden jackals	14.2% (N=42)	0% (N=7)	0.28

Discussion

As a result of our survey, a recognizable difference could be confirmed between the prevalence of sTBL on the jackal site and on the adjacent area. On the other hand, the infection of *E. multilocularis* reached a considerable rate within the jackal area; though it did not differ significantly from the adjacent area. These experiences reassure the controversial role of the species. Based on the finding that trends of bTB within an ecosystem with dense jackal population is advantageous, we might conceive that jackal as a scavenger animal eliminates infective materials, like hunting offals from the environment; and as a predator removes the weakest, probably sick, individuals from ungulate populations. With these characteristics, jackals can contribute to ecosystem health. An additional beneficial effect of these mesopredators that they consume a lot of rodents, which are also play a role as vectors of diseases. Nevertheless, our survey raised the question whether golden jackal might be the reservoir of *E. multilocularis* within the Pannonian region. Until our survey just one *E. multilocularis* infected golden jackal was found (Széll et al. 2013) in Hungary. The present prevalence of infection in the jackals proved to be higher, while the mean intensity was lower than in former studies in red fox in Somogy County (Tolnai et al. 2013). The difference in prevalences between the two final hosts might be explained by their population density. In the case of mean intensity, we hypothesize the lower infection level derives from the different host-adequacy of the two carnivore species. Based on the phenomenon that prevalence of *E. multilocularis* infection on the two sites is very similar, we assume that an on-going migration makes a connection between the two sites. Another possible explanation is that outside the jackal area, only vagrant animals were sampled during the study.

Notwithstanding, this small sample size (N=7 versus N=42) is not eligible to form an adequate opinion. Experiences on the trends of bTB in a habitat with very dense jackal population show a good example of improvement of ecosystem services and call the attention on necessity of multidisciplinary approach to epidemiological problems. Nevertheless, the *E. multilocularis* reservoir status of the species and the real epidemiological risk have to be ascertained by further investigations.

Conclusion

In this study, we attempted to show the possibilities of a new epidemiological investigation method, which considers an epidemiological problem as the part of the ecosystem, in which it occurs. The golden jackal as a characteristic element of the occupied ecosystems has a remarkable influence on the environment. Its sanitary effect as a predator and scavenger is incontestable, as it can eliminate infected materials. On the other hand, predators can harbour infections and spill-back phenomenon can eventuate. The drives of this spill-back and the risk caused by predator populations should be in the focus of investigations on ecosystem health.

Abstract

Artificial neural network (ANN), multiple linear regression (MLR) and sediment rating curve (SRC) were compared to model the daily suspended sediment load in Karehsang gauging station in Haraz River, Haraz-Gharesoo watershed, Iran. The suspended sediment load was related to the average rainfall and streamflow. In this study, eight input combinations, which fell in two groups, were used. Models in Group I used both climatic (Rainfall) and hydrologic variables (streamflow) as inputs. Models in Group II tried to predict sediment from streamflow only. Root mean square error (RMSE) and correlation coefficient (R) statistics were employed to evaluate the performance of the ANN, MLR and SRC models for forecasting suspended sediment load. It is demonstrated that ANN is capable of modeling the daily suspended sediment load with fairly good accuracy when proper variables and their lag effect on the suspended sediment load are used as inputs. Compared with multiple linear regression and sediment rating curve models, ANN can generate a better fit under the same data requirement. In addition, ANN with previous three days rainfall and streamflow information can provide more reasonable predictions because of the distributed information processing system and the nonlinear transformation involved and also importance of lag-effect in input variables.

Keywords:*Artificial neural network, multi linear regression; sediment rating curves; daily suspended sediment load; Haraz river.*

Introduction

Correct estimation of sediment load carried by a river is important with respect to channel navigability, reservoir filling, hydroelectric-equipment longevity, river aesthetics, fish habitat and scientific interests. In environmental engineering, if the particles also transport pollutants, the estimation of river sediment load has an additional significance. McBean and Al-Nassri (1988) investigated the uncertainty in suspended sediment curves and they concluded that the practice of using sediment load versus discharge is misleading because the goodness of fit implied by this relation is spurious. They have instead recommended that the regression can be established between discharge and sediment concentration. Artificial neural network (ANN), a massively parallel distributed information processing system, is based on concepts derived from research on the nature of human brains (Müller et al., 1995). ANN was introduced into hydrological modeling in the1990s (Singh et al., 2002). In the suspended sediment forecasting context, recent experiments have reported that artificial neural networks (ANNs) may offer a promising alternative (Abrahart and White, 2001; Jain, 2001; Tayfur, 2002; Cigizoglu, 2004; Kisi, 2004; Cigizoglu and Kisi, 2006; Tayfur and Guldal, 2006; Ardiclioglu et al., 2007; Zhu et al., 2007).

In this research, we applied ANN to simulate discrete daily suspended sediment load from 1968 to 2005 in the Haraz River of the Haraz-Gharesoo Catchment, Iran. Instead of using water discharge and suspended sediment as inputs, we attempted to relate the suspended sediment load to the original driving force, i.e., climatic variable (rainfall), to establish an ANN model that can be used to explore the relationships between the rainfall, streamflow as inputs and sediment responses. The advantages of ANN were also evaluated by comparing its performance with that of multiple linear regression (MLR) models and Sediment rating curves (SRC) model.

Material and Methods

The study area along the Haraz river is located at 35°45′N~36°08′N and 51°36′E~52°26′E, North of Iran. The daily rainfall (P), streamflow (Q) and suspended sediment (S) time series data belonging to Karehsang Station (station no: 15-017). The Karehsang gauging station is located at the lower reach of the river, which has a drainage area of 4023 km^2 .The station height is 220 m above sea level.
The daily rainfall, suspended sediment load (ton/day) and water discharge (m^3/s) data at the Karehsang gauging station from 1968 to 2005 was collected. Iran Ministry of Power measures rainfall and water discharge every day and suspended sediment concentration (SSC) manually some days plus more samples during floods. The suspended sediment load data are not continuous in both gauging stations, since the observations just for some days are measured. But we have all the rainfall, suspended sediment load and streamflow discharge data simultaneously in sampling days. The statistical parameters of the streamflow, sediment and rainfall data for the Karehsang station is given in Table 1.
In this table, the X_{mean}, S.D., C_v, C_{sx}, X_{max} and X_{min} denote the mean, standard deviation, coefficient of variation, skewness, maximum and minimum, respectively. As can be seen from the Table 1, the sediment and flow data show a significantly high skewed distribution. This is confirmed by the high ratio between standard deviation, mean and C_v. This creates additional difficulties for the models in prediction. The maximum– mean ratio (X_{max}/X_{mean}) for sediment series in the training period is also quite high (12.41). All these statistics indicate the complexity of the discharge–sediment phenomenon.

Table 1. The statistical parameters of data set

Data set	Data type	Mean	S.D.	C_v	C_{sx}	X_{max}	X_{min}

For developing an artificial neural network (ANN) model the original data must be processed through two steps: data standardization and data set partition. The original input and output data consist of different parameters with different physical meaning and units, and thus their ranges are highly variable. The input and output variables for the present study were standardized into the interval [0.1, 0.9]. Of the many ANN paradigms, the backpropagation network is by far the most popular (Lippman, 1987). The networks were trained with a Back-Propagation (BP) algorithm. The most common transfer function implemented in the literature is the sigmoid function. In this study both Log-Sigmoid and Tan-Sigmoid transfer functions were examined for hidden neurons but the Tan-Sigmoid function gave the better results compared with Log-Sigmoid. Therefore, the Tan-Sigmoid function was preferred for hidden neurons and linear activation function for output neurons. The Levenberg-Marquardt algorithm (LM) is employed during the training of the ANN models since the incorporation of LM into ANN speeds up the convergence (Hagan and Menhaj, 1994; Kisi, 2007). The hidden layer node numbers of each model were determined using trial-error method.

Multiple linear regression (MLR) was employed to simulate the relationship between the input variables and the suspended sediment load. Two MLR models with the same input combinations as the best performing networks from ANN Group I, Group II, respectively, were established. Sediment rating curve consists of a graph or equation, relating suspended sediment load to streamflow, which can be used to estimate sediment load from the streamflow records. The performances of the MLR and SRC models were also evaluated using RMSE and R, and were compared with those of ANNs which have the same inputs.

Results and Discussion

In this study, eight input combinations, which fell in two groups, were used (Table 2). The networks in different groups were designed to compare the performances of different sets of causal variables; while those in the same group were designed to examine the degree of lag-effect between the inputs and the outputs. Networks in Group I used both climatic (Rainfall) and hydrologic variables (streamflow) as inputs. Networks in Group II tried to predict sediment from streamflow only. The RMSE and R statistics of ANN, MLR and SRC models is given in Tables 2. It can be seen from Table 2 that the networks in Group I based on the streamflow and rainfall show relatively good performances. The R of ANN1, ANN2, ANN3 and ANN4 during the validation period are 0.875, 0.803, 0.865 and 0.911, respectively and the RMSE of them are 1725.214, 1869.65, 1892.65 and 1684.61 ton day^{-1} respectively. ANN4, with the lowest RMSE and highest R, is identified as the best performing network of this group which is in bold type in the Table 2. The networks in Group II are based only on the streamflow. In this group, the RMSE and R of ANN5 during the validation period are 1685.6 ton day^{-1} and 0.791, respectively but ANN8 shows a significant improvement, due to the inclusion of more information for the previous days, with an RMSE of 1653.73 ton day^{-1} and an R of 0.895. ANN8 is selected as the best performing network of Group II which has been shown in bold type in the Table 2. It shows that in group I, ANN1 are close to ANN4. In Group II, as more previous information is used, the performances of the networks tend to increase during the calibration, testing and validation periods. It can be observed that the performance of both models is very close to each other, this means that the water discharge cover the effect of rainfall in suspended sediment yield process so it has not improved the performances of the models effectively. The MLR1 and MLR2 with RMSE values in the validation period 2280.95 and 2270.831 ton day^{-1}, respectively overestimates the peaks. The SRC1 model with R value of 0.818 and RMSE of 1758.415 ton day^{-1} in the validation period underestimates the suspended sediment load. When the performance of each neural network group was compared with the corresponding the MLR and SRC models, the best performing network in each group was considered. The ANN4 models perform better than others because it has been established based on the major driving forces of suspended sediment load. When the suspended sediment load is very low, the MLR models predict negative values. Whereas the neural networks can generate reasonable estimation due to the nonlinear transformation process involved.

Table 2. Performances of ANN, MLR and SRC models for the Karehsang station

Model	Group: Inputs	Structure	Training		Testing		Validation	
			RMSE	R	RMSE	R	RMSE	R
ANN1	I: $(P,Q)_t$	2-1-1	5743.507	0.82	4602.116	0.80	1725.214	0.87
ANN2	I: $(P,Q)_t$, $(P,Q)_{t-1}$	4-2-1	5501.64	0.84	4477.942	0.88	1869.650	0.80
ANN3	I: $(P,Q)_t$, $(P,Q)_{t-1}$, $(P,Q)_{t-2}$	6-4-1	5008.75	0.86	4442.241	0.86	1892.243	0.86
ANN4	**I: $(P,Q)_t$, $(P,Q)_{t-1}$, $(P,Q)_{t-2}$, $(P,Q)_{t-3}$**	**8-5-1**	**5331.544**	**0.84**	**4480.12**	**0.80**	**1684.610**	**0.91**
ANN5	II: Q_t	1-1-1	5787.801	0.84	4589.476	0.82	1658.600	0.79
ANN6	II: Q_t, Q_{t-1}	2-3-1	5070.301	0.874	4455.832	0.88	1759.212	0.81
ANN7	II: Q_t, Q_{t-1}, Q_{t-2}	3-2-1	4929.702	0.872	4553.424	0.88	1678.496	0.84
ANN8	**II: Q_t, Q_{t-1}, Q_{t-2}, Q_{t-3}**	**4-3-1**	**4935.543**	**0.88**	**4544.253**	**0.88**	**1653.729**	**0.89**
MLR1	$(P,Q)_t$, $(P,Q)_{t-1}$, $(P,Q)_{t-2}$, $(P,Q)_{t-3}$		5399.345	0.83			2282.950	0.75
MLR2	Q_t, Q_{t-1}, Q_{t-2}, Q_{t-3}		5402.085	0.83			2270.831	0.75
SRC1	Q_t		6034.808	0.79			1758.415	0.81

To summarize, the ANN models seem to be more adequate than the MLR and SRC in modelling suspended sediment. Suspended sediment estimation requires nonlinear mapping. The MLR and SRC models are not adequate in view of the complexity of the problem since it assumes linear relationship between $\log Q_s$ and $\log Q_w$ values. Such models require that the variables are normally distributed. It is evident from Table 1 that the streamflow and sediment data have scattered distribution (see C_{sx} values in Table 1). The main advantages of using ANNs are their flexibility and ability to model nonlinear relationships. In general, the ANN model can be considered relatively superior to the MLR and SRC models. This observation can play a vital role in hydrological modelling studies where estimates of sediment values are not available. The performances of ANN4 and ANN8 models are very close to each other, this means that the water discharge cover the effect of rainfall in suspended sediment yield process so since the ANN4 is the best models to estimate the suspended sediment load. The best performing network is those with the information of the previous three days, suggesting that three days lag-effect exits between the climate inputs and sediment load which seems logical for the studied area.

Conclusions

The performances of the ANN, MLR and SRC models for estimation of daily suspended sediment load by relating it to average rainfall and water discharge in Karehsang station were evaluated in terms of goodness-of-fit. The goodness-of-fit was examined by comparing the statistics of the results (RMSE and R). Based on the comparison results, the ANN model was found to perform better than the MLR and SRC models. It is demonstrated that ANN is capable of modeling the daily suspended sediment load with fairly good accuracy when proper input variables and their lag effect on suspended sediment load are included. ANN can generate a better fit to the observed suspended sediment load than the multi linear regression models and the sediment rating curve model under the same data requirement. The most prominent feature of ANN is that it can provide more reasonable predictions for extremely high or low values, because of the distributed information processing system and the nonlinear transformation involved. It leads to the conclusion that we can use other techniques such as neuro-fuzzy to reach more accurate results.

Abstract

The trial was conducted to investigate the supplementation of NSP degrading enzymes, prebiotics and its combination on the laying hens' performance and quality of eggs. *Lohman Brown* laying hens aged 38 weeks were assigned to 4 dietary treatments for 8 weeks. The dietary treatments were: 1) control (C), 2) compound feed supplemented with enzymes (endo-1,4-β-xylanase 22000 VU/g, endo-1,3(4)-β-glucanase 30000 VU/g and endo-1,4 -β-glucanase (cellulase) 6400 DNS units/g of feed) (E), 3) compound feed with prebiotics (mannanoligosaccharides (MOS) 1.0 kg/t of feed) (P), 4) compound feed with NSP degrading enzymes (endo-1,4-β-xylanase 22000 VU/g, endo-1,3(4)-β-glucanase 30000 VU/g, endo-1,4 -β-glucanase (cellulase) 6400 DNS units/g of feed) and prebiotics (MOS 1.0 kg/t of feed) (EP). All laying hens were kept under the same conditions. Egg's quality was determined using automatic egg quality analyzer and thickness of eggshell was evaluated with electronic micrometer. The texture characteristics were determined with the universal texture analyzer Instron 3343. Instrumental colour measurements of eggs were performed using a spectrophotometer Konica Minolta. Egg weight of E group was increased by 6%, but feed conversion ratio to produce 1 kg of eggs was decreased by 11%, compared to C group ($P<0.05$). Enzymes and MOS did not significantly effect egg quality parameters, but in E group shell weight increased by 9% ($P<0.05$). In addition of enzymes, the hens had produced eggs with higher albumen L* scores ($P<0.05$). Diet supplementation with enzymes had no significant effects on the yolk colour. In E group of laying hens, the egg mass and egg shell thickness were improved. The addition of enzymes and MOS mixture had highest positive effect on egg quality parameters, but had no statistically significant influence of egg's texture and colour.

Keywords: *mannanoligosaccharides, enzymes, laying hens, texture analysis.*

Introduction

Egg shell quality and egg internal quality are of major importance to the egg industry worldwide. Egg internal quality is measured as yolk colour, the integrity of the perivitelline membrane, and albumen quality. Egg internal quality may be affected by storage; hen strain and age; induced moulting, nutrition, and disease. An understanding of the range of factors that affect egg internal quality is essential for the production of eggs of high quality (Roberts, 2004). Xylans are the principal NSP of grain, and high levels of wheat in poultry diets can increase the viscosity of the gut contents, which impedes the circulation and absorption of nutrients, causing reduced feed intake, body weight (BW) gain, and feed efficiency (Annison and Choct, 1991). Xylanases used extensively in grain-based diets to counteract the effects of

NSP in broiler (Bedford and Schulze, 1998). Prebiotics, non-digestible feed ingredients, have selective effects on the intestinal microflora. In the last decade, the use of mannanoligosaccharides (MOS) in poultry production has received increased attention due to its beneficial effects on poultry productivity. The MOS, derived from the cell wall of *Saccharomyces cerevisiae*, is neither hydrolysed by endogenous digestive enzymes nor absorbed by host, and it is considered as a prebiotic agent. It has been claimed that the benefits of MOS based on its specific properties, these properties have the potential to enhance growth rate, feed efficiency and liveability in commercial broiler and turkeys, and egg production in layers (Shane, 2001). Therefore, this study was performed to investigate the effects of probiotic and enzymes supplementation on hen‘s productivity (feed conversion ratio), egg quality and egg‘s texture profile.

Materials and Methods

The feeding trial was performed on 40 laying hens of breed *Lohman Brown* the age of 38 weeks. During the feeding trial, laying hens were kept in individual cages (40 × 50 cm) in a four tiers battery with stationary drinking-bowl and feed box under the same feeding and keeping conditions. The hens were divided into 4 groups, 10 hens in each group. The laying hens were fed with 125 g compound feed per day. Laying hens of all groups were fed with standard compound feed (basal diet). Based diet formulated to meet the nutrient and energy requirement for poultry (NRC, 1994). Hens in control group were fed with basal diet only (C group), E group was fed with basal diet + enzyme (endo-1,4-β-xylanase 22000 VU/g, endo-1,3(4)-β-glucanase 30000 VU/g and endo-1,4 -β-glucanase (cellulase) 6400 DNS units/g of feed), P group was fed with basal diet + prebiotic at a level of 1.0 g/kg and EP group was fed with basal diet + enzymes (endo-1,4-β-xylanase 22000 VU/g, endo-1,3(4)-β-glucanase 30000 VU/g and endo-1,4 -β-glucanase (cellulase) 6400 DNS units/g of feed) + prebiotic at a level of 1.0 g/kg. *Rovabio® Excel AP* enzyme mixture (containing mainly endo-1.4-β-xylanase, endo-1.3/1.4-β-glucanase and endo-1,4 -β-glucanase (cellulase)) used in this study was provided by Adisseo (France) and produced from *Penicillium cerevisiae*. *Agrimos®* (Lalleman Inc., France) is a specific combination of mannanoligosaccharides and glucose (β-glucans) extracted from the yeast cell walls of *Saccharomyces cerevisiae.* Housing and feeding conditions were the same for all groups and met the requirements of laying hens. Duration of the experiment was 8 weeks. During the feeding trial all the eggs were calculated and weighted every day, every 14 days was determined egg production capacity of laying hens, feed conversion ratio (FCR) to produce 1 kg of eggs. Egg weight, albumen high and Haugh unit were determined by multifunctional automatic egg characteristics analyzer „Robotmation (Japan) Egg Multi–Tester EMT–5200“, hardness of eggshell – by „Egg Shell Force Gauge MODEL–II“ device, and thickness of egg shell – by electronic micrometer „MITUTOYO Digimatic Micrometer“ (sharp and blunt ends, and equator). The egg shell index was calculated according Ahmed *et al.* (2005) as: SI (shell index) = (SW/S) × 100, where: SW = shell weight; S = shell surface (cm^2) calculated as $S = 4.68 \times$ egg weight $(EW)^{2/3}$. The eggs were stored at 4°C for 28 days before texture evaluation (10 eggs from each group). For preparation of the egg sample the modified Woodward and Cotterrill (1987) method was applied taking into account the remarks of Shafer *et al.* (1998) adjusted to the present conditions. The egg albumen was separated carefully from the yolk. The acquired samples of albumen and yolk were put into plastic cylindrical boxes designed for boiling. The contents were mixed lightly in order to eliminate air bubbles and after putting into special holding form it was boiled in water-bath for 12 minutes. Samples were removed from the water bath and allowed to cool to room temperature. Thereafter, they were refrigerated at 6ºC for 40 min. The texture characteristics were determined with the universal texture analyzer

Instron 3343 (Instron Engineering Group, High Wycombe, UK) equipped with a 1kN load cell and Bluehill software. The samples, measuring 2.0 × 2.0 × 2.0 cm, were compressed perpendicularly using a 50 mm diameter cylindrical probe. The testing conditions were two consecutive cycles at 50% compression, cross-head movement at a constant speed of 1 mm/s. Texture variables (rigidity in Newtons, N), cohesiveness (ratio of positive area during second compression to that during the first compression), springiness and resilience (the energy required to mastificate a solid food product to prepare for swallowing) were calculated as described by Bourne *et al.* (1978). Instrumental colour measurements were performed using a spectrophotometer Konica Minolta, calibrated throughout the study using the reference illuminate C which is close to the average radiation daylight. The measurements were averaged and colour for each sample was expressed in terms of CIE L*a*b* values for lightness (L*), redness (a*) and yellowness (b*). $h^*=\arctan(b^*/a^*)$; $C^*=((a^*)^2+(b^*)^2)^{1/2}$.
Statistical significance was established using one – way analysis of variance (ANOVA), and data were reported as a mean of standard deviation. Mean comparison and separation were done using Duncan's *t*-test (P<0.05). ANOVA were conducted using the statistical package SPSS 22.

Results and Discussion

The effects of dietary treatments on laying performance parameters as egg weight, feed intake, feed conversion ratio (FCR) to produce 1 kg of eggs are shown in Table 1.

Table 1. The effect of feed supplementation of NSP degrading enzymes, prebiotics and its combination on the laying hens' (38-46 week) performance parameters

Studied character	**Groups**			
	C	**E**	**P**	**EP**
Average feed intake (g/hen/14 day)	1714.05±64.99^a	1694.61±68.34^a	1702.03±55.71^a	1698.40±75.11^a
Feed intake (g/egg)	147.05±21.76^a	138.92±22.18^a	140.35±20.42^a	137.75±15.45^a
Average egg-mass	63.68±5.22^a	67.71±4.60^b	64.78±4.26^{ab}	65.58±3.88^{ab}

a, b For each row, mean values with the same subscripts are not significantly different, P<0.05

The addition of enzymes and mannanoligosaccharides hadn't effect on feed intake, egg production and laying intensity of laying hens in comparison to the group C. During 38–46 weeks of age in E group egg mass increased by 6%, but FCR to produce 1 kg of eggs decreased by 11% compared to C group (P<0.05). Shalaei *et al.* (2014) found, that MOS supplementation to the laying hens' diet significantly increased egg weight. Mirzaie *et al.* (2012) studies found that multi-enzymes and xylanase supplementation of laying hens improved egg production, egg mass and decreased the FCR. The results of egg quality are shown in Table 2. Enzymes and MOS did not significantly affect of egg quality parameters, but in E group increased shell weight 9% (P<0.05).

Table 2. The effect of feed supplementation of NSP degrading enzymes, prebiotics and its combination on the egg quality of laying hens (38-46 week)

Studied character		**Groups**			
		C	**E**	**P**	**EP**

a, b For each row, mean values with the same subscripts are not significantly different, P<0.05

These results are in agreement with Mirzaie *et al.* (2012) xylanase diet did not affect egg quality, Shahbazi (2012) studies found that diet enzyme supplementation decreased yolk index and egg shell thickness. Shalaei *et al.* (2014) found that egg quality parameters were higher of the laying hens that received the feed with MOS and MOS supplementation to the laying hen's diet significantly increased egg weight.

a, b, c For each row, mean values with the same subscripts are not significantly different, P<0.05

The instrumental analysis of albumen texture of 28 days storage eggs showed (Table 3), that analysed samples according to the albumen rigidity can be divided into three statistically different groups (P<0.05). After 28 days of storage yolk springiness was lower in experimental groups with enzymes and MOS in comparison to the C group (P<0.05). Yolk cohesiveness and resilience of all groups did not differ, and springiness depended on the feed composition. Albumen and yolk colour results of the colorimetric evaluation of the CIELAB values of L*, a*, and b* are shown in Table 4. Laying hens fed diets containing enzymes to produce eggs with higher L* scores and the differences were significant. Enzyme supplementation had no significant effects on yolk colour. These results are in agreement with those of Mourão *et al.* (2006) who found that supplemental enzyme culture had no effect on egg yolk colour. These results were less evident than those observed by Çiftci *et al.* (2003), who reported a significant improvement in egg yolk colour in response to enzyme supplementation on triticale and wheat–triticale-based diets.

Conclusions

Supplementation of enzymes and prebiotics to the diet of laying hens improved egg intensity as well as egg shell thickness and positive effect on egg's quality and no significant influence on egg's texture and colour. Supplementation of enzymes significant (P<0.05) reduced feed conversion ratio 11 % compared to control group.

Abstract

The aim of this paper is to examine the fatty acid composition of the fat from pork and poultry meat before and after heat treatment. For the examination of chemical changes in fat lard, palm and sunflower oils have been used. The changes in weight of the meat before and after heat treatment are followed by measuring with an electronic scale. The contents of total and free fatty acids were assessed before and after heat treatment by gas chromatography. The average quality loss of pork meat after heat treatment was 39.16%, while in the poultry meat was 45.68%. After the heat treatment fatty acid composition from the pork and poultry meat fried in lard showed decreasing of the content of C18: 2n6s and increasing of C16: 0 and C18: 0. Regarding the fatty acid composition from the pork meat fried in sunflower oil, the content of C14:0, C16: 1, C17: 0, C18: 3n6 were decreasing while the content of C16:0, C18:0, C18: 1n9s, C18: 2n6s increased. C21:0 and C22:0 occurred at the fatty acid composition of the poultry meat fried in sunflower oil. When the pork meat was frying with the palm fat, the content of C14: 0 and C16: 0 decreased, while the content of C18:0, C18:1n9s and C18:2n6s increased. In poultry meat, it reduced C16: 0, C18: 3n3 and C18: 3n6, and increased C14: 0 and C18: 0.

Keywords: *pork, poultry, meat, fatty acid, heat treatment.*

Introduction

Thermal processing of meat is regular action in cuisine and in the meat industry. The objective of thermal processing of meat is to prepare the meat for consuming and to increase its sustainability. One of the most applied and fastest ways of thermal processing of meat for consuming in households is frying. Soft, boneless pieces of meat from the shoulder part, the thigh, the loin and the neck, and from which the visible fat tissue was removed, are usually used for frying. Sunflower oil and lard are used in the households to fry meat, and lately the palm oil became very popular. During frying with less or more oil, sensory characteristics which are very alike to those formed during grilling or roasting, are formed in the meat. During frying of the meat with less or more oil, attractive chestnut brown color is being formed on its surface, while golden yellow to chestnut color is formed on the surface of the fat tissue. The chestnut brown color of the meat surface is consequence of Maillard reaction, which occurs during thermal processing.

During thermal processing – frying of meat, the temperature on the meat surface reaches 180-150^{o}C (Rahelic *et al.*, 1980) and numerous physical and chemical reaction happen within the meat. As a result of the heat, the water evaporates from the meat, the fats are extruded and they leak into the frying pan.

Changes that occur in the oils, in which meat is fried in, are primarily a result of heat denaturation of fats, as well as a result of reaction between fats in the meat and soluble proteins.

Materials and methods

Pork loin and poultry are used as material for work. The pork and poultry that are used for examination are purchased from trade network wherein they were cut down to size and shape as for frying. Thermal processing – frying of the meat is performed in laboratory, and lard, sunflower oil and palm oil are used for frying. The changes in meat weight were monitored by measuring meat before and after thermal processing with electronic weighing scale accurate to 0.1 g. Examination of changes in fatty acid composition of the fats is conducted before and after thermal processing. The analyses of changes in fatty acid composition of the fats are examined on a gas chromatograph in the laboratory of the Food Institute at the Faculty of Veterinary Medicine in Skopje. The obtained results from conducted examinations for changes that occur in meat and fats after thermal processing are processed according to SAS software and procedures (SAS, 2005).

Results and discussion

Significant physical changes, which contribute to change of basic characteristics of meat and forming new sensory characteristics important to his quality, occur during thermal processing of meat. One of the basic changes which occur during thermal processing is weight loss – meat shrinkage. The weight loss of the meat which occurs after thermal processing could be seen best from data given in (Table 1).

Table 1 Changes in the weight loss of pork during thermal processing

Thermal process of fried	**Weight loss of the meat**	x	SD	CV	min.	max.
Sunflower oil	Before heat treatment (g)	92.40	6.62	7.16	82.00	102.00
	After heat treatment (g)	62.40	5.98	9.59	52.00	70.00
	Shrinkage (%)	32.60	2.33	7.15	31.00	37.00
	Before heat treatment (g)	89.20	21.85	24.50	64.00	130.00
	After heat treatment (g)	52.80	13.06	24.73	36.00	76.00
Lard	Shrinkage (%)	40.08	3.70	9.09	34.00	44.00
Palm oil	Before heat treatment (g)	93.60	9.99	10.67	82.00	106.00
	After heat treatment (g)	53.40	7.73	14.48	46.00	60.00
	Shrinkage (%)	44.80	1.72	3.84	43.00	48.00

As seen from the given data in Table 1, the average shrinkage after thermal processing of pork fried in sunflower oil is 32.62% the average shrinkage of pork fried in lard is 40.08% and of pork fried in palm oil is 44.80%. The meat shrinkage depends largely on physical composition of meat, age of the animal before slaughtering and the way of thermal processing. The weight losses of pork which occur after thermal processing are in relation to literature data indicated by a number of authors (Rahelic *et al*,. 1980).The results from performed examinations of changes in weight of animal meat which occur after frying in sunflower oil, lard and palm oil are presented in (Table 2).

Table 2 Changes in the weight loss of poultry during thermal processing

Thermal process of fried	Weight loss of the meat	x	SD	CV	min.	max.
Sunflower oil	Before heat treatment (g)	85.60	5.42	6.33	82.00	94.00
	After heat treatment (g)	55.20	5.74	10.40	48.00	64.00
	Shrinkage (%)	35.66	2.49	6.99	32.00	39.00
	Before heat treatment (g)	84.80	8.06	9.50	70.00	94.00
	After heat treatment (g)	46.80	5.74	12.26	42.00	56.00
Lard	Shrinkage (%)	44.00	8.36	19.01	34.00	55.00
Palm oil	Before heat treatment (g)	92.40	13.52	14.64	76.00	106.00
	After heat treatment (g)	57.40	10.15	17.68	44.00	66.00
	Shrinkage (%)	38.20	2.31	6.06	35.00	42.00

As seen from data presented in Table 2, the average waste during thermal processing of poultry by frying with sunflower oil is 35.667 %, by frying with lard is 44.00 % and by frying with palm oil is 38.20%. The obtained results in our examinations are in relation to the results stated by other authors. The meat shrinkage during thermal processing depends on the reached temperature in the centre of the product. The weight loss of meat will be as bigger as the temperature of oils in which the meat is thermally processed gets higher Rohman, A. and Che Man, Y. B. 2009a ; Naz Shanina, *et al.*, 2005; Gunston, F.D. 2004).Significant changes of fatty acid composition occur after thermal processing of meat, which is caused by the temperature during thermal processing, as well as the interaction of fats and soluble proteins and the interaction of other meat substances and oils used for thermal processing – frying of meat, (Rashood, *et al.*,1996; Marina, *et al.*,2010; Marikkar *et al.*, 2011; Indrasti, *et al.*, 2010).
The changes that occur during thermal processing of meat – frying with sunflower oil could be seen best from Table 3.

Table 3 Changes in the fatty acid content before and after heat treatment of pork and poultry meat - fried with sunflower oil

Fatty acid	**Pork meat**		**Poultry meat**	
composition	Before frying	After frying	Before frying	After frying
C16:0	11.08	12.34	10.58	11.57
C16:1		0.15	-	-
C18:0	3.33	3.91	3.49	3.58
C18:1n9c	45.43	46.08	45.42	45.51
C18:2n6c	40.16	37.52	40.06	38.80

Four fatty acids are identified in the sunflower oil before thermal processing, of which the following are most prevalent: C18:1n9c with 45.43 %, C18:2n6c with 40.16 %, C16:0 with 11.08 % and C18:0 with 3.33 %. After thermal processing of pork – frying, there are insignificant changes of the fatty acid composition of the sunflower oil; the amount of C18:2n6c has been decreased to 37.52%, and at the expense of it new fatty acid – C16:1, which accounts for 0.15% total fatty acids has been formed. The changes that occurred during frying of poultry in sunflower oil are identical to those changes that occur during frying of pork.
The changes that occurred during thermal processing – frying of pork and poultry with sunflower oil are not statistically significant. As seen from data presented in Table 4, a total of 10 fatty acids is identified in the lard, of which C18:1n9c is most prevalent with 40.04%,

followed by C16:0 with 34.59 %, C18:0 with 13.73%, C18:2n6c with 5.21 and other fatty acids which account for significantly smaller amount. After performed thermal processing of pork fried in lard there are no changes in the fatty acid composition, but however, there are insignificant changes in their content, which are not statistically significant.

Table 4 Changes in the fatty acid content before and after the heat treatment of pork and poultry meat - fried with lard

Fatty acid composition	**Pork meat**		**Poultry meat**	
	Before frying	After frying	Before frying	After frying
C14:0	1.63	1.31	1.22	1.43
C16:0	34.59	35.15	29.55	27.45
C16:1	3.13	2.35	2.36	2.79
C17:0	0.58	0.32	0.23	0.28
C17:1	0.34	0.17	0.15	0.23
C18:0	13.73	14.10	10.18	7.45
C18:1n9c	40.04	41.03	45.84	49.05
C18:2n6c	5.21	5.38	9.00	9.31
C18:3n6	0.30	0.19	0.39	0.45
C21:0	-	-	-	0.45
C18:3n3	0.50	-	0.45	0.86
C22:0	-	-	-	0.25

It is ascertained that two fatty acids are formed in poultry fried with lard, such as C21:0 in an amount of 0.45% and C22:0 in an amount of 0.25 %. During the thermal processing of the poultry, the content of C18:1n9c has increased from 45.84% to 49.05%, while C18:0 has decreased from 10.18% to 7.45%, C16:0 has also decreased from 29.55% to 27.45%. These changes are statistically significant at the level of ($p<0.5$).
The changes in the rest of the fatty acids are minimal and do not show statistically significant differences.
From data presented in Table 5 it could be noticed that the palm oil contains 5 fatty acids of which C16:0 is most prevalent, followed by C18:1n9c with 40.17 %, C18:2n6c with 4.90% , C18:0 with 3.22 % and C14:0 with 0.83 %.

Changes in the fatty acid content before and after the heat treatment of pork and poultry meat - fried in palm fat

Fatty acid composition	**Pork meat**		**Poultry meat**	
	Before frying	After frying	Before frying	After frying
C14:0	0.83	0.86	0.65	0.75
C16:0	50.88	47.27	46.15	44.43
C16:1		0.34	-	0.36
C18:0	3.22	3.99	3. 21	3.25
C18:1n9c	40.17	41.64	44.40	44.77
C18:2n6c	4.90	5.90	4.06	6.21
C18:3n3	-	-	-	0.23
C18:3n6	-	-	-	0.21

After the performed thermal processing of pork fried with palm oil there are changes in the content of fatty acids. Thus, the content of C16:0 has been decreased from 50.88% to 47.27 %, while there is insignificant increase in other fatty acids. Total changes in the fatty acid composition of palm oil before and after thermal processing of the pork do not show statistically significant differences.

During frying of poultry with palm oil there is minimal decrease of the content of C16:0 from 46.15 % to 44.43 %, and at the expense of it new fatty acids appear, such as C18:3n3 and C18:3n6, which are either result of denaturation changes which occurred in the palm oil during thermal processing of the meat, or extracted from poultry.

The changes which occur in fatty acid composition of fats after thermal processing of the meat are minimal and do not show statistical significance.

Most probably, the new fatty acids which appear in fats after thermal processing of the meat are either extracted from the meat or newly created fat acids from the existing ones, under influence of high temperature during thermal processing of the meat.

Conclusion

Based on the investigations carried out on chemical changes that occur in fats after the heat treatment, the following conclusions can be made:

- The average shrinkage of the pork fried in lard is 32. 60%, sunflower oil 40. 08% and palm fat 44.80%;
- The average shrinkage during heat treatment of poultry meat in sunflower oil is 35.667%, lard f 44.00% and palm fat 38.20%;
- After frying of the pork in sunflower oil, there is a new fatty acid C16:1 which is present in the total fatty acids with 0.15%;
- After frying of poultry in lard, there is an occurrence of C18:3n3 with a representation of 0.45% and C22: 0 of 0.25%;
- After frying of pork in palm fat there is a new fatty acid C16: 1 where its presence is 0.34% and in poultry meat 0.36%. In palm tree fat after heat treatment, in addition to C16:1, there is a C18: 3n3 representation of 0.23% and C18: 3n6 of 0.21%.

Abstract

In farmed fallow deer (*Dama dama*) behavioural changes associated with reproductive period are much more difficult to identify than in other domesticated animals. The aim of the study was to determine the applicability of selected devices and diagnostic and laboratory methods for oestrus and pregnancy detection in fallow deer does reared in farm conditions. The tested instruments were an electronic oestrus detector, a pregnancy detector and an ultrasound scanner. Blood progesterone levels were determined in the evaluated animals. Not all of the analysed methods of pregnancy detection were equally applicable in a fallow deer farm. The electronic oestrus detector was easy to use, however, animals had to be chased and captured for the tests, therefore, the device is not highly practical in commercial deer farms. The electronic pregnancy detector was the most useful tool for early detection of pregnancy in fallow deer. Its greatest advantages include considerable ease of use, instant results and relatively low cost. Ultrasonography was 100% effective in diagnosing late pregnancies. Pregnancy in fallow deer was most effectively confirmed by an ultrasound examination between day 50 and day 80 after fertilization when bones and cartilage were visible The determination of progesterone levels in blood samples also delivered highly reliable results, but blood tests have to be performed after the spring equinox.

Keywords: *Deer farming, Dama dama, welfare, diagnostic devices*

Introduction

The number of farms rearing selected cervid species, in particular red deer (*Cervus elaphus*) and fallow deer (*Dama dama*), has increased in the 20th century. The provision of high welfare standards in deer farms can be a challenging task due to cervids' specific biological needs, absence of behavioural patterns and low levels of domestication in comparison with livestock animals (Janiszewski *et al.*, 2016). In cervids, behavioural changes associated with oestrus are much more difficult to identify than in other domesticated animals, and they may be difficult to detect based on observation alone. Breeders may not be able to identify the symptoms of oestrus in farm enclosures occupied by female deer without bucks (Asher *et al.*, 2005; Cilulko *et al*. 2013; Mulley, 2007). The oestrus cycle does lasts 24-26 days and can be repeated up to 7 times, but the fertilization usually occurs during the first cycle. It is so important to detect it at the beginning of its duration. Fertilization success and parturition dates are also very important considerations in deer farms (Pollard and Stevens, 2003). In farms characterized by small (pens) enclosures, high stocking density and an insufficient number of hiding sites, many females are forced to give birth in a small common area. The above can prevent the formation of health bonds between the mother and its offspring, and it can lead to the abandonment of calves (Asher et al. 1996). Breeders need the above information to prepare adequate facilities for fawning and offspring rearing and to maximize the animals' wellbeing. The objective of this study was to determine the applicability of selected diagnostic methods and devices for enhancing the welfare of farmed does during the reproductive period.

Materials and methods

The study was conducted in a cervid farm at the Research Station of the Institute of Parasitology of the Polish Academy of Sciences in Kosewo Górne (north-east Poland). Around 300 fallow deer (*Dama dama*), 120 red deer (*Cervus elaphus*) and 90 sika deer (*Cervus nippon*) are raised in the farm each year. The farm has the required facilities and equipment (buildings, devices, etc.) for handling the stock and mechanically immobilizing individual animals.

The following diagnostic methods and devices were used in the study:

- Oestrus detector. Oestrus was detected in fallow deer does with the use of an electronic oestrus detector (Dramiński®, 2014) which measures the electrical resistance of vaginal mucus. Resistance is measured on a scale of 0 to 1990 units. The test was conducted twice on 8 November 2011 and 17 November 2011 on 6 does. The animals were immobilized in a mechanical crash during mucus collection. The procedure was performed based on the method described by Zink and Diehl (1984).
- Ultrasound pregnancy detector. Pregnancy was diagnosed with the use of an ultrasound pregnancy detector (Dramiński®, 2014). Fourteen does were tested on 20 March 2013, and 8 does were subjected to the test on 16 January 2013. Before the exam, the udder region was covered with vegetable oil to promote better contact between the ultrasonic probe and the skin and to facilitate the transmission of ultrasound waves.
- Ultrasound scanner. The ultrasound examination was performed with the use of the ANIMALprofil portable ultrasound scanner with a mechanical abdominal probe operating at 5.0 MHz frequency. During the exam, does were immobilized in a mechanical crush in a position which allowed access to the abdomen, according to the method described by Mulley *et al.* (1987). Ultrasound exams were performed three times on 30 March 2011, 21 December 2011 and 20 March 2012.
- Determination of blood progesterone levels. Blood was sampled from does on three dates: 18 April 2012 (25 does), 16 January 2013 (27 does) and 20 March 2013 (24 does). Blood samples were transported to the Analytical Laboratory of the Municipal Hospital in Olsztyn, and progesterone concentrations were determined by the ECLIA method in Roche Diagnostics COBAS e411 and COBAS 6000 analysers.

The measured data were analysed and presented in table format. They were compared with the results of previous studies conducted in cervid farms and the parameters determined in other farm animals.

Results and discussion

Oestrus detector

Electrical resistance of vaginal mucus was measured twice with the use of an oestrus detector. The results are presented in Table 1.

Table 1. Electrical resistance of vaginal mucus measured with an oestrus detector

Doe No.	**Electrical resistance of vaginal mucus (in units of resistance – 10 units = 1 ohm)**	
	8 November 2011	17 November 2011
2	420	490
25A	370	380
27A	440	340
198	440	410
287	500	440
785	450	340

The results in Table 1 indicate that during the second test, electrical resistance of vaginal mucus increased in 2 does (2 and 25A) and decreased in 4 animals. A decrease in mucus resistance in the reproductive tract of fertile females could be indicative of the follicular phase of the oestrous cycle which directly precedes oestrus and ovulation (Rorie *et al.*, 2002). The tests performed in fallow deer does suggest that an electronic oestrus detector is not a highly practical solution for large cervid farms. To obtain reliable results that accurately predict the onset of ovulation, the test has to be performed at least twice a day during the reproductive period which lasts from several to more than 10 days (Bartlewski *et al.*, 1999; Dramiński, 2014; Dusza *et al.*, 1996). Before oestrus, the stress associated with immobilization can disrupt and delay ovulation by 2-3 weeks and, consequently, delay insemination (Asher and Wilson, 2011). Fallow deer does which were placed in smaller pens 8-12 hours before artificial insemination (24-48 hours before ovulation) were characterised by significantly lower fertilization rates. The above can be attributed to a stress-related increase in progesterone levels (Asher *et al.*, 1996). Animals kept in small and densely populated pens can also develop antagonistic behaviours (Blanc and Thériez, 1998; Matiello, 2009; Pollard and Littlejohn, 1996; Pollard and Stevens, 2003; Ceacero *et al.*, 2012). In this study, only several measurements were performed with the use of the electronic oestrus detector, and the resulting data do not support the formulation of far-reaching conclusions. Nevertheless, our experience has demonstrated that the applied device can be used to detect oestrus in fallow deer does. Tests which rely on measurements of electrical resistance of vaginal mucus to determine the optimal mating dates could be useful in small farms or zoos where animals are more accustomed to humans and when the timing of ovulation has to be accurately determined, including in protected species or conservation herds.

Pregnancy detector

Pregnancy detection is important in animal breeding because the resulting information is vital for the operations of a deer farm. Breeders rely on the results of pregnancy tests to manipulate the animals and change their distribution in pens to enhance the welfare of pregnant does and their offspring. None of the 14 does examined on 20 March 2012 (first exam) were diagnosed as pregnant with the ultrasound detector, although pregnancy was confirmed with the use of other diagnostic methods. During the second exam (16 January 2013), the ultrasound detector diagnosed pregnancy in all 8 does (Table 2). The first test produced negative results in all animals probably because it was conducted too late at a stage when the foetus occupied most of the uterus with very small amounts of amniotic fluid. Other possible reasons were the tester's insufficient experience and weak contact between the probe and the animals' skin. Blood progesterone levels were analysed on 20 March 2013 to confirm the diagnostic efficiency of the previous testing methods. Based on the results, pregnancy was ruled out in two females in the group that had been tested with the pregnancy detector. Those females could have been pregnant during the pregnancy detection test, however,

pregnancies could have been lost due to embryonic resorption or miscarriage by the time blood progesterone test was conducted. The false positive results of the pregnancy detection test could also be attributed to a measurement error where the ultrasound beam was directed towards a full bladder rather than the uterus with amniotic fluid (the ultrasound beam crossed a fluid-filled cavity). The diagnostic efficiency of the pregnancy detector can be estimated at 70% on the assumption that false positive results were due to a measurement error. However, loss of pregnancy cannot be ruled out in females with low progesterone levels at a later date, in particular in doe 40 C13 whose progesterone levels were determined at 1.94 ng/ml. If doe 40 C13 was still pregnant during the pregnancy detector test, the diagnostic effectiveness of this device in early stages of pregnancy can be estimated at 87.5%.
The results of this study indicate that the pregnancy detector is a useful tool for diagnosing early pregnancy in fallow deer does. Its greatest advantages include considerable ease of use, instant results and relatively low cost.

Ultrasound scan
Ultrasound scans were performed three times. The first exam (30 March 2011) produced low-quality images which did not support reliable diagnosis of pregnancy. The second exam (21 December 2012) was performed on 7 does, and pregnancy was diagnosed in 3 animals. The obtained ultrasound scans (Fig. 1 a, b) were compared with published data (Scott and Asher, 2014) to determine that the examined animals were 30-35 days pregnant. The third exam (20 March 2012) was performed on 22 does, and pregnancy was ruled out in 5 females. Based on the results of blood progesterone tests performed on the same day, pregnancy was ruled out in 4 animals in the above group of 5 does (Table 2), which indicates that 80% of the animals were correctly diagnosed based on the results of the blood test. Pregnancy was confirmed in the remaining does, and foetal development was estimated at 90 days (Fig. 2a, b). The results of blood progesterone tests confirmed pregnancy in all does that were diagnosed as pregnant in the ultrasound exam. The diagnostic effectiveness of the ultrasound exam was 100% (Table 2).

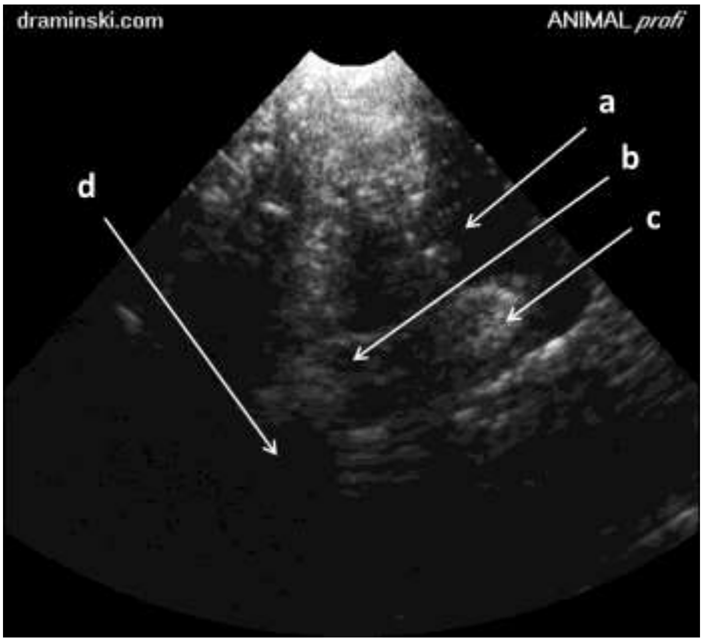

Figure 1 a. Ultrasound scan of a fallow deer doe at around 35 days of pregnancy: a - yolk sac; b - endometrial fold; c - placenta; d - embryo (phot. J. Cilulko-Dołęga)

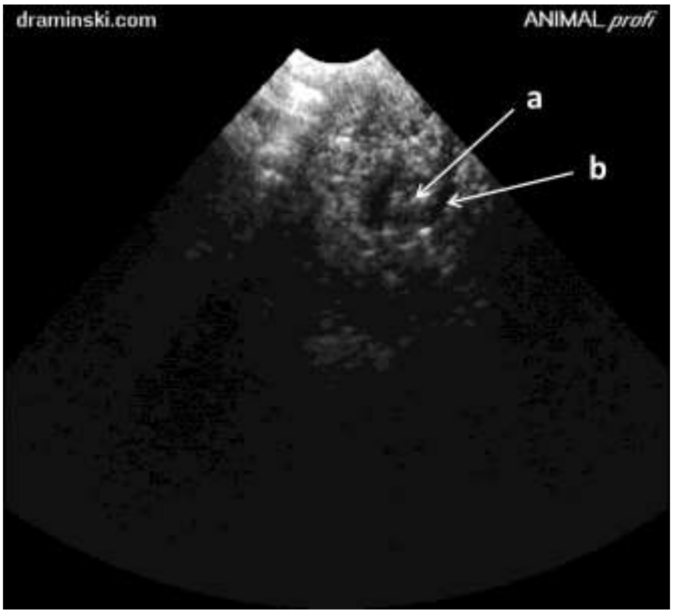

Figure 1 b. Ultrasound scan of a fallow deer doe at around 35 days of pregnancy: a – embryo; b - amniotic membrane (phot. J. Cilulko-Dołęga)

Figure 2a. Ultrasound scan of a fallow deer foetus at around 90 days with a visible spinal cord (a) (phot. J. Cilulko-Dołęga)

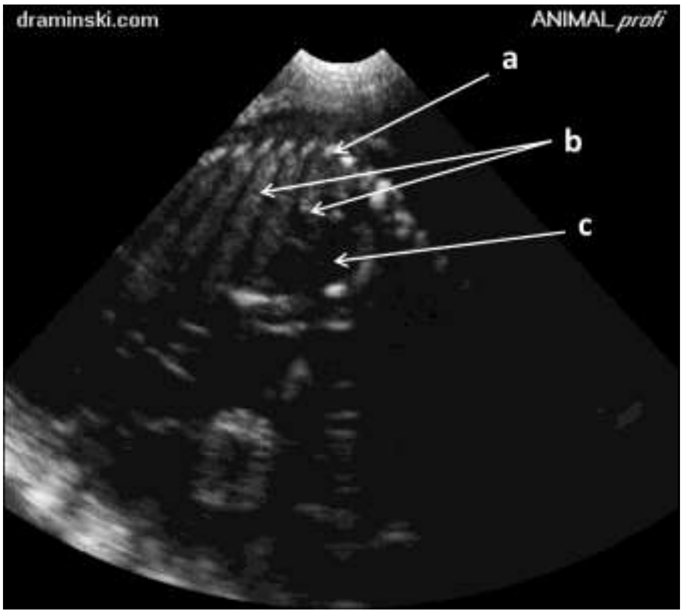

Figure 2b. Ultrasound scan of a fallow deer foetus at around 90 days: a - spinal cord; b – ribs; c - heart (phot. J. Cilulko-Dołęga)

The results of the study indicate that in fallow deer, pregnancy can be diagnosed by abdominal ultrasonography already 30-35 days after mating (Willard *et al.*, 1999). However, the diagnostic effectiveness of ultrasound scans is relatively low in very early stages of pregnancy. An ultrasound exam conducted around 90 days after fertilization was much more accurate, and a false negative result was noted in only one pregnant female. Our results and published findings suggest that pregnancy is most effectively confirmed by an ultrasound examination between day 50 and day 80 after fertilization when bones and cartilage are visible (Scott and Asher, 2014, Mulley, 2007; Revol and Wilson, 1991; Wilson and Haigh, 2007b). A pregnancy may be difficult to confirm or rule out in early stages of embryonic development (Scott and Asher, 2014; Savela *et al.*, 2009).

Progesterone levels

Blood samples for the determination of progesterone levels were collected three times. The first samples were collected (18 April 2014) to verify the results of the ultrasound exam. Four of the 25 examined does were diagnosed as non-pregnant based on their plasma progesterone levels which ranged from 0.03 to 0.69 ng/ml (Table 2).

In 2013, progesterone levels were determined on 16 January and 20 March. The results were used to validate the diagnosis of pregnancy made with the use of the pregnancy detector. On 16 January, progesterone concentration in 27 does ranged from 3.66 to 11.01 ng/ml and were determined at around 6 ng/ml in most animals (Table 2).

Progesterone levels higher than 6 ng/ml are indicative of pregnancy (Plotka *et al.*, 1977; Willard *et al.*, 1998; Shipka *et al.*, 2007). In view of the above, only 13 of the evaluated females could be diagnosed as pregnant. In does with lower progesterone levels, pregnancy could not be diagnosed or ruled out due to the possibility of repeated oestrus, a period during which progesterone concentrations increase.

On 20 March 2013, progesterone levels were measured in 24 fallow deer does and were determined in the range of 0.29 to 13.18 ng/ml (Table 2). The above results were clearly indicative of pregnancy because oestrus is not repeated in female fallow deer in March, therefore, elevated progesterone levels can be solely attributed to pregnancy (Wilson and Haigh, 2007b). Pregnancy was ruled out in 4 does with progesterone concentrations in the range of 0.29 to 1.94 ng/ml. Doe 40 C13 with progesterone level of 1.94 ng/ml probably lost

the pregnancy before the test, and high (in comparison with other non-pregnant females) progesterone levels could have been maintained for several weeks after embryonic death (Willard *et al.*, 1998). The above hypothesis was validated by the results of the pregnancy detector test also which also confirmed early pregnancy (16 January 2013). Females diagnosed as pregnant had progesterone levels in the range of 5.96 to 13.18 ng/ml.
In fallow deer does, progesterone concentrations increase from 6 ng/ml on pregnancy day 19 to around 15 ng/ml on pregnancy day 86. Unfertilized does which repeat the oestrous cycle have progesterone levels of 0 to around 6 ng/ml (Plotka *et al.*, 1977; Wilard *et al.*, 1998; Shipka *et al.*, 2007). After the spring equinox, which takes place on 20/21 March in Poland, the oestrous cycle ceases in cervids, and non-pregnant females have very low blood progesterone levels. During that period, pregnancy can be reliably confirmed or ruled out based on the results of a single blood test without the need for other diagnostic procedures (Wilson and Haigh, 2007b). Progesterone concentrations in the remaining does diagnosed as pregnant ranged from 6.62 to 13.32 ng/ml.
In cervid farms, the losses generated by non-productive animals can be minimized by diagnosing pregnancy at an early stage and identifying and eliminating non-pregnant females from the herd. According to Bazer *et al.* (2007), the annual upkeep cost per one non-pregnant ewe is equivalent to the profit generated by 6-7 females that had offspring. In cervid farms, early detection of pregnancy also delivers non-financial benefits. Pregnant does can be grouped in separated facilities and fed appropriate diets (Asher, 2003). Optimal nutrition, stocking density, organization of pens and optimal herd management practices enhance animal welfare and increase fertility rates, birth rates and fawn survival rates (Asher *et al.*, 2005; Audigé *et al.*, 1998; Audigé *et al.*, 1999a; Audigé *et al.*, 1999b; Audigé *et al.*, 2000; Birgersson and Ekvall, 1997; Carrión *et al.*, 2008; Mulley, 2007; Pollard and Stevens, 2003; Tuckwell, 2003; Wilson and Haigh, 2007a). By monitoring foetal development, breeders can estimate parturition dates and group does with similar calving dates. Calves born later in the same season have greater chances of healthy development and survival. In farms with a rotational grazing system, the division into groups ensures that animals can be safely grazed and moved to another paddock (after the postpartum period) without the risk of leaving fawns hidden in grass (Scott and Asher, 2014).

Conclusions

The results of this study indicate that the tested diagnostic methods and devices enhance the welfare of farmed fallow deer during the reproductive season, pregnancy, parturition and offspring rearing. In the study, oestrus and pregnancy were diagnosed with the use of an electronic oestrus detector, a pregnancy detector, an ultrasound scanner and blood progesterone tests. The pregnancy detector seems to be the most convenient device for fallow deer farms. The oestrus detector is suitable for determining ovulation dates in small herds. Ultrasound scans of the abdominal region effectively detect pregnancy in fallow deer does already 30-35 days after mating.

Abstract

The main goal of this paper was to experimentally determine the effect of estrus synchronization on the percentage of fertility and fattening performance of lambs in a specific period. The percentage of fertility in sheep synchronization was 74% and 100% in the control group. 53.83% of male and 46.15% of female lambs were obtained. The average body weight of all lambs at birth was 3.48 kg, and the differences between the groups were not statistically significant ($P > 0.05$), it was 11.29 kg in 30 days of age and 20.64 kg for 90 days old lambs. Differences in lambs weight between gender and type of birth are very significant ($P < 0.001$), while among the groups they are not statistically significant ($P < 0.01$). The average daily growth of lambs in fattening 6 to 8 months old was 180g, and the estrus synchronization did not have any effect on the production traits.

Key words: sheep, estrus synchronization, fertility, fattening.

Introduction

Compared to other branches of animal husbandry, sheep husbandry is considered highly important, although it does not hold great significance from the economical perspective.

The main characteristic of sheep is their capability to live in harsh climatic conditions, on poor natural pastures, at hilly terrains and salty soils. Sheep utilize very well wealthy pasturages on cultivated, high yield pastures in plans, as well as secondary production crops and processing industries (raw and dried loaf noodles, molasses, beer by products, etc.). Cabbage nutrients in sheep nutrition are represented by about 90%, which distinguishes them from other species of domestic animals. With the aim of intensifying sheep production and organizing technological processes, scientific attempts have been made to manage the sheep breeding process more efficiently. In many countries, methods of synchronization of sheep estrus are used to control the reproductive properties of sheep. This process achieves a full drive during and after the mating season in order to carry out fertilization and yean as many sheep in a short period of time. This method allows sheep to yean twice or more in two years.The main goal of this paper was to experimentally determine the effect of estrus synchronization on the percentage of fertility and fattening performance of the lamb in specific period. The results of these surveys could represent the significant contribution to zoo-technical theory, given the very scarce literature in the field of sheep farming. The results obtained will enable a more complete overview of the production and reproductive possibilities of sheep breeding, which would make a significant contribution to further breeding selection work.

Materials and Methods

The study of the effect of estrus synchronization on fertility and fattening performance of sheep was carried out at a private farm in Krusevac. The farm's capacity was 100 sheep with offspring. The tests were carried out in cooperation with the Veterinary Specialist Institute in Kraljevo.

Sixty healthy, normally nourished, tended sheep of Pirot breed were selected for the study. Before introducing the sheep to the experiment, they were subjected to a detailed veterinary examination. It was noted that sheep were in good health and physical condition. Two groups of sheep were formed, the experimental group (n = 30) and the control group (n = 30). In the experimental group, the estrus synchronization method was applied, and the control group was kept according to the standard farming method where the seasonal character of the fertilization was applied. With controlled fertilization, which is done through the synchronization of estrus, there is the possibility of sheep yeaning three times in two years period, or every eight months.

Synthesis of estrus was done in 2014. For the synchronization and induction of estrus, the technique of intra vaginal sponges with gestagens (*Veramix, Pharmacia & Upjohn, Belgium*) was applied. Natural mating was carried out in the period November-December 2014. The mating was conducted between Pirot breed sheep and Virtemberg breed rams.

Determination of production results, body weight and daily increment, was performed separately and collectively for both groups. The body weight of newly born lambs, body weight of 30 days old lambs, body weight of lambs 90 days of age, frequency of occurrence of body weight of 180 days of age and daily increase of 90 days and 6-8 months old lambs were measured. The average body weight was determined by individual measurement of lambs and the total weight distribution divided by number of lambs. The average daily lamb increment was calculated by dividing the total increase with the number of feeding days with deducted birth weights. Services of the Agronomy Faculty in Cacak were used for the procession of these data. Statistical and variation parameters for the analysis of the obtained data were calculated.

The analysis of the obtained data from the test in this study was carried out using the usual methods of variation statistics.

In the first part of the statistical analysis, the parameters of descriptive statistics for all product characteristics were calculated. Significance of differences in the distribution of production characteristics by yeaning were calculated using the analysis of variance. Individual tests were performed by the LSD test. The parameters of descriptive statistics compute: arithmetic mean, standard deviation, standard error of arithmetic mean, variation coefficient, variation interval, and variance analysis.

Results and Discussion

The results of the study, in accordance with the applied method of work, have been presented and considered in four parts: sheep fertility, production characteristics, and daily lamb growth.

Sheep fertility is a breed feature that can be improved through selection and selection of twins, provided that improved nutrition and care conditions are given.

Lamb weight is defined by genetic and para-genetic factors, among which the most important are the breed, gender, type of birth, mother's age, and lamb’s nutrition.

Table 1. shows the weight of lambs at birth and their variability depending on the group, gender, and type of lamb birth.

In Table 1., the absolute, relative, cumulative and relative-cumulative frequency of appearance of lambs' body weight at birth of the experimental group are shown. Border classes ranged from 2.4 to 3.8 kg, with a variation range of 1.4 kg. The largest number of samples (20.00%) had a percentage of body weight of lambs at birth ranging from 3.5 to 3.6 kg, with a mean value of 3.55 kg and a relative cumulative frequency of 49.99%. Eights heads or 26.66%, were concentrated at the mean value (= 3.48), indicating that the values of body weight of the lambs at the birth significantly varied. It should be emphasized that 6.66% of the samples had a mass range of 2.4 to 3.0 kg, 13.33% of the samples had a weight of 3.0 to 3.4 kg, and 80.00% of the samples from 3.4 to 3.8 kg.

Table 1. Frequency of appearance of weight of lambs at birth (for experimental group)

Class borders	Class mean value	Frequency of appearance			
		Absolute	Cumulative	Relative %	Relative-cumulative %
2.4-2.5	2.45	1	1	3.333	3.333
2.5-2.6	2.55	1	2	3.333	6.666
2.6-2.7	2.65	-	-	-	-
2.7-2.8	2.75	-	-	-	-
2.8-2.9	2.85	-	-	-	-
2.9-3.0	2.95	-	-	-	-
3.0-3.1	3.05	1	3	3.333	9.999
3.1-3.2	3.15	-	-	-	-
3.2-3.3	3.25	3	6	10.000	19.999
3.3-3.4	3.35	-	-	-	-
3.4-3.5	3.45	3	9	10.000	29.999
3.5-3.6	3.55	6	15	20.000	49.999
3.6-3.7	3.65	5	20	16.660	66.665
3.7-3.8	3.75	5	25	16.666	83.331
3.8-3.9	3.85	5	30	16.666	100.000

Weight of 30 days old lambs

Table 2. gives the body weight of lambs 30 days old and their variability depending on group, gender and type of lamb birth.

The average body weight of 30 days old lambs of the experimental and control group is 11.29 kg. The lowest average weight of female lambs of the experimental group is 10.73 kg, with variations from 9.5 to 12 kg. The highest body weight is in the male lambs of the control group (11.88 kg), with variations from 11 to 12.5 kg. Differences in body weight of lambs 30 days old in groups are statistically insignificant ($P > 0.05$).

Weight of lambs 30 days old were higher in males than in female lambs, and in single born larger than in twins and triplets. Experimental group female lambs weighed 11.03 kg and were heavier than twins (by 0.53 kg). These differences are statistically significant ($P < 0.05$). Differences in body weight between the single born and triplets of 1.28 kg were statistically significant ($P < 0.01$). In male lambs, the single born were heavier than twins and triplets (by 0.52 and 0.85 kg). These differences are statistically significant ($P < 0.05$). The body weight of female lambs of the control group, was 10.74 kg (in single born 11.10, twins 10.00 and triplets 9.75 kg), and male lambs weighed 11.88 kg (12.07, 11.33 and 11.00 kg). The difference between genders and the type of birth is statistically significant ($P < 0.01$).

Body weight of 90 days old lambs

Table 3. presents the body weight of 90 days old lambs and their variability depending on the group, gender, and type of lamb birth.

The average weight of lambs 90 days of age was 20.64 kg, with variations from 19.00 to 22.50 kg, a 4.37 kg variation coefficient and a standard deviation of 0.90 kg. Differences in body weight of lambs of 90 days per groups are statistically not significant (P> 0.05). The influence of the type of birth and gender on the body weight of 90 days old lambs is statistically significant (P <0.01). The single born were heavier than twins and triplets of female gender in the experimental group (by 0.61 and 0.86 kg). This difference is statistically significant (P <0.01).

The interaction between the type of birth and gender of lambs (P <0.01) significantly influenced the body weight of 90 days old lambs. Based on the results obtained by the statistical test, it is noted that the differences between genders and between the type of birth are statistically significant, in favor of male lambs and single born (P <0.01). Tested differences within the same genders and between the body weights of the lambs 90 days of age are statistically insignificant (P> 0.05).

Table 3. Mean values of body weight of 90 days old lambs

Body weight of lambs in fattening 180 days old

Table 4. shows the body weight of 180 days old lambs in fattening and their variability depending on the group, gender, and type of birth of the lamb.

The average body weight of lambs in fattening 180 days of age, in the third phase of the fattening in experimental and control group was 37.50 kg, with variations of 30 to 42 kg and a coefficient of variation of 8.60%. Differences in body weight of lambs in fattening of 180 days for both groups are statistically insignificant ($P > 0.05$).

Table 4 shows the absolute, relative, cumulative and relative-cumulative incidence of body weight of experimental group lambs in fattening 180 days of age. Border classes ranged from 30 to 42 kg with a range of variations of 12 kg. The largest number of samples (23.33%) had a body weight of lambs in fattening from 40 to 41 kg, a mean value of 40.5 kg and a relative cumulative frequency of 76.66%. Approximately 6 heads or 20.00% were concentrated around the average value (= 37.50) indicating a significant variation of the body weight of 180 days old lamb in the fattening.

Table 4. Frequency of body weight of lambs in fattening 180 days old (experimental group)

Class borders	Class mean value	Frequency of appearance			
		Absolute			Absolute
30-31	30.5	1	1	3.333	3.333
31-32	31.5	-	-	-	-

42-43	42.5	2	30	6.666	100.000

Daily increase in lambs 90 days of age

Table 5 shows the mean and absolute values of daily growth of 90 days old lambs, between groups and genders.

Table 5. Mean value of daily lamb growth 90 days of age

Group	Gender	N	$\bar{x}$ (kg)	$S\bar{x}$ (kg)	$\bar{S}d$	$C_{V\%}$	Inter. variations	
							Min	Max
Experimental	♀	13	0.219	0.002	0.008	3.652	0.200	0.238
	♂	17	0.236	0.002	0.008	3.390	0.222	0.250
	Average	30	0.228	0.002	0.011	4.825	0.200	0.250
Control	♀	17	0.221	0.001	0.005	2.262	0.211	0.233
	♂	18	0.238	0.002	0.007	2.966	0.222	0.244
	Average	35	0.230	0.002	0.009	3.947	0.211	0.244

The average daily growth of 90 days old lambs was 229 g. The lowest daily gain in the female lamb of the experimental group was 219 g, with variations from 200 to 238 g, coefficient of variation 3.65% and standard deviation of 0.008 g. The highest daily increase was found in the male lamb of the control group, which was 238 g, with variations from 222 to 244 g, with a variation coefficient of 2.96%. The differences in daily lamb growth between the experimental and control group were statistically not significant ($P > 0.05$). The daily increase in male lambs in both groups was higher than the increase in female lambs. Interactions between female and male lambs are statistically highly significant ($P < 0.01$).

Daily increase in lambs 6-8 months old

Table 6 shows indicators of average and absolute value of daily growth of lambs in fattening 6-8 months old, between groups (experimental and control), gender (female and male).

Table 6. Average value of daily growth of 6-8 months old lambs in fattening

Group	Gender	N	$\bar{x}$ (kg)	$S\bar{x}$ (kg)	$\bar{S}d$	$C_{V\%}$	variations	
							Min	Max
Experimental	♀	13	0.164	0.003	0.001	7.317	0.142	0.190
	♂	17	0.190	0.002	0.007	3.684	0.171	0.200
	Average	30	0.177	0.003	0.001	8.989	0.142	0.200
Control	♀	17	0.170	0.002	0.008	4.848	0.152	0.180
	♂	18	0.195	0.001	0.006	3.141	0.176	0.205
	Average	35	0.183	0.002	0.015	8.427	0.152	0.205

Within each group, male lambs were found to have a higher daily gain than female lambs. Differences between groups are statistically insignificant (P> 0.05). The highest daily increase was in male lambs of the control group of 195 g, with variations from 176 to 200 g, the variation coefficient 3.14%, and the standard deviation of 0.006 g. Gender differences were statistically very significant (P <0.001). The largest daily gain of 190 g in the experimental group was in male lambs. The difference in relation to female (0.026) lambs was statistically very significant (P <0.001). The results of individual tests of daily growth of lambs in fattening, 6-8 months old, per groups and gender, LSD indicates that gender differences were very statistically significant in favor of male lambs (P <0.001). Differences between the same gender and between daily increase of lambs in fattening 6-8 months of age of experimental and control group were statistically not significant (P> 0.05).

Conclusion

Based on the study on the effect of estrus synchronization on fertility and sheep fattening, by descriptive statistical analysis of reproductive and production properties, it can be concluded:
The average body weight of all lambs at birth was 3.48 kg. In the experimental group, female lambs had an average weight of 3.27 kg and male 3.66 kg. In the female lamb of the control group, the average body weight was 3.31 kg, and for male 3.67 kg. Differences between groups were not statistically significant (P> 0.05). The weight of the female lambs of the experimental group was 3.47 kg, twins 3.20 kg, triplets 2.45 kg, and male lambs (depending on the type of birth) 3.71, 3.50 and 3.50 kg. The average weight of the female lamb of the control group was 3.47 kg (single born), 3.20 kg (twins) and 2.50 kg (for triplets). In single born male lambs, the average body weight was 3.74 kg, for twins 3.43 kg and triplets 3.40 kg. The differences between gender and type of birth among the lambs' weight at birth were statistically very significant (P <0.001). The average weight of all 30 days old lambs was 11.29 kg. In the experimental group, the weight of male lambs was 11.70 kg and the female 10.73 kg. In the control group, the weight of male lambs was 11.88 kg and the female 10.74 kg.

The influence of gender and type of birth on 30 days old lambs' weight was statistically significant (P <0.01), while it did not have significant influence (P> 0.05) among groups. The average lamb weight, 90 days old, was 20.64 kg, in experimental group lambs was 20.61 kg and in the control group, it was 20.66 kg. The average weight of the female lambs of the experimental group was 20.11 kg for the single born, the twins were 19.50 kg and the triplets were 19.25 kg of weight. In male lambs, depending on the type of birth, the average body weight was 24.45, 21.00 and 20.00 kg. The weight of the single born male lambs of the control group was 21.39 kg, the twins were 21.33 kg and the triplets 20.00 kg, while the female lambs (by type of birth) were 20.15, 19.83 and 19.25 kg of weight. The average daily increase in lambs on the 90th day of life was 229 g. The average daily growth of experimental group lambs was 228 g and for the control group 229 g. The differences between the groups in the daily lamb increment did not have any significant effect. Gender impact was statistically very significant (P <0.01). The average daily growth of lambs in fattening 6-8 months old was 180 g. In the experimental group, female lambs had an increase of 164 g and a male of 190 g. The average daily gain of female lambs of the control group was 170 g and in male 195 g.

Since the organization of raising was adequate for both groups, the estrus synchronization had no effect on the production characteristics.

Abstract

During the production cycle of dairy cows, all necessary conditions, with care and nutrition above all, must be provided. Housing must have good beds that are spacious and comfortable with a good and dry mat, a sufficient quantity of drinking water and adequate mangers. Ventilation, lighting, and humidity in the housing must comply with animal hygiene standards. In this sense, the objective of this paper was to obtain data i.e. parameters speaking of the condition of facilities and quality of dairy cows breeding in the municipality of Vrnjačka Banja and Kraljevo. The paper presents tabular data on the condition of facilities for housing dairy cows, construction characteristics of facilities, accommodation capacities, ventilation method, facilities lighting and relative humidity in facilities for animals. On the other hand, animal nutrition must meet both physiological and productive needs with enough proteins, carbohydrates, macro- and microelements and to vary by the physiological process and season. For this reason, during a visit, the authors gave farmers appropriate professional recommendations for feeding dairy cows according to the method of cultivation or depending on whether livestock breeding is of indoor type or combined with grazing.

Keywords: *housing facilities, cow nourishment, feeding dairy cows*

Introduction

The production of dairy cows is based to the greatest extend to the connected type of housing. In order to have a comfortable staying of animals during the production process, all necessary conditions must be provided for the animal: proper housing, care and nutrition (Jevtić *et al*., 2016). The beds need to be spacious and comfortable with enough mats, they need to fulfill the basic conditions of hygiene, i.e. to absorb the moist and unpleasant gases well, not to irritate the animal skin and not to cause changes in it and not to be sticky (Jevtić, 1990; Jevtić, 2007; Pešev, 2004). During 24 hours a cow leaks from the organism about 6 to 20 litars of urine so it is necessary to provide 3 to 3.5 kg of mat per animal on a daily basis. It is determined that the replacement of the mat is done in a satisfactory manner, i.e. once per day. In that respect, the aim of this paper was to obtain the data, i.e. parameters which evidence the condition of the facilities and quality of dairy cow breeding. The recommendations for nourishment of these domestic animals are given, too (Jevtić *et al*., 2016). In the conditions of individual agricultural production, at the territories of municipalities of Vrnjacka Banja and Kraljevo, the manner of housing the livestock is stable and in the summer months it is combined, with pasture nutrition. At the surveyed households enough appropriate mats were provided: straw, corn stalks, sawdust, fern, leaves, etc.

Material and Methods

The authors of this paper visited the cow housing facilities at the territories of Vrnjacka Banja and Kraljevo municipalities (Serbia) during 2015. The presented data have been evidenced on five cow farms where have been housed a total of 21 cows of the native colourful breed of Simmental type. These farms are located in the villages eastbound from the municipality Vrnjačka Banja (Rudinci, Stulac), northbound (Vrnjci, Novo Selo) and westbound (Gracac).The obtained results of measuring and the found state are presented in Tables 1-5 in the following chapter. The measuring of relative humidity (%) in the facilities for housing animals (Table 5) was performed using special measuring equipment (Dukić, 2006). UNI-T Higrometer was used and it represents mini digital temperature and air humidity measuring device of high accuracy. The device is user-friendly, which makes it an excellent tool for monitoring internal "climate" in agriculture, livestock farming, public facilities and many other fields.

Results and discussion

Tables 1 –5 present the equipment of the facilities for housing dairy cows, construction characteristics of facilities with the biggest number of livestock, mangers in the facilities for housing cows, the ventilation in the facilities for housing cows, lighting of the facilities for housing cows and relative humidity in the facilities for housing animals at the territories of Vrnjacka Banja and Kraljevo municipalities during 2015. All these factors influence in the corresponding manner the status of these animals'organisms. (Jevtić *et al*., 2016). The facilities are equipped with water troughs, all provided with water for filling, with mangers for nourishment and suitable mat(Table 1).

Table 1 –The equipment of the facilities for housing dairy cows

Equipment %	Location				
	Vrnjci	Rudjinci	Stulac	Novo Selo	Gracac
Water trough	19.96	14.19	52.38	7.20	13.00
Water in the facility	39.70	36.92	68.50	18.00	22.30
Manger	96.02	92.04	98.88	86.82	86.80
Met	82.00	92.20	96.00	82.88	82.86

Mangers are most frequently made of wood of various origins and in percentage they are expessed as 78.00%. Less frequently mangers were made of concrete, which is in percentage expressed as 9.70% at the surveyed locations. The length of mangers depend on the volume of livestock in the facility and their depth was about 60cm with 45cm width
(Table 2).

Table 2 –The construction characteristics of facilities with the biggest number of livestock

Number of livestock units	Cubage m^3	The length of stable m	The width of stable m	The height of stable m	Floor surface m^2
5.00	73.60	8.00	4.00	2.30	32.00
4.00	56.96	7.50	3.50	2.17	26.25
3.00	8.84	10.00	4.20	2.10	42.00
4.00	148.80	10.60	5.20	2.70	55.12
5.00	96.76	9.60	4.20	2.40	40.32

The facilities are most frequently placed along the longer axis in East-West direction due to the wind strength. On average, they are 20-40m distanced from other facilities, as individual facilities, they have adequate cubage with suitable lengths and widths of stables and appropriate floor surface (Jevtić et al., 2016).

Table 3 –The form of mangers (%) in the facilities for housing cows
and the type of ventilation (%) in the facilities for housing cows

Form of manger (%)	Location at the territories of the stated municipalities				
	Vrnjci	Rudjinci	Stulac	Novo Selo	Gracac
Concrete	28.02	19.00	17.00	9.90	9.70
Wooden	68.00	72.20	82.00	69.10	78.00
Other	3.98	8.80	1.00	21.00	12.30
Ventilation %					
Natural	81	88	97	99	99
Artificial	19	12	3	1	1

The ventilation in most of the facilities is natural, which according to the facility size enables proper coefficient of ventilation, i.e. the necessary number of air changes (Table 3).
There are three types of lighting in the facilities, most frequently artificial, then combined and in the smallest portion of surveyed stables it is natural (Table 4).

Table 4 –The type of lighting (%) of the facilities for housing cows

Lighting (%)	Location at the territories of the stated municipalities				
	Vrnjci	Rudjinci	Stulac	Novo Selo	Gracac
Combined	20	19	16	16	4
Natural	18	13	18	4	6
Artificial	62	68	66	80	90

The humidity at the surveyed stables was 61 to 84% at the first stable and in the second from 70 to 87%, which had a corresponding positive impact on animals (Table 5). Desinfection, desinsection and deratization is occasionally done at stables, most frequently without the control and supervision of competent persons. The cooperation of agricultural households and veterinary service is satisfactory.

Table 5 –The relative humidity (%) in the facilities for housing animals at stables A and B

Month	A	B	Month	A	B	Month	A	B
I	81	78	V	63	70	IX	61	79
II	79	85	VI	60	75	X	64	80
III	74	87	VII	62	68	XI	79	76
IV	61	70	VIII	61	74	XII	84	81

Cattle breeding is developed exclusive at private properties and the most important branch is cow breeding for the production of milk and calves. Steers are bred for reproduction and slaughtering. The most widespread is the domestic versatile cattle of Simmental breed. There are no farms of milking cows but there are small mini-farms whose owners are individual agricultural producers. The manner of cattle breeding is stable, combined and during the summer, autumn and spring the animals go to pastures. The purchase of milk is organized (Dairy plant of Kraljevo and two private entrepreneurs, owners of dairy plans at the territories of mentioned municipalities).

Recommendations for cow nutrition

The determination of the nourishment level depends on the body weight of the cow, quantity and quality of milk produced during the day and pregnancy stage. During the determination of the needs, the size of the meal, possibility of consumption based on the raw substance, energy value of the meal (in nutritive units), the quantity of digestible raw proteins, and quantity of calcium, phosphor and salt are standardized (Rajić, I. et al. 1999). The estimated needs in proteins for dairy cows are 60g SSP per 100g of body weight and 60g SSP/kg 4% milk. In new recommendations, depending on the percentage of fat in milk and quantity SSP is changed to 53 g/kg of the produced milk. Bulky food should be given, by the rule, in fresh and green condition because it is quality and tasty food then and animals are willing to eat it. During the summer the cows eat at pastures (Jevtić *et al*., 2009). Apart from grazing, cows use concentrate which is given in the quantity of 5kg per day with 12% of digestible proteins. As a supplement to the pasture nutrition, bran in the quantity of 1.5kg, 0.5kg of sunflower pellets and 1.5kg to 2kg of beet noodles are given. One daily meal of dairy cows must include the supplement of cattle chalk and salt in the summer period. For a dairy cow of 500-600kg body weight, 16kg of straw can be given per day. For a bigger milk production the cow should be fed on concentrates as following: for 1kg of milk 0.45kg - 0.50kg and for 2kg 0.9kg – 1.0kg of concentrate.

Conclusion

It is possible to conclude, on the basis of presented data, that livestock breeding in Vrnjačka Banja is developed on the private estates exclusively. Big farms of milk cows are not represented here, but there is certain shift and certain farms have begun to be built. Contribution to this is given by provided purchase of milk.

Small individual farms are the most represented and the method of breeding cattle is not so profitable; but with the advancement of nutrition and with the help of subsidized by the state it has a perspective for gradual recovery.

Abstract

The pea and oat were tested at five different mixture rates: A_1-100% pea + 0% oat; A_2-0% pea + 100% oat; A_3- 25% pea + 75% oat; A_4-50% pea + 50% oat and A_5- 75% pea + 25% oat. The pea:oat mixtures were ensiled without (B_1) and with bacterial inoculant (B_2). The objective of this experiment was to assess the effects of pea proportion and bacterial additives on carbohydrate fractions of ensiled pea:oat mixtures. Silage samples were assayed for DM (Dry Matter), CP (Crude Protein), CHO (Total Carbohydrates), NSC (Non-Structural Carbohydrates), Starch, NFC (Non-Fiber Carbohydates), aNDF (Neutral Detergent Fiber), ADF (Acid Detergent Fiber), HCL (Hemicellulose), Lignin and DMD (Dry Matter Digestibility) and carbohydrate fractions by CNCPS (Cornell Net Carbohydrates and Protein System). It was realized that pea and oat can be planted succesfully for herbage production, and these mixtures can be succesfully ensiled and obtained high quality silages. The addition of bacteria slightly decreased ($P< 0.05$) the CP and NSC contents of silages but increased ($P< 0.05$) the aNDF, ADF and DMD. Ensiled 100% pea had the highest CP and NFC content and the highest DMD. The pea: oat (75 : 25) silage had the lowest aNDF (560.3 g kg^{-1} DM), ADF (425.8 g kg^{-1} DM) and lignin (79.0 g kg^{-1} DM), but had the highest DMD (612.0 g kg^{-1} DM). CB_3 fraction of carbohydrates was the highest fraction in the pea: oat silage.

Keywords: *bacterial inoculant, pea:oat mixtures, silage, carbohydrate fractions*

Introduction

Forage pea (*Pisum sativum subsp. arvense* L.) is an annual plant which is grown in many parts of the world. It is highly valued for its high crude protein content. Cultivation of field pea is also beneficial to improve soil fertility by the root-nodule bacteria (*Rhizobia sp.*) that are able to introduce atmospheric nitrogen into soil (Kwabiah, 2004). Although it is mainly used for seed production in Serbia, the whole plant can be processed into silage. Oat is commonly used for greenfeed (hay). However, it also presents some less desirable characteristics such as low protein content (6.45-7.84%) compared to other cereals used for other forms of livestock feeding systems such as grazing and silage (Omokanye, 2014). Combining annual crop species for improved forage productivity should clearly have nutritional and financial benefits in the overall livestock production (Kwabiah, 2004). Bi-crops of various grain legumes and cereals have received much attention because of their high yields (Salawu et al., 2001). In particular, bi-crops with pea varieties or mixtures with high grain to straw ratios are considered to have a good balance of energy and protein contents (Anil et al., 1998). One anticipated advantage of feeding bi-crop silages of cereal and legumes is an improvement in the efficiency of nutrient utilization due to the possible synchronous supply of readily fermentable energy and protein in the rumen (Adesogan et al., 2002).

Forage pea have higher CP (Crude Protein) and *in vitro* digestible organic matter, and lower neutral detergent fiber (NDF) and acid detergent fiber (ADF) than wheat (Salawu et al., 2001), and higher CP contents than oats (Faulkner, 1985). However, adding pea to wheat, oat or barley increases forage CP concentration and decreases NDF and ADF (Salawu et al., 2001). Mustafa and Seguin (2004) found that whole-crop pea silage has similar yields, but higher CP and lower NDF contents than pea-cereal silages and that the *in vitro* DM digestibility of pea silage is higher than that of pea-cereal mixtures. The objective of this experiment was to assess the effect of pea proportion and bacterial additives on carbohydrate fractions of ensiled pea:oat mixtures.

Materials and methods

The experiment was designed with three replications according to a randomized complete block. Experiment was established in autumn in 2012, on October the 20th and the samples were taken in spring in 2013. Pea and oat were grown in binary mixtures at the experimental field of Institute for forage crops, Kruševac – Serbia (21º19´35´´ E, 43º34´58´´ N). The pea and oat were tested at five different mixture rates: A_1-100% pea + 0% oat; A_2-0% pea + 100% oat; A_3- 25% pea + 75% oat; A_4-50% pea + 50% oat and A_5- 75% pea + 25% oat. All mixtures were sown on plots of 20 m^2. Initial soil test from 0-30 cm soil depth before the trial commenced showed 0.16% N, 4.9 mg P_2O_5 / 100 g of soil, 23.1 mg K_2O / 100 g of soil, 3.5% organic matter and a pH of 5.7 in N KCl. One level of fertilizer was applied, 300 kg ha^{-1} NPK (15:15:15) before the seeding. Plant samples were taken in spring 2013, at forming the first pods on 2/3 plants of pea. The pea:oat mixtures were ensiled in the experimental containers holding 130 dm^3, with three replications. After compaction, silos was covered with plastic wrap, and covered with a layer of sand thickness of about 10 cm as the main load. Bacterial inoculant *BioStabil Plus* which contained homo-fermentative lactic acid bacteria (*Enterococus faecium* and *Bacillus plantarum*) and hetero-fermentative lactic acid bacteria (*Bacillus brevis*) with a concentration of 5×10^{10} cfu per gram was added, and ensiled in anaerobic jars for 45 days. Silage samples were assayed for DM (Dry Matter) by oven drying at 60º C for 48 h. Standard procedures described by the AOAC (1990) were used to determine ash (AOAC, 942.05), Crude Protein (CP; AOAC 984.13) and ether extract (EE, AOAC 954.02), but ash and EE were not presented in this paper. Total carbohydrates [CHO = 1000 – (CP + Ash + EE)] and Non-Fiber carbohydrates [NFC = 1000 – (aNDF + CP + Ash + EE)] were calculated according to NRC (2001). NDF assayed with heat stable α-amylase (aNDF), acid detergent fiber (ADF), hemicellulose (HCL) and lignin content were determined according to Van Soest et al. (1991). NSC (Non-Structural Carbohydrates – monosaccharides and disaccharides) were determined as total ethanol soluble carbohydrates according procedures described by Hall et al. (1999), and starch content was determined according enzymathic method by Hall (2000). Two stage pepsin-cellulase method was used for *in vitro* DM digestibility (De Boevar et al., 1986). Total CHO are divided into five fractions: instantaneously solubilizable CHO (CA, *i.e.* NSC); rapidly degradable CHO (CB_1, *i.e.* starch); intermediately degradable CHO (CB_2, *i.e.* NFC – NSC – starch); slowly degradable CHO (CB_3, *i.e.* ANDF – CC) and undegradable CHO (CC, *i.e.* aNDF × (Lignin / aNDF) × 2.4) composed of completely undegradable NDF (Lanzas et al., 2007). The experimental data were analyzed by a two-way analysis of variance for silage samples using a model that accounted for the main effects of pea:oat mixtures and addition of inoculant. Effects were considered different based on significant ($p< 0.05$) F ratio. The significance of differences between arithmetic means was tested by LSD test (STATISTICA 6, Stat. Soft. 2006).

Results and discussion

The chemical composition of pea:oat silages are presented in Table 1. DM content in silages ranged from 270.6 g kg^{-1} in pea silage to 276.6 g kg^{-1} in oat silage. The main effect of pea proportion in the mixtures was significant ($p < 0.05$) for several variables. The CP and NFC content was the highest in pea silage, whereas content of CP and NSC increased with increasing pea proportion in pea:oat mixtures.

A_1-100% pea + 0% oat; A_2-0% pea + 100% oat; A_3-25% pea + 75% oat; A_4-50% pea + 50% oat; A_5-75% pea + 25% oat. B_1-control, treatmant without bacterial inoculant; B_2-treatmant with bacterial inoculant. DM-Dry Matter; CP-Crude Protein; CHO-Total Carbohydrates; NSC-Non-Structural Carbohydrates; NFC-Non-Fiber Carbohydrates; aNDF-Neutral Detergent Fiber; ADF-Acid Detergent Fiber; HCL-Hemicellulose; DMD-Dry Matter Digestibility. Different letters denote significantly different means ($P < 0.05$)

The highest content of starch was recorded in silage with 75% pea proportion in pea:oat mixture, whereas starch content in pea silage and oat silage was similar and there was no significant difference ($p > 0.05$). Despite the CP and nonstructural carbohydrates, content of structural carbohydrates and lignin was higher in oat silage (Table 1). aNDF, ADF, hemicellulose and lignin content was the highest in oat silage, and decreased with increasing pea proportion in pea:oat mixtures ($p < 0.05$). With increasing structural carbohydrates and lignin content dry matter digestibility decreased. Results obtained in this study indicate that the highest DMD was recorded in pea silage (678.4 g kg^{-1}) and the lowest in oat silage (433.0 g kg^{-1}). With increasing pea proportion in the mixtures, DMD of ensiled pea:oat mixtures increased from 459.4 g kg^{-1} to 612.0 g kg^{-1} (Table 1).
The addition of bacterial inoculant decreased ($p < 0.05$) CP and NSC content, but increased ($p < 0.05$) aNDF and ADF content in pea:oat silages. The addition of bacterial inoculant was not significant for pea:oat silages DM, CHO, starch, NFC, hemicellulose and lignin content. The bacterial inoculant increased DMD of pea:oat silages. The results of this investigation indicate that NSC and starch content was lower in pea and oat silages than in pea:oat silages, which is result of nonstructural carbohydrates fermentation to lactic acid and acetic acid. The digestibility values of the pea:oat silages were generally lower than those found for the pea silage. The lower digestibility may be partly attributable to their higher indigestible cell wall contents and unavailable CC fraction of CHO. Mustafa et al. (2000) reported that whole pea silages, harvested at full pod stage, can successfully replace barley or alfalfa silage as a forage source for high yielding dairy cows in early lactation, whereas Børsting and Weisbjerg (2002) found that feeding pea silage harvested with undeveloped seeds to dairy cows led to a lower dry matter intake, milk yield and milk protein yield in comparison to perennial ryegrass silage made with a comparable crude protein content.

A_1-100% pea + 0% oat; A_2-0% pea + 100% oat; A_3-25% pea + 75% oat; A_4-50% pea + 50% oat; A_5-75% pea + 25% oat; B_1-control, treatmant without bacterial inoculant; B_2-treatmant with bacterial inoculant; CA-Instantaneously solubilizable CHO; CB_1-Rapidly degradable CHO; CB_2-Intermediately degradable CHO; CB_3- Slowly degrable CHO; CC-Undegradable CHO; Different letters denote significantly different means ($P < 0.05$)

When CNCPS CHO fractions of pea:oat silages (Table 2) were interpreted, it was observed that silages with higher pea proportion contained higher CA fraction indicating that these silages were better sources of fermentable CHO to ruminants. Among pea:oat silages, silage with the highest pea proportion contained the highest CB_1 fraction. CB_2 fraction was the lowest in oat silage, and its content increased with increasing pea proportion in pea:oat silages. The amount of fraction CB_3 is very important as this fraction represents the available cell wall portion of ruminant feeds (Das et al., 2015). Pea silage contained the lowest CB_3 fraction as pea is high in protein content and low in aNDF and ADF content. Among other silages the highest CB_3 fraction was detected in oat silage, and content of this fraction decreased with increasing pea proportion in pea:oat mixtures. Fraction CC is the lignin bound cell wall content of a feed and this fraction is indigestible both by ruminal microbes and the animal itself. Feeds with low CC fraction will be of superior quality in terms of CHO supply to ruminants and vice-versa (Das et al., 2015). On this aspect, silages like pea and ensiled pea:oat mixtures with higher proportion of pea were found to be better feeds. Bacterial inoculant addition increased CB_2 and CC fraction, but decreased CA and CB_3 fraction of investigated ensiled pea:oat mixtures. Most studies performed with pea-based silages in the diets of dairy cows have used cows of low or intermediate yield, i. e. about 20 kg day^{-1} (Salawu et al., 2002, Adesogan et al., 2004) and few published studies have described the effects of using pea-based silages in diets of intermediate or high-yielding dairy cows (Mustafa et al., 2000; Pursiainen and Tuori, 2006; Rondahl et al., 2006).

Conclusions

According to the data obtained from this research work, it was realized that pea and oat can be planted succesfully for herbage and hay production. Moreover, pea and oat mixtures can be succesfully ensiled and obtained high quality silages. The highest CHO fraction of ensiled pea : oat mixtures was CB_3. Pea silage had the highest CB_2 fraction of carbohydrates. Application of bacterial inoculant affected higher CB_2 and CC fraction, but lower CA and CB_3 carbohydrate fraction of ensiled pea:oat mixtures. Increasing pea proportion in the mixtures affected increasing CA and CB_2 fractions, whereas CB_3 and CC carbohydrate fractions decreased.

Abstract

Urea is a metabolic product in cow's milk and affected by nutritional and some non-nutritional factors. The study was conducted in order to determine the effect of seasons and stage of lactation on milk urea (MU) and other milk production traits (fat, protein and daily milk yield) in Holstein breed cow's milk, from 11 dairy cattle farms in Province of Vojvodina (Republic of Serbia). This research included 35,467 milk samples, from 3223 cows, which were analyzed as a part of Dairy Herd Improvement (DHI) program, from June 2013 to January 2016. Statistical data processing was carried out by applying General Linear Model procedure, Statistics 13. Significant differences in MU concentrations and milk parameters were observed between seasons ($P<0.01$) and stage of lactation ($P<0.01$). The seasonal observation shows the lowest MU concentration (20.61 mg/dl) in autumn period and the highest in spring period (26.89 mg/dl). The highest milk fat and protein content was in autumn, when the daily milk production was the lowest. The lowest concentration of MU was at the beginning of lactation (21.91 mg/dl) and the highest (26.11 mg/dl) was from 121 to 180 days of lactation. The maximum daily milk yield (32.42 kg) was between 61 and 120 days of lactation. It was concluded that milk urea concentration should be evaluated in association with season and stage of lactation and also in association with daily milk yield, fat and protein content in the milk. It could contribute to improving feeding on dairy farms and lead to reduction of feeding costs too.

Keywords*: milk urea, Holstein breed, season, stage of lactation*

Introduction

Milk is a complex food which composition includes fats, proteins, lactose, mineral, vitamins and other micelle constituents dispersed in water. Urea as a part of non-protein fraction of nitrogen in the milk represents the final product of protein metabolism in the rumen of ruminants. MU concentration can be used as a practical tool to monitor dietary crude protein and energy intake, relative to requirements. Improving the efficiency of dairy production by the proper nutrition balancing can contribute of less nitrogen losses, environmental pollution and more profitable milk production. The aim is to improve efficiency, reduce cost of production and reduce nitrogen excretion into the environment (Stoop et al., 2007). The main components of milk are influenced by several factors such as genetics, age, stage of lactation, udder health, diet, season (Festila et al., 2012). Milk urea content can be influenced by: herd (Rajala-Schultz and Saville, 2003), season (Hojman et al., 2004; Fatehi et al., 2012), milk yield (Arunvipas et al., 2003; Hojman et al., 2005), stage of lactation (Godden et al., 2001; Rajala-Schultz and Saville, 2003; Fatehi et al., 2012), parity (Arunvipas et al., 2003; Wood et al., 2003; Hojman et al., 2004;), breed (Rodriguez et al., 1997; Wattiaux et al., 2005), body weight (Jonker et al., 2002; Hojman et al., 2005), etc.

The objective of this study was to determine how seasons and stage of lactation have an effect on the milk parameters and urea concentration in Holstein breed cow's milk in Province of Vojvodina.

Material and Methods

The study included 3223 Holstein cows, from 11 Vojvodina dairy farms. 35,467 individual cow milk samples were collected by monthly DHI milk test from June 2013 to January 2016. Milk urea and milk chemical composition were determined by the infrared test method (ISO 9622:2013) by MilcoScan FT. To convert MU to MUN (milk urea nitrogen), the following conversion formula was used MUN (mg/dl) = MU (mg/dl) x 0.4667 (Oudah, 2009). Dataset included: farm code, date of test (season), days in milk – DIM (interval between date of calving and milk test day), daily milk yield, milk fat and milk protein content and MU concentration (mg/dl). According to the season of sampling, milk samples were divided into four groups. Lactation was divided into 6 DIM intervals of 60 days each (first 60 days, 61 to 120 days, 121 to 180 days, 181 to 240 days, 240 to 300 and greater than 300 days). The average values and variability of examined traits as well as the effect of factors on mentioned traits were studied by means of the PROC UNIVARIATE and PROC GLM procedures within the Statistic software package (ver. 13 Stat-Soft Company, 2016). Post-hoc analysis (Duncan test) was used to determine the statistically significant differences between the mean values of different classes, with a significance level at P <0.05 and P <0.01. The model equation used for the evaluation was as follows:

$Yij = \mu + Si + DIM_j + eij$
where:
Y_{ij} = MU, MF, P and DMY (dependent variable)
μ - mean value of dependent variable;
Si - fixed effect the Season i (i = 1 - winter, 2- spring, 3-summer, 4-autumn),
DIM_j - fixed effect the days in milk – stage of lactation, j= 1, 2, ...6
eij - other random effects.

Results and Discussion

The mean MU value in these data was 24.78 mg/dl (with standard deviation of 8.80 mg/dl) (Table 1) and within the optimal values from 15 to 30 mg/dl (Carlson and Pehrson, 1993; Moore and Varga, 1996). Average cow – level MU concentration was higher than values reported in the study of Kohn et al. (2004), but lower than values reported by Wattiaux and Karg (2004), Zadeh-Hosseein and Ardalan (2011) and Fatehi et al. (2012) for Holstein dairy cows. The coefficient of variation for the milk urea content (35.50%) was higher than the coefficient of variation for the other milk components. Stoop et al. (2007), Bastin et al. (2009), Bouwman et al. (2010), Zadeh-Hosseein and Ardalan (2011) and Čobanović et al. (2015) also found higher CV for MU then other milk ingredients.

Table1. Means, standard deviation (SD) and coefficient of variation (CV) of analyzed variables

Trait	N	Mean	SD	CV (%)
MU (mg/dl)	35467	24.78	8.80	35.50
MUN (mg/dl)	35467	11.57	4.11	35.50
Fat (%)	35467	3.78	0.87	23.11
Protein (%)	35467	3.31	0.42	12.55
DMY (kg)	35467	26.70	10.05	37.66

MU – milk urea; MUN – milk urea nitrogen; DMY – Daily milk yield (kg) on the test day

According to the data in Table 2, season had significant effect on MU concentration in Holstein cows and other examined traits (the values of F-test in all cases are highly significant). Konjačić et al. (2015) and Kučević et al. (2016) found that season statistical significant influenced on milk parameters. Fat (3.88%) and protein (3.44%) content of milk were significantly higher in autumn and the lowest in the summer season (milk fat 3.66%, protein 3.19%). Bendelja et al (2011) and Zlatković (2014) also reported higher milk fat and protein content in autumn-winter season and lowest in spring-summer season.
Milk urea concentration (20.61 mg/dl) and also DMY (24.56 kg) were lower in autumn. During the spring MU concentration was the highest (26.89 mg/dl). Similar results have been reported by: Hojman et al. (2004), Abdouli et al. (2008), Bastin et al., (2009) and Fatehi et al. (2012). Higher MUN concentration in the winter period was reported by Jilek et al. (2006). DMY was the highest in the winter (27.90 kg). Zlatković (2014) found the lowest DMY in the August and the highest in the March.

Table 2. Effect of the season on milk fat and protein content, daily milk yield and milk urea concentration

Season of sampling	N	Trait			
		Fat (%)	Protein (%)	DMY (kg)	MU (mg/dl)
1	8764	3.83[a]	3.38[a]	27.90[a]	24.96[a]
2	8448	3.76[b]	3.24[b]	27.83[a]	26.89[b]
3	9216	3.66[c]	3.19[c]	26.61[b]	26.79[b]
4	9057	3.88[d]	3.44[d]	24.56[c]	20.61[c]
F		**126.0****	**944****	**170.2****	**954.21****

- [a,b,c,d] Means within the same column with different superscripts differ statistical significantly (P<0.01)
- Statistical significant differences: * P<0.05; ** P<0.01;

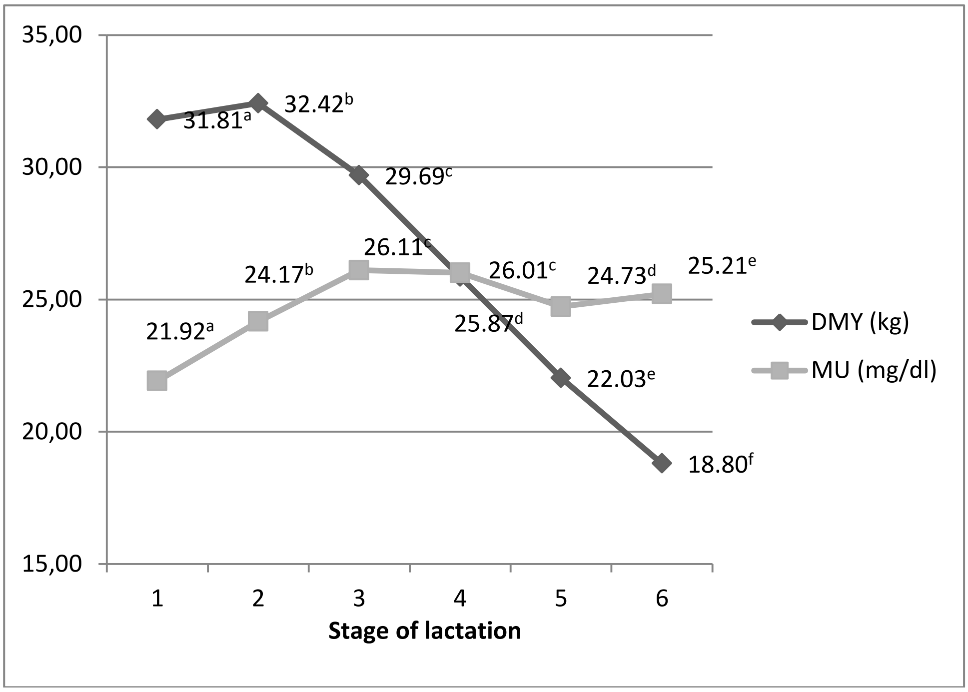
The content of milk fat, protein, MU and daily milk yield, were significantly influenced by the stage of lactation (Table 3). The high values of the F- ratios are the proof of the important influence of the stage of lactation on the examined variables.

Table 3. Effect of the stage of lactation on milk fat and protein content, daily milk yield and milk urea concentration

Stage of lactation	N	Trait			
		Fat (%)	Protein (%)	DMY (kg)	MU (mg/dl)
1	4948	3.85[a]	3.03[a]	31.81[a]	21.92[a]
2	6265	3.56[b]	3.06[b]	32.42[b]	24.17[b]
3	6284	3.61[c]	3.21[c]	29.69[c]	26.11[c]
4	6125	3.75[d]	3.34[d]	25.87[d]	26.01[c]
5	5773	3.89[e]	3.52[e]	22.03[e]	24.73[d]
6	6072	4.06[f]	3.69[f]	18.80[f]	25.21[e]
F		296.6**	3437**	2374.9**	170.6**

- [a,b,c,d, e, f] Means within the same column with different superscripts differ statistical significantly (P<0.01)
- Statistical significant differences: * P<0.05; ** P<0.01;

The concentration of MU was significantly (P<0.01) lower in the first 60 DIM (21.92 mg/dl). Carlsson et al. (1995) explained the lower MUN content in the first month of lactation as the inability of cows to digest a sufficient amount of feed at the beginning of lactation which resulted in a relatively lower intake of proteins. On the Graf 1. it can been seen that the peak of lactation was between 60 and 120 days. Some authors found out that peak of lactation is between 4 and 8 weeks (Čobić and Antov, 1996; Park and Lindberg, 2004), but Piccardi at el. (2014) reported that peak of lactation about 122 days. Maximum MU level was between 121 and 180 DIM (26.11 mg/dl), this was a signal of the excess protein in diet of cows in period after the peak of lactation. Similar results were reported in other studies (Hojman et al.. 2004; Fatehi et al.. 2012).



Different letters of superscript mean statistical significant difference at the level of P<0.01

Graf 1. Daily milk yield and milk urea concentration in milk by stage of lactation

Conclusion

The obtained results indicate that the season and stage of lactation had a highly significant effects (P<0.01) on milk urea concentration, milk fat and protein content and daily milk yield. The results suggest that MU should be evaluated in the association with the season and stage of lactation when determining the efficiency of N utilization.

Maintaining and monitoring MU in dairy herds provide an opportunity to formulate the dietary protein constituency that optimizes nitrogen utilization for milk production and to have more profitable milk production and less environmental pollution.

Abstract

The quality of slaughtered animals is a subject of interest, of both primary production and the meat industry. The aim of the study was to analyze the effect of age of Simmental young beef cattle (bulls) on the class and degree of fat tissue carcass covering in a slaughterhouse in Raska district, according to the standard applied in the European Union (Council Regulation (EC) N 1234/2007, Commission Regulation (EC) N 1249/2008; European Commission, Directorate-General for Agriculture and Rural Development). The rules defining the quality of meat have been partially applied in Serbia (Official Gazette of the SFRJ 34/74, 26/75, 13/78). The quality assessment, classification and determining the degree of the carcass fat tissue covering is performed immediately after a veterinary examination and measurement of the carcasses weight. The study was conducted on 116 young cattle (young bulls) carcasses of domestic Simmental breed from redemption, which are divided into two age groups. The first group were cattle of age from 269 to 350 days (n = 78) and the second 351- 450 days of age (n = 38). The results showed that the tested groups differed significantly ($P < 0.05$) in the values of animals weight prior to slaughter and carcasses weight after primary processing. The average weight of cattle in the first group was 508.89 kg and 531.2 kg in the second, while the average slaughter weight of the hull in the first group was 268.83 kg and 279.97 kg in the second. Both observed age groups had identical average class 4.66. Fat tissue coverage degree of carcass in the first group was estimated an average score of 3.09, while the average rating of fat tissue coverage degree of carcass in the second group was somewhat higher (3.21), but this difference was not statistically confirmed ($P > 0.05$). The given results show that it is necessary to intensify the upgrading of primary production in order to achieve better quality of meat.

Key words: *Age, Simental cattle, Class, Fat tissue coverage.*

Introduction

Global population growth in last few decades increases the livestock products demand, therefore in 2016, according to FAO data (*Food Outlook, Biannual Report on Global Food Markets, 2016*) 320.7 million tons of meat were produced worldwide which is by 0.3% more compared to production in 2015. Beef world production in its scope is in third place, behind pork and poultry meat. In total production, poultry participates with 36.23% (116.2 tons), 36.3% pork (116.4 million tons), beef 21.32% (68.4 million tons) and mutton 4.4% (14.1 million tons) according to FAO 2016. On the other hand, the US (19%), Brazil (15%) and the European Union, (13%) produce approximately 47% of global beef production, i.e. less than one-half of the beef in the world. Globally observed, since 1960 the entire meat production tripled, milk production nearly doubled, and egg production increased four times (Speedy, 2003). The world's average annual meat consumption per capita in 2016 amounted 43.4 kg. In the EU countries there are significant differences in the beef consumption between the individual member states. Thus, in 2011 per capita consumption in France was 25.4 kg, 19.7 kg in Slovenia, 17.3 kg in Austria, in Romania it was 6.5 kg while in Bulgaria it was only 4.5 kg (Grgić and Rakić, 2015). In the last decade, in Serbia is present continuously negative trend of total number of cattle with an average annual decline by 2-3% (Petrović et al., 2011). Number of cattle in 2013 was only 913. 000 and it is the smallest in the period since 1995 to 2013 and a slight increase was recorded in 2014 (920.000). In registered slaughterhouses 302.000 bovines were slaughtered in 2015, which is by 45.9% less than in 1995 (658.000 slaughtered animals). According to official statistics in Serbia 70.000 tons of beef have been produced in 2013, 73.000 tons in 2014 and 77.000 tons in 2015. The low production of beef in Serbia has also resulted in low consumption - the annual consumption in 2003 was 6.1 kg, 3.6 kg in 2005, 4.5 kg in 2007, and only 3.5 kg in 2010 (Zlatanović, 2012). However considering current situation, production and consumption of beef in the Republic of Serbia is very low despite natural resources and Simmental breed of cattle with a predisposition for fattening. In last 20 years, the selection was enacted for the purpose of milk production, but it can be said as well that the production of meat was developed through selection work. This is best indicated by the fact that young bulls were first tested for growth traits and physical development, and tested to progeny test for milk traits and conformation. Maternal characteristics, feed conversion ratio, as well as the quantitative and qualitative characteristics of carcass and meat are substantial for meat production (Bogdanović et al., 2005). Having in mind that the beef production in Serbia is based on Simmental race, selection must be meant to improve fattening and slaughter characteristics and to ensure retention of already achieved level of milk production. It is necessary to breed the domestic cow with lower production traits with bulls of breeding races such as the French, Italian and English. The aim of this crossing is the usage of heterosis effect in creating the genotype, which will result in the final body weight in the F1 generation of 550 kg, the average daily weight gain of 1500 g, carcass yield of above 60% and the content of the muscle tissue in the body of more than 60% (Petrovic et al., 2007). On the other hand, the Republic of Serbia is currently in the process of joining the EU and it is necessary to make certain amendments to the existing regulations and adopt new ones in order to make meat originating from Serbia competitive on the European market. This will mean that payments to farmers-owners of animals will be conducted according to the achieved quality, not live weight.

Material and Methods

According to the Rulebook on the quality of animals for slaughter, poultry and game (Official Gazette of SFRY 34/74, 26/75, 13/78) carcasses or half-carcasses in Serbia are classified into categories according to age (three age groups): (1) veal (age in both sexes up to 6 months); (2) beef (bull the age of 6 to 18 months; female and castrated males between the ages of six to 30 months); (3) of cattle (bull the age over 18 months; female and castrated males over the age of 30 months). Within each of these age groups, grading of carcasses is provided according to certain criteria such as: (1) carcass weight (or mass of the two halves); (2) conformation of the carcass; (3) fat tissue covering and meat marbling of carcass; (4) color of muscle and fat, and (5) texture and consistency of muscle and fat tissue.

Weight of the carcass implies carcass with removed skin, head, lower legs (separated in the compartment and the carpal joint), tail and all the viscera thoracic, abdominal and pelvic cavities have been removed, with the exception of kidney and renal adipose tissue. Half is represents the slit carcass along the line of separation, through the center of the vertebrae, pelvic and thorax. A favorable conformation (excellent) of carcass implies that all profiles are extremely well developed and convex. Butch fleshy carcasses have a convex profile, the back are

well developed and wide, and the blades are filled and well-formed. Poor or unfavorable torso / hemisphere conformation is characterized by concave, but poorly developed, back are narrow, the blade is straight and noticeable are convex bones (Regulations of quality of beef carcase and half, Official Gazette of R. of Croatia no. 2/09).
Fat tissue coverage refers to the amount and allocation of subcutaneous, kidney and pelvic fat tissue and residues on the inside surfaces of the chest and abdominal cavity. From a quality point of view, it is considered a favorable overlap when the carcasses or hemispheres have a uniform and well-distributed, continuous, but not too thick layer of fatty tissue.
Following parameters are used for classification of cattle carcasses in the EU countries: carcass weight, category of slaughtered animal according to age and physiological condition, class based on conformation, muscular development of the carcass or half as well as the development of the basic parts (but, the back and shoulders), the degree of coverage of fat tissue, etc. Carcasses or half-carcasses are classified into categories based on the age and physiological status of the animal on: calves (up to eight months old), elderly calves (from eight to 12 months old), heifers (female animals that have not calved), young bulls (up to 24 Month olds), bulls (older than 24 months), castrated male animals and cows (female animals that have calved) (Council Regulation (EC) N° 1234/2007, Commission Regulation (EC) N° 1249/2008; Commission European, Directorate-General for Agriculture and Rural Development).
Based on the development of the carcass, the carcasses are classified into one of six classes according to the system represented in the EU: S (superior), E (excellent), U (very good), R (good), O (fair), and P (poor), image 1.

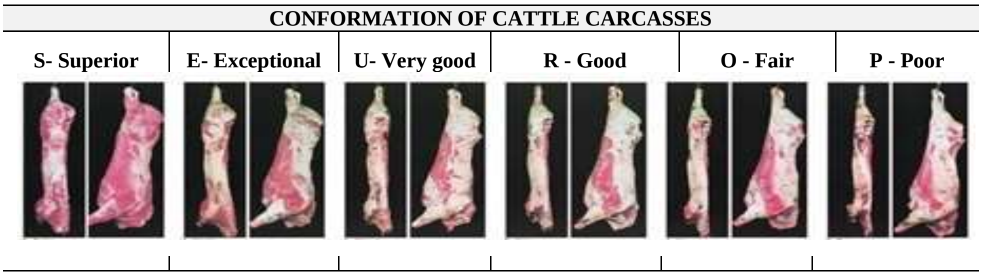

Image 1. Carcass of adult cattle and grading (SEUROP) in EU countries (*Council Regulation (EC) N° 1234/2007, Commission Regulation (EC) N° 1249/2008; Commission European, Directorate-General for Agriculture and Rural Development*)

Fat tissue coverage (Image 2) is assessed by numerical grades from 1 (very low coverage) to 5 (very strong coverage).

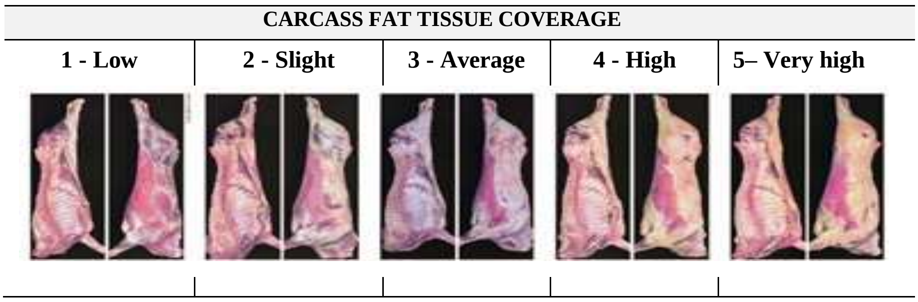

Image 2. Adult cattle carcass fat tissue coverage and evaluation in the EU countries (*Council Regulation (EC) N° 1234/2007, Commission Regulation (EC) N° 1249/2008; Commission European, Directorate-General for Agriculture and Rural Development*)

The study was conducted in the period from 10.07.2014 to 04.08.2014, in one slaughterhouse in the Raska district. The study was included 116 carcasses of young cattle (young bulls) of domestic Simmental breed, which were divided into two groups according to age. The first group were cattle age from 269 to 350 days (n = 78) and the second 351- 450 days (n = 38). The aim of this study was to examine the effect of age of young Simmental cattle (young bulls) to class and fat tissue

coverage degree in slaughterhouse by following appropriate criteria. In order to accomplish this objective, tasks were set to test the quality of beef cattle (bulls) by monitoring the following parameters: live animals mass, slaughtered weight of the carcass, carcass class on the basis of conformation, fat tissue coverage, the accuracy of the slaughter of carcass.
Measuring the weight of the animal prior to slaughter was carried out on the scale with accuracy of ± 0.5 kg, immediately after animals were brought to the slaughterhouse. Measuring the mass of the carcass after slaughter was carried out on the scale with accuracy of ± 0.5 kg, at least 45 minutes after the slaughter. Carcass weight includes processed carcass without internal organs (with the exception of the kidneys), skin, head, lower parts of legs (separated in the lower part of the carpal, tarsal joints is measured respectively), large blood vessels, spinal cord and the genital organs.
At the end of the processing line, assessment of slaughter processing of carcass was performed by the classifier (veterinary or agronomist staff): carcass without internal organs (except kidneys), skin, head, lower parts of the legs (separate in the lower carpal or tarsal joint), large blood vessels, spinal cord and the genitals. After data have been collected, ANOVA procedure was applied for the statistical analysis. Statistical analysis was performed in a statistical package StatsSoft INC (1995).

Results and Discussion

Sampling covered 116 cattle (young bulls). All of the carcasses have been processed adequately.
Table 1 shows the average values per groups that include several parameters: live weight, slaughter weight, carcass class and fat coverage degree for all 116 carcasses of cattle that have been tested.

Table 1. *Phenotypic manifestation and variability of slaughtering characteristics of young bulls of the Simental race, depending on age at slaughter*

Weight before slaughter – *WBS;* Carcass weight – *CW ;* Class of carcass – *COC; Degree of total fat cover (1-5) – DOTFC;* ns - P>0.05; * - P<0.05; ** - P<0.01; *** - P<0.001;

Results from Table 1 indicate that examined groups differed statistically significant (P<0.05) in the weight values of the animals before slaughter and the carcass mass after primary treatment. The average weight of cattle prior to slaughter in the first group was 508.89 kg and 531.2 kg in the second, while the average slaughter weight of the carcass in the first group was 268.83 and 279.97 kg in the second.
Both age groups tested, had identical average class rating - 4.66. Fat tissue coverage degree of carcasses in the first group was assessed with the average score of 3.09, while the average estimated fat tissue coverage degree of the carcasses in the second group was somewhat higher (3.21), but this difference was not statistically confirmed (P>0.05).
Petrović et al. (2017) came to similar results by analyzing the fat tissue coverage degree. The analysis included 123 young bulls. Three categories were stated (2, 3, 4). Only one carcasses was of the category 2. The category 3 was found at 107 carcasses, which is significantly more (p<0.01)

than in the category 2 and in category 4 (15 trunks).) Aleksić et al. (2002) state the following production results of male beef of domestic Simental breed (weight of animals before slaughter 592.7 kg, weight of warm halter with basil 329.9 kg, yield 55.66%. In their experiment, Ostojić et al. (2011) found statistically significant differences ($p<0.01$) between crossbreeds and domestic Simmental breeds in terms of trophic conformation. Crossbreed Charolais achieved best assessment of conformation of carcasses (3.94), however slightly less than in our experiment. Also, significantly more fatt tissue on the outer part of the carcass was found in the domestic Simental breed (3.44) compared to the Charolais crossbreed (3.27). Ostojic et al. (2007) came to similar results in their researches. In 477 days a final weight of Simmental bulls of 579 kg was achieved. In the same study, crossbreed of Charolais and Limousine at a younger age (446 and 443 days) achieved higher body weight at the end of the fattening (621 kg and 590 kg).
Results matching this were also published by Kögel et al. (1995), who found that crossbreed of Simmental with French flesh-colored races, Limousine and Blonde Aquitaine had better slaughter values than the Simental breed: a higher randman, a better conformation of the hull, a larger proportion of muscle, and a smaller proportion of fatt tissue and bones in carcass.

Conclusions

Based on the results and their critical consideration, following can be concluded:
• Average weight of live animals and slaughter weight in the first group (508.89 kg, 268.83 kg) were significantly lower ($P<0.05$) compared to the second group (531.2 kg and 279.97 kg);
• Both examined groups had identical average class rating grades - 4.66;
• There was no significant difference ($P>0.05$) in the fat tissue coverage degree (3.09: 3.21).
Consequently, the obtained results indicate that the age of the bulls does not affect the carcass class and the degree of fat cover.

Abstract

Grains of triticale cultivars from Kragujevac Kg 20, Favorit and Trijumf, produced on the field of Small Grains Research Center in Kragujevac, has been used for fodder mixture preparing. In that moment there are formed four groups of chicken: A group: classical mixture for broiler fattening, B group: mixture with genotype Kg 20, C group: mixture with genotype Favorit and D group: mixture with genotype Trijumf. The feeding experiment lasted 42 days. Based on the recorded productive traits of the examined groups of chicks the researches came to a conclusion that the best results for mortality, feed conversion, production index, average body weight before butchery, handled and cooled carcass weight after 42 days of age are achieved by the group C. The average live body weight on the 42nd day of fattening was the highest in the experimental groups C and D (2054.50 g and 1984.00 g), which is by 5.09% and 1.71% higher than the body weight of the broiler chicks in the group A. Insignificantly higher values for all three dressing yields ("conventional processing", "ready to roast" and "ready to grill") were found in the group C, with the addition of the triticale Favorit (83.18%, 77.73% and 71.20%).

Key words: *broiler chikens, growth, feeding, triticale*

Introduction

Triticale is the very suitable nutrient for all animal variety. Nutritive value of grain depends on protein content in the grain, and therefore the product. Some studies demonstrated that triticale grains are a good source of protein and energy. For example, Emam (2010) and Djekic et al. (2011.a) reported that triticale grains contain 9.5% and 13.20-13.61% for moisture crude protein, respectively.

Triticale is already widely used for poultry worldwide. The quality of poultry products may be modified or enriched by the addition of triticale as a nutrient for animal feed rations, and in recent years there has been considerable scientific interest for the use of triticale in animal feed (Djekic, 2010), but data in the published research in the field of livestock productivity and quality of meat and eggs is scarce in relation to the one of the positive impact of this plant type on ruminants and pigs (Barneveld and Cooper, 2002).

In broiler production studies include the determination of the effect of nutrition using mixtures with different participation/share of triticale, on the performance and both quantitative and qualitative traits of broiler meat. The impact of nutritional value of triticale

on the production traits of heavy line hybrids in the world was studied by numerous international researchers (Emam, 2010), but no domestic studies were ever performed.
The obtained results (Boros, 2002; Djekic et al., 2011.b; Vohra et al., 1991) indicate that triticale has great potential as a feed for feeding chickens and that it could replace wheat, in mixtures for fattening, and that, in fact, there is no significant change in their production and slaughterhouses characteristics. Numerous literature data indicate that the body weight of chickens fed with triticale did not differ significantly from body weight of chickens fed wheat (Djekic, 2010; Korver et al., 2004; Savage et al., 1987). The research results of Hermes and Johanson (2004) showed that triticale in feed for chickens did not have negative effects on production traits of investigated chickens.
The an objective of this research was to determine the effects of the introduction of triticale on the production characteristics of broiler chickens in feeding.

Materials and methods

Winter triticale cultivars Kg 20, Favorit and Trijumf were produced in the 2009 year at the Small Grains Research Centre at Kragujevac location in Serbia (44° 22′ N, 20° 56′ E, 173-220 m a. s. l.) on the smonitza soil in degradation (Vertisol), has been used for fodder mixture preparing. Chickens were assigned in four groups, of 100 birds each. On that occasion, formed four groups of broiler chickens, or treatment, of 100 each in group. Namely, the control group-A (was fed standard mixture), while the experimental groups B, C and D were fed diet containing triticale (mixture with triticale genotypes Kg 20, Favorit and Trijumf). Trial groups received in the same mixture addition of 7.5%, 12%, 15% and 18% triticale. Chickens were fed four basal diets: starter, grower I, grower II and finisher. Ross 308 hybrids were used for the investigations. The research was carried out in 2009, on farm in Kragujevac, central Serbia.

Table 1. *Ingredient composition of the mixtures for feeding broiler chickens*

Diet (%)	Starter		Grower I		Grower II		Finisher	
	C	E	C	E	C	E	C	E
Wheat	40.00	40.00	42.00	35.30	43.10	35.10	48.30	35.10
Corn	19.80	12.20	19.00	13.50	19.10	12.00	18.30	13.50
Triticale		7.50		12.00		15.00		18.00

Diets compositions are presented in Table 1 and chemical composition in Table 2. Fattening of chickens lasted 42 days. During whole chickens growing period water and feed were fed *ad libitum*. During feeding the following parameters were followed health state and mortality. Basic chemical composition (moisture, crude proteins, crude fat and mineral matters) of chicken feed was determined according to official A.O.A.C. (1984).

Table 2. *Chemical composition of the of the mixtures for feeding broiler chickens*

The chemical composition:	Starter				Grower I			
	A	B	C	D	A	B	C	D
Crude protein, %	22.37	22.38	22.40	22.40	20.17	20.20	20.25	20.27
Fat, %	6.36	6.37	6.38	6.38	9.51	9.67	9.46	9.54

Ca, %	1.29	1.20	1.23	1.16	0.79	0.77	0.85	0.85
P (available), %	0.53	0.47	0.37	0.34	0.42	0.42	0.42	0.42
The chemical composition:	Grower II				Finisher			
	A	B	C	D	A	B	C	D
Crude protein, %	19.70	19.64	19.76	19.82	18.42	18.44	18.50	18.49
Fat, %	9.90	9.78	9.72	9.79	8.47	8.68	8.46	8.54
Metabolic energy, MJ/kg	12.86	12.85	12.87	12.87	13.39	13.39	13.40	13.40
Ca, %	0.79	0.77	0.85	0.85	0.88	0.89	0.90	0.90
P (available), %	0.42	0.42	0.42	0.42	0.64	0.64	0.66	0.66

The results were processed statistically by analysis of variance (ANOVA); all calculations were performed in the module Analyst Program SAS/STAT (SAS Institute, 2000). Mean values were compared by Duncan's test at a significance level of 0.05.

Results and discussion

Average body mass of broilers breeds Ross 308 in groups are shown in Table 3.

Table 3. *General performance of broilers given triticale*

Parameters	A	B	C	D
Live weight, g/bird	1950.00^{b}	1935.50^{b}	2054.50^{a}	1984.00^{b}
Feed intake, g/bird	4.222^{b}	4.155^{c}	4.239^{a}	4.177^{b}
Feed conversion ratio	2.414^{b}	2.450^{a}	2.370^{c}	2.406^{b}
Production index	186.56^{b}	184.33^{b}	204.33^{a}	186.52^{b}
Mortality, %	3.0^{c}	2.0^{b}	1.0^{d}	5.0^{a}

[*]Means in the same row wich different superscript are significantly different (p<0.05)

As it could be seen from the presented results, after the six weeks, higher live weight achieved C-group (2054.50 g), had slightly lower body weight than while the A-, B- and D-groups. During the 42th day, live weight of chickens from the experimental C-group which were fed triticale cultivar Favorit in mixture, was higher by 5.09%, respectively, compared to A-group, and live weight of chickens from the D-group which were fed triticale cultivar Trijumf, was higher by 1.71%, of chickens fed mixtures without triticale. At the days 42 of fattening, the body weight of chickens from control A-group, was by 0.74% higher, respectively, compared to the B-group, which were fed triticale in mixtures. Our results are consistent with the results of Djekic et al., (2011.b). Similarly, with broiler chickens, live body weight feed with triticale is not significantly different from the same trait of chicks feed with wheat (Hermes and Johnson, 2004 and Korver et al., 2004). During the entire trial, triticale in the experimental B-group and D-group reduced feed intake by 1.59% and 1.07% compared to the A-group of chickens. Average daily food consumption of chickens in trial C-group during initial and the fattening period was higher by 0.40% compared to A-group. However, the research results of Korver et al. (2004) showed that feed intake with broiler chickens did not differ significantly from the wheat/triticale or corn/triticale based diets. During the finishing period, feed conversion ratios values for chicks fed dry fat B-group (2.450) were significantly lower compared with the

C-group fed triticale cultivar Favorit, but did not differ when compared with the control (A-group) and D-group. The performance index of broiler chickens fed triticale the C-group (204.33) were significantly higher during these periods when compared with those fed the control (186.56) and B (184.33) and D-groups (186.52). Hermes and Johnson (2004) found that feeding broiler chickens triticale up to 15% with corn did not affect their performance. In chickens growing, the most evident positive results of the diet with triticale, low mortality should be emphasized (Table 3). In control and experimental groups (B, C and D) the total number of dead chickens was 3 and 2, 1 and 5 respectively.

Table 4. *Yield of processed carcasses*

Group	Trait	Body mass prior to slaughter, g	Conventional processing		Ready to roast		Ready to grill	
			Mass, g	%	Mass, g	%	Mass, g	%
A	x	1950.00	1695.33	82.82	1531.67	77.51	1416.25	70.54
	Sd	194.665	154.78	3.766	204.654	3.646	195.240	3.507
B	x	1935.50	1634.27	82.09	1495.00	76.33	1385.00	69.92
	Sd	207.892	161.25	2.361	182.685	2.195	173.581	2.026
C	x	2054.50	1773.19	83.18	1615.42	77.73	1453.75	71.20
	Sd	228.466	179.84	1.978	194.158	1.873	169.855	1.785
D	x	1984.00	1665.78	81.06	1522.92	75.68	1369.58	67.70
	Sd	179.224	184.25	3.006	160.262	2.984	135.805	2.986

By analysis of values of slaughter yields "conventional processing" it was established that there were significant differences between investigated groups, whereas the slaughter yield "ready to roast" and "ready to grill" in statistically significant differences (Table 4). Insignificantly higher values for all three dressing yields were established in C-group, with the addition of triticale Favorit (83.18%, 77.73% and 71.20%), followed by group A with the addition of control (82.82%, 77.51% and 70.54%, respectively), followed by group B with the addition of triticale Kg 20 (82.09%, 76.33% and 69.92) and group D (81.06%, 75.68% and 67.70%). The data obtained from the average values of slaughter yield ready to roast slightly higher than results achieved with chickens fed triticale in tests conducted by Rao et al., (1976) and most are in agreement data quoted by Camiruaga et al., (2001). The results presented in this paper are in accordance with those reported by Barneveld and Cooper, (2002), as well as Djekic et al., (2011b; 2012).

Conclusion

The best results on recorded productive traits achieved are of broiler chickens in C group. In regard to slaughter yield (ordinary processing, ready to roast and ready for the grill), the best results are achieved chickens from C group and A group. According to exposed, the conclusion can be that broiler chickens from examined groups are achieved satisfied results of productive and abattoir traits after 42 days. During the finishing period, feed conversion ratios values for chicks fed dry fat B-group were significantly lower compared with the C-group fed triticale cultivar Favorit, but did not different when compared with the control (A-group) and D-group. Performance index of quails fed triticale the C-group were significantly higher during these periods when compared with those fed the control (A-group) and B- and D-groups. Recorded data are showing that triticale had a great potential as fodder in broiler diet because it could be a successful replacement for wheat in broiler diet mixture. It does not affect significant changes in productive and abattoir traits of chicken, in other words broiler chickens body weight feed with triticale is not significantly different from the same trait of broiler chicken feed with wheat.

GENETIC PARAMETERS OF CLAW CONFORMATION IN SLOVAK HOLSTEIN COWS

Michal VLČEK*, Radovan KASARDA

Department of Animal Genetics and Breeding Biology, Slovak University of Agriculture in Nitra, Slovakia
* Corresponding author: xvlcekm@uniag.sk

Abstract

The estimation of heritability of claw measures is needed for implementation of selection indexes, which are used in many European countries in breeding for better claw health and conformation traits. The aim of this study was to estimate the heritability of claw parameters (claw angle, claw length, heel index, claw height, diagonal and claw width were taken after functional claw trimming on lateral side of right hind leg) in Holstein cows in Slovakia. The analysis was based on 482 observations taken from 439 Holstein cows measured between 2012 and 2014 on three farms. On transformed measurements we used animal model with fixed effects as number of lactation, stage of lactation, year of calving, season of calving, year of trimming, season of trimming and sire. Heritability of claw parameters ranged from 0.01 to 0.26. Highest heritability estimate were observed in claw length and claw height. In case of claw angle the heritability was 0.14 and claw width was 0.13. Heritability of heel depth was not estimable. One of possible causes could be small number of observations. Our results are preliminary and further research with higher number of observations and animals is required to obtain more reliable estimates.

Key words: *Holstein, cow, heritability, claw measure, animal model*

Introduction

During the last decade functional traits became more important in all dairy cattle breeding programs as reported Reinhardt et al. (2005).Correct claw conformation and good locomotion of dairy cows are important. Fast increase in dairy herd size over the last decades, and a change from tie stalls to free stalls it is imperative from an economic and welfare point of view to have a good claw health reducing the risk for lameness as reported Uggla et al. (2008). Choi and McDaniel (1993) reported that is necessary to use claw traits in selection index for genetic improvement for economic efficiency and Miglior et al. (2005) reported that traits associated with feet and legs are included by most countries in their national selection index. Boelling et al. (2001) reported that objectively measured traits has high correlation to body conformation traits in the following generation and offer the possibility of improving feet and legs in dairy cattle and Strapák et al. (2011) reported that feet had significant effect to length of productive live. One of possible selection ways for improving of claw health can be indirect selection on correlated conformation traits that are currently recorded as reported van der Waaij et al. (2005). The aim of this study was to estimate the heritability of claw parameters and correlations between them in Holstein cows in Slovakia.

Materials and methods

The parameters of hind lateral claw were observed on 439 Holstein cows kept on 3 farms in west part of Slovakia. The observations were made between 2012 and 2014. Claw measures as claw angle, claw length, heel depth, claw height, diagonal and claw width according to Vermunt and Greenough (1995) were observed. Totally 482 records were included into the study. On transformed measurements the animal model with fixed effects as number of lactation, stage of lactation, year of calving, season of calving, year of trimming, season of trimming and sire was used for the estimation of claw parameters heritability. Statistical analysis, correlations and animal model were in SAS (version 9.2, SAS Institute Inc., Cary, NC) performed.

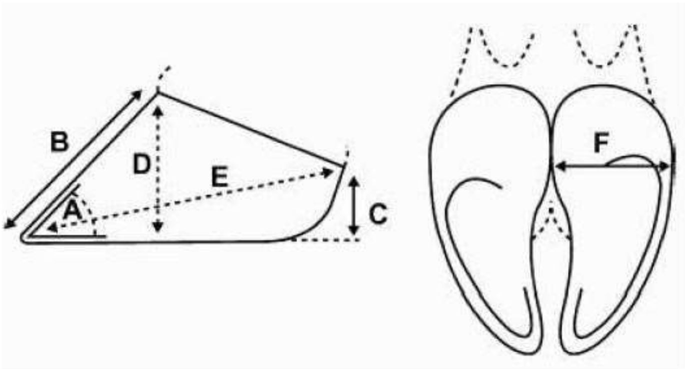

Figure 1 Claw measurements (Vermunt and Greenough, 1995)
A – claw angle, B – claw length, C – heel depth, D – claw height, E – diagonal, F – claw width

Results and discussion

In dataset of 482 observations were found the average values as 49.46 ± 5.73° for claw angle, 78.44 ± 9.87 mm for claw length, 34.21 ± 8.83 mm for heel depth, 69.98 ± 6.16 mm for claw height, 133.18 ± 8.60 mm for diagonal and 56.30 ± 4.60 mm for claw width.

Table 1 Estimated heritabilities on diagonal and phenotypic correlations under diagonal between claw measurements

	A	B	C	D	E	F
A	0.14					
B	0.19399 **<0.0001**	0.26				
C	-0.04947 0.2784	-0.38109 **<0.0001**	-			
D	0.15079 **0.0009**	0.15451 **0.0007**	0.13438 **0.0031**	0.26		
E	-0.0601 0.1877	0.06575 0.1495	0.29789 **<0.0001**	0.22137 **<0.0001**	0.01	
F	0.13935 **0.0022**	0.16111 **0.0004**	0.00187 0.9673	0.27388 **<0.0001**	0.14196 **0.0018**	0.13

A – claw angle, B – claw length, C – heel depth, D – claw height, E – diagonal, F – claw width

The estimated heritability of claw parameters ranged from 0.01 to 0.26. The lowest was estimated for diagonal and the highest for claw length and for claw height (Table 1).

Heritability of heel index was not estimable. One of possible causes could be small number of observations.
In studies of Choi and McDaniel (1993) and Smith et al. (1986) estimated the heritability by using the claw measures. Choi and McDaniel (1993) found the heritabilities for claw angle 0.18, claw length 0.25 and heel depth 0.07. Smit et al. (1986) found the heritabilities 0.16 for angle, 0.26 for length and 0.16 for heel depth. Choi and McDaniel (1993) found higher heritabilities of claw traits for later lactations than for earlier lactations. In present study the heritabilities were not estimated separately for each number of lactation so it was not possible to compare them. Estimated heritability by Smit et al. (1986) and Choi and McDaniel (1993) were very similar to results obtain in present study except the heritability of heel depth, which was not estimable. Similar heritability of claw angle also found Boelling et al. (2001), Onyiro and Brotherstone (2008) and Laursen et al. (2009). Boelling et al. (2001) reported 0.11 for Jersey, 0.13 for Danish Friesian and 0.15 for Danish red dairy cows. Onyiro and Brotherstone (2008) reported 0.11 and Laursen et al. (2009) reported 0.13 for heritability of claw angle. Uggla et al. (2008) fund the heritability of claw angle 0.16 for Swedish Holstein and 0.23 for Swedish Red.. Van der Waaij et al. (2005) reported 0.18. Häggman et al. (2013) estimated the heritability 0.7 and Ødegård et al. (2015) found 0.9 for claw angle. The heritabilities estimated in studies of Boelling et al. (2001), Uggla et al. (2008), Laursen et al. (2009),Häggman et al. (2013) and Ødegård et al. (2015) were estimated by using the conformation traits with linear scale from 1 to 9. Van der Waaij et al. (2005) used the same evaluation but for trait feet and legs they used points from 70 (poor) to 89 (very good) and also Onyiro and Brotherstone (2008), but for trait leg and feet composite they used points from 65 (poor) to 95 (excellent). On the other hand, in present study the heritabilities were estimated with using the claw measures. In general the heritabilities estimated in present study are similar to heritabilities found in previous studies. Riecka et al. (2008) found the highest positive correlations between claw length and claw height. In this study the highest positive correlations were found between heel depth to diagonal and claw height and claw width. The highest negative correlations were found in claw length and heel depth. Riecka et al. (2008) reported the highest negative correlations in claw angle to claw width. Haggman and Juga (2013) found small negative correlations of foot angle to side and rear view of rear leg as conformation trait. Associations of higher claw angle and shorter claw length with longer lives of individual cows reported Choi and McDaniel (1993). Also Onyiro and Brotherstone (2008) found that steeper foot angle and well-fitted mammary systems are associated with better locomotion.

Conclusion

Correct claw conformation is important for better locomotion and longevity. It is necessary to use claw parameters in selection indexes for genetic improvement. This can lead to longer productive life and finally to lower number of culled cows per year and better economic efficiency of dairy industry. Our results are preliminary and further research with higher number of observations and animals is required to obtain more reliable estimates.

Abstract

The aim of this study was to prepare a low cost custom genotyping array to service all of requirements for dairy cattle breeders. Our study presents the panel of SNPs mainly with respect to the needs of Pinzgau cattle breeders in Slovakia. Overall 152 animals, representing the genepool of active Slovak Pinzgau population, were genotyped with Illumina bovine SNP50 BeadChip. The quality control of data was carried out to remove any markers assigned to unmapped regions, SNPs with unknown chromosomal position and loci positioned to sex chromosomes. The following control of genotyping data were performed to exclude any autosomal loci with call rate lower than 90%, minor allele frequency lower than 0.05 and HWE limit of 0.0001. The final dataset was composed of 41,720 autosomal loci covering overall length 2,500,315 kb of the genome. To produce the low-density array only SNPs located in the regions near genes significantly associated with dairy production according to the previously published studies were selected. Subsequently, the genetic potential of analysed animals was evaluated in order to fulfil farmers' requirements and also in broader sense to achieve the genetic improvement of breed. Despite the fact that the high density SNP arrays are currently utilized for many purposes, the challenge for the cattle industry still remains to successfully present and incorporate this technology to the common practice on farms. One of the ways how to do this is to prepare low cost custom genotyping panel in view of farmers' requirements.

Keywords: *breeding program, bovine SNP panel, dual-purpose breeds, Pinzgau cattle.*

Introduction

Currently, development and advancement in the area of genomic technologies provide new opportunities for genetic improvement of livestock production as well as fitness traits. Genomic tools are used for various purposes, including genetic evaluation (Kasarda et al., 2015; Kukučková et al., 2017), parentage verification (McClure et al., 2013; Lyons et al., 2015), screening for recessive disorders (Sonstegard et al., 2013; Agerholm et al., 2016) and other mutations with large effect on production and reproduction traits in different cattle breeds (Nayeri et al., 2016; Magalhães et al., 2016). Many of these studies are routinely performed independently of each other and based on different genotyping arrays (Khatkar et al., 2012; Mullen et al., 2013). However, the relatively high cost of animals' genotyping, even by using commercially available low-density Illumina arrays, prevents its widespread use and application to common practice on farms. One of the ways how to reduce the cost of genotyping for an animal is to use of arrays with even lower SNPs density that can be if necessary imputed up to higher number of markers (Dassonneville et al., 2012; Piccoli et al., 2014; Judge et al., 2016).
A number of SNP genotyping platforms are available for cattle, including 3K (Wiggans et al., 2012), 7K (Boichard et al., 2012), 15K (Khatkar et al., 2007), 25K (Raadsma et al., 2009),

50K (Matukumalli et al., 2009) and more recently 700K from Illumina, and 650K and 3 million SNP panels from Affymetrix. In addition, the NGS technology (next generation sequencing) with decreased cost and increased sequencing speed is currently available also for livestock species (Bai et al., 2012). Although the use of genotyping data from those high-throughput SNP arrays can improve the accuracy of genomic selection, it also may increase the total genotyping or sequencing costs. Therefore for some application, low-density SNP array e.g. 3-7K can be cost effective alternative in comparison to application of high density arrays (for example selection of heifers to be kept in dairy or beef production system) (Khatkar et al., 2012). On the other hand the utilization of low-density SNP arrays and subsequent imputation of genotyping data can be also promising way how to reduce costs of genotyping and increase the number of genotyped animals (Mulder et al., 2012). Selection of markers for low-density arrays can be based on several possible strategies (Moser et al., 2010; Mullen et al., 2013; Szyda et al., 2013; Judge et al., 2016).
The aim of this study was to prepare a low-density genotyping array to service all of requirements for breeders of Pinzgau cattle in order to obtain extensively information of animal's genetic potential based on SNPs located in the QTL genomic regions affecting milk production and mastitis resistance.

Materials and Methods

The sampled population of Slovak Pinzgau cattle covered living animals: 37 sires representing active breeding bulls (19 animals) and AI doses deposited in reproduction centres (18 animals), 35 dams (mother of breeding bulls) and 80 cows. All of animals have been genotyped in commercial lab for 54,906 SNPs using Illumina BovineSNP50 BeadChip V2 (Illumina Inc., San Diego, CA). The quality control of genotyping data was performed by PLINK (Purcell et al., 2007). In first step, all of markers assigned to unmapped regions or with unknown chromosomal position according to the latest bovine genome assembly (Btau 4.0) and SNPs positioned to sex chromosomes were removed (1723). In the subsequent quality control of genotyping data only autosomal SNPs with a call rate higher than 90%, minor allele frequency (MAF) higher than 0.01 that adhered to mendelian inheritance patterns, and did not deviate from Hardy-Weinberg equilibrium (HWE limit of $1x10^{-5}$) were retained.
The selection of genetic markers in order to prepare low cost custom genotyping SNP panel was based on the quantitative trait locus (QTL) database containing candidate genes for mammary gland development, milk production, and mastitis resistance. The database of QTL genomic regions with appropriate candidate loci was created based on the information stored in the Cattle Quantitative Trait Locus Database (Cattle QTLdb) (http://www.animalgenome.org). After selection of specific QTL genomic regions corresponding map file was generated to retain only loci of interest in resulting low-density SNP array. The final dataset based on reduced low-density SNP panel, containing 4133 candidate loci, was prepared by using PLINK (Purcell et al., 2007).

Results and discussion

All samples have been genotyped successfully (99.23% of SNPs) with average call rate 99.77%. Obtained level of call rate was comparable with previously reported results for various dairy or beef cattle breeds (Cooper et al., 2013; Mullen et al., 2013). After quality control of genotyping data in total of 41,720 autosomal loci were identified as polymorphic and covered overall length 2,500,315 kb of the genome. The total number of detected polymorphic loci in the present study was higher compared to results of Mai et al. (2010) or

Hulsegge et al. (2013). The minor allele frequency, referring to distribution of the least common SNP allele, reached the level 0.28 ± 0.11.

Despite the fact that the high density SNP arrays are currently utilized for many purposes, the challenge still remains how to successfully present and integrate this technology to the common practice on farms. As presented many studies (Miller, 2010; Pryce and Hayes, 2012; Saatchi and Garrick, 2014; Judge et al., 2016) one of the ways may be the utilization of low-density arrays. In present study the low-density SNP panel was prepared firstly to decrease cost of genotyping and secondly to increase number of genotyped animals with respect to the current requirements of Pinzgau cattle breeders. The SNPs were selected to obtain comprehensive information of QTL genomic regions important for milk production and mastitis related traits. In the future, selection of animals with core genotypes can increase not only genetic potential of an individual but also the economic value of traits of interest in a genetic improvement program of a breed.

In order to prepare a low cost custom genotyping panel overall 4133 markers were selected from 50K genotyping array. The database of usable loci was prepared by using information stored in the Cattle Quantitative Trait Locus Database that contains cattle QTL and association data resulting from current published studies. Generally, the Cattle QTLdb database is designed to facilitate the process for users to compare, confirm, and locate the most likely location of the genes responsible for the quantitative traits relevant to cattle production. With regard to obtain extensively information of animal's genetic potential based on SNPs located in the QTL regions for milk production and resistance to mastitis totally 16 genomic regions was selected. Figure 1 shows the distribution of selected SNPs across bovine autosomes obtained in our study. Most of SNPs were located on the BTA5 (1062), whereas the lowest proportion of SNPs was found for BTA11 (6). Across selected genomic regions in reduced SNP panel 4583 genes have been identified using the NCBI database (https://www.ncbi.nlm.nih.gov). Description of selected genomic regions and identified genes linked to milk production and occurrence of mastitis is listed in Table 1. We found 39 candidate genes of which 29 were significantly associated with production of milk, 5 with resistance to mastitis and 5 with both traits.

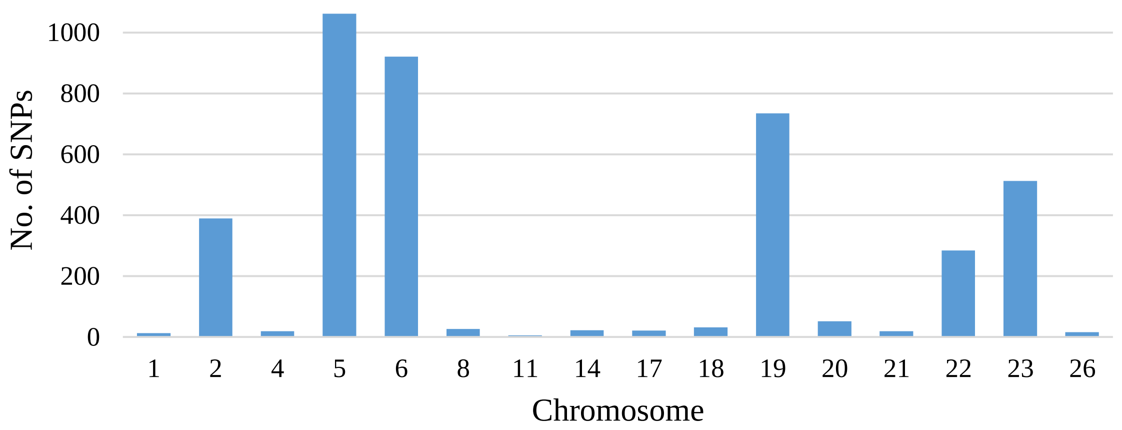

Figure 1. Distribution of selected SNPs across chromosome in low-density SNP panel

The highest number of genes linked to dairy performance was found on the BTA6. One of the most important gene family located on the BTA6 is casein family. The casein family consists of genes (*CSN1S1*, *CSN1S2*, *CSN2*, *CSN3*, *LALBA*, *LGB*) that exist in different genetic variants. Each of these variant encode chemically different protein. In addition, each of the genetic variant of milk proteins affects milk composition and cheese make ability in a different way (Ogorevc et al., 2009). Until now, many studies reported significant impact of casein genes on milk yield as well as its composition (Miciński et al., 2007; Hristov et al., 2012; Deb et al., 2014). Among the other genes identified in the same area on BTA6 belong *PPARGC1*, *SPP1*, and *ABCG* genes. Each of these genes have been previously significantly associated with milk production (Weikard et al., 2005; Leonard et al., 2005; Olsen et al., 2007). For mastitis overall 10 genes were identified within reduced SNP panel (*IL8RA*, *IL8RB*, *TLR4*, *CYP11B1*, *FGF2*, *NOD2*, *CCR2*, *FEZF2*, *LTF*, and *BoLA-DRB3*). The significance of their impact on mastitis related traits has been studied mainly through expression experiments (e.g. Pant et al., 2007; Wang et al., 2007; Kaupe et al. 2007; Leyva-Bacca et al. 2008).

Table 1. Description of genomic regions included in low-density SNP panel and corresponding candidate genes involved in control of milk production and mastitis resistance (Author s' elaboration based on the obtained results)

Chr.	Start position (Mb)	End position (Mb)	No. of genes in region	Genes for milk production and mastitis related traits	Gene name
1	35.01	36.04	10	POU1F1	POU class 1 homeobox 1
2	83.35	110.79	289	IL8RA	Interleukin 8 receptor, alpha
				IL8RB	Interleukin 8 receptor, beta
				CYP27A1	Cytochrome P450 Family 27 Subfamily A Member 1
				STAT1	Signal transducer and activator of transcription 1
4	93.04	96.03	19	LEP	Leptin
5	34.00	107.34	1072	IGF1	Insulin-like growth factor 1
				LALBA	Lactalbumin, alpha
				OLR1	Oxidized low density lipoprotein (lectin-like) receptor 1
6	37.02	88.59	411	PPARGC1A	Peroxisome proliferative activated receptor, gamma, coactivator 1 alpha
				ABCG2	ATP-binding cassette, sub-family G (WHITE), member 2
				SPP1	Secreted phosphoprotein 1
				CSN1S1	Casein alpha s1
				SCN1S2	Casein alpha s2
				CSN2	Casein beta
				CSN3	Casein kappa
8	112.02	112.97	26	TLR4	Toll-like receptor 4
11	107.02	107.25	17	IL1A	Interleukin 1 alpha
				IL1B	Interleukin 1 beta
				POMC	Pro-opiomelanocortin
14	1.70	2.83	80	DGAT1	Diacylglycerol O-acyltransferase 1

				SERPI1A1	Serine protease inhibitor
				IGHG1	Immunoglobulin Heavy Constant Gamma 1
21	33.09	34.24	32	IGHG2	Immunoglobulin Heavy Constant Gamma 2
				IGHG3	Immunoglobulin Heavy Constant Gamma 3
				FEZF2	Fez family zinc finger 2
22	39.03	54.40	320	LTF	Lactoferrin
				CCR2	Chemokine (C-C motif) receptor 2
				PRL	Prolactin
23	7.00	35.57	967	MHC complex	Major histocompatibility complex
26	21.06	21.98	26	SCD	Stearoyl-CoA desaturase

Conclusions

Despite the fact that the high density SNP arrays are currently utilized for many purposes, the challenge for the cattle industry still remains to successfully present and realize this technology to the common practice on farms. One of the ways how to do this is to prepare low cost custom genotyping array in view of farmers' requirements. The use of low-density SNP arrays can be promising way how to reduce costs of genotyping and increase the number of genotyped animals. We prepared the low density SNP panel in order to provide farmers extensively information of animal's genetic potential with respect to increase of milk production and animals' resistance to mastitis occurrence. With respect to genetic improvement programs, the selection of animals with favourable genotype can increase not only genetic potential of an individual but also the economic value of traits of interest.

Abstract

This is the first on-farm study looking at the influence of spraying laying hens with two non-toxic bird repellents on feather coverage on six body regions, egg quality and laying performance of the Slovenian Prelux-R layer strain. A total of 180 18-wk-old non trimmed cage hens were randomly assigned into 3 treatment groups (P, T, C) with 6 replicates of 10 birds each (60 hens per group) and for 20 weeks at two week intervals sprayed with two dimethyl anthranilate-based repellents (P and T), each being used on one group of the birds. Group C served as a control group, sprayed with distilled water only. Mean body weights of laying hens at the start of first experimental period, at 26 weeks of age were 2083.42 ± 156.69, 2107.08 ± 194.76 and 2078.75 ± 183.96 g for the P, T and C groups, respectively. We found that hens sprayed with repellents T and P had greater ($P<0.05$) feed intake than group C. The dispersion of repellent T significantly ($P<0.05$) increased the albumen pH and yolk diameter and decreased the egg shape index compared with group P. The egg shell strength and yolk pH were significantly ($P<0.05$) lowered with T treatment in comparison with C group. The administration of the repellents resulted in poorer feather condition compared with group C. The yolk from group P was more intensively ($P<0.05$) coloured than the yolk in other groups. There were no other differences between the treatments. Based on these results, we can conclude that physical egg quality, plumage condition and especially feed intake in commercial flocks of laying hens can be significantly influenced by feather spraying with bird repellents.

Introduction

In laying hens, feather cover condition during the laying period is known to be affected by moulting, abrasion and feather pecking. Bad feather cover may lead to a greater skin exposure, which results in greater heat loss due to deteriorated heat insulation and as a consequence to a greater feed intake in cold seasons (Glatz, 2001). Feather pecking is a well-known behavioural disorder in all domestic poultry species (hens, turkeys, ducks, etc.). It is characterized as a painful feather removal (with bleeding) that can consequently lead to cannibalism (Harlander-Matauschek and Rodenburg, 2011). The poultry industry is often criticized for using beak trimming to solve the problem of feather pecking and cannibalism. Beak trimming, both by hot-blade and infra-red techniques, has significant adverse consequences for laying hens' welfare and should be avoided. Recognising that the requirement to stop routine beak trimming represents a major technical challenge to the poultry industry the goal of the study was to develop an animal-friendly method for preventing feather pecking and cannibalism and eliminating beak trimming by using non-harmful repellents. Many studies (e.g. Hile et al., 2004; Lourdes et al., 2016; Linz and

Homan, 2013; Ahmad et al., 2016) have been conducted where different aversive tastants were used for preventing crop damage caused by pest birds by treating the birds edibles. Research evidence of using repellents for preventing feather pecking under commercial farm conditions is scarce. There are only few studies (e.g. Harlander-Matauschek et al., 2009, 2010) that report repellency effects of substances applied on the laying hens which lead to a reduction in feather pecking among them. The main objective of our study was to find out if the application of different non-toxic bird repellents would have a significant improvement in feather coverage. Additionally, we were interested to look at the impact of the dimethyl anthranilate-based taste repellents on the production traits.

Material and methods

Animals and housing system

A total of 180 non-trimmed Prelux-R brown strain hens, hybrids from Slovenian silver-gold cross (silver female × gold male) were used. The chicks were first raised on floor pen on litter until the age of 18 weeks. At the age of 18 weeks, the pullets were randomly assigned to 3 experimental groups and transferred to enriched battery cages (Facco, Italy). Each experimental group consisted of 6 replicated cages comprising 10 layers. The cages were in 3 tiers. Hens in each group were put into cages in upper, middle and bottom levels. Cage was considered the experimental unit, giving 6 replicates per treatment. All birds were marked individually by metal leg rings. Layer chicks got chick starter feed up to ten weeks of age (11,9 MJ ME kg-1; 20% crude protein), at ten weeks they were changed over to grower feed (11,4 MJ ME kg-1, 15% crude protein) and at eighteen weeks they were changed over to layer ration (11,3 MJ ME kg-1; 16,2% crude protein**).** Feed in crumble form and water were supplied *ad libitum* throughout the experimental period. All feeding mixtures were purchased from Jata Emona Ltd. animal feed manufacturer (Ljubljana, Slovenia). The light regimen consisted of 15 h of red light and 9 h of dark. The average light intensity measured at the feeding trough level varied from 0.3 to 3.3 lux. The study was conducted with birds from 20 weeks of age until 40 weeks of age and comprised 2 periods (Period I = 26 to 28 weeks; Period II = 38 to 40 weeks).

Repellent application

Control birds (group C) were sprayed with distilled water only. Hens in the group P were sprayed with a repellent P containing in terms of percent by weight 0.78 dimethyl anthranilate, 12.5 methyl phenyl acetate and 86.7 propylene glycol and hens in the group T with a repellent T containing in terms of parts by weight 4.5 dimethyl anthranilate, 0.5 geraniol, 5.0 Tween 80 and 90.0 distilled water. Compressed air spray paint guns were used for repellent and distilled water dispersion. During the pilot study, we experimentally determined that 300 ml of liquid sprayed over one group of birds (60 hens in 6 cages) is sufficient to ensure good coverage of plumage areas needing protection. Each experimental group of birds was subjected to a spray treatment at 14 day intervals from 20 weeks of age onwards.

Data collection

Four classes of variables were measured: variables concerning feather cover; those related to egg production, egg and shell quality; those related to body weight and those concerning feed intake. For feather condition evaluation the scoring system of Tauson et. al (2005) was used. Scores, varying from 1 to 4 were given for each of the following body parts: back, wings, tail, cloaca area, neck and breast. Higher scores represented better feather condition. Feather condition was scored individually, at the age of 20, 26 and 38 weeks. Over the two periods of

14 successive days between the ages od 26-28 and 38-40 weeks feed intake was measured. Daily feed intake was calculated for each cage by subtracting the left over feed in the feeder from the total weight of feed given during that day. Egg production was recorded daily. Hen-day egg production for a particular day and cage was calculated by dividing the total number of eggs produced on a day in a cage by the total number of hens present on that day in a cage and multiplying by 100 to convert to a percentage. Hen-housed egg production for a particular day was reached by dividing the total number of eggs laid on a day in a cage by the total number of hens housed at the beginning of the experiment in a cage and multiplying the resulting quotient by 100 to convert it to a percentage. Egg quality parameters were determined at the end of each experimental period. A total of 272 eggs were randomly collected from 3 groups and analyzed for the following physical characteristics: egg width, length and weight, colour and strength of egg shell, yolk diameter and colour, height of albumen. Based on egg weight and albumen height, the Haugh units were calculated. Shape index was calculated using the formula: shape index = (egg width, cm/egg length, cm) × 100. Yolk diameter, egg length and width were measured with digital caliper, egg shell strength with Instron 3342 device (Instron, USA). All other characteristics were measured with a set of electronic apparatus developed at the University of York, Great Britain (Technical Services and Supplies, York). Albumen and yolk pH were measured with S47-K Seven Multi dual meter pH/conductivity (Mettler-Toledo, Switzerland) device.

Statistical analysis

Data obtained were subjected to statistical analysis using the GLM (feather condition scores) and MIXED (feed intake, egg production, egg quality) procedures of SAS Institute (2008). The sum of the scores of the six body parts and the sum of the scores for back and vent/cloaca were used for analysis. Data of feed intake, egg production and egg quality were untransformed. Experimental period and treatment group were the fixed effects and cage was random effect. When the main effects were significant at $P<0.05$, differences between means were tested using Tukey's test.

Results and discussion

The usage of repellents affected the cumulative plumage variable back+vent/cloaca as well as the variable total feather score ($P<0.05$). For the variable back+vent/cloaca, hens from treatment C (7.81±0.05) had the highest feather score compared to hens from P (7.66±0.05) and T (7.57±0.05). Looking at the variable total feather score, hens from treatment C (23.4±0.08) had the highest feather score compared to hens from P and T (22.9±0.08). Hence it is evident from this comparative study that the use of two repellents didn’t improve feather cover when compared with hens in the control group. This result is not in accordance with study results of Harlander-Matauschek and Rodenburg (2011) who reported that soaking feathers in eleven chemical substances reduced feather plucking and consumption. However, results from our study are not directly comparable with those from the Harlander-Matauschek and Rodenburg (2011) for several reasons but mainly because of different experimental conditions and different repellents used. Different distasteful substances have different active repellent ingredients and probably have different lasting effect on different bird senses. The results will most likely become clearer by the end of this on-going study.

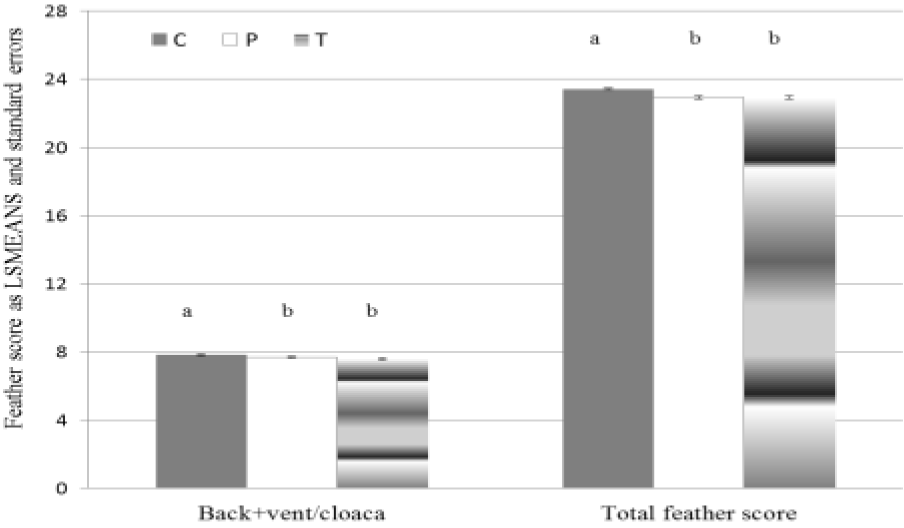

Fig. 1: The feather condition by treatment (C - control, P - repellent P, T - repellent T). [a,b,] Means followed by the different letters are significantly different (P < 0.05)

A non-significant (P>0.05) difference was found when compared the effect of repellent application on the body weight of hens at the start of the second experimental period. Thus, it can be concluded, that repellents did not affect the weight of laying hens during the experimental period. At 38 weeks of age the body weights of the three experimental groups were in terms of LSM ± SE 2124.41 ± 26.60, 2173.77 ± 27.29 and 2119.03 ± 27.29 g for the P, T and C groups, respectively. The peak hen-day egg production was at 84,97%, for the hens from C group, 83,71 % for the hens from T group and 82,68% for the hens from P. During the experimental period (20-40 weeks of age), the overall percentage of hen-day egg production was not significantly different between the three treatments. At the 40 weeks of age, differences in egg production were also insignificant between the groups (P>0.05). Our results differ from Yamak and Sarica (2012) who found the positive correlation between the better plumage condition and the increased egg production. The feed consumption in T (average 138.24 ± 1.16 g/hen/day) and P groups (average 135.21 ± 1.16 g/hen/day) were significantly (P<0.05) higher in compared to C group (average 130.20 ± 1.16 g/hen/day). This could be explained by the better feather cover of hens in C group. These hens may as a consequence have better heat insulation and a lower feed intake request. Similarly, Glatz (2001) reported that naked hens compared to fully feathered birds consume 31 g/bird (18 °C) to 41 g/bird (15 °C) more feed. A significant difference (P<0.05) was also found in the feed consumption between the two experimental periods (Table 1). Hens in the second experimental period consumed significantly more feed than the hens in the first period. This was expected in regards to a higher body weight of older laying hens in the second period. In agreement with the present results, Leeson and Summers (1987), Harms et al. (1982) and Lacin et al. (2008) reported that feed consumption increased as the body weight of hens increased.

Table 1: Feed intake (g) by experimental period and treatment group

Trait	Experimental period	Treatment group	LSM ± SE
Feed intake (g/hen/day)	Period I		132.35 ± 0.949[a]
	Period II		136.75 ± 0.949[b]
		C	130.20 ± 1.163
		P	135.21 ± 1.163[a]
		T	138.24 ± 1.163[a]

LSM – estimated mean value of trait, calculated using the least squares method, SE – standard error of estimation; [a,b,c] Means followed by the different letters in the same column are significantly different ($P < 0.05$)

Table 2 shows the egg quality parameters of experimental periods and treatment groups. Egg shape index, yolk diameter, albumen pH, yolk pH, shell colour and strength were affected by the particular experimental period (I, II). There were significant differences among C and T groups for shape index, yolk diameter, albumen pH, yolk pH and egg shell strength. P group had lower yolk pH value, shell colour and yolk colour than hens placed in C group (Table 2). Walker and Hughes (1998) reported that hens who have experienced stress retain eggs in their oviduct for prolonged periods of time leading to deposition of calcium carbonate and consequently whiter eggs. The darker egg shell colour in the repellent groups as well as nonsignificant differences in egg production indicate that the welfare status of hens was similar in both treatments and was not worse in comparison to control group. The yolk diameter of eggs from the 2nd experimental period was greater due to a larger egg weight. It is a general consensus that older hens lay heavier eggs than younger hens (Perić et al., 2017) and this was further supported in this study. On the other hand, the egg shell strength decreases with increasing hen age (Perić et al., 2017), that was the reason for lower shell strength of eggs from 2nd experimental period.

Table 2: Egg quality traits by experimental period and treatment group

Trait	Experimental period	Treatment group	LSM ± SE
Egg shape index	Period I		76.66 ± 0.192[a]

	Period II		41.18 ± 0.746[b]
		C	44.08 ± 0.798[a]
		P	43.04 ± 0.789[ab]
		T	41.11 ± 0.803[b]

Conclusions

In conclusion, this study shows that the use of two repellent compounds influenced some important parameters of laying performance and egg quality in commercially reared laying hens. Daily feed consumption was found to be higher in repellent treated groups than in the control group. Body weight, egg production and egg weight variables were similar in all experimental groups. However, some measures of egg quality, e.g., egg shell strength and yolk diameter were significantly worse in T group in comparison to C group. Feather condition was better in C hens than in P and T hens. Since feather scores provide information about the welfare status of the hens we can conclude that spraying repellents in our study did not improve feather cover (welfare status) but the final results will be seen at the end of our one year lasting study.

Abstract

Natural additives, particularly essential oils, phenolic and aromatic compounds and some secondary metabolites originated from herbal sources became popular at last decades in ruminant nutrition by limiting or banning the use of antibiotics, performance enhancers and other growth promoters. In brief, these products help in providing better ruminal ecosystem, preventing excess degradation of soluble protein in rumen and maintaining ruminal ammonia and decreasing energy losses. Consequently, this leads not only to enhancing protein and energy utilization but also to elevating milk production and herd health status of dairy cattle. The objective of this work is to determine the duration of the effect of herbal mixtures on group fed dairy cattle at initial and post-trial period practically and, to determine the reflections of group milk yield. In this study, 98 days-data of high milk producing group (average N, 165) was evaluated for yield, protein, fat, lactose and dry matter contents of milk. Herbal mixture commercially formulated containing aromatic compounds with tannin was added to diet as "on top" 20 g day^{-1} per head. Observation period is described as three session before test (BT-without supplement), test (T), after test (AT- without supplement) and, 18 days, 43 days and 37 days respectively. It was observed that milk yield increased and continued to rise until supplement removing date. While milk protein increasing, milk fat is decreased in (T) test period. There was no decrease in milk yield during the 17 days of the AT. It may be concluded that herbal mixtures can help in sustaining milk production.

Keywords: *Herbal mixtures, additive, dairy cow, nutrition.*

Introduction

A healthy rumen should produce volatile fatty acids, supply microbial protein and support energy and protein metabolism by helping rumen microorganisms during fermentation process. To ensure ruminal fermentation many feed additives such as ionophore antibiotics are widely used to maintain better ruminal ecosystem and to increase feed efficiency since January 1st, 2006 in EU and also in Turkey. Afterwards, by the end of 2005, EU Commission announced to ban ionophore antibiotics already used as growth promoters like Monensin, Salinomycin, Avilamycin and Flavophospholipol (EC, 2005). Meanwhile, natural additives, particularly essential oils, phenolic and aromatic compounds and some secondary metabolites originated from herbal sources became popular at last decades in ruminant nutrition by limiting or banning the use of antibiotics, performance enhancers and other growth promoters (Wallace et al, 2002; Benchaar et al, 2009; Patra and Yu, 2012; Matloup et al, 2017). Actually, herbal sources are well known products since ancient times and the dates back to Mesopotamia (Greathead, 2003; Benchaar. and Greathead, 2011). A great variety of them used for human health and Benchaar et al, 2011 are stated it briefly in their respectable review. In addition to these studies, in recent years, there have also been some essential oil

studies for the preservation of foods with their antimicrobial properties (Calo et al, 2015). In brief, these products help in providing better ruminal ecosystem, preventing excess degradation of soluble protein in rumen and maintaining ruminal ammonia and decreasing energy losses (Anantasook, 2016). Consequently, this leads not only to enhancing protein and energy utilization but also to elevating milk production and herd health status of dairy cattle.
The objective of this work is to determine the duration of the effect of herbal mixtures on group fed dairy cattle at initial and post-trial period practically and, to determine the reflections of group milk yield.

Material and Methods

In this field case study, 98 days of test day milk records and milk analysis data obtained from a private farm, dates from October, 1st 2016 to February, 6th 2017 is evaluated. Subjected to research group size of dairy cattle is continuously changed during the test period between minimum 151 and maximum 175 heads and averagely 165.75 heads. Lactation statuses of cattle are changed between 111 and 144 days in milk (DIM), averagely 123.58 and all of test group is accepted homogenous. Similarly, dairy cattle are fed in one group and consumed the same diet during the observation period. Diet is consisted of corn silage, alfalfa hay, wheat straw, compound feed and by-pass fat. Diet composition is given below in Table 1. All cattle consumed same diet. Tested aromatic mixture containing tannin (58800 mg/kg), Valopro is given “on top” 20 g daily per head. Valopro is provided by Tecnofirm Yem Katkı Maddeleri Gıda Hayvancılık İlaç Sanayi ve Ticaret Ltd Şti., İzmir, Turkey. Observation period is described as three session before test (BT-without supplement), test (T), after test (AT-without supplement) and, 18 days, 43 days and 37 days respectively. Dairy cattle are milked three times in a day with 2 x 8 milking system and daily milk production is recorded. Protein, fat, lactose and dry matter contents of milk samples are analysed daily by Bentley 150 Infrared Milk Analyzer. Descriptive statistics of collected data is analysed by SPSS Statistical software.

Table 1. Diet ingredients*

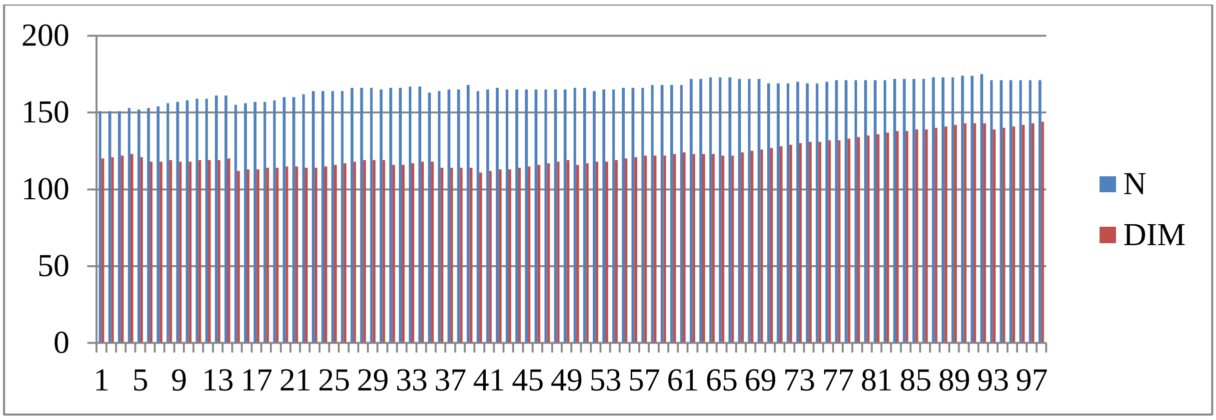
Ingredients	As fed, kg	As fed, %	Dry Matter, kg
Corn silage 32.2% DM, 29.8% Starch, 810 Kcal/kg ME	22,5	52,02	7,25
Wheat straw	0,5	1,16	0,44
Alfalfa 18% CP	4,75	10,98	4,13
Compound feed 23% CP, 3000 kcal/kg ME	15	34,68	13,35
By-pass fat	0,5	1,16	0,45

*Due to the preliminary private farm study, only available analysed results given in the table. All cows are consumed same diet.

Results and Discussion

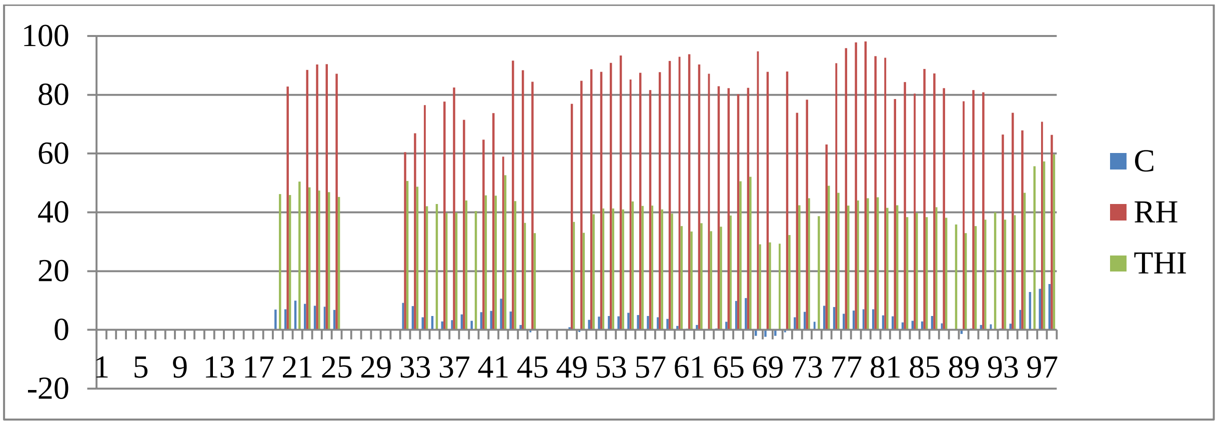
Number of dairy cattle and their days in milk status is given in Figure 1. As described above in material chapter, the group is accepted homogenous.

Figure 1.Group size and cattle's DIM status



During the 98 days of study, observed climatic conditions and calculated temperature humidity index (THI) is given in Figure 2 below. Average, minimum and maximum temperatures are observed 4.5 ^{0}C, -2.4 ^{0}C and 15.6 ^{0}C, respectively. Whole period relative humidity (RH) and THI values are observed 82.6% (min. 58.9%, max.98.2%) and, 41.8% (min.29.1%, max. 59.7%), respectively. According to available data, during the experiment time, climatic conditions is accepted similar.

Figure 2. Climatic conditions of whole period



As described above, whole experimental period evaluated three sessions. In Table 2 and Figure1, whole period, before test, test and after test descriptive statistics of milk yield (MY), milk fat, milk protein, milk lactose and milk dry matter contents are given detailed.

Table 2. Descriptive statistics of measured parameters

		N	Minimum	Maximum	Mean	Std. Err.
Whole Period	MY	98	31,0	36,0	34,15	,1196
	Fat	91	3,1	3,8	3,39	,0108

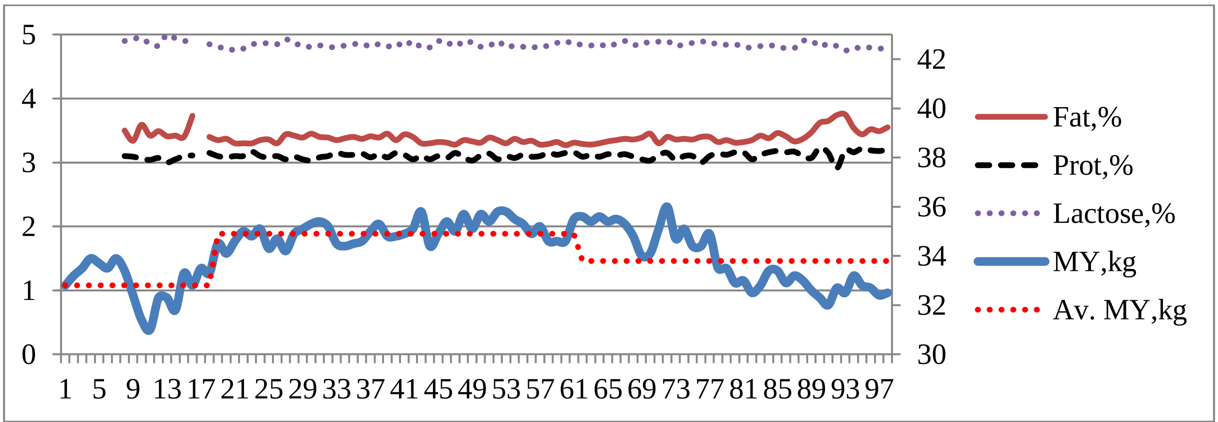
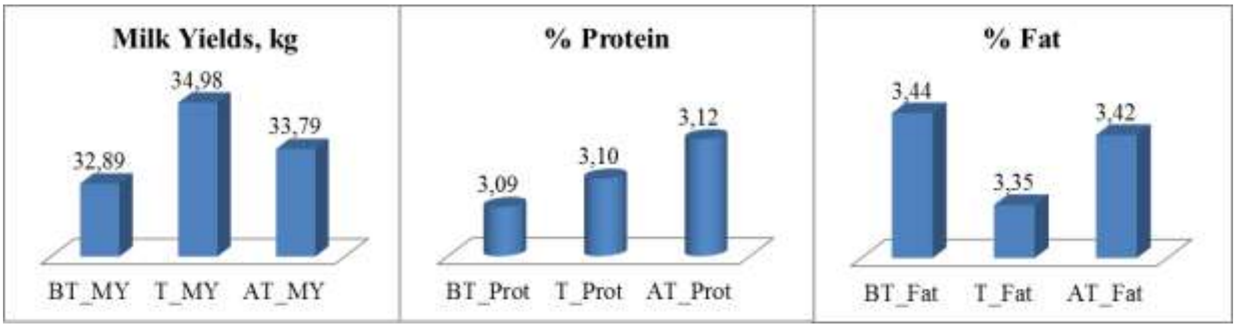
	AT_DM	37	11,6	12,6	12,02	,0528

Figure1. Changes of milk yield and milk components



According to the collected data, it is observed that Valopro aromatic herbal mixture increased milk yield and milk protein. First 18 days, without supplement, milk yields and other ilk components of group were recorded. Then, from day 19 to 61, 43 days long, supplement was added. When supplement is cut off on 61st day (last day of 43 days test period), an ongoing effect of aromatic compound for 17 days until 78th day of experiment without supplement was observed.

Figure 3. Effect of supplement on milk yield, milk protein and milk fat during test period.



With supplementation of aromatic compound, milk yield of group is increased to 2.09 kg and it can be concluded that the supplement established convenient rumen conditions. Milk increase is agreed with many studies results Benchaar et al, 2007; Matloup et al, 2017. The essential oils prevent deamination of protein and N sources in rumen and support microbial protein production while decreasing ammonia production. That means more efficient protein and energy utilization in the digestive system (McIntosh, 2003; Castillejos et al, 2006; Calsamiglia et al, 2007; Canbolat et al, 2011; Flores et al, 2013). Similarly, milk protein percentage increased particularly "after test period" and the remarkable increase is observed at 0.03% level. Probably, additional tannin in the aromatic mixture ensured this effect (Decruyenaere, 1996; González et al, 2002; Wanapat et al, 2013; Lui et al, 2016). But, on the other hand, milk fat content is decreased. This result can be attributed to the adverse effect of essential oils on milk fat percentage (Benchaar et al, 2006; Calsamiglia et al, 2007). (Figure 3).

Conclusions

As a result of this study, it can be concluded from current observations, supplementation of Valopro aromatic mixture seemed to have positive effect on milk yield not only during supplementation period but also without supplemented post 17 days long at group fed dairy cattle. After supplement added to TMR, the effect was observed in one week. Although milk production and protein content affected positively, milk fat percentage decreased. Further studies will be helpful.

Abstract

In goat breeding, several traits can be explained not by the single variable, but by the possible connection of the common several dependent or independent variables. For this purpose, the mentioned variables must be taken together and defined multi-dimensionally. In this study; the relationships of herd, year of birth, birth type, sex, weight at birth, weight at thirty day of age and weight at weaning age effects of Turkish Hair Goats were investigated by canonic correlation analysis. The data were utilized from 1020 male and 1011 female Hair goat kids which were born in the period 2013 until 2016. The herd, year of birth, birth type and sex are analyzed as first set of variables (X); weight at birth, weight at thirty day of age and weight at weaning age effects are analyzed as second set of variables (Y). By performing canonical correlation analysis, canonical correlations between the first, second and third pair of canonical variates were estimated and three canonical correlation were found significant ($P < 0.01$). The biggest correlations between year of birth, sex, birth type variables and v1, v2 and v3 canonical variates were found -0.77%, 0.87% and -0.82%, respectively. The biggest correlations between weight at birth, weight at thirty day of age and weight at weaning age and w1, w2 and w3 canonical variates were found 0.84%, -0.97% and -0.78%, respectively. As a result it has been determined that sex and birth type plays an important role in the formation of the goat kid's body weights.

Keywords: *Hair Goat, Canonic correlation, Body weight*

Introduction

Turkey is taking a very important position with geographic location and livestock production of Europe. In the last 15 years, goat is one of the two species that has significantly increased in population of the World. This increase could be due to the scarce conditions created by global warming or the better understanding of the importance of goat products. In terms of goat population Turkey is ranked 23th in the world, seventh in Europe. Also Turkey 9.2 million goats which is represent 63% of the European Union goat population. 23.3% of the small ruminants in Turkey are goats and 98% of this consists of hair goats (Ataç and Burcu, 2014; TUIK, 2013). Milk often comes to mind when goat or goat farming is mentioned. However, the goats are mostly used for their meat. This is primarily due to the fact that most goat farmers are mainly from villages in mountainous and forested areas where they implement traditional farming, and the farmers do not have the courage, strength or reason to change these traditional methods. Additionally they do not have any financial or moral support, they are unaware or ignorant of any support available to them, and generally there is inadequate support given to agriculture, especially in small ruminant farming in Turkey. Often the farmers would add some of the born and surviving kids to the rest of the herd. The remaining goats are sold around 3-4 months old in Turkey's western regions and as adults towards the eastern regions (Ataç and Burcu, 2014).

Most studies on hair goats have been on the cross breeding of the goats out of their natural habitats and at intensive enterprises. As hair goats are the dominant goat breed in Turkey, great variations can be observed in its outer features even in the same herd (Ataç and Burcu, 2014). The technical specifications of businesses in Turkey raising goats are summarized as follows (Kaymakçı and Engindeniz, 2012; Ataç and Burcu, 2014). Canonical correlation analysis is a multivariate technique that generalization of multiple regression analysis. This analysis describes the relationship between two variable sets by calculating the linear combinations which are maximally correlated (Tabachnick and Fidel, 2001). It was used to identify the combination of variables that best separate the two genetic groups. This technique has gained acceptance in various scientific fields such as psychology, social science, animal science, ecology, education etc. In goat breeding however, there are a few studies (Keskin *et al.*, 2005; Çankaya and Kayaalp, 2007) that canonical correlation analysis was applied. Keskin *et al.* (2005) were studied the relationships between some characters of Akkeçi kids. They investigated the pre-slaughtering and post-slaughtering by using canonical correlation analysis. Seven pre-slaughtering characters (slaughter weight, body length, wither height, heart girth depth, heart girth width, heart girth circumference, leg circumference) constituted the X variable set while eight post-slaughtering characters (head weight, feet weight, skin weight, omental and mesenteric fat weight, weights of heart, lung, and liver, spleen weight, hot carcass weight, and cold carcass weight) constituted the Y variable set. The correlation between the first canonical variable pair was found as 0.962. Çankaya and Kayaalp (2007) were applied to canonical correlation analysis to estimate the relationship between eight different morphologic characters (X set – height at withers, body length, chest width, chest girth, chest depth, front, middle and hind rump width and the live weights at three different periods (Y set – birth weight, weaning weight and weight at sixth month) from 86 kids of German Fawn x Hair Crossbred at Çukurova University. They estimated significant canonical correlation coefficient as 0.931 between the first pair of canonical variables. In this study, relationships among the herd, year of birth, birth type, sex, weight at birth, weight at thirty day of age and weight at weaning age effects of Turkish Hair Goats were investigated by canonical correlation analysis. For this purpose, the data obtained from the farms cultivated under the few semi-intensive and most extensive conditions, without intervention in growing conditions, were evaluated by canonical correlation analysis.

Material and Methods

Material

The material of this study consist of 1020 male and 1011 female Hair goat kids which were born in the period 2013 until 2016 in Aegean region of Turkey, Izmir-Karaburun. The herd, year of birth, birth type and sex are analyzed as first set of variables (X); weight at birth, weight at thirty day of age and weight at weaning age effects are analyzed as second set of variables (Y) which are illustrated as shown: Y_1 is weight at birth, Y_2 is weight at thirty day of age, Y_3 is weight at weaning age, X_1 is herd, X_2 is year of birth, X_3 is birth type and X_4 is sex.

Method

Canonical correlation analysis linear combinations of the variables in two sets of variables. Therefore, useful for predictive or comparative purposes the canonical variates representing the optimal linear combinations of dependent and independent variables and the canonical correlation showing the relationship between them are results of interest (Hair *et al.*, 1998). W_m and V_m are canonical variates are defined as below:

$$W_m = a_{m1}X_1 + a_{m2}X_2 + ... + a_{mp}X_p$$

$$V_m = b_{m1}Y_1 + b_{m2}Y_2 + ... + b_{mq}Y_q$$

The canonical correlation (C_m) is the correlation between W_m and V_m. Canonical roots or eigenvalues represents the amount of variance in one canonical variate accounted for by the other canonical variate (Hair *et al.,* 1998). When the canonical correlation is maximum the canonical coefficients (a_{m1}, a_{m2},......a_{mp} and b_{m1}, b_{m2},.......b_{mq}) were estimated. The maximization technique as follows: Let the first group of p variables is represented by the random vector, $X_{(px1)}$, and the second group of q variables is represented by the random vector, $Y_{(qx1)}$. For the random vectors X and Y, population mean and (co)variances would be as:

$$E(X) = \mu \qquad E(Y) = \mu \qquad Cov(X) = \Sigma_{11} \quad Cov(Y) = \Sigma_{22} \qquad Cov(X,Y) = \Sigma_{12} = \Sigma_{21}^{'}$$

Furthermore, X and Y random vectors and (co)variance matrices can be written as follows:

$$\begin{bmatrix} X_{px1} \\ Y_{qx1} \end{bmatrix} = \begin{bmatrix} X_1 \\ X_2 \\ \vdots \\ X_p \\ Y_1 \\ Y_2 \\ \vdots \\ Y_q \end{bmatrix}; \qquad \Sigma = \begin{bmatrix} \Sigma_{11_{pxp}} & \Sigma_{12_{pxq}} \\ \Sigma_{21_{qxp}} & \Sigma_{22_{qxq}} \end{bmatrix}$$

So that, a linear combination of the components of X and the components of Y would be W=a'X and V=b'Y, respectively. Then, W and V have expectation of zero and (co)variances as:

$$\text{var}(W) = a^{'}Cov(X)a = a^{'}\Sigma_{11}a \qquad \text{var}(V) = b^{'}Cov(Y)b = b^{'}\Sigma_{22}b$$

$$\text{cov}(W,V) = a^{'}Cov(X,Y)b = a^{'}\Sigma_{12}b.$$

For testing the statistical significance of the canonical correlations used the Wilks' lambda test statistic is used.

Large canonical correlation always does not mean that there is a powerful relationship between the two sets of the traits. Because canonical correlation maximizes the correlation between linear combination of variables in two groups and not maximizes the amount of variances accounted for in one set of variables by the other set of variables. Therefore, it is suggested to calculate the redundancy measure for each canonical correlation to determine how much of the variance in one set of variables is accounted for by the other set of variables (Sharma, 1996).

The canonical correlation analysis was performed by means of PROC CANCORR procedure of SAS 9.0 software (2002).

Results and Discussion

The correlations between the variables were analyzed by canonical correlation analysis. These correlations give us the chance to estimate the correlation between two sets of variables including more than one trait in each at the same time. Because, the number of canonical correlations that needs to be interpreted is minimum number of traits within X or Y set. Estimated canonical correlations between the pairs of canonical variates were found 0.33, 0.27 and 0.088 and to be significant (P<0.01) from likelihood ratio test given in Table 1. Significance of likelihood ratio test is also equal to the significance of Wilks' Λ.

Table 1. Canonical correlations between two sets of variables, eigen values, likelihood ratios and their probabilities

	Canonical correlation	Squared canonical correlation	Degrees of freedom	Eigen values	Likelihood ratio	Probability Pr>F
1	0.33	0.11	12	0.12	0.82	<0.0001
2	0.27	0.07	6	0.08	0.92	<0.0001
3	0.088	0.008	2	0.008	0.99	0.0004

In present study, the canonical correlations between all pair of canonical variates were found to be significant from the likelihood ratio test in table 1. On the other hand, Tatar and Elçin (2002) and Çankaya and Kayaalp (2007) found only the first coefficient significant among all estimated conanical correlation coefficients ($P<0.001$). Estimated canonical correlation was the highest (0.33) for the first pair of canonical variates (W_1 and V_1) but the smallest (0.088) for the third pair of variates (W_3 and V_3). It seems that herd, year of birth, birth type and sex are correlated with weight at birth, weight at thirty day and weight at weaning age.
The coefficients of canonical variates obtained from the raw data are given in Table 2 Magnitudes of these weights represent their relative contributions to the related variate.

Table 2. Canonical coefficients of variates

	W1	W2	W3		V1	V2	V3
Herd	0.418	0.384	0.409	Weight at birth	-0.00005	-0.0004	-0.00011
Year of birth	-0.949	-0.370	-0.061	Weight at thirty day	0.00009	0.00004	0.00017
Birth type	-0.794	0.478	2.564	Weight at weaning age	0.0011	0.00002	-0.0008
Sex	-0.723	1.720	-0.716				

Because of the coefficients of canonical equations are not unique, they should be scaled that the resulting canonical variates have a mean of zero and variance of one. Standardized canonical coefficients or canonical weights for the *X* and *Y* variables are given in Table 3. Magnitude of these weights represents their relative contribution to the related variate

Table 3. Standardized canonical coefficients of variates

	W_1	W_2	W_3		V_1	V_2	V_3
Herd	0.465	0.427	0.456	Weight at birth	-0.0120	-1.0641	-0.2920
Year of birth	-0.893	-0.348	-0.0580	Weight at thirty day	0.5350	0.2192	0.9426
Birth type	-0.259	0.156	0.8372	Weight at weaning age	0.8112	0.1489	-0.5700
Sex	-0.361	0.860	-0.3583				

There is high positive standardized canonical coefficients for weight at thirty day at V_3 (0.9426). It follows by weight at weaning age (0.8112) and weight at thirty day at V_1.

Table 4. Correlations between the variables and related canonical variates (canonical loadings)

	W1	W2	W3		V1	V2	V3
Herd	0.2120	0.3284	0.4475	Weight at birth	0.2398	-0.9668	0.0887
Year of birth	-0.7702	-0.2334	0.1249	Weight at thirty day	0.5876	-0.2203	0.7786
Birth type	-0.3224	0.1781	0.8216	Weight at weaning age	0.8488	0.1310	-0.5122
Sex	-0.3587	0.8722	-0.3213				

Table 5. Correlations between the variables and the other set of canonical variates (canonical cross loadings)

	W_1	W_2	W_3		V_1	V_2	V_3
Herd	0.0700	0.0891	0.0396	Weight at birth	0.0791	-0.2624	0.0078
Year of birth	-0.2542	-0.0633	0.0111	Weight at thirty day	0.1939	-0.0598	0.0689
Birth type	-0.1064	0.0483	0.0727	Weight at weaning age	0.2801	0.0356	-0.0453
Sex	-0.1184	0.2367	-0.0284				

The loadings are shown in Table 5. The loadings for the weight at birth, weight at thirty day and weight at weaning age suggest that weight at weaning age is the most influential variable in forming V_1 compared to weight at birth and weight at thirty day. On the other hand, for the second pair of canonical variate V_2, weight at birth and weight at thirty day are about equally negatively influential in forming V_2. For the last canonical variate V_3, weight at weaning age has negatively impact in forming V_3. When the investigate he loadings for herd, year of birth, birth type and sex, it seems that only herd has positively and the others have about equally influential in forming W_1 (Table 5). While the loadings ignore the presence of the other variables, canonical coefficients give the contribution of each variable in the presence of all the other variables. Therefore, canonical coefficients are important to determine the importance of each variable in canonical variates. However, loadings provide substantive meaning for the canonical variates (Akbaş and Takma, 2005).

Conclusions

It can be concluded that canonical correlation analysis has been able to determine the relationships between the variable sets and it is an appropriate method to obtained the correlated patterns of traits in Hair goats.

Abstract

The gilthead sea bream is a large demanding marine fish which is popular in Turkey and other Mediterranean countries. After the European sea bass, it is the second most cultured species in Turkey with a well-designed protocol of growing. Nevertheless, as a result of high product necessities, high stock density and feeding with high energy dense diets, fish liver accumulates lipid droplets that can cause fatty liver. On the other hand skeleton deformations are very significant biological problem in finfish hatcheries affected by various biotic and abiotic factors and affect 5-20% on average of the young fish. In this sense, in this study, the researchers compared the effects of different tank shapes (38 tons raceway and 130 tons cylindrical) and two differently formulated diets on the liver histology and external morphology of the gilthead sea bream with two repetitions. At the beginning, the fish were separated into two groups; the Group A (38 t raceway and 130 t cylindrical) was lasted for 27 days and comprised 2.149,487 fish and the Group B (38 t raceway and 130 t cylindrical) lasted for 29 days and comprised 2.193,689 fish. At the end of the study, there was no statistically difference of biomass between the two groups ($p>0.05$). The Group A was weighed 3,474 kg and the Group B weighed 3,511 kg. Survival rates were 93% for the both groups. The last weight of the Group A was 1,733 gr and the Group B was 1,709 ($p>0.05$). FCR were calculated 1.13 and 1.05; SGR were 3.47 and 3.91, skeleton deformations were 0.19% and 0.18% at the beginning of the study, 0.14% and 0.13% at the end of the study, respectively. The deformations were mostly found on the vertebrae, less on head, jaw and mouth. In histological results, during the study in the Group A all fish showed moderately fatty liver and in the Group B 50% of the livers were moderately fatty and rest 50% were fatty.

Key words: *Gilthead sea bream, Sparus aurata, Histology, Liver, Growth.*

Introduction

Gilthead sea bream is one of the major cultured finfish in the Mediterranean area and second most cultured fish after European sea bass in Turkey. However still there are some problems such as fatty internal organs and skeletal deformities in commercially are run gilthead sea bream farms. For satisfying animal protein demand with increasing human population, producers feed their fish with high energy dense diets (Dalay *et al.*, 2013; Shrivastava *et al.*, 2013). High energy demanding feeding with high stock density have been resulted with accumulations of fat in the internal organs and symptoms generally occour at the fish liver (Storch and Juario, 1983; Caballero *et al.*, 1999; 2004), which shows fatty sendrom has been explained with nutritional imbalance, increasing dietary lipid content (Caballero *et al.*, 1999), high protein sources (Shrivastava *et al.*, 2013), an essential fatty acid deficiency (Montero *et* *al*., 2001) and the inclusion of vegetable oils (Alexis, 1997; Caballero *et al*., 2002) in gilthead sea bream. This abnormal accumulation of lipid (triglycerides) in hepatocytes can also affects fish survival (Dalay *et al*., 2013; Shrivastava *et al*., 2013). On the other hand, skeleton deformations affect seriously production costs by external morphology, grown and survival rate of fish (Koumoundouros et al., 2002; Fernandez *et al*., 2008). Beside broodstock and egg quality, some biotic (air bladder formation, some parasites et.) and abiotic factors (light, temperature, salinity et.) (Koumoundouros *et al*., 1997; Cobcroft and Battaglene, 2009), also nutritional conditions are very important in bone development especially in larval also young fish period (Mazurais *et al*., 2009; Tocher, 2010; Boglione *et al*., 2013). The objectives of this study were effects of different type tank shapes and different formulated diets on deformation and liver fatty syndrom in young gilthead sea bream.

Material and Methods

Study was conducted in a commercial marine fish farm Muğla/Turkey. It was lasted in 29 days from September to October in 2015 and samples were evaluated in laboratory of Department of Aquaculture Engineering, Adnan Menderes University. Two different shaped tanks were used and two different formulated commercial diets were applied and results were evaluated regarding to effects on fish growth. At the beginning, ramdomly 100 juvenils put into either 38 tons rectangular raceway or 130 tons cylindrical tanks. Fish was feed with 4-6% of their biomass during the study. Bimass was calculated at the beginning 0,5 kg/m3 and planned as 4,5 kg/m3 at the end of the study. Study design was showed in Table 1 and diet contents was in Table 2. Water temperature was stabilized at 24,68±0,41 ºC during the study. Other parameters oxygen and pH were calculated as 11,70±1,04 mg/L and pH 7,82±0,15 respectively. At the beginning, every sampling days (every 10 days) and end of the study 50 samples were obtained from tanks ramdomly. Samples was measured for total lenght, total weigth, dry weigth, visseral organs weigth, FCR and spesific growth rate (SGR).

Table 1. Study design

Diet A	Diet B
38 tons raceway (2 tanks)	38 tons raceway (2 tanks)
130 tons cylindrical (2 tanks)	130 tons cylindrical (2 tanks)

Table 2. Chemical composition of the experimental diets (g/100g dry matter)

Extruder Granule Diet	Diet A	Diet B
Crude protein	58	62
Lipid	9	14
Ash	10	9
Cellulose	1,4	0,5
Phosphor	1,7	1,5

*Source: Author s' elaboration based on the obtained results

For observation skeleton deformations, fish were sampled at the beginnig and at the end of study. Samples were anaesthetised (Ethylene Glycol Monopehyl Ether, Merck, 0.2-0.5 ml/lt) and taken photos (Nikon Coolpix 5000, Japan) on the left side, then observed under light microscope. Total leght was calculated from these photos by computer programme (TpsDig/ Ver. 1.37) (Çoban *et al*, 2007).
For the histologic sampling, at the beginning, every sampling days (every 10 days) and end of the study 50 samples were obtained and put into 10% formalin solution. As represent visceral

organs, liver and spleen were cut with cryostat (Leica CM 1100) at 5-6 μ. After Hematoxylin and Eosin staining slides were examined by light microscope (Novex Cmex DC 5000). Degree of fatty liver was evaluated visually under light microscope and took micro photos with micro camera (Culling *et al*., 1985; Timur, 2013).

Results and Discussion

For optimal growth and minumum costs on final fish, fish meal percent, lipid content in diet and their quality are critically important in marine fish culture (Andrades *et al*., 1996; Caballero *et al*., 1999; Boglione *et al*., 2001; Caballero *et al*., 2002). Also, liver is a important indicator in fish feeding studies regarding to histological structure (Caballero *et al*., 1999; 2004). These feeding studies showed effects of different lipid sources (vegetable and fish oils) (Tucker et al., 1997, Benedito-Pallos *et al*., 2008, Caballero *et al*., 2002, Wassef *et al*., 2007), different lipid percent and different quality fish meal (Caballero *et al*., 1999) on fish growth and liver histology. Different vegetable oils (soybean, menhaden, rapeseed, palm and olive) and fish oils (capelin and anchovy) can be used as an alternative lipid sources (Tucker *et al*., 1997, (Caballero *et al*., 2002). When vegetable oils were used partially 33, 66% (Benedito-Pallos et al., 2008) and 60% (Wassef et al., 2007), fish showed accumulation of lipid droplets in cytoplasm of hepatocytes in different amount which shifted cytoplasmic organeles and nuclei to cell wall by lipid droplets (Wassef et al., 2007). When studied different fish lipid content (15, 22, 27%), liver showed same nuclei displacement in 22 and 27% lipid content (Caballero *et al*., 1999). Also, when 50% of total oil was switched with soybean oil results showed that SGR became lower from 1,81±0,05 to 1,72±0,13, FCR changed from 0,726±0,03 to 0,723±0,02 (Caballero *et al*., 2002).
In present study, fish was in Group A and B, liver similar to prior studies (Benedito-Pallos et al., 2008; Caballero *et al*., 1999, 2002; Wassef et al., 2007) nuclei was shifted to cell wall by lipid droplets, but also in Group B 50% of the livers were similar Group A, others had bigger lipid droblets than Group A for both cylindirical and raceway tanks. Spleens had no any inflammation findings. In spleens, major cells lymphocytes and erythrocytes showed normal morphology. According to histological results, there was more fatty livers in Group B.

Table 3. Growth parameters during experiment

Parameters	Group A	Group B
Beginning of Experiment		
Total Fish (number)	2.149,487	2.193,689
Biomass (kg)	594	612
Weight (g.fish-1)	0,276	0,278
Length (mm. fish-1)	3,094	5,185
End of the Experiment		
Total Fish (number)	2.004,572	2.053,530
Biomass (kg)	3,474	3,511
Weight (g.fish-1)	1,733	1,709
Length (mm. fish-1)	3,094	6,503
Survive (%)	93	93
FCR	1,13	1,05
SGR (%)	3,47	3,91

*Source: Author s' elaboration based on the obtained results

In culture systems, there are plenty of tank types depend on voice hydrodynamic, water quality and other biological, economic and ergonomic principles (Cripps and Poxton, 1992;

Planas and Cunha, 1999; Başaran et al., 2004). In some studies, for turbot, tanks were shallow, circular and had light gradient (Cripps and Poxton, 1992), while for gilthead sea bream larvae, tanks were 5-15 tons circular tanks (Başaran *et al*., 2004) were used succesfully. Depend on results of present study both circular and raceway tanks worked with similar performance.

Morphometrically growth is effected by culture type, water parameters, feeding diversity, growth performance and specific morphometry in commercial fish farms (Wiegand *et al*., 1989; Andrades *et al*., 1996; Boglione *et al*., 2001). Morphometric deformities may depend on high stock density, insufficient feeding (Kanazawa, 1985) and some genetical factors (Aulstand and Kittelsen, 1971). Morpho anatomical anomalies responsible for 5% of total product of fish farms and final product were affected badly (Marino *et al*., 1993; Çoban *et al*., 2007). According to Boglione *et al*., (2001), gilthead sea bream showed hemal and caudal region deformations particularly and Andrades *et al*., (1996) showed that adult gilthead sea bream mostly showed vertebral deformities. Similar to prior studies, our results showed deformations mostly found on the vertebrae, less on head, jaw and mouth. In this study, according to deformations results at the beginning and at the end of the study (Table 4), different tank shapes and diets had no effect differently for young gilthead sea bream in culture conditions.

Based on Table 3 there was no statistically difference of biomass and last weight between the two groups ($p>0.05$) at the end of the study. Survival rates were 93% for the both groups. According to these results, there was no important difference between different tank shapes and diets with regard to biomass, weight and survival parameters.

At 78 DAH, visseral organs weight was 0,098±0,029 mgr and dry weight was 0,085±0,043 mgr for both groups. End of the study at 105 DAH for Group A, visseral organs weight 0,351±0,098 mg, dry weight 0,505±0,156 mgr, while at 107 DAH for Group B, visseral organs weight 0,575±0,156 mgr and dry weight 1,083±0,403 mgr. According to these results in Group B both visseral organ and dry weight were more higher. When compared two groups according to SGR and FCR (Table 3), Group B had more efficiently results for both different tank shapes and different diets.

Table 4. Skeleton deformations

		Fish number	Vertebral deformities		Head, jaw, mouth		Total deformation rate (%)
			Number	Rate (%)	Number	Rate (%)	
Diet A	Beginnig	1348	205	0,15	48	0,04	0,19
	Final	617	43	0,07	43	0,07	0,14
Diet B	Beginning	1017	160	0,16	22	0,02	0,18
	Final	620	59	0,10	23	0,04	0,13

*Source: Author s' elaboration based on the obtained results

Conclusions

Mediterrenean aquaculture is a enormous productive sector depends on European sea bass and gilthead sea bream. While this sector works high productively with well designed culture protocoles still there is some bottlenecks like skeleton deformations, some illness, fatty visceral organs et. Thus, scientific researches are valuable to better fish culture management. For this reasons, in this study different tank shapes and different formulated diets were researched to see their effects on fish development. Depend on the results, SGR, FCR and dry weight were better in Group B and in histological results there was bigger lipid droblets in liver hepatocytes in Group B for both different tank shapes and different diets. Also there was no mortality by fatty liver syndrom. According to all these results we concluded that raceway or cylindrical tank shapes had no different effects importantly on young gilthead sea bream with respect to biomass, weight, survival parameters and deformations. Also according to different formulated diets, there was no difference between different crude protein (58 and 62%) and different lipid (9 and 14%) content on fish growth. There was only Group B had a better SGR and FCR may these results come from more qualified egg and larvae were used at the beginning in Group B. It can be suggested that these results will be helpful in the future in commercial gilthead sea bream farms.

Abstract

Sheep farming in arid and semi-arid regions of Algeria faces large fluctuations in the availability of fodder. This deficiency is particularly burdensome for pregnant ewes whose needs are the maximum. This situation will lead to the appearance of metabolic disorders such as subclinical pregnancy toxemia. The present study was conducted to determine the biochemical profile of ewes in late pregnancy with this metabolic disorder. Blood samples were obtained from eighty ewes in late pregnancy (2 to 4 weeks of lambing), aged 3 to 5 years, clinically healthy, multiparous, from eight farms located in an arid area of South Eastern Algeria. Serum concentrations of glucose, cholesterol, triglycerides, and beta-hydroxbutyrate, were determined using specific commercial kits. Ewes were classified as having subclinical pregnancy toxemia or as controls on the basis of BHB results. Biochemical results were compared between the 2 groups using the statistical software Epi Info (version 3.4.3. November 8, 2007), Differences were considered significant when $p <0.05$. The metabolic profile of sick animals was characterized by significantly lower ($p<0.01$) serum glucose and triglycerides, and significantly elevated ($p < 0.05$) rates of cholesterol, and beta-hydroxbutyrate. Pregnancy Toxemia is a major problem in the sheep industry and early dosage of ketone bodies B-hydroxybutyrate in the six weeks before lambing prevent and reduce economic losses caused by this desease.

Key words: *biochemical profile, Ouled Djellal sheep, subclinical pregnancy toxemia, late gestation*

Introduction

The sheep is a gregarious and rustic animal. It adapts to many climatic conditions. It is found in almost all the latitudes of the globe. It makes it possible to develop pastures that are difficult to access for other species or for agricultural machines. Due to the current economic imperatives, the breeder demands more and more performance from his herd. The sheep has therefore not escaped the modernization and the intensification of its breeding. This search for maximum profitability in the sheep sector has led to new diseases linked directly to the breeding conditions. As a result, we are confronted with diseases whose origin is no longer an infectious agent but a disorder of the metabolism such as the pregnancy toxemia. Pregnancy toxemia is a metabolic disease of ewes, occurring during late pregnancy and with a high mortality rate (Caldeira and al., 2007). It occurs independently of age or breed of animals, but ewes carrying twin or triplet fetuses are more prone to develop the disorder (Firat and Ozpinar, 2002; Sargison, 2007). Poor nutrition of ewes, especially during late pregnancy, also predisposes to the disease (Liamadis and Mills, 2007). This study was performed to evaluate serum biochemical findings in Ouled Djellal ewes in late pregnancy with subclinical pregnancy toxemia.

Materials and methods

Animals

This study concerned Ouled Djellal ewes, an excellent meat breed adapted to arid area, which is dominant in the region. Pastoralists practice extensive and semi-extensive breeding. Animals are left outdoors during the day during most of the year. In winter, they are kept completely in the sheepfold only for a limited period, depending on the weather conditions. Group antiparasitic treatments, without distinction between young and adult, are generally carried out in early spring and autumn. The Ouled Djellal breed is seasoned; the rams are permanently in the herds and the fight is free. The lambing takes place mostly in the autumn but begin in September. Young animals and adults use the same pasture.
The livestock concerned by the present study is composed of 80 clinically healthy Ouled Djellal ewes, in the last trimester of pregnancy from 08 herds in an arid area of South Eastern Algeria, multiparous and primiparous, aged between 3 and 5 years.
The ewes were divided into two groups according to the results achieved in the serum BHB.

Blood samples

Blood samples were taken by puncturing the jugular vein at 7 am before feeding in sterile heparinized tubes and then centrifuged at 1500 g for 10 minutes at 4 ° C. The corresponding plasmas were stored at -20 ° C. until analyzed. The assays were based on biological constants (glucose, cholesterol, triglycerides, and BHB). The serum BHB concentration is determined by the enzymatic method with a commercial kit, following the manufacturer's instructions. The serum concentration of β-hydroxybutyrate is used as a reference method for determining subclinical ketosis (Schultz and Myers, 1959, Herdt and al., 1981, Andersson and Lundstrom, 1984).

Results and discussion

Table 01: Blood metabolites concentrations in ewes having subclinical pregnancy toxemia and controls group

	Ketotic ewes **n=30**	**Control group** **n=50**
BHB (mmol/l)	0.91±0.25*	0.49±0.15
Glucose (g/l)	0.30±0.21*	0.45±0.32**
Cholesterol (g/l)	0.70±0.23*	0.48 ±019*
Triglycerid (g/l)	0.33±0.23	0.40±0.29

*p<0.05 **p<0.01

The results show that thirty sheep were suffering from subclinical pregnancy toxemia (BHB > 0.86 mmol / L), and fifty ewes constituted the control group (BHB ≤ 0.86 mmol / L).
The determination of blood glucose and serum level of B-hydroxybutyrate is very important for the early diagnosis of pregnancy toxemia as reported by Bickhardt and König (1985), because hypoglycemia and hypercetonemia are the biochemical symptoms characteristic of the disease (Fırat and Özpınar, 2002). Furthermore, it has been suggested that blood ketone body levels in ruminants can be considered as an indicator of their energy status (Bowden, 1971). During the final 6 weeks of pregnancy, plasma concentrations of BHB less than 0.8, 0.8–1.6 and greater than 1.6 mmol/l represent adequately nourished, moderately undernourished and severely undernourished ewes, respectively .

In late pregnancy, fetal growth is rapid and the demands for energy are markedly increased. Although glucose is the primary metabolic fuel and is absolutely essential for vital organ function, fetal growth and milk production, it is an insensitive measure of energy status, as it is subject to tight homeostatic regulation.
From the results mentioned in Table 01 we note that glucose and triglyceride levels in ketotic pregnant ewes are significantly ($p < 0.05$) lower than those obtained in the controls at the same physiological stage, however for cholesterol levels the positive subjects have the highest values.
Several researchers reported higher blood cholesterol and triglyceride concentrations during late pregnancy in sheep. (Singh and al., 1996). This increase during the last weeks of pregnancy appears to be related to the energy demands of the fetal-placental unit in pregnant ewes. Another explanation for an increase in the serum cholesterol concentration recorded in the late pregnancy compared to day seven post-partum may be due to insulin. Its response is significantly reduced in ewes during late pregnancy. The diminished response of the target tissue to insulin during late pregnancy predisposes the ewes to an increase in blood cholesterol and lipoprotein concentrations (Schlumbohm and al., 1997; Burtis and Ashwood, 1999).
Our results are in agreement with those of El-Din and El-Sangery (2005), who noted low blood glucose values and corroborated those reported by (Sigurdsson, 1988, Singh et al., 1992, Bickhardt and al., 1993, Scott et al 1995, Van Saun 2000 and Mavrogianni and Brozos 2008), which reported low triglyceride levels in affected ewes compared to controls but were in partial agreement with those found by Kabakci and al . (2003), who noted that triglyceride levels were higher in ewes with pregnancy toxemia, while the blood glucose and cholesterol levels observed by these researchers are still low.
Everts (1990) pointed out that the lowest plasma glucose levels were observed in sheep with ketosis. The same researcher also indicated that severe energy deficiency is not the only cause of ketosis, and that the weak control of glucose homeostasis is a predisposing factor in the onset of this pathology.
In addition, Schlumbohm and Harmeyer (2008) have reported that hypoglycaemia is a symptom that characterizes this metabolic disorder, in fact the hyper ketonemia seen in subjects depresses the serum glucose concentration as described by several authors (Bergman et al., 1963, Kammula, 1976, Radcliffe et al., 1983).
In goat with pregnancy toxemia, very low blood glucose values (Bani Ismail et al., 2008) and cholesterol levels (El-Bealawy, 2000) have been reported.
On the other hand, in sheep and goats, the severity of toxemia gestation is linked to hypoglycemia. Indeed, the plasma concentration of glucose is closely related to its concentration in the cerebrospinal fluid.
Van Saun (2000) reported that ewes at the end of gestation are in negative energy balance, implying excessive lipomobilization as well as fat overload of the liver, and food analysis has shown a deficit in rations distributed to these females in fermentable carbohydrates capable of supplying the glucose necessary to satisfy the additional needs of the ewe during this period. However, it is also interesting to note that the supply of glucose to the pregnant uterus at the end of pregnancy does not increase as dramatically as for the mammary gland in early lactation. These observations lead to the question of whether reduced maternal glucose production contributes to the onset of hypoglycemia and the development of pregnancy toxemia rather than an increased demand for glucose by the pregnant uterus. This hypothesis implies that the main cause of pregnancy toxemia is not due to a high fetal consumption of glucose but rather a lack of glucose production by the mother possibly caused by a failure of the maternal system of glucose homeostasis (Schlumbohm and Harmeyer, 2008).On the other hand, the high values of the cholesterol levels may be due to a mobilization of the lipids to

compensate the hypoglycemia observed in the positive pregnant ewes. Ozpinar and Firat (2003) reported a plasma cholesterol level of 82.0 mg / dl on the 100th day of gestation and 84.0 mg / dl on day 120. These levels were higher than those of Hallford and Galyean (1982), and Shetaewi and Ross (1991) as well as those recorded in this study. This could be explained by the multiple lambing of the ewes.

Conclusion

Results of this study indicate that the biochemical profile of ewes with subclinical pregnancy toxemia differs from that of other pregnant ewes. BHB should be measured in pregnant ewes in late stages of gestation with hypoglycemia to prevent and reduce economic losses caused by this desease.

Abstract

The rates of infection among wild carnivores in the Kabarbino-Balkarian Republic and fur animals of cage management in the Kirov Region were investigated. Echinococcus granulosus and Toxocara canis infections appeared to be the most common helminthoses among wild carnivores. In Kabardino-Balkaria the number of wolves infected by E. granuloses and T. canis increased from 28.6 to 78.6% (on average 54%), jackals – from 26.9 to 88.5% (58.5%), raccoon dogs – from 18.2 to 81.8% (51.0%), foxes – from 13.3 to 73,3% (45.3%). The comparative analysis of the infection rates with E. granulosus and T. canis in different age groups of wild carnivores was carried out. The highest level of infection was revealed in adult animals. Though for the trial period the values of infection extensity in wolves increased from 7.1 to 21.4% (on average 7.1%); in jackals – from 7.7 to 27.0% (4.7%); in raccoon dogs – from 9.1 to 18.2% (10.9%) and in foxes – from 6.7 to 20.0% (18.7%). The obtained data evidenced about existence of E. granulosus and T. canis infection stable natural foci supported by high levels of infection in wild carnivores. It caused a dangerous epizootic situation on these helminthoses. The investigation of caged fur animals was carried out in the Kirov Region before planned dehelminthizations. It was found that helminthoses caused by Toxocara canis and Toxascaris leonine were the most common ones. At fur farms of the region during the study period the number of polar foxes infected by T. canis increased from 53.34% to 74.0%; of raccoon dogs – from 65.0 to 87.5%. The level of T. leonina infection among polar foxes increased from 43.34 to 52.0% and in raccoon dogs reached 75.0% during the same period. On basis of the obtained results we can conclude that dehelminthizations are necessary for fur animals of cage management.

Keywords: *Canids, wolf, echinococcosis, toxocarosis, toxascaridosis.*

Introduction

Echinococcus granulosus and Toxocara canis infections appear to be the most dangerous helminthozoonoses (in epidemiological terms) among wild carnivores. According to Sokolov (1998), Bilankin (2004) and Davletova (2002) the extensity of infection (EI) with E. granulosus in wolves, jackals, foxes and raccoon dogs ranges from 60 to 100%. With the help experimental studies it is possible to reveal significant rate of soil contamination by eggs of different helminth species: T. canis, cestodes of Taeniidae family including E. granulosus. As a rule mixed infections with E. granulosus and T. canis are registered on the territory of the Russian Federation (Osipov, 2000). So according to Esaulova and coauthors (2012) helminth fauna of wolves in the reservation «Kaluzhskie zaseki» consists of trematodes, cestodes and nematodes and EI reaches 82.5%. E. granulosus and Taenia hydatigena are found in natural ecosystems of the Voronezh region; wolves and foxes are their definitive hosts (Romashov and coauthors, 2013). On the territory of the Volghograd region helminth fauna of wolves consists of 15 helminth species, E. granulosus (EI 23.5%) and T. canis (EI 35.2%) are the most common ones among them (Shinkarenko, Kolesnikov, 2011). Considering that the both helminth species are dangerous to humans investigations on their prevalence in nature among wild carnivores can be of great scientific and practical interest. And results of these studies can be taken into account for planning preventive measures. Based on this we carried out research of prevalence of E.g. and T.c. infections among wild carnivores (wolf, jackal, raccoon dog, fox) in Kabardino-Balkaria as well as T. canis and T. leonine in fur animals of cage management in the Kirov Region (Russia).

Materials and methods

Prevalence of Echinococcus and Toxocara infections among wild canids was studied in 2011-2015. The study was conducted in animals of different age groups. 14 wolves, 26 jackals, 11 raccoon dogs and 15 foxes were examined by the method of helminthological autopsy according to K.I. Skryabin at the periods of sanitary shooting. Extensity and intensity of infection of each animal species were evaluated according to the results of collected helminth material. Processing of the data was carried out according to the computer program " Biometry". Coproovoskopy according to the method of Fulleborn was used for examination of fur animals of cage management. Data of autopsy during slaughter were also used. Serological tests served as auxiliary methods.

Results and discussion

Analysis of epizootic situation on Echinococcus and Toxocara infections among abovementioned wild canids showed a significant deterioration (Table 1). From 2012 to 2015 one observed an increase of the number of E. granulosus and T.canis infections in all animal species of tested canids. In wolves EI increased 2.8 times (from 28.6 to 78.6%), in jackels – 3.3 times (from 26.9 to 88.5%), in raccoon dogs – 4.5 times (from18.2 to 81.8%), in foxes – 5.5 times (from 13.3 to 73.3%). However the given values of infection level among wild canids were not objective enough and did not demonstrate real epizootic situation in the region. One could observe a similar tendency during analysis of age dynamics of the infection by these helminth species (Table 2). From 2011 to 2015 the rate of infection in young wolves (from 6 months to 1.5 years old) by Echinococcus increased 3 times (from 7.1 to 21.4%), in jackals – 3.5 times (from 7.7 to 27.0%), in raccoon dogs – 2 times (from 9.1 to 18.2%), in foxes – 2.98 times (from 6.7 to 20.0%).

Table 1. The rate of infection by Echinococcus and Toxocara among wild canids in the Kabardino-Balkarian Republic

Species	The number of examined animals in average during a year	The number of animals infected by Echinococcus and Toxocara				
		2011	2012	2013	2014	2015
wolf	14	4 (28,6%)	6 (42,8%)	8 (57,1%)	9 (64,3%)	11 (78,6%)
jackal	26	7 (26,9%)	10 (38,5%)	15 (57,7%)	18 (69,2%)	23 (88,5%)
fox	15	2 (13,3%)	5 (33,3%)	7 (46,7%)	9 (60,0%)	11 (73,3%)
raccoon dog	11	2 (18,2%)	4 (36,4 %)	6 (54,6%)	7 (63,6%)	9 (81,8%)

Table 2. The rate of infection by Echinococcus and Toxocara spp. in young wild canids depending on their age

Year	The rate of infection by Echinococcus and Toxocara in wild carnivores, %		
	The number of animals examend during a year	The number of young animals at the age from 6 monthes to 1.5 year	EI,%
Wolf			
2011	14	1	7,1
2012	14	2	14,3
2013	14	2	14,3
2014	14	3	21,4
2015	14	3	21,4
Jackal			
2011	26	2	7,7
2012	26	3	11,5
2013	26	4	15,4
2014	26	5	19,2
2015	26	7	27,0
Raccoon dog			
2011	11	-	-
2012	11	1	9,1
2013	11	2	18,2
2014	11	1	9,1
2015	11	2	18,2
Fox			
2011	15	-	-
2012	15	1	6,7
2013	15	2	13,3
2014	15	2	13,3
2015	15	3	20,0

The obtained data indicate that the situation for these helminthozoonoses in Kabardino-Balkaria is unfourable and requires proper (due) attention of the competent authorities as this may be the cause of deterioration of epidemiological situation.

Investigations of caged fur animals carried out in the Kirov region in 2013-2016 at fur farms before planned dehelminthizatons reveald that T.canis and T.leonina infections were the most common ones. Animals could become infected with T.canis intrauterine as well as during contact with food, dishes, care items, etc. (Zhdanova and others, 2016; Napisanova and others, 2016). It should be noted that infection caused by T.canis is dangerous for people too. The results of our work for these years are given in Table 3.

The highest exstensity of Toxocara canis infection in polar foxes was registered in nine-month-old animals (Table 3). The obtained results showed that for the trial period the values of infection exstensity in polar foxes increased. In 2015-2016 the rate of T. canis infection reached 74%. The highest level of infection with Toxascaris leonine was revealed mainly in adult animals. One could observe a tendency to increase of this infection too: to 2015-2016 EI in polar foxes reached 70%.

Table 3. The rate of infection by helminths among fur animals of cage management in the Kirov region.

Species and age of animals; species of helminths	The number of tested animals		The number of infected animals, heads, (%)	
	2013-2014	2015-2016	2013-2014	2015-2016
Polar fox: 1) 9 months	30	50		
T. canis			16 (53,34%)	37 (74,0%)
T. leonina			8 (26,67%)	17(34,0%)
2) Adults	30	30		
T. leonina			18(60,0%)	21 (70,0%)
Raccoon dog: 1) 9 months	20	40		
T. canis			13 (65,0%)	35 (87,5%)
T. leonina			18 (90,0%)	0 (0%)
2) Adults	20	20		
T. leonina			12(60,0%)	13 (65,0%)

The highest level of infection with these helminths in raccoon dogs was revealed in very young animals and in nine-month-old ones. Since 2013-2014 the exstensity of infection with Toxocara increased by 22.5% and reached 87.5% in 2015-2016. The same tendency was noted in toxascaridosis in nine-month-old raccoon dogs, their exstensity of infection was 90% in 2013-2014. For this reason unplanned dehelminthizations were carried out in 2015 and in 2016 which affected the results of the study (Table 3). The rate of infection whith T. leonine in adult raccoon dogs during the study period increased slightly (by 5%) and in 2015-2016 was 65%. Coproovoscopy showed low and moderate intensity of infection (67-282 eggs per 1 g of feces) which was confirmed at autopsy (1-4 helminths per an animal) as well as by serological studies.

Conclusion

The obtained results of our study allow to conclude that Echinococcus granulosus and Toxocara canis infections in wild canids are widely spread in Kabardino-Balkaria and represent a serious social problem. So we consider it expedient to draw the attention of competent authorities to the problem. As for helminthozoonoses in fur animals it is necessary to carry out planned dehelminthizations. If the rate of infection in animals is very high unplanned treatments also should be conducted.

Abstract

The aim of this study is to evaluate various zootechnical and biochemical parameters at a poultry farm following the use of dietary exogenous enzymes. This study was conducted on a total of 7,400 chicks from Arbor Acres strain. They were divided into two groups, one received a basic diet (standard) not supplemented with enzymes as control throughout the rearing period and the other a diet supplemented with enzymes. Growth performance, feed efficiency and mortality were recorded at the end of each week. From our results it was observed that the addition of the enzymes does not significantly improve body weight of feed conversion ratio during the breeding period. However, the mortality rate was higher in the control group compared to that supplemented with the enzymes. The diet based on exogenous enzymes decreased the level of serum glucose (2.16± 0.07 vs 2.60±0.18), respectively for the control and experimental group). It increased not significantly, the levels of triglycerides (0,87±0.18 vs 0,53± 0.06), HDL (0,79±0.14 vs 0,75±0.06), LDL (0,28±0.10 vs 0,16±0.05). Exogenous enzymes proved a positive effect on zootechnical parameters and serum glucose in Algerian broiler chicks.

Key words: *Broiler, enzymes, performances.*

Introduction

Since the 1940's antibiotic growth promoters (AGPs) are an integral part of livestock production. However, the excessive use of antibiotics led to the development of antibiotic resistance, a serious risk for animal and human health. Resistance is developed as a reaction of the bacteria to defend itself and offer resistance to antibiotics through mutation, but there has been a lot of research activity looking at possible alternative compounds. Public pressure and concerns about food and environmental safety (antibiotic residues, antibiotic-resistant pathogens) have driven researchers to actively look for alternatives to antibiotics. Some of the alternatives include pre- and probiotics, organic acids and essential oils (Diarra and Malouin, 2014). Feed additives based on plant extracts aim at improving the animal health and the qualities of its feed: added in small quantities to the raw materials, they preserve the animal health, improve the rations efficiency, reduce the production costs, enhance the product features.

Many alternatives to AGP, such as pre- and probiotics, symbiotics, hormones, organic and inorganic acids, ionophores, herbs and ethereal oils, methane inhibitors and other additives including enzymes in animal diets, have been explored for a decade. These practices not only impose an extra financial burden on animal producers but they also leave residues in animal products, which may cause health concerns (Sharma et al., 2008). Among these products, enzymes have a great interest. They act as catalysts, improve the digestibility of food components and reduce wet droppings and odors.

It is in this context that it is proposed in this study to evaluate the nutritional enzymes efficiency in broiler chickens as well as its impact on some biochemical parameters.

Materials and methods

Place and duration of the study

This study was carried out on 7400 arbor-acre stalk chicks, distributed in two groups, but under identical ambient conditions, a control group (n = 3700) and an experimental group (n = 3700) .

The birds were placed in the battery cages, and the temperature was controlled and gradually reduced from 30∘C to 20∘C on day 42.

The birds were vaccinated against New castle and Gumboro’s diseases. A fresh feed and water were provided daily ad libitum.

The birds in the control group were given a diet without additives (T_1). The ingredient and chemical composition of the control diet (maize, soya bean meal, salt, vitamin and trace element mixture). The experimental group was given the same diet as fed to the control group but was supplemented with 350g / tonne enzymatic complex (cellulase, xylanase, alpha-amylase, beta-glucanase, phytase, protease).

Statistical analysis

The evolution of the zootechnical parameters was compared with the "separate-slopes model" of the Statistica General Linear Model (GLM) test.

After verifying the homogeneity of the variances of the biochemical parameters, the means of the control and experimental groups were compared by Student tests and the differences considered significant for $p < 0.05$.

Parameters

The body weight of birds was recorded on the individual basis at weekly intervals. The cumulative feed consumption was also recorded on the weekly basis. Feed conversion ratio was worked out at weekly intervals by taking into consideration the weekly body weight gain and the feed consumption.

This experiment has a biochemical and a zootechnic component. From zootechnical parameters, the growth, the consumption index and the mortality rate of the two groups were compared.

Blood samples were collected from the slaughtered birds in nonheparinised tubes. The samples were centrifuged at 3000 rpm for 15 minutes, and the serum obtained was stored at −20∘C until analysis. serum glucose, and cholesterol, triglycerides, creatinine, urea, HDL, LDL were determined by the auto analyzer using commercially available kits. Blood samples were taken at the age of 56 days.

Results and discussion

Zootechnical parameters

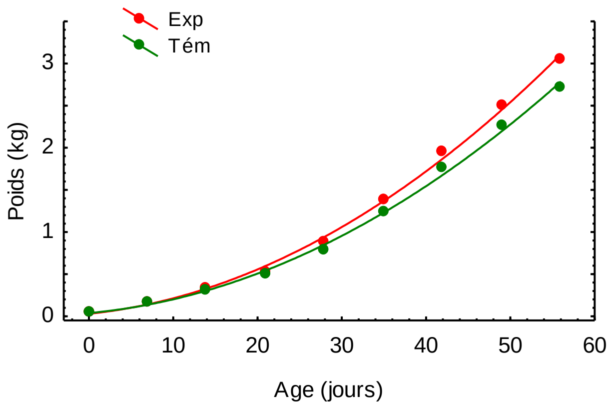
<u>Weight gain</u>

The chickens in the experimental group showed a higher growth than the control group. The mean weights at the end of the experiment, after 56 days, are 3040 g for the experimental group and 2713 g for the control group. Nevertheless, this difference is not significant ($p = 0.83$, figure 1).

Our results are close to those reported by Mathlouthi et al. (2011), performing at 52-day (1953 vs 2017 g).

Khan et al. (2006) and Abudabos et al. (2010) found significant improvements in growth and feed conversion when broiler chickens were fed with corn based diets supplemented with enzymes

Figure 1. Evolution of mean weight according to age



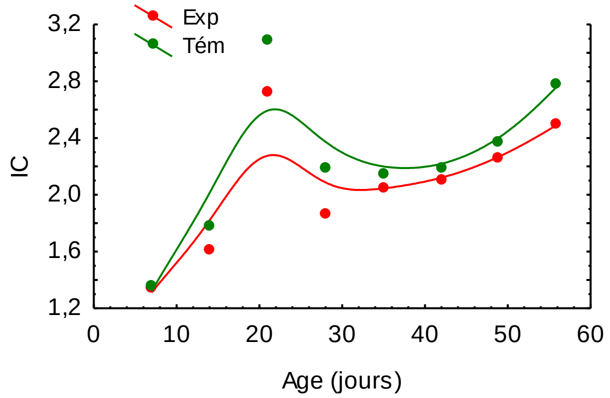
Consumption Index

The statistical analysis revealed no significant difference between the values of the consumption indices in the various staps of breeding ($p = 0.75$). Nevertheless, the chickens of the experimental group have an improved consumption index compared to the control group (FIG. 2). The control group always had a higher consumption index than the experimental group but remained statistically insignificant.

According to Abudabos et al. (2011), a diet based on exogenous enzymes results in a decrease in the consumption index compared to controls in experimental chicks.

Similarly, administration to broilers of exogenous enzymes improves the growth of animals at day 42, and reduces the consumption index in comparison with a control group.

Figure 2. Weekly change in the consumption index



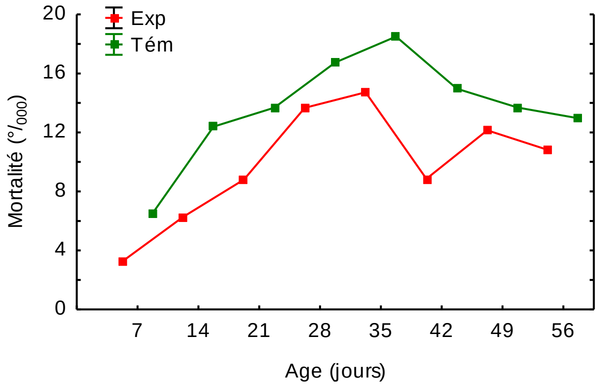
Mortality rate

Our results show that the mortality rates recorded in the chickens of the control group are higher than those observed in the chickens of the experimental group throughout the trial period (Figure 3).

The GLM test shows that there is a slight effect of age ($p = 0.03$) and a slight effect of the group ($p = 0.03$). Mortality increases slightly with age and remains slightly higher for the control group, which is consistent with the two pathological episodes of coccidiosis and colibacillosis during the experiment.

A low mortality rate in the experimental group can be explained by the effectiveness of the enzymes in reducing the mortality rate in chickens.
According to Bedford (2000), the use of exogenous enzymes affects populations of intestinal microbial flora in the small intestines and caeca. Rosen (2001) reported a positive effect of enzymes on chick survival.

Figure 3. Evolution Weekly mortality rate



Biochemical Parameters
The biochemical parameters of the control and supplemented groups of broiler chicken enzymes are presented in Table 1.

Table 1. Biochemical parameters of bloire of two groups

Parameters ($g.L^{-1}$)	Group		p
	Exp	control	
Glycemia	2,60	1,75	0,11
Triglycerides	0,53	0,87	0,11
Cholesterol	1,01	0,91	0,50
HDL	0,75	0,79	0,81
LDL	0,16	0,28	0,31
Creatinine	3,40	3,00	0,35
Urea	0.02	0,03	0,38

The glucose concentration was higher in the experimental batch than in the control batch (2.6 vs 1.75) without being significant (p = 0.11). This result is higher than that obtained by Fontaine (1.50 to 1.80 g.L-1), and which is similar to our control group (1.75 g.L-1). This can be explained by the effect of enzymes that improve digestibility, which induces an increase in blood glucose after ingestion of a significant amount of carbohydrates.
The results obtained show a reduction in triglyceridemia values for the experimental compared to the control group (0.53 vs 0.87 g L -1), but this difference is not significant (p = 0.11).
This result does not exclude the role of exogenous enzymes in reducing cholesterol. Thus, a low value of cholesterol in the control group can be explained by the intestinal or hepatic impairment resulting from diseases (coccidiosis and colibacillosis) or intense metabolism at the administration of treatments, thus leading to a decrease of the anabolism of cholesterols.
This hypothesis could be confirmed by the remarks made in 2004 by Koolman et al. (2005), Which state that the external dietary intake of cholesterol has very little influence on the blood cholesterol level, The endogenous biosynthesis which takes place, inter alia, at the hepatic and intestinal level.

The statistical tests to which the test results were subjected did not show any significant difference in HDL during the last step between the experimental and control groups (0.75 vs 0.79 gL-1).
In light of our results, we can say that exogenous enzymes do not affect serum creatinine in broiler chickens. This resulted in a non-significant difference ($p = 0.35$) between the experimental and the control group (3.40 vs 3.00 g / l). The difference was not significant between the mean urea level of experimental group and the control group (0.02 vs 0.03 g / l).

Conclusion

Our experiment made it possible to specify, in our local conditions, the impact of the enzyme food supplementation on the zootechnical performances and the biochemical parameters of the broiler chicken.
It appears that the use of exogenous enzymes in diets allows an improvement in zootechnical performance, but also seems to have effects on biochemical parameters even if they are still not really significant. The results of this study appear to be interesting.

Abstract

In the past, poultry nutritionists were interested in establishing nutrient requirements of poultry to support maximum performance of laying hens. The aim of this study was to investigate the effects of diets supplemented with organic and inorganic iron in different amounts on the productivity and blood parameters of laying hens at 28-36 weeks of age. A total of 36 *Lohmann Brown* laying hens at 28 weeks of age were assigned to three treatment groups (12 hens per each treatment group) and fed experimental diets for 8 weeks. The diets comprised 70 mg FeSO4 (Control group I), 150 mg iron sulphate (Group II), 70 mg FeSO4+72 mg of iron glycinate (Group III) and birds were keeping in the same conditions. Organic and inorganic iron in different amounts did not have statistically significant effect on the productivity of the laying hens. When analyzed the data on laying hens' blood parameters, the results were statistically significant when it comes to the concentration of iron (in Group II it increased 29%, $P<0.05$) and concentration of ALAT (in Group III –it increased 36% $P<0.05$). Alkaline phosphatase, however, had a tendency to decrease in all experimental groups, from 1.45 to 6.71 times ($P<0.05$) compared to the control group. When analyzed the morphological composition of blood, statistically significant results were obtained in Group III on platelets; it decreased 25 % compared to the control group. To conclude, it could be said that different origin and amount of iron did not have any effect on laying hens' productivity, but had a positive effect on some blood parameters.

Key words: *Iron, laying hens' productivity, blood parameters.*

Introduction

Poultry nutrition is focused on the major dietary components (protein and energy) and vitamin and mineral supplements, from both organic and inorganic sources, that are normally incorporated into the diets to meet the bird's requirements (Zhao et al., 2010, Yuan et al., 2011). Trace minerals (TM) are essential in the diets of poultry because they participate in the metabolic processes required for optimum growth and development (Soetan et al., 2010). Traditionally, supplementation of TM to the commercial poultry diets has been achieved through the use of inorganic salt forms, such as sulfate, oxides, and carbonate. However, because of low TM availability from this source, substantial efforts have been devoted to improve its utilization by animals. Organic/chelated TM (CTM) have been considered as an alternative to inorganic TM (Yuan et al., 2011; Mondal et al., 2007; Dobrzanski et al., 2008; Salim et al., 2012; Ivanišinova et al., 2016). Thus, the aim of the trial was to investigate how organic forms of iron influence the laying hens productivity and blood morphological composition and parameters.

Materials and methods

A total of 36 *Lohman Brownn* laying hens which were 28 weeks old were assigned to three treatment groups (12 hens per each treatment group) and fed with the experimental diets for 8 weeks, which containing 70 mg $FeSO_4$ (I control group), 150 mg iron sulpahate (II group), 70 mg $FeSO_4$+72 mg of iron glycinate (III group) and keeping in the same conditions. All diets were formulated to meet or exceed the nutritional requirements of birds as suggested by NRC (1994) with the exception of Fe concentration (Table 1). The hens were fed with 125 g compound feed per day. The main ingredients of compound feed have been wheat, wheat flour, sunflower cake, soybean cake, NCl, methionine and lysine (Table 1). Source of Fe glycinate (25 percent of glycine, 18 percent of Fe), Glystar®Forte Fe, ARKOP, Poland.
During the feeding trial, these parameters were analyzed: daily calculated and weighed all the eggs, the calculated of the group of egg weight; every 14 days weighed on feed remain and calculated feed conver-sion ratio of 1 kg of egg mass produced; every 14 days are calculated eggs number dynamics and egg pro-duction intensity. At the end of the trial of each group were selected after 5 laying hens, were killed by experimental animal euthanasia guidelines (Close *et al.*, 1997) and perform the following research - in the blood serum were identified the following indicies: blood morphological composition, triglycerides, total cholesterol, HDL- and LDL-cholesterol, globulins α1, α2, β, γ, GGT, GOT, alkaline phosphatase, total protein, bilirubin levels were determined blood analyzer INTEGRA 400/700/800.
Statistical Analysis. The results of the experiment were analyzed using the 1-way ANOVA test, and significant differences between groups were determined by Duncan's multiple range test. Statistica 8.0. for Windows™ software was used. Differences were considered significant at $P<0.05$.

I group -70 mg of $FeSO_4$, II grou-150 mg of $FeSO_4$, III group – 70mg of $FeSO_4$ + 72mg of Fe glycinate

Results and discussions

As a feed additive, iron is usually used in the form of an inorganic salt, such as sulfates, oxides and carbonates. Current nutrition standards for poultry assume 80 mg Fe/kg of dry matter in broiler feed, while a dose above 2000 ppm is considered toxic (Theil, 2004; Vieira, 2008).
Similarly, the use of compound poultry feed enriched with iron chelates, alone or in combination with methionine, affects the content of this component in hen eggs and poultry meat (Park et al., 2004; Bao et al., 2007; Seo et al., 2008). In searching for new solutions to achieve measurable benefits such as improved health and production performance, scientists became interested in glycine chelates (Bovell-Benjamin et al., 2000; Kegley et al., 2002; Feng et al., 2007, 2009). Recent studies (Pineda and Ashmead, 2001; Ettle et al., 2008) suggest that glycine-chelated iron (Fe–Gly) is more easily absorbed and utilized than iron from other amino acid chelates. Männer et al. (2006) determined that the stability and availability of intestinal chelates based on the smallest amino acid, that is glycine, is 25% higher than in older generation chelates based on lysine or methionine. In studies by Petrovič et al. (2010), when Fe was used in the form of proteinates covering 20% of the requirement, no reduction in the final body weight of chickens nor in the intake and utilization of feed was observed compared to groups where recommended doses of inorganic Fe were used. In turn, Abdallah et al. (2009) showed that chickens whose diet contained 100% of organic Fe were heavier compared to those receiving inorganic iron. Also, Ao et al. (2009) observed improved production performance when using organic Fe. In contrast, studies by Nollet et al. (2005) showed that when 40 ppm of Fe was added, both from inorganic sources (sulphates) and from bioplexes, no statistically significant differences were found in the body weight of chickens.
The laying hens' productivity is presented in Table 2. There have not been any significant treatment effects on egg production, feed consumption and feed conversion ratio. In tendency, egg production was highest and FCR was best in Group II.

Table 2. Influence of organic and inorganic iron on laying hens productivity

Parameter	Groups		
	I (control)	II (experimental)	III (experimental)
Total feed consumption, g	1687.50±30.62	1697.75±18.28	1655.25±31.60
Laying rate, %	89.30±2.63	92.80±1.95	90.30±2.78
The average of egg weight, g	67.80±1.41	66.70±1.46	67.20±2.20
Feed conversion ratio, kg	2.02±0.07	2.00±0.06	2.07±0.07

A positive effect of chelates on certain immunological indicators has been noted as well, for example as increased activity of anti-oxidation enzymes (Pineda and Ashmead, 2001). In experiment, the highest concentration of iron was determined in group II, it increased 29 percent ($P<0.05$) compared to control group. The highest concentration of aminotranspherase was determine in group III, it increased 36 percent ($P<0.05$), when analysed data of alkaline phosphatase in the laying hens blood, we determined that using 150mg of $FeSO_4$ this parameter decreased by 6,7 times ($P<0.05$) and when compound feed was supplemented with 70mg of $FeSO_4$+72mg of Fe glycinate – it also decreased 31 percent ($P<0,05$) compared to the control group. For other laying hens blood parameters it did not had statistically significant effect, the data was insignificant.

Table 3. Influence of organic and inorganic iron on laying hens blood parameters

Parameter	Groups		
	I (control)	II (experimental)	III (experimental)
Iron	66.76±1.09	86.42±1.22*	73.47±6.47
Ferritin	0.50±0.01	0.50±0.01	0.50±0.01

*-data statistically significant at P<0.05

In evaluating the effectiveness of inorganic and organic sources of microelements, the course of metabolic processes may be significant; this is reflected, among other things, by variable values of biochemical and haematological indicators of blood (Ganong, 2005; Kaneko et al., 2008). In the studies, the values of the above-mentioned parameters were within the reference range for chickens (Thrall, 2004; Kaneko et al., 2008).Selected haematological indicators were also determined in the experiment to evaluate the iron metabolism of the birds. When analyzed laying hens morphological blood composition, statistically significant results were get just in platelets (PLT), in group III it decreased 20 percent (P<0.05) and platelet distribution width (PDW) – in group II it increased 18 percent (P<0.05), but in group III it decreased by 24 percent (P<0.05) compared to the control group.

Table 4. Influence of organic and inorganic iron on laying hens morphological blood composition

Parameter	Groups		
	I (control)	II (experimental)	III (experimental)
Leukocytes (WBC)	675.14±47.65	693.90±44.45	667.36±36.19
Erythrocytes (RBC)	2.53±0.13	2.71±0.06	2.45±0.26
Hemoglobin (HGB)	81.38±2.38	84.50±0.50	81.00±8.00

Mean Cell Hemoglobin Concentration (MCHC)	265.00±2.75	262.50±5.65	267.50±3.50
Platelets (PLT)	1.88±0.38	2.00±0.61	1.50±0.50*
Platelet Distribution Width (PDW)	7.39±0.79	8.70±0.98*	5.65±1.15*
Mean platelet volume (MPV)	8.79±0.35	8.05±0.25	8.90±0.30
Basophils (BASO)	0.24±0.10	0.20±0.09	0.35±0.12

*- data statistically significant at P<0.05

Conclusions

So in concluded it could be said that different origin and amount of iron did not had effect on laying hens productivity, but had positive effect on some bloods parameters.

Abstract

In the search for alternatives to antibiotics, several non-therapeutic Extracts of plants, are increasingly being proposed and studied for increasing performance and control of Coccidiosis of chickens. The aim of this study was to evaluate the efficacy of plant extract supplementation For Origanum majorana to improve zootechnical performance and control broiler chicken coccidiosis. For 54 days, an experimental group A (1200 chicks) receiving water supplemented with an anticoccidial based on plant extract (OREGO-STIM, 150 ml per 1000 L) was compared with a control group C (1200 chicks) receiving in the drinking water a chemical anticoccidial, As well as a group B (1200 chicks) receiving the two anticoccidians in the drinking water. Zootechnics performance results showed a difference in weight in favor of lot A (lot: A 3182 g, lot B: 2610 g, lot C: 3050) at the end of the period breeding. Consumption indices were similar. Subsequently, lot A showed significant difference compared to lots B and C. The cumulative mortality rate recorded at the end of the rearing period was similar (5-6%) in the three lots. The lesion scores obtained in the animals of group B at autopsy showed more important signs than those of group A and C revealing clinical and subclinical forms of coccidiosis. Under the present experimental conditions, the addition of an extract of Origanum majorana in drinking water improved the zootechnical performance of chickens. Nevertheless, the impact of this supplementation requires further studies to confirm or Control of coccidiosis.

Key words: *Influence, plant extract, zootechnical parameters, broiler, Algeria.*

Introduction

The abusive use of anticoccidials in the production of has promoted the emergence and dissemination of antibiotic resistance and a significant increase of the cost of the medication (Yvore, 1992). In order to reduce the exorbitant costs and propose a alternative to resistance phenomena of coccidia, it is necessary to find other solutions, apart from the Pharmaceuticals, for the control of coccidiosis avian.

We tested the effect of oregano (OREGOSTIM) incorporated into the drinking water in this work which aims to evaluate, under local conditions, its Coccidiostatic effect to improve performance and control of coccidiosis in chickens of flesh.

Material and methods

The study was carried out in three broiler farms of Bejaia in Algeria from 1 August to 30 October 2015.

Animals: The animals were divided into 2 lots:
A / Lot A: composed of 1200 chicks on a specific day Gallus gallus domesticus, of strain Cobb500.
B / Lots B and C: each of 1200 chicks of one day of species Gallus gallus domesticus, of strain Arbor Acres.
Food: A farinaceous food is consumed. The food is consisting of corn, soybean meal, wheat bran, phosphates Bicalcium, limestone and mineral-vitamin concentrates.
L A "start-up" food distributed from the 1st to the 15th day.
L A "growth" food from the 16th to the 40th day.
L A "finishing" food from the 41st day until slaughter.
Drinking water
The drinking water distributed to the three lots came from water from where many families get their supplies. This source is registered by the hydraulic services and controlled by the municipal hygiene office.
ORIGO-STIM
It is a natural product extracted by distillation of a plant called Origanum majorana, in liquid form. Animals of lots A and B, receiving water with a Coccidiosis based on plant extract (OREGO-STIM), 150 ml per 1000 L were compared with those of a control C.
Plan of prophylaxis
A vaccination schedule was established as follows:
L 7th day against Newcastle with a reminder to the 28th day,
The 14th day against the Gumboro.
Experimental protocol
Lot A: receiving a food adapted to each age and source water supplemented with Origo-stim.
Lot B: receiving a food to each age and source water supplemented with Origo-stim. After Resistances, we have used chemical antimicrobial agents (Algicox and Joprox).
Lot C: receiving a food at each age and supplemented water of chemical anticoccidiens (Algicox).

Results and discussion

Zootechnical parameters
Weight gain
The results obtained showed weight gain Slightly higher on the 52nd day in experiments group A≈ 3042 g with respect to control group C ≈ 2847 g and B≈2466 g.
The good growth achieved in group A is undoubtedly attributable to the efficacy of the anticoccidial drug used in The OREGO-STIM and the absence of clinical coccidiosis because it depresses the zootechnics by reducing the rate of growth and by increasing the consumption index (Yvore, 1992).
Consumption indices (IC) : Our results show that the consumption index at the end of each rearing phase:
L Lot A: 1.93
L Lot B: 2.1
L Lot C: 1.93
The results on the consumption index show that groups A and C (1.93) were better than B group.
B (2.1). There is a better consumption index for lots A and C in relation to the group B. The increase in the latter follows on from the of pathological episodes during breeding (coccidiosis and other complications such as respiratory diseases) and which contributed to these poor performances.
Mortality rate

The results obtained show mortality rates of 5; 45; 5.83 and 6.50% respectively for groups A, B and C. It should be noted that the mortality rates recorded in groups A and B are comparable to the reported standard by Villate (2001) and which is 5%. One can explain these results by the good husbandry conditions in which took place our experimentation. Though These are not strictly observed on the Algerian ground (thermal insulation of the building, Ventilation, density, respect of the sanitary barrier, Equipment and type of power supply).
The slightly higher mortality rate for Lot C (From the 6th to the 7th week) could be due to embrittlement the immune system of the individuals by coccidiosis and the appearance of respiratory diseases (colibacillosis).

Conclusion

The results obtained in this study show that the incorporation of anticoccidial extracts
Plants "OREGO-STIM" extract of oregano (Origanum Vulgare) in drinking water allows:

- Improved weight.
- An improvement in the consumption index.
- A reduction in the mortality rate while preserving
- Good animal health status

Therefore, and on the basis of the foregoing, the addition plant extracts is a better alternative to Chemical antibiotics and other antibiotics as they to address the problems of resistance to coccidiosis. In addition, Oregano and marjoram do not Development of resistance to coccidia following use. They can be used in poultry (flesh, Laying hens, turkeys), and should be tested in ruminants.

Abstract

A total of twenty-three camels (age range: 4 months-15 years) from both sexes and belonging to Sahraoui and Targui breeds were slaughtered following the normal abattoir procedures in Ouargla (Algeria). Samples of *Longissimus dorsi* were collected and the collagen content was determined. Mean value was 2.20±0.27 % on fresh materiel.Higher collagen content was recorded in animals more than 8 years old when comparedtoanimals from 0 to 4years old (p=0.024). The difference between the breeds was not significant (2.13 *vs*2.39% in Sahraoui and Targui breeds, respectively). Meat from the femaleshad significantly higher values than that of the males (4.77 *vs*1.82%).

Key words: camel- collagen- sex- breed.

Introduction

Dromedary camel is one of the most important domestic animals in arid and semi-arid regions as it is equipped to produce high quality food at low costs under extremely harsh environments compared to other animals **(**Yagil, 1982; Yousif and Babiker, 1989). It is a good source of meat in areas where climate adversely affects the efficiency of production of other animals (Kadim and al., 2006). Moreover, camel meat has low fat content and is rich in some healthy nutrients (Sahraoui and al., 2014). Few studies performed on camel meat (Babiker and Yousif, 1990; Kadim et al., 2008) suggested that the quality of camel meat is comparable to beef if animals are slaughtered at comparable ages, whereas, physicochemical and textural characteristics of camel meat have not been fully exploited.

Basically, meat can be considered in its simplest form as a myofibrillar structure, a collection of parallel fibers, bound together by a connective network tissue composed of collagen and elastin (Icier and al., 2009). The texture of meat mainly depends on zootechnical parameters such as breed, age and sex (Huff-Lonergan and Lonergan, 2005), and on anatomical characteristics such as type of muscle (Zamora, 1997). Structure of collagen and elastin is a significant factor that affects meat texture (Takagi and al., 1992). Hydroxyproline is a major component of the protein collagen, comprising roughly 13.5% of mammalian collagen. Hydroxyproline and proline play key roles for collagen stability. They permit the sharp twisting of the collagen helix (Szpak, 2011). To our knowledge, the connective tissue composition of meat is unknown in Algeria. The aim of this study was thus to measure the levels of collagen in the meat from camels belonging to Algerian population.

Materials and methods

Animals and muscle sampling

Twenty-three Algerian camels, aged between 4 months and 15 years, fattened by local camel herders in Ouargla (Algeria), were selected and slaughtered following the normal abattoir procedures. The samples of *Longissimus dorsi* muscle were removed from each carcass within 1 h post-slaughter. Muscle samples were cut cylindrically (5 cm diameter and 10 cm length). Samples were sealed in plastic bags and transported to the Faculty of Veterinary Medicine, University of Liege, in an insulated box filled with ice, where samples were packed and stored at –18°C until analysis in the Laboratory of Food Science.

Chemical analysis

Hydroxyproline estimation

The hydroxyproline (OH proline) content in meat was determined according to ISO 3496 method performed by ISO 3496 (1994). Briefly, 6-7 grams of fresh meat sample was hydrolysed with 8, 4 N sulfuric acid for 16 h at 105 °C. Hydrolysate was filtered, and solution was diluted to volume with distilled water. One millilitre of hydrolysate was pipetted into a 100 ml volumetric flask and filled to mark with H_2O. Two milliliters of colour reagent was added and mixed. Tube was then placed in a water bath at 60°C for 20 min, then cooled to room temperature and absorbance measured.

A standard calibration curve was carried out from OH proline proanalyzer at concentrations ranging from 0.25 to 3.2 µg / mL. The calibration line related optical density to concentration of OH proline expressed in µg /mL. The OH proline content in the collagen is being considered as 12.5%. The collagen content was calculated from hydroxyproline content using the coefficient 8

Statistical analysis

The analysis was performed on Statistica 10, Statsoft, USA. The collagen concentrations were compared by age groups, gender and breed using the Student t-test or ANOVA procedure**.** Differences were considered significant at $p<0.05$ level. The data were expressed as % in fresh meat.

Results and discussion

Results showed that the mean collagen content in meat was 2.20±0.27 %, with maxima value of 6.27% and minima value of 1.26%.

Regarding to age, the results showed that higher collagen content was recorded in animals over than 8 years, when compared to animals between the age of 0-4 and 4-8 years age groups ($p=0.024$; Table 1). A strong gender effect was observed on collagen content. Significantly higher collagen content was measured in females compared to males (Table 2). By contrast, no significant difference in total collagen content in meat was observed between Sahraoui and Tergui breeds (Table 3).

Collagen is the most abundant mammalian and avian protein and is found in all tissues, particularly skin, tendon, and bone (Piez, 1966; McCormick, 1999) but there is little data on camel's collagen content as reported by Kadim and al. (2013) and very few studies have explored the collagen content in camel meat (Babiker and Yousif, 1990; Siddiqi and al., 2000).

Our results showed that the mean collagen content in meat camel was 2.20±1.26%. Hadi Eskandari and al. (2012) reported largely lower total collagen content in camel meat, with values ranging from 1.67 to 2.03 mg/g of meat for *Longissimus dorsi* and *Psoas major* muscles from one-humped male camels. Kamoun and al. (1995) indicated that the total collagen content was 3.3 to 7.5 mg/g in six major muscles. Nevertheless, Babiker and Yousif (1990) indicated that the total collagen content is greater in camel *Longissimus dorsi* than in *Semitendinosus* or *Triceps brachii*, possibly due to the morphological requirement for stabilizing the hump attached to the *Longissimus dorsi*.

Numerous investigations have determined total and insoluble collagen contents in bovine meat (Torrescano and al. 2003). However, Torrescano and al. (2003) reported that total collagen content of bovine muscles showed a wide range of values (0.31 to 1.15%). Mamani-Linares and Gallo (2013) indicated that soluble collagen was only 1.28 mg/g (20.28% of total collagen content) in llama *Longissimus lumborum* muscle. Other studies have reported that texture of meat fibers, aggregation and gel formation in bovine meat mainly depend on myofibrillar and sarcoplasmic proteins, on characteristics of animal such as breed, age and sex (Huff-Lonergan and Lonergan, 2005), on anatomical characteristics such as type of muscle, and on collagen solubility (Zamora, 1997).

Tenderness of meat is rated as the most important quality attributed by the average consumer and appears to be sought at the expense of flavor or color (Lawrie, 1979). The most marked difference in meat quality characteristics between camel and other livestock is believed to be tenderness. Camels are usually slaughtered at the end of their productive life (>10years) which is the reason that camel meat is classified as a low quality meat. In Kenya, the average age for camels slaughtered was 14.5 years (Mukasa-Mugerwa, 1981).

General consumers' view is that camel meat is unacceptably tough, but in fact meat from young camels has been reported to be comparable in taste and texture to beef (Kurtu, 2004).

For age, we observed that higher collagen content was recorded in animals over than 8 years, when compared to animals aged between 0-4 and 4-8 years. The same observation was made by Kadim and al. (2006) who suggested that male camels should be slaughtered between one to three years of age. Kadim and al. (2008) reported that Warner-Bartzler shear force (WBSF) values in 5–8 years old camels were significantly higher than 1–5 years old ones. Increase in toughness due to age may be related to changes in muscle structure and nature and quantity of connective tissue in the meat (Kadim and al., 2014). The collagen content of muscle increased from 18 to 20% between 9 and 13 months of age; above 13 months, muscles had lower variations in content. The gradual decrease in solubility of collagen would explain the decrease in meat tenderness with age of animal. However, Duarte and al. (2011), reported that total collagen content in muscle does not increase significantly with physiological maturity in cattle; however, collagen solubility is correlated with dental maturity since meat from animals with 2 and 4 permanent incisors has greater collagen solubility compared to that of animals with 8 permanent incisors. Intermolecular cross-links present in collagen found in muscle of young animals are unstable to heat but these links are converted into complex structures as the animal ages, becoming thermostable (Robins and al., 1973), tending to make the meat less tender.

Nevertheless, the total collagen level was found to be higher in females (Table 2). Abdelhadi et al. (2015) indicated that OH proline contents did not differ between male and female camel. Total collagen values decreased in the strong male lambs, while soluble collagen did not vary significantly.

The influence of gender on connective tissue is reported and refers to content and solubility of collagen. Collagen content is observed to be higher among males than in females. The collagen content of females is close to that of castrated males. Collagen solubility is similar in castrated males and females; It was low in all males (Monin, 1991). These differences are corresponding with the animal's age, since they are relatively poor in young animals and then increase with age (Kopp, 1982).

Collagen content also decreases with muscle development, it is linked with physiological period among genotypes, which can also contribute to differences in tenderness (Boccard and Bordes1986; Renand, 1988). When reported to the breeds, no significant difference was observed between total collagen content in meat. Al-Owaimer et al. (2014) reported that cross sectional area of muscle fibers did not differ between the animal's breeds. Though, in the literature, many authors have reported the effect of breeds on beef tenderness. In semi-tropical region of Argentina, breeds effect on tenderness was observed between Criollo Argentino and Brasford steers raised on forage (Orellana and al., 2009). Breeds specialized for meat production (Limousin and blonde of Aquitaine) have a lower value of shear force than other breeds (Holstein and Old Brown Swis) (Monsón and al., 2004). In indigenous African cattle breeds, meat of Santa Gertrudis is less tender than those of Sanga, Afrikaner, Nguni, Brown Swiss, Pinzgauer and Bonsmara (Strydom et al., 2000). According to this author, in the arid subtropics of South Africa, breeds effect on tenderness and shear force were not significant, and as a rule, meat quality characteristics from young camels are comparable with those of beef.

Conclusion

This study evaluated the content of collagen in Algerian camel meat. Results showed low mean levels but higher collagen content was recorded in the elderly**.** In addition, female camel meat had significantly higher collagen values but probably owing to an age effect. The values remained similar for Sahraoui and Tergui breed.

Abstract

In the context of the search for alternatives to antibiotics, several non-therapeutic substitution methods can be envisaged; including the use of plant extracts, The objective of this study was to evaluate the efficacy of natural plant extract supplementation (Volarom) to improve zootechnical performance and the health status of broiler for 50 days: an experimental group (1200 chicks) receiving a vegetable extract (volarom) in the added water was compared to a control group 'A' (3000 chicks). Results on zootechnical performance showed a difference in weight and mortality between the two groups. Under experimental conditions, the addition of a natural plant extract to drinking water showed significant performances, namely zootechnical performance and an improvement in the state of health of broiler.

Key words: *broilerchicken, homogeneity, zootechnical performance.*

Introduction

The use of medicinal plants all over the world predates the introduction of antibiotics and other modern drugs into Africa continent. Herbal medicine has been widely used and formed an integral part of primary health care in China, Ethiopia, Argentina and Papau New Guinea. Traditional medical practitioners in Southwest, Nigeria, use a variety of herbal preparations to treat different kinds of microbial diseases including MRSA-associated diseases.

Material and methods

I.1.Material

I.1.1. Place of study:

This study was carried out during a period running from October 15 to December 4, 2016. It was carried out in a broiler farm, the building of which is located in the BLIDA Wilaya.

VOLAROM:
It is a natural product by distillation of the following natural plants (turmeric, olive leaf, grape fruit seeds, thyme, Rosemary). This product is in liquid form.

Animals:
The animals were divided into two groups:
- Lot A (control group) consisting of 3000 day-old chicks Gallus gallusdomesticus, of strain al Bouraque.
- Lot D (experimental group) comprising 1,200 one-day Gallus gallusdomesticus chicks of the Bourca strain were used during this experiment.

Food:
A plug-type food is consumed. The food is composed of maize, soybean meal, wheat bran, calcium phosphate, salt, table oil, limestone, and mineral vitamin concentrates.
- A "start" food: distributed from the 1st day to the 15th day.
- A "growth" food: from the 16th day to the 40th day.
- A "finishing" food: from the 41st day until the slaughter.

Parameters studied

We have determined:
1) zootechnical performance: live weight, consumption index and mortality rate.
2) Biochemical parameters: triglycerides, cholesterol weight of viscera

I.2.3.1. Evaluation of zootechnical performance:
Determination of average weight:
In each group, an animal sample randomly selected from 10 subjects was weighed at 1, 15, 30, 45 days using an electronic scale. The means shall be determined by the following ratio:
Mean weight (gr) = overall weight of subjects / number of animals weighed.
Determination of the consumption index: with the zootechnical parameters
The consumption index was determined on the 1st, 15th, 33rd, 50th day after having recovered the feed in the feeders to have the quantity consumed, it is calculated according to the following formula:

IC = amount of food consumed / sum of weight gains
Determination of the weight of the digestive organs and of the heart:

During the study period, five subjects were randomly taken in the morning of each group, which animals were sacrificed for the determination of organ weights, intestinal size and blood sampling for biochemical parameters.

Biochemical parameters

30 blood samples from 30 randomly selected subjects at the end of each rearing period at the rate of 5 chicks from each batch and at the end of each rearing period. These animals were sacrificed at the alar vein.

Zootechnical parameters:

Weight gain:
The mean weight of the animals during the rearing period is given in the following table:

Table 1: Weight of chicks.

Days	A	D
1	186± 81.9	204 ± 93.1
15	895± 286.6	1035± 282.5
30	1678.5± 468.1	2105.5± 468
50	2327± 321	2733.5 ± 111

The chicks in the experimental batch showed a significant weight compared to the control groups. It is established that the weight gain is closely related to the quality of the feed and to the respect of the conditions of rearing the type of feed used for the three phases of the breeding is of the cap type (meal) And better homogenized keeps its nutritive values as well as possible.

The good growth obtained in batch D is undoubtedly attributable to the efficacy of the plants used in this case VOLAROM resulting in the absence of clinical colibacillosis because colibacillosis affect zootechnical performance by decreasing the growth rate and increasing the consumption index

Mortality Rate (MR):

The observed mortality of the animals in the first three days is mainly due to stress, transport, manipulation during the installation of the chicks, the results of the mortality rates recorded for each phase are reported in the following table.

Table 2. mean and standard deviation of the mortality rate

Phase	Start up	Growth	Finsh
Age (days)	1 – 20 D	35 D	47 D
M R (%)	1.6 ± 1.6	0.9± 0.9	0
M RD (%)	0.4 ± 0.4	0.6± 0.9	0

Our results showed that:
Lot A: the average of the total percentage of mortality is 2.5%
Lot D: the average of the total mortality percentage is 1%
The high mortality rate observed for batch A could be due to the embrittlement of the immune system of the subjects by the presence of respiratory diseases (colibacillosis).

Consumption Index (CI): The consumption of food is reported in the following table.

Table 3. Amount of consumption

Age (Day)	A	D
20	0.86	1.16
40	1.50	1.59
47	1.16	1.22

It is established that the weight gain is closely related to the quality of the feed and to the respect of the conditions of rearing the type of feed used for the three phases of the breeding is of the cap type (granulated) And better homogenized keeps its nutritive values as well as possible.
The good growth obtained in batch D is undoubtedly attributable to the efficacy of the plants used in this case VOLAROM resulting in the absence of clinical colibacillosis because colibacillosis affect zootechnical performance by decreasing the growth rate and increasing.

The consumption index
Weight of the viscera of the chicks during the periods of rearing (heart, liver, proventricule) and intestinal morphometry.

The weight of the viscera (viscera yield) and the size of the intestines are reported in the following tables.

Table 4. Viscera and intestinal morphometry

	Start up A	Start up D	Growth A	Growth D	Finish A	Finish D
Heart	6.2 ±2.2	7.2±1.8	7.8± 1.3	10.8± 3.4	8.2± 2.2	11.4± 1.5
Liver	22± 6.8	24±6.4	37.2± 6.7	56.8± 6.8	34.6± 6.1	56.8± 7
Gizzar	11.8± 2.9	13.2±4	22± 4.7	42.4± 4.4	33.6± 2.3	43.2± 10
Proventriculus	2±0.7	2.6±0.9	3.2± 0.8	5.2± 0.8	6± 1.2	6.4± 0.9
Fat mass	5.6±1.7	5.8±1.1	16.2± 6.4	21± 7.7	15.6± 3.7	27.2± 13.1
Intestines	1.516±0.2	1.626±0.2	2.376± 0.5	2.720± 0.2	2.948± 0.1	3.008±0.3

The results relating to the weighings carried out show that group D is better than batch A. In numerical terms, a better weight of the organs for batch D is compared with batch A, taking account of what confirms the advantage of our product as a growth promoter with homogeneity, and it improves the weight gain. Lipid balance during different periods: The results of the lipid balance are reported in Table 5.

Table 5. Lipid balance results

Parameters	Start up Lot A	Start up lot D	Growth lot A	Growth lot D	Finish lot A	Finish lot D
Cholesterol M mol/l	2.164± 0.3	2.355± 0.3	2.02± 0.3	2.657± 0.4	1.722± 0.4	2.220± 0.2
Triglyceride M mol/l	1.542± 0.3	1.146± 0.7	0.653± 0.1	1.177± 0.3	1.069± 0.4	1.604± 0.5
HDL M mol/l	1.439± 0.2	1.594± 0.2	1.480± 0.2	1.712± 0.1	1.146± 0.2	1.506± 0.1
LDL M mol/l	0.416± 0.2	0.531± 0.2	0.409± 0.2	0.71± 0.2	0.362± 0.2	0.464± 0.2

There is a somewhat high result for lot D, which confirms the advantages of VOLAROM, concerning the batch A, this observed decrease may be due to hepatic or intestinal disease, consequent diseases (colibacillosis) or intensive metabolism following The administration of the treatments, thus inducing a decrease in the anabolism of cholesterol. This hypothesis could be confirmed by the remarks made in (2004) by Koolman et al, which state that the external dietary intake of cholesterol influences very little on the blood cholesterol level, because the majority comes from the Endogenous biosynthesis, which takes place, among other things, at the hepatic and intestinal level.

This hypothesis is also based on the remarks made by Leveille et al (1975), which states that the liver is the main organ responsible for lipid neosynthesis and that any damage leads to metabolic disorders.

Conclusion

The results obtained in the present study show that the incorporation of natural plant extracts VOLAROM in drinking water allows a better improvement of the weight performances, an improvement in the consumption index, a decrease in the mortality rate while maintaining good animal health status, maintaining a satisfactory level of production.

6. RURAL DEVELOPMENT AND AGRO-ECONOMY

THE CONTRIBUTION OF GEOGRAPHICAL INDICATIONS IN SUSTAINABLE RURAL DEVELOPMENT (EVIDENCE FROM NORTHERN ALBANIA)

Roland BARDHI[1*], Ilir KAPAJ[2]

[1]Mountain Areas Development Agency (MADA), Tirana, Albania
[2]Department of Agribusiness, Faculty of Economy&Agribusiness, Agricultural University of Tirana, Tirana, Albania
*Corresponding author: lbardhi@mail.com

Abstract

Geographical indications (GIs) are a form of protective labeling used to indicate the origin of food and agricultural products. The role of protected geographical indicators as a promising sustainable rural development tool is the basis for this paper. The protection of geographical indications is a new practice and much research is still required for both sides of the debate. The focus of this debate is: Can a Geographical Indication (GI) which indicates that a certain product originates from a certain region with a given quality being attributable to its place of origin, become a tool to promote socio-economic livelihoods of rural communities? The research method employed for this study is a qualitative research approach. Two potential GI products are used to investigate the benefits brought to rural areas through the protection of GIs. The case studies include the GIs Chestnut and chestnut honey in two geographical Albanian areas, Tropoja and Reç of M. Madhe areas. Twenty-five in-depth interviews were conducted in 2016 for this study. The study identifies predominantly indirect links between GIs and sustainable rural development (SRD), through economic and social benefits brought to rural areas by the GIs investigated. This finding suggests that GIs are worthwhile for implementation in Albania as a rural development tool. The initiative for development of GI products was undertaken by BiodivBalkan Project, implemented in the North Albania, aiming to link biodiversity with development of quality signs (GIs) in order to support rural development and poverty reduction in the poorest areas of Albania.

Keywords: *Geographical Indications, Agrobiodiversity, Rural development, BiodivBalkan Project.*

Introduction

There are two decades or so that the biodiversity issue was enriched by a new dimension called "Agrobiodiversity". Geographical indications have been developed for primary and processed products of biodiversity.

A geographical indication (GI) is a form of protection highlighted in the Trade Related Aspects of Intellectual Property Rights (TRIPS) Agreement of the World Trade Organization (WTO). It protects intangible economic assets such as the quality and reputation of a product through market differentiation (Vandecandelaere, E., F. Arfini, G. Belletti and A. Marescotti (eds.) (2010).

It is considered a promising tool at the international level to maintain multi functionality in rural landscapes and involve local populations in biodiversity management and conservation. Using the examples of creating GI for "Chestnuts" and "Chestnut Honey", we discuss how a GI can be successfully used by local producers and what conditions are needed for it to have a positive impact on the rural development and its associated biodiversity.

GIs, in a general sense, are signs placed on products that have a clearly established origin and poses qualities and reputation derived from its place of origin. GI provides a relevant tool to protect and promote or enhance biodiversity (Larson Guerra, 2004). It is important therefore not to only consider the biological characteristics of a geographical area, but also the local knowledge and practices involved (Bérard and Marchenay, 2006) in order to achieve biodiversity benefits.

It is generally agreed that GIs promote sustainable rural development because they:

- Help producers obtain premium prices for their products whilst guaranteeing safety and quality to consumers;
- Improve redistribution of the added value to the actors (producers, processors etc) throughout the production chain;
- Bring added value to the region of origin;
- Increase production, create local jobs and prevent rural exodus;
- Preserve landscapes, traditional knowledge and biodiversity;

Giovannucci et al., (2009) emphasizes that even with originality of a potential GI product, the benefits will not accrue to the actors without the support of the legal and institutional frameworks. Other factors that support GIs registration of products include; collective action, prices and market for the product, specificity and reputation of product, support from other actors along the value chain, production methods and link of a product characteristics to history or tradition of the geographical area (Bramley and Biénabe, 2013).

There is much reference in economic and agrofood literature to the contribution of geographical indications to rural development. This reference is predominantly theoretical, signifying that there is a need for more empirical evidence demonstrating that geographical indications promote rural development. Furthermore, there are many forms of geographical indications each possibly impacting rural development differently (Barham, 2003). There is far less literature specifically concentrating on the influence of GIs on sustainable rural development than there is on origin labeled products in general. However from the many researches done it is generally believed (Babcock & Clemens, 2004; Barham, 2002; O'Connor and company, 2005; Rangnekar, 2004) that GIs do promote sustainable rural development.

GIs serve also as a marketing tool that can add economic value to agricultural products by conveying a cultural identity using the region of origin, acknowledging the value of specific human skills and natural resources in the production process, and creating a unique identity for the products (Babcock and Clemens, 2004).

GIs as promoters of rural development

Studies have shown that when the name of a product obtains a protection as a geographical indication, there is a positive socio-economic impact on local communities. This is because GIs:

- increase production, create local jobs and prevent rural exodus;
- help producers to obtain a premium price for their products in exchange for guarantees offered to consumers on production methods and quality;
- allow for a better redistribution of the added value in the production chain;
- bring value to the land of origin;
- have other indirect positive effects, such as on tourism (O'Connor and Company, 2005).

Chestnut and chestnut honeys in northern area of Albania are two potential GI products.

Chestnut. The chestnut (Castanea sativa Miller.) production in northern Albania (Tropoja and Reçi regions) is one of the most important economic activities, providing good incomes for the local population, which is considered as the poorest areas in Albanian. On the other hand many stories aspects are related with this specie and could be considered as a logo for both Reçi and Tropoja regions. There are a lot of traditional foods prepared by the chestnuts.

The forest stands are managed traditionally by the local population for timber production, fruit production, shelter and recreate properties (MADA). Chestnut stands are an important component of the Balkan Alps, which together with Spruce forests (Piceaexcelsa (Lam) Link.), Beech forests (Fagussylvatica L.), Oaks and Hornbeam forests (traditionally managed mostly assilvo-pastoral systems), Mediterranean evergreen shrubs (dominated by Pomegranate-Punicagranatum L.) as well as alpine grass and dwarf vegetation, where Blueberry (Vacciniummyrtyllus L.) takes place, but not only; represent a beautiful diversified landscape, much preferred for the tourists and high potential for the economic development and poverty eradication. Biological points of view, all the chestnut stands are natural or naturally regenerated, which locally isolated, represent, we think, a specific genetic patrimony. *Chestnut honey* is one of the most a favorite honey varieties. It is not just unique flavor, not very sweet and with an almost bitter aftertaste, that stimulates the taste bud that makes it so special. Chestnut honey is also one of the healthiest honeys. It is rich in, mineral salts and tannin, with a high proportion of fructose that resists crystallization and a relatively low acidity, dark in color, ranging from yellowish brown to almost black. Of all the varieties of honey, he has the most pronounced antimicrobial, antibacterial and antiseptic properties, and therefore applies not only inside but also outside in the treatment of wounds, ulcers and sore throat (MARDWA, 2012). Due to this characteristics chestnut honey is much requested and its price is higher than most of the other honey varieties. The chestnut honey produced in both regions (Tropoja and Reçi) is well known. Perceptions on chestnut and chestnut honey reputation and quality by the producers and consumers of these products have identified as potential for GI registration in Albania, which have been attributed to the geographical area where the products are produced and the initiatives by the stakeholders.

The honey has a unique taste and a white color which is attributed to specific floral plants where bees obtain their nectar (Blakeney et al., 2012). Apart from increasing monetary value and employment creation, this honey has promoted forest and biodiversity conservation through a number of programs that include reforesting degraded areas (Bainkong, 2014) for sustainable production.

Materials and Methods

The study was conducted in northern area of Albania aiming to assess how production of the potential GI chestnut and chestnut honey can contribute to rural development of these areas (MADA, 2012).

In the framework of BiodivBalkan Project–Sustainable Rural Development, a comprehensive inventory of the various local traditional products suitable for GIs development scheme has been drawn up in 2013, through focused interviews with expert, farmers and other stakeholders related to the traditional products. Based on this inventory, a typology of stakeholders was prepared, comprising production practices and unique and typical characteristics associated to the local production. This typology has been used in gathering quantitative and qualitative data through structured interviews. Two questionnaires were designed and prepared.

A questionnaire was prepared with different sections aiming at identifying the characteristics of chestnut farms and production, chestnuts distribution and sale, technology used for production; problems faced by chestnut and chestnuts honey producing farms. The areas included in the study are Tropoja region and Malesia e Madhe region (Reç County). Face to face interview with representatives of two chestnut and chestnut honey producers association was conducted.

These areas have already seen the development of two GIs products (chestnut and chestnut honey), which are official registered at Patents and Marks Office in Albania in 2016 and their brand names are in use by their associations established in each areas.
The other questionnaire was used to assess the changes and implications of geographical indications in rural development of respective areas (MADA, 2016). Twenty-five interviews were conducted in both areas in late 2016, 11 stakeholders for each case study and a further 3 large retailers who were questioned about both products. The interviews for both case studies were chosen from almost the same list of stakeholders directly involved in producing and/or marketing of products.
The research method employed for this study was a qualitative research approach. The interviews were conducted to the primary producers, collectors, processors and enterprises. Than a comparison analysis of data between two periods, the inventory and data collected in 2013 and the data and results from interviews of 2016 was done.
The study identifies also predominantly indirect links between GIs and sustainable rural development (SRD), through economic and social benefits brought to rural areas by the GIs. This finding suggests that GIs are worthwhile for implementation in Albania as a rural development tool. In this paper are described main results on the chestnut and chestnut honey products, after their development as GIs product and their implications on economic, social and environment aspects.

Results and discussion

Results from both questionnaires indicate that the GIs products (chestnut and chestnut honey) are considered as very important contributors to the yearly income of farming family. In general, all families interviewed admitted they are in better economic conditions after their chestnut and chesnut honey production was launched in market with a brand new name and with quality signs (GI indications).
The table below gives some information about the surface, number of trees, number of beehives and total production for both products, in two regions in two periods.

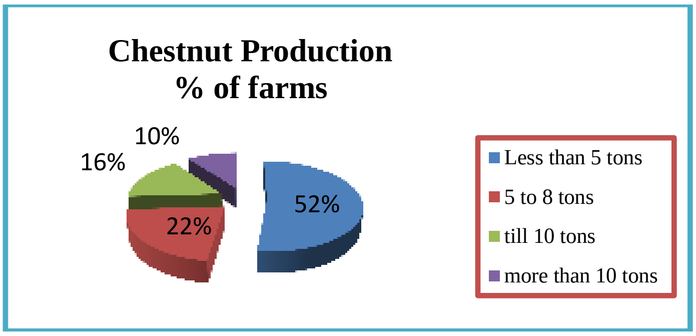
Table 1: General situation of Chestnut and honey in Tropoja and Reçi.

No	Description of products	Unit	2013		2016	
			Reçi Area	**Tropoja Area**	**Reçi Area**	**Tropoja Area**
	Chestnut					
1	Total surface	ha	600	2000-2400	600	2000-2400
2	Total number of trees	no	33 000	188600	33 000	188600
3	Total chestnut production	tons	350	1500	500	1680
	Chestnut Honey					
1	Number of Beekeepers	no	125	400	130	420
2	Number of Beehives	no	2500	6550	2650	7100
3	Total of Chestnut honey produced	tons	24	60	27	70

Changes on productivity
Compared with the productivity of 2013 the productivity of chestnut and chestnut honey is increased. The total chestnut production in Reçi area was increased by 150 tons, while in Tropoja area by 180 tons. The increase in production was due to more people were involved in harvesting of chestnuts.
The same increase was noticed in the productivity of chestnut honey. The quantity of chestnut honey produced in Tropoja area in 2016 was 10 tons higher than in 2013, while in Reçi was 3 tons higher 2016 compared with 2013.

Taking in account the total of chestnut production of two regions, the majority of farmers (52 %) produce less than 5 tons, about 22 % of farmers produce 5-8 tons, 16 % produce about 10 tons and 10 % of farmers produce more than 10 tons.

Chart1. Structure of Chestnut production by farms



Prices

The chestnut prices have been increasing every year despite the production increase. Actually the price of fresh chestnut in both areas is almost the same. It varies from 100 ALL/kg to 130 ALL/kg and depends on the season. Compared to the 2013, the price of chestnut was increased by 20-30 ALL/kg.

The superior quality chestnut was sold in Reçi with 280 ALL/kg. From the data gathered, the price of Tropoja and Reçi chestnut is 20% higher than the chestnut coming from other regions of Albania, although the origin of the product sold in the market is not always clear.

Regarding chestnut honey, due to its higher antiseptic and antioxidant properties, it is considered as a natural medicament. These characteristics increase the price of chestnut honey which actually is almost 30% higher than the price of mixed flower honey.

Actually the price of 1 kg of chestnut honey is 1500-2000 ALL, which is triple higher compared to 2013. There is a high demand in the internal and international market for chestnut honey, which is promising for high prices even in the situation of a possible increase of the production. Since the price of the chestnut honey is very much related to its chemical and organo-leptical characteristics, an improvement in logo and labeling, where these characteristics are easily noticed by customers, has contributed in increasing the prices.

Marketing channels

In 2013 the chestnut commercialization was not everywhere well organized. In most prominent chestnut production areas in Albania (Reç and Tropoja areas) there were collectors and wholesale traders that deal exclusively and continuously with fresh chestnuts, while in other areas commercialization was performed sporadically by traders that deal mainly with other agricultural products.

Based on the data of 2013, the most important chestnut collector and trader entity in Tropoja was “AMLA Company”. In 2013 “AMLA” has collected, processed and traded almost 500-600 tons of chestnut which was almost 45% of the total amount traded in the Tropoja area. The other chestnut percentage (65 %) was sold direct by producers to local shops or consumers.

Based on the data of 2016 the structure of marketing has changes. A high quantity of chestnut was exported in Kosovo. The price was decided through negotiations between the farmers and traders. The price of the chestnut was around 100-120 ALL/ kg. Since there is no selecting process, the price is unique for whole production quantity. It changes only according to the season. At the beginning of the harvestin period it is higher and it falls to 100 ALL/kg in November-December.

During the last year, 50% of chestnut produced in Tropoja has been exported to Kosovo. Due to the short distance many farmers invented themselves as traders and started to export chestnuts. These traders sell the collected product also in the local market, mainly in Tirana and Shkodra. Based on the assessment made by the Project, small traders collected last year almost 1500 tons, half of it was sold in Kosovo and half in the internal market.
The main chestnut trader's entity is the Cooperative "**Reçi Prodhimtar**". They sold last year more than 500 tons of chestnut. Almost 90% of the product was exported. The largest quantity is exported in Italy, where the cooperative has established good business linkages. Smaller volumes of the product are sold to Kosovo traders. The main Albanian market is the area between Tirana and Durrës, but part of the product is sold also in Shkodra and other Albanian important cities.

Chart2. Main distribution channels -Tropoja region

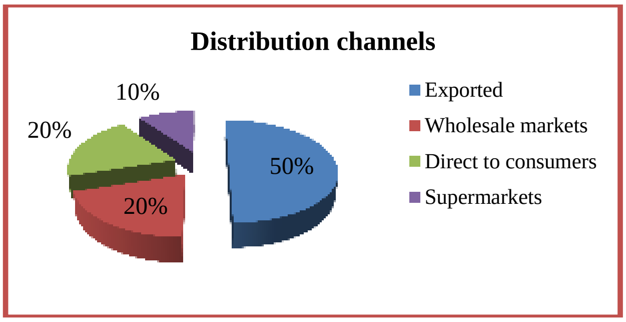


Chart3. Distribution channels -Reçi region

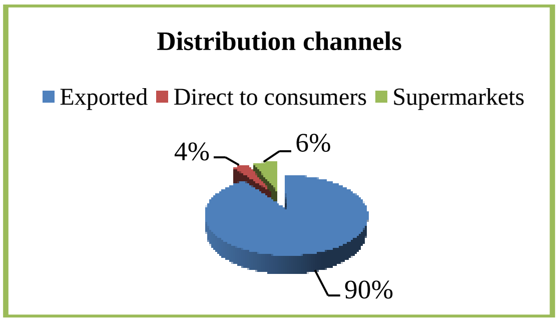

Compared to some other fruits and agriculture products, producers of chestnut do not have problems with the chestnut sale. Since there is no selecting process and standardization of the product, the price is unique for whole production quantity. It changes only according to the season.

The marketing of chestnut honey in general and in particular in Tropoja and Reçi village is moderately organized. Each beekeeper sells its own honey to occasional buyers or different mediators. No defined marketing channels exist or are used for honey. Since the chestnut honey product has a logo and label the price increased and no market problems were faced.
In fact the demand for this product is high. For this reason the producers have not yet face any difficulties in marketing it.

Incomes
Most of the chestnut and chestnut honey producers confirmed that their incomes by both products have been increased during 3 last years. Based on their responses their incomes have been increase by about 30-35 %.
They admitted that the biggest incremental income share is dedicated to the increase in chestnut production, considering two reasons, productivity and prices increase.

Conclusions

Literature indicates many positive effects of GIs on sustainable rural development, very simply these can be categorized into ecological, economic and social effects. The two products investigated do not have profound direct links to all of these elements, however many indirect links were found. The Geographical Indications evaluated were least strongly tied to ecological benefits, with stronger ties to economic and social values.

The rural development of the Northern Albania can be improved through the creation of value added marketing channels for typical products, and GIs are a possible means towards that and where products have particularities and a preferential position in markets.
Both products have: (i) better price in the market compared with similar production produced in the other areas of the country; (ii) their specifities and characteristics have strong links with their geographical area (territory); (iii) there is a high demand for these products in the domestic and regional markets; (v) these products have a strong link with biodiversity.
In both areas the local stakeholders (farmers, processors and traders) have a satisfactory level of organization, which should be strengthened. "Reçi Prodhimtar" and "AMLA Company" are two structures that can keep around them most of the farmers engaged in this sector. On the other hand there is willingness for collaboration between the local actors.
There is enough evidence to show that the GIs investigated in this study are linked to more than just economic benefits and are therefore trending toward Sustainable Rural Development; however these links alone are not strong enough to say that GIs promote sustainable rural development. A promising finding of the study was that although many of the links between the GIs investigated and Sustainable Rural Development were indirect all stakeholders agreed that GIs promote Sustainable Rural Development.
Protection of GIs could help to sustain economic activities and settlement in rural areas and increase the life standards of the residents. Rural population is the prime beneficiaries of these kinds of products in terms of income and employment generation. Moreover, under an effective protection and marketing process, the economic activities in rural areas could increase further not only by the growth of GI production but also by developments in the other sector as well. While it is hard to obtain a competitive advantage based on technology in rural areas and that advertisement costs are high for the local producers, GIs provide important alternative advantages for the rural development by sending direct signal to the consumer that the product is originated from a specific region with a certain quality not requiring big investments on technology and advertisement.

Acknowledgements

This study was prepared under the BiodivBalkan Project – sustainable rural development of Balkan Mountain areas.
The idea was to produce an inventory of the products arising from the biodiversity of the Northern Albanian Mountains and study the commodity chains for these products. The chestnut and chestnut honey products were pre-selected as two potential products, whose characteristics and their quality is so linked with their territory. An additional objective was to have the analysis of changes and improvements after the development of two GIs products, focusing on their economic, social and ecological effects.

Abstract

The application of Information and Communication Technology (ICT) advances in agriculture has completely revolutionized this sector. Unfortunately, alongside numerous advantages such as increased agriculture productivity and profit, the ICT has many disadvantages. ICT can harm the land, biodiversity and water sources and it can generate significant amounts of greenhouse gas (GHG) emissions. Therefore, the current research is being focused on finding novel approaches which will increase productivity in the agriculture sector with no or minimum impact on the environment and human health. Novel technological approaches, Green Internet of Things (G-IoT) and Green nanotechnology appear as the adequate solutions to create smart and sustainable agriculture and food industry. Production automation, precision farming, remote monitoring, traceability, decision making and forecasting, promise to completely transform agriculture and the food supply chain. Green nanotechnology brings more efficient use of agrochemicals and more advanced food production processes. More productive, sustainable and precise agriculture practices and enhanced food production will lead to increased productivity and profit while at the same time the usage of raw and non-renewable resources will be reduced. This will be accompanied by decreased pollution and emissions what will lead to the realization of smart and sustainable agriculture. Hence, this paper represents an analysis of G-IoT and Green nanotechnology concepts and their role in revolutionizing agriculture sector accompanied with eliminated or minimized negative influence on human health and environment. The realization of smart and sustainable agriculture will substantially provide significant economic and social benefits.

Keywords: *G-IoT, Green nanotechnology, Sustainable agriculture, Food, Environment.*

Introduction

Technological achievements in recent years have significant influence to every facet of peoples' lives. Numerous sectors have been dramatically transformed and like many other sectors, agriculture didn't remain immune to novel technological advances and results. Only revolutionizing agriculture can satisfy an increase in agriculture demands followed by continuous population growth. Opara (2004) has identified a technology triad (biotechnology, ICT (Information and Communication Technology), and nanotechnology) that has the potential to revolutionize agriculture in the 21st Century.

Since its appearance, the Internet of Things (IoT) as the global network of interconnected smart things/devices, has been implemented in agriculture for monitoring soil, plants, animals, food supply chain, greenhouse gasses (GHG), etc. (Patil et al., 2012). The automation of production, cultivation factors, and inputs, precision farming, logistics, traceability, remote monitoring, decision making, forecasts, etc., are the main benefits that

IoT brings in agriculture towards achieving sustainable agriculture (Fig. 1) (Maksimovic, 2018; FAO, n.d.). At the same time, nanotechnology, as a research area that covers a wide scope of technologies carried out on the nanometer scale, is becoming increasingly important for the agricultural sector (Manjunatha, 2016). It has already shown its huge potential in crop production, soil improvements, diagnostic, plant breeding, etc.

Despite the numerous benefits technological innovations bring, the consequences of their utilization are more waste, increased GHG emissions and/or the consumption of natural and non-renewable raw materials what may have negative effects on human health and the environment (Maksimovic, 2018). Therefore, to move towards sustainable development and sustainable place for living, it is demanded to reduce the technology's negative influences. The solution is seen in green technologies, Green IoT and Green nanotechnology particularly. The implementation of

- green design (designing energy efficient and environmentally aware products/devices),
- green manufacturing (products/devices production with minimal or no impact on the environment),
- green use (reducing energy and other resources utilization and products/devices applications in an eco-friendly way),
- green communication (reasonably priced, low-power, long-range communications), and
- green disposal (reliable, low cost, reusing, recycling),

will significantly contribute to achieving the full potential of technological progress in revolutionizing agriculture alongside reduced negative impact on the environment and human health (Nandyala and Kim, 2016).

Therefore, this paper represents a study of G-IoT and Green nanotechnology's role in achieving smart and sustainable agriculture.

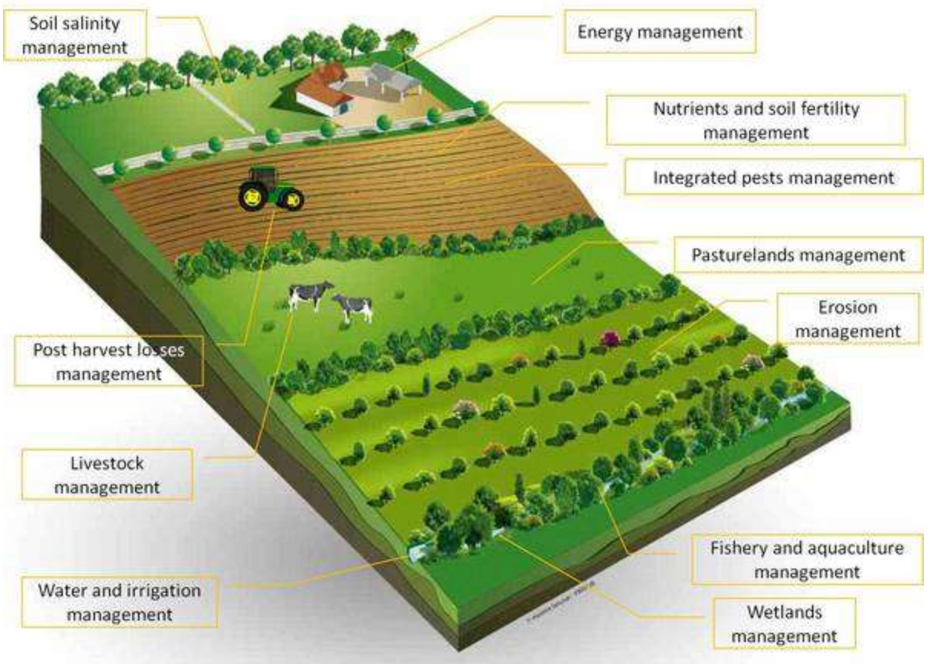

Figure 1. Sustainable agriculture platform (FAO, n.d.)

G-IoT supported agriculture

Recognizing that the agriculture is fundamental to economic development and environmental sustainability, the research interest to improve the agriculture sector is more than justified. The result of technology involved in agriculture is the development of smart, efficient and sustainable agriculture, where the balance between increased agricultural productivity and environmental impacts is mandatory. The IoT implementation in agriculture is based on utilization of a large number of diverse sensors and Wireless Sensor Networks (WSN) that are able to measure the parameters of interests (e.g. temperature, humidity, pressure, gas concentrations, etc.). With the help of RFID (Radio Frequency Identification) tags and GPS (Global Positioning System), food products can be located and tracked from farm to fork. After the measuring and collecting data on a real-time basis at the sensing layer of IoT, the information is being transmitted further for analysis and storage. The implementation of Cloud or Fog computing enables easier handling and processing diverse and voluminous data. The data procession is essential for obtaining valuable insights and knowledge demanded to make appropriate decisions, forecasting, performing adequate actions and developing an extraordinary predictive business model on different agriculture sectors (Balamurugan et al., 2016). As can be seen, the IoT utilization in agriculture enables remote and real-time monitoring of various elements (soil, plant, food products, etc.) and making appropriate actions regarding soil improvements, plant breeding, pesticide control, diagnostic, food packaging, traceability and safety, animal feeding, and so on. In other words, technologies like sensor-based, satellite remote sensing, WSN, RFID, GPS, GIS (Geographical Information Systems), advanced data analytics and smart information platforms significantly contribute to more efficient and effective farming practices and therefore contribute to associated environmental and social benefits (Sarni et al., 2016). According to Beecham Research (2015), the IoT with new techniques holds the potential to increase agricultural productivity of 70% by 2050. The inclusion of G-IoT will significantly contribute to these anticipated achievements, by revolutionizing whole agriculture sector and the food supply chain through more productive, sustainable and precise agriculture practices. The benefits of G-IoT application in agriculture are better management of soil fertility, more effective utilization of water and fertilizers, pesticides, and herbicides, crop and livestock diversification as well as appropriate farm automated machinery (Maksimovic, 2018). In this way, the G-IoT significantly reduces the negative influence on the environment successfully dealing with the climate change that represents the biggest issue in agricultural paradigm (Nida et al., 2015).

The main benefits of G-IoT inclusion in agriculture can be summarized into (Patil et al., 2012; Nida et al., 2015):

- The remote and real-time monitoring and enhanced utilization of inputs (soil, water, fertilizers, pesticides, etc.) as well as monitoring of animal health,
- Decreased production costs,
- Increased profitability, new financial opportunities, and development,
- Sustainability,
- Improved food safety,
- Environmental protection.

Evidently, G-IoT inclusion in agriculture enhances productivity, energy and resource efficiency while at the same time reduces waste and contamination. As agriculture covers a range of sources (and some sinks) of GHG, it is forecasted that through the implementation of smart agriculture, 2 Gt CO_2 (carbon dioxide) equivalent emissions per year could be averted by 2030 alongside 16% of global hazardous emissions reduction. Smart agriculture also provides substantial economic and social benefits, and G-IoT represents an important support for the realization of high-quality, high-efficiency, intensive, safe, and environmentally aware agriculture (Bo and Wang, 2011). It is anticipated that through intelligent detection, cultivation control and precise irrigation in agriculture, by 2030 1 billion MW of energy will be saved, 897 average kg/Ha of land yield will increase, while cost-savings through reduced water use could amount up to $110 billion. Additional revenues to companies across the sector are expected to reach $2 billion (GeSi, 2015).

Green nanotechnology role in agriculture

Nanotechnology and nanomaterials in agriculture aim to reduce the amount of sprayed chemicals by smart delivery of active ingredients, minimize nutrient losses in fertilization and increase yields through optimized water and nutrient management. Devices based on nanotechnology are being explored in the field of plant breeding and genetic transformation. Based on traditionally harvested materials (e.g. wheat straw and soy hulls) bio-nanocomposites with enhanced physical-mechanical properties can be produced for bio-industrial purposes (Parisi et al., 2015).

The most relevant agricultural nanotechnology applications are (Parisi et al., 2015):

- Crop production: Plant protection products and fertilizers belong to this group. Nanocapsules, nanoparticles, nanoemulsions and viral capsids are main plant production products and fertilizers based on nanotechnology. They are used as smart delivery systems of active ingredients for disease and pest control in plants or for the delivery of nutrients to plants. Nanofertilizers have broad application today. The main representatives are nitrogen fertilizers, potash fertilizers, nanoporous zeolite, zinc nanofertlizer, nanoherbicide, nanopesticide (Rameshaiah et al., 2015).
- Soil improvement: Nanomaterials can be applied in water/liquid retention. Some examples of the application are zeolites and nanoclays used for water or liquid agrochemicals retention in the soil for their slow release to the plants; nanoclays can be used as filters for removal of variety of toxic substances from the environment.
- Water purification and pollutant remediation: Nanomaterials, nanoclays can be used as filters for removal of variety of toxic substances from the environment.
- Diagnostic: Nanosensors as highly sensitive bio-chemical sensors can be implemented for monitoring environmental conditions, plant health and growth (e.g. nanofibers, fullerens, electrochemically active carbon, nanoaptamers, wireless sensors, smart dust technology) (Rameshaiah et al., 2015).
- Plant breeding: Nanomaterials can be used as carriers of DNA (deoxyribonucleic acid) or RNA (ribonucleic acid) for their delivery to plant cells, for their genetic transformation or to trigger defence responses, activated by pathogens.
- Nanomaterials from a plant: Nanomaterials can be produced from engineered plants or microbes and through the processing of agricultural products waste.

The main goal of the application of green nanomaterials in modern agriculture is to decrease usage of environmentally harmful inputs, reduce losses of costly fertilization, increase inputs use efficiency and yields through need-based management. Green nanomaterials are materials synthesized based on environment-friendly principles. These materials play a key role to minimize GHG emission to the atmosphere, a particularly significant decrease in releases amounts of CO_2, N_2O (nitrous oxide), and CH_4 (methane) from the agriculture field. Furthermore, green nanomaterials minimize the troubles in agricultural practices concern to the human health and environment under a changing climate, increase food and nutritional security, and agricultural productivity as required to rapidly increasing global population (Ashoka et al., 2017).

In summary, the main features of Green nanotechnology concept are safe and energy efficient products and processes, reduced waste, lessen GHG emissions and usages of renewable materials (Maksimović and Omanović-Mikličanin, 2017). A symbiotic approach of G-IoT and Green nanotechnology refers to Green Internet of Nano Things (G-IoNT), which holds a potential to make a whole world of remarkable improvements in the agriculture sector. Green nanoparticles, nanosensors, nanorobots and other green nanodevices connected in green nanonetworks via G-IoNT, create a completely new environment for the revolutionizing agriculture and food industry in 21st Century.

Conclusions

Agriculture sector and food industry are facing today the great challenges due to a growing global population and climate change. Thus, application of nanotechnologies and IoT in this sector can greatly contribute to address the issue of sustainability. However, as with the application of all new technologies, there is the need to perform a reliable risk-benefit assessment, as well as a full cost accounting evaluation.

Application of nanotechnologies and IoT in agriculture and food industry has disadvantages such as potential harmful influence on the land, biodiversity and water sources and increased amounts of GHG emissions. Therefore, novel technological approaches, G-IoT and Green nanotechnology were developed as the adequate solutions for smart and sustainable agriculture and food industry. The benefits of G-IoT application in agriculture are better management of soil fertility, more effective utilization of water and fertilizers, pesticides, and herbicides, crop and livestock diversification as well as appropriate farm automated machinery which at the end leads to significant reduction of the negative influence of IoT on the environment successfully dealing with the climate change that represents the biggest issue in agricultural paradigm. On the other side, Green nanotechnology plays a key role to minimize GHG emission to the atmosphere, to minimize the troubles in agricultural practices concern to the human health and environment under a changing climate and increase food and nutritional security. G-IoT and Green nanotechnology together create G-IoNT that will significantly contribute to the revolutionizing agriculture practices and techniques, making agriculture sector and food industry more efficient, safe and sustainable as never before.

CURRENT FUNDING SOURCES FOR AGRICULTURE IN THE ENTITYOF REPUBLIC OF SRPSKA (BOSNIA AND HERZEGOVINA)

Radomir BODIROGA*, Grujica VICO, Goran PERKOVIC

Faculty of Agriculture, University of East Sarajevo,Republic of Srpska, Bosnia and Herzegovina
*Corresponding author: radomir.bodiroga@gmail.com

Abstract

Fulfilling the needs of business entities with the basic activities in the field of agriculture certainly implies securing a sufficient amount of funds in both quantitative and qualitative terms. For the agrarian sector financing is one of the limiting factors and for this reason in the paper we analysed the current funding modalities of agriculture in the Entity of Republic of Srpska (Bosnia and Herzegovina) and pointed to their specificities, advantages and disadvantages. The results indicate that there are four most important modalities that are present individually or in combination with a different participation in the total financial system(self-financing,state-supported financing, financing by the loans from the commercial banks and financing through donations) as well as the importance of development of potential modalities and those which still do not have a significant share in the financing (foreign direct investments (FDI), securities, and concessions).

Keywords: *Financing of agriculture, sources of funding agriculture*

Introduction

In the literature it has often being emphasized the importance of the agrarian sector as the sector of high priority for the development of the national economy. One of the basic constraining factors of its development is a lack of effective funding sources, which is essential both for the procurement of the necessary equipment and machinery, and purchase of the land, as well as the construction of transport and communal infrastructure, and also the creation of other necessary conditions for unimpeded manufacture in rural areas. For the economical and profitable business operations of commercial entities, with agriculture as its primary occupation, it is necessary to provide the financial resources to match their needs both in quantitative and qualitative terms. Accordingly, an adequate funding source is a source that places assets to a longer repayment period without demanding collaterals. Financing of agriculture should take into account biological specificities and socio-economic conditions for the development of agriculture in certain countries (Radovic, 2015). Due to the specificity of agricultural production and the low level of reproductive capacity, external sources of financing are often necessary for investments in agriculture (Ramic and Vasiljevic, 2009). In this paper, current modalities for funding of the agriculture of the Republic of Srpska have been analysed and its specifics, advantages and disadvantages have been indicated.

Material and methods

The data on which the study on current funding modalities of the agriculture of the Republic of Srpska is based were collected from the secondary sources published by the relevant public and private institutions. To the study of the aforementioned documents and databases as well as other used literature the analythical method was applied, along with the method of synthesis and the historical and comparative method. The analythical method was intended to parse the complex terms to easier whereas the method of synthesis led to the conclusion about certain modalities by connecting up the elements into the logical whole. Historical method was used to perceive the changes in the level of the agrarian budget and in its share in the total budget of the Republic of Srpska. In order to achieve the simplicity and neatness, the results are shown graphically.

Current modalities for funding of the agriculture

During the present period in the Republic of Srpska, the following modalities for funding of the agriculture with different contributions, either individually or in combination, were present:

- Self-financing
- State-supported financing
- Financing by the loans from the commercial banks
- Financing through donations

Certainly, self-financing is one of the most common modalities used by the business entities of the Republic of Srpska who have agriculture as their main activity. It is a stable, easily accessible and safe method of financing which implies the use of manufacturers' own funds (Vasiljevic and Sevarlic, 2005). The reasons for high representation of this model lie in low costs of capital usage, poor access to other available modalities, the manufacturer's distrust, or the low level of information about other available modalities, etc. However, in the literature this mode of funding is not considered to be free of charge, and its costs are expressed as the loss of profit which could have been achieved by investing in more profitable project. The advantage of the use of one's own funding sources is in the financial stability of the commercial entity (Radovic, 2015).

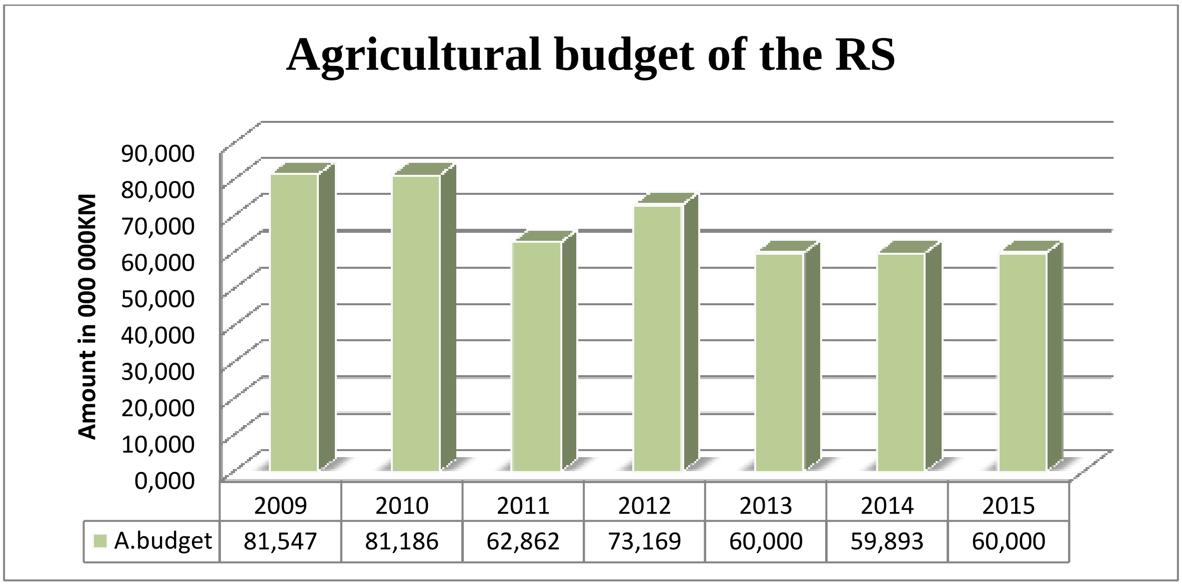
The loans from the commercial banks are often to be used as one of many possible funding sources of agriculture. Both the interest to be paid for the use of the loan as well as the means used as the collaterals are different depending on whether the borrowed funds are to be used in the short, medium, or long term. Immovable property on the estate, movable property, various forms of guarantees, etc can be used as collaterals. This is also the main concern of agricultural manufacturers in the Republic of Srpska who use this model of funding: How to solve the problem of adequate collateral? In this case, the land wins the position of the best collateral because it is an indestructible and fixed asset owned by majority of agricultural manufacturers. However, commercial banks are rarely interested in accepting this form of collateral mostly because of unresolved ownership relations and the absence of an adequate register of land plots. When it comes to the issue of collaterals one of the possible solutions may be in the use of guarantees from the Guarantee Fund of the Republic of Srpska.

Guarantee Fund of the Republic of Srpska is an institution which has for its main objective supporting enterpreneurship through issuance of various types of guarantees for ensuring liabilities or other financial obligations between enterpreneurs on the one side, and bank or other financial institution on the other. The users of guarantees can be any individual or legal entities headquartered in the Republic of Srpska, and from the agrarian field in APIF (IT and Financial Sources' Brokerage Agency) registered agricultural estates, and legal entities dealing with the production and refining in the fields of agriculture and fishery.

State support is considered to be one of the most important modalities of financing of agriculture and rural development of the Republic of Srpska. Thanks to this funding source,

projects of construction of transport and communal infrastructure, telephone lines, and the like, as well as the different types of granted support (premiums, allowances, subsidies, compensations, etc) that participate in co-financing of agricultural production of the registered agricultural estates are funded, either partially or completely.
The agricultural budget is the main source of support by the Republic of Srpska for the development of agricultural production through various forms of incentives. The agricultural budget is managed by the Ministry of Agriculture, Forestry and Water Management of the Republic of Srpska through the Agency of Agricultural Payments of the Republic of Srpska. Level of the agricultural budget in the period from 2009 to 2015 is given in the following chart:

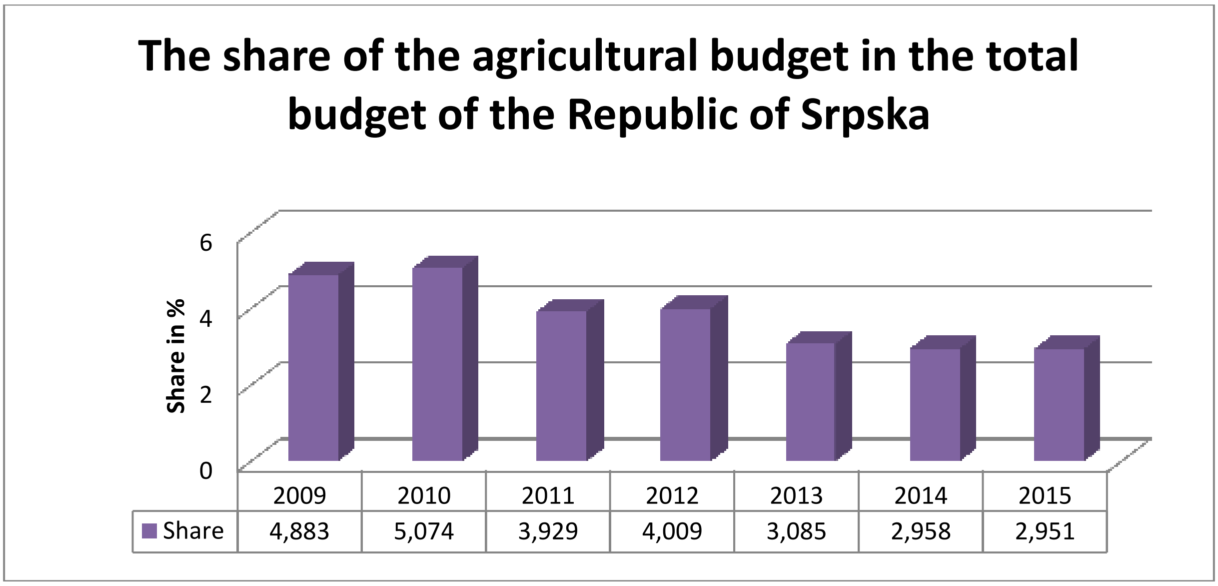
Chart 1: The level of the agricultural budget of the Republic of Srpska (RS) in the period from 2009 to 2015



Source: The annual report from the agriculture,foodand rural development of Bosnia and Herzegovina in 2015

From the chart it can be seen that the Republic of Srpska has a modest agricultural budget to support agriculture and rural development. In addition to the modest budget, there is an evident decline in allocation of funds compared to that in 2009. The height of the agricultural budget accompanied by occasional oscillations gradually declined in the period from 2009 to 2013, and has remained at that level until the year of 2015. During the period, the maximum height of the agricultural budget was achieved in 2009 in the amount of 81.547.000 KM while at the end of the reporting period the budget was reduced by about 20 million KM. The share of the agricultural budget in the total budget of the Republic of Srpska has varied during the period from 2,951% to 5,074%, as can be seen in the following chart.

Chart 2: The share of the agricultural budget in the total budget of the Republic of Srpska from 2009 to 2015



Data source: The annual report from the agriculture food and rural development of Bosnia and Herzegovina in 2015, author's calculation

The maximum share was achieved in 2010 while the minimum value was recorded at the end of the period, ie in 2015. Recommendation of the Agricultural Development Strategy 2009-2015 was that the share of agricultural in total budget of the Republic of Srpska increases and stabilizes at 6% share during the first three years, and then increases to 8% and to remain thus by the end of the 2015. Also, by the changes of the Law of Provision and Allocation of Funds for Agricultural and Rural Development in 2009, the share of the agrarian in the total budget was planned to be of at least 6%. According to the chart, however, it is evident that the proposed recommendations were not implemented. It is also important to mention that the specific provisions suggested by the Agricultural Development Strategy were entirely omitted. The Government suggests that the results of this decision and implemented support are the problems with the funding of the budget that affected the total amount of funds allocated for the agriculture.

The Investment and Development Bank is in the 100% ownership by the Republic of Srpska from 2006 and its primary purpose is to support the development and encourage investments in the Republic of Srpska. The IDB supports financially various forms of projects of which the agricultural loans, loans for micro-business in agriculture, and grants for primary development projects in the municipalities of the Republic of Srpska are of great importance.

Agricultural loans are intended for legal entities and enterpreneurs for the acquisition of fixed assets and working capital, refinancing, or paying taxes in the field of production and refining in agriculture and fishery.

Loans for micro-business in agriculture are intended for agricultural estates that are registered as legal entities or individuals for the purpose of acquisition of fixed assets and working capital.

Grants for primary development projects in the municipalities of the Republic of Srpska support projects which contribute to the realization of the third and fifth objective of the Agricultural Development Strategy of the Republic of Srpska for the period from 2016 – 2020 (Increase of the level of marketability and finalization of agricultural products and

integrated rural development).
The IDB loans in the Republic of Srpska are characterized by significantly more favourable interest rate in comparison with commercial loans, and the existence of priviledged groups with the additional reduction of the rate (for projects implemented in less developed or extremely underdeveloped municipalities, for cluster members, short-term loans for processors, etc). All IDB loans are invested through financial intermediaries, ie commercial banks and microcredit organizations.
According to the reports from the IDB database of the Republic of Srpska, total amount of loans implemented by the end of 2016 for legal entities and individuals in the field of agricultural production and processing of the agricultural products reached 201.083.018,46 KM. Financing through donations involves the use of funds without the obligation to return them to the donor or to pay the costs of the use of the capital and interest rates. Funding source of this type usually comes from the state or other native or foreign donors (international organizations, non-government organizations, etc) in order to assist the recipient of the grant in specific areas of its activities. The Directorate for European Integration (for donors from the EU) and the Ministry of Finance and Tresury of Bosnia and Herzegovina (for other donors and international financial institutions) are in charge of the coordination with donors in the field of agriculture in the territory of Bosnia and Herzegovina.
According to the *Report of international support for agriculture, nutrition and rural development in 2015*, the group of active donors to agricultural sector of Bosnia and Herzegovina include: the European Union, Japan, the Netherlands, Sweden, Czech Republic, Germany, USA, Italy, Switzerland and the UN organizations (UNDP and FAO). The aforementioned donors actively participate in strengthening the competitiveness of the agricultural sector, convergement of legal regulations with the EU, improving economic integration with the EU, etc.
It is important to add that a significant number of EU member states provide individual assistance to given agricultural sectors. However, despite the large number of donors, it is evident that this modality of financing has a potential for significantly higher utilization rate.
Bosnia and Herzegovina, and therefore the Republic of Srpska, has no access to pre-accession programs offered by the European Union. Ever since 2008, the criteria were to be fulfilled in order to be able to use pre-accession funds of the European Union, and for the implementation of these all the necessary technical support was provided. The criteria were primarily concerned to establish adequate operational structures, and since they were not completed, the IPA2008, IPA2010 and further assistance for their implementation were suspended. In 2014, a IPAII Strategy document for Bosnia and Herzegovina have been adopted by which support for agriculture and rural development was not provided. Currently, Bosnia and Herzegovina can use two types of assistance, ie assistance in transition and institutional development and cross border cooperation. These programs are intended to assist in cross-border cooperation between EU members and current and potential candidates (eg. Croatia – Bosnia and Herzegovina), as well as in cooperation between countries of current and potential candidates (eg. Bosnia and Herzegovina – Serbia).
Other modalities of financing of the agriculture that were present with a minimal participation in total financing involve foreign direct investments (FDI), securities, and concessions.
The importance of FDI is particularly evident in situations of insufficient national investments when they can have a positive inpact on development in all sectors of economy. Therefore, this modality can play an important role in financing of agriculture of the Republic of Srpska.
When it comes to agriculture, the Republic of Srpska issues the concession to unexploited

agricultural land in the state ownership. Up to the 2015, concessions on agricultural land and water resources have been active in a total of 55 companies in the Republic of Srpska. The area of 17,164.155 ha was coneded to aforementioned customers to use[10].
By the emission of securities it would also be possible to collect additional funds in priority sectors including agriculture, and use them to cover temporary budget deficites. The collected funds can be used for a variety of activities in order to improve the stability and the competitiveness of the agricultural sector.

Conclusion

For cost-effective and profitable operations of economic entities, agriculture being their main economic activity, it is necessary to provide in time the financial resources to meet their needs both quantitatively and qualitatively. Resources of quality will take into account the biological and socio-economic specificities which make the agrarian sector more demanding for funding. In the recent period, self-financing was one of the most frequently used modalities, characterized by its insufficiency to meet the needs of modern agriculture. Additional funding sources included the use of loans from commercial banks, state support for agriculture, and international donations, while others sources were insufficiently represented. Among these sources, the lowest share was recorded by the commercial banks due to a number of characteristics which made this source of financing less competitive in comparison to other available modalities. In the following period, it is necessary to intensify efforts towards the elimination of all obstacles and strengthening the potential modalities that can play a key role in solving the problem of financing of the agriculture.

Abstract

In order to achieve an adequate business results in agricultural production, the primary task is to provide financial resources on time. This task is achieved through the development of various forms of financing agriculture. Current funding modalities that have a significant share in total financing are not sufficient to meet the needs of an agricultural producer. Accordingly, in the paper the potential and insufficiently represented modalities were analysed, the establishment and development of which would significantly improve the financing of the agrarian sector. The results of the survey indicate that the Agrarian Bank have not been established yet on the territory of the Republic of Srpska, and agriculture as a branch of economy is not an attractive sector for foreign direct investments, since their share in total foreign direct investments is only 1.60%. The securities market is not sufficiently developed, and only the Banja Luka Stock Exchange operates with them. A similar situation is with other analyzed modalities that exist but with insufficient participation in total financing of agricultural production.

Keywords: financing of agriculture, funding sources, Republic of Srpska, Bosnia and Herezgovina.

Introduction

Agricultural production occupies a significant place in the economic structure of one country. The reason for this is in securing the employment of the population, significant share in gross domestic product (GDP), the main source of raw materials for industrial processing, and the like. The analysis of the state of agriculture of the Republic of Srpska (RS) indicates the necessity of replacing obsolete technology and equipment, improving the existing infrastructure of the agricultural sector, and modernizing all segments of agricultural production, which requires additional sources of its financing.

The importance of financing of agriculture and rural tourism is in timely provision of the necessary and adequate sources of financing for the purpose of realization of agricultural production, as well as the realization of economic and profitable business of economic entities (Radovic, 2015).When choosing adequate funding modalities, it is necessary to give priority to those who respect the biological and socio-economic specificities of this economic branch. Such a source will take into account the seasonal character of agricultural production, increased costs due to the impossibility of high specialization and high production risk, the influence that the size of the plots, the market situation, the state, the various associations and the like can have on financing.

In the recent period, on the territory of the RS, the most important sources in financing agriculture were the use of their own funds (self-financing), funds from state support, funds from international donations, and loans from commercial banks.
While drafting the paper attention is focused on potential modalities whose existence would significantly improve the financing of the agrarian sector, as well as the modalities with still insufficient participation in the financial structure. Financing of agricultural production is at this moment the most important problem of agricultural policy, starting from the fact that no economic activity can have good performance if the issue of its financing is not adequately solved (Curkovic, 2013).

Material and Methods

In order to get to the basic conclusions on the problems of financing agriculture, a detailed and comprehensive analysis of relevant public and private publications on a given topic was carried out. The information obtained were synthesized into logical units that were used to make concrete conclusions. The graphic presentation sought to achieve the simplicity and transparency of research results. In order to gain insight into the dynamics and the amount of foreign direct investments, the historical method was applied, while the comparative method was used when comparing foreign direct investments in different sectors of the economy.

Results and Discussions

The modalities that agricultural producers from the territory of the RS use to the fullest extent are important but not the only sources of financing the agriculture. The attention should certainly be focused on strengthening the modalities already present in the RS, but without significant participation, as well as the modalities that could be used to finance the agriculture in the coming period. Consequently, significant resources in the financing of the agrarian sector could be provided by using the following sources:

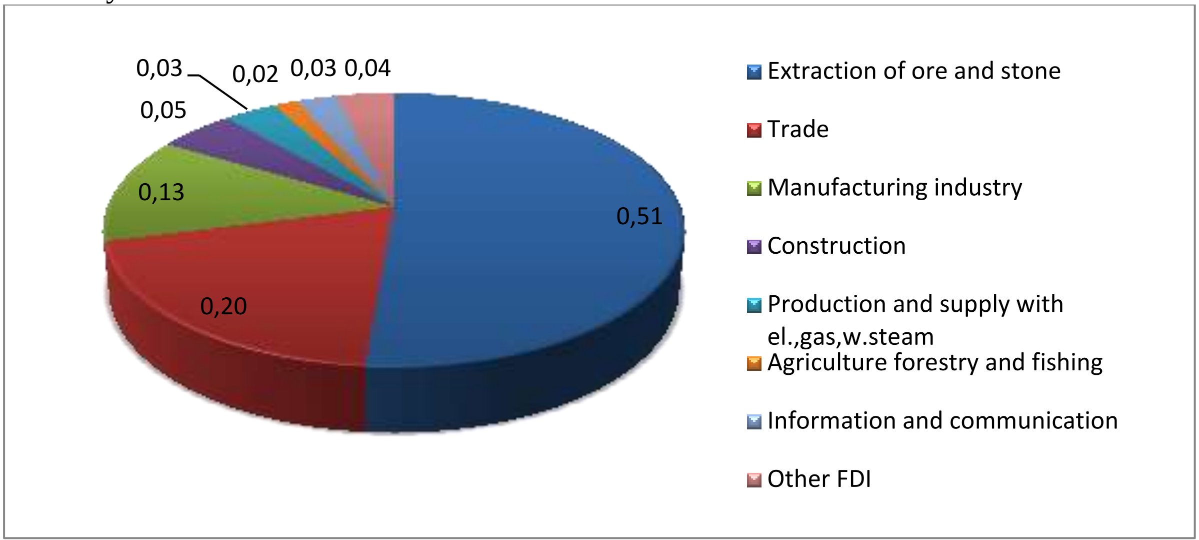
- Agrarian bank
- Foreign direct investments
- Joint ventures
- Leasing
- Securities
- Concessions
- Business angels

The establishment of a specialized **Agrarian Bank** would enable the concentration of funds for this purpose from various sources and their rational and efficient use for various purposes in primary agricultural production, processing of agricultural products, and multifunctional agriculture. The existence of a specialized agrarian bank would positively influence the development of the agrarian economy, and the development of the agrarian economy plays a key role in the overall economic development of the RS. The establishment of such a financial institution should be regulated by an adequate law that would specify the objectives of its business, the conditions under which loans, start-up capital and the like can be realized. The initial capital for the establishment of agrarian bank could be provided from different sources. *(Radovic, 2015)*

- Part of the funds of agrarian budget
- Funds of state financial institutions for agricultural loans
- Funds from the local self-government budget
- Funds from the lease of state agricultural land, etc.

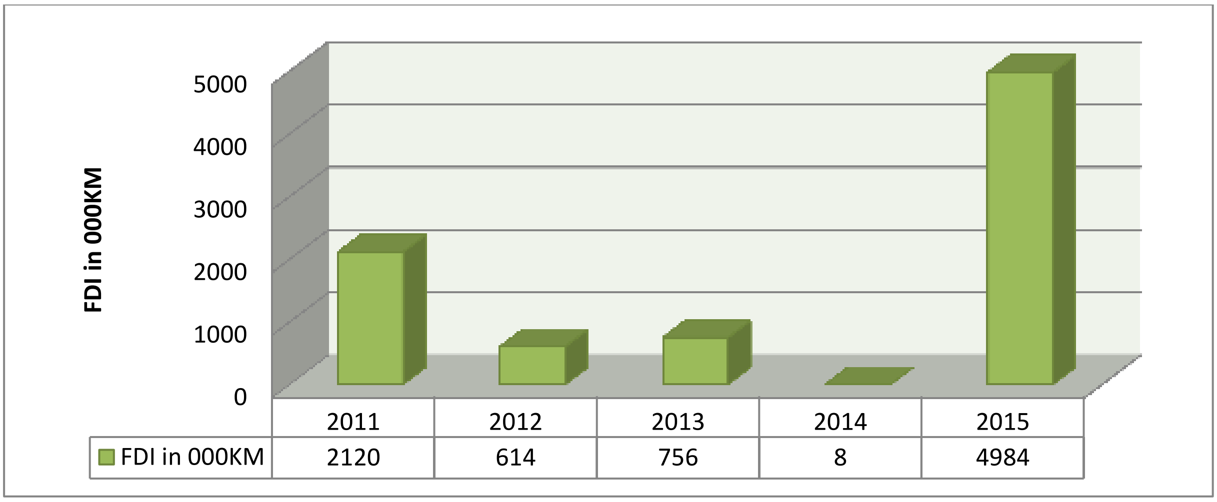
In the previous period, there were initiatives by agricultural associations to establish an institution of this kind, which has not yet yielded results. The Ministry of Agriculture, Forestry and Water Management of the RS has reasons for failing to establish an agrarian bank in an insufficient amount of capital and the necessity of involvement of international institutions in the implementation of such a project.

Foreign direct investments (FDI) differ from other foreign investments in the fact that they include only investments of foreign investors in the establishment or construction of a new company, or the purchase of shares i.e. ownership shares in already existing enterprises. FDI are a key developing factor in the modern economy, and with the trade, the most important means of business of the company, organization of production, supplying of goods and services on a global scale. *(Velagic, 2011)* In the period from 2006 to 2014, according to the data of the Central Bank of Bosnia and Herzegovina (BiH), the total FDI in the RS amounted to KM 4,158.1 million. Agriculture, however, as a branch of the economy is not an attractive sector for FDI. This is supported by data from commercial courts and Intermediary Agency for IT and financial services (APIF) on the participation of FDI in certain sectors of the economy.



Graph 3. Structure of FDI by sectors in the Republic of Srpska in the period 2011-2015
Source: Strategy for the Promotion of Foreign Investments in the RS from 2016 to 2020. Data from the Commercial Courts of RS and APIF

It is evident from the chart that the largest share in the total realized FDI have FDI from the field of mining and stone extraction, then from the field of trade, while the FDI realized in agriculture, fisheries and forestry in the total FDI in the RS is only 1.60%. The amount of total foreign investments in agriculture during the period from 2011 to 2015 is given in the following chart.



Graph 4. FDI in the period from 2011 to 2015 for agriculture, fisheries and forestry

Source: Strategy for the promotion of foreign investments in the RS from 2016 to 2020. Data from the Commercial Courts of RS and APIF.

The highest amount of FDI was realized during the observed period in 2015 in the amount of 4.984.000 KM, while in 2014 the minimum amount was 8.000 KM, which was certainly contributed by the weather in May of that year. Although the level of FDI in agriculture is low in comparison to other sectors, this sector of the economy has a number of comparative advantages that can stimulate potential foreign investors.

Joint ventures involve a time-limited form of association for the realization of a common project, after which the distribution of profits proportional to invested funds is made. It is realized through the cooperation of two partners on the principle of distribution of profits and coverage of losses proportional to invested capital. The main reason for such a form of cooperation between companies is the inability to finance independently a particular business venture.

Also, one of the priority objectives of the joint venture is to achieve a positive financial result that the partners would allocate in proportion to invested capital. The negative aspect of this form of cooperation can occur when partners have the same ownership over a joint project but cannot agree on important issues, while in the case of unequal participation in the project, a significantly higher risk is taken by a partner with a smaller share.

Recently, the Government of the RS has intensified efforts to find various foreign partners that would be interested in this kind of cooperation and investments in the agricultural sector.

Leasing represents a newer model of financing of investments that is widely used in developed market economies, but which has been expanding in developing countries in recent years *(Vasiljevic and Sevarlic, 2005)*. Financing of agriculture through leasing allows agricultural producers to have for a subject to leasing a means of securing debt collection under a financial leasing agreement, i.e. that the costs of financing do not burden the costs of bank guarantees. *(Radovic, 2015)*. This modality of financing is particularly suitable for agricultural enterprises that are unable to extract the necessary funds for the purchase of the necessary equipment, and do not have an adequate loan history or required collateral for the realization of a bank loan. Leasing as a form of financing can be found in the offer of commercial banks active in the territory of BiH (Raiffeisen, Unicredit, Sparkasse, etc.), among other things, for the purchase of agricultural machinery and equipment, but it is still an underdeveloped modality. For the sake of its significant representation, it is necessary to eliminate legal restrictions and to improve the system of forced collection, which would certainly lead to a faster development of leasing operations.

According to the Law on **Concessions** of the RS, published in the Official Gazette of the RS No. 59/13 under this term it is understood that the concessionaire's right is to perform economic activities by using public goods, natural resources and other goods of general interest, as well as the right to perform activities of general interest, for a limited period of time, under the conditions defined by the law and by paying appropriate compensation. The objective of granting concessions is to achieve foreign investment that will improve the economic development of the RS, thus providing the necessary funds, and focusing the budget resources for other needs. By the end of 2015, the concession on agricultural land and water resources was active with a total of 55 companies from the RS. The mentioned land users have been allocated an area of 17,164,155 ha[11] of agricultural land. Since the concessionaire is obliged to pay compensation for the granted right, as well as the compensation for use, the funds for this purpose become the revenue of the budget of the RS and the units of local self-governments, depending on the competence to award the concession. In order to make this modality more important in the financing of RS agriculture, its revenues could be directly included in the financing of the agricultural budget of the RS and the local agricultural budget.

In the coming period, the RS should pay considerable attention to the financing of agriculture in the **securities** market. With the adequate development of the capital market, improving the financing of this branch of industry can contribute to the use of different forms of securities (shares, bonds, commodity bills, commodity-commercial bills, as well as derivative securities, futures and options).

In the RS, currently there is a stock exchange called "Banja Luka Securities Exchange, j.s.c. Banja Luka".

The process of trade in the capital market of the RS is carried out through relations: the issuer of securities from which the whole market process originates and which in the capital market also has a role that the commodity producer also plays on the commodity market; trader of securities as a person who professionally deals with the resale of securities; the market organizer, the person performing the activity of organizing trade in securities; capital investors, persons who in this market have the role of consumers in the commodity market *(Drljaca, 2016)*. By issuing securities, the RS could collect additional funds in priority sectors, as well as in the agricultural sector, in order to cover temporary budget deficits. The collected funds can be used for various activities in order to improve the competitiveness and stability of the agricultural sector.

The **business angels** are also one of the potential modes of financing agriculture. This method involves the use of informal individual investors who have money, skills and business contacts during the initial stages of business development. Funds which investors invest in the company most often do not have to be repaid, but are replaced by participation in ownership over the same. Business angels invest in sectors and regions they know and can be organized in the form of networks and associations in order to increase their investments and joint management with the companies they invested in. In newly-formed companies that do not have a loan history or the necessary funds, this modality can be taken as a favorable solution. One of the characteristics of business angels as a modality of financing is investing in projects that can quickly make money. Therefore, this source is not suitable for all agricultural activities, but only those more profitable and more innovative than the current offer on the market. For this function it is necessary to animate successful individuals from

[11]Calculation by the author on the basis of the *Report on the Work of the Concession Commission for 2015(agricultural land - valid contracts).*

these areas who live and work abroad, and have the necessary free capital, skills and contacts whose engagement in this field will actively contribute to the development of agriculture.
On the BiH market there is a network of business angels called “Bizoo Angel Network”, formed by national entrepreneurs, for the purpose of discovering and investing in small and medium enterprises and innovative companies from all sectors of the economy.

Conclusion

Timely provision of financial resources is the primary task of an agricultural producer for the purpose of achieving adequate business results. In order to make this task easier, it is necessary to intensify efforts to develop additional modalities for financing of agricultural production. Among the analyzed modalities, the agrarian bank has not yet been established in the RS, and the presence of the same would allow the concentration of funds for this purpose from different sources, and their rational and efficient use for various purposes in primary agricultural production, processing of agricultural products, and multifunctional agriculture. The other analyzed modalities were present in the territory of the RS in the minimum and insufficient scope as well as the participation in the structure of the total sources of financing of agriculture. In the forthcoming period, efforts should be intensified to eliminate all obstacles and strengthen these potential modalities that can play a key role in resolving the problem of agrarian financing.

Abstract

For more than 25 years, agricultural cooperatives in Bulgaria have been operating in conditions of a rapidly changing socio-economic and political environment. The Institutional changes, blurring property rights, the separation of between ownership and management and change of the decision-making process, all required from agricultural cooperatives to undertake changes in the governance structure in order to answer the challenges of the dynamic environment. This means changing the direction of governance according the resources' empowerment by the management bodies. Cooperative management leads the decision-making process and fully accepts the management from the owners, changing its behavior model, in relation to the situation on the market. The increased competition and a rapidly changing market environment lead to convergence between the governance structure of the agricultural cooperative and the corporation. In that very long lasting and still ongoing transition period in Bulgaria, there is almost no sustainable cooperative model. In addition to the above, the cooperative management is transient, changing goals and values. Simultaneously, the cooperative governance structure is in the process of change, often deviating significantly from the formal and adopting the characteristics of the corporate one. The paper aims to explore changes and transitions in the governance structure of the Bulgarian agricultural cooperatives that lead to a balance between the interests of owners and managers, and guarantee the sustainability and efficiency of the structure.

Keywords: *Governance structure, Transformation, Agricultural Co-operatives, Bulgaria*

Introduction

The cooperative and in particular the agricultural cooperative, as a specific form of doing business, is part of the world economy. In the global world in which it operates, market conditions and increasing competition have a significant impact on it: its vision, strategy, governance, and governance structure are changing. Governance is the systems and processes concerned with ensuring the direction, effectiveness supervision of an organization. In this paper, the concept of the governance structure in the agricultural cooperatives should be understood as the interrelationships between governing bodies and members, as well as the influence of the external environment (institutional environment, market mechanisms, etc.).
Over the last decades, the changes in the governance structure of agricultural cooperatives have focused the attention of a considerable number of researchers, practitioners and policymakers in Europe and North America. Part of the researches support the thesis of radical deviations from the traditional (classic) governance where property rights belong not only to members of the cooperative (Chaddad and Cook, 2003). Typologies have been developed, with a different ownership structure (investing members and accumulation of votes), focusing on the investors of the capital investors (Nilsson, 1999). Other researchers

(Van Der Sangen, Jos Bijman, Markus Hanisch, 2012) discuss the decision-making process, the changes in the formal rights of the governing bodies (General Assembly, the Board of Directors, the Supervisory Board, the Chairman), and the introduction of innovations in the governance structure (inclusion of non-members and external experts in the governing bodies, appointment of a professional manager, introduction of a proportional vote, depending on the amount of the capital invested, etc.). These concepts respond to the understanding of the adaptation of agricultural cooperatives to the external environment. They explain the deviations between the principles of traditional cooperatives and the requirements of the modern governance.

In Bulgaria the issues related to the governance and the governance structure of the agricultural cooperatives generated wide interest among the scientific community (Bachev, H. (2009), Boevsky, I. (2012), ets. Over the past decade, as a result of increased competition from the corporate structures, the agricultural cooperative is forced to focus on its survival and adequate behavior. During this period, a continuous decrease in their number is reported. The cooperatives are not overrun by markets forces, and they have proactive positions in the design of the governance model. We are witnessing the introduction of innovative approaches to the governance of cooperatives borrowed from the conventional business units. To achieve the objectives, the governance of the agricultural cooperative needs new knowledge related to improving the organizational relationships. The cooperative has been gained its important place and role in the country's economic activity. It contributes to improving the quality of life of members and the employment in rural areas.

After the democratic changes in Bulgaria, the difficulties of cooperatives' functioning have been related to the ongoing demographic changes in the Bulgarian society. The deepening of migration processes, the low payment levels, the reduction of the workforce, the aging population, the shortage of young and educated people lead to significant social and economic difficulties in rural areas. They have been associated with poorly trained and qualified staff. Managers are experiencing a shortage of knowledge and work skills. The agricultural cooperatives must undertake changes in the governance structure to meet the challenges of the dynamic environment.

The aim of the paper is to study the changes and transformations of the governance structure of the Bulgarian agricultural cooperatives, which balance the interests of the owners and the managers and guarantee the structure sustainability and efficiency. *The governance structure of the co-operative units should be understood such as a system of relationships between managers and owners. It is formed under the influence of formal internal and external rights and obligations, informal rules, and external environment. The cooperative governance structure reflects the decision-making processes, protects owners' interests and guarantees the property rights and the fulfillment of the goals* (Sarov, 2017).

Materials and Methods

The paper is based on a qualitative analysis. It allows deep reflection of the changes in the governance structure, the natural behavioral processes in the organization, the tracking of relationships dynamics between the governing bodies and the interested parties (cooperative members and owners of agricultural land), the decision-making processes, the property rights, the control over management rights, etc. Changes in the external environment (social, cultural, political, legal, market, competition and distribution network) are analyzed. This method is a kind of descriptive: in-depth study, gathering data for participants through: analytical narratives, poll, interview, combining different techniques in interviewing, interactive approaches, community cohabitation, direct observations, trust, protocols, record reviews . The use of the case allows the interaction of all the variables and processes taking place in the cooperative governance structure, the circumstances, the behavior and the characteristics of the members in the cooperative and the community. The application of a depth study, for its part, includes an analysis of demographic characteristics, values, attitudes and motivation. Holistic and integrated case study have been combined. The case studies present the vision, the state and the main changes of the governance structure in the Bulgarian agricultural cooperatives. The focus is on changes in the decision-making process, the dilution of property rights, the right to control, the distribution of benefits, the change of objectives. Basic information has been gathered through the implementation of an embedded case that proved to be a successful strategy for the researcher to get into the depth of the problems.

The survey scope of the survey is the agricultural cooperatives operating on the territory of the Republic of Bulgaria located in the following planning regions: North-West, North-East, South-West and South Central Region. The analysis is based on empirical evidences - case studies of 32 agricultural cooperatives carried out during the period 2013-2016.

Results and discussion

The agricultural cooperatives in Bulgaria operate under conditions of continuous market influence. In addition, increased competition requires transformation of the governance structure, resulting in unbalanced interests between owners and managers. As a result, the cooperative model is not sustainable. This means that in time, cooperatives will likely continue to decline and change in the direction of getting closer to corporations.

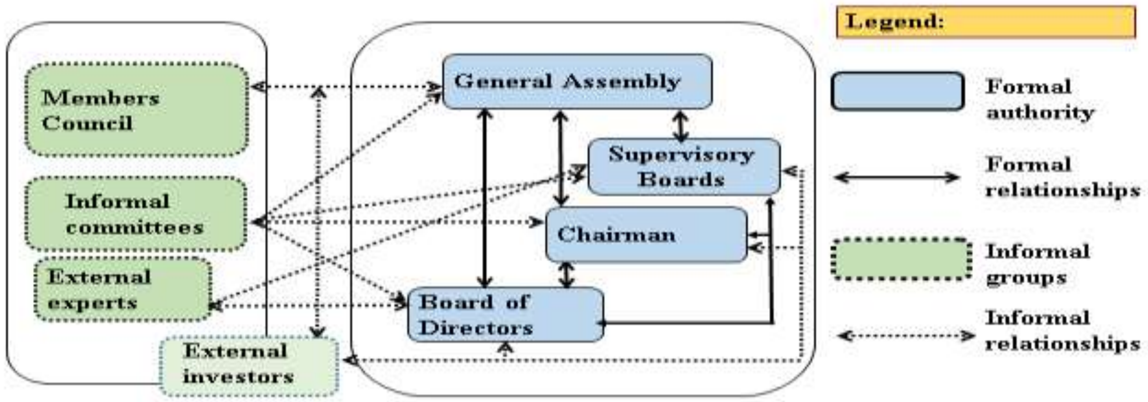
The cooperatives, examined as a governance structure, actively interact with the external environment: Institutions - define the rules of the game and regulate formal rights (legal norms) and informal rules; Political parties - related to the activities of agricultural cooperatives, both of which, to one degree or another, derive economic and lobbying benefits from such interaction; The market environment, which includes all the interaction partners - suppliers, buyers, consultants, competitors.

The integration of the majority of the functions of governing bodies in the person of the Chairman of the cooperative violates democratic character in the governance structure. He accepts the assignment to carry out the operational management of the cooperative. In order to establish market sustainability, management needs to be professionalized. The participation of the members in the management is limited to the need of their votes in the election of governing bodies: Chairman, Board of Directors and Supervisory Board. The commonality of these governance mechanisms, the limited efficiency and the manipulation of the formal framework is a challenge for cooperatives. Such informal relationships with members do not identify with co-operative essence. The Chairman imposes an authoritarian decision-making process and this transforms the formal governance structure. The explanation for this action is in his strong desire and striving to centralize the distribution of information channels and to exercise sole power resources seized by the Board of Directors and Supervisory Board. Members increasingly lose confidence in the democratic government. Evidence of this is that the. The Chairman is the one who imposes his own opinion in front of other members in the decision-making process. He controls the distribution of the benefits of members' property rights. For some of them, it is pointless to continue their membership in such a structure. Such a governance structure means that the Chairman as the main operating and management body is in a situation in which he controls himself. The identification of such actions further put a lot of research questions.

The transformations in the governance structure of agricultural cooperatives in Bulgaria show a "reversal" of the model. If an attempt is made to visualize the change, the figure would look like this: At the top of the structure, instead of the General Assembly in the person of the

members, the Chairman adopts a dominant position. Conversely, members are positioned in the "periphery" and their participation in the cooperative's activities does not have any influence. Members are increasingly not perceived as part of this structure and are not involved in its governance mechanism. The relationship and interaction between the formal bodies in the governance structure are broken. In the corporate firms, those who invest capital (investors), like the owners of capital (members) in the agricultural cooperative, often do not receive timely operational information about the organization's activities. The agent (Chairman or Executive Director) has access to all the information and limits the flow of information channels to principals (members or investors). The Board of Directors and the Supervisory Boards in the examined cases do not fulfill the statutory obligations in the governance structure. In such a situation where the Chairman seizes their functions, there is a problem. There are doubts about the correctness of these governing bodies. Their lack of interest and the failure to perform the assigned tasks are usually the result of personal benefit interests. In the corporate firms, as already noted, investors are traditionally members of the General Assembly and members of the Supervisory Board which elects the Board of Directors. This reconciliation of these two governing bodies by investors predisposes for such opportunistic behavior by the agent (the Board of Directors) to the principal.
The case studies prove that informal relationships (deviations from the legal framework) in the management structure of cooperatives are "formalized"(Figure 1).

Figure 1. Informal and formal governance structure of Bulgarian agricultural cooperatives



Source: Own figure

In some of the investigated cooperatives, non-formal governing bodies have been identified. First, it is the one who accepts the functions of the General Assembly, defined as the Members Council. The principle is based on reducing the number of members who are empowered to represent the rest and to participate in the management of the cooperative. The proximity of these members to the land and their small number helps them to gather quickly when important management decisions are needed. The reason for this action is that the General Assembly fails increasingly to fulfill its role as a supreme governing body in the governance structure. This is because the collection of all members is a slow process and often accumulates high transaction costs, which usually do not cover their potential membership benefits.
Secondly, informal interest groups have been identified. Cooperative members living near the land are united in informal committees and exercise effective control and monitoring in the cooperative. This innovation prevails in practice in most cooperatives and shows good results but is often associated with a lot of time and costs for the participants. By their very nature, they seize the functions of the Supervisory Boards in the governance structure. Under certain

circumstances, this transformation may lead to some conflicting situations among the rest of the members.

The case studies show a positive attitude of the agricultural cooperatives members to implement organizational innovations. When it comes to "outside" non-participating members of the cooperative, opinions are bipolar. On the one hand, members accept similar experts or investors to help with management and funding. On the other hand, it is the unanimous opinion that such „inflows" in the cooperatives are possible, but without the right to vote in the General Assembly. This behavior of members can be assumed to be the result of their desire to preserve (protect) the cooperative community and to prevent external interests from influencing the organization.

The case studies confirm the idea that agricultural cooperatives in Bulgaria are active participants in local initiatives, social support and preservation of Bulgarian identity, culture and faith. However, the cooperative governance is transformed and shifted to the focus of the cooperative. The direction is changed - by a member-supporting organization (social group), it is increasingly directed towards end-users (economic goals). In this way, the members of the cooperative lose confidence in its principles and terminate their membership. As a result, the agricultural cooperatives in Bulgaria are not sustainable models and in the last decade their number has been sharply decreasing.

The competition has a significant impact on the vision and strategy of the agricultural cooperatives. The governance structure in the Bulgarian agricultural cooperatives functions in a kind of innovative model. Changes that lead to changes in governance of co-operatives are the most controversial points in this discussion. Many politicians, economists, scientists and practitioners of agriculture who know and recognize the potential dangers are afraid that cooperatives will lose their typical (traditional) characteristics. They arise where there is a free market niche or a market. At the same time, the cooperatives are under the influence of market conditions. Proof of this is their hybrid form - cooperatives are increasingly growing vertically. Examples include not only consumer and credit cooperatives, but also the agricultural cooperatives that adopt features and elements of the corporate firms. This means that in the future, the distinction between the cooperatives and he corporations will be increasingly difficult. The basis for such an assertion consists of the following elements: professionalization of the management, lack of cooperative identity (values and principles), increased profit orientation, economics goal. There is a change in the cooperative strategy aimed at building trust with the distribution network (suppliers, buyers and consultants). Their interaction is based on the respect of ethical norms, in compliance with the legal framework in the country.

Conclusion

Over the last decade Bulgarian agricultural cooperatives has been faced challenges from the external environment (political, institutional, market), forcing them to increasingly turning to external users and change their goals.

The agricultural cooperatives focus primarily on: reducing production costs and introducing innovative technologies; purchase of own land; capital increase through the admission of new members; policies aimed at stimulating the increase of additional capital from members. A tendency is observed in reducing the number of cooperatives and diminution of arable agricultural land, which affects their sustainability. The dynamic market environment (increasing competition, changes in market structure, changing preferences and customer demand) alters some of the functional and organizational features in the governance structure. They are caused by transformation in the decision-making process. This leads to distortions in the governance structure model and thence to the following results: blurring of property rights, increase the powers of the governing bodies (seizing power resources, reducing the channels for disseminating information), weak motivation of the members to participate in the decision-making process, lack of clear vision and strategy (goals, production structure, distribution networks), insufficient managerial skills (investment and innovation activity) and trust. As a result of in-depth interviews, deviations from the legal framework have been recorded. Informal supporting bodies of the governance structure in the Bulgarian agricultural cooperatives – Members Council, informal interest groups, attracting external experts were identified. The lost a trust from the part of members to the management leads to their leaving from the cooperative and redirecting to corporate structures.

Under the influence of increased competition, the orientation and objectives of the cooperative have changed, and they are already connected with the realization of higher profits and transactions with non-members (as in the corporation), in other words: market-oriented. This means that the relationships of management with members is loosened. As a result of this trend, the management is "professionalized" and there is a process of "economizing" the objectives. The traditional cooperative is changed and transformed as an entrepreneurial corporate structure. The transformations in the governance structure increase the competitiveness and sustainability of the agricultural cooperatives.

Under condition of transition, prerequisites for the development and emergence of modern hybrid cooperatives are created. They occupy a key position in the country's economy, which further increases their role and importance. Consequently, the functioning of cooperatives and their sustainable development should be improved. The presence of discussion points indicates that is necessary informal changes to be regulated of the legislative framework in a way that equally protects the interests of the stakeholders.

PRODUCTION OF BIOACTIVE CONJUGATED LINOLEIC ACID BY LACTIC ACID BACTERIA FROM TRADITIONAL BULGARIAN FERMENTED PRODUCTS

Galya BLAGOEVA[1], Angel ANGELOV[2], Velitchka GOTCHEVA[2]*

[1]Primoris Bulgaria, 134 Bratia Bakston Str., Plovdiv 4004, Bulgaria

Abstract

Conjugated linoleic acid (CLA) is a group of positional and geometric isomers of linoleic acid (LA; c9c12-C18:2). Two of the most biologically active forms of CLA - *cis-9, trans-11* and *trans-10, cis-12* have beneficial effects on consumers related to anticarcinogenic, immune modulation, antiatherosclerotic, and antiobesity activities. Some lactic acid bacteria (LAB) are found to produce CLA in synthetic media or milk. However, most screening methodologies for CLA-producing LAB are laborious, complex and time-consuming. The aim of the present study was to assess the ability of 35 LAB strains isolated from traditional Bulgarian dairy and cereal-based fermented products to convert free LA to CLA isomers (*cis-9, trans-11* and *trans-10, cis-12*) by using a rapid spectrophotometric method. Thirty-five LAB strains were tested, and the applied rapid and sensitive screening approach showed that all except for one strain were able to produce CLA at different levels. Most of the strains belonged to *Lb. plantarum* and *P. acidilactici*. Nine of the tested strains converted more than 22% of the LA to CLA in the culture supernatant. The highest conversion capacity of LA to CLA isomers was shown by *Streptococcus bovis* 1.1 (29%) and *Lb. plantarum* 5.2 (28%). The maximum concentration of CLA isomers reached 0.145 mg/ml. However, the spectrophotometric method could not differentiate between CLA isomers since it is based on measurement of the conjugated double bond in the fatty acid. In conclusion, the present study revealed the capacity of LAB strains isolated from traditional Bulgarian fermented foods to covert free LA to CLA. The applied analytical method proved to be highly time- and labour-efficient for screening a large number of bacterial isolates for the ability to produce conjugated fatty acids.

Keywords: *Bioactive conjugated linoleic acid, Lactic acid bacteria, Bulgarian fermented products*

Introduction

Conjugated linoleic acid (CLA) is a naturally occurring *trans* fat commonly found in a variety of foods, such as meat, poultry, seafood, dairy products, vegetable oils, and some other food sources, being most abundant in foods from ruminants (beef, lamb and dairy products) (Chin *et al*., 1992; Lehnen et al., 2015; National Cattlemen's Beef Association, 2008).

CLA is a collective term used to describe a mixture of positional and geometric isomers of linoleic acid, an essential fatty acid. Conjugation of the double bond is generally in positions 9 and 11 or 10 and 12, and may be a *cis* or *trans* configuration (Lehnen *et al*., 2015). The isomerization and biohydrogenation of linoleic and linolenic acid to CLA in rumen are performed by some ruminal bacteria and through conversion of vaccenic acid in the mammary gland (National Cattlemen's Beef Association, 2008; Sieber *et al*., 2004). So far,

28 different CLA isomers have been identified and it is possible that a number of them have beneficial biological activity. However, all of the known physiological effects of CLA to date are attributed to two isomers, on which most research is focused. These are the *cis*-9, *trans*-11 isomer (*c*9, *t*11 CLA (9-CLA), also called rumenic acid), which accounts for 72 to 94% of total CLA in foods from ruminant animals, and the *trans*-10, *cis*-12 isomer (*t*10, *c*12 CLA (10-CLA)) is found mainly in vegetable oils and partially hydrogenated oils (Liu *et al*., 2011; National Cattlemen's Beef Association, 2008; Wall *et al*., 2008).
Starting in the 1980s, there has been considerable interest in these biogenic isomers due to their potential health-promoting properties and the potential health benefits of CLA, including anticarcinogenic effect, immune modulation, antiatherosclerotic effect, ability to reduce body fat while enhancing lean body mass, positive effect on insulin resistance and on bone health (Belury, 2002; Park and Pariza, 2007; Soel et al., 2007; Tricon and Yaqoob, 2006; Wang and Jones, 2004). The isomer 9-CLA, which has been considered to have the main biological activities, is mainly responsible for the anticarcinogenic effect, while 10-CLA isomer is involved in the lipid metabolism and body composition, and in some cases the health-promoting effects appear to be the synergistical interactions of these two isomers (Bhattacharya *et al*., 2006; Churruca *et al*., 2009; Pariza *et al*., 2001; Park and Pariza, 2007).
To increase the intake of CLAs, dietary and non-dietary manipulations on food products have been routinely employed, such as supplementing the ruminant diet with plant oils or animal fats that contain either LA or linolenic acid (Liu et al., 2011; Wall *et al*., 2008). Substantial amounts of 9- and 10-CLA can be produced commercially by chemical isomerization, but they are contaminated with a variety of other isomers and toxic compounds and cannot be used directly. Due to the high cost and difficulties in isomer purification, such synthesized CLA is not reliable a dietary source (Liu *et al*., 2011; Pariza *et al*., 2001). On the other hand, the potential of CLA synthesis by food-grade bacterial strains is attracting more and more attention as a promising approach for the production of dietary CLA (van Nieuwenhove *et al*., 2007; Wall *et al*., 2008).
Some researchers suggest that the high levels of CLA in fermented dairy products are attributed to the activity of Bifidobacteria and lactic acid bacteria (LAB), however the contribution of presently used dairy starter bacteria to increased CLA content in cheese is found to be relatively minor (Sieber *et al*., 2004). Bacterial strains belonging to a few genera such as *Lactobacillus*, *Propionibacterium*, *Bifidobacterium* and *Enterococcus* have been reported to produce CLA in either synthetic media or milk, but the ability to produce CLA can vary from strain to strain (Alonso *et al*., 2003; Ogawa *et al*., 2005; Sieber *et al*., 2004; Zeng *et al*., 2009). Therefore, isolation of LAB with the ability to produce significant amounts of CLA is of high interest for the application of such bacteria as starter cultures for functional foods with high CLA content and as industrial CLA strain-producers (Al-Hindi and El Ghani, 2015; Kuhl and Lindner, 2016; Meraz-Torres and Hernandez-Sanchez, 2012).
Therefore, the aim of the present study was to assess the ability of 35 LAB strains isolated from traditional Bulgarian dairy and cereal-based fermented products to convert free LA to CLA isomers (*cis-9, trans-11* and *trans-10*, *cis-12*) by using a rapid spectrophotometric method.

Materials and Methods

The present study was carried out with 35 LAB isolates originating from traditional Bulgarian cereal-based and dairy fermented products and belonging to the following species: *Lactobacillus plantarum (*strains 5.2; 3.2; BB2; Bom2; Lin2; Pro; K4, Bom 816), *Lb. fermentum* (strains 21.1; 26.1; 3.1; 3.2; 11, BH6; Ed2; K4), *Lb. rhamnosus* (strain 18), *Lb. pentosus* (strains BH3; N3), *Lb. casei* (strains A; Pro1), *Lb. paracasei* (strains LC1; Pr1, ya2, DA1), *Lb. paralimentarius* (strain C3), *Pediococcus acidilactici* (strains BH5; BB1; Bom3; Lin1; Pd3; LP), *P. pentosaceus* (strain K3), *Streptococcus bovis* (strain 1.1), and *Enterococcus faecium (*strain B). Their ability to produce CLA was tested according to the method of Barrett *et al*. (2007). The strains were incubated in MRS broth containing 0.5 mg/ml free linoleic acid and 2% (wt/vol) Tween 80 at 37°C for 48 h. The cultures (1 ml) were centrifuged at 20,000x *g* for 1 min. The culture supernatant was mixed with 2 ml of isopropanol by vortexing and allowed to stand for 5 min. The fatty acids were extracted with 1.5 ml of hexane preceded by vortexing. The presence of CLA in the culture supernatant was assayed spectrophotometrically by measuring the absorbance at 233 nm. *Cis*-9, *trans*-11 and *trans*-10, *cis*-12 isomers of CLA were used for standard curves in order to calculate the concentration of CLA produced by the tested LAB strains.

Results and Discussion

The ability of some strains of *Lactobacillus*, *Propionibacterium*, *Bifidobacterium* and *Enterococcus* to produce CLAs in synthetic media or milk has been reported only in the recent years (Alonso *et al*., 2003; Ogawa *et al*., 2005; Sieber *et al*., 2004; Zeng *et al*., 2009). Due to the beneficial physiological effects of CLA, and the difficulties related to its production by chemical synthesis, the isolation of LAB with the ability to produce significant amounts of CLA is of high interest for the application of such bacteria in functional foods with high CLA content. This ability is also regarded as a probiotic property of microorganisms (Wall *et al*., 2008).

In the present study, 35 LAB strains isolated from traditional Bulgarian dairy and cereal-based fermented products were assayed for their ability to convert free LA to CLA. Biotransformation of LA to CLA is performed by the enzyme linoleate isomerase which is bound to the bacterial membrane (Ogawa *et al*., 2005; Van Nieuwenhove *et al*., 2007). Results showed that all tested strains except for one (*Lb. plantarum* Pro) were able to produce CLA at levels ranging from 0.031 mg/ml to 0.132 mg/ml (Figure 1). The spectrophotometric method applied for analysis was rapid and sensitive to determine the amount of CLA produced. However, the method could not differentiate the isomers of CLA since it is based on measurement of the conjugated double bond in the fatty acid. In order to identify CLA isomers, GC/MS analysis must be applied (Al-Hindi and el-Ghani, 2015; Alonso *et al*., 2003).

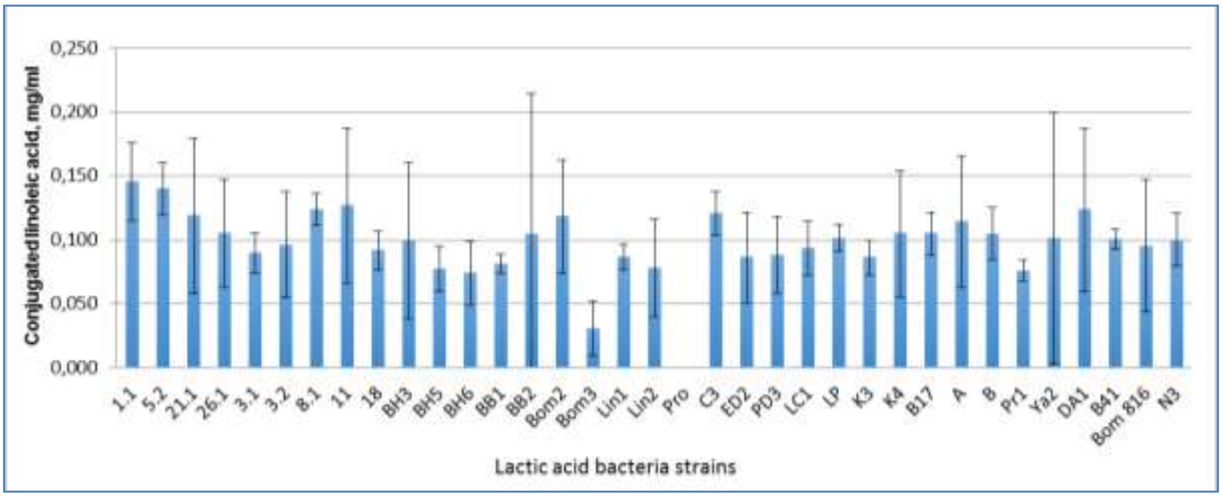

Figure 1. Production of conjugated linoleic acid by lactic acid bacteria

Eighteen of the strains, most of which *Lb. plantarum*, produced CLA of 100 mg/ml and higher. Zeng *et al*. (2009) reported 0.623 mg/ml CLA for *Lb. plantarum* NCUL005 isolated from sauerkraut. Similar results were obtained in another study with 43 *Lb. plantarum* strains originating from fermented pickles which yielded levels of 0.1 to 0.6 mg/ml (Liu *et al*., 2011). Results from the present study showed significant variability of CLA production and conversion ration both between species and between strains from the same species. Nine of the tested strains converted more than 22% of the LA to CLA in the culture supernatant (Figure 2). The highest conversion capacity of LA to CLA isomers was shown by strain *Streptococcus bovis* 1.1 (29%) and *Lb. plantarum* 5.2 (28%). The tested *Lb. fermentum* strains also showed good conversion capacity of approximately 24-25%. These levels were similar to that reported for *Lb. plantarum* by Zeng *et al*. (2009) - 26.7%, and Liu et al. (2011) – 25% CLA conversion. In another study, six LAB strains were found able to form CLA in MRS broth after 24 h of incubation, with varying percentage of LA conversion between 17% and 36%. Of the tested strains, *L. casei*, *L. rhamnosus*, and *S. thermophilus* showed the highest LA conversion (Van Nieuwenhove *et al*., 2007).

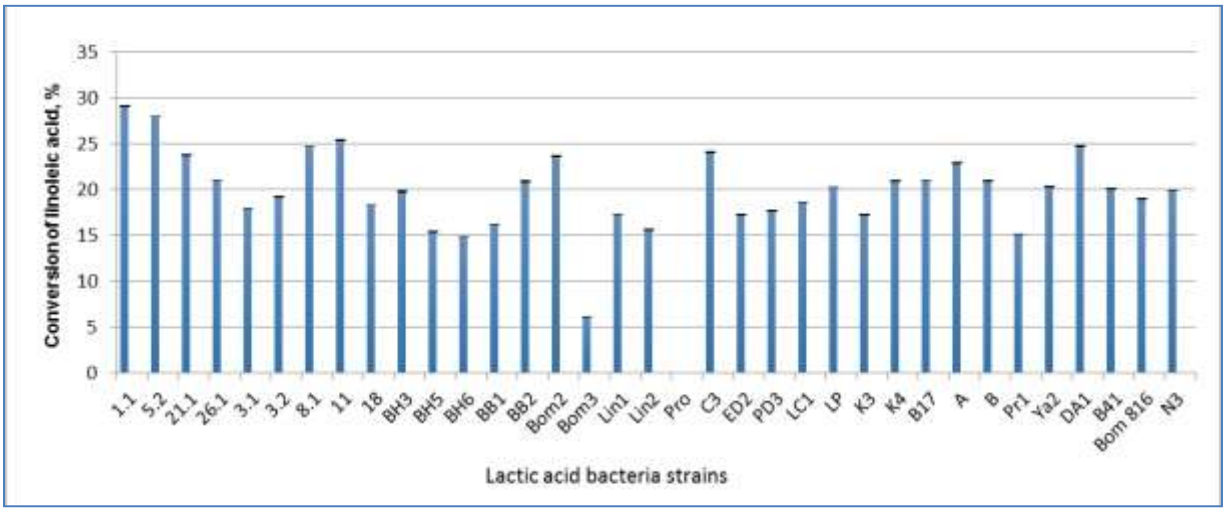

Figure 2. Conversion of free linoleic acid to conjugated linoleic acid by lactic acid bacteria

Some authors found a positive correlation between CLA production and tolerance to LA. However, the efficiency of CLA production in some LAB and *Bifidobacterium* decreased at higher levels of free LA in the medium (Van Nieuwenhove *et al*., 2007; Xu et al., 2008).

Despite that most strains studied for CLA production belonged to *Lb. plantarum*, it is estimated that this ability is strain-specific and depends on the culture medium, the carbon source used, as well as the cultivation conditions and duration. The types of the produced isomers are also strain-specific, with some strains producing only one isomer and others – more than two. It is also interesting to note that while most LAB produce CLA only by converting LA, some strains show the ability to produce CLA from other substrates (Kuhl and Lindner, 2016; Liu *et al*., 2011; Ogawa *et al*., 2005; Van Nieuwenhove *et al*., 2007; Xu *et al*., 2008).

Conclusions

In conclusion, the present study revealed the capacity of LAB strains isolated from Bulgarian cereal-based and dairy fermented foods to convert free LA to CLA. The spectrophotometric method applied for analysis was rapid and sensitive to determine the amount of CLA produced, but could not differentiate CLA isomers. The strains belonged to several LAB species, with highest CLA production observed mostly for *Lb. plantarum* strains. The rapid methodology used facilitated and greatly reduced the time and labour needed to screen a large number of bacterial isolates for the ability to produce conjugated fatty acids.

The use of LAB for the bioconversion of LA to CLA isomers can contribute to increased functionality of probiotic foods which could be an excellent source of CLA for a healthy diet. However, more research is needed to assess how to enhance CLA production by LAB and to determine the optimal requirements for those microbial cultures which show ability to produce CLA.

ROLE OF WOMEN IN DECISION MAKING IN THE FIELD OF AGRICULTURE A STUDY AT BIHAR (INDIA)

Arunima KUMARI, Pooja KUMARI, Richa KUMARI, Kritika

Department of Home Science Extension and Communication Management
College of Home Science, Dr. Rajendra Prasad Central Agricultural University, Pusa Bihar (Samastipur), India
Corresponding author: arunima.rau@gmail.com

Abstract

Agriculture is the main engine of growth for economic development as well as to eradicate the poverty in almost all developing countries. Women are the main pivot around which this whole phenomenon rotates. They play key role in not only producing and preparing food but in raring animals, collecting fuels, caring for family members and maintaining their homes, nursery gardening, rural marketing and trading, fetching of water and many more activities related to farm and production. For total livelihood sustainability it is the women who play a major role but somehow it has been found that their role in decision-making has been gradually diminished from Vedic era to modern era (particularly in case of Indian context). In India women were more privileged and bold in our early civilization. That is why the present study was conducted in 2015 in a small district of Bihar (India) in order to access their percentage in decision-making process in the field of agriculture. During early age women were allowed to take decision not only in ruling the kingdom but in war field too. As the age turned on due to different emperors their role went down but still few examples are there in front of us (Rani Laxmibai, Indira Gandhi, Pratibha Singh Patil etc.). The result of collected data out of 100 respondents depicts that only 8.33% landless women farmers take decisions in the field of agriculture followed by 19.27 % of medium women farmers and 20.47% of small women farmers and maximum of 29.35% by marginal women farmers.

Keywords:- *Landless, Medium, Small Women farmer.*

Introduction

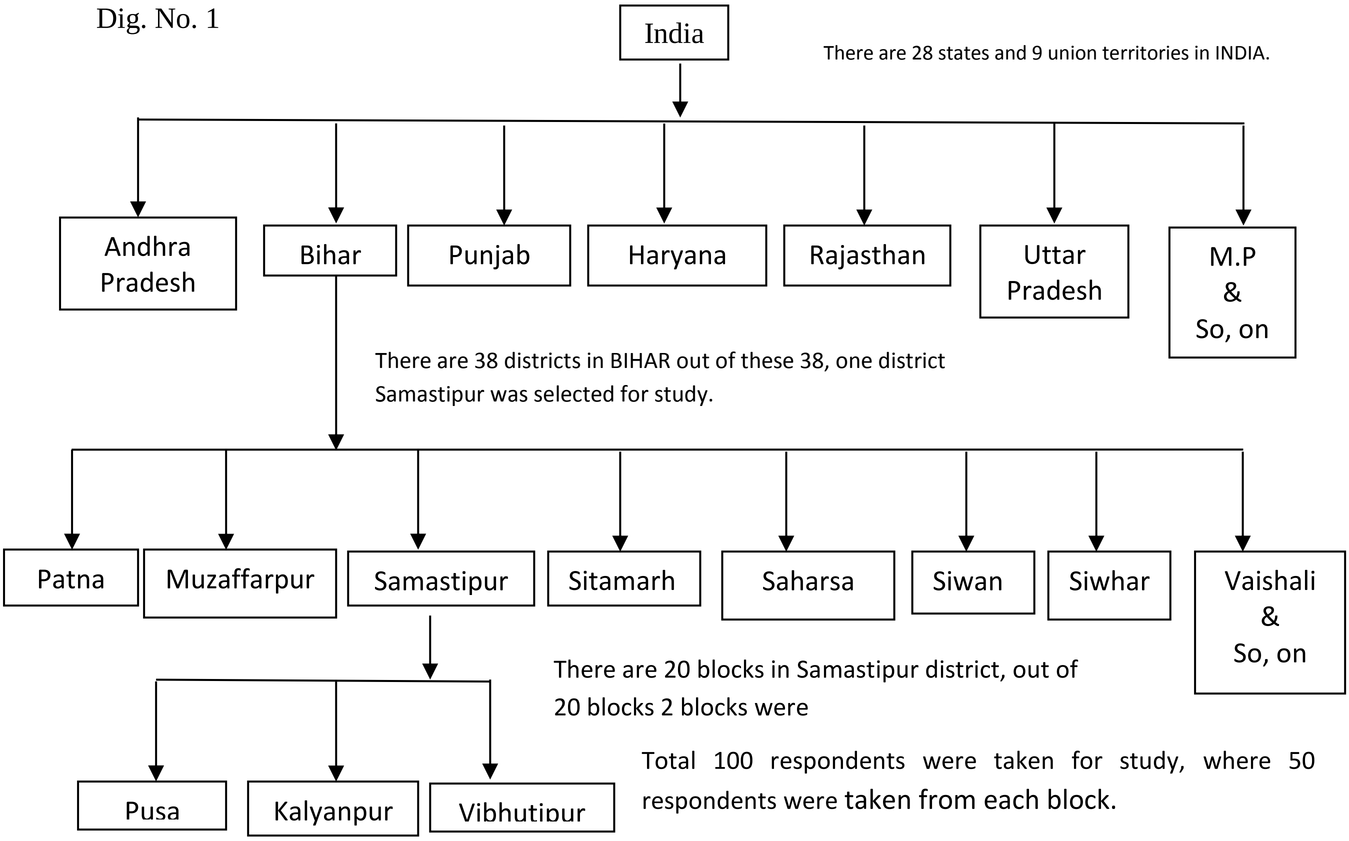
Women are the backbone of the rural & national economics. Women comprise 43% of the world's agricultural labour force which rises to 70% in some countries. In Africa 80% of the agricultural production comes from small farmers who are mostly rural women. Women comprise the largest percentage of the workforce in the agricultural sector, but do not have access and control over all land and productive resources. (SOFA Team & Cheryl) Women in agriculture are often physically visible but conceptually invisible & remain marginalized. Rural women besides their normal household responsibilities play a very significant role in agriculture and allied activities. In India, women as farmers are involved in pre-sowing, post-sowing, harvesting & post- harvesting operations as well as allied activities through physical participation & supervision. Their activities typically include producing agricultural crops, tending animals, processing & preparing food, working for wages in agricultural or other rural Enterprises, collecting fuel & water, engaging trade & marketing caring for family members and maintaining their homes. Many of these activities are not defined as "economically active employment" in national accounts but they are essential to the well being of the rural households. Despite their important role, women farmers face several disparities in different areas of agriculture even though their significant contributions in different agricultural activities. Brar ,Gill And Walia(2007) observed that 42.9 percent of the total surveyed Farmers consulted women in decision making regarding number of hierd labourers and kind of wages,while in 11.3 percent cases their opinions were considered in this areas of decision making in agriculture,only 9.3 percent of the total surveyed farmers considered the opinion of women , while 68.7 percent not even consulted the women of family during marketing of their farm produce.Decision making refers to the mode of decisions taken by farm women regarding various aspects of agricultural activities either solely or jointly with husband & family members (Gondaliya and Patel (2012) Sharma *et. al.*, (2013) ound that maximum number of farm women i.e., 58.33% were not taking active part in decision –making. Only 19.17% of farm women were taking active participation in decision making. Hence to know women contribution and pattern to take decision in agricultural activities present study was conducted with following objectives:-

1. To know the socio-economic characteristic of rural farm women.
2. To study the decision –making pattern of farm women in different agricultural activities.
3. To ascertain the relationship between selected socio-economic characteristics with the decision – making pattern of farm women.

Materials and Methods

When women are empowered they can claim their rights and access to land, leadership, opportunities and choices, economies grow, food security is enhanced and prospects are improved for current and future generations", Michelle Bachelet – Under- Secretary –General and Executive Director of UN Women.The study was undertaken at Samastipur district which is situated in one of the state of India i.e., Bihar. Out of its 20 blocks 2 blocks namely, Pusa & Kalyanpur were selected purposively for the study. From these 2 blocks, 4 villages, 2 from each block i.e. Gorai, Madhurapur, Harpur & Mahmadda were selected. The selection was based on assumption that there was having maximum number of farm women involved in agricultural activities. A total of 100 respondents were taken for the present study. Keeping in view the objectives of the study, well structured interview scheduled was developed. The data was collected from the respondents through personal interview method. It has been shown through dig. No. 1

Dig. No. 1



Results and Discussion

General information: The women respondents were categorized into four categories based on the size of land holding they possess i.e., landless laborers (having no land), marginal farmers (Upto 2.5 acres), small farmers (2.5 to 5.00 acres) and medium farmers (5.01 to 10.00 acres). No respondents were found having above 10 acres of land holding.

Socio- economic information:

Table. 1: Distribution of respondents according to their caste, marital status, education level and land holding size

Sl. No.	Category		Landless (N=13) %	Marginal (N=45) %	Small (N=11) %	Medium (N=11) %	Pooled (N=100)
1	Caste	Forward	0.00	2.23	27.28	45.46	9.00
		Backward	30.31	86.67	72.73	54.55	63.00
		Schedule caste	69.70	11.12	0.00	0.00	28.00
2	Marital status	Married	81.82	84.45	100	90.91	86.00
		Widow	18.19	15.56	0.00	9.09	14.00
3	Education Level	Illiterate	87.88	44.45	27.28	18.19	52.00
		Read and write only	9.09	13.34	9.09	36.37	14.00
		Primary	3.03	31.12	54.55	18.19	23.00
4	Land-holding size		33	45	11	11	100

Classification of the respondents Caste-wise Marital status and Education level possessing various landholding categories:

Caste of an individual is defined as a hierarchy of endogamous divisions in which membership is hereditary and permanent In this study, caste has been categorized as forward, backward and scheduled caste categories. It can be observed from Table no. 1, that 63 per cent of the respondents belonged to backward class followed by 28 per cent of scheduled caste and only 9 per cent of the respondents belonged to forward class and majority of them were from small and medium land holding category of farmers. The respondents were classified into two categories on the basis of their marital status viz., married and widow. Table no 1 also inferred that majority of the respondents i.e., 86 per cent were married followed by 14 per cent of widow respondents. No respondents were unmarried or divorced. Education is the individual's ability to read and write, and the amount of formal education possessed by them. In the present study, it refers to the extent of formal schooling undergone by the respondents. It also appears from Table 1, 52 that per cent of the respondents were illiterate, 23 per cent were having primary education, 14 per cent can only read and write, 7 per cent have middle education and only 2 per cent were high school passed and graduate. This has also been depicted in the fig. 1.

Fig. 1. Distribution of respondents according to their caste, marital status, education level and land holding size.

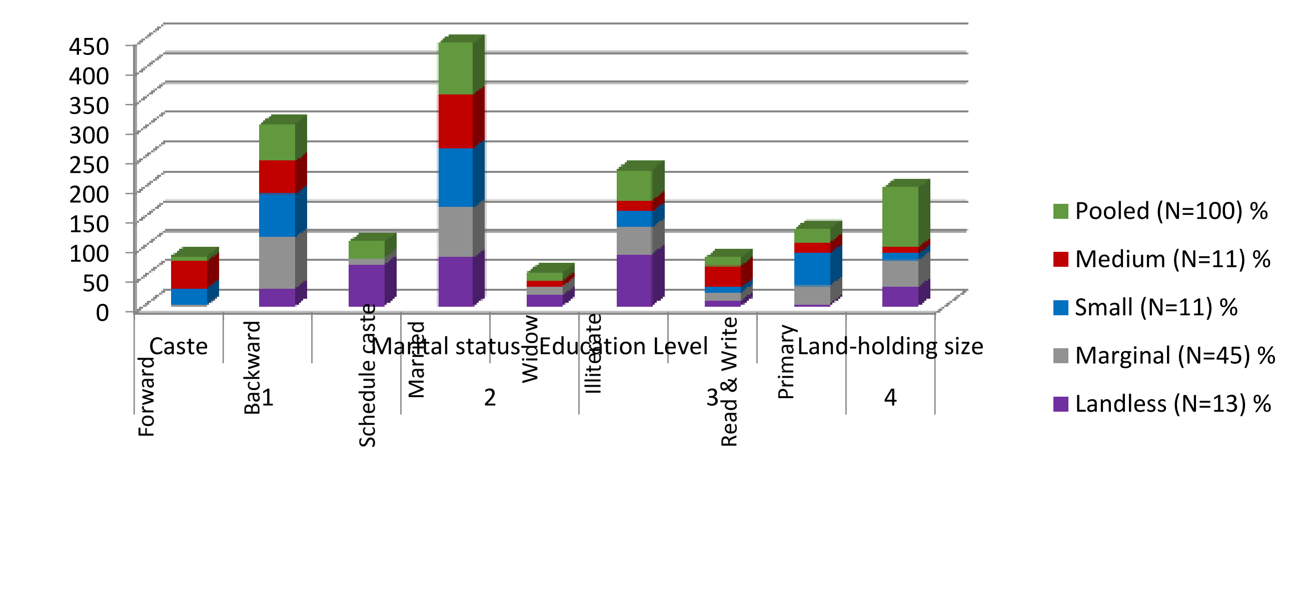


Table 2: Percentage Participation of women in overall decision – making pattern in Agricultural Activities.

Sl. No.	Decision making area	Landless (N=13)	Marginal (N=45)	Small (N=11)	Medium (N=11)
A	Agriculture decision	0.0	20.22	13.64	14.54
B	Labour allocation decisions	0.0	28.89	22.72	18.18
C	Livestock related decision	21.21	40.0	27.17	27.27
D	Selling of crops related decision	0.0	37.78	31.89	20.45
E	Loan related decision	20.45	19.86	6.81	15.91
	All Farm related decision (mean)	20.08	29.35	20.47	19.27

Table no2 indicates that the mean score value of percentage participation of women farmers (i.e. landless, marginal, small & medium farmers) in decision making process–in different areas of agricultural activities.

- Agricultural decision – Table 2 showed 20.22 per cent marginal land holding women farmers took decision related to agriculture followed by 14.54 per cent medium land holding category of women farmers & 13.64% by small farmers respectively. Landless labourers do not participate in agricultural decision – making process. This result was also similar to study observed by Kumari A (2001) that men dominated women in making independent decision related to all the three sub areas of farm related decision namely crop production decision (81%),labour allocation decision (73.2%) and livestock related decisions (76.2%).

- Labour allocation decision –It is clearly indicated that 28.89, 22.72 & 18.19 per cent of marginal, small & medium land holding category of women farmers take decisions.
- Livestock – related decision – It has been showed that 40 % of marginal land holding category of women farmers participated in livestock related decision followed by 27.27 % of medium & small land holding category of women farmers, 21.21 % by landless laborers.
- Selling of grains related decision – 37.78, 31.89 & 18.38% of marginal, small & medium category of women farmers took decision related to selling of grains as show in table 2.

Loan related decision – Table 2 showed that 20.45, 1986, 6.81 & 15.92% of landless, marginal, small & medium land holding category of women farmers took decisions. This has also been depicted in the fig.

Fig 2: Decision making pattern of four categories of women farmers in agriculture

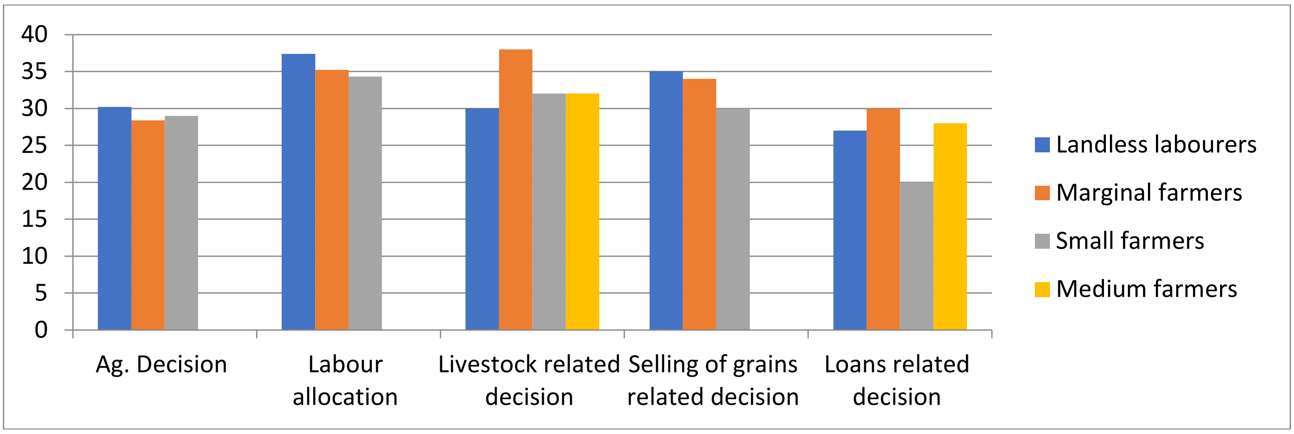

Table 3: Coefficient of correlation between decision – making pattern of women farmers with the independent variables.

Variable	Value of 'r'
Age (X_1)	-0.55
Cast (X_2)	0.110
Marital Status (X_3)	0.347**
Education respondent (X_4)	0.045
Type of family (X_5)	-0.119
Size of land holding (X_6)	-0.006
Family income (X_7)	-0.006
Domestic animal (X_8)	0.046
Social participation (X_9)	0.050
Knowledge level (X_{10})	0.050
Agricultural implements(X11)	0.036*

*= Significant at 5% level of probability
**= Significant at 1% level of probability

An individual's contribution in decision – making has been found to be influenced by numbers of Socio-economic characteristics.

Table 3 showed that only marital status (r =0.347) & knowledge level (r=0.050) were found significant & positive with decision making pattern of rural women. All other independent

variables were non-significant. The variables age, type of family, size of land holding & family income were negative while caste, respondents' education, domestic animals & social participation were positive.
Lad ,Wattamwar and Bothikar (2012) observed that majority of farm women (50.83%) were found in medium decision making category followed by 32.50 % in low decision making category ,where as only 16.67 % in high decision making category.
It means majority of respondents involved in medium to low category of decision making in different categories.

Conclusion

The study confirms the universal fact that women play a very crucial role and contribute a lot in income generation. Women's having more involvement in production process were participating more in decision – making process. It can be also as concluded from the study that women having higher educational status & knowledge level were participating more in decision – making process.

INTERNATIONAL NETWORKING FOR RURAL AREAS SUSTAINABLE DEVELOPMENT: THE CASE STUDY OF A.M.A.R.-W.F.A.R.A.

Adriano CIANI

General Secretary of AMAR-WFARA, University of Perugia, Italy
Corresponding author: adriano.ciani@unipg.it

Abstracts

The number 17 Goal of the SDG 2015-2030 entrusts us with the task of *Strengthen the implementation instruments and revitalize the global partnership for sustainable development.* In the paper is make the analysis of the role of the international networking to apply the new paradigms for the sustainable progress of all rural areas population around the world. The author sustain that is time to apply, as best practice, some experience with modern and updating vision concerning the achievement by the Rural Areas the base for to be transformed in this century in Smart Territories and Smart Communities.
He present the proposal of the implementation of a A.M.A.R:-W.F.A.R.A. (Associazione Mondiale di Amicizia delle Aree Rurali -World Friendship Association of Rural Areas) that it's in ongoing foundation with the launching on 22th April 2017 (the Earth Day) and signature of a MoU toward the final approval of the Statute in 2018.
The paper show all motivations, targets, structure and management of the A.M.A.R.-W.F.A.R.A. that will promote and will put in place all the actions at the local, national and international in order to make repeatable and transferable models of local development, and process and product innovations that could be, the same, repeatable and transferable and in meantime can contribute to the concrete improvement of quality of life in the rural areas around the world toward the Gross National Happiness indicator for it's measurement.

Keywords: *rural areas, international networking, smart territories, smart communities, sustainable development*

Introduction

The 21th century is characterized for three challenge represented by the :Age of Sustainable Development, Green and Circular Economy , 4th Industrial Revolution. In this framework of reference is a strongly movement and approach a the vision of "act locally" and "think globally". The world is in the way gradually to abandon the hold monocriterial approach to measure the level of development with the only one indicator of IGP-Internal Gross Product towards a substitution with a multicriterial approach trough high number of the indicators that minimum must take into account the economic, social, environmental, managerial and cultural aspects. The HLPF-High-Level Political Forum last July 2017 have left us that for the implementation of the 17 Goals and the 169 targets of Sustainable Development for 2015-2030*(UN, 2015)* we need to use 232 complex indicators *(UN, 2017).*In this way there are also a movement that try to substitute the IGP with synthetic indicator of development that must be measured trough the IGH –Internal Gross Happiness where the happiness same it's measured by a list of indicators of SWB-social well-being *(SDSN, 2017)* . The human world road map at the International Policy Level is to achieve for any people peace and happiness. This challenge anyway even must, day by day, running ,when meantime in many areas, special in the rural location , of the world we have hungry, deep poverty, the big problem of

the access(education, Energy, ICT, social and health services, etc.) and the safeguard and promotion of the territories.
The framework of reference require for all actors of the society and all stakeholders a strong change driving, in all the world and specially in the rural areas , any process of development for each Community in each own Territory, with the strictly observation of the vision *act locally* and *thing globally* .This because any Community need to accelerate the process and to avoid the mistake done in similar actions. In this way the updating networking that could contain also some dreams to be everybody citizens with acceptable level of happiness of the global village*(Mc Luhan, 1962*) in the current and future time.
In this vision the idea of a World Network of the Rural Areas have derived the practical application.

Literature on issue

The networking it's a pillar of the society in 21th Century. Social network is a social structure made up of a set of social actors (such as individuals or organizations), sets of iterative and interactive exchange of knowledge , and other social interactions between actors. The networking is in continue evolution and more and more acquire prominent role in each development process. In fact the social network perspective provides a set of methods for analyzing the structure of whole social entities as well as a variety of theories explaining the patterns observed in these structures. The study of these structures uses social network analysis to identify local and global patterns, locate influential entities, and examine network dynamics.
Social networks and the analysis of them is an inherently interdisciplinary academic field which emerged from social psychology, sociology, statistics, and graph theory. In the late 1890s, both *Émile Durkheim(1982)*and *Ferdinand Tönnies(1998)* foreshadowed the idea of social networks in their theories and research of social groups. *Georg Simmel(1908)* authored early structural theories in sociology emphasizing the dynamics of triads and "web of group affiliations". *Jacob Moreno (1934)*is credited with developing the first_*sociograms* in the 1930s to study interpersonal relationships. These approaches were mathematically formalized in the 1950s and theories and methods of social networks became pervasive in the social and behavioral sciences by the 1980s. Social network analysis is now one of the major paradigms in contemporary sociology, and is also employed in a number of other social and formal sciences. Together with other complex networks, it forms part of the nascent field of network science. The social network referred in the current time at many different types of relations, singular or in combination, form these network configurations. Network analytics are useful to a broad range of research enterprises. In social science, these fields of study include, but are not limited to anthropology, biology, communication studies, economics, geography, information science, organizational studies, social psychology, sociology, and sociolinguistics.
By the 1970s, a growing number of scholars worked to combine the different tracks and traditions. One group consisted of sociologist *Harrison White(1997*) and his students at the Harvard University Department of Social Relations. Also independently active in the Harvard Social Relations department at the time were *Charles Tilly(1988),* who focused on networks in political and community sociology and social movements, and *Stanley Milgram(1977),* who developed the "six degrees of separation" thesis *Mark Granovetter (2005)* and *Barry Wellman (2001*) are among the former students of White who elaborated and championed the analysis of social networks.
Beginning in the late 1990s, social network analysis experienced work by sociologists, political scientists, and physicists such as *Albert-László Barabási(2013), James H. Fowler(2007,,* and others, developing and applying new models and methods to emerging

data available about online social networks, as well as "digital traces" regarding face-to-face networks. The dynamics evolution of the theoretical concept and the practice day by day of the networking open the perspective concrete to built a true egalitarian world village.(*Dawes, C. T. & Others, 2007).*For the rural areas very important is the contribution by Granovetter with is vision concerning the strong role in the development process and the improvement of the quality of life by the informal or week network

Targets, Material and Method

The paper have the target to demonstrate that for the Rural Areas to implement the SDG 2015-2030, the principles of the Green and Circular Economy and to go ahead i the way of the 4th Industrial Revolution it's essential try to arrange an large International cooperation trough a not formal and strong infrastructure but under the approach of the bottom- up and subsidiarity a profitable, repeatable, transferable , effective and efficient networking process. The materials used derive from a deep literature research about the origin, history and updating vision on the networking role in the society in the current time. After that was used the material derived by the memorandum signed by 39 partners of 20 countries the 22 April2017 /(the Earth Day 2017) creating the AMAR-WFARA(Associazione Mondiale di Amicizia delle Aree Rurali –World Friendship Association of Rural Areas).The method it's concrete empirical approach a sit show a practical case of networking.

Result and discussion

The aims of the Memorandum of Understanding signed the 22 April 2017

The promoted document take the inspiration by the framework of reference of the international policy of the main institutions at the world level .The same have the following contents:

"TAKING INTO ACCOUNT

the documents of the UNGASS "Our Future City, (1987)", "The future we want" the WSSD in 2012 (Rio + 20), "Transforming our world: the 2030 agenda for sustainable development", with the promotion of SDG-2015 -2030, (2015), the Encyclical "praise You" by Pope Francis, (2015), l ' "Paris agreement" of UNFCCC COP-21, (2015), l' "Marrakesh Agreement" of UNFCCC COP-22 (2015) Charter of the Milan 'Expo 2015' s "Marrakesh Agreement Uruguay Round in 1995," the objectives and conclusions of the 'international Year of the ground in 2015, the objectives of the Year International sustainable tourism for development in 2017, the Horizon 2020, the circular of the EU on 'circular Economy Principles, the CAP from 2014 to 2020, the II Cork Declaration of 2015, the Industrial Revolution IV-IV-RI 2016 and the strategy of SDG 2015-2030, the Declaration of Rome on 25 March 2016 by the EU,

VERIFIED TO EACH OTHER THE VOLUNTY

to put in value their own experiences inspired to improving the quality of life, in terms of economic, social, environmental, managerial and cultural, rural populations around the world and anchored in the principles of peace, intercultural and interfaith and on this basis of

create A.M.A.R. (World Association of Friendship of Rural Areas.

CLAIM UNDER THE VISION OF AMR-WFARA

that international cooperation, to achieve positives field results, it needs a coherent, comprehensive, operational plan of interrelations among peoples. All this to allow the gradual creation and placement of the elements that bind science as peace and solidarity instrument, through the use of technological innovations, increasing the friendly use and general accessibility. All initiatives must follow the guidelines of the ambitious program, *which aims to achieve the creation of a "common house", the supply of scientific research on a global scale, involving in its planning at the level of the whole mond, the potential that every reality socioeconomic can bring: in education, science and technology, and the "spearhead" of the necessary actions to support the culture of sustainable development.A scientific society in which the University can be once again the "Universita"s, as the starting point of a new Renaissance, a process related to each country and the Company throughout the world. What the multitude of young people living today needs to receive, are concrete signs of hope and freedom, leading to a more sustainable lives and livelihoods, and overcome the current systematic way of working, which dominates our modern times "like a prison" in order to achieve a happier and sweeter now.*

The AMAR-WFARA Association aims to improve a method of administration of the territories can ensure - through continuous monitoring - development, good quality of life, and the protection of environmental resources, especially the landscape and biodiversity. In this sense, science must facilitate the removal of barriers, the ancestral values of ancient societies often imprisoned and put in the shade, not to be dealt with as if they belonged in a museum rather with the spirit of rebirth and rediscovery: a type of science that values have but especially being. The growth of associations like AMAR-WFARA stand out even more, as a conscientious window along with their spirit of analysis, and expertise offered by all of the Autonomous Communities' Clubs in the World level.

AMAR-WFARA takes as the keyword "TRADI-OVATION" (TRADITION-INNOVATION) (for short) stands for "Territory, Rural Areas, through the Development, Innovation, Organization, Promotion, user friendly, Technology, ICT sharing, Networking, Online ".

SHARE THAT THE OBJECTIVES OF AMAR ARE REPRESENTED BY:

1-The Sustainable Development Goals SDG-2015-2030

AMAR has primarily aims to promote at local and International level the objectives of the Agenda for Sustainable Development for the period 2015-2030 as a result reported.

1. Put an end to poverty in all its forms, anywhere.

2.Ending hunger, ensuring food security, improving nutrition an promoting sustainable agriculture.

3. Ensuring a healthy lifestyle and promote the welfare of all for all ages.

4. Ensure all inclusive education and promoting life long learning opportunities and fair quality.

5. Achieving gender equality by empowering women and girls.

6. Make sure all the availability and sustainable management of water and sanitation.

7. Ensure the availability of affordable energy, reliable, sustainable and modern for all.

8. To promote an inclusive economic growth, sustained and sustainable, full and productive employment and decent work for all.

9. Build a solid infrastructure, promote inclusive and sustainable industrialization and foster innovation.

10. Reducing inequalities within and between countries.

11. Create sustainable human settlements and towns that are inclusive, safe and sound.

12. Ensuring sustainable consumption and production patterns.

13. Take urgent measures to combat climate change and its consequences.

14. Store and sustainable use of the oceans, seas and marine resources for sustainable development.

15. To protect, restore and promote the sustainable use of terrestrial, manage forests sustainably, combat desertification, halt and reverse land degradation and halting the loss of biodiversity.

16. Promote peaceful and inclusive societies for sustainable development, ensuring that every one has access to justice and create effective, accountable and inclusive at all levels.

17. Strengthen the implementation instruments and revitalize the global partnership for sustainable development.

2-The objectives of CORK 2.0

AMAR makes its own decisions of the 2nd Declaration of CORK-5-6 September 2016 better known as CORK 2.0 and with the title "Improving the quality of Life in Countryside e" that encloses the 10 points indicated hereinafter

1. *To promote prosperity in rural areas*
2. *Strengthening the value chains in rural areas*
3. *Investing in accessibility and in the viability of rural areas*
4. *Preserving the rural environment*
5. *Managing natural resources.*
6. *Encourage the climate action*
7. *Stimulating the knowledge and innovation*
8. *Strengthening governance of rural areas*
9. *More targeted policies to results and simplification*
10. *Improve the performance and responsibilities*

3-The Principles of the Charter of Milan EXPO 2015

***4-AMAR will promote and will put in place** all the actions at the local, national and international in order to make repeatable and transferable models of local development, and process and product innovations that are repeatable and transferable and can contribute to the development of quality of life in rural areas around the world with objective reference pillar of National Gross Happiness.*

GIVE MANDATE TO THE ORGANIZING COMMITTEE

➢ *-to prepare the Statute and the Regulations AMAR on the basis of the attached Draft that is an integral part of this Memorandum (Annex 1)*

➢ *-to bring locally, nationally and internationally every action and take action to widen to as much 'as possible the number of partners in the project;*

➢ *to activate the Web Site;*

➢ *to start fund raising activities, crowfounding, required funding and sponsorship and to open special c / bank account;*

➢ *to prepare logo can also through local or international bid, but at no cost;*

➢ *to initiate contacts with all national and international institutions that may be involved in the establishment of AMAR;*

➢ *to create a temporary stamp and a simple letterhead with the words in Italian and English AMAR based at the Municipality of Montecastrilli.*

The undersigned and adherent subjects of the Memorandum

COMMITT THE ORGANIZING COMMITTEE

to prepare and report between now and the date of April 1, 2018 with a special payable quarterly report of the President and Secretary General, on the progress of the assigned the same step, at least in Italian and English, and to prepare everything necessary for the Notarial Act Official creation of AMAR in the next edition of Agricollina in 2018. "

At this document have, with direct signature the date of 22 April 0217 or previous official letter 39 differents subjects represented by Ngo, LAG, Municipalities, Villages,

Universities, Entreprises, declared the direct involvement till July 2017 number 39 partners by 20 countries of all 5 Continents.
Now we are ongoing to prepare the International Statute and Regulation trough the activity of the Staff of General Secretary and the Presidence Commission. The targets is to achieve for the next Earth Day that will be the 22 April 2018 the Official Foundation with a noter act the AMAR- WFARA. And to increase the activities and acquire a strong role a the International Level as important stakeholder concerning the Rural Areas Policy all around the world.

Conclusions

The paper has shown that the networking, specially for the rural areas it's a very important modality try to achieve the SGD for the Sustainable Development Agenda 2015-2030.
The study case of AMAR –WFARA have permitted to achieve a result very positive that encourage the perspectives of the increasing and improving of the networking for development to create the basis in all the world to transform the weakness of the rural areas in a opportunities of development .In this way it's crucial a very strong campaign of the use and diffusion of the ICT and suitable and friendly platform to put inside a intuitive and concrete useful and appointed services for the Local Population . All of this to create a world situation for all rural areas to be smart, sustainable and inclusive. To transform the vision of the smart cities and smart lands in a Smart Communities and Smart Territories.

Abstracts

The 2017 is declared the International Year of Sustainable Tourism for Development. The authors demonstrate that the Agritourism and Rural Tourism are the main important forms of Sustainable Tourism that can contribute at the innovative and inclusive Local Development because are linked respectively with the agricultural or others activities in the rural areas.
Georgia is a prevalent mountainous country with till current time an high relevance of the agriculture and the other production sectors disseminate in the rural areas. The authors present the analysis of the potentiality of these two forms of Sustainable Tourism in Georgia trough the territorial analysis and presentation of the SWOT. In this framework they make a concrete case study that is referred at the Municipality of Sachkere in the Western part of the Country. The municipality contains 13 administration units and have 54866 inhabitant, the relief is average and low mountainous, with many natural resources and rich with historical and touristic objects. The culture and tradition of the territory joint with a typical food, drinks and handcraft and textile represent the important elements on which to set up the growth of the Agritourism and Rural Tourism and the creation a sample of model for all the Georgia and the Others Caucasus Area.

Key Words: sustainable tourism, agritourism, rural tourism, local development, Georgia Country

Introduction

The rural development model established in the last twenty years attaches particular importance to the productive diversification of a territorial context and recognizes the opportunities that rural tourism can offer to those areas that are no longer competitive due to the dynamics of markets and the evolution of agricultural policies. It can, in fact, bring a number of benefits from the economic, social, cultural and environmental point of view, provided it is characterized by an intersectoral, integrated, endogenous, sustainable and qualitative development process.
The territory represents the size from which to start to interpret the characters of sustainability. From its distinctive features and its peculiarities, it is possible to intercept and orient the trajectories necessary to a more sustainable development in terms not only of economic but above all social, environmental and generational *(Cesaretti 2011,Ciani 2015)*
The territory becomes a place where social, political, cultural and economic relations are developed and consolidated *(Ciani 2015,Granados Cabezas 2015, Valls & Porta 1997).* In this context, the different subjects, the different activities and components that characterize a territory become the protagonists of its success. From this point of view, it is crucial to re-read the territories in the light of a multidimensional and integrated vision of their

specificities, but above all in the light of a new culture of rurality. The latter is to be understood as a living expression of increasingly diverse and multifunctional agriculture strongly rooted in the territory, environmental and landscape resources increasingly integrated into identity and innovation matrices, relational and institutional assets based on sustainability-oriented systems *(Andreupoulou, Cesaretti, Misso 2012)*

Sustainable development of tourism is one of the challenges launched by Europe's main travel destination in the world: a challenge that Georgia can gather through its cultural and environmental artistic heritage. Tourism contributes to economic growth and job creation.

According to the definition provided by WWF, sustainable tourism must be able to "coexist, in the short and long term, the expectations of residences with those of tourists without diminishing the qualitative level of tourist experience and without harming the environmental values of the territory".

Rural Tourism and Sustainable Development

General Overview

Over the years, definitions and general principles of sustainable tourism have been identified in a number of important documents such as the "European Charter for Sustainable Tourism" 25 of 1995, the Charter "Tourism: Basic Principles for Sustainable Development" .The WTO (World Tourism Organization) in 1996 and the Berlin Declaration on "Sustainable Tourism and Sustainable Development" of 1997, the result of the International Conference of Environment Ministers on Biodiversity and Tourism. Integration between the environment and tourism and sustainability considerations become fundamental issues in the field of rural tourism development, as it is an activity closely linked to natural resources and small local communities.*(George & Other 2009,Cohen 1988, Hunter 2002)*

Sustainable Tourism and Sustainable Development Goals

In 2012 at the Rio + 20 Conference on Sustainable Development, the United Nations declared that well-managed and well-managed tourism contributes to sustainable economic, social and environmental development *(Sachs, 2015)* All seventeen can be a priority for tourism, but it is explicitly provided for three: SDG 8 (tourism as a driver for global, lasting and inclusive economic growth, already able to provide jobs every eleven in the world) ; SDG 12 (tourism that adopts sustainable patterns of consumption and production can accelerate the global transition to sustainability) and SDG 14 (coastal and maritime tourism - the most important in terms of global turnover and especially for the development of small states Is closely related to the well-being and defense of the marine ecosystem*).(E.Marchiafava, 2017).*

The Benefits of Sustainable Rural Tourism

Achieving the goals of sustainable development, as they are rich in natural, but also cultural and social resources. For these territories, quality rural tourism is an opportunity for development thanks to the many benefits it can make from the economic, social, cultural and environmental point of view(*Kaján,& Saarinen 2013, Lane, 2009*). It can therefore be stated that tourism can play an important role in the development of rural areas thanks to its high expansion capacity, for which the benefits will not be limited to the economic sphere but will also affect the protection of the environment,culture and quality of life of the host population, activating a virtuous circle of valorisation of both resources and local activities**.**

Rural tourism and agriculture

The rural area has a strong agricultural characterization of the use of local resources and a centrality of agriculture in the landscape and in landscape management; here agriculture maintains a primary position in cultural terms, though not in economic terms from a "functional" point of view, the rural world is characterized by its multifunctionality (*Ohe Y. (2007)*. Within the rural area, the following functions are integrated:

- "economic": agricultural production, raw materials, crafts, tourism and recreation ";
- "environmental ": safeguarding the very bases of life (soil, water, air), protection of biotypes and landscape, conservation of biodiversity ";
- "socio-cultural": preservation of the socio-cultural characteristics of local communities.

Agriculture, while being one of the many components of the economic, social, cultural and environmental structure of a rural area, plays a central role in these areas, as it is still strongly present and decisive in the local system. Traditional farming, which distinguishes rural areas, provides the basis for the development of sustainable rural tourism

Analysis of the potentiality of Sustainable Tourism in Georgia

Territorial Analysis Synthesis and Potentiality of Sustainable Tourism in Georgia

Georgia**,** country of Transcaucasia located at the eastern end of the Black sea on the southern flanks of the main crest of the Greater Caucasus Mountains. It is bounded on the north and northeast by Russia, on the east and southeast by Azerbaijan, on the south by Armenia and Turkey and on the west by the Black Sea. Georgia is spread over 69,700 km2 with a population of 37 million people. Other ethnic groups include Abkhazians, Armenians, Assyrians, Azerbaijanis, Greeks, Jews, Kists, Ossetians, Russians, Ukrainians,Yezidis and others. The Georgian Jews are one of the oldest Jewish communities in the world. Once Georgia was also home to significant ethnic German communities, but most Germans were deported during World War II. Conservation International has identified the Caucasus region as a global "hotspot", that is one of the 25 most biologically rich and *most endangered* terrestrial ecosystems in the world. These hotspots have been identified based on three criteria: the number of species present, the number of those species found exclusively in an ecosystem and the degree of threat they face *(USAID 2000,FAO 2015).*

The term "Georgian" does not derive from Saint George but from the ancient Persian Gurgor Gorg, meaning wolf, "supposedly a totemic symbol, or from the Greek "georgios" ("farmer," "cultivator of land"). Starting from the early 16thcentury,although certain aspects of more recent times were already incorporated since the 12th century, until the course of the 19th century, Georgian culture became significantly influenced by Persian culture. During the modern period, from about the 17th century onwards, Georgian culture has been greatly influenced by cultural innovations imported from elsewhere in Europe.

Georgian culture suffered under the rule of the Soviet Union during the 20th century, during which a policy of Russification was imposed but was strongly resisted by many Georgians. Since the independence of Georgia in 1991, a cultural resurgence has taken place, albeit somewhat hampered by the country's economic and political difficulties in the post-Soviet era.

Georgian cuisine is considered one of the main attractions for tourists in Georgia, and it is particularly popular throughout the former Soviet Union..

The importance of both food and drink to Georgian culture is best observed during a feast, or supra, when a huge assortment of dishes are prepared, always accompanied by large amounts of wine, and dinner can last for hours. In a Georgian feast, the role of the *tamada* (toastmaster) is an important and honoured position.

The Georgian economy includes diversified and mechanized agriculture alongside a well-developed industrial base. Agriculture accounts for about half of the gross domestic product and employs about one-fourth of the labour force; the industry and service sectors each employ about one-fifth of the labour force. About rural areas, poor diversification of the rural

economy and the low productivity of the agricultural sector underpin the chronic weakness of the rural economy. In fact, more than 48% of the total added value is created in Tbilisi, which shows that the urbanization level of Georgia's economy is very high.
Georgia's typical food products are probably the most important attraction in the country. Since the traditional Georgian festival is an integral part of culture, Georgian entertainment should match its top level. The Georgians have been able to make their cuisine not only magical delightful but also bright, original, exquisite, unique and unforgettable.

The study case of Municipality of Sachkhere in Georgia

The Municipality of Sachkere
Sachkhere is a town at the northern edge of the Imereti Province in Western Georgia. It is the center of the Sachkhere Municipality.The relief of Sachkhere Municipality is average and low mountainous. From minerals sulphury water of Kvereti, quartz sand and marble are considerable.
There are 54866 inhabitant in the municipality of Sachkhere and many of them are Georgian, only few of them are Ossetian, Russian and Jewish.
On the territory of the municipality there are the following reservoirs deposits:

- Ceramic clay ore of "Perevi";
- Marmorous limestone of the Skitator (Bajte District) ;
- Sachkerer limestone (II degree calcium cigar) ;
- Lashuri (175m) clay ore, stock;
- Quail-sourced sand quarries, supplies;
- Jruchula's sand-gravel;
- River Exposure of inert materials to Kvirila and Chikhura;

Farming is a major contributor to the economy of Sachkhere. Alva LLC estimates that there are 4,000 small and medium-sized farms and ranches in the region, supported by a program of technical assistance sponsored by USAID and administered by the Farmer-to-Farmer program of CNFA.
The agricultural lands hold about 17 380 hectares, which is 22.5% of the total area and approximately 60,000 ha (78%) are covered by forests In Sachkhere Municipality agriculture is the main source of income for the population, despite the scarcity of agricultural lands.In recent years the agricultural land area has not decreased, but land degradation has been caused by erosion processes. According to the information provided, 5% of agricultural land is eroded. Apparently, one of the causes of erosion is excessive grazing because the municipality faces this problem. In the municipality of Sachkhere arable land resources are scarce and only 7 962 hectares. Cultivars are the priority cultures: maize, beans, vine and fruit. The yield of maize is 3-3.5 ha / ha, the tree fruit - 6-6.5 t / ha, the beans - 1.8-2 t / ha and the vines 4-5 t / ha. According to the Municipality data , as of 2012, the administrative unit has 24 200 souls of cattle. 0.3 ha of hay cattle come in one of the cattle. As the calculation shows, the livestock are suffering from hay-grassage deficiency. The reason for the lack of hay-pastures is the excessive grazing and drought. Passing through the municipality is one of the causes of erosion.
Forest resources are large in Municipality of Sachkhere .The main problems related to forest resources are forest cutting (including illegal), which seems to have a growing trend and a significant reduction in windbreaks. Forest cutting can be the reason for the rise of natural threats.
In consideration at this reality the perspectives of Sustainable Tourism in Sachkhere have very high potentialities.

The SWOT of Sustainable Tourism in Georgia

The SWOT of the Strategic Plan of Sustainable Tourism it's show in the following Fig1.

Figure 1_ SWOT Analysis of Sustainable Tourism in Georgia

Strengths	Weakness
Natural attractions: **Rich Tradition& Culture** **Handicraft:** **Typical products** **Friendly and laborious people** **Upgrading road connectivity** **Near from capital city** **Inside a the actractive Caucasus area Recent local-level restructuring**	**Human Resources:** **Traditional Technology** **Quality products and services** **No Irrigation** **Soil Erosion** **Road system specially in rural areas** **Internal Transportation System** **Professional Organizations** **National Policy Role of the Local Community**
Opportunity	**Threats**
Government policy **The gradual increment of the international visitors** **Workforce** **Development spirit and commitments:** **Improve the the incomes of the small farmers** **Improve the cash follow of the small farmers** **Introduction and diffusion of the ICT** **Improvement of the quality of life in the rural areas** **Increasing of the small business network in the Country**	**Termination of interest of the people** **Competition** **Natural disasters** **Failure of the local participation Not activation of the Local Community** **Failure of the Pilots Project** **Gap between policy and not enough financial resources** **Loss of the traditional behaviour** **Gradually broken of the social cohesion in the Villages.**

*Source: Author s' elaboration based on the obtained result.

Results, discussion and open questions

One of the primary factors of the project success is the appropriately formulating the project. On the other hand, proper formulation of the project depends upon the quality and reliability of the available data. Thus, the first step of the project should be on the in-depth study and analysis of the local conditions and confirmation such that it can have an influence and significance into the national level strategy of Nepal for developing the sustainable tourism. Particularly, agricultural sector of the remote village should be linked with the agritourism. The collection of proper data, analysis of it and the involvement of the local community remains the major aspect of the project success.

Conclusions

The preliminary result of the pre-feasibility analysis of the project provides the clear picture that developing National Plan for Sustainable Tourism in Georgia needs to focus on the agritourism. It can be argued on the basis of information gathered in the project development phase. Furthermore, agritourism can also be a very successful way of improving the sustainable development of the agriculture. This concept is more evident in case of Sachkhere Municipality where the aforementioned strengths are more incisive. Nevertheless, the successful implementation of the project first needs the introduction of a strategy at the national level that try to implement the opportunities of the new paradigm as:

- *The didactical and socially inclusive farms for expanding the provision of service of the farmhouse with the educational farm service that can also include direct participation of young people and children in sharing the know-how of some of the family farm production such as homemade breads, jams, crafts etc.*;
- *Territorial laboratory to support in the activity of agricultural enterprises to be transformed through activities of inclusion for the individuals who are more vulnerable and marginalized that can be an instrument in facilitating the social cohesion.*
- "*farm culture and heritage museums"*, the *training and professional learning, the renewable energy production, the short food chains, the restaurants of local food, the landscape promotion and fruition, the leisure time.*

This could activate a vital process of transformation of the rural areas which we call the *Green Virtuous Territorial Circuit.*

The farmers are those that can guarantee the continuity of supply of these services. The territory should be understood as an intelligent cognitive system that educates and makes learning as the cornerstone in building this perspective. It is demonstrated that the *Territorial Management Contracts*, the activation, and exploration of good management practices and promotion of the area are the concrete model which can ensure the *viability of good quality of life* and*well-being* in the rural areas.

The exploratory analysis is ongoing and future activities could permit to achieve the targets of the project.

FOOD WASTE AND LOSSES: INITIATIVES FOR SUSTAINABLE DEVELOPMENT

Rosalina GRUMO, Simona GIORDANO*

University of Bari "Aldo Moro", Bari, Italy
*Corresponding author, simo_giordano@yahoo.it

Abstract

Rural exodus represents a major cause of urbanization processes in Third world countries. This phenomenon is particularly evident where the failure of markets regulatory mechanisms together with the lack of governance of the agroindustrial sector on an international scale have brought about several effects on a market where global dynamics prevail over local ones. Global food scenarios show a deep contrast between extreme hunger on one side, and food waste and losses on the other one. Therefore, the real issue to take into consideration is not the lack of food but its limited access, or no access at all, especially in less developed countries, as well as the inability of the agricultural sector to play its historical and fundamental role of socioeconomic growth booster. The mentioned subject matter, in particular, has been ignored for a long time, thus resulting in a current limited availability of data and of specific literature and bibliography. Recently there has been a growing interest in this theme, due to its relevance in facing environmental, economic and social challenges. The considered scale is both international and Italian, through the employment of a territorial approach. The identified initiatives consider the phenomenon of waste and losses in a global aspect and refer to companies, foundations and organizations of the large scale retailer sector.

Keywords: Sustainable agriculture, Rural development, Food waste, Governance, Food supply chain, Global famine

Introduction

The global scenario is characterized by the abandonment of the countryside as a result of the urbanization process that has reduced the presence of arable land and has produced a scarcity of food resources. A scientific approach detects a two-way relationship between agriculture and hunger and poverty. About three-quarters of the world's poor people live in the rural areas of underdeveloped countries and derive their main livelihood from subsistence agriculture on marginal areas. However, there is also a relationship between hunger generated by food insecurity and poverty. The strategies of the rich countries in the primary sector have predicted major material interventions (construction of irrigation networks, processing facilities, machinery for working the land) to provide modern skills in countries with predominant traditional agriculture, leaving the beneficiaries in condition of dependence.
Great importance has been given to the theme of food waste in the last years and this has brought to a considerable increase of scientific research on the topic. The European project FUSIONS[12] is a clear example of this, and a great deal of recent research has been carried out within this project. Significant importance is also to be given to factors that concern population growth that makes the gap between demand and domestic supply of increasingly growing quantities of food and other environmental issues as population pressure on natural

[12] Cf.: https://www.eu-fusions.org/

resources in rural areas often results in degradation and resource depletion. In the face of agricultural production that is increasing faster than the population and the availability of sufficient food to feed twice the entire global population, so as to determine the waste phenomenon or even to over-nutrition, it raises a paradox concerning the presence of people who suffer from hunger (about one billion). So the problem is not related to lack of food but is linked to the accessibility of the food source. The contribution is intended to offer some reflections on the various issues mentioned in the international and Italian scale, through a regional economic approach and aims to analyze the phenomenon of food waste by focusing on rural areas and their development, on the food chain and the waste phenomenon finally, highlighting the strategies adopted by companies and international bodies for the redistribution of food and implementation of sustainable development.

Materials: Global Food supply chain, with particular reference to Italy

Nowadays, the primary sector goes through a phase of profound transformation, if not even of revolution, that regards agriculture and, more in general, agri-food supply chains[13], intended as the set of all the stakeholders playing a role in the production of a certain final product; from raw materials purchase to transformation, to delivery of the end product to consumers. These stakeholders are actors of different nature: production enterprises and workers, including representatives of the same category and trade associations, consultants, brokers and traders, institutional bodies and consumers organizations. In particular, the world of institutions and administrations play a vital role through intervention in support and regulation of all the activities and phases of the supply chain itself. Different attributes can be used to qualify a supply chain: long or short, regional or national up to global, with different concentration levels at various stages of production and, finally, a stable or variable composition in relation to the strength of the relations between all the stakeholders. The combined effect of increased speculative activities on commodities and protectionist decisions from some countries regarding governance, has resulted in a significant markets volatility, increasingly globalized and open to the entry of new potential operators and new categories of consumers. As a consequence, it is possible to encounter an upheaval of the traditional competitive equilibrium and, to an increasing extent, the spread of new technological applications. All the above mentioned elements are accompanied by a parallel restructuring of the same equilibrium of agricultural and food systems. New competitive structures are determined both from the production and from the distribution side, that, according to the different ability to control all the phases of the supply chain, cause a smaller or greater imbalance in the allocation of the value between the operators, often to the detriment of farmers and consumers.
The European agricultural sector is experiencing a phase of decisive and complex restructuring characterized by elements such as: the decrease in employment, the aging of the operators and the lack of generational change, the arrival of new immigrant labor force, the extreme heterogeneity of types of farms (ranging from small family businesses to large capitalist realities, with higher financial resources, particularly in the enlarged Europe scenario), whose different needs and priorities require specific policies.
The current global economic environment, characterized by the above elements as well as continuous innovations and evolving relationships, requires policies regarding agriculture and, in particular, the agri-food sectors to adapt to the mentioned environment, in view of the considerable complexity of the systemic interrelations. There is, therefore, a clear need to

[13] Cf.: Gereffi G., Humphrey J., The governance of global value chains, Review of International Political Economy, 12-1, pp.78-104, 2005.

break the isolation of the Common Agricultural Policy (CAP) and to integrate it into an overall framework of governance for agricultural and food systems in the European Union, in harmony with all other Community policies.
The global food system shows a series of paradoxes, examined below, that make it necessary to rethink the entire food supply chain, from production to transformation and consumption, in order to make it more efficient and sustainable; the creation of a viable long-term alternative to common practices such as "land grabbing", the increasing intensification of agriculture through the use of a massive use of fertilizers and pesticides, and the introduction of genetically modified organisms (GMOs).
The lower technological innovation capacity and the lack of openness to global markets have caused, in the last decades, an increasing gap of growth in Europe compared with other industrialized countries[14]. Notwithstanding the above, it is interesting to note that, compared to other world economies, the United States and the European Union recorded the highest values related to trade in goods[15]; in 2013, the EU-28 recorded exports for about 1.736,6 trillion euro, the highest value in international trade. China and the United States follow at short distance, with 1.663,3 trillion euro and 1.188,2 trillion euro, respectively. The United States have experienced a decrease in their relative weight in recent years, especially in exports, starting from 2007, that is the year when China overtook the US and became the second largest exporter of goods, after the EU-28.
The Italian economic scenario is in line with the above mentioned "picture", in relation to a production system characterized by low tech industries, suffering strong competition from emerging countries. In this context, the agri-food sector has been a resource for the country, showing substantial stability and contributing positively to the growth of the domestic product; this performance is even more impressive if one takes into account the context of declining markets and the sharp decrease in families food consumption. The introduction of the new Common Agricultural Policy (CAP) brings new challenges at a geopolitical-economic level: on one hand, in fact, the agricultural sector has to deal with the structural changes resulting from the new EU rules; on the other one, the fortunes of the industry are related to the ability of our "country-system" to seize opportunities arising from more competitive national and international markets.
Some data regarding the Italian agricultural balance should be emphasized[16]; in 2014 it recorded a deficit of around 6 billion euro, in a scenario of increasing agri-food trade flows. In particular, it should be noted data relative to growing exports (2.7%), amounting to about 35 billion euro, and imports (2.9%), amounting to just over 41 billion euro.
Regarding the geographic distribution of agri-food trade, in 2014 the European area accounted for just over 66% of our exports and about 70% of imports; North America is our second largest market, followed by Asia.
At dynamic level, the development of trade by geographical area shows a good increase in exports towards South and North America; on the contrary, exports to the EU-28 recorded a more modest increase. Similar figures can be noted regarding imports, with a decrease of approximately 21% of imports from Mediterranean African countries. Looking at the distribution of agri-food trade linked to the income level of the partners, the developed countries have the largest share of trade.

Methods: the phenomenon of food waste and territorial, economic and social impacts

The largest share of production and trade in Developed Countries, as mentioned earlier, however, creates a corresponding high level of surplus and food waste, which information must be made in relation to countries in the developing world. In analyzing the phenomenon of food waste one first notices the absence of a definition both at institutional level and in the scientific literature. In this context an important role is played by the FAO (Food and Agriculture Organization of the United Nations) which refers to the food waste as any healthy and edible substance that instead of being used for human consumption is wasted, lost, degraded or consumed in any phase of the agri-food chain. Furthermore, in a recent study conducted by the Swedish Institute for Food and Biotechnology commissioned by FAO, there was a distinction between food losses "food losses during the agricultural production, post-harvest and processing of food and food waste" wasted food that occur in the latter part of the food chain (distribution, sale and final consumption). The first depends on logistical constraints and the latter by behavioral factors (FAO, SIK, 2011)[17]. There are, however, some studies relating to the waste and losses that do not take into account the whole food chain. The definition of "food waste" actually varies depending on the country. In Europe there is still no single definition, but recently, within the Commission for Agriculture and Rural Development, it is emphasized that food waste can be understood as "the sum of the products discarded from the food supply chain for economic reasons, cosmetics or for the proximity of a use by date, albeit still edible and therefore potentially destined for human consumption, in the absence of a possible alternative use, are intended to be discarded and disposed of, producing adverse effects from the environmental point of view, economic and missed Speeds earnings for companies (European Parliament, 2011)[18].

At the root of the phenomenon can be highlighted some global nature trend with significant implications in the volumes of losses and food waste, in the relationship between developing countries and PS. This refers primarily to the urbanization that has resulted in the progressive extension of the agri-food supply chain to meet the food needs of the population living in cities. The greater distance between the place of production and place of final consumption, in fact, creates the need to transport food over long distances, with the need to improve transport infrastructure, storage and sale and avoid additional losses. The second element is the change of the composition of the diet, due to the increase in disposable income. This phenomenon, particularly evident in transition economies such as Brazil, Russia, India and China, imply that instead of starch based foods tend to favor the more meat, fish and fresh produce, such as fruit and vegetables, all the most perishable.

Finally, the third element is the increasing globalization of trade and the rapid spread of the mass distribution (GDO) in many emerging countries. The supermarkets in fact have become the dominant intermediary between farmers and consumers, replacing the retailers in areas such as Africa, Asia and South America, allowing a wider diversification of the diet. In addition, the need for better quality and food safety standards for consumers and the increase in the volume of marketed foods have consequences on the level of generated waste (BCFN, 2012)[19]. The analysis made in 2011 by the FAO estimates food waste in the world's 1.3 billion tons per year, equal to about a third of the total production of food for human consumption. But what are the reasons for food waste? In agriculture, food losses are due in

[17] Cf.: FAO, SIK, *Global Food Losses and Food Waste*. Extent, Causes and Prevention, Roma, 2011, pp. 5-6.

[18] Cf.: Parlamento Europeo, *Evitare lo spreco di alimenti: strategie per migliorare l'efficienza della catena alimentare nell'UE*, Commissione per l'Agricoltura e lo Sviluppo Rurale, 22 giugno 2011.

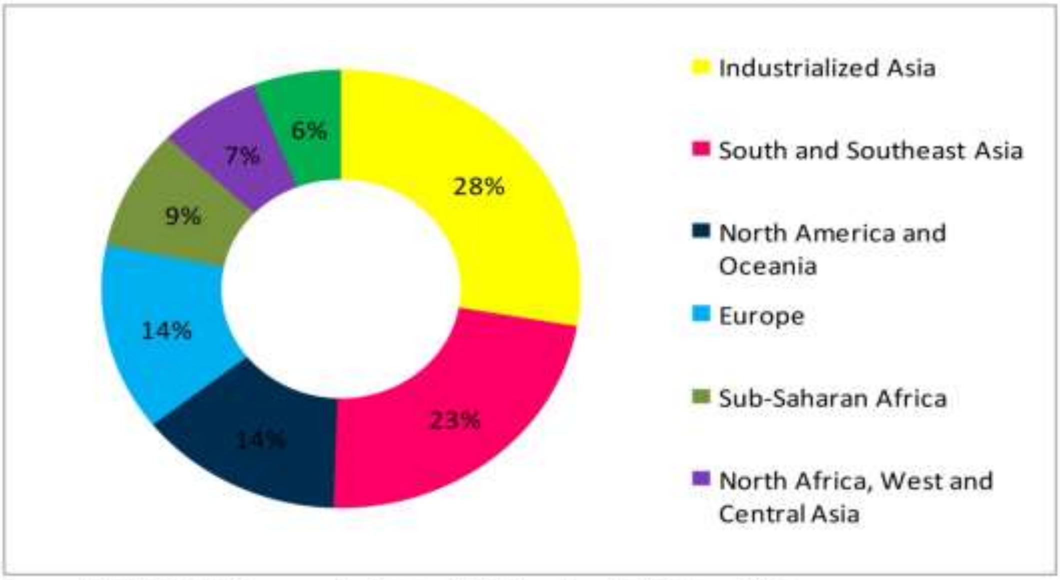
[19] Cf.: BCFN (Barilla Center For Food Nutrition), *Lo spreco alimentare. Cause, impatti, proposte*, Roma, 2012, p. 17, 42.

the first analysis to climatic and environmental factors, the spread of diseases and parasites. Technological and infrastructural facilities, agronomic skills and techniques of soil preparation, planting, cultivation, harvesting, processing and storage are behind the significant differences between countries in the developing and developed countries found in this stage. In developed countries, but sometimes also in developing, they are relevant all the regulatory and economic justification.
But there is much still to be done to understand the causes of the losses in the initial part of the supply chain. In the first processing of the agricultural product phases and finished the causes of waste are primarily detectable in technical malfunctions and inefficiencies in production processes: Normally we talk about "production waste". In the distribution and sale (whether wholesale and retail) waste depend on multiple causes, including improper orders and erroneous demand forecasts. Domestic waste arise from the difficulty of the consumer to correctly interpret food labeling; because they are prepared too generous portions (both in restaurants and at home); because of errors made in the process of procurement planning (often induced by promotional offers); when food is not properly stored (Slow Food, the Ministry of Agriculture Food and Forestry Policies, 2012)[20]. The distribution of food waste along the various links of the global food supply chain is as follows: in agricultural production (32%); in the immediate aftermath to the collection (post-harvesting and storage) (22%); on the consumer (in household and catering) (22%); during deployment (13%); in industrial processing (11%). The phenomenon of waste and food losses assumes different proportions in different regions of the world. Overall, about 55% of waste take place in developed countries, the remaining 45% in countries in the developing as can be seen from Figure 1 (Fig. 1) (FAO, 2013). The data show that even between developed countries and those in developing countries, with the exception of South-East Asian countries, the levels of waste and per capita losses that occur in the upstream stages of final consumption differ but didnt. In particular in developing countries causes the upstream waste are: farming techniques and crop inefficient, lack of infrastructure (which hinder the transport and distribution operations), storage and conservation systems inadequate, often adverse weather conditions. What is the main difference between developing countries and developed countries is mainly the amount of waste in the final part of the supply chain. We notice, in fact, that in Europe and North America such waste amounts to 95-115 kg per capita per year, mind in the South, South-East Asia and in sub-Saharan Africa counted only 6-11 kg (WRI, 2013)[21].
There are also differences in what is wasted with regard to agricultural products: mostly fruits and vegetables and roots and tubers (45% respectively) followed, fish (30%) and 20% meat, dairy products and oilseeds and legumes. In particularly in Italy specialized literature and surveys on the subject official statistics are almost non-existent. In Italy food waste amounts to 2.4% of GDP and it is traceable at every link in the food chain: agricultural production, food industry, wholesale and retail distribution, catering, household consumption. Every year in Italy will lose 20 million tons of food. The main culprit is the agricultural sector: in the fields, in fact, are not collected, over 17 million tons of fruit, vegetables and cereals, 87% of the lost food before reaching the final consumer. Several reasons: aesthetic, commercial and market. The main cause is that the surplus production that stands out in cyclical or structural

[20] Cf.: Slow Food Italia, Ministero delle politiche agricole alimentari e forestali, *Il nostro spreco quotidiano*, Slow Food Editore, Bra, 2012, pp. 1-17.
[21] Cf.: WRI (World Resource Institute), *Reducing Food Losses and Waste,* Working Paper, June 2013, Washington, p.14.

surplus (Segrè, Falasconi, 2011)[22]. All this creates some impacts. Regarding the first impact of environmental concerns waste water, climate change, soil extension (FAO, 2013)[23].

Fig 1: Global food losses and waste per regions of the world



Source: WRI (World Resource Institute), 2013, based on FAO data, 2011

The economic impact and the costs of food wasted globally are around $ 1,000 billion / year. Costs "live" food production should be added the "hidden" costs such as those attributable to the conflicts linked to the control of natural resources, the treatment of diseases related to the use of pesticides in agriculture, to water purification, the loss of natural habitats and the related ecosystem services, the effects of climate change and the reduction of water availability, erosion and reduction of the health status of agricultural land, to public subsidies for food production. The estimate that results (2,600 billion dollars) into account only in part of the "hidden costs" of food globally waste. Many other aspects were not taken into account for the lack of reliable estimation methods (FAO, 2014)[24]. Besides the ethical impact is related to the paradox of the food that ends up in landfills (in industrialized countries 222 million tons, an amount equal to the available food production in sub-Saharan Africa which is of 230 million tons). and the number of people without access to food, not only in low-income countries, but also in Europe. In fact, according to Eurostat, 81 million people in Europe are at risk of poverty (the equivalent of 17% of the European population) and 42 million already living below the poverty line. Wasted global production (around 40%) can feed 12 billion people with a world population in 2014 it was just over 7 billion. The over-production system and persists food waste at the expense of the right to food in quantity and quality adequately and sufficiently conform to the cultural traditions of the people to which the consumer and to guarantee a physical and mental life, individual and collective, fulfilling

and dignified and access that must be continuous, constant and unlimited, directly or through purchases (BCFN, 2012, p. 42)[25].

Results and Discussion: the initiatives promoted

Globally it is considered important to launch some recommendations. For example developing protocol measures to food waste. In this sense the movement in the direction of standardized measurement is underway. FAO is in the process of developing a standard method to assess and monitor food losses at the national level, with a focus on developing countries. The European Union is developing a method for assessing and monitoring food waste. WRAP, in conjunction with UNEP and FAO, has developed methods for measuring food waste within corporate supply chains. Several European countries such as Denmark, Sweden, and Norway are exploring establishing food loss and waste reduction targets and metrics. We recommend bringing these and related efforts together in collaboration with other stakeholders to establish a food loss and waste measurement protocol that will be robust, globally relevant, and universally adopted by countries and companies.

Recently the Council of the European Union has expressed its concern about the amount of food that is produced but not eaten, estimated in nearly a third of the food produced for human consumption. In terms of money, food waste has a terrible influence on the global economy with a cost of approximately USD 990 billion per year. In addition, even the food that is lost requires water to grow up, a vast cropland area and produces gas emissions.

The target to be reached is the Zero Hunger, through an increase of the availability of food able to meet the global demand of a population that is estimated to grow to 9 billion people by the year 2050. If only a quarter of the food currently lost were saved, it would feed about 900 million people starving. So, the reduction of food waste has many positive benefits because it not only reduces negative impact on climate water and land but also improves the economy of companies and households and, above all, makes it possible to feed a larger number of people with the food produced.

But there are also other recommendations as: Set food loss and waste reduction targets. Setting quantifiable, time-bound targets could raise awareness, stimulate focused attention, and mobilize resources toward reducing food loss and waste. Targets could be adopted across a range of geographic scales and types of entities. Four in particular come to mind: Global target, National Target, Sub National Target, Corporate Target; Increase investment in reducing postharvest losses in Developing Countries; Create entities devoted to reducing food waste in Developed Countries and Accelerate and support collaborative initiatives to reduce food loss and waste (WRI, 2013, pp. 28-31)[26].

Worldwide there are numerous organizations and intervention initiatives aimed at reducing and / or recovery of food products no longer sold but still edible that can be classified into the following types, depending on the nature of being a promoter and / or the objectives to be achieved:

- Organizations (profit and non-profit). It is mainly voluntary organizations (the Food Bank and the Company of the Daily Bread in Italy, Fare Share in Britain, City Harvest in the United States and Mesa Brazil SESC in Brazil) or private (the Italian spin-off Last Minute Market that favors the direct meeting of supply and demand). Finally, directly from the agricultural sector (Feeding America and the Society of St. Andrew in the United States may collect discarded food).

[25] Cf.: BCFN (Barilla Center For Food Nutrition), *Lo spreco alimentare. Cause, impatti, proposte*, Roma, 2012, p. 17, 42.

[26] Cf.: WRI (World Resource Institute), *Reducing Food Losses and Waste,* Working Paper, June 2013, Washington, p.14.

- Initiatives to reduce, recycle and reuse of food, promoted by government agencies, local or municipal government agencies: the WRAP (Worldwide Responsible Accredited Production) in Britain; EPA and the certification made by supermarkets recycling (SRPC), sponsored by the Massachusetts Department of Environmental Protection in the United States; the information campaign "Too good for the bin!" of the Federal Ministry of Food, Agriculture and Consumer Protection in Germany or the Good Samaritan project of the City of Torino in Italy.
- Public awareness campaigns on food waste (Love Food, Hate Waste WRAP nationwide and This Is Rubbish in Britain, at the local level; the ADEME campaign in France and the movement "Stop Wasting Food" in Denmark. Sometimes campaigns They are aimed specifically at teenagers, through projects undertaken in schools (the Edible Schoolyard project in the United States and the Manger autrement dans les collèges in France).
- Cooperatives in private households in the agricultural sector, (the Grow Sheffield's Abundance Project in Great Britain and the City Slicker Farms in the United States).
- Initiatives of the major retail chains, through the collection and distribution of surplus food (Happy End of Coop in Italy), the purchase deferral of commercial promotions (the formula "buy one, get one later" adopted by Sainsbury's and Tesco in Great Britain); the use of food waste as a fuel for electricity generation (Sainsbury's and Tesco in Britain); the joint acquisition mechanism (A.N.D.E.S. in France): the improvement of packaging (Morrisons and Marks & Spencer in the UK); offering suggestions to customers on its mode to a better food preservation, indicated on product labels or the web (Morrisons).
- Internet sites which market at discounted food prices close to the recommended expiration date (the experience of What's in Italy and Approved Food in Britain).
- Initiatives "zero impact" of catering to the recovery of leftover food and wine left by customers (in the case of the Italian countryside "The good that advances" in Lombardy and "Buta Stupa" in Piedmont, or the campaign "Take me away "Italian Sommeliers Association).
- Initiatives launched by individual structures (the reorganization of the catering service at the Hospital of Hvidovre in Denmark and the People's Supermarket in London involving the local communities) (BCFN, 2012, pp. 82-108; Slow Food Italy, 2012**)**[27]**.**
As mentioned in the introduction, the project FUSIONS provides a definition of food supply chain: “Any substance or product, whether processed, partially processed or unprocessed, intended to be, or reasonably expected to be ingested by humans. ‘Food’ includes drink, chewing gum and any substance, including water, intentionally incorporated into the food during its manufacture, preparation or treatment” (the so called “FUSIONS Definitional Framework for Food Waste”, Östergren et al. 2014)[28]. The food supply chain is the connected series of activities used to produce, process, distribute and consume food. The FUSIONS report adopts the definition given by the FAO (FAO 2011)[29] of food waste (any food removed from the food supply chain) and indicates that EU countries produce about 100 Mtonnes of food waste every year, and that about 45% of this is generated from households. The FUSIONS Project is coordinated by the Wageningen University (Holland) and the University of Bologna (Italy), together with Last Minute Market, a Spin Off from the

University of Bologna, founded in 1998, and nowadays an entrepreneurial society working at Italian national level for the recovery of unsold goods in favor of non-profit organizations.

Conclusions

In the world, the present system reduces farmers and food processors to producers of goods. In particular in developing countries, this system deprives peasants of access to land and water and the communities as a whole, access to food. The land is not often cultivated by local people to meet their needs, while respecting food sovereignity[30]. In some cases the land is used to grow export crops, promoting the importation of food from abroad whose price is highly volatile and co-responsible for the food crisis in the southern hemisphere. Moreover, the current food system download the unwanted food in the North to the South of the world markets at prices that exclude from local producers market. Finally, the system based on overproduction and waste is responsible for the waste of the threat and pollution of our limited public resources: water, soil and air, reducing the living creatures, such as plants and animals, commodities exploited to produce as much as possible and as quickly as possible.
The main flows of FW are generated by a variety of causes and they require specific prevention measures. For example, to avoid the waste of products that are edible but not harvested for not being in line with the required commercial standards, something could be done to foster new market opportunities (dedicated shops, community catering etc) or to promote a sort of reduced price sale within the great food retailing chain. This analysis originated by the presence of so many questions that giving an answer to them ends with even more questions: what attitude you decide to take against the global world and common goods like air, water and soil, on which one depends the future of the next generations? Responding to these issues and looking for solutions corresponds to what can be described as a correct and responsible approach to a live and sound research to support a just and sustainable model.

RURAL POVERTY AND RURAL DEVELOPMENT: A CASE FOR FAMILY FARMING AND SUSTAINABLE TOURISM IN THE NATIONAL PARK of gargano (ITALY)

Simona GIORDANO

Université Paul Valéry Montpellier, University of Bari "Aldo Moro"
*Corresponding author simo_giordano@yahoo.it

Abstract

Nowadays agricultural markets are going through a process of radical transformation and chances arise to make significant progress in the fight against rural poverty. Although during the past ten years more than 350 million people in rural areas have reached a standard of living out of the state of absolute poverty, global poverty itself remains a phenomenon predominantly rural. In order to put in place effective strategies, it is fundamental to create an environment that allows people living in rural areas to overcome all the challenges they face in their efforts to successfully manage their economic activities. This is particularly true with reference to Family farming in protected areas; in the National Park of Gargano, in Puglia region (Italy), the Park authority recognizes the important role of farmers in managing the territory of the Park itself, and in fostering rural development; an in-depth analysis of the Park agro-ecosystems constitutes the starting point to develop effective governance tools to preserve the agro-pastoral traditions of local communities and to enable the National Park of Gargano and the farmers operating in it to interact in order to develop a "management model" capable of assessing the agro-environmental sustainability of farms and promote their multifunctionality, with particular regard to sustainable tourism, leading the National Park of Gargano to become member of the Europarc Federation.

Keywords: *Rural poverty, innovative agriculture, agro-ecosystems, agro-biodiversity, sustainable tourism*

Introduction

The concept of agro-biodiversity has emerged in the last fifteen years as the intersection between biodiversity and agriculture. According to the definition given by the FAO, "agro-biodiversity is the result of processes of natural selection and of the careful selection and developments in the inventiveness of farmers, herders and fishers over millennia. The agro-biodiversity is a vital by-product of biodiversity"[31]. The agro-biodiversity reflects the existing dynamic relationships in each ecosystem between human activities, cultivated plants and domestic animals (Cromwell et al., 2003); it is perceived as threatened and in need of protection by means of ad hoc innovative legal instruments both at national and international level. As a result, and perhaps for the first time, lawmakers are engaged in a major process of innovation that aims to protect and improve local and traditional agricultural systems seen as incubators of the agrobiodiversity itself; in this context a crucial role is played by the preservation of agro-ecosystems, defined by the OECD as "an ecosystem subjected to agricultural management, connected to other ecosystems"[32]. In the Puglia region, in the context of the Gargano National Park, in the Province of Foggia[33], an important initiative is

[31]Source: http://www.fao.org/docrep/007/y5609e/y5609e01.htm
[32] Source: http://stats.oecd.org/glossary/detail.asp?ID=82
[33] Site http://www.parcogargano.gov.it/servizi/notizie/notizie_homepage.aspx

carried out in order to enhance the fundamental role of farmers in protecting and managing the environment, and to involve them in a number of actions for the protection of the Park and to keep up the efficiency of the companies/farms themselves.
As argued by Vedeld et al. (2012), parks and protected areas are established to solve challenges of biodiversity conservation and to secure different environmental services, all with the aim of contributing to local livelihood improvements. The bad consequences brought by unmanaged tourism have more and more highlighted the importance of developing strategies carefully worked out to achieve sustainability in those natural areas usually devoted for tourism. Different aspects of the relationship between tourism, on one side, and local agriculture and local people, on the other one, need to be explored; it is necessary to investigate, for example, whether an increased interest in local food and traditions can really help to develop a sustainable tourism industry focusing not just on academic debates, but taking into consideration the responses of tourists and the opinions of local people (Sims, 2009). Though rural tourism is not a recent phenomenon (Lane, 2005), nowadays, rural areas are living a complex process of development and change that needs to be carefully dealt with in order to avoid the negative impact that can come from the inflow of tourists; this is particularly true with reference to protected areas (Lane, 2005).

Materials and Methods

The project proposal springs up from the need to create a network whose main actors are the Gargano National Park (Table 1) and the various farms operating in the Park territory, through the identification of so called "Park Friends Enterprises", i.e. those farms that decide to join a "Convention" for the Park territory proper environmental management[34]. The purpose, in general, is to come to develop a "business management model ideal and environmentally sustainable" both in valuable natural areas as well as in the territories used for agricultural and forestry equipment, and to draw up a Catalogue of the "Park Friends Enterprises" in order to enhance the productions and the tourist offers of the farms involved in the initiative.

Table 1 - Mastery of the National Park Authority of Gargano

Organization name	Gargano National Park Authority
Classification of the area	National Protected Area
Total area	118.144 ha
Municipalities included in the territory of the Park	n. 18 Municipalities: Apricena - Cagnano Varano - Carpino - Ischitella - Isole Tremiti - Lesina - Manfredonia - Mattinata - Monte Sant'Angelo - Peschici - Rignano Garganico - Rodi Garganico - San Giovanni Rotondo - San Marco in Lamis - San Nicandro Garganico - Serracapriola - Vico - Vieste.
Otherprotectedareas	Protected sea area (Area Marina Protetta: AMP) Isole Tremiti

[34]The need for a Convention for the correct environmental management of the Park territory arises from the desire of the Park Board to set up with farmers working relationships for the proper management of the territory of the protected natural area.

Special Protection Areas ("Zone a Protezione Speciale: ZPS") present in the territory of the Park	n. 5
Sites of Community Importance (SIC) in the Park Area	n. 13

From the ecological point of view, the project is grounded in the high biodiversity and geological diversity of the territory of the Park, and aims both at recording the productions and the agro-environmental resources of the farms, and at identifying a series of synthetic indicators capable of obtaining a "qualitative model" for a proper business management, both biocompatible and environmentally friendly. The project can be described through the identification of three main activities, highly connected the ones with the others; the Park institution is currently engaged in the promotion of alternative economic activities, identified through 8 main Projects (Table 2), aimed at adopting restoration strategies and actions based on a clear understanding of the context in which different agro-ecosystems evolve, first of all the wealth status of the farmers (Belem et al., 2011).
As to Activity 1, the farms identified on the basis of those who joined the aforementioned "Convention" for the correct environmental management of the Park territory are divided by uniform size classes, in blocks according to the farm agreed area and proportioned in number to the "weight" of the same dimensional block on the total. The profile of each farm is described through the creation of an interview sheet in Excel format, aimed at reporting the data collected during the inspection on the field and the interview with the farm owner[35], and the subsequent visit to the farms, it is possible to describe the "profile" of the single farm.

Table 2: Intervention Axes and Projects

The documentary material collected is subsequently filed using a logical pattern and the data are then sorted and digitized in a holding file[36]. Synthetic information can be extrapolated, needed to fill out a card and a descriptive text representative of each farm within the catalogue; technical details and practical information are both merged with others more strictly functional to the practical use of the farm land and the surrounding area (Table 3).

[35]The factors taken into account are: farmland, crop types, presence of breeding animals, presence of valuable architectural manufacts, crop management and production companies of excellence, local products and high biodiversity value crops, the presence of karstic caves and peculiar views of the landscape, wildlife and flora life relevant stations, architectural and naturalistic emergencies, legends about places or people who have lived in it, origin of place names.
[36]Each monitored company has its own file, which consists of: the Excel sheet of business survey; georeferenced photographs of the farm territory and the main structures; a technical report in Word format that describes extensively the farm in all its aspects ("Agrostorie");a shapefile of "significant" points manageable through GIS programs.

As regards the selection criteria of the companies mentioned within the project, it is fundamental that they hold a stable business center within the Park Area[37]; they are divided into groups based on the size of the farm agreed area. Within these groups, a certain number of farms is selected appropriate and proportionate to the total number of farms belonging to the Park. In this way, a large database, interactive and heterogeneous as to content (reports, tables, digital images, shapefiles)[38], can be developed; the mentioned proportions among the dimensional blocks can help to give a true idea of how farms different in size (in relation to an agreed area on the total surface) carry on their agro-environmental commitments. Moreover, a database is created, in order to evaluate the spatial distribution of farms among the municipalities of the Park (Figure 1). Using this method it is certainly possible to reach a representative sample, considering the division of the area subjected to the Park bond among different municipalities. Stated the respect of geographical and size criteria of the farms in the Park, the project aims to give farmers the awareness that they are the main actors of the Gargano National Park[39]. The choice of the farm to "investigate" is followed by a series of preliminary steps carried out during a visit to the field, aimed at knowing in advance the complex agro-environmental features; analysis of AGEA questions ("bibliographic analysis")[40]; mapping survey of the farm area through GIS, focusing on the farm area internal to the Park and on the one adjacent to the protected area boundaries (scale landscape

[37]These companies are also registered with the Chamber of Commerce as farms or as individual farmers.

[38]In completing the project, this material is merged in the drafting of a catalogue of the farms involved in the project, each of which is represented by a "business farm card" where various aspects of the farm are described.

[39]The parameters, the techniques and the information used to select the farms to be evaluated are integrated with: previous case studies, in order to have a basic set to start from ; experiences of previous collaborations (eg. excursion activities promoted by the Board and by local associations) with farmers; direct observations of various kinds; semi-structured individual interviews on several occasions; analysis of secondary sources of data (eg. maps, archives).

[40]It is the case of the AGEA applications submitted by the farms in the phase of drawing up of the agreements for "good agricultural practices"; from the analysis of AGEA file registered at the Park Authority, it is possible to extractall the data related to the owner of the farm, the use of farm areas, the presence of animals, the type of management, the UAA, the surface devoted to each crop, the natural vegetation portion.

analysis)[41]; detailed analysis of natural areas or not typically cultivated ones (accurate cartographic analysis); definition of a list of hot-points that, loaded on the GPS, are observed in the field. After the preliminary phase it is possible to proceed to visit all the hot-points, to detect flora and fauna features not recognizable on aerial photo[42]. The photographic data and field notes are then computerized and translated into the farm survey form and in a set of data, complex and multidisciplinary, available for future Board projects and future actions of land management.

In Activity 2, the main objective to pursue is the definition of a methodology for the monitoring and the evaluation of individual farms in the area of the Park; the methodology has to meet the following characteristics simultaneously:

1) Conciseness. It must be able to offer a concise opinion on the coherence of enterprise management systems (land use, crop choices, management techniques, aspects of flora and fauna) with the objectives of nature conservancy and sustainable development suggested by the Park, including tourist activities.

2) Reproducibility. It must be applicable in any farm present in the park and offer comparable results.

3) Sharing and appropriateness. It must not be imposed, but accepted by the farms in the Park as fully corresponding to real situations, without reference to external models difficult to apply.

4) Functionality and easeness. It must allow a continuous adaptation and improvement of the concrete conservation actions promoted by the Park Authority.

The purpose is to define the parameters and conditions necessary to detect the so-called "ideal farm", i.e. a company that through the management strategies will be able to improve production performance and, at the same time, help to save the natural resources of the territory. As to this stage, it is feasible to set a series of indicators on the basis of theoretical and conceptual models consistent with each other and combined with a view to their practical application in the context of the Gargano National Park. A first level of classification consists in organizing the indicators in four dimensions of sustainability (physical, ecological, productive-economic and socio-cultural) corresponding to respective domains in the agro-eco-system (Pacini et al., 2009); for each of these dimensions, a precise number of systems can be identified (Lazzerini&Vazzana, 2005). The indicators themselves are finally grouped according to the belonging systems and to the functions they represent. The functions are then categorized on the basis of studies of international importance such as the Millennium Ecosystem Assessment (De Groot et al., 2010) and interdisciplinary European research projects on the assessment of sustainable impact of land management policies (Paracchini et al., 2011). The development of an evaluation system of indicators and indexes according to their importance is set, as well as the translation of the valuation rules in an automated program[43], on the basis of data collected in "case study" farms; then, for the evaluation of agro-environmental sustainability of these selected farms, the application of the Program is carried out as assessment tool of the mentioned "case study" farms, on the total number of farms involved in the project. In detail, in each of the dimensions of sustainability, the system identifies within each dimension and eco-systemic functions, as well as in relation to each

[41]The presence of geomorphological features of particular interest is recorded.

[42]Data on plant and animal communities present in the farm territoryare of "qualitative" kind, linked to the presence of certain target species, but they are certainly influenced by the time period when the measurements were made and are therefore not comparable.

[43]This program is similar to the Dexi-sustainability farms Alta Murgia Park program is built on the basis of an open-source software Dexi (http://wwwai.ijs.si/MarkoBohanec/dexi.html). The software comes with an original manual in English language.

indicator, some weights to be assigned[44]. The approach to be used is based on a multi-criteria linear additive model that assumes that each of the indicators listed represents, through the level of its score, the performance produced by a company in relation to a particular eco-systemic function. To each indicator it corresponds a utility function of its own, that represents the contribution that each farm gives with respect to each of the eco-systemic functions identified; the utility function is a linear function, or function at fixed coefficients. Each coefficient depends, in the chosen model, on the number of indicators that contribute to the achievement of a given level of utility for the farmer/actor linked to an eco-systemic function. The model is additive in that the sum of the level of utility of the functions related to each indicator gives, as a result, the level of the eco-systemic function achieved by a single farm analyzed. This result is then given by the sum of the products of the business performance (values of the indicators, standardized to sustainability scores between 0 and 1) multiplied by the relative weights (percentage calculated dividing by 100the number of indicators of each eco-systemic function). Such method ensures equal distribution and importance to the various aspects to be measured; the calculation of the overall agro-environmental sustainability of a farm cannot be positive if one of the four dimensions (physical, ecological, productive-economic and socio-cultural) is negatively evaluated, in order to select only those companies really engaged in all the aspects taken into consideration.

As to Activity 3, in order to actively engage all the farms in the Park in the territorial liveliness and let the public know the features of the same farms, a set of tours is organized, whose itineraries start from local farms; during the tours, participants have the opportunity to discover the naturalistic beauties of the Gargano area and to approach the farms that brighten up the Park through the knowledge of their activities and their products. This action is an important local promotion intervention; in particular, the overall goal is to allow people to discover the reality of farms in the Park and then bring citizens closer to the agro-livestock operators, as major knowers of the area[45]. In order to manage the organization of the general program a "Laboratory"is established; the function of the secretariat is to manage the project as a whole, from the contacts with the companies/farms to the overall organization of the project excursions[46].

Conclusions

As argued by Valbuena et al. (2014), the analysis of the diversity of current states, life cycles and past trajectories of local farms and agro-ecosystems is vital to effectively design more sustainable management tools of the same agro-ecosystems. The analysis of the strengths and weaknesses of the investigated area highlights, considering the socio-economic characteristics and their evolution, the need to adopt strategies able to improve the regional competitiveness of the area; a first objective is the launching of processes to improve the

[44]The assignment is carried out as proposed by Paracchini et al., 2011.

[45]For all the excursions, a top limit of 40-50 people will be set up, in order to ensure the best possible service and guarantee a low level of inconvenience to the places visited.

[46]In detail, it will carry on the following tasks: manage the relationships with the farms contacted (appointments, etc.); contribute to the archiving of the material collected and of all the material collected throughout the project (photos, popularity cards, etc.); provide logistical and organizational support to the organization of public events where required (spread promotional material, contact the speakers, organize and book meeting rooms etc.); collaborate in the monitoring of the Project; manage the relationships with the press and media organs and provide a logistical support to the correct carrying outof all the activities involved in the project.

quality standards of agricultural products and to ensure the integration of the supply chain. These processes will allow the improvement of competitiveness in domestic and international markets, through interventions on productive structures, but also on marketing strategies. All these strategies towards the revaluation of local food and wine products must be related to the enhancement of environmental and cultural resources and the diversification of business activities in rural areas, towards an effective multifunctionality; another goal is the promotion of innovation and integration along the supply chain, aimed at the introduction of all those technical and organizational innovations that improve the competitiveness of the agricultural sector and, consequently, the tourist one.

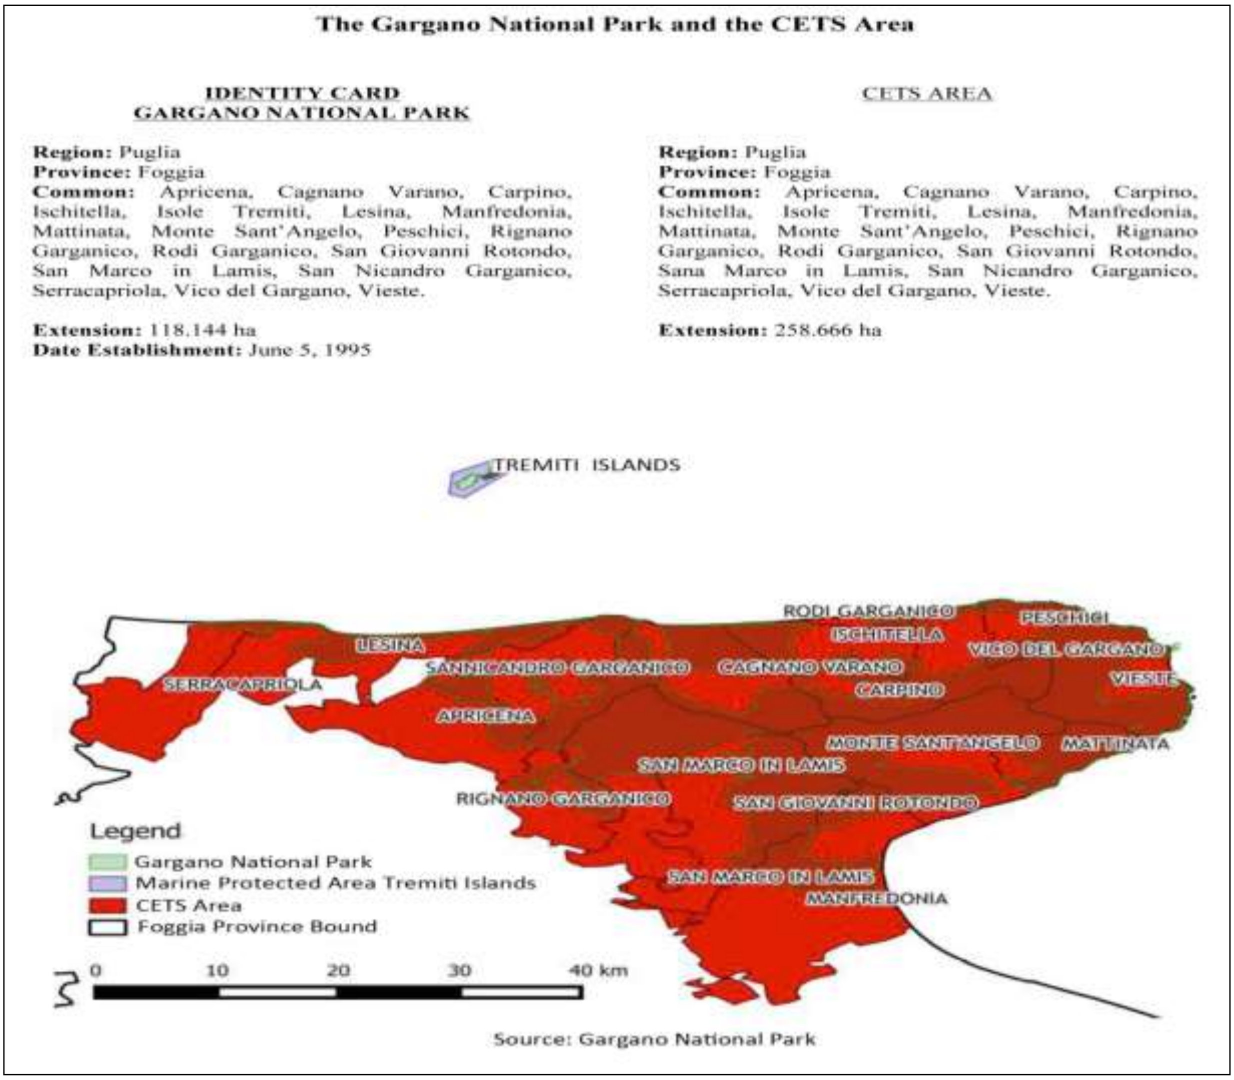

Figure 1: The Park Territory

Particular attention should also be given to investments in public infrastructures in support of marketing and, above all, to promote the diffusion of technological innovations; ultimately, it is vital to improve the entrepreneurial and professional skills of local players. All of these goals are attainable bringing together the different professionalisms in the area, in order to take advantage of all the skills needed for a better carrying out of actions for local development; all this combined with the aim of the conservation of biodiversity, key resource within each protected area. In this regard, the primary sector can contribute through the diffusion of agro-forestry systems of high naturalistic value; the protection of biodiversity in agriculture is not only an issue regarding habitats and wild species, but it is also related to the

genetic diversity of the species cultivated and raised. This involves the introduction or continuation of support of extensive and organic production methods, as well as the protection and safeguard of animal and plant genetic resources, and the diversification of agricultural activities towards the creation of new environmental services, comprising the tourist ones. Everything mentioned is at the basis of a project aimed at giving to a group of farmers the awareness to be key players in local dynamics and in the decisions of the Park Board, as well as in the further development of the tourism sector and its sustainability. Local participation is also to be stressed in any plan-making process and decision making (Lane, 2005).This idea of “all-round sustainability” (Sims, 2009) is perfectly coherent with the aims of the mentioned Slow Food movement[47], its concern with the consequences on the environment of a highly industrialized food systemand the necessity to foster a food system based on principles of high quality and taste, environmental sustainability and social justice.
Successful sustainable tourism needs a long term strategy based on a wider perspective that starts from the analysis of the different needs of the area (cultural, economic, environmental, and so on) and of how tourism can help to improve the local economy; the same strategy, then, develops, through the active participation of local people to plans and decisions, a long-term program able to protect the environment, to foster new local enterprises, to support local farming and agriculture, in a word the regional economy.

ROLE AND IMPORTANCE OF SMALL AGRICULTURAL HOLDINGS IN LATVIA

Aina DOBELE*, Andra ZVIRBULE

Faculty of Economics and Social Development, Latvia University of Agriculture, Latvia
*Corresponding author: Aina.Dobele@llu.lv

Abstract

An opinion is being popularised nowadays that the future production of food and other goods may be only industrial, large-scale and uniform. The Common Agricultural Policy of the European Union and the Rural Development Programme of Latvia has directed agricultural and rural development towards this particular goal, focusing less on small agricultural holdings. Four land reforms in Latvia have been implemented within a relatively short period (during the last century), making significant effects on the size of farms and agricultural development in Latvia. The research *aim* is to identify the role of small agricultural holdings by examining the historical background of formation of agricultural holdings in Latvia. Based on data provided by the Central Statistical Bureau, small agricultural holdings, in terms of utilised agricultural area and standard output, accounted for 90% of the total agricultural holdings in Latvia in 2010 and 2013. However, the number of such farms decreased year by year. For this reason, the preservation and development of small and medium agricultural holdings in the rural areas of Latvia is an essential matter. The insolvency and liquidation of small agricultural holdings can only increase the number of poor families, depopulation and unemployment in rural areas and in Latvia as a whole. In Latvia, small agricultural holdings are defined as those with an annual standard output of less than EUR 15 000 and an agricultural area of less than 50 ha. Small agricultural holdings perform not only economic but also ecological functions, and they play an essential social role in rural development.

Keywords: *small agricultural holdings, land reform, standard output*, *Latvia.*

Introduction

Nowadays an idea is popularised that the future production of food and other products could be only industrial, large-scale and uniform. According to rural development experts of the Latvian Farmers Federation, the *capture of land resources, the standardisation of products, the use of pesticides, the cooperation of the financial market with large producers, the unavailability of credit for small farms, the production of monocrops in large areas, agricultural land depletion, increase in unemployment and rural depopulation* are the most visible problems in rural areas that affect the development of small agricultural holdings. For many years, the Common Agricultural Policy of the European Union and the Rural Development Programme of Latvia have directed agricultural and rural development towards the expansion of large farms, placing less focus on small agricultural holdings. After regaining independence, farms of various sizes emerged in Latvia. Some farms had a lot of technological resources, agricultural constructions and adapted and appropriate local infrastructures, whereas others had limited resources, low production capacity and poor infrastructures. Since the independence, there has been a popular conclusion that large farms had undoubted advantages in production, business development and competition. There is no single definition of an agricultural holding; however, in its July 2011 report „*What is a small farm?*" the European Commission's Directorate-General for Agriculture and Rural

Development pointed out that the definition of a small agricultural holding has to be associated with such aspects as poverty risk, farm disadvantages, a lack of opportunities for development and the necessity of support, as well as certain criteria of such farms and their performance have to be set; this information could be used for statistical analyses and for defining agricultural policy goals. Beginning with the end of the 19th century, the political and economic literature often predicted no long period of operation for small farms. In reality, the predictions did not prove to be true, and an important factor – **family teamwork** – contributed to it. The produce of small agricultural holdings is not intended only for the market. Part of the produce is used to meet the needs of family members – for self-consumption – that is not affected by market price fluctuations, while the other part is intended for other consumers, yet it is not sold in the market and often takes the form of reciprocal private relationships with locals and neighbours.

Materials and Methods

The present research is based on an analysis of specific literature and information from scientific databases (Science Direct). Regulations of the European Union, laws and Cabinet regulations of the Republic of Latvia were used to examine the legal framework, and quantitative data were acquired from the database of the Central Statistical Bureau of the Republic of Latvia. Since 2010, a new classification of agricultural holdings and their economic sizes has been employed in Latvia, and the type of farming of a holding is determined calculating its **standard output** (SO). The sum of standard outputs of all products of a holding represents the **economic size** of the holding. The purpose of determining economic sizes is to compare agricultural holdings being different in terms of production (e.g. holdings growing different crops and having different cropped areas and numbers of livestock) and economic performance. Every EU Member State sets its own economic size threshold, and agricultural holdings are classified into economic size classes. An economic size threshold of an agricultural holding set by the FADN of Latvia equals EUR 4 000 (Latvijas lauku saimniecību..., 2014). Various sources provide different definitions of a small agricultural holding. The present research employed a definition available in the legal framework of Latvia for small agricultural holdings, which specifies some criteria: a **small agricultural holding** *is a natural or legal person, the place of residence of which is declared in a rural area or a legal person whose registered office is in a rural area and whose* ***total standard output*** *is in the range of* ***EUR 2 000 – 15 000*** *and the owned or rented* ***utilised agricultural area*** *of which is less than* ***50 ha*** (Valsts un Eiropas…).

Results and Discussion

The formation of agricultural holdings in Latvia was influenced by a number of political and economic processes. After 1920, there was a need to develop an independent national economy and a new management model. Because of the war, the population of Latvia decreased (from 2.5 million in 1914 to 1.6 million in 1920); buildings, infrastructure and farms were destroyed and farmland was overgrown (Boruks, 2003).

However, in 1929, after the *second agricultural reform* (1920-1937) (the *first land reform* began in 1861 in Russia after feudalism was abolished and the land of large land owners – German feudal lords – was distributed among Latvian peasants) when a decision was made to distribute the land of landlords among landless and small peasants, paying no compensation for the nationalised land to the former owners, the total number of agricultural holdings increased by 37%.

An analysis of changes in the number of agricultural holdings broken down by land area reveals that in the 1920s and 1930s the number of those being called family farms with an area in the range of 10-30 ha increased the most, reaching 115 thousand or 49% of the total agricultural holdings. However, the proportion of large farms holding a land area of more than 50 ha decreased (from 10.5% in 1923 to 6.8% in 1939) (Ozols et al., 2012). In the result of the *third land reform* (in 1940), which involved enforcing the system of collective farming, the land was again expropriated from its owners, and everything what was achieved during the earlier two reforms was eliminated. Private property was abolished, and land was nationalised and became the property of the state. The advantages of large collective farms, compared with small private ones, were stressed, avoiding defining their negative aspects. Positive changes towards private farming began on 6 May 1989 when the earlier abolition of individual farming was annulled. After the economic and political crisis in the Soviet Union, which resulted in its collapse and Latvia became a parliamentary republic, privatisation was started, and one of its goals was transition from socialism to a market economy. Small family farms emerged in rural areas. During the restoration of ownership of land and other property at the beginning of 1991, land in rural areas was granted to almost eight thousand individuals who managed a total area of 152 thousand ha, and many former collective farmers gradually established their own private farms and household plots. The liquidation of collective farms and the *fourth land reform* affected the size of agricultural holdings – small holdings emerged and prevailed and the utilised agricultural area (UAA) was fragmented – which, in its turn, influenced agricultural output and farmland management techniques. As shown in Table 1, at present agricultural holdings that are small in terms of economic size account for 90% of the total, while in Latvia as a whole the number of agricultural holdings decreases. This is mainly due to a decrease in the number and proportion of very small holdings (with a SO of less than EUR 4 thou.). The calculations showed that the process of production concentration took place in the agriculture of Latvia.

Table 1. Distribution of agricultural holdings by economic size in Latvia

Standard output	**2010**		**2013**		**Change from base year**
	number	percentage	number	percentage

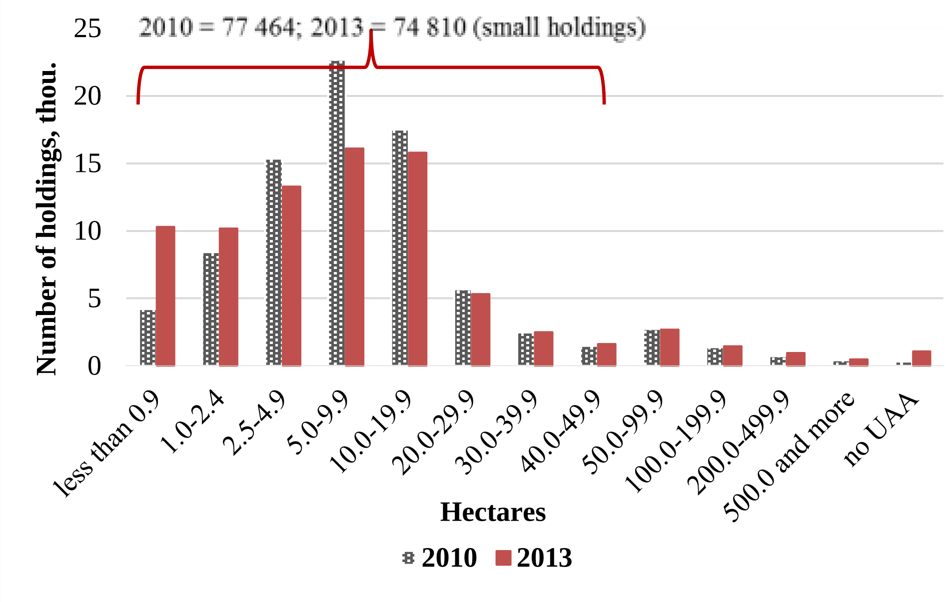
Source: authors' calculations based on CSB data, 2014

After summarising the CSB data on agricultural holdings broken down by UAA for 2010 and 2013 (Figure 1), one can find that very small holdings comprised more than 90% of the total. In 2013 compared with 2010, the number of very small holdings decreased (-3%), while the number of those holding 50 ha and more increased (+18%). After 2010, the decrease in the number of small agricultural holdings and the increase in the numbers of medium un large ones were affected by:

- modernisation and expansion of agricultural holdings;
- depopulation.



Source: authors' construction based on CSB data
Figure 1. Distribution of agricultural holdings by utilised agricultural area in Latvia

The number of small agricultural holdings is directly associated with territorial development as well. Latvia is a small country with a great diversity of natural and human resources and disparities in the development of its regions. Most small holdings operate in Latgale region, which is an economically less developed region. However, small holdings play an important role in this region in relation to the development of rural environment. Based on the available CSB information, small agricultural holdings mainly specialised in field crop farming, and the number of the holdings increased by 5% in 2013 (Table 2). The fewest holdings specialised in vegetable farming, yet it has to be mentioned that the number of holdings of this particular specialisation increased by 48% in 2013, and the greatest increase in the number of holdings was observed only for one more specialisation – permanent crops (+75%). A trend emerges – small holdings shift from livestock to crop farming, which is affected by both political and economic processes in the world.

Table 2. Types of small agricultural holdings in Latvia

Type of farming	**2010**		**2013**		**Change from base year**

Source: authors' calculations based on CSB information

The decision of small agricultural holdings to engage in both types of farming – crop and livestock – is determined by a number of factors:

- it ensures a steady cash flow;
- less problems due to price hikes;
- changing demand;
- limited resources or, conversely, their abundance.

Small agricultural holdings do not have the same production capacity as large ones; therefore, their revenues are lower, their opportunities for development are more limited and their production costs are higher. However, in this case too particularly the family factor allows improving the situation – in most of the instances, remuneration for the work of family members is not included in production costs, which allows having the production cost at a level that keeps the farm solvent. The problem of such a situation is that it is impossible to reach a high quality of life; however, living and working on a family farm is a lifestyle.

Conclusion

The formation of agricultural holdings in Latvia has been affected by four land reforms. In Latvia, small agricultural holdings make up 90% of the total, yet their distribution across the regions of Latvia is uneven. The highest proportion of small agricultural holdings was reported in Latgale region (92%), whereas the lowest was in Kurzeme region (86%). Small agricultural holdings were engaged in both livestock and crop farming; however, the calculations showed that the number of holdings, the main economic activity of which was crop farming, tended to increase. The development of small agricultural holdings, the use of their advantages and the avoidance of their disadvantages are determined by the common vision of family members regarding their farm goals, a critical vision of the disadvantages and a search for effective solutions to avoid the disadvantages.

PERSPECTIVES FOR BEEF CATTLE PRODUCTION AND SALES IN LATVIA

Andra ZVIRBULE, Aina DOBELE

Latvia University of Agriculture, Faculty of Economics and Social Development, Jelgava, Latvia
*Corresponding author: andra.zvirbule@llu.lv; aina.dobele@llu.lv

Abstract

Production of beef cattle is one of the most prospective agricultural industries in Latvia. This consideration could be made based on the following preconditions - suitable climate conditions, suitable land areas for beef cattle production, gained management experience, rational opportunities for industrial by-product (manure) use and a wide range of opportunities to increase product sales both in the domestic and foreign markets.

In Latvia, the beef cattle industry showed increase during 2011-2015, which had been supported by the positive outlook for beef cattle farming in the entire European Union (EU) market, intensification of rural area diversification in accordance with increased requirements for agricultural land management as well as economic considerations.

The topicality of the research is determined by the trends of the beef cattle market, which are assessed as stable in the whole world. In the EU, the number of slaughtered cattle has increased by 4%, while meat production – by 3.70%. The total number of live cattle exports in the EU Member States has also increased by 7.30% during the last five years.

In Latvia, the transition to beef cattle farming is stimulated by low milk prices and the limited milk sales market, where there is a tendency that many dairy farms have started parallel beef cattle farming.

The aim of the research is to explore prospects for the production and sales of beef cattle in Latvia. The specific tasks of the research: 1) to characterise trends in the production and sales of beef cattle in the world and the EU; 2) to explore the conditions that influence the production and sales of beef cattle in Latvia; 3) to determine the prospects for the production and sales of beef cattle in Latvia.

The research results shows dynamic changes in beef cattle production in Latvia. In the in the period 2011-2015 the key trends of which were as follows: with the number of beef cattle farms increasing insignificantly, the number of beef cattle and the number of beef cattle herds increased fast.

Keywords: *beef cattle production; beef sales; production and consumption balance; price of beef; Latvia*

Introduction

A number of authors and organisations that research agricultural development (N.Alexandratos and J.Bruinsma,2012; FAO, 2012) stress the variables trends in the production and sales of beef cattle in the world, yet, at the same time, they identify several global problems. The livestock sector is one of the most dynamic parts of the agricultural economy. The sector has expanded rapidly in recent decades and demand for livestock products is expected to continue growing strongly through the middle of this century, driven by population growth, rising affluence and urbanisation. Decisive action is required if the sector is to satisfy this growth in ways that support society’s goals for poverty reduction and food security, environmental sustainability and improved human health. It is believed in

Latvia too that beef cattle production is one of the most prospective agricultural industries that considerably enhanced its competitiveness in the domestic market owing to the intensive popularisation of beef cattle breeding and the activities of the Latvian Beef Cattle Breeding Association in recent years.

There are all the necessary preconditions for the development of the beef cattle industry in Latvia: suitable climate conditions, suitable land areas for beef cattle production, gained management experience, rational opportunities for industrial by-product (manure) use and a wide range of opportunities to increase product sales both in the domestic and foreign markets. A number of authors and research studies (V. Muriel *et al.*, 2015; M. McCarthy *et al.,* 2003; C.A. McAlpine *et al.*,2009; A.Hessle *et al.*,2017.) emphasise economic, social and sustainability aspects in the production, processing and consumption of beef. In the global beef market, discussions increasingly focus on problems that relate to the cattle raising stage – the problem of CO_2 emissions, the problematic aspects of meat quality, environmental impacts and, at the same time, cost optimisation. However, in view of the fact that the beef cattle industry is only at the initial stage of development, the key objective of this industry is the production of high-value and quality beef, the supply of domestically produced meat of beef cattle to consumers in Latvia as well as the enhancement of its competitiveness and opportunities for export.

The above-mentioned considerations formed the basis for the present research on the prospects for the production and sales of beef cattle in Latvia, taking into consideration the overall trends in this industry in the world and the EU.

The following research aim was set: to explore prospects for the production and sales of beef cattle in Latvia. The specific tasks of the research: 1) to characterise trends in the production and sales of beef cattle in the world and the EU; 2) to explore the conditions that influence the production and sales of beef cattle in Latvia; 3) to determine the prospects for the production and sales of beef cattle in Latvia.

Materials and Methods

The following research methods were employed to achieve the aim and perform the tasks: logical construction, analysis and synthesis, the graphic method as well as statistical analysis methods to compute annual changes and changes from the base year.

The authors of the paper used the following materials: research papers for theoretical justification; data on the situation in the industry in Latvia and in the world from FAO and from annual reports of the Ministry of Agriculture of the Republic of Latvia; information provided by the Latvian Beef Cattle Breeding Association for the assessment and analysis of the industry as well as practical research and observations done by the authors.

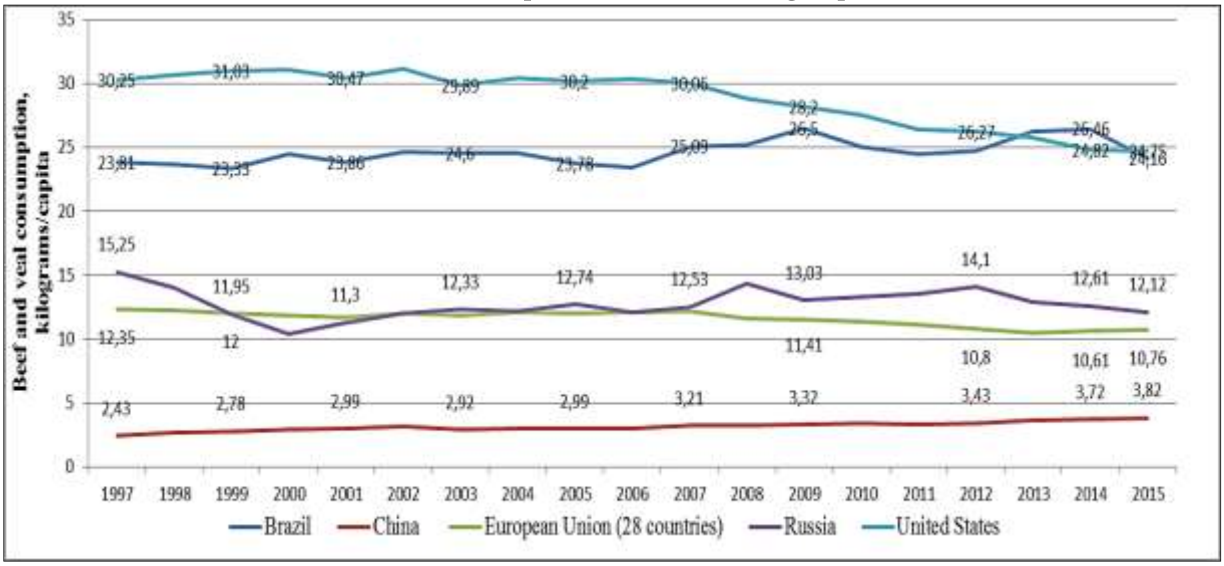
Results and Discussion

Trends in the production and sales of beef cattle in the world and in the EU

In view of the fact that the potential quantities of beef produced and sold in Latvia are relatively insignificant, Latvia is not going to be a significant market player on a global scale due to its small capacity. However, an analysis of the trends in the production and consumption of beef in the world allows identifying the key potential courses of development for this industry.First of all, an analysis of the output of beef and veal in the world allows concluding that the USA, Brazil, the EU Member States and China are the leading beef suppliers and beef market shapers in the world. An analysis of the statistics by country shows that in the period 2011-2015 insignificant changes in output were observed in all the leading countries. Such a situation indicates that the supply of beef was quite steady and no fast and dynamic changes occurred in the markets of the leading countries. A positive fact is that from the perspective of Latvia, a quite steady situation in the output of beef was in the EU Member States that took high and stable positions in the world market.

Further, an analysis of the consumption of beef and veal reveals that the average per capita consumption of both kinds of meat was equal to 6.50 kg/year. However, a lot of various factors affect the consumption of beef: the standard of living, religion, food consumption behaviour, price, the quality of an assortment etc. In 2015, according to the OECD, the highest per capita consumption of beef and veal was reported in Argentina, 41.80 kg/year, whereas the lowest – 0.60 – in India. In the European Union Member States, this indicator was, on average, 10.76 kg/year per capita.

Fig. 1. Trends in the consumption of beef and veal in the leading beef consumption countries in the period 1997-2015, kg/capita



**Source: authors' construction based on FAO data*

The data on the trends in the consumption of beef and veal in the period 1997-2015 indicate that unlike the trends in the output of both kinds of meat, dynamic changes were observed in the sales of both kinds of meat in the world. Annual change rates for the consumption of beef by country reveal that the largest changes in consumption in the period of analysis were reported in Brazil (-8.69%....+7.08%), China (-8.17%....+8.64%) and Russia (-14.64%....+14.60%). The steadiest situation was in the USA (-4.02%....+2.19%) and the EU Member States (-4.03%....+2.91%). Furthermore, only China and Brazil demonstrated an increasing trend in the consumption of beef. Such overall trends in consumption were affected by change in food consumption habits, which was specific to China, quite dynamic fluctuations in the global beef markets where beef prices reached a record high level in 2014 and interaction among the meat markets – an increase in the price of pork due to the outbreaks of swine diarrhoea in the USA and African swine flu in Europe as well as an increase in the price of mutton in New Zealand where the number of herds decreased for several years.

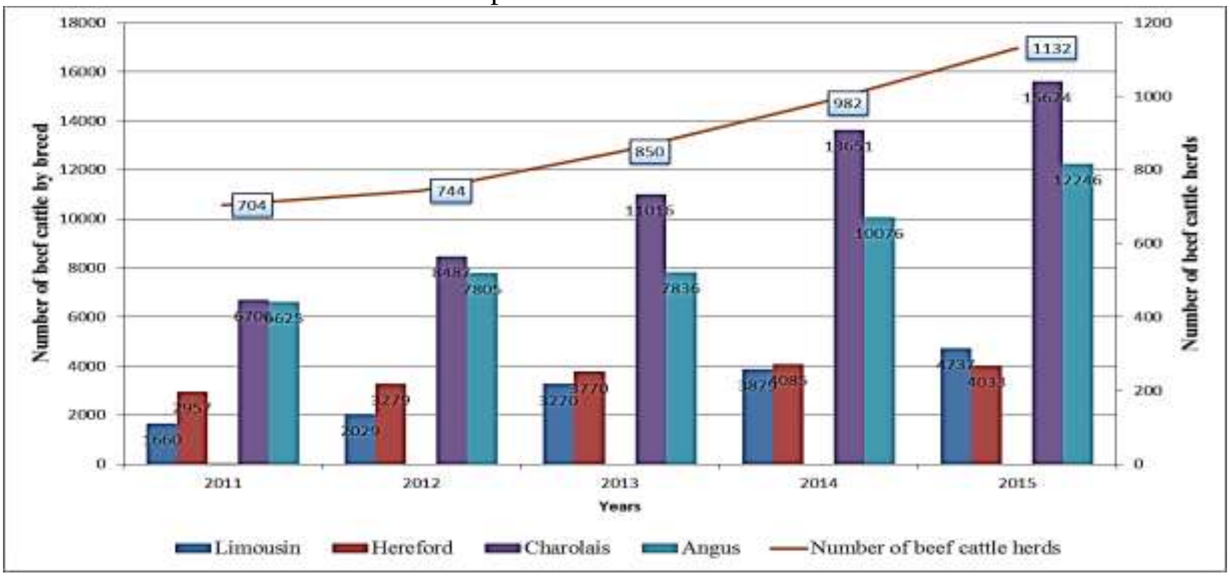
Production and sales of beef in Latvia

After analysing the situation in Latvia within the context of global trends, one could make an assumption that dynamic changes occurred in the production of beef. The changes were due to the following key trends – with the number of beef cattle farms increasing insignificantly, the number of beef cattle and the number of beef cattle herds increased fast.

In 2015, with the number of farms increasing insignificantly, the number of beef cattle reached 59250 (pure-breeds and crosses of beef cattle), which was 9.8% more than in the previous year. However, according to the Agricultural Data Centre (ADC), there were 27229 farms with 419 084 cattle recorded in the register of animals, which was 0.7% cattle less than in 2014, which indicated that a number of farms engaged in cattle farming professionally, keeping beef breed cattle in particular.

A further analysis focuses on changes in the numbers of beef cattle and beef cattle herds in Latvia by year.

Fig. 2. Changes in the numbers of beef cattle and beef cattle herds in Latvia in the period 2011-2015



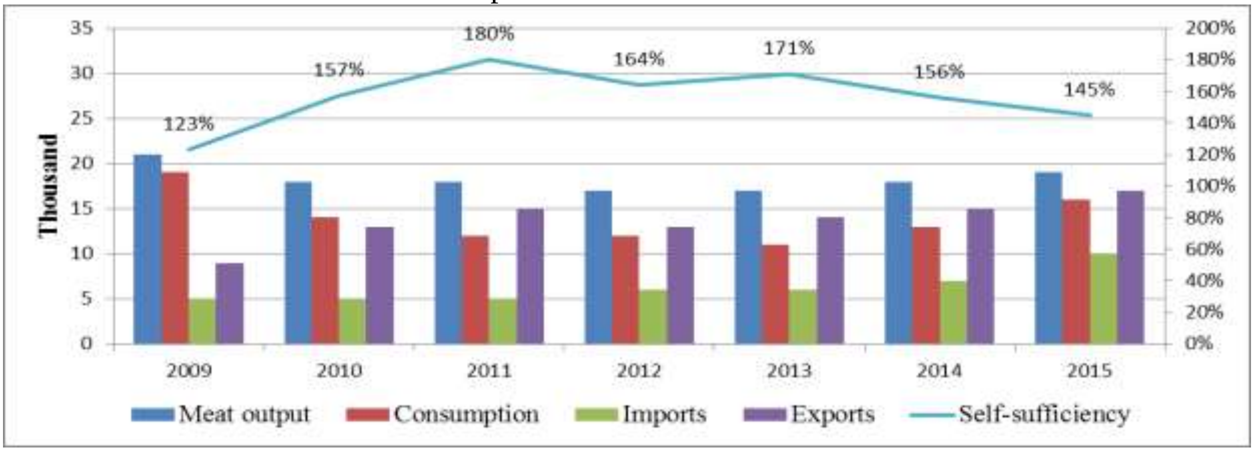
**Source: authors' construction based on ADC data*

As shown in Figure 4, the number of beef cattle herds increased by 60.79% from the base year, which was fast growth. Such growth was fostered by quite low milk purchase prices and the limited milk sales market. A lot of dairy farms began engaging in beef cattle farming in parallel with dairy farming. On the one hand, such a trend could be viewed positively, as the beef cattle industry grew, while on the other hand beef cattle were not mainly raised and fattened to produce quality meat on such farms, as most of the farms sold calves in particular (weaned at the age of 6-8 months) for export. In Latvia, mostly four beef cattle breeds are widespread: Charolais, Limousine, Hereford and Angus, as well as Simmental and Highland become popular. In raising beef cattle, the following objectives are set: high live weight gains through feeding economical diets, quality carcases according the SEUROP classification, easy farrowing, high fertility rates, body structure typical of the breed and a calm temperament.

Prospects for the production and sales of beef cattle in Latvia

The prospects for the production and sales of beef cattle are mainly determined by domestic consumption, changes in beef purchase prices and export opportunities.

Fig. 3. Production and consumption balance of beef and its products in Latvia in the period 2009-2015



The production and consumption balance of beef and its products in Latvia shows that the output of beef in 2015 compared with 2014 increased by 6%, while beef consumption rose by 20%. A trend was observed – the imports of beef rose by 32%, while the exports of it increased by only 15%.

The beef purchase price factor contributes to the use of opportunities for beef export, yet the beef is imported because of growing domestic consumption. For example, the average price of a cow carcass in Latvia in January 2016 was EUR 1.67 per kg of meat, while in the EU it was EUR 2.72. However, the average price of veal in Latvia was EUR 1.90, compared with EUR 3.87 in the EU.

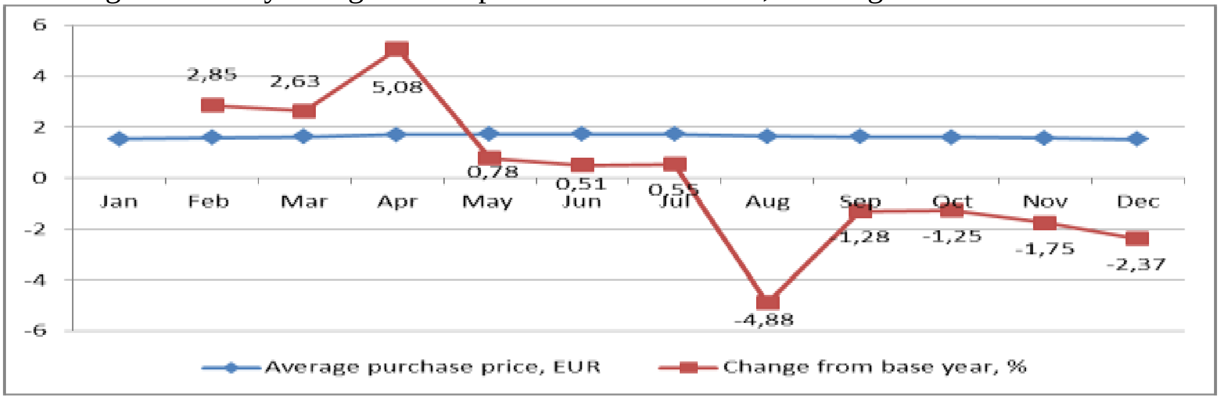
Fig. 6. Changes in the average purchase price of beef in the period 2011-2015

**Source: authors' construction based on CSB data*

Furthermore, a negative trend in beef purchase prices was observed in the period 2011-2015, as the prices decreased. Overall, such a trend did not contribute to the growth of the beef cattle industry but led to practising a certain management pattern. Namely, at present in Latvia, the most widespread management pattern observed on beef cattle farms is as follows: calves are weaned at 6-7 months and sold through an auction house or to an intermediary. The advantages of such a management pattern are as follows: 1) no need to feed the cattle for a long period; 2) no need to restructure the herd; 3) no need to buy follow-on feed; 5) cash flow is faster, compared with the production cycle involving cattle fattening.

Beef price fluctuations are observed every year; besides, there are seasonal price changes as well.

Fig. 7. Monthly changes in the price of beef in Latvia, EUR/kg



**Source: authors' construction based on CSB data*

As shown in Figure 7, a price increase is usually observed in the beginning of a year, reaching the highest level in spring, whereas a price decrease occurs at the end of summer. Overall, the average purchase price declined in 2016, which could be explained by the large number of slaughterhouses in the country. The slaughterhouses were not exploited at full capacity; therefore, there were interruptions and losses in production, which directly affected the cost of slaughtering and, consequently, there was no opportunity to offer a higher purchase price. Beef cattle purchase prices varied among some meat processing enterprises, yet the reason was the cattle quality standards set according to the EUROP classification, which was employed to calculate how much to pay farmers for the carcass weight of their cattle. However, no quality characteristics are specified when selling the beef at supermarkets as well as it is not specified whether the beef is from a heifer or a bull. This means that the strategy of a supermarket is a hindering factor for beef cattle farmers in making use of their advantages.

Conclusions

There was a quite steady situation in the output of beef in the EU Member States in global context, which served as a positive signal for beef cattle producers in Latvia.

The average per capita consumption of beef and veal in the EU Member States was equal to 10.76 kg/year, yet quite significant changes (-4.03%....+2.91%) were reported in the period 1997-2015.

In Latvia, dynamic changes were observed in beef cattle production, the key trends of which were as follows: with the number of beef cattle farms increasing insignificantly, the number of beef cattle and the number of beef cattle herds increased fast.

The output of beef in Latvia in 2015 compared with 2014 increased by 6%, while beef consumption rose by 20%. The trend was that the imports of beef increased by 32%, while the exports of it rose by only 15%.

A negative trend in beef purchase prices was observed in the period 2011-2015, as the prices decreased. Overall, such a trend did not contribute to the growth of the beef cattle industry but led to practising intermediary deals. Beef cattle purchase prices varied among some meat processing enterprises, yet the reason was the cattle quality standards set according to the EUROP classification, which was employed to calculate how much to pay farmers for the carcass weight of their cattle.

Abstract

Recently, especially big concern is that the consequences of the development of suburban areas are usually manifested by the reduction of productive agricultural land area. Agriculture in Lithuania is very important not only for enshrining agricultural traditions, but for the national economy as well. The tests involved suburban sub-districts bordering the three largest Lithuanian cities (Kaunas, Vilnius, Klaipeda). The study found that in suburban areas the influence of urban development on the use of agrarian land areas was manifested in the fact that they have been suffering from the decrease of agricultural lands, farms and the number of domestic animals more rapidly than in other areas. During the ten-year period in Vilnius, Kaunas and Klaipeda districts the area of the used agricultural land decreased by an average of 4.2 percent (throughout Lithuania it increased by 7.2 percent.), the number of farms producing crops decreased by 36.6 percent (in Lithuania – by 32.5 percent), the number of cows kept in farms decreased by 39.6 percent (in Lithuania – by 21.8 percent.). The average area of legally registered agricultural plot of land in Vilnius district is only 2 hectares, in Kaunas district – 2.2 ha, in Klaipeda district – 2.1 hectares. Such kind of fragmentation of the fields and agricultural land plots, the increasing concentration of the population as well as the rapid decrease of agricultural land areas with negative impact on agricultural development potential in these areas occurring due to the decline in urbanization and self-renaturalization of land, determine peculiarities of the use of agrarian landscape features. Therefore, according to the territorial planning documents, the layout of areas used for agricultural activities in these areas and farm land holdings prospective limits formation must be provided for intensive agricultural activities through creating opportunities for agricultural traders to specialize in horticulture, gardening, and livestock farming, combining land users' preferences and legal requirements for fertile agricultural land preservation.

Keywords: *land use, agricultural production, suburban areas, territorial planning.*

Introduction

In the process of global integration and with the ever-increasing population of cities, urbanized areas have been developing quite intensively lately. Europe is one of the most urbanized continents. About 75 percent of its population lives in cities. It is estimated that by the year 2020 this proportion will make up about 80 percent of the total population. According to the data of the European Environment Agency since 1950 urbanized areas increased by more than 78 percent (Urban sprowl ..., 2006). All this increases the demand for land for urban development within city limits and the surrounding territories. Urban development in Lithuania has its own characteristics. At the level of urbanization, Lithuania lags behind the countries of Western Europe. Only the regions of big cities, such as Vilnius, Kaunas and Klaipeda have reached the level of these countries (Vanagas, 2008). The suburbanization process is first and foremost the fastest in the largest cities, but it also affects smaller settlements located in the metropolitan area. Even before the 20th century, the cities of Europe and North America were surrounded by residential suburbs. In Lithuania, this phenomenon has become particularly evident in the last 10-20 years. In the context of such intensive urbanization, the problem of land use is becoming more acute. At the beginning of the 21st century, it was about 3.2 billion ha of land suitable for agriculture in the world. At present, almost all arable land is used – 1475.43 million ha, i.e. 0.24 ha per capita, but its area decreases by about 16 million ha annually. It is predicted that by 2025 the agricultural land will fall to 0.17 ha per capita, at 8.4 billion of earth's inhabitants. 25 years later, this volume would reach 0.13 ha per capita globally if 9.8 billion of people live in the world. In addition, from an ecological point of view, it is estimated that about 10-12% of land used now for agriculture should be eliminated from agricultural and forestry accounting and "returned to nature" for environmental purposes – for preserving biosphere self-regulation functions and biodiversity (Bučas, 2010). The Lithuanian general plan also foresees that the area of agrarian territories may decrease annually by an average of 0.7 percent per year. According to the data of state land registration in 2017, there were 3421.53 thousand ha of agricultural land in the territory of Lithuania, of which the largest part – 3052.91 thousand ha consisted of arable land. Compared to the previous year (2016), agricultural land fell by about 10.02 thousand ha per year, it is 0.29% of the total area. On average, in the last 15 years, agricultural land has decreased by almost 0.7 thousand ha according to their statistical accounting. This was influenced by the afforestation of infertile agricultural land areas, the process of self-transformation, when most of the meadows and pastures swallow due to inappropriate use, the overgrowth with shrubs or trees, and the development of indigenous urbanized areas. Meanwhile, the area of built-up areas grew in both cities and around them. For the target planning period (until 2020) the level of urbanization determined by the urban population in the total population of Lithuania is 72-75 percent (Lietuvos ..., 2002). According to the data of state land registry, during the last 15 years the area of the built-up areas in Lithuania has increased by more than 6,600 ha, i.e. about 5 percent. Although in the context of urbanization the territorial integrity, ecological stability of the countryside and biodiversity preservation are emphasized, however the importance of economic priorities is raised, which results in more uncoordinated intensive use of suburban areas. It is of great concern that the consequences of urban (suburban) development are often the reduction of productive agricultural land and, exceptionally, the destruction of forest areas. It is increasingly acknowledged that the boundary between the city and the countryside becomes difficult to describe, volatile, conditional. World urbanists, cultural landscape and environmental analysts (D. Lowenthal, A. M. Tung, O. L. Boon, J. Jacobs, A. Berger, etc.) argue that in the 21st century, the city became an antropoecosystem tumour of rural landscape, which is rapidly expanding into the natural and rural landscape environments with urban enclaves (Bučas, 2010). However, when viewed strategically, we must adhere to the notion that agriculture in Lithuania is very important not only for the cultivation of agricultural traditions, but for the economy of the country as well – even in suburban areas. Suburban territorial planning and development problems are relevant in all countries with large urban agglomerations, however, territorial planning methods applied in foreign countries are intended not for adaptation of non-agricultural territories to specialized farming, but for rational harmonization of the layout of urbanized areas and green spaces (Metods ..., 2001; Green ..., 2005). Meanwhile, the rational use of the Lithuanian Land Fund is associated with the formation of a cultural landscape, in which issues of conservation of suitable agricultural land are to be addressed through the development of territorial planning documents based on scientific recommendations and proper organization of their implementation. The purpose of this article is to analyse the use of the land of suburban territories of the major cities of Lithuania and the peculiarities of agricultural production in these territories.

Material and Methods

The methods of analysis, comparison, graphical modeling, generalization and logical abstraction of scientific literature, territorial planning and other documents related to the analyzed topic were used during the research. The management of agricultural areas and the changes they are undergoing are not only intended for the development of agriculture, they reflect the needs of different branches of industry. This is most pronounced in suburban areas of major cities, which are characterized by more intensive urbanization processes, population concentration, increasing land demand for industrial and warehousing enterprises, residential and recreational construction sites. Therefore, three major Lithuanian cities Vilnius, Kaunas and Klaipeda and their suburban territories, i.e. detailed analyzes of those sub-districts that have a common border with the respective metropolitan area. The main data for the study were obtained from the Lithuanian Department of Statistics and the National Land Service under the Ministry of Agriculture. For the performance of analytical surveys the layers of the KDB10LT sub-district and residential areas and subdivisions of the mapping database of the topographical map M 1:10 000 of the Republic of Lithuania, data from the general agricultural census, 2002-2017 State accounting data of the land were used. In order to determine the impact of urban development on agricultural production and land use, the features of agricultural production as well as land use and its changes (structure of land utilities) were analyzed in suburban areas. Based on theoretical and analytical researches and the analysis of the data obtained, the corresponding conclusions were formulated.

Results and Discussion

In analyzing land use and volume of agricultural production in suburban areas, land areas were divided into the following parts: 1) built-up land; 2) the areas of human activity started to be used for agricultural activities (conditionally called agricultural land, although in this area there are intruded other land utilities which contours have not been mapped on a small scale); 3) man's little redeveloped territories (the rest of the land, the majority of which is made up of forests, as well as swamps, shrubs, other natural or semi-natural land). Due to the impact of urban development, the structure of these components has changed, mainly by reducing agricultural land. Analyzing the data of land registration of the last 15 years, it is evident that the development of urbanized territories in Kaunas and Vilnius districts was at similar rates – almost by 657 and 729 ha, i.e. an average of 69 ha per year. Slower than 3 times the area of built-up areas has changed in Klaipeda district. The built-up areas here increased by about 222 ha, i.e. by 7.71%. However, considering the inaccuracies in accounting for land use changes, the actual area of the built-up areas may be even higher: for the most intensive urban development period in these cities and their suburbs an average of 715.5 hectares were transferred annually from agricultural land to the land used for other purposes.

On average, rural areas of Lithuania (excluding urban land) account for 53.8% of the total agricultural land, 46.0% in Vilnius district, 52.0% in Kaunas district, 55.8% in Klaipeda district. In suburban areas, these indicators are distributed in the following way: in the Vilnius suburban territories – 58.5 percent, Kaunas district – 62.5 percent, Klaipeda district – 71.7 percent. The percentage of built-up areas in Vilnius and Kaunas suburban areas is almost the same, respectively 11.3 and 11.2 percent, while in Klaipeda is slightly smaller – 8.2 percent. (Table 1). However, as can be seen from the data presented above, agricultural land areas, especially in suburban territories, decrease dramatically, mainly at the expense of the rise of built-up areas. Such trends are also very clearly reflected in the general plans of each of the analyzed areas, where the development of urbanized areas, especially larger suburban settlements, at the expense of agricultural land is very clearly visible. Due to the increasing use of land resources in suburban areas, land plots are shrinking and the area of agricultural land is decreasing.

Table 1. The structure of the agrarian landscape of suburban sub-districts of Vilnius, Kaunas and Klaipeda districts

Sub-districts of suburban district	Number of villages	Area, ha	Built-up territories		Agricultural land		Forests and other lands	
			ha	percent	ha	percent	ha	percent
Vilnius district	245	40011.7	4503.5	11.3	23422.7	58.5	12085.5	30.2
Kaunas district	192	60017.9	6705.8	11.2	37531.8	62.5	15780.2	26.3
Klaipeda district	146	46295.2	3800	8.2	33206	71,7	9289.1	20.1
Total in suburban sub-districts:	583	146324.8	15009.3	10.3	94160.6	64.4	37154.8	25.3

Note: the table does not include villages in which forests and other natural land utilities make up more than 70% of the total area

Thus, in suburban areas, the influence of urban development on the use of land for agrarian territories is manifested in the fact that there is a decrease in the area of agricultural land in them faster than in other areas. However, opportunities for the development of agricultural activities remain in suburban areas as well. Agricultural production indicators that can characterize the impact of a city on specialization of farms include the composition of agricultural plants and the number of domestic animals and poultry per unit area. The amount of livestock held in the farms of suburban sub-districts of Vilnius district per 100 hectares of agricultural land is, in some cases (poultry), considerably higher than in the remaining sub-districts, and the land is more intensively used for potato and vegetable production, and, in some cases, for cereals and industrial plants (Table 2).

Table 2. Comparative indicators of agricultural production (according to the data of the 2010 Census of Agriculture)

Sequence number	Indicators	Vilnius district		Kaunas district		Klaipeda district		Republic of Lithuania
		Suburban subdistricts	Remaining subdistricts	Suburban subdistricts	Remaining subdistricts	Suburban subdistricts	Remaining subdistricts	
1.	Agricultural land efficiency score	36.6	36.2	44.0	47.2	39.9	37.6	42.3
2.	Average farm size, ha	4.2	5.4	5.4	17.6	11.3	9.2	13.7
3.	Structure of agricultural lands and crops, percentage from agricultural land:							
3.1	orchards	1.1	1.0	1.1	0.6	0.4	0.3	0.7
3.2	cereal and industrial plants	28.7	24.2	48.6	69.3	42.9	23.0	49.3
3.3	potatoes and vegetables	6.2	4.5	2.3	1.2	2.6	1.5	1.5
3.4	other plants, perennial grasses, meadows and pastures	53.8	62.2	40.6	24.6	47.9	69.3	43.4
3.5	fallow land and unused land	10.2	8.1	7.4	4.3	6.2	5.9	5.1
4.	Number of livestock per 100 hectares of agricultural land:							
4.1	Cattle	21.5	19.9	27.6	27.6	21.8	31.4	26.9
4.2	Pigs	11.6	67.1	14.9	14.9	7.6	53.7	31.4
4.3	Poultry	21654	127.8	91.9	11.7	64.6	65.4	365.2
4.4	Sheep, goats, horses	17.5	12.5	3.1	3.5	4.0	4.1	4.0

This can be explained by the denser number of farmsteads and the agricultural production adapted to the needs of the urban population, where more potatoes, vegetables and fruits are grown in suburban territories. During the period between the years 2003 and 2010 according to the data of the Universal Agricultural Census, the area of agricultural land used in the districts of Vilnius, Kaunas and Klaipeda decreased by 4.2% on average (in Lithuania it increased by 7.2%). The number of farms growing crops decreased by 36.6% (in Lithuania – 32.5%), the number of farm cows decreased by 39.6% (in Lithuania – 21.8 percent). Due to the ongoing sale of private land or its use for urban construction and other non-agricultural activities in Kaunas district suburbs, fallow land and unused land make up as much as 7.4% of agricultural land (in the remaining sub-districts only 4.3%). In the suburban areas of Vilnius district, this indicator reaches 10.2 percent, while in Klaipeda district 6.2 percent. It needs to be noted that in the district of Vilnius, due to the higher concentration of rural population, farms are the smallest in comparison with other analyzed areas, agricultural land areas are smaller as well.

The largest difference in the size of a medium-sized farm between the suburban and the remaining sub-districts is observed in Kaunas district, i.e. in the suburban areas the average size of the farm is almost 3 times lower than in the remaining sub-districts. Meanwhile, the average area of legally registered land plot used for agricultural purposes in the district of Vilnius is only about 2 ha, in Kaunas district – 2.2 ha, in Klaipeda district – 2.1 ha.

According to the latest data, one person declaring land in Kaunas district used 13.7 ha of agricultural land, on average in Lithuania – 15 ha, and 11.1 ha and 6.1 ha in Klaipeda and Vilnius districts respectively. The largest amount of agricultural land is declared by farms up to 3 ha. The distribution of farm holdings according to the area of agricultural land declared by them is presented in Figure 1.

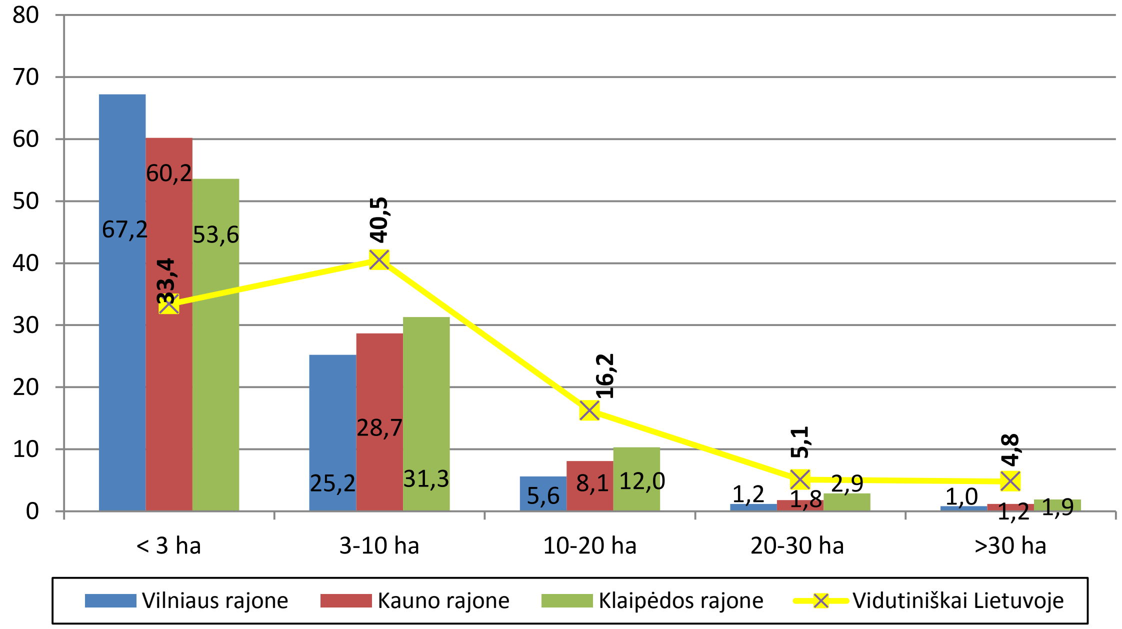

Fig. 1. The structure of farms registered in the Farmer's Farm Register according to the declared agricultural land area in 2011, in percentage

In Vilnius district In Kaunas district In Klaipeda district On average in Lithuania

Such fragmentation of fields and plots of other land utilities and a larger number of small farms determine not only peculiarities of the use of agrarian landscape but agricultural production ones as well: it enables the intensification of agricultural production, in the suburban areas specializing farms to grow the production necessary for the inhabitants of the city – fruit, berries, vegetables, milk , poultry and so on. However, in the absence of intensive land use, in the suburban areas, the rapid decrease in agricultural land area due to the use of the territory for the layout of structures, the afforestation and the renaturalization of self-propelled land on unused agricultural land limits the possibilities of agricultural development more than in the rest of the territories. Therefore, according to the territorial planning documents, the layout of areas used for agricultural activities in these territories and the formation of outlook for farm land holdings should be foreseen by combining the wishes of land users and the requirements established by legislation for the conservation of productive agricultural land areas.

Conclusions

In Lithuania, as in the whole world, the development of suburban areas is rather intensive, and these tendencies are especially characteristic to the metropolitan areas of large cities, where the influence of urban development on the use of agrarian territories is indicated by the fact that there is a faster decrease (in comparison with other locations) in the area of productive agricultural land, the number of farms in them and their average size as well as the number of animals most commonly held. According to the latest agricultural census data (2003-2010), the area of agricultural land used in Vilnius, Kaunas and Klaipeda districts decreased by 4.2% on average (the total increase in Lithuania was 7.2%), the number of farm crops decreased by 36.6% (in Lithuania – 32.5%), the number of farm cows decreased by 39.6% (in Lithuania – 21.8 percent). The average size of a farm in suburban areas in some cases (in Vilnius district) is even 3 times lower than the average in Lithuania (13.7 ha). According to the territorial planning documents, the layout of areas used for agricultural activities in the suburban territories and the formation of perspective outlets for agricultural holdings should be foreseen for intensive agricultural activity, allowing agricultural entities to specialize in horticulture, gardening and livestock farming, by harmonizing the requirements of land users and the legal requirements for the preservation of productive agricultural land areas.

MODEL OF REGIONAL DEVELOPMENT THROUGH RURAL AREAS AS RURAL ECONOMIC DEVELOPMENT POLES: CASE OF THE REPUBLIC OF MACEDONIA

Blagoj GORGIEVSKI [1]*, Marija GJOSHEVA KOVACHEVIKJ[2],

Abstract

During the regional economic development certain rural areas become attractive owing to concentration of economic activity through different channels of economy of scale, external economies and agglomeration of economic activities. Its has been formed like rural areas with certain formative economic development forces. Furthermore, their "spread effects" from growth poles cause induced growth in the remaining peripheral areas. These rural areas as a rural regional development poles are able to generate respectable economic impact in the geographical area becoming pole of the rural development in a certain rural region. In the Republic of Macedonia the model of regional economic development trough rural areas as a rural economic development poles need to have a major role in the formulation of a rural regional economic development policy, respecting the specificities of the regional development of small and underdeveloped economy.

Key words: *rural areas, rural development poles, regional development*.

Introduction

Perroux (1955) defined growth poles in terms of what he called *abstract economic space*. According to him "growth does not appear everywhere at the same time; it becomes manifest at points or poles of growth with variable intensity and spreads through different channels with variable terminal effects on the whole of the economy". Perroux and other writers on Growth Pole tried to base the concept on the notion of external economies, agglomeration and linkages. It was believed that beneficial "spread effects" from growth poles would eventually induce development in the remaining peripheral areas, and that they would have a significant relay function in the process of innovation diffusion through the urban hierarchy. Economic geography contends that proximity is essential in order to access spillovers, pecuniary and non- pecuniary, originating in the interaction between people, firms and institutions, through vertical and horizontal linkages. Furthermore, concentrated production also gives rise to external scale effects. Thus there would appear to be a clear link between growth and densely concentrated production. This has preciously been discussed in the theoretical literature (Fujita and Thisse, 2002; Perroux 1961; Kaldor 1961; Myrdal 1957; Hirschman 1958). The neoclassical regional growth model primarily focuses on the long-run potential growth path of the economies. Further to this is the 'Circular and Cumulative Growth Model' enunciated by Gunnar Myrdal. This model advocates a regional growth approach, which is sought to be "selfequilibrating". It is assumed that the expansion of a business or industry would create a multiplier effect, which would lead to more jobs and business as money flows through the economy. This growth would increase the likelihood of new inventions or innovations, thus creating another round of expansion. So, in the polycentric model articulated on the only urban poles, the dynamic principles of social, economic and territorial cohesion are imperfectly implemented whereas one of the initial characteristics common to the European States is to have rural areas with strong cultural and social expression, and inhabited everywhere. Without mobilizing the building capacities of rural territories, one misses a genuine social, economic and territorial engine for sustainable development. The right thing to do is thus to organize social, economic, territorial exchanges balanced between rural territories and urban poles. The recognition of the rural areas as development poles, and neither only as natural and agricultural spaces, is a precondition to stimulate advantageous and balanced exchanges between the urban and rural poles and to motivate the convergent mobilization of the urban and rural actors. The rural areas becoming development poles are able to meet, as partners, the great rural and societal questions, but according to programmed and prospective steps. They can in this context accommodate new populations and offer to them a real statute of inhabitant. They can offer new activities linked with the territory project and the local resources or integrated in the relationships with the rural poles of proximity and their own sector of development. In term of regional planning, this multipolar approach is also a response to the continuous extension of the rural centres; it allows, through land planning perspective shared between urban and rural poles, to preserve green and open spaces between high-density areas. The rural pole of development is an inhabited territory where the social, economic and residential evolutions are led within the framework of an integrated and prospective project of development. The rural pole is not a small town, an agglomeration, but a rural territory as a whole and guided by an integrated project of territory. The rural pole of development is an inhabited territory where the social, economic and residential evolutions are led within the framework of an integrated and prospective project of development. In the first stage of elaboration, were identified priority rural areas in consultation with various rural sector stakeholders. Initially, this study was prepared for priority sub-sectors in the rural regions (milk and dairy, meat and meat products, fruit and vegetables and wine and grapes) to identify the major potentials to be boosted.

Material and methods

The four sub-sectors and into its rural areas were selected based on their importance in the agricultural GDP and according to the process of adoption of the EU acquis according to the National Programme for Adoption of Acquis (NPAA) and institutions related (self-governments, regional agricultural departments, regional offices of the National Extension Agency, Farmers Federation and Non-governmental organisations). The programme was based on the National Development Plan (NDP), the National Strategy for Agriculture and Rural Development, as well as the Multi-annual Indicative Planning Document (MIPD), framework of available measures under Instrument for Pre-accession Assistance for Agriculture and Rural Development (IPARD) and the results of the independent sub-sector and rural areas analysis.

Results and Discussion

In the Republic of Macedonia., the concept of rural growth poles has usually emphasised geographic locations, which are called *Growth Rural Centres*. Altogether, the concept of Growth Poles has been of only marginal importance in analysing rural regional economic problems. Throughout the country the concept of Rural Growth poles has not had a major role in the formulation of a rural regional economic development policy.

Rural areas have tended to be forgotten in Macedonian development strategies in the past. However, their development must now become the main objective and this has also been linked to growth pole strategies.

For administrative purposes, the differentiation between rural and urban areas in the country is based on the local territorial divisions according to the Law on Territorial Organization of the Local Self-Government (official gazette OG - 55/2004, 12/2005) i.e. Article 6: The Definition of the Populated Areas (settlements) of the Territory of the country providing definitions of towns and villages as presented below:

- The towns are compactly built up residential areas with a population exceeding 3000, has a developed structure of various economic activities, above 51% of the employees are working in the secondary and tertiary sector, has an urban physiognomy of zones for residence, recreation and green area (parks), town square, street infrastructure, communal services and acts as a functional centre for the surrounding populated places.
- Villages are defined as mono-functional populated areas, in which one business activity is prevalent and whereas the area has agricultural physiognomy and function. According to the Law all Municipalities being with headquarters settled in villages.

The rural territory of the country includes all territory of the country, except towns, which have no rural territories or characteristics of villages pursuant to the Law on Territorial Organization of the Local Self-Government (OG 55/2004, 12/2005) and Determination of a Status of Populated Areas in Article 6.

Rural areas abound of high quality of natural environment (lakes, mountains, protected areas), attractions (landscapes, traditional villages, hunting, fishing, SPA resort, etc.) and of rich historical/cultural heritage for the development of rural, cultural, religious and agri tourism. Furthermore, availability of raw materials (timber, region-specific products, local traditional agricultural and livestock products) and so existence of traditional skills, crafts and food production.

The main opportunities in the rural development poles in the R. Macedonia are:

- geographic diversity of culture, customs, traditional events
- labour- force from decreasing agricultural sector is open for other rural activities, for which there are available natural resources
- growing demand for well-established tourist destination in the country is generating foreign visitors interest in rural tourism
- increased government concerns about rural/urban and regional disparities and the environment, and formulation of consistent policies
- possibilities for production and sale of high quality/typical/organic local rural produce
- creation of new entrepreneurs, family businesses and additional jobs in rural areas
- new important transit corridors will soon be completed.

The growth poles strategies, can be proposed and implemented in widely diverse ways in various settings, have a set of general characteristics among them and:

- Involve increasing the growth of employment and population within rural areas at particular locations or planned poles over some specified period.
- Require a limitation on the number of locations or centres which are designated as planned poles.
- Necessarily require spatial discrimination or selectivity among locations.
- Inevitably involve modifications of spatial structure of employment and population within a rural areas.

The common method, which will be applied for the purpose of implementing Rural policy programme can be defining rural areas as rural development poles being located outside of urban area and characterised by three main characteristics:

- settlements placed in municipalities based in rural centers (rural Municipalities);
- settlements placed in municipalities based in town centers with predominantly agricultural and forests land use systems (urban versus agriculture land (incl. forests, pastures, marshland, fishponds); and
- towns with population of less than 30,000 inhabitants with predominantly agricultural and forests land use systems (urban versus agriculture land (incl. forests, pastures, marshland, fishponds) and rural identity of the community.

Generally, rural areas have certain problems about attractiveness to businesses for several reasons: lack of concentration of population, poorer educational levels, lesser flexibility of the potential workforce, and distances from potential markets (for both inputs and outputs), all putting businesses in rural areas at a cost disadvantage. Poorly developed and diversified economic infrastructure and the consequent lack of quality jobs are common features of rural areas in the country. These are also the main causes of development lag typical of these areas which need to play a role like a rural development poles.

Conclusions

The above analysis has singled out a series of aspects, by no means comprehensive, to highlight issues arising from the rural areas as rural development poles. In the country the concept of Rural Growth poles has not had a major role in the formulation and implementation of a rural regional economic development policy Rural policy programme, can be defining rural areas as rural development poles being located outside of urban area.

Futhermore, to poin out the main opportunities in the rural development poles in the R. Macedonia. Rural areas abound of high quality of natural environment, attractions and of rich historical/cultural heritage for the development of rural, cultural, religious and agri- tourism.

The main opportunities in the rural development poles are geographic diversity of culture, customs, traditional events, growing demand for well-established tourist destination in the country is generating foreign visitors interest in rural tourism creation of new entrepreneurs, family businesses and additional jobs in rural areas and new important transit corridors will soon be completed. Generally, rural areas have a certain problems about attractivness to businesses for several reasons: lack of concentration of population, poorer educational levels, lesser flexibility of the potential workforce, and distances from potential markets (for both inputs and outputs), all putting businesses in rural areas at a cost disadvantage. Poorly developed and diversified economic infrastructure and the consequent lack of quality jobs are common features of rural areas in the country. These are also the main causes of development lag typical of these areas which need to play a role like a rural development poles. A growth pole strategy for Macedonian economic growth is what a country pursues unconsciously in practice. The eligible measures and areas of development support include implementation of the economic infrastructure projects and, also, implementation of non-economic infrastructure projects.

Abstract

The turbulent global environment and the current conditions in the economy are forcing agribusiness companies for a fast and flexible adaptation to the changes. A precondition for that is an effective system of management and application of appropriate leadership style. The management is a process of creating and maintaining a business environment where individuals work in teams to achieve the set goals. The leadership as a function of management involves the establishment of interpersonal relationships, leadership, employee motivation and communication. The purpose of this paper is to determine the capacity of managers as leaders of certain organizational levels in enterprises in the field of agricultural business. Considering the absence or presence of certain characteristics, it is estimated the extent to which managers express their leadership potential. To achieve the goal of the research, we applied the method of questionnaire survey conducted in ten medium-sized enterprises (from 50-250 employees) in the field of agribusiness in Republic of Macedonia, at a strategic, tactical and operational management level. The results from the conducted survey indicate that managers in agribusiness companies mostly expressed tendency to think like leaders and their behavior is close to modern knowledge for effective leadership. In the agricultural business sector in Republic of Macedonia predominates the known and stable management practice. It is a fact that the dynamic business environment of the food industry requires particularly high professionalism, innovation and ability to coordinate their leading personnel. Regarding the actuality of the topic of leadership and its importance for the business success of the company, this research provides an overview of the functions of management in some selected Macedonian enterprises in the area of agricultural business.

Key words: *Management, Leadership, Agribusiness, Business success.*

Introduction

Management has been studied for hundreds of years, and its beginnings date back thousands of years before our era. Despite the nature of the business revolution that caused management, it is still occupied with its fundamental problem - optimal use of resources in the organization in conditions of uncertain everyday life. Already in the last decades of the last century, and especially today, companies have become a mix of increasingly complex networks of relationships in which it is difficult to determine effective communication and create a favorable environment for employees, while at the same time achieving the desired business results. Management requires greater engagement of managers with respect to their time, knowledge and social skills, and precisely the high demands and their successful fulfillment represent the fundamental difference between the successful and the less successful managers.In this sense, modern theory leads to a systemic approach by which the

organization is seen as a whole consisting of related components and unforeseen (situational) approach, where each situation is unique because there is no single, perfect style of leading.
Leadership involves a set of qualities and managerial knowledge that have influence on the success of companies through segments of relationships between levels of management, business decision-making, communication, understanding of the goals and vision of the company and as a result - the product or service of the company. For this reason, the topic is multidimensional, and the paper is an approach from a theoretical, descriptive and empirical aspect of conducting survey questionnaires. Leadership (leading) is referred as the most important function of management, according that the success does not depend to any extent on any other function. When mentioning leadership, it is necessary to distinguish two basic relationships: leadership and leading, as well as management and leading. In the first case, leading is superior because leading with motivating employees and interpersonal relationships is part of its action. Leadership acts as a subset i.e. presents one of its functions. In that sense, theorists strive to distinguish the managerial characteristics from the leading that in some cases results in a (too) extensive division in which deliberately or not are specified the positive aspects of the characteristics of the leading. Experts are still divided about leadership, more precisely whether it is a process or ability. This approach strongly is connected with the question of whether leaders are born or created? Northaus (2007) removed the thinking that leading is not characterized by one person only and is not reserved for several defenses, but it is a transaction of events between leaders and followers in which each side contributes. In this sense it is a matter of two-way events because the leader has influence and is influenced by his followers (Northaus, 2010). Contrary to Northhaus's perceptions of leading as a process, the authors Robbins and Judge (2009) attach importance to the ability and the art, thereby emphasizing its less mysterious side. However, everyone is unanimous about one thing - the influence of the leader of a group of people in common would be focused on achieving the common vision and goals (Northaus 2010; Robbins and Judge, 2009). Agribusiness enterprises as a food sector are resistant to the effects of crises due to the profitable inelasticity of food costs in relation to non-food companies (Hadelan et al., 2012). Related to the success of the companies, the main subject of the research revolves around examining the characteristics of the managerial levels i.e. the assumptions in the Macedonian agribusinesses compared to the success, grows the ‘value’ of the managers in terms of their management, decision-making, horizontal and vertical relations with co-workers, i.e. - whether the quality of management is in line with the success of the company.
The subject of research is the managerial function of leading and its contribution to the success of the agribusiness organizations through exploring the theoretical foundations of management and leading and questioning the managers in the randomly selected agribusiness enterprises from Republic of Macedonia. Collecting data about their profile characteristics and actions given the hierarchical levels was done in order to further interpretation of the difference of the leader from the manager. The assumption is how the highest levels of management in percentages have characteristics of leaders because it is needed for their work, and middle and low level managers have more pronounced managerial qualities that are suitable for their day-to-day tasks. Finally, the search for leaders in agribusiness is a guide to this research.

Materials and methods

For the needs of the labor, the descriptive method was used as the basis for providing facts about the observed behavioral phenomena and striving to explain them by means of statistical analysis of the data.Furthermore, a survey method was used to collect data for the characteristics of the managers of Macedonian agribusinesses by means of questionnaires.

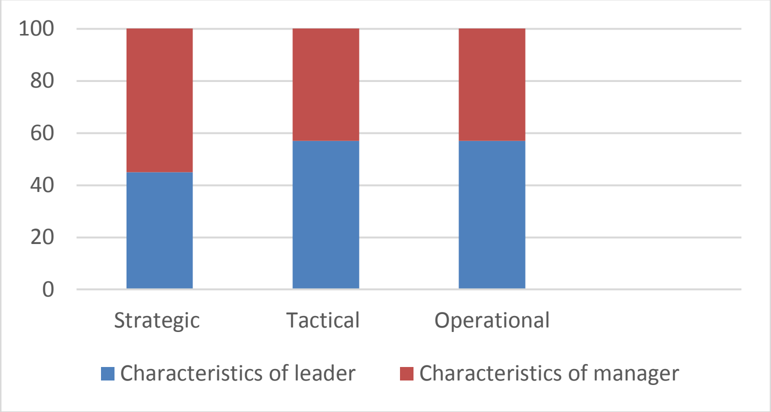
Compilation and comparison methods are used in terms of comparing the results of the researches with those of the existing literature.For the survey is applied questionnaire. In this research, the survey questionnaire acts as a verification method that will help to check the hypothesis based on the collected data and information. The survey procedure started with the selected voluntary sample, which is unique available in such surveys. The main activity of the examined enterprises covers the production of agro-food products. In 100% of cases, respondents probably for the efficiency and time savings have chosen the online service option which greatly facilitates the procedure itself.An online survey allows quick answering of the questions and an automatic reply to the sender. The selected sample consists of managers who are in the higher (strategic), middle (tactical) or low (operational) level of management. The survey has been implemented between March 15 and April 15, 2017. In the survey participated 5 agribusiness enterprises and two companies from the banking sector as a control group. The survey examined 11 agribusiness managers (n = 11).

Results and discussion

The main framework refers to a horizontal comparison of levels of management (strategic, tactical and operational), which seeks to determine and describe the manager's behavior depending on his hierarchy. Most of the agribusinesses in terms of legal form belong to joint stock companies, while to a lesser degree are companies with limited responsibility. In the agribusiness there are three levels of management (37%), although there are firms with two levels (31%) and with four levels (27%) are also known. In terms of professional training, all managers at the highest level have a high degree of preparation (100%), while at the secondary levels except high (50%) there are still higher professional training (25%) and master specialization (25%). At low levels, all surveyed managers also have a high degree of preparation (100%). According to the above, it is obvious that the representation of higher education in the workforce at the managerial levels in the Macedonian agribusinesses is evident. In the field of professions, leads the economic (high level 75%, intermediate and low level 100%), and specialist knowledge of agricultural sciences is highlighted only by one high-level manager. Male managers predominate at high (100%), secondary (75%) and low level (100%). The age structure indicates that the oldest managers (between the ages of 41-50) are the most represented in strategic positions while the tactical and operational ones are younger (between 31-40) years. The opinion of the managers on the importance of the function shows that the high and low levels of management as the most important evaluate cost control, and the middle function - the organization. The low level pleads with high scores for functions that are typical of their superiors - organizing (4.5), goals and strategy (4.5), while contrary to that developing and empowering employees at this level lags behind what was not expected. On the question of the nature of the relationship to management, all the examined levels consider that the skill is to a large extent, with which the characteristics of knowledge and the arts are suppressed in the background. Managers at high and low levels think that their own skills and the capabilities of their co-workers are most deserving of their success. The middle managers besides the stated, as a reason for success, also indicate the situation that surrounds them.According to the above, the success of the company arises the most from the ability of its management. In the surveyed enterprises, the line management system predominates (83%) in which employees receive orders from one senior manager. No presence of modern project or matrix forms of organizational structure has been noticed yet.
According to the answers of the respondents, the most important features of managers at all levels are: the ability to transfer knowledge, innovation and coordination of activities, decision-making speed and expertise. Higher general education and great managerial experience are considered as least important for managerial success.

Indication of one's own characteristics is neither simple nor precise, and it is massive to perceive the desired qualities as those already possessed. High levels of management are completely committed to work and are capable of motivating collaborators and deciding in different situations. Medium managers are considered as trustworthy people. Low managers perfectly understand their work and give freedom to collaborators in deciding. The groups of variables that determine whether managers have expressed characteristics of leaders in the research are set in the form of a choice between two offered assertions that describe the attitude of the respondent. Given the tested group of properties, the first group contains 6 questions, the other group contains 4 questions, the third group one question, and the fourth group contains 4 questions.

Figure 1 Comparison of characteristics of leaders and managers according to management levels (in %) – survey results



Source: Author’s research

Medium and low level managers show a greater inclination to thinking as leaders (57%) in terms of senior management (45%) (Figure 1). These results need to be seen from the aspect of the environment in which managers act - at strategic and tactical levels are the characteristics of managers and leaders, deployed with only a little overpower of one of them. The Great Hierarchy requires individuals who are both quality managers and dedicated leaders. The survey showed that in agribusinesses at the highest levels largely dominated the managerial way of thinking and at the other levels the respondents gave greater importance to leadership.One of the most difficult tasks of management is the decision-making, in particular the choice of the direction of taking action to solve the problems (Schermerhorn et al., 2002). Professional ability, responsibility, as well as objective information the best encourages good decision-making at all levels of management. Senior and middle managers carry not programmed decisions that are based on objective rationalities in a changing environment.

In contrast, low levels of management often decide on the basis of the estimation whose results are programmed decisions. The risk aversion is greatest in the low levels of management that can be brought about in terms of their position on the hierarchical scale which generally requires making less responsible decisions with short-term consequences in terms of decision-making at higher levels.The autocratic leadership style maximizes the authority and power of a person who makes decisions and for subordinates applies a system of rewards and punishments. In contrast, superiors who in the decision-making process include their subordinates and give great attention to the positive, interpersonal relationships using democratic style of leadership. Managers in Macedonian agribusinesses do not apply an autocratic management style. To a large extent, the democratic style is practiced (60%). Apart from the second style, there is also a style that is characterized between autocratic and democratic (40%). The stated styles are in line with the high and low levels (size 50:50), while the democratic style predominates at the middle levels (80%).

Table 2 Profile of agribusiness manager according to levels – survey results

Variables	Strategic level	Tactical level	Operational level
Leader's characteristics	45%	57%	57%
Democratic leadership style	50%	80%	50%
Non-programmed decisions	52%	51%	31%
Strong risk tendency	25%	60%	100%
Management as a skill	100%	100%	100%

Source: Author's research

In accordance with the hierarchy, senior managers spend an average of 35%, middle managers around 33% and low managers 25% more than the established working hours.
Intermediate managers spend most of their time communicating with their superiors, while high and low levels of management often address to collaborators inside the organizational unit. On the basis of the conducted research, a profile of the agribusiness manager has been constructed by levels (Table 2) which shows their main characteristics.

Conclusion

The assumption that at higher levels, managers in larger percentages have the qualities of leaders, and managers at medium and low levels expressed managerial attributes has not been verified. Managers in agribusiness, according to the average for all levels, express the qualities of leaders in 53% of cases. High levels of management in agribusiness enterprises express the attributes of leaders in 45% of cases. At medium and low levels, contrary to expectations, the characteristics of leaders predominate (57%). In agribusiness, the most democratic is the leading style (60%) and the style between autocratic and democratic (40%). According to the above, it is confirmed the assumption for agribusiness as a sector whose management operates in accordance with other economic activities. Managers at higher levels of management in agribusiness are male at the age of 41-50, have economic training, make un programmed decisions, are partially risk-prone, prefer democratic as well as a style between autocratic and democratic, and 45% of their characteristics describe them as leaders.
Medium sized agribusiness managers are generally male, aged 31-40, economists, often make un programmed decisions, they are risk-prone, and largely use a democratic style of leading and accomplish 57% of the characteristics of leaders. At low levels, predominate male managers with 31-40 years of age, from an economical profession, make programmed decisions, the most are prone to risk. They direct their leading to the democratic style as well as to the style between autocratic and democratic and express 57% of the characteristics of the leaders. The research of the characteristics of the examinee as well as the linking of their characteristics with the success of the enterprises points to the great potential of agribusiness management in Republic of Macedonia and serves for further direction of scientific researches. The central thinking that arises refers to the lack of strictly separated boundaries between managerial and leadership style, it is difficult to accurately define a person who completely reflects the characteristics exclusively of one of them, but that is not the final goal. In their combination and manifestation of a separate style, given certain factors from the immediate and wider environment depend the management success, and preconditions are the knowledge, skills and abilities of the leaders and the employees. In the modern dynamic and

uncertain environment, a sharp increase in the significance of the quality of interpersonal relationships is expected in every connection, and especially in business, which requires researches with which the attributes of managers and leadership styles will reach a recognizable and clear dimension just like the size of their impacts on the success of the operation.

Abstract

Sustainable rural development is important for the society, posing a challenge for rural households, in terms of ensuring continuous improvement of the quality of life and wellbeing for present and future generations. The equal participation of rural women and men is crucial for sustainable development but still remains a complex goal. The aim of this paper was to review the status of women in rural areas from the perspective of gender balance and to highlight the role of the equality in the activities related to sustainable rural development. The methods of descriptive statistics of data were used to process the official data for gender balance in the labour market. Additionally, a field interview for gender equality in decision-making and management was conducted on 140 rural households in Macedonia. The findings demonstrate that the employment rate of rural women amounted to 34%, what is lower than the employment rate of men in rural areas (66%). According to the structure of the status of employees in rural areas, women in the "unpaid family workers" category amounted to 8%, compared to women in urban areas amounting to only 1%. Additionally, the data from the field research show that rural women have very low levels of decision-making in the family and leadership of family businesses, especially in the rural areas with predominantly Muslim population. By identifying gender-differentiated opportunities and constraints, policy makers in Macedonia can develop gender-responsive actions that can lead to more effective measures for the overall improvement in natural resources management.

Key words: *Gender, Rural women, Sustainable rural development, Macedonia.*

Introduction

Sustainable development is a multidimensional principle which calls for integrating social, ecological and economic objectives at various geographical scales, and ensuring compliance with general system requirements, such as ecological and cultural integrity, economic stability, social equity, and economic efficiency (Hediger *et al.*, 1998). Sustainable rural development, as a crucial component for many societies, especially for the countries with predominant rural areas as it is Macedonia, poses a big challenge to ensure mitigation of the unsustainable trends regarding climate changes, energy usage, poverty and social exclusion, demographic pressure and aging, threats to public health, use of natural resources and loss of biodiversity.

Inspired by the common agricultural policy of the EU, the Republic of Macedonia reaffirmed its rural development policy in order to increase the competitiveness of family businesses and to improve the living conditions in rural areas. This is in particular important as rural areas cover 80% of the total territory of the country and 59% of the total population lives in predominantly rural regions (compared to 22,5% in the EU 27, according to the Eurostat). However, the indicators show that the country has modest improvements or even negative trends in some areas consider as significant for rural sustainable development. For those who live in rural areas, the problem of access to banking services face 36%, access to postal services 24% and access to cultural facilities 20%. Basic transportation services are not available or are difficult to access for 22% of the populations in rural areas. The need to improve the road network in rural areas is highlighted as a high priority, both in lowland villages (51%) and in the mountain villages (54%) (MAFWE, 2015). Furthermore, internal migration data show an increase from rural to urban migration. In 2015, the total number of migrants from rural to urban areas increased by 2.7% in comparison with the previous year. The number of migrants aged 15-29 decreased by 2.0%, while the number of working-age migrants (30-64) grew by 9.0%. Considerable share (13,4%) of rural population above age of 15 has insufficient or total lack of education, 2,6% are illiterate and 10,9% have not completed primary education. Illiteracy is higher among women (4,5%) than among men (1,3%) and it is particularly worrisome among the female adult population as there are more than three times as many adult illiterate women as there are illiterate men. The educational problem is obvious among the unemployed, since only 16% of them have higher or university education, the majority (55%) has secondary education, and the remaining 29% are unqualified (MAFWE, 2015). These facts designate that the development of the the socio-economic situation in the rural areas should be high priority for the country at all levels. Studies from FAO (2015) and World Bank group (2010) indicate that the women's empowerment is a pre-condition for achieving of the sustainable rural development goals, such as poverty, responsible consumption and production, migration, affordable and clean energy, clean water and sanitation and others. Consequently the rural women and men have different needs, priorities, and knowledge about diverse crops, plants, and animals what play important roles in resource management and genetic diversity. Women, therefore, play an important role in maintaining biodiversity, working against the decrease in biodiversity caused in part by men favouring cash-oriented monocultures (Lope-Alzina, 2007). Gender inequality in the rural society cause increased vulnerability of women with the inappropriate management of the natural resources, what are the main sources for living of the rural population. The aim of this paper is to provide an overview of the current situation of the rural women in Macedonia, and highlights the importance of the gender dimensions in the planning and implementation of the strategies for rural sustainability.

Material and Methods

The research is based on primary and secondary source of data. The target group are the rural households in Macedonia, which according to the Statistical data cover 59% of the total population. The survey refers to the 2015, encompassing data from 140 rural households from two different regions in Macedonia, Polog and Pelagonia. The questionnaires are composed of three sections. One section contained questions about households' characteristics (location, nationalities, gender structure of the families and family holders), the second focus on the source of incomes in the family and involvement of the rural woman in the family rural businesses, and the third asked about role of women in decision-making in the family in terms of children nutrition and task assignments, family businesses, spending of the family budget and selling of the family produced products and services.
Apart from field survey, the research use secondary source of data, mainly from official statistics. The methods of descriptive statistics of data were used to process the official data for sustainable indicators in the Republic of Macedonia, in order to get the general picture of the current situation, as well data for the gender balance in the labor market were provided by Labor force survey in 2016 and from the publication for women and men in Macedonia for 2016. In addition, research data for gender equity in education, land ownership, migration

agricultural production in Macedonia, conducted by concerned institution on this issue, such as FAO, World Bank group, Ministry of agriculture, forestry and water economy, UN women, CRPM (Centre for research and policy making in Macedonia), have been used.

Results and Discussion

According to the field survey, for most of the interviewed rural households (75% or 105 rural households) agriculture is the primary activity and the main source of income, followed by households with main incomes from own small businesses (crafts, rural tourism, processing of agricultural products) representing around 10% (14 households), 13% (18 households) live from salaries from employments at others and about 2 % from pensions.

The research revealed that out of the total surveyed rural households; there are only 9 women family holders (7%). The situation is worse in the Polog region with predominantly Muslim population (Albanians and Turks are around 65% of total interviewed households) with share of only 3% of women family holders compared to the Pelagonia region with share of 10% (Table 1). This indicates a low level of gender equality in terms of ownership, i.e. the holder of the rural economy, but the involvement of women in production, especially labor in harvesting as a family, is a highly prevalent and an average of 33% of the total family labor. In most cases, the woman is the owner of the rural family business as formality due to higher state support for rural women.

Table 1. Structure of family holder according to the gender and nationality

Nationalities/Regions	**Macedon.**	**Albanian.**	**Turks**	**Vlachs**	**Others**	**Total**	**Share**
Pelagonia	**54**	**10**	**2**	**3**	**1**	**70**	100%

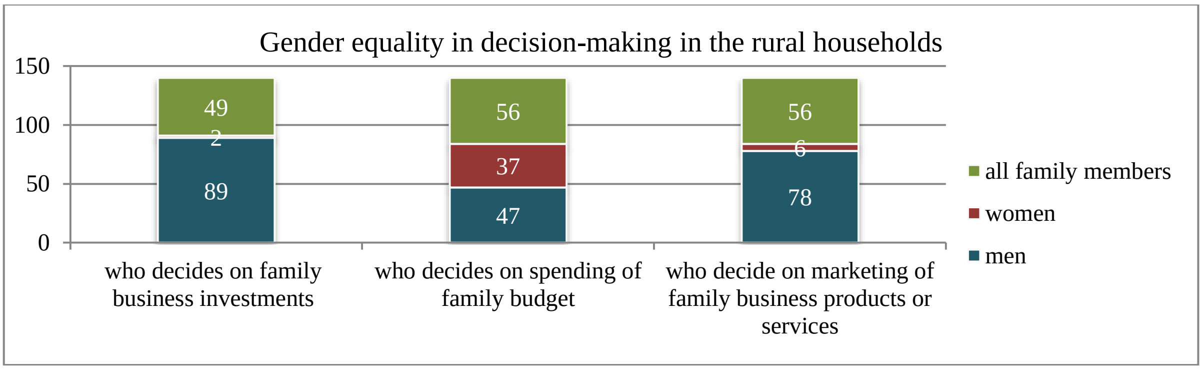
Sources: Own field survey, 2015

The most of the interviewed family members (72%) consider that the role of rural women have decision making power in assigning working tasks to the children and nutrition. In addition, the field research indicates that the main decision making power in Macedonian rural families lies with males who make almost all decisions concerning family business investments (less than 1% of the rural women population has role in taking decision for family business occupation). About 26% (37 women) of the rural women take decisions on spending of the family budget and only 4% (6 women) on marketing of the family business products or services. However, the rural women are involved in the groups where the decisions are taken by all family members, with a share of approximately 40% or 56 responds to this group.



Graph 1: Gender equality in decision making in rural households
Sources: Own field survey, 2015

The labour market in Macedonia is characterized by a gender imbalance in favour of males in both, rural and urban areas. In 2016, the employment rate for women in urban areas (43%) is lower than the employment rate for men (57%), but this ratio is much higher in rural areas, where employment rate for women is 34% compared to 66% of employment rate for men (Table 2). In addition, the gender gap between unpaid rural male workforce and unpaid rural female workforce sees disparity in favour of women, accounting 5% and 8% respectively, while the share of unpaid women labor in urban areas is even less than 1%. Only 4% of rural women are registered as self-employed mainly because in less than 6% of rural households, women own farmland or a house (CRPM, 2012). On contrary, 16% of the total male labour force in rural areas is self-employed, what are the mostly agricultural workers. The share of businesses run by women is very low in rural (1%) and in urban (2%) areas as well, with little advantage in urban areas.

*Source: State Statistical Office, 2016.

Women's participation in agriculture in the country is also characterized by lack of land ownership, little input into agricultural decision making, and lack of control over their time and labour (FAO, 2015). Women in rural areas tend to have primary education only, while in the urban areas, they tend to complete secondary levels at least. According to the survey of rural women by UN Women, in the majority of households women and men together make the important decisions concerning children (CRPM, 2012). Access to new technology, information, and training related to natural resource management remains highly gendered, with most of the related initiatives targeted to men (World Bank group, 2010). It is known that communities are better off during natural disasters when women play a leadership role in early warning systems and reconstruction. Other studies have found that women tend to share information related to community well-being, choose less polluting energy sources and adapt more easily to environmental changes when their family's survival is at stake (International Union for Conservation of Nature and Natural Resources, 2007; Women's Environment and Development Organization, 2007). Despite numerous efforts to mainstream gender, many governments, nongovernmental organizations (NGOs), and development agencies find these efforts particularly difficult in the agriculture and natural resource arenas. For example, extension personnel in agriculture and natural resources frequently speak only to men, often erroneously expecting that the men will convey information to their wives. Until gender is successfully mainstreamed, women's groups, organizations, and networks can increase women's access to knowledge, information, and technologies (Enarson and Meyreles 2004). Women are still absent from the climate change and natural resource-related decision-making processes at all levels (World Bank group, 2010). Equal participation in community-based decision making remains a complex and difficult goal to achieve, especially in the contexts of highly unequal gender and class relations. At the local level, more natural resource projects and interventions emphasize community-level participation (World Bank group, 2010).

Conclusions

The sustainable rural development is a crucial for growing of the Macedonian economy take into consideration that rural area cover 80% of the total territory of the country and 59% of the total population. Data from the field research and official sources demonstrate that the population in rural areas in the country is significantly deprived in terms of population in urban areas in many respects. For example, the rural areas in Macedonia outside urban municipalities experience higher population decline; less access to public services; have less-educated labour force; experienced much higher unemployment rates and have lower incomes. Furthermore, the figures show that the Macedonian rural woman faces various challenges in terms of gender equality in many areas such as: daily activities and households, receiving of incomes (in most cases the rural women occurs as unpaid workers), access to education, participation in decision making at the households level and employment representation in the decision making at local and national levels. Women and men of varying ethnic groupings have varying levels of socio-economic status, political participation, and access to resources, all of which affect their ability to cope with and respond to sustainable development challenges. Various studies determine that women's role in families and communities, as well as their local knowledge in rural areas of environment, soils, water and production, are valuable resources for reduction and adaptation sustainable strategies—making them effective actors and agents of change. According to these finding, the gender equality is a prerequisite for sustainable rural development of the Republic of Macedonia, contributing to reducing of migration, unemployment and poverty. Sustainable development as a key principle for rural policy is a big challenge for all involved and concerned actors in the country. If women are more involved in decision-making, and if they had the required and needed access as men to productive and financial resources, income, education and services, agricultural yields would increase and the number of poor and hungry people would fall (FAO, 2015). Traditional agricultural support policies are increasingly ineffective in accomplishing rural sustainable development objectives. For this purpose, a comprehensive analysis is required to deal with the inter-linkages between the agro-food sector and the economic, societal and environmental systems of rural areas, and the national and international political and economic context with accent on gender sensitive procedures and mechanisms:

- Equal opportunities in employment and equal wages for rural men and women commensurate with the nature of work must be ensured.
- Community and institutional system for increasing of knowledge for natural resource management, climate changes, biodiversity and energy efficiency by ensuring of women participation should be set up.
- Women should be given rights over village common property land to access the resources for their livelihood, and benefit-sharing mechanisms should be developed for wider participation.
- Common property resources must meet daily household needs for fuel and fodder and provide livelihood options for women. Social fencing creates hardships for vulnerable groups. To circumvent the long gestation period for realizing the benefits, a buffer zone approach should be used to develop common property land.

In general, greater female participation in economic development poses an asset to a community's and country's ability to recover and sustain growth in times of change and stress. (Aguirre et al, 2012).

Abstract

Social struggles of agricultural marketing in the Philippines' rural communities remained understudied despite its viewable effect to the patterns of local rural development and agricultural systems. Given the complex and disorganized nature of the country's agricultural marketing, the smallest stakeholders playing in the grassroots—farmers and small village traders—were usually overlooked with regards to the problems they face, especially on pre-production, production, post-production and postharvest, transportation, and sales stages. Interviews among selected farmers and traders in the community of *Barangay* Bukal, Nagcarlan, Laguna, Philippines and key informants were conducted to elicit a narrative representative of the community's social panorama. Collectively, results show that issues on variable climatic conditions, overproduction, flexible market prices and price margins dictated by the middlemen and big traders, and land tenure surfaced as Bukal farmers' and traders' major struggles against economic good. Although the Local Government provided ample technical-political-cultural support to address these issues, the root cause of this struggle was not responded thoroughly due to the degree of willingness of farmers to reorganize their paths towards a more successful agricultural marketing activity.

Keywords: *Agricultural marketing, middlemen, Philippines, social struggles*

Introduction

Agricultural marketing is a "process which starts with a decision to produce a saleable farm commodity, and it involves all the aspects of market structure or system, both functional and institutional, based on technical and economic considerations, and includes pre- and post-harvest operations, assembling, grading, storage, transportation and distribution" (National Commission on Agriculture XII Report, 1976 as cited by Kiruthiga, Karthi, and Asha Daisy, 2015). As an agricultural activity, it is one of the aspects that plays an important and crucial role in rural development, as it is the "heart" of the economic growth process for developing countries who rely on farm production (FAO, Undated). Although, some parts of the Asian region suffer from social barriers from the following economic aspects of the agricultural system: entry to the market, massive asset polarization, debt relationships between large and small traders and farmers, diverse institutional and contractual arrangements, and collusive behavior, enforced in part by manipulation of the state regulatory system (Jones, 1996 as cited by Kindness and Gordon, 2001). Some of the most common problems in agricultural marketing existing in developing countries are related to product quality, market information, product quantity, functionaries' participation, lack of transportation facility, and inadequate storage facility (Kiruthiga, Karthi, and Asha Daisy, 2015). Intal and Ranit (2001) also stated price margins, monopoly power in agricultural distribution, and technology as other common issues in agricultural marketing. Delving to one if its problems, the ‘middlemen’ tend to take advantage poor consumers and small-scale farmers through monopolizing pricing systems in the market, as well as illegally lending money with expected high interest. High competition was also existing in wholesaling by mills to retailers as well as retailing to consumers (Ruttan, 1969; Mears, 1974, 1981, as cited by Hayami, Kikuchi, and Marciano, 1999). In postharvest, some barriers such as relatively minute exposure and access of farmers to postharvest facilities, cold storage, farm-to-market roads, trading posts and the likes, and lapses on extension services on crop production are experienced by farmers (Andales, 2000 as cited by Castro, Undated).

Report and Recommendations of the Congressional Commission on Agricultural Modernization of the Congress of the Philippines in 1997 (as cited by Intal and Ranit, 2001) exposed that as a system, Philippine marketing is complicated and disorganized. Supply chain of agricultural products from the producers to consumers are operational but constantly experiences constraints at various levels. Most consumers lack direct contact to producers, as contributed by intermediaries such as the middlemen. Problematic marketing constraints--inequitable trading margin, marketing infrastructure, taxes and the likes are associated as major factors affecting imbalances on costs of marketing. As a developing country, the Philippines is more likely to experience various issues and constraints meddling with its agricultural marketing processes, starting from the local level. One of the most interesting location to study regarding this matter is Brgy. Bukal, Nagcarlan, Laguna. At present, some Brgy. Bukal farmers who are also known as the ‘*mang-aangkat*’ are those individuals who transport their produce in bulk on a regular basis, linking themselves to traders who could manage and market these goods further. Bukal farmers are known to travel to sell their produce as far as the markets of San Pablo, Laguna, Tanauan, Batangas, and Antipolo, Rizal.

At least for the past decade, research about the area’s agricultural system focus mostly on agricultural production, agricultural extension and technology adoption schemes, and even developmental programs and policies that the local government are implementing, but lack emphasis on the social-ecological aspect. As the whole process of farming--from pre-production and post-production and its challenges, constraints from production, harvest to post-harvest have to be taken into account with emphasis on its social implications.

Materials and Methods

Respondents of the study include five (5) smallholder local farmers and farmer-traders of different agronomic and horticultural crops who also transport their produce independently or through a community trader to areas such as Tanauan, Batangas, San Pablo, Laguna, and Antipolo, Rizal. Farmers and traders that were interviewed are determined through purposive sampling. Nagcarlan Municipal Agriculturist, Barangay Chairman of Brgy. Bukal, Nagcarlan and Barangay Councilor for Agriculture were interviewed as Key Informants. Farmers’ and traders’ situation and specific marketing challenges when it comes to pre-production, production, post-production and post-harvest, transportation, sales, and contingency plans for unmarketed goods with respect to social, economic, technological, biophysical and policy-institutional factors were determined. The role of the Local Government Unit, the *barangay* and the Municipal Agriculturist Office (MAO) in addressing related issues will also be gathered. Farmers’ and key informants’ perceptions about the involvement of middlemen in the marketing process are included. Pre-formulated guide questions were utilized to elicit information and thematic analysis has been employed to synthesize perceptions and opinions.

Results and Discussion

Farmers and village traders has established a strong link when it comes to securing produce for trading. While smallholder and medium-to-large local farmers manufacture various cash crops in certain timeframes, village traders centralize farmers' harvest. At some cases, farmers also assume the role of traders, especially when they are logistically and financially capable. In an environmental perspective, Barangay Bukal is able to produce crops all year round. Farmers have areas where chayote, tomato, cabbage, cucumber, beans, and the likes are germinated: Mabuna and Silangan, among others. Tramlines are considered as a postharvest infrastructure as it helps hasten transport of produce from upland areas. This structure, which has been granted by the Philippines Department of Agriculture, has been functional and accessible at least for the past three years.

Minot and Hill (2007) pointed out that one of the policy options to establish connection among markets and farmers is the establishment of farm-to-market roads as it optimizes cost and lessen the duration of transporting the harvest to markets. In Barangay Bukal, this infrastructure allows them to transport at an easier rate. The most accessible farm-to-market road is the *Banago-San Francisco-Abo-Bukal* farm-to-market road which meets the Nagcarlan-Rizal road. Postharvest techniques farmers are using include simple processes for cooling, cleaning, drying, sorting and packing. Farmers situate their harvest accordingly in empty rice sacks, pack them, and take them to their homes or under their roofed garage through manual means (back carry) or through a horse--depending on the distance and volume of yield. Village traders collate species of produce by conducting farmer's house-to-house collections either on a daily basis (if the crop of interest is at its peak season), or when a farmer could provide some amounts of produce; or by allowing these farmers to go and transport their harvest directly to these village traders' areas. Then, sacks are dismantled by batch and cleaned through water washing. After washing, crops are transferred to a flattened plastic sheet (e.g. tarpaulin) for drying and let it stood until it's ready for packaging. When dried, crops are then packaged in polyethylene sheets according to class. Some farmers still consider putting the packs into another layer of sack for harvest' double protection. Farmers and village traders tend to skip the postharvest cooling process since the *barangay* is an upland area where temperature is relatively low.

Quality of harvest is directly proportional to its marketability. Interviews among farmers have validated that in fact, fruits and vegetables are designated with classes where the relatively most marketable falls under 'Class A' or *primera*, and those that are minutely damaged or relatively not aesthetically appealing would be downgraded to 'Class B' or *segunda*. Rejects or the worst-looking but could still be sold in very cheap prices falls under 'Class C' or *tricera*. Although farmers claimed that they make sure that all they have harvested have been pre-selected accordingly by its external appearance, they cannot avoid instances where some produce get scarred and damaged while transporting them from farms to trading areas. Instead of securing 100% assurance of the quality of Class A harvests, some were rejected and were resold the other day under the lower classes. According to some accounts, there were times when the agent or middleman returns some bulk of produce because those were not accepted by the standards set by stockists, wholesalers and retailers.

Supply chain begins with local farmers who produce fruits or vegetables. After harvest, all applicable postharvest techniques will be undergone and later be linked to prospect buyers. Following the chain, there will have two possible passages where the produce could be taken to, depending on the capabilities of the farmer: First, if the farmer also plays the role of the trader, he or she could go straight to his or her '*suki*' or buyer/ middleman/ agent where they could agree on the prices of goods right away and complete a transaction. Second, if the farmer lacks ways and means to transport the goods immediately--due to financial, logistical and other relevant concerns, he/she could coordinate with a local trader who may have or have not predetermined the prices before coming to the market. Local traders will later negotiate with those agents. The difference with the two options at this point is that the farmer-middlemen would offer market-updated prices for goods. Meanwhile, the former could just charge the farmer with an amount that could be lower or higher than the current price being followed, and so, could possibly mean a relatively lower revenue on the farmer's end, or lack of net income on the side of the village trader. From the middlemen, the goods could proceed to variable recipients like stockists (supermarkets who sell wet goods, etc.), wholesalers (wet and dry market dealers, etc.), factories needing raw materials and the likes. Unfortunately, further positions the supply chain were not traced beyond this point.

Farmers and farmer-traders subscribe to the '*suki*' system where they have pre-established connections among agents and middlemen, and consider some as their regular buyers. A day or a night before transporting the goods to the trading post, village traders are contacted by these agents and cast bulks of orders. Most of the time, the amount of produce traders carry was reserved and considered sold. Otherwise, they stay in the market for some couple of hours (or the whole morning) and make some price adjustments. Worst case, farmers will have to lower the price of their produce, either on or below breakeven just to convince prospect buyers to purchase theirs. It is better for them to have it sold than not at all. In effect, these farmers would suffer from the consequences of a low income. In some cases where goods are not sold, traders decide to re-sell them the next day depending on the price that is applicable (as price margins are very flexible), or depending on its freshness, marketability and aesthetic value.

Those crops that were not qualified from pre-selection or were unaccepted by buyers and intermediaries after reselling are either dumped back to the farms and spoiled (as organic fertilizers), or used as alternative feeds to their swine, cattle or horse, integrated with their roughage formulations (grasses) and leaf meals (*Gliricidia sepium)*. Also, there are cases when unsold goods are given for free among barangay residents and neighboring communities upon request. Unsold goods rarely happen, but given the situation, they really have no productive or money-generating backup plans aside from re-selling it over and over.

Farmers and traders consider a healthy competition among their ranks since according to them, they are not negatively affected by their co-existence. In fact, a culture or helping each other in selling the goods apply. While farmers and traders have secured their own '*suki*', in the macro scale, competition and its effects are interrelated. For example, in the market situation in Baguio and Divisoria, the prices introduced or agreed on by agents coming, and dealing from and within these areas would possibly be used as standard throughout the national market. Whenever sellers from these areas assign a certain price for a certain good with the intermediaries, the rest will have to follow in order for their produce to be sold.

Commodities, especially crops grown in the Philippines have variability when it comes to demand. Seasonally, there are specific cash crops that increase in demand because of various considerations and events (holidays, etc.). Farmers attempted to take advantage of these events and produce these goods in their own areas. Having this familiar mindset among themselves, the tendency is for them to produce in large amounts without considering that other farmers think likewise. In the locality, significant amount of produce turns into surplus, and surplus implies socio-economic problems related to overproduction, as well as farmers and village traders' revenues. In order to deal with this lapse, farmers and village traders' had to set lower prices for their crops and end up earning minute amounts.

Prices set per kilogram on each crop is very flexible and according to farmers, there is an external body that manipulates pricing on each. Before entering the market, they are really unsure of how much their goods cost. They cannot do anything about standardizing the ever-changing crop prices on the micro level, yet. The only resolution they could work on is innovating and integrating more ways where they could earn. For example, some farmers venture to cropping with different types of crops in a given season. At times where a demand for a certain crop increases, and there's a verge of oversupply and lowering of prices, at least they set some backup plan where losses and lapses in income would somehow be lessened. Also, they have been provided with options to develop products by which they could sell at a relatively higher price although, it is more costly than that of a raw produce. Say, banana chips, cassava chips, or the likes. These farmers, through agricultural extension, were also exposed to facilities like the tomato paste maker so they could somehow improvise and/or become skilled on this procedure, especially when the facility is made available in the barangay in the future. When all these means are already exhausted but the goal to earn deservingly is still out of reach, their last resort is to pray for a bountiful harvest and high pricing on the crops they produce the next time they engage in such agricultural marketing activities.

Middlemen, as a part of the supply chain, possess positive and negative characteristics in the perception of farmers and village traders. Without them, selling goods would be difficult for farmers. These intermediaries, for one, are those who buys in bulk because they have a larger market to respond to (wholesalers, retailers). These people coordinate to the farmers and smaller village traders and cast orders a day before. But then, in a different perspective, even though they appear to be 'sure buyers', they tend to manipulate selling prices and farmers are somehow restricted to cover for their computed expenses.

Among the interviews, most of them are fully aware of this discrepancy. Although, as a social phenomenon, some see it as a normal occurrence and just take into account the positive effects of having middlemen while considering less about its repercussions. In contrast, some see it as a type of oppression the government and the community should deal with accordingly. As of now, middlemen are tagged as a major intervention that elaborates the supply chain in Brgy. Bukal, and so, even though the local government and the people of the municipality continue to innovate and resort to more efficient means to improve their incomes, circumstances still make farmers resort to tolerance.

Frequent destructive rainfalls/typhoons during the rainy season and cases of *El Nino* mixed with precipitation when dry season is assumed as another concern Bukal farmers are facing. An old farmer respondent regards this phenomenon as a major threat to his farming activities, especially on the marketing of goods. Climatic constraints could hinder his productivity, because for one, instead of going out to the field and perform necessary agricultural activities, the farmer stays at home to secure his safety instead. Second, it could distract the growth and development of crops undergoing maturity. Such phenomena also decrease how much a farmer normally harvests, and eventually affects the expected income negatively. Although there were large scale and grassroots strategies to combat climatic constraints such as climate change adaptation and even the planting of *Gliricidia* trees throughout the barangay implemented, some farmers still lack involvement to help, and enough consciousness to appreciate these initiatives.

With all the advisory services, seminars, trainings, information drive, field trips, referral to marketing outlets and other forms of promoting local produce from the Local Government through the MAO, as well the barangay council that have delivered to the local farmers, some concerns are left unaddressed. The MAO may have claimed that they have done all the possible ways to heighten farmers' interest in various marketing approaches or to develop various products from the locality, but stakeholders at the grassroots could not easily respond to these options without being completely confident on their financial, social and cultural capital. They might have been exposed to solutions but they lack expertise and long-term guidance. At some point, farmers' common social mindset also remained unpolished or insufficient and they just settle to keeping up with these conditions. More so, farmers, thinking about loads of everyday struggles, could not see the relevance of those policy-institutional interventions because it does not directly solve what they think should be prioritized.

Conclusion

Production-wise, concerns farmers face are linked to climatic conditions where the dry season gets too dried with some hints of destructive rains on some days, and rainy season brings totally devastating super typhoons, among others. Some have observed such changes and unconsciously, they are starting to adapt strategies to combat these changes. But then, more farmers are not fully informative about it. It is high time to let the farmers know how this biophysical occurrence is actually threatening to their marketing activities in the long run so they could be advised accordingly and respond in a good light.

Overproduction in Bukal is a decade-age issue but accounts reveal that their mindset about responding to the demand hype at a certain point in time is very detrimental. For further research, combating overproduction and establishing a more efficient marketing strategy makes a very interesting angle to be understood and be shared more.

Problems on varying market prices and the involvement of middlemen has been the most highlighted issue farmers and traders have imparted. With all the unpredictability in the prices of vegetables in the market, small traders-big traders competition, subtle oppression by the middlemen in terms of harassment, too much lowering of price equivalence per kilogram of goods, late payments, returns and exchanges, and the likes, it is not a good move to stay silent about this discrepancy. Although the local government is proactive about delivering agricultural marketing services to farmers through extension and advisory services, exposure to innovations, training, outsourcing, and promotions, solving this middlemen fiasco as a root cause of inequality could somehow provide a different degree of freedom among farming societies. Government officials and concerned government units should act upon this irregularity because up to the present, farmers cannot get the best out of their hard work, and it is really unfair for their well-being.

Contributing and limiting factors influencing the marketing activities of Brgy. Bukal farmers and traders, is somehow similar with the issues and concerns they have encountered all throughout the process. With all the concerns surfaced, the nature of these factors is more of socio-economic, socio-political and biophysical. Understanding the social implications of the marketing system in the country should be given the limelight to improve the current knowledge base available locally. In order to track the similarities and patterns occurring among farmers and local traders' experiences in the market, such type of research must be expanded to neighboring municipalities of the area.

SOCIO-CULTURAL ROLE OF GREEN AREAS IN THE RURAL DEVELOPMENT

Agnieszka JASZCZAK

Department of Landscape Architecture, University of Warmia and Mazury in Olsztyn, Poland
*Corresponding author: agaj77@tlen.pl

Abstract

Contemporary village space is "multi-layered" and it consists of the forms, functions and historical structures and new elements, which are important in the creation of its future image. The research focuses on the analysis of the Polish countryside (Warmia and Mazury Region) in terms of the use of green areas in social and cultural development. During the study, the directions of villages development under the Rural Renewal Program in the context of improving the quality of inhabitants life and alternative forms of development were analyzed. The research was based on the goals of the village network and the results of existing spatial and social development initiatives. The examples of actions connected with protection and the landscape shaping as well as designing of green areas are also indicated. It is hypothesized that rural areas may compete for large urban structures as spaces for peace and health (so-called green therapy) in the future. The research, analysis and design tasks started in 2013 and they are still continuing. So far 6 from 80 villages participating in the rural renewal program since 2012 have acceded to the full research project and participated in planning process (Stare Siedlisko, Nowe Monastarzysko, Żytkiejmy, Wójtowo, Ruszajny, Kronowo). While additional studies, including a fragment of the village were taken in more than 20 villages.

Keywords: *rural renewal program, green areas, village space, design*

Introduction

Uneven social and economic development in rural areas, cities and suburban zones that require considerable investment is a problem that affects Poland as well as many other European countries. Various efforts have been initiated to address this issue and develop strategies for the harmonious development of regions in observance of their national and cultural identity, including the international project entitled "Hinterland potentials for a spatial development under the aspects of decline" (Jaszczak, 2009)while the answer to problems of space transformation, economic development or identification of the rural community are activities concentrated on the Rural Renewal Program in Europe. According to Damyanovic and Reinwald (2014) changes in social structures and demographic problems are challenges for local governments and thus are seen as a central task for the future development of the municipalities and village renewal programme. Intensification of social capital through networking and participation of citizens in local development are important for the proper development of rural areas (Husak, 2012, Falk and Kilpatrick, 2000).

The reconstruction, restoration, revitalization and creation of community-friendly spaces are important goals of the movement's social and spatial development strategies. Programs and projects are initiated by the local authorities, institutions and associations as well as members of the local communities who actively participate in the process of shaping the village's image to acquire a sense of belonging and shared responsibility for their surroundings. The anticipated results can be achieved only through a community-driven approach (Jaszczak

2015). Villages and surrounding rural areas offer an alternative path of development and can set an example for other towns and areas on the regional and national scale. This paper discusses the goals of the Rural Renewal Program and the outcomes of social and spatial development projects initiated by the network. Examples of regional projects aiming to improve the local quality of life, protect and shape the local landscape are presented. This paper explores the hypothesis that green spaces play a significant role in the inhabitants' integration and are a cultural value which builds a "village image". They also help to preserve the traditional character of a village and affect the health of residents and tourists using agritourism offers.

Material and Methods

The research and the choice of the area stem from actions implemented under the project "Renewal of Village" in the Warmia and Mazury region. It was a tree-step procedure to pursue aims. In the first step, it was important to assess the rural renewal program using a compound of different sources including contemporary resources, national and regional documents. Information on rural renewal have been captured in a wide range of sources containing archives, primary and secondary literature. In the second step, distinctive rural areas of both social and cultural importance (including green areas) were identified by means of an analytical survey conducted to understand individual preferences of the area. A number of direct interviews primarily with the staff of the Marshal's Office in Olsztyn (Poland), local leaders, as well as persons responsible for the implementation of the village renewal program in Warmian-Masurian Voivodship were conducted. The meetings with inhabitants were particularly important. They helped to determine preferences for planning of common areas and those ones with cultural importance in the countryside. Additionally, the author has completed a number of training courses in the field of landscape analysis and planning of green areas for particular groups of recipients.In the third stage, analytical and inventory work was started, which resulted in the project's completion. Students of the University of Warmia and Mazury in Olsztyn were invited to this stage. It was also very important that inhabitants were attended at every stage of design works. After identifying the places requiring revitalization or new planning in the villages, the design process was started. The research, analysis and design tasks started in 2013 and they are still continuing. So far 6 out of 80 villages participating in the rural renewal program since 2012 have acceded to the full research project and participated in the planning process (Stare Siedlisko, Nowe Monastarzysko, Żytkiejmy, Wójtowo, Ruszajny, Kronowo). On top of that, additional studies focusing on fragments of villages were taken in more than 20 villages.

Results and Discussion

The main goals of the renewal program in the region of Warmia i Mazury (Poland)

Village renewal is a direction of development of rural areas, combining respect for tradition with the need to search for an appropriate place for the village in a changing world. It is a process and constant adaptation to social and economic, internal and external changes, which leads to the overall shaping of the living conditions of the rural population. The concept of village renewal comes from German *Dorferneuerung* because the village renewal movement began in Germany in the sixties of the last century. Then Austria, Luxembourg, Hungary, Romania, Slovenia, the Czech Republic, Slovakia and Poland joined the movement. In Poland, the program of the village renewal occurred in 1997, as a formal movement, covering the region of south-western Poland. The first region that started it was Opole province. Historical background of this movement was the work of many social activists, scientists and entrepreneurs who contribute to improving the lives of rural residents and to preserving their identity (Idziak and Wilczynski, 2013). Implementation of the Programme of Warmia and Mazury was started in 2011 by the development of the General Basic Principles. The main objective of the initiative is to increase the activity and the integration of rural communities and the involvement of citizens in their efforts to [create/govern] village councils, as well as to improve the living conditions of the rural population. This is a valuable support for the residents' activity and practical implementation of the village renewal plans . Additionally, within the framework of the competition "Active village of Warmia, Mazury and Powiśle", Warmia and Mazury voivodships allocate funds from their budgets for the implementation of small investments. Small projects include the construction of playgrounds, bridges, development of beaches or cents, construction of arbors and outdoor gyms. It is important to ensure the proper management of green areas in the countryside. Therefore, the Marshal Office has partnered with the Department of Landscape Architecture since 2013. The cooperation encompasses the planning of green areas in the countryside. Additionaly, the author conducted the training workshops for rural inhabitants concerning: landscape planning, selection of plants, creation of aesthetics places during the yearly conference "Rural Renewal" which took place in Galiny 2013, Ryn 2015, Mrągowo 2016. She also provides the expert assistance with respect to the planning of green areas in the countryside.

Socio-cultural role of green areas in villages

In the era of intensification of urbanization and industrialization processes as well as demographic problems, it is the man who needs a "green space" for rest, relaxation or healing (Nilsson et al. 2011). Interdisciplinary research confirms the special role of greenery in therapy (Kaplan 2001, Mitchell and Popham 2008, Björk et al. 2008, Shukor et al. 2012) and social integration. Green therapy is increasingly included in the development programs of regions with high natural and cultural potential and widely used in health resorts and tourist resorts in rural areas. Green therapy is also utilized by small towns and villages where green tourism is developing, wherein the green areas are used not only by tourists, but also by the locals. The development of public places in the countryside affects social integration. It should be added that green areas are often part of the cultural landscape (historical green areas - historical parks, gardens, greenery near sacred objects, gardens in rural farms, roadside alleys). For this reason, green space plays an equal role with architecture in preserving the cultural potential of the countryside. In recent years a positive reverse trend has been noticed with regard to the design of green areas in country style. This is reflected in the return to nature, the use of traditional forms, rural plants and materials. In the program of village renewal, the greatest importance is attached to giving new image, aesthetisation of space and identification of villages. There are several examples of the creation of a "village image" through the green conception (tab.1.).

Table 1. Program of creation the common areas (including greenery) in selected villages

Proposal	Examples	Main goals
Aesthetisation of the village	Conscious planning of green areas with expert cooperation	Improving the quality of rural space Improving the aesthetics of common places to residents Improving the cleanliness and order of areas
Spatial identification	Compositional and material linkage of green areas	Conferring a common system of green planning Defining one style and template Homogenous composition for places with different functions

		Introduction of the marking system
Thematic identification	Identifying the leading theme of village (especially in thematic villages)	Use of forms and materials related to the village’s topic
Planning of the village entries	Arrangement of the entrance zones (so called "gates to the village" and "introduction zones")	Selection of forms and inscriptions on boards which are similar to the identification system and the theme of a village Use of ornamental plants to highlight the entry zones
Village center planning	Preparation of common places for residents being "the showcase of a village"	Planning of places such as central village squares, markets, squares, creating spaces

*Source: Author’s elaboration

The author is the initiator of the program "Creation of the new image of a village" in which students with inhabitants work on the design of the green areas, gardens and a small architecture in selected villages. They also provide ideas for the village marking system (welcome boards, thematic signs, information boards, details). So far, a number of projects of squares, lawns, beaches, greenery near educational, sport and social objects, greenery near sacred sites in selected villages were submitted. Among the most commonly designed green areas in villages are:

- Parks, squares, green areas (including historical monuments)
- Greenery near recreational and tourist facilities
- Greenery near educational facilities
- Greenery at sacred sites
- Green roadside, squares, roundabouts, green at the crossroads
- Greenery at sports facilities
- Farm greenery, home gardens (tab.2)

Table 2. Examples of the designed green areas in selected villages

Village	Year	Examples of the designed areas	Project stage
Nowe Monasterzysko	2015	Project of an area near a community room Restoration of cemetery Project of parking for bicycles on the bike path Project of sport facilities Projects of individual gardens Project of visual identification	ready for realization Work in progress Ready for realization Ready for realization Work in Progress Work in Progress
Stare Siedlisko	2015	Project of a BBQ area Project of a village’s square near a church Project of an area for village festivals and events Projects of individual gardens Project of visual identification	Completed Ready for realization Ready for realization Partly completed Completed for realization
Żytkiejmy	2015	Project of an educational garden near the Department of Landscape	Partly completed

		Park "Romnicka Forest" Project of an area for village festivals and events Projects of individual gardens Project of visual identification Project of a central square	Partly completed Partly completed Ready for realization Ready for realization
Wójtowo	2016	Project of greenery near children playground Project of sport facilities Project of an area near water ponds Project of a sacral area near a church Projects of individual gardens Project of visual identification	Ready for realization Ready for realization Ready for realization Ready for realization Partly completed Completed
Ruszajny	2017	Project of an area near a community room Project of a sacral area near a small chapel Project of a recreational area and technical equipment Project of an area near water ponds Projects of individual gardens Project of visual identification	Ready for realization Ready for realization In the project phase Ready for realization In the project phase Ready for realization
Kronowo	2017	Project of a recreational area with playground Project of an area near a community room (recreational path) Project of an area in the village centre (natural path) Projects of individual gardens Project of visual identification	Ready for realization Ready for realization In the project phase In the project phase Ready for realization

*Source: Author's elaboration

The given examples of projects of green areas have individual character. In the initial phase it was particularly important to identify the potential of the countryside, including architecture, architectural details and unique elements in the countryside. On this background, the characteristic features were defined. They were the basis for the creation of projects in the next stage. It had a great significance in the projects of visual identification of the village. Some of the projects are fully implemented, others are partially implemented or prepared for implementation (tab.2). Some of the projects from 2017 are in the deployment phase (in the project phase). However, in most cases the projects; execution ratio depends on the possibility of funding from the Rural Renewal program (so called small projects), regional competitions and regional, national and EU funds for rural areas. As previously noted, local leaders and villagers played a very important role in the green space planning . It should be underlined that only collaboration between the scientific center (in this case the University of Warmia and Mazury in Olsztyn), regional government (Marshal's Office in Olsztyn) and rural administrative unit can bring tangible results.

Conclusions

Rural renewal is a joint action aimed at improving of the quality of residents' lives, including all what the countryside is extremely valued for: landscape, architecture, historical and important places, sacred objects, technical objects. This is a trend of rural development assuming that the identity of the village and the values associated with rural life have a special role to play.

The Village Renewal Program also takes into account the development of cultural ecosystem services, which include recreational functions for both residents and tourists travelling in the region. It was arranged for them the space of the village, including the elements of sport, recreation and leisure. Therapeutic role of greenery increasing now; therefore, vegetation with special health significance has been included in the projects, as well as "sensory paths" were arranged. It is also important to use the planned spaces for educational purposes. Referring to the cultural ecosystem services it is important to remember about the natural and cultural heritage. Within the framework of co-operation with Marshal Office and local population there were prepared projects of development of sacred green areas with special attention to the symbolism of greenery. The village renewal is also a project resulting from the inhabitants' needs of the for, the development of common places, renovation and restoration of historical objects, historical, rural space, playgrounds, outdoor gyms, etc. In the Warmia and Mazury region Marshal Office plays a special role in the implementation of these tasks. It initiated the implementation of the Rural Renewal Program with a range of socio-cultural initiatives and activities that have influence on the improvement of rural areas planning, including green areas.

The paper presents briefly the essence of the Rural Renewal program in Poland and its objectives in the area of rural space management. The basic principles for the creation of common spaces in rural areas and the possibilities of their planning based on social participation were also defined. Presented examples of greenery projects in selected villages of the Warmia and Mazury region were developed together with inhabitants, with particular attention to their remarks. Ultimately, some of the projects have been completed so far, others are expected to be realized. Hopefully their implementation will be possible from the funds raised under rural support programs.

THE ROLE OF COOPERATIVE MOVEMENT IN DEVELOPMENT OF RURAL AREAS: A CASE STUDY OF POLAND

Maria ZUBA-CISZEWSKA

Institute of Economics and Management, The John Paul II Catholic University of Lublin, Poland
*Corresponding author: maria.zuba@kul.pl

Abstract

The cooperative movement evolves in contemporary economies through care for interests of its members and as a result of professing practical ideas (economic solidarity, collective resourcefulness, mutual cooperation). Cooperatives mainly serve local communities, since they often are their closest partner. Agriculture is one of the sectors of the Polish economy with the largest number of cooperatives (2629 in 2015 or 15% of all in the country). Cooperatives still play an important, though decreasing role in agriculture. There are several types of well-functioning rural cooperatives that support the development of agriculture and rural areas. There are the so-called cooperatives "Farmers Mutual Aid" (over 1100) engaged in retail and wholesale trade, food production. Agricultural production cooperatives (700 cooperatives), which are focused on plant and animal production. Cooperatives of Farmer's Circles (517) mainly provide services to farms and other entities in the countryside. Dairy cooperatives (140) hold 60% in purchasing and processing milk in the country. The development of agriculture and rural areas also supports a specific type of cooperative, ie. co-operative banks (559 in 2016). They have a dense network of outlets (4633 or 38% of the banking sector with 33,000 employees or 20% in the banking sector). Tradition of credit cooperatives in Polish lands in the field of financing rural and agriculture is over 140 years. Cooperative banks include in their operating activities capital needs of agriculture, finance structural transformations in this sector. Agricultural cooperatives in Poland face developmental challenges. The opportunities for growth is the revival of trust among farmers for this form of cooperation.

Keywords: C*ooperatives, Cooperatives movement, Rural development, Poland*

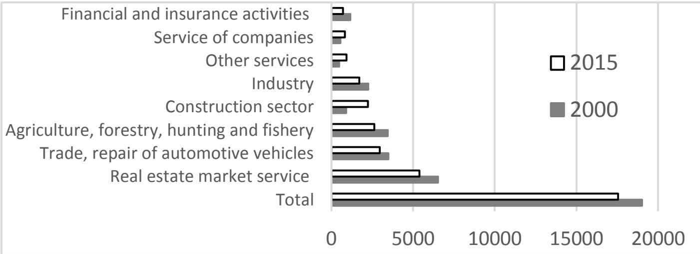
Introduction

A co-operative is an autonomous association of persons united voluntarily to meet their common economic, social, and cultural needs and aspirations through a jointly owned and democratically-controlled enterprise. Cooperative's values concern:
- ideological (democracy, equality, self-aid),
- ethical (fairness, integrity, thoughtfulness, faith in cooperative ideas),
- related to cooperative principles (voluntary participation, participation in management, autonomy, training and personal development for the good of a cooperative, and interaction).

The cooperative movement holds an important position in the global economy, cooperatives employ worldwide 250 million people, generated $ 2.2 trillion of revenues. There are over 2.6 million co-operatives in the world with about 1 billion members. Agricultural cooperatives are the largest group among all cooperatives in the world (26% in 2016) (ICA, 2017). The agriculture and food industries sector groups together all co-operatives that operate along the entire agricultural value chain, starting from the cultivation of agricultural products and livestock farming to the industrial processing of agricultural products and animals. Agricultural cooperatives are one specific typology of farms. They are unique enterprises that combine economic and social goals, rather than the pursuit of profit alone. This being the case, they can contribute to reducing poverty, improving food security and nutrition, as well as to promoting the sustainable use of natural resources.

In the last 15 years the number of cooperative initiatives in Poland dropped by almost 8% to 17.5 thousand entities. Farming is one of the branches that still has relatively large number of cooperatives, with 2600 active in 2015, which is still ¼ less than in 2000.

Figure 1. Number of cooperatives in Poland
Source: CSO



There were 430 active cooperatives in food and beverage industry (529 in 2010), that is the subsequent link in food manufacturing chain. The increase of number of cooperatives is mainly observed in services. Even when the value of GDP created by the cooperative sector in Poland increased by 22%, its total share in the economy fell down from 1.8 to 0.7%. The cooperative sector now employs 221 thousand people, half of the 2000 number. The aim of the work was to show the role of cooperatives in rural development on the example of Poland. The paper presents comparative analysis in time. The work uses statistical data published by Central Statistical Office (CSO), National Council of Cooperative (NCC) and literature on cooperives in Poland.

Result and Discussion

There are several traditional types of cooperatives supporting the development of rural areas. First of them is the Self-help Farmers Cooperatives (Pol. "Samopomoc Chłopska"), which is closely bound with village and rural society. Up to the market transformation of 1989 this cooperatives were well developed and had large economic base (tab. 1). Their main task was to provide inhabitants of rural areas with food and industry products, production aids and provision of purchasing centers for farm products. They were also active as manufacturers, processors and service providers. They promoted advances in farming.

Tab. 1. Scopes of activity of the self-help farmers cooperatives in Poland

Earlier period	Currently
- number of cooperatives rose from 1279 to 1912 between 1945 and 1988, number of members from 694 to 3532 (thousand) that is to 24% of the total rural population, employment figure was 468 thousand. - they were formed on the basis of farming cooperatives and small processing plants - their task was to provide rural population with food, industrial products, production means and purchase farm products - organize and leading manufacturing and processing activities (bakeries, butcher's works, sparkling water factories, small processing plants for fruits and vegetables), services for rural population (transport, construction and repairs, gastronomic) - their tools were retail outlets (71452 in 1988), retail centers for farming supplies (9311), farming produce purchasing centers (36067) production and service facilities (4988) gastronomic facilities (5500), technical bases for transport (777), training bases (399), social and cultural establishments (5374)	- 1193 cooperatives and 150 thousand members in 2013 - task is to provide the rural and small town population with basic food and industrial products and farming supplies - 10 thousand retail stores, 450 bases for sale of bulk farming supplies (e.g. coal, artificial fertilizer), 200 food and industry product wholesales, 100 gastronomic facilities, 600 production facilities (bakers, confectioneries, butcher's shops, water and beverage production facilities, fodder mixing plants and other food processing facilities) - introduction of HAACP system and Good Manufacturing (GMP) and Hygienic (HMP) Practices

Source: own work based on NCC; Brodziński, M., G., (2014). Aspects of rural cooperatives, FREL, Warszawa, p. 103-111, 178-192

After transformation to market economy system the central and regional cooperative associations were disbanded by an act of law, and support forms for cooperatives, their legal, economic counseling and training services, their cultural and social activities abolished. This cased a drop in the number of cooperatives, their members, employees, dissolution of social bonds between cooperatives and their members, employees and also contractors. Many cooperatives went bankrupt due to indebtedness incurred due to detrimental credit facilities and a tax system that was more severe than in the private sector. In the result of abolishment of the regional cooperative associations the basic cooperatives were left without logistic services and organization for purchase of farm product. They were unable to use their manufacturing potential and base, which made them loose the majority of their assets (through sale, rental or creditors entering the property). They were eliminated by private companies from the sector of purchase of farm products and slaughter animals. The scope of their remaining activity decreased significantly. Also the Farmer's Production Cooperatives (Pol. "Rolnicze Spółdzielnie Produkcyjne") did not cope with the consequences of economic reform (they were to be "3S" - self-governing, self-sustained, self-financing) (tab. 2). Even with the value of purchased farm products increased 3-fold in the last twenty years, their role in that process was diminished (from 26 to 17%). Their main activity is plant production (mainly grain crops) followed by animal farms and mixed production. The advantage farmers have in participating in cooperative is the increased scale of production, concentration and specialization and the contracting deals for farm produce with prices higher than in case of individual farmers. These entities also receive direct support from CAP funds for their production and activities conducted in detrimental farming conditions.

Tab. 2. Scopes of activity of the Farmer's Production Cooperatives in Poland

Earlier period	Currently
- created after WW II as element of state farming policy that assumed that this leads the path for transformation of individual farms in collective farming companies - between 1950 and 1988 the number of cooperatives rose from 635 to 2207, number of members from 25.3 to 190.4 thousand, and the area of arable land from 190 to 701 thousand hectares - the aim of their activity was to lead common farm and activities for individual farms (aiding them in field works by lending modern equipment, organization of purchase of materials for cooperative food processing plants)	- 694 cooperatives with a total of 40 thousand members and 235 thousand hectares of arable land - some 8 thousand people find seasonal employment in those cooperatives – member's relatives, several thousand farmers cooperate with production cooperatives on regular basis - large production cooperatives also create their own retail networks - additional services for individual farmers, transport, construction and repair services, agritourism

Source: own work based on NCC; Brodziński, M., G., (2014). Aspects of rural cooperatives, FREL, Warszawa, p. 139-145, 218-222

Also the next type of farming cooperatives that is the cooperatives of farmer's circles (Pol. "Spółdzielnie Kółek Rolniczych") suffered from systemic transformation.

Tab. 3. Scope of activity of the Cooperatives of Farmer's Circles in Poland

Earlier period	Currently
- farmer's circles are the oldest farmer's association (dating back to 19th century); prior to WW II they supported different forms of aid for their members and local communities, including education of farmers, introducing technical, technological and biological improvements in farms; They also organized mechanization and chemization services in individual farms - they were re-established in 1956. Their aim was to service the works	- 517 cooperatives - production services for farmers (mechanization of field work), production supplies, non-farming services (e.g. production of

connected with mechanization of farming and provide specialized rural transport. They were also active in manufacturing and processing sector. - In 1973 they were reformed in farmer's circles cooperatives. Their main roles was food production, mechanization, irrigation, use of meadows and pastures, produce seed material, increase the productivity of green pastures and production of fodder, improve fertilizer use. The number of these cooperatives rose from 1889 to 2006 between 1980 and 1988, with the number of members growing from 55.5 to 113.6 thousand and the employment figure dropping from 230 to 154 thousand.	construction materials, construction and repair services, construction of waterworks and sewage networks, construction & repairs of local roads, transport) sales (fuels, mineral fertilizers, plant protection agents, petrol stations) food processing (fodder factories, mills).

Source: own work based on NCC; Brodziński, M., G., (2014). Aspects of rural cooperatives, FREL, Warszawa, p. 150- 153, 234-241

The number of these institutions fell dramatically (tab 3). Currently only 1/3 of them offer traditional faming services, with the remaining ones acting in different fields. They use their service and production facilities to a small extent only, as majority of services in rural areas were taken over by private enterprises or went to the so called "gray zone" – that is aid by neighbors. Additionally the technical equipment of farms improves and there is no need for services of those cooperatives. At the same time these cooperatives still have to pay the costs of maintaining their technical facilities.

Dairy cooperatives have the biggest share in production services for farms. There are currently 147 cooperative dairy plants, employing over 20 thousand employees, with over 130 thousand milk suppliers as members-co-owners of dairy cooperatives. The dense national network of dairies has good material base. Most of the regions with large number of dairies are also characterized by high volumes of milk production and sales. This enables the national dairies to offer a broad range of products. Most of dairies offer full range of dairy products, including the basic and more differentiated dairies, including innovative products, e.g. for sportsmen, ecological or for lactose-intolerant. Many diaries also offer traditional and regional products, with appropriate certificates. The national dairy cooperative movement is characterized by its experience and long tradition of making dairy products, which wins them customers concentrated on local culture. First Polish diaries were founded at the end of 19th century, at rich mansion houses, as private initiatives or companies of landlords, but also as peasant's cooperatives. Immediately before Second World War there were already 1475 dairy cooperatives, with some 700 thousand members. Ever since their creation the objective of dairy cooperatives remains unchanged – to improve profitability of farm production and improve the market position of milk suppliers. Dairy cooperatives were also centers for civilizational improvement in local communities, with its educational activities, and in some periods acting as centers of movements for national liberation (KZSM, 2017). It were the dairy cooperatives that adopted best, among different branches, to functioning in conditions of market economy. This was accompanied by processes of consolidation, concentration and specialization of dairy cooperatives (Zuba-Ciszewska, 2015). Still, after the economic transformation the share of dairy cooperatives in purchase of cow milk fell down from 100% to now 65%. In the result of modernization the dairy cooperatives hold one of the most modern milk processing facilities in Europe, successfully competing in European and World markets, which is further proven by the growing value of Polish export of dairy products, and in particular after EU accession (from 618 to 1650 million Euro). Some of dairy cooperatives: SM "Mlekpol" in Grajewo, SM "Mlekovita" of Wysokie Mazowieckie or the OSM Łowicz took over from several to over ten other, smaller diary cooperatives each, thus improving their market position.

Gardening and apiarian cooperatives are one of the younger forms of cooperative farming organizations in Poland. They were first founded a hundred years ago. In their golden age they held a 2/3 share in purchase of fruit and vegetables, 1/3 share in retail sales and 40 and 50% share in national processing of frozen fruit and vegetables, respectively (tab. 4). In the new economic system these cooperatives were left without central management, organizational, economic and legal support, with 90% of the assets of the central transferred to the privatized company. That is why the scope of activity of those cooperatives shrunk to several percent. There are several cooperatives with brands that are recognized throughout Europe, but the vast majority slowly ceases their activities.

Tab. 4. Scope of activity of traditional gardening-apiarian cooperatives in Poland

Earlier period	Currently
- between 1945 and 1988 the number of cooperatives rose from 46 to 140, and the number of members from 6.5 to 371 thousand - number of permanent purchasing centers rose from 110 to 1113, of retail outlets from 40 to 6455, number of fruit & vegetable processing plants from 9 to 210 - these cooperatives were involved in gardening, beekeeping, purchase and processing of honey, vegetables and fruits, retail and wholesale of fresh produce, products and flowers	- 72 cooperatives - several cooperatives with good position in European market (e.g. APIS – manufactures meads, Grzybek Łosicki – mushrooms, Spółdzielnia Ogrodnicza w Grójcu – apples) - they include vegetable, fruit and flower producers, as well as producers of honey and derivatives - they keep purchasing centers for fruits and vegetables, fruit and vegetable stores, florists'; provide seed stores with gardening supplies, seeds, tools and plant protection agents - other activities, such as sale of planting stock (trees, shrubs) from qualified nurseries

Source: own work based on Brodziński, M., G., (2014). Aspects of rural cooperatives, FREL, Warszawa, p. 134-138, 244-252

The new (introduced in 2000) form of cooperatives in rural areas are producers' groups. They have limited administration, use the technical infrastructure of producers (warehouses, transport, packaging). Their aim is to jointly sell the products of farms of their members, concentrate the demand, improve the efficiency of farming, increase farmers' income by reducing costs (e.g. joint purchases of production supplies), plan and prepare large and homogenous batches of high quality products. The advantages the membership in such group bring to farmers also include joint investment (capital, credit facilities, machines, warehouses, cold storages, etc.), introduction of new technologies, distribution of risk on all group members and joint problem solving, use of consultancy services, exchange of information and expertise (KSOW, 2017). There were 524 producers' groups with some 8 thousand farmers in 2015 that were functioning in form of cooperatives, accounting for 31% of the total number of groups. (Brodziński, Leśniak, Bomba, 2015). Their intensive development is the result of financial support for this organizational form within the framework of the CAP. These cooperatives are involved in plant or animal production, including their specific types, such as fuel or technical plant production, production of seed and planting material or ecological production.

And the ecological farming in Poland is growing very dynamically. This is further confirmed by the growing retail sales of ecological food in the period from 2004 to 2015, from 25 to 165 million Euro, which is part of the worldwide trend (21 to 76 billion Euro in respective period). In the years 2004-2014 the share of ecological farms in the total number of farms in Poland increased 13-fold, up to 1.8% (some 25 thousand farms) and their area 8-fold to 3.5% (660 thousand hectares). The main stimulating factor for development of ecological farming in Poland, especially since 2004, are the subsidies to ecological production within the CAP. The development of farming, including ecological farming is further fostered by the fact that the majority of Poland is located in lowlands, and 60% of its area is occupied by arable land, that is directly used for farming or horticulture. Ecological farming can improve the issues of poor soil quality. By using crop rotation and proper fertilization strategies farmers improve the fertility of soil and crop yields. There are also large workforce resources in the national farming industry, which means large fragmentation of farms and large proportion of population living from farming, as well as the need for better allocation of the potential of workforce both outside farming and in the farming industry. That is why the introduction of ecological farming practices, that frequently require larger workloads than conventional farming, allows the improvement in use of workforce resources allocated to farming. Creation of cooperatives could help overcome the development barriers in this branch of farm production. The scattered, small and frequently changing character of ecological production causes problems of processing plants that are unable to acquire large batches of farm products with similar characteristics, that would allow them to broaden their sales to foreign markets. Farmers are poorly organized, and have problems in receiving thorough support services. There are no organizational structures (e.g. wholesales) that would actually integrate the links of the ecological production chain. There are obstacles (mainly legal) for direct sales, which does not foster building direct bonds of producers with consumers. That is why there is still place here for not only producers' but also processing cooperatives. Even with the number of ecological processing plants growing 11-fold in Poland – between 2004 and 2014 – from 55 to 484, they still account only for 3% of food and beverage manufacturing bodies (Zuba-Ciszewska, Zuba 2016). The development of agriculture and rural areas also supports a specific type of cooperative, ie. cooperative banks. Cooperative banks are more stable institutions than large commercial banks. They are focused mostly on ensuring access to basic bank products, in particular beneficial credits for the local community. Their local character results from legal regulations. As a result, they play crucial role in regional and local development, especially in the areas far from large cities where commercial banks often do not serve well. The offers of cooperative banks are well adjusted to the needs of farmers, micro, small and medium-sized enterprises (SMEs), due to knowledge of their operating conditions (Zuba, 2013). A long, several-century-long tradition of the development of banking cooperatives in Poland explains the large number of cooperative banks (559) and the dense network of outlets (4633 or 38% of the banking sector with 33,000 employees or 20% in the banking sector).

Conclusion

Cooperatives still play an important, though decreasing, role in agriculture in Poland. As the development encompasses a long period of time, the author presents in a long time the perpship of the review of the activities of different types of cooperative. As a result of market transformation, the role of cooperatives in the economy of Poland has decreased. Not all types of agricultural cooperatives coped with the need to adapt to fierce competition in the market (except dairy sector and financial). Agricultural cooperatives need farmers, their members, employees and contractors. The efficiency of cooperation, e.g. in raw material collection, prices of raw materials or products, the availability of services for farmers, is the basis for evaluation of functioning of cooperatives by farmers. Therefore, it appears that traditional cooperatives in rural areas that do not achieve satisfactory economic results should adapt their activities to the needs of the market by searching for new, maybe niche activity such as e.g. ecological production and processing cooperatives, cooperative groups of agricultural producers.

THE ANALYSIS OF THE PROJECTS IMPLEMENTED BY MEASURE 313, IN TIMIS COUNTY (WEST ROMANIA)

Adrian BĂNEȘ[1], Manuela-Dora ORBOI[2*], Tiberiu IANCU[2], Vasile GOȘA[1]

[1]Romanian Academy – Timişoara Branch, Timişoara, Romania
[2] Faculty of Agricultural Management, Banat's University of Agricultural Sciences and Veterinary Medicine "King Michael I[th]" from Timisoara, Timişoara, Romania

Abstract

Measure 313 "Encouragement of tourism activities" falls under Axis III - "Improving the quality of life in rural areas and diversifying the rural economy" and has as general objective the development of tourism activities in rural areas that contribute to increasing the number of jobs and alternative incomes, as well as increasing the attractiveness of rural space. The financial support of Measure 313 was allocated from the European Agricultural Fund for Regional Development. Eligible beneficiaries were: Micro-enterprises (private equity companies, including craft and consumer cooperatives that have set up activities related to rural tourism in the constitutive act); Individuals (not registered as economic agents) who, until the date of signing the grant agreement, will be authorized with a minimum status of authorized natural person; Communes through their legal representatives, as well as intercommunity development associations made only between the communes; NGOs. As a result of the analysis of the projects submitted on Measure 313 "Encouragement of tourism activities", on 30.06.2011, in Timis county the number of submitted projects was only 50 (226 in the whole 5 West region), of which only 18 (out of 113 from total region) financing contracts, so the absorption level being 0.02% of the total public expenditure allocated at country level. Thus Timis County was ranked second to last in the four counties that form the Region 5 West Romania. In addition to these data, the paper also presents the distribution of projects submitted and concluded on localities, value, domain (public or private), as well as demographic details of legal representatives of applications for funding (age, gender, training, etc.).

Keywords: *funds absorption, tourism activities, financing contracts, Timis County*

Introduction

Measure 313 "Encouraging tourism activities" falls under Axis III - "Improving the quality of life in rural areas and diversifying the rural economy" and has as a general objective the development of tourism activities in rural areas that contribute to increasing the number of jobs and alternative incomes, as well as increasing the attractiveness of rural space. The specific objectives of this measure refer to: creating and maintaining jobs through tourism, especially for young people and women; increasing the added value in tourism activities; creation, improvement and diversification of tourism infrastructure and services; increase the number of tourists and the duration of visits (***, PARDF Timiş report, 2011, ***, Applicant's Guide "Encouraging Tourism Activities" Measure 313, Ministry of Agriculture and Rural Development, Bucharest).

Operational objectives relate to: increasing and improving small-scale tourist reception facilities; development of tourism information and promotion systems; creating recreational facilities to ensure access to natural areas of tourist interest (Feher *et al.*, 2010).

The public contribution related to measure 313 was 388.280.074 Euro (9.540.000 Euro represents the financial allocation related to the SME Guarantee Scheme) of which the Romanian Government's contribution from the central state budget - 20%, the European Union contribution - 80%. The total cost, made up of the public contribution and private contribution, was 597.353.960 Euro (***, Annual Progress Report on the Implementation of the NRDP in Romania in 2011, 2011).
Eligible beneficiaries for support under Measure 313 "Encouragement of tourism activities" are: Micro-enterprises (private equity companies), Physical persons (not registered as economic agents), Communities through their legal representatives, NGOs.

Materials and methods

In order to see the number, value and scope of the projects, we used a qualitative study, namely interviews with the people in the leadership of the communes. The interview was applied for two areas: public and private. For both, public and private sectors were considered 14 municipalities, with 14 projects in the first case and 29 for the second case. The questions in the interview referred to the submitted projects (name, value) and to the legal representative (his / her position, age, sex and training). All the interviews took place in the mayor's office, lasted between 10 and 15 minutes and were applied in August-September 2011 period.

Results and discussion

In table 1, we present the situation of compliant submitted projects number and the eligible public declared value, number of contracts and total value of contracts (euro) and the total amount paid to the concluded contracts on the West Region of Romania – Measure 313, Caras-Severin County with 85 applications having the largest share.

Table 1.The status of the projects and the value of the contracts submitted and concluded in the West Region for Measure 313 "Encouragement of tourism activities"

Region / County	Compliant submissions		Contracts concluded		
	Number	Amount of non-reimbursable public aid (RON)	Number	Total public value of contracts - Euro	Total amount of payments - EURO
West Region	**226**	**164.008.862,59**	**113**	**20.598.793,0**	**515.555,20**

Source: Synoptic table, PARDF Timiş report, 31.06.2011

Out of the total of 226 projects submitted on the West Region, in Timis County were submitted only 50 applications, of which 18 were concluded, with a paid value of 3317193 Euro.
As a result of the analysis of the projects submitted on Measure 313, public domain, in the period 2010-2011, in Timis county, it was found that 14 applications for funding were submitted, all in rural areas, in Balint, Barna, Belinţ, Bethausen, Coşteiu, Criciova, Fârdea, Gavojdia, Nădrag, Pişchia, Satchinez, Sânandrei, Traian Vuia and Victor Vald Delamarina. The execution time was 12 months (7 applications), 15 months (1 project) and 36 months (6 projects), the title of the projects being (table 2):

- Tourist information center in Belinţ / Coşteiu / Criciova / Fârdea / Gavojdia / Satchinez / Traian Vuia (6 financing requests).

- Establishment of a local tourism information center and tourism promotion / Establishment of tourist information center and development of marketing services related to tourism / Establishment of local tourist information and marketing services related to rural tourism in Balint / Barna / Bethausen / Nădrag / Pişchia / Sânandrei / Victor Vlad Delamarina, Timiş County (7 applications for funding).

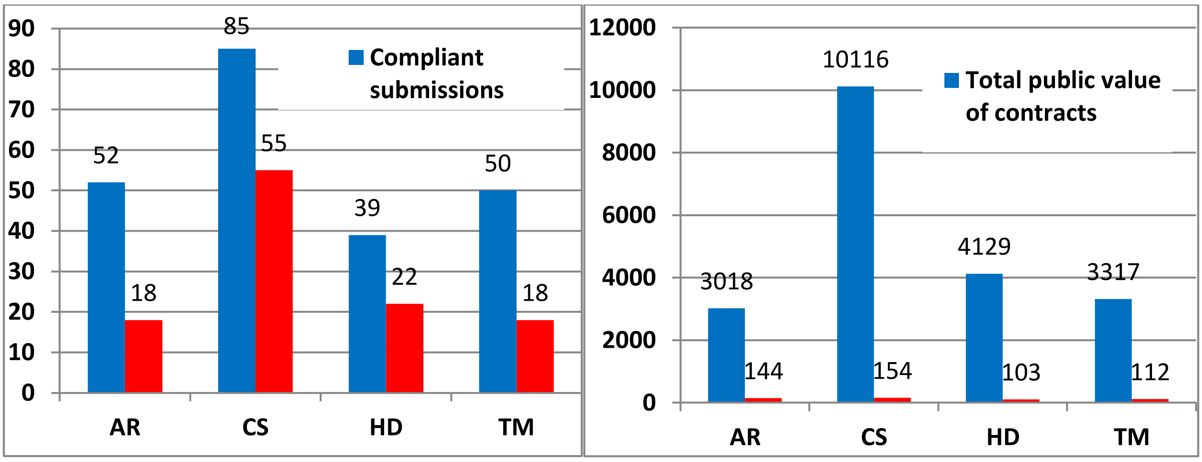

Figure 1. Number of projects submitted/number of contracts concluded and Public value of the concluded contracts/public value of the contracts paid for Measure 313 – mil. EUR

Source: Interview Guide applied on the field

The results show that the declared value in the application was in the range 210409 to 257451 Euros, and the value declared eligible in the application was in the range 167497 to 200000 Euros. In all cases, the legal representative of the funding applications was the mayor from the respective localities, aged 40-44 years (3 persons), predominantly 45-49 years (6 persons), 50-54 years (3 persons), 60-64 years (1 person), 65-69 years (1 person), all male. In the case of the studies, 12 persons gave a "Declaration that will follow a qualification course" until project finalization and implementation, 1 person has higher education and 1 person has medium education.
In the private sector, following the analysis of the projects submitted on Measure 313, in the period 2008-2011, Timis County, it was found that 29 requests for funding were submitted (***, NRDP – National Rural Development Programme, 8^{th} version, March 2012), all in rural areas, in Beregsău Mare (2 projects), Cenei, Chevereşu Mare, Coşteiu, Dumbrava, Fârdea (4 projects), Gavojdia, Mănăştiur (2 projects), Pădureni, Parţa (4 projects), Periam, Săcălaz (8 projects), Sânandrei, Surduc (2 projects), the execution time being 18 months (1 project), 22 months (6 projects), 24 months (11 projects), 30 months (1 project) and 36 months (8 projects). Project names are very varied, as seen in table 3.

Table 3. Analysis of projects submitted and concluded in Timis County for Measure 313 - private domain

Project name	Project location, residence environment, locality	Legal representative			
		Position	Studies	Sex	Age
Arranging recreation area	R, Cenei	Unique associate	Faculty of Economics	F	30-34
Construction of swimming pool and amusements mini-park, including administrative building	R, Săcălaz	Manager	Statement that it will follow a qualification course	F	20-24
Construction of swimming pools, leisure base - mini golf and bowling	R, Săcălaz	Manager	Statement that it will follow a qualification course	M	25-29
Construction of swimming pools, including ground floor commercial administrative building	R, Săcălaz	Manager	Statement that it will follow a qualification course	F	40-44
Construction of leisure center	R, Parţa	Manager	Statement that it will follow a qualification course	F	40-44
Constructing horse manege	R, Săcălaz	Manager	Statement that it will follow a qualification course	M	35-39
Construction of boarding house	R, Săcălaz	Manager	Statement that it will follow a qualification course	M	65-69
Construction of fitness building and sports field	R, Săcălaz	Manager	Statement that it will follow a qualification course	M	45-49
Construction of tourist reception and recreational activities	R, Săcălaz	Manager	Statement that it will follow a qualification course	M	35-39
Construction of tourist boarding house by consolidating and changing the destination of existing built spaces	R, Sânandrei	Manager	Faculty of Agriculture	F	45-49
Construction of tourist boarding house, courtyard fitting, swimming pool location, indoor parking and field fencing	R, Beregsău Mare	Manager	Statement that it will follow a qualification course	M	35-39
Construction of boarding houses, garages and changing rooms, fencing	R, Beregsău Mare	Manager	Statement that it will follow a qualification course	F	25-29
Construction of tourist board and landscaping	R, Parţa	Manager	Certificate	F	20-24
	R, Parţa	Manager	Certificate	M	20-24
Boarding house construction, dismantling, removing land from agricultural use	R, Pădureni	Legal Administrator	Statement that it will follow a qualification course	F	50-54
Construction of a rural tourist boarding house in the recreation area	R, Fârdea	Manager	Faculty of Economics and Business Administration	F	25-29

Expansion of hunting lodge, swimming pool construction, parking and installation of solar panels	R, Mănăştiur	Manager	Certificate	M	40-44
Establishing a recreational base	R, Mănăştiur	Manager	Statement that it will follow a qualification course	M	20-24
Establishment of an agro-tourist boarding house	R, Dumbrava	Manager	Statement that it will follow a qualification course	F	30-34
Establishment of an tourist boarding house	R, Fârdea	Manager	Statement that it will follow a qualification course	F	35-39
	R, Chevereşu Mare	Titular	Statement that it will follow a qualification course	F	35-39
Establishment of tourist boarding house with restaurant	R, Gavojdia	Manager	Statement that it will follow a qualification course	F	35-39
Setting up a tourist board and leisure activities	R, Parţa	Manager	Faculty of Tourism and Commercial Management	M	25-29
Establishing a tourist pension and parking	R, Fârdea	Manager	Statement that it will follow a qualification course	F	35-39
Establishment of tourist pension, parking and access road	R, Fârdea	Manager	Statement that it will follow a qualification course	F	35-39
Agrotourist boarding house	R, Coșteiu	Legal representative	Statement that it will follow a qualification course	F	40-44
Tourist guesthouse	R, Surduc	Manager	Statement that it will follow a qualification course	M	40-44
Rural tourism "bed and breakfast"	R, Săcălaz	Manager	Tourism certificate	M	40-44
	R, Periam	Legal representative	Statement that it will follow a qualification course	M	45-49

Source: Interview Guide applied on the field

The amount declared in the application was in the range of 140981 – 1395707 Euros, and the declared value in the application was in the range 100000 – 646750 Euros. The amount declared in the application was lowest for the project "Establishment guesthouse in Dumbravita, Timis" - 140981 Euro, and the highest for the project "Construction of boarding house, dismantling, removing land from agricultural town Pădureni, Timiş county "- 1395707 Euro. Regarding the declared value eligible in the financing application the lowest was for the project "Agrarian tourism Gardenia, height Demisol + Ground floor + floor, Coşteiu locality, Timiş County" - 100000 Euro, and the highest for project "Construction of boarding house, dismantling, removing land from agricultural use", Pădureni locality, Timis County – 646750 Euros.

The legal representative of the grant applications was: the administrator (24 projects), legal administrator (1 project), sole associate (1 project), legal representative / representative (2 projects), holder (1 project). The age of the legal representative was between 20-24 years (4 persons), 25-29 years (4 persons), 30-34 years (2 persons), - predominantly - 35-39 years (8 persons), 45-49 years (3 persons), 50-54 years (1 person) and 65-69 years (1 person). As legal representative by sex, there are 12 male and 17 female persons. With regard to the studies, 22 persons submitted a "Declaration that will follow the qualification" until the project is finalized and implemented, 1 person has a tourism certificate, 3 persons have a professional qualification certificate and 4 persons have graduated higher education diplomas.

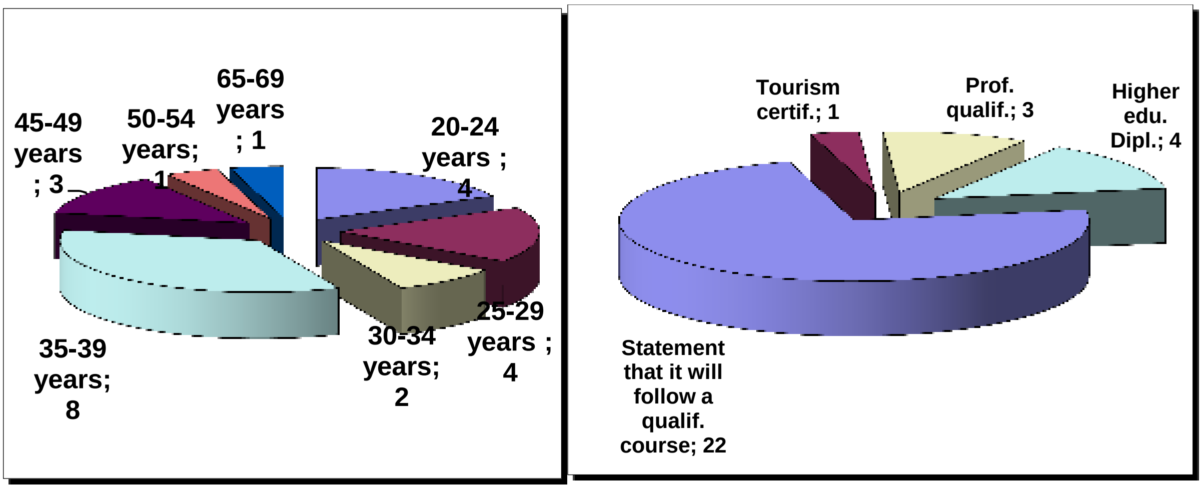

Figure 2. Legal representative of the projects submitted for Measure 313 - private domain (age and studies)

Conclusion

If we refer to public sector projects, all have been applied to create a tourist information center. Thus, there is a desire on the part of the local authorities to develop the tourist component in the area, especially since the vast majority do not have the necessary studies and have declared that they will follow qualifying courses. Still, it remains a question: in the localities where the legal representative will change after the local elections in 2012, who will state that he has passed the qualification course submitted with the application for funding and what will happen if the new representative does not have the necessary studies?

In the private sector it was found that most of the funding applications were for the construction of pensions and the extension of existing ones with new facilities such as parking, swimming pools and other recreation places (generally, with few exceptions, a project at every locality). Unlike the public domain, the age of legal representatives is lower (18 persons under 40 years, to 5 over 40 years) and women predominate (17 to 12). Also, the percentage of those who already have the necessary studies is almost double that of the public sector. Last but not least, due mainly to the reduced tourist potential, the percentage of projects in Timis county was lower compared to the other counties in the region, both in number and value.

Abstract

The opportunity represented by the European funding, which the Romanian rural and urban system of settlements was able to benefit through European programs, was a topical element. In order to identify the importance and role of European projects in the development of rural communities in Timis County, we conducted a study through a qualitative analysis. In conducting this analysis we used an application of an interview guide to the local authorities, mayor or deputy mayor, from 22 communes of Timis County. The Interview Guide has 4 distinct parts: Sustainable Development / Rural Development, National Rural Development Program / Operational Programs, Development Issues and Perspectives. As a result of the analysis, it was observed the maximum exploitation of the opportunities offered by the projects with European financing and the focus of the interest in the directions established as priority by the European Union only in some communes. The paper presents the number of applications submitted, as well as the title of the project and the extent to which these applications have been submitted. Also, there is the respondents' answers to the reasons why they did not apply for funding, as well as their response on the role of European projects in the development of their rural communities. As a result of the implementation of the European projects, there are changes in the rural area, which make the rural space a tempting space with facilities similar to those in the urban area, but there are problems like lack of jobs, in some areas insufficient infrastructure development, lack of projects and means of capitalizing the agricultural products.

Keywords: Rural community, opportunity, role, development, Timis county

Introduction

To achieve our goals of sustainable development, we need more effective, democratic and accountable international and multilateral institutions (***, Johannesburg Declaration on Sustainable Development, 2002). Starting with 2007, Romania is a member of the European Union and has taken the first steps on the EU market. Restructuring, modernizing and developing the agri-food sector, as well as the forestry and wood processing sector, pose a great challenge to increase their competitiveness (Otiman P.I. *et al.*, 2006). In December 2005, the National Development Plan (NDP) for 2007-2013, a tool for prioritizing public investment for development, was completed, in which Romania tried to recover as soon as possible the socio-economic development disparities towards the EU member countries. NDP has established the allocation of public funds for investment with significant impact on economic and social development from internal sources (state budget, local budgets, etc.) or external (Structural and Cohesion Funds, EU funds for rural development and fisheries, external credits, etc.). The National Rural Development Program targeted a number of objectives that support the increase of agro-food and forestry competitiveness, improve the environment and rural area, improve the quality of life in rural areas, diversify the rural economy, start and operate local development initiatives. The objectives of the program was made by implementing measures provided for each axis. (***, RDP 2007-2013, 2012).

The programming of support operations through the National Rural Development Program focuses on four priority axes: (***, Annual Progress Report on the Implementation of the National Rural Development Program in Romania in 2011, 2011).

• Axis 1 "Increasing the competitiveness of the agricultural and forestry sectors", aimed at improving the efficiency of the agricultural and forestry sectors in order to prepare them for the competition in an open commercial environment.

• Axis 2 "Improving the environment and rural areas" - the general objective of Axis 2 measures is to improve the environment in rural areas and to preserve biodiversity through sustainable land and forest management.

• Axis 3 "Quality of life in rural areas and diversification of the rural economy" - the strategic objectives of this axis are to improve the quality of life in rural areas, diversify the rural economy, promote knowledge and improve human potential.

• Axis 4 "LEADER" - aims to support rural development by improving local governance and promoting endogenous potential. The Leader approach will contribute to achieving the Axis 1, Axis 2 and Axis 3 objectives through integrated local development strategies and innovative actions.

Within each axis, depending on the type of investment and the areas concerned were established concrete measures to be implemented under the program. The opportunity represented by the financing that the settlement system could have benefited through the European programs was a novelty element for the Romanian settlement system and was an additional argument for the attention and importance given to the cities, considered the main engines of the growth, the real factories of materials and energy, which ensures the optimal functioning of the settlement system (Feher *et al.*, 2011).

Materials and methods

The opportunity represented by the European funding, which the Romanian rural and urban system of settlements was able to benefit through the European programs, was a topical element (Orboi Manuela–Dora *et al.*, 2016). In order to identify the importance and role of European projects in the development of rural communities in Timis County, we conducted a study through a qualitative analysis. In conducting this analysis, we have resorted to the application of an interview guide to local authorities, mayors or deputy mayors, from 22 communes of Timis County, in a predetermined meeting. We used the "funnel" semistructured interview, where the interview begins with general questions that graduate to the particular, as the interview progresses, focusing on a single subject. The Interview Guide has 4 distinct parts: Sustainable Development / Rural Development, National Rural Development Program / Operational Programs, Development Issues and Perspectives. The selected communes for this study from Timis county are: Biled, Birda, Boldur, Cărpiniş, Cenei, Checea, Dudeştii Noi, Dumbrăviţa, Giarmata, Giroc, Lenauheim, Lovrin, Orţişoara, Otelec, Remetea Mare, Satchinez, Săcălaz, Sânandrei, Şag, Uivar, Valcani and Variaş, around Timişoara. The interviews took place in the mayor's office and lasted between 10 and 15 minutes. The period in which these interviews were applied was August 2011.

Results and discussions

The question "Your City Hall has submitted funding applications for projects under available operational programs?" Is a closed question with a well-defined answer with two variants of the answer, in which the interviewee had to choose a variation of answer. Thus, the question "Your City Hall has submitted applications for funding for projects under the operational programs available?", 20 people responded "YES" and 2 persons "NO" (Figure 1). The following question, "If YES, could you please tell me, the title of the project and the Operational Program / Measure", is closely related to the previous question, the subject answered freely, the answers were those indicated in Table 1.

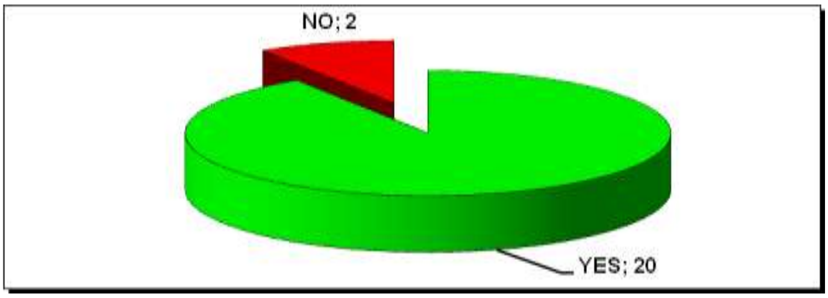

Figure 1. Number of financing applications submitted by the City Hall
Source: Interview Guide applied on the field

Tabel 1. The answer to the question, "If YES, could you tell me the title of the project and the Operational Program / Measure?"

"Title of the project, Operational Program / Measure" - details
- Rehabilitation of water supply and sewer system - Measure 322
- Rehabilitation and modernization of the park - Environment Operational Program
- Green House - Environment Program; Modernization of agricultural exploitation road - Measure 125; Integrated project: modernization of communal roads and streets, development of community social services (rehabilitation and endowment of cultural homes + after-school construction and endowment) - Measure 322
- Modernization of the communal road, establishment of "after school" children's center, preservation and promotion of local cultural traditions through folk ensemble "Ghiocelul" - Measure 322; Implementation of an innovative document management system and modernization of the Citizens Information Center within the City Hall - Administrative Capacity Development Operational Program
- Domestic sewer system, water treatment plant and extension - Measure 322; Modernization of agricultural infrastructure - Measure 125; Improvement by cleaning and afforestation of degraded land - Environmental Program; Green Commune - Operational Program Increasing Economic Competitiveness; Water World - Tourist Recreational Park - Regional Operational Program; Rehabilitation and inclusion in the tourist circuit of the Roman Catholic Church - Regional Operational Program; Platform E - PCDN - Operational Program Increasing Economic Competitiveness
- Rehabilitation of streets, establishment of water supply network, establishment of sewerage network in localities and purification station, acquisition of folk costumes, establishment after school - Measure 322
- For the future and progress. Elaborating the development strategy - Administrative Capacity Development Operational Program
- Street modernization; Upgrading, fencing and landscaping; Domestic sewage network; Harvest day festival - Measure 322
- Construction of the sewage system, construction of the wastewater treatment plant, modernization and extension of the centralized water supply system, modernization of the street, endowment of the cultural center and establishment of a after-school center - Measure 322
- Developing administrative capacity. Efficient Management System - Administrative Capacity Development Operational Program
- Integrated project "Establishment of the public sewerage network and extension of the public water supply network" - Measure 322

- Establishment of 1 MW photovoltaic park - Operational Program Increase of Economic Competitiveness
- Public lighting project with unconventional energy, solar energy - Environmental Operational Program
- Modernization the streets, setting up and after school, arranging recreational spaces and purchasing popular costumes - Measure 322
- Improving Physical Infrastructure and Basic Services - Measure 322
- Modernization of streets, construction of a nursery and investment to preserve the local specificity and cultural heritage - Measure 322
- Sewerage network and sewage treatment plant, modernization and extension of water supply, modernization of streets, rehabilitation of cultural house in order to promote local traditions, establishment after school - Measure 322
- Roads modernization, renovation and repartitioning cultural center, nursing home - Measure 322
- Modernization of streets, sewerage system (sewerage network and sewage treatment plant), establishment and endowment of a after-school assistance center and modernization and rehabilitation of the cultural center and the purchase of popular costumes - Measure 322

Source: Interview Guide applied on the field

Of the total of 20 affirmative responses, there is a town hall where most of the projects have been submitted - 7, in two other municipalities two applications have been submitted, and in the other municipalities one project has been submitted for financing . The distribution of projects by measures, respectively operational programs, is presented in figure 2.

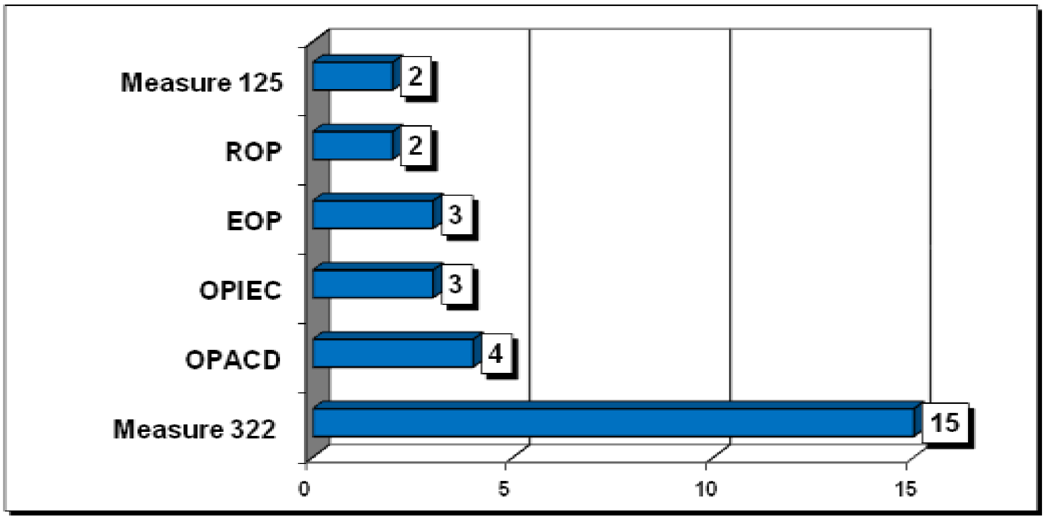

Figure 2. Top of applications for funding on operational programs and measures
Source: Interview Guide applied on the field

It can be noticed that most of the projects were submitted on Measure 322 - 15 applications for funding, on the Operational Program Administrative Capacity Development - 4 applications for funding, Operational Program Increase of Economic Competitiveness - 3 applications, Environment Operational Program - 3 applications for funding. It can be seen making the most of opportunities offered by European funded projects and interest in the directions set as a priority by the European Union, in some communities. Unfortunately, we have not noticed the capitalization of tourist potential in areas that have what "looks" and no immediate prospects for this to happen. Concerning the "reasons for the City Hall to submit project applications", they are presented in Table 2. Generally, the reasons are of a general nature - "lack of funds from own resources to achieve investments / development of the commune / modernization of the existing objectives / modernization of the commune /

continuation of older investments / sustainable development of the commune ". Only 3 mayoralties have clearly stated which was the reason for submitting the applications -" obtaining the ISO certificate (quality, environment, work safety) In the submission of projects "," the decrease of the public lighting expenses / the decrease of the electricity consumption in the public institutions ".Interviewed subjects (2 people) who gave the answer "NO" to the first question went to the question "If you have not submitted applications for funding for projects, why have you done so?" and he was in both cases this was "Lack of money for co-financing (2%)".

Tabel 2. The answer to the question, "Could you tell me, in the case of your commune, what were the reasons that prompted you to apply for funding for projects?"

"Reasons for submitting applications" - details
- Lack of funds from own resources to make investments; Obvious access to European funds as our country is a contributing member
- Development of the commune; Modernizing existing objectives
- Development of the commune (5 replies)
- Rural development; Attracting funds that cannot be received from the local budget
- Local needs
- Modernization of the commune
- Continue of older investments
- Raising the commune to higher standards
- Obtaining the ISO certificate (quality, environment, work safety), help in projects submission
- Need
- Development of the commune; Decreasing electricity consumption in public institutions
- Lowering public lighting costs
- Sustainable development of the commune
- Development of the commune, lack of funds from the local budget
- Community development
- Continue of older investments and Development of the commune

Source: Interview Guide applied on the field

The question "Do you think that this kind of projects could help your commune?" Is also an open question that allowed the respondents to give a very wide range of answers, the answers were those shown in fig. 3. Subjects gave the following answers: "YES" - 16 subjects, "YES, very much / YES, obviously, YES, surely" - one answer, general answers, "YES, Ensures standards close to the city "- one answer each.

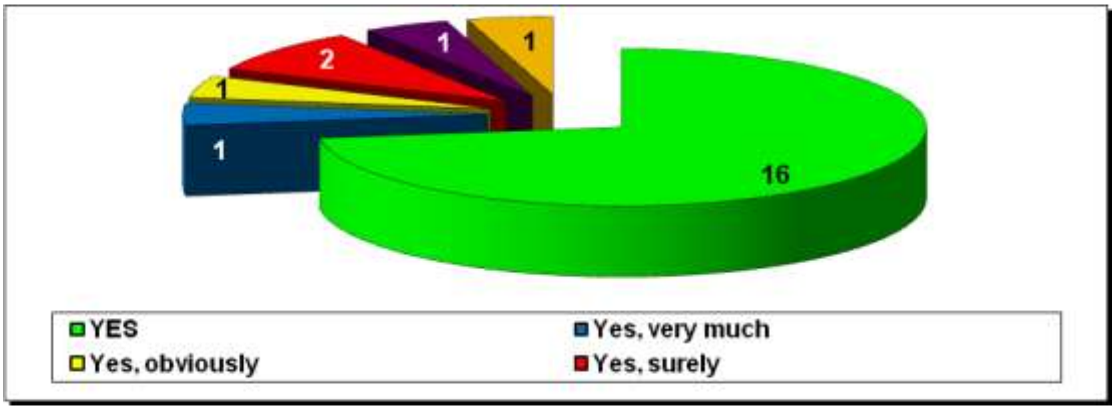

Fig. 3. Distributing of the answer to the question "Do you think this kind of projects could help your commune?"
Source: Interview Guide applied on the field

After a careful analysis of all the opinions expressed in the study, we noticed how recent changes make rural space a tempting place with facilities similar to those in the urban area, but there remain problems such as lack of jobs, in some areas insufficient infrastructure development and lack of the possibilities of capitalizing agricultural products. However, the main problem of the rural environment is the predominant share of the agricultural sector in the economy, non-diversified and with a mono-economic structure, a trend contrary to the European economic policies, low level of infrastructure and services development, lack of alternative sources of employment and income for the aging population of this area.

Conclusions

The development of the Romanian village is a topic of real interest, both from a theoretical and practical point of view, in various fields - social, economic, political etc. In recent years, the village has seen a remarkable development, investments in infrastructure, drinking water supply, sanitation, modernization of schools, kindergartens, dispensaries, parks and sports halls are just a few of the projects implemented in these areas that have radically changed, both the life of the people and the prospects for their development. From the analysis of the answers to the questions we noticed that in recent years the authorities have launched a series of large-scale projects meant to improve the rural area, to bring more comfort to the rural population and to create new opportunities for development. The views of mayors / vice mayors on the difficulties encountered in recent years are varied and they highlight the bureaucratic problems faced by authorities in developing investment projects but also other issues specific to the so called ”mioritic” space: the importance of ”attention”, the mentality of the Romanians, the benefit of communes that have representatives of the same "political color" as those from the government. A delicate and hard-to-manage issue by authorities is also the resistance of change in rural areas - resistance often justifiable and in terms of costs associated with it. The fact is that each implemented project should bring new jobs, new personal development perspectives for those who access it. Rural development projects for Timis County should be based on local specificities and should take into account a polysectorial development, a development in which agriculture is no longer the sole source of income for the inhabitants.

Abstract

Agrigultural production is a main resource for food products and prevention of malnutrition of world population. Arable land is a limited resources for agricultural production - 0.4 ha per capita in the world. This requres attention for rational and optimal use of natural resources for agricultural production, particularly because of the fact that the rise of world human population in the future is predicted, over ten billions citizens. In previous century progress in agricultural production was achieved by developing conventional agriculture and industrial revolution, particularly from the begining of „Green Revolution" which was characterized by growing technology with a greater use of fertilizers and pesticides. Agricultural resources are under preasure of spreading urbanization, and arable land used for developing factories, towns, industrial buildings, landfills, roads, railways etc., from the period of the Industrial Revolution, up to nowdays. Another problems that disrupts agricultural production is pollution from metal and chemical industry, towns, while in the future a new challenge is climatic changes. Since the beginning of the Industrial Revolution, the concentration of carbon dioxide in the atmosphere has increased by 30%, the concentration of methane has doubled and the sodium oxide increased by 15%. These increases affect the retention of heat in the earth's atmosphere on the principle of the greenhouse effect. The influence of unfavorable condition on agricultural production requires intensive work on resolving adaptive and efficient model(s) of agricultural production under the global climate changes and trend of increasing human world population.

Key words: *agriculture, producttion, economy, rural development, technology*

Introduction

Agriculture is an important branch for production food to the human population, as well as provides a various of raw materials for the textile, tobacco, leather industry, etc., Also, agriculture realizes a surplus of products, which are exported to the world market and creates profit. In Serbia, agriculture is important for the economic, social, environmental and rural development, that in this decade participates about 10% of GDP, while in the previous decade, its share in GDP was higher (25%). The high share of agriculture in GDP confirms its importance for the overall progress of the national economy, although it is necessary to establish a balance between the value of primary agricultural production and processing of food industry (Mićanović and Zecevic, 2012). The improving productivity in agriculture is directed particularly through efficient water and soil management practices, crop nutrition and protection from pests an diseases. This program need support from national and International organization in food and agriculture. The average rate of growth of agricultural production in Serbia, at the beginning of the 21st century, is 1.3% of net worth, with dominant plant production. This trend in agricultural production in Serbia is in agreement with global prediction that meet of needs of the world population for food in 2050 will be necessary to increase crop yields by 1.3% per annum (Fischer et al., 2014). The basis for intensive agriculture has remained the selection of new cultivar and hybrids of plant species and breeds of domestic animals, which had greater potential productivity. Today, the main task is the creation of high-yielding varieties and hybrids, which are the basis for increasing food production (Fridman and Zamir, 2012). However in developed Country within agriculture production, te dominant role is production of domestic animals and better market linkage.

The statement of agriculture production is the reflection of statement of overall economy and the degree of technology in processing industry as well level of integration with the institutions and programs of socio-political system.

Climate change is one of the disturbing problems that is currently happening, and already expected global warming in the future is greater than previously predicted. Prevailing view of scientists that we now face an inevitable increase in global temperature and that is great probability that climate change has already occurred. With the threat of climate changes, more and more regions of the world are also at risk of drought and desertification. In order to mitigate the negative effects of climate change, it is necessary to take advantage of current scientific knowledge and develop new ones (Lin et al., 2005). Improved irrigation practices will help conserve water and protect vulnerable land. Stable and radioactive isotopes can be used as “tags” at the molecular level to monitor how plants use essential nutrients as well as to study crop growth and nutrient requirements to increase yields, while conserving water and preventing further degradation of marginal lands.

In economically developed countries, agriculture is characterized by high productivity, which is based on modern technical and technological means and methods of production, then a high degree of organization adapted to the type of agricultural production and integration with modern systems of processing and the appearance on the market of finished products, a further and product placement and income and profit (Knezevic and Micanovic, 2013).

This paper aimed at estimating agriculture’s role on economic growth and its impact on poverty reduction.

Agriculture influence to economic and social development

Agriculture can contribute to growth of economy and modernisation of society, because of its abundance of resources and its ability to transfer surpluses to the industrial sector. Crop production as well livestock production need to be more intensive in the purpose to satisfy demand of increasing world population for food, what require additional investments of 80 billion Euros every years for reducing poverty. Agricultural investments can generate benefits as increasing productivity and food availability, employment of people, reducing poverty, introducing and transfer modern technology and access to capital and markets. In agriculture most resources are used for food production and have role as a one way flow of resources towards the industrial production, because of weak possibilities for trade. For developing economy agriculture is important for food production for different purposes as well population with different incomes. Agriculture represents source of accumulation for new investment in industry and contributes to the enlarging market for industry products. In addition agriculture supply primary products for processing industry. Also, agriculture earnings in export provide for payment of imported goods (Timmer, 2002).

However, industry produce modern machine and equipment which contribute to improving technology of agricultural production and increasing production per hectare and per worker what significantly modernising economy. In the purpose to comercialise products, producers in cooperation with service sector and partly substitute chemicals and machines for their labour and for remain products receive lower price, in return, their spend less time on the market. This indicate that added values falls over the time, from labour, land and capital of agricultural producers as a share of the gross value of agricultural output. The increasing of purchased intermediate inputs and services can influence to decline of production in agriculture as well in GDP and employment.

The linkages between agriculture and industry is not simple, and share of agriculture to industry and services varied in dependance of level of agricultural and industrial development. For modernisation of agriculture and getting income is necessary supply incentives to realize agricultural goods without rising prices and resources in agriculture need toward industry centres (Rosandic and Knezevic, 2014). On the base of primary production we can estimate demands of industry and urban centres, as well potential agriculture. General estimation is that agricultral production is main base for economic growth and contribute to generate income in agricultural (rural) and urban areas and results of increasing incomes increasing of investment. Agrculture provides tax revenues and supplies materials to agricultural-based manufacture which contribute to lower price of products and have positive impact to economic development.

The impact of agriculture in GDP depends from linkage of agriculture and technology, human resources which directly support to farm productivity and reducing costs, as well connection agriculture and technology. The significance of agriculture share in GDP also, connected with macroeconomic policies through measue of taxation of food producers, traders and exporters, by investment in producing technological innovations and investment in rural incomes to generate social progress and infrastructure.

However, the industrialized management of agriculture refers to the management system that established agricultural bases with enterprises involved in agricultural product processing, sales or technical service as leading force and lead farmers in the agricultural production bases to embark on specialized production of agricultural products. This management can effectively solve the linkage problem between agricultural households of small-scale operation and domestic and foreign big markets, increase the value-added of agriculture by elongating the industrial chain, and improve the management efficiency.

Role of science in agriculture developing

The increasing of agricultural production based on aplication scietntific measure of farming and growing high yielding and quality cultivars and hybrids which were created through breeding by using scientific methodology (Knezevic et al., 2016). The aim of breeding is creation genotypes with enhancing nutritional components and residue as a reason to be performed for the purpose of improving the yield and quality as well resistance to biotic (viral infections, mycoses) and abiotic stresses (drought, cold, salinity). In breeding program were created cultivars and hybrids with double and more increased yield, protein contents, content of fat, carbohydrates (Knezevic et al 2013), eg. in barley and oat content of antioxidants, β-glucan content, in sunflower specific fatty acids (oleic acid), in cotton cellulose extensibility characteristic, in wheat contents of essential amino acids, antioxidants etc. (Menkovska et al., 2015). The biological quality have great importance for human health, to prevent certain diseases occur due to lack of the presence vitamin D (rickets), an amino acid (e.g., phenylalanine, is created from dopamine and two hormones adrenaline and noradrenaline, which lack in certain cases causes Parkinson's disease). This progress is achieved in a relatively small number of plant species, mainly in species which are the most use in the diet.

At the beginning of the Green Revolution, i.e. in the time of application of new scientific farming measures, creation of new hybrid and cultivars the production of food was increased. This progress based on increasing yield thanks to the introduction of new genotypes and increased application of fertilizers and pesticides in plant production practice. However in all developed and developing economy the significant effect on increasing of agricultural production had introduction of agricultural machinery (tractors, seed, combines, mowers) and than authomation of processing production (mills, processing plants, milking cows and sheep) which contribute to decline manual labour. The strong interdependence between agriculture and science and industry, through which agricultural growth supports overall economic growth and reduce poverty.

Human population rise is imposed by the production of large quantities of food. The required food production can be realize by conducting production on larger metering surfaces or through increasing yield per unit area (Fischer et al., 2014). Increasing of agricultural productivity can increase farm incomes through introduction new technical equipment for transport, processng and marketing and satisfiyng demands of consumers and services. This is associated with economic growth and poverty reduction (Rosandic and Knezevic, 2014).

Climate change is estimated on the base of increasing of temperature in some area 5-6 ^{0}C, approximately; ice sheets in the Arctic melt significantly, increasing of carbon dioxide in the atmosphere etc., as a consequence of natural disasters (earthquakes, floods, hurricanes, cyclones) non-rational exploatation non-renewable and renewable energy resources, increasing of indusry pollution (Jolánkai and Birkás, 2007). Pollution is a very important factor of extinction, and the consequences of which are present in the agricultural practice after the use of toxic chemicals. Use of toxic hydrogen chloride, dihlor-difenil-trihloretan (DDT) and polychlorinated biphenyl (PCB) has a negative impact on the species that are at the top of the food chain (soften and distort the eggshell will develop a bird, disrupt reproduction carnivores, cause cancer in animals and are probable human carcinogens). This suggests that is need to maintain the coexistence of crops and weeds by application adequate herbicide, otherwise it disrupts soil microfauna, food chains and disappearance many insects, invertebrates and other species in the ecosystem (Pachepsky et al., 2007). Survival depends on ecosystem biodiversity, so that eviction or the loss of one or more species can disrupt ecosystem to decay and brought into question the survival of man, if it is known that over 40% of new drugs in medical pharmacy obtained from plants and animals.

A more economical aspect is to produce plants with an increased yield wherein the significant role had accomplishment in biotechnology through the creation of transgenic plants. The transgenic plants have higher yield, as well as resistance to pests, diseases and tolerance to herbicides, insecticides, etc. However, the occurrence of adverse effects of the use of food from genetically modified plants, aroused caution to the opposition and rejection of the newly plants, as well as due to the risk upsetting the balance in the ecosystem and the negative impact on communities biocenoses (Fridman and Zamir, 2012). It came to initiate a new approach to the growth of plants in natural conditions for food production. In contrast, very intensive requirements present for organic production. The areas for production of organic wheat in 2002 were the largest in Australia 7.7 million ha, in Europe 4.3 milion ha, in Central and North America 3.6 million ha, in North America 1.3 million ha, and at least in

Asia (94.000 ha) and Africa 60.000ha (FAO, 2002). There is a trend of increase in area under organic production. In fact, based on a harmonized ecosystem simulation wants to produce biologically valuable and safe food.

The perspective in agricultural production is in recognizing the importance of innovation, knowledge and education. The registration, acceptance and implementation of innovation can contribute to launching the economic development in all Countries. The transfer of knowledge in economy is not simple, but can contribute to improving technological development of the country, and as well as to accelerate progress of modern economy, particularly agriculture as well improve rural livelihoods, protect biodiversity and environment.

The perspective of the rural economy development

The one of the former form of organization of agricultural production based on cooperatives farm, today is less and less present. The reasons for this are varied, and among them manifested unprofitable existence, emphasized trade and administration functions, unjustified borrowing for investment, low productivity results and others. On this basis, the cooperative could not fulfill its primary function in the interest of members. Also, the complex ownership structure of assets in cooperatives aggravated their renewal. Instead arise new forms of organization of small and medium-sized enterprises, which have an impact on the development of social relations and economic development.

It is certain that the necessary association of producers in order to strengthen production safety, contribution to meeting the demands of the market for the quantity and quality of products. Whether the small land holders are merged and enlarged in the future so the plot or to larger companies buying or renting land plots enlarged in the future production, to creating better adopted for higher productivity. Small producers themselves can hardly meet the criteria of competitiveness in agricultural production. All farms according to their capacity to perform the production and control as in plant and animal production, which is a function of a higher level of consumer protection and food safety. The key for food and nutrition security is agricultural investment by farmers or the public sector. The investment can contribute to increasing productivity at the farm production and can increase quantity and quality of food on the market, decline price and stronger connection between rural and urban consumers.

The introduction of technical-technological innovation in agriculture can contribute to its development, which is based on the concentration of technical means and enlargement of land areas, whereby the developed new agricultural and manufacturing relations (Knezevic and Micanovic, 2013). To cooperative could operate successfully, it is necessary to their establishment on a voluntary basis, in which all operations of the cooperative must have the abillity of control operations, economic investment in the development of cooperatives, private education, modernization of equipment. Also, it is necessary to contribute to the strengthening of the independence of cooperatives, strengthening its own budget, and have an impact on the development of the environment and society. Cooperatives could autonomously decide on the structure of production in line with available resources and market needs within the business environment. Achieved by integration of small agricultural areas in larger systems (cooperative farms, combines, mixed holdings) and also all stronger connections agriculture and industry such as agricultural products were used as raw materials for industrial production. These dynamic changes in the organization, structure and modernization of agriculture were present in Western Europe, the United States, the former Soviet Union, etc.

The future progress of agricultural production will based on using of new technologies in farmers production and developing an open market environment to make the resulting production as profitable to producers as employment opportunities in other sectors. In environment where agricultural development is not possible, rural poverty will only be solved by migration to urban areas (Rosandic and Knezevic, 2014).. Too little public and private capital was invested in rural areas as well in raising rural productivity. The improving of public investments and favorable policy stimulate growth in the agricultural sector is possible achieve through the opportunity for farm investment without financial intermediaries, and the potential to earn high rates of return on public investments that correct for urban bias (Timmer, 2002). The agriculture growth have share in economic growth and direct contribution to growth in GDP.

The scientific potential that we have put into operation improving the level of technological development of the economy, above all, bridging the gap between science and economy (Mićanović et al., 2011). Incentives should be provided for according to the foreseen quotas and applicable standards in manufacturing, whether it is a plant species or species of domestic animals as well as products from them. Also, the stimulus should be reinforced in case the diversification of production, which is required for proper disposal of waste (fertilizer in growing animals), biomass (in the cultivation of cereals, etc.). Thereby manure produced can be used in the nutrition of the plants, which can not be greater than 170 kg ha^{-1} per year.

Labeling throat domestic animals, bee colonies increases the level of protection of the environment and human health. In order for Serbia to be recognized on the EU and world market, it is necessary to protect the originality of agricultural products, the geographical origin of the product or process in the manufacture of a product, especially a product of the grapes (wine), dairy products (cheese, cream), bee products (honey, royal jelly, propolis) and fish products.

Agricultural production and poverty reduction

The high level of production and export of agricultural products, achieved in developed countries, thanks to the use of modern technology and encouragement of the European Union. Agriculture in the European countries, after a period of protectionism, the deflection in the single market, on which it freely without customs costs, makes the sale of agricultural products on the one hand, while also implementing protective tariff rates on imported products. This approach was developed in the EU in order to protect the single market of goods produced in the European Union, as well as assistance for the export of goods to other markets in the world. Strengthening agriculture in the European Union is based on: improving the competitiveness of the agricultural sector, improving the quality of agricultural products and environmental protection, development of farmland diversity, and justification for spending the EU budget for agriculture.

In the European Union, of the total agriculture, the production of 75% is achieved in 7 countries as follows: France (18%), Germany (14%), Italy (13%), Spain (10%), the UK (8%), the Netherlands (7%) and Poland (5%). France has become a leading producer and exporter thanks to the effect of incentives of agricultural production eg., in 2007 year. The France, after export of agricultural products was the third in the world, of which the most important export products were wheat, poultry, dairy products, beef, pork, champagne burgundy. In France, the 3.8% of the active population is employed in agriculture and the food industry had a share of 4.2% of GDP. France after export of agricultural products was the third in the world, of which the most important export products were wheat, poultry, dairy products, beef, pork, champagne burgundy.

In the structure of the agricultural production in the EU, the production of cereals represent about 13% of the total production (330 million tons). The largest increase in cereal production was recorded in Slovenia (over 40%), similar in Slovakia and in Austria, Hungary, the UK and Estonia is ok increase of 20%.

The production of pigs, cattle and sheep represents around 17% of total agricultural production in the EU. In France, it is grown around 22% of the total production of about 88 million cattle heads in the EU, followed by Germany 14%, UK 11%. Of the total production of sheep in the EU (84 million head), about 23% is grown in the UK, 15 million in Spain, Romania and Greece, with more than 9 million head. The EU has grown about 148 million pigs, of which more than a third of the products together in Germany (26 million individuals) and Spain (24 million individuals). In production of livestock in Serbia, is dominated production of pigs (3.2 mil. Individuals) which is higher than in neighboring countries (11th place in Europe), than are bred cattle around 920000 and 1.7 million sheep. The Serbia need focused on improving economy with reducing food imports and by increasing food production in agriculture and processing industry. In Serbia present resources to support agricultural based economy.

In the model of the EU agricultural provided market intervention for products that are important to food security and revenue producer, such as sugar, wine, olive oil, etc., Wherein is carried out foreign-protection intervention buying and other forms of product withdrawal from the market, and support consumption and production of certain products. Agriculture and food industry in the EU play an important role in ensuring the health of the population, in rural development and environmental protection. Some 500 million EU consumers spend nearly a quarter of their earnings on food. In the agricultural production is employed about 2% of the labor force, which contributes to more than 4% of the GDP of the EU, and the food industry are employed, about 3% of the labor force, which contributes to more than 3% of the GDP. The potentials of the food sector are significantly higher in the EU for employment (20%) and thus a better share of GDP (about 10%). In terms of the current economic situation establishes a system of organization of agricultural production, transport, and joint tehnolologies of launch of agricultural product (Latacz-Lohmann and Hodge, 2001)

Today's volume of agricultural production in Serbia is at the average level of developing countries, which is paradoxical given the existing professional human and natural resources. This is due, obsolescence and lack of technical resources, unfavorable age structure and the number of agricultural population, as well as the inexperience and incompetence of returnees from urban areas in agriculture (Micanovic and Zecevic, 2012). Also, a significant factor affecting the maintenance of stagnation in agricultural production is the presence of competition, the presence of managers in comes to building production without adequate education and experience, insufficient investment in science and support scientific and mid-career programs, if they exist at the level of analysis without further implementation of the formulated conclusions and the program of measures for development of agriculture (Fridman and Zamir, 2012). Also, a significant inhibition factor is the lack of investment and existing expensive investment in agriculture

Conclusion

For efficient agricultural development is necessary financial resources, revision current import and export regulations and stronger subvention and realisation on the market. Also, is necessary mobilize human resources and use natural resources to make strong agricultural sector which will be the main source of revenue for the Country. The intensification of agricultural production is based on the development and application of new technologies of cultivation of plants and animals, technology, nutrition, harvest, storage and marketing. Improving productivity in agriculture in a sustainable manner is today a realistic target. The future progress of agricultural will based on using of new technologies in farmers production and developing an open market environment to make the resulting production as profitable to producers as employment opportunities in other sectors. In environment where agricultural development is not possible, rural poverty will only be solved by migration to urban areas. The intensive investment in agriculture, application of scientific methodology, achieve production with low imput and high output and provision open market for agricultural product will contribute to economy strengthening and reduction of poverty.

Abstract

The traditional model of fruit drying in Serbia is founded upon small family dryers, which are used for drying plums and occasionally apples. Such model features a sustainable energy supply due to utilizing biomass as an energy source. However, a serious technological disadvantage of the model is reflected in the employment of direct drying, which inevitably results in fruit oxidation. Changes in consumers' habits, accompanied by increased sanitary and health requirements, have made this technology obsolete on the market. The contemporary production of dried fruit necessitates "friendly technologies" with a stable and inexpensive energy support. Therefore, a number of researches at the Faculty of Agriculture in Novi Sad examined the adoption of friendly fruit drying technology with a sustainable energy supply. Consequently, the solution was found in the combined fruit drying technology powered by renewable energy sources. Using the combined technology, the production of dried fruit in small drying facilities on family farms can be very profitable. On the basis of the financial analysis of dried plum production, the total and variable costs were calculated for a dryer with a capacity of 450 kg of fresh plums per day. The contribution margin was computed as the difference between the total sales revenue and variable costs, whereas the profit was calculated as the difference between the value of production and total costs. The cost price of dried plum halves was 187.3 RSD/kg (1.52 €/kg). A retail price of 504 RSD/kg was set for dried plum halves by adding an average trade margin of 20% and a value-added tax of 20% to a wholesale price of dried plum halves totalling 350 RSD/kg. The calculations showed that a gross margin of 843,960 RSD (6,861 EUR) and a profit of 729,480 (5,931 EUR) was generated during 40 days of production, using the given purchase and selling prices.

Key words: *dried plums, cost price, contribution margin, profit, Serbia.*

Introduction

The industrial significance of plums is determined by their usability, prevalence in the total fruit and agricultural production, share in international trade, production workforce requirements, processing and marketing, as well as their contribution to sustainable agriculture and environmental protection (Lukač Bulatović, 2014). Plums are consumed fresh or used in domestic and industrial processing. According to Vlahović (2003), plums are mostly used for plum brandy production (approximately 65%), processing (21%), fresh (8%) and dried (4%) consumption, whereas the smallest share of plums is utilised in jam production (2%). The Serbian plum production ought to be enhanced by applying contemporary growing and protection technologies.

The development of fruit production in Serbia greatly depends on the prospects of marketing fresh and frozen fruit, as well as processed fruit products. Fruit processing is primarily focused on producing juices, alcoholic beverages, aromas, jams and marmalades (Lukač Bulatović at al., 2013). Furthermore, there is a possibility of producing dried fruit, which is, with the exception of dried plums, present to a lesser extent on Serbian family farms. An increase in dried fruit consumption in the world emphasizes the potential of domestic dried fruit production. Relative to the available production resources, the dried fruit production in Serbia ought to be enhanced, particularly the production of dried apricots, pears, apples, nectarines, peaches, plums and sour cherries. Contemporary fruit preservation and storage technologies encompass drying as one of the fundamental and most frequently used processes (Živković et al., 2006). There are various fruit drying systems, ranging from the simplest such as direct drying to highly automated systems with predetermined drying parameters. Drying results depend on the quality of dried products and drying costs, which mostly include energy consumption and investments in the facilities and equipment. The development of small and medium-sized enterprises could be substantial in fruit processing, offering a vast array of possibilities to entrepreneurs. Fruit drying is a fruit processing technology with a respectable domestic tradition (Babić et al., 2005). However, traditional drying methods do not meet the quality requirements of contemporary markets as products feature poor organoleptic properties, appearance and marketing (i.e. poor advertising, packaging and design). Regarding plums as a raw material in processing, the purpose of this paper is to examine the principal economic effects of dried plum production on family farms. In order to reduce the plum production costs, certain production lines were located in the immediate vicinity of raw material sources, whereas the final production lines were established near consumer centres.

Material and Methods

One of the most comprehensive and effective technological solutions for drying fruit, based on the combined drying technology, was developed by a group of researchers at the Faculty of Agriculture in Novi Sad. In the initial stage of drying, this technology uses osmotic pretreatments in a sucrose and water solution. Upon reducing the fruit moisture content by one-third to one-half (using osmotic pretreatments), fruit is further dried in a classic heated-air dryer. During the entire process, the temperature of fruit does not exceed 45^{o}C. Drying at lower temperatures preserves high quality and nutritional values of fruit.

This paper examines the major economic impacts of dried plum production using the combined fruit drying technology. The analytical calculations performed were based on the data collected from the fruit drying facility at the Faculty of Agriculture in Novi Sad. The calculations were primarily based on the cost calculation of dried plum production, i.e. the direct variable costs, production value and contribution margin.

The contribution margin (gross margin, marginal result and net income) is the key indicator of business results, particularly from the perspective of short-term decision-making (a period of 1 year). In order to fully investigate the profitability of dried plum production, additional performance indicators were also provided (total costs, revenues and cost prices). An analysis of the main economic indicators was carried out in 2016.

Results and Discussion

The following fruit species can be dried using the equipment designed at the Faculty of Agriculture in Novi Sad and combined drying technology: apricots, peaches, nectarines, vineyard peaches, pears, apples, quinces, plums, sour cherries and cherries. The equipment can also be used for the conventional drying (without osmotic pretreatments) of the following fruit crops: sour cherries, cherries, plums, apples slices (chips), soft fruit and seedless grapes.

In addition to fruit drying, a convective tray dryer is used for drying vegetables, medicinal plants, forest fruits, etc. (Babić Ljiljana et al., 2003).
The cost calculation of dried plum production was made for a dryer with a capacity of 450 kg of fresh plums per day. The drying duration was 40 days with a total of 18,000 kg of fresh plums dried (1 EUR= 123.0 RSD).
The major economic impacts of agricultural production are chiefly reflected in the gross margin (contribution margin, marginal result, contribution margin income, net income, etc.). As an indicator of economic impacts and relative to final financial results, the contribution margin comprises the amount for covering the fixed costs incurred and the amount of the profit generated (Milić i Sredojević, 2004). As an economic indicator, the gross margin is increasingly used in analyzing the business results of a farm. The gross margin indicates the profit of a farm exceeding the production costs (Ivana S. Ivkov et al., 2008).
The gross margin represents the production output (value) reduced by the production-specific variable costs. Chadwick (2000) argues that the gross margin is not profit. The total amount of gross margins of all production lines on a farm is deducted by all the fixed costs incurred in order to calculate the profit of a farm.
The production value reflects the conditions on a farm and the market value of outputs during a fiscal year. The economic effects of a farm depend on production outputs and costs, i.e. financial gains generated by their difference. Moreover, the production value is a result of the production volume and the unit selling price.

Table 1**.** The cost calculation of dried plum production by cost types

No.	**Costs**	**Units**	**Amount**	**Price (RSD)**	**Total** RSD/day	RSD/kg	**Structure (%)**
1	Fresh plums	kg	450	15	6,750	60.3	32.2
2	Sugar	kg	7.6	60	456	4.1	2.2
3	Water	l	1,000	0.113	113	1	0.5
4	Packaging and etc.				2,860	25.5	13.6
I	**Material costs (1-4)**				**10,179**	**90.9**	**48.5**
5	Electrical energy	kwh	61.6	8.12	500.2	4.5	2.4
6	Heat energy (straw)	kg	168	3.7	621.6	5.6	3
7	Labour costs	h	40	170	6,800	60.7	32.4
A	**VARIABLE COSTS (1-7)**				**18,100.8**	**161.7**	**86.3**
8	Equipment and facility depreciation				2,242.4	20	10.7
9	Overhead costs				620	5.6	3
B	**TOTAL COSTS (1-9)**				**20,963**	**187.3**	**100**
No.	Results	Unit	Amount	Price (RSD)	Value RSD/day	RSD/kg	Cost price
10	Dried plums	kg	112	350	39,200	350	187.3
C	**PRODUCTION VALUE (10)**				**39,200**	**350**	
D	**CONTRIBUTION MARGIN (C - A)**				**21,099.2**	**188**	
E	**PROFIT (C - B)**				**18,237**	**163**	

The material costs, amounting to 90.9 RSD/kg and accounting for 48.5% of the total costs, exerted the most significant effect on the cost price of dried plums (Table 1). The labour costs claimed the second largest share in the total cost structure, amounting to 60.7 RSD/kg and accounting for 32.4% of the total costs. The energy costs amounted to 10.1 RSD/kg. The fixed costs accounted for 13.7% of the total production costs. The equipment and facility depreciation accounted for 10.7% of the total costs. The overhead costs of dried plum production accounted for 3% of the total costs, and were forecast on the basis of empirical estimates. The cost price of dried plum halves was 187.3 RSD/kg (1.52 €/kg). A retail price of 504 RSD/kg was set for dried plum halves by adding an average trade margin of 20% and a value-added tax of 20% to a wholesale price of dried plum halves totalling 350 RSD/kg. The calculations showed that a gross margin of 843,960 RSD (6,861 EUR) and a profit of 729,480 RSD (5,931 EUR) was generated during 40 days of production, using the given purchase and selling prices.

Conclusions

There is an increase in the production and consumption of dried fruit both in Serbia and the world. The existing volume of fruit drying in Serbia is minute because the traditional drying model is founded upon small family dryers, mostly used for drying plums and apples. A serious technological disadvantage of this model is reflected in the employment of direct drying, which inevitably results in fruit oxidation. Therefore, strict domestic regulations and international standards ought to render such models obsolete by promoting latest drying technologies. The contemporary production of dried fruit in Serbia ought to comply with the international standards and regulations, using stable and inexpensive energy sources. The existing level of fruit drying ought to be enhanced due to the enormous processing potential, which could be exploited on family farms and in small and medium-sized enterprises.

The material costs, amounting to 90.9 RSD/kg and accounting for 48.5% of the total costs, and the labour costs, amounting to 60.7 RSD/kg and accounting for 32.4% of the total costs, exerted the most significant effect on the cost price of dried plums. The cost price of dried plum halves was 187.3 RSD/kg (1.52 €/kg). A retail price of 504 RSD/kg was set for dried plum halves by adding an average trade margin of 20% and a value-added tax of 20% to a wholesale price of dried plum halves totalling 350 RSD/kg. The calculations showed that a gross margin of 843,960 RSD (6,861 EUR) and a profit of 729,480 (5,931 EUR) was generated during 40 days of production, using the given purchase and selling prices.

Dried plums are the most important plum product in Serbia from the nutritional and economic perspective (95% of the total dried plum production is exported). Plums are dried in industrial, mini- and farm dryers. In order to produce high-quality dried plums, indirect drying methods ought to be employed in concurrent-flow dryers. Plum drying encompasses all the requisite procedures leading from fresh plums to final products (packaged and ready for market).

Abstract

In this paper, a general mathematical model of the multi-criteria linear programming problem has been developed that can be used to optimize the production processes and services, offered by multifunctional farms. The model comprises the following components: independent variables, the matrix of limitations and two objective functions. The independent variables for plant production, husbandry another processes and services are defined individually. The model also takes into the account internal (production and technology related, biological) limitations as well as external (market related, financial) limitations. The objective functions of the model deal with both, the total maximal effectiveness and the overall efficiency of the farm. The economic effectiveness within the model is represented by the total gross margin (difference of the total income and the direct variable costs), whereas the farm efficiency defined as the quotient of total income divided by the total costs. For solving the model, which deals with the maximization of the total gross margin, a linear optimization method has been applied, while for the maximization of the farm's efficiency a non-linear approach has been utilized. Also, by applying two different optimization methods, two different optimal solutions have been received. Eventually, the farmer must decide, which solution is the most suitable for him/her. The model has been tested on a multifunctional farm in Germany.

Keywords: *model, linear optimization, multifunctional farm.*

Introduction

The paper deals with a multifunctional farm. The aim of the paper is to define a general, theoretical mathematical model for optimization of total farm business operations on the basis of two economic optimality criteria: effectiveness and efficiency. Defining of the mathematical model of production and services (business operations) of a farm is transformation of the actual relevant relations determined for the object of research into a set of logical relations defined by mathematical symbols. Setting a mathematical model is the basis for solving the defined problem of agricultural production structure optimization, by applying exact mathematical methods. The general mathematical model for optimization of the production and service structure of a multifunctional farm encompasses all elements for determining independent variables, the matrix of the constraining conditions and the function of the optimization criteria. Factors which determine to which extent a specific model will adopt all of these parameters for defining dependent variables, constraining conditions and criteria function, include: the available information basis, assessment of how relevant individual parameters are in relation to independent variables and individual constraints, as well as the specific goal of the optimization. These issues were studied thoroughly over the long-term period by the authors of this paper (Šomođi, Novković, 1989; Novković, 1990, Novković, Šomođi, 1991; Novković et al. 2013, Husemann et al. 2012; Paunović et al. 2016).

Material and Methods

This paper is of a methodological nature. It presents an algorithm for solving of the model set as described above. The method applied for maximization of the effectiveness (net income) is classical linear programming, while the method applied for maximization of the efficiency (cost-effectiveness) is fractional linear programming.

Results and Discussion

Defining of the general mathematical model includes defining of independent variables, objective function and constraint matrix.

Independent variables

The mathematical model for optimization of a multifunctional farm can include four types of independent variables: crop production, livestock, primary processing of agricultural products and services.

Crop production

B_{cde} = crop area "c", of the variety (hybrid) "d" on the plot "e" (ha)
$B_{cde} \geq 0 \quad c = 1(1)i; \quad d = 1(1)j; \quad e=1(1)k;$
i = the number of crop production lines; j = the number of varieties / hybrids / individual production lines; k = the number of plots

Livestock

S_{lmn} = the number of structural heads of the livestock production line "l", of the breed "m", in the livestock keeping conditions "n"
$S_{lmn} \geq 0 \quad l = 1(1)p; \quad m = 1(1)r; \quad n =1(1)s$
p = the number of livestock production lines; r = the number of breeds of certain livestock types; s = the number of different livestock keeping conditions

Primary processing

P_g = the annual volume of the processed product "g" (unit of measure)
$P_g \geq 0 \quad g = 1(1)q;$ q = the number of types of processed products

Services

U_t = the type of the service "t"
$U_t \geq 0 \quad t = 1(1)y;$
y = the number of different types of services

Objective function

Maximum economic effectiveness is typically the objective function in the models of linear programming. In order to meet the demands of linearity, net income (gross margin), i.e. the difference between the production value and direct variable costs, is usually taken as a category which represents economic effectiveness. If all direct variable costs (costs of direct material, services and labor) are taken into account when determining the net income, then determination of the maximum net income is an indicator of the maximum profit; and if the cost of the farmers' own labor is not included into the calculation (as it is the case with farms), then the net income indicates the maximum earnings, i.e. newly generated values.
The other, equally important economic goal of business operations of agricultural business systems is efficiency. The basic measure of production and business efficiency is cost-effectiveness. Cost-effectiveness, as the ratio between the total income and total operating costs of the farm, is an economic category, which indicates to which degree the investments

in the production process and the business process are efficient. It is different from maximization of the net income, where fixed costs in the short term have no impact on the optimal production structure in determining the maximum cost-effectiveness.

Production effectiveness, measured by the net income, and production efficiency, measured by cost-effectiveness, are not mutually proportional categories. Since effectiveness is a measure of the absolute performance and efficiency is a measure of the relative performance of the production process, both categories are equally important economic objectives that must be taken into account in the planning process.

Maximum business effectiveness of a multifunctional farm:

$$\sum_{c=1}^{i}\sum_{d=1}^{j}\sum_{e=1}^{k} \mathbf{np_{cde}B_{cde}} + \sum_{l=1}^{p}\sum_{m=1}^{r}\sum_{n=1}^{s} \mathbf{np_{lmn}S_{lmn}} + \sum_{g=1}^{q} \mathbf{np_q\,P_g} + \sum_{t=1}^{y} \mathbf{np_tU_t = NP_{max}}$$

np_{cde} = planned net income per hectare; np_{lmn} = planned annual net income per structural head; np_g = planned annual net income per processing unit ; np_t = planned annual net income per unit of service; NP_{max} = maximum total net income of the farm

Maximum production efficiency:

$$\frac{\sum_{c=1}^{i}\sum_{d=1}^{j}\sum_{e=1}^{k} \mathbf{up_{cde}B_{cde}} + \sum_{l=1}^{p}\sum_{m=1}^{r}\sum_{n=1}^{s} \mathbf{up_{lmn}S_{lmn}} + \sum_{g=1}^{q} \mathbf{up_qP_g} + \sum_{t=1}^{y} \mathbf{up_tU_t}}{\sum_{c=1}^{i}\sum_{d=1}^{j}\sum_{e=1}^{k} \mathbf{vt_{cde}B_{cde}} + \sum_{l=1}^{p}\sum_{m=1}^{r}\sum_{n=1}^{s} \mathbf{vt_{lmn}S_{lmn}} + \sum_{g=1}^{q} \mathbf{vt_qP_g} + \sum_{t=1}^{y} \mathbf{vt_tU_t + FT}} = \mathbf{Ek_{max}}$$

up_{cde} = planned total income per hectare; np_{lmn} = planned annual total income per structural head; np_g = planned annual total income per processing unit; np_t = planned annual total income per unit of service; vt_{cde} = planned variable costs per hectare; vt_{lmn} = planned annual variable costs per structural head; vt_g = planned annual variable costs per processing unit; vt_t = planned annual variable costs per unit of service; FT = total fixed costs of the farm; Ek_{max} = maximum cost-effectiveness of the farm

Constraint matrix

For most farms, important constraining factors include the available area of the farm, labor or working hours, time spent using mechanization, animal reproduction rate and market sales. However, certain less obvious factors, such as planned crop rotation, also constrain the extent of the farmer's freedom in decision-making (Novković 1988).

1. <u>*Capacity constraints*</u>

Constraints of the land

$$\sum_{c=1}^{l}\sum_{d=1}^{j} B_{cde} = P_e$$

P_e = available area of the land of the plot “e” in hectares

Constraints of livestock capacity

$$\sum_{m=1}^{r} S_{imn} \leq K_{\ln}$$

K_{ln} = available capacity for keeping livestock of the production line "l" in the keeping conditions "n" in structural heads.

Processing capacity

$$P_g \le K_g$$

K_e = available capacity for processing of the product "g"

- **Service capacity**

$$U_t \le K_t$$

K_t= available capacity of the service "t".

2. Biotechnological constraints

$$\sum_{d=1}^{j}\sum_{e=1}^{k} B_{cde} \le c_c \sum_{e=1}^{k} P_e$$

c_c = coefficient of the maximum share of the crops B_c in the total area of the farm

3. Maximum (minimum) placement constraints

Crop production

$$\sum_{d=1}^{j}\sum_{e=1}^{k} q_{cde} B_{cde} \frac{>}{<} Q_c$$

Q_c = maximum possible (minimum required) amount of the product "c" that can be placed on the market in kg; q_{cde} = technical coefficient, which indicates the yield of the crop "c", of the variety / hybrid "d" on the plot "e" in kg/ha.

Livestock

$$\sum_{m=1}^{r}\sum_{n=1}^{s} q_{lmn} S_{lmn} \frac{>}{<} Q_l$$

Q_l = maximum possible (minimum required) amount of the livestock product "l" that can be placed on the market (kg, l, head)

q_{lmn} = technical coefficient, which indicates the yield of the livestock product "l", of the breed "m" in the keeping conditions "n" in kg (l, head)/structural head.

Processing

$$P_g \frac{>}{<} P_{gu}$$

P_{gu} = maximum possible (minimum required) amount of the product "g" that can be placed on the market in appropriate units of measure.

Services

$$U_t \frac{>}{<} U_{tu}$$

U_{tu} = maximum possible (minimum required) amount of the service "t" that can be placed on the market in appropriate units of measure.

4. Constraints linking interdependent production lines

Crop production – Livestock

$$\sum_{d=1}^{j}\sum_{e=1}^{k} q_{cde}B_{cde} - \sum_{l=1}^{p}\sum_{m=1}^{r}\sum_{n=1}^{s} c_{lmn}S_{lmn} = 0$$

c_{lmn} = technical coefficient, which indicates the annual demand of the structural heads of the livestock production line "l", of the breed "m" in the keeping conditions "n", for the field crop product "c".
The number of such constraints in the model will be equal to the number of the field crops used as raw materials for the farmer's own livestock production.

Crop production – Processing

$$\sum_{d=1}^{j}\sum_{e=1}^{k} q_{cde}B_{cde} - \sum_{g=1}^{q} c_g P_g \geq 0$$

c_g = technical coefficient, which indicates the annual demand of the processed product "g" for the field crop product "c".

Crop production – Services

$$\sum_{d=1}^{j}\sum_{e=1}^{k} q_{cde}B_{cde} - \sum_{t=1}^{y} c_t U_t \geq 0$$

c_t = technical coefficient, which indicates the annual demand of the service "t" for the field crop product "c".

Livestock production – Processing

$$\sum_{m=1}^{r}\sum_{n=1}^{s} q_{lmn}S_{lmn} - \sum_{g=1}^{q} l_g P_g \geq 0$$

l_g = technical coefficient, which indicates the annual demand of the processed product "g" for the livestock product "l".

Livestock production – Services

$$\sum_{m=1}^{r}\sum_{n=1}^{s} q_{lmn}S_{lmn} - \sum_{t=1}^{y} l_t U_t \geq 0$$

l_t = technical coefficient, which indicates the annual demand of the service "t" for the livestock product "l".

Processing – Services

$$P_g - \sum_{t=1}^{y} g_t U_t \geq 0$$

c_t = technical coefficient, which indicates the annual demand of the service "t" for the processing product "g".

5. *Constraints of direct labor*

$$\sum_{c=1}^{l}\sum_{d=1}^{j}\sum_{e=1}^{k} r_{cde}B_{cde} + \sum_{l=1}^{p}\sum_{m=1}^{r}\sum_{n=1}^{s} r_{lmn}S_{lmn} + \sum_{g=1}^{q} r_g P_g + \sum_{t=1}^{y} r_t U_t \leq R_u$$

r_{cde} / r_{lmn} / r_g / r_t = technical coefficient, which indicates the required annual number of working hours per capacity unit of crop production / livestock / processing; R_u = total available annual number of working hours of direct labor.

Since agricultural production is seasonal, it is possible to set constraint for certain periods of working peaks.

6. *Constraints of operative mechanization*

$$\sum_{c=1}^{l}\sum_{d=1}^{j}\sum_{e=1}^{k} mk_{cde}^{t}B_{cde} \leq MK^{t}$$

mk^{t}_{cde} = technical coefficient, which indicates the required number of working hours of the category of operative mechanization “mk”, per hectare of the independent variable in the time period “t”; $\mathbf{MK^t}$ = total available number of working hours of the category of operative mechanization in the time period “t”.

Conclusion

The general mathematical model for optimization of business operations on multifunctional farms represents a theoretical basis for constructing specific models of optimization on individual farms. Application of this model is useful because it provides the farmer with the possibility to choose between two optimal variants, as well as to define one’s maximum economic potential. Application of this model requires a good information basis, as well as constant monitoring of business activities on the farm and monitoring of external conditions and possibilities (price, placement...).

Abstract

There is growing importance of econometric analysis of intangible assets impact on the performance of companies, what seems apprehensive concerning the innovations, new technologies, brand, knowledge and other components of intangible assets for improving the companies' performance. To our knowledge, there are a few papers dedicated to the research of specifics of intangible assets impact on the performance of trading and retailing companies, food retailers, respectively. One of the reasons for this we find in lack of adequate data, especially for econometric analysis, because many companies do not enclose full data on intangible assets in their financial reports, or do it partially. Taking all this into account, we intend to elaborate the specifics and impact of intangible assets on the performance of global food retailers, with particular emphasis on Serbia. We ground our research on theoretical and methodological knowledge and reliable empirical data. The aim of the research is to thoroughly elaborate on theoretical and practical issues of non-material assets in retail. The knowledge of significance and the structure of non-material assets is fundamental prerequisite for its efficient management so as to meet the desired profit in concrete retail food company. As far as we know, there are no fully written papers dedicated to the analysis of intangible assets in retail food, especially in Serbia, in what we find our contribution to the treated problems. There is growing contemporary literature written on the general analysis of intangible assets of companies, both from the accounting point of view, and from its influence on performance. Nevertheless, as far as we know, there are no fully written papers dedicated to the analysis of specifics of size and structure of intangible asset in retail food. We strive to research the issue, especially on the examples of global, and food retailers in Serbia, in what we find scientific and professional contribution of this paper. Adequate managing of intangible investment can fulfil the desirable profits of retailing companies. Under the influence of different factors, above all technology innovations, development of private brand and advancement of knowledge, the share of intangible assets in total assets in trade and retail (food) differs among countries. So, for example share of intangible assets in total assets of retail (food) companies is Serbia is significantly lower compared to countries of developed market economies. It reflects their overall performance. That is why there should be more investments in creating intangible assets, especially private brand, information and communication technologies and advancement of knowledge. (**Jel classification:** L810, M420, Q320)

Key words: *innovation, customers, brand, technology, knowledge*.

Introduction

Intangible assets have profound influence on company's value, productivity of work (Marrocu, 2011) and performance in trading companies (including retailing, food retailers). Due to that, detailed analysis of the impact of intangible assets on the performance of companies is given a considerable importance. Starting with the significance of the issue, this paper lay emphasis to specifics and the impact of intangible assets on the performance of trading, especially retailing companies, food retailers. We aim at pointing that managers can exert its influence in improving the desired profits of trading companies (Christine, 2015), food retailers. Innovations, human resources, intellectual capital, information, goodwill etc. are regarded as crucial factors of creating companies' value and sustainable growth (Sorescu et al., 2011; Greuning, 2011; Vidracsu, 2015; Lev, 2004; Villalonga, 2004; Acito, 2007; Marrocu, 2011; Lukic et al., 2016; Lukic, 2017). In its character, they are nothing else than the elements of non-material investment (intangible assets), and inasmuch as of this, careful research attention is devoted to them in theory and practice. We will draw our attention to the specifics of their impact on the performance in retail food globally, and particularly in Serbia. The aim of the analysis is to point to the significance of managing intangible assets so as to accomplish targeted profit of retail companies, food retailers. The aim of the research is to thoroughly elaborate on theoretical and practical issues of non-material assets in retail (food). The knowledge of significance and the structure of non-material assets is fundamental prerequisite for its efficient management so as to meet the desired profit in concrete retail (food) company. As far as we know, there are no fully written papers dedicated to the analysis of intangible assets in retail (food), especially in Serbia, in what we find our contribution to the treated problems. There is growing contemporary literature written on the general analysis of intangible assets of companies, both from the accounting point of view, and from its influence on performance. Nevertheless, as far as we know, there are no fully written papers dedicated to the analysis of specifics of size and structure of intangible asset in retail (food). We strive to research the issue, especially on the examples of global, and (food) retailers in Serbia, in what we find scientific and professional contribution of this paper.

The primary hypothesis of the research is increasing significance of intangible assets on the performance of global (food) retailers. For that reason, it is necessary to manage non-material assets more effectively. Given hypothesis is also confirmed through empirical research conducted in retail (food) companies in Serbia.

Material and Methods

Basic methodology of research is founded on comparative analysis, ratio analysis and statistical analysis. For the sake of implementation of econometric analysis in the future it is necessary to develop unique enclosure system of intangible assets in financial reports of retails companies, especially in Serbia. It will contribute to better analysis of non-material assets in retail (food). (Primary restriction of research in this work is reflected in notion that reliable empirical data are not fully comparable since retail companies differently enclose data in financial reports. Partially, it was due to frequent normative change of International standards for financial reporting and others. Nevertheless, we consider that research results in this work can serve as basis for further theoretical, methodological and empirical analysis of the given issue, and especially to managers in retail to efficiently manage the non-material assets so as to make desired profit. In that we also find scientific and professional contribution of this paper.) Relevant data for the research in this work were collected from different sources, such as: literature, studies, papers, annual financial reports of analysed retail companies. Web sites also served as sources (Brand Finance, GIFT (Global Intangible Financial Track) 2016, May 2016; available at: http://brandfinance.com/images/upload/gift_report_2016_for_print.pdf (September 20, 2016) and (KPMG – The Application of IFRS: Retail companies, March 2013; available at: https://www.kpmg.com/Global/en/IssuesAndInsights/ArticlesPublications/ILine-of-Business-publications/Documents/LOB-retail-companies-march13.pdf (September 27, 2016). Data on trade and analysed retail companies in Serbia we collected from Business registers Agency of the Republic of Serbia.

Results and Discussions

The structure of assets in retail (food) is specific compared to other economy sectors, and so is the structure of intangible assets. This is due to the nature of its business – bulk purchasing and selling in small quantities of goods, primarily to end customers (Acito, (2007). In accordance with specifics of business operation in retail (food), there is system of (ratio) indicators of intangible value that has been developed (Acito, (2007). Adequate measure of intangible assets' contribution to the market value is considered to be Tobin's *q* racio (Dybvig, 2010). It is defined as relation of firm market value and its assets replacement value, i.e. Tobin's *q* = Total market value of firm / Total assets value of firm Reduced version of Tobin's Q ratio is: Tobin's *q* ratio = Market equity value / Account equity value In contrast to return on equity, as a measure of past firm performance, Tobin's *q* ratio refers to measurement of firm performance in the future (Villalonga, 2004; Acito, 2007). Table 1 illustrates top ten retailers by Q ratio.

Table 1. Top ten retailers by Q ratio

Company	Country	Q ratio
H & M Hennes & Mauritz AB	Sweden	6.465
Tractor Supply Company	U.S.	5.176
BİM Birleşik Mağazalar A.Ş.	Turkey	4.759
Next plc	U.K.	4.679
Inditex, S.A.	Spain	4.570
Dollar Tree, Inc	U.S.	4.514
Nike, Inc.	U.S.	4.353
The TJX Companies, Inc.	U.S.	4.338
Ross Stores, Inc.	U.S.	4.331
Fast Retailing Co., Ltd.	Japan	3.951

Source: Deloitte. Global Powers of Retailing 2015 Embracing innovation, available at: https://www2.deloitte.com/content/dam/Deloitte/fpc/Documents/secteurs/consumer-business/deloitte_global-powers-of-retailing_2015-en.pdf (September 30, 2016)

As we can see, retailers which prevail by Q ratio come from the United States of America. There are major differences in food retail between retailers in relation to Q ratio. This is shown by the data in Table 2.

Table 2. Tobin's Q ratio of food retailers

Food retailer	2000	2005	Changes
Whole Foods Market	2.53	5.71	3.18
SuperValu	0.56	1.08	0.52
Ingles Markets	0.76	0.97	0.21
Albertsons	1.09	0.82	-0.27
Winn-Dixie	1.02	0.59	-0.43
Ahold USA	1.46	0.86	-0.60
Kroger	1.65	0.98	-0.67

Source: Acito, (2007)

Altogether, Tobin's Q ratio is adequate measure of intangible assets and its impact on market value of retail companies. Non-material assets have been significant factor of performance in economy, especially in trade sector and retail (Yu, 2014, Mohr, 2014). There are differences among countries concerning intangible assets in service and retail sector and their share in gross domestic product. So, for example, share of non-material assets in gross domestic product in retail, hotel and transport amounted as follows: Japan 2.7% (2010), Korea 2.1% (2010), Germany 3.5% (2004), and UK 6.4% (2004) (Chun, 2015). Likewise, it differs among retail companies, types of store and category of products. Under influence of numerous controlled and uncontrolled factors, intangible assets in retail are dissimilar from country to country. Table 3 show non-material assets and intellectual capital of retail in the US for 2009.

Table 3. Non-material assets and intellectual capital in U.S. retail, 2009

	Intangible assets as a share of market value (%)	Intellectual capital on and off the balance sheets ($ billions)	Intellectual capital share in market value (%)	Economic competence on and off the balance sheets ($ billions)	Intangible assets: Intellectual capital + Economic competence ($ billions)
Retail	78.4%	$267	43.69%	$211	$478
Food retail	75.3%	$161	41.97%	$128	$288

Source: Hassett, (2011)

We came to conclusion that the share of non-material assets in market value of US retail is high, what is also the case in other countries with developed market economy. The fact that speaks in that favour is growing share of private brands in contemporary retail (Kelle, 2006).In other words, there is emerging power of brand as a component of non-material asset in retail. So, for example, in February 2016 the value of brand (in million dollars) of selected retail companies amounted: Wal-Mart (US) 53,657, Home Depot (US) 28,798, CVS Caremark (US) 22,891, IKEA (Sweden) 17,009, Target (US) 15,331, Aldi (German) 14,552, Lowe's (US) 12,712, Tesco (UK) 12,499 (According to: Brand Finance: Global 500 2016, The annual report on the world's most valuable brands, February 2016, available at: http://brandfinance.com/images/upload/global_500_2016_for_print.pdf) (September 21, 2016). To a great extent it determines the performance of global retail companies. There are also significant investments in development of new information and communication technologies and knowledge advancement (competences) of the employed in retail. Share of intangible assets in market value is also high in all companies (Vidrascu, 2015), including retailing. Table 4 shows the non-material value (assets) of selected retailers.

Table 4. The estimate of intangible assets of selected retail companies, (September 22), 2016

Company	Market value (billion dollars)	Accounting value (billion dollars)	Non-material value (billion dollars)	Share of non-material value in market value
Wal-Mart	222,62	83,61	139,01	62.44%
Home Depot – non food	156,71	6,32	149,68	95.51%
Target	39,45	12,96	26,49	67.14
Tesco	18,38	8,62	9,76	53.10%
Kroger	36,88	6,80	30,08	81.56

Note: Calculation performed by the author based on the data: Market Watch: Stock Market News - Financial News; We mark market value of firm with MV and accounting value with A, we came up with: Non-material assets = (MV – A). Source: http://www.marketwatch.com/ (September 22, 2016)

The data in the given table show high share of non-material value (assets) in market value of presented retailing companies. Therefore, it belongs to important factors of business success of the observed companies. The similar trend is with the other companies that operate on the global level. In order to thoroughly envisage the importance of non-material assets in retail, Table 5 shows the share of non-material assets in total assets of selected retailing companies for the period 2011 – 2015.

Table 5. Share of non-material assets in total assets of selected retail companies, 2012 – 2015

Company	2012	2013	2014	2015
Wal-Mart	10.67%	10.09%	9.52%	9.09%
Home Depot – non food	2.76%	2.84%	3.18%	3.39%
Costco	-	23.14%	23.22%	23.03%
Target	0.25%	0.22%	0.74%	0.72%
Tesco	9.09%	8.69%	7.57%	8.52%
Marks & Spencer	8.03%	9.13%	10.22%	10.46%

Note: Calculation performed by the author based on annual reports. Source: http://www.marketwatch.com/ (September 23, 2016)

Data in the given table show great share of non-material assets in total assets in retail companies Wal-Mart, Tesco and Marks & Spencer, in what we recognize the fact that those companies have major investments in innovation, as crucial factor of business success.
In order to deeply contemplate the importance of intangible assets in retail we will analyse data from company Fast Retailing. U Table 6 shows the data on intangible assets of company Fast Retailing for the period 2013 – 2015.

Table 6. Share of intangible assets in total assets of the company Fast Retailing, 2013 – 2015

	2013	2014	2015
Goodwill	4.10%	2.69%	2.33%
Other intangible assets	5.86%	4.73%	3.52%

Note: Calculation performed by the author. Source: Fast Retailing – Annual Report, available at: http://www.fastretailing.com/eng/ir/financial/bs_5yrs.html (October 4, 2016)

The data derived from this table indicate that the share of intangible assets (Goodwill and other intangible assets) in total assets of the company Fast Retailing is less compared to Wal-Mart and Mark & Spencer.
Unlike the trade sector, information and communication (IT) sector is unique to intangible assets influence on performance. As illustration, we will analyse the world wide known company Apple, which has very high level of intangible assets share in its economic value.
Data in the table show that In company Apple intangible assets participate in total value with 49%, what is very significant from the impact on total performance point of view. The peculiar is that only 3.4% of intangible assets is disclosed. As crucial factors of business performance, share of technology and marketing is substantial in the structure of intangible assets. Also, there is major share of brand value in total intangible assets. (Source: http://brandfinance.com/images/upload/gift_report_2016_for_print.pdf (September 19, 2016)
Given the fact that Delhaize Group (as part of Ahold Delhaize from 2016) does business in Serbia with important market share, we will analyse in detail its non-material assets with special insight into one of its entities which does business in Serbia (Delhaize Serbia). Table 7 show data on Goodwill and intangible assets share in total assets of Delhaize Group for the period of 2013 – 2015.

Table 7. Percentage share of Goodwill and intangible assets in total assets of company Delhaize Group, 2013 – 2015

	2013	2014	2015
Share of Goodwill in total assets (%)	25.52%	25.95%	26.58%
Intangible assets share in total assets (%)	6.31%	6.29%	6.13%
Intangible investment depreciation share in gross margin (%)	0.57%	0.56%	0.48%

Note: Calculation performed by the author based on Annual Report 2015 data
Source: Delhaize Group – Annual Report 2015, available at: https://annualreport.delhaizegroup.com/wp-content/uploads/2016/04/160407_DLZ_RA15_UK_WEB.pdf (October 3, 2016)

According to the data showed in the table, share of intangible assets in total assets in slightly higher than 6%. It is lower than in Wal-Mart (2015 – 9.09%) and Marks & Spencer (2015 – 10.46%). Intangible investment depreciation share in gross margin ranges from 0.48 – 0.57%. It is similar to other retail companies in the world (for example, Russia).
In order to envisage the trends of intangible assets development in Delhaize Group, Table 8 shows data on its market capitalisation for the period 2011 – 2015.

Table 8. Market capitalisation of company Delhaize Group, for the period 2011 – 2015

	2011	2012	2013	2014	2015
Market capitalisation (million €, end of year)	4423	3083	4425	6213	9339
Enterprise value (million €, end of year)	7082	5155	5899	7210	10119
Total capital (million €, end of year)	5416	5186	5073	5453	6171
Intangible assets (million €, end of year)*	-993	-2103	-648	760	3168
Intangible value share in market capitalisation (%)*	-22.45%	-68.21%	-14.64%	12.23%	33.92%

Note: Value of enterprise = Market capitalisation plus net debt. Net debt = Financial obligations minus cash. Financial obligations = Short-term loans plus long-term loans. *Calculation performed by the author. Source: Delhaize Group – Annual Report 2015, available at: https://annualreport.delhaizegroup.com/wp-content/uploads/2016/04/160407_DLZ_RA15_UK_WEB.pdf (October 3, 2016)

In the given table intangible assets is measured as difference between market capitalisation and total assets (as a measure of accounting value of the firm). It shows the tendency of positive increase in the last two years of the analysed period, what positively reflects in the performance of company Delhaize Group. Table 9 shows intangible assets of company Delhaize Serbia, (part of Ahold Delhaize since 2016) in 2014 and 2015.

Table 9. Intangible assets of company Delhaize Serbia, 2014 and 2015

	2014	2015	Index 2015/2014*
Intangible investment (000 RSD)	3,942,314	4,785,547	121,35
Goodwill	197,432	197,432	100,00
Depreciation of intangible investments	88,900	82,521	92,82
Material physical assets	35,895,916	38,945,414	107,65
Total assets	66,600,435	73,304,405	110,06
Total business expenses	71,646,608	73,853,030	103,07
Share of intangible assets in total assets (%)*	5.91%	6.52%	110,32
Relation between intangible assets and material physical assets*	0,1096 (10.98%)	0,1228 (12.28%)	111,83 (111,29)
Share of Goodwill in total assets (%)*	0.29%	0.26%	89,65
Share of depreciation of intangible assets in total operating expenses (%)*	0.12%	0.11%	91,66

Note: * Calculation performed by the author. Source: Delhaize Serbia Ltd., Belgrade, Notes to financial statements 31. December 2015. Business registers agency, The Republic of Serbia

According to the data in the given table, intangible assets in 2015 in Delhaize Serbia increased by 21.35% compared to 2014. The share of intangible assets in total assets of company Delhaize Serbia is on the level of parent company, considerably higher compared to average of total trade in Serbia, but it is lower in relation to companies such as Wal-Mart and Tesco. All in all, it has positive effect on its total performance, considering intangible assets as crucial factors of business success.
In order to enlighten the specifics of accounting treatment of intangible assets we will bring one case from concrete trading practice. So, for example retail company Delhaize Serbia applies the following concept of accounting treatment of intangible assets: “Intangible assets are non-monetary assets (they do not represent tangible physical assets) such as patents, licences, concessions, trademarks, hallmark, accounting software, franchise, investment in development of new products, processes and devices, copyright and other. There is a possibility that there will be an economic benefit for these resources in the period longer than one year, to the amount that exceeds costs. Intangible assets are initially measured by purchase price or cost price. After initial recognition, intangible assets are expressed as cost less accumulated depreciation and impairment. The right to use the land, even though it is limited to 99 years, due to the very essence and the anticipated conversion to ownership of the land, the Company is considered to have an indefinite useful life on land and after the expiry of this period, it has opportunity to turn the right to use to the right of ownership of construction land, without compensation. Subsequent expenditure on investments in intangible assets can be capitalized only regarding the expected future benefits of assets they refer to. All other expenses represent expenses for the period in which they were made. Depreciation of intangible assets starts with the following month in relation to the month in which the assets were available for use. The basis for depreciation is purchase price. Intangible assets are depreciated on straight-line method within five years, with depreciation rate of 20%. Depreciation method and useful life is estimated at the end of each reporting period and when necessary, they are corrected" (According to: Delhaize Serbia Ltd., Belgrade, Notes to financial reports 31. December 2015. Business registers agency, The Republic of Serbia). In 2015 depreciation rate of intangible assets in Delhaize Serbia was

20%, and the estimated lifetime 5 years (According to: Delhaize Serbia Ltd., Belgrade, Notes to financial reports 31. December 2015. Business registers agency, The Republic of Serbia). In the same (2015) year, depreciation of intangible assets participated in total expenditures with 0.060% (Calculation performed by the author based on the data: Delhaize Serbia Ltd., Belgrade, Notes to financial reports 31. December 2015. Business registers agency, The Republic of Serbia). The situation is similar in other retailing companies in Serbia (Mercator-S, IDEA). The share of intangible investment depreciation in total expenditures in trade is insignificant, and differs among countries. For example, in Russia 2014 it amounted: motor vehicle and repair 0.10%, wholesale 0.10%, retail 0.50% and social nutrition 0.40% (Torgovia v Rossii 2015, Statističeskij sbornik, Moskva, 2015).

Conclusion

Intangible assets gradually became crucial factor of retail companies' business success. There is increasing share of intangible assets in trade value and total assets of global (food) retailers. It specially refers to innovation, brand, knowledge and technology. Special system of intangible investments indicators for trading business was developed, within which more attention is paid to Tobin's Q ratio. Fundamental prerequisite for efficient managing is integrated approach in the analysis of indicators of intangible assets in retail (food) (based on econometric analysis). Adequate managing of intangible investment can fulfil the desirable profits of retailing companies. Under the influence of different factors, above all technology innovations, development of private brand and advancement of knowledge, the share of intangible assets in total assets in trade and retail (food) differs among countries. So, for example share of intangible assets in total assets of retail (food) companies is Serbia is significantly lower compared to countries of developed market economies. It reflects their overall performance. That is why there should be more investments in creating intangible assets, especially private brand, information and communication technologies and advancement of knowledge.

Abstract

Current global trends in the development of rural areas are increasingly developing in the direction of strengthening the role of the non-agricultural sector, which is synchronized with the development of agriculture. The objectives of this work were aimed at identifying the presence of non-agricultural activities in the area of Fruška gora (Vojvodina Province, Serbia), and their impact on rural development in this area. A survey was conducted in 2014 in the area of Fruška gora in order to achieve the objectives of this research. The research analyzed the attitudes of 117 residents of the area from different socio-economic categories. The sample of the respondents was relatively balanced by gender (53.8% females and 46.2% males), with greater participation of young and middle age respondents (aged under 50 years). The SPSS statistical package was used for the purpose of the statistical analysis of the obtained data. The research results show the positive orientation of the respondents regarding the economic importance of non-agricultural activities in rural development, as well as the development of agriculture. In this context, a significant number of the respondents highlighted tourism as the most important non-farm activity, and then forestry, fruit and vegetable processing and catering. The results indicate that there is a variety of choices for the respondents regarding the importance of certain forms of tourism for rural development in this area (agrotourism, sports and recreational tourism, wine tourism, religious tourism etc).

Key words: *non-agricultural sector, rural development, tourism, Fruška gora, survey.*

Introduction

Current trends in the world show that agriculture is no longer a dominant economic activity in rural areas, non-agricultural activities have received increasing attention. Strengthening the rural economy is often associated with the continual introduction of new, non-agricultural enterprises (Van der Ploeg et al., 2000). Also, there are frequent cases of agricultural households in rural areas having diversified economic activity, so agricultural and non-agricultural activities co-exist. Reardon at al. (1998) point out that there are production linkages between the farm and non-farm sectors:

- The linkage is upstream when growth in the farm sector induces the non-farm sector to increase its activities by investing in productivity or additional capacity for supplying inputs and services to the former.
- The linkage is downstream when the non-farm sector is induced to invest in capacity to supply agroprocessing and distribution services, using farm products as inputs.

Haggblade et al. (2010) define the key components of the rural non-farm economy are: mining, manufacturing, utilities, construction, commerce, transport, financial, personal, and government services, as well as agroprocessing (the transformation of raw agricultural products by milling, packaging, bulking, or transporting). Diversification of the rural economy can contribute to (Bogdanov et al., 2007):

- accelerating the growth of the local economy,
- reducing the gap between rural and urban areas, and
- reduction of rural poverty.

The area of Fruška gora occupies the southeastern part of the Autonomous Province of Vojvodina (Republic of Serbia). This unique geographical area extends over an area of 139,430.01 ha, and the National Park "Fruška gora" is located in the center of this area. There are eight territorial-administrative units in this area (municipalities Bačka Palanka, Beočin, Irig, Inđija, Šid, Petrovaradin, Sremski Karlovci, Ruma and town Sremska Mitrovica). The settlements within the area of Fruška gora are mostly rural, except the two municipalities Petrovaradin and Sremski Karlovci that have the attributes of urban communities (Njegovan, Pejanović, 2009; Pejanović, Njegovan, 2011). Fruška gora as rural area is faced with a number of developmental problems, where infrastructural development is crucial to the survival of the population in this area (Njegovan et al., 2011; Đukić, Pejanović, 2014). The main economic activity in the area of Fruška gora is agriculture (Pejanović et. al., 2012). According to Spatial Plan for the special purpose of Fruška gora until 2022, in this area beside agriculture, there are several activities: forestry, tourism, catering, mining, trade, crafts, industry, transport, public utilities. Developmental characteristics of existing activities in the Fruška gora are as follows (Official Gazette of the AP Vojvodina, 2004):

- there is a different level of development of certain economic areas in relation to available resources, the comparative advantages of the area and the real expressed needs;
- there is a concentration of the population, the capacity of industry, trade, service industries and hospitality in the following settlements: Beočin, Sremski Karlovci, Petrovaradin, Šid and Irig, as a result of the existing raw materials basis and favourable conditions for transport links with broader region;
- the use of natural and man-made comparative advantages is incompletely and unevenly, particularly in the field of agriculture (fruit growing, viticulture, animal husbandry), as well as tourism and catering industry;
- excluding economic development on the line Sremski Karlovci-Petrovaradin-Beočin-Šid, basically it can be observed that the area has a picture of an under-developed and the monofunctional economy in stagnation;
- agriculture is the dominant economic activity.

The purpose of this study is to determine the presence of non-agricultural activities in the area of Fruška gora, and their impact on rural development in this area.

Material and Methods

For the purpose of this research was made a specific questionnaire where questions were close-ended type and the five point Likert scale was used. The survey was conducted in 2014 in the area of Fruška gora (Autonomous Province of Vojvodina (Republic of Serbia), which included 117 respondents. A standard type questionnaire was applied which consisted of six questions. The questionnaire is structured on three levels. The first level is the identification part consisting of sociodemographic questions (gender, age and interest group affiliation). The second level of the questionnaire consisted of questions aimed at the identification and significance of certain non-agricultural activities, and the third level of the questionnaire concerned the determination of the significance of certain forms of tourism in the area of Fruška gora. During the research there were obstacles due to the different level of education of the respondents, so that their answers do not have an equal value. Descriptive statistical method was used in order to adjust the survey data (arithmetic mean, median, mode, and standard deviation). Data were analyzed with the SPSS software package.

The purpose of this study is to determine the presence of non-agricultural activities in the area of Fruška gora, and their impact on rural development in this area.

Results and Discussion

The socio-economic structure of respondents included the different categories: municipal/city administration, regional organization, the media, non-government organization, financial organization, a public company, the private sector: industry, service sector, agriculture, hunting, forestry, fisheries, water management (table 1). The sample of the respondents was relatively balanced by gender (53.8% females and 46.2% males), with greater participation of young and middle age respondents (aged under 50 years).

Table 1. Socio-demographic structure of respondents

Variables	Frequency	%
Interest group		
municipal/city administrations	8	6.8
regional organizations	3	2.6
the media	1	0.9
academic institutions	0	0
non government organizations	5	4.3
financial organizations	6	5.1
public companies	9	7.7
private sector (industry)	7	6.0
private sector (service industries)	39	33.3
private sector (agriculture, hunting, forestry, fishery, water management)	32	27.4
other	7	6.0
Gender		
female	63	53.8
male	54	46.2

tourism	54	46.2
industry	3	2.6
other service activities	6	5.1
do not know or have no opinion about it	1	0.9
Total	117	100

Source: Author's calculation based on the survey data

Assessing the important of current economic activity in the area of Fruška gora, respondents (table 2) highly valued tourism (46.2%) and agriculture (45.3%). Although previous studies (Njegovan et al., 2011; Đukić, 2015) have shown that agriculture was the dominant economic activity. In this study was observed that the respondents did not give such priority to agriculture. Non-agricultural activities which respondents most valued are tourism, forestry, processing of fruits and vegetables, catering, where the average values were in the range of 3.22 to 3.44, the values of mode for all variables were 4. The standard deviation for those variables was less than 1 which indicated the high level of agreement among the respondents. Contrary to that, energy, mining, industry and civil engineering are non-agricultural activities (according to the respondents) did not have any significant development potentials, where the average values were in the range of 1.83 to 2.03. Between these two extremes, it can be noticed something more important potentials of other non-agricultural activities: processing of milk and meat, water management, production of renewable energy, traditional crafting, trade, transport and communications and other service activities. The average value for those variables were in range of 2.45 to 2.80 (table 3).

Table 3. The potential of development of non-agricultural activities in the area of Fruška gora

Variables	Mean	Mediana	Mode	Standard deviation
Processing of Fruits and Vegetables	3.41	4.00	4.00	0.767
Processing of Milk and Meat	2.74	3.00	3.00	1.070
Forestry	3.44	4.00	4.00	0.814
Water Management	2.54	3.00	3.00	1.087
Production of Renewable Energy	2.57	3.00	3.00	1.140
Tourism	3.60	4.00	4.00	0.732
Traditional Crafting	2.81	3.00	Multiple	1.159
Trade	2.50	3.00	3.00	1.149
Catering	3.22	3.00	4.00	0.975
Other Industrial Activities	1.94	2.00	1.00	1.003
Other Service Activities	2.56	3.00	3.00	1.102
Transport and Communications	2.45	3.00	3.00	1.082
Mining and Energy	2.03	2.00	1.00	1.062
Civil Engineering	1.83	1.00	1.00	1.036

Table 4. The importance of certain forms of tourism in the context of rural development of Fruška gora

Variables	Mean	Mediana	Mode	Standard deviation
Agrotourism	3.35	3.00	3.00	0.735
Wine Tourism	3.44	4.00	4.00	0.803
Hunting Tourism	3.21	4.00	4.00	1.022
Spa Tourism	3.17	3.00	4.00	0.959
Fishing Tourism	2.70	3.00	3.00	1.069
Ecotourism	3.14	3.00	3.00	0.890
Geotourism	2.75	3.00	3.00	0.991
Sports and Recreational Tourism	3.36	4.00	4.00	0.845
Cultural Tourism	3.38	4.00	4.00	0.935
Religious Tourism	3.40	4.00	4.00	0.799
Gastronomic Tourism	2.93	3.00	3.00	1.006
Manifestation Tourism	3.07	3.00	3.00	0.917

Source: Author's calculation based on the survey data

Respondents had the opportunity to assess the importance of certain forms of tourism in the context of rural development of Fruška gora (table 4). According to their opinion, the greatest development potentials have the following forms of rural tourism: wine tourism, agrotourism, religious tourism, cultural tourism, and sports and recreational tourism. The average values for these variables mean value were in the range of 3.36 to 3.44, the values of mode for all variables were 4. The survey results indicate that hunting tourism, spa tourism, manifestation tourism and ecotourism had mediocre development potentials, while fishing tourism, geotourism and gastronomy tourism had the least development potentials. In most of these variables the standard deviation was less than one, and it can be noted that there was a high degree of agreement among interviewees on this issue.

Conclusions

The improvement of rural areas implies most often their change, and above all their economic structure. Alongside agriculture, a variety of other non-agricultural activities can be found within rural areas. The results of the research showed a significant degree of agreement of the respondents regarding the possibility of diversification of the rural economy in the area of Fruška gora, and tourism was given almost the same importance as agriculture. These results were in line with the real state of the development of rural economy in the area of Fruška gora. It should be emphasized that this area possesses significant potential for the development of other non-agricultural activities, which have not been significantly used. In this regard, the results of the research showed that this area had industrial potential, since forestry and food industry had the greatest potential for development in the area of Fruška gora. When it comes to the services sector, respondents highly valued the potentials of tourism and hospitality for the further development of this area. Tourism in rural areas gives a good basis for securing additional activities in agricultural holdings. Accordingly, the results of the research provide information that agrotourism and wine tourism have significant potentials in the area of Fruška gora. In addition, this area has the potential to develop tourism that is not closely related to agricultural resources (religious tourism, cultural tourism, and sports and recreational tourism). Having all this in mind, there are specific circumstances for the area of Fruška gora that should be taken into consideration when planning the rural development, primarily through the provision of investment for the development of non-agricultural activities, as well as rural infrastructure.

Abstract

Vojvodina is a rural area that is located in the northern part of the Republic of Serbia. The authors analyzed seven administrative districts of Vojvodina which meet the criteria for classification at NUTS 3 level. The research had two objectives: (1) determining socioeconomic disparities as a development factors of rural areas of Vojvodina (at the level of administrative districts); (2) clustering of Vojvodina`s districts based on selected socioeconomic indicators. The following socioeconomic indicators were used for comparison of Vojvodina`s districts: population density, dependency ratio, the share of the population with secondary, higher and university education, as well as the average net salary. Authors ranked Vojvodina`s districts for two reference periods (2010 and 2015), using the obtained values of selected indicators. Statistical software Statistica 13.2. was used for the purposes of the cluster analysis, and the results were displayed in the form of dendrograms. The results showed that there is an imbalance of development in Vojvodina`s rural districts in the context of selected socioeconomic indicators. In accordance with this, the authors concluded that rural area of Južnobački district had the most favourable socioeconomic profile. By contrast, two rural districts of Banat (Severnobanatski and Srednjebanatski) had extremely unfavourable socioeconomic characteristics. The authors estimate that there will be no drastic changes in socioeconomic characteristics of Vojvodina`s districts in the coming period.

Keywords: *socioeconomic indicators, rural districts, Vojvodina, cluster analysis.*

Introduction

Rural development indicators serve to measure different dimensions of rural development. Socioeconomic indicators of rural development are different depending on the applied methodology. According to the OECD methodology (UNECE, FAO, OECD, WB, Eurostat, 2007) rural development indicators are defined through four groups of topics: population and migration; economic structure and performance; social well-being and equity; environment and sustainability. Within the indicators of rural development of the European Union (UNECE, FAO, OECD, WB, Eurostat, 2007) there is a narrow group that relates to the following areas: population and migration - demographic structure and evolution; social well-being - quality of life; economic structure and performance. Rural Development Indicators of the World Bank for development (UNECE, FAO, OECD, WB, Eurostat, 2007) are divided into the following groups: basic socio-economic data; enabling environment for rural development; broad based economic growth for rural poverty reduction; natural resource management and biodiversity; social well-being (education and health). FAO rural development indicators (UNECE, FAO, OECD, WB, Eurostat, 2007) are classified by groups: poverty alleviation with equity; access to land, water and other natural resources; access to inputs, markets and services; development of non-farm rural activities; education, training and extension; growth. In the case of rural regionalization of the area of AP Vojvodina (Njegovan, Pejanović, 2009) there are three groups of indicators: socioeconomic indicators, indicators for the agriculture sector and indicators of living and welfare conditions were used. In the analysis of socio-economic indicators of AP Vojvodina were used the following indicators (Njegovan, Pejanović, 2009): population density, dependency ratio, share of the population with secondary, higher and university education and average net salary.

Respecting the criteria of Eurostat, it is possible to divide the territory of AP Vojvodina into NUTS territorial units (Njegovan, Pejanović, 2009). Accordingly, the rural area of AP Vojvodina can be divided into NUTS level 2, where three regions are defined: Bačka, Banat and Srem. Administrative districts represent NUTS 3 territorial units (Južnobački, Severnobački, Zapadnobački, Srednjebanatski, Severnobanatski, Južnobanatski and Sremski). In determining rurality of areas in Vojvodina by the OECD methodology, six out of a total of seven districts (Zapadnobački, Severnobački, Severnobanatski, Srednjebanatski, Južnobanatski and Sremski) can be considered predominantly rural regions because more than 50% of the population lives in rural municipalities. Južnobački district only meets the criteria for partial (mixed) rural regions where about 44.5% of the inhabitants live in rural areas (Njegovan, Pejanović, 2009).

Previous studies of rural development of Vojvodina indicate that the limiting factors for this rural area are processes of depopulation and deagrarization (Pejanović, 2010). Also, Čobanović and Petrović (2006) have found that there has been a significant change in the rural structure of AP Vojvodina, which is evident in the processes of deagrarization, senilization and depopulation. Rodić et al. (2013) point out that the demographic characteristics of the rural population might be a serious constraint on rural economy diversification and rural development in Vojvodina, so that decision makers must be aware of this and adjust development policies to the existing conditions. Ivkov et al. (2007) point to problems in the labour market (high unemployment, high hidden unemployment and insufficient mobility of the labour force). Košić et al. (2015) highlight the following elements of rural development in the area of AP Vojvodina: out of 465 inhabited places in the Autonomous Province of Vojvodina in total, 415 are rural settlements, and an average Vojvodina rural settlement has around 2,200 inhabitants and 22.94% of them are older than 60.

Material and Methods

The basic assumption in this research refers to the possibility of development disparities in the socioeconomic dimension of rural development of the AP Vojvodina. The research had two objectives: (1) determining socioeconomic disparities of Vojvodina (at the level of administrative districts); (2) clustering of Vojvodina`s districts based on selected socio-economic indicators. As a source of data, the authors used information available from Republic Institute for Statistics of Serbia. The methodological framework in this paper is the analytical-synthetic method, method of comparison, historical method, and from the statistical methods cluster analysis was used. Statistical software Statistica 13.2. was used for the purposes of the cluster analysis, and the results were displayed in the form of dendrograms. The time frame of observation includes the period of the second decade of the twenty-first century.

Results and Discussion

Socioeconomic indicators are indicators that can be defined as general. This group includes those variables that relate to: the population (total population; population density; age, gender, education and occupational structure of the population), salary (average net salary denominated in local currency), total area, etc. The following socioeconomic indicators were used in this research:

- population density (PD),
- dependency ratio (DR),
- share of the population with secondary, higher and university education (EDU)
- average net salary (ANS).

Population density is calculated as the number of inhabitants per square kilometer, and in general this indicator is used as a criterion for determining rural areas. Dependency ratio is an indicator that shows how much of the working population is burdened with dependent non-working population. This indicator is calculated as the ratio of non-working segments of population (younger than 15 and older than 65 years) and the working part of the population (aged 15 to 65 years). The share of the population with secondary, higher and university education is significant indicator for assessment of the extent to which the favourable educational structure of the population. The indicator which refers to average net salary, takes into account those salaries generated by operations in a given territory (municipality, district...).

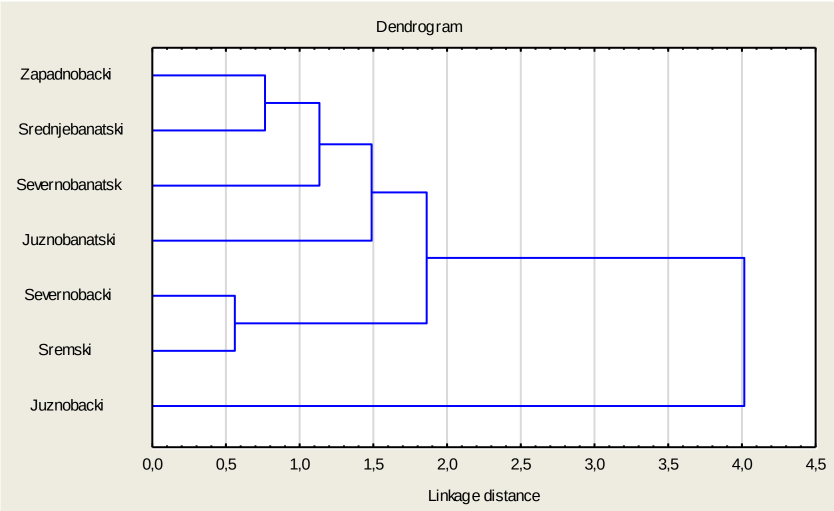
Based on the table below (table 1), it can be noticed that Južnobački district has the most optimal values of socioeconomic indicators for 2010 (the table shows the ranking of the rural districts of AP Vojvodina for the observed indicators). This district had the highest values for: population density (151 inhabitants /km^2); the share of the population with secondary, higher and university education (59.89%) and average net salary (36,327 dinars). Also, this district had the lowest value for the dependency ratio (44.12%). Somewhat more favourable values of socioeconomic indicators had Severnobački district, with the values for: population density (107 inhabitants/km^2), dependency ratio (46.06%), share of the population with secondary, higher and university education (52.17%) and average net salary (30,998 dinars). The relatively low values relating to (table 1): population density had Srednjebanatski district (59 inhabitants/km^2) and Severnobanatski district (65 inhabitants/km^2); share of the population with secondary, higher and university education had Severnobanatski district (46.87%) and Južnobanatski district (49.67%), and average net salary had Sremski district (29,442 dinars) and Zapadnobački district (30,291 dinars). The relatively high values for the dependency ratio have Srednjebanatski district (47.69%) and Severnobanatski district (47.51%),

Table 1. Socioeconomic indicators for 2010 (by rural areas of AP Vojvodina)

District	PD*	Rank*	DR* (%)	Rank*	EDU* (%)	Rank*	ANS (dinars)	Rank*
Zapadnobački	80	4	47.28	3	52.43	6	30,291	2
Južnobanatski	70	3	46.70	4	49.67	2	35,212	6
Južnobački	151	7	44.12	7	59.89	7	36,327	7
Severnobanatski	65	2	47.51	2	46.87	1	30,467	3
Severnobački	107	6	46.06	5	52.17	5	30,998	4
Srednjebanatski	59	1	47.69	1	52.01	4	32,358	5
Sremski	93	5	46.04	6	51.00	3	29,442	1

**Authors' calculation*
Source: www.stat.gov.rs

Cluster analysis for 2010 for the observed indicators gave the distribution of the rural districts of AP Vojvodina to four clusters. Within the first cluster belongs Južnobački district, which from all other districts stood out with the most favourable values of socioeconomic indicators. The second cluster includes two districts: Sremski and Severnobački. These two districts had a somewhat higher density of population and a lower burden of the working population with dependent non-working population than other districts (except Južnobački district). Within the third cluster is the Južnobanatski district, which compared to other districts, had relatively higher average net salaries (except Južnobački district). The fourth cluster consists of three districts: Severnobanatski, Srednjebanatski and Zapadnobački. Those three districts had the highest burden of the working population with a dependent non-working population (dendrogram 1).



Dendrogram 1. Cluster analysis of socioeconomic indicators by rural areas of AP Vojvodina for 2010

**Authors' calculation*
Source: www.stat.gov.rs

Based on the table below (table 2), it can be noticed that the Južnobački district had the most optimal values of socioeconomic indicators for 2015. This district had the highest values for: population density (153 inhabitants/km^2), share of the population with secondary, higher and university education (71.32%), and average net salary (47,445 dinars). Also, this district had the lowest value for the dependency ratio (43.04%) Somewhat more favourable values of socioeconomic indicators had Sremski district-population density (87 inhabitants/km^2), dependency ratio (43.56%), share of the population with secondary, higher and university education (63.76%) and average net salary (39,195 dinars). The relatively low values relating to (table 2): population density had Srednjebanatski district (56 inhabitants/km^2) and Severnobanatski district (61 inhabitants/km^2); share of the population with secondary, higher and university education had Severnobanatski district (57.44%) and Južnobanatski district (61.44%), and average net salary had Zapadnobački district (37,593 dinars) and Severnobanatski district (38,630 dinars). The relatively high values for the dependency ratio had Severnobanatski district (46.21%) and Zapadnobački district (46.10%).
Cluster analysis for 2015 for the observed indicators gave the distribution of the rural districts of AP Vojvodina to four clusters. Within the first cluster belongs Južnobački district, which from all other districts stood out with the most favourable values of socioeconomic indicators. The second cluster includes two districts: Sremski and Južnobanatski. These two districts had a lower burden of the working population with dependent non-working

population than other districts (except Južnobački district). Within the third cluster is the Severnobanstki district which, in relation to other districts had the most unfavourable constellation of observed socioeconomic indicators. The fourth cluster consists of three districts: Severnobački, Srednjebanatski and Zapadnobački. Those three districts had a mediocre burden of the working population with dependent non-working population and the share of the population with secondary, higher and university education (dendrogram 2). This constellation of the values of socioeconomic indicators as development factors of the rural development of AP Vojvodina (for 2010 and 2015) indicates that there is no balanced development of this area.

Accordingly, socioeconomic characteristics as a factor of rural development of AP Vojvodina give an expression of the differentiation of rural districts for both observed years: Južnobački district-most developed (leader), Sremski district- developed, Zapadnobački, Južnobanatski, Severnobački and Srednjebanatski districts-in development, and Severnobanatski-undeveloped.

Table 2. Socioeconomic indicators for 2015 (by rural areas of AP Vojvodina

District	PD*	Rank*	DR* (%)	Rank*	EDU* (%)	Rank*	ANS (dinars)	Rank*
Zapadnobački	72	4	46.10	2	63.40	5	37,593	1
Južnobanatski	67	3	44.87	5	61.44	2	45,928	6
Južnobački	153	7	43.04	7	71.32	7	47,445	7
Severnobanatski	61	2	46.21	1	57.44	1	38,630	2
Severnobački	102	6	45.61	3	62.54	4	39,216	5
Srednjebanatski	56	1	45.31	4	61.98	3	39,054	3
Sremski	87	5	43.56	6	63.76	5	39,195	4

Dendrogram 2. Cluster analysis of socioeconomic indicators by rural areas of AP Vojvodina for 2015

**Authors' calculation*
Source: www.stat.gov.rs

Conclusions

The results of the research show that in terms of socioeconomic conditions there is a very unbalanced development of the rural districts of AP Vojvodina. Socioeconomic characteristics as a factor of rural development of AP Vojvodina give an expression of the differentiation of rural districts for both observed years: Južnobački district-most developed (leader), Sremski district- developed, Zapadnobački, Južnobanatski, Severnobački and Srednjebanatski districts-in development, and Severnobanatski-undeveloped. Južnobački district for both periods had a much higher value of selected socioeconomic indicators. By contrast, Severnobanatski district had extremely unfavourable socioeconomic characteristics. During 2010, Severnobački district had somewhat more favourable development of the socioeconomic dimension of rural development. However, already in 2015, that constellation of socioeconomic characteristics of rural development was more favourable in Sremski district. The authors emphasize that it is realistic to expect that in the future Južnobački district will continue to maintain its dominance over the socioeconomic framework of rural development. A somewhat more favourable development of socioeconomic indicators of rural development can be expected in two districts: Sremski and Severnobački, while these indicators will remain unchanged for other districts. The authors conclude that it is necessary to take into account the socioeconomic specificities of all districts of AP Vojvodina in the further planning of rural development.

THE POTENTIALS FOR ORGANIC PRODUCTION OF SERBIA AND OTHER EUROPEAN UNION (EU) CANDIDATE COUNTRIES

Sanja ĐUKIĆ*, Mirela TOMAŠ-SIMIN, Janko VESELINOVIĆ

University of Novi Sad, Faculty of Agriculture, Department of Agricultural Economics and Rural Sociology, Novi Sad, Serbia
*Corresponding author: sanja.djukic@polj.edu.rs

Abstract

Organic agriculture is an important element of agricultural and environmental policy of the European Union (EU), which aims to ensure the sustainability of agriculture and environmental protection. In this paper, the authors analyzed the potential for organic production of countries that are candidates for membership in the European Union (Albania, FYR Macedonia, Montenegro, Serbia and Turkey). The authors analyzed three characteristics for observed countries manifested during the second decade of the XXI century: 1) legal framework and support policy, 2) agricultural area for organic production (including those areas that are under conversion), 3) other areas that are in a broader context classified under organic areas, 4) the number of participants in organic production (producers, processors, importers and exporters). As a source of data, the authors used information available from: Research Institute of Organic Agriculture (FiBL), International Federation of Organic Agriculture Movements (IFOAM), as well as data from the Ministry of Agriculture and Environment of the Republic of Serbia and the Republic Institute for Statistics of Serbia. The research results showed that the greatest potential for organic production has Turkey. Turkey has the highest representation of agricultural organic areas and the most developed network of participants in organic production. After Turkey, significant potential for organic production has Serbia, which recorded the highest growth of organic agricultural areas, and FRY Macedonia with the largest total organic area.

Keywords: *Potentials, Organic production, European Union candidate countries, Serbia.*

Introduction

Consumer awareness in terms of quality and health-safe food and growing ecological movements have led to more intensive growth of organic agriculture in the world during the 20th century. During 1972, IFOAM was formed (International Federation of Organic Agriculture Movements), and only eight years after the same organization brings basic principles on organic production. On these principles are designed other documents of the European Union on organic farming. In the present conditions, in Europe Union there are several regulations: Council Regulation (EC) No 834/2007, No 889/2008 and No 1235/2008, as well as some updates the European Commission for organic yeast, organic aquaculture and organic wine.

In the context of Europe Union (EU) enlargement towards the Balkans, at the moment the current candidacy five countries: Albania, The Former Yugoslav Republic of Macedonia, Montenegro, Serbia and Turkey. Unlike Montenegro, Serbia and Turkey, The Former Yugoslav Republic of Macedonia and Albania have not yet started accession negotiations with the European Union. The European Union strongly supports the accession of the candidates from Western Balkans states to World Trade Organization (WTO) membership.

Turkey, Albania, the Former Yugoslav Republic of Macedonia and Montenegro are already WTO members, while negotiations with Serbia are still in progress. In the framework of an analysis of organic production potential of the EU candidate countries, Bteich et al. (2014) emphasized that all the EU candidate countries have already started the process of harmonising their national laws on organic production, but Serbia and Former Yugoslav Republic of Macedonia are particularly well advanced in the process.

Material and Methods

The basic assumption in this research stems from the belief that there are different potentials for the development of organic agriculture among the candidate countries for EU membership. Accordingly, the main goals in this paper are focused on determining factors for organic production of countries that are candidates for membership in the EU (Albania, FYR Macedonia, Montenegro, Serbia and Turkey). As a source of data, the authors used information available from: Research Institute of Organic Agriculture (FiBL), International Federation of Organic Agriculture Movements (IFOAM), as well as data from the Ministry of Agriculture and Environment of the Republic of Serbia and the Republic Institute for Statistics of Serbia. The methodological framework in this paper is the analytical-synthetic method, method of comparison, as well as historical method, while the time frame of observation includes the period of the second decade of the twenty-first century.

Results and Discussion

Legal framework and support policy (subsidies)

Legislation on organic production in Albania exists since 2004, when it was adopted the Law on the Production, Processing, Certification and Marketing of “Bio” Products. Also, there is a subsidy scheme for organic farmers since 2008. In that context, Bernet and Kazzazi (2012) highlighted the constraints that exist in this field: “the lack of structures to allocate these subsidies, the unclear and complicate procedures, and the relatively small amounts per farm hampered the efficiency of this new measure”. In FYR Macedonia the Law on Organic Agricultural Production was adopted in 2004, and there is also The Law on Agricultural Development Support. El Bilali et al. (2014) noticed that organic production in Macedonia is still in an early stage of development, but there are aggressive marketing and high support from government for this sector. Funds for organic production are divided between the different segments of the supply chain: production, processing and trade (Vittuari, 2011). In Montenegro the organics law was adopted 2004, and there are payments granted under a special scheme. Since 2009, direct payments in organic agriculture per hectare and livestock unit have been introduced (National Action Plan for the Development of Organic Agriculture 2012-2017, MARD, 2012). Legislation on organic production in Serbia was adopted 2010, and the Rulebook on the control and certification of organic production and organic production methods in 2011. The legal framework for subsidies in organic production of Serbia is provided through two acts: The Law on Subsidies for Agriculture and Rural Development and The rulebook regulating the subsidies for organic production. Incentives can be achieved at a premium for milk produced with organic production method, then in organic crop production, followed by the recovery of plant nutrition products are allowed for use in organic crop production, as well as in organic livestock production (Nikolić et al., 2017). Nikolić et al. (2017) also noted a reduced level of incentives for organic production in 2016 (747,359.87 euro), compared to the level of incentives for 2013 (1,745,200.70 euro). In Turkey the organics law was adopted 1994. Turkish organic producers can also make use of additional direct income support payments since 2005, but the level of state recognition and the financial support for organic agriculture are really insufficient (Özbilge, 2007).

Agricultural area for organic production

There were 507.345 hectares of organic agricultural land in 2015, including in conversion areas in EU candidate countries. Turkey has the largest total agricultural area under organic production in 2015 (486.069 hectares) compared to other EU candidate countries (chart 1). However, in 2015, the organic share of total agricultural land was the highest in Montenegro (1.4%). With respect to other candidate EU countries, in 2015 Albania had the lowest total organic agricultural area (515 hectares), and the organic share of total agricultural land (0.04%) (chart 2).

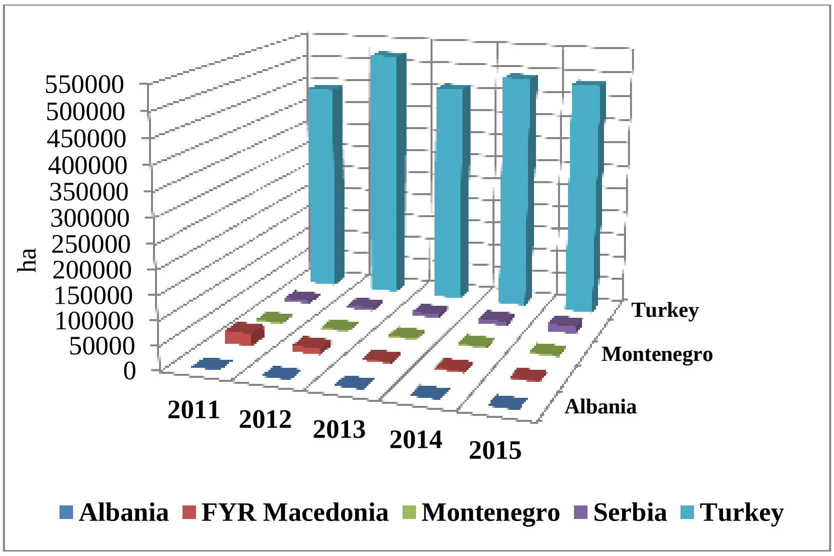

Chart 1. Total organic agricultural area by country in hectares (2011-2015)

Source: FiBL, 2017

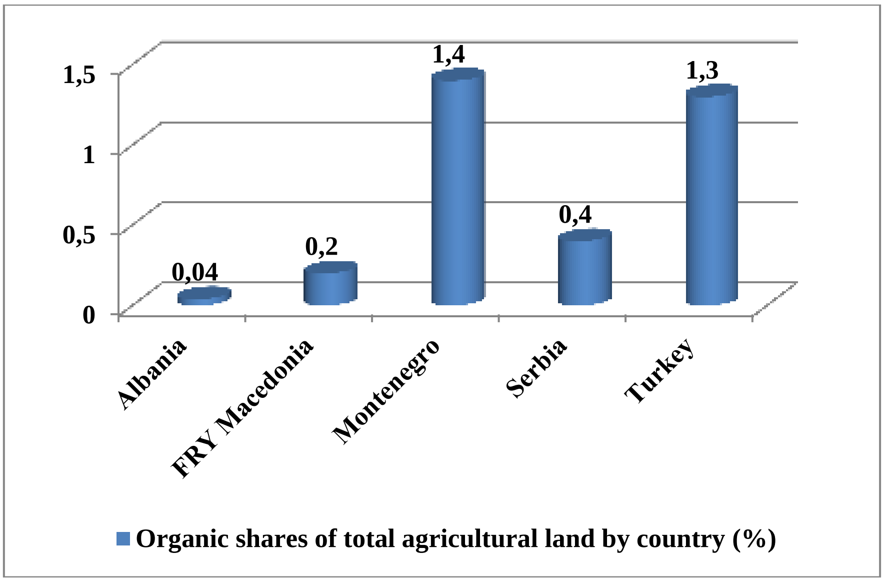

Chart 2. Organic shares of total agricultural land by country (%) (2015)

Source: FiBL, 2017

In the observed period, all EU candidate countries (except FRY Macedonia) recorded the growth of agricultural land under organic production (table 1). The highest growth rate of agricultural land under organic production in the period from 2011 to 2015 was recorded in Serbia (19.66%), while there was a decline in these areas in FRY Macedonia (-39.32%).

Table 1. Annual rate of change of the total organic agricultural area by country (2011-2015)

Country	Annual rate of change (2011-2015)*
Albania	2.83
FRY Macedonia	-39.32
Montenegro	1.4
Serbia	19.66
Turkey	1.89

Source: Authors' calculation based on FiBL data

Other areas that are in a broader context classified under organic areas

Distributions of other areas that can be classified as organic surface are different in the EU candidate countries (table 2). During 2015, FYR Macedonia in relation to other observed countries had a major area of its territory falling within other organic surfaces (8,122 hectares grazed non agricultural areas and 556,600 hectares areas as wild collection). Except Macedonia, significant presence of other organic surfaces (for 2015) was in Albania (467,783 hectares of the wild collection) and in Montenegro (139,809 hectares of the wild collection).

When looking at the total organic areas in the EU candidate countries, a completely different picture is obtained about the potentials of organic farming for observed countries. Namely, during 2015, Macedonia stood out with the highest total organic area in relation to the other countries (566,886 hectares). The areas under the pastures in FRY Macedonia are almost four times higher than organic agricultural areas, which provide a good basis for the development of organic livestock. Also, the greater the overall organic surfaces have been recorded in Albania (468.298 hectares), and Turkey (547,299 hectares).

Table 2. Total organic and other organic areas by country (2015)

Country	Other organic areas (hectares)					All organic areas (hectares)
	Aquaculture	Forest	Grazed non agri. land	Wild collection*	Other non agri. land	
Albania	-	-	-	467,783	-	468,298
FRY Macedonia	-	-	8,122	556,600	-	566,886
Montenegro	-	-	-	139,809	-	143,097
Serbia	-	-	-	1,550	-	16,848
Turkey	-	-	-	61,230	-	547,299

**Wild collection and beekeeping areas*

The network of participants in organic production

During 2015, Turkey has the most developed network of participants in organic production (producers, processors, importers and exporters). In addition to Turkey, the developed networks of processors in organic production were Serbia and Albania. Regarding importers operating in the organic production sector, Turkey and Serbia had a developed network of these participants in relation to other observed countries. On the other hand, Turkey and Albania had a developed network of exporters of organic products (table 3). The small number or lack of participants in organic production shows a relatively still underdeveloped organic product market, whose development should be encouraged by various financial measures (higher level of subsidies in production, providing facilities for trade and investments).

Table 3. The number of participants in organic production by country (2015)

Country	Network of participants			
	Producers	Processors	Importers	Exporters
Albania*	39	22	4	25
FRY Macedonia	460	7	-	6
Montenegro**	167	9	-	-
Serbia	264	37	30	3
Turkey	69,967	1,064	44	42

** Available data refers to 2012*
*** Available data refers to 2014*

Conclusions

Legislation and support policy related to organic production is present in all EU candidate countries, which is an important factor for the further development of organic production. However, there are significant differences between the observed countries, both in the length of the implementation period of the legal frameworks, and in the amount of subsidies (as one of the measures of support policy) that are granted to organic producers. In the observed period Turkey most stood out with its total organic agricultural areas. Positive trends in the development of organic production are present in Serbia (the highest growth of organic agricultural areas for the observed period). Considering that the potential for organic production on other organic areas, FRY Macedonia was distinguished by significant potentials due to large areas under pastures and wild collection. In addition to Turkey, in all other observed countries there was a relatively underdeveloped network of participants operating in the organic production sector (producers, processors, importers and exporters). Despite existing potentials, there are limitations that can affect the further development of organic agriculture: insufficient subsidies (Albania, Serbia and Turkey); decline in organic agricultural areas (FRY Macedonia), underdevelopment of participants' network in organic production (Albania, FRY Macedonia, Montenegro and Serbia). The authors conclude that a more important role of the state is needed, primarily through the growth of subsidies for organic producers, as well as the improvement of investment and trade facilitation in the organic production sector.

Abstract

Agriculture production development in contemporary social and economic conditions shall be considered from aspect of its economic efficiency. Fragmented holdings which characterize the state of the art of the agricultural property represent the basic and biggest source of superfluous and unnecessary costs of agricultural production. Inadequate infrastructure for agricultural production (property disposition and irrigation systems) as well as unsolved property rights are the crucial factor of inefficient land utilization and consequently reduce the competitiveness of agricultural products on the market. Economic dimension of land consolidation is also not negligible. Bearing in mind today's low price of geodetic works in region it may be considered as a chance for providing land consolidation at a very reasonable costs. Also, low cost of land consolidation is a chance for return on investment in a short period of time with additional benefits of solving property rights and establishing an updated cadastral system. In this paper the model for calculating return on investment period of land consolidation process was used in order to highlight the economic benefit of land consolidation. In spite of the fact that obstacles in land consolidation process exists it is proved in theory and practice that land consolidation remains the best method for agriculture development and land management. This paper aims to point out the significance of land consolidation as a factor of agricultural production development with special emphasis on the state in entity of the Republic of Srpska (Bosnia and Herzegovina).

Key words: *Land consolidation, Agriculture development, Parcel, Irrigation systems, economics.*

Introduction

Land is undoubtedly the main source of food and as well todays' agricultural economy. Agricultural land as a base for agricultural production is the ultimate source of food production and significant economic resource especially for developing countries. Extensive use of land has a consequence in losses of its characteristics and consequently decreasing its capacity for agricultural production. Considering agricultural land as a non-renewable resource warns the humanity on its importance as well as on its limited utilization.

Degradation of land is an issue of numerous studies but the main characteristic of degraded land is that, "when land becomes degraded, its productivity declines unless the steps are taken to restore that productivity and check further losses" (Piers and Brookfield, 2015). As a consequence of land degradation appears additional costs including time lost for land productivity restoration.

Additional losses in land productivity seem to be also significant and not obvious in short period of time. Extreme farmland ownership fragmentation is becoming a limiting factor for sustainable land management in some countries, and example of the Czech Republic as a state with extremely high farmland ownership fragmentation shows that this phenomenon can currently determine the land use of up to 40% of the country's farmland (Sklenicka *et al*., 2015).

According to FAO document (FAO, 2017) the situation about soil resource utilization for agricultural production in Central and Eastern Europe is estimated as follows:

- The great majority of farms are very small, usually under five ha and with many smaller than one ha;
- Farms comprise a number of parcels. About 4-5 parcels in a holding is common and some farmers have over 15 parcels. The size of the parcel is between 0.25 and 0.6 ha.
- Parcels are often some distance apart, sometimes up to 20 km, and can be in different administrative districts.
- Parcels are often awkwardly shaped for agricultural purposes. Some parcels are very narrow and long, e.g. three metres wide and 1 000 metres long.
- Farms are often owned by the elderly.
- Farms are often jointly owned by a number of people.
- Farm owners are often absent, with many living in urban areas.
- Owners sometimes do not have legal titles.

The state of agricultural land according to described situation points out serious problems in land management and also implicates that chances for earning a decent living in both agricultural and non-agricultural sectors in rural areas in Central and Eastern Europe are decreasing. These trends shall to be considered very seriously especially bearing in mind importance of agricultural land and its potential for rural areas development.

Attempts for increasing the chances in land utilization are mainly related to land consolidation. Land consolidation is firstly originated as a tool for grouping small parcels into bigger ones but its development showed that it land consolidation possess potential for solution wider area of rural areas' problems.

Analysing the effects of land consolidation (LC) in Spain for about half of century (since the 1950) the researches formulated five questions as follows (Crecentea and Alvarezb, 2006):

Q1. Has LC influenced property structure in rural areas?

Q2. Has LC influenced land usage?

Q3. Has LC intensified agricultural and forestry production?

Q4. Has LC tended to reduce emigration from rural areas?

Q5. Does the paralysis of LCPs depend on local socioeconomic factors, and if so, on which?

The results of this research are obtained as follows:

Q1. LC has indeed favoured reductions in both the number of plots of land per municipality and the number of plots per active holding.

Q2. LC has lessened the conversion of agricultural land to forestry that is associated with the generalized decline in rural population.

Q3. Regardless of LC activity, there has been an overall increase in land devoted to forestry at the expense of agriculture. However, this trend was almost twice as marked where no LC had been carried out where LC schemas had been implemented.

Q4. The results are that losses of population have been less severe where LC has been carried out than where no LC processes has been completed.

Q5. Here results were that the larger the percentage of the working population is involved in agriculture, the more likely are LC processes to be paralyzed. This may be attributed to the fact that it is harder to design LCPs that satisfy all owners in areas where a relatively large number of owners work a small amount of good-quality agricultural land. Summing up these results it is clear that land consolidation has positive effects whenever it is provided related to areas where it was not.

According to (Đokić and Marošan, 2017) land consolidation is a very successful instrument that can be used for rural development and as such it should provide:

- Improvement of rural living conditions and not only the improvement of agricultural production;
- Renewal of villages by permanent economic and political development of the community and the protection and permanent management of natural resources;
- Active and democratic participation;
- Assistance to villagers in order to define the new use of community resources and appropriate spatial rearrangement and
- Connection between the elements of wider regional development including between rural and urban area.

Above quoted papers implicate that land consolidation could be considered as a very useful and applicable tool for solving wide area of problems in rural areas. The main questions of land consolidation utilization from aspect of agricultural development are related with its contribution to increase efficiency, other possible gains and costs reduction in agricultural production. In this paper the case of entity of Republic of Srpska (RS) in Bosnia and Herzegovina is analysed.

Material and Methods

The methodology of land consolidation contribution to agricultural development will be utilized as proposed by Trifković and Nestorović (2017) and slightly modified in order to highlight the agricultural development. Proposed methodology includes only measurable and experiential verified gains from land consolidation. The model for potential contribution of land consolidation to agricultural development is used as follows.

The model of potential contribution of land consolidation to agricultural development is explicated in following way:

$$LC_{CAD} = PC_{ALALC} - PC_{ALBLC} - I_{LC} \qquad \ldots (1)$$

where:

- LC_{CAD} – Land Consolidation Contribution to Agricultural Development;
- PC_{ALALC} – Production Capacity of Agricultural Land After Land Consolidation;
- PC_{ALBLC} – Production Capacity of Agricultural Land Before Land Consolidation and
- I_{LC} – Investment in Land Consolidation.

Because of different units in which it is possible to explicate the terms in equation (1) it is suitable to use coefficient of land consolidation contribution “c” to multiply the term PC_{ALALC}. Modified equation (1) then could be explicated as follows:

$$LC_{CAD} = PC_{ALBLC} * c - I_{LC} \qquad \ldots (1a)$$

Considering alternative investment is not utilized in model (1), because importance of aims which shall be reached by land consolidation is crucial.

Mathematical model which describes the period of time in which the return on investments could be expected shall include relation between invested amounts of money and expected additional earnings caused by land consolidation project. It means that expected earning shall be expressed in the same money unit as the invested amount. Then the period of time in which the return on investment could be expected may be calculated in simple way as follows:

$$t = \frac{I_{LC}}{A} \quad \dots (2)$$

Where:

- t – period of time in which investment will be fully returned;
- I_{LC}– amount of invested money and
- A – additional agricultural production per year as a consequence of land consolidation project expressed in same money units.

In that case formula (1), including express of additional agricultural production in units of money, will read as follows:

$$t = \frac{I_{LC}}{A * p} \quad \dots (3)$$

where p is the price per unit of additional agricultural production.

Equation (3) also could be explicated as:

$$t = \frac{I_{LC}}{PC_{ALBLC} * c * p} \quad \dots (4)$$

Production capacity of land is considered only from aspects of increased agricultural area (which is estimated on 10%) and increased production (estimated on 2%). Another gains obtained by land consolidation such as: improved irrigation systems, road networks through agricultural land and additional benefits discussed by (Crecentea, and Alvarezb, 2006) and (Đokić and Marošan, 2017) were not included in model.

Benefits of land consolidation as well as natural process of parcels fragmentation creates the need of repeating land consolidations especially in regions with high value of land or high potential of agricultural production.

For entity of RS according to “Statistical Yearbook of Republika Srpska 2014” there exists 582 000 of hectares of arable land and gardens thereof the 136,000 of hectares are sown by maize and 45,000 hectares are sown by wheat. The production of maize and wheat is 550,000 of tones and 180,000 of tones respectively. This means that average production is approximately 4 tonnes per hectare both for maize and wheat.

Results and Discussion

The relevant data in this research for entity RS, according to Republic Geodetic Authority of Republika Srpska are:

- Population: 1,425,549;
- Households: 408,825;
- Cadastral municipalities: 1670;
- Cadastral parcels: 3,986,799 and
- 843,525 legal owners.

Presented data indicate that average owner possess approximately 5 parcels which is in accordance with above mentioned FAO result. Also bearing in mind that land consolidation was not provided in entity RS other results may be considered accordant with the situation in Central and Eastern Europe. This assumption implicate that there exist potential for agricultural production development in RS.

Assuming:

- $c = 0.10 + 0.02 = 0.12$

- $PC_{ALBLC} = 730{,}000$
- $I'_{LC} = 200$ €/ha
- $p = 100$ €/t

and using formula (1a) we obtain

$$LC_{CAD} = PC_{ALBLC} * c = 87{,}600 \text{ ha}$$

where LC'_{CED} denotes the potential contribution of land consolidation to agricultural productivity. As said before this contribution includes only benefits from grouping fragmented parcels and increased agricultural productivity caused by rearranged and consolidated land property. Other benefits including reduced costs for agricultural production, reduced time for agricultural works and increased efficiency are not included in model.

Assuming that all 730,000 hectares will be included in process of land consolidation the total investment in land consolidation will be

$$I_{LC} = I'_{LC} * 730{,}000\text{ha} = 200\frac{€}{\text{ha}} * 730{,}000\text{ha} = 146{,}000{,}000 \text{ €}$$

Land consolidation contribution to agricultural development after land consolidation explicated in € is as follows

$$LC_{CAD} = PC_{ALBLC} * c = 87{,}600 \text{ ha} * 100\frac{€}{\text{t}} * 4\frac{\text{t}}{\text{ha}} \cong 35{,}000{,}000€$$

Using formula (4) we obtain:

$$t = \frac{I_{LC}}{PC_{ALBLC} * c * p} = \frac{146{,}000{,}000€}{35{,}000{,}000\frac{€}{year}} = 4.17\ year \qquad \text{... (4)}$$

Utilization of proposed model with data for entity of Republic of Srpska (Bosnia and Herzegovina) resulted with return on investment period of approximately 4 years. This result, even though considered as imprecise is important. The importance of this result is explicated by its only economical meaning. Other benefits as a consequence of land consolidation could be only positive and additionally shortening the period of return on investment.

Conclusion

Land consolidation is an inevitable tool for successful land management. Utilizing land consolidation wide spectra of problems in land management could be solved but also lot of additional benefits could be obtained. Considering land consolidation strictly economically, even excluding a benefits which hardly could be measurable in the phase of its planning, the results indicate that period of return on investment is very short (in case of entity Republic of Srpska that period is approximately 4 years). That fact favours land consolidation as a toll which shall be considered seriously in decision making for agricultural development. It is possible to state that absence of land consolidation disables agricultural development. In that sense, especially for countries in economic development the land consolidation could be treated as imperative and necessary condition for agricultural development.

Abstract

This paper highlights the factors affecting market participation of rural small-scale farmers in Ehlanzeni South District Municipality. Project assessment was conducted in Ehlanzeni South District by the Agricultural Research Council (ARC) in collaboration with the Department of Rural Development and Land Reform (DRDLR) with an attempt to identify market needs in the district. A total of 54 horticultural projects with 538 beneficiaries participated in the study, coming from the following local municipalities: Mbombela, Umjindi and Nkomazi. Quantitative and qualitative designs were used as a detailed questionnaire written in English, with a focus group discussion, stakeholder's discussion and field observations as part of the data collection. A purposive sampling technique was used to select fifty-four (54) projects, in order to cover uniformity and homogenous characteristics, such as infrastructure requirements, skills availability, production challenges, agricultural training needs, water source needs, educational level, market availability and other factors. Data were coded, captured, and analysed using SPSS. The descriptive and univariate regression analyses were conducted. The results showed a positive association among the following variables: age, educational level, farming experience, land size, planted crop, water source, land acquisition, production inputs, fulltime farming, agricultural training and market participation. It is evident that interventions should be implemented, with a focus on the identified factors in order to improve market participation of small-scale farmers.

Key words: *Market Participation, Horticultural Projects, Ehlanzeni South District Municipality, Mpumalanga Province and South Africa.*

Introduction

Smallholder farmers, irrespective of their selected farming niche are faced with many difficulties before being able to enter the market. Most smallholder farmers lack the knowledge, information and resources required to meet formal market specifications. Baloyi (2010), stress that it is easy to link farmers to markets, but it is difficult for a smallholder farmer to satisfy the market. A lack of formal contractual agreements to enable them to meet these requirements further discourage these farmers from investing in such an enterprise. In addition, these requirements (quality of the product, sanitary measures) are that they overwhelm the technical and organisational capacities of the small entrepreneur (Bienable and Sautier, 2005). In South Africa there is a dual agricultural sector, dominated on the one hand by modern capital intensive organised agriculture, and on the other, by a tradition subsistence small-scale communal sector. According to Barret, 2007; Machete et al., 1997 since 1980s, market liberalisation has prompted rapid industrialisation of the agricultural

sector. This created both new opportunities and challenges for smallholder farmers in South Africa. Agro-industrialisation has stimulated an improved agricultural industry, with farmers and agribusiness being able to position themselves in a globally competitive environment. This has increased the gap between the small-scale communal and extensive capital intensive agricultural sectors. According to Bienable and Sautire (2005) the exclusion of small farmers from dynamic markets emanates from current economic and historical perspectives. As a result, these farmers are economically neither enough in the production environment for successful integration into the mainstream agribusiness, nor are they empowered to commercialise their production. Agriculture in Ehlanzeni District has annual turnover of R1, 5 billion consisting of subtropical fruit farming and processing, avocados, bananas, mangoes, litchis, macadamia nut, sugar cane cultivation by large and small-scale farmers and sugar production at two mills producing nearly 20% of South Africa's sugar (EDM, 2014). Ehlanzeni produces 16% of South Africa's citrus crop and export 70% (EDM, 2014).
The key rationale for the study was based on the South African government focus on establishing agricultural markets in 44 districts in South Africa. Two billion rands was allocated by President Jacob Zuma to Department of Rural Development and Land Reform during 2015 state of the nation address for the establishment of agricultural markets. The establishment of this markets will ensure increased production and consumption of fruit and vegetables, creating a complete and viable agro-value chain that will expand community-driven agricultural production and processing, enhance the role of horticultural crops in addressing the immense malnutrition problem of vulnerable groups in South Africa and to capacitate rural communities to reduce wastage of produce, address food security and add value through small-scale agro-processing operations. The Agricultural Research Council (ARC) is involved in an agricultural project in the Ehlanzeni South district in Mpumalanga Province where beneficiaries were trained and mentored so as to implement sustainable production and develop markets. In the present study, research was conducted with the overall aim of establishing if sustainable agricultural markets are viable in the Ehlanzeni South district. The major objectives were: (1) To identify and describe the characteristics of selected agricultural projects in the Ehlanzeni South district (Table 1 – Table 4). (2) To determine factors that affect decision making to participate in agricultural markets in Ehlanzeni South district (Table 5).

Materials and methods

The research used quantitative and qualitative methods. A detailed questionnaire written in English was developed as a quantitative data collection method. The questionnaire used both open and closed ended questions. Qualitative data collection method included focus group discussions and field observations. As part of standard protocol for conducting the study, meetings were held with all stakeholders in the Ehlanzeni South district namely: (1) Local municipalities, (2) Department of Agriculture, Forestry and Fisheries (DAFF), (3) Department of Rural Development and Land Reform (DRDLR), (4) Local economic agencies and (5) Local farmers. The aim of the meetings was to introduce and explain the aim of the study. A purposive sampling technique was used to select 54 agricultural projects. The sampling was used to assess uniformity and homogenous characteristics like infrastructure needs, skills availability, production challenges, agricultural training needs, and water source needs, educational level, land acquisition, size of land farming experience, source of water, inputs and implements used. Agricultural projects visited in the Ehlanzeni South district were prioritized based on the agriculture potential of the area namely project type, numbers of projects around an area, size of the land, chances of extending production, water availability, commitment of members to their projects, internal conflicts and working material and infrastructure. As indicated in Figure 1, Ehlanzeni South district has 3 local municipalities, namely: Mbombela, Umjindi and Nkomazi (StatsSA, 2011).

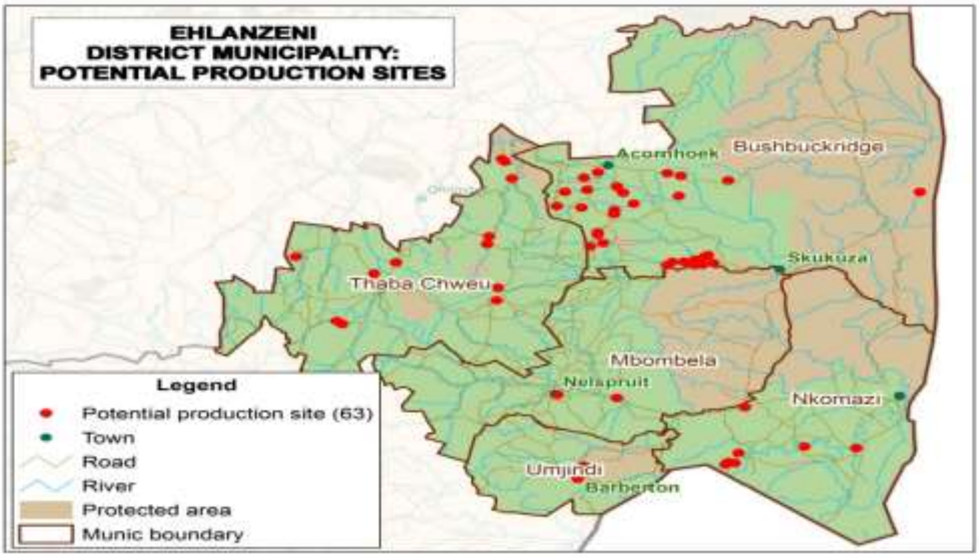

Figure 1: Ehlanzeni District Map

Results and Discussion

A total of 54 projects in 3 local municipalities were visited and they all formed part of the AgriPark project. As shown in Table 1, three local municipalities were visited: Mbombela (35%), Umjindi (11%) and Nkomazi (54%). Agricultural projects visited were prioritized based on the agriculture potential. Ehlanzeni South District has a total of 538 beneficiaries and spread across local municipalities: Mbombela (179), Umjindi (61) and Nkomazi (298).

Table 1: Ehlanzeni South projects per local municipality

Local municipality	Projects	% per Local Municipality
Mbombela	19	35
Umjindi	6	11
Nkomazi	29	54
Total	**54**	**100**

The age distribution of project respondents indicated that the majority were in the age group of 46 – 60 (40%). As indicated in Table 2, youth involvement is 17%, 36 – 45 (13%) while > 61 had 30%. In this project, 19% had incomplete primary education, 28% had completed primary education, 4% had incomplete secondary education, 44% of project respondents had completed secondary education and 5% had completed tertiary education. The results in Table 2 indicated gender composition with females at 35.2 % and males at 64.8 %. Majority of farmers (96%) were farming full time (Table 2). This results are in line with project sampling criteria, which targeted fulltime farmers.

Table 2**:** Ehlanzeni South District Age, Gender, Educational level and Employment characteristics

	Respondents	% of Socio- economic Characteristics

Farming fulltime, unemployed	1	2
Total	**54**	**100**

Table 3 indicated that most projects were engaging in informal markets (70.4%) with 16.7 % trading in both formal and informal markets. Ehlanzeni South district projects have been presented to Fruit and Vegetable City and Woolworths SA. Supermarket chains like Woolworths, Fruit and Vegetable City, Massmart etc. provide lucrative market for smallholder farmers. According to Reardon and Barret (2000) these linkages between smallholder and supermarket chains is only limited to smallholder farmers that meet product variety and quality standards. Smallholder farmers in Ehlanzeni South district often find their prices undercut by produce that informal traders buy from commercial farmers.

Table 3: Ehlanzeni South District markets access per project

Markets access	Projects	% of Market Access
Formal market	7	13
Informal market	38	70.4
Formal and Informal Markets	9	16.6
Total	**54**	**100**

A large percentage (50%) of projects utilized 1-5 hectares (Table 4) while 28 % utilized (6 – 10 hectares). Some projects were using different land sizes as indicated in Table 4. This results indicated Ehlanzeni South district is dominated by small scale farmers and more support is needed to enable them to be commercial as recommended to other district (Maponya et al., 2014 and Maponya et al., 2015).

Table 4: Ehlanzeni South District land size per project

Size (Ha)	**Projects**	**% of Land Size**

11- 20	7	13
21 49	1	2
50>	4	7
Total	**54**	**100**

Results in Table 5 showed that there is positive association among the following variables; age, education, farming experience, land acquisition, land size, crops planted, water sources, agricultural training, production inputs, farming fulltime and market participation. This was supported by more than 1 estimate values at the 95% confidence interval. The results in Table 5 further predicted 82 % (R - squared = 0.82) variation in the dependent variable was explained by the independent variables. Prediction accuracy were assessed based on the coefficient of determination (R - squared). The coefficient of determination R- squared was used to explain the total proportion of variance in the dependent variable explained by the independent variable. The R- squared removes the influence of the independent variable not accounted for in the constructs. R-squared is always between 0 and 100%. In general, the higher the R-squared, the better the model fits the data.

It must be emphasised that social-demographic characteristics of the farmers play a very important role in either promoting or impeding their participation in agricultural markets. As indicated in Table 5, farmers age had a positive association with market participation (>1). Studies by Barret (2007) indicated that younger farmers participated more in the market because they are more receptive to new ideas and are less risk averse than older farmers. This information is in line with studies by Maponya et al. (2014); Maponya et al. (2015) and Makhura (2001) who found that age is positively associated with market participation. There is a positive association among farming experience, farming fulltime, education and market participation as indicated in Table 5. A well-educated, fulltime farmer with experience will always understand market conditions better and will enhance smallholder farmer's market orientation. Advancement in education increases the education level and the ability to obtain better market information Maponya et al., (2015) and Makhura (2001). Agricultural training is also positively associated with market participation as smallholder farmers need to be equipped with technical skills to improve their productivity and to negotiate in the agricultural markets.

As indicated in Table 5, there is a positive association among land acquisition, land size and market participation (>1). Land acquisition and size are generally acknowledged to be a necessary condition for agricultural growth and development and ultimately successful agricultural commercialization of smallholder farmers. Smallholder farmers with land and bigger land size were found to participate more because of their ability to produce bigger volumes to the market. According to Alene et al., (2008) land acquisition and land size enables smallholder farmers to produce surplus to the market. The results are also in line with

Azam et al., (2012) who recognised that Cambodian farmers with larger land sizes are more likely to participate in the markets. A positive association existed between production inputs and market participation (>1). Production inputs availability will go a long way in improving smallholder's farmer's participation in the market. Majority of smallholder farmers in Ehlanzeni South district have on several occasions been supplied with fertilisers by both local and provincial government in order to assist them in their farming operations and enhance productivity. According to Van Schalkwyk et al., (2012) production inputs used is an important determination of smallholder access to agricultural markets. The research had distributed sweet potatoes cultivars and fruit trees as part of popularising Agricultural Research Council cultivars. Production inputs were also distributed as it was found that low crop yields was attributed to farmers to use improved inputs and it led to lack of competitive production and low market participation.As shown in Table 5, there is a positive association among water sources, crop planted and market participation. This is true as available water resources and their level of assurance of supply would inform types of crops to be planted at specific times to avoid crop failure (Evans and Sadler, 2008). Thus ensuring long sustainability of water sources and crops planted will accelerate production and market participation.

Table 5: Univariate Regression Analysis of factors affecting market participation in Ehlanzeni South District

Variable	**Total**	**(%)**	**OR [95%CI]**
Farming Experience	54	100	1.11[0.45-303]1
Age	54	100	1.34[0.058-2.9]1
Land Acquisition	54	100	1.09[0.272- 3.9]1
Education	54	100	1.29[0.226- 13.6]1
Farming fulltime	54	100	1.33[0.23–4.3]1
Land Size	54	100	1.05[0.24–5.57]1
Crops Planted	54	100	1.11[0.18-4.5]1
Water Source	54	100	1.07[0.10- 5.011]1
Agricultural Training	36	66.7	1.12[0.28 – 4.88]1
Production Inputs	54	100	1.66[0.18 – 4.14]1

OR= Odds ratio; 95%CI = 95% confidence intervals; 1< = no association; 1> = association

Conclusions and Recommendations

Different socio-economic characteristics of smallholder farmers were described and determined. It is apparent that factors like age, educational level, farming experience, land size, crop planted, water source, land acquisition, production inputs, farming fulltime, agricultural training positively influences the decision to participate in the market. The identified factors will affect the manner in which smallholder farmer's benefit from the opportunities available in the agricultural markets in respect of the quality and quantity of the agricultural produce. It is expected that addressing such factors may create enabling conditions that would encourage smallholder farmers to access and participate more effectively in markets. Such efforts could improve the ability of smallholder farmers to become part of the mainstream or commercial agricultural economy. Based on the findings, the research recommends that for holistic market participation among smallholder farmers in Ehlanzeni South District, the government and other policy makers should increase the knowledge, experience and skills of farmers. This will go a long way in assisting farmers to supply quality products to the market and improve their livelihoods.

Abstract

Nowadays, new technological developments in smart farming have contributed to horticulture, greenhouse, and livestock production. Wireless Sensor Networks (WSN) and Internet of Things (IoT) technologies can be used in data-driven intelligent agriculture applications. With the more efficient use of energy, water and fertilizers, the increase in productivity and efficient management of all processes from production until storage can be provided by using WSN and IoT technologies. The correct irrigation, fertilization and pesticide spraying applications will contribute to low cost production and the protection of the environment, as well as making things easier of farmers. The local agro-meteorological and field data based on sensors are important. These data can be used to evaluate meaningful outcomes for risk estimation, agricultural insurance, financial support and compensation mechanism. In this study, a cheap prototype system for greenhouses was developed by using WSN and IoT technologies. The system consists of four wireless sensor nodes: one master node and three slave nodes. A Raspberry Pi-2 board was used as the master computer. A DS18B20 temperature sensor was used for each node. Raspbian Linux OS run the master computer to measure the temperature of master nodal point, link wireless with slave nodes, and record data coming from slave nodes. As slave nodes, a Raspberry Pi-2 board, a NodeMCU module and an ESP8266 WiFi module were used. The air, substrate, leaf and water temperatures for soilless crop cultivation applied in greenhouses were measured in real time. Data coming from slave nodes were recorded on the SD card of the master node.

Keywords: *Smart farming, Greenhouse, Internet of things, Wireless sensor network.*

Introduction

Agriculture, which provides the employment in large-scale for peoples, plays a vigorous role in economy of countries. However, agriculture is highly dependent upon weather and climate due to changes in temperature, soil moisture and carbon dioxide. In order to manage crop growth and increase the agricultural production yield, the monitoring of environmental parameters is important (Cao-hoang and Duy, 2017). The recent developments in the area internet of thigs based on wireless sensor networks have created many opportunities for environmental monitoring. Wireless sensor networks (WSNs) consist of in a large number of sensor nodes distributed to monitor the physical environment. Sensor nodes distributed in the wireless sensor networks can be used to sense the change of single or multiple physical parameters (Dargie and Poellabauer, 2010). Internet of Things (IoT) has emerged as a technological revolution which relies on the development of wireless sensor networks, cloud computing and information sensing (Padalkar and Pacharaney, 2016). IoT has provided flexible access among the objects over the internet according to different structural characteristics of each sector in environment, industry, agriculture, health, security sectors

(Borgia, 2014; FAO, 2015; ITU and Cisco, 2016).

IoT and WSN technologies have provided the more efficient use of energy, water, fertilizer, fuel and resources, as well as increasing productivity by using smart systems and machines in agriculture. In agriculture, all processes including cultivation, production, storage and distribution of plants can be efficiently managed via IoT (ITU and Cisco, 2016).

In recent years, many studies and projects based on IoT and WSN had conducted: Cropinfra Platform (Blank *et al*., 2013), iGreen project (Pesonen *et al*., 2014), weather forecasting, wildlife management, forestry, livestock farming, market identification and rural financing in rural areas (Dlodlo and Kalezhi *et al*., 2015), applications on precision irrigation, fertilization and climate management (Guo and Zhong, 2015), using a wireless sensor information archive (Wisekar) in India (Sarangi *et al*., 2016), using a wireless sensor network for greenhouses (Ugur, 2016). Local sensor information including air and soil temperatures, relative humidity of air, soil moisture levels, solar radiation, wind direction and wind speed, atmospheric pressure, rainfall, soil electrical conductivity can be measured, and local image information can be obtained. These data can be used to evaluate meaningful outcomes for risk estimation, agricultural insurance, financial support and compensation mechanisms (FAO, 2015; ITU and Cisco, 2016). Temperature, relative humidity, light, carbon dioxide levels in the greenhouses are important for plant health, yield and quality. This information involving real-time data can be used for saving energy, water and fertilizer. In this study, a cheap prototype system was developed, which could be measure the temperatures at different points with wireless sensor nodes that could be connected to internet, intranet and web network by using Internet of Things technology.

Material and Methods

The prototype system involves four sensor nodes, one of which is master node that is used of Raspberry Pi 2 board, three of which are slave nodes that are used Raspberry Pi 2 board, NodeMCU-v2 and ESP8266-01 modules. One DS18B20 temperature sensor for each sensor node is used to develop prototype applications. A DS3231 module was connected to master node for measuring with real time clock (RTC).

The system was designed based on three-layer architecture: user layer, software layer and hardware layer (Figure 1). User layer covers all devices, such as personal computers with internet access, smart phones and other smart devices. Software layer performs database, Web server and data processing tasks. Hardware layer includes single card ARM computer, sensor and wireless modules.

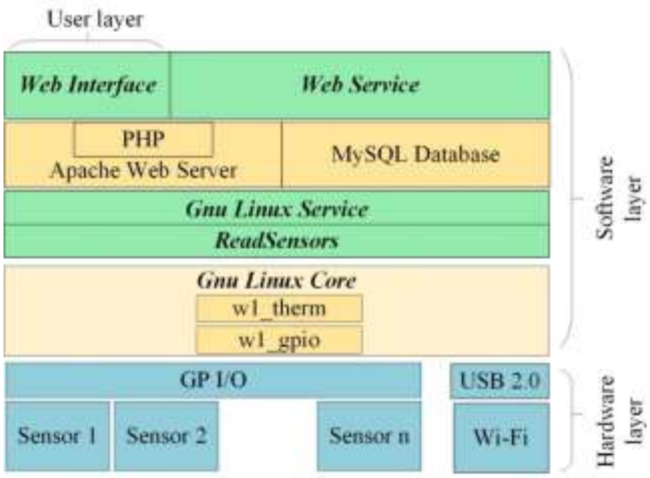

Figure 1. Three-layer architecture for WSN

The wireless sensor network was designed according to star topology. The wireless sensor nodes are programmed according to the hardware and software specifications of the system. The wireless sensor network system proposed for IoT in greenhouses is shown in Figure 2. WSN involves a master node (SN 1) and three slave nodes (SN 2, SN 3, SN 4). Raspberry Pi 2 Model B board was used as master node. For wireless access on Raspberry Pi 2 board, a wireless network adapter (ZyXEL NWD-270N) was used. DS3231 module was used to determine the real-time as independent from internet.
DS18B20 sensors were used to measure the temperatures of various mediums at different positions in greenhouse. Nodes were programmed as based on the one wire protocol for master and slave operating modes. The 64-bit serial number of each sensor was assigned as address information. A single program was written to use in both master and slave nodes of network.

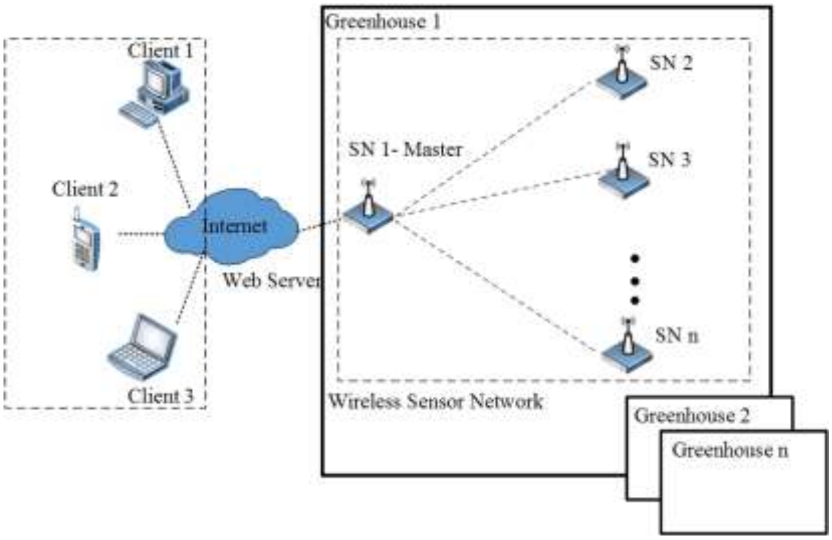

Figure 2. Greenhouse wireless sensor network system for IoT

IP (Internet Protocol) address and API (Application Program Interface) key were defined for each slave node. API keys were entered as same code in all nodes. Internet access of the sensor network inside the greenhouse was activated on only master node. If the serial number of each sensor corresponds with the node number, the measurements are made, and results are returned. After reading the temperature data, a cyclic redundancy check (CRC) was performed. The confirmed data set including "*node nickname*", "*serial number of the sensor*" and "*temperature data*" were stored in database of the master node.
The backbone of system was set on software sub-structures involving Linux service, Web service and user interface. The Linux service is the most important component of the system. It is responsible for preparing the service core modules, taking measurements from the sensors at specified time intervals and sending these measurements to the local or remote server. The service software was compiled using the Mono C # compiler. The web service bridges between the Linux service and the intranet-database server, and stores in the database the information read from the sensors. To protect from the unauthorized access the system, the web service compares the data packet incoming with the API key at the node. In the case of API key matching, data packet stores in the database. The user interface of the system is prepared with Html5, PHP, JS and CSS and was designed to be flexible for installation and remote monitoring of nodes. The interface was improved with the help of Bootstrap 3 CSS framework to improve user efficient. The measurement results can be accessed by using the web interface and the sensor node input information; the configuration of nodes can be easily done. A password authentication feature was added to the system to prevent unauthorized attempts. For this purpose, two different functions were defined for the user interface: Active

user functions and passive user functions. User can monitor measurement results and can changed node settings by active functions. On the other hand, the passive user only uses the node-tracking feature. The authority of the logged-on person was restricted to browsing the node's general information and monitoring the measurement results.
The prototype system was made up of a four-node wireless sensor network that can be connected to the Web environment. Experiments were carried out under laboratory and greenhouse conditions at Department of Agricultural Machinery and Technologies Engineering of Ankara University. The field trials of the system were carried out between July 29 and August 1, 2016 in a greenhouse having a size of 64 m^2, covered with polycarbonate, with steel construction and suitable for a soilless production substructure. Figure 3 shows the positions (a) of the wireless sensor nodes (b) in greenhouse. API key and the measurement interval were set as "1234567890" and one minute, respectively.
Air temperature (T_A: SN-1), substrate temperature (T_S: SN-2), crop leaf temperature (T_L: SN-3) and water temperature (T_W: SN-4) were measured in real time. IP values for master and slave nodes were "*192.168.42.1*", "*192.168.42.36*", "*192.168.42.31*"and "*192.168.42.45*", respectively.

Figure 3 (a) Positions of sensor nodes in greenhouse, (b) Greenhouse experiments

Results and Discussion

The prototype WSN system proposed for greenhouses was developed as simple application. In this study, unlike study done by Ugur (2016), no wireless gateway was used. Furthermore, the cheaper NodeMCU-v2 and ESP8266-01 modules were used. Sensor nodes were set up via Wi-Fi connection of laptop, tablet or mobile phone; and the streaming data were monitored. Data of master node and slave nodes were recorded in real time to SD card on the Raspberry Pi 2 board.
The daily variations of temperatures in various mediums given in Figure 3 (a) are graphically shown in Figure 4. Average temperatures for the air, substrate, leaf and water mediums measured by sensor nodes were calculated as 26.74°C, 25.81°C, 24.57°C and 23.86°C, respectively. Although the expected number of data to be retrieved is 17,284, 17,260 of which were received. Only 24 data (13 data of SN-3 and 11 data of SN- 4) were lost. The wireless data transfer without being error is at rate of 99.86%. Information detailed about experiments is given in Table 1.

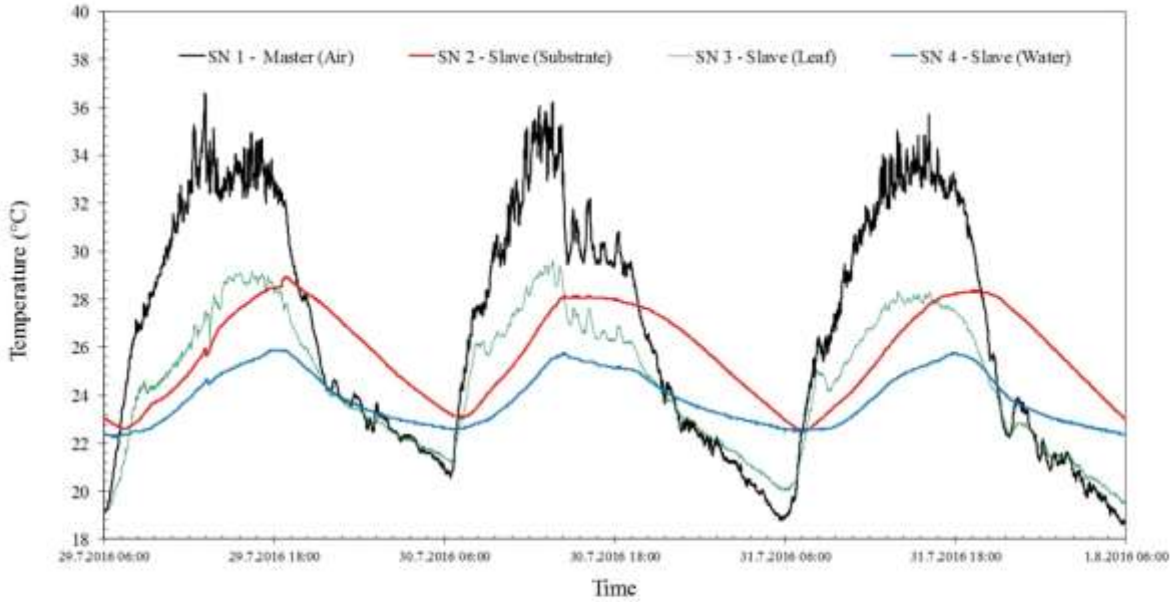

Figure 4. The daily variations of air, substrate, leaf and water temperature data.

Table 1. Information detailed about greenhouse experiments.

	Master Node (1)	Slave Node (2)	Slave Node (3)	Slave Node (4)
Data number	4321	4321	4308	4310
Minimum	18.62	22.56	19.13	22.25
Maximum	36.56	28.94	29.63	25.88
Average	26.74	25.81	24.57	23.86
Standard deviation	4.94	1.89	2.75	1.11

Temperature data measured in the greenhouse were used to determine microclimatological information. Information detailed about physical, biological, and chemical environments around the greenhouse was obtained by using wireless sensor nodes to be placed to different positions. Greenhouses can be managed like an industrial facility. The management organization can be integrated based on energy and climate management, water-fertilizer management, disease-quality management.

Conclusions

A prototype system consisting of four wireless sensor nodes was designed by using ARM based mini computers and Wi-Fi modules. The system was programmed as master and slave nodes for temperature measurements in the scope of IoT technology. The nodes with different hardware and cost were used in the same system. The performances of those were tested for simple and inexpensive solutions. Thanks to the embedded web server on the master node, it is possible to use the system via intranet without internet connection. A network adapter that is compatible with Linux for access to other wireless nodes and clients such as mobile phones, tablets and laptop computers over master node was used. For this reason, there is no need to use a wireless gateway in the system. The system was designed, and programmed to be multifunctional.

The fact that hundreds of wireless sensor nodes will be used in future systems will be important for ensuring cheap solution.

Wireless sensor network and IoT technologies have expected to provide a flexible and inexpensive solution to many agricultural applications such as climate management for greenhouses, water management for vineyard and field, weather forecasting, plant-animal disease tracking, transportation and storage of agricultural products.

Abstract

In recent decades, the greenhouse area has risen to grow the vegetables, ornamentals and fruit crops at worldwide year-round. Today, the greenhouse farming has been carried out in modern production facilities. The greenhouse management is a key factor at all growing stages, different timescales and market patterns. The sub-sectors such as energy, climate and water-fertilizer crop quality, and pest-disease in greenhouse can be integrated under management concept. In this paper, the hierarchical manager method is proposed for profitable and sustainable crop growth and production in greenhouse. This method involves three layers named as climate and nutrition manager layer, crop growth manager - layer and tactical manager layer. The greenhouse management is carried out based on fast crop dynamics (transpiration, photosynthesis, and respiration), and slow crop development (crop growth and fruit changes). High-tech greenhouses can be managed according to the strategic, tactical and operational levels based on computer, sensors, communication, and software sub-systems.

Keywords: *Greenhouse, Greenhouse management, Multilayer hierarchical control.*

Introduction

A modern greenhouse is a plant factory where a lot of equipment is used to control the growth and development of the plant (Dayioglu, 2014). Greenhouse is a complex system along with physical and biological environment. The crop is its main element directly influenced from different variables, such as weather variations (temperature, humidity, photosynthetic active radiation [PAR], and carbon dioxide concentration) nutrition (water and nutrients), biotic (pests, diseases, viruses, bacteria, and weeds), and cultural management (pruning, spraying). Today, the greenhouse farming has been carried out by using automation technologies in modern production facilities (van Straten *et al.*, 2011). The crop production at large-scale greenhouses requires a lot of energy, water and chemicals. In recent years, it is accepted that greenhouses consist of sub-sectors of crop, water-fertilizer, climate, energy, crop quality (Dayioglu, 2014). Some authors have studied on energy management (Kolokotsa, 2010), climate management (van Henten, 1996), water-fertilizer management (Pardossi *et al.*, 2011), crop management (De Pascale and Leonardi, 2012), quality and pest-disease management (Albajes *et al.*, 2000). These sub-sectors along with automation, computer and sensor technologies can be considered for the sustainable production. All those sectors and technologies required for greenhouses can be integrated for a successful management. Modern greenhouses can be managed by using the hierarchical control architecture derived from industrial automation systems (Scattolini, 2009). There are seven layers for industrial automation systems: 1) primary technology, 2) sensors and actuators, 3) low level control, 4) group control, 5) supervision, 6) manufacturing, 7) enterprise. These layers are configured for greenhouse climate in Watergy project (Speetjens *et al.*, 2008). The crop growth system can be defined by using a hierarchical control architecture. In this paper, the hierarchical manager method is proposed for profitable and sustainable crop growth. The integrated management concept based on crop is defined for smart greenhouses.

Material and Methods

Greenhouses are equipped with many sub systems to meet the climate and nutritional requirements of crops. Sub-systems such as heating, ventilating, cooling, shading and fogging are used to control the greenhouse climate. Irrigation and fertilization sub systems are combined with dosing systems suitable to the soilless culture. The modern greenhouses can be managed as to the simplified automation scheme shown in Figure 1.

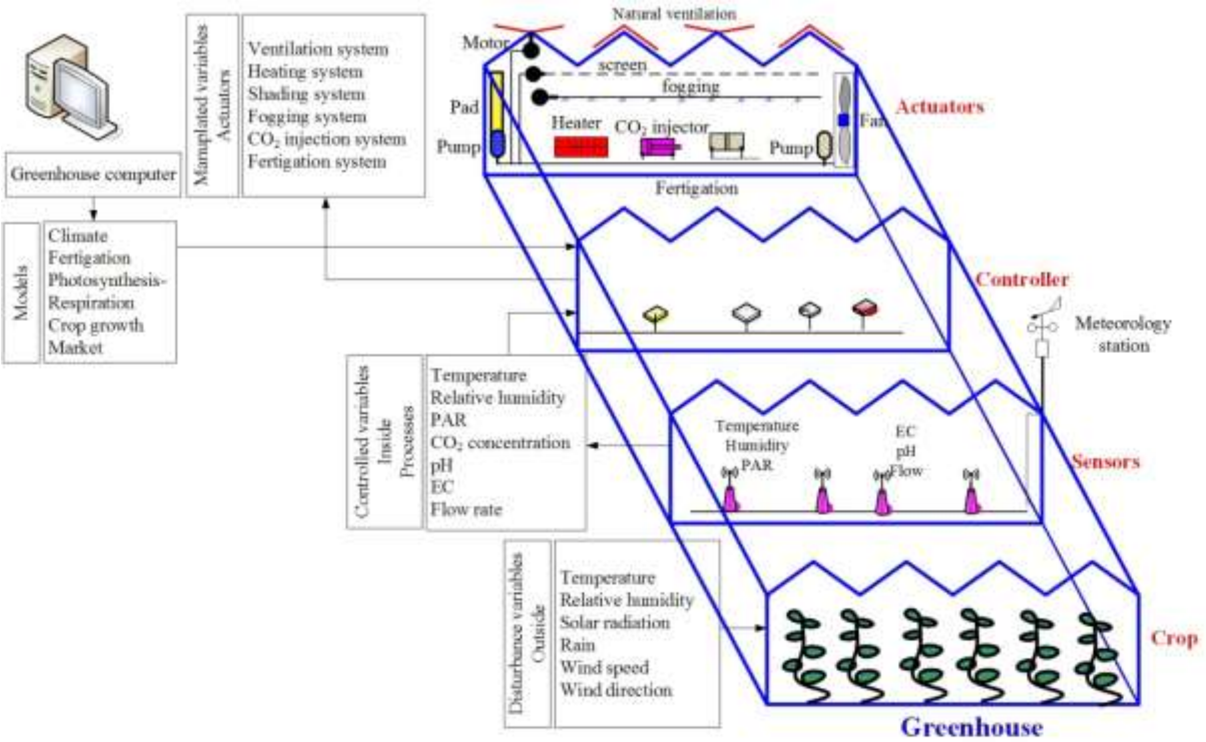

Figure 1. Greenhouse automation scheme

In this scheme, the modern greenhouse components such as crop, sensors, controllers, actuators are stratified to illustrate processes realized in background. Greenhouse processes are controlled in conformity with information flows among sensors, controller, and actuators. The disturbance variables including temperature, relative humidity, solar radiation, wind speed and direction at outside of greenhouse are taken into account for the successful climate management. Inside variables such as temperature, relative humidity, PAR, CO_2 concentration, pH, electrical conductivity (EC), water flow rate to be controlled according to seasons, day – night courses and crop growing levels must be properly set. Greenhouse computers are used so that farmers and/or engineers can follow the climatologic and nutritional variables and the control parameters, pest-disease and crop status, as well as alarm information arranged automatically. The control algorithms, expert software, predictive crop growing models are the most important tools for modern greenhouses. The dynamic models are used to define the knowledge among all the interactions and processes, to obtain efficient automation and optimum crop growth (Fortuna *et al.*, 2000). The wired systems such as Ethernet, RS485, CAN, ModBus and/or wireless systems including Bluetooth, WiFi ZigBee, as well as GSM for long range (Serodio *et al.* 2001; Pawlowski *et al.*, 2009) are need for the successful management.

Hierarchical Manager Method

The greenhouse-crop growth system can be managed by *"hierarchical manager method"* with three layers in the light of information given by (Ramirez-Arias *et al*., 2012; Rodríguez *et al.*, 2015). In this method, three layers are defined at various the time scales such as seconds/minutes, minutes/hours, months/season, hours/days: (1) *Climate and nutrition manager layer, (2) Crop growth manager layer, (3) Tactical manager layer.* Furthermore, three different levels are taken into account at hierarchical control architecture: (1) *Real system level, (2) Model level, (3) Controller level.* Figure 2 shows schematically the application of the hierarchical manager method with three layers defined for greenhouses:

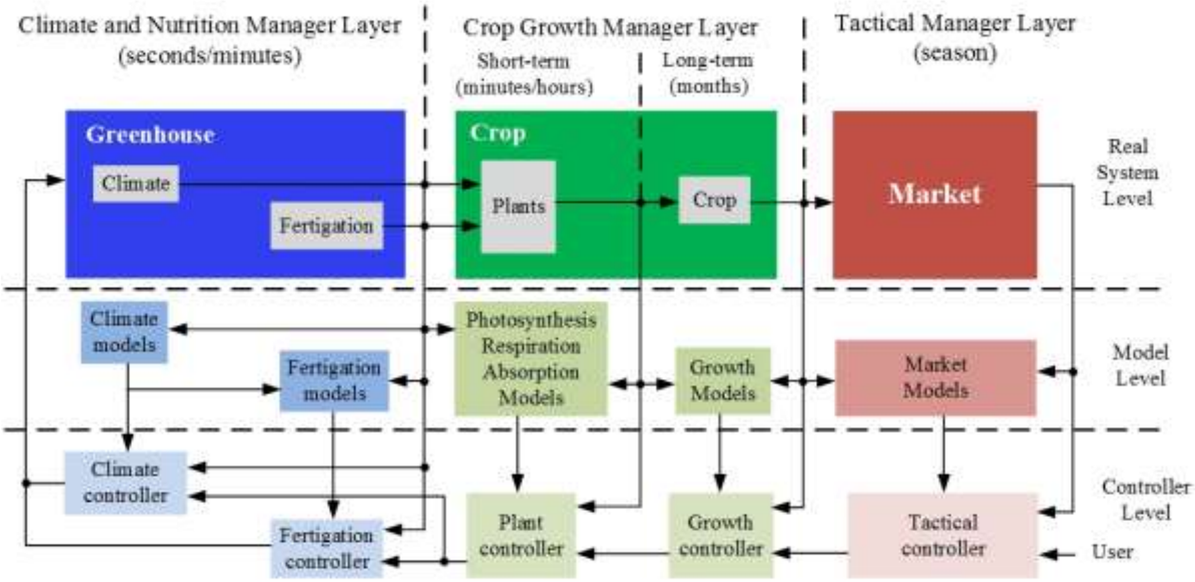

Figure 2. Hierarchical manager method with three layers (modified and adapted from Rodríguez *et al*., 2015)

Results and Discussion

Greenhouses can be managed by the hierarchical control approach to provide the optimum crop growth based on economic criteria. We offer a hierarchical control scheme for greenhouses. Hierarchical layers consist of climate and nutrition manager layer, crop growth manager-layer and tactical manager layer. The proposed hierarchical control scheme corresponds to that given by Ramírez -Arias *et al.* (2012) and Rodríguez *et al.* (2015).

- *Climate and nutrition manager layer* is responsible from computing of control signals to be sent to the actuators by using temperature and EC set-points calculated by the tactical manager layer. The control algorithms such as feed-forward control, adaptive control, predictive control and hybrid control have been proposed for greenhouse control (Rodriguez et al., 2008; Rodríguez et al., 2015).
- *Crop growth - manager layer* finds the growth trajectories from tactical manager layer and calculates the set points suitable air temperature and electrical conductivity (EC) trajectories for the greenhouse crop according to long-term and short-term weather predictions. The daytime and night-time temperature levels and the EC set points are calculated. Generally, this layer is divided into two levels: Short-term growth control, Long-term growth control.
    - *Short-term growth control:* The physiological processes such as photosynthesis or crop respiration, which directly influence the crop growth, are taken place at

temporal horizon of hours. In this level, the set points for the next day are calculated by using short-term weather predictions, the actual state of the crop, and the short-term grower goals according to crop status.

- *Long-term growth control:* This contains the decisions about the total production schedule of the crop. These decisions are taken by using information based on the growing rate, vegetative features and the crop specific climatic set point values. The main variables are the dry matter production and leaves production matching with the crop growth process. Thus, the climatic and irrigation set points are calculated according to probable harvesting date or an expected growth curve.

- *Tactical manager layer* solves the optimization problem that is defined for different objectives. The outputs of this layer are the growth trajectories limited by the crop to maximize the profit. The long-term objectives and the long-term predictions are taken into account. The long-term objectives are market prices, harvesting dates, and required quality.

The greenhouse climate is managed according to outputs of climate model and climate controller. The fertigation process is controlled with outputs of fertigation model and fertigation controller taken from optimization procedure of tactical manager layer. The mechanisms of decision support of greenhouse are defined from crop growth models. The fertigation balance is set from crop growth and market variations. The growth models of crop are affected from market models defined in tactical layer. Many devices including sensor and actuator, and expert model and software are used to control the climate and fertigation processes.

Smart greenhouses can be designed based on *"hierarchical management method"* defined in above and *"integrated management concept*" shown in Figure 3.

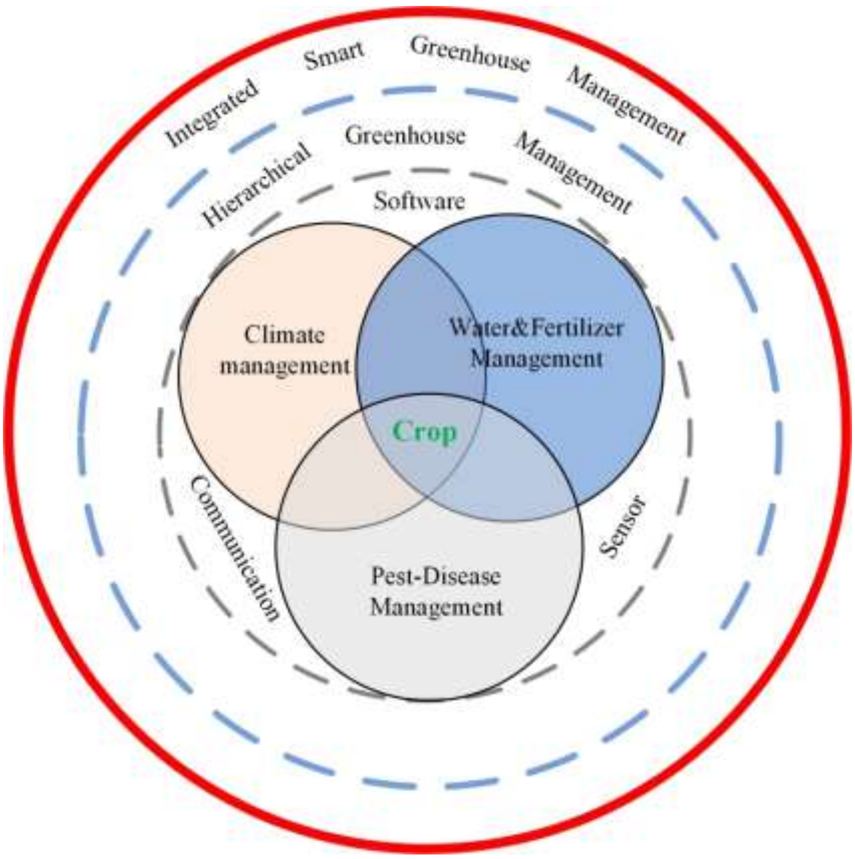

Figure 3. Integrated smart greenhouse management

The sophisticated greenhouse management relies on the use of information and automation technologies including monitoring and controlling of all processes in the production cycle for high quality products (Aaslyng *et al.*, 2005). Furthermore, the integrated smart greenhouse management is planned to be provided the following outputs:

- Increasing in production,
- Decreasing in product cost,
- Improving in product quality,
- Decreasing in labor use,
- Flexible use for coming up with short-term and long-term targets,
- Decreasing in energy use,
- Increasing the efficiency in using of energy,
- Using of alternative energy sources and industrial waste heat,
- Decreasing in greenhouse gas emission,
- Decreasing in environmental pollutions and wastes,
- Decreasing in pesticide use.

Conclusions

The greenhouse is a closed environment where climate and fertigation processes must be controlled for ideal crop growing. The greenhouse agro-system is a complex system including physical, chemical and biological processes in which are take place simultaneously. Therefore, the crop growing conditions can be just controlled by sub-systems including heating and screening system, ventilating system, cooling and shading system, fogging system, CO_2 injection system, irrigation and fertilization system and automation system, as well as transportation and packaging. Greenhouses can be managed by using hierarchical methods like an industrial facility. Modern greenhouses can be operated as smart facilities based on the integrated management concept and hierarchical method. The management organization for greenhouses can be integrated based on energy and climate management, water-fertilizer management, disease-quality management. Greenhouse computers are the strategical devices to manage the climate and fertigation procedures of greenhouse. These are usually programmed based on crop and market models. High-tech greenhouses can be run at the strategic, tactical and operational levels by using computers, sensors, wired-wireless communication and software sub-systems. Information detailed about physical, biological, and chemical environments of the greenhouse can be obtained by using wireless sensor nodes and actuators to be placed to different positions.

Abstract

Recently, measurement of the optical characteristics of vegetation at specific wavelengths has been adopted for N status assessment in various crops. Optical sensing instrumentation can be used to calculate vegetative indices, which are indicators of a plant’s photosynthetic potential and above ground, living biomass. Development of NDVI for prediction of sugar beet yield and quality during the growing season would be of value to producers and industry. During the growing season, monitoring the status of the plant in sugar beet production system will enable farmers to improve nitrogen management. The main objective of this study was to determine in-season nitrogen status in sugar beet using the mobile optical sensor. An experiment was established to determine the effect of nitrogen on root yield, sugar content and α-amino N content using a randomized block design by applying five different rates of nitrogen (0, 60, 90, 120, 150 kgN/ha) for two sugar beet varieties. The amount of 115.64 kgN/ha was determined as economic optimum nitrogen rate when quadratic polynomial model was used to describe the relationship between nitrogen and root yield, sugar content, and α-amino N content. The use of NDVI values were proposed 93 days after sowing at approximately 1486 CGDD. Thus, N status in plants and in-season N requirement could be determined taking advantage of the relationship between N rates and NDVI values. So, the variable rate nitrogen fertilization process can be realized as an important element of precision agriculture. Environmental pollution will be minimized due to increasing nitrogen use efficiency.

Keywords: *Sugar beet, Nitrogen management, Optical sensor, Variable rate nitrogen application, root yield, sugar content.*

Introduction

All crops require nitrogen (N) for the production of a photosynthetically active canopy, whose functionality will strongly influence yield. There is an absolute requirement for N for plant growth, and crop yields and quality depend upon substantial N inputs. Profitable sugar beet production requires wise use of technology and precise management of fertilizer especially nitrogen fertilizer. This new technological approach to the nitrogen management has the potential to increase sugar beet yield and quality as well as other nitrogen consumed plants. This strategy allows for fertilizing more productive area across the field and decrease nitrogen fertilizer cost. High root yield production means successful sugar beet production in many regions. But successful sugar beet production is a combination of high root yield, sugar yield and low impurities. Site specific management of inputs can be applied not only by using soil analyzing but also by employing various remote sensing techniques to monitor plant status in different growing stages, for instance to suggest the optimal rate of nitrogen. A study conducted by Weisler et al. (2002) can be referred to as an example of using remote sensing in sugar beet production. They used a hand-held multispectral scanner for canopy light reflectance measurements and calculated sensor values as an indicator for canopy greenness. Franzen et al., 2003 investigated the advantages of using ground based sensors rather than satellite images. For this purpose, the value of dry matter content and nitrogen content in sugar beet were compared with NDVI values obtained from ground based sensor (Greenseeker). Hoffmann and Blomberg, 2004 investigated the possibility of using remote sensing in order to estimate variation in leaf area development of sugar beet from different agronomic application. The results indicated a very close relationship between LAI and NDVI in all trials and the coefficient of determination of the functions was highly significant. Along with considering weather condistions another way of predicting the potential sugar beet yeild is the use of crop growth models combined with NDVI data. Humburg et al., 2002 used a fertility experiment to linking canopy reflectance measurements to a portable spectroradiometer and airborne images in sugar beet to a set of root quality measures. Prediction of nitrogen status during fertilizing application is extremely important to manage nitrogen application. The aim of this study is to use optical sensor to establish a model to determine actual in-season nitrogen requirements according to the relationship between NDVI index and N status in midseason.

Material and Methods

Field experiments were carried out in a complete randomized block design with five replications at two different locations (Altinekin and Alakova) in central Anatolia, Konya, Turkey. Each experiment included 50 treatments which were the combinations of two commercial varieties of sugar beet (T_1 = Mohican, T_2 = Eldorado) and four nitrogen rate as urea fertilizer (0, 60, 90, 120, 150 kgN/ha). All other culture practices, including bottom fertilizing were carried out as recommended at experiment region. The root yield obtained from 10 m^2 of each plot were weighed and sucrose content, α-amino N were analyzed in laboratories. NDVI values were collected in different stage of plant growth (45 day after planting (before fertilizing), 74, 93, 127 days after planting (after fertilizing) respectively) using the Green Seeker handheld sensor (NTech, Ukiah, California). The data collected at each experimental location was analyzed as a five-replication in randomized complete design. The data were also analyzed using analysis of variance and Tukey's multiple comparison method was applied to determine differences between treatments. Statistical Analysis System (SAS) programs were used for analyses of variance and determination of variance components. To describe the sugar beet yield and sucrose content response to nitrogen fertilizer, quadratic regression models were fitted to the data as the best statistical model (Cerrato and Blackmer, 1990, Sayılı and Akça, 2004). The acquired models for estimating root yield and sucrose content were used to determine the economic optimum rate of nitrogen fertilizer. In order to determine the economic optimum nitrogen rate, a net return function combined with the price-sucrose relationship function was used when nitrogen fertilizer takes into account as a production input (Gandorfer et al., 2008, Baker et al., 2004):

$$\boldsymbol{NR} = \boldsymbol{p}_{ş}.\boldsymbol{f}(\boldsymbol{N}) - \boldsymbol{p}_{\boldsymbol{N}}.\boldsymbol{N} + \left(\frac{\boldsymbol{g}(\boldsymbol{N}) - \mathbf{3}}{\mathbf{13}}.\boldsymbol{p}_{ş} - \boldsymbol{p}_{ş}\right).\boldsymbol{f}(\boldsymbol{N})$$

Where;
NR : Net return (TL/ha),
$p_{ş}$: base price (TL/ton) and
p_N : price of nitrogen fertilizer.

In order to determine the best appropriate time of fertilizing, the concept of RI (Response Index) was exploited. This index was calculated for NDVI and Yield separately. Response index for yield is known as $RI_{harvest}$ and indicates the actual crop response to applied nitrogen

(Johnson and Raun, 2003) and in-season sensor measurements of NDVI that indicates N uptake between plots receiving nitrogen and those not receiving nitrogen can be used for calculating NDVI response index (Mullen et al., 2003) by using following equitions:

$$\mathbf{RI_{NDVI} = NDVI\ (max) / NDVI\ (control)}$$
$$\mathbf{RI_{harvest} = Yield\ (max) / Yield\ (control)}$$

The calculated value related to response index in terms of yield and NDVI was compared with each other. As a result of the correlation analysis, the measurement period with the highest R-square obtained from comparing two series of data was identified as appropriate period for applying fertilizer. After determining the appropriate time for applying nitrogen fertilizer, the relationship between corresponding NDVI values and nitrogen rates was determined using linear regression method in order to estimate the nitrogen requirement in sugar beet. The concept of INSEY (in-season estimated yield) was used to estimate potential yield using GreenSeeker readings (Franzen et al., 2013). In-season estimated yield (INSEY) values were computed using NDVI readings in any period of growth divided by the cumulative growing degree day (CGDD) over the same time period from planting to sensing (Lukina et al., 2001, Teal et al., 2006). Equation resulted from regression analysis between INSEY values as an independent variable (x) and sugar beet yield of the same pilot as response variable (y) may be used as a calibration equation in variable rate nitrogen application.

Results and Discussion

The influence of different nitrogen rate on sugar beet quantity (yield) and some quality index (sucrose concentration, α- amino N) in two experiments are shown in Table 1. The result of variance analysis showed that all quantities and quality parameters were affected significantly by N rates.

Table 1. Effect of nitrogen fertilizer rate on sugar beet yield, sucrose content and α-amino N in Altınekin ve Alakova experiment location*.

N rate KgN /ha	Altınekin						Alakova					
	Sucrose content		Yield		α-amino N		Sucrose content		Yield		α-amino N	
0	19.38±0.71	ab	70.94±7.10	b	1.91±0.58	b	16.18±0.42	b	65.12±10.52	b	1.90±0.84	bc
60	19.46±0.78	ab	84.54±11.70	ab	2.55±0.58	ab	16.60±0.60	ab	68.88±6.95	ab	1.88±0.84	c
90	19.60±0.68	a	86.36±12.07	ab	2.92±0.83	a	17.11±0.27	a	74.75±5.50	ab	2.04±0.65	bc

* Means with the same letters are not significantly different at the 5% probability level.

As a result, the relationship between nitrogen fertilizer rate and yield, sucrose content and α-amino N values were statistically significant at 0.05 probability level. The P value obtained for yield, sucrose concentration and α-amino N at Altinekin and Alakova locations were determined as 0.01, 0.01, 0.02 and 0.008, 0.019, 0.003 respectively. However, according to results obtained from the experiment, the effect of seed varieties on sucrose content were statistically significant at the same probability level, but in terms of yield and α-amino, were not significant. Based on results from both experiments, while 90 kgN/ha was found as the appropriate nitrogen fertilizer rate in terms of sucrose content, the highest root yield was obtained when 120 kgN/ha was applied. The amount of α-amino N at Altınekin location increased with increasing nitrogen fertilizer rate, but the same trend was not observed in another experiment.

Determination of economically optimum nitrogen fertilizer rate

Determination of optimum nitrogen rate in nitrogen fertilizer consumption is important because of its impact on the sugar beet quantity and quality. In spite of observing the positive effect of using nitrogen fertilizer above the optimum rate on sugar beet yield, excess nitrogen rate, reducing the sucrose content and increasing the impurity index in sugar beet root, therefore cause to decrease the amount of refinable sugar in the sugar production process (Franzen et al., 2010). On the other hand, since nitrogen is a mobile nutrient (Harper, 1994) unnecessary use of this fertilizer leads to leaching nitrogen into ground water which it also leads to contamination (Spalding and Exner, 1993). Therefore, determination of the economical optimum rate of nitrogen is required. In order to determine optimum nitrogen rate, the average of yield and sucrose content values from two experiment were used to estimate response functions to nitrogen (Figure 1).

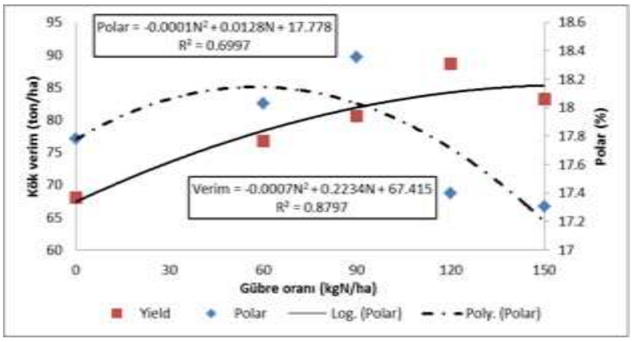

Figure 1. Estimated sugar beet yield and sucrose concentration response function to nitrogen rate.

Quadratic polynomial curves, as the most appropriate statistical model, were used to estimated yield and sucrose content values. Economically optimum nitrogen rate corresponding to sugar beet yield, sucrose content, sugar beet price and net return derived from net return equation using mean values of two experiments was determined as 115.64 kgN/ha. According to the result of statistical analysis related to yield and sucrose content, as it was mentioned before; the high sucrose content was obtained when the amount of 90 kgN/ha nitrogen was applied.

Evaluation of NDVI results

Descriptive statistics related to NDVI readings achieved from different measurement periods at two experiments are shown in Table 2. Considering the average NDVI value from two experimental locations, these values were changed from 0.22 to 0.71 and 0.35 to 0.68 in Altınekin and Alakova, respectively. Measurements were performed at four different cumulative growing degree days; the first one (before fertilizing) at 561 CGDD and the other three measurements (after fertilizing) at 1083.6, 1486.7 and 2235.3 CGDD, respectively.

Table 2. Descriptive statistics of NDVI readings at two experimental locations.

Measuring interval	ALTINEKIN				ALAKOVA			
	Min	Max	Mean	STDEV	Min	Max	Mean	STDEV
NDVI (before fertilizing)	0.13	0.39	0.22	0.056	0.24	0.43	0.35	0.043
NDVI 1(after fertilizing)	0.39	0.54	0.46	0.041	0.18	0.51	0.42	0.072
NDVI 2 (after fertilizing)	0.54	0.69	0.62	0.046	0.32	0.67	0.50	0.082
NDVI 3 (after fertilizing)	0.63	0.75	0.71	0.029	0.38	0.77	0.68	0.082

Green seeker sensor reading and root yield values were used to determine optimum timing of nitrogen fertilizing. For achieving this purpose, response index calculated from different NDVI readings and root yield at different measurement periods were utilized. The results of regression analysis to determine the relationship between RI_{NDVI} and corresponding $RI_{harvest}$ are reported in Table 3.

Table 3. Relationship between RI_{NDVI} ve RI_{Hasat} from two locations (R^2).

RI_{NDVI}	$RI_{Harvest}$	
	Altinekin	Alakova
RI_{NDVI} - first reading after fertilizing	0.27	0.46
RI_{NDVI} - second reading after fertilizing	0.38	0.63
RI_{NDVI} - third reading after fertilizing	0.11	0.45

As given in Table 3, the linear regression results indicated that the highest correlation value (R^2) was obtained during second Green Seeker readings (1486.7 CGDD) after fertilizing in both trial locations. According to this result, second Green Seeker reading period (93 day after planting) was determined as an appropriate time to apply variable rate nitrogen application. The impact of different nitrogen fertilizer rates on NDVI values that obtained before fertilizing application at the Altınekin trial site were not statistically significant (probably due to poor germination of seeds). Therefore, despite the impact of nitrogen rate on the percentage increase of NDVI values when compared with NDVI readings from the first fertilizing application, the significant relationship was not found between nitrogen fertilizer rate and NDVI values at the time of planned variable rate nitrogen application. However, the results of variance analysis at the Alakova trial site indicated that the differences between both NDVI value and their percentage increase response to nitrogen fertilizer rates were statistically significant (Table 4).

Table 4. The effects of different nitrogen fertilizer rate on NDVI values at second Green Seeker readings after fertilizing*.

N Rate	Altınekin			Alakova		
	NDVI	Increase (%)		NDVI	Increase (%)	
0 KgN/ha	0.58±0.029	192.24±50.34	ab	0.40±0.405	26.64±4.77	b
60 KgN/ha	0.64±0.035	125.84±45.45	b	0.46±0.039	33.93±19.23	b
90 KgN/ha	0.64±0.035	181.36±32.92	ab	0.48±0.035	35.56±8.42	b
120 KgN/ha	0.65±0.044	203.92±39.34	a	0.54±0.055	51.18±16.15	ab
150 KgN/ha	0.59±0.049	254.14±46.59	a	0.61±0.037	70.81±20.18	a

* Means with the same letters are not significantly different at the 5% probability level.

Because of the importance of yield potential for determining nitrogen application rate, INSEY index were used to predict potential yield by Green Seeker sensor readings. In order to create this equation, INSEY index calculated from second NDVI readings after fertilizing

(93 day after planting that have high correlation with $RI_{harvest}$) was used. The following equation estimated the potential yield at Alakova trial site (where NDVI values response to nitrogen fertilizer were significant) without additional nitrogen fertilizer:

Potential Yield = 81769 INSEY +37.855 **(R^2=0.51)**

Considering that CGDD were 1486.7 °C at 93th day after planting and with reference to INSEY=NDVI/CGDD, the relationship between Potential yield and NDVI values can be calculated as follows:

Potential Yield = 55 NDVI + 37.8

So, using INSEY index can be used to determine potential yield without additional nitrogen fertilizer.

Determination of variable nitrogen rate using green seeker readings

In order to drive nitrogen rate using a NDVI-based calibration equation, the data from Alakova trial site with meaningful data were used. Using obtained equation resulted in maximized economic return by avoiding unnecessary use of nitrogen and balancing between yield and sucrose content and harmful nitrogen. Because of statistical significance of the effect of two seed variety on NDVI values ($p<0.05$), the relationship between NDVI and additional nitrogen rate were determined for both seed varieties. The results were expressed by the following equations:

First seed variety (Mohican):

N Fertilizer Rate = 591.21 NDVI – 227.02 (R^2=0.76)

Second seed variety (Eldorado):

N Fertilizer Rate = 596.44 NDVI – 199.14 (R^2=0.80)

Nitrogen fertilizer rate obtained from above equations was determined as nitrogen level in sugar beet. Therefore, calculated NDVI values using Green Seeker sensor can be used to estimate the nitrogen status in sugar beet. So, the recommendation of nitrogen rate that should be used in the variable rate nitrogen application can be done by subtracting estimated nitrogen level in plants from predetermined optimum nitrogen rate (115.64 kgN/ha).

Conclusions

The adoption of precision nitrogen management in sugar beet production based on implementing soil and plant properties can increase sugar beet yield and quality as well as other nitrogen consumed plants, maintain its quantity and quality in low producing areas across the field and reduce cost of inputs. Sugar beet processing efficiency is directly related to root yield and quality that is greatly affected by nitrogen fertilizer. In addition, the percentage of sucrose and the level of impurities are two concepts of sugar beet quality which affect sucrose extraction by the processor. Production of high quality sugar beet is especially important to growers whose payment is based on the extractable sucrose content of their beets (Cattanach et al., 1991). In this study, applying different nitrogen fertilizer rates has significant impact on the yield and quality parameters. According to the result, maximum root yield and sucrose content were achieved when 120 and 90 kgN/ha was applied, respectively. The result of an anticipatory research conducted by Bauer and Stevenson, 1972 shows that, maximum level of sucrose content can be achieved by the use of a moderate rate of nitrogen (112 kgN/ha), so, maximum root yield can be obtained by applying 224 kgN/ha. The value obtained for nitrogen rate related to root yield in this study agreed with what resulted from a research reported by El-Sarag et al., 2013. α-amino N values in sugar beet root were increased with addition of nitrogen that were similar to the result of a study carried out by Gehl and Boring, 2005. Determined economically optimal nitrogen fertilizer rate in

terms of beet price and nitrogen fertilizer price on the basis of root yield and sucrose content response to applied nitrogen is one of the important steps to determine nitrogen requirement. To achieve this goal, quadratic model was used to determine the relationship between applied nitrogen rate and root yield and sucrose content (Adams et al., 1983, sayılı and Akça, 2004). The results show that the estimated economically optimal nitrogen rate for mean values of two experimental sites was 115.64 kgN/ha when the relationship between the sucrose content and the price are considered. In previous research, the results of determining economically optimal rate were carried out using only root yield values without considering sucrose content (Rezvani et al., 2012). Only a few studies related to winter wheat investigated economic consequences with regard to quality factors response to nitrogen fertilizer and the relationship between protein content and yield (Baker et al., 2004, Gandorfer and Rajsic, 2008).
Based on the results of NDVI readings from experimental pilots, the relationship between in-season estimate yield (INSEY) computed from NDVI readings collected from second sensor reading after fertilizing divided by the number of days from planting to the reading date, and measured sugar beet yield were used to determine potential sugar beet yield. With regard to response index of NDVI readings and yield at harvest, the application of nitrogen fertilizer at 1486.7 °C CGDD was suggested when the highest correlation were obtained between NDVI indeces. Nitrogen fertilizer requirement can be calculated using response function of NDVI to different fertilizer rate. The method of in-season prediction of nitrogen requirement in winter wheat by using INSEY values were also used to improve the yield potential model compared to using NDVI readings in sugar cane and sugar beet (Lofton et al., 2012, Franzen et al., 2013).

CLASSIFICATION OF AGRICULTURAL TRACTORS BASED ON ENERGY EFFICIENCY IN TURKEY

Ufuk TURKER*, Mehmet Ali DAYIOĞLU

Ankara University, Department of Agricultural Machinery and Technologies Engineering, Ankara, Turkey
*Corresponding author: uturker@agri.ankara.edu.tr

Abstract

Testing tractors to make sure that they meet their advertised performance claims has been a central focus of the manufacturers and farmers for decades. Agriculture uses energy directly as fuel to operate machinery and equipment and indirectly in the fertilizers and chemicals produced off the farm. There has been a continuing growing interest in fossil fuel economy and reducing greenhouse gas emissions in terms of economic and ecological reasons. A general goal of more energy efficiency encourages the use of tractors with better energy performance in agricultural operations. Tractor manufacturers report that customers are beginning to factor in fuel as part of the tractor-buying equation. Farmers are adding fuel efficiency to their list of purchasing criteria. In this study, an efficiency index, using the specific fuel consumption as a benchmark was applied to 58 tractors for classification of agricultural tractors derived from official tests that fallow the OECD (Organisation for Economic Co-operation and Development) codes. The survey was based on the results of tests conducted between 2010-2014 by TAMTEST (Agricultural Machinery Test Center of Ministry of Agriculture in Turkey). 58 models of tractors from 13 different tractor brand ranged from 10 kW (13.4 BG) to 119.3 kW (160 BG) sold in Turkish market were taken into account for classification. 24 tractors were fallen into average energy index category. 18 tractors out of 58 tractors are ranked above the average energy efficiency level. 15 tractor among the 55 tractor are found to be under the average energy efficiency level. This index provides a good option for comparing the fuel-efficiency tractors under standardised conditions. Additional testing is needed on other models of tractors from other manufacturers in order to determine whether the trends found in this study pertain to all tractors or if they are specific to this tractor model and manufacturer.

Keywords: Tractors, energy efficiency, consumption rates, engine.

Introduction

Energy efficiency of tractor is one of the most important factor influencing the progress of energy conservation and emission reduction for agricultural mechanization. The energy input in a tractor comes from the fuel introduced into its engine. From this energy, tractors provide energy outputs for drawbar pull, power take-off (PTO) and hydraulic power. Energy losses happen in engine and transmission. Knowledge of energy efficiency of tractor can guide farmers to select their best energy efficient tractor. However the energy efficiencies of tractors in Turkey expressed by specific fuel consumption are not well understood. Tractors are more difficult to rate because their performance is based more on kilograms pulled than kilometers traveled. It is impossible to establish an efficiency classification based on data of actual work due to variability of conditions in agriculture. The only reliable data come from the standardized PTO and drawbar tests performed according to the OECD test codes.

There have been number of studies to classify tractors depending on their energy efficiency. Harris (1992) developed a method to obtain the performance of the engine based on the data given by OECD tests. Souza et al. (1994) explained two functional relationship for the efficiency of tractors. They stated that multiple parameter curves are adequate to analyze the overall tractor efficiency. According to Siemens and Bowers (1999), “Depending on the type of fuel and the amount of time a tractor or machine is used, fuel and lubricant costs will usually machine is used, fuel and lubricant costs will usually represent at least 16 percent to over 45 percent of the total machine costs. Thus, fuel consumption plays a significant role in the selection and management of tractors and equipment.
Grisso et al.(2004) predicted fuel consumption of a tractor (Lh^{-1}) for any engine speed and load. Similarly, ASABE (2005) developed an estimation of average annual consumption of dieasel-powered tractors. With the general adoption in 2005 for OECD test code 2 of the new 6 points tested at the PTO (OECD Standard Code 2, 2008). Gil-Sierra et al.(2006b) studied the relationship between the coefficient Cj and rated to 206 tractors, pidindo them into five categories.
Gil-Sierra et al. (2007) classified tractors based on their efficiency in Spain. They used theoretical assumptions of Grisso et al.(2004) to fit the fuel consumption of a tractor at full throttle with variable loads measured during PTO test using the equation indicated below:

$$Q\ (L/h) = (a*X+b)*P_{pto}\ (kW) \qquad (1)$$

Where Q is the engine fuel consumption at partial load, X is the ratio between the power at any partial load and at the rated power, P_{pto} is the rated power at the PTO, and a and b are the parameters. This equation was extended to evaluate the consumption at lower engine speeds as:

$$Q\ (L/h) = (a*X+b)[A*X*N_{red}+B*N_{red}]*P_{pto}\ (kW) \qquad (2)$$

Where N_{red} is the percentage of reduced engine speed for a partial load from full throttle (%) and A and B are the parameters.

In March 2005 the OECD code 2 has introduced six points to be included in the test report whose coordinates of engine speed and power are shown in figure 1 (OECD,2007). The 6 points are: 1) maximum power at rated speed b) 80% power at rated speed 3) 80% power at 90% rated speed 4) 40% power at 90% rated speed; 5) 60% power at 60% rated speed and 6) 40% power at 60% rated speed as it can be seen from figure 1.

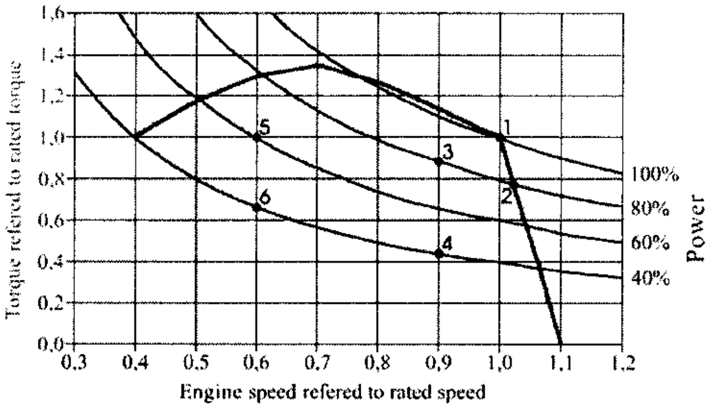

Figure 1. New points tested in the PTO incorporated in march 2005 in OECD

Material and methods

Tractor test data was obtained from TAMTEST reports performed for tractors tests starting from 2010 according to OECD test procedure. In those data, PTO test data including power, engine speed and corresponding fuel consumption data running the PTO at its standard speed at full and 5 partial loads were taken into account. One example of points tested at the PTO to measure power, engine speed and fuel consumption given in figure 2.

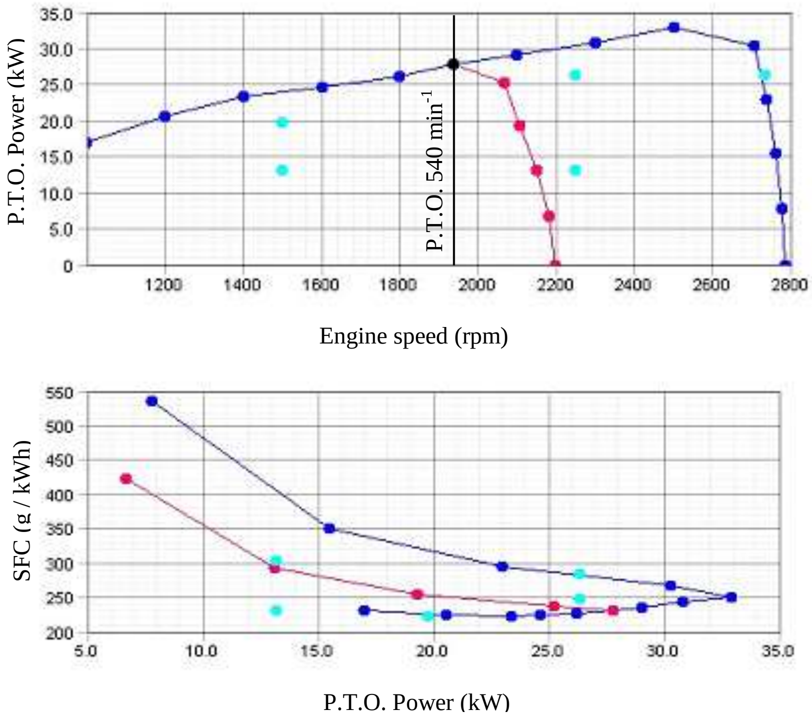

Figure 2: Points tested at the PTO to measure power, engine and fuel consumption.

Engine efficiency index development from tractor tests

Tractor test reports according to the OECD test codes 1 and 2 give data of fuel consumption, power and engine speed for the following points; a) rated power and full throttle at partial loads; b) standardized PTO speed at full and partial loads and c) maximum power. It has been possible to have better overall information of the fuel consumption of the tractor engine with the general adoption in March 2005 for OECD test code 2 of the new 6 new points tested at the PTO (Figure 1). PTO tests are given these 6 points for each tractor. An example of the tractor PTO test results are given in table 1. Considering the 6 new points, an index 'C_k' of the energy efficiency of the tractor engine was defined according to OECD code 2 and Ortiz-Sierra (2007).

The index C_k is calculated as the average specific volumetric fuel consumptions (SVFC) of these six points;

$$C_k = \sum_{i=1}^{6} \frac{SVFC}{6}$$

From the six points, C_k is calculated for each tractor. These calculated C_k was plotted versus the rated power of each tractor and an exponential regression line was fit to represent an average value of all tractors tested, meaning that approximately 50 % of tractors are above this line and 50% below. Then tractor models were classified according to their index C_k in seven categories with a bandwidth of 7 % around the average line. According to this categoric classification, a tractor which is represented by a point in one specific area was assigned to that category. In this way, the seven categories were created from lower efficient to higher efficient values of C_k as A,B,C,D,C,E,F and G.

Table 1. An example of PTO test results for new 6 points of a tractor used in Turkish agriculture according to OECD code 2.

Power	Speed			Fuel consumption			Specific Energy
	Engine	PTO	Fan	Hour		Specific	
kW	min^{-1}			kg/h	l/h	g/kWh	kWh/ l
3.1.6.1. Maksimum power at rated speed							
32.9	2500	697	2950	8.21	9.80	249	3.36
3.1.6.2. 80% power at rated speed							
26.3	2734	762	3226	7.49	8.93	284	2.95
3.1.6.3. 80% power at 90% rated speed							
26.3	2250	627	2655	6.52	7.78	248	3.39
3.1.6.4. 40% power at 90% rated speed							
13.2	2250	627	2655	4.01	4.78	304	2.75

Results and conclusions

Plotting the value of SFC versus rated power of every tractor, figure 3 is obtained in which there is a trend to reduce the value of SFC while rated power is increasing. In the figure is represented the exponential line (with a higher determination of coefficient of straight line) which represents average the trend of SFC versus rated power.

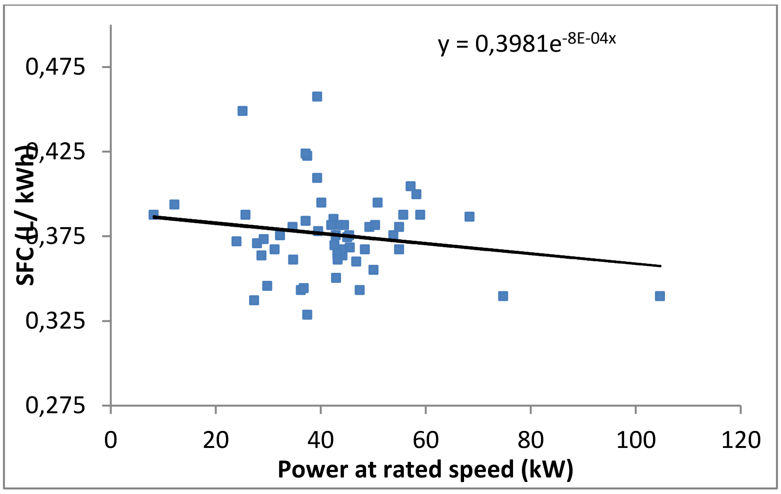

Figure 3. SFC (L/kWh) versus power at rated speed for all tested tractors

The tractor models were classified according to their index $SVFC_{PTO\text{-}d}$ in seven categories with a bandwidth of 5 % around average line. A tractor which is represented by a point in one specific area belongs to that category. The seven categories are called from lower to higher values of $SVFC_{PTO\text{-}d}$: A, B, C, D, E, F, and G, "A" being the most efficient and "G" the least efficient (fig4 and fig. 5). It is also useful to represent them with different colors, ranging from dark green through green, pale green, yellow, orange, pale red to red.

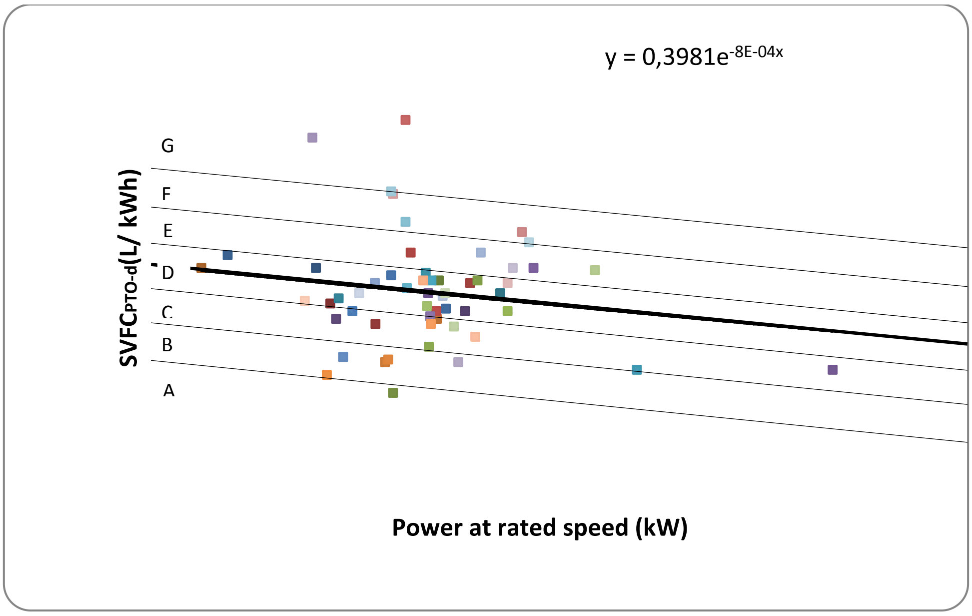

Figure 4. Areas in which the $SVFC_{PTO-d}$ versus rated power plot is divided around the average line

The number of tractors in each category is shown in each column. There are a smaller of models in the most and least efficient categories and a large number in the middle categories. The tractor models were classified according to this histogram follow a normal distribution. Therefore it is justified to assume that this method chosen to classify agricultural tractors according to the energy efficiency of PTO and drawbar test

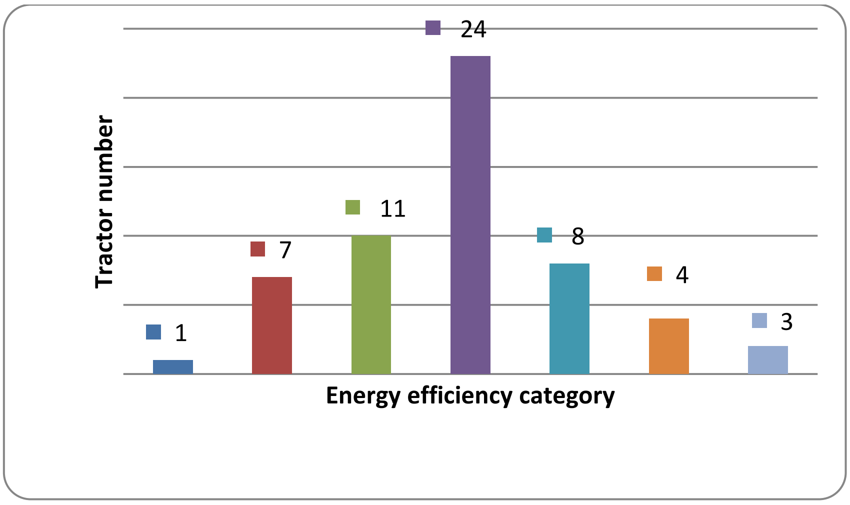

Figure 5. Histogram for 58 tractors in each category according to the efficiency index $SVFC_{PTO-d}$

The results are shown as a histogram in figure 5 for the 58 tractor models considered. The number of tractors in each category is shown in each column. There are a smaller number of models in the most and least efficient categories, and a larger number in the middle categories. The tractor models classified according to this histogram follow a normal distribution. This is verified by the Kurtosis normality test where, for a 5% level of significance the valué obtained is 0.2 (very close to 0) showing that that the distribution can be considered to be normal. Therefore it is justified to assume that this method chosen to classify agricultural tractors according to the energy efficiency of the engine is satisfactory.

When the graphic is examined; it can be seen that category A which is the most energy efficient tractor of whole tractor that tested. Only 2 of the tractor out of 58 has fallen category G as indicating least energy efficient tractors. Majority of the tractors have fallen between B and E. Average energy efficiency level category include 24 tractors, 19 tractors out of 58 tractors are above the average energy efficiency level. 15 tractor of 58 tractor are under the average energy efficiency level.

Conclusions

The results demonstrate that there is an energy efficiency differences between tractor models. So a new approach before buying a new tractor should involve the energy efficiency level of tractors. But farmer selection of a tractor cannot be based on only to energy efficiency. There other factors like operational flexibility, continuously variable transmission (CVT), hydraulic power, etc. A further study should also be included these factors. Consequently, this study is an example to classify agricultural tractors in terms of energy efficiency sold in Turkish market and farmers in Turkey may benefit to select more efficient tractor for their field operations.

Abstract

Straw mushroom sector has been strongly growing in Vietnam since last decade with more than 64,500 tons/year of production. The development of the sector helps improving both farm household's income and the environment by reducing pollution from rice straw burning at the end of the rice cultivation season. Basing on the potential of the sector, Vietnamese government issued an agricultural development programme in 2010 in which mushrooms will be the focus to develop as one of five national strategic commodities. In order to help the sector reaching this goal and growing more sustainably, the study was carried out in 2014 and 2016 to identify its opportunities and challenges by analysing stakeholders in the fresh straw mushroom value chain. The study was carried out through different meetings among the main actors of the straw mushroom value chain in August 2014 in Can Tho and in 2016 in Dong Nai province, Vietnam, to get opinions of target groups, key persons, as well as information concerning the aims of the study. An analysis of the main stakeholders was conducted to identify opportunities and challenges for the sector to grow more sustainably. Low investment costs, depending on production scale, quickly received income circle, low land and labour effort use are the main opportunities for farmers while limited use of improved production/processing technologies, limited production due to the seasonal character and climatic conditions are the main challenges for the other stakeholders of straw mushroom value chain. To enhance the use of hi-technology in production, preservation and processing and to build a brand for the Vietnamese straw mushroom are proposed to improve the current issues of the sector.

Keywords: *Mushroom, value chain, stakeholder, Vietnam*

Introduction

Straw mushroom is known as a new food for the future thanks to its clean, safe and high nutrition content (Getachew, 2016). This sector has been strongly growing in Vietnam since the last decade with more than 64,500 tons/year of production (Nguyen and Pham, 2013). The development of the sector helps improving not only farm household's income but also the environment by reducing pollution from rice straw burning at the end of the rice cultivation season. In 2010, basing on the ready available input materials from by-products of rice production and potential demand, the Vietnamese government decided to make mushrooms become one of five national strategy products (Ho, 2014) which means more investments received by the sector. In order to help the sector reaching this goal and growing more sustainably, the study was carried out in 2014 and 2016 to answers the questions what are the current status of mushroom value chain as well as its opportunities and challenges, and what does the sector needs to improve by analysing stakeholders in the fresh straw mushroom value chain.

Materials and methods

The research was conducted in the Mekong Delta, Vietnam which accounts for more than 90% of straw mushroom production of the country (MARD, 2012). The Participatory Rural Appraisal (PRA) (FAO, 1999) and Key Informant Interview (KII) (USAID, 1996) methods were applied to collect primary data through vary open questions and discussion with the different groups of actors in the value chain. Different meetings among the main actors of the straw mushroom value chain were organised in August 2014 in Can Tho University and in 2016 in Dong Nai province, Vietnam to get opinions of target groups and key persons, as well as information concerning the aims of the study. Relying on the discussion, it was easier to understand real problems and needs of each target group. In addition, potential solutions proposed by local communities that are appropriate for the existing problems and feasible to local community's resources were well understood for a qualitative analysis. Data were analysed by the Stakeholder Analysis method created by the UK Department for International Development (Brugha and Varvasovszky, 2006; DFDI, 2008).

Results and discussion

Fresh straw mushroom value chain in Vietnam

Straw mushrooms are usually cultivated in the tropical climate condition like Vietnam or other South-Eastern Asian countries with the temperature at about 28^0C-35^0C and air humidity at about 75-90%. Currently, there are more than 100 species of straw mushrooms in Vietnam (Rice 2, 2017) which is a high potential for the country to develop the sector. Straw mushroom production process starts by producing spawn in combination with a paddy straw preparation for both in house and open air type of cultivation and as followed by different stages to the fully fruiting development. The process duration is only 10-18 days from the button, eggs, elongation to mature stages when the fruiting bodies form looks like an umbrella. In Vietnam, more than 80% of the population follow the Buddhist religion and almost eight percent are real Buddhists. Therefore straw mushroom market has a very high demand due to its high vegetarian protein content which is the main meal of Buddhists. Straw mushroom product has high demand on the first, fourteenth, fifteenth and thirtieth day of the lunar month and the seventh month of the lunar calendar due to the tradition of culture as a Buddhist country. Hence, fresh mushroom production is also very highly seasonal and focuses very much on above mentioned days. Farmers always have to calculate their cultivation calendar to supply to the market in order to get higher prices at high demand period in the market. Out of those days, the product prices could be dropped down by three or four times. Demand of the product in the market has a high potential. The fresh straw mushroom distributes in the markets through the three following flows:

1)Flow 1: Farmers → Collectors → Retailers (at supermarkets or markets) → Consumers;

2) Flow 2: Farmers → Collectors → Processors;

3) Flow 3: Farmers → Consumers.

The first flow is the main distribution channel of fresh mushroom from farmers to consumers followed by the second, and the third, respectively.

Different stages of the production process and product flows enlighten the role of main actors in the fresh straw mushroom value chain in Vietnam involving primary and secondary ones. The main primary actors of fresh straw mushroom value chain include input suppliers, production farmers, collectors, processors, retailers and consumers (Figure 1). Secondary actors of the fresh straw mushroom value chain are noted as Extension services which support technique and market information for farmers, research institutions which carry out the studies on techniques to produce better quality of spawn and other techniques concerning the sector, local authorities represented by the Department of Agriculture and Rural Development of provinces, and bankers.

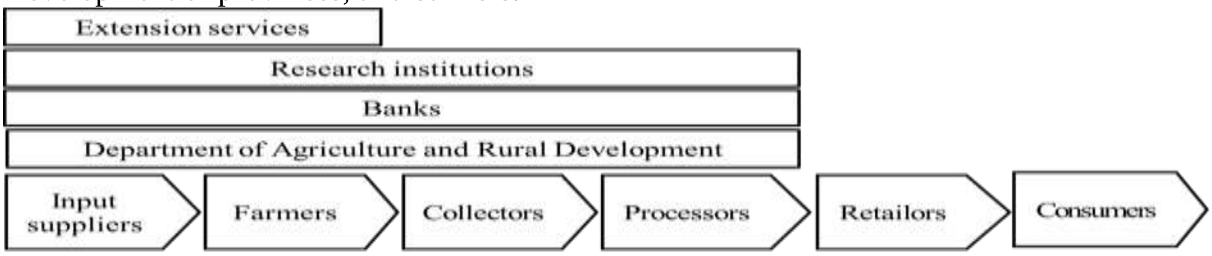

Figure 10 Fresh straw mushroom value chain in Vietnam

Analysis of main fresh straw mushroom stakeholders

Input suppliers provide input material such as spawn, paddy straw and chemicals for farmers to cultivate. They are one step backward of farmers in the straw mushroom value chain. Currently, farmers buy spawn and pay cash for input suppliers. There is no credit form for this action. Though the straw mushroom production sector exists since a long time in Vietnam, spawn producers are known as small scale, too low technique and skill level to produce high quality outputs. Therefore, spawns provided to farmers are often of low quality, lead to low yield of mushrooms on farm. The study observed that spawn diseases in recent years are also a very big problem which prevents the sector to increase its production.

Production farmers play a very important role in the fresh straw mushroom value chain in Vietnam. Farmers made up their paddy straw to cultivate mushrooms at the early step of the sector history. By the time, when the product became an important commodity for the country defined by the government in the national product strategy, farmers invested more with an expectation to get a higher profit. Presently, there are two mushroom cultivation types such as in house and outdoor. Average production area is 70-150 m^2/in house farm and 1,500/outdoor farm, showing the small scale of mushroom farmers. Farmers reached an average yield of 8-10 tons/ha and sold at VND 40-60 billion/ton depending on harvest time of the day and season. Mushrooms were cultivated two or three times per yers depending on rice production seasons and climate conditions.

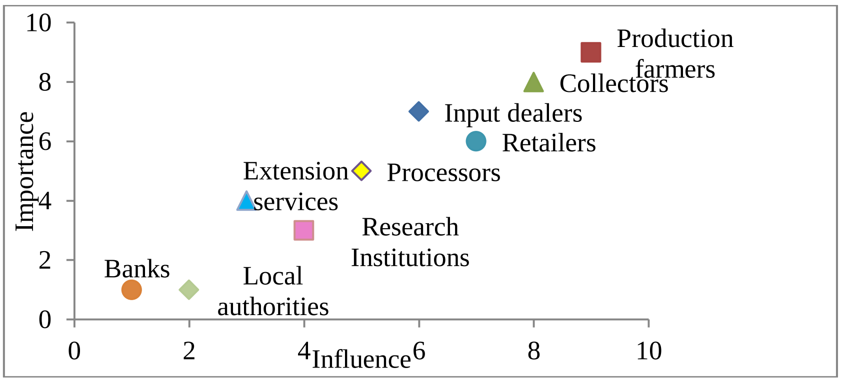

Figure 11 Influence and importance matrix of farmers in the straw mushroom chain in Vietnam

The influence and importance matrix of farmers in the straw mushroom value chain is presented in the figure 2. Farmers stay at the highest position in the matrix compared to other primary actors like input suppliers, collectors, retailers and processors showing that the sector is still supply-driven rather than demand-driven. This trend created excess product volumes on the market the next days after traditional demand days as mentioned above. As the product is a fresh food with short life duration of 3-4 days, selling price will drop down sharply on the next days after harvest. Nevertheless, a short production circle will help farmers to get a return on investment faster.

Cultivation outputs were presented to collectors at around 9am on local market. Due to its typical fresh product character, farmers only brought their mushroom sample to the market and sold them under informal auction form. The selling price was decided by farmers after consulting different prices given by collectors basing on their product quality. Harvest of mushrooms only started after this action until 12am. Only a direct cash payment relation exists among collectors and farmers. Therefore banks do not have much influence on farmers' activities and demand.

Most of straw mushroom farmers are also rice producers. They cultivate mushrooms after rice harvest period by making up their family labour and land. For that reason, mushroom production is not the main activity of farmers. Consequently mushroom income is not the main income source of the household. This observation is confirmed in a research of Ngo (2017). Hence, farmers do not invest a large amount in mushroom activities. This leads their technical level staying at a low, old and early stage compared to current advanced techniques of the sector in the world. Low yields and low economic efficiency are obvious results. Furthermore, as the market is the supply-driven one, famers have been presently concentrated their actions on technology, and much less on marketing.

Collectors rank at the second most important position in the fresh mushroom value chain after farmers, and before processors and retailers. In this value chain, collectors also play the role of wholesalers to supply fresh products to retailers and processors. This is the different point compared to other agro-product value chains in Vietnam mentioned in Ho (2012), and Ho and Burny (2016). Collectors provide reference market information to farmers on product price, demand and production period. However, the study noted that there is not any product quality preferences provided by collectors to producers. There is no official cooperation between farmers and collectors. The relationship among them is not strong.

Processors do not play a very strong role in the fresh straw mushroom value chain in Vietnam. They bought their input only from collectors. There is not any quality standard for straw mushroom products set up by the government therefore they do not have preferences for their input materials. Currently, processors do not get enough fresh mushrooms for their process. Boiled, cut and salty mushrooms conserved in cans and dried mushrooms are the main outputs of processors. Most of their products are for exports and a very small volume is supplied to the domestic market. No official relation among processors and other actors in the value chain was found during the study.

Retailers are one step forward of collectors in the fresh straw mushroom value chain in Vietnam. They are the main fresh mushroom suppliers to consumers in Vietnam. The product is often sold in the traditional markets rather than specialised shops or supermarkets due to the habit of Vietnamese customers to buy fresh food. Harvested mushroom arrived usually to retailers from collectors within maximum one day. Retailers just keep their goods for 2-3 days basing on its level of freshness. Currently, there is not any conservation technique to prolong mushroom life.

SWOT analysis of fresh straw mushroom value chain in Vietnam

Table 1 shows an analysis of fresh straw mushroom value chain in Vietnam where there is no official collaboration among the primary actors.

Table 5. SWOT analysis of straw mushroom value chain in Vietnam

Strengths	Opportunities
• Lack of collaboration resulting in high transaction costs and high consumer prices • High tech skill on spawn production • Limited plant protection knowledge: mushroom disease • Limited use of improved production/processing technologies • Limited production due to seasonal character and climatic conditions	• A clean, safe and high nutritious food • Abundance of low cost mushroom growing materials: straws, logs, enriched sawdust → reducing the loss of roots and tubers • Low investment cost, depending on production scale. Quickly received income circle. • Low land use, labour effort use and water use • Great potential: could reach 40 million tonnes per year • Enhancing the use of hi-technology in production, preservation and processing and build brand for Vietnamese mushroom
Weaknesses	**Threats**
- Low technical skills - High capital requirement - Low education level to learn new technology	- No support from government - High competitiveness among actors - Seasoning of straw mushroom production

Conclusions

Primary actors of fresh straw mushroom value chain currently do not play very well their roles to help the product become a main commodity in the market as expected by the Vietnamese government. Though farmers have many opportunities thanks to the quickly received income circle, low land and labour effort use, farmers and processing plants still have limited use of improved production/processing technologies and their investments remain low. The limited production due to its seasonal character and climatic conditions is also a challenge that hinders the increase of the farmers' production. Consequently, processors do not have enough raw materials to deal with. No official relation among actors is also a restrain of this value chain.

Enhancing the use of hi-technology in production, preservation and processing for the Vietnamese straw mushroom and building a mushroom brand name are proposed to improve the current status of the sector in order to achieve the government's national product development strategy issued in 2010.

Further quantitative analysis of the fresh mushroom value chain needs to be conducted to confirm the results of this study and to get a more precise and in-depth knowledge of this sector.

Abstract

The research objective of this paper is preliminary justification of the need to support the transfer of innovations to the food-processing sector. Another objective of the study is also to determine changes in the last period in policies to improve innovativeness and induced by them changes in legislation related to the system of innovation transfer. The basis for the research was studied literature, especially in the field of main stream economics, New Institutional Economics, public choice theory. According to the literature review the public financial support generally slows down the process of innovation transfer, but it is necessary if other countries apply such instrument. The empirical material for analysis was the statistical data of the Central Statistical Office (CSO) for the years 2010-2015 and Agency for Restructuring and Modernization of Agriculture (ARMA). The findings show that in the case of food processing sector the efficient policy support in innovation transfer seems to be needful. Conducted research also shows that it is very urgent issue. Reached findings lead also to the formulation of questions for further research, i.e. what are the appropriate policy measures to induce innovativeness improvement in food processing sector.

Key-words: innovation policy, food processing, law, fiscal policy.

Introduction

Poland is now a country with a relatively low level of innovation in the economy. According to the report of the European Commission (2014), a synthetic innovation indicator of the Polish economy amounted to 0.279, which put Poland in the group of countries with moderate innovation (Tusinska 2015). In fact, Poland was ahead in terms of innovation to only those European Union countries such as Bulgaria, Latvia and Romania. Reasonable seems to be speculation that one reason for this may be unreliable transfer system of innovation in the sector engaged in research and development to manufacturing and services. The increase innovativeness of the economy is, however, one of the priorities of European Union policy for 2014-2020. Under this policy, Poland should receive from structural funds the amount of EUR 82.5 billion, much of which can and should be used for the development of innovativeness.

Low level of innovation in the economy or its specific sector may be due to market failures that are related to the extent of the occurrence of certain internal structures (Hewitt-Dundas, Roper 2017). This provides grounds to the introduction of various institutional arrangements - e.g. to prepare and implement appropriate policies - supporting the transfer of innovation. When undertaking such initiatives with respect to a particular sector, it is worth to examine whether they are justified by the importance of this sector to the national economy. Another aspect to be considered is the current use of knowledge in the business. It may turn out that the sector does not require state intervention. Therefore the research objective of this study is preliminary justification of the need to support the transfer of innovations to the food-processing sector, which seems to be very important for rural economy as well as whole economy of Poland. Another objective of the study is also to determine changes in the last period in policies to improve innovativeness and induced by them changes in legislation related to the system of innovation transfer.

Methodical approach

The paper presents the results of the first stage of the research on institutional determinants of transfer of innovation into economic activity with particular focus on agri-food sector and rural areas in Poland. The basis for the research was studied literature, especially in the field of main stream economics, New Institutional Economics and public choice theory, referring to the question of the importance of knowledge transfer to business. Documentation studies were carried out also in the field of literature consolidating issues related to innovation and process of innovation transfer, the development strategy of determining the directions of the policy and the main acts forming the regulatory environment. Assessment of the importance of food processing and innovation in this sector were carried out using methods of descriptive and comparative analysis. The empirical material was the statistical data of the Central Statistical Office (CSO) for the years 2010-2015 and Agency for Restructuring and Modernisation of Agriculture (ARMA). Empirical studies were conducted at the national level.

Theoretical background

When considering the issue of institutional support for the transfer of innovation must be first and foremost in mind the fact that it can be a form of state interference in market processes. From the theory of prosperity, it is clear, however, that the market economy is inherently efficient (Feldman, Serrano 2006 Mas-Colell et al., 1995, Herbener 1997). The existence of a market economy in the European Union should therefore lead to the widespread use of innovation as a source of performance (Aghion, Jarave 2015 Arrow 1962 Thirtle, Ruttan 1987). In this case, support the transfer of knowledge and implementation of new innovative solutions should be superfluous and even leading to deterioration in efficiency. This can in fact be considered as a form of interventionism, which is not conducive to improving efficiency (Ajefu, Barde 2015, Cordato 1980, Grand 1991) - of course if these activities are directed only to a specific group of companies.

The economic literature indicates, however, the existence of market failure (Stiglitz 2004), which is a source of inefficiency. Therefore, we can believe that imperfect competition, asymmetric information and other market failures are limiting to a certain extent the use of innovation as a source of efficiency. An example of this is large diversity of innovative economies of the European Union (European Commission 2014) and the fact that the policy of support for the transfer of innovation not always causes an adequate growth of economic innovation (European Commission 2013). In practice, the country's economic growth - at least in the short term - is not necessarily due to the transfer of knowledge to industry and services sectors. Its source may be the low price of labour factor, the availability of cheap raw materials and favourable conditions on the world market (Kasperkiewicz 2008). According to Kasperkiewicz (2008), Polish economic growth in recent years has also resulted primarily from the use of these factors. Underestimation of the importance of knowledge transfer has led, however, to maintain, and even the rise of the technological gap between Poland and the most innovative economies of the European Union.

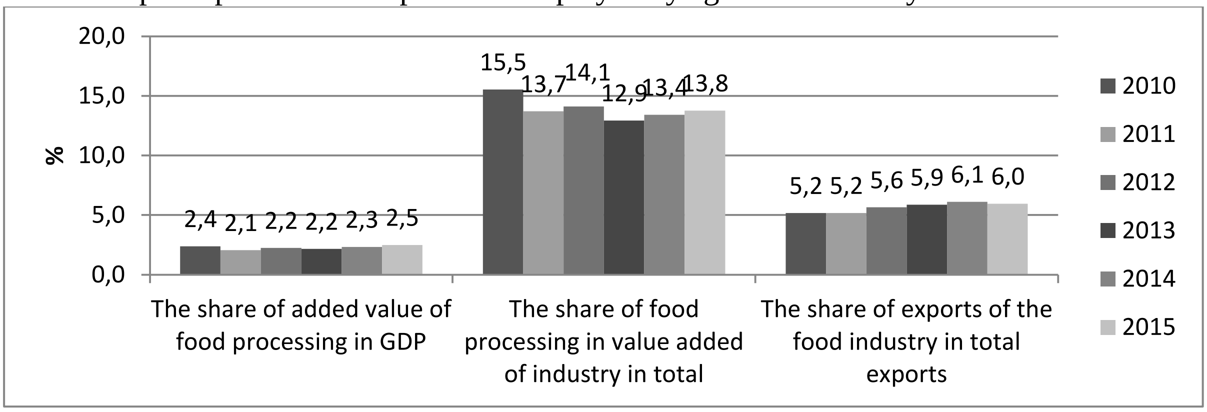
Limited use of knowledge as a factor of development and economic growth may concern the entire national economy and its individual sectors (Consortium Europe INNOVA 2011, Pavitt 1984, Malerba et al. 1997). All sectors, including food processing sector, are exposed to it.

One of the main reasons for limited innovation is existing structural conditions of a particular sector in a particular state. It can be exemplified by the implementation of organizational innovations related to new methods of human resource management in Serbia (Ratković 2015). According to Ratković (2015), the implementation of these innovations was conditional upon both the size of the company and form of ownership. It is generally that innovation results from complex interaction mechanisims. In small food firms innovation is strongly interwoven with the dynamics of the local environment, are also related to the characteristics of the firm (Noronha Vaz at al. 2004). The specificity of the structure of the food industry in Poland (Mroczek 2014) may also condition the specific institutional arrangements for promoting innovation transfer. The specific structure of the sector can be a barrier to the transfer of innovation to be taken into account when planning policy of support for this process. The internal structures of a particular sector are tied to a certain extent market failures. Example may be the unreliability of competition and information asymmetry. The severity of specific market failure is linked in turn to the degree of utilization of knowledge as a factor of efficiency improvements. This in turn may lead to institutional changes in the area of knowledge transfer, as exemplified by various policies oriented to support this process. Currently, one of the main trends of dealing with the role of the institution is the New Institutional Economics. With reference to the relationship between competition and knowledge transfer one of the leading representatives of this trend, namely North (2005) states that "... companies, political parties, and even higher education institutions in the face of competing organizations must strive to improve efficiency." According to the author muffled competition limits the motivation of organization to invest in new knowledge and, consequently, does not cause sudden institutional changes. On the other hand, strong competition accelerates institutional changes. In these considerations, the author concludes, therefore, that the cause of improvement of the effectiveness is generally the competition, and the measure for this is raising the level of knowledge.

Assuming the occurrence of dependences indicated by North it can be said that the support of the transfer of knowledge, e.g. by pursuing specific policies should take into account the competitive environment in which the organization operates, i.e. the company. If competition is negligible, the support for entrepreneurship through subsidizing the transfer of knowledge can bring marginal results, because companies will not be motivated to use it. Whereas the opposite effect will be in a highly competitive environment. From the above relationships, it also appears that some policies to support economic activity, as a form of assistance that utilize transfers of funds to selected companies, can cause the elimination of competitive companies in the long term to limit the willingness to invest in new knowledge, due to the lack of sufficient competition. So designing institutional support for the transfer of innovation should be taken into account the interactions that may occur between the hitherto functioning forms of business support, and the new - that should be considered for public support for transfers of innovation. Under certain conditions, however, policies may complement each other. Such a situation appears when in the conditions of zero competition financial transfers will contribute to the creation of new businesses, which will motivate existing businesses to improve efficiency, e.g. by implementing new innovative solutions. Institutions supporting the transfer of knowledge could then make a big difference for those companies that cannot cope with its acquisition on market principles. The consequence may then form an even more competitive environment. The scale of this support and the conditions, under which it is granted, however, should be defined in such a way as not to eliminate companies from the market using a particular policy.

Results and discussion

The study confirmed to a certain extent the importance of food processing for the Polish economy. Generally importance of this sector is primarily due to the fact that it allows the use of domestic raw materials produced in agriculture. However, the gross value added produced in this sector in 2015 reached over PLN 43 billion. It is 2.5% of Polish GDP (Figure 1). The share of manufacturing in gross domestic product, however, maintained since 2010 at a relatively constant level. Since 2010 a downward trend in the share of the food processing in industry value added is shown (Figure 1). In the analyzed period, this decline amounted to 1.7 percentage point. This may to some extent indicate that opportunities for further development based on the existing structure of production factors have been exhausted.
The processing of domestic raw materials, a significant role in the creation of Polish GDP and declining share in the added value of the industry is already some evidence to justify the institutional support for transfer of innovation in the food industry. However, the importance of this industry in the Polish economy much more indicates its achievements in terms of exports. Analyses show that in 2010-2015 exports of this sector accounted for over 6% of total exports in the economy and it showed an upward trend. This means that Polish food processing industry is competitive on the international market. It is also able to improve its competitive position. Foreign net trade of food processing is growing steadily. In 2013, this industry exports exceeded imports of more than 60%. In the case of the entire national economy, in the analyzed period, there was a negative balance of foreign trade. These relationships emphasize the important role played by agri-food industry in Poland.



Source: Calculations based on statistic data from the Central Statistical Office.

Fig. 1 The importance of food processing for the Polish economy in years 2010-2015.

Food processing industry also plays an important role in shaping the labour market in Poland. The sector employs about 450 thousand people, representing about 16.5% of all those working in the industry. The share of food processing in employment is therefore higher than the share of value added. This phenomenon can be seen on one hand as positive because the food industry produces relatively more jobs and to some extent, more than other sectors it contributes to reducing unemployment. On the other hand, such relations testify to the lower labour productivity. This is confirmed by further studies, which indicates that labour productivity measured in terms of gross value added per 1 employee was lower in the food processing than in the industry in general. In addition, in 2010-2013, growth in labour productivity in the food industry amounted to PLN 8.1 thousand, while in industry up to PLN 25.5 thousand. The growth rate of labour productivity in food processing was so much lower. This in turn is another prerequisite to the conclusion that the development of this sector to a lesser extent, based on the implementation of new, innovative production technologies, and the basis of this development are still low labour costs.

The research shows that only less than 12% of enterprises engaged in food processing in 2011-2013 has been introducing any innovation. Throughout the industrial sector such enterprises was 6.5 percentage points more. In the agri-food industry was relatively fewer companies than in the whole industrial sector, for both product innovation and process. Differences in the implementation of different types of innovation, however, were developed at a similar level. This means that the improvement in innovation of agri-food processing can be associated with significant changes in both the technology used in production and organization of the production process. This observation is confirmed by the fact that only 6% of companies in this sector both implemented the considered types of innovation.
The development strategy of Poland also includes the growth of economic innovation as a separate objective. In Poland is not expected the increase in expenditure on R&D to 3% of GDP, as in the Europe 2020 strategy, but only a "substantial increase in spending”, which is quite imprecise term. However, it is expected to take measures to increase demand for innovative solutions among entrepreneurs. Among the instruments that are geared to achieving this objective are mentioned:

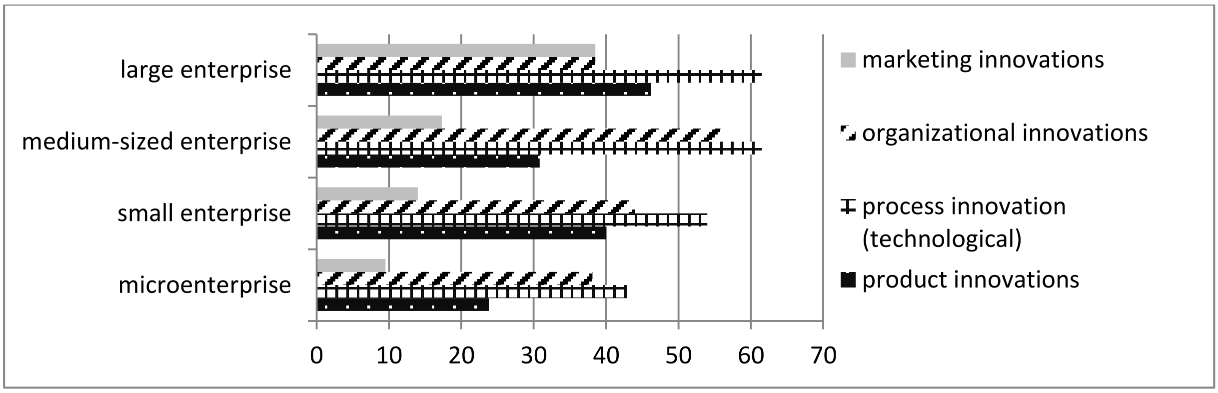
- tax instruments,
- loan guaranties,
- revolving instruments,

Support for investments in the food industry in Poland under EU aid programmes implemented in period 2003-2015 exceeded 1.4 billion Euro, including the share of European funds – over 1 billion Euro. The RDP program 2007-2013 was supported 996 food companies with funds in the amount of 0.5 billion Euro, and the total amount of investment has exceeded 1.6 billion Euro. The table 1 and figure 2 present in sequence number of enterprises introducing new products or techniques nad percentage of enterprises implementing different types of innovation projects in RDP 2007-2013.

	New product	The new technics (including technology)	New products and new techniques
Food industry	61	124	26
Industry non food	23	16	2
Wholesale	15	35	2
Total	99	175	30

Source: Monitoring data from the ARMA.

Table 1. Number of enterprises introducing new products and / or techniques in RDP 2007-2013



Source: Calculations based on monitoring data from the ARMA.

Fig. 2. Percentage of enterprises implementing different types of innovation projects in RDP2007-2013, by size of enterprises

In addition, this strategy involves the development of the financial market enhancing innovativeness. A special role will play:

- capital funds,
- loan or guarantee funds,
- leasing companies.

In connection with the implementation of the objectives of these development strategy aimed at improving innovation in the economy, some steps have already been made in aligning legislation. This is reflected in the Act of 25 September 2015 on the change of certain acts in relation to the promotion of innovation (Journal of Laws 2015).

Conclusions

According to persisting economic theories each policy is a form of the interventionism, which disturb market processes. Usually it is justified by government failure, which leads to the inefficient resource allocation. Therefore policy measures should be as much market-friendly as possible. In the last period we observe the evolution in policy measures focused on innovativeness improvement. Both EU policy measures and national ones are more oriented on the utilisation of repayable financial instruments than on the support in the form of direct subsidizing of economic activity linked to the innovation transfer. It seems to be right way to increase the efficiency of EU and national policy.

In the case of food processing sector the efficient policy support in innovation transfer seems to be needful. Conducted research also shows that it is very urgent issue. The high input in GDP and positive balance of foreign trade justify the importance of this sector for Polish economy. Food processing creates also a lot of jobs for rural people. But the reason of its success is still low labour cost – not the innovativeness of products and processes. It can be the barrier of its development or even defeat in the long run. Reached findings lead also to the formulation of questions for further research, i.e. what are the appropriate policy measures to induce innovativeness improvement in food processing sector, which will be efficient and acceptable and do we really need to create a new set of measures or we can introduce the solutions existing in other EU and non-EU countries.

Abstract

The government of the Kingdom of Saudi Arabia (KSA) is increasingly emphasizing the importance of institutional re-arrangements. One area of current interest to the Ministry of Environment, Water & Agriculture involves reforming public agricultural extension system. This research aimed to assess the external environment of KSA national system of agricultural extension. A scale concerning the external environment of organization (seven dimensions with 39 statements) was used for the assessment. The reliability of the scale was estimated by Cronbach's alpha; reliability coefficient was 0.813. Data were collected using an internet-based questionnaire form (in collaboration with Extension Administration, Ministry of Agriculture) with 81 extension personnel representing all extension directories in the country during the period May-August 2016. Percentages and mean scores were used for data presentation. The findings revealed that scores for extension personnel’s perceptions of the external environment scale were above average levels for four components (socio-cultural, political, administrative, and geographical environment) of the scale and below average levels for the remaining three components (technological, legal and economic environment). The mean score of socio-cultural environment was at the top of the list with the mean score of 3.98 (66.3% of the maximum score), followed by political environment (63.1%). While the mean of extension personnel's perception of the economic environment reached 4.5 (37.6%) followed by legal environment with about 45.6% of the maximum score. The result also showed that the mean score of the total scale reached 41, which represent 52.63% of the total score of the scale. Finally, some interventions for more enabling external environment of extension organization were recommended.

Keywords: *Organizational environment, Agricultural extension, Saudi Arabia*

Introduction

Approximately spreading over an area about four-fifths of the Arab Peninsula, with a total area of around 2,000,000 square kilometers, the kingdom of Saudi Arabia is the home of 31.8 million masses. It comprises about 80 percent of the Arabian Peninsula. It has borders with Jordon, Iraq and Kuwait in the north; Arab Gulf, Bahrain, Qatar and the United Arab Emirates in the east; the Sultanate of Oman and Yemen in the south and the Red Sea with a coastline of 1750 km in the west. The climate of Saudi Arabia varies from one region to another because of its diverse topographical features. As a result of a subtropical high-pressure system, the Kingdom is generally hot in summer and cold in winter where rains fall often. Moderate climate is seen in the west and the southwestern part of the Kingdom; dry hot summer and cold winter in the interior parts; and high temperature and humidity in the coastal areas. Major parts of the Kingdom usually receive scanty amounts of rain in winter and spring. However, in the summer, rainfall is significant in the southwestern mountains. Humidity is high on the western coasts and mountains almost all year and it gets lower as we go inland. The Kingdom is divided into 13 administrative regions. Each one of them is divided into a number of governorates differentiating in number from one region to another. And each governorate is divided into centers linked administratively to the governorate itself or the emirate. The emirate, governorate or center includes a number of population settlements linked administratively to it (GASTAT, 2016).

The Ministry of Agriculture has an elaborate network of centers, branches and facilities located across the country that provide various agriculture-related services to the farmers and other stakeholders in line with the mandate of the Ministry. The network comprises the following: six main sectors (five technical i.e. agriculture, agricultural development, livestock and fisheries, as well as agricultural natural resources and one for administrative and financial affairs), thirteen general directorates for agricultural affairs, located in main provinces, twelve directorates, 122 branches, 28 agricultural plant and animal quarantines, 34 veterinary units, 5 agricultural research centers, one olive research unit, three aquaculture research centers, 10 centers and branches for fisheries services, a national research center for combating locusts, eight veterinary diagnostic laboratories, a veterinary vaccine production center, a gene bank and artificial insemination, eight veterinary laboratories, and four agricultural training centers. The ministry has overall responsibility for providing public agricultural extensions services to the farmers. The Extension and Agricultural Services Division, performs this function in collaboration with the extension staff located in the General Directorates for Agricultural Affairs (Alsaghan, 2006, 2011; Ministry of Agriculture, 2016; Alsaghan et al., 2017; GFRAS, 2017).

Organizations are social entities oriented to certain goals. They are characterized by a designed structure and coordinated activities, and are open in terms of closeness with their environment (Fabac, 2010: 34). Organizations could be handled as open systems getting influences from the environment where they act, but the influence is not only unilateral; organizations also target shaping and reshaping the environments for themselves (Reino, et al., 2007: 124). The organization does not exist in a vacuum. It is located in a country and region to which it is inextricably linked. It operates within a legal and cultural context. These and other external-environment variables influence how an organization operates and what it produces. Such variables can shape the ways an organization defines itself and the ways it defines good performance (Lusthaus *et al.,* 1999: 52). The organizational environment is defined as all elements that exist outside the boundary of the organization and have the potential to affect all or part of the organization. The environment of an organization can be understood by analyzing its domain within external sectors (Daft, 2010: 53).

The development of any organization is one of the most important goals of its policy makers, so as to achieve the organization's objectives and programs to promote and grow at the level of the organization (Al-Qahtani, 2015). The process of improving the performance of any organization is the essence of comparing the actual performance of the organization with predetermined standards and measures. It aimed to diagnose, shed the light on the deviations and identify causes in order to taking the necessary rearrangements (AbdulRahman and Majeed, 2012: 191).

The organizational environment could be subdivided into the task environment and general environment as follows (Daft, 2010: 54-55): i) The task/ internal environment includes sectors with which the organization interacts directly and that have a direct impact on the organization’s ability to achieve its goals. The task environment typically includes the industry, raw materials, and market sectors, and perhaps the human resources and international sectors; and ii) The general/ external environment includes those sectors that may not have a direct impact on the daily operations of a firm but will indirectly influence it.

The general environment often includes the political, sociocultural, legal conditions, technology, and economic resources sectors. In contrast to the specific or task environment, the general or external environment mostly influences many enterprises at the same time. The term 'external environment' means the total of all individuals, institutions and other forces that are outside the control of the organization but that may affect its performance (Kattookaran, 2015: 5)

A good understanding of environment by managers enables them not only to identify and evaluate, but also to react to the forces external to their organizations. Thus, the economic, social, political, technological and other forces which operate outside the organization are part of its environment (ICSI, 2014: 2).

Dimensions of, or the factors constituting the external environment include economic, social, technological, political and legal conditions, which are considered relevant for decision-making and improving the performance of an enterprise. However, management of every organization can benefit from being aware of these dimensions instead of being disinterested in them. Elements constituting the external environment of organization are given below (Lusthaus *et al.*, 1999: 52-56; ICSI, 2014; Kattookaran, 2015):

1. **Administrative Environment** includes all administrative issues that can affect the organization i.e. administrative norms and values, rules of related organizations, bureaucracy, etc.
2. **Economic Environment:** Interest rates, inflation rates, changes in disposable income of people, stock market indices and the value of SR are some of the economic factors that can affect management practices in an organization.
3. **Socio-cultural Environment:** The social environment of organization includes the social forces like customs and traditions, values, social trends, society's expectations from business, etc.
4. **Technological Environment** includes forces relating to scientific improvements and innovations which provide new ways of producing goods and services and new methods and techniques of operating a business.
5. **Political Environment** includes political conditions such as general stability and peace in the country and specific attitudes that government representatives hold towards organization.
6. **Legal Environment** includes various legislations passed by the Government, administrative orders issued by government authorities, court judgments as well as the decisions rendered by various commissions and agencies at every level of the government.
7. **Geographical Environment** includes geographical conditions such as location, climate, and natural phenomenon and ecological factors that can effect on the organization.

Extension organization does not exist in isolation. Each organization is not an island unto itself; it exists, survives and grows within the context of the element and forces of its environment. While an individual organization is able to do little to change or control these forces, it has no alternative to responding or adapting according to them. Based on this quick discussion, this study is aimed to assess the external environment of KSA public system of agricultural extension.

Materials and Methods

A scale for organizational external environment (seven dimensions with 39 statements) was developed based on review of literature in the field of organizational environment. Respondents were asked to indicate their opinion on each statement on a 3-

point scale ranging from zero to 2 (not applicable, somewhat, applicable). The reliability of the scale was estimated by Cronbach's alpha. Data were collected using internet-based questionnaire (in collaboration with Extension Administration, Ministry of Agriculture) form within personal interviews with 81 extension personnel representatives from the extension directorates around the nation during the period from May-August 2016. Percentages and mean scores were used for data presentation.

In order to confirm the reliability of the used scale, reliability analysis (for the items of each component and the overall scale) was carried out via Cronbach's alpha by SPSS software. Findings in table 1 show that reliability coefficient (Cronbach's Alpha) was about 0.813 for the overall scale. While it ranged from 0.656 to 0.879 for the components of the scale. These findings indicate that the scale is reliable and could be used for measuring the external environment of agricultural extension system in KSA.

Table 1. Number of items of organizational environment dimensions and corresponding values of Cronbach's Alpha.

No	Dimensions of external environment	No. of items	Cronbach's Alpha
1	Socio-Cultural Environment	3	0.665
2	Political Environment	6	0.825
3	Administrative Environment	10	0.880
4	Geographical Environment	3	0.656
5	Technological Environment	5	0.847
6	Legal Environment	6	0.875
7	Economic Environment	6	0.879
	Overall External Environment	39	0.813

Source: The study’s findings.

Results & Discussion

Table 2 shows mean scores and percentages for extension workers' perception of the organizational environment dimensions. It can be realized that the respondents’ overall perception of the enabling environment for extension system is 40 which represents 52.6% of the total score; this implies that extension workers barely perceive the enabling environment for public agricultural extension organization in KSA. The table also revealed that scores of four dimensions of external environment are above overall average of scale while the remaining three are under the overall average scores.

The table revealed also that “Socio-cultural environment” received the highest score among the seven components (66.3% of the maximum score) followed by the “political environment” (63.1%). This implies that public agricultural extension system has gained the socio-cultural advocacy as well as the political advocacy which could be reflected in its potential success.

On the other hand the “economic environment” received the lowest score (37.6%) followed by the “legal environment” (45.6%) and the "technological environment" (52%); this indicates that the low satisfaction of the extension personnel on the economic circumstances around extension organization, the disabling legal environment as well as inappropriate technical resources available for public agricultural extension system.

Findings also revealed that administrative and geographical environments have gained a moderate satisfaction of extension personnel with percentages of 55% and 54%, respectively. This result indicates that these dimensions do not act as inhibitors or as catalysts for the extension organization, so some more efforts in these directions may improve the performance of extension organization.

Table 2. Means and percentages of extension workers' perceptions of the organizational environment dimensions.

No	Dimensions of external environment	Max. score	Mean		Gap*	
			Score	%	Score	%
1	Socio-Cultural Environment	6	3.98	66.33	-2.02	-33.67
2	Political Environment	12	7.57	63.08	-4.43	-36.92
3	Administrative Environment	20	11.09	55.45	-8.91	-44.55
4	Geographical Environment	6	3.25	54.17	-2.75	-45.83
5	Technological Environment	10	5.19	51.9	-4.81	-48.1
6	Legal Environment	12	5.47	45.58	-6.53	-54.42
7	Economic Environment	12	4.51	37.58	-7.49	-62.42
	Overall external environment	78	41.05	52.63	-36.95	-47.37

Source: The study's findings. * gap score = mean score – maximum score.

The radar chart as shown in Figure 1 was used to illustrate the gap between maximum and mean scores of extension workers' perceptions of the studied scale components; this gap could be calculated by subtracting the maximum scores from the mean ones. It could be noticed that gap score have negative signs, indicating a value of reduction in the respondents' perceptions compared to the maximum scores of each component

The Figure also revealed that the component "socio-cultural environment" showed the lowest gap (33.7%), followed by "political environment" component with value of (37%). While the component "economic environment" received the highest gap value (62%), followed by component "legal environment" (54%), and component "technological environment" (48%).

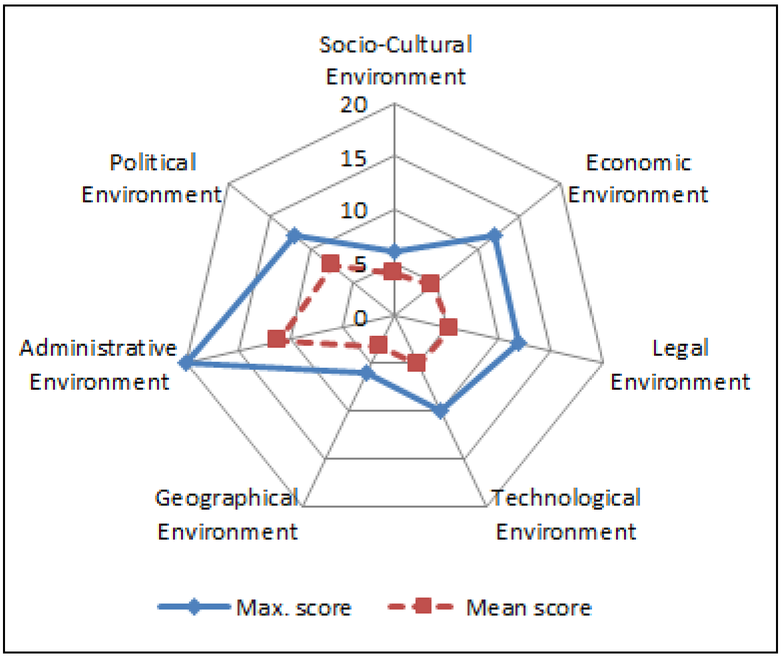

Figure 1: Radar chart displays of gaps of the external environment dimensions.
Source: The study's findings.

Conclusion

This study highlighted the significance of recognizing extension workers' perception of the enabling environment for the national system of agricultural extension. It could be noticed that scores of administrative, political, and socio-cultural dimensions of organizational environment are above the overall average of scale while legal, economic and technological dimensions are under the overall average scores.

It could be concluded that there is high opportunity to support the organizational environment of extension system concerning all studied dimensions, much effort has to be done to reach an enabling environment for extension system. One of these efforts is policy-makers' faith on the importance of creating an enabling environment for agricultural extension through planned, purposeful and constructive vision.

Since, the government (The Minister of Agriculture, Director of the General Administration of Agricultural Extension, Director of the Department of Agricultural Extension) tend to achieve more enabling external environment for extension organization, bellow some suggestions to improve agricultural extension in Saudi Arabia: 1) Moving towards digitalization of agricultural extension system and utilization of ICTs services provision as well as extension management; 2) Establishing a flexible organizational structure to respond to changes and modern trends; 3) Availability of financial and human resources needed to support agricultural extension projects and plans; 4) Supporting public-private and local-international partnerships; and 5) Improving the efficiency of the institutional performance by applying quality assurance criteria in extension organization.

STATE AND PROSPECTS OF RURAL TOURISM DEVELOPMENT IN KOLUBARA DISTRICT (SERBIA)

Dragan STEVANOVIC*

Municipality Ljig, Tourist organization of the municipality Ljig, Serbia
*Corresponding author: belipersin@gmail.com

Abstract

The paper is based on a multifunctional model of agriculture, which in addition to manufacture of vegetable and livestock production, implies development of other complementary activities for the economic viability of rural households and their family farms.
The implementation of this model of agriculture on small family farms in Serbia, puts a special emphasis on rural tourism. The study analyzed Kolubara District, and six municipalities and their villages: Valjevo, Ub, Lajkovac, Mionica, Ljig and Osecina. The expected results of this work are the promotion of Kolubara District, as a new destination rural tourism at national, regional and European tourist market.
Taking into account the level of research for this study, the expected contribution would be to identify tourism products of Kolubara District and to identity tourist attractions and potential for rural tourism development. Kolubara District with natural resources its cultural and historical heritage of traditional architecture, cuisine, folk traditions, local crafts, native livestock breeds and plant varieties has the potential for development of rural tourism. The offer of the rural tourism in Kolubara District includes villages, ethnic villages, ethnic houses and events that give tourists an authentic experience of a rural environment.
Development of rural tourism in Kolubara District is directly connected with the income from tourist consumption because the purchase of additional products and special services outside of rural household, income can increase by 50 percent or more.
All municipalities in the Kolubara District have a strategy for the development of agriculture and tourism, which emphasize rural tourism as an important factor of mutual development. Their implementation would be applied in practice multifunctional model of agriculture and rural development, and rural tourism.

Keywords: *Rural tourism, tourist services market, promote, Kolubara district*.

Introduction

Tourism in rural areas has become a reality, a need and a desire of tourists, but also a carrier and instrument for the development of rural areas (Koscak M., 1998). Rural capital includes various components of rural wealth. They can be natural (eg agricultural or forest populations), then infrastructure (eg built village settlements and other infrastructure facilities necessary for the life and work of residents and visitors and users of rural tourism services), or social, such as local cultural tradition, historical monuments, and more.
Serbia has great untapped potential for the development of rural tourism, due to the preserved nature, traditional architecture, local cuisine, folk customs, homemade crafts and indigenous breeds of cattle and plant varieties. Rural tourism in Serbia, as well as in other European countries, is a significant factor in the multifunctional development of agriculture and rural

areas in general - which "involve 85% of the territory of Serbia, with 55% of the population living in them and forming 41% of the country's GDP" (Bogdanov N., 2007 : 31).
Rural tourism in Serbia does not have a long tradition. The beginnings of the development of rural tourism in our country date from the 1970s, and the pioneers are the villages of Seca Reka (Kosjeric), Sirogojno (Cajetina) and others. Although Serbia has a diverse and attractive structure, it is not accompanied by an adequate profile of tourism products. Prior to the above mentioned period, rural tourism rarely appeared in the tourist offer of Serbia. Despite the initial offer 40 years ago, fragmented and dispersed peasantries, insufficiently developed awareness of the value of the environment, and primarily the focus on other forms of mass tourism (marine, urban, spa and mountain), have affected the poor development of rural tourism. The absence of Serbia from the international tourist market in general, and in particular the rural tourism market during the sanctions and other consequences of the disintegration of the former SFRJ, contributed to the absence of Serbia, so rural households as potential bidders remained unprepared and unorganized to form more serious offers to potential users of this type of tourist services.
Rural tourism in the wider context of the topic of this work includes not only a holiday in rural households, but also all other tourist activities in rural areas: tourist events dedicated to traditional agricultural production, participation in agricultural works and works in the household, brandy road, wine roads, sports -requirements (hiking trails, riding, cycling tours, paragliding, rafting, boating and kayaking, ...), hunting, fishing and photo safari, visits to natural, historical and cultural monuments, religious sites, harvesting and processing of forest fruits, medicinal and other wild plants, etc.

Table 1. Basic information about Kolubara District

Municipality	Area (in km^2)	Population (Census 2011.)	Population density (inh./ km^2)	Number of suttlements	Number of households	Average household size
Valjevo	905	90312	100	73	30728	2,9
Ub	456	29101	64	38	9119	3,2
Lajkovac	186	15475	83	19	5050	3,1
Ljig	279	12754	46	27	4407	2,9

Kolubara District	2474	174513	62,67	213	58031	3,0

Source: Republican Bureau of Statistics, Belgrade

Kolubara District is located in the northwestern part of Serbia and covers a space of 2.474 km², which represents 2.8% of the total area of the Republic of Serbia. The municipalities include Valjevo, Lajkovac, Ljig, Mionica, Osecina and Ub. In 213 settlements there are 174.513 inhabitants or 2% of the total population of the Republic of Serbia (Table 1). The seat of Kolubara Administrative District is the city of Valjevo. The municipalities of Mionica and Osecina from the area of the district belong to the group of underdeveloped areas of the Republic of Serbia.
The comparative advantages of the Kolubara District are: agricultural, mining, traffic and tourism potentials.

Natural conditions allow 80% of the surface of the district to be favorable for the development of livestock and fruit growing, and about 90% of the surface of the district is favorable for agriculture in general.
Natural potentials and ambient values combined with favorable tourist geographical position in relation to the sources of demand, are a good basis for the development of health and recreational (industry, health), mountain, rural, transit, eco, religious, hunting and fishing tourism.
Priority of the development of the Kolubara District economy is the activation of tourism potentials in already well-known tourist destinations, by raising the quality of the tourist offer (improvement of the off-site content), with the implementation of new projects.

Material and Methods

The following methods of research were used in this paper:

• Historical method and method of content analysis are used in the study of archival material and other historical documents important for the consideration of the development of rural tourism, statistical data and for the research of results related to thematic in other countries;

• Cartographic method is also used to determine the state of rural tourism in the Kolubara District and for the comparison of Serbia and other countries, a comparative method is used;
• A method of interviewing is used to determine the situation in selected households that provide rural tourism services in the Kolubara District;
• In the formulation of attitudes about the tourist potentials and significance of individual rural areas, the assessment of the current development, the current situation and the indication of possibilities for further development of rural tourism in Kolubara District, the method of trivial conclusion is used.

Results and Discussion

Rural tourism in the Kolubara District began to develop in the 1960s, and is associated with villages with tourist attractions, such as Brankovina, Valjevska Kamenica, Slavkovica, Belanovica, Struganik and others.
The beginnings of the organized development of rural tourism in Valjevo region and Kolubara District are related to the year 2000, when one enthusiast, according to the expert forestry engineer, Dragić Tomić, initiated an initiative and wrote a project entitled "If he is, I will." Tomic has very well understood the problem of thinking and functioning of a man in the village, especially when it comes to matters and material attitudes. Thanks to this project, Tomic succeeded in using this Serbian initiative in direction of healthy competition, in a way that the host will be convinced of the material and social benefits that his neighbor accomplishes in this activity. Of course, this is primarily meant for the fact that rural tourism is an activity that provides additional income for the provision of accommodation and food, but also additional services such as trips in nature, walking through the forest and surrounding areas, reading mushrooms and forest fruits, storing healthy food with the housekeeper in a traditional manner, keeping cattle grazing, etc.
The next step in the promotional activities was made by the members of the Internet club from Ljig in 2004, by launching the project "Development of rural tourism of Serbia" with the help of the funds of the Ministry of Agriculture, Forestry and Water Management at the then Ministry of Agriculture for the allocation of incentives for development of agriculture. The funds used were used for the visit of the households and the launch of the website www.selo.co.rs.

The continuation of the development of rural tourism in the Valjevo region followed in 2005 when Tomić formed a non-governmental organization called the Association of Hosts „Valjevo“, with the main goal of improving rural life with a special emphasis on the development of rural tourism as one of the best ways to goal achieves. At the very beginning, a survey was conducted, that is, about a hundred rural households were interviewed, 60 of whom wished to engage in rural tourism. The survey wanted to determine what potentials were and how the general situation was related to households, number of members, capacities, etc (Stevanović D., 2012).
After this research it was established that there are good bases for the development of rural tourism in Valjevo region. Immediately started with the process of categorizing objects, but also educating the host about the proper engagement with this activity.
Analyzing the total accommodation capacities in Kolubara District, it can be concluded that 94 households in 56 villages are currently categorized for rural tourism, that there are available 250 rooms with 479 beds as well as 14 modern apartments.
It can also be seen that these are rural households who provide accommodation and meals as a form of supplementary activity, which provides additional income for the household. So these are households that mostly issue rooms within their houses or the whole floor, or the whole house. In this case, it would be desirable that hosts are housed in another house in the same courtyard, but this is not always the case.
But, this is also about the hosts who live and work in the city, while the village households are betrayed. Nutrition of tourists is provided by engagement of the nearest neighbor, or they are given a ready meal. This can not really be called true rural tourism, since there is no clearly defined host-to-host relationship, nor does it create an impression of the host's gallantry.
Accommodation capacities vary from household to household, although these are family houses where two, three or four generations live. The courtyards are classical countryside, with large lawns and plenty of flowers, and sometimes with which old object such as vajat[48] or dairy. In the vicinity there is an economic part with stables, hens, pigs, тhere are also gardens and orchards all in the function of food production, both for hosts and for guests.
However, there are outdated facades of houses, worn furniture, etc. which has to be restored. It is necessary to pay more attention to aesthetics, interior and exterior. This implies the use of old furniture, which often goes down somewhere in a basement, and whose restoration would return to its function, and in appearance would satisfy the ethno style. The use of any ethnic object is welcome in the form of a small garden exhibition, or for use when serving food (wooden bowls for cream and cheese).
When collecting data from official statistics, there were problems with the records of tourist traffic and overnight stays in the field of rural tourism. Namely, the Republican Bureau of Statistics does not have official data (such records are not kept), but they came through the Tourist Organization of Serbia (TOS), tourist organizations (TO), associations and others.

Observing the estimated data on the number of overnight stays in rural tourism received from the Association "Rural Tourism of Serbia", we can conclude that the participation of overnights of rural tourism in the Kolubara district in relation to the overnights of rural tourism in the Republic of Serbia in 2007 reached a maximum of 8,77%, when it started its constant decline to a minimum of 3,34% in 2010. In the observed period, this phenomenon can be characterized as a permanent development of rural tourism and an increase in the number of overnight stays in the Republic of Serbia, and on the other hand, the stagnation and decrease in the number of overnight stays in the Kolubara District since 2007. In support of this, the fact that the Kolubara District still does not have an adequate strategy for the

[48] Vajat - a small wooden house without windows in the yard.

development of rural tourism, but its development took place in a styche with an inadequate base of serious rural tourism households.

Table 2. Tourism turnover and share of rural tourism turnover in R. Serbia and Kolubara District

Year	Number of overnight stays in rural tourism in Serbia	Number of night. in rural tourism in the Kolubara District	Participation rates of rural tourism Kol. District overnight stays in rural tourism R. Serbia (in %)
2007.	131130*	11500*	8,77
2008.	177455*	11000*	6,20
2009.	220505*	12500*	5,67
2010.	284320*	9500*	3,34
2011.	241321*	11350*	4,70
2012.	279337*	10500*	3,76
2013.	265556*	9890*	3,72
2014.	220450*	8210*	3,72
2015.	291300*	12105*	4,16
2016.	271852*	11892*	4,37

*Assessment - Data obtained from the Association "Rural Tourism of Serbia", Ljig, Karadjordjeva 7.

Regarding the turnover of tourists in rural tourism, official data are scarce and unreliable, mostly because this type of tourism is still in development. The biggest problem is the poor organization of the competent institutions, but a few people from the villages who irregularly report their guests.

Comparing the data of the non-governmental organization responsible for the development of rural tourism in the Kolubara District - "Village tourism of Serbia", it can be noted that, in 2016, 11892 nights were registered, in july and august, mostly in july and august they stay 3-5 days. Families with small children are usually on vacation or it is about older clients. It was also noted that in all villages there is not equally represented the visit, so most tourists go to the villages: Popucke, Brezovica, Bacevci (Podbukovi), Valjevska Kamenica, Milicinica, where they are households that have been serious for four, five and more years deal with this business, and which have made remarkable results in recent years.

It is necessary to point out, and according to the research in the territory of the Kolubara District, that in the period from 2007 there was a certain filtration and selection of rural tourist households who want to deal with this business seriously. These include those of agricultural holdings and ethno-households who have the necessary conditions and accommodation capacities in accordance with the requirements of tourists. However, there are also a group of registered, for various interest reasons, who cease to deal with and slowly gas, which can be understood as a legal phenomenon in this perspective branch of tourism, which should now be developed qualitatively and in line with market demands.

Research of rural tourist households in Kolubara District

The author conducted a survey of 19 owners of rural households and ethno-households on the territory of the Kolubara District. The rural households that were included in the survey are located in the municipalities of Valjevo, Ljig, Mionica and Osecina.

- A large number of facilities in rural tourism started operating between 2004 and 2009 (89%), while only 2 buildings (11%) started to work between 1985 and 2004;
- It was found that 17 facilities (89%) provide services throughout the year, while 2 facilities (11%) work either seasonally or by announcement.
- Most rural households employ 3-5 household members;
- Equal representation of agriculture and tourism as primary activities in the proportion of 50: 50 percent;
- 100% of households offer accommodation and meals;
- The most frequent activities during their stay in rural households are trips and walks in the environment (47%), and sports and recreational activities (26%);
- It was found that the largest number of respondents has area of 5-10 ha (37%), while at least those are up to 1 ha (10%);
- The most common cultivated crop is maize (53%), followed by wheat and leguminous plants (37%), while (26%) of the surveyed owners do not have arable land at all;
- The most common cultivated fruit crop is plum (95% of the respondents), second place is apple and pear tree (74%), third place raspberries (42%);
- The majority of owners (79%) are engaged in sheep farming, second place is poultry (74%), pig farming (68%), while the fourth place belongs to cattle breeding (58%);
- The tractor and all ground handling machines are 63%, 42% seedling and sprinkler, 37% tractor and cultivator, 21% motocultivator, and 16% of the hay baling machine.
- Most respondents have a passenger car (95%), a van has a 16%, a freight and off-road vehicle has 11%, while the delivery vehicle is only 5%.
- Production of cheese over 500 kg has 21%, up to 500 kg 16%, over 300 kg 21%, up to 100 kg 5%, and 37% of them do not produce cheese.
- The largest production of kajmak (cream speciality) up to 100 kg has 26%, up to 50 kg 21%, over 200 kg 11%, up to 200 kg kajmak produces 5%, the other 37% does not have this production;
- Over 100 liters of brandy are produced by 58% of the tested, from 50-100 liters 11%, to 50 liters 5%, while 26% do not produce brandy at all;
- Poor use of the Internet: only 26% of households have a web site and e-mail;
- The largest number of households sell their services on their own (63%), while through travel agencies it makes up 37%;
- Only 21% of rural households are included in a tourist arrangement;
- A relatively smaller number of households have their own prospect (32%), while at fairs they rarely perform independently;
- The cooperation with the tourist organization of the municipality and the host associations has the highest percentage of respondents 42%, while 16% of respondents do not cooperate with any tourist organization or association;
- 95% of tourists are of domestic origin;
- The average length of stay is 3-5 days.

Research of tourist organizations in Kolubara District

The survey questionnaire encompassed 5 tourist organizations in the Kolubara District. The survey was attended by employees in the following tourist organizations: Tourist Organization of the Municipality of Valjevo (by 2011. J.P. "Valjevo-turist"), Tourist Organization of Ljig Municipality, Tourist Organization of Mionica Municipality, Tourist Organization of Osecina Municipality and Tourist Organization of Lajkovac Municipality . The test was carried out individually.

It should be noted that the Municipality of Ub still has no established tourism organization.

- Most tourist organizations were established between 1994 and 2005;
- On average, rural tourism is in second place by importance and development in the observed municipalities;
- All surveyed tourist organizations have precise data, i.e. They know their accommodation capacities in rural tourism;
- Association of providers of rural tourism services exist in as many as 3 out of 4 surveyed municipalities that have rural tourism in development (75%);
- 50% of tourism organizations believe that rural tourism in their municipality is of local importance, while the other 50% say it is of regional importance;
- All tourism organizations that have rural tourism have their own website;
- The most common form of promotion of tourist organizations is the participation in fairs.

Regarding the limiting factors for the development of rural tourism in the municipalities of the Kolubara District, the main factor limiting the number of tourist organizations was the human factor, i.e. Poor interest and poor education of the local population to deal with this type of tourism. The second place is the lack of financial resources, then there is no legal basis for this type of tourism, i.e.

The incompatibility of the regulations on the registration of rural households and the lack of a development strategy in many municipalities. Some tourist organizations, as limiting factors, have also identified poor infrastructure, poor marketing and political factors.

As an advantage for the development of rural tourism in municipalities, favorable tourist-geographical position, natural environment, cultural heritage, healthy environment, good traffic connections, developed agricultural production are listed.

The strategies for the development of agriculture and tourism in Kolubara District

The strategies for the development of agriculture and tourism of municipalities in Kolubara District were made by eminent institutions in cooperation with local authorities and non-governmental organizations.

Strategies have their own form and form, but they propose activities of a general character, which should be concretized and clearly defined.

Almost all strategies involve rural tourism, but its ranking of development priorities is clearly not seen, and then it can be understood as a declarative item.

Except for some municipalities that have proposed concrete projects for the development of rural tourism, in others it is related to the overall rural development.

As local tourism products are weak and insufficiently attractive, the only way to increase visibility and attractiveness is the development of a regional, destination product, which will clearly profile and position the region.

Conclusion

Previous development of rural tourism in the Kolubara District, despite numerous available resources, took place styly, and has no long tradition.

The fact is that in this area, there are 94 households registered in the private accommodation that are registered to engage in tourism activity. These households now have 479 beds, which is certainly not a small number for some initial steps. Out of the above number of registered, only 20 are truly engaged in this activity. In preliminary research, it was found that almost 80% of categorized do not have adequate conditions for reception of guests and are still in the phase of re-examination whether they should start this job at all. The causes of these

phenomena are the following: lack of financial assistance, demographic factor, lack of promotion and cooperation with the TO, indecision and uncertainty of the host in gaining economic profit.
The possibilities for the development of rural tourism, which is the most frequent in the Kolubara District, will depend on three factors:

• The level of income that the household provides on the basis of agricultural production,
• Existence of tourist resources, and
• Accessibility by interested tourist regions.

The existence of appropriate resources for the development of tourism and traditions in the development of rural tourism in the Kolubara District is the basis for distinguishing two specific types of approaches related to the planning and management of tourism development, for:

• Rural areas with a tradition in the development of tourism,
• Rural areas with significant resources, but not enough tradition in tourism development.

Both of these types require different types of approaches and strategies, with the existence of a common methodology of planning and management.
All municipalities in the district have developed strategies for the development of agriculture and tourism, in which rural tourism is emphasized as an important factor of mutual development. Implementation of these Strategies will result in multifunctional development of agriculture and villages, and in this regard the development of rural tourism.
From the above it can be concluded that rural tourism in the Kolubara District has not been sufficiently developed and that the overall results of rural tourism development in Kolubara District can not be satisfied, since in the years of the economic crisis, conditionally speaking, it is partially in stagnation.
In order for the rural tourism of the Kolubara District to achieve sustainable development, it is very important that the progress of this activity fits into the development of Serbia's entire tourism. This implies competitiveness, improvement of the entire value system, ie adaptation and sustainability, with as few negative effects as possible. Assuming that economic, organizational and other conditions are gaining, with the willingness of the population to deal with this activity that is present in many villages and households, more intensive development of rural tourism could give multiple positive effects on the overall development of the villages in Kolubara District.

Abstract

Global food losses and waste has received much attention recently in the world. According to FAO, from almost 1/3 of food produced for human consumption approximately 1.3 billion tons per year is either lost or wasted globally. Reduction of food losses and waste (FLW) is presented as essential to improve food security and reduce the environmental footprint of food systems. The objective of the study is to assess FLW and critical loss points (CLPs) in the agri-food chain for fruits and vegetable in Turkey. When all fruits and vegetable types and varieties are considered, Turkey is one of the top 10 countries in the world. In this study, to determine FLW as well as CLPs along supply chains, in-depth interviews were done with key experts from the sector. In these interviews, semi-structured questionnaires were used and set five stages for losses emerging in agri-food chain as: 1.Agricultural production, 2.Postharvest handling and storage, 3.Processing and packaging, 4. Distribution, 5.Consumption. According to research results, FLW ratios along the agri-food chain respectively were determined as 20%, 8%, 10%, 10% and 5%. The highest rate of loss was observed in the agricultural production chain. The structural problems of Turkish agriculture such as small and fragmented farms, low cooperation level were the main causes of losses at this stage. Losses were mainly associated with farmers' traditional methods, habits and practices. Losses emerge from farmers' unwillingness to seek information related to agricultural production. Furthermore agricultural production was generally undertaken by elderly people since rural youth were willing to immigrate to urban areas and preferring to work in non- agricultural sector.

Keywords: *Food loss and waste, Agri-food chain, Fruits and vegetable, Turkey.*

Introduction

This study is carried out to validate food losses and waste in fruits and vegetable agri-food chain which is one of the primary agri-food sub-sectors in Turkey. Fruits and vegetables are among the indispensable food groups of the nutrition of individuals. The various studies conducted to determine the eating behaviors of the individuals, were determined that vegetables were the second mostly consumed product group after cereal and cereal products (Köksal 1974, Scherz and Senser 1989, Arslan *et al* 2006, Pekcan 2009).
Turkey is one of the top 10 countries in fruit and vegetable production in the world. Tomato is the leading product in vegetable production and followed by green pepper and cucumber. Besides, Turkey ranks 4th in the world in tomato production with annual production of 11.9

[49] This paper is part of Turkish Country Report which was prepared on request from Food and Agriculture Organization(FAO) of United Nations in 2013.

million tons (FAO 2017) and mainly consumed in the domestic market; only 2% of the vegetable production is exported (Keskin and Gun 2004).
The leading regions of Turkey in vegetable production are the Mediterranean, Aegean, Marmara and Black Sea regions. While Aegean region leads the list in terms of area under vegetable production, yield per unit of land is the highest in the Mediterranean region since quite widespread greenhouse production in that region (Anonymous 2012a). In terms of foreign trade, Turkey is a net exporter of vegetables. As in production, in exports to the first place belongs to tomato (50%), followed by dry onion (24%), cucumber (8%) and green pepper (7%). Tomato are consumed both as fresh and also as processed (tomato paste, tomato juice, tomato puree, sun dried tomatoes) (Anonymous 2012b).
Food loss and waste is one of the policy issues in recent years and getting much more attentions of public and researches. Some of the studies estimated that as much as half of all food grown is lost or wasted before and after it reaches the consumer (Lundqvist et al 2008). According to FAO, from almost 1/3 of food produced for human consumption approximately 1.3 billion tons per year is either lost or wasted globally. Reduction of food losses and waste (FLW) is presented as essential to improve food security and to reduce the environmental footprint of food systems (FAO 2012). Such estimates are difficult to scrutinize but highlight the need for greater resource efficiencies in the global FSC (Parfitt et al 2010). Although it is an important issue, there are still few studies on food loss and waste measurement and assessment in research area (Rolle 2006, Morgan 2009, FAO 2011, FUSIONS 2016).
The objective of this study is to provide an overview of food loss and waste in fruits and vegetables in Turkey with a particular focus on tomato food chain. Also, critical loss points in the chain were identified and analysed.

Material and Methods

The paper is based on secondary data and primary data. The sources of secondary data used were from the FAOSTAT Food and Balance Sheet, Turkish Statistics Institute (TURKSTAT), and various reports prepared by the public and private sector as well as related NGOs. The primary data was collected by interviews with key experts in tomato and products (tomato paste, tomato mash, etc). In this study, the methodology developed by the FAO and Swedish Institute for Food and Biotechnology was used (FAO 2011, Erden et al 2013). The eleven experts from Ministry of Food, Agriculture and Livestock, Turkish Chamber of Agriculture, fresh fruits and vegetable farmers and processors, wholesalers, grocers were visited and contacted by phone and e-mail. The semi-structured questionnaires were used in the interviews. In these questionnaires, loss ratios in food supply chain were considered in the context of five stages. These are: 1.Agricultural production, 2. Postharvest handling and storage, 3. Processing and packaging, 4.Distribution and 5. Consumption. Food loss and waste ratios and Critical Loss Point(CLP)s along the food supply chain were identified on the basis of discussions with key experts.

Results and Discussion

In order to analyze FLW as well as CLP for tomato and tomato products, firstly supply chain were determined. Wholesalers have an important role in the marketing of fresh vegetables and fruits. Processed amounts in industry vary from year to year and have been around 2 million ton (15-20% of total production) recently. Export, though, is rather low as a quarter million ton (Keskin et al 2009). Sales in domestic market are mostly performed by wholesalers and persons called trader-wholesaler. The domestic trade in vegetables is

characterised by the (long) length of the marketing channel, the highly perishable nature of vegetables, being a product ready to eat, and the inefficiency of producer unions.
Big supermarkets have entered the marketing channel for fresh vegetables and fruits in recent years. They generally work together with a broker in wholesale markets and products are purchased directly without entering the market physically. The share of supermarket chains in fresh vegetable and fruit marketing is not known but is increasing..

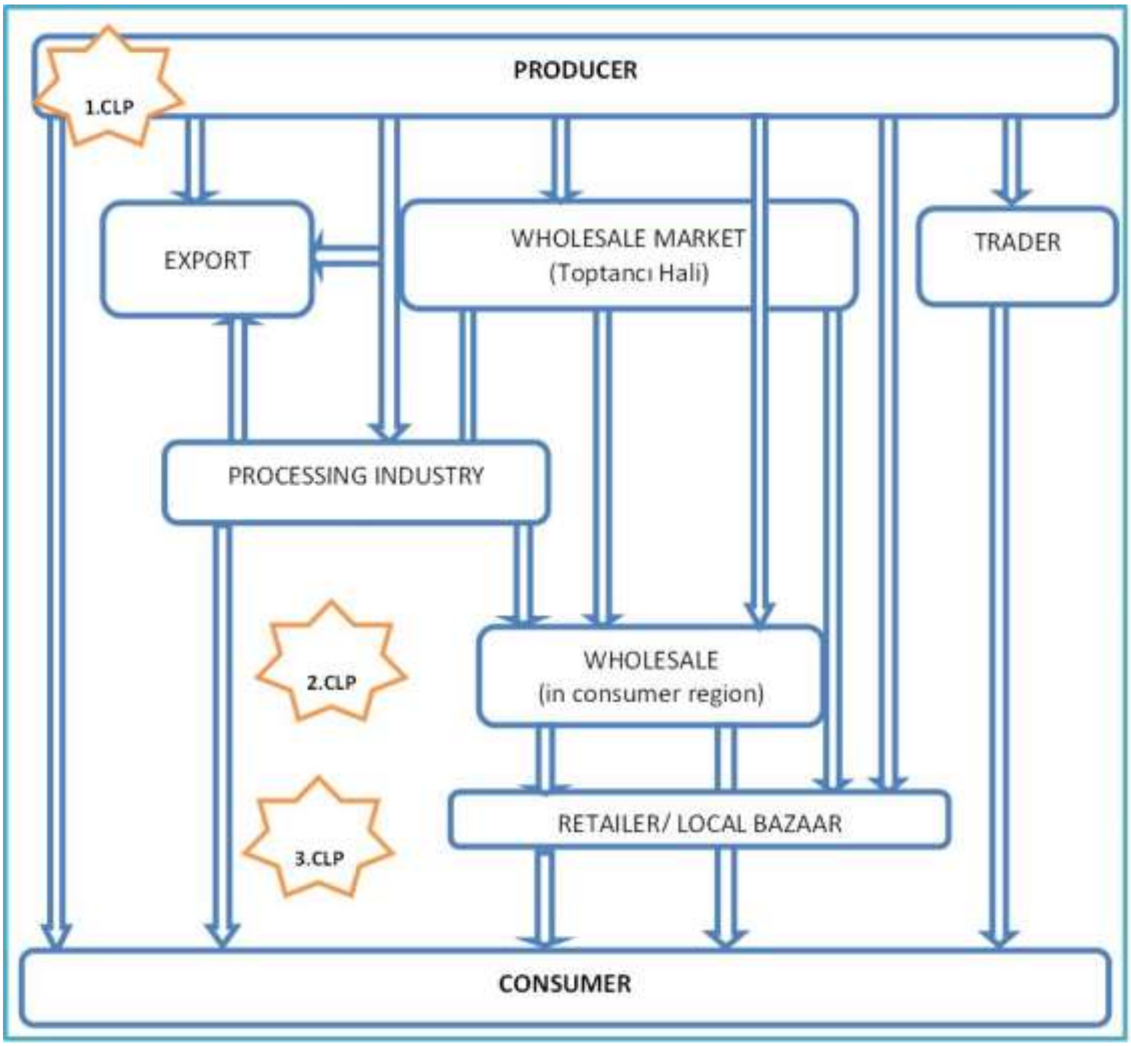

Figure 1. Tomato supply chain in Turkey and CLPs (Erden et al 2013).

As a result of study; the agricultural production stage of the food supply chain has the highest losses of all stages. Tomatoes have the greatest loss ratio as 20% in agricultural production stage since their perishable structure. The loss ratio in the post-harvest handling and storage stage of the food chains is 8%.
The processing and packaging stage of the tomato supply chain, loss ratio was determined as 10%. The reason of high loss ratio in tomato processing and packaging are improper work while loading and dumping, keeping the production in improper conditions, improper storage conditions, absence of a clean and sterile environment, insufficient ventilation and cooling systems, absence of pre-cooling after loading, absence of a sterile environment and failure in packing and sizing of tomatoes.
At the distribution stage, losses are estimated as 10% because of uninformed transportation practices, keeping the produce in unfavourable conditions, delays in reaching the consumer

and failure in selecting good packing materials. At the consumption stage, waste ratio was determined as 5%.

Reasons of FLW in different stage are given Table 1. In tomato, the leading cause of losses at production stage is climatic conditions. Such events as extremely high temperature and wind in field cropping and hail in the case of greenhouse farming cause losses. In extremely high temperatures damage takes place in the form water loss and defoliation while same conditions after ripening lead to sun burns. Other causes of loss at this stage include diseases and pests harming roots, trunk, leaves and fruit. Together with these, there are also losses emerging from various other factors including untimely harvest, harvesting by inexperienced persons, use of inappropriate harvesting methods, use of transportation cases which are worn out and having collected tomato to remain for a long time under sun.

Table 1:Reasons of FLW in different stages

Step in FSC	Reasons of FLW
1.Agricultural production	Too early or too late harvesting, Using incorrect harvesting methods Uninformed practices during harvesting
2.Postharvest handling and storage	Using low quality and insufficient cases while carrying, Leaving the produce under sun for too long time after harvesting, Delays in transportation
3.Processing and packaging	Improper work while loading and dumping Keeping the produce in improper conditions Improper storage Absence of a clean and sterile environment Insufficient ventilation and cooling Absence of pre-cooling after loading Absence of a sterile environment Failure in packing and sizing
4.Distribution	Uninformed transportation practices Keeping the produce in unfavourable conditions Delays in reaching the consumer Failure in selecting good packing materials
5.Consumption	Delays in consuming Wrong storing (absence of refrigerator) Damage to produce while carrying

Source: Erden F.F., Dellal, İ., Bayramoğlu, Z. 2013.

After harvesting and till the reach of wholesale market, transportation process is also marked with some causes of loss as produce getting damaged during loading and dumping, letting the produce remain in unsuitable places and unclean cases that may infect the produce and long periods of storage.

In the processing stage, losses can be classified as follows: Processing: bad practices during loading and dumping; storing in unfavourable conditions; wrong maturation practices and absence of sterile environments; packing: selection of rotten and damaged pieces; poor ventilation and cooling, absence of pre-cooling after loading; wrong packing and sizing practices and failure in selecting proper packing materials.

At the distribution stage, untidy work during transportation, undue delays and unsuitable conditions in transportation vehicles are the main case of losses.

At the consumption stage, delays in consuming, wrong storage, damage during carrying are the reason of waste of tomatoes.

Conclusions

Food is wasted throughout the FSC, from initial agricultural production to the final household consumption. The biggest loss is occurred in the first step which is agricultural production for fruits and vegetables FSC of Turkey. Hence measures could be taken from the first chain to reducing losses during agricultural production. Some measures to elaborate the losses can be listed for fruits & vegetables production as follows:

- proper preparation of soil,
- correct selection of the type of seed,
- promotion of the use of certificated seed,
- informed and timely combat against diseases and pests,
- building awareness among farmers,
- training of persons involved in harvesting,
- training farmers about production techniques,
- development and implementation of early warning systems,
- use of advanced technology machinery in harvesting.

At other stages of FSC the following may be adopted to reduce losses:

- informing farmers/truck drivers about transportation requirements and training workers involved in loading and dumping operations
- informing and training farmers, drivers, workers
- selecting materials used in transporting harvested production (sacks, cases etc) so as not to allow any compromise in terms of product quality and quantity
- being tidy on storage conditions and informing farmers about what is necessary for keeping storages clean and hygienic
- informing and training consumers about conserving ways and using food
- informing consumers by public spots on food use, conservation and recycling
- regular maintenance and keep up of machinery and equipment
- responding to need for trained personnel
- creating a labelling system to cover information at all stages from farm to table
- operating and control of feedback monitoring systems and mechanisms
- using cold chain channels at all stages.

GOVERNMENT'S INTERVENTIONAL TRAINING IMPACT ON FARMERS COMPETITIVENESS

Vlada VITUNSKIENĖ, Edvardas MAKŠECKAS*

Institute of Economics, Accounting and Finance, Aleksandras Stulginskis University. Universiteto str. 10, Akademija, Kaunas distr., Lithuania

Abstract

The agricultural sector, in most cases is supported in developed countries and one of the support measures (government interventions) is training of the sector's actors. The research is carried out to determine the training as a research object for competitiveness theories, analyze the impact of these interventions to farmers' competitiveness and its reflection in indicators that farmers' competitiveness is described with. The research is based on the counterfactual impact evaluation method, scientific literature as well as data from year 2008 and 2012 Lithuanian government's interventional farmers training, linked with respondent's data provided by Farm Accountancy Data Network. During the research, eligibility for counterfactual impact evaluation method was confirmed, similarity criteria of farms were developed, according these criteria, nearest neighbor matching performed and impact detected. Research shows that trainings as a government intervention affect competitiveness of farmers and how these effects can be measured. Trainings can be a governmental instrument to foster farmers' development.

Keywords: *competitiveness, intervention, training, agriculture.*

Introduction

This paper analyzes how the informal training influences competitiveness of the agricultural sector. In scientific literature researchers answering to the questions what are the sources of competitiveness, how the governments can influence the competitiveness developments; how efficient different government interventions on resources (financial, capital and human) are; what determines the behavior of economic entities; can training influence behavior and competitiveness; whether training can cause changes in competitiveness. In researches training effects often seen through the prism of satisfying the expectations of learners. There is a lack of objective evaluation of training effectiveness. Studies usually are based on interviews, surveys, lacking of tools for connecting trainings with farms development indicators.

Competitiveness (farm, industry, country) consists of many components and is influenced by many factors. The company can be acknowledged competitive when its impact on the market certain share changes. However, there is no universal competitiveness acquisition and retention techniques. R. Jasinavičius (2011) linked competitiveness as opportunity to fight against competitors with the ability to produce and sell products, withstand competitive pressure, by increasing the return on (inputs) used resources. According to the authors A. Griffiths and F. R. Zammuto (2005), the company's competitiveness - the ability to manage their own resources, such as finance, personnel, technology, marketing, production, knowledge, resulting full potential. Productivity and efficiency are often seen as a factor in

competitiveness, it is the most reliable indicator of long-term competitive advantage (European Commission (EC), 2011).
L.Latruffe in agricultural competitiveness study, states that the training effect is definitely positive, because better educated farm managers have the skills to effectively manage farms (L.Latruffe, 2010). Agricultural market participants' training should be encouraged by the state, G.Boyle notes that the absence of these public goods, the private sector would provide them enough or do not provide it at all (G.Boyle, 2002).
While evaluating support measures, it is important to determine whether the benefits remain in the business for which it is awarded. It is thought that the benefits can be expressed in profit. There is no doubt that the support can increase revenues, but also on the support may increase and entrepreneurs (farmers) the costs and benefits can also support redistribution to other market participants. It was found that production subsidies and investment support of gain (excluding it received production subsidies) are very weak, but the average gain (subsidies) are marked. This suggests that both production subsidies and investment helps to cover the costs and affect the return, but the real benefit of these support measures for farmers do not receive.
Training has its price. These can be tuition fees, time, opportunity cost. It can be emotional costs, because returning "back to school" can be traumatic. Some farmers will not be willing to accept discipline, attending evening classes after a day of physical activity and the time to work through the exercises. In addition to the emotional and disciplinary matters, the decision to initiate service training covers economic issues. You need to assess the costs and compared with a profit of better governance (Nuthal, 2010).
Training is used as a public market interventions. This is evidenced also in the OECD producer support calculation manual, because training in the agricultural sector financed from the budget counts as support for the sector (OECD, 2011).
Governments intension to increase farmers' competitiveness in comparison with other forms of support, is most useful to support the dissemination of knowledge, because this support payback most, of all kinds of the support (in comparison with other forms of support: investment support and production support (subsidies), which are aimed directly at farmers) .
Support for the effective dissemination of knowledge, also has negative characteristics. First, higher administrative costs than other instruments. Second, the fictitious support risk, which is because of low tangibility (Jasinskas, 2012).

Material and Methods

Scientific literature discusses a variety of methods, for non-formal education of farmers impact assessment. Focus group studies are carried out, training effects evaluated using indicators and data, by econometric tools. The training is a governmental intervention, so to assess its effects, the same methods and methodologies can be adapted as well as for other interventions (eg. capital interventions, etc.).
Lithuanian rural development programs are developed in accordance with the corresponding period of the European Council, the European Commission regulation of the rural development strategic guidelines, which are transferred to the corresponding period of Lithuanian national rural development strategy. Rural development programs and are designed to implement this strategy.
The strategy provides activities aimed at strengthening human resources in rural areas, thus addressing the limited opportunities, lack of education and lack of information. It is expected that the implementation of measures under this priority for people engaged in agriculture, forestry and rural development will not only strengthen the agricultural, food and forestry sectors, but also to create alternative sources of income in rural areas, improve the

environment condition (by increasing people's awareness and knowledge), so will goals of the other - II, III and IV - measures (DG AGRI, 2004, 2006).
Evaluation of rural development programs requires types of indicators as a contribution rates in relation to the budget or other resources allocated at each level of the assistance (e.g. the declared costs incurred in the implementation of the measure); capacity indicators to measure the direct implementation of the program actions (eg. training sessions organized, number of farms receiving investment support, total amount of investment); result indicators, which measure the direct effects of the intervention. From them you can learn about, (e.g., the direct beneficiaries of behavior, capacity or performance changes). They are measured in physical or monetary units (e.g. investment implementation, training successfully completed the number of farmers). Impact indicators related to the program's benefits, both at the level, but also more generally in the program area. Impact indicators linked to the wider objectives of the program (e.g. more jobs in rural areas, increased productivity of agricultural sector, increased production of renewable energy).
As used herein, counterfactual impact assessment method enables evaluate governmental intervention impact, excluding other factors (e.g., macroeconomic situation, foreign investment) effects. In other words, this approach responds to the question "Does the intervention work?" And "What are the effects?". It compares two situations: the implementation of public policy and its failure to implement the measure. It measures what happened to intervention experienced operators and compares this situation with a hypothetical situation in which they are to themselves, if intervention is not implemented. The net impact of the intervention shows the difference between the real situation and what would have been "situation.
At present, use of EU support for impact measurement indicators is a major drawback - they measure not only specific intervention, but also other factors influence the final result. Counterfactual impact assessment method eliminates the influence of other factors, and thus "purifies" the impact of the intervention and provides more accurate exposure readings. Although even if method has important advantages, it is important to emphasize that it cannot answer the question "Why did the intervention works or does not work?". (EC, 2009).

The net effect of intervention in this study is determined as follows:

The net effect of the intervention in the target group = difference before and after the implementation of the policy - the difference in the control group before and after the implementation of the policy.

In ideal case, the most important target group members and control characteristics should be identical, they should only differ by the presence intervention fact. When preparing the target and control groups, it is important to assess whether the intervention in question experienced operators could be exposed to other interventions. When preparing the target group, it is often assumed that all subjects experienced the same impact of the intervention. However, some entities may participate in intensive intervention, while others - not so intense. This determines the intervention and sustained impact strength.
The target and control groups can be made up of different interventions seasoned. The control group and target group subjects important to choose, so they both observable and invisible properties were as similar as possible (EC, 2011).

Table1. Intervention of farmers informal training suitability for counterfactual impact evaluation

Necessary condition	**Feature that allows to say that the impact of the intervention can be applied to determine**	**Feature that allows saying that farmers training intervention satisfies the condition**
Intervention leads to behavioral change	Possible to identify clear criteria to determine whether a change in the target group entities behavior	Competitiveness indicators change in farms that experienced intervention.
Intervention is homogeneous	Entities involved in the same or similar activities, which are based on the same causal chain	All trainees are farmers keeping agricultural holding registered in Lithuanian agricultural and rural business register
Intervention is repeatable	The intervention can be re-implemented in the future.	Farmers' training regularly conducted and funded by the Rural Development Program
Interventions involved a sufficient number of subjects	At least 100 subjects participated in intervention	Analyzed training had about 20 000 participants
Suitable impact analysis variables (indicators)	Impact analysis variables are closely related to measures of intervention logic and to supported activities	The training aims to increase the competitiveness of farms. Impact analysis of selected variables reflecting changes in farm competitiveness
Directly comparable target group and control group	A clear difference between the target and the control group (strong indicator of whether the entity has suffered the impact of the intervention or not). Integrated interventions monitoring system, especially if the target group or the control subjects experienced the impact of other interventions.	It is possible accurately identify farmers participated in training
Monitoring and administrative data availability	Sufficient and available administrative data (or data can be collected by surveys) needed to set up the target and control groups (additional analysis variables) and calculate the net impact of the intervention (impact analysis variables)	Training and FADN data availability and entanglement

***Source: Gertler et al., 2011**

Results and Discussion

Farmers continuing vocational training as an intensive intervention was carried out in three stages in the implementation of Community Special pre-accession to the European Union Agriculture and Rural Development (SAPARD) in 2000-2006., under the Single Programming Document (SPD) 2004-2008 Priority IV and for the period 2007-2013. Rural Development Plan (RDP). During the research, it was selected around 20 thousand farmers that have been participating in trainings during period 2009-2010. Next step was to identify which of the participants are respondents of Farm accountancy data network (FADN) after the intervention at year 2012. It was around 200 of such farmers identified. Last step, from these farmers around 100 selected, control and target groups were formed.

Table 2. Analyzed farm characteristics

Farm features		**The structure of the target respondents (%)**	**The structure of the control respondents (%)**
Farming type	Crop	33	30
	Mixed	67	70
Utilized agricultural area	below 250 ha	75	73
	251–1000 ha	19	22
	above 1000 ha	6	5
Staff employed	Yes	81	86
	No	19	24
According to the hours worked in agriculture	below 3000	20	19
	3001-6000	73	71
	above 6000	7	10
According to the soil fertility score	below 33	8	11
	34 – 43	71	68
	Above 43	21	21

While selecting farms and forming control and target group, each farm was described by 192 features from FADN forms (EC, 2010). In order to carry out the grouping of farms nearest neighbor matching according 5 similarity criteria was performed. The similarity criteria were agricultural area / soil fertility score, own land part as percentage, arable land part as percentage, total labor costs, number of animal units.
According nearest neighbor matching method, for each individual farm, according to all similarity criteria, nearest similar farm selected by algorithm:

$$C\,(P_i) = \min_j \; \| P_i - Pj \|$$

Where C (Pi) - the distance between the similarity of the estimate P (propensities score) between farms, i and j (Thoemmes, 2012)
While matching for a particular farm is found in only one match among the remaining farms data. The biggest disadvantage that method does not ensure compliance with the wrong case when the closest neighbor of the control group is relatively far away from the target group.

3 Table. Detected intervention effects

Variable	**Measurement units**	**Type of group**	**Value before intervention Year 2008**	**Value after intervention Year 2012**	**Intervention effect**
Labor productivity	Litas*/hour	control group	23,7	20,0	10,5
		target group	29,0	35,8	
Land productivity	Litas*/hectare	control group	4468,0	4538,0	366,0
		target group	2090,0	2526,0	
Margin’	Cost vs income with subsidies	control group	1,01	0,91	-0,03
		target group	1,07	0,94	
Margin’’	Cost vs income without subsidies	control group	1,19	1,14	-0,13
		target group	1,41	1,23	

*- 1 euro is equal to 3,4528 litas

Conclusions

Over time the sources of competitiveness as well as the concept has changed, but the concept of competitiveness and competitive sources are still relevant research object. Competitiveness is a relative measure. Companies, countries need to be compared with each other. Production in absolute terms for a particular country or industry, is meaningless. If two players have

reduced the costs of production that does not mean that either of them to increase their competitiveness, increase competitiveness occurs when an entity reduces its costs compared to those faced by competitors. In assessing competitiveness in order to obtain a more detailed assessment should include several elements or indexes, but the question remains open how to evaluate the weight of each component. Assessing the competitiveness of the sector is necessary to take into account the state support, this is especially the case in the agricultural sector. Competitive advantages can be created or encouraged to change the behavior of market actors. This is particularly inconceivable without government intervention.
The most important aspect of competitiveness assessment, modeling and management is that the higher the level of competition does not necessarily correlate with the welfare or other social indicators. Investment in human capital is not less important than investment in physical capital. Their aim is to increase productivity. Human resources are one of the factors of competitiveness, training changes the quality of these resources, so the effect can be, should be and are analyzed. Most of the competitiveness index as an indicator in the training and education system. Some indices even emit continuous training as a separate criterion or factor of competitiveness. Competitiveness change can be informal continuing vocational training effect. Acquisition of data research, and in particular the primary data collection and compliance is a challenge for researchers.

RISK ASSESSMENT IN AGRICULTURE: PROBLEMS AND PERSPECTIVES

Laura GIRDŽIŪTĖ

Faculty of Economics and Management, Aleksandras Stulginskis University, Lithuania
*Corresponding author: girlau@gmail.com

Abstract

Agriculture is an economic sector facing large risk, mainly from natural factors and despite of relatively low price responsiveness to supply and demand causes output volatility in general. It is a risky business, and risk assessment and management tools have become increasingly important in recent years. Risk assessment and management is a complex process, since the risk arises from different sources. Due to different risk sources, it is important to consider such factors: seasonality, agricultural products are perishable; variability in prices of raw materials and a long production cycle; climate changes; agriculture is impacted by environmental protection restrictions; fluctuations in agricultural produce demand, supply and prices; high transportation prices lead to an increase in product prices, which entails higher economic risk; climatic conditions; animals and plant welfare, and etc. Typically, scientific literature analyses only one type of risk. As a result of the research, financial, business, credit, and currency risk models were created and adapted to the various countries conditions (mostly in banking sector). Meanwhile risk in agriculture should be analysed as holistic phenomenon, that is affected by different source of risks (economic, political, financial, human, production). It should be noted, that there is a lack of research related to agricultural activities and their specific features. Risk assessment in agriculture is relevant on both the theoretical and practical level, so it is important to identify main risk factors in agriculture, to investigate their evaluation models/methods, to distinguish their advantages and disadvantages for farmers.

Keywords: agriculture risk, risk assessment, risk factors.

Introduction

Risk makes an inseparable part of every business and agribusiness is not an exception. However, the display of risks in the agricultural sector has a certain specificity which is associated with dependence upon climatic conditions and work with biological assets. Scientists indicate the following factors predetermining the specificity of agriculture:

- seasonality (Harangus, 2008; Brain, 2010);
- agriculture is impacted by environmental protection restrictions (Brain, 2010);
- climate changes (Harangus, 2008);
- agricultural products are perishable (Harangus, 2008);
- high transportation prices lead to an increase in product prices, which entails higher economic risk (Brain, 2010; Harangus, 2016);
- variability in prices of raw materials and a long production cycle (Brain, 2010);
- fluctuations in agricultural produce demand, supply and prices (Harangus, 2008).

Typically, scientific literature analyses only one type of risk. As a result of the research, financial, business, credit, and currency risk models were created and adapted to the various countries conditions (mostly in banking sector). Meanwhile risk in agriculture should be analysed as holistic phenomenon, that is affected by different source of risks (economic, political, financial, production). It should be noted, that there is a lack of research related to agricultural activities and their specific features. Risk assessment in agriculture is relevant on both the theoretical and practical level, so it is important to identify main risk factors in agriculture, to investigate their evaluation models/methods, to distinguish their advantages and disadvantages for farmers.

Material and Methods

The paper is based on general scientific research methods of generalization and comparative analysis. The analysed literature included publications in economics, management, and other areas. Data analysis was conducted using FADN database, research period 2004-2015 year. Analysed countries are 28 Europe Union countries.

Results and Discussion

The completed systematic analysis of scientific literature on agricultural risks suggests that in the last sixteen years various researchers addressed issues related to risk assessment in agriculture. In foreign scientific works, considerable attention to agricultural risk analysis was given by H. L. Pfleeger (2000), A. A. Batabyal, H. Beladi (2001), J. B. Hardarker, R. B. M. Huirne, J. R. Anderson, G. Lien (2004), P. Chitakornkijsil (2009), H. Qi, A. Y. Xie, Sh. Liu (2010), Lipinska, I (2016), D. Kong et al. (2008), B. J. Barnett, K. H. Coble (2009), J. A. Lopez (2008), M. P. M. Meuwissen, J. B. Hardaker, R. B. M. Huirne, A. A. Dijkhuizen (2001), T. Vermeire et al. (2007), P. Slovic (2001), R. A. Unks, L. Thor (2008), M. Hagigi, K. Sivakumar (2009), L. Kapustka, K. Froese, R. McCormic (2010), etc. Those works mostly 1) analyse the manifestation of different risk types in agriculture and 2) identify agricultural risks. However they do not aggregate the risk types in agriculture, do not offer a comprehensive classification of agricultural risk factors, do not merge those aspects in a systematic agricultural risk approach neither seek an integrated assessment of different risk types.

In scientific papers, the problems of integrated risk assessment are checked by means of empiric research: 1) integrated assessment deals with two types of risk in the banking sector (Tanaka, Muromachi, 2003; Iscoe, Kreinin, Rosen, 1999; Medova, Smith, 2005; Dimakos et al., 2004) and due to the specific features of this sector, the research results can be useful for the banking sector only; 2) integrated assessment aims to measure factors of one risk type arising from different sources (Greiving, Fleischhauer, Ckenkotter, 2006; Bechmann, 2009) and the application of integrated assessment is limited to natural risks.

Analysing risk in agriculture, it is important to determine what is risk. Risk as a process is also interpreted in two different ways: 1) risk as a probability (Clark, Maroi, 1996; Hardarker, Huirne, Anderson, Lien, 2004; Cindyniques, Antipolis, 2008; Rainey, 2002); 2) risk as an adverse effect (Vaughan, 1997; Rejda, 2008; Laskienė, 2004).

This paper offers a concept of risk in agriculture, which says that risk in agriculture represents a potential adverse effect on risk subjects (country groups, countries, farms), which stems from different controlled and uncontrolled risk factors and which is related to agricultural activities of risk subjects. In view of the broad typological diversity of risks in agriculture, the agricultural risk concept includes different types of risk in agricultural activities.

Most popular risk fragmentation in scientific literature is following: economic, political, financial and production risk. It is important to point out that scientific literature analyses the agricultural risk types at different aspects: economic and political risks are analysed as uncontrolled risk; production, financial are analysed as controlled risk.

In this article one of the production risk factors is natural condition. Agribusinesses can not control the natural conditions and climate change. Therefore, based on these conditions they may take appropriate management decisions, i.e. agricultural activities diversification, use of insurance services, change the nature of their activity and the like. Main agriculture risk types and their factors are identified if figure 1. Only by knowing main risk factors it is possible to find best way to evaluate and manage risk in agriculture.
Agriculture is unique sector because its production is related to biological asset and agribusiness success directly depends on climate conditions, so farmers it is very important to evaluate and manage agriculture risk on time.
The main problem for evaluating risk in agriculture is it's complexity, for example, in order to evaluate politic and economic risk you need strong background in macroeconomics, in tax policy, in political regulations, environmental law. In order to make some mathematical predictions decision maker has to have knowledge how to adapt deferent econometrics models for example Monte-Carlo Simulation, Variation-Covariation Method, Cost-to-Benefit Analysis (CBA), Fuzzy matrix (Rasche, 2001; Laskienė, 2003; Ahmed, Kays, Amornsawadwatana, 2007; Bandyopadhyay, Mykytyn, 1999; Bagliano, Favero, 1998; Dimitrakopoulos, Kavussanos, Spyrou, 2010). Adaptation of these models requires specific knowledge that is not common for most of businessman.

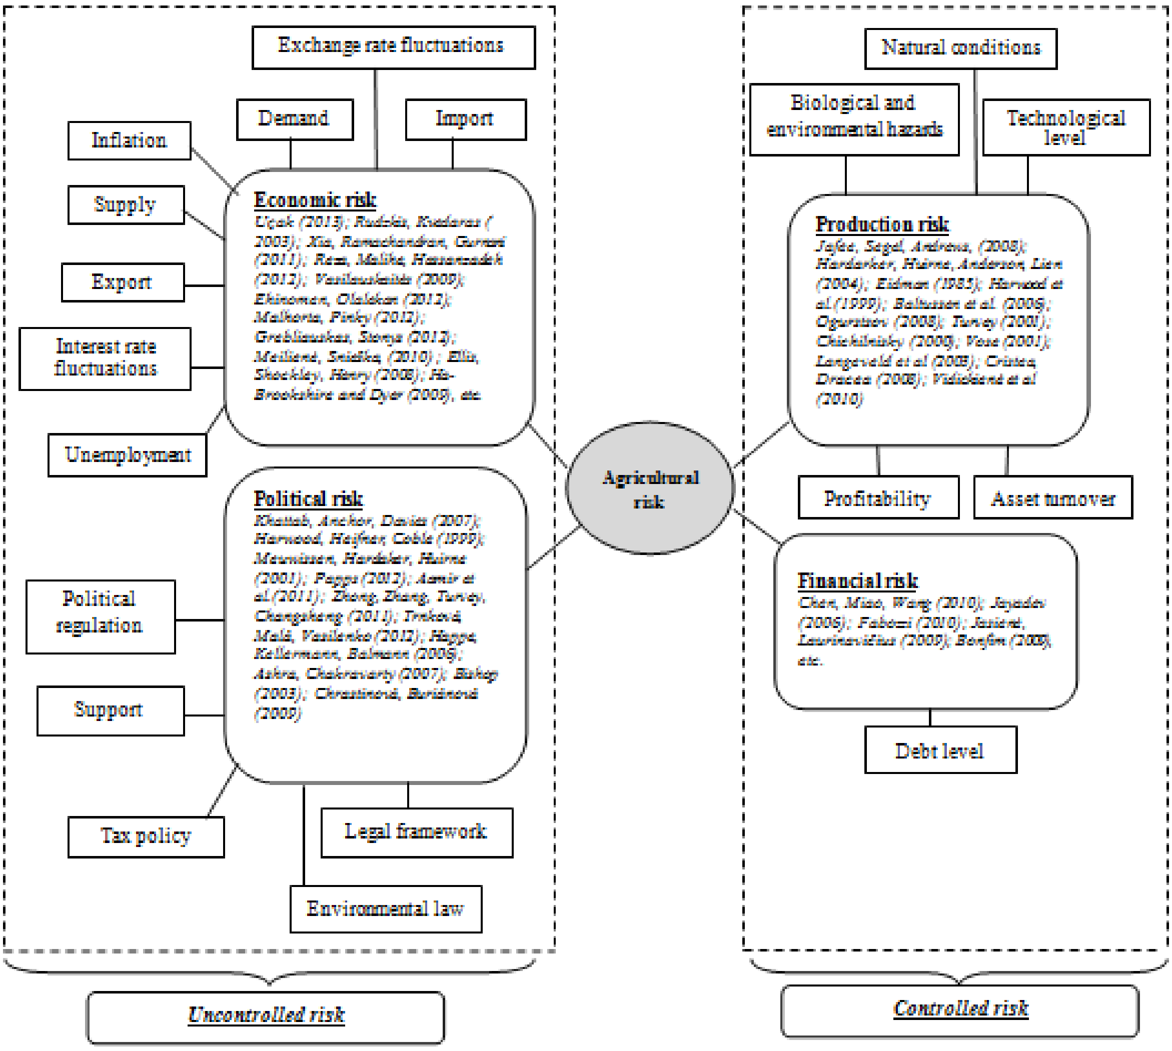

Figure 1. Agricultural risk and it's main factors (made by the author)

Meanwhile analysing production risk it is huge uncertainty concerning biological and environmental hazard. All these arguments shows that in agribusiness have a great need for agriculture risk assessment model. In order to check is this problem is only theoretical or practical as well, the income and expenses ratio has been calculated for 28 European union countries. Data was taken from FADN database, research period 2004-2015 year, target group – agribusiness. As mostly risk conception is related to negative aspects, such us profit loss, so the income and expenses ratio fluctuation can show problems in agribusiness.

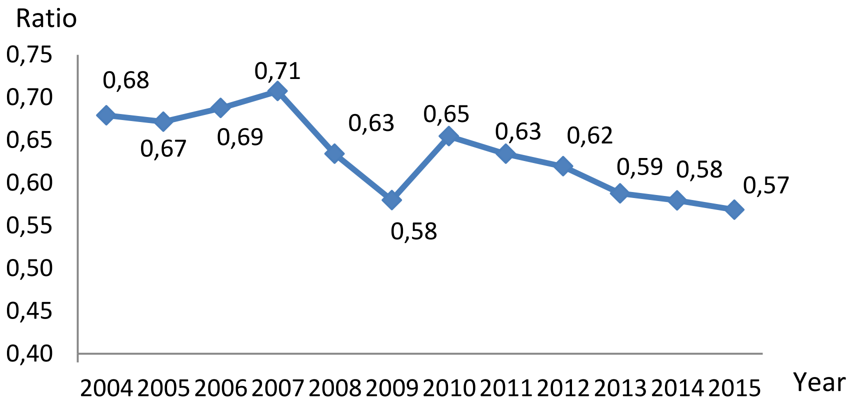

Figure 2. The income and expenses ratio of EU agribusiness during period 2004-2015 (made by the author)

As it is seen from figure 2 there is constant ratio luck from 2010 year. That there were problems in agribusiness production and finance risk management.
From 2011 year scientist paid more attention to risk evaluation and management in agriculture. Few integrated risk assessment models were created.

Table 1. Research into integrated assessment of agricultural risks (made by the author)

Researchers	Research	Methods	Weaknesses
R. Toledo, A. Engler, V. Ahumada (2011)	An integrated risk assessment algorithm for specific regions in Chile	hierarchical holographic method; expert evaluation	The calculations rely only on expert evaluation; No assessment of internal (unsystematic) risks
X. Su, Z. Zhao, H. Zhang, Z. Li, Y. Deng (2011)	An integrated agricultural risk assessment model for integrated assessment in one farm	hierarchical holographic method; fuzzy matrix; risk matrix	The calculations rely on a subjective opinion of the decision-maker in both defining the most dangerous risk factors and identifying their scope and likelihood
L. Girdžiūtė (2013)	An integrated risk assessment index for Lithuanian Farm	Factor and reliability analysis	Calculations are difficult, require huge data spectrum and special knowledge for processing information.

*Source> Results based on author`s elaboration

As it is seen in table 1, the created integrated risk assessment models are characterized by certain limitations. As agriculture risk is unique and complicated phenomena it’s evaluation requires specific knowledge, huge data spectrum or some restrictions based on subjective opinion. Scientific literature review has showed that there is lack of scientific models for integrated risk assessment for agriculture risk.

Conclusions

Risk in agriculture is complex and unique phenomena. It can be dialysed into two main categories: uncontrolled risk (economic, political risks) and controlled risk (production, financial risks). In order to evaluate risk it is important to understand it's primary sources or factors. From theoretical perspective, they were found to be:

- production risk: natural conditions, which include weather conditions and natural hazards, the technological level, and biological and environmental hazards;
- economic risks: export, unemployment level, import, exchange rate fluctuations, gross domestic product (GDP), interest rates, supply, demand, taxes;
- financial risks: debt level and borrowing power, i.e. ability to get a loan;
- political risks: taxes, subsidies, legal framework, and environmental requirements.

The above risk types are interrelated. The production risk is related to political and economic risks. Government decisions on business regulation, for instance subsidies and grants, affect the decisions of agribusiness entities regarding preferred product types. In the production process agribusiness entities must also take into account safety requirements, which means that they must guarantee environmental and product safety. Market demand also affects production decisions and constitutes a part of the economic risk. Political events, in their own turn, affect the government policy and the national economy, i.e. they can influence the currency exchange, price regulation or taxation policies. The level of the financial risk depends on the economic and political situation in a country and the interest rates.

There were several attempts to create risk assessments models for agriculture, biggest limitations of these methods is that it is very difficult to use them for small farmers, because adaptation of these methods require specific econometrics knowledge. If we analyse these models in wider context, for detailed agriculture risk analysis it is lack of statistical data, that's limits research itself. From social point of view there is demand for agriculture risk assessment models that be adaptable for farmers and can be used for daily decision making in farms.

Abstract

Dairy production does not directly depend on climate and other natural factors. Its specificity is that it depends on a number of other factors. Gross margin of dairy production, depends not only on simple products produced volumes of milk and the price, but also includes other elements such as the amount of milk that is consumed in the household, for calves aged up to 10 days, the manure, the premium for milk as the amount of incentives for quality breeding cows (subsidies). This means that the value of production, in addition to the quantity and quality of milk affect the prices of all the elements involved, which are largely determined by measures of economic policy and producers have no influence. The quantity and quality of milk is mostly affected by the quality of food, but also reproductive cycle in cows, fertility and mortality. Data for gross margin (GM) calculations were collected through a questionnaire from dairy production farms in Pomoravlje region (period 2011-2014). GM was calculated as the total value of a production line subtracted by the direct costs for the production line in question. Milk yield per cow is a parameter that has minor fluctuations in the observed period, which shows little variation coefficient of only 4.76%. The average milk yield per cow was 5,626 liters per year and has a tendency to slight increase at the rate of 0.22% per annum. The price of milk is also as the yield, stable and given the negligible value of the rate of change, of only 0.05%, could be said to be at a constant level. It was present slightly higher fluctuations of yield and price (Cv = 13.93%), and slightly more pronounced increase at an average annual rate of 0.76%. The average value of gross margin amounted in the reporting period to about 636 EUR/cow. Gross margin is also characterized by significant fluctuations because the value of the coefficient of variation in this parameter is much higher than in milk yields, prices and variable costs (Cv = 33.75%). GM in the production of cow's milk is characterized by the tendency to decrease by an average of 0.64% per annum.
Observed variations in GM have been confirmed by the results of t-test. The maximum value of the GM was in the initial year of monitoring (2011), and this value is significantly different from the value in the control year, 2015, when we have recorded much lower value. On the other hand a significant difference compared to the control one has realized the value of the GM in 2014, which is the lowest value of the monitoring period.

Keywords: *gross margin, dairy, milk, variable costs, yield, price.*

Introduction

The production of cow's milk in Serbia regards close to 156,000 farms, which according to the total number of 456,000 throats give an average of 2.9 dairy cows per farm. In the structure of agricultural holdings dealing with the production of cow milk, 95% are family farms and other legal entities and entrepreneurs. For ten years or more, in parallel with the decline in the number of agricultural holdings that dealt with cattle breeding and quenching of large cattle farms and systems due to transition, all in 2013, a decline in the total number of cattle and therefore cows. Livestock farming has significance for rural development, as 80% of farms are engaged in at least one kind of livestock production. In 2014, compared to 2013, the number of dairy cows increased by 2.2% after a long period, along with the increase in the total number of cattle. Simmental cattle breed (meat-milk) is mainly represented in central Serbia and in the Pomoravlje region.

The biggest problems of livestock production in the cow's milk production segment are low milk yields on the throat in relation to other countries and poor quality of milk. Adequate measures of the agrarian policy of the state, as well as acquiring new knowledge by the producers and interest in the association of these, would significantly contribute to the improvement of the production of cow's milk and dairy products in Serbia. Milk production in farms is accompanied by numerous problems, low purchase prices of milk, constant increase in imput prices, lower production capacities with outdated facilities and equipment (Radojković et al., 2009).

Household management analysis is essential. It helps farmers to understand how the farm functions, and to determine its profitability. The gross margin is an indicator of the profitability of agricultural holdings and production lines. It is obtained by subtracting variable costs from gross income. It can be used to analyse the impact of existing farms and assess the profitability of proposed new production lines. Gross margins became widespread in the United Kingdom in the 1960s and were first used by farm management advisers for analysis and planning (Barnard and Nik, 1979). The aim of this work is to estimate gross margin as an instrument for assessing milk yield in the region of Pomoravlje.

Materials and Methods

In addition to standard descriptive statistical methods, the authors used gross margins as an indicator of the economic effects of the milk production. In order to determine the effects of milk production in agriculture through the calculation of the gross margin of milk production, a survey was carried out over a five-year period in the territory of the Pomoravlje District, where the production line of milk was monitored by agricultural advisors from the Serbian Agriculture Advisory Service (PSSS) in Jagodina, to a total of 66 households/farms; 15 farms in 2011, 15 farms in 2012, 18 households in 2013, 17 holdings in 2014, and 1 farm in 2015. The basic factors on which the gross margin depends are: yield (volume of production), selling price of products and variable costs. Based on the value of the gross margin, the present and future economic position of the farm is assessed, as well as the economics and profitability (Haluška and Rimac, 2005). Basic elements for gross margin calculation were used: yield and price; quantity and value of fertilizers, pesticides, and fuel, as well as costs of contracted services. All prices are given in EUR, but original data were collected in Serbian dinars (RSD). Prices were calculated based on Serbian National Bank average exchange rate against major world currencies for particular year (www.nbs.rs/internet/cirilica/scripts/kl_prosecni.html). Indicators of the value of production, total variable costs and gross margin were calculated according to the methodology provided by the website of the Serbian Agriculture Advisory Service (www.psss.rs). For data processing and GM calculating, we used *Microsoft Excel.* The program was set to calculate the average value of each element of the calculation.

Results and Discussion

Serbia is a country, which, as well as for plant production, has excellent conditions for livestock production, even when it comes to natural conditions - climate, soil, wealth in animal feed, water and other.

The average milk yield per cow was 5.626 liters per year and has a tendency of a slight increase of 0.22% per annum. Production of cow's milk in 2014 increased by 2.8% compared to 2013. The average price in the analyzed period was 35 din / l. The average value of gross margin was ca. 634.58 euros/cow, in the observed period. The gross margin is characterized by a significant oscillation because the value of the variation coefficient for this parameter (Cv = 33.75%) is more than that of yield of milk, prices and variable costs.

The gross margin in the production of cow's milk is also characteristic of the fact that in this production there is a tendency to reduce the gross margin, on average of 0.64% a year.

Table 1. Basic indicators of the dairy production parameters in the period 2011-2015.

Production parameters	Average value	Variation interval		Coefficient of variation (%)	The rate of change (%)
		Min.	Max.		
Yield (l/cow/year)	5.626	5.050	6.200	4.76	0.22
Price (Euro/l)	0.31	29	0.26	9.23	0.05
Total Variable Costs (Euro/cow)	1841.10	142.064	1252.11	13.93	0.76
Gross Margin (Euro/cow)	634.93	22.093	194.72	33.75	-0.64

All observed factors have a statistically significant impact on the change in the gross margin, with variable costs having the greatest relative impact. Milk yield (Beta values) has the smallest relative impact on the gross margin.

The absolute impact of the observed factors, expressed by the regression coefficients, shows that if the milk yield increases by one litre, the gross margin will be higher by 0.38 euros/cow/day. Increase in the price of milk by 0.881 euro cents/litre, will result in an increase in the gross margin of 45.16 euros / cow.

The observed oscillations in gross margin values were also confirmed by the results of the t-test (Table 2).

Table 2. T-test of gross margin values.

Year		Average value first year	Average value second year	t- quotient (value)	p- value
2011	2015	827.53	588.43	2.70747*	0.017006
2012	2015	667.36	588.43	0.48902	0.632399
2013	2015	724.32	588.43	1.14001	0.270091
2014	2015	827.53	588.43	-2.37276*	0.030528

* $p < 0.05$, significant difference between the calculated values

Conclusion

The observed change in gross margin in all households shows a slight decline of 0.6% annually. Unlike crop production, cattle breeding, or more precisely, cow's milk production does not directly depend on climate and other natural factors. Its specificity is that it depends on a number of other factors. Variable costs in the production of cow's milk, whose increase results in a reduction in the gross margin, also include a greater number of elements, of which the largest percentage (over 90%) of the amount of the necessary means for feeding cows (e.g. hazel and concentrated feed). The survey shows that milk yield per cow on all observed farms increased from 2011 to 2015 at a rate of 0.22% per year.

Abstract

Sour cherry, after plums and apples, holds third place in Serbia in terms of volume and area of production. Serbia, within the CEFTA countries, is the largest exporter of sour cherries (approx. 4.4% of total exports of fruit in Serbia). Farmers need to be introduced to the economic effect of a sour cherry production and gross margin (GM). GM is a quick and efficient indicator for comparing production lines in different conditions and it was used as an indicator of economic effects of production. Data for GM calculations were collected through a questionnaire from sour cherry production farm in Pomoravlje region in the period 2011-2014. For calculating the basic elements of gross margin, the following data were used: data on yield and price, by-product price, quantity and value of fertilizers, pesticides, and fuel, and costs for contracted services. GM represents the total value of a production line subtracted by the direct costs for the production line in question (purchased inputs). Price of sour cherry shows considerable variability during the observation period (Cv= 54.95 %). The average price of sour cherries in the reporting period was approx. EUR 530/t, while the maximum price recorded was almost twice higher (1,016 EUR/t). In contrast to the yield, price showed significantly more pronounced tendency to increase - an average annual rate of 9.72%. The average value of total variable costs was approx. 1406 EUR/ha. A positive feature of variable costs of the sour cherry production is that they show a tendency to decrease, with an average annual rate of 2.64%. The average value of gross margin in the observed period amounted to approximately 4013 EUR/ha. The value of rate of change shows that the gross margin year on year growth records an average of 11.71% annually.

Keywords: *gross margin, sour cherry, variable costs, yield, price.*

Introduction

After plum and apples, sour cherry holds the third place in Serbia on the basis of land area and production. The areas under the sour cherries in Serbia in 2010 amounted to close to 15,000 hectares, from which the area was reduced to about 14 000 hectares, which has been a constant area under these plants for three years. Total yields in 2014 were 22.4% lower than in 2013. Average yields vary, regardless of the constant area, and in 2014 they were 33.7% lower than in 2013. The average cherry yield in the observed period is 7.76 t/ha in Serbia.
The purchase of sour cherries is mainly focused on refrigerating and exports. Sour cherry is also used in processing as frozen, for juices and other canned products. The least is used for consuming and selling on the market. In 2014, the purchase of cherries was lower by 25% than in 2013, and 91.6% was used for processing from the total quantity purchased.
The average producer prices for sour cherries are the lowest in relation to all European countries (except Bulgaria and Macedonia). Within CEFTA countries, Serbia is the largest exporter of sour cherries, and even within the EU countries, only Poland, Bulgaria and

Hungary export more than Serbia. Sour cherry participates in about 4.4% of total fruit exports in Serbia. In 2014 the largest quantities of cherries are exported to Germany, Russia, France, then to Austria, the Netherlands and Italy.

Significant improvements in the production of sour cherries could be achieved by intensifying production and selecting the appropriate market, as well as selecting the appropriate land and applying adequate agro-technology.

The region of Sumadija and Western Serbia, in relation to Serbia, has an area of 17% under sour cherry. The area in the region has been growing for three years. The total yields vary from year to year, and the average yield in the observed period is 7.84 t/ha and is slightly higher than the average yield in Serbia (7.76 t/ha).

Gross margin (GM) was used in this paper as an indicator narrower than an analytic calculation and it shows the difference between the cost of production and direct costs, which makes it an important tool from the economic aspect (Barnard and Nix, 1979; Anđelić et al., 2010; Stanković et al., 2015; Filipović et al., 2015). We used the methodology for calculation of a standard GM as a scientific tool to support technical and economic orientation of farms, in order to analyze economic results in fruit production.

Materials and Methods

Data on sour cherry production were collected from a questionnaire survey conducted on a representative farm in Pomoravlje region during the period 2012–2014. GM calculations, as a standard descriptive statistic method, were used as an indicator of economic effects of sour cherry production. Basic elements for gross margin calculation were used: yield and price; quantity and value of fertilizers, pesticides, and fuel, as well as costs of contracted services. Original data were collected in Serbian dinars (RSD), but all prices are given in EUR. Prices were calculated based on Serbian National Bank average exchange rate against major world currencies for particular year (www.nbs.rs/internet/cirilica/scripts/kl_prosecni.html). Indicators of the value of production, total variable costs and gross margin were calculated according to the methodology provided by the website of the Serbian Agriculture Advisory Service (www.psss.rs). We used *Microsoft Excel* for data processing and GM calculating; The program was set to calculate the average value of each element of the calculation. GM is the difference of total income and total variable costs (TVC), achieved in a line of agricultural production per unit of production area (in crop production). We also calculated the critical values (Stanković et al., 2015, Filipović et al., 2016) with the aim of estimating results of production under conditions of uncertainty. Critical values are those values at which the GM equates to zero.

Results and Discussion

Values of basic statistical indicators of sour cherry production parameters in farms, monitored by the advisory service in the period 2011-2015 are shown in Table 1. The average yield of sour cherry was 11.2 t/ha, ranging from minimum 7 to maximum 15 t/ha. For sour cherry yield, it can be noticed that it shows oscillations during the analyzed period. The rate of change in value is negligible and amounts to only 0.06% per year.

The price of sour cherry shows significant variability during the observed period (Cv = 54.95%). The average price of sour cherries in the analyzed period was close to 528.82 euro/t, while the maximum price recorded was almost twice as high as 1,013.57 euros/t. The price, unlike yield, shows a significantly more pronounced tendency of growth, which is an average annual rate of 9.72%.

The average value of total variable costs in the analyzed period was at about 1402.26 euros/ha. The positive characteristic of variable costs in cherries is that they show a tendency to decrease, on average annually at the rate of 2.64%.

The average value of the gross margin in the analyzed period amounted to about 4000 euros/ha. The value of the change rate shows that the gross margin grows annually on an average of 11.71%.

For efficient cost management and decision-making, GM is adequate analytical basis. In addition for such analysis advisors requires data on what, when and how much of something is produced, so that one can compare the performance of individual production lines and make decisions on the future structure of production (Munćan and Živković, 2006; Munćan et al., 2013). Gross margin can be used as a criterion for determining the structure of financial and performance analysis. GM is not the most important analytical model, but it is a good starting point. It also requires relatively simple data and methodology.

The above characteristics of the sour cherry production parameters are given on the basis of the calculated values of the basic indicators of the descriptive statistics shown in Table 1.

Table. 1. Basic indicators of the production parameters of sour cherry (2011-2015).

Production parameters	Average value	Variation interval		Coefficient of variation - Cv (%)	The rate of change (%)
		Min	Max		
Yield (t/ha)	11.20	7.00	15.00	19.60	0.06
Price (euro/t)	528.23	193.90	1013.57	54.95	9.72
Total Variable Costs (euro/ha)	1402.22	965.94	1623.04	15.91	-2.64
Gross Margin (euro/ha)	4001.27	500.84	13,692.49	96.13	11.71

The gross margin is to a certain extent the result of the impact of yield, prices and variable costs, and accordingly regression analysis quantified the impact of these factors on its value. The change in the gross margin was 97.8% explained by the impact of the observed factors. The results of the analysis show that with the increase in the yield of sour cherries by 1 t/ha, the gross margin is increased by 756.65 euros/ha. Variable costs have a negative impact on the gross margin of sour cherries. However, the results of the estimated regression model show that the impact of variable costs is not statistically significant.

The values of standardized regression coefficients (Beta values) show that the greatest relative impact on the change in gross margin is the price of cherry, and the smallest relative impact has variable costs and it is not significant.

Due to the insufficient number of observation units, it was not possible to check the significance of the difference in gross margins in observed years, by t-test, with the value of the gross margin in 2015. During 2013 and 2014, the number of sour cherries farms was increased, and it was possible to carry out the test. The results of the test (Table 2) show that the gross margin achieved in 2014 is statistically significantly different from the gross margin in the control year.

Table 2. T-test of gross margin values.

Year		Average value first year	Average value second year	t-quotient (value)	p- value
2011	2015				
2012	2015				
2013	2015	2968.69	4313.90	-1.47936	0.213137
2014	2015	2636.07	4313.90	-4.42858*	0.011435

* $p < 0.05$, significant difference between the calculated values

Conclusion

Price of sour cherry shows considerable variability during the observation period (Cv= 54.95%). The average price of sour cherries in the reporting period was approx. EUR 530/t, while the maximum price recorded was almost twice higher (1,016 EUR/t). In contrast to the yield, price showed significantly more pronounced tendency to increase - an average annual rate of 9.72%. The average value of total variable costs was approx. 1406 EUR/ha. A positive feature of variable costs of the sour cherry production is that they show a tendency to decrease, with an average annual rate of 2.64%. Occasional increases or decreases in the gross margin of the plant production lines in the years 2011 to 2015 have the highest increase in the price of products (2012), or the decrease in product prices (2014).

Abstract

Serbia has a good climate and soil conditions for growing grapes. In Serbia three growing regions are determined, with a 22 rayon and 77 vineyard areas, for the production of grape and production of a wine with the geographic origin. Based on the Census of Agriculture in 2012, it was found that 13% of the total number of farms are engaged in viticulture, but 92% of the production is performed at less than 50 acres area. In the production of grapes, family farms are in the first place then a small number of large wineries. Data for gross margin (GM) calculations were collected through a questionnaire from grape wine production farms in Pomoravlje region in the period 2011-2014. For calculating the basic elements of gross margin, we have used data on yield and price, by-product price, quantity and value of fertilizers, pesticides, and fuel, and costs for contracted services. GM was calculated as the total value of a production line subtracted by the direct costs for the production line in question (cf. purchased inputs).
The yield of grapes in the period 2011-2014, was approximately one tonne higher than the average yield of grapes in Serbia according to official statistics. Average yield was determined at 8.2 t / ha, and varied in the range from 5.5 t / ha up to a maximum of 12 t / ha. This presents relatively normal fluctuations in the yield, which indicates the value of the coefficient of variation (Cv) of 16%. Also grape yield had a tendency of slight decrease with an average annual rate of 0.3%. The average price of grapes in the reporting period was at about 390 EUR/t. A positive value indicates that rate of change of prices in the reporting period tends to increase by 0.77% per annum. The variable costs (VC) of the grape production in this period were on the average 1408 EUR/ha. VC show a tendency to decrease by 0.56% per year and was the most stable production parameter (Cv = 10.53%). Reduction in variable costs and the relative stability of the characteristics are favourable for the producers of grapes. Gross margin of the grape production in households was observed at an average level of about 1760 EUR/ha. Characteristic gross margin has significantly higher variability in relation to other parameters indicating the value of Cv of almost 31%. Although there are fluctuations in the values of gross margins, this parameter tends to increase at a rate of 1.06% per annum.

Keywords: *gross margin, grape, variable costs, yield, price.*

Introduction

Using gross margin (GM) for agricultural advisors is a quite useful tool for assessing the economic importance of a certain production line, comprising solely the production value and variable costs. GM gives the result calculated only in relation to what has been invested to produce the quantity in question, giving the best overview over time. In the 1960s, GM became widespread used in the UK, by farm management advisors for making analyses and planning purposes (Barnard and Nix, 1979).

GM was used in this paper as an indicator narrower than an analytic calculation and it shows the difference between the cost of production and direct costs, which makes it an important tool from the economic viewpoint (Janković et al., 2009; Anđelić et al., 2010; Stanković et al., 2015; Filipović et al., 2015). We used the methodology for calculation of a standard GM as a scientific tool to support technical and economic orientation of farms (Iurchevici and Chetroiu, 2011), in order to analyze economic results in grape production.

Materials and Methods

GM calculations, as a standard descriptive statistic method, were used as an indicator of economic effects of grape production. Data on grape production were collected from a questionnaire survey conducted on a representative farm in Pomoravlje region during the period 2012–2014. Basic elements for gross margin calculation were used: yield and price, quantity and value of fertilizers, pesticides, and fuel, as well as costs of contracted services. All prices are given in EUR, but original data were collected in Serbian dinars (RSD). Prices were calculated based on Serbian National Bank average exchange rate against major world currencies for particular year (www.nbs.rs/internet/cirilica/scripts/kl_prosecni.html). Indicators of the value of production, total variable costs and gross margin were calculated according to the methodology provided by the website of the Serbian Agriculture Advisory Service (www.psss.rs). For data processing and GM calculating, we used *Microsoft Excel.* The program was set to calculate the average value of each element of the calculation. GM is the difference of total revenue and total variable costs (TVC), achieved in a line of agricultural production per unit of production area (in crop production). We also calculated the critical values (Stanković et al., 2015; Filipović et al., 2016) with the aim of estimating results of production under conditions of uncertainty. Critical values are those values at which the GM equates to zero.

Results and discussion

For efficient cost management and decision-making, GM is adequate analytical basis. In addition for such analysis advisors requires data on what, when and how much of something is produced, so that one can compare the performance of individual production lines and make decisions on the future structure of production. Gross margin is one of the derived indicators that can be used as a criterion for determining the structure of financial and performance analysis. GM is not the most important analytical model, but it is a good starting point. It also requires relatively simple data and methodology. Simplified, gross margin represents the total value of production, subtracted by the direct (variable) costs (purchased inputs).

Grape yield in the analyzed period 2011-2015 was about one tonne higher than the average yield of grapes in Serbia according to the official statistics. The average yield was 8.2 t/ha, ranging from a minimum of 5.5 t/ha to a maximum of 12 t/ha. There are relatively normal oscillations in yield, which shows the value of the coefficient of variation of 16%. Also, the yield of grapes had a tendency for a slight decline, with an average annual rate of 0.3%.

The average price of grapes in the observed period was around 390 euro/t. The positive value of the rate of change shows that the price in the observed period has a tendency to increase by 0.77% annually.

The variable costs of grape production in the analyzed period amounted to almost 1.405 euro/ha. This production parameter shows a decrease of 0.56% per year and is the most stable production parameter (Cv = 10.53%). Reducing variable costs and relative stability provide favorable characteristics for grape producers.

The gross margin in grape production in the observed farms was at an average level of about 1,755.68 euro/ha. The characteristic of the gross margin is also significantly higher variability compared to other parameters, which explains the value of the coefficient of variation of almost 31%. Although oscillations in the realized gross margin are present, this parameter has a tendency to increase at a rate of 1.06% per annum.
The above characteristics of the grape production parameters are given on the basis of the calculated values of the basic indicators of the descriptive statistics shown in Table 1.

Table 1. Basic indicators of the production parameters of grapes in the period 2011-2015.

Production parameters	Average value	Variation interval		Coefficient of variation - Cv (%)	The rate of change (%)
		Min	Max		
Yield (t/ha)	8.20	5.50	12.00	16.02	-0.30
Price (euro/t)	390.08	264.41	528.82	15.73	0.77
Total Variable Costs (euro/ha)	1404.81	1036.89	1810.24	10.53	-0.56
Gross Margin (euro/ha)	1755.55	391.55	2993.57	30.73	1.06

The impact of yield, prices and variable costs on the value of gross margin in grape production is quantified by applying regression analysis. All three of these factors show a statistically significant impact on the achieved gross margin level. The change in gross margin values by 96.6% can be explained by the impact of yield, price and variable costs. The highest relative impact on the gross margin has the price of grapes (0.77%). The next factor for the significance of the impact is the yield, and if it increases by one ton, this will result in a 356.39 euro/ha increase in the gross margin. Unlike yields and prices that have a positive impact on the gross margin, the impact of variable costs is negative and their increase decreases the value of the gross margin. If the total variable costs increase, the gross margin will be reduced by the same amount.

Table 2. T-test of gross margin values.

Year		Average value first year	Average value second year	t-quotient (value)	p-value
2011	2015	1468.09	1871.63	-1.22564	0.243847
2012	2015	1965.81	1871.63	0.20201	0.843033
2013	2015	2168.17	1871.63	0.74269	0.470877
2014	2015	1330.57	1871.63	-0.93614	0.369297

* $p < 0.05$, significant difference between the calculated values

The lowest average value of gross margin was recorded in the last year of the observed period (2014). Gross margins realized in the period 2011-2014 do not differ significantly from the reference (control) value recorded in 2015 (Table 2).
The fluctuation of gross margin values by years, illustrates that in some years there is a tendency of increase of this parameter (GM), but that its values are close to the 2015 control value.

Conclusion

Gross margin of the grape production in farms was observed at an average level of about 1760 EUR/ha. A characteristic of gross margin is significantly higher variability in relation to other parameters indicating the value of Cv of almost 31%. Although there are fluctuations in the values of gross margins, this parameter tends to increase at a rate of 1.06% per annum.

Abstract

Urbanization, one of the biggest problems in 21st century, causes many environment problems such as structure areas and population increase. The decline of urban green spaces and environmental problems in cities have made rural life and rural values again important in recent years. In this context, the concept of rural tourism, which emerges as a kind of alternative tourism in line with the changing income levels, needs and wants of the people covering the whole of the tourism activities in the rural areas, is getting more and more important day by day. Rural tourism, which enables rural areas to develop socio-culturally and economically, also offers tourists the chance to get in touch with natural beauties and meet local cultural characteristics. Turkey has a high potential for rural tourism, which plays an important role in preserving natural and cultural heritage as well as providing local sustainable development. In order for this potential to have a significant share in the development of Turkey, the right perception and development of the concept of rural tourism must be planned correctly. With this study, the importance of rural tourism will be emphasized and suggestions will be developed for our country by giving examples of rural tourism from Australia, South Africa and Turkey.

Keywords: *Rural tourism, Rural development, Sustainable development, Turkey.*

Introduction

Urbanization, one of the biggest problems in 21st Century, causes many environment problems such as structure areas and population increase. The decline of urban green spaces and environmental problems in cities have made rural life and rural values again important in recent years. The concept of rural area can be defined in different forms considering; demographic structure, geographical situation and administrative form.According to the OECD (Organisation for Economic Co-operation and Development) areas where the population density is 150 persons or less per km^2 fall within the scope of the rural area (Kiper, 2006). Rural tourism concept covers the whole of the tourism activities in the rural areas and emerges as an alternative tourism type in accordance with the changing income levels, needs and wants of the people (Karaman et al., 2015). Rural tourism can be described as a set of activities that take place in a rural settlement in order to relax people in the natural environment and to coexist with different cultures and to live there and to watch or participate in activities specific to the locality (Baykal and Toprak, 2010). According to Soykan (2002), rural tourism is a form of tourism integrated with natural environment, rural settlement and local economic activities.

Rural tourism which enables rural areas to develop socio-cultural and economically also offers tourists the opportunity to get in touch with natural beauties and meet local cultural characteristics. Rural tourism has an important place in ensuring the sustainable development of rural areas. Sustainable rural development aims to improve the level of production, income

and quality of life that will change the socio-economic structure of the people living in rural areas and to bring the differences between the urban and rural areas to an optimum balance and to develop the rural population in its place. Thus, it also aims to prevent migration from rural areas tourban. Sustainable rural development,in line with these aims, is an approach that protects nonrenewable natural resources in rural areas while making use of them and transfers these resources to future generations(Geray, 1999; Güngör et al., 2013; Baykal and Toprak, 2010; Anonymous, 2017).For rural areas, development no longer involves only the growth of certain areas or agricultural development. Sharing, marketing, organization, local products, organic farming and different community dynamics are becoming more and more important in development. Rural development policies are now transforming into "functional and integrated approaches involving agriculture and non-agricultural sectors in rural areas for the welfare of rural communities, and policies to strengthen rural dynamics and priorities in all areas" (Gülçubuk, 2012).In the scope of rural tourism; many features such as the increase in infrastructure, health and education services in rural areas, increase in employment, increase in income after the development of tourism and accordingly increase the standard of living of the local people reveal that rural tourism is very important in terms of sustainable rural development (Ahipaşaoğlu andÇeltek, 2006).
The purpose of this work to provide examples of rural tourismfrom Australia, South Africa and Turkey and to transfer its positive impacts, and to develop recommendations for rural tourism studies in Turkey.

Material and Methods

Rural tourism concept constitutes research material. The emergence of rural tourism concept, its importance and its impact on sustainable rural development has been examined primarily. Later, the benefits provided by rural tourism have been revealed. It has been emphasized that rural tourism has an important place in ensuring the sustainable development of rural areas and examples of rural tourism has been given from Australia, South Africa and Turkey. As a result, proposals for rural tourism studies in Turkey have been developed.

Results and Discussion

Open and green spaces are the areas where people come together to have fun and rest, while having great importance in the establishment, maintenance and development of social relations (Arslan, 2016). In recent years, many studies have been carried out in order to determine the amounts of urban green spaces.When these studies are examined, it is seen that the amount of public green spaces (parks and gardens) in the cities is decreasing. For example, the amount of green space in London was %38.4 in 2003 but it was %33 in 2013. In the same way, the amount of green space in Hong Kong was %41 in 2012 but after two years it was %40 (Anonymous, 2013; Anonymous, 2015). The decrease in the amount of green space in the cities and inadequacy in the face of the rapidly increasing urbanization cause many environmental problems to arise. The decrease in quality of life due to these environmental problems in the cities, the tiring of tourists from coastal tourism, the change of expectations about tourism and the development of the idea of utilizing the four seasons, not just summer, benefiting from tourism are the factors that make rural tourism popular in recent years (Akyol et al., 2014; Avcıkurt and Köroğlu, 2008).
Other positive effects of rural tourism, which emerged as an alternative type of tourism, increasingly appreciated in recent years and played an important role in ensuring sustainable rural development, can be listed as follows; (Dinçer et al., 2015; Karaman et al., 2015)

- By ensuring that the population develops in place, it prevents the people of the region from migrating to other regions,
- It provides softening of the differences between urban and rural areas,
- It contributes to the country's economy by providing sustainable development of rural areas,
- People in rural areas have the opportunity to earn income from various sources (handicrafts, accommodation, eating and drinking, etc.) as well as agriculture, which is the main source of livelihood,
- With the development of rural areas, it provides increased infrastructure, health and education services,
- It eases the burden of coastal tourism and creates new places for tourists,
- It allows the people, who are breaking from the nature, to approach their physical and psychological needs and nature,
- It plays an important role in preserving natural and cultural heritage.

It is possible to see very successful examples of rural tourism activities in different countries of the world. Especially fiestas and festivals related to the harvesting period are watched with interest and attract a lot of visitors.In all seasons of the year in the Central and Southern European cities, vineyards and wine cellars are very popular places.An interesting example of rural tourism is found in Lebanon.Caves De Ksara, located in Bekaa valley, is an extremely important facility in the production of wine ever since 1857.Today the facility is an important place with vineyards, gardens, wine cellars and loungesfor tourists coming to the region. In addition to Caves De Ksara, examples of rural tourism from Australia, South Africa and Turkey were examined within the scope of the study.

Tjapukai Aboriginal Cultural Park

The Tjapukai word means "Rain Forest" and is often used to describe the "Rainforest Peoples". Established in 1987 as the aboriginal dance theater in the village of Kuranda near Cairns in Australia's Queensland province, the park was later supported by a variety of activities, transforming it into an area where tourists can find themselves in Australia's 40,000-year history. In this cultural park, aboriginal culture from the beginning to the present day is described as a theatrical expression. The cultural park serves tourists with full day, half day and night tour options. Tjapukai Aboriginal Cultural Park, built on an area of 25 acres; is composed of 7 different sections such as; History Theater, Creative Theater, Dance Theater, Didgeridoo Area Aboriginal Food and Drugs, Boomerang and Spear Throwing Area, Art Gallery and Boomerang Restaurant (Anonymous, 2017a).

Lesedi Cultural Village

South Africa's Lesedi Cultural Village, near Johannesburg city; are the cultural village where Zulu, Xhosa, Pedi, Basotho and Ndebele tribes and their daily lives are exhibited. In Lesedi Cultural Village, which defined by the word “Our culture is the light of our nation – whoever walks here amongst our cultures at Lesedi can also see the light”, it is possible to observe the different architectural structures, the goods they used, the home lives of the five villages in the forest with the guide. There is also a restaurant serving traditional African cuisine as well as a tent theater displaying local music and dance shows in the cultural village. In addition, it also has accommodation in colorful and fascinating structures, with the traces of traditional residential architects (Arslan, 2016).

Sun City Cultural Village

Sun City Cultural Village, which founded in 1979 and located on the north-west of South Africa, is located 187 km. distance from Johannesburg.In addition to amusing night and day

activities (golf courses, water activities, children's playgrounds, safari tours, etc.), it also offers accommodation for tourists with four different themed hotels. In the valley of waves, which located in the cultural village, there is an artificial beach giving an impression of a tropical island and a large entertainment pool where artificial waves are created. There is also a kindergarten in the village that offers babysitting services for children in the 0-5 age group. For children between the ages of 5 and 12, there is a camp, “Kwena”, and it is designed for enjoyable time. In the village there are also art events offering music, dancing, cinema and theater shows as well as shopping opportunities for tourists (Anonymous, 2017b).
It is possible to see penguins in "South Africa Penguin Island" located in the south of the country.It is also possible to get information about the natural life in the cheetah, lion and crocodile park, and to watch the animals at a reachable distance from the Sun City Cultural Village.

Beypazarı Living Museum

Beypazarı Living Museum was founded in 2007 as the first and only applied cultural museum of Turkey with the idea of displaying public life and its productions. Beypazarı Living Museum adopts as a principle this idea; “I hear and I forget. I see and I remember. I do and I understand” and it gives its visitors the opportunity to practice and cultivate this culture beyond showing them the rich and deeply rooted Turkish cultures. Being the first open air museum of Turkey, Beypazarı Living Museum aims visitors to have a pleasant time with various animation, interpretation techniques and interactive exhibition methods. There is a tale world within the museum that aims to convey the cultural heritage to future generations in an educational and amusing way through the tale. There are also” Karagoz Scene” where they can create their own shadow games, fabric design, marbling and wood carving arts, as well as "Trophy House" where they can shop for souvenirs (Anonymous, 2017c).

SafranboluYoruk Village

"SafranboluYoruk Village" is located in Safranboludistrict of Karabuk province.The village, which is 20 km away from the district center and has a history of 750 years, is famous for its houses with traditional architecture. Handcrafted products and products made by the local people from the land for agriculture and animal husbandry are presented to thevisitors of the village.There is almost no accommodation available in the village where restaurants serving regional specialties are served.The reason for this is that the village is close to the district center.The most important feature of "SafranboluYoruk Village" is that it is virgin in every direction.There are two museum houses in the village where traditional handicrafts, fabrics and clothes are exhibited as well as examples of traditional architecture.There is also an art workshop where visitors are shown pictures of traditional houses.Rock tombs, aqueducts, mound-like remains, canyons, caves, forests and plains in the immediate vicinity of the village are other interesting natural attractions (Kiper, 2006; Anonymous 2017d).

Conclusions

Rural tourism concept, which emerges as a kind of alternative tourism in the direction of changing income levels, needs and wants of people and covers the entire tourism activities in rural areas, offers tourists the chance to get acquainted with natural beauties and to meet local cultural characteristics.Rural tourism areas are alternative tourism places that play an important role in economic and sustainable rural development while contributing to the promotion of the countries. And also these areas require comprehensive and detailed planning-design studies.
Turkey has a high potential for rural tourism, which plays an important role in preserving natural and cultural heritage as well as providing local sustainable development.In order for

this potential to have a significant share in the development of Turkey, the right perception and development of the concept of rural tourism must be planned correctly.Rural tourism can play an active role in preventing migration from rural areas tourban, which is one of Turkey's biggest problems, if it is planned properly.If it develops unplanned, it can cause negative effects such as, the decline of agricultural land and the destruction of natural and cultural heritage.

The existing rural tourism areas planned in Turkey are far behind in terms of the number of visitors compared to other examples in the world.In order to overcome this problem, it is necessary to increase the diversity of activities in the rural tourism areas with an understanding that protects the irreplaceable natural resources. In addition, promotions of these areas need to be made more efficiently and easy access must be ensured.It is very important to provide government grant to the rural tourism and to transfer the necessary points to the local people and to establish the associations, foundations and federations in the field of rural tourism.

7. FORESTRY AND AGRO-FORESTRY

THE INFLUENCE OF LIGHT FACTORS AND COMPETITION AMONG THE CROWN OF THE ALLEY TREES OF *TILIA TOMENTOSA* (MOENCH) IN THE URBAN AREA OF SARAJEVO (BOSNIA AND HERZEGOVINA)

Selma HARAČIĆ-BERBIĆ*, Ćemal VIŠNJIĆ, Besim BALIĆ

University of Sarajevo, Faculty of Forestry, Bosnia and Herzegovina

Abstract

This paper analyzes the influence of light factors and competition between alley trees on development and deformation of the silver linden. Researches were carried out on the alley′s silver linden trees of different age in urban green areas of Sarajevo (Bosnia and Herzegovina). Research have shown that light is a key factor for the development of silver linden tree crown, and that the eccentricity of the crown to a greater extent occurs in the age of over 60 years. The deformation of the crown is particularly conspicuous towards the open side where the most light comes from. The silver linden is extremely responsive to light, therefore in the course of forming an alley it must be taken into account the planting distance, direction of the alley, and the intensity of sidelight that should be in optimum during the growth and development of alley. At afforesting the semi-urban barren lands, i.e. forming of urban forests or park forests using linden, it should be taken into account the planting distance and the edge of the stand, as the deformation of the crowns occurs most frequently with marginal trees. With thinning activities it is possible to optimize the amount of light within the forest, necessary for proper development of the crowns and the good stability of the trees, and by the planting of other tree species on the edge of urban forest, it can be avoided the deformation of the marginal silver linden trees and other species of linden used in forestry and urban forestry.

Keywords:, *the influence of light, eccentricity of the tree crown, Tilia tomentosa Moench, Urban forestry*

Introduction

Silver linden (*Tilia tomentosa* Moench) originates from the Balkan-Pannonian region of Europe. It has been used as a species planted in parks since 1767 (Banusevac et al.,1971). It is used today as an exclusive species in urban and park forests. Based on the historical data on the development of green surface in the city of Sarajevo (Beus 2009), Silver linden has been used as an element of the urban green surfaces since long time ago and it represents a species frequently used in Sarajevo's green surfaces. Its significance in the urban zones reflects in the beauty of its leaf, odoriferous flower, an interesting habitus and the form of the crown as a special element in an urban landscape. Most of the trees of the urban green surfaces in Sarajevo are developing in unfavorable conditions, the crowns and roots do not have enough space to grow. Due to changed external conditions, competition and given that the measures of cultivation are not being imposed, only rare specimen grow into individual ones which in morphological sense manifest representative characteristics of their species. Great number of trees have bad habitus, many damages done by decaying fungi and anthropogenic effect, badly formed crowns that are not trimmed regularly with a lot of dried and broken branches.

Eccentricity of the crown is defined as asymmetrical growth and development of the crown according to some authors. Symmetrical growth is the characteristic of regular growth and development of the crown. The phenomenon of eccentricity is very frequent in urban areas and happens most frequently with the lack of light on one of the sides of the crown. There are numerous consequences of the eccentricity and they lead to static instability and increase the possibility of breaking. Apart from that, the tree loses its aesthetic appearance and it needs regular interventions to naturally grow again. Larsen and others (2002) state that urban trees have different growth intensity because of the specific conditions of developing and growth, as well as cultivation, specific urban environment and microclimatic characteristics as compared to the same species located in a natural habitat. The Silver Linden imposes itself as an essential element of tree alleys in our region due to its adapting to urban environment. (Coder 1996).

Materials and methods

The object of this research are Silver linden (*Tilia tomentosa* Moench) trees of different age located in tree alleys, avenues and park surfaces in multiple locations in Sarajevo. Six different locations were chosen in immediate vicinity between which there are no bigger differences in eco-climate and habitat characteristics : (1) Wilson's avenue, (2) Linden Alley– left bank of Miljacka 3) Linden alley – next to the Bridge of Suada and Olga 4) Topal Osman Street – on the nothern part of the Loris building 5)Mutevelic's Street – near the mall 6) Dobrinja, Sarajevo. In order to observe the method and character of the manifestation of light influence and competition between trees, analyses were carried out in chosen locations on the influence of distance in planting and the direction of crown branches spread on the crown radius. That is why we created the bifactorial experiment 3^2 (two factors with 3 modalities) where the most influential factors used are: distance between trees (factor A) whereas the manifestation of this factor was followed through three modalities: A_1 – distance between linden trees < 7 m; A_2 – distance between linden trees 7 m – 10 m and A_3 – distance between linden trees > 10 m. The second most influential factor is the age of the linden trees (factor B) whose manifestation was analyzed through the following three modalities: B1 – linden trees 30 years old, B2 – linden trees 60 years old, B3 – linden trees 100 years old. In order to observe the steadiness of the influence of the planting distance (competition) and the influence of the direction in which the branches spread on the crown radius we applied the method od multiple variant analysis test (ANOVA) while the Fisher LSD test was used to evaluate the significance of differences between the environments where the influences were analyzed. The analyses were carried out separately by the age of trees.

Results and discussion

In order to observe the method and character of the influence made by the planting distance (competition) and the influence of the direction in which the branches spread on the crown radius we applied the method od multiple variant analysis test (ANOVA). The analyses were carried out separately by the age of trees. In order to find out which side of the world stands out as the special homogenous group as well as to find out between which differences of crown radius average values there are statistically significant differences for the level of probability of 95%, multiple tests were made by Fisher LSD tests. Due to the extensiveness of the result tables, only the graphic ANOVA results are presented where the existence or nonexistence of the significance of differences in analyzed characteristics can be clearly perceived. On the following chart there are average heights for the crown radiuses with a 95% LSD interval of the evaluation reliability depending on the three different linden tree planting distances (chart 1) and the exposure of the linden tree crowns to the primary and secondary sides of the world (chart 2) that are 30 years old. From the following charts it can be concluded that the average values of crown radiuses of the trees with the smallest planting distance are statistically notably different in comparison with the other two planting distances. It can also be concluded that the differences in average crown radiuses within the planting distance of R=7-10 m and R>10 are not statistically significant. Apart from that it can be concluded that, despite the planting distance, the side of the crown exposed from the south could be singled out.

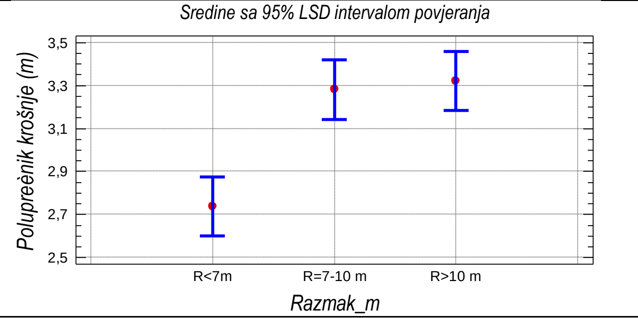

Chart 1. Average values with the interval of crown radius evaluation reliability depending on the planting distance of the 30 year old trees

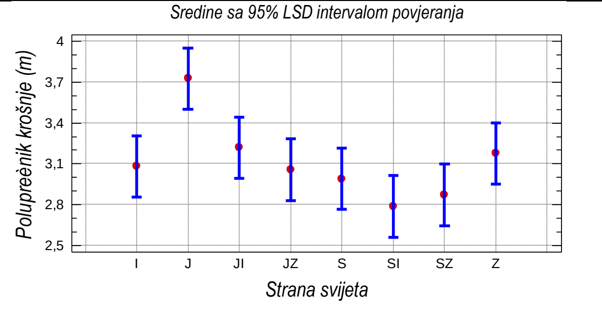

Chart 2. Average values with the interval of crown radius evaluation reliability depending on the exposure to the sides of the world of the 30 year old trees

The biggest crown radius was noted in the crowns exposed to the southern side with the biggest planting distance which is logical, if you take into consideration that southern exposure gives more light to the crown as well as that with bigger planting distances there is more space for growth and development, especially in younger trees with a progressive height increment. In similar way the results of ANOVA were presented for the analysis of the planting distance influence and different sides of the world on the crown radius (m) of the 60 years old linden trees.

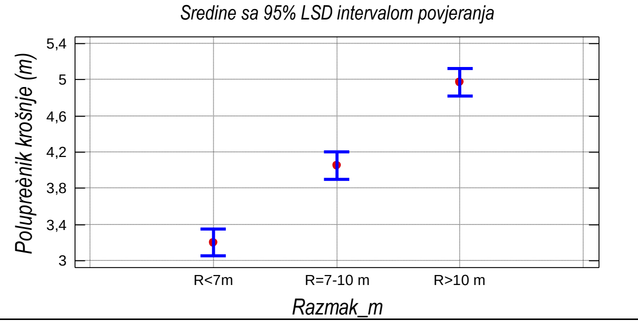

Chart 3. Average values with the interval of crown radius evaluation reliability depending on the planting distance of the 60 year old trees

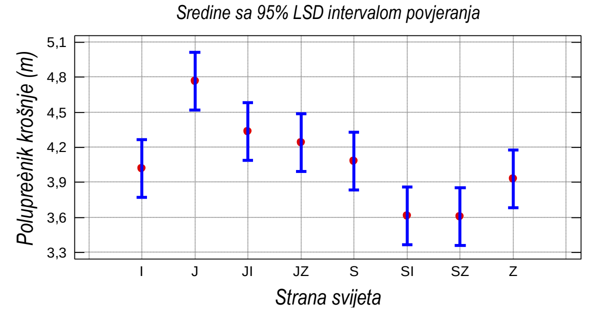

Chart 4. Average values with the interval of crown radius evaluation reliability depending on the exposure to the sides of the world of the 60 year old trees

Chart 3 gives a visible evidence of statistically noticeable differences between all three planting distance modalities where the group of trees with the biggest distance have the biggest crown radiuses and the trees with the smallest distance - the smallest crown radiuses.
In this case it can be seen that the southern side of the crown stands out as statistically noticable because of the biggest crown radius while the smallest size radius was noticed on the crowns exposed on the Northeastern and Western side.

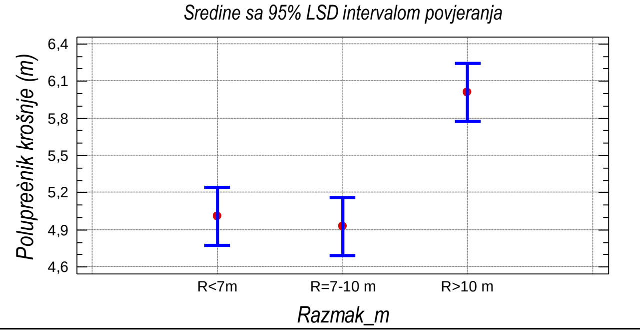

Chart 5. Average values with the interval of crown radius evaluation reliability depending on the planting distance of the 100 year old linden trees

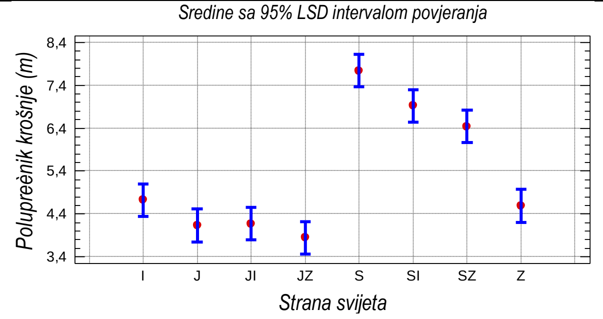

Chart 6. Average values with the interval of crown radius evaluation reliability depending on the exposure to the sides of the world of the 100year old trees

Unlike the previous charts, in this case the trees that especially stand out are the ones with the biggest planting distance, despite the sides of the world, as statistically noticeable regarding the crown radius, while between the first two planting distances there are no noticeable differences in the crown radius size. Regarding the other factor the crowns that stand out are the ones exposed to the North, Northeast, and Northwest and have the biggest crown radius while the smallest radiuses were seen in the trees exposed to the South. This can be explained by knowing that after some time there was a culmination of the height increment as well as branches growing in length so the influence of light manifests less compared to the planting distance. Apart from that, it is not known whether the older trees with eccentric crown had their branches broken by the impact of snow, wind or man.

Discussion

This study analyzed the influence of the distance between trees (competition) and the exposure of the crown to the sides of the world on the difference in crown radius whose size directly influences the phenomenon of the crown eccentricity. Unequal branch growth is a direct consequence of a stronger or weaker exposure of the sides of the crown to sun, which causes the phenomenon of the eccentric and asymmetrical crown form. Eccentricity of the crown is defined as asymmetrical growth and development of the crown according to some authors (Sjöman and Oprea, .2010). Symmetrical growth is the characteristic of regular growth and development of the crown. The phenomenon of eccentricity is very frequent in urban areas and happens most frequently with the lack of light on one of the sides of the crown. There are numerous consequences of eccentricity and they lead to static instability and they increase the possibility of breaking. The young tree crowns grow more towards the south sides where there is morelight, and later on the crown grows more on the norther side because of the competition between trees and lack of light which the results also show. We can already see the negative manifestation of the crown's eccentricity in the mentioned location. The results of the research done until now show that because of the specific conditions in which the urban trees develop and grow they have shorter life span (Roman 2011). That is why it is very important to pay attention when choosing the species that can grow in the urban environment and also try to enable the best habitat conditions for the growth of the chosen species. The given results show the complexity of the growth and development of the trees in the alleys and avenues where frequently the man negatively influences and shapes the growth of the trees with its activities. We can conclude that those activities have restrictive characteristic and that the man reacts too late and especially only when the crown branches are damaged or dried up. These analyses show that due to the crown's eccentricity the trees are less stable in these locations so there were fatal damages that pose threat on property and people's lives (Picture no 1). Therefore the gotten results can represent an excellent foundation that can be used to work out an elaborate study with the aim of preventing this type of damage on the avenue tree species.

Picture no 1. Crown deformities caused by the intense eccentricity that impacts the tree's stability. The trees included in the research before the snow in April of 2017 (source: www.faktor.ba)

Conclusions

The results of the research show the significance of the influence of light on the phenomenon of the crown eccentricity in the neighboring trees of the Silver linden in the function of time. It is established that competition, as a visible manifestation in the form of drying and branch overlap is more visible from the age of 60 years and become more so over the futher growth and development. The studies show that the light is an essential factor for the Silver linden tree crown development and that the crown eccentricity happens on a larger scale in the older trees up to age of 60. Crown deformity is especially pronounced towards the open side where there is more light coming in. the Silver linden reacts strongly on light so the planting distance must be considered when forming an alley or avenue, or the direction of the alley or avenue or the intensity of the side light which has to be optimal during the growth and development of the tree alley. It is necessary to cultivate each tree depending on its needs. Some species need to have their crown trimmed, reduced, form it and clean it. It shows that before trimming the tree one needs to do a study where these and similar studies could be a basis for the prompt carrying out of protective measures and cultivation of these valuable biological elements. When carrying out a forestation of the semi urban city barren land in growing urban forests of park forests with linden trees it should be taken into account to perform the correct planting distance and the edge of the stand because the trees on the edge have the most frequent occurrence of crown deformities. Thinning procedures can optimize the light necessary for the regular development of the crown and good tree stability. Planting other tree species on the edge of the urban forest the crown deformity can be avoided of the Silver linden trees and other Linden trees used in urban forestry and forestry in general.

CANOPY GAP CHARACTERISTICS IN A RESERVED ORIENTAL BEECH FOREST, NORTHERN IRAN

Masoud TABARI*, Saied KIAN, Omid ESMAILZADEH, Seyed JALIL ALAVI

Department of Forestry, Faculty of Natural Resources, Tarbiat Modares University, Noor, Iran
*Corresponding author: mtabari@modares.ac.ir

Abstract

Canopy gap characteristics were investigated in a reserved oriental beech (*Fagus orientalis* Lipsky) stand in the Caspian forests, northern Iran. Seventy six percent canopy gaps were sampled at 5 transects of 625 to 2000 m parallel to slope contours. Gap area was estimated using field method of measurement of non-convex polygonal. Transects were separated by 50 m to ensure that large gaps are not sampled more than once. Median and mean area of gap was 120.7 and 159.2 m^2, respectively. Mean canopy gap fraction was 8.4%. Most frequent gap makers (36%) belonged to DBH class of 82.5-107.5. Sixty eight percent of canopy gaps were smaller than 200 m^2 but only 1.4% bigger than 500 m^2 consisting of 5.8% proportion of the total gap area. The proportion of middle gap sizes (100-500 m^2) was nearly 5 fold of gaps of smaller than 100 m^2. The maximum of gap-makers per gap was 6 trees but 56.6% of gaps were formed by the death of up to 3 trees; 43.4% of gaps were expanded after the initial gap formation, due to recurrence of disturbance events. Most (60.4%) of the gap-makers were at medium and old decay stages; 4.5% of gap-maker species and 12.4% of mortality mode of gap-makers were unknown. However, 60.4%, 19.3%, 5.8% and 2.1% of the all gap-maker trees were snapped-alive, uprooted, snapped-down and standing-dead (deadwood), respectively. Exogenous agents, such as chronic winds, could have a prominent role in initial formation and expansion of canopy gaps.

Keywords: *disturbance regime, canopy gap, gap-maker, gap fraction.*

Introduction

Caspian forests with an area 1.9 million ha have been located mainly in the south coasts of the Caspian Sea in northern Iran over altitudinal gradient of -20 to 2200 m a.s.l. The region is covered with temperate deciduous forests. Oriental beech (*Fagus orientalis* Lipsky) is the most important commercial species, which forms pure and mixed stands between 700 and 2000 m.a.s.l. in these forests (Sagheb-Talebi and Schültz, 2002). Managed plans had been organized for merely 60% of the surface of these forests, this is while that the undisturbed, unmanaged and natural semi-virgin beech stands are still existent within the region (Sagheb-Talebi *et al*., 2005). Therefore, intact oriental beech stands provide a unique prospect to study the disturbance regimes of these forests in the absence of anthropological interventions (Sefidi *et al*., 2011).

Natural disturbances (happened by winds, insects, diseases, acidic deposition, drought and climate change) with low intensity and relatively high frequency caused the formation of gaps with different sizes, driving the forest dynamics in the absence of human interventions (Schliemann and Bockheim, 2011). Canopy gap is a space in the forest stand induced by the death of at least one over-storey tree, where the active recruitment of new individuals was already occurring (Watt, 1947); it is a measurable indicator of past small-scale disturbances (Lundquist and Beatty, 2002). Gap frequency, gap size, and gap shape are the most important among the several metrics used in describing such disturbance patterns (Gagnon *et al*., 2004). Gap size represents the magnitude of the disturbance, which has a direct influence on gap microclimate, under-storey damage levels, nutrient cycling and growth of the gap-border trees as well as vegetation elements within gaps (Gray *et al*., 2002; De Lima *et al*., 2008; Muscolo *et al*., 2015). Scientific report on gap-maker trees in forest stands has been rarely published in the country. The purpose of this study is to gain a better understanding of gap characteristics in a reserved oriental beech forest, in Northern Iran.

Materials and Methods

We selected an area ~190 ha with 870 to 1130 m a.s.l. with northern aspect and slope of 15-60%, situated between 36°41′ and 36°47′ N, and 54°20′ and 54°24′ E. The study area has been involved a typical old-growth stand in a reserved beech forest, including very large and old trees, heterogeneous vertical and horizontal structure at small spatial scales and profuse coarse woody debris. Canopy gaps as openings in the canopy larger than 20 m^2 caused by the mortality of a tree with a diameter larger than 20 cm at 1.30 m height (DBH) were chosen. Dead trees with DBH smaller than 20 cm were not large enough to create a canopy gap (Nagel and Svoboda, 2008; Nagel *et al*., 2010; Bottero *et al*., 2011). When gapfillers reached a height of 24.5 m, the gap was considered closed. DBH and height of 150 trees measured in canopy gaps, regularly distributed in all size classes, were measured too.

We sampled 76 gaps by using line-intercept sampling method over 5 transects varying in length from 625 to 2000 m parallel to slope contours. The gap area was estimated using field method of measurement of non-convex polygonal (NOPO). Transects were separated by 50 m to ensure that large gaps are not sampled more than once. Gap fraction was determined in each transect. Besides, characteristics of gap-makers comprising: species, DBH (if not possible the DBH class was determined), mortality mode (i.e., standing dead, uprooted and snapped) were recorded and, snapped gap-makers categorized into one of three classes (i.e., snapped alive, snapped dead, or snapped-down) (Nagel and Svoboda, 2008).

Results and Discussion

Canopy gaps in the present research were highly variable in size, ranging from 10.5 to 696.6 m^2 with a median of 120.7 and mean area of 159.2 m^2 over all five transects (Table 1). The most frequent diameter classes of gap makers belonged to 82.5-107.5 DBH. Gap fraction ranged from 6.8% to 9.4% in different elevation of the study site. Mean canopy gap fraction was 8.4% that is almost similar (9.3%) to old-growth *F. orietalis* dominated forests in middle Hyrcanian forests of northern Iran (Sefidi *et al.*, 2011), but it was nearly two fold of that in other old-growth forests of eastern Hyrcanian (Amiri *et al.*, 2015). It is noticed that the previous study in Hyrcanian forests had a limited area (smaller than 25 ha) and was carried out in mixed beech old-growth stands.

The studies on the gap disturbance regime of intact beech forests in Europe have also varied results on the gap fraction. The gap fraction in oak-beech forest of Romania, 12.8% (Petritan *et al.*, 2013), beech-fir forest of Slovakia, 11.3% and 15-16% (Kucbel *et al.*, 2010; Drösser and Van Lüpke, 2005), mixed beech and coniferous forests of Bosnia and Herzegovina, 14% and 19% (Nagel and Svoboda, 2008; Bottero *et al.*, 2011), pure beech forests of Slovenia, 5.6% (Zeibig *et al.*, 2005), and mixed beech and coniferous forests of Czech, 9%-11% (Kenderes *et al.*, 2008) was reported. This attributes in American mixed-beech forests was 9.5% and 17.7% (Weskittel and Hix, 2003) and in beech forests of Japan was 1.7% to 20% in stands with different age classes (Yamamoto and Nishimura, 1999).

In our study, most of the canopy gaps (68.4%) were smaller than 200 m^2, whereas only 1.4% was larger than 500 m^2 that comprised 5.8% of the total gap areas. In contrast, 40.8% of gaps were smaller than 100 m^2 that their proportion of the total gap areas was nearly 2.2 fold of gaps > 500 m^2. However, the proportion of middle gap sizes (100-500 m^2) was considerable (nearly 5 fold of gaps < 100 m^2) (Table 2). In other words, 40.8% and 57.8% of the gaps belonged to the small (< 100 m^2) and medium (100-500 m^2) gap sizes, respectively. However, the most of gaps allocated to medium-sized gaps, indicating the prominent influence of such gaps on forest dynamics in comparison with small gaps. At the same time, small gaps are more likely to be closed by the lateral crown growth of the gap border trees.

Table 1. Summary statics of canopy gap characteristics in oriental beech forest of the site study

Gap size (m^2)	Median	120.7
	Mean ± Sd	159.0 ± 14.2
	Range	10.5 - 696.6
Gap fraction (%)	Mean	8.4
	Range	6.8 - 9.4
Gap maker-tress	DBH Classes	Frequency (%)
	7.5-32.5	10
	32.5-57.5	12
	57.5-82.5	24
	82.5-107.5	36
	>107.5	18

Maximum size of gaps in beech forests of Iran have been reported often from 622 to 1250 m^2 (Amiri *et al*., 2015). However, all of these researches support the role of gaps < 500 m^2, especially medium-sized gaps in the dynamics of forest stands, whereas the large gaps (>1000 m^2) are known as a rare occurrence in these forests. In European beech forests, frequency of gap sizes is followed by a negative exponential form (Nagel and Svoboda, 2008; Bottero *et al*., 2011) and log-normal (Drösser and Van Lüpke, 2005) and gaps < 100 m^2 are more frequent (61% to 70%) in comparison with those in the beech forests of Iran. This can be resulted from the minimum area which was explained for 1) gap, 2) the age structure of gap, 3) the presence of coniferous trees with a relatively smaller crown compared to broad-leaved trees in the composition of stands. Nevertheless, in European beech forests, the role of medium and large gaps in forest dynamics is more influence than that of small gaps (Nagel and Svoboda, 2008; Kucbel et al., 2010).

Table 2. Frequency and area of canopy gaps size classes in oriental beech forest of the site study

Gap size class (m^2)	Frequency		Area	
	Absolute	Cumulative (%)	m^2	Cumulative (%)
< 100	31	40.8	1803	14.9
100-200	21	68.4	2901	38.9
200-300	13	85.5	3114	64.7
300-400	8	96.0	2742	87.4
400-500	2	98.6	829	94.2
500-600	-	98.6	-	94.2
600-700	1	100	697	100
Total	76	-	12086	-

From 76 recognized gaps, 47.4% were formed by the death of 1 tree and the rest had 2 or more gap-makers (Table 3). Although the maximum number of gap-makers per gap is 6 trees, but such gaps rarely are seen in the study area. The use of decay classes of gap-maker trees to identifying the recurrence of disturbance events in each gap indicates that most of gaps (56.6%) were formed due to a single disturbing event happened by the death of up to 3 trees. These gaps include of several gaps with multiple gap-makers (2 and 3 trees), as well; however, their portion is < 10% of total gaps (Table 3). As a whole, in our research like the above mentioned studies, such individual gaps were rare and most contained < 4 gap-makers (Table 3). The majority of gaps in the mixed beech-fir forests of Bosnia and Herzegovina were multiple-phase (Nagel and Svoboda, 2008; Bottero *et al*., 2011). Conversely, the most of the gaps in beech forests of Czech were formed from the concurrent death of 1-3 trees at the same place (Kenderes *et al*., 2008). Gap expansion due to chronic winds stress has been also reported in subalpine *Picea-Abies* forests in the northeastern United States (Worrall *et al*., 2005). Therefore, the gap expansion at the length of time could not be received as a prevailing phenomenon among all multiple-tree gaps. The mortality of 43.4% of gap-makers was asynchronous, indicating such gaps were expanded after initial gap formation (Table 3). In spite of several disturbance events occurred in the study area, many single-phase gaps did not experience the recurrence of disturbance events (Table 3).

Table 3. Frequency of gaps by number of disturbing events and of gap-maker trees in oriental beech forest of the site study

Min. number of decay classes (disturbance events)	Number of gap-maker trees						Total
	1	2	3	4	5	6	
1	36 (47.4)	6 (7.9)	1 (1.3)	-	-	-	43 (56.6)
2	-	22 (28.9)	3 (4.0)	2 (2.6)	-	-	
3	-	-	2 (2.6)	-	3 (4.0)	-	33 (43.4)
4	-	-	-	-	-	1 (1.3)	
Total	36 (47.4)	28 (36.8)	6 (7.9)	2 (2.6)	3 (4.0)	1 (1.3)	76 (100)

The numbers in parentheses are relative frequency.

There are many reports regarding to multiple-tree gaps, showing the such gaps are resulted from a single event or that several disturbing events caused by individual gaps in the Caspian Forest Regions of northern Iran. In various researches the maximum number of gap-makers was reported from 4-7 trees within the individual gaps (Delfan Abazari *et al*., 2004; Sefidi *et al*., 2011; Amiri *et al*., 2015). In our findings 83.3% of canopy gaps were formed by single gap-makers, whereas only 4.6% of these gap-makers were health and the remaining (79.2%) in different stages of decay (Table 4). Canopy gaps of two gap-maker trees were at medium, old and very old decay stages and those of three gap-maker trees presented only medium decay stage. In overall, most (60.4%) of the gap-makers were at medium and old decay stages (Table 4).

Generally, of the 139 existing gap-makers within 76 gaps, 78% were oriental beech, 10%, 2.8%, 2.8% and 1.4% were *Carpinus betulus*, *Acer velutinum*, *Parrotia persica* and *Alnus subcordata*, respectively. The remaining 4.5% was considered unknown species because of their advanced decay state (Table 5). We were not able to identify the type of species of all gap-maker trees; nonetheless the oriental beech was the most frequent gap-maker tree among different species in the site study. We could not find the mortality mode for 12.4% gap-makers and tree species for 4.5% of them. However, 60.4%, 19.3%, 5.8% and 2.1% of the all gap-maker tress were snapped-alive, uprooted, snapped-down and standing-dead (deadwood), respectively (Table 5). Exogenous agents, such as chronic winds, could have a prominent role in initial formation and expansion of canopy gaps.

Table 4. Frequency of single-phase gaps by number of gap-maker trees and decay stage

Number of gap-makers	Decay stage of gap-maker trees					Total
	Without decay	Early	Medium	Old	Very old	
1	2 (4.6)	6 (14.0)	11 (25.6)	11 (25.6)	6 (14.0)	36 (83.8)
2	-	-	1 (2.3)	2 (4.6)	3 (7.0)	6 (13.9)
3	-	-	1 (2.3)	-	-	1 (2.3)
Total	2 (4.6)	6 (14.0)	13 (30.2)	13 (30.2)	9 (21.0)	43 (100)

The numbers in parentheses are relative frequency.

Table 5. Frequency of gap-maker tree species by the mortality mode, decay stage and tree species

Mortality Mode	*Fagus orientalis*	*Carpinus betulus*	*Acer velutinum*	*Parrotia persica*	*Alnus subcordata*	Unknown	Total
Snapped alive	72 (51.9)	7 (5.0)	3 (2.1)	1 (0.7)	1 (0.7)	-	84 (60.4)
Uprooted	17 (12.2)	7 (5.0)	-	2 (1.4)	1 (0.7)	-	27 (19.3)
Snapped down	8 (5.8)	-	-	-	-	-	8 (5.8)
Standing dead	3 (2.1)	-	-	-	-	-	3 (2.1)
Unknown	9 (6.5)	-	1 (0.7)	1 (0.7)	-	6 (4.5)	17 (12.4)
Total	109 (78.5)	14 (10.0)	4 (2.8)	4 (2.8)	2 (1.4)	6 (4.5)	139 (100)

The numbers in parentheses are relative frequency.
The remnants of 3 gap-maker trees were not seen within the gap; we classified them as unknown.

Conclusions

Generally, the small and the medium gaps in our study indicate that periodic low-intensity disturbance events play a major role in forest dynamics. The high proportion of rotten trees in the above-storey indicates that single trees are prone to wind-breakage, which promotes these small-scale dynamics. Of course, the various pathogens can make gap-makers more susceptible to wind or snow related mortality (Nagel and Svoboda, 2008). The stem-breakage in different height of trees and tree uprooting may be the dominant modes of gap-maker mortality in the study area. Despite that we observed the stem structural defects in a considerable number of such gap-makers, but the exogenous agents, especially chronic winds, could have been a prominent role in initial formation and expansion of gaps.

EFFECTS OF RETENTION IN FOREST THE DRAINAGE WATER FROM AGRICULTURAL AREA

Magdalena JANEK[1], Kamil MAŃK[1], Edward PIERZGALSKI[1]

Abstract

The poor quality of the Baltic Sea waters is a serious environmental problem, but also negatively affects the efficiency of maritime economy and the health of the population, the development of tourism, etc. One of the important sources of the Baltic Sea pollution is agriculture. The large amounts of nitrogen and phosphorus compounds from Poland to the Baltic come from drainage systems of agricultural land. In order to reduce these loads water from drainage systems is retained, among others, in water ponds on agricultural area. Besides the problem of water pollution, for the last 30 years water resources in Poland have been reduced mainly due to climate change. This phenomenon also occurs in the forests, so it is considered to retain the drainage outflow from agriculture area in the forests area. However, there is a fear whether the biogenic compounds contained in drainage waters will not harm the forest ecosystem. In order to verify this question, a pond was constructed in the forest for water from drained agricultural land. The quality of water flowing from farmland to pond as well as quality of groundwater at different distances from the reservoir was investigated. The paper presents the technical solution of the water retention system in the forest as well as the load of nitrogen and phosphorus compounds retained, which does not pollute the Baltic Sea. The results of research indicate that so far changes of groundwater quality in the vicinity of the pond don't threaten the forest ecosystem.

Key words: *Baltic Sea pollution, drainage outflow, water retention, forest*

Introduction

The Baltic Sea is a receiver of heavily contaminated waters from the 14 surrounding countries. An especially large source of nitrogen and phosphorous pollution is the developed agriculture in these countries (Aeheimer, 2000, Banaszuk *et al*., 2005). In order to improve the quality of waters in the Baltic Sea, various political, economic, and scientific activities are undertaken. It should be emphasized the role of the Helsinki Commission (HELCOM) in coordinating since 1974 the activities aimed at reducing pollution loads and improve water quality in the Baltic Sea. The various projects are being undertaken to promote a good water management practices in agriculture and in the forests such as projects within The Interreg Baltic Sea Region Program: Comprehensive Policy Actions and Investments in Sustainable Solutions in Agriculture in the Baltic Sea Region (Baltic COMPASS, 2009-2012) and Water Management in Baltic Forest (WAMBAF, 2016-2019). Poland, due to its size and population, belongs to the countries most polluting of this area (Ericsson, 2007). A large amount of nitrogen and phosphorus pollution from Poland comes from agricultural areas (Rauba, 2009). It is estimated (Behrendt *et al*., 2005, Kowalkowski and Buszewski, 2006), that the share of chemical compounds in drainage outflow in the total load of pollution flows to the Baltic Sea is approximately 30% in the case of nitrogen and 4% in the case of phosphorus. Besides of the need to reduce the pollution load entering the Baltic, a significant problem of water management in Poland is a decrease of water resources which has been observed for about 30 years. The main factor of this process is climate change, especially the rise of air temperature. Taking into account the problem of quality and quantity of water resources, attempts are made to retention of water from drainage systems in small ponds, reservoirs, etc. There is also a concept of retaining drainage water in forest areas where a water deficit is observed in many areas. However, there is a question if content of nitrogen and phosphorus in drainage outflow will cause harmful changes in the forest ecosystem. In order to verify this hypothesis, an investigation of the quality of drainage outflow from agricultural land retained in the reservoir located in the forest as well as the quality of groundwater in the vicinity of the reservoir were carried out. The paper presents the technical solution of the water retention system in the forest as well as the load of nitrogen and phosphorus compounds retained in the forest, which does not pollute the Baltic Sea.

Material and Methods

The study was conducted on a water reservoir located in the Pułtusk Forest District [Lat. (Dec.) 52.8810, Lon. (Dec.) 21.4962]. The reservoir was made in 2008. In the vicinity of the reservoir there are permeable soils: medium and fine sand, loamy sand and sandy loam. The outline of the pond surface is shown in the Figure 1. Water from a drainage systems which was made on about 1000 ha arable land is collected in the well (S1) and flows by a 225 mm diameter PVC pipeline into the reservoir. A flowmeter was installed in this well for measuring the amount of water flowing into the reservoir. The basic parameters of the pond are as follows:

- Surface of the reservoir: 1,25 ha,
- Pond capacity: 29600 m^3,
- Maximum pond depth: 4,3 m.

Water gauge was mounted in the pond. Two transects of 8 observation wells with electronic devices were installed for determination of an impact of the pond on the changes in groundwater level and their physicochemical parameters (Figure 1). The quality of water flowing into the reservoir was analyzed at various dates from 2009. Groundwater quality was tested after 8 years of operation of the reservoir. Water samples for physicochemical analyzes were taken from wells once a month between December 2016 and June 2017.

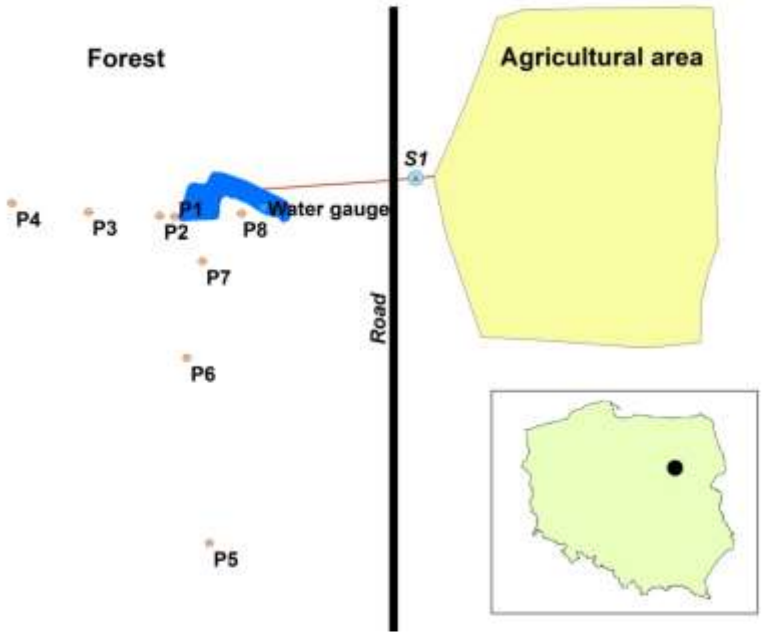

Figure 1. Scheme of research facility and location of observation wells.

Physicochemical properties of water probes were determined in the Laboratory of Environmental Chemistry, Forest Research Institute. The following methods were used to determine physicochemical parameters of water:
pH: potentiometry,
EC : conductivity,
Concentration of anions (Cl^-, NO_3^-, SO_4^{2-}, PO_4^{3-}): ion chromatography,
Concentration of ammonium NH_4^+: ion chromatography,
Total concentration of bound nitrogen (TNb): chemiluminescence.

Results and Discussion

The volume of water which flowed from drainage system into the pond in the period from 21 March to 27 June 2017 amounted to 96000 m^3. This means that due to the infiltration of water through the bottom of the pond, three times more water was retained than its capacity. The decrease of the water level due to the infiltration was 3-5 cm per day. Rainfall in this period was 146 mm. The range of impact of the reservoir on the level of groundwater retention can be estimated at 300-400m. Figure 2 shows the results of the measurements of March 21, 2017 in transect II when the water level in the reservoir was 95,40 m. asl.

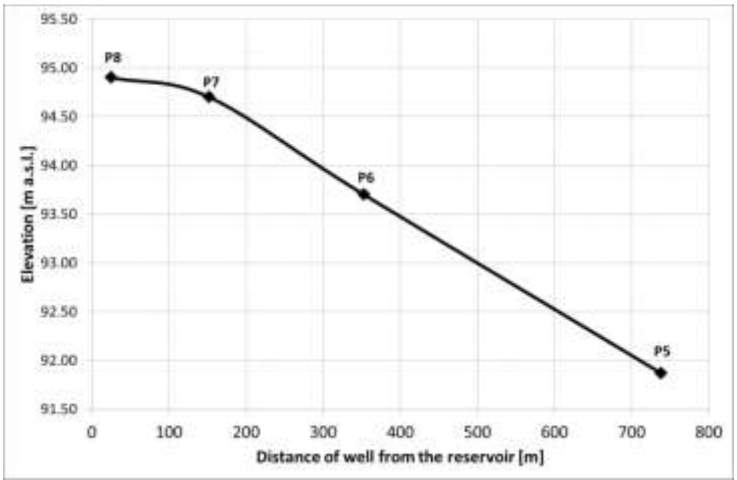

Figure 2. Groundwater level in observation wells - transect II.

The characteristic feature of drainage outflow is the high concentration of nitrogen compounds. The concentration of different forms of nitrogen in water flowing into reservoir as well as in the groundwater is given in Table 1. The quality of water flowing into the pond was studied in 2009-2012 (Pierzgalski *et al*., 2012). It was then found that the quality of water was reduced mainly due to too high concentrations of total bound nitrogen, nitrate nitrogen and ammonium nitrate. The range of variation of nitrogen compounds was quite significant and was at:
- TNb: 0,62-10,89 [mg·dm^{-3}],
N-NO_3: 2,51-7,44 [mg·dm^{-3}],
N-NH_4: 0,27-1,29 [mg·dm^{-3}].
Comparing these ranges of variation with the results given in Table 1 (well S1) can be concluded that they are comparable. Taking into account the limit of pollutants for I and II of water classes of 5,0-10,0 [mg·dm^{-3}] for TNb, 2,2-5,0 for N-NO_3, and 0,78-1,56 for N-NH_4 respectively, it can be stated that only for N-NH_4 they were not exceeded.

Table 1. Concentration of total bound nitrogen, nitrate nitrogen and ammonium nitrate in water from drainage system and in groundwater at different distances from the pond

Name of well	Distance of well from the reservoir [m]	Total bound nitrogen TNb $[mg \cdot dm^{-3}]$		Nitrate nitrogen $N\text{-}NO_3 [mg \cdot dm^{-3}]$		Ammonium nitrate $N\text{-}NH_4 [mg \cdot dm^{-3}]$

The drawings 3, 4, 5 present changes in the analyzed parameters depending on the distance from the pond. In the case of TNb it can be stated that the range of impact of the reservoir is about 100-150 m in transect I and about 200-250 m in transect II. It should also be noted that in the well P5 located 750 m away from the pond TNb value increased, which can be explained by the influence of pollution not from the pond. Similar dependencies can also be seen for $N\text{-}NO_3$ and for $N\text{-}NH_4$.

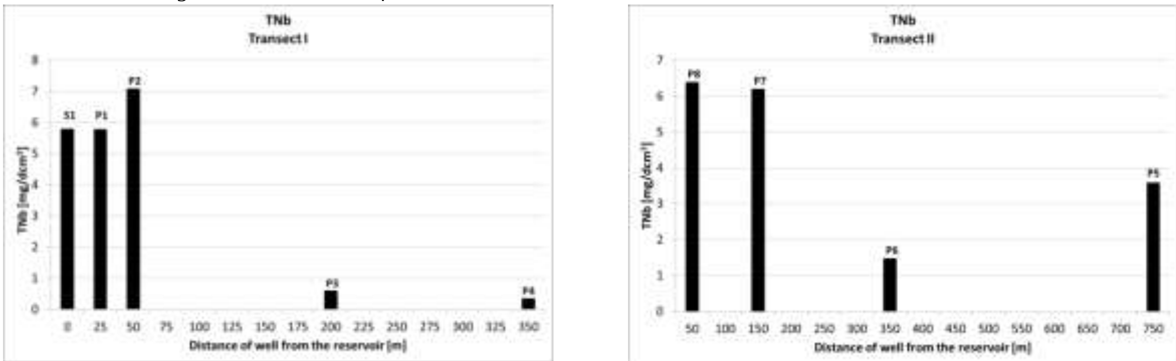

Figure 3. Concentration of total bound nitrogen in groundwater depending on the distance from the pond.

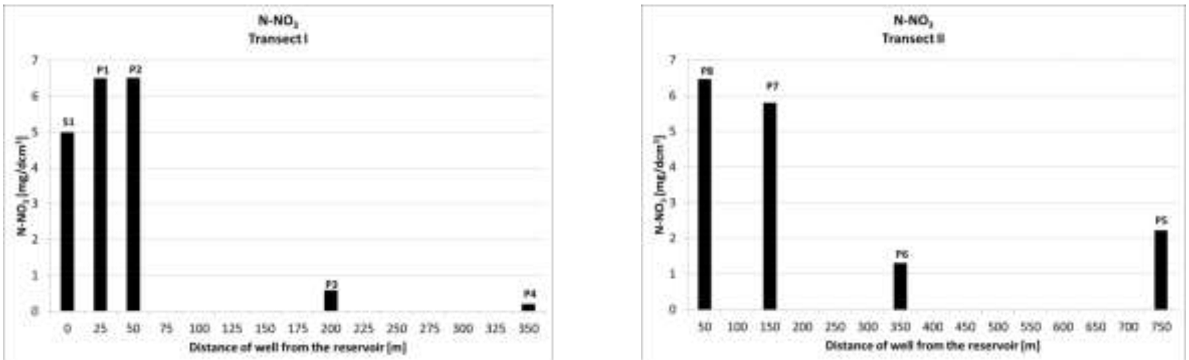

Figure 4. Concentration of nitrate nitrogen in groundwater depending on the distance from the pond.

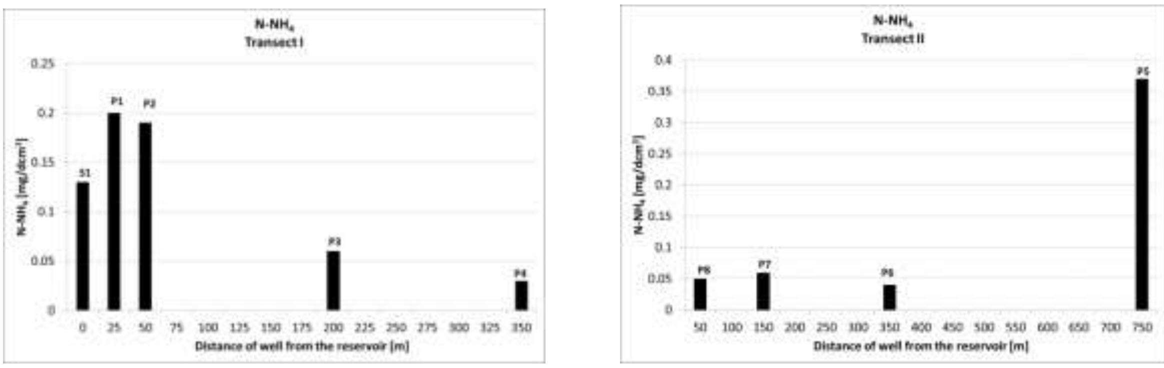

Figure 5. Concentration of Ammonium nitrate in groundwater depending on the distance fromthe pond.

Taking into account the average concentration of TNb and the volume of water flowing into reservoir, it can be stated that about 560 kg of nitrogen was retained in the forest area in the period from March to June 2017. Phosphorus compounds in the drainage outflow are much less than load of the nitrogen, but it is a main factor causing water eutrophication. Table 2 shows the concentration of phosphates in water samples taken from the same sites as for nitrogen compounds.

Table 2. Concentration of phosphates in water from drainage system, and in groundwater at different distances from the pond

P6	353	0,0 - 0,08	0,04
P5	738	0,0 - 0,05	0,01

The results show that the concentration of phosphate was very low both in drainage water and in groundwater. The reason for this is the low mobility of phosphorus, especially in mineral soils. These results confirm the information given in the literature (Behrendt *et al*., 2005, Kowalkowski and Buszewski, 2006), according to which from Poland to the Baltic in the drainage ditch there is more than 100 times more nitrogen than phosphorus. Analysis of phosphate content in groundwater does not indicate their correlation with the distance of wells from the reservoir.

Conclusions

The purpose of the study was to determine the impact of the retaining the drainage outflow from agricultural areas in reservoir located in the forest. The influence of the reservoir on the increase of water resources and on the content of nitrogen and phosphorus compounds in groundwater in the vicinity of the reservoir were assessed. The volume of drainage outflow which flowed into the pond in the period from 21 March to 27 June 2017 amounted to 96000 m^3, which is three times that capacity of the reservoir. Due to the high permeability of the pond bottom the ground water was raised on the area from 400 to 500 m. from the pond improving the water conditions of the forest habitats. Analysis of groundwater quality leads to the conclusion that there is relationship between the content of nitrogen compounds in the outflow of the drainage and in the groundwater to a distance of 400 to 500 m from reservoir. On the other hand, the phosphate content of both drainage and groundwater was low. There wasn’t also relationship between the phosphate content of groundwater and the distance from the reservoir. The obtained results indicate that during the 9 years of operation of the reservoir there have been no changes threatening the forest ecosystem. The solution applied is assessed positively in terms of improvement of local water resources and positive influence on the quality of flowing into the Baltic Sea.

THE VULNERABILITY TO CLIMATE CHANGES OF PINE FOREST CULTURES FROM OUTSIDE THEIR NATURAL RANGE

Cristinel CONSTANDACHE*, Lucian DINCĂ, Nicu Constantin TUDOSE

National Institute of Research and Development in Forestry ”Marin Drăcea” – Romania
*Corresponding author: cicon66@yahoo.com

Abstract

The pine forest cultures installed outside their areal are exposed to the action of some harmful abiotic factors (drought, wind, snow), being rather vulnerable and sometimes suffering from important assaults, so that their ecological reconstruction is a necessity. The pine cultures from outside the areal were realized starting with the year 1972, by replacing some derived stands (linden stands, hornbeam stands etc.) or low productivity *Quercus* stands. They were intended for the production of colophon, but also for wood production. During their evolution, in the absence of a guiding scientific substantiation, the risk that these stands should be harmed by the action of harmful factors before they reach the intended cycle has increased. In order to substantiate the ecological reconstruction methods of the affected ecosystems, the monitoring/evaluation and their structural-functional analysis are necessary. The current paper presents the results of the investigations regarding the structure (structural parameters and structural diversity) of some pine stands situated in the forest steppe area from the East part of Romania. Analysis of the structure of the stands is very important for determining the stand’s degree of assault and vulnerability, regarding which urgencies and methods of restoration can be established. In order to establish the ecological reconstruction solutions, experiments have been realized in different situations. The reconstruction of pine stands from outside their natural range is extremely important for preventing the environment’s degradation risks and for achieving the protection or production functions of these stands.

Keywords: *pine cultures, natural range, vulnerability, abiotic factors.*

Introduction

Pine forest cultures installed outside their areal are occupying important surfaces and are also exposed to certain risk factors (drought, wind, snow, anthropic factors). They can be sometimes really vulnerable and, as such, can suffer important damages (drying, breaks/windfalls etc.) (Allen et al., 2010; Dobbertin et al., 2007; Oberhuber, W., 2001). The last years have witnessed an alarming evolution of the drying phenomenon for pine stands situated outside their natural areal. For example, in the year 2015, the surface of pine stands affected by drought was of 3427 ha (MMAP report, 2015), which represents approximately 5% of the surface of pine stands installed outside their areal in Romania. Accomplishing the protection functions depends on the state/structure of protection forest cultures, so that the ecological reconstruction of the stands affected by harmful factors is a necessity. These cultures were realized starting with the year 1972 and were intended for the production of cellulose wood (spruce) or for the production of colophon (pine).

The pine cultures were installed in the place of some stands that had a low productivity (IV and V) or derived (linden stands, hornbeam stands, etc., Arhip, 1998). Extending the pine cultures was realized as follows (Barbu, 2004):

- Scots pine, replacing low productivity beech and holm stands;
- black pine, replacing many degraded and inferior productivity holm, oak, etc. stands;

Both species were also frequently used for the afforestation of degraded fields (Constandache *et al.*, 2015).

During the evolution of resinous cultures outside the areal and in the absence of a leading scientific substantiation, the risk of harming them by perturbation factors before they can reach an optimal age has appeared and amplified. Some of the mentioned stands were strongly affected during their prime by wind or snow falls and breaks. On the other side, the drought from the last years has significantly aggravated the situation of resinous cultures from outside their natural areal. As such, the drying phenomenon was signaled on more and more surfaces. The resinous cultures from outside their areal (pure pine or spruce plantations) are inferior from a functional point of view to the ones substituted by local species. The excessive artificial phenomenon of forest regenerations has created a paradoxical discrepancy between the site diversity and their multifunctional efficiency. Monocultures of spruce, pure pine or mixtures between them were created and endowed with an immense potential for ecological instability. Their state was further aggravated by the fact that they are not followed up by maintenance works necessary for strengthening their resistance towards adversities (wind, snow, rime etc.) (Barbu, 2004; Constandache *et al*., 2015). The climatic changes from the last years are leading towards an increase of their harming risks and for the degradation of the environment through the conjugated action of some harmful agents. As such, monitoring the stands and quantifying their ecological impact on the environment in order to substantiate the ecological reconstruction methods for the affected ecosystems is a necessity.

Materials and methods

In order to achieve the proposed objectives, measurements and field observations were realized, together with processing and analyzing statistically the data. Taking into consideration the complexity of the studied phenomenon and the intended objectives, pine stands situated in areas with different site conditions from the East part of Romania were chosen.

Table 1. Location and general characteristics of the analyzed stands

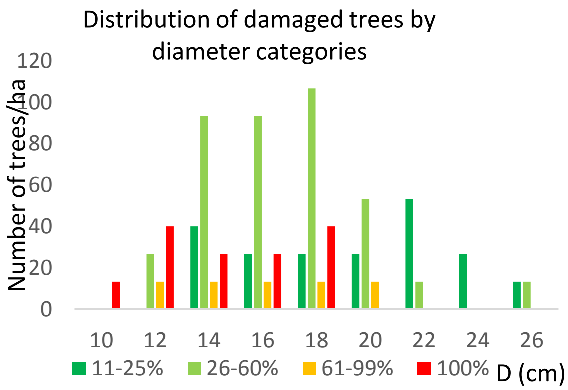
In order to emphasize the structural characteristics of stands, an analysis of the experimental distribution of the main biometric parameters of trees was realized by theoretic distribution functions (normal, beta) that correspond to the horizontal structure. Another analysis method for stand structure was represented by analyzing the correlations between different qualitative and quantitative characteristics through general statistical methods. Studying the quality of stands from degraded lands and establishing some dependency links between different qualitative and quantitative characteristics has also implied the usage of structure analysis in regard with stational conditions. In regard with the harmful degree, the evaluation was realized based on the evaluation methodology of forest's health state. The intensity of tree damage based on the crown's defoliation percentage was realizes in accordance with the methodology adopted at European level. As such, 0 defoliation class (0-10%)- healthy tree; 1st defoliation class (11%-25%) – weakly damaged tree; 2nd defoliation class (26%-60%) – moderately damaged tree; 3^{d} defoliation class (61%-99%) – strongly damaged tree; 4th defoliation class (100%) – dead tree.
The structural diversity analysis was realized with the help of Shannon index, while the Camino and Gini indexes were used for testing structural homogeneity under the report of basis surface.

Results and discussion

From a phito-climatic point of view, pine stands from outside their areal are situated in forest steppe areas and *Quercus* floors, areas frequently reported for damages caused by drought (exsiccation), wind, storms or snow (breaks). The terrains on which these stands are vegetating are different both as altitude, slope aspect, inclination, configuration, as well as with regard with pedological conditions.
Fields with pine stands are situated in the following types of forest sites:
-normal field stations (unaffected by degradations) from the external forest steppe area (with soft or brown oak), with chernozem soils on loess materials and other clays; *Quercus* and oak stands with luvisol soil types;
-degraded field stations from the same areas: external forest steppe, floors of *Quercus* with oak (on strongly eroded slopes) or *Quercus* with holm, Hungarian oak, Turkish oak, with small edaphic podzol soils.
All these characteristics were analyzed with the purpose of emphasizing the factors that determine the behavior and evolution of pine stands in regard with harmful factors. The structure analysis for pine stands from outside the areal has followed the composition, consistency, biometric characteristics and so on. The majority of analyzed pine stands have an age of 35-40 years. The biometric conditions are differentiated in regard with the specie and site conditions (lower sizer in harsher conditions). As such, the average diameter has values between 12.2 and 18.5 cm for the black pine and between 14.9-24.4 cm for the Scots pine. The average height varies between 9.5 abd 13.1 m for the black pine and 10.3-18.7 m for the Scots pine. By analyzing the composition of stands, it has resulted that approximately 25% of these are pure pine stands (predominantly black pine), 60% are mixture stands with up to 30% mixtures species, while the difference (15%) is represented by black pine stands mixed with broad-leaved species (with over 30% mixture broad-leaved species). As for the number of disseminated species (under 10%), two up to four disseminated broad-leaved species were identified. Their origin comes from the natural regeneration (sprouts, suckers) of replaces species.
In regard with the stand's state (consistency, number of trees/ha), they are thinned in most cases (consistency: 0.5-0.6), with a low number of trees as result of previously realized works

(that have extracted trees affected by drought). In certain situations, different species of mixture broad-leaved were naturally installed and are completing the consistency of thinned pine stands. The stand's structural diversity analysis has proved that most stands have a low variability, indicated by a value of <25% of the variation's coefficient. The maximum recorded value is of 49.1% (pine and locust mixture), while the minimum value is of 11.27% (pure Scots pine stand). The optimal values for this parameter are situated between 25 and 35% and are represented by stands composed of broad-leaved species in a percentage of 10-30% (Galaţi 40 B, Vidra 162, Podu Iloaiei 3C, Tecuci 30B – table 1). This aspect emphasizes the fact that the broad-leaved species that have appeared in the composition of pine stands from outside their areal are positively influencing the value of the mentioned statistic parameter. The pronounced variability (49.14%) highlights an atypical structure, which indicates an inappropriate mixture (pine and locust) that is especially used in the afforestation of degraded lands (Lukić *et al.*, 2016). The analysis of tree distribution on diameter categories is in a direct relation with the number of species from the stand's composition. As such, the stand distribution on diameter categories is realized in accordance with the normal theoretical distribution, in the situations in which the presence of other species was not registered, but only of those initially used for creating the cultures (pure stands). For the case in which the presence of more species (naturally regenerated) is noted, the tendency of by-levels (multiple levels) is evident. This is the consequence of the appearance of a new vegetation level composed of local species from the forest subarea in which the forest pine cultures were installed. The structural diversity is oriented towards the grouping of individuals in space, their functional reports and dimension variability, emphasizing the stability and capacity of stands with different compositions for adapting at stational conditions Analyzing the structure and diversity of pine stands, expressed through the value of the average diameter variation coefficient, emphasizes the low variability of pure Scots pine and black pine stands. This denotes the low diversity and high vulnerability of these stands in regard with harmful factors. Although the Scots pine has achieved larger dimensions (diameter, height) than the black pine in the same site conditions, it has also suffered damages (breaks, drought), which has led to the reduction of tree consistency and thickness. These aspects are also emphasized by the real number of trees, which is in most situations lower with 35-76% than the normal number of trees (according to biometric tables). Furthermore, in the pine stands where the consistency was much reduced, namely the number of trees affected by damages, special conditions for installing/developing local broad-leaved species and substands are created. This leads to a structural and ecological diversity of the stands. The structural diversity indexes (Gini, Camino, Lorent) calculated for the analyzed stands are showing an accentuated homogeneity for pure stands. In the case of mixture stands, the low homogeneity expresses their diversification tendency. It is also observed the aberration of Lorent curve for the mixture stands in comparison with the pure or almost pure stands, which indicates the growing diversity and complexity of the stands, favoring their stability and natural regeneration. In most cases, the diversification is caused by mixture broad-leaved species (naturally regenerated and which form an inferior level). The higher diversity of pine stands in mixture with broad-leaves expresses a higher stability, the stand's capacity for adapting at site conditions and also their capacity for natural regeneration and ensuring protection functions. By analyzing the damage degree of pine stands it can be observed that the percentage of damaged trees (affected by drought in a percentage of over 25%) is over 50% for most analyzed situations and can reach even 75-77%. The larger percentage of damaged trees is observed in most stands situated in the forest steppe areas in which extraction works were not realized. The percentage of dry trees is also different, depending on the works previously realized and is frequently situated between 10 and 25% (Figure 1). An exception is recorded for the stands in which the extraction works of damaged trees were realized recently and had a lower consistency.



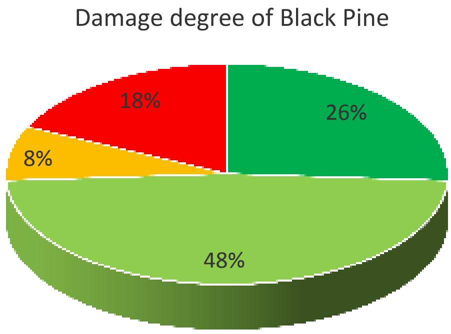


Fig. 1. Characteristics of damages (Forest district Galaţi, UP III Zărneşti, u.a. 8A)

Decreasing the stand's consistency is accompanied by an overall reduction of structural heterogeneity (which means a higher structural homogeneity), expressed through the Camino homogeneity index. This, through the value interval gathered between 2.43 and 12.34, indicates the stands that have an equine to relatively equine structure. As a consequence of reducing the structural variability of biometric elements (diameter/basis surface) together with the aging of Scots/black pine after extracting the damaged trees, they have reacted by an increase in structural diversity even in accentuated degraded land conditions, by installing/regenerating some broad-leaved species either from the old stand or from the nearby ones. This diversity had as effect in the recovery of the dynamic equilibrium which was affected by previous interventions. In order to sustain the above mentioned facts, the Gini index was calculated. Its values (0.121-0.495) are confirming the affirmations mentioned above. In order to determine future interventions in the management of pine stands situated outside the areal, the evaluation of stand vulnerability and their adaptation capacity is necessary. The evaluation can be realized based on the analysis of ecosystem states under the report of composition, structural complexity, age etc. in regard with site conditions. The vulnerability can be calculated as a product of exposure to climatic changes (Ex) and stand sensitivity (Sz), (Barbu *et al.*, 2016). The exposure to climatic changes (Ex) will be appreciated in regard with the phito-climatic area (altitude) and pedostational conditions (relief, soil). The structural parameters that have to be taken into account in order to estimate the sensitivity (Sz) are: composition, consistency, age and vertical structure. In regard with the urgency of applying ecological reconstruction works in affected stands, tree situations were differentiated based on the damage degree. Each implies different methods/urgencies for applying the works.

Conclusions

Pine stands from outside their areal are situated in forest steppe areas and *Quercus* vegetation floors from fields with different site conditions where they were introduced for the substitution of degraded trees (generally *Quercus*) or derived (linden, hornbeam), as well as on fields with more difficult site conditions (degraded).
In most part, pine forest cultures have an age between 35 and 45 years; their biometric characteristics are correlated with the phito-climatic floor and site conditions of fields, emphasizing the sensibility of these species in the forest steppe, on degraded lands.

In 75% of the analyzed situations it was observed the presence of broad-leaved species naturally regenerated (originated from the old substituted stands), which have an important role in ensuring the consistency and structural diversity of pine cultures; the higher diversity of pine stands in mixture with broad-leaves expresses a higher stability, their capacity for adapting and site conditions as well as their natural regeneration capacity.
The pine cultures from outside the areal have suffered damages caused by drying, especially after the age of 35 and predominantly in the forest steppe area. Through silvotechnical works, the strongly damaged trees (over 60%) were extracted, so that the number of trees and the consistency were significantly reduced.
The intervention urgencies with ecological reconstruction works are established in regard with the stand's structure and the degree of damage. However, establishing the ecological reconstruction solutions is hard and implies differentiated solutions and techniques based on the site conditions as well as the characteristics of the affected stands.
Evaluating the vulnerability of pine stands from outside their areal is necessary in the conditions of climate changes in order to know the stand's direction of evolution and to prioritize future interventions for leading and regenerating pine stands.

PAULOWNIA SPP. AND TRUFFLES (*TUBER* SPP.) PLANTATIONS IN ROMANIA

Lucian DINCĂ, Diana VASILE, Vlad CRIȘAN

National Institute of Research and Development in Forestry "Marin Drăcea" – Brașov, Romania
*Corresponding author: dinka.lucian@gmail.com

Abstract

The agroforestry systems that use this type of plantations have important social and ecological value and represent a direct contribution to rural economies. From this point of view, the plantations with *Paulownia* spp. or another one trees for truffle productions represent a good opportunity for some countries that present a surplus of surfaces that are not covered with agricultural or forest cultures as is the case of Romania. This article's main objective was to analyses the evolution of *Paulownia* plantations and of seedlings inoculated with truffles from Romania during the last years. In order to achieve this objective, 6 *Paulownia* plantations and 2 truffle plantations were studied. The investigations carried out prove the fact that the realization of cultures for wood (*Paulownia* spp.) or for the production of truffles can be achieved in good conditions only if the ecological requests of the plants and the site conditions of future cultures are taken into consideration. Unfavorable results were obtained for the *Paulownia* plantations due to frosts from higher altitudes (where the culture of this species is not recommended for the future) or due to some technical mistakes (cutting too strongly the roots, not removing the weeds). However, the two types of cultures are recommended for usage in the future (only in proper site conditions) as they bring numerous advantages to field owners (primarily financial, but also ecological).

Keywords: *Agroforestry, afforestation , Paulownia spp., truffles.*

Introduction

The agroforestry system can be defined as an important land management system which realizes increases of the land efficiency, that combines the production of tree crops and forest plants on the same unit, and which applies management practices that are suitable with the cultural practices of the local population. Also, the agroforestry practices maintain watershed functions, retain the carbon in the plant-soil system, and support the conservation of biological diversity by increasing levels of wild biodiversity on farmland. In Europe there are six agro-forestry practices, namely: silvo-arable agro-forestry, forest farming, riparian buffer strips, improved fallow, multipurpose trees and silvo-pasture (Mosquera-Losada et al. 2009). *Paulownia* spp. and truffles plantations in Romania are two of the six agro-forestry practices from Europe. They belong to the "improved fallow" practice, which represents fast growing woody species that improve soil fertility and may yield economic products. *Paulownia* plants have fast growth and can produce as much biomass in one year as other species in several years. The trees grow much faster than other tree species, reaching large sizes in 6-9 years. Another advantage is that after harvesting, the plantation does not need replanting, because new trees grow from the stumps. *Paulownia* spp. wood is very light, with densities around 0.300 g/cm^3 (Akyildiz & Kol, 2010; Kiaei, 2012) and for this reason is used for making musical instruments, boxes, chests, lightweight skis, furniture, doors and windows (Clapa et al., 2014). *Paulownia elongata* S.Y. Hu and *Paulownia fortunei* Hemsl belong to the family of *Bignoniaceae* and this species are mostly grown on plantations. Sometimes, in agroforestry

systems, they are planted with agricultural cultures (Knezevic et al., 2009). By cultivating *Paulownia* spp., the soils are becoming very rich, because the root distribution results in more efficient use of water and other limited resources. Furthermore, the plantations are very efficient in afforestation and protection of soil against erosion (Wang & Shogren, 2003).
Truffle plantations belong to the "multipurpose trees" category, which represents: trees randomly or systematically planted in cropland or pasture for the purpose of providing fruit, fuel wood, fodder and timber on farms and rangelands. Truffles belong to diverse groups of both *Ascomycetes* (spore sac fungi) and *Basidiomycetes* and are forming macro fungi underground (hypogenous) fruit bodies. A lot of truffle species live in ectomycorrhizal association with various trees and shrubs. Some species of the genus *Tuber* are very appreciated as delicacies. One of these species is the black Burgundy truffle (*Tuber aestivum* Vitt.) (Weden *et al.,* 2009). In this paper, we use the older name *Tuber aestivum*, because *T. uncinatum* Chat. is a synonym for *T. aestivum* (Paolocci *et al.,* 2004; Weden, 2004; Weden *et al.,* 2005). *Tuber aestivum* Vitt. forms ectomycorrhizal with oak (*Quercus* spp.), beech (*Fagus sylvatica* L.), hornbeam (*Carpinus betulus* L.), linden (*Tilia* spp.) and hazel (*Corylus* spp.) (Chevalier & Frochot, 1997a). The development of cultivation of *T. aestivum* first took place in France and Italy (Chevalier & Frochot, 1987, 1989, 1997b, 2002; Giovanetti et al., 1994; Belloli et al., 2001). The first truffles were produced in 1976 in Italy (*T. melanosporum* Vittad.) in a truffle orchard (truffiere) of inoculated seedlings, 6 years after planting, while in France the first truffles were produced in 1977 (*T. melanosporum*) from inoculated seedlings, 3.5 years after planting (Chevalier & Grente, 1979). By contact with germinating spores, mycelia or mycorrhizae, roots of an ectomycorrhizae forming tree can be inoculated with an ectomycorrhizal fungus. The entire plant or pieces of a root system with mycorrhizae can be put together with the seedlings to be inoculated (Chevalier & Grente, 1973; Chira D. & Chira F., 2012) and on the new seedlings the mycorrhizae may develop within 2 or 3 months. This method is applicable to many *Tuber* species (Giovanetti *et al.,* 1994).

Material and Methods

In this paper , 6 *Paulownia* plantations and 2 truffle plantations from Romania were analyzed.The *Paulownia* plantations were realized with hybrids obtained by crossing *Paulownia elongata* (S. Y. Hu) and *P. fortunei* (Hemsl.): *Paulownia* clona in Vitro 112® and *Paulownia* Cotevisa 2. The 6 analyzed plantations were: 1. Cataloi (Tulcea County): a culture of 3 years, planted in the spring of 2013 on a surface of 1.4 ha; 2. Arpaș (Sibiu County): a culture of 3 years, planted in the spring of 2011, on a surface of 1 ha; 3. Hetiur (Mureș County): a culture of 4 years, planted in the spring of 2012 on a surface of 5 ha; 4. Jucu (Cluj County): a culture of 2 years, planted in the spring of 2012 on a surface of 2.5 ha; 5. Mihaesti (Arges County), a culture of 2 years, planted in 2015 on a surface of 0.5 ha; 6. Baraganu (Calarasi County), a culture of 2 years, planted in 2015 on a surface of 0.6 ha.
Trees were planted at the beginning of spring. Special treatments were not necessary before the plantation. A southern facing exposure with some protection from wind was preferred. Furthermore, young trees were protected from grazing animals, as animals tend to feed on the bark, damaging the trees and limiting the growth. The site was pre-irrigated to moisten the soil and to reduce the amount of labor required. Holes were dug at 5 m x 4 m or 5 m x 3 m, providing 500-700 trees per ha. The holes were of 70-80 cm on each side and 50-60 cm deep. After planting, 15-20 cm of soil was heaped around the sapling. *Paulownia* spp. is very tolerant of adverse soil conditions, but is very sensitive at waterlogging, requiring good drainage, needing between 500 mm and 2600 mm of rainfall annually. Therefore, saplings were irrigated on the day they were planted and again a few days later. For the first year, it was necessary to practice weeding, such that weeds do not overgrow the young trees.

In Romania, 2 truffle species are spread naturally: *Tuber aestivum* Vitt. and *T. magnatum* Pico and are harvested in important quantities in the country's forest areas (Dincă M. & Dincă L., 2012). The two realized truffle plantations are: a pedunculated oak (*Quercus robur*, L.) plantation of 3 years, 2 year Turkey oak (*Quercus cerris*, L.), 2 year sessile oak (*Quercus petraea*, Liebl.), 2 year hazel (*Corylus avellana*, L.), and 2 year Turkish hazel (*Corylus colurna*, L.) (originally from Hungary), inoculated with *Tuber aestivum* at Prejmer plantation and one with Turkey oak seedlings (originated from Italy) replaced with *Tuber melanosporum* at Moldova Noua (Figure 1). Truffle cultivation needs a detailed study of the site, which includes soil physical-chemical analysis, climate, topography, vegetation, etc., and also pre-and post-plantation farming operations, fundamental for successful production of fruiting bodies (Bencivenga & Baciarelli Falini, 2012). Generally, well-drained calcareous soils are preferred, with alkaline pH between 7.5 and 8.0, medium humus content and good aeration (Granetti *et al.*, 2005). It should be considered that fruiting bodies of truffles are vulnerable and damaged by extreme temperatures and dry conditions (Trappe et al., 2009). Also, it was taken into account that T. *melanosporum* prefers permeable soils, never saturated with water and well heated by sun rays, while T. *aestivum* tolerates soils with neutral pH values. Both species are cultivated with equal success in a broader range of hosts and habitats (Danesh, 2015).

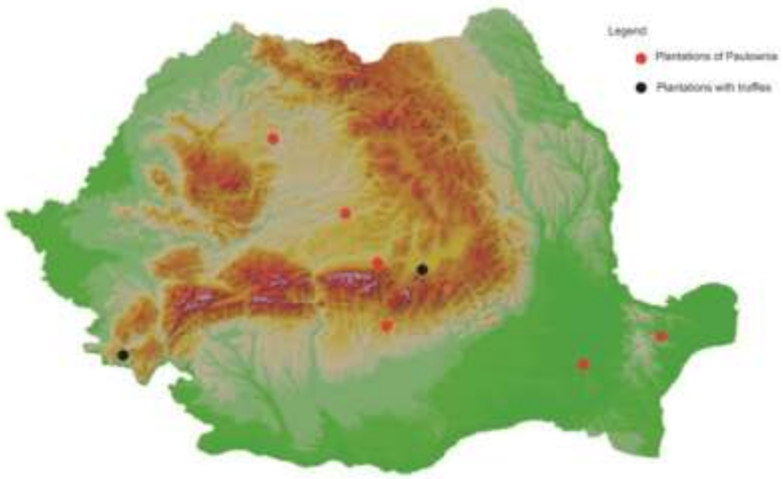

Figure 1. The repartition of *Paulownia* spp. and truffle plantations in Romania

Results and Discussion

Paulownia plantations: if the correlation between the specie's ecological conditions and the site are taken into account, and if the creation and maintenance works are properly applied, these plantations (exemplified by Jucu and Baraganu plantations) present a good growth. The unsuccessful plantations (Hetiur, Arpaș) are caused by inappropriate climatic or edaphic conditions and technical mistakes (cutting too strongly the roots, not removing the weeds). The losses caused by frosts are higher at Mihaesti and Arpas, where over half of the seedling's height was affected by this phenomenon. The plantation from Hetiur was completely compromised because: the inadequate planting location (an area renowned for its unproductive fields, with a very weak soil) and due to excessive cuttings of the seedling's roots (obtained through cuttings, imported from Spain and contained too long before planting in inappropriate conditions). The plantation from Arpas was also compromised due to low

temperatures from the area and by not removing on time the herbaceous vegetation that can sometimes completely cover the *Paulownia* seedlings.
In non-warming greenhouse and outdoors condition at 800 m elevation in Kastamonu, Turkey in 2002 were used one-year old seedlings, which were propagated from seeds of 16 origins of *P. tomentosa, P. elongata, P. fortunei and P. fortunei* x *tomentosa* obtained from China (Anonymous 1998) - there were large differences among the origins within the species for seedling height and root collar diameter. In this case, the early frost (-0.8 ºC) occurred at night of 2 nd November 2002 damaged to the top sprouts of all origins because the fast height growth do not give enough time to the lignification of a plant caused to severe early frost damages (Ayan et al 2005).

Figure 2. Successful 2 year *Paulownia* plantation at Jucu, Romania (photo Dinca L.)

Truffle plantations: the truffle plantation from Prejmer was realized on a proper field, pH between 6.9 and 7.7, soil rich in nitrogen (0.35-0.40%), of the gleysol type. On the other hand, the soil from Moldova Noua is not appropriate for realizing truffle plantations (Dincă M & Dincă L., 2015), having a too low pH (6.1). In order to remediate this lack, amendments with lime were applied, in accordance with the literature (Dincă L & Dincă M., 2014): a quantity of 0.3 kg/m^2 reaching a total of 400 kg for the entire surface. Each sapling was protected separately against rabbits, through cylinder fences. Both plantations have a good vegetation state (normal growths of seedlings, for example: a growth of saplings in the first year of 3.5 cm in height and 2.5 mm in diameter at Moldova Noua (Cântar et al., 2014) and were not affected by biotic or abiotic factors. Until now, there are not scientific confirmations for the presence of *Tuber melanosporum* in Romania, but we consider that the realized plantations can offer this type of mushrooms by taking into account the fact that it was located in the most favorable location for this species from a climatic viewpoint (an area with sub-Mediterranean climate, near the Danube, safe from lower temperatures or strong frosts).
In Sweden tree seedlings of *Quercus robur, Corylus avellana* and *Carpinus betulus* were inoculated with spores from *T. aestivum* fruit bodies to study the effects of pot substrate, tree species and time on *T. aestivum* mycorrhiza formation. Even if in Sweden is a shorter growing season, 6 years after planting, the first *T. aestivum* fruit body was found in a

Swedish truffle orchard (Weden et al.2009), while in France, fruit bodies of *T. aestivum* usually occure 5-10 years after plantation (Chevalier & Frochot, 1997a).

Figure 3. Seedlings inoculated with truffles used at Prejmer plantation in Romania (Photo Dinca L.)

Conclusions

Numerous *Paulownia* plantations were realized in Romania in the last years. The used clones were Cotevisa 2 and In Vitro 112, all of Spanish origin. These plantations have reduced surfaces (an average of 1-3 ha) and were realized either by the firms that traded the seedlings, either and most of all by the owners of the fields. If the planting area was appropriate (from a climatic and pedologic point of view) and the planting and maintenance techniques were rigorously applied, the results for these plantations (at 2-3 years from planting) are very good (Baraganu and Jucu surfaces). However, if the geographic range is not adequate with the species ecological requests, the results are mediocre and even completely unsatisfactory. This is the case of some areas from Arpas or Mihaesti, where early or late frosts have significantly affected the seedlings. In other situations, the causes of unsuccessful plantations are represented by not knowing and wrongly applying the plantation or maintenance techniques (for example: the excessive cutting of seedling roots from Hetiur, a too strong pruning from Cataloi, or not removing the weeds from Arpaș).

The irrigation of cultures, especially in the country’s more dry areas, is a mandatory condition for proper plantations (a good example in this case is represented by Jucu plantation). The plantation’s soils with a good or average result are of fluvisol, phaeozem or chernozem type, and present calcium carbonate at the surface, neutral pH or weakly alkaline, with an average texture and well supplied with nitrogen and humus. Truffle plantations can be successfully realized in Romania if all their requests are taken into consideration, especially in choosing the field (alkaline soils), together with their proper maintenance methods.

Abstract

Following the results of the last National Forest Inventory Serbia is a medium forested country with forest coverage of 29,1%. State owned forests cover an area of 53%, while private forests are represented with 47%. Private forests are characterized by small property size, high fragmentation, and high numbers of owners, but these forests are very important, because they have significant potentials in production of wood and non-wood forests products, carbon storage, and biodiversity protection. Utilization of private forests depends on reasons such as property size, fragmentation of the property, main purpose of forest use etc. Research that was done during the 2012, examined socioeconomic aspects and attitudes of private forest owners within the selected districts: Zlatiborski (Western Serbia) and Borski (Eastern Serbia). The main results of this research showed that in relation to property size, the average was determined as 4,12 ha per owner, where the biggest property size was 92 ha, while the smallest one was just 0,09 ha. Average number of parcels per owner was 3,91, and these properties were in 87,5% inherited, while only 2,5% of properties were bought by their owners. Concerning the utilization of forests, 86,5% of interviewees named firewood production for personal use as the main reason for utilization. The biggest problems during the forest management and utilisation were recognized as missing of appropriate equipment for utilisation, bad condition or shortfall of forest roads and complicated administrative procedures for timber production, transport and trade. Definition of issues and problems concerning private forests management could provide a solid base for defining a platform on national level, for better management and utilisation of private forests.

Keywords: *Private forests, Private forest owners, Utilization, Property rights, Serbia.*

Introduction

Serbia is according to the last National Forest Inventory (Banković, et al. 2009) a medium forested country with forest area of 2.254.000 hectares, which is coverage of 29,1%. State owned forests are slightly bigger category which covers an area of 53%, while privately owned forests covers 47% of forest area. According to the results of the research (Glück, et al., 2010) private forests in Serbia are characterized by small property size with only 4,1ha per owner and high fragmentation of properties. According to this research, estimated number of parcels in private forests is 3.900.000, while the number of owners is estimated to 900.000. Nevertheless, these forests have significant potentials in production of wood and non-wood forests products, biodiversity protection and climate change mitigation and adaptation. Another issue that is characteristic for private forests is that process of migration from countryside to big cities is present during the last 50 years and emerging of new categories of forest owners, so called "urban" owners (Schraml et al, 2004) that lives in big cities, and have their property at the rural area of the country. The start of implementation of Law on the restitution of property to Churches and Religious communities in 2006, bigger part of nationalized land is returned to Serbian Orthodox Church, and now Church is the biggest private forest owner in Serbia, and important player on the wood market. Process of restitution of forests and forest land to previous owners, is regulated by the Law on general restitution from 2011, and this process is still ongoing, so it can be expected that number of private forest owners will be increased (Petrović, 2012) because this Law predicts restitution of nationalized property through compensation in land or paying with Government bonds.Law on forests, as the main legal act for forestry sector, was in force from 1991 until 2010, and during 2010 new Law on forests was adopted. This law brought certain changes in rights and duties of private forest owners toward their forests, and prescribes some new features like private forest owners associations, subsidies for private forest owners, developing of Small and Medium Enterprises in forestry etc. This Law was amended in 2012 and 2015. Serbia is in the process of the EU accession and needs to harmonize national legislation with the EU and other international commitments. The legislation becomes more complex for the forestry sector, which is in close connection to the nature protection sector, having on mind that production in forestry demand long time period and needs to adjust itself to constant social, economic and environmental change. (Mitchell-Banks, P. et al., 2006) During the 2010 new Law on forests was proclaimed, and this law brought certain changes in defining of rights and duties of private forest owners toward their forests. It defines two types of ownership and predicts some new features like private forest owners associations. New Law on forests kept some provisions from the old Law (Law on forests, 1991) concerning private forests, including tree and timber marking, issuing of delivery notes, and payment for cuttings. Law from 2010 predicts subsidies for private forest owners, developing of small and medium enterprises for providing of technical support in private forests, establishment of new bodies (e.g. Council for forests) etc.

Material and Methods

Aim of this paper is to present an overview of the main socioeconomic characteristics of private forests and their owners in the selected districts, as well as legal prescriptions related to the utilization of these forests. Research is done in 2012. as part of the project "National inventory of private forests"[50], and for the purpose of this paper is are selected districts: Zlatiborski in Western Serbia and Borski in Eastern Serbia. Sample for the purpose of this paper was 807 private forest owners within two districts. For data collection is used semi structured interview which consists of four parts: 1) Introductory part, 2) General information, 3) Information on forests and 4) Institutional aspects. The introductory part contains general information on the questionnaire, such as: region, municipality, city, date, project name, name of the institution implementing the project, purpose of the questionnaire, the purpose of conducting the questionnaire and the part about the confidentiality of the information that will be collected. The first part of the questionnaire refers to the general data of the respondents. This section contains seven questions that are of an open type, closed type with one possible answer, or simple questions with sub-questions. The second part of the questionnaire refers to data on forest property. It contains fifteen questions and is characterized by a variety of question types. The third part of the questionnaire refers to institutional aspects and contains nine questions, where the most of the questions are closed questions with several possible answers. Apart from these, there are also closed questions with one possible answer and questions with the Likert scale. Mask for inputting survey data

[50] The Project "National inventory of private forests", 2012

in Excel was prepared. After entering data into the Excel database, the data are exported to the SPSS (Statistical Package for Social Sciences) software, where are calculated frequencies and correlations for specific variables.In addition to the data collected during the field work, for the preparation of this paper are used secondary data from the literature review of legal acts and scientific papers.

Results and Discussion

The main results of this research shows that forest owners are male in 78,8% of interviewees, while female forest owners are represented with 21,2%. This can be explained by historical and cultural heritage of Serbia, where male are represented as inheritors, while female inherits the property usually in case when there is no male inheritors. Average age of interviewees is 58,7 years, where the oldest interviewee is 91 years old, while the youngest is in the age of 19. The greatest number of interviewees (73,6%) have more than 50 years in age. In comparison to this, age in some countries of Europe varies considerably, so the oldest forest owners have Belgium, over 60 years old is more than 65%, and the youngest forest owners are in Poland with only 12% of forest owners over 60 years old (Schmithüsen and Hirsch, 2010). When observing the occupation of private forest owners within these districts more than one third of them or 32,0% is dealing with agricultural production, while pensioners are with 36,8% represented as the largest group of interviewees. Entrepreneurs, managers and students are represented with 6,5% in total, while public servants and physical workers are represented with 20,2%. Concerning property size, the average was determined as 4,12 ha per owner, which is close to the average of 4,1 ha gathered as the result of PRIFORT[51] project. The biggest property size is 92 ha, while the smallest one is just 0,09 ha. Average number of parcels per owner is 3,91, and these properties are in 87,5% inherited, while only 2,5% of properties is bought by their owners. Almost 10% of properties is combined as inherited and bought, while only 0,5% of interviewees doesn't know the origin of their property. Concerning the future of these properties, 93,8% of owners will give properties to their children. Only 1,2% of them will sell their property, while 2,9% doesn't know what will be the future of their property. According to the results of this research, the forest market in Serbia almost does not exist, and more than 90% of the respondents did not sell their forests nor do they want to do it, but mostly try to leave the forests to their children, which is identically to the situation on the national level (Petrović, 2012). When asked for the main purposes of their forest use (multiple answers was possible), 86,5% of them named firewood production for personal use as the main reason. 16,7% of interviewees use their forest for the production of saw logs for personal use, while 5,7% uses their forest for the production of saw logs and firewood (including charcoal) for further selling. Only 3,0% use their forests for nature conservation, tourism and grazing. As the biggest problem in management of private forests within these districts (multiple answers was possible) is recognised missing or bad condition of forest roads which is mentioned in 68,5% of cases. Based on the research (Avdibegović et al., 2010) the roads were recognized as the main reason for establishing of Private forest owners associations, in Bosnia and Herzegovina, Croatia, Macedonia and Serbia. Shortfall of appropriate equipment for the utilisation of private forest is recognised in 18,6% of cases, while 20,1% of interviewees considers the lack of State subsidies as the main problem in forest management. These three problems are directly connected with economic and financial situation of forest owners, because they don't have enough financial means to invest in new equipment, but use modified agricultural equipment. From the other side, entrepreneurs dealing with jobs in forestry have certain

[51] The Project "Research into the Organization of Private Forest Owners Interest Associations in the Western Balkan Region PRIFORT. 2007

equipment for the utilisation of forests, but costs of their maintenance are sometimes too expensive for owners. Complicated administration and shortfall of adequate professional help for forest management are recognised as the main problems in 33,6% of cases. Umbrella institution in charged for forestry sector in Serbia is Directorate for Forests, as integral part of the Ministry for Agriculture, Forestry and Water Management. State enterprises for forest management „Srbijašume“ and „Vojvodinašume“ provides technical support in management of private forests. When asked about institutional help in management of their forests, 42,6% of interviewees recognized forest extension service, as public body that should be in charged for this issue. 16,1% of interviewees stated that themselves are competent for managing of their forests, and there is no need for institution that would deal with private forest management. State forest enterprises are recognized as the most suitable in 28,4% of cases, while association of private forest owners are mentioned in 10,2%. Almost 10% of the interviewees stated that they don’t know which institution could help them in forest management. As the main legal prescription that burdens private forest owners in management of their forests is recognised issuing of cutting permit before felling, which is mentioned in 43,9% of cases. At the second place, with 38,7% is ranked an obligation of tree marking before felling, while paying a tax for felled wood is ranked as the third one with 32,0%. Issuing of permit for wood transport is represented with 23,4%. It is interesting to mention that 4,2% of interviewees mentioned that obligation of preparation of management plans burdens them in management of their forest, although according to the articles 30. and 70. of the Law on forests, for the preparation of management plan are in charged State enterprises for forest management or State enterprises of National parks, dependently where private forests are located. In the research from 2007, Boon and Meilby describes that in order to be effective, the policy instruments must motivate private forest owners to adapt their decisions/behavior to the objectives of the forestry policy (Boon &Meilby, 2007).

Table 1. Forest policy instruments that addresses different PFOs categories

Church forests recognized by Forest Law	**Owners of privatised forests recognized by Law**	**Physical persons**
Financial incentives available for this new category Regular income tax apply for forestry activities Management organization still in progress No advice or extension support Play potential role of the voice of private forests at national level	Financial incentives available for this new category Regular income tax apply Management organization still in progress No advice or extension support Play potential role of the voice of private forests at national level	Financial incentives available only for owners that have more than 100 ha Regular income tax apply Technical support from “exclusively” State Enterprises although forest act give freedom in case they are associated Extension and advisory service is missing Play potential role of the voice of private forests at national level No active PFOAs – no demand for change in policy.
Note: **For the owners of restituted forests** – process of general restitution is still ongoing		

*Source: Author’s elaboration based on the questionnaire survey results.

According to the ownership structure, owners of private forest can be divided in four categories: 1) Church, 2) Physical persons (owners close to the property and owners away from the property), 3) Owners of restituted forests and 4) Owners of privatised companies.Migration of inhabitants from rural to urban areas in last 50 years amounts around 40.000 people annually, which leads to the result that now in rural areas are predominant alder categories of population. Having on mind this fact, what should be taken into consideration is that now emerges new category of owners. Those are owners that live in the city, but own property which is more than 50km away from their place of living, and they have low interest in forest management, and if there is certain interest, utilization aspects of those owners are different.This type of forest owners is known as “Urban Forest Owner” that hasdifferentinterest in comparison to one that livesclose to forest. Forest policy should address specific forest policy instruments in order to secure sustainable forest management within this owner’s category.In addition to this, at the state level are implemented same policy instruments for owners close to forest and those away from forest. Nevertheless, establishing of Private forest owners associations (PFOAs) started in 2006, as a result of UN-FAO project, and until 2009 in Serbia has been established 20 associations (Nikolić, 2009). Nevertheless, today existsless than ten of them, but they implement only certain activities on a small scale.

Conclusions

Based on the presented results of the research it can be concluded that the main reasons for the utilisation of private forests are fuel wood and timber production for domestic use, as well as for sale. The biggest problems during the forest management and utilisation are recognized as missing of appropriate equipment for utilisation, bad condition or shortfall of forest roads and complicated administrative procedures for timber production, transport and trade. After defining the problems during the utilization of private forests, institutions that can provide professional help to private forest owners are recognized as Forest extension service, State enterprises for forest management and Directorate for forests. Legal preconditions that burdens private forest owners in utilisation of their forests are obligation of tree marking before felling, complicated administration and issuing of cutting permit. Definition of issues and problems concerning private forests management could provide a solid base for defining a platform on national level, for better management and utilisation of private forests.State is providing different support measures to private forest owners, such as financing, co-financing and subsidiaries for certain activities, and also consultation, education and technical support. Nevertheless, the condition of the private forests, problems in management and unused production potential require an organized and effective support from the State and active participation of forest owners in order to achieve ecologic, social and production functions of these forests with appreciation of sustainable and multifunctional management.

Recommendations

As a result of the research and overview of the condition of private forests and socio-economic characteristics of their owners are prepared the following recommendations. At the first place should be done land consolidation of forest properties, which can include purchase of forest land among forest owners, or among owners and State. Another recommendation is that condition of forest roads should be improved, and that beside of the maintenance of existing forest roads, new forest roads should be constructed.Issue that is actual at this moment is the utilisation of forest biomass, where the wood from private forests can take significant part in market supply. Of course, what should be considered is the establishment of new organizations of private forest owners, in forms of associations or cooperatives, as well as an umbrella association on national level. Of course, the State should formulate and implement new innovative approach for different PFO categories – as a good precondition for trade on wood market. One of the recommendations is that in close future should be established Forest extension service, as the unit that should provide advices and services to PFOs. Recommendation also connected to this issue is to simplify the administrative procedures which burdens PFOs in management of their forests. In addition, existing instruments of forest policy should be adjusted toward forest owners and their demands (especially for new categories of owners) by proper extensionservice and financial instruments. Having on mind that more than 75% of people have more than 50 years, instruments of the forestry policy should be directed to those owners, in terms that there is an option for small and medium enterprises to performs works on utilization for them, as contractor.

Abstract

The aim of this paper is to analyze the regulatory (strategic and legal) framework of the hunting sector in Serbia and the system of wildlife protection, as well as the stakeholders' attitudes towards it. Primary and secondary data were used for conducting such an analysis. Secondary data were collected from national strategic documents, laws and by-laws. Primary data were collected by using face-to-face and e-mail interviews, which were conducted with 13 professionals from public administration, services and organizations, responsible for hunting in Serbia. The results show that, although in Serbia there is no single strategic document in the hunting sector, a number of other sectoral strategies (forestry, agriculture, spatial planning, biodiversity, etc.) have an impact on it. Similarly, a number of laws are important for hunting issues in Serbia. In addition to being influenced by the Law on wildlife and hunting, the sector is affected by the legislation in the following fields: forestry, environmental protection and nature conservation, associations, weapons and ammunition, etc. The results of the analysis of the stakeholders' attitudes indicate the necessity of adopting a strategic document for the hunting sector. Most of them believe that the current legal framework is good and that it provides the framework for sustainable hunting management in Serbia. At the same time, they stress the need for certain amendments to the existing law and by-laws, so that implementation would be better. On average, the respondents see the current system of wildlife protection as "neither effective nor ineffective" (avg. grade 2.8). On the other hand, they believe that the current system of penalizing persons engaged in illegal hunting as "ineffective" (avg. grade 1.8). The explanations of such a low grade of system efficiency are: mild penalties, long court processes, and lack of a control system.

Key words: *hunting sector, stakeholders, regulatory framework, wildlife protection*

Introduction

Hunting in Serbia is a complex and legally regulated organized activity, which is classified into the subgroup of the field of forestry. Contemporary hunting is based on breeding, protection and sustainable use of "partially renewable" natural resources (wildlife populations), which are a common social good in Serbia. Hunting grounds and populations of autochthonous wildlife species (e.g. roe deer, wild boar, deer, hare, partridges, bear, wolf) are a highly valuable natural resource and significant economic, touristic, hunting and sports and recreational potential.

According to §3 of the Law on wildlife and hunting (2010/b), the protection of wildlife populations and their habitats is a matter of general interest and involves taking measures to ensure the conditions for the survival and development of the population of a particular wildlife species, as well as its protection against illegal use. The system of hunting fauna protection in Serbia is based on the adoption of basic planning documents (2010/b): the

Strategy of hunting development adopted by the Government for a period of 15 years, hunting plans adopted by users of hunting grounds for a period of 10 years, and the annual hunting management plan, which is adopted by hunting grounds users for each hunting year[52]. Other wildlife protection measures are: monitoring of wildlife populations and their habitats, support hunting grounds users, providing funding for the establishment and maintenance of the hunting information system (Hunting Cadastre and Central Database), research and development work, as well as supervision of work and enforcement of regulations in hunting (Danilović, Gačić, 2014, Gačić, 2016).

It is well known that "*hunting and game-preservation are interrelated: hunting must respect the intentions of game-preservation, and game-preservation must rely on hunting as one method to achieve its intentions*" (Hasenkamp, 1995). Effective application of hunting regulations is important for the protection of wildlife populations and their habitats, as indicated by the results of previous research (Gandiwa et al., 2013), which found that in cases where the application of the law is strict, the number of activities in illegal hunting is reduced. It was also noted that "*political instability and economic collapse do not necessarily lead to increased hunting in situations where policy instruments, such as law, are enforced*" (Gandiwa et al., 2013).

The preservation of wildlife and natural habitats is of great importance within the EU "*whose wildlife protection law and policy paternalistically impose a duty on EU Member States to conserve wildlife and impose criminal sanctions on those committing serious breaches of environmental law*" (Nurse, 2017). Today, wildlife protection and legislation in this area are accepted as problems that are resolved in the public interest. National game laws are often defined and interpreted in the context of prevailing social conditions (Nurse, 2017).

In those terms, **the aim** of the paper is to determine the content of the regulatory (strategic and legislative) framework of the hunting sector in Serbia, as well as the views of respondents on them and the system of protection of wildlife populations and their habitats. The **subject** of this research is the views of professionals on the above issue, while the **purpose** is to give recommendations for the improvement of the aforementioned framework and the system of protection.

Material and methods

In this research we applied a mix of the following methods: literature review, secondary data analyses and in-depth interviews. The sources of secondary data were national strategic documents, laws and by-laws. Primary data were collected using face-to-face and e-mail interviews, which were conducted with 13 professionals working in public administration, services and organizations, responsible for hunting in Serbia (Table 1).

Table 1. Number of interviewed experts per institution/organization

Institution / organization		**Number of respondents**
Public administration	Ministry of Agriculture and Environmental Protection-Directorate for Forests	3 currently employed experts and 2 formerly employed experts
Services	Institute for nature conservation	1 expert
Organizations	Hunting Association of Serbia	3 currently employed experts and 1 formerly employed expert
	Faculty of Forestry	1 expert
	Public enterprise for state forest management	1 currently employed expert and 1 formerly employed expert

The respondents were selected by using the judgmental sampling technique, because we focused on the attitudes of those individuals who possess knowledge and working experience related to the research problem.

[52] From 1st April of the current year to 31st March next year

The interviews were conducted during March 2017. The topics of these interviews covered five thematic segments: 1) strategic and legal framework, 2) institutional framework, 3) institutional and cross-sectoral cooperation, 4) support measures; 5) management and reintroduction of dear in Serbia. The questionnaire consisted of 21 questions, and in this paper, we analyzed answers to 6 of them (Table 3), in which we asked the interviewees about their opinion on the strategic and legal documents that provide frameworks for implementing hunting policy in Serbia (questions 1-4)[53], the current system of wildlife protection and penalizing persons engaged in illegal hunting, as well as the possibilities for improvement (questions 5 and 6)[54].

Data were analyzed using the qualitative content analysis (Kvale, Brinkmann, 2009). Descriptive statistics (arithmetic mean) was used for the analysis of data related to the respondents' evaluation of the current system of wildlife protection and penalizing persons caught illegal hunting.

Results and discussion

The structure of this chapter follows the order of questions, as they were given in the questionnaire and explained in the methods.

The respondents have similar attitudes towards the **strategic framework of hunting** (questions 1 and 2) in Serbia. In the first place, they emphasize (7 respondents) that there is no single strategic document, "*which would provide long-term guidelines*" (Int-5), i.e. which "*defines the directions for the development of hunting*" (Int-4) and "*goals and measures for achieving objectives in the function of Serbian hunting development* "(Int-1).

Table 2. Strategic documents that provide frameworks for implementing the hunting policy in Serbia.

Document title	Explanation
Strategy for forestry development	Initiates the adoption of the Strategy for hunting development Prescribes objectives and measures for sustainable wildlife management
National Sustainable Development Strategy	Defines the objectives of sustainable development of hunting
National Strategy for Sustainable Use of Natural Resources and Goods	Initiates the adoption of the Hunting Development Strategy, as well as the creation of "*legal, institutional and economic frameworks for implementing the Hunting Strategy*", with the "*institutional strengthening and building of existing research capacities in forestry and hunting*" (2012) Public enterprises for state forest management, Public enterprises national parks, Hunting Association of Serbia and Hunting associations are listed as responsible institutions for the implementation of the Strategy
Biodiversity Strategy	It is alleged that illegal hunting is one of the most significant factors for endangering biodiversity, but there are no defined objectives and measures related to hunting and wildlife
Spatial Plan of the Republic of Serbia 2010-2020	Initiates the adoption of the Hunting Development Strategy Zoning of the habitats of basic wildlife species and spatial-functional arrangement of hunting-breeding centers "*In the sector of hunting and fishing, the spatial plan is being implemented by creating planning documents [55]for the hunting area"* (2010 / c)

[53] Question1: Which strategic documents provide frameworks for implementing the hunting policy in Serbia? What is their application by your institution / organization?
Question 2: What is your opinion on the existing strategic frameworks of hunting in Serbia?
Question 2a: If you think that it is necessary to improve the strategic frameworks of hunting in Serbia, please explain why. How could this be done?
Question 3: Which legal documents regulate hunting issues in Serbia? What is their application by your institution / organization?
Question 4: What is your opinion on the existing legislative frameworks of hunting in Serbia?
Question 4a: If you think that it is necessary to improve the legislative frameworks of hunting in Serbia, please explain why. How could this be done?

[54] Question 5: Please evaluate (1-5) the current system of game conservation and punishment of persons caught in illegal hunting in Serbia. Please explain your attitude.
Question 6: If you believe that the current situation regarding the prevention or significant reduction of illegal hunting is not satisfactory, please explain how it could be improved. What measures do you propose?

[55] The Law on Wildlife and Hunting (2010/b) prescribes the Program of Hunting Area Development, which has not been adopted yet, and the division into hunting areas has not taken off. Currently, hunting grounds in the hunting area are managed on the basis of hunting grounds and annual management plans for each hunting year.

This indicates that the hunting policy in Serbia (Table 2) is currently "*defined through legislation and certain strategic documents as the basis for the development of the sector*" (Int-2). In addition, it is stated that "*the existing documents, which in part, establish a strategic framework for hunting, do not define the strategic requirements for further development precisely enough*" (Int-1). Also, 3 respondents believe that there is a lack of conformity among these documents, i.e. that "*there is a problem with the harmonization of the regulations in agriculture, hunting and forestry*" (Int-3). In addition to the above mentioned strategic documents, the hunting sector in Serbia is affected by numerous international conventions (Berne Convention, Bonn Convention, CITES Convention, Convention on Biological Diversity), which were ratified by Serbia. In previous research, it was emphasized that the effective implementation of adopted national strategic documents is an important measure for fostering the development of hunting (Gačić *et al.*, 2015).

All respondents (Table 3) agree that it is necessary to improve the strategic frameworks of hunting in Serbia (question 2a), and, first of all, adopt the Strategy of Hunting Development. In addition, the following is proposed:

harmonization of objectives and measures with international and EU regulations, in accordance with the obligations undertaken by the ratification of agreements "*dealing with the preservation and improvement of the environment, which directly or indirectly affect the development of hunting*" (Int-2);

intensification of cross-sectoral cooperation and harmonization of regulations in different sectors (Int-3, Int-9, Int-12);

involvement of all stakeholders in the development of strategic documents (Int-7, Int-11, Int-13).

Table 3. Matrix of topics

Respondent	Framework improvement		System		Q 6. Current state (prevention and significant reduction of illegal hunting): satisfactory or unsatisfactory

Regarding the **legislative framework for hunting** in Serbia (questions 3 and 4), the respondents explained that the Law on wildlife and hunting (2010/b) and the accompanying bylaws provide the framework for sustainable hunting management (Table 4).

Table 4. Legislative documents regulating hunting issues in Serbia.

Document title	Explanation
Law on Wildlife and Hunting	The basic law, which "*regulates the protection, management, hunting, use and improvement of wildlife populations in hunting grounds*; *Protection, conservation and improvement of wildlife habitats; Protection, management and maintenance of hunting areas and other issues of importance for wildlife and hunting*" (2010/b)
Law on Forests	Wild animals and other animals living in the forest are considered forest products. The number and species of wildlife must be maintained at a level that does not impair the biological balance of forest ecosystems and does not prevent the implementation of forest management objectives Necessary harmonization of planning documents of forestry and hunting Prohibition of breeding of large game in forests undergoing regeneration

	The Forest Council's activities include, inter alia, "*consideration of research programs, development plans and knowledge transfer in forestry and hunting, rural development and nature conservation and providing opinions on the proposed projects*" (2010/a)
Environmental Protection Law	Strategic Environmental Assessment is carried out for strategies, plans, programs and bases in the field of hunting Prohibition of harassment, abuse, harassment and destruction of wild fauna and destruction of habitats Restricting cross-border traffic of wild fauna (import, export, import, export, export) and their developmental forms and parts
Law on Nature Protection	The protection regime of the II degree of protection limits the construction of facilities for wildlife breeding, fishing, hunting, etc. Measures for the protection of strictly protected wildlife species Prohibited means of capturing and killing wild animals Reintroduction of wild species Breeding of highly protected and protected species of wildlife species Trade in strictly protected and protected wildlife species The jobs of guardians of protected areas (at the same time doing the jobs of hunting guards, only in protected areas smaller than 100 ha)
Law on Associations	Establishment and functioning of hunting associations
Law on Weapons and Ammunition	Procuring, holding, carrying, trade and transport of weapons and ammunition Defining the term "hunting weapons" and conditions for its carrying, storing, etc. Carrying, storing and use of official weapons

Source: Gačić *et al*., 2015 and supplements by the author

It is noticeable that the legislative framework of hunting in Serbia is complex, because it is affected by many other documents, for example, in the fields of nature conservation, environmental protection, forestry, etc. Hunting regulations are also complex in other European countries, and France can be taken as an example, including "*a tax on the individual hunter's harvest, a levy on hunting licenses, schemes for compensating landowners, and detailed administrative regulation of the number of animals bagged*" (Abildtrup, Jensen, 2014). However, the authors point out those even such complex regulations failed to provide the optimal size of large wildlife populations in France. Hunting revenues are often an important part of rural economy, which is an important reason for the views and interests of hunters to be taken into consideration when passing laws and other legal acts (Heberlein, Kuentzel, 2002, Sharp, Wollscheid, 2009, Wam et al., 2012). This approach is not a novelty, but it is also present in other sectors. Thus, the involvement of various stakeholders in political processes has become common in practice and is an integral part of all forestry policy processes (Nonić et al., 2014). All these processes should be followed by the appropriate level of partnership, transparency, education and public relations (Nonić, 2008).

Although 4 respondents consider that the legislative frameworks are good (Table 3), it was also pointed out that "*there are legislative solutions that can be reconsidered for a potential change*" (Int-1), especially since "*certain provisions of the Law on Wildlife and Hunting are not fully applicable*" (Int-4), or "*they are difficult to implement in practice*" (Int-8).

Eight respondents believe that the legislative framework of hunting needs to be improved (question 4a), in particular "*in terms of mutual alignment and in relation to contemporary needs and general social development*" (Int-2), but also with "*new regulations defining the rights and obligations of institutions and individuals existing in the hunting sector* (e.g. *the Law on Inspection Supervision, the Law on Public-Private Partnership and Concessions*)" (Int-1). They also suggest:

amendments to the penal provisions, which are "*poorly defined*" (Int-3);

that hunting planning should be better systematized;

amendments to some articles of the law, in order to enable reorganization of the professional hunting service, in the sense that they should be "*civil servants, and not employees of hunting associations*" (Int-3);

better definition of how to increase the number of wildlife populations and improve their structure.

The main problems in the hunting of Serbia are the non-compliance of the legislative framework, the lack of funding for the implementation of planned provisions, the lack of specific planning documents, the existence of many conflicts in forest management and hunting grounds, as well as negative impacts and consequences of the economic crisis (Danilović, Gačić, 2014).

On average, respondents consider the current **system** of protection of wildlife populations and their habitats (question 5, Table 3) "*neither efficient nor inefficient*" (average score 2.8). On the other hand, they consider that the system of punishing persons engaged in illegal hunting (question 5, Table 3) is "*inefficient*" (average grade 1.8), and they listed the following reasons for that:

the absence of a penal policy and a mild penalties: "*penalties are too mild*" (Int-12); "*these are mostly fines paid for charities*" (Int-5); "*inadequate penal policy*" (Int-2);

inadequate work of the judiciary: "*charges pressed by the competent authorities are most often subject to the statute of limitations*" (Int-12); "*trials last for a long time*" (Int-5); "*processes are delaye*d" (Int-13); "*courts are slow*" (Int-4); "*inconsistency in the processing of illegal hunting*" (Int-2);

poor control: "*a system of control is missing*" (Int-4); "*hunting guards have the status of state clerks, but limited power*" (Int-5).

In addition, one of the respondents believes that the inefficiency of the system partly stems from insufficient cooperation with the Ministry of interior, i.e., that "*hunting guards need police support, which is often not there*" (Int-5).

Previous research in Serbia found that, regardless of the changes in sector's regulations, the unfavourable situation regarding illegal hunting was not improved (Gačić et al., 2015). Similarly, illegal hunting is a serious problem worldwide and represents an important form of law violation, especially in rural areas (Eliason, 2003). However, in many countries, like in Serbia, competent institutions and organizations do not pay enough attention to these problems, because "*the activities are viewed as less serious, perhaps even trivial, when compared to other types of unlawful behaviour*". In this regard, there were situations in which "*many instances of wildlife law violation never come to the attention of law enforcement authorities*", and some estimates were that "*ratios of discovered offenses to actual offenses ranged from 1:83 to 1:30*" (Eliason, 2003).

The current situation regarding the **prevention or significant reduction** of illegal hunting (question 6, Table 3) is characterized as unsatisfactory by the majority of (i.e. 10) respondents. To this end, they propose certain measures for:

the improvement of cross-sectoral cooperation, especially with police and prosecutors;

strengthening the penal policy and its consistent approach

speeding up the process of court proceedings;

harmonization of existing legal regulations (Law on Weapons and Ammunition, Criminal Code and Law on Wildlife and Hunting);

a more frequent control of hunting associations and hunters;

defining the status of hunting guards and professional services and their relocation from the existing users of hunting grounds.

Conclusions

Based on the results obtained, it can be concluded that:

the hunting sector policy is defined by numerous documents, in the field of forestry, sustainable development and nature protection;

there is a complex legislative framework, which, in addition to the basic law, includes regulations in the field of forestry, nature conservation, environmental protection, etc.;

the system of protection of wildlife populations and their habitats, in the opinion of the respondents, is "*not efficient or inefficient*", while the system of punishing persons engaged in illegal hunting is considered "*inefficient*", which is explained by the following reasons: mild sentences, long judicial processes, the lack of a control system and insufficient cooperation with the police;

the respondents generally characterized the current situation regarding the prevention or significant reduction of illegal hunting as being unsatisfactory.

The basic recommendations for improving the strategic and legislative frameworks of the hunting sector in Serbia, as well as the system of protection of wildlife populations and their habitats are:

to develop and adopt a Strategy for hunting development, that is, a strategic framework that, based on previous results and reliable determination and analysis of the current state, should define the general and specific objectives of hunting development and management of wildlife populations and their habitats, as well as measures for their realization;

harmonization of the objectives and measures when adopting strategic documents in other sectors, which are directly or indirectly related to hunting;

amendments to the Law on Wildlife and Hunting (2010/b) and numerous accompanying regulations, primarily with regard to the supervision of the application of the law, as well as the penal provisions, including harmonization with the Criminal Code and the Law on Wildlife and Hunting;

establishment of a new (modern) system for the protection of wildlife populations and their habitats.

Acknowledgement

This study was conducted within the project: “Research of the causes and consequences of the disappearance of red deer in central Serbia, defining areas suitable for reintroduction (settlement) and measures for improving the reintroduction process - Phase I”, financed by the Ministry of Agriculture and Environmental Protection - Directorate for Forests of the Republic of Serbia.

Abstract

This paper presents the analysis of the institutional framework and measures for the improvement of the hunting sector in Serbia. In addition to that, the paper deals with cooperation and relations between institutions and organisations, in charge of several aspects of hunting in Serbia. For data collection, 13 face-to-face and e-mail interviews with hunting experts from public institutions (administration and services), and organizations (enterprises and associations) were conducted. The respondents' perception of the institutional framework of hunting, the current state of hunting grounds management, cooperation with other institutions and organizations and available measures for the improvement of the hunting sector were analyzed. Two respondents have a positive opinion about the work of public administration responsible for hunting. The largest number of them believes that the Forest Directorate lacks personnel and that improvements should be made in that direction. Only three respondents consider the current organization of hunting grounds management in public enterprises in Serbia satisfactory, while only one of them has the same opinion about hunting grounds management in hunting associations. The respondents have given the highest average grade to the cooperation with the Hunting Chamber of Serbia (4.4) and the lowest grade to the cooperation with the Hunting Association of Serbia (2.7). The majority of respondents notice the following obstacles to the improvement of the current state of hunting management: lack of funding, personnel structure, technical infrastructure and the system of organization. Around half of the respondents believe that an organized system of implementation of support measures for hunting development is present in Serbia. They explain that it is prescribed by the law (regulatory, financial, and informational measures). The other half of the respondents believes that Serbia is lacking such a system, because there is neither an overall hunting strategy nor an action plan. They stress that some measures exist (e.g. Budgetary Fund for Hunting Development, education organized by the Hunting Chamber), but also that these are not defined or implemented in a systematic way.

Key words*: hunting sector, institutions, organisations, cooperation, support measures*

Introduction

Hunting is a multifunctional phenomenon that greatly contributes to the development of rural areas and tourism, and there is a clear connection between hunting and spatial planning (Fischer et al., 2013, Gačić et al., 2015). Therefore, management and decision making in hunting often involve many stakeholders and users with different and sometimes even opposing attitudes and goals (Dandy et al., 2012). In that sense, complex institutional frameworks have been developed to meet such different objectives and interests, which stem from the multifunctionality of hunting (Fischer et al., 2013). It is precisely through the institutional frameworks that *"the implementation of national, regional and local politics is carried out"*, which has an impact on the development of the entire sector (2011). However, when it comes to the institutional framework, a *"wide range of organizations, incentives, mandate systems and regulations"* which *"affect the results of the sector"* should be taken into account (2005).

Hunting in Serbia has a long tradition and *"at the end of the 19th and the beginning of the 20th century it is described as unorganized, which inflicted damage both on game and the economy"* (2017). This was one of the reasons for the establishment of numerous hunting clubs and associations, which aimed to *"enable hunters to organize hunting and achieve one of the most important goals of modern hunting - sustainability of management"* (2017). In accordance with the current reform processes and the need to harmonize national legislation with EU regulations, the current Law on Wildlife and Hunting (2010) was adopted, which has led to changes in the organization of hunting in Serbia, such as, for example, the establishment of the Hunting Chamber, the obligation to adopt new planning documents (Hunting Development Strategy and the Hunting Area Development Program), to manage the Hunting Cadastre and the Central Database for all hunting grounds, and establish and maintain an information system on wildlife populations and their sites. However, the impact of the adopted laws and by-laws in the field of hunting, forestry, agriculture, nature protection and environmental protection will depend largely on their application, control of enforcement and possible amendments and harmonization (Danilović, Gačić, 2014).

The **aim** of this paper is to analyze institutional frameworks and measures for improving the state of hunting in Serbia, as well as cooperation between institutions and organizations responsible for different aspects of the hunting sector. The **subject** of this research are the views of hunting experts on this issue. The **purpose** is to provide recommendations for the improvement of institutional frameworks, measures and cooperation in the hunting sector, which would contribute to the creation of a consistent hunting and forest policy, and thus to the improvement of the management of the important national and "partly renewable" natural resources.

Material and method

In this research we followed the qualitative research approach, which is often used in studying certain hunting-related issues (e.g. Arroyo et al., 2012, Dandy et al., 2012, Veríssimo, Campbell, 2015).

For data collection, 13 face-to-face and e-mail interviews with hunting professionals from public institutions (administration and services), and organizations (enterprises and associations) were conducted. The respondents were selected by using the judgmental sampling technique because we focused on the attitudes of those individuals who possess the knowledge and working experience related to the research problem.

The interviews were conducted during March 2017 and the questionnaire covered five thematic segments. It consisted of 21 questions, and in this paper, we analyzed answers to nine of them. In these questions, we first asked interviewees to express their opinions about the institutional framework of the hunting sector and the need for its improvement, as well as their attitudes towards the current organization of hunting grounds management. The next set of questions was related to institutional and cross-sectoral cooperation and here we asked the respondents to explain the cooperation with several institutions and organizations in charge of forestry and to evaluate it. The last set of questions analyzed in this paper was related to the measures for the improvement of the hunting sector in Serbia. With the interviewees we discussed the sources of funding for the improvement of the hunting sector and the available measures. They also expressed the attitude towards the current system of measures and needs for its development and improvement.

The data were analyzed using the qualitative content analysis and matrix tables. Descriptive statistics was used for the analysis of data related to the respondent’s evaluation of the current systems of wildlife protection and of penalizing persons engaged in illegal hunting.

Results and discussion

Opinions of the respondents about the institutions and organizations responsible for national issues are different.

When it comes to the Forest Directorate (FD), as the state authority directly responsible for hunting, it was emphasized that this institution "*should be the major party in the coordination of hunting development*" (Int-11). However, respondents had different opinions about the work of the FD. Thus, two respondents consider that "*doing their job well*" (Int-4), that is, "*it is good that the FD has strengthened the capacities for performing hunting activities, first of all by establishing an organizational unit responsible for hunting*" (Int-1). Although they have a positive opinion on the work of the FD, these respondents also point out that the "*Inspection Service should have been strengthened*" (Int-4), that is, "*currently, there are not enough capacities to exercise control of the implementation of laws and by-laws regulating hunting*"(Int-1). Another 5 respondents believe that FD lacks staff engaged in hunting.

Regarding the work of the Hunting Association of Serbia (HAS), one respondent points out his positive opinion, stating that "*it is good that there is a unique HAS that respects the existence of regional hunting associations*", but also states that "*there is no clear HAS attitude regarding further development Hunting in Serbia, as well as the development of the Alliance itself*"(Int-1) Two respondents have a negative attitude towards the work of HAS, while others with a neutral attitude can be divided into two groups of respondents:

those who believe that HAS lacks professional staff (hunting experts);

those who believe that it is necessary to precisely define the function of HAS, and that this organization needs to be reorganized.

All respondents who answered the question regarding the improvement of the institutional framework of hunting (Table 1) consider that such a need exists, and suggested the following:

to provide capacities for a smooth operation of the FD (equipment, personnel, finance, etc.);

to improve the work of the FD in terms of better control over the implementation of regulations and the work of all its subjects.

The opinion of the respondents about the organization of hunting management in central Serbia varies and can be classified into (table 1): positive, neutral and negative opinions.

Table 1. Matrix of topics

Respondent	Improvement of the institutional framework		Is the organization of hunting grounds management satisfactory?		Existence of an organized system of the implementation of support measures for hunting improvement	Is there a system? Is it necessary for it to be improved?

Int-12	+	+	+/-	+/-	+	+
Int-13	+	+	-	-	-	

Legend: + advocates; − opponents; +/− indifferent; n.d. no data; idnk I do not know	

In the group that has a positive opinion on the organization of hunting management in public enterprises (PE), one of the respondents states that "*the situation is satisfactory, but with a lot of potential for further improvement*", that is, "*hunting is not on the list of priorities of PEs*" (Int-1). Another respondent believes that "*the organization has been improved: hunting services have been "lowered" to the level of forest estates. There is a sector as well as vertical jurisdiction and a hierarchy of responsibilities*" as well as "*within the forest estates, there are employees dealing exclusively with hunting (and fishing)*" (Int-5). On the other hand, respondents with a negative opinion (6 respondents) point out that *"there is a problem of recruiting inadequate staff*" (Int-9), and that "*there are laws and by-laws and everything works perfectly on paper, although it is different in operation*" (Int-11). Regarding the organization of hunting management in hunting associations (HA), one of the respondents states that the situation is satisfactory, but that there is room for improvements (Int-1). However, 7 respondents emphasize that the situation is "*partially satisfactory*" and that there are major differences between individual HAs, i.e., *"there are both very positive and unfortunately very negative cases*" (Int-4). All respondents believe that the organization of hunting management in Serbia can be improved through reorganization, with a clear definition of tasks and a strict application of regulations, i.e. "*a clear system establishment (defining roles and rules) and the prevention of interest grouping*" (Int-3), then by investing more funding in the development of hunting (Int-4) and better technical equipment (Int-7), as well as staff changes and education (Int-6). By all means, in order to ensure sustainable management of natural resources, there needs to be a systemic approach to identifying key issues and framework development, that will enable their unhindered solving, as well as to the process of planning and implementation and subsequent monitoring of the results (Nonić et al., 2014). Based on the views of the respondents, the main obstacles to the development of hunting are the following: financial resources (7 respondents), staff structure (11 respondents), poor technical equipment (for example, off-road vehicles) (8 respondents) and the organization system (9 respondents).

However, there is a contrary opinion, according to which (Int-1) "*there are no obstacles to the development of hunting because*:

adequate funding has been provided, both from the funds of the users of hunting grounds, and from the budget fund for the development of hunting;

formally educated staff are working in hunting grounds, with a compulsory annual training through the work of the Hunting Chamber;

the users of hunting grounds are equipped with vehicles and information technologies;

the organization of hunting is adapted to the current situation and is not imposed by any regulation".

It should be emphasized that public authorities, especially those responsible for forestry and nature protection, are not only in Serbia, but also in other countries responsible for adopting strategies that must be in line with public and private interests. This requires that decision-makers have information on the views of different stakeholders (Dandy et al., 2011), which points to the need for cross-sectoral cooperation, with the aim of sustainable management of hunting grounds.

Table 2 lists **institutions and organizations** that are directly or indirectly involved in the hunting sector of Serbia. In addition to that, the forms of cooperation with the institutions and organizations indicated by the respondents, as well as the average grades of the assessed success of cooperation are listed below.

Table 2. Institutional and cross-sectoral cooperation

Institutions and organizations	Form of cooperation	Average grade

		for cooperation success (1-5)*
Public administration		
Ministry of Agriculture and Environmental Protection		
Forest Directorate	Design and adoption of hunting plans Control of hunting ground users Allocation of funds from the budget fund for forests	4.2
Veterinary Directorate	FD cooperates with it when adopting regulations (harmonization) Meat trade and defining solutions for the export of game meat (especially small game)	3.9
Sector for Environmental Protection	FD cooperates with it when adopting regulations (harmonization) Issuance of the CITIES certificate	3.3
Ministry of Defence	Management of some hunting grounds Aid to users of hunting grounds in case of flooding, etc.	3.0
Ministry of Internal Affairs	- Aid to game wardens	3.7
Public prosecution		
	Reporting and processing of persons engaged in illegal hunting	4.0
Public services (professional institutions)		
Nature Conservation Institute of Serbia (NCIS)	FD cooperates with it in the production of professional documents Defining of conditions for the creation of planning documents and settling of game	3.9
PE for the management of state forests		
PE „Srbijašume“	FD gives consent on planning documents and controls the implementation of laws, while also providing support to the implementation of management measures	3.7
PEs of national parks		
PE NP Đerdap	FD gives consent on planning documents and controls the implementation of laws, while also providing support to the implementation of management measures NCIS cooperates with it in the creation of hunting plans	3.7
PE NP Tara	FD gives consent on planning documents and controls the implementation of laws, while also providing support to the implementation of management measures NCIS cooperates with it in the creation of hunting plans PE Srbijašume – Joint project for wild goat reintroduction	3.6
PE NP Kopaonik	FD gives consent on planning documents and controls the implementation of laws, while also providing support to the implementation of management measures NCIS cooperates with it in the creation of hunting plans	3.6
Educational and research organizations		
Faculty of Forestry	Scientific and research work	4.0
Faculty of Veterinary Medicine	PE Srbijašume: Creation of a study on the construction of facilities for meat storage	4.3
Hunting organizations		
Hunting Association of Serbia	FD controls and supports the implementation of management measures NCIS cooperates with it in the creation of hunting plans	2.7
Hunting Association of Central Serbia	FD controls and supports the implementation of management measures NCIS cooperates with it in the creation of hunting plans	3.2
Serbian Hunting Chamber	Education of the staff employed in the hunting sector Issuance of licenses	4.4
Other organizations		
Serbian Orthodox Church	HAS cooperates with the Serbian Orthodox Church in forest areas that were given back to the church in the process of restitution	4.0

**1 (very bad); 2 (bad); 3 (neither good nor bad); 4 (good); 5 (very good)*

The respondents <u>cooperate</u> with competent ministries, public services, state forest management enterprises and national parks, scientific and educational organizations and the Serbian Orthodox Church. The respondents gave the highest average grade (4.3) to cooperation with the Hunting Chamber, which educates hunting personnel and issues licenses, while the lowest rating (2.7) was given to the cooperation with the HAS. Cooperation between different stakeholders takes place in one of the following ways:
drafting and passing of regulations (FD and the Veterinary Directorate and the Sector for Environmental Protection);

drafting, defining of the conditions and giving consent to the planning documents (FD and the Institute for Nature Conservation of Serbia between each other and with the users of hunting grounds);
control of the implementation of laws (FD with the users of hunting grounds);
issues related to trade in meat and game trophies (Users of Hunting grounds with the Veterinary Directorate and the Sector for Environmental Protection);
aid to the users of hunting grounds in case of natural disasters (Users of hunting grounds with the Ministry of Defence);
issues related to illegal hunting (Hunting Area users with the Ministry of Internal Affairs and the Public Prosecutor's Office);
education and scientific research (and hunting personnel with the Faculty of Forestry, Veterinary Faculty and the Hunting Chamber).

Support measures provided to users can be grouped into: 1) regulatory, 2) economic, and 3) information measures (Janota, Broussard, 2008). Regulatory measures are prescribed by strategies, laws and bylaws, and provide a real and sound basis for the development of the sector. Economic measures are related to financial support, while information measures are necessary help from the state, and they are implemented through the activities of counseling, education and propaganda (Nonić, 2015). Respondents believe that all types of support measures are present in the hunting sector of Serbia, but that they are mostly regulatory and financial (only 3 respondents reported information measures). They listed the adoption of regulations and the control of implementation as regulatory measures, and as financial measures they listed the use of funds from the Budget Fund for Forests[56]. Information measures refer to the training organized by the Hunting Chamber.

Respondents have different opinions regarding the existence of an organized system for implementing measures for the promotion of hunting in Serbia (Table 1).

About half (7) of the respondents consider that such a system does not exist, for the following reasons: "*there is no strategic umbrella document that defines long-term goals*" (Int-5), that is, "*there is neither a strategy, nor an Action Plan*" (Int-6); "*laws and regulations are not enforced*" (Int-13); "*there is no continuous training of hunters, nor the financial resources provided at the annual level for each individual HA*" (Int-4).

In order for this system to be established, it is necessary to: *"adopt the strategy and define measures, objectives, etc."* (Int-5), as well as "*strict compliance with laws and procedures*" (Int-6).

The respondents who believe that there is an organized system for implementing measures for the development of hunting (6 respondents), explain that it is "*envisaged by the Law on game and hunting, because there is no adopted Strategy for Hunting Development*" (Int-1). In this regard, the respondents propose the adoption of a national strategy of the hunting sector as an improvement of this system, since "*the improvement of the general system of support for the development of hunting would be achieved by passing an umbrella strategic document that would define the directions of development in the hunting sector in Serbia with guidelines for its improvement*" (Int-2). They also believe that "*although there are clearly defined regulatory and financial measures that are prescribed and implemented by the FD*" (Int-3), it is necessary to "*create information measures that are currently lacking*" and, above all, "*deal with the development of a central database that is very important, for decision making, planning and everything else in hunting*" (Int-3).

[56] Funding is provided from the budgetary fund for the development of hunting of the Republic of Serbia and the budgetary fund for the development of hunting in the autonomous province (§78 of the Law on Wildlife and Hunting), which are "*financed from the revenues generated from the fee for the use of hunted protected game species and the hunting ticket*"(2010). In addition, the respondents indicated that HAs provide funding from membership fees, donations, issuing of facilities, local government assistance, etc.

Conclusions

Based on the results obtained in this study, it can be concluded that:
the institutional framework consists of public administration responsible for hunting, veterinary services, environment, defence and internal affairs, as well as professional services in nature protection, the court and the prosecutor's office, PEs in forestry and nature protection, as well as scientific and educational, hunting and other organizations;
Most respondents consider that the main obstacles to the development of hunting in Serbia are financial resources, personnel structure, poor technical equipment and the system of organization;
respondents are the most satisfied with their cooperation with the Hunting Chamber (average grade 4.3), and least satisfied with their cooperation with HAS (average grade 2.7);
financial resources for improving the state of hunting in Serbia are provided in several ways, but primarily from the budget fund for the development of hunting;
support measures are regulatory, economic and informational, and respondents have different opinions about the existence of an organized system of implementation of support measures.
The basic recommendations for the improvement of the institutional framework, measures and cooperation in the hunting sector are:
drafting and adoption of a Strategy for the Development of Hunting in Serbia, i.e. an umbrella strategic document that should define support measures and their implementation;
involvement of scientific-professional institutions and experts in the field of hunting in the process of drafting and passing of legislation.
improvement of the personnel capacities of the FD and the improvement of cooperation with the HAS;
more intensive and better education in the field of hunting with the protection of hunting fauna;
the formulation of information support measures, as well as the practical application of regulatory frameworks.
However, the improvement of the current situation must be based on an adequate combination of all hunting policy instruments (regulatory, economic and informational) resulting in the creation of a so-called "*smart-regulation*" approach.

Acknowledgement

This study was conducted within the project: “Research of the causes and consequences of the disappearance of deer game in central Serbia, defining areas suitable for reintroduction (settlement) and measures for improving the reintroduction process - Phase I”, financed by the Ministry of Agriculture and Environmental Protection - Directorate for Forests of the Republic of Serbia.

IMPACT OF THE FUNGAL PATHOGEN *ENTOMOPHAGA AULICAE* ON BROWNTAIL MOTH PARASITOIDS

Mara TABAKOVIĆ-TOŠIĆ*, Marija MILOSAVLJEVIĆ

Department of Forest Protection, Institute of Forestry Belgrade, Serbia
*Corresponding author: mara.tabakovic@gmail.com

Abstract

In the period 2015-2016, parasitoids of the order Diptera of the browntail moth *Euproctis chrysorrhoea*, some of the most economically harmful, outbreaking species of forest defoliators, were studied in 12 forest stands in the region of Novi Pazar (south-west Serbia), in which the browntail moth increased its numbers and where the entomopathogenic fungus *Entomophaga aulicae* was found. In the investigation period, 40 newly browntail moth litters were collected and analyzed. In the litters, there were 388 pupae, of which 23% were parasites from the order Diptera. Host mortality caused by parasitoids in different localities varied from 11.2% to 33.1%. A total of 89 Diptera pupae were reared from browntail moth pupae. Out of these, 83 died as pupae, resulting in an extremely high overall mortality of 93.2%. Only six tachinid adult specimens of 2 species (*Compsilura concinnata* and *Exorista larvarum*) emerged from tachinid pupae. In a detailed microscope survey, *E. aulicae* resting spores were observed on the surface of 72.8%, but not in internal tissues of the dead pupae. The lack of resting spores inside the dead Diptera pupae is an indication of the absence of direct effect of fungal pathogens on parasitoids. The Diptera evidently does not become infected by *E. aulicae* while parasitizing the infected host, but the presence of resting spores on the surface of Diptera puparia is the evidence of the development of the entomopathogenic fungus in parasitized browntail moth larvae and pupae. The causes of Diptera mortality during their development in host parasitized by *E. aulicae* have not been clear enough but it is likely a result of the competition between the fungus and parasitoids.

Key words: *Entomophaga aulicae, impact, browntail moth, parasitoids.*

Introduction

The browntail moth *Euproctis chrysorrhoea* (Linnaeus, 1758) (Lepidoptera: Erebidae), is one of the major serious defoliators of broadleaved forests and orchards throughout Europae. It is characterised by high reproductive capacity, considerable ecological plasticity and polyphagia (26 genera of trees and shrubs belonging to 13 different families). Browntail moth populations undergo periodic outbreaks to extremely high densities. Although it is found in many European countries, the pest causes the greatest damage to the forests of Balkan Peninsula, which have all the favourable environmental conditions for browntail moth development, and it often increases its number. In Serbia, it occurs periodically in high numbers (outbreak) on a relatively small area of a few hundred hectares.

The population density of *E. chrysorrhoea* is regulated by many biotic factors – parasitoids, predators and pathogens (microsporidial and fungal diseases), as well as intraspecific competition. Based on the literature data, more than 60 insect species of parasitoids have been reported in Europe as natural enemies of browntail moth. Regarding the number of the species, the representatives of Diptera and Hymenoptera orders are the most frequent and most important ones (Cerretti & Tschorsnig, 2010; Hubenov, 2008; Shima, 2006; Vaňhara et al., 2009).

The fungal order Entomophthorales in the class Entomophthoromycetes (Humber, 2012) is mainly composed of obligate pathogens that infect arthropods. More than 300 species within fam. Entomophthoraceae are well-known for their ability to cause dramatic epizootics in populations of aphids, leafhoppers and planthoppers, flies, grasshoppers, cicadas, and coleopteran and lepidopteran larvae (Georgiev et al., 2010; Hajek, 1999; Keller, 1987, Mirchev et al., 2013; Pilarska et al., 2001; Tabaković-Tošić et al., 2012; Tabaković-Tošić, 2014), and play an important role in regulation host populations under certain conditions.

Entomopathogenic fungus *Entomophaga aulicae* (Reichardt in Bail) Humber (Entomophthoromycotina: Entomophthorales, Entomophthoraceae) is a widespread Holarctic species, with many host insects from the order Lepidoptera [Arctiidae: *Spilosoma niveum* (Memetries); Geometridae: *Enypia griseata* (Grossbeck), *Lambdina fiscellaria* Guenée, *Lambdina fiscellaria lugubrosa* (Hulst), *Rheumaptera hastate* (Linnaeus); Lasiocampidae: *Dendrolimus spectabilis* (Butler), *Malacosoma disstria* Hübner; Erebidae: *Euproctis chrysorrhoea* (Linnaeus), *Orgyia vetusta* Boisduval, *Estigmene acrea* (Drury); Noctuidae: *Aedia leucomelas* (Linnaeus), *Autographa gamma* (Linnaeus), *Mamestra brassicae* (Linnaeus), *Pseudaletia* sp.; Notodontidae: *Heterocampa biundata* Walker, *Heterocampa guttivitta* (Walker), Pieridae: *Colias erate poliographus* Motschulsky; Saturniidae: *Dryocampa rubicunda* (Fabricius), Sphingidae: *Eumorpha fasciata* (Sulzer); Tortricidae: *Choristoneura fumiferana* (Clemens)] including some of the most economically harmful, outbreaking species of forest defoliators (*L. fiscellaria*, *L. fiscellaria lugubrosa*, *D. spectabilis*, *M. disstria*, *O. vetusta*, *H. guttivittata*, *C. fumiferana*, *E. chrysorrhoea*, *E. acrea*, *E. griseata*) (Hajek et al., 1991; Humber & Hansen, 2005).

In biological control programs it is important to evaluate impact on other biological agents of the target host. This is especially true for the parasitoids in the family Tachinidae, which are strongly associated with late instar browntail moth larvae and pupae, where *E. aulicae* also develops but insufficient information in entomological literature occurs.

Material and Methods

The studies were conducted during the growing season in the period 2015-2016, in 12 forest stands (Table 1) in the region of Novi Pazar (south-west Serbia: Public Enterprise Srbijašume, Forest Estate Šumarstvo Raška, Forest Administration Novi Pazar), in which the browntail moth increased its numbers and where the entomopathogenic fungus *E. aulicae* was found.

Figure 1. Browntail moth larval litter (A) and imago of tachinid on them (B).

In the investigation period, 40 newly litters (Figure 1) were collected, transported to the laboratory of Institute of Forestry (Belgrade) and then analysed. Individual Diptera and browntail moth dead pupae were placed in Petri dishes with wet filter paper (relative humidity of 75-80% was maintained in order to prevent drying of pupae). They were kept 7 days in the laboratory and then stored in the refrigerator for 3 months.

Microscopic examination of dead Diptera and *E. chrysorrhoea* pupae were carried out using a MOTIC optical Trinocular, model Sextuple BA410E, equipped with a camera MOTICAM 10.0 (10 Mpix, 12.5", CMOS, MOTIC), and for processing the measurements of *E. aulicae* hyphal bodies, primary conidia and resting spores the software Motic Images Plus 2.0 ML, gauging with the MT-40X was used.

The evaluation of *E. aulicae* infections was recorded as positive when fungal structures were detected in dead Diptera and browntail moth pupae. The species identification was based on the size, shape and structural characteristics of different microstructures of the fungus (Humber, 1984; Keller, 1987; Keller & Petrini, 2005).

Table 1. The main characteristics of the stands, where samplings of browntail moth caterpillars litters were done.

Results and discussion

Order Diptera occupies an important place among the parasitoids, not only by the richness of species and wide geographical distribution but also because they parasitize a large number of economically important insect pests. In 40 newly browntail moth litters, there were 388 pupae, of which 23% were parasites from the order Diptera. Host mortality caused by parasitoids in different localities varied from 11.2% to 33.1%. A total of 89 Diptera pupae were reared from browntail moth pupae. Out of these, 83 died as pupae, resulting in an extremely high overall mortality of 93.2%. Only six tachinid adult specimens of 2 species [*Compsilura concinnata* (Meigen) and *Exorista larvarum* Linnaeus] emerged from tachinid pupae.

In a detailed microscope survey, *E. aulicae* primary conidia and resting spores, which the morphological data [the mean dimensions of resting spores are 44.1 µm (33.7 – 49.7 µm; n=213)] (Figure 2) correspond to descriptions given by MacLeod & Müller-Kögler (1973), Hamm (1980), Pilarska et al. (2001), and Kalkar & Carner (2005), were observed on the surface of 72.8%, but not in internal tissues of the dead pupae. In addition, the presence of primary conidia of this pathogen species was reported, but the number of them was considerably smaller (Figure 2). The lack of resting spores inside the dead Diptera pupae is an indication of the absence of direct effect of fungal pathogens on parasitoids. The Diptera evidently does not become infected by *E. aulicae* while parasitizing the infected host, but the presence of resting spores on the surface of Diptera puparia is evidence of the development of the entomopathogenic fungus in parasitized browntail moth larvae.

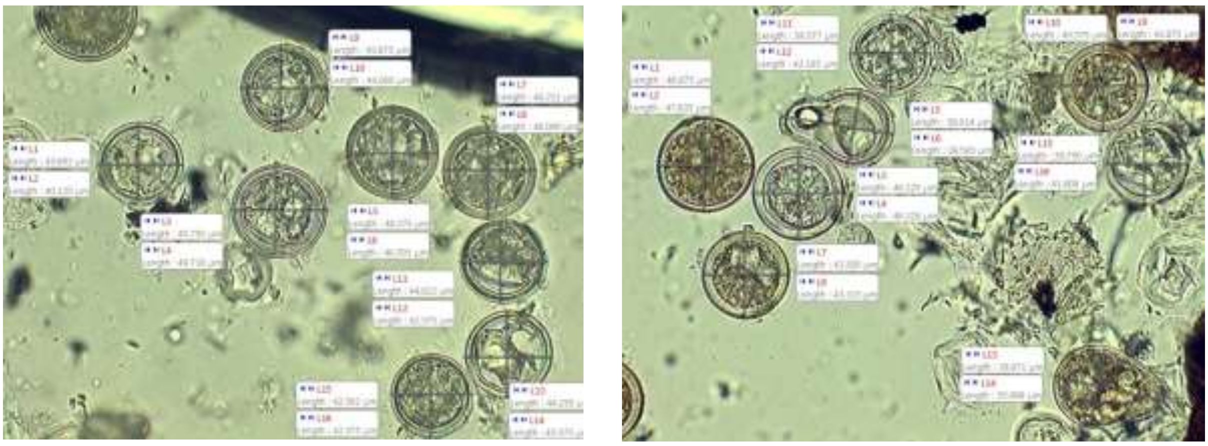

Figure 2**.** Resting spores and primary conidia isolated from dead Diptera pupae.

The causes of Diptera mortality during their development in browntail moth larvae which have been parasitized by *E. aulicae* are not clarified but it is likely a result of the competition between the fungus and parasitic Diptera. *E. aulicae* has become the primary biological control agent in browntail moth populations in Novi Pazar region, but its impact on other natural enemies of browntail moth is still not well known. Additional studies are needed to clarify the specific causes of mortality of Diptera parasitoids in order to obtain an objective assessment of the impact of *E. aulicae* on browntail moth and role of the pathogen in programs for biological control of the pest.

Conclusion

In this study which were conducted during the growing season in the period 2015-2016, in 12 forest stands in the region of Novi Pazar (south-west Serbia), higher mortality of Diptera pupae (93.2%) was established during their development in browntail moth larvae and pupae infected with *E. aulicae*, in comparison to a similar study in in Serbia and Bulgaria (Tabaković-Tošić et al, 2014; Georgiev et al., 2013) higher mortality of tachinid (Diptera) pupae (97.1% and 86.5%) were established during their development in gypsy moth larvae infected with *E. maimaiga*, hypothesized that, during fungal development, nutritional resources available to the parasitoids decrease, limiting available energy for successful pupation and eclosion.

Acknowledgment

The study was partly financed by the Ministry of Science of the Republic of Serbia, the Project 31070 - SUBPROJECT: New technological methods in the integral protection of forests with the focus on the entomopathogenic fungus *Entomophaga maimaiga*, as the possible solution to the problem regarding the frequent occurrences of the outbreak of gypsy moth in the forest ecosystems of Serbia.

Abstract

The Cornelian cherry is ornamental, low maintenance, drought-resistant species, which has the high potential for sustainable organic production as valuable fruit species. It can grow on shallow soils and on the different soil types, from sandy to clay soils, having good potential as a species for erosion control. In this study, the effect of cutting type and auxine concentration on rooting of softwood cuttings of cornelian cherry was investigated. Different types of cuttings were taken from selected mother trees in the urban forest in Belgrade area. Cuttings were treated with auxine (0.2% or 1.0% IBA, indole-3-butyric acid) before sticking and rooted under intermittent mist. The obtained data (the rooting percentage, the number and length of primary roots, the frequency and the number of secondary roots) were statistically analysed and the obtained results showed that cutting type, cutting size and auxine concentration influenced rooting of cuttings. Cutting length didn't affect rooting percentage but affected the number of primary roots and the longer cuttings had more primary roots Best results (more than 90% rooted cuttings) were achieved with terminal cuttings treated with 1% IBA.

Keywords*: Cornus mas, IBA, green cuttings, auxine, vegetative propagation.*

Introduction

The cornelian cherry (*Cornus mas* L., fam. *Cornaceae*) is a medium to large deciduous shrub or small tree, growing on warm and sunny forest margins, open forests, and coppices on dry and warm slopes, in altitudes of up to 1400 meters. It is native to Southern Europe and Southwest Asia. The Cornelian cherry is low maintenance, undemanding plant, which can grow on the different soil types, from sandy to clay soils, as well as on shallow soils. Also, it is drought-resistant species, suitable for hedges, anti-erosion protection and for planting in urban areas, tolerating high levels of air pollution (Mratinić, Kojić, 1998, Bijelić et al., 2012b, Dokupil, Řezniček, 2012). Furthermore, Cornelian cherry is important honey plant, which blooms early in the spring. Its fruit is red drupe, ripening from August to September. *C. mas* has high potential for organic production as valuable fruit species, having good yield potential even without special care (Demir, Kalyoncu, 2003, Cakmakci, Tosun, 2010, Bijelić et al., 2012b). Its wood is strong and extremely dense, and valuable in carpentry (Mratinić, Kojić, 1998).

The Cornelian cherry could be mass-propagated by seed or cuttings (Piotto, Di Noi, 2001). Generative propagation is complicated and time demanding due to long stratification period (18-36 weeks) and not very high germination rate (50-60%) (Piotto, Di Noi, 2001). The propagation by softwood cuttings is simple method which could be recommended for production of *C. mas* (Bijelić et al., 2012a, Klimenko, 2004, Korszun and Kolasinski, 2002, Marković et al., 2014a,b, Yalcinkaya et al., 1999).

C. mas is rarely grown species in the Belgrade area, and its planting should be promoted according to the principles of natural landscaping which promote the use of native plant species instead of neophytes as way of "creative conservation" of the wild, local genotypes (Marković, 2013). Therefore, possibility of propagation of local superior genotypes in Belgrade area was investigated in order to establish the method for obtaining high quality and well adapted planting material (Marković et al., 2014a,b). Previous research investigated the effect of application method and concentration of indole-3-butyric acid (IBA), the influence of cutting type (apical or single-node) and the influence of time of taking cuttings on rooting of softwood cuttings of selected *C. mas* trees from the Belgrade area (Marković et al., 2014a,b). However, some researchers report that cutting size have considerable influence on rooting and the futher survival of rooted cuttings (Beyl et al., 1995, Burgess et al., 1990, Gerrakakis and Özkaya, 2005, Gopale and Zunjarrao, 2011, Vigl and Rewald, 2014, Yang et al., 2015). Thus, the aim of this study was to investigate the influence of cutting size on rooting of selected *C. mas* trees.

Material and method

The group of *C. mas* vigorous and healthy trees in the natural population in Belgrade area (Miljakovacka forest) was selected. In July, from the selected trees, 2 groups of cutting were taken. The first group consisted of 4 types of cuttings: (1) terminal cuttings with current season's wood only, (2) terminal cuttings with a section of 2-year-old wood, (3) single-node cuttings with current season's wood only, (4) single-node cuttings with a section of 2-year-old wood, and the second group consisted of same types of cuttings as first one, but all cuttings were longer with one more node. The cuttings were treated by 0,15% dilution of fungicide Previcur and then their base was dipped in dust preparation of 0.2% or 1% IBA. In the control the auxine treatment was omitted. The rooting was performed in sand, under intermittent mist, in greenhouse of the Faculty of Forestry, Belgrade.

Rooting percentage and other parameters such as the number and length of primary roots, as well as the frequency and the number of secondary roots were determined 10 weeks after placing of cuttings. Eight explants were used per treatment with three replications. The significance of differences between the means was determined by the analysis of variance (ANOVA, $p < 0.05$) and the least significant difference (LSD) test. Before the analysis, arcsine transformation was used to convert the percentage data.

Results and discussion

After the removal from sand, the cuttings were classified into four categories: rooted cuttings, unrooted with callus, necrotic, unchanged cuttings. The obtained results varied depending on cutting type and IBA concentration (Table 1). However, IBA concentration strongly affected rooting rate, and the best results were achieved with cuttings treated with 1% IBA where rooting percentage was higher than 63%, in most cases ranging between 87% and 97% (Table 1). Cuttings treated with 0.2% IBA had lower rooting percentage, but the obtained results differed depending on cutting type, and the better results were achieved with terminal and nodal cuttings only with current season's wood than with cuttings containing a section of 2-year-old wood. However, in the control, the nodal cuttings with 2-year-old wood had highest rooting rate.

Table 1 State of cuttings ten weeks after sticking

Cutting type	Hormone	State of cuttings			
		rooted (%)	unchanged (%)	callusing (%)	necrotic (%)

Values followed by different letters are significantly different at the $P < 0.05$ level according to the LSD test

Nodal cuttings treated with 1% IBA formed the highest mean number of roots (9.6 - 14.3) (Table 2). Similarly, terminal cuttings with only current season's wood also formed high number of roots in 1% IBA treatment (9.6-10.6). However, the mean number of primary roots of all types of cutting was low in the 0.2% IBA treatment and control, and obtained values mostly varied between 2.3 and 6.7. The mean length of roots ranged between 17.0 mm and 57.7 mm, and the longest roots were developed from nodal cuttings in control treatment (38.3 - 57.7 mm) (Table 2). However, there was no statistically significant difference among mean length of roots developed from any of types of cuttings treated with 0.2% or 1% IBA (19.6 - 35.6 mm), with the exception of two-nodal cuttings treated with 0.2% IBA (46.2 mm).

Table 2 Number and lenght of primary roots

Cutting type	Hormone	Mean No. of roots	Mean length of roots (mm)
nodal cuttings	0.2% IBA	4.3a	20.1a
nodal cuttings + node		6.2abc	46.2cd

Values followed by different letters are significantly different at the $P < 0.05$ level according to the LSD test

The mean number of secondary roots was very variable, ranging from 1.3 to 26.3 (Table 3). Nevertheless, in the 1% IBA treatment it was quite low, not exceeding 7.3, without statistically significant difference among different cutting types. On the contrary, the best results were achieved in the control treatment where number of secondary roots developed from nodal cuttings ranged between 15.5 and 26.3, but two-nodal cutting had more secondary roots (22.7-26.3) than single node cuttings (15.5 - 17.0).

Table 3 Number of secondary roots

Cutting type	Hormone	Frequency * (%)	Mean No. of roots
nodal cuttings	0.2% IBA	33.3	3.3a
nodal cuttings + node		50.0	14.7c
nodal cuttings with 2-year-old wood		50.0	6.0ab
nodal cuttings with 2-year-old wood + node		0.0	-
terminal cuttings		57.1	11.5bc
terminal cuttings + node		55.0	7.0ab
terminal cuttings with 2-year-old wood		50.0	14.0bc

terminal cuttings with 2-year-old wood		100.0	6.0ab
terminal cuttings with 2-year-old wood + node		0.0	-

Values followed by different letters are significantly different at the $P < 0.05$ level according to the LSD test
*Frequency represent the percentage of rooted cuttings which have formed secondary roots

Results obtained in our research showed that the highest influence on rooting had IBA concentration, because rooting percentage and mean number of primary roots were noticeably high for all cutting types in 1% IBA treatment. Differences in rooting rate and mean number of primary roots for nodal and terminal cuttings were recorded, but in most cases they were not statistically significant. This is contrary to the results obtained during propagation of this species using cuttings taken earlier in June where cutting type strongly influenced rooting percentage, and the terminal cuttings with current season wood were rooted in higher percentage (96.7%) than terminal cuttings with 2-year-old wood (38.4%) or nodal cuttings (37.5 - 58.3%) in the 1% IBA treatment (Marković et al., 2014a). However, in presented research, in the 1% IBA treatment rooting rate was high for terminal as well as for nodal cuttings (88.0 - 95.8%) with the exception of the nodal cuttings with 2-year-old wood (63.1%) and the terminal cuttings with 2-year-old wood with node (70.8%).

Influence of hormone concentration and time of taking cuttings on rooting rate was previously described for Cornelian cherry (Bijelic at al., 2012a, Kosina and Baudyšová, 2011, Korszun and Kolasinski, 2002, Marković et al., 2014a,b, Pirlak, 2000), but optimal concentrations differed depending on author. On the other hand, in the mentioned researched different cutting types of *C. mas* were used, in some cases two-nodal green cuttings (Bijelic at al., 2012, Korszun and Kolasinski, 2002), but in some cases hardwood cuttings were used (Hassanpour and Ali Shiri, 2014, Pirlak, 2000). However, there were no investigations of influence of cutting size on rooting rate. In our research, length of cuttings influenced the rooting rate differently, depending on cutting type and hormone concentration. The most obvious difference was in 0.2% IBA treatment, where terminal cuttings with node was rooted in noticeably higher percentage (87.5%) than terminal cuttings with apical bud only (29.2%), but in the control this difference was smaller (37.8% and 12.5%), and finally in the 1% IBA treatment there were almost no difference (91.7% and 90.3%). Although some authors (Beyl et al., 1995, Burgess et al., 1990, Gopale and Zunjarrao, 2011, Vigl and Rewald, 2014, Yang et al., 2015) emphasize the importance of cutting size for the succesfull rooting and growth of some species, for some other species cutting length didn't affect their rooting percentage (Bona et al., 2012, Miller et al., 1982, Owuor et al., 2009), but affected the number of primary roots and the longer cuttings had more primary roots (Bona et al., 2012, Miller et al., 1982) which can be also observed in our research. Previous investigations also showed that cutting diameter have significant influence on rooting, more important than cutting length, probably due to higher carbohydrate reserves in cuttings with greater thickness relative to thinner cuttings (Beyl et al., 1995, Biondi et al., 2008, Zhang et al., 2010). However, in some cases rooting percentage could decrease with increasing cutting diameter (Howard and Ridout, 1991).

Conclusions

According to the results obtained in our research, it can be concluded that the selected elite trees can be propagated by soofwood cuttings treated with 1% IBA taken in July. For propagation, terminal as well as nodal nodal cuttings can be used. Rooting rate was not affected by a cutting size, but larger cuttings should be used in order to obtain better developed root system.

Abstract

The paper presents the characteristics of soil in the area of the right bank of the Sava River. The research was conducted in areas managed by Public Enterprise „Šume Republike Srpske“, forest economy „Gradiška“ (Republika Srpska, Bosnia and Herzegovina). In this area, two soil profiles were opened in central zone of bottomland. Studied soil is moistened by flood waters and ground waters which movement depends on the water level of the Sava River. In this area soil belongs to hydromorphic order, type of soil is alluvial semigley, and the morphology composition is: Aa-IGso-IIGso. These soils are neutral to slightly alkaline. Humus content ranges from 2.32 to 3.01%, which classified this soil in a soil group with moderate humus content. The humus surface horizon potential of 10 to 15 cm depth is textured according to the following composition: loam to clay loam soil, while in the deeper strata or subhorizons to 150 cm depth, the texture classes are: sandy loam, loam and clay loam. Such a mechanical composition results in a relatively favorable water-air properties which is complemented by moisturizing with the groundwater, and its periodically raising and decreasing below the height of the lower limit of the surface horizon. On the basis of examined characteristics of these soils, as well as their geographical distribution within the bottomland of the Sava River, it can be concluded that the soils have the potential for the cultivation of broadleaves from a complex of the alluvial hygrophile forests, or clonal mixture: euro-american poplar (*Populus x euramericana* x (Dode) Guinier), american black poplar (*Populus deltoides* W. Bartram ex Marshall) and white poplar (*Populus alba* L.).

Key words: *Hydromorphic soil, bottomland, populus, the Sava river.*

Introduction

Aluvial semigley, as a subtype of semigley soil, is formed in the central part of the bottomland on the alluvial deposits (Antić et al, 1965). According to the same authors this soil has isolated humus horizon with a tendency of deepening, under which there are situated homogeneous layers of alluvial material. According to Živanov and Ivanišević (1986) humus horizon of these soils, according to texture composition is sandy loam to loam, rarely clay loam, while deeper layers have sandy character. Also, same authors stated that significant areas of semiglay soils for poplar growing are located in the central part or on the contact of the central and coastal part of the river bottomland. Alluvial semigley soil according to the current classification of soils (Škorić et al, 1985) is denoted as fluvial meadow soil (humofluvisol) or according to the classification of global WRB Gleyic Phaeozem (Pachic, Siltic), IUSS Working Group WRB (2006). Natural habitat of poplars and willows are so called "swamp forests" in lowland terrain around rivers, and their characteristics have been mainly caused by the flooding of rivers according to Marković and Živanov (1986). On the alluvial semigley (meadow black soil on the alluvial deposits) morphology Aa or Amo-IGso-Gso ... Gr, natural poplar forests in the Sava alluvium (Forest Management Plan, ŠG Sremska

Mitrovica) can be found. By studying poplar plantations on the alluvial semigley of the River Sava in Srem, Andrašev et al. (2010), noted that clone I-214 showed a high potential for production according to the elements of the trees' growth, suggesting that on these soils can be achieved high-production effects by providing all the necessary technological measures. In support to the good potential of the studied area for the poplar cultivation, Keča (2014) stated that the length of the poplar production cycle on semigley in Ravni Srem, in the areas near the Sava River should be between 15-19 years. With regard to the properties of alluvial semigley for establishment of poplar plantation, this paper shows the characteristics of the soil and its potential for establishment of new poplar plantations in the bottomland of the Sava River, on the area of Forest unit "Gradiška", in the bottomland close to the River Sava upstream of the place Gradiška.

Material and methods

In the area of Public Enterprise "Šume Republike Srpske", in bottomland of the Sava River, was conducted study on soil in order to determine appropriate soil areas for the establishment of poplar clonal plantations. Two soil profiles were opened in the area of management units "Prosara" in forest unit "Gradiška" which is located west of the town Gradiška, in village Bistrica. During the examination of soil profiles was described external and internal morphology of both soil profiles that are located on the right bank of the Sava river at about 400 m distance from the river bed. On the field, soil samples were taken in the impaired state in order to determine the physical and chemical characteristics of soils in the laboratory of the Institute of Lowland Forestry and Environment. On taken soil samples following analysis were made:

-the particle size distribution was determined according the international B-pipet method with preparation in the sodium-pyrophospate,

-chemical reaction of soil, pH in water electrometrically with a glass electrode,

-content of humus in the soil after method of Tjurin, modificated according to Simakov,

-total nitrogen content according to the metod of Kjedahl.

-easily available phosphorus and potassium, according to the Al-method, Egner Riehm - Dominigo.

Figure 1 Types of soil profiles, and their distance from the Sava River

Results and discussion

According to shown granulometric composition of the analyzed soils (Table 1) in soil profile P1 may be seen that the surface horizon Aa (0-15 cm) is textural class clay with 55.0% of the total clay, and most powerful IGso (15-120 cm) layer / subhorizon has a heavier texture, i.e. clay loam, with 62.40% of the total clay, and the lowest layer / subhorizon IIGso with a depth beneath 120 cm has a lighter mechanical composition in comparison to previous two and the content of the total sand is 75.52% and the total clay 24.48% and its texture class is sandy loam. The analysis of particle size distribution of soil profile P2 (Table 1), showed that this soil has a heavier texture in comparison to the previous profile. Total content of clay is almost uniform through the entire profile depth, in Aa horizon (0-15cm) it amounts 64.76%, and in IGso (10-135 cm) layer / subhorizon the total content of clay was 66.28%, so the texture class of P2 soil profile to the depth of 135 cm is of heavier texture, i.e. the clay loam soil. At IIGso (135-150cm) layer / subhorizon the total content of clay is lower, i.e. 61.72% and at this depth prevalent texture class is loam.

Table 1 Granulometric composition of soil

Profil	Horizon	Depth (cm)	Coarse sand	Fine sand	Silt	Clay	Total sand	Total clay	Textural class
P1	Aa	0-15	16,53	28,47	32,64	22,36	45,00	55,00	loam

P1 Morphology: Aa-IGso-IIGso

P2 Morphology:Aa-IGso-IIGso

Figure 2 The internal morphology of soil profiles

Chemical properties of the investigated soils (Table 2), showed that these soils have a pH value in the range of 6.70 to 7.69, which indicates that the reaction of these soils is neutral to weakly alkaline. The analyzed soil humus content ranged from 2.32 to 3.01%, which classified these soils into a soils with moderate humus content, except for the value of 0.87% in IIGso horizon of profile P1, which is weakly humic. According to the content of nutrients in these soils, they are moderately supplied with total nitrogen, moderately supplied with easily available phosphorus and they contain easily available potassium in low to medium amount.

Table 2 Chemical properties of soil

Profil	Horizon	Depth (cm)	pH (in H_2O)	Humus (%)	Total N (%)	P_2O_5 mg/100g	K_2O mg/100g
P1	Aa	0-15	6,75	2,32	0,121	11,76	9,52
	IGso	15-120	7,41	2,77	0,138	13,08	10,63
	IIGso	120-150	7,69	0,87	0,048	6,28	4,95

P2	Aa	0-10	6,70	2,92	0,144	13,51	10,98
	IGso	10-135	6,92	3,01	0,148	13,78	11,21
	IIGso	135-150	7,29	2,72	0,137	12,96	10,53
Average		*0-150*	*6,97*	*2,89*	*0,143*	*13,41*	*10,91*

In analyzed soil profiles, humic horizon potency of 10 - 15 cm in depth is expressed more clearly, and it is more sharply separated from the rest of the soil profile. Accumulation of humus in this horizon is a consequence of the development of ground flora, as well as of retention of floodwaters of the Sava River in certain periods of the year, which is located at 400 to 500 meters from the profiles. Mentioned distance from the shore of the Sava River and mechanical composition of the soil indicate that studied soils are located in the central part of the bottomland, or on the crossing of the central and coastal parts. Surface horizon is rich in organic matter and it has grainy to fine grainy structure.

Lower layers/subhorizons of soil profiles, under the surface of horizon, are more homogenous and heavier texture, which is composed of a clay loam soil to a depth of 120, or 135 cm. Therefore such a particle size distribution results in a relatively favorable water-air properties, and moistening of such soils comes from flood and underground water, or from its periodical oscillation to the height of the lower limit of the surface horizon in both soil profiles. Based on the showed soils characteristics, it can be concluded that these soils fulfill ecological conditions for growing soft or hard wood trees from a complex of alluvial hygrophilous forests. Due to the texture class of clay loam, which prevails in depth in most parts of the profile, it is necessary after cleaning existing weeds or woody vegetation at the studied sites, to provide complete agro-technical measures, including plowing and disking of surface intended for planting, in order to improve the water-air properties of the soil and conditions for a better survival and growth of seedlings. It is also necessary, for the same reasons, in the next 3 to 4 years to provide the inter-row disking of areas under established poplar plantations. Based on the obtained results, studied site is recommended for planting of broadleaves, or clonal mixture: Euro-American poplar (*Populus x euramericana* (Dode) Guinier), American black poplar (*Populus deltoides* Marshall) and white poplar (*Populus alba* L.). Also, examined habitat can be used for planting of common oak (*Quercus robur* L.) and ash (*Fraxinus angustifolia* Vahl.).

Conclusion

This paper presents characteristics of the soil on the right bank of the Sava River in the area of forest unit “Gradiška” Public Enterprise “Šume Republike Srpske”, Bosnia and Herzegovina, in order to establish new plantations of broadleaves in this area. Analyzed soils are hydromorphic from the class of semiglay soils and are located in the central part of the bottomland classified as alluvial semigley. Moisturizing of the soil is caused by the flood and groundwater. Analyzed soil are characterized by heavier granulometric composition with texture classes from sandy loam, loam to the clay loam. These soils are moderately humic, neutral to slightly alkaline reactions. Studied soils have the potential for growing soft and hardwoods trees from the complex of the alluvial-hydrophilic forests. Since heavier granulometric composition is prevalent in most parts of the profile, it is necessary to apply complete agro-technical measures on the areas intended for planting, in order to additionally improve the water-air properties of soil and achieve favorable conditions for better survival and growth of newly established poplar plantations.

Abstract

The study tested the effect of salinity on growth and development of the shoots of five white poplar (*Populus alba* L.) genotypes in culture *in vitro*. After 35 days of cultivation following characters were measured: height of shoot, number of roots, length of the longest root, percentage of survival and rooting. The effect of six different concentrations of NaCl in the standard rooting medium (1 mM, 3 mM, 10 mM, 33 mM, 100 mM and 150 mM), and the standard rooting medium without salt (used as Control) were studied. The medium with 150 mM NaCl produced toxic effect, so these explants were excluded from further statistical analysis. The salinity tolerance of examined genotypes was evaluated by tolerance index by Turner and Marshal (TI), calculated for every examined character. According to analysis of variance, the main effect of medium was significant, but not the interaction genotype × medium for all of examined characters. Considering significant genotypes' differentiation and significantly lower tolerance indices compared to others on the most of characters, medium with 100 mM NaCl was proposed to be used for the evaluation of white poplar genotypes *in vitro*. The best tolerance achieved genotype L-80, which had the highest tolerance index for the length of the longest root. Results of this study suggest that *in vitro* culture could be usefully implemented in evaluation of salt tolerance of white poplar genotypes.

Keywords: *Populus alba, micropropagation, salt tolerance.*

Introduction

Soil salinity is abundant and ever growing problem on our planet. It is one of the major constraints to global food crop production, jeopardizing the capacity of agriculture to sustain the burgeoning human population increase (Flowers, 2004). It is estimated that 20% of all cultivated land and nearly half of irrigated land is salt-affected, greatly reducing yield well below the genetic potential (van Schilfgaarde, 1994; Munns, 2002; Flowers, 2004). Soil salinity is becoming a more acute problem, primarily because of declining irrigation water quality (Rhoades and Loveday, 1990; Ghassemi *et al.*, 1995; Flowers, 2004). Soil or water salinity is considered to be the major environmental factor limiting plant growth and productivity, especially in arid and semi-arid regions. Salinity has a two-fold effect on plants: the salt in the soil solution decreases the availability of water to the roots (osmotic stress), and the salt taken up by the plant can accumulate to toxic levels in certain tissues (ionic stress) (Munns *et al.*, 1995, Bottela *et al.*, 2005). Salt stress causes disruption of ionic equilibrium, inhibition of enzymatic activity, osmotic imbalance, membrane disorganization, inhibition of cell division and expansion, reduction in photosynthesis and production of reactive oxygen species (ROS) (Mahajan and Tuteja, 2005).

White poplar (*Populus alba* L.) is tree species widely spread throughout Europe, eastern Asia and northern Africa. However, in spite its high adaptability, it is considered as a threatened species and indicator of biodiversity (Kovacevic *et al.*, 2010b). There is also general interest in the utilization of white poplar in horticulture and landscape architecture (Eggens *et al.*, 1972). Along with "piramidal" or "fastigiata" tree shape and male sex, tolerance to the environmental stresses is desired feature. *In vitro* evaluation of abiotic stress tolerance of interesting genotypes, and of salt tolerance in particular, could be useful method, considering problems regarding the establishment of field trials with large long-lived tree species (Vuksanovic *et al.* 2017; Khattab and El-Garhy, 2016; Vuksanović *et al*., 2017). In addition, white poplar (*Populus alba* L.) is one of the most interesting model tree species in biotechnology, where the tissue culture is an important propagation technique (Confalonieri *et al.*, 2000).

The aim of this research is to assess the variability of morphometric parameters associated with salt tolerance in five white poplar genotypes *in vitro*.

Materials and methods

Plant material

Five white poplar (*Populus alba* L.) genotypes, interesting for wood production, horticulture and landscaping were examined: widespread Italian selection "Villafranca", and Serbian selections in experimental phase: L-12, L-80, LBM and LCM. Shoots of all five tested genotypes were multiplied by culture of axillary buds, as described by Ahuja (1984) and Kovacevic *et al.* (2010a). The cultures were sub-cultured at 4-week intervals and kept at 26±2 ºC, under a 16 h photoperiod (cool white fluorescent lamps, 3500 lx), till their use in the experiment.

Media preparation and experiment establishment

Mineral growing medium ACM (Aspen Culture Medium), described by Ahuja (1984), supplemented with $9gL^{-1}$ agar, $20gL^{-1}$ sucrose and with no growing hormones, was used in the experiment as rooting medium. The effect of six different concentrations of NaCl in the rooting medium (1 mM, 3 mM, 10 mM, 33 mM, 100 mM and 150 mM), and the rooting medium without salt (used as Control) were studied. Media were autoclaved at 120^oC for 25 min. Five shoot tips were cultured per 190 ml jar with 25 ml of rooting medium. There were five jars per examined medium within a genotype. The explants were cultured at temperature of 26±2 ºC, under a 16 h photoperiod (cool white fluorescent lamps, 3500 lx). After 35 days of cultivation following morphometric characters were measured: for every plant: shoot height, number of roots and length of the longest root, and for every jar: percentage of survival and percentage of rooting.

Statistical analysis

The salt tolerance of examined genotypes was evaluated by tolerance indices. The tolerance index (TI) was calculated according to Turner and Marshal (1972), as a ratio between the value of a parameter on the medium with a particular salt concentration ($X_{c(NaCl)}$) and the value obtained on the Control ($X_{Control}$): $TI = \frac{X_{c(NaCl)}}{X_{Control}}$.

Tolerance index was calculated for all examined characters at the level of jars. The obtained data were analyzed by two-way factorial analysis of variance and Fishers' Least Significant Difference test (LSD-test) with STATISTICA 12 (StatSoft Inc., 2013) statistical program.

Results and discussion

Salt at higher concentrations in apoplast generates primary and secondary effects that negatively affect plant's survival, growth and development. Primary effects are ionic toxicity and disequilibrium, and hyperosmolality (Jenks and Hasegawa, 2005). In concentrations higher than 0,4 M salt inhibit most enzymes because of disturbances to hydrophobic – electrostatic balance that is necessary to maintain the protein structure (Jones and Pollard, 1983). High concentrations of salt also impose hyperosmotic shock by lowering the water potential causing turgor reduction or loss that restricts cell expansion (Munns and Termaat, 1986; Hasegawa *et al.*, 2000; Zhu, 2002). Principal secondary effects of NaCl stress include disturbance of K^+ acquisition, membrane dysfunction, impairment of photosynthesis and other biochemical processes, generation of reactive oxygen species (ROS) and programmed cell death (Serrano et al., 1999; Hasegawa et al., 2000; Rodriguez-Navarro, 2000; Zhu, 2003). In our study, considerable cytotoxic effect, manifested in appearance of chlorosis and necrosis, as well as absence of root formation was found on medium with 150 mM NaCl. So, these explants were excluded from further statistical analysis (Figure 1).

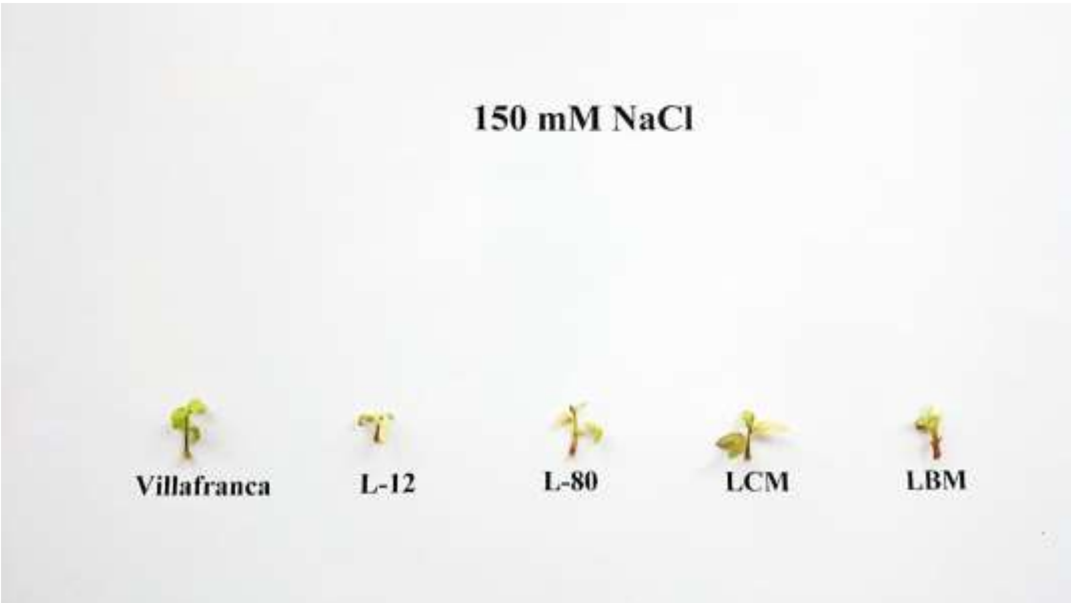

Figure 1. Rooted shoots of examined genotypes on medium with 150 mM NaCl

The results of analysis of variance of tolerance indices after 35 days of cultivation *in vitro* showed that in all tested morphological parameters the main effect of medium is not only statistically significant but also according to F-values, the strongest among examined controlled sources of variation. The main effect of tested genotypes is statistically significant, while the interaction of the genotype × medium, which describes differences in the response of the genotype to the investigated media, showed no statistically significant influence on tolerance index of any of the parameters tested (Table 1).

Table 1. The results of two-way factorial analysis of variance of tolerance indices of examined characteristics for examined white poplar genotypes and concentrations of salt [a)]

Character	Mean square			F-test		
	Genotype (A)	Medium (B)	Interaction A × B	Genotype (A)	Medium (B)	Interaction A × B
Shoot height (mm)	0,14	0,17	0,03	5,14** b)	39,18**	0,98
Root number	0,16	1,42	0,06	2,58**	22,59**	1,03
Length of the longest root (mm)	0,27	0,51	0,07	5,17**	9,83**	1,42
Percentage of survival	0,03	0,03	0,01	2,51	1,88*	0,85
Percentage of rooting	0,08	0,15	0,01	4,94**	9,24**	0,77

a) Degrees of freedom: for genotype was $DF_A = 4$, for medium $DF_B = 4$, for interaction genotype × medium $DF_{A\times B} = 16$, for error $DF_{ERR} = 100$ and for total $DF_T = 124$.
*b) Labels for F-test: * - significant at the level $\alpha_{0,05}$; ** - significant at the level $\alpha_{0,01}$*

The concentrations of the salt of 1 to 33 mM NaCl did not show a statistically significant effect on tolerance indices for examined characters in most cases, which proved to be in total, as well as between genotypes within this treatment. However, tolerance indices for examined characters on medium with salt concentration of 100 mM NaCl were in most cases significantly lower than on other media with lower salt concentrations. Also, the differences between genotypes were the most significant on medium with 100 mM NaCl, and that is why this medium was used for the evaluation of tolerance in the examined group of white poplar genotypes. It was clearly demonstrated by the response of tolerance indices for length of the longest root and shoot height. The best tolerance achieved genotype L-80, which had the highest tolerance index for the length of the longest root and rooting percentage (Table 2).

Table 2. LSD-test for tolerance index for measured morphological characters of examined white poplar genotypes a)

[a)] The differences among values of particular characteristic marked with the same letter are not significant at the level $\alpha_{0.05}$.

Reduced growth of tissues in stressful media is a usual phenomenon (Das *et al.*, 1990, 1992; Misra *et al.*, 1996) and it has been interpreted that a metabolism is channeled to resist the stress. *In vitro* evaluation (Khattab and El-Garhy, 2016) of salinity effects on male aspen clone W52 (*Populus tremula* L.) and the hybrid aspen clone T89 (*Populus tremula* L. × *Populus tremuloides* 'Michx') were investigated after seawater treatments (control, and 'concentrations' of 8,0, 12,0 and 14,0 dS/m). They found salinity level of 14,0 dS/m to be lethal, which closely corresponds with the effect of medium with 150 mM NaCl whose electrical conductivity was 17,04 dS/m. All the vegetative parameters of both *Populus* clones were significantly decreased at 12,0 dS/m, which is relatively close to the electrical conductivity of 11,40 dS/m in medium with 100 mM NaCl, which we used for the evaluation of examined genotypes.

Conclusions

After 35 days of cultivation *in vitro* the variation of all tested morphological parameters was found to be significantly influenced by the main effect of medium. According to the results of the LSD test there is a significant difference in the tested properties between examined media. Because of toxic effect of medium with 150 mM NaCl, and the fact that the best diferetniation of genotypes was achieved on medium in which the salt concentration was 100 mM, medium with 100 mM NaCl was used to compare examined genotypes. The best salt tolerance achieved genotype L-80, which had the highest tolerance index for the length of the longest root and for shoot height. The most negative effect on the shoot height on the medium with a concentration of 100 mM was observed in the genotype L-12. The medium with 150 mM NaCl produced toxic effect.

Abstract

The comparative morphometric analysis of 11 half-sib family of the sycamore maple showed variability of the seedlings within and between lines. The seed used for the analysis was collected from micro-populations on the territory of Belgrade (Serbia). The trial was established at the seedling nursery of the Institute of Forestry in Belgrade (Serbia). At the age of 30 days on a sample of 30 seedlings per the half-sib family following characteristics were measured: length of root as well as length of epicotyl, hypocotyl and cotyledon, cotyledon width, weight of seedling, root collar diameter and number of cotyledons. The obtained results contribute to acquiring knowledge on the analyzed characteristics, give a preliminary assessment of the genetic variability of the studied half-sib family and make a good basis for an adequate use of the genetic potential of the species.

Key words: *sycamore maple, seedling, half-sib family, variability.*

Introduction

The sycamore maple (*Acer pseudoplatanus* L.) is the most commonly found maple in Europe and an important species in its woods (Spiecker *et al.*, 2008) that has been presented on this continent since glacial (Svenning and Skov, 2004, 2005). The presence of the sycamore maple enhances the humus formation and the nutrient cycling (Wittich, 1961; Weber *et al.*, 1993; Heitz and Rehfuess, 1999). The preservation of the sycamore maple as a species can increase the ecological values of the habitat and the landscape diversity (Stern, 1989; Pommerening, 1997; Bell, 2008). The sycamore maple is mentioned in many studies as a species that is well adapted to the anticipated future climate conditions in Central Europe (Kölling and Zimmermann, 2007; Kölling, 2007).

Most researches on the sycamore maple have been performed in later stages of the development of an individual tree whereby the specificity and the variability of the juvenile and adult trees have been recorded (Bojović, 1989; Šijačić-Nikolić *et al.*, 2009; Ivetić and Tucović, 2003; Popović *et al.*, 2015). The morphology and the variability of the seedlings of the sycamore maple are very significant for better understanding of the variability and the taxonomy of the species, the seedling production and the breeding in the stand conditions. Having in mind the importance of the information gained in the earliest stages of the development of the seedlings, variability of eight morphometric characteristics of the seedlings of eleven half-sib family of the sycamore maple was analyzed in this paper.

Material and Method

The seed used for the analysis of the characteristics and the variability of the sycamore maple (*Acer pseudoplatanus* L.) seedlings was collected from micro-populations on the territory of Belgrade (Serbia). 11 mother trees were selected for the test trees using the individual selection on the field. The seed was collected from each tree with the aim to breed the half-sib family using the method for the genetic analysis of trees (Isajev and Mancic, 2001). The pre-sowing seed treatment included the stratification of the seed in the moist sand for 5 months at the temperature 3-5° C. The sowing was conducted in April 2012 at the seedling nursery of the Institute of Forestry in Belgrade (Serbia), in a hotbed size 1x10 meters. The space between rows in the hotbed is 15 cm, and the rows are parallel with the longer side of the hotbed.

The analysis of the morphometric characteristics and the variability within and between family of the seedlings was performed 30 days after sowing. In a sample of 30 seedlings from each half-sib family the following characteristics were measured: length of root as well as length of epicotyl, hypocotyl and cotyledon, cotyledon width, weight of seedling, root collar diameter and number of cotyledons. The descriptive statistics (boundary values, mean value, standard deviation and coefficient of variation) was performed for each characteristic. The variability between family of the seedlings, at the level of the analyzed characteristics, was determined by the one-way analysis of variance (ANOVA). The measured data are statistically processed by the software package Statistica 7 (StatSoft, Inc. 2004).

Results and Discussion

Several parameters of descriptive statistics for the examined morphometric characteristics of seedlings of 11 half-sib family of the sycamore maple are presented in Table 1. The analysis of seedlings characteristics is very significant for studying the variability in some species. By studying the morphometric characteristics of seedlings in the early stage of the development the differences that mostly are the consequence of the genetic variability can be detected. The studied morphometric characteristics of the seedlings can also be the basis for the assessment of the further development of the seedlings.

The most variable characteristic is the weight of the seedlings, and the lowest variability was recorded in the number of cotyledons (Table 1). The obtained data show the presence of the genetic variability between half-sib family.

Table 1:Variability of the morphometric characteristics of 11 half-sib family of the sycamore maple seedlings

10	2	3	2.03	0.18
11	2	3	2.03	0.00

Based on the obtained data (Table 1) the following can be concluded:

The root length ranges from 59to196 mm. The highest mean value of the root length has the half-sib line 1(124.17 mm) and the lowest the half-sib family 5 (100.87 mm);
The hypocotyl length in all 11 half-sib family ranges from 19to79 mm. The highest mean value of the hypocotyl length have the seedlings of the half-sib family 4 (59.77 mm) and the lowest the seedlings of the half-sib family 1 (37.73 mm);
The epicotyl length ranges from 11 to 81 mm. The highest mean value of the epicotyl length have the seedlings of the half-sib family 4 (56.57 mm) and the lowest the seedlings of the half-sib family 6 (28.07 mm);
The cotyledon length of the seedlings ranges from 31 to 61 mm. The highest mean value of the cotyledon length have the seedlings of the half-sib line 4 (48.7 mm)and the lowest the seedlings of the half-sib family 6 (35.8 mm);
The cotyledon width of the seedlings ranges from 5 to 14 mm. The highest mean value of the cotyledon width have the seedlings of the half-sib family 4 (10.07 mm) and the lowest the seedlings of the half-sib family 6 (7.13 mm);
The weight of the seedlings ranges from 0.39 to 2.25 g. The highest mean value of the weight have the seedlings of the half-sib family 4 (1.13 g) and the lowest the seedlings of the half-sib family 10 (0.79 g);
The root collar diameter of the seedlings ranges from 1.12 to 2.74 mm. The highest mean value of the root collar diameter have the seedlings of the half-sib family 7 (2.01 mm)and the lowest the seedlings of the half-sib family 6 (1.59 mm);
The number of cotyledons ranges from 2 to 3. The highest mean value of the number of cotyledons have the seedlings of the half-sib family 1, 2, 5 (2.07 pieces), and the lowest the seedlings of the half-sib family 3, 6, 7, 8, 9 (2 pieces).

Comparing the obtained data it can be concluded that the seedlings of the half-sib family 4 have the highest mean values for the most analyzed characteristics, while the seedlings of the half-sib family 6 have the lowest mean values.

For every studied characteristics the one-way analysis of variance (ANOVA) was performed to determine if there are statistically significant effect of differences between half-sib family on the total variation (Table 2). The results of the analysis of variance show that effect of differences between 11 half-sib family of the sycamore maple on total examined variation is statistically significant for all studied characteristics of the seedlings except for number of cotyledons.

For a long time there was a viewpoint that the parameters of the variability of the seedlings' characteristics are not very significant, so the characteristics of the seedlings were presented only at a typological basis (Anić, 1983). This viewpointis not accepted nowday.The variability of the seedlings is an adaptive characteristic and it is controlled by the natural selection because the genetic factors determine the extent and the direction of the permitted phenotypic plasticity (Tucović, 1990). The variability of the seedlings could be interpreted as a result of the interaction between genetic heritage and selection. Age changes throughout the life cycle are the result of two contradictory tendencies. One tendency is towards a higher differentiation from germination to maturity and the other is towards the adaptation in every stage of the life cycle. Determining what is a share of the heritage or the environment in a particular character is of a great importance in the field of production and cultivation of species (Tucović and Isajev, 2000.). The first, and often the strongest, selection takes place when the plant is in the germination phase. The larger dimensions of cotyledons, the characteristics of a hypocotyl or an epicotyl, the surplus of cotyledons, the features of the root system lead to the better characteristics of mature trees. Therefore studying of these seemingly minor qualities of the seedlings becomes increasingly significant (Tucović and Isajev, 2000.).

Conclusion

The comparative analysis of the morphometric characteristics of the seedlings was performed in order to determine the character of the genetic and morphological variability of the analyzed half-sib lines of the sycamore maple. Based on the comparative analysis of the 11 half-sib family the detailed data on morphology and variability of several characteristics of the seedlings have been presented. Based on the obtained statistical parameters it can be concluded that there is the genetic variability both within and between the analyzed half-sib lines. The analyzed characteristics of the seedlings are quantitative, controlled by many genes. The variability of the quantitative characteristics is continuous, and it is influences by the genetic and environmental factors and their interaction.

For the preservation and the direct use of the available gene pool of the studied mother trees of the sycamore maple it is necessary to know the genetic variability. The determined variability of the morphological characteristics of the seedlings can serve as an indicator of the further development of the seedlings of the selected half-sib family, which contributes to the improvement of seed and nursery production.

Abstract

The aim of this work was to study forest stand management of two oak species that inhabit the major surface in Galicia (northwestern Spain), Quercus robur L. and Quercus pyrenaica Willd. To achieve this goal, we have started with the characterization of the forest site occupied by natural forests of both species. Since some parameters have greater meaning than others regarding environment descriptors, we carried out a discriminant plot analysis for each species in order to identify parameters with greater descriptive weight, using the program Two-Way Indicator Species Analysis (TWINSPAN). This analysis is based on the estimate of 25 ecological parameters (i.e., topographical, climatic and edaphic) through sampling of 39 Quercus robur and 40 Q. pyrenaica plots. The results demonstrate that the distribution of oaks is related principally to the climate and the topography, and to a smaller extent to soil factors. Therefore, it is necessary to find out silvicultural treatment alternatives in order to obtain economic production that would be more profitable than the one being obtained now with traditional methods and inadequate forestry practices (pollarding and felling of the best trees). Some alternative methods could be the following ones: i) conversion to high forests, ii) maintenance of coppice forests in areas of certain quality and homogeneity where firewood is still used, iii) silvopastoral improvement in zones with grazing importance, and iv) restoration of degraded stands through reforestation with other native broadleaved species.

Key words: *Ecological factors, northwestern Spain, TWINSPAN, oak species*

Introduction

The *Quercus* species cover a great part of the temperate climax forests of the northern hemisphere as well as the subtropical transition area (Pulido, 2002). Over 400 oak species occur within these regions. The majority of oaks are found in Mexico, but also extend throughout North America, Europe, and Asia, excluding the southern hemisphere (Miller and Lamb, 1985; Rangel *et al*., 2002). In Galicia, the climax vegetation should consist of different oak species were part of deciduous forests of *Querco-Fagetea* class (Rivas-Martínez, 1987). From the phytosociological viewpoint, these forests correspond with the following associations (Rivas-Martínez, 1987; Izco *et al*., 1999; Rivas-Martínez *et al*., 2001): *Myrtillo-Quercetum roboris* P. Silva, Rozeira & Fontes 1950, *Rusco aculeati-Quercetum roboris* Br.-Bl., P. Silva & Rozeira 1956, *Blechno spicanti-Quercetum roboris* Tx. & Oberdofer 1958, *Linario triornithophorae-Quercetum pyrenaicae* Rivas-Martínez *et al*. 1984, *Holco mollis-Quercetum pyrenaicae* Br.-Bl., P. Silva & Rozeira 1956, and *Genisto falcatae-Quercetum pyrenaicae* Rivas-Martínez in Penas & Díaz 1985.

Within the Galician region, the natural distribution of *Quercus robur* L. and *Q. pyrenaica Willd.*, overlap with a wide range of transition (Diaz-Maroto *et al*., 2006) causing introgressive hybridization forming *Quercus x andegavensis* Hy (Amaral, 1990). The *carballeiras*, pure stands of *Quercus robur* or mixed with other deciduous trees occupy a

surface of 246,445 ha, 18% of the total woodland area of Galicia, while the *rebollares*, forests of *Quercus pyrenaica* occupy 76,571 ha, 6% of the total forest area (MAGRAMA, 2011). From the forestry standpoint, many of these oak forests have suffered abusive and inadequate silvicultural treatments such as selection felling of the best trees or pollarding which together with their breaking up for agricultural earth, the forest fires and the abandonment of its traditional use for firewood and vegetable coal, has driven the oak forests to its deteriorated present situation (McCreary, 2004; Diaz-Maroto *et al*., 2005). The largest stands of deciduous oaks are located in mild-slope zones where they have remained given that the topography limits the potential use (Ruiz de la Torre, 1991). Most of Galicia has an oceanic climate characterized by high rainfall, although towards the southeast the climate is Mediterranean (Carballeira *et al*., 1983). The substrates are of siliceous nature (i.e., granite and schist…), with deep soils, mostly cambisol and regosol (Carvalho *et al*., 2005).
We hypothesize that the distribution of the natural stands of *carballo* (*Quercus robur*) and *rebollo* (*Q. pyrenaica*) in Galicia depends mainly on the topography and the climate and to a lesser extent on the edaphic factors. The aim of our study was to analyze and to compare the distribution of the two species trees in relation to the ecological characteristics of the land.

Material and Methods

The area studied covers the "Comunidad Autónoma de Galicia" (NW Spain). We choose the sample areas and tried to select a number of representative oak stands based on the information of the "Mapa Forestal de España" (Ruiz de la Torre, 1991). In order to avoid edge effect worked with a minimum area between 0.5 and 1 ha (Hummel *et al*., 1959), and to select the suitable location of the plots inside each forest stand, the prevailing environmental conditions were analyzed by selecting the site of standard characteristics (Zhang *et al*., 2006). A network of rectangular sampling plots with 39 plots for *Quercus robur* and 40 for *Q. pyrenaica* was established. Plots were of variable dimension, depending on the number of trees, so that the inventory trees (Ø ≥ 5 cm) were not less than 50 (Hummel *et al*., 1959).
The topographical and edaphic information was collected and together with climatic data adapted to each point of sampling according to the methodology of Carballeira *et al*. (1983), allowed us to elaborate in each plot the characteristic parameters of its physiography, climate and edaphology. Twenty-five ecological parameters were recorded (four topographical, five climatic and sixteen edaphic) (Table 1). The parameters used to describe the physiography of each plot were (Diaz-Maroto *et al*., 2005; Diaz-Maroto *et al*., 2006): mean altitude, mean slope, soil depth to parent rock, and closest distance to the sea in a straight line. The climate was described using the following parameters (Retuerto and Carballeira, 1991): annual total precipitation, summer precipitation, mean annual temperature, and annual mean of absolute maximum and minimum temperatures. Finally, to evaluate the chemical properties and soil fertility, 16 edaphic parameters were analyzed (Rubio *et al*., 1997; Bravo-Oviedo and Montero, 2005; Diaz-Maroto and Vila-Lameiro, 2006): pH in H_2O, organic matter, nitrogen, carbon-nitrogen ratio, available phosphorus and exchangeable potassium, calcium and magnesium. For all of these parameters we determined both their total value, calculating the weighted-average of all the profile through Russell and Moore method (1968), and the surface one with the edaphic epipedon data (higher than 20 cm), except when there is more than one horizon in that deep, 20 cm, and in these cases it is necessary to calculate a weighted-average.
We used univariate analysis to determine which parameters influence distribution of stands (Walpole *et al*., 2002). Since some parameters have greater meaning regarding environment descriptors than others (Hix, 1988; ter Braak, 1994), we carried out a plot discriminant analysis for each species in order to identify the parameters with greater descriptive weight

for habitat, continuing the proposed methodology by Hill (1979) and using the program Two-Way Indicator Species Analysis (TWINSPAN) (Pisces Conservation LTD., 2004). Each parameter was divided into three intervals, establishing limits so that the number of plots included in each interval was approximately equal to a third of the total using the mean and standard deviation. With this division, we can include easily any other plot that we would like to analyze in any of the groups obtained in the classification (Martínez *et al*., 1992):

Lower interval < Mean of the parameter – Standard Deviation (< M – SD)
Medium interval Mean of the parameter ± Standard Deviation (> M – SD; < M + SD)
Upper Interval > Mean of the parameter + Standard Deviation (> M + SD)

Table 1. Parameters calculated in each plot

Number	Parameter (units)	Code
1	mean altitude (m)	ALT
2	mean slope (%)	SLP
3	soil depth to the parent rock (cm)	DPT
4	closest distance to the sea (Km)	DS
5	annual precipitation (mm)	AP
6	summer precipitation (mm)	SP
7	mean annual temperature (ºC)	MT
8	annual mean of absolute maximum temperatures (ºC)	AMT
9	annual mean of absolute minimum temperatures (ºC)	AmT
10	total pH in H_2O	PH
11	surface pH in H_2O	SPH
12	total organic matter (%)	OM
13	surface organic matter (%)	SOM
14	total nitrogen (%)	N
15	surface nitrogen (%)	SN
16	total C/N ratio	C/N
17	surface C/N ratio	SC/N
18	total available phosphorus (ppm)	P
19	surface available phosphorus (ppm)	SP
20	total exchangeable potassium (ppm)	K
21	surface exchangeable potassium (ppm)	SK
22	total exchangeable calcium (ppm)	Ca
23	surface exchangeable calcium (ppm)	SCa
24	total exchangeable magnesium (ppm)	Mg
25	surface exchangeable magnesium (ppm)	SMg

Results and Discussion

The information of the inventory allows an analysis of the distribution of the Galician oak forests depending on the site characteristics. Table 2 shows the descriptive statistic for the parameters for both species. In the case of *Quercus robur*, SLP, AmT, P, SP, Ca, SCa, Mg and SMg parameters have the highest variability with a coefficient of variation (CV) > 70%. The high CV (> 40%) of the annual mean of the absolute minimum temperatures (AmT) turns out to be especially significant as well as also of certain edaphic parameters. On the contrary, less variability parameters (CV < 30%) were: DPT, AP, MT, AMT, PH, SPH and SC/N. For *Quercus pyrenaica*, the climatic and topographical parameters with a higher irregularity, CV > 50%, were: SLP, DPT and AmT. On the other hand, AP, MT and AMT parameters present a CV < 20% (Table 2). There is also a great heterogeneity of several edaphic parameters; even more marked than in *Quercus robur*. The discriminant parameters obtained in the characterization of groups correspond in all the cases with the topographic parameters (ALT, SLP, DPT and DS) and the climatic parameters (AP, MT, AMT and AmT). For *Quercus pyrenaica*, the resultant classification has given rise to eleven groups, being corresponded the discriminant parameters with physiographic (ALT, DPT and DS), climatic (SP, AMT), and even edaphic variables (P).

The value obtained for the mean slope (SLP) indicates the present location of many Galician oak forests in marked slopes with a complicated topography due to the difficulty of the physiographic characteristic (Ruiz de la Torre, 1991). The high heterogeneity of the annual mean of absolute minimum temperatures (AmT) in *carballo* as well as in *rebollo* is due to the high existing thermal rank in the area of study as extensive as Galicia (NW Spain) (Retuerto and Carballeira, 1991), accentuated by the altitudinal variation existing among the plots of each one of the species, with extreme altitudes that differ more than 1000 m. The values of the remaining climatic parameters are quite homogeneous which indicates the existence of a humid oceanic climate with Mediterranean conditions in certain zones (Carballeira *et al*., 1983). The wide variety of lithologies, mainly siliceous, where *carballeiras* and *rebollares* are located, and give rise to acid soils with scarce variation of pH values (Table 2) (Diaz-Maroto and Vila-Lameiro, 2006). The difference in the behaviour of the parameter soil depth to the parent rock (DPT), among both species, is due to the fact that the soil where *Quercus robur* lives is quite deep; since it has a highly developed root system with strong roots that can penetrate the soil up to 1.5 m (Diaz-Maroto *et al*., 2005). Nevertheless, although the soils on which the *Q. pyrenaica* stands are establish are also, generally deep, they have shallow depths in certain plots where they have suffered repeated forest fires, but this does not represent a problem for its adequate development given the root system of this species (Carvalho *et al*., 2005; Diaz-Maroto *et al*., 2010).

The method used to analyze the distribution of the Galician oak forests proved to be adequate for the classification of areas occupied by different tree species (Hix, 1988; Kent and Coker, 1996). For example, Aude and Lawesson (1998) studied the vegetation of the Danish beech forests in relation to ecological factors and their management; Lawesson (2000) carried out an analysis of the vegetation of the native forests of Denmark, and Grabherr *et al*. (2003) in the Austrian forests. Also, recently Zhang *et al*. (2006) studied the relationships between environment and plant communities in North China.

In the two species tested, the majority of end groups belong to the fourth level of hierarchical classification and some of them on the third level, since the characteristics of certain groups of plots are not significant enough to belong to the fourth level of classification (Hill, 1979; Hill and Šmilauer, 2005). We have neither considered in any case a minimum number of plots by final groups of the classification, and no limit the maximum number of parameters. We have used all the calculated parameters, namely the 25 parameters of the described site, since we consider that none of them have a special characteristic in relation to the distribution the forests of *Quercus robur* and *Q. pyrenaica* in Galicia (Buide *et al*., 1998; Diaz-Maroto *et al*., 2005; Diaz-Maroto *et al*., 2006).

When determining the final groups of the TWINSPAN in the *Quercus robur* forests, only topographical (ALT, SLP, DPT and DS) and climatic (AP, MT, AMT and AmT) parameters were considered. Many of the stands are located in zones of complicated physiography with marked slope, although some of them are located in the bottom of valleys. They are located in low or average altitude areas and variable orientation with preference to shady places. On the other hand, the edaphic depth is high due to the presence of numerous areas in thalweg zones where depth, fresh, and loose soil are particularly appropriate for *Quercus robur* given their root system and strong main root that deeply penetrates the surface (Timbal and Aussenac, 1996). The values of the straight line distance to the sea parameter are between 1 and 135 km (Table 2), which coincides with the potential distribution of the vegetation in Galicia (Rivas-Martínez, 1987; Izco *et al*., 1999). Even so, some stands of *carballo* are found far away of their normal area of distribution, in these cases there may appear hybrids with other species of *Quercus* spp., such as *Quercus petraea* (Matts) Liebl. in Ancares and Invernadeiro plots and *Q. pyrenaica* in Valdín plot (Diaz-Maroto and Vila-Lameiro, 2007). These regions are found in higher altitudes and have high continental influences which are not optimum for the presence of *Quercus robur* (Diaz-Maroto et al., 2005).

As for the climatic characteristics, the majority of *Quercus robur* forests are located in zones with annual precipitation around or over 1000 mm and summer precipitation between 100 and 200 mm which indicates high environmental humidity requirements (Timbal and Aussenac, 1996). These show scarce amplitude in the values of the thermal parameters, except for the annual mean of absolute minimum temperatures, AmT, due to the fact, as we mentioned, that the inventoried stands are located inside a very extensive land, with great thermal amplitude even more marked given the high altitudinal rank (Retuerto and Carballeira, 1991). It is also important to emphasize that the existence of *carballeiras* in areas with scarce summer precipitation is a factor that does not favour the development of *Quercus robur* (Diaz-Maroto *et al*., 2005). Although in these areas, the shortage of precipitation in the summer months may be compensated by the effect of the maritime mists and fogs. They are stands located in the south of Galicia, mainly in the province of Ourense, where there is a climate with some Mediterranean trend (Carballeira *et al*., 1983).

The discriminant parameters of the eleven final groups obtained as a result of the application of the TWINSPAN to the forests of *rebollo* were: three physiographic parameters (ALT, DPT and DS), two climatic parameters (SP and AMT) and one edaphic parameter (P).

Similar to the *carballeiras* much of the sampled *rebollares* occupy zones of upper-middle slope conditions. The *rebollares* are also located in thalweg as a result of human pressure, mainly forest fires and use of firewood and vegetable coal (Carvalho *et al*., 2005). These forests are located at average and high altitude areas with variable orientation, but with preference to sunny orientation, especially in the northern part of the study area. However, toward the southern portion of their range they prefer the shady areas due to greater Mediterranean conditions (Carvalho *et al*., 2005). Although many stands lie on deep soils in the valley bottoms, others lie on areas with shallow soils along sharp slope zones where repeated fires have caused soil loss. *Quercus pyrenaica* adapts well to both situations due to its root system with a powerful main root that penetrates deeply and numerous superficial secondary roots (Carvalho *et al*., 2005). The DS parameter (distance to sea) covers between 29 and 144 km (Table 2), which again coincides with the potential distribution of the vegetation inside the area of study (Izco *et al*., 1999).

The annual precipitation varies between 748 and 1460 mm, with summer precipitation between 55 and 167 mm (Table 2), which indicates an environmental humidity requirement although to a lesser extent compared to *Quercus robur* (Carvalho *et al*., 2005). Regarding the thermal pattern, there is scarce amplitude of the values corresponding to climatic parameters except for the AmT as in the *carballeiras* (Diaz-Maroto et al., 2006). On one hand, it is important to stand out the existence of *rebollo* stands in relatively far away areas of its potential habitat, areas that present an oceanic hyperhumid climate less appropriate for the presence of *Quercus pyrenaica* and, on the other hand, zones with scarce summer precipitation and AMT > 25ºC, which emphasizes the fitoclimatic position, more Mediterranean of *Quercus pyrenaica* with respect to the European Atlantic oaks (pedunculate and sessile oaks) (Del Rio *et al*., 2005).

The mean value of the phosphorus macronutrient is lower than the one obtained in the *Quercus robur* forests, which is similar to the data obtained by other authors for this type of formations (Gallardo *et al*., 1995; Carvalho *et al*., 2005). This may indicate that the occupied zones by *rebollares* now have not suffered a change due to the soil use, (e.g., agriculture) (Diaz-Maroto *et al*. 2006). The rest of the macronutrients show higher values (Table 2).

The oak forests studied have a wide range of ages and site qualities as a consequence of the different anthropogenic uses and its current conservation status (Diaz-Maroto *et al*., 2005). The dominant type of oak stand in Galicia is the coppice forest which requires constant management, otherwise, the stands age, stop growing, and eventually disappear (Carvalho *et al*., 2005). The future of these forests depends on the problem both silvicultural and economic transformation (McCreary, 2004), and the present situation is characterized by: 1) Slow growth, scarce seeding, and unfavourable conditions for the development of the seedlings; 2) Risk of vegetation decline due to aging of the shoots, 3) Closed canopy with trees of small diameter, some of them top-dried and prevalence in the understory of heliophilous scrubs that gives rise to a high risk of forest fire. The morphological features and the mesophytic nature of *Quercus pyrenaica*, as well as its silvicultural characteristics ones give them a transitional meaning between the European oaks (*Quercus robur* and Q. *petraea*) and the Mediterranean species of *Quercus* genus (Amaral, 1990; Diaz-Maroto and Vila-Lameiro, 2007). As mentioned before, the natural stands of *carballo* and *rebollo* within the study area, represent a marked transition zone (Diaz-Maroto *et al*., 2006), which can influence on the recurrence of discriminant parameters obtained in the division of groups by the application of TWINSPAN. Within the topographical variables, the parameters ALT, DPT and DS, appear in both cases and, in the climatic variables, the annual average temperature of the absolute maximums is repeated (AMT). It is also striking that the annual precipitation (AP) is a discriminating parameter for *Quercus robur*, whereas for *Quercus pyrenaica*, is a summer precipitation (SP), although you might think that is logical given the sites of both species (Diaz-Maroto *et al*., 2005; 2006; 2010).

In the first case, the environmental humidity requirements turn out to be essential (Diaz-Maroto *et al*., 2005) and in the *rebollo* habitat, minimum value of summer precipitation is fundamental (Diaz-Maroto *et al*., 2006). For *Quercus pyrenaica*, the phosphorous presence as a classification parameter can be attributed to its greater concentration in the *carballo* soils, which indicates the existence of old fields in zones that were abandoned and colonized by this species (Diaz-Maroto and Vila-Lameiro, 2005). Summarizing, the environmental conditions do not preclude the application of an alternative forestry for more profitable results than with traditional methods and inadequate forestry practices used (pollarding and felling of the best trees). Regarding the final groups of TWINSPAN, there is not any pattern for the two species (Grabherr *et al*., 2003). In the *carballo* stands, the final group with greater number of plots corresponds to H with 9 plots, and the ones with smaller number correspond to F and K with a single plot. In the *rebollares*, the final groups V and VII have 6 plots and the groups III, VI, VIII and XI, 2 plots.

Conclusions

The discriminant analysis method has been proven effective to study the distribution of the sites occupied by *Quercus robur* and *Q. pyrenaica* in Galicia (northwestern Spain), obtaining a hierarchical classification of plots, through the Two-Way Indicator Species Analysis (TWINSPAN) application. We can say that the distribution of the oak forests within the study area depends on the physiographical and climatic characteristics rather than edaphic conditions. Therefore, the environmental conditions do not exclude the application of a different silviculture to obtain more profitable results than with the traditional methods, and inadequate forestry practices used (pollarding and felling of the best trees). As alternative methods such as the high forest conversion of the stands, the maintenance of the coppice forest in areas of certain quality and homogeneity where the firewood is still used, the silvopastoral improvement in zones with grazing importance and the restoration of very degraded stands through the reforestation with other native broadleaved species.

Abstract

This study contains evaluating runoff and physicochemical parameters data from some different tributaries of Oltu stream and it has been provided by interpreting Pearson correlation analysis. The watersheds dominated by Scots pine (Pinus sylvestris L.) In the data set used in the study, runoff (Q), water temperature (WT), pH, electric conductivity (EC), sodium (Na+), potassium (K+), calcium(Ca2+) and magnesium (Mg2+), carbonate (CO32-), bicarbonate(HCO3-), chloride (Cl-), sulfate (SO42-), sodium absorption factor (SAR), and boron (B) concentration results of measurements were present. Correlation analysis were explained to relations between hydrologic and physiochemical parameters. According to the results of the analysis, some strong negative relations between the runoff and some other parameters (electric conductivity, sodium, chloride, sulfate, sodium absorption factor, and boron concentration) were found. The runoff and salinity have been found as hydrochemical parameters working as the key consideration. The physicochemical characterization of Oltu stream might be strongly influenced by the soil-water interaction. Besides, the dilution effect was shown in Oltu stream which has characterized snowmelt-dominated stream.

Keywords: *Runoff and physicochemical parameters, Oltu stream, Dilution effect*

Introduction

Water quality of streams is mostly influenced by anthropogenic activities other than the physicochemical feature of the rain water which is affected by geologic and biotic conditions of the watershed (Lenat and Crawford, 1994). When water quality is measured from natural or nature-like watersheds where there is no or rare anthropogenic activity, the results are generally influenced either by geological structure and vegetation or their effects. For instance, the pH values of the water in river watersheds, which is composed of coniferous trees, are high because those trees' resin, tannin, etc. substances are washed or dissolved into the water. In the subject of this study, the watershed of Oltu stream, especially in the tributaries of the stream are included mature *Pinus sylvestris* L. stands. It has been observed that the land where *Pinus sylvestris* L. trees are located, the pH is much higher compared to other parts (Bergkvist and Folkeson, 1995). Accordingly, the soil acidity is observed to increase. In a study conducted in the same way, even though *Pinus sylvestris* L. stands increase the nitrogen portion of the soil, it is seen to have a diminishing influence on phosphorous (P), potassium (P), and calcium (Ca) concentrations (Prietzel et al., 2008). Oltu watershed has alkaline bedrock which is easily dissolved and is composed of limey groundling sandy and pebbly soil (Atalay, 1982). In this kind of soils, the rain water is easily mixed with subsurface water as infiltrate and feed the river or the stream. Accordingly, the stream's qualitative features are influenced by the physicochemical features of the vegetation and the soil because of dilution effect (Bis et al., 2000).

In order to identify the physicochemical features of Oltu stream which is the subject of the study, some research has been done in the past (Yıldırım, A., 1997; Yıldırım et al. 1999). However, none of these studies are done for the purpose of finding the physicochemical indicator parameter or parameters of the water.

Material and Methods

The research area has been conducted in some different sample points on Oltu stream which is on the borders of Oltu town in the city Erzurum. The sample points are operated by State Hydraulic Works. The subject data set of the study is composed of monthly data and this data set contains 2003-2008 years. The area of Oltu watershed is 3605.3 km^2. Dominating tree species in the region is *Pinus sylvestris* L. for many years, the semi-precious mineral known as Oltu Stone, which is formed by fossilization of Pinus sylvestris L. and other tree species, has been one of the sources of living. The regional soils are intrazonal soils with C horizon in which parent material easily dissolves and there cannot generally be covered to surface by soil (Atalay, 1982). The very alkaline soil material has appeared to the soil surface because of the erosion which is created by deterioration of the mature *Pinus sylvestris* L. in some parts of the forest and the area has high slope (Atalay et al.,1985).

Results and Discussion

The twelve streamwater quality parameters and runoff were used to evaluate the average monthly values of three different station and standard deviations in Oltu stream (Table 1).

The Table 1 was shown that the large differences were not generally showed during the twelve months, although the averages of WT and EC have a big difference according the monthly average values. The average runoff values have increased in the March and April, although the concentrations of chemical parameters have decreased in these months.

The decreases of chemical parameters may be exhibited dilution effect in streamwater. The maximum dilution effect was shown in sodium concentration. Increasing the flow especially in the months of March and April was shown to effect of snowmelt-dominated stream. Despite large differences in runoff regimes in monthly trends, pH had not affected this runoff behavior.

The correlation matrix of variables was produced by Pearson Correlation Analysis (Table 2). The correlation coefficients were calculated by among the water quality parameters that affected by temporal variations. In addition to this, the coefficient should be explained the relationship statistically significant and negative correlations can be calculated between pH, Ca^{2+}, Mg^{2+}, EC, Na^{+}, K^{+},HCO_3, Cl^{-}, SO_4^{2-}, SAR and B (r = 0.55 to 0.82).

Conclusions

The physicochemical characterization of Oltu stream might be strongly influenced by the soil-water interaction. Besides, the dilution effect was shown in Oltu stream which has characterized snowmelt-dominated stream (Table 1). Physical parameters (EC, WT and pH) has not influenced to the dilution effect of runoff. McNeil et al. (2005) emphasized in their study that the chemistry limits of the waters might be changed the geologic condition of the region. Determining the average pH value of Oltu stream water which has calcareous soil composed of alkaline bedrock as 8.5 constitutes the simplest example of this influence. Anderson et al. (1993) revealed in their study that when an acidic characteristics stream meets with a shunt coming from a calcareous region. The water turns into alkali character. The findings similar to our study have shown that bedrock may a very important factor on hydro-chemical features of the watershed. But, it is also true that the stream turns into an acidic structure when coniferous trees, resin, tannin etc. are dominant in a region because they hold acidic matters on themselves (Wiklander et al.. 1991). However, the findings of this study were observed to be similar with the findings of Anderson et al. (1993). Oltu stream which has a slightly acidic structure because of mature *Pinus sylvestris* L. located especially on upper zones of its watershed. In fact, the stream has an alkaline structure because of its dominant geologic conditions of watershed.

Abstract

Turkey has a wide genetic variation for almond species (*Prunus amygdalus* L.) in some of its regions due to open pollination (heterozygous) conditions and seed propagation since thousands of years. This study was conducted to almond genotypes grown in forest area of Hilvan district of Şanlıurfa province of Turkey between the years of 2011-2012. Because no studies have been made on almond genotypes in forest area of Hilvan (Sanliurfa) district by researchers up to now, the research in this natural habitat has a special importance with respect to promising almond genotypes. Therefore, the aim of the study was to select superior genotypes from native almonds populations grown from seed in this area. At the begining of the study, 152 genotypes were sampled from native populations according to some selection criterias. At the end of the study, 9 promising genotypes were selected using standard selection criterias for almonds. The first, full and last flowering dates of the almond genotypes were recorded as 9-10 March, 14-15 March and 19-20 March, respectively. The latest flowering date was observed in 63-HVO-32 numbered genotype. In the study, fruit weight with shell, kernel weight and shell thicknes of the promising genotypes were ranged from 2.29 (63-HVO-32) – 6.31 (63-HVO-25) g, 0.53 (63-HVO-65 and 63-HVO-103) - 1.04 (63-HVO-18) g and 2.63 (63-HVO-103) – 4.36 mm (63-HVO-25), respectively. In addition, double kernel and twin kernel ratios of the promising genotypes were determined as 0.00% in all surveyed genotypes.

Keywords: *Almond, Selection, Şanliurfa, Turkey.*

Introduction

Almond (*Prunus amygdalus* L.) is one of the most important and the largest productions of nuts in the world (Kester and Gradziel, 1991; Simsek and Kizmaz, 2017). In addition, it is one of the oldest crops used by humans but its enviromental requirements have restricted its commercial production to specific areas of the world (Kester and Asay, 1979; Simsek *et al.*, 2010). Turkey is one of the significant countries in the world in terms of almond production. Almond is grown in a lot of areas of Turkey (Dokuzoguz *et al.*, 1968; Gulcan *et al.*, 1989; Karadeniz and Erman, 1996; Aglar, 2005; Simsek and Kuden, 2007; Yildirim 2007; Simsek *et al.*, 2009; Sumbul, 2009; Simsek *et al.*, 2010; Simsek and Yilmaz, 2010; Simsek 2011; Kose, 2013; Gulsoy and Balta, 2014). Turkey ranks sixth in the world, producing 73.230 tons of almond (FAO, 2014).

Almond spesies is one of the most investigated fruit species in selection studies in Turkey. The richness of Turkey on genetic variation of this species has provided facility for achievement in breeding studies in a short period of time. Because almond tree is cultivated in many regions of Turkey, it is very important to develop varieties suitable to a certain area. Therefore, several superior almond genotypes such as Gülcan I and Dokuzoğuz-II were

obtained during the selection studies performed in different areas of our country and were registered as cultivars (Gülsoy *et al.,* 2016; Anonim, 2017).
With hard climatic conditions, Southeast Anatolia Region of Turkey has mostly seedling almond genotypes and cultivars. Most of the almond trees grown in the region were grown with seed and generally grown in sides of fields and polyculture with the fruit species such as pistachio, olive, figs, walnut and some other fruit species (Simsek and Demirkiran, 2010). Monoculture almond orchards have been established for 15-20 years.
Existing almond types and cultivars differ widely from each other in many characteristics, especially flowering time, yield, quality of nuts and tree vigour. This variability has provided an invaluable material for almond selection. Many researchers have executed almond selection studies in most parts of Turkey (Dokuzoguz and Gulcan, 1979; Cangi and Sen, 1991; Simsek, 1996; Gercekcioglu and Gunes, 1999; Simsek and Kuden, 2007; Simsek, 2008; Simsek *et al.,* 2010; Simsek and Yilmaz, 2010; Simsek 2011). However, the forest area of Hilvan (Şanlıurfa) district of Southeast Anatolia Region is an exception. There was no selection study executed in this site, which makes the present study is original. Late flowering, high yield and quality-almond genotypes were selected in this research. In followup studies, these genotypes should be tested regarding adaptability in the same ecological conditions with standard almond cultivars in order to obtain the best almond genotypes and cultivars to contribute to the national economy.

Materials and methods

This study was conducted in forest area of Hilvan district of Şanlıurfa province in Southeast Anatolia Region of Turkey between the years of 2011-2012. Selected almond genotypes was compared according to weighted-ranked method to Gulcan et al. (1989), Gulcan (1985), Gulcan *et al.* (1989), Simsek *et al.* (2010), Simsek and Yilmaz (2010), and Simsek (2011). In this context, firstly, natural almond populations of forest area of Hilvan district were surveyed and 152 genotypes which had late flowering according to the other almond genotypes were labelled and evaluated for breeding objectives. Later, 30 fruits were randomly taken from each of the almond trees in summer season. In the second year, late flowering 90 out of 152 previously selected almond genotypes and 30 fruits were randomly taken again from each of the almond trees in summer season. Finally, 9 promising genotypes were selected according to this method. Flowering and pomological characteristics of the selected almond genotypes were made according to Godini et al. (1977), Gulcan *et al.* (1989), Simsek *et al.* (2010), Simsek and Yilmaz (2010), Simsek (2011) and Gulcan (1985), respectively. Altitudes and coordinates were measured with GPS tool. The beginning of flowering in various almond genotypes delay one day at each 35 m in altitude (Ozbek, 1977; Gulcan *et al.,* 1989; Simsek *et al.,* 2010; Simsek and Yilmaz 2010; Simsek 2011). The fruit weight with shell and kernel weight were measured with a scale sensitive to 0.01 g. In addition, the fruit length with shell, fruit width with shell, kernel length and kernel width were measured with a digital compass (Gulcan *et al.*, 1989; Simsek *et al.*, 2010; Simsek and Yilmaz, 2010; Simsek, 2011).

Results and discussion

Almond is the earliest flowering species among the temperate climate fruits. For this reason, this species can be affected by late spring frosts. First flowering dates started between 09 March in 7 genotypes (63-HVO-7, 63-HVO-18, 63-HVO-65, 63-HVO-74, 63-HVO-75, 63-HVO-103 and 63-HVO-150)-10 March in 2 genotypes (63-HVO-25 and 63-HVO-32) (Table 1). Full flowering dates started between 14 March in 5 genotypes (63-HVO-7, 63-HVO-18, 63-HVO-65, 63-HVO-74, 63-HVO-75 and 63-HVO-103)-15 March in 3 genotypes (63-HVO-

25, 63-HVO-32 and 63-HVO-150) (Table 1). Last flowering dates started between 19 March in 8 genotypes (63-HVO-7, 63-HVO-18, 63-HVO-25, 63-HVO-65, 63-HVO-74, 63-HVO-75, 63-HVO-103 and 63-HVO-150)-20 March in 1 genotypes (63-HVO-32) (Table 1). It was determined that flowering period of the selected almond genotypes lasted to be 11-12 days. Kuden *et al.* (2001) determined that flowering occurred to be 25th February - 26th March in 1999 and 10th March -24th March in 2000. Simsek (2011) observed as from 1 March to 11-12 March for flowering dates of the promising almond genotypes in Cinar District of Diyarbkir province. Simsek and Osmanoglu (2010) observed as from 26 february-2 March of first flowering, 2-7 March of full flowering and 7-10 March of last flowering of superior almond genotypes in Derik (Mardin) district. Simsek *et al.* (2010) observed as from 8-15 March of first flowering, 12-19 March of full flowering and 15-24 March of last flowering of superior almond genotypes in Kocaköy and Hani Counties of Diyarbakir province.

One of the most important selection criterions were the date of full flowering (Gulcan, 1985; Gulcan *et al.*, 1989; Simsek, 1996; Balta, 2002; Simsek, 2008). The flowering dates of almond genotypes and cultivars can vary with the environmental conditions, horticultural practices and genetic characteristics. Choosing late-flowering, high fruit quality and high yielding almond genotypes is a major commercial advantage.

In this study, it was determined that the tree habit of promising almond genotypes changed as spreading of 6 genotypes and upright as 3 genotypes (Table 1). Simsek and Yilmaz (2010) observed as dropping and spreading of the tree habit of almond genotypes in Silvan district of Diyarbakir province.

It was determined that the fruit weight with shell, kernel weight, shell thicknes and kernel ratio of promisin almond genotypes ranged from 2.29 (63-HVO-32)–6.31 (63-HVO-25) g, 0.53 (63-HVO-65 and 63-HVO-103)-1.04 (63-HVO-18) g, 2.63 (63-HVO-103)–4.36 mm (63-HVO-25) and 15.86 (63-HVO-25)-23.41 (63-HVO-32), respectively (Table 1). In addition, it was determined that the suture opening of the shell, kernel taste, percentage of double kernels, percentage of twin kernel and yield of all of proising almond genotypes ranged from 0.00 mm, sweet, 0.00%, 0.00% and intermediate, respectively (Table 1). Simsek and Yilmaz (2010) determined that kernel ratio, the fruit weight and the kernel weight of the selected genotypes were determined and changed from 18.76 to 4.00%, from 2.99 to 4.53 g and from 0.61 to 1.18, respectively. Double kernel ratio and twin kernel ratio weren't found in the selected genotypes. Simsek *et al.* (2010) determined that the fruit weight with shell, kernel weight, kernel ratio, double kernel ratio and twin kernel ratio of almond genotypes in Kocaköy and Hani districts ranged from 1.15 to 2.14 g, 0.69 to 1.25g, 37.43 to 62.81%, 0.00%, 0.00% and 100%, respectively. In some other studies, fruit weight with shell changed from 3.45 to 5.86 g (Bostan *et al.*, 1995), 2.18 to 7.58 g (Gercekcioglu and Gunes, 1999), 3.39 to 7.58 g (Simsek, 1996), 1.21 to 2.75g (Simsek and Kuden, 2007) and 1.42 to 4.93 g (Simsek, 2008). Karadeniz and Erman (1996), Simsek and Kuden (2007) and Simsek (2008) determined that the kernel weight of the selected genotypes changed from 1.01 to 1.80 g, 0.51 to 1.52 g and 0.66 to 1.14 g, respectively. Simsek and Kuden (2007), and Simsek (2008) determined that kernel ratio changed from 25.39 to 62.41 % and 13.91 to 60.16%, respectively. Simsek and Kuden (2007) and Simsek (2008) determined that the double kernel ratio changed from 0.00 to 28.00%, and 0.00%, respectively. Desirably, double kernel ratio should not exceed 5% (Ozbek, 1978; Simsek *et al.*, 2010).

The values obtained on tree and fruit characteristics in this study were in agreement with the values reported in some similar studies (Simsek and Yilmaz, 2010; Simsek *et al.*, 2010). Although the yield is an inherited property, it can change according to pollination, maintenance requirements and ecological conditions of almond genotypes and cultivars.

Table 1. Some properties of the selected almond genotypes.

Characteristics	63-HVO-7	63-HVO-18	63-HVO-25
Date of first flowering	9 March	9 March	10 March
Date of full flowering	14 March	14 March	15 March
Date of Last flowering	19 March	19 March	19 March

Fruit weight with shell (g)	2.55	2.71	3.19
Suture opening of the shell (mm)	0.00	0.00	0.00
Kernel Taste	Sweet	Sweet	Sweet
Percentage of double kernels (%)	0.00	0.00	0.00
Percentage of twin kernel (%)	0.00	0.00	0.00
Kernel weight (g)	0.54	0.53	0.59
Shell thicknes (mm)	2.80	2.63	2.59
Kernel ratio (%)	21.17	19.59	18.33

Conclusion

In general, the difference between the flowering periods of almond genotypes and cultivars can change according to altitude, ecological conditions and genetic characteristics. The selected almond genotypes in forest area of Hilvan (District) of Sanliurfa province were seen in their outcome in most characteristics. Selected genotypes in this study should be tested in the same ecological conditions with standard almond cultivars to bring them into the commercial almond production. It can be concluded that selected almond genotypes have a great potential of high yielding, high quality and late flowering new cultivars to be registered after follow up adaptation studies.

EVALUATION IN BIO-COMPOSITE FILM PRODUCTION OF SOME AGRICULTURAL PLANTS GROWING IN TURKEY

Saim ATEŞ*, Ekrem DURMAZ

Department of Forest Industrial Engineering, Kastamonu University, Turkey
*Corresponding author: saimates@kastamonu.edu.tr

Abstract

Plenty of and a large variety agricultural resources are grown in different regions of Turkey and abundant wastes emerge from these. Owing to their large amounts, storing or annihilating of them is not too easy. Nonetheless, these materials can be evaluated in a lot of purposes. One of these is bio-based composite films. It is known that the bio-composite films are more eco-friendly and biodegradable than the petroleum-based products. In production of bio-based composite materials, agricultural plant wastes have to be converted the nano/micro scale to disperse in the films homogeneously. According to sizes and obtaining methods, separated fibers are termed as microfibril (MF), microcrystallinecellulose (MCC), nanofibril (NF), nanocrystallinecellulose (NCC) or cellulose whiskers (CW) etc. in the literature. Micro/nano fibers have some advanced mechanical, physical and thermal properties. Therefore, the composite films produced with these materials can be preferred in industries like medical, electronic, coating etc. instead of plastic-based materials. In this study ten different agricultural wastes growing in Turkey were selected. Wheat straw, barley straw, rye straw, rice straw, sunflower stalk, cotton stalk, corn stalk, tobacco stalks, reed and hemp were collected from different regions and their anatomical, chemical and morphological properties were discussed for producing bio-composite film.
Consequently, while hemp fibers were the longest fiber length, cotton and tobacco fibers showed the shortest fiber length. Also the lowest lignin content and the highest cellulose ratio were found in hemp. Although all lignocellulosic materials can be used for nano/micro crystalline cellulose production, some of them need additional pretreatment processes.

Keywords: *Agricultural resources, nanofibril, bio-composite film*

Introduction

In recent years, the production of durable and eco-friendly materials has attracted the attentions of researchers. Furthermore, it is expected that bio-based composite materials will eliminate various drawbacks of synthetic polymers like restricted fossil resources such as petroleum and this derivatives, a constantly fluctuating price scale and greenhouse gas emissions. Bio-based composites are preferred owing to its low cost, low density, high resistance properties, high electrical, mechanical and optical properties, low energy consumption, their eco-friendly, conformance to environmental conditions and ensuring environmental cycle in short time by disintegrating naturally. Owing to all these properties, bio-based composites can be used in different industries such as technology, communication, structure, material science, medical, military, production of aircraft and automobile, optic and magnetic zones (Jamshidian et al., 2010; Jose et al., 2012).
Researchers around the world have utilised various cellulosic raw materials for nanocellulose production. Because of wide availability and high cellulose content, wood was used, too, but the production nanocellulose from wood involves multi-stage treatment. In general, purified

wood or bleached kraft pulp is preferred to manufacture nanocellulose (Hubbe et al. 2008). Although wood is the most productive natural fiber resource for producing nanocellulose, recently due to excessive raw material necessity, researchers are considering usage of annual plants and agricultural residues. For nanocellulose manufacturing cotton, hemp, jut, sisal, corn stalk, flax, sugar cane bagasse, sugar beet pulp, wheat straw, soy hulls, potato root, coconut, mulberry, rutabaga, banana rachis and palm can be used (Hubbe et al. 2008; Peng et al. 2011).
Although every year nearly 60 million ton agricultural residues emerge in Turkey, these residues can't evaluate effectively. They are either burned or binned. Part of these materials are utilized in production of animal feed. Usability ratios of some of the agricultural residues were given following: wheat straw, 3.514.486; corn stalk, 2.982.158; sunflower stalk, 1.355.472, cotton stalk, 1.512.169 and rice straw 125.719 ton (Acar et al. 2016). Agricultural residues can be converted to bio-based products such as biocomposite, biofibre, polyester, polyethylene, polystyrene, ketone, epoxide, acid, alcohol, polyamide with regard to different physical/mechanical, biological, chemical and thermochemical treatments (Alkaya et al. 2010)
Within the context of this study, morphological, chemical and anatomical characteristics of some annual plants and their residues growing in Turkey were investigated with regard to opportunities of bio-composite film production.

Materials and methods

Materials

Wheat straw, barley straw, rye straw, rice straw, sunflower stalk, cotton stalk, corn stalk, tobacco stalks, reed and hemp used as raw material were obtained from Konya, Adana, Samsun, Tekirdağ, Çorum, Afyon and Kastamonu in Turkey. All of the chemical materials and equipment in the analyses supplied from the laboratories of Department of Forest Industrial Engineering, Kastamonu University.

Methods

For morphological characteristics, wheat straw, barley straw, rye straw, rice straw, sunflower stalk, cotton stalk, corn stalk, tobacco stalks and reed samples were prepared from their stems, whereas hemp samples were prepared from its steles. Schultze maceration process (1857) was performed to separate fibers of raw materials.
For anatomical characteristics, after the samples were boiled in water until they soften, the water in cell wall and lumen were removed by doing dehydration with alcohol and alcohol-xylene. Very thin samples were cut with a sliding microtome after dehydrated raw materials were embedded in the wax. Prepared anatomic samples were stained with safranine as well as these samples were immobilized with Canada balsam between lamina and cover glass. Then these slides were monitored with a light microscope by using in 10x16 magnifications and the images were achieved.
For chemical characteristics, all analyses of the samples were conducted according to TAPPI standards (Hafızoğlu and Deniz 2011). Before the chemical analyses, the samples were grinded in a Wiley Mill and they were prepared according to TAPPI T 257 cm-85 standard. All of the analyses were repeated three times to provide consistency.

Results and Discussions

The morphological measurement results of wheat straw, barley straw, rye straw, rice straw, sunflower stalk, cotton stalk, corn stalk, tobacco stalk, reed and hemp fibers and some of the studies in literature were indicated in Table 1. The fibrous and anatomical images of samples were obtained with Digimizer which is scanning software programmer and they were given in Figure 1, 2, 3, 4, 5, 6, 7, 8, 9 and 10. For hemp sample, anatomic cross section images couldn't be obtained because its stem comprises only fibers.

Table 1. Morphological properties of samples and comparing with literature (Ateş et al. 2011)

Raw material	Fibre length (mm)	Fibre width (µm)	Lumen width (µm)	Cell wall thickness (µm)	
Wheat straw	0,93	15,75	5,25	5,25	Measurement
Wheat straw	1,17	15,5	5,8	4,9	Reference
Barley straw	1,07	11,25	4,53	3,36	Measurement
Rye straw	1,14	15,56	6,25	4,66	Measurement
Rye straw	1,15	14,7	4,2	5,3	Reference
Rice straw	1,08	12,52	6,02	3,25	Measurement
Rice straw	0,89	14,80	6,40	4,20	Reference
Tobacco stalk	0,98	25,75	17,25	4,25	Measurement
Tobacco stalk	1,07	26,8	16,3	5,3	Reference
Cotton stalk	0,97	23,75	16,72	3,52	Measurement
Cotton stalk	0,81	24,98	16,75	4,12	Reference
Hemp	28,74	25,53	7,54	8,99	Measurement
Hemp	25,24	27,10	7,18	9,96	Reference
Reed	1,52	16,25	7,00	4,63	Measurement
Reed	0,95	14,3	6,4	4,0	Reference
Sunflower stalk	1,32	21,35	16,25	2,55	Measurement
Sunflower stalk	1,28	22,1	15,6	3,3	Reference
Corn stalk	1,23	19,25	9,25	5,02	Measurement
Corn stalk	1,32	24,3	10,7	6,08	Reference

When the fiber images of samples were looked, fragment fibers were noticed abundantly in wheat straw, rice straw, barley straw, tobacco stalk and sunflower stalk. As can be seen in Table 1, all measurements are almost coincide with literature.

According to Table 1, the highest fiber length was obtained in hemp samples with 28,74 mm. In terms of fiber widths, tobacco stalk (25,75 µm), hemp (25,53 µm), cotton stalk (23,75 µm) and sunflower stalk (21,35 µm) attracted the attention rather than the others. Likewise, lumen widths of tobacco stalk (17,25 µm), cotton stalk (16,72 µm) and sunflower stalk (16,25 µm) were higher than the other samples considerably as well as maximum cell wall thickness was found in hemp fibers with 8,99 µm. Due to high fibre length and high cell wall thickness, it can be thought that biocomposite films produced from hemp nanofibril will have higher tensile strength and Young's modulus (Wang and Sain 2007c; Cao et al. 2008). Likewise, because tobacco stalk, cotton stalk and sunflower stalk have higher lumen widths than the others, it is predicted that mechanical and barrier properties of biocomposite films produced from these kind of samples' nanofibril will be lower than the others. Nonetheless, it can be seen that annual plants and agricultural residues are appropriate to production of bio-based composite films when the studies in literature are investigated (Oun and Rhim 2016; Smyth et al. 2017; Zhang et al. 2017).

When anatomical images of samples were investigated, epidermis, collencyhma cells, sclerencyma cells, tracheid, vessel, xylem, phloem, cortex, parenchyma and cambium were clearly seemed in cross sections of the samples in Figure 1, 2, 3, 4, 5, 6, 7, 8, 9 and 10.

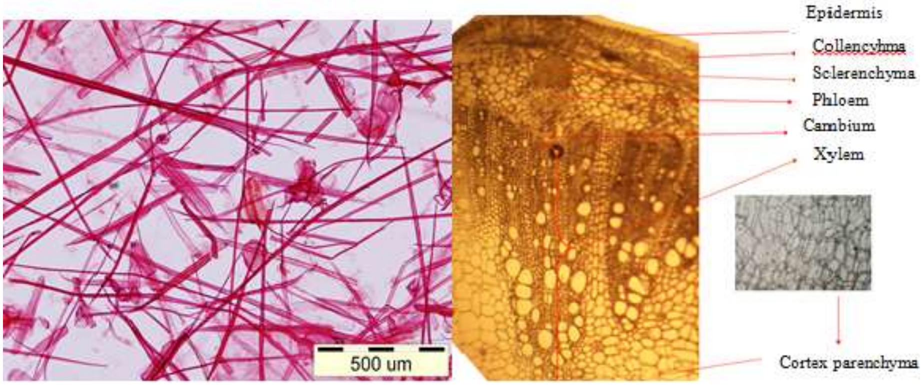

Figure 9. The microscopic images of fibre and stem cross section of sunflower stalk

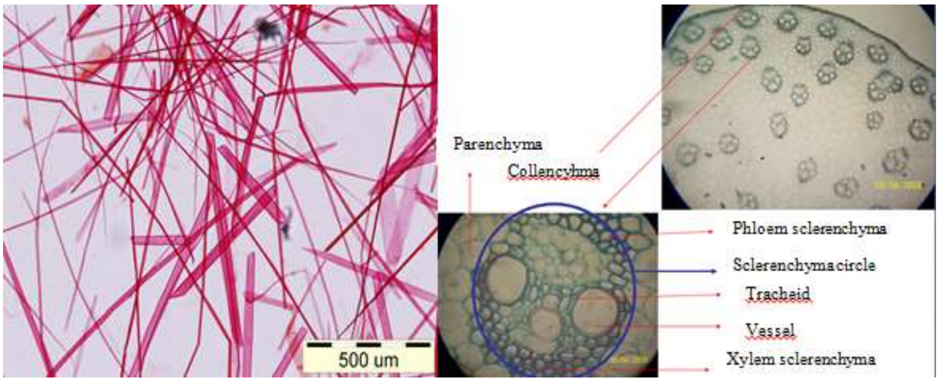

Figure 10. The microscopic images of fibre and stem cross section of corn stalk

According to anatomical images, uniserial epidermis layer was found in outmost of stem and 3-6 serial collenchyma layer under epidermis were seen in all of the samples except hemp. It was noticed that cambium layer which provide diameter increment of wood and non-wood products were between phloem and xylem. Vessels and tracheids in xylem tissues provided transmission of water and food substances. Collencyhma, sclerenchyma, vessels and tracheids formed sources of the fibers. Transmission members alined as both uniform and nonuniform in cross section and sides of each transmission members encircled with sclerenchyma cell layer. If raw materials have thick latewood layer, necessary processes for obtaining of nanofibrils from them are more difficult and the processes take more times because of high density of latewood layer. However because of porosity structure of the selected raw materials that they have abundantly parenchyma and vessel cells, penetration time of the acid solution for dissolving the cell wall components is becoming shortly (Abe and Yano 2010; Wang et al. 2015). As a result, analyses of chemical component values of the samples were determined and they were compared with the other results in literature. All of the values were demonstrated in Table 2.

Table 2. Chemical properties of samples and comparing with literature (Ateş et al. 2011)

Raw Materials	Holocellulose (%)	Cellulose (%)	α–cellulose (%)	Lignin (%)	Silica (%)	Ash (%)	Alcohol-benzene (%)	Acetone (%)	1% NaOH	Hot water (%)	Cold water (%)

Coniferous tree	70-81	42-51	40-45	24-32		<1	1-8		8-14	1-6	1-4	Reference
Deciduous	63-90	55-38	36-49	21-25		<1	1-7		15-22	1-8	1-5	Reference

It was seen that the highest holocellulose value obtained as 86,08% in hemp sample according to Table 2. Alike the highest values was achieved in hemp sample with 80,70% and 75,29% with regard to cellulose and α-cellulose contents, respectively. Maximum lignin content was found as 23,79% in cotton stalk sample. It was seen that rice straw sample had maximum silica (15,67%) and ash (15,44%) content. The highest alcohol-benzene solubility value was determined as 9,3% in wheat straw sample, whereas the highest acetone solubility value was determined as 8,1% in corn stalk sample. Maximum 1% NaOH solubility value was found as 56,25% in barley straw sample. It was confirmed that sunflower stalk had maximum hot water solubility with 24,26% and maximum cold water solubility with 21,08%. When it was looked the studies in the literature, it was noticed that similar results were obtained.

According the results, hemp can be the most suitable raw material for nanofibril obtaining and so production of bio-based composite films with regard to chemical components because it has the highest cellulose content and the lowest lignin content. In this case, the amount and time of necessary chemical processes to purify cellulose by removing of lignin and hemicellulose will decrease. Bhatnagar and Sain (2005) and Wang et al. (2007) used hemp as raw material in their studies and they determined that nanofibril can be obtained from hemp in high yield due to its high cellulose content and purification easily. Silica content is very significant factor to determine some properties of rice straw nanofibril composite films (Kim et al. 2004). Because rice straw has the highest silica content, these particles can be decrease the hydrogen bonding between the nanofibrils. Therefore, tensile strength and modulus of films produced from rice straw nanofibrils are less than those of films produced from the other raw materials (Hassan et al. 2012). However high silica content can improve the last product burning properties. It was stated in some researches in the literature that annual plants and agricultural residues were appropriate for production of nanofibrils and biocomposite films because most of them have more cellulose content than wood.

Conclusion

In this study ten different agricultural wastes (wheat straw, barley straw, rye straw, rice straw, sunflower stalk, cotton stalk, corn stalk, tobacco stalk, reed and hemp) growing in Turkey were selected and morphological, anatomical and chemical characteristics were determined for opportunities of biocomposite film production from them. As a result of morphological analyses, the highest fiber length was found as 28,74 mm in hemp, whereas the least fiber length was found as 0,97 mm and 0,98 mm in cotton stalk and tobacco stalk, respectively. It was seen that tobacco stalk and hemp had maximum fiber widths with 25,75 µm and 25,53 µm. It was confirmed anatomic units of the samples such as collencyhma, sclerenchyma, parenchyma, cambium, epidermis, xylem, phloem, tracheid, and vessel with anatomical analyses. According to chemical analyze results, the highest cellulose content and the lowest lignin content were determined as 80,70% and 6,42% in hemp. Rice straw drew attention in the samples because it had maximum silica (15,67%) and ash (15,44%) contents.
As a consequence, it was seen that agricultural wastes were suitable to applications in the production of nanocellulose and biocomposite films with morphological, anatomical and chemical analyses. Nonetheless, additional treatments and processes should perform to diminish to micro/nano scale dimensions of the samples in biocomposite film production.

SHORT-TERM DIAMETER AND HEIGHT INCREMENTS OF ORIENTAL BEECH AND BLACK ALDER SEEDLINGS IN PURE AND MIXED SITES

Sinan GUNER*, Askin GOKTURK, Mehmet KUCUK

Artvin Çoruh University Forestry Faculty, Department of Forest Engineering, Turkey

Abstract

Black alder (*Alnus glutinosa* subsp. *barbata* (C.A.Mey). Yalt) enriches soil with nitrogen through a symbiotic relationship with bacteria found in its roots. Because of this characteristic, alders can be evaluated as a natural fertilizer. In this study, it was investigated whether there could be an important contribution of black alder to the increment of oriental beech (*Fagus orientalis* Lipsky) when oriental beech and black alder were grown together in afforestation sites. In 2014, 15 sample plots each of them 200 m^2 were established according to the randomized complete block design with five replications in Arhavi district of Artvin province located in the eastern Black Sea Region of Turkey. Five of the sample plots were planted with 2-year-old eastern beech, 5 with 1-year-old black Alder 5 mixed with 1-year old alder and 2-year old eastern beech. Seedlings were planted with 1m x 1m spacing distance. Changes in root collar diameter, height of all seedlings in pure and mixed sample plots were measured in the fall annually. An Independent Samples T Tests was conducted to determine whether planting type had a significant effect on differences in root collar diameter and height of seedlings. Assessment made two years after planting showed that black alder grows more rapidly than oriental beech in pure sample plots. It has been determined that the growth (increment of root collar diameter and height growth) of oriental beech seedlings is better in mixed black alder and oriental beech plots compared to pure oriental beech plots.

Key Words: Black alder, Oriental beech, root collar diameter, diameter increment, height increment

Introduction

Fertilization is one practice employed to obtain high yields in a short amount of time in plantation based operations. Several studies have shown that fertilization has led to increased yields (Aronsson *at al.,* 2014; Bergh *at al*., 2014). However, mineral fertilizers in particular may lead to environmental problems such as nitrate accumulation and carbon loss in soils (Nkoa, 2014; Quiao *at al.,* 2015; Moreno-Jiménez, 2016). They also can suppress the growth of plants when applied in large quantities contrary to expectations (Conway and Pretty, 2013; Rigby *at al.,* 2016). Environmental organizations recommend the use of natural fertilizers in agriculture and forestry.

Natural fertilizers are produced by composting organic waste or directly applied as organic waste to soil. There are leguminous and actinorhizal plants, which have natural fertilizer characteristics. They convert atmospheric nitrogen into forms that can be used by plants through symbiotic relationships with *Frankia* and *Rhizobium* bacteria in their roots and improve the nitrogen content of soil (Smith *at al*, 1992; Weber *at al.*, 1987; Carro *at al.,* 2015; Kumar *at al.,* 2015; Cao *at al*., 2017).

Nitrogen is the most important macronutrient that supports growth in plants. Nitrogen as a primary macronutrient is found in the organic structure of plants and provides faster growth (Kaye and Hart, 1997; Haynes, 2012).

One tree species that can be used as a live fertilizer is alders. The *Frankia* bacteria that form symbiotic relationships with alders in root nodules enrich the soil by converting atmospheric nitrogen into forms that can be used by plants and soil organisms (Cole and Newton, 1986; Genç, 2004). Alders are also among fast growing industrial forest tree classes in addition to harboring nitrogen-fixing bacteria. Alders grow in northern regions of Turkey. For growth, they require a humid climate with precipitation exceeding 2000 mm (Yaltırık, 1993; Anşin and Özkan, 1997). Various studies have shown that alders improve (Meiden, 1961; Miller and Murray, 1978; DeBell and Radwan, 1979), have no effect (Dale, 1963) or have negative effect (Miller *at al*., 2005; Sayyad *at al.*, 2006) on the growth of the species with which they are coplanted.

Oriental beech is an important industrial forest species. Like alder, it is generally distributed in northern regions of Turkey in humid environments, on north facing slopes within a 700-2000 m elevation range (Yaltırık, 1993; Kandemir *at al*., 2016). Oriental beech forests are managed within 100-140 year periods.

The Black Sea Region, where oriental beech and bearded alder coexist, has a humid, temperate climate with precipitation throughout the year. Annual precipitation average exceeds 3000 mm/m^2 especially in the areas where eastern beech grows in the region (TMA, 2017). Plant nutrients, mainly nitrogen, get washed away with the precipitation. Growth deficiencies like yellowing of the leaves, nutrient deficiencies and smaller shoot and leaf sizes due to nitrogen deficiency are observed in the beech forests of the region.

In this study, it was investigated that whether there would be a positive contribution to the growth of oriental beech seedlings in mixed plantations of oriental beech and black alder. In order to make this determination, the change in root collar diameter and seedling height incremenet of oriental beech seedlings was tested when alder for the growth of oriental beech provided nitrogen support.

Material and Methods

The study was conducted at a rehabilitation area in Ortacalar- Arhavi (41° 17' 10" N - 41°23'72" E, elv. 950m) in the eastern Black Sea Region of Turkey. The size of the study site is 1.5 ha. The amount of precipitation at the site is 2400 mm/m^2 according to Arhavi Meteorological Station data. In the fall of 2014, the site was clear-cut and cleared and then soil was prepared. Afterwards 15 sample plots of 10 m x 20 m were established according to the randomized complete block design with five replications. Five of the plots were planted with 200 1-year old black alder, five of them were planted with 200 2-yr old oriental beech seedlings immediately following the establishment of sample plots. A hundred 1-yr old black alder and 100 2-yr old oriental beech seedlings were planted in mixed order in the remaining five sample plots. Planting types were applied to the sample plots randomly and each plots of pure and mixed plantings was taken into consideration as a replication of planting types. The plantings were done at 1m x 1m spacing distance in all of the sample plots. In total, the study site was planted with 3000 seedlings including 1500 oriental beech and 1500 black alder. Root collar diameter (nearest 0,5 mm at ground level) and height of the seedlings (nearest 0,5 mm from the ground to the terminal bud) were measured following the planting. Root collar diameter and height were measured with a millimeter digital caliper and a ruler, respectively. Root collar diameter and height of the seedlings were re-measured in order and recorded at the end of the vegetation periods in 2015 and 2016.

The changes in the root collar diameter and height of alder and beech seedlings in pure and mixed plots between 2014 and 2016 were analyzed by SPSS Version XIX. An Independent Samples T Tests was conducted for each species to determine whether planting type (pure and mixed) had a significant effect on the observed differences in root collar diameter and height of seedlings between 2014 and 2016. Mean values of differences in root collar diameter and height were used in independent Samples T Tests.

Results and Discussion

The mean, minimum and maximum values of root collar diameter and height of black alder and oriental beech seedlings grown in pure and mixed plots between 2014 and 2016 are displayed in Table 1. Alders grown in pure plots had a root collar diameter of 13.38 mm and reached a height of 162.2 cm at age 3. Alders had a root collar diameter of 13.69 mm and a height of 167.0 cm at age 3 when grown in mixed plots. Oriental beech grown in pure plots had a mean root collar diameter of 8.83 mm and a mean height of 67.3 mm at age 4. When beeches were grown mixed with alder, they had a mean root collar diameter of 8.94 mm and reached a mean height of 74.3 cm at age 4 (Table 1).

Table 1. Root collar diameter and seedling height measurement data (2014, 2015, 2016)

Year	Pure/ Mix	Species	N	Root Collar Diameter Mean mm	Root Collar Diameter Minimum mm	Root Collar Diameter Maximum mm	Seedling Height Mean cm	Seedling Height Minimum cm	Seedling Height Maximum cm
2014	Pure	Alder	1000	5.70	5.51	5.85	35.6	32.4	39.2
		Beech	1000	7.83	7.72	7.86	34.0	22.9	35.2
	Mix	Alder	500	5.70	5.66	5.74	35.6	25.0	37.9
		Beech	500	7.83	7.80	7.85	34.0	33.0	34.9
2015	Pure	Alder	1000	7.10	6.78	7.21	112.4	88.5	132.5
		Beech	1000	7.93	7.88	7.98	40.9	36.8	44.2
	Mix	Alder	500	7.14	7.05	7.21	115.3	90.5	124.9
		Beech	500	7.95	7.90	8.01	41.0	36.0	45.5
2016	Pure	Alder	1000	13.38	12.12	14.12	162.2	114.4	194.8
		Beech	1000	8.83	8.75	8.90	67.3	58.9	74.9
	Mix	Alder	500	13.69	12.60	15.20	167.0	129.1	182.7
		Beech	500	8.94	8.78	9.07	74.3	60.4	89.7

The change in root collar diameter and height of alder and beech seedlings grown in pure and mixed plots in 2014, 2015 and 2016 are displayed in Figure 1. As can be seen in the figure, alders grew faster than beeches.

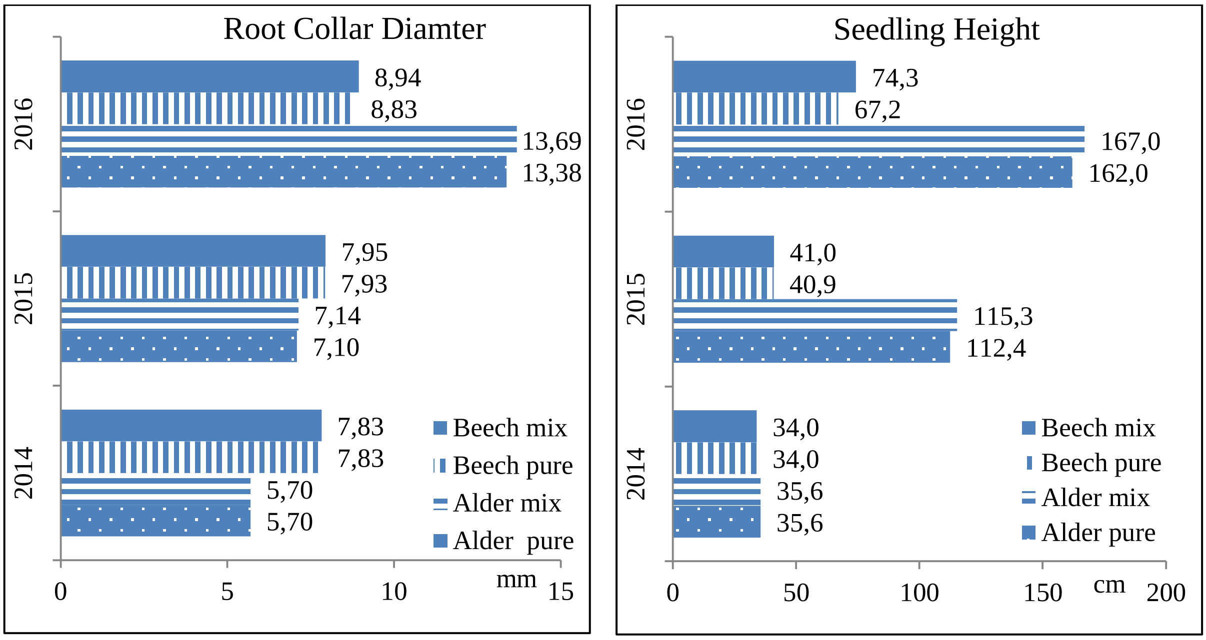

Figure 1. The change in root collar diameter and height of black alder and oriental beech seedlings grown in pure and mixed plots.

Independent samples t-test results showed that the pure and mixed beech groups were different from each other. The difference between the increments of root collar diameter and height of beech grown in mixed plots with alder and beech grown in pure plots was significant. However, there was not a significant difference between pure and mixed alder groups. The difference between the increments of root collar diameter and height of alder grown in mixed plots with beech and alder grown in pure plots was not significant (Table 2).

Table 2. Independent samples t-test results of differences in seedling root collar diameter and height between 2014 and 2016.

Species	Variables		Levene's Test for Equality of Variances		T-test for Equality of Means		
			F	Sig.	t	df	Sig. (2-tailed)
Beech	Diameter	Equal variances assumed	4,968	,056	-10,164	8	,000
		Equal variances not assumed			-10,164	6,451	,000
	Height	Equal variances assumed	3,053	,119	-5,895	8	,000
		Equal variances not assumed			-5,895	6,509	,001
Alder	Diameter	Equal variances assumed	,388	,550	-1,081	8	,311
		Equal variances not assumed			-1,081	7,839	,312
	Height	Equal variances assumed	2,840	,130	-1,359	8	,211
		Equal variances not assumed			-1,359	7,087	,216

Beech grown in pure plots had a mean root collar diameter increment of 1 mm. Oriental beech grown in mixed plots had a mean root collar diameter increment of 1,12 mm. The mean height increment in beech seedlings grown in pure plots was 33.2 cm whereas the increment in beech seedlings grown in mixed plots was 40,3 cm. Alders grown in pure plots increased their root collar diameter 7,68 mm whereas in mixed plots grown with beech, alders had a higher root collar diameter increment of 7,99 mm. Mean seedling height increment in pure alder plots was 126,6 cm and increased to 131,4 cm in mixed plots (Table 3).

Table 3. Group Statistics of differences in seedling root collar diameter and height between 2014 and 2016

Species	Variables	Planting Type	N	Mean	Std. Deviation	Std. Error Mean
Beech	Diameter (mm)	Pure	5	1,0012	,02211	,00989
		Mix	5	1,1176	,01293	,00578
	Height (cm)	Pure	5	33,2696	2,29202	1,02502
		Mix	5	40,2970	1,36096	,60864
Alder	Diameter (mm)	Pure	5	7,6811	,48769	,21810
		Mix	5	7,9928	,42209	,18877
	Height (cm)	Pure	5	126,6254	6,52244	2,91693
		Mix	5	131,4348	4,48002	2,00352

Positive effects on the growth of the species grown with alders generally have been observed in similar studies. Miller and Murray (1978) found that *Pseudotsuga menziesii* ((Mirb.) Franco.) had better growth over shorter periods in mixed plantations containing proportions of 59% *Alnus rubra* (Bong.). DeBell and Radwan (1979) showed that *Populus trichocarpa* (Torr. & Gray) had improved growth over shorter periods when grown in plantations containing proportions of 50% *Alnus rubra*. Similarly, Maiden (1961) found that planting alder in the understory of poplar plantations resulted in greater height and diameter growth. However, there were cases in which alders had negative effects on the growth of coexisting species. For example Sayyad et al. (2006) found negative effects of *Alnus crispa* on growth of *Pinus contorta* and *Picea glauca*. Miller *et al*. (2005) found that proportions of 7-27% *Alnus rubra* had no effect on growth of *Pseudotsuga menziesii* var *menziessi* ((Mirb.) Franco) but in areas where *Alnus rubra* was taller, the death rate of *P. menziesii* var *menziessi* ((Mirb.) Franco) was higher.

Alders had a positive contribution to root collar diameter and height increment of oriental beech in the second year according to the results of the current study. These results are in agreement with the findings of Miller and Murray (1978), who showed positive contributions of *Alnus rubra* on *Pseudotsuga menziesii* (Mirb.) Franco.) growth and Van der Meiden (1961), who found higher increments in poplars when grown with alders. However, whether this positive contribution will continue and the nature of future interaction between the two species will be only reliably identified by measurements in upcoming years.

Conclusions

After two years of growth, it was found that oriental beech seedlings grown in mixed plots with alder had greater increments of root collar diameter and height compared to oriental beech seedlings grown in pure plots. The differences between the increments in pure versus mixed plots were significant based on statistical analyses (alpha<0.05).

Abstract

Provenance in forestry refers to the population of trees growing at a particular place of origin. Provenance research defines the genetic and environmental components of phenotypic variation associated with geographic source. This article summarizes the results from a Serbian - wide series of 24 provenance trials of native provenances of Douglas fir (*Pseudotsuga menziesii*/Mirb./Franco) from the USA and 7 provenance trails of native provenance of Norway spruce **(***Picea abies Karst* **)** from Slovenia and Serbia. The seedlings from all collection locations are planted together in a systematic experimental design on multiple sites. Multi annual research included comparative analyses of intra- and inters-provenance variability of several quantitative characters: a) trees – volume, basal area and volume increment, as well as of qualitative characteristics: a) the main physical and mechanical properties of felled stem wood at the height from 0.3 to 1.3m. The data on the variability of air temperature and precipitation at the study localities were obtained from the Republican Hydro-Meteorological Institute of Serbia. The effects of air temperature and precipitation on the study parameters were determined by Pearson's correlation coefficient. Environmental differences between the location of origin and the planting (test) site have been calculated by principal component analysis and termed ecological distance. Consideration of ecologically important genetic variation within species is important and this information should be integrated into seed collection strategies for ecological restoration.
The aim of these analyses is to study the interaction between the genetic potential of the introduced provenances and the environmental conditions at the provenance test sites, aiming at the more reliable selection of forest-economic works on the establishment, silviculture, tending and utilisation of Douglas-fir and Norway spruce plantations.

Key words: *provenance trails, genetic diversity, geographic sources*

Introduction

Provenance trials have been used in Serbian forestry since the middle of 20th century for detecting populations with economically desirable characteristics to be targeted for tree-breeding programmes, (Isajev et al., 1997, 1999, 2003.) Provenance tests offer an excellent resource for making predictions of growth changes associated with climatic change. The big advantage is that many tests involving in several forest species are already in place, with results available and published. The growth-loss estimates are not very precise, but are probably as accurate as extrapolations based on growth chamber data. The source of material included in such trials is known so, existing trials may be utilized to study variation of ecologically important traits and identify appropriate source populations for restoration. For long-lived, slow-growing species, such as many forest trees, long-established trials provide a unique opportunity to examine later life-history traits, which may reveal important variation not evident in younger plants. In the last three decades, the aim of investigation is to study the interaction between the genetic potential of the introduced provenances and the environmental conditions at the provenance test sites. The results are of importance for the more reliable works on the establishment, silviculture, tending and utilisation of Douglas-fir and Norway spruce plantations in Serbia.

Material and Methods

DOUGLAS-FIR (*Pseudotsuga menziesii Mirb. Franco*) PROVENECE RESEARCH IN SERBIA

Douglas-fir (*Pseudotsuga menziesii* /*Mirb.*/ *Franco*) provenance tests in Serbia consist of 29 provenances, originating from almost entire natural range of this species, table 1. One experiment is in the area of Mt. Juhor (central Serbia) at the site of the montane beech forest (*Fagetum moesiaca montanum* Jov. 1976) and the other one is at Tanda near Bor (eastern Serbia), at the site of Hungarian oak and Turkey oak forests (*Quercetum frainetto-cerris* Rud. 1949).

Table 1. Geographical co-ordinates of the tested Douglas fir provenances in Serbia

Origin and number of provenance			Latitude (^{o})	Longitude (^{o})	Altitude (m)
1	Oregon	205-15	43.7	123.0	750
2	Oregon	205-14	43.8	122.5	1200
3	Oregon	202-27	45.0	122.4	450
4	Oregon	205-38	45.0	121.0	600
5	Washington	204-07	49.0	119.0	1200
6	Oregon	205-13	43.8	122.5	1050
7	Oregon	205-18	44.2	122.2	600
8	Oregon	202-22	42.5	122.5	1200
9	Washington	202-17	47.6	121.7	600

11	Washington	204-06	49.0	120.0	750
12	Oregon	202-19	45.3	123.8	300
13	Oregon	205-11	45.3	123.0	150
14	New Mexico	202-40	45.0	105.7	2682
15	New Mexico	202-10	36.0	106.0	2667
16	Oregon	202-31	44.3	118.8	1500
17	Oregon	205-29	42.6	122.8	900
18	Oregon	205-08	42.7	122.5	1050
19	Oregon	204-04	45.0	121.5	900
20	Washington	205-02	47.7	123.0	300

In Douglas-fir plantations, numerous researches have been undertaken in various spheres of forestry, Lavadinović V. et al.1995. 1997., 1998., 2001., 2003., 2005. By analyzing the values of mean heights and diameters, the significant differences among the provenances and the differences between the tests have been recorded.

This paper deals with the dependence of the provenance latitude, longitude and altitude on the height increment of test trees grown on allochthonous sites, Figure 1.

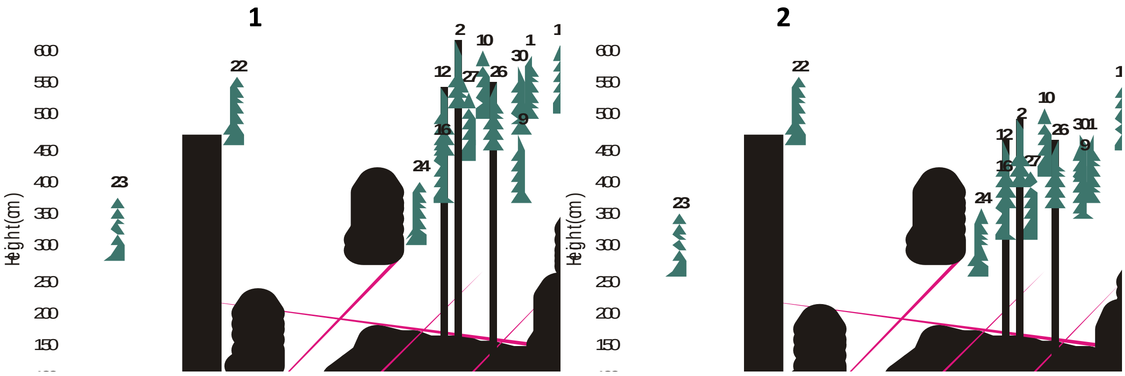

Figure 1.Provenance height in relation to altitude and elevation of origin, locality Tanda (1) and locality Juhor (2)

The results show that latitude has a low effect on height increment of plants of different provenances and that the effects of longitude and altitude are very important.

Dependence of height increment of provenances (*Y*) on latitude (*X*1): parabolic dependence in this case is not statistically significant Figure 2. Parameters of regression are as follows:

$Y = -1975.33 + 91.52\ X1 - 1.018\ X12$ (1)

$Se = 12.8$ cm, $r2 = 0.1095$, $r = 0{,}3309$

($F < F\ 0{,}05$; $2.60 < 3.40$)

Dependence of height increment of provenances (*Y*) on longitude (*X*2): parabolic dependence is clearly expressed, Figure 3. With the increase of longitude, height increment of provenances also increases to a certain level. Parameters of regression are as follows:

$Y = -36967.0 + 604.15\ X2 - 2.463\ X22$ (2)

$Se = 5.6$ cm, $r2 = 0.8309$, $r = 0.9115$

($F > F0{,}01$; $64.88 > 5.61$)

Dependence of height increment of provenances (*Y*) on altitude (*X*3): this dependence is clearly expressed. With the increase of altitude, height increment of plants drops. Parameters of parabolic correlation are:

$Y = 85.02 + 0.0102\ X3 - 0.00002\ X32$ (3)

$Se = 10.4$ cm, $r2 = 0.4520$, $r = 0.6405$

($F > F0.01$; $10.04 > 5.61$)

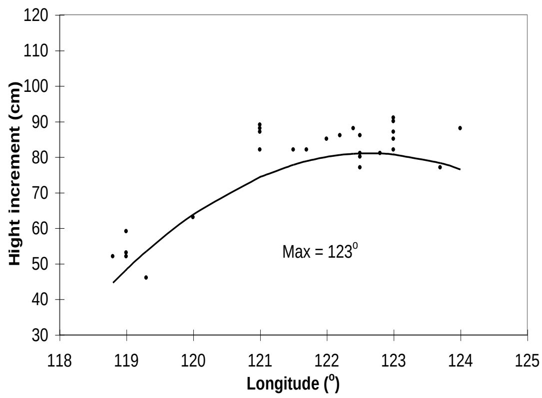

Figure 2. Dependence of height increment of Douglas fir provenances on longitude

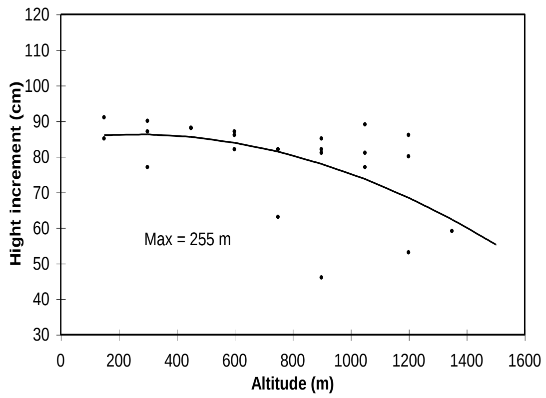

Figure 3. Dependence of height increment of Douglas fir provenances on altitude

The statistical analyses in this study confirmed the significant differences among provenances at these two locations. In approximately 50% cases, there is a hightly statistically significant difference. As all the provenances were primarily brought to a approximately the same site conditions, the observed differences in tree development are ascribed to genetic factors. (Lavadinovic and Koprivica 1996, 1999). By analyzing the dependence of the provenance latitude, longitude and altitude on the height increment we recorded significant differences among the provenances and differences between the tests.

The plants at the sample plot Juhor, at the same age, had a considerably higher value of taxation elements than the plants of the same provenances at the sample plot at the locality Tanda. This means that the beech site (Juhor) has better ecological adaptability than the oak site (Tanda).

Based on the analyzed characteristics, the most successful provenances are:

at the locality JUHOR: Oregon: 205-14, Oregon: 202-19 and Washington: 205-02

at the locality TANDA: Oregon: 205-14, Oregon: 202-19 and Washington: 205-31

Statistical analyses prove there are highly significant differences between provenances; thus, careful attention should be paid to the choice of which provenances to use. Based on the above ranking, it can be concluded that the provenances 3 and 18 showed good adaptation to site conditions, both at beech site, and at oak site; provenances 9 and 24 were poor and at both localities.

NORWAY SPRUCE (Picea abies /L. / Karst.) PROVENECE RESEARCH IN SERBIA

Norway spruce *(Picea abies /L. / Karst.)* provenance tests in Serbia consist of eight provenances, Isajev et al. 1992. Three provenances of this species are from Slovenia – Mašun, Menina and Jelovica; and five provenances are from Serbia – Golija, Zlatar, Čemerno, Radočelo and Kopaonik. The monocultures near Ivanjica were established by planting four-year old seedlings at three localities, at the altitudes of 600, 1100 and 1600 m. Isajev et al. 1992., 1999. The aim of the research was to identify the spruce differential characters and variability in the part of its natural range in the south-east Europe and to study the production capacity and the differences between individual provenances in more or less identical and different ecological conditions in Serbia, Šijačić-Nikolić et al. 2000.

In Norway spruce plantations, numerous researches have been undertaken included several morphometric characters of juvenile plants, for each year between 7 and 14 years of age, Ivetić 2004. The measured characters are height and height increment at the annual level, root collar diameter and diameter increment and the number of branches. The study results of metric properties were analysed by standard statistical methods.

The data on the variability of air temperature and precipitation at the study localities were obtained from the Republican Hydro-Meteorological Institute of Serbia. The effects of air temperature and precipitation on the study parameters were determined by Pearson's correlation coefficient. The values of temperature and rainfall were previously fitted separately for each locality. The soil characteristics were investigated by topographic observations and the soil profiles were opened for soil sampling. The laboratory analyses were performed at the Faculty of Forestry in Belgrade.

The results of the study of spruce potentials of different provenances confirm that the free genetic variability of this species is very high, and that, according to the results of the analyses, the Serbian provenances are characterised by higher adaptivity to very different ecological conditions. In this provenance test, in the plantation at the montane beech site where, as a rule, spruce does not occur naturally, its growth and adaptation are successful. This indicates that, in addition to the natural optimum in the zone of spruce belt *Picetum abietis serbicum,* its technogenic optimum can also occur at the site of other species. The study results obtained from all three altitudinal belts confirm the specificity of the spruce gene pool in Serbia, which conditions the phenomenon of its special climatogenic belt in Serbia, compared to other countries of the Balkan Peninsula. After the culmination of height increment of spruce trees and after the test plantations pass from the juvenile stage into the reproductive stage of development, by the establishment of tests with generative progeny, the nature of the interprovenance variability will be closer understood. The test results will enable the more reliable use of provenances with the most suitable potential for the establishment of stable and productive cultures on the concrete sites in Serbia. The comparative research of eight provenances shows that the provenances Golija and Zlatar are characterised by high adaptability and growth dynamics, so they should be more intensively applied in future activities of plantation establishment or afforestation of bare lands in Serbia. This study includes several morphometric characters of juvenile plants, for each year between 7 and 14 years of age. The measured characters are height and height increment at the annual level, root collar diameter and diameter increment and the number of branches. The study results of metric properties were analysed by standard statistical methods, figure 4.

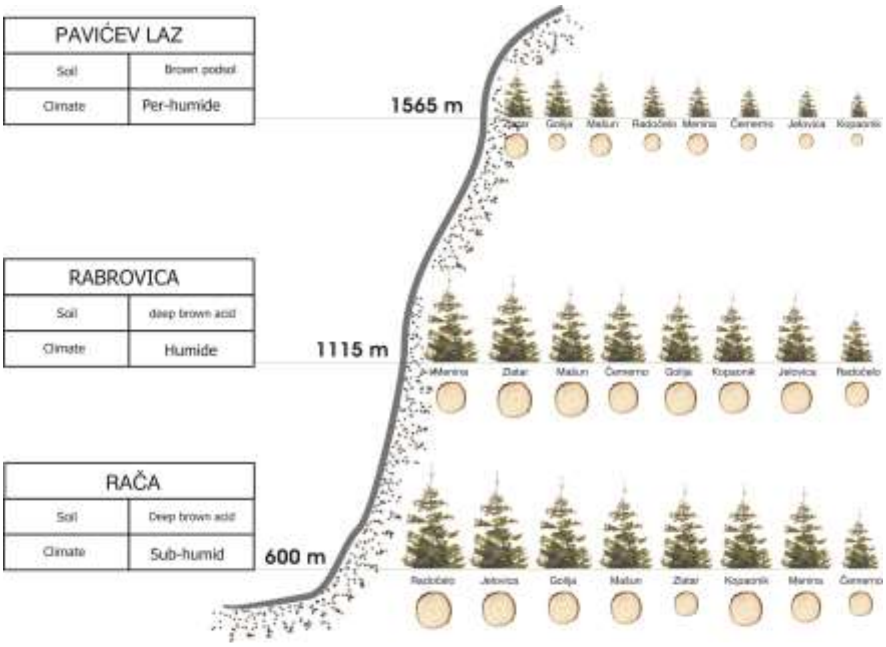

Figure 4. Comparative analyses of the Norway spruce provenance test in Serbia, Ivetić 2004

The results of the study of spruce potentials of different provenances confirm that the free genetic variability of this species is very high, and that, according to the results of the analyses, the Serbian provenances are characterised by higher adaptivity to very different ecological conditions. In this provenance test, in the plantation at the montane beech site where, as a rule, spruce does not occur naturally, its growth and adaptation are successful. This indicates that, in addition to the natural optimum in the zone of spruce belt *Picetum abietis serbicum*, its technogenic optimum can also occur at the site of other species. The aim of the research was to identify the spruce differential characters and variability in the part of its natural range in the south-east Europe, to study the production capacity and the differences between individual provenances in more or less identical and different ecological conditions in Serbia.

This study includes several morphometric characters of juvenile plants, for each year between 7 and 14 years of age. The measured characters are height and height increment at the annual level, root collar diameter and diameter increment and the number of branches. The study results of metric properties were analysed by standard statistical methods.

Conclusions

The aspects discussed in the present review are intended to assist in assessing the importance and potential of provenance research. They highlight the particular features of older experiments and indicate new uses which could be made of them which extend beyond the objectives for which they originally established. Therefore, existing field experiments should not be abandoned but thorough consideration should be given to their potential use in future research. They are often increasing in value because the genotypic responses to varying environmental influences are accumulating over time. With regard to the establishment of new field experiments the present review provides some guidelines and aims to stimulate the motivation to continue with this research. Douglas fir and Norway spruce provenance trials in Serbia are a special type of plantation experiment that helps us understand how trees are adapted to different environmental conditions through genetic adaptation or phenotypic plasticity. The fact that the provenance origin is known and that the ecological parameters of the provenance test sites are researched makes the study results applicable in future establishment of special-purpose Douglas-fir and Norway spruce plantations in Serbia for the production of good-quality wood. By different silvicultural measures, it is possible to control and direct the dynamics of tree increment in artificially established populations, which is the base for the production of raw materials suitable for both wood processing industry and end users of wood products. O. K.

Abstract

Selenium contents were analysed in eleven wild Amanita taxa: *A. caesarea* (Scop.) Pers., *A. excelsa* (Fr.) Bertill., *A. franchetii* (Boud.) Fayod, *A. gemmata* (Fr.) Bertill., *A. mairei* Foley, *A. muscaria* (L.) Lam., *A. pantherina* (DC.) Krombh., *A. phalloides* (Fr.) Link, *A. rubescens* Pers., *A. vaginata* (Bull.) Lam. and *A. verna* (Bull.) Lam. from Marmara region of Turkey by ICP-AES equipment. The common forest vegetation types in the research area are *Fagus orientalis*, *Carpinus betulus*, *Castanea sativa*, *Abies nordmanniana* susbp. *bornmulleriana*, *Pinus sylvestris*, *Pinus maritima* (cultivated) and *Quercu*s sp. communities. Selenium uptake were observed reaching different levels (from 0.1 to 11.5) in Amanita species in order to demonstrate possible spatial variations in Se composition of Amanita species by using multivariate analysis [cluster (CA)]. Selenium levels were determined as 0.1-1.10 mg.kg^{-1} (*A. citrina*), 0.1-2.20 mg.kg^{-1} (*A. gemmata*), 0.10-3.80 mg.kg^{-1} (*A. muscaria*), 0.30-3.80 mg.kg^{-1} (*A. excelsa*), 0.20-11.50 mg.kg^{-1} (*A. rubescens*), 1.10-2.70 mg.kg^{-1} (*A. caesarea*), 1.60-4.40 mg.kg^{-1} (*A. mairei*), 0.30-0.90 mg.kg^{-1} (*A. phalloides*), 0.70-2.50 mg.kg^{-1} (*A. vaginata*), 0.20 mg.kg^{-1} (*A. pantherina*), 3.70 mg.kg^{-1} (*A. franchetii*) and 3.20 mg.kg^{-1} (*A. verna*). The highest Se concentrations were determined at 11.5 mg.kg^{-1} in *A. rubescens*

Keywords: *Se, Amanita, Mushroom, Turkey*

Introduction

Many macrofungal species (mushrooms) have been used both for human's food and treatments of some diseases as well as for some different ethnobotanical purposes for centuries. They can be divided in two groups; first is a wild-growing group of fungi, from nature and the second is a group of cultivated mushrooms. Furthermore, according to their nutritional values, macrofungi can be grouped as poisonous, edible or inedible if they cause many types of poisoning affecting on the lungs, liver, stomach, kidney and central nervous system (Seeger and Stijve, 1980). Macrofungi contain the highest amount of water (approx. 92%) but also vitamins and mineral substances important for human health., 8% of fresh mushrooms in the remaining dry weight (d.w.) formed from the ash contains protein, fat, carbohydrate, vitamins, calcium, phosphorus, potassium, iron, copper, and fibre (Matilla et al., 2002). Since mushrooms are rich in mineral resources some minerals found in macrofungi can be used to treat people with mineral deficiencies (Nakalambe et al., 2015). Minerals can be grouped as macroelements (calcium, phosphorus, potassium, sulphur, chlorine, sodium, and magnesium) and microelements (iron, manganese, cobalt, copper, zinc, molybdenum, vanadium, chromium, tin, fluorine, silicon, selenium and iodine (non-metal)). Some authors have reviewed data about the heavy metal concentration in mushrooms and presented few data for the genus Amanita (Rudawska and Leski, 2005; Michelot and Siobud, 1998; Demirbaş, 2001; Falandysz et al., 2008; Kalać, 2010) whilesome reports concerning the selenium contents of mushrooms are also available (Michelot and Siobud, 1998; Cocchia et al., 2006; Tüzen et al., 2007; Falandysz, 2008). *A. caesarea* and *A. excelsa* are consumed by local people and they are expressed to be very delicious. Selenium, an essential trace mineral, has fundamental importance to human's health. As a constituent of selenoproteins, selenium has structural and enzymes roles, in the latter context being best-known as an antioxidant and catalyst for the production of active thyroid hormone (ref). Selenium is needed for the proper functioning of the immune system, and appears to be a key nutrient in counteracting the development of virulence and inhibiting HIV progression to AIDS (ref). It is required for sperm motility and may reduce the risk of miscarriage. Deficiency has been linked to adverse mood states. Findings have been equivocal in linking selenium to cardiovascular disease risk although other conditions involving oxidative stress and inflammation have shown benefits of a higher selenium status (Rayman, 2000). Selenoproteins have a role in maintaining redox balance, other functions are becoming increasingly recognized. As the roles of these selenoproteins are further characterized, a better understanding of the true physiological significance of this trace element will arise. This knowledge will be essential in defining optimum intakes to achieve cellular homeostasis in order to optimize health, including a reduction in cancer, for diverse populations (Davis et al., 2012). Due to the lack of studies concerning the content of selenium in the genus Amanita from Turkey, it is intended within this research to reveal the selenium content of 11 different species of Amanita. For this purposes 3 edible species (*A. caesarea*, *A. rubescens*, *A. vaginata*), 3 inedible species (*A. excelsa*, *A. franchetii*, *A. mairei*) and 5 poisonous species (*A. gemmata*, *A. muscaria*, *A. pantherina*, *A. phalloides*, *A. verna*) were selected. Selenium quantities were compared between edible, inedible and poisonous species.

Materials and Methods

Marmara region is located in northwest side of Turkey. Collection and identification of Amanita samples were collected from the nature and their collected localities, habitat are given Figure 1 and Table 1.

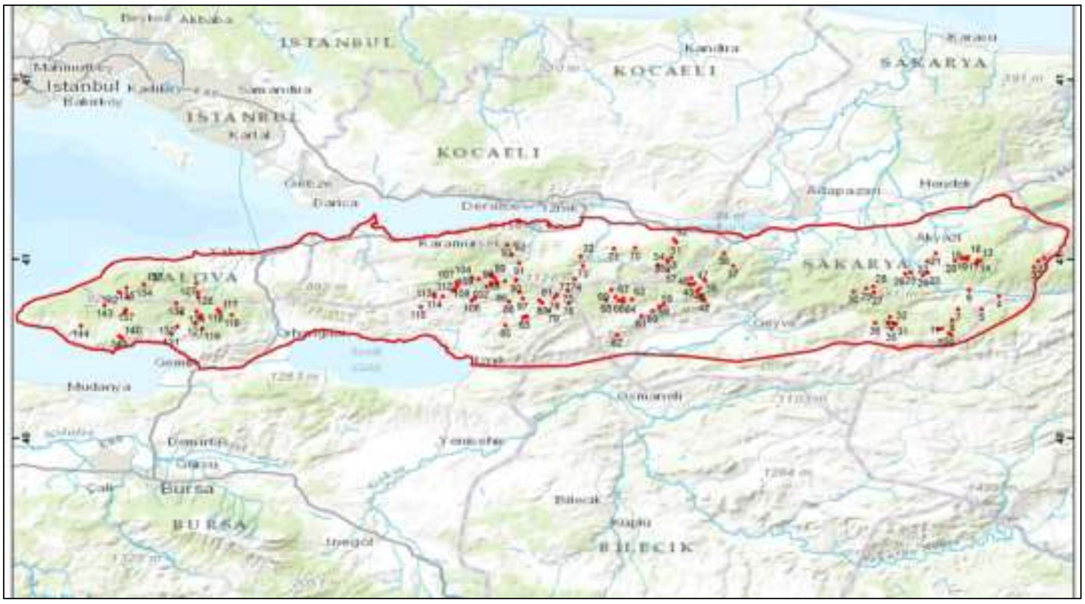

Figure 1. The sampling localities of *Amanita* taxa in the map.

For the identification of samples, the habitat and morphological characteristics of the mushrooms in the localities were noted and photographed, and then samples were placed in separate wicker containers to avoid mixing. The spore prints of mushroom samples were obtained and spore measurements were determined in the laboratory by using reference books (Moser 1983; Breitenbach and Kränzlin 2000). A voucher sample for each identified and dried material was kept at Selcuk University, Mushroom Application and Research Centre, Konya/Turkey.Dried and ground mushroom samples are digested in 1:1:1 aqua regia then analyzed by inductively coupled plasma-mass spectrometry (ICP-MS) ICP-ES/MS (AQ200) equipment of Bureau Veritas Element Company (Ankara and Canada). Cluster analysis of Selenium uptake in Amanita species obtained by Statistica 8.0 software were done to make a chemo taxonomical group along with morphological and anatomical identification.

Results and Discussion

Selenium content of Amanita species are given in Table 2. The reported Se contents of Amanita species in the literature are given in Table 3. The Cluster Analysis was presented in Figure 2. The Secontents for the studied species vary between 0.1 mg.kg^{-1} in *A. citrina* and 11.50 mg.kg-^{1} in *A. rubescens*. The ranking among taxa according to Se absorption of the species were as follows: as 0.1-1.10 mg.kg^{-1} (*A. citrina*), 0.1-2.20 mg.kg^{-1} (*A. gemmata*), 0.10-3.80 mg.kg^{-1} (*A. muscaria*), 0.30-3.80 mg.kg^{-1} (*A. excelsa*), 0.20-11.50 mg.kg^{-1} (*A. rubescens*), 1.10-2.70 mg.kg^{-1} (*A. caesarea*), 1.60-4.40 mg.kg^{-1} (*A. mairei*), 0.30-0.90 mg.kg^{-1} (*A. phalloides*), 0.70-2.50 mg.kg^{-1} (*A. vaginata*), 0.20 mg.kg^{-1} (*A. pantherina*), 3.70 mg.kg^{-1} (*A. franchetii*) and 3.20 mg.kg^{-1} (*A. verna*) (Table 2). The minimum and maximum Se uptake levels for edible fungi inedible fungi were between 0.2-11.50 mg.kg^{-1} in *A. rubescens*, for were 1.60-4.40 mg.kg^{-1} in *A. mairei* and for poisonous fungi were 0.1-6.30 mg.kg^{-1} in *A. muscaria*. According to the obtained results, the ratio of Sewas observed more frequently in edible fungi. The Se contents were reported 0.2-48.5 mg.kg^{-1} 48.5 mg.kg^{-1} in *Amanita muscaria* by Michelot et al., 1998 (Table 3). In our study, Se level was detected 0.1 to 6.3 mg.kg-1 in *A. muscaria*. Since Amanita taxa can not be classified systematically according to Se contents obtained by Cluster analysis, we assume that they do not have any features for chemo taxonomically sight although some groups were divides in cluster analysis (*A muscaria* group, *A gemata*, *A vaginata*)

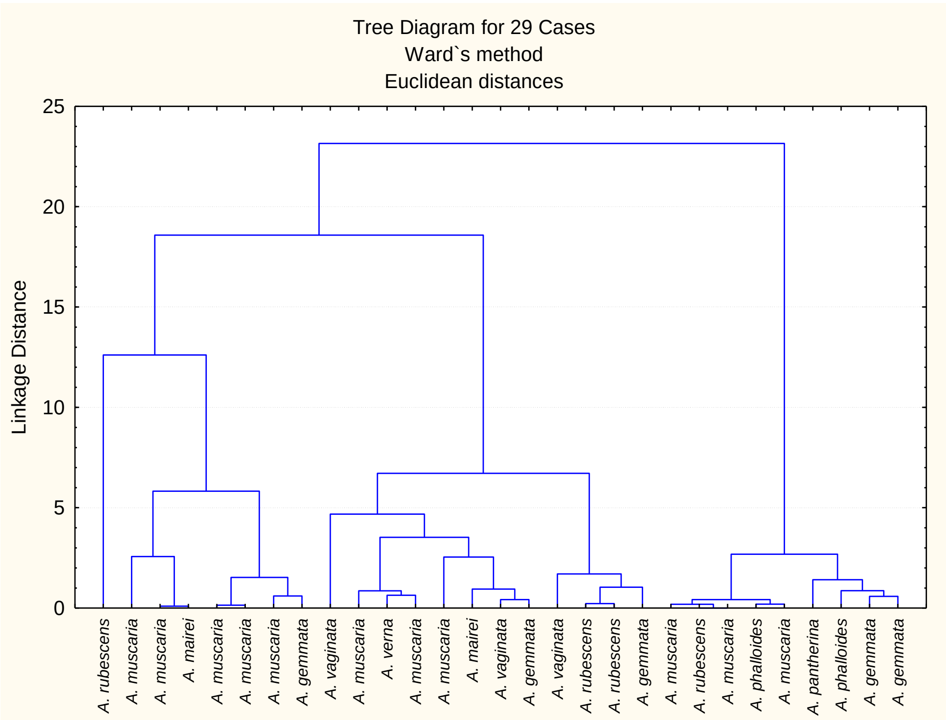

Figure 2. The Cluster Analysis of Se content of Amanita taxa.

Conclusion

Edible *Amanita* taxa, especially *A. rubescens* may become important in the diet as a possible source of Selenium. Poisonous or inedible *Amanita* mushrooms should not be consumed as food although they contain
According to our results, *Amanita* taxa cannot be classified for Selenium contest.

Abstract

In this research, special attention was focused on the correlation between biometric parameters of Norway spruce undergrowth's assimilation apparatus and the life viability of undergrowth. Biometrical parameters, such as mass, length and relative mass of spruce needles can be indicator of undergrowth's capability to change life viability category. Our study shows that positive transition of spruce undergrowth from category of "non-viable" to category of "viable" is mostly related with gradual changes of light conditions after non-clear cuts. All researches were conducted in Leningrad region which refers to the transition zone from the middle to southern boreal forests. There were selected objects with relatively heterogenic soil conditions, but related to same forest type (forest typology by Sukachev, 1961). This study was focused on biometrical characteristics of assimilation apparatus (measuring of average length and weight of needles with their pre-drying) of marked samples of spruce undergrowth before and after decreasing of stand completeness (after shelterwood cuts). Other needles parameters, such as specific weight and the lateral surface area, were defined analyticaly.

Keywords: *assimilation apparatus, Norway spruce undergrowth, vitality of undergrowth, light-conditions, stand completeness.*

Introduction

Assimilation apparatus is the basis of all physiological processes in plants. Therefore it is necessary to study in more detail the connection of the structure of this assimilation apparatus with viable undergrowth.

It has long been considered that the assimilation apparatus of representatives of one specie is morphologically different for the others not only depending on site conditions, but also depending on the position it has in the crown of the tree. (Maksimov, 1971; Alekseev, 1975; Yakushev, 1994; Gryazkin, 1999, 2001). The main reason for this is the different intensity of photosynthetically active radiation and a special microclimate.

It is well known that the regime of solar radiation and the efficiency of its use by plants depends on the he characteristics of the forest ecosystem itself. (Alexeev, 1975; Yakushev, 1994; Gryazkin, 1999). This study gives special attention to the connection of biometric characteristics of needles (Picea abies Karst.) with the life condition of spruce. These characteristics (in particular its abilities to adapt to changes of site conditions) are indirect confirmation of spruce's undergrowth ability to change its life viability in positive direction (especially with gradual changes of light conditions).

The objects of the study were three forestry enterprises in Leningrad region (North-West of Russia - the transition zone from the middle to southern boreal forest) with relatively large differences in soil conditions, however all of the objects belong to the «Piceetum oxalidosum» type of forests.

Materials and methods

The Lisinsky forest enterprise is characterized by heavy loamy soil with the formations of wetlands micro-depressions. Kartashevsky forest enterprise, which is located on the Silurian plateau, is characterized by well-drained fertile sandy soil. Roshinsky forest enterprise is characterized by the domination of sandy soils. Out of the total sample studied, the Kartashevsky forest enterprise is represented by 35 samples, Lisinsky by 45, and Roshinsky by 18 samples. Lisinsky samples of spruce undergrowth were marked before the non-clear cut was made. This fact allowed us to understand the connection between the dynamic of biometric characteristics in spruce needles, and changes of light conditions under the canopy. The distinguishment was made between three categories by the spruce undergrowth height (<0.5 m - small; 0,51-1,50 m - medium;> 1.50 m - large), and three categories of life viability (viable; unviable; dry).
To study the assimilation apparatus of spruce, its qualitative and quantitative indicators, the following indicators were measured: length and weight of 100 needles with pre-drying of needles until air drought was reached. Out of every model sample (which belonged to different categories of height and of life viability), a needled branch was taken. From every sample (by same height and life viability category), the branches of the same height level and cardinal directions were measured. After that, each branch was subdivided into annual shoots, and from these shoots needles were selected for further laboratory studies (minimum three samples of hundred needles each). After this, other relative indicator were analytically determined: specific weight (the weight ratio of 100 pieces of needles to their total length) and the lateral surface area of the needles (Gryazkin, 1999, 2001).All these biometrical indicators of assimilation apparatus were statistically analysed.

Results and discussion

The analysis of average indicators length, mass and specific weight of all needle samples, regardless of the category of height and viability, has shown that all biometric indicators of spruce undergrowth, growing under the canopy of the parent stands, are increasing with the relative decrease of completeness of the stand.

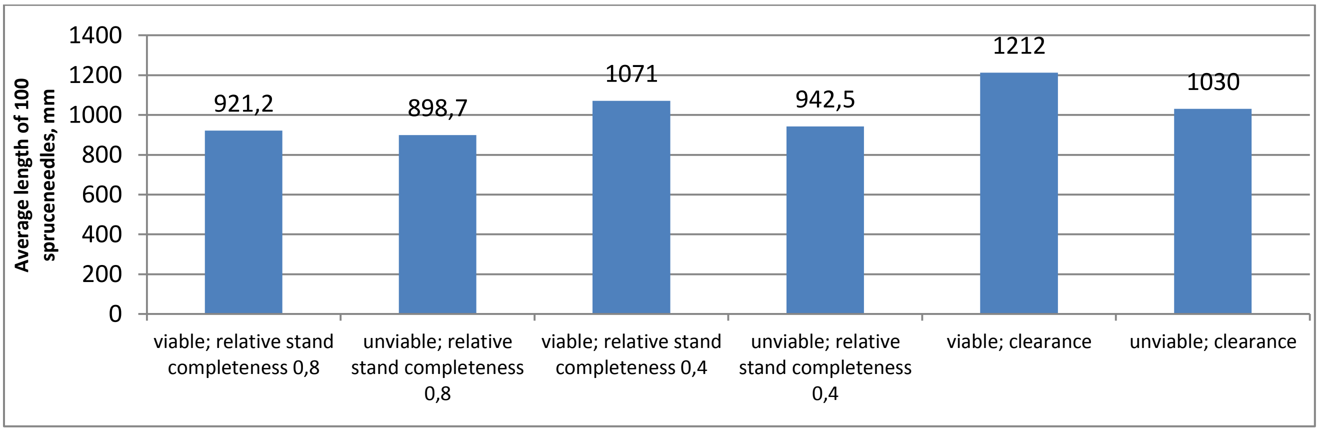

Figure 1 - Changes in the average length of the needles of spruce undergrowth, with different relative completeness of stand and life viability of undergrowth (Lisino forest enterprise)

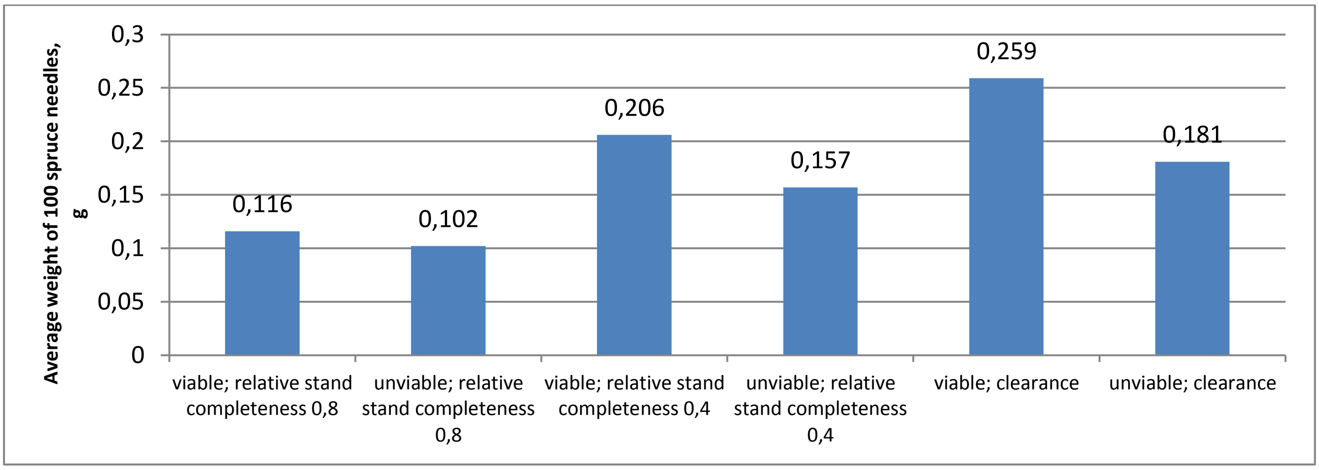

Figure 2 - Changes in the average weight of the needles of spruce undergrowth, with different relative completeness of stand and life viability of undergrowth (Lisino forest enterprise)

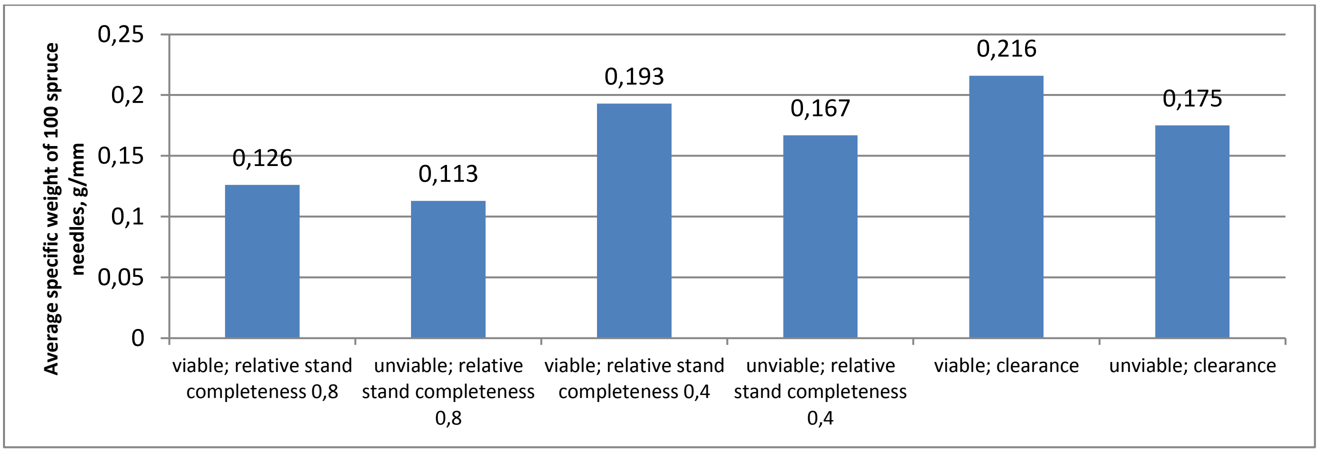

Figure 3 - Changes in the average specific weight of the needles of spruce undergrowth, with different relative completeness of stand and life viability of undergrowth (Lisino forest enterprise)

The most stable indicator, which describes the efficiency of photosynthetic apparatus in specific site conditions, is specific weight. The value of this parameter indicates that the fastest growing spruce undergrowth is located in cleared areas (if it appeared after cutting), and then gradually decreases, as the completeness of stands rises (see figure 3).

The specific weight is also a stable indicator of spruce undergrowth life viability. It is found that the greater the average value of the specific weight of the needles, the better is the life viability of regrowth in general.

The research of biometric parameters of spruce was directed to finding the correlation of its dynamics, depending on the life viability of spruce undergrowth. It was found that the average length, mass and specific weight of needles is, as a general rule, lower in unviable than in viable spruce undergrowth.

Table 1 presents data on the biometric characteristics of the average height of needles, under the canopy of spruce grove with completeness of 0.5 (Lisinski forestry).

Table 1. Average value of spruce needle's biometric characteristics (height of samples 0,5-1,5 m)

Categories of life viability and height	Average length of 100 needles (l_{100}), mm	Average weight of 100 needles (m_{100}), g	Average specific weight of 100 needles, g/cm*10^3
Viable spruce undergrowth (0.51-1.51 m)	1068±74.2	0.166±0.011	0.151±0.009
Viable spruce undergrowth (0.51-1.51 m)	879±81.1	0.103±0.013	0.120±0.010

The specific weight of needles in unviable undergrowth, when the relative completeness of stand is 0.5 is higher than the specific weight of needles in viable undergrowth that has relative completeness of stands of 0.8.
The research done by Z.M. Neumenko (1962) showed that the effect of clear-cuttings (in the «piceetum myrtillosum / oxalidosum» type of forest – completeness of stands 0,7-0,9) is that the spruce undergrowth that that is left over mostly died. The reason of that is the inability of assimilation apparatus to adapt to dramatically changed light conditions. However, the measurement of biometric parameters of marked samples of spruce in Lisinsky forest enterprise until and after the gradual cut (in which the completeness of stands decreases by few units) has shown that with the improvement of light conditions, many od unviable spruce undergrowths have become viable.
Comparison of biometric parameters of spruce needles in three forest areas (Lisisnkoe, Roshinsky and Kartashevskii) was carried out by the average values for all categories of size and viability.
All biometric parameters (length, weight and specific weight of needles) have the highest rates in Lisinsky forest enterprise, and the lowest in Kartashevskii forest enterprise (in which the full grown spruces are the most productive) (Table 2).

Table 2. Compare of average values of biometric characteristic of spruce undergrowth needles in three different forest enterprises; *relative completeness of stand 0,7-0,8; *«Piceetum oxalidosum» type of forests

Average value	Kartashevski forest enterprise		Roshinski forest enterprise		Lisinski forest enterprise	
	Viable	Unviable	Viable	Unviable	Viable	Unviable
Length of 100 needles, mm	815,0±72,1	763,9±79,5	894,3±62,9	847,9±67,4	921,2±84,2	898,7±86,1
Weight of 100 needles, g	0,072±0,008	0,061±0,011	0,087±0,012	0,074±0,015	0,116±0,017	0,102±0,021
Specific weight, g/cm*10^3	0,087±0,003	0,079±0,005	0,096±0008	0,087±0,008	0,126±0,007	0,113±0,008

Environmental conditions the Lisinski forest enterprise are in the best accordance with the needs of spruce undergrowth. The specificity of Lisinski forest enterprise microclimate and soil conditions are allowing for spruce undergrowth to better show their competitive abilities. This is reflected in the development of the assimilation apparatus undergrowth. In the Kartashevskii and Roshinsky forest enterprises, environmental conditions are accompanied by great biological diversity, hence, the sharper competitive relationships, in which the development of spruce undergrowth is hindered, especially in early stages of its life.

Conclusion

Specific weight is the most meaningful measure of the activity of development of assimilation apparatus, reflecting differences in environmental conditions. This indicator differs slightly

for the undergrowth in clearings and those under the canopy of low-density stands (relative completeness of stands of 0.4). This leads to the conclusion that the relative completeness of stands of 0,4 is close to ideal for the growth and development of the assimilation apparatus of spruce undergrowth, in other words for the formation of viable spruce undergrowth.
Specific weight is a stable indicator of spruce undergrowth life viability in general. The higher the average value of the specific weight of the needles is, the better is the life viability of the undergrowth.
The average length, weight and specific weight of needles of unviable spruce undergrowth is, as a general rule, lower than those indicators of viable undergrowth, regardless of its height.
All main biometric parameters have the highest value in Lisinsky forest enterprise, and the lowest in Kartashevsky forest enterprise. Consequently, spruce undergrowth best shows its competitive ability on heavy loam soils.

Abstract

Trebević is mountain located in southeastern part of Bosnia and Hercegovina. Located southeast from Sarajevo, 1627 meters high and it is attached to mountain Jahorina. In the area of Trebević there is characteristic vegetation of Dinarids in which prevail forests of beech *Fagetum montanum ilyricum* (Fuk.et Stef. 1958), forests of oak and black hornbeam *Querco-Ostryetum carpinifoliae* (Horv, 1971), forests of beech and fir *Abieti-Fagetum dinaricum* (Treg 1957 em. P. cer 1976), forests of beech and fir with spruce *Piceo-Abieti-Fagetum* (Horv, 1967), forests of fir and spruce *Abieti-Picetum illyricum (*Horv *et al*., 1974), secondary forests of white pine and spruce, *Piceo-Pinetum illyricum* (Horv *et al.*, 1969). According to some authors 99 rare herb species and 14 species of mushroom were found in this area. Mountain area of Trebević has 146,22 ha of private forests in 294 plots with tree supply of 33358,43 m³/ha , also minefield area in 199,87 ha. Forests in state area equals 841,42 ha with tree supply over 107019 m³/ha.

Keywords: *Trebević Mountain, vegetacion of Dinarids, forest communities, condition of forests.*

Introduction

The biggest part of Trebević mountain belongs to climatic forest of beech and fir with spruce, in which are interpolated thermophilic phytocenosis, pine and oak forests. Lowest parts belong to beech and oak zone. Orthographic conditioned forests of oak (*Quercus petraea*) occupy warmer areas, and colder areas belong to beech forests, mostly acidophilus character (Bojadžić, 2001). In canyon of Miljacka river below Trebević mountain exist forests of oak (*Quercus petraea*) and standard hornbeam, with orthographic conditioned forests of oak (*Quercus petraea*) that are in similar conditions spreading much more. According to horizontal sorting of forest vegetation in ex Yugoslavia (Braun-Blanquet) according to (Stefanović *et al.*, 1977), this region belongs to domain of inner dinarids, region of eastern-bosnian plateau. Region of eastern-bosnian plateau covers mountain areas around Sarajevo and Varšen till canyon of Drina river with large plateau of Romanija mountain (Bucalo, 2002). Protected plant species that we find in the Trebevic area which are on the red list are: *Picea omorica* Pancic., *Orchis mascula, Scabiosa leucophylla* (Šilić, 1990). In the geological heritage of this region, various sedimentary, magnetical and metamorphic rocks are involved – paleosolic, Mesozoic and kenozoic (Antić *et al.*, 1982) The Trebevic area belongs to the zone of Mesozoic limestone, besides Trebvic in the mentioned zone there are the mountains Maglic, Bjelasnica , Igman, Visocica, Treskavica and others. This zone is dotted with river valleys, cliffs and canoyns. The core of this zone is the Sarajevo-Zenica basin (Ćirić, 1989). The aim of this work is to collect data related to ecological parameters, as well as to present the exact surfaces of a certain area, depending on the forest category in the area of Trebevic Mountain.

Material and Methods

In this text will be mentioned what are the vegetation communities that are deployed in the Trebevic area. In addition to the above, we will analyze the threat of forests in terms of ‘’natural enemies’’ as well as what protected areas are defined. In the Trebevic Mountain area, the most commonly used forest breeding tupe is: high forests of fir and spruce with beech on lime and dolomite series of mostly shallow soil (area 266.58ha). Largest part of area is above 1000m high. Climate is having mountain character, but from november till may it is noticed influence of continental climate. During vegetational period falls around 52 % of all yearly rainfalls. From forest-breeding and areal arrangement standpoint of forests total area of Trebević mountain is spread across 1,302.95 (ha), with minefield area of 177.82 (ha). According to performed vegetational and pedologic mappings on Trebević mountain area, production types of forests are selected and formed next classes:

Wider category of forests: ***High forests with natiral regeneration***
Narrow category of forests:

1. *High forests of fir and spruce with beech from series of limestone and dolomit mostly shallow grounds* (area 266.58 ha)
    - *High forests of fir and spruce in shallow limestone grounds* (area 9.02 ha-minefield)

Wider category of forests: ***Forest culture***
Narrow category of forests:

1. *forest culture of spruce in field of beech forests and fir with spruce at mostly shallow limestone grounds* (area 33.12 ha)
2. *forest culture of pine (munika)and dark pine in field of beech forests and for with spruce in shallow limestone grounds* (area 1.47 ha)
3. *forest cultures of white pine in field of beech forests and fir with spruce in mostly shallow limestone grounds* (area 51.33 ha)
4. *forest cultures of white pine in field of beech and fir with spruce at mostly shallow limestone and dolomit grounds* (area 17.02 ha)
    - *forest cultures of white pine in field of beech forests and fir with spruce in mostly shallow limestone and dolomit grounds* (area 130.22 ha-minefield)

Wider category of forests: ***Offspring forests***
Narrow category of forests:

1. *offspring forests of beech and other leaf-trees in mostly shallow limestone grounds* (area 2.80 ha)
2. *offspting forests of other leaf-trees at mostly shallow limestone and dolomit grounds* (area 184.05 ha)
    - *offspring forests of other leaf-trees at mostly shallow limestone and dolomit grounds* (area 4.23 ha-minefield)

Wider category of forests: ***Areas available for tree planting and management***
Narrow category of forests:

1. *thorns* (area 128.86 ha)
    - *thorns* (area 31.82 ha-minefield)

2. *grass field* (area 48.50 ha)
    - *grass field* (area 2.31 ha-minefield)

Wider category of forests: ***Areas non-available for tree planting and management*** (area 382.19 ha)

- *Areas non-available for tree planting and management* (area 0.22 ha-minefield)

Wider category of forests: ***Usurpation*** (area 16.21 ha)

When we talk about forest vegetation, most common are forests of beech and fir with spruce (*Piceo-Abieti-Fagetum*) in which are oftenly widespread secondary forests of white pine and spruce, (*Piceo-Pinetum illyricum*), *also* forests of fir and spruce, (*Abieti-Picetum illyricum*). Lesser areas occupy secondary forests of beech (*Fagetum montanum et Luzulo-Fagetum*). Oak group, forests of oak (*Quercus petraea*) and oak (*Quercetum petraeae-cerris*), also forests of oak (*Quercus petraea*) and hornbeam (*Querco-Carpinetum*), forests of oak (*Quercetum petraeae montanum*) (Stefanović *et al.*, 1983), are mostly connected to lower areas towards field of Sarajevo (Bucalo, 2002), and basin of Željeznica and Dobropoljska river.

Results and Discussion

Forests in teritorry of Trebević mountain, like all other forests, have their „enemies", natural and others, biggest enemy for forests are humans. Natural factors, as connected part of ecosystem, are working constantly and they are affecting living stability, and humans, besides their effort to help forests, are making mistakes that somethimes have catastrophic consequences for forests (Medarević, 2005). Procedures of degradation and ruination of living habitat take place constantly and continously, their intensity depends on infavorable natural processes and events (natural dissasters, calamities and other), human activities and technical-technological development. Most common factors are: consequences of strong winds (windbreakings and wind roll-outs), consequences of huge snowfall (snowbreakings and snow roll-outs), fire consequences, consequences of air-pollution (sour rains), ground pollution and other. Insects, herbal disseases and pests are constantly present and besides beneficial functions of forest as community, when too much multiplied, can cause huge damages. For forests in private ownership there is no exact data on how much is ruined from insects. In forests managed by state most usual and ,,mosts attractive" insects in this region are *Ips typographus, Pitiogenes chalcographus and Xyloterus lineatus*, so it can be assumed that those are biggest pests in private areas too. There is large number of wild junkyards at forest areas, which are consequence of carelessness of citizens, catering facilities and woodworking capacities. Ministry of forest areas from past warfare occupies (177,82 ha), and majority of this area is at tall forests with natural regeneration. Consequence of that is in innability to access and usage of required managmement systems, which can cause ecosystem instability and damaging impact to surrounding area. All forests have global, regional and local value, but when some of those values are considering extremly important, forest can be defined as forest of high protected value (HPV). It means that in forests like that should be performed apropriate management to save and promote existing values. First steps for separating high protective value presume gathering specific documentation (international, state and entity legislation, decision of local comunities, forestry managements, special studies, mapings, etc.) that represent basics for selection of field that need to be investigated for this purpose. For some categories of high protective value somethimes is nessesary to publish more investigations in diferent seasons, which is specially associated to different and migrational kinds of organisms. In area of Trebević mountain important boundary in forestry management implies existance of mine-explosives. Forest minefields from past warfare occupies (177,82 ha). Consequence of that is in innability to access and usage of nessessary management systems, that can lead to instability of ecosystem and it's damaging influence on surrounding area. Highly protected values, also covers exeptionally ecological attributes and ecosystems products and social functions. With coordination of existing lawful regulations and definitions HCVF (High Conservation Value Forests), there is six diferent categories „highly protected values“. In the area of Trebević there are separated two categories of highly protected values and their criteriums and sub-criteriums:

HPV-1: forest areas that contain global, regional and stat important concentration of biodiversity (area 974.07 ha).

1a: protected areas

1b: endangered species and specoes in danger

1c: endemic species

1d: important occasional concentrations

HPV-4:forest areas that supply basic natural protection in critical situations**.**

4a: forests important for water flow

4b: forests important for erosion control

4c**:** forests that create big obstacles to wildfires.

Conclusions

-Planning the management of forests in Trebevic area has a limiting character, both due to the presence of protected areas, due to mined terrain (177.82ha). Forest planning and management should be based on the objective of preserving and improving the stability, productivity and diversity of forests of fir and spruce with beech on limestone substrates.

Abstract

In recent years there has been a change in perception towards gardens in urban and peri-urban areas. In addition to the attractive appearance, plants are also expected to provide a certain benefit to their host, in the form of food, spices, medicine or other. In the city gardens of Banja Luka, Bosnia and Herzegovina, for a long time have been present Damask rose and Maule's quince. In recent years appears the plant stevia.
Samples of fresh flowers of Damask rose, fresh fruits of Maule's quince and fresh leaves of stevia were collected from a large forest garden and analyzed on the content of secondary metabolites and antioxidant activity. Analyzes were carried out in six parallel repetitions and the results are expressed as mean value ± standard deviations. The analysis was carried out on the following: total phenols, flavonoids, flavonols, anthocyanins, and monomeric anthocyanin, the effect of the sample on DPPH radical and the ABTS test. Values of listed parameters were compared to data from other countries, since in B&H similar research has not been executed so far. Obtained results indicate that all three observed species exhibit undoubted antioxidant properties, apart from their aesthetic and other use values.

Key words: *Damask Rose, Maule's quince, stevia, secondary metabolites, antioxidants activity*

Introduction

Not so long ago beautifully landscaped gardens were the privilege of upper class and wealthy individuals. Today, almost every family house in the urban and peri-urban areas has a garden. In it, depending on the owner's commitment and available space, they encounter not only decorative but also medicinal and nutritional plant species (MacCaskey, 2006; Remiaz, 2017). With the affirmation of so-called forest gardens, the classical division into a floral garden, orchard and vegetable/kitchen garden, slowly disappears.
Concise definition of forest gardens is given by Jacke and Toenmeier (2005). *They are perennial polyculture of multipurpose plants*. Perennial, because they are renewed every year, without the need for new planting. Polyculture, because more different plants live in harmony, sharing the common space. Multipurpose plant properties, implies that plants are in the garden for more purposes: aesthetic, nutritious, protective, etc. The forest garden looks like a forest because there are herbaceous plants, shrubs and trees in it, but in any case it does not even have to be its imitation. One forest garden is the unique and unrepeatable creation of its designer or owner. This is where
lies the greatest attraction and the challenge of forest gardens, to design an ecosystem according to own wishes, which does not exist elsewhere on planet Earth, and on top of that gain some benefits from it.
Guided by the principle of originality, we have focused on three species in a forest garden in Banja Luka, Bosnia and Herzegovina, analyzing their aesthetic values, antioxidant properties and some other benefits. While the usability properties can be sufficiently approximated by

chemical composition or pure number, the aesthetic value estimation is burdened by the subjectivity of individual perception; what is being said - *De gustibus (et coloribus) non est disputandum.* Since there is still no uniform or at least a slightly widespread acceptance of methodological approach for assessing aesthetic values of forest gardens or gardens as a whole, we have applied a simple own concept. It is based on five characteristics in four gradations.

Materials and methods

The experimental materials were flowers of Damask rose, fruits of Maule's quince and leaves of stevia, collected in a forest garden of the city of Banja Luka (Ph. tab. 1) during 2016 and 2017.

Photo table 1: Experimental material (taken by S. Ljubojević)

Flower of Damask rose

Fruit of Maule's quince

Leaves of stevia

Damask rose

Damask rose, rose of Castile (*Rosa* × *damascena* Mill.) is a flowering bush that is no longer found growing wild. It has been considered a cultivar that springs from *Rosa gallica* L. and *Rosa moschata* Herrm., leading the origin of the Middle East. However, Iwata *et al*. (2000) have shown that her roots go to central Asia, and that one more rose, *Rosa fedtschenkoana* Regel, is included in her genetic record. Damask rose is a deciduous bush that reaches 2 meters in height. Its dominant feature are numerous, large, pink flowers of intense and pleasant odor. The Turks brought Damask rose to the Balkans in the 16th century, and in the 17th century its mass cultivation in Bulgaria began to produce the famous rose oil (Kapetanović, 1988). In Bosnia and Herzegovina it was never used for oil production. Its role was of decorative nature and from the flowers were prepared juice, fragrant rose water and vinegar, and sweet as well. Today flowers of Damask rose are a highly valuable raw material of wide use. Apart from the essential oil, one can find other various commercial products such as: cosmetics (fragrances, shampoos, mouth fresheners), food, sweets, healing preparations etc. Recent studies have shown that leaves of Damask rose also possess respectable antioxidant properties and can be used without restriction as a healthy tea (Baydar and Baydar, 2013).

Chemical composition and antioxidant activity of Damask rose flowers from different part of the world is quite variable (Tab. 1). More detailed chemical analysis has yet to be done in B&H.

☒Maule's quince

Maule's quince, Japanese quince belongs to the genus *Chaenomeles*, so-called flowering or Japanese quinces. According to Rumpunen *et al*. (2003), the most commonly cultivated "japonica" *Chaenomeles* are actually the hybrid *Ch.* × *superba* and *Ch. speciosa*; *Ch. japonica* itself is not commonly grown. Japanese quince is a dense shrub covered with thorns, up to 2 m high. The flowers are with five petals, in the color scale from pink, over pale red, orange to extremely red, sometimes in two colors with the addition of white. The fruit is roundish-oblong pome (Ph. tab. 1), initially green and in the stagnant stage yellowish or yellow. It is smelly and remains for a long time on branches after ripening. Japanese quince fruit is a quality raw material for the production of various healthy nutritional products such as: caramels, juices, syrups, carbonated soft drinks, liqueurs, jams and preserves (given the high pectin content). Also recognizable feature of Japanese quince is the beauty of its flowers. Except as a decorative individual shrub or as a spiny live fence, Maule's quince is also suitable for cultivation as a bonsai (Kawolek, 1987).

1/ catechin equivalent

The chemical composition of the fruit is variable and dependent on the climate (Hafez-Taghva *et al*., 2015; Lesinska *et al*., 1988). According to analyzes performed in Lithuania and Poland, the fruit of Japanese quince, among other things, possesses enviable content of total phenols and antioxidant properties (Tab. 2). Considering the better geographic position, in terms of a greater number of sunny days and higher mean annual temperatures, it is expected that the material from our climate will show similar, if not better, characteristics. However, no one has yet been involved with such chemical analysis in B&H.

Stevia

Stevia (*Stevia rebaudiana* Bertoni) is a herbaceous perennial plant that belongs to the *Asteraceae* (*Compositae*) family. Genus *Stevia* consists of approximately 230 species native to the South and North America. The plant reaches a height of 80 (100) cm. Leaves are tiny, elliptical, in alternate arrangement. The flowers are gathered in the inflorescence *capitulum* with five white tubular flowers, coming out from leaf armpits (Ph. tab. 1). It is a short-day plant that blooms from September to December in our environment. In its native range, stevia behaves like a perennial plant that can last four to five years, but in colder climate it is treated as an annual plant.
Stevia tissue has a complex chemical composition, well-known for its high content of sweet components. Their concentrations decline from leaves, over flowers, stem and seeds to roots, so the leaves are double sweeter than the flowers. Apart to the sweet components, it is considered that leaf extract possess a high level of antioxidant activity and useful phenolic compounds (Tab. 3). In addition to its use as a natural sweetener, the leaf of stevia has an important place in traditional medicine, first of all in South America.

Table 3: Chemical composition and antioxidant activity of stevia leaf

Origin of the material	Value	Unit	Source
Total phenols			
Dried leaves from a shop, Germany	63.8 ± 1.3	mgGAE/g	Periche *et al*., 2014
Dried leaves from a farm, South Korea	130.76	μg CAE[1]/mg	Kim *et al*., 2010
Total flavonoids			
Dried leaves from a shop, Germany	22.2 ± 0.9	mg CAE/mg	Periche *et al*., 2014
Dried leaves from a farm, South Korea	15.64	μgQc/mg	Kim *et al*., 2010
Antiradical activities			
Dried leaves from a shop, Germany	48 ± 2	mg Trolox/g	Periche *et al*., 2014
Leaves from dedicated plantation, India	38.24 0 ± 0.36	mg Trolox/$g_{d.w.}$	Tadhani *et al*., 2007

Preparation of materials

Five grams of each kind of material was weighed and transferred to the Erlenmeyer flask with 20 ml of 80 % ethanol. Thereafter, the sample flask was placed in an effervescent bath (50 Hz), twice for five minutes, and then connected to the return cooler. The extraction lasted 10 minutes after the boiling moment. After cooling to room temperature, filtration is performed and the remaining precipitate is returned to the conical flask with addition to 20 ml of 80 % ethanol and extracted for another 10 minutes, then filtered again in a flask containing the first filtrates and supplement by 80 % ethanol up to the mark. In this way, a parent liquor concentration of 0.1 g/ml was obtained which was used for all other determinations.

Determination of the content of secondary metabolites and antioxidant activities

Total phenols were determined by modified Folin-Ciocalteu assay (Wolfe *et al*., 2003). For making of calibrated line, the gallic acid was used (thereby, y = 0.003x - 0.0226, R^2 = 0.9975, y - absorption, x - concentration of gallic acid in μg/ml). The results are expressed as phenol equivalent to gallic acid, i.e. mgGAE/$g_{f.w.}$. Determination of total flavonoids was done using the method of Ordoñez *et al*. (2006). Total flavonoid content is counted as the flavonoid equivalents of quercetin (μmolQc/$g_{f.w.}$) using the equation of the calibration line (thereby, y = 0.0368x - 0.135, R^2 = 0.9996), y - absorption, x - concentration of quercetin in μg/ml). The results are expressed as μg Qc/$g_{f.w.}$. Total flavonols was determined by the method of

Kumaran and Karunakaran (2007). For making of calibrated line, the quercetin hydrate was used (thereby, $y = 0.0214x + 0.004$, $R^2 = 0.9993$, y - absorption, x - concentration of quercetin in μg/ml). The results are expressed as μg Qc/$g_{f.w.}$. The DPPH test was carried out applying the method Liyana-Pathirana and Shahidi (2005), while the ABTS test was performed using modified method of Re *et al*. (1999). Trolox was used to create calibrated lines. For the DPPH test equation was: $y = 7.0993x - 0.434$ with $R^2 = 0.9722$, and for the ABTS test: $y = 15.94x + 10.527$ with $R^2 = 0.9984$. The results were expressed with TEAC (Trolox equivalent antioxidant activity) value, i.e. as μg Trolox/$g_{f.w.}$. All experiments were performed in three parallel repetitions, and the results are expressed as the mean ± standard deviation (Table 4). Quantitative determination of total anthocyanins is based on the anthocyanin's ability to reversibly alter their structure by changing the pH of the medium, resulting in an absorption spectrum change. The content of total anthocyanins was determined by the "single" method by which anthocyanin absorbance was measured at pH 1.0, proportional to the total anthocyanins content. The content of monomeric anthocyanins was determined by the pH differential method based on the monomeric anthocyanins characteristic that they are in oxonium form (colored in red) at pH 1.0, while at pH 4.5 they are in hemiketal form (colorless) (Giusti and Wrolstad, 2001); concentration was calculated as the equivalent of cyanidin-3-glucoside.

Evaluation of aesthetic values

Since there is still no uniform or at least widely accepted methodological procedure for assessing aesthetic values of forest gardens, or gardens as a whole, we have applied a simple own concept. It is based on five attributes (given in declining rank): I - aesthetically pleasing, II – odor, III - companionability, IV - maintainability, V - soundness. Under aesthetically pleasing we consider: nice color and elegant and harmonious form (habitus). Odor is expected to be pleasant and to provide a sense of comfort and relaxation. Companionable means that plant has a stable and non-expansionist footprint, and is able to fit nicely into available space. Maintainability means ease of pruning and absence of thorns. Under the soundness we understand resistance to diseases and pests, as well as not providing the shelter to the same. Each of these attributes can be expressed in four gradation: 1. – negative (when the plant species or its properties reduces the overall value of the forest garden), 2. – unenlightened (when the plant species or its properties does not adversely affect the garden, but also does not contribute to its overall value), 3. – positive (when the plant species or its properties increases the overall value of the forest garden), 4. – decisive (when the plant species or its properties has a big to crucial impact on the overall value of the forest garden).

Results and discussion

The obtained results show that all observed species contain significant amounts of phenols. It is preceded by the Damask rose flower, followed by the stevia leaf and the fruit of Maule's quince (Tab. 4). Absolutely the highest concentration of flavonoids and flavonols has the fruit of Maule's quince. Anthocyanin content can not be compared because no analyzes were made on fruits of Japanese quince and leaves of stevia. When it comes to ability of herbal material to scavenge the DPPH radical, the greatest potential shows fresh leaf of stevia, while the best ability to quench the ABTS+ has fresh fruit of Maule's quince.

Table 4: Chemical composition and antioxidant activity of observed species

Paramerters	Units	Fresh flowers of Damask rose	Fresh fruit of Maule's quince	Fresh leaves of stevia
		Mean value ± standard deviation		
Total phenols	$mgGAE/g_{f.w.}$	26.412±0.886	6.385±0.479	8.805 ± 0.493
Total flavonoids	$\mu gQcE/g_{f.w.}$	14.539±0.682	74.391±12.75	2.31 ± 0.49
Total flavonols		1.485±0.045	11.535±0.496	2.292 ± 0.352
Total anthocyanins	$mg/g_{f.w.}$	4,874±0,01		
Total monomeric anthocyanin		4,062±0,006		
DPPH (IC_{50})[1]	μg Trolox/$mg_{f.w.}$	0.2985±0.0035	1.306±0.269	2.507 ± 0.08
ABTS (IC_{50})		0.1065±0.0015	7.64±0.029	4.862 ± 0.029

1/ IC_{50} (concentration required for 50% inhibition of DPPH radicals

Results for flowers of Damask rose are inferior to the results achieved in the southern and warmer regions, by all parameters (Tab.1). One part of the differences is likely to be explained by a better starting material. Namely, the samples for analysis in Saudi Arabian work have been taken from a farm of roses and in Turkish work from a research center for selection. The second part of the difference is certainly due to natural factors. Findings of Vinokur *et al*. (2006) and Ginova *et al*. (2013) that the antioxidant capacity of Damask rose petals correlated well with the contents of total phenols, has not been confirmed. We have gain a relatively high content of phenols but a relatively lower antioxidant capacity. Compared to the types of fruit that are known to have high content of anthocyanins (bilberries, blackberries, black currants etc., Giusti and Wrolstad, 2001), our results are better.

The content of total phenols in the fruit of Maule's quince is somewhat lower (by about 30 %) compared to the material originating from Poland and the Baltic countries (Tab. 2). For other parameters, it is ungrateful to compare quantitative parameters since they are calculated in different ways and expressed in different units. And in this case, one part of the difference is likely to be explained by the better starting material, bearing in mind that the Japanese quince is a popular domestic fruit in this areas.

Locally produced leaf of stevia has the slightest arrear in the observed parameters compared to the other two species, especially when it comes to flavonoids (Tab. 3).

As has been said, a deeper and more comprehensive comparative analysis complicates the differences in the methodology of collecting, processing and interpretation of data, especially when it comes to units in which a particular parameter is expressed.

From the aesthetic point of view, all three species meet the highest standards (Tab. 5). The most prominent attributes have Damask rose. If there is no thorns, which to a certain extent makes maintenance and passage of a forest garden a little bit difficult, this plant could be considered perfect, especially its cultivars and varieties with a prolonged period of flowering. Very close to Damask rose is Maule’s quince, which also has thorns, with the difference that its odor is somewhat less pronounced. At first glance stevia may be considerably smaller and inconspicuous than these two bushes. However, it has its own trumps, which are reflected in excellent companionability, ease of maintenance and soundness.

Table 5: Evaluation of aesthetic values

Rank	Attributes	Plant species/gradation of attributes											
		Damask rose				Maule's quince				Stevia			
		1.	2.	3.	4.	1.	2.	3.	4.	1.	2.	3.	4.
I	Aesthetically pleasing												
II	Odor												
III	Companionability												
IV	Maintainability												
V	Soundness												

Conclusions

Damask rose, Maule's quince and stevia deserves to be found in every forest garden. They have undoubtedly multipurpose properties that are reflected in utilitarian and aesthetic attributes. All three species are also suitable for the green spaces designed for health and well-being, so call healing garden, which was not the subject of this paper. All observed species contain secondary matabolites at concentrations that contribute to their antioxidant properties. In case of desire or need, with Damask rose and Maule's quince there is a significant space for increment of these parameters by the introduction of superior herbal material, considering that traditional and unselected herbal material has been analyzed, which has existed for years in the observed area.

Damask rose possesses the most prominent aesthetic attributes in accordance with the set criteria. It stands out with a nice appearance, a pleasant odor, with companionability and soundness. From her flowers, one can get juice, fragrant rose water, fragrant vinegar, sweet, even essential oil, and from flowers and leaves, fragrant, refreshing and healing tea.

From aesthetic point of view, the Maule's quince is very close to the Damask rose. In the flowering phase, which, unfortunately, is relatively short, its occurrence is simply incomparable. Its fruits are also beautiful and attractive, especially because they remain on the branches for a long time. From fresh fruits owners of the gardens can prepare juices, syrups, liqueurs, jams, and from dried ones nice and healthy vitamin tea.

In terms of appearance, stevia may be considerably smaller and inconspicuous than previous two bushes. However, it also has several affirmative aesthetic traits, which are reflected in excellent companionability, ease of maintenance and soundness. From the utilitarian point of view, stevia probably provide the most useful benefit to garden owners because it permanently deprives them of the need to procure voluminous and unhealthy crystalline sugar. In addition to its use as a natural sweetener, overhead parts of the plant are suitable for the preparation of traditional medicinal products of wide use.

PHENOTYPING TREES FOR TRAITS RELATED TO DROUGHT STRESS TOLERANCE – IMPORTANCE AND CHALLENGE

Doris KRABEL*, Matthias MEYER, Bayartaa NYAMJAV, Birgit REICHE, Alexander SOLGER

Molecular Physiology of Wood Plants Group, Institute of Forest Botany and – Zoology, Dresden University of Technology, Tharandt, Germany
*Corresponding author: doris.krabel@tu-dresden.de

Abstract

Results from green-house experiments on the early development of shoots and roots from hardwood cuttings of three different poplar genotypes and seedlings from oak (*Quercus petraea* and *Quercus robur*) will be presented. Already after an experimental time of 65 days (poplar hardwood cuttings) respectively 73 days (oak seedlings) in pots, the young plants showed a clone/ species specific growth performance. For all the species the plants were treated with two levels of irrigation (fully and reduced irrigation). For aboveground components traits of interest have been fresh and dry mass, number of shoots, length of shoots, number of leaves and leave area. For the belowground components root fresh and dry biomass, the total root length were analysed for each clone resp. each population. The results will highlight the effects of different irrigation treatments on the plant's growth performance which emerge already after just a few weeks from the beginning of the experiment. Based on our experimental design, it should be possible to develop a robust method for high throughput phenotyping of trees in an early developmental stage.

Keywords: *poplar, Quercus spec., pot experiment, early root/ shoot development*.

Introduction

Within the last decades tremendous efforts have been undertaken on the development of efficient methods for phenotyping crop plants (e.g. Fiorani and Schurr 2013, Araus and Cairms 2014). These efforts are justified insofar as their application produces results which are essential for the interpretation of results from genetic and genomic analyses. The combination of both approaches improves the understanding of biomass regulation and lead to the development of crops with superior agronomic performance (Zhu et al. 2011). Although enormous progress has been achieved in the automation of measuring a bunch of phenotypic traits of various economical important plant species, these approaches don't include the characterization of phenotypic traits of trees (Krabel *et al.*, 2015). There are several reasons for disregarding woody plant species: 1. most traits of interest (e.g. wood quality, resistance to biotic and abiotic factors) are only apparent after the plant was growing for several decades. 2. This implies that at this time trees are mostly several meters high and therefore they cannot be transferred into a green-house or kept elsewhere under controlled environmental conditions. 3. The economically most relevant tree species of European forests are almost ever cultivated from natural regeneration. In this case family structures are mostly unknown and pedigrees of F1 and F2 families don't exist except for a very limited assortment of woody species/families. Nevertheless, what's true for agricultural crop plants is also valid for woody plants - the improvement of a trees performance requires a combination of a detailed phenotypic characterisation and genomic analyses (Krabel *et al.*, 2015).

For molecular and phenotypic investigations, poplar species show some advantages compared

to tree species like oaks. Generally, poplars are flowering after a period of less than ten years, so controlled crossings for the establishment of F1 and F2 families are possible in a manageable period of time. Vegetative regeneration is easily possible (except for *Populus tremula*) and therefore the testing of clonal material for various treatments and applications on genetically homogenous plant material in a large scale is no problem. Last but not least the economic importance of the genus *Populus* increased throughout Europe and North America within the last decades (Dickman 2001, Zalesny *et al*. 2004) because of the usability as energy plant and the broad application of the timber.
Oak species belong to the beech family *Fagaceae* and genus *Quercus*. There are approximately 600 extant species of oaks, which include deciduous and evergreen species extending from cool temperate to tropical latitudes in America, Asia, Europe, and North Africa. *Quercus petraea* and *Quercus robur* are the main species that are found in the European deciduous forests (Thomas and Gausling, 2000). About 7% of the forest area in Europe is covered by oak trees (Szezepkowski *et al.* 2007). Here both species do not only play an ecological role in terms of biodiversity but also derive economic value for the wood industry and forest enterprises. Nevertheless, within the past decade the vitality of these two species severely decreased due to the changes of climatic conditions especially that of repeated drought events.
Especially during the first month of the plant's development, drought events cause severe problems not only for the plant's vitality but also for the economic success of the stand. Green-house experiments under controlled environmental conditions are a first step to identify plant material better adapted to dry periods especially during the critical phase of early plant development.
The present studies aimed to study the responses of early growth of roots and shoots of 3 hybrid poplar cultivars and the two species *Quercus robur* and *Quercus petraea* to two different irrigation regimes. Therefore glasshouse experiments were conducted with hardwood cuttings respectively seedlings grown in pots under well irrigated and under water stress conditions. The aims of these studies were to quantify responses of length growth, fresh and dry mass of roots and shoots in the early phase of plant development and to find out hints on the 'strategy' of the various genotypes dealing with deficit irrigation..

Material and Methods

Plant material – poplar cultivars: For this part of the investigation hardwood cuttings (20 cm long and ca. 1.5 cm in diameter) of three commercially available hybrid poplar varieties 'Max 3' (*P. maximowicii x P. nigra*), 'Muhle Larsen'(*P. trichocarpa x P. trichocarpa*) and 'Hybride 275' (*P. maximowicii x P. trichocarpa*) have been investigated. For the experiment 100 cuttings of each variety were assorted for homogeneity and then placed in 2 L polypropylene plant pots, one cutting per pot. The plant's substrate was 40% washed sand and 60 % potting soil (for more details see Krabel et al., 2015).
Plant material – oak species: 30 two year old seedlings from acrons of *Quercus petraea* (Tharandt 50,981675 N; 13,576199 E and 373 m above sea level) and 48 seedlings from *Quercus robur* (Graupa 51,00 N; 13, 550 E and 164 m above sea level) collected in autumn 2012 were placed in 4 L polypropylene pots in April 2014. The plant's substrate was 30% washed sand and 70 % potting soil.
The experimental design in the green-house followed the same procedure for both groups (poplar and oak) of plant material. Initially, all pots were automatically irrigated to saturation for approximately 20 days (poplar) and 50 days (oak). During this period of adaptation the young plants developed new roots and shoots. Then the groups were divided into a well irrigated collective and a collective with diminished water supply. For the water-stressed

group the water content was kept at 10% soil water content (measured with time-domain reflectometry) by irrigation by hand with a graduated beaker. The well-watered group was still irrigated by an automatic irrigation system and kept at 25% volumetric soil water content.
Processing of plant material: For poplar, at 5 dates, 10 plants per variety and treatment group were extracted from the soil. *Quercus* plants were extracted once. The experiment was finished after 65 (poplar) resp. 73 (oak) days of growth under experimental conditions. The plants were taken out of the pots and dissected into stem, leaves and roots. Fresh mass and length of longest roots and shoots as well as their numbers (results not shown) were determined. Subsequently, the plant material was oven dried (model FD 115; Binder GmbH, Tuttlingen, Germany) at 105 °C for 3 to 4 days for dry mass determination.
Statistical methods: All statistical test procedures were carried out using the SPSS Statistics software (version 22.0.0; IBM Corporation, Munich, Germany). Preliminary analyses and calculations of deduced variables were done with Microsoft Excel 14 (Microsoft Office Pro Plus 2010). For more details concerning the statistics see Krabel *et al*. (2015).

Results and Discussion

The early root development is essential for vegetative but also generative reproduction of woody plants. In order to afford an optimal aboveground plant development, roots are the organs which enable a sufficient water and mineral supply. Though, different genotypes within one species may show different abilities and strategies in developing an efficient root system (Günes, 2000; Pallardy and Kozlowski, 1979; Zalesny et al., 2005).
The part of the paper dealing with the response of poplar genotypes to irrigation treatments is based on results published in an extended article by Krabel *et al*. (2015).
Regarding the fast growing hybrid poplar varieties, optimal irrigation conditions lead for Hybride 275 to the highest root dry mass (Figure 1) and the longest roots. During the entire period of the experiment a significant influence of the genotype could be observed. In comparison with Hybride 275, the genotypes Max 3 and Muhle Larsen showed for some traits more similarities, so for example Max 3 and Muhle Larsen showed a comparable number of roots, whereas Hybride 275 is characterized by significantly less roots (data not shown). Concerning the root length, the influence of the genotype decreased with time of development. Interestingly, after only 14 days of experimental time the roots reach nearly half the length of the length at the end of the experiment. Regarding the shoot growth the genotype Max 3 shows superior development. Although shoot growth of Hybride 275 is delayed, after 65 days of development the growth rate per day is as high as that of Max 3, which confirms the results of (Schildbach et al., 2012; Schirmer, 2010).
The influence of drought stress on the physiology of trees is purpose of many investigations (e.g. Lösch, 2001; Matyssek et al., 2010). Dependent on the duration and intensity of the stress application the reactions that follow may be quite different. Hartung (1996) reports that moderate drought stress is answered with increased root length growth. This reaction can be explained as the attempt to increase water uptake. In our experiments such reaction couldn't be observed. All the varieties showed a significant decrease in root mass and – length when reducing water availability. Such a reduction of root growth seems to be typical for severe drought events (Hartung, 1996; Tschaplinski et al., 1998; Zhijun and Dickmann, 1992).
The shoot to root ratio, which shows the relocation of biomass indicates that under drought stress Hybride 275 relocates only slightly biomass in favour of roots, whereas for Max 3 the ratio decreases more than to the half compared with optimal irrigation.

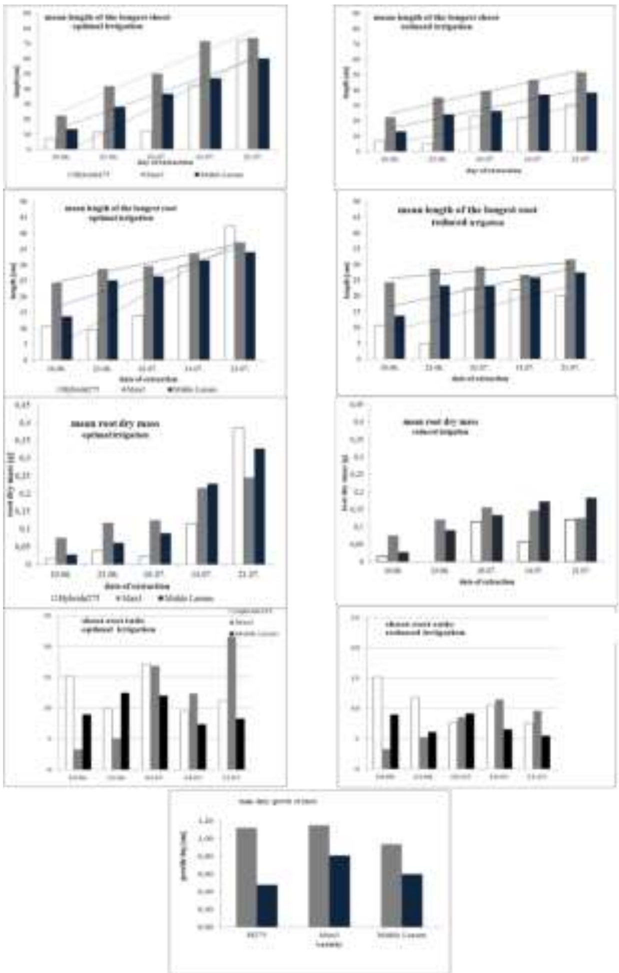

Figure 1: Hybrid poplar experiment - differences in growth performance of the genotypes Hybride 275, Max 3 and Muhle Larsen under different irrigation treatments. Traits of interest are longest shoot, longest root, root mass (fresh weight), shoot-root ratio (fresh weight) and the mean daily growth of the shoot.

Both oak species are regarded as relatively drought tolerant even though there is some variability between *Q. robur* and *Q. petaea*. The depth growth of both root systems and the xeromorphic structure of their leaves are preconditions to keep a high water potential in the cells even during dry periods (Abrams, 1990). But, generally *Q. robur* is classified as the species which needs a bit more humidity than *Q. petraea* and *Q. petraea* colonises the more extreme sites. Typically *Q. robur* is a species of floodplain forests and the lowlands and *Q. petraea* can be found on hilly sites.

Regarding the oak greenhouse experiment the results confirmed the above mentioned statements (Fig. 2). Under well-watered conditions *Q. robur* showed a superior growth in root and shoot development compared with *Q. petraea*, and under dry conditions a significant decrease of aboveground and belowground biomass can be observed. Interestingly, sessile oak (*Q. petraea*) develops a less pronounced root system than pedunculate oak (*Q. robur*), therefore under reduced water supply the breakdown of fresh root biomass is less intense. Whereas root biomass for *Q. robur* decreased to more than a half of the value compared to the well-watered conditions. The shoot-root ratio of *Quercus petraea* indicates that for both treatments the partitioning of biomass is relocated in favour of roots. This might be a hint that the species follows a 'different strategy' with regard to water availability - less aboveground biomass but a more efficient root system.

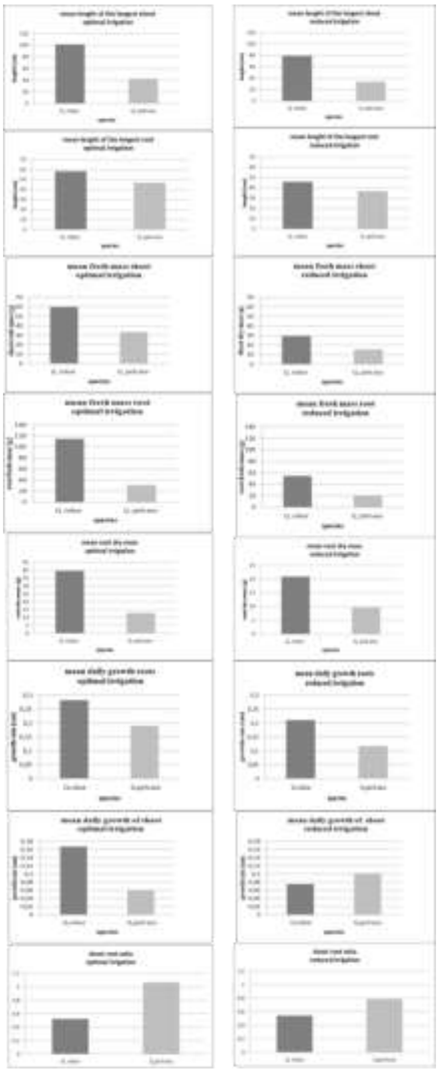

Figure 2: Quercus experiment - differences in growth performance of *Quercus robur* and *Quercus petraea* under different irrigation treatments. Traits of interest are longest shoot, longest root, root mass (fresh and dry weight), the mean daily growth of the shoot and shoot-root ratio (fresh weight).

Conclusions

In our studies we tried to quantify the performance of shoot and root growth of young trees under green-house conditions. The results showed that even within a short experimental time (65 resp. 73 days) individual growth characteristics can be observed for fast growing as well as slow growing tree species. The phenotyping of growth related traits during an experimental time of few weeks can’t replace field trials, but experiments under well-defined environmental conditions can help to simulate specific conditions like for example defined drought stress conditions even for woody plant species. Therefore, greenhouse experiments should be an inherent part of testing tree provenances and populations especially in the context of global change.

Acknowledgements

Our work was based on funding by the German Agency for Renewable Resources (http://www.fnr.de) and the German Federal Ministry of Food and Agriculture. The project acronym is “FastWOOD I- III” (support code: 22002911). The oak experiments were enabled by financial support from Deutsche Akademische Austausch Dienst (DAAD) given as a grant to Mrs. Bayartaa Nyamjav. Many thanks to Staatsbetrieb Sachsenforst, Graupa who gave us access to the greenhouse facilities.
