Abstract

Climate condition of Bursa province (Turkey), characterized with temperate and humid conditions, is ideal for growing many cultivated plants. This climate also enables quickly development of many insect and mite pests and they generally cause high economic damage in these plants. Although the Turkish Food, Agriculture and Livestock Ministry has been regulated Integrated Pest Management programs and registered new synthetic insecticides to target specific as well as biorational, biotechnological and biological products, the usage habits of these products by growers has not been determined in Bursa, yet. This face to face survey study aims to evaluate both common pests and their management strategies based on grower declarations in Bursa from October 2016 to April 2017. Among 542 growers, most of respondents were middle and old aged (40-50 years old in 34%; 50< years old in 49%) and low education level (86% graduated from primary school). Reflecting production pattern of the region, 15 and 14% of our participants have grown olive and wheat, respectively. Among other 26 cultural plants, the second common species were corn, tomato, cherry, sunflower and pepper with 5-9% of all participants. Moth (14.5%), fruit fly (13.8%) and mite (10.2%) species were reported as key pests. While most of the respondents (90.8%) have used just synthetic insecticides to these pests, few participants have applied biotechnical materials (%1.6), microbial toxins (4.6%) and botanical extracts (4.6%) self-prepared from stinging nettle, tobacco and chili pepper. An aqueous extract obtained from cigarette butt was the most common usage of nicotine extract. Except these traditional method, all of respondents declared that they have never used any commercial biological and botanical products. It seems that Bursa farmers are not aware of registered environmental friendly products against above mentioned pests. In order to change this situation, further education and advertising activities about new environmentally compatible pest management strategies should be performed in Bursa.

Keywords: *Botanical insecticides, Bursa, Pest management, Survey, Synthetic insecticides*

Introduction

Bursa province (Turkey) is characterized by temperate and humid climatic features, which enables growing a variety of cereal, vegetable and fruit crops throughout the year. More than twenty-five kinds of crops are economically grown (TUİK, 2016). Depending on temperate and humid climatic condition of the region, insect and mite pests are main problem in growing these crops (Gencer *et al.*, 2005; Kumral and Kovanci, 2007; Kovanci and Kumral, 2008; Kovanci *et al.*, 2010). Consequently, insecticides and acaricides are the most commonly used pest control tools based on Turkey's statistically records (FAO, 2014; TUIK, 2016). Although there are numerous scientific notes and introduction brochures on existing plant pests in the region (Anonymous, 2017), Bursa farmers' knowledge level about major pests and their pest control attitudes and practices against them have not ever examined. However, the Turkish Food, Agriculture and Livestock Ministry (FALM) has been regulated Integrated Pest Management programs for four decades and registered various synthetic insecticides as well as biorational, biotechnological and biological products (Anonymous, 2017), but the usage habits of these products by growers has not been determined in Bursa, yet. Since years, producers have been made many decisions about how to control pests and which control tools to use against pests. But, there is very little information about their control tactics and preferential decisions. Generally, cost, efficiency, accessibility and simplicity in implementation of the pest management products are guided to farmers' pest management decisions. Therefore, because synthetic pesticides are quick acting and cheap, these chemicals have been used more frequently (Simon, 2014). However, the widespread use of these synthetic compounds can cause serious ecological problems due to kill non-target organisms and to threat human health. The other issues are pesticide residues on crops and resistance developing of the pests to these compounds (Simon, 2014). There is no evidence on the awareness level of Bursa farmers about adverse effects of pesticides on environment and human health. Prior to the discovery of these products, plant-derived botanical insecticides were the main insecticidal compounds used by farmers. Because overwhelming superiority of synthetic pesticides (%33 organo-phosphates; 9% synthetic pyrethroids; 4% carbamates; %53 IGRs, neonicotonids and others) in the world pesticide market, the consumption of botanical and biological products had been just 0.54% of the world market (FAO 2014; Simon 2014). Similarly, among 225 active substances, the majority of insecticides are organo-phosphates (64%), synthetic pyrethroids (11%), neonicotonids (16%) and others (9%) in Turkey (Anonymous, 2017). Furthermore, the restriction of pesticide use in agriculture by the European Union has increased the interest in alternative management options (Freier and Boller, 2009). One hundred and eighty active substances which are hazardous on non-target organisms and environment have been forbidden by FALM and simultaneously 13 microbial products, 2 botanical insecticides, 6 pheromones mediated mating disruption, 5 attract-kill and 25 colour traps, and 22 predator and parasitoid biological control agents are registered against numerous pests within last decade in Turkey (Anonymous, 2017). Except for marketing statistics, we have poor information about actual use of these compounds by Bursa's farmers. A survey study was conducted to assess the knowledge level of Bursa's farmers on the main pests and their management practices.

The aim of this research is to obtain data to determine the most consumed pesticides and alternative pest management tools. In addition, the second aim of this study is to learn whether the farmers still use any traditional botanical pesticides.

Material and Methods

Data of the present study are provided from face to face farmers' survey from 9 districts of Bursa province (Turkey) during 2016-2017. Five hundred and forty two farmers who cultivated different plants belong to cereals, vegetables and fruits were randomly selected for this survey. For analysing effects of socio-economic factors on results of this study, some parameters like age, education and income were collected independent variables. However, lands were classified into four different categories according to agricultural practices: (1) conventional land (intensively synthetic pesticide use), (2) traditional land (rarely synthetic pesticides and combined botanicals) and (3) GLOBALGAP lands (Good agriculture practise certificate) (4) organic lands (certificated as organic farmer). Data on insecticide use of the farmers was computed and categorized into three levels: (1) Those who know the used pesticide name (2) Those who do not know the used pesticide name (3) Those who use pesticides based on advices of experts. Also, the data on main pest problems of farmers were collected. Based on the data, the pest problems were classified according to their pest statutes: (1) key pests (which cause economic damage at each year) and (2) occasional pests (which are only occasionally reach economic injury level). However, their other pest management practices and traditional botanical pesticides that they used based on anonymous information were requested from farmers. Minimum sample size was calculated as 42 for each district based on the method of Vural (2012). In order to explore whether different socio-economic groups of respondents differed with respect to the data, some cross-tabulations were done in SPSS version 23 testing for significance with chi-square test.

Results and Discussion

Among 542 growers, most of respondents were middle and old aged (34% 40-50 years old; 49% 50< years old) and low education level (86% graduated from primary school). The most of respondents' income varied between 5000-7500 €/year. Reflecting production pattern of the region (TUIK, 2016), the current study shows that 15 and 14% of our participants have grown olive and wheat, respectively. Except for these crops, most of the growing crops were corn (8.7%), tomato (7.8%), cherry (9.1%), pepper (5.4%) and sunflower (4.8%). The other crops were barley, alfalfa, sugar beet, onion, grape, fig, plum, almond, walnut, melon, watermelon, chick-pea, artichoke, strawberry, eggplant and bean with 0.1-3.6% of respondents. When asked to pest problems, moth (14.5%), fruit fly (13.8%) and mite (10.2%) species were reported as key pests (Table 1). Depending on crop species, some respondents described these as occasional pests (Table 1). In both cases, the most important pests ranged as both moths (23.5%), fruit flies (20.3%) and mites (17.0%), respectively. From the reported pest problems, 8 species considered key pests *Cydia pomonella* (L.) (Lepidoptera: Tortricidae), *Helicoverpa armigera* (Hübner) (Lepidoptera: Noctuidae), *Prays oleae* (Bernard) (Lepidoptera, Yponomeutidae), *Ostrinia nubilalis* (Hübner) (Lepidoptera: Pyralidae), *Anarsia lineatella* (Zeller) (Lepidoptera: Gelechiidae), *Bactrocera oleae* (Rossi) (Diptera: Tephritidae), *Rhagoletis cerasi* (L.) (Diptera: Tephritidae) and *Tetranychus urticae* Koch (Acari: Tetranychidae). In accordance with previous researches obtained from the region, the study showed that these are the most important pests (Karsavuran and Durmusoglu, 2004; Gencer *et al*., 2005; Kovanci and Kovanci, 2006; Kumral and Kovanci, 2007; Kovanci and Kumral, 2008; Kovanci *et al*., 2009; Kovanci *et al*., 2010). Because moths and fruit flies are among the most widespread pests in Bursa, synthetic pyrethroids and neonicotonids were the most commonly used insecticides having been employed by more than 65% of the respondents (Table 2). In fact, IGRs, Organo-phosphates and Ryanodines were also used against these pests with approximately rate of 22% of farmers. In addition, Tetraonic and Tetramic acid derivatives and some microbial toxins were used for control of mite pests. Thus, the results of pesticide use are harmonious with pest problems reported by respondents. More than one-tenth of the respondents used highly hazardous insecticides (Organo-phosphates) against these pests. As a positive reflection of the FALM's ban policy on hazardous insecticides, it was seen that the use of highly hazardous insecticides at the region was lower compared to average use rate of world (FAO, 2014). One of the socio-economic variables, age, showed significantly relationship with insecticide knowledge (X^2= 20.821; P=0.002), but there was no statistically relationship with pest knowledge and production practice type (Table 3). The current study shows that up to 40 years old farmers have more insecticide knowledge probably based on their experience. Other variables, education, showed no significantly important relationship with three independent variables (Table 4). Lastly, the income of farmers were significantly affected their insecticide knowledge and production practice type (X^2= 80.203; P<0.01, X^2= 78131; P<0.01, Table 4). The survey results indicated that low- income farmers do not know insecticides or use according to adviser comments. However, low-income farmers prefer more conventional type.

Table 1. Pest problems in Bursa province, based on a farmer survey in 2016-2017.

Pest Problem	Percent of farmers considering pest problem (%)		
	key pests	occasional pests	total
Mites	10.2	6.8	17.0
Moths	14.5	9.0	23.5
Fruit flies	13.8	6.5	20.3

	organic land	0	0	0	0	78.131	8	<0.01

Conclusions

The current study showed that most farmers (91%) use synthetic insecticides against pests and depending on their age and income level a significant part of the farmers do not know the name of insecticide used. According to FALM's regulations, insecticides should be recommended by an adviser, but the results show us that farmers are not aware of the adverse effects of the compound on environment and humans. They also are not aware of registered environmentally safe many products against above mentioned key pests in Turkey. Although it is reported that few microbial, botanical, and repellent or attractant-trap combinations are used but the attempts are not adequate to provide the safety of non-target organisms. In order to change this situation, further education and advertising activities about new environmentally compatible pest management strategies should be performed in Bursa.

Abstract

Many buprestid species use visual cues to locate hosts and potential mates. Standard yellow sticky cards tend to capture less buprestid individuals than blue traps. Since some semiochemicals are attractive to buprestid adults, they can be used for trapping them. The hypothesis of this study was to test if trapping capacity of buprestid adults on yellow traps can be increased by semiochemicals. In Bursa region of northwestern Turkey, we investigated the variation in adult captures of a common buprestid beetle, *Anthaxia anatolica anatolica*, on yellow sticky traps baited with synthetic semiochemicals, methyl salicylate (MeSA), benzaldehyde (Be), linalool (L) and farnesene (F) alone and their binary combinations (MeSA + Be; MeSA + F; MeSA + L; F + Be; Be + L; F + L). The study was conducted at three plots in an apple orchard in Bursa, Turkey in 2013. Buprestids were monitored weekly at each plot. In field studies, 52% of jewel beetles were attracted to the synthetic semiochemical formulations. The highest number of adults was caught in traps with Be (2.4 adults/trap), followed by those with F (1 adult/trap) and MeSA + F (0.7 adults/trap) combination. The lowest number of buprestid adults was observed in MeSA + L (0.2 adult per trap), followed by the Be + L (0.3 adults per trap) combinations. Overall, yellow sticky traps impregnated with Be were significantly more attractive to *A. anatolica anatolica* adults compared with other traps. The effects of benzaldehyde on other harmful buprestid species should be investigated in future studies.

Introduction

Jewel beetles (Buprestidae) one of the most beautiful families of the Coleoptera. It is a large one, containing over 15,000 described species and divided into five subfamilies. The entire family includes 185 genera (Levey, 1977). Larvae whitish, flat, with a long, thin abdomen and expanded prothorax, without legs, a small dark head retracted into prothorax (Volkovich, 2006). Nearly of all Buprestidae larvae feed within plant tissues. Many young adult species of Buprestidae feed on shoots and branches of tree before copulating and oviposition (Haak and Slanxsky, 1987). *Anthaxia* is the common and quite rich genus in Turkey. The first study made by Bily (1984) has made great contribution to the richness of Turkish fauna. Lodos and Tezcan (1992) cited 69 *Anthaxia* species from Turkey. In another study, 39 species of *Anthaxia* (subgenus *Anthaxia*) have been evaluated (Karaman and Tezcan, 1998). Ulay and Tezcan (1998) cited 22 species *Anthaxia* (subgenus *Haplanthaxia*) from Turkey. One of the common species in the genus, *A.* (*Anthaxia*) *anatolica anatolica* Chevrolat distributes Armenia, Azerbaijan, Bulgaria, Georgia, Greece and Turkey (Bily, 1997). *Ferula communis*, *F. nidiflora*, *Hippomarathrum bocconei*, *H. pterochloenum*, *Magydaris tomentosa*, *Scorodosma foetida* and *Thapsia villosa* were recorded as host plants of species (Curletti,

1994). But there has been performed no study about the biology and ecology of *A.* (*A.*) *anatolica anatolica*, yet.
Semiochemicals are cue chemicals used to convey information between plant, pests and their predators or parasitoids. They are typically volatile compounds released after pest damage that are active at low concentrations. Herbivore-induced plant volatiles (HIPVs) released while any herbivore damages a plant. Therefore, HIPVs are secondary protection system in plants which provides to signal to natural enemies of pests (Mumm and Dicke 2010; Rodriguez-Sauna *et al.*, 2012). But, an important noted that the volatiles were able to attract some phytophagous species such as thrips *Frankliniella occidentalis* (Pergande) (Thysanoptera: Thripidae), Green leaf bug, *Apolygus lucorum* (Meyer-Dür) (Hemiptera: Miridae) and Plum curculio, *Conotrachelus nenuphar* (Herbst) (Coleoptera: Curculionidae), (Roditakis and Lykouressis, 1996; Sun *et al.*, 2014; Leskey and Wright, 2004). These volatiles could be used to collect and monitor *Anthaxia* adults. It is critical decision to select the right compound or compound combinations. Because, plants have more than 1000 kinds of HIPVs and various volatiles can be composed by combining hundreds of volatiles (Gaquerel *et al.*, 2009; Kaplan 2012). Many HIPVs have been studied and they are addressed some compounds i.e. methyl salicylate (MeSA), benzaldehyde (Be), linalool (L) and farnesene (F). In recent years, field experiments on HIPVs (or a combination of HIPVs) have been shown that the effectiveness of the volatile varied depends on insect species and volatile combination (Leskey and Wright, 2004). To collect and monitor the specimens in field, developing a new method will be made great contribution to the richness of Turkish fauna. In this study, we used field trapping (yellow sticky trap) as a method to investigate beyond attraction response of *A.* (*A.*) *anatolica anatolica* to synthetic HIPVs, alone and in dual combinations.

Material and Methods

Field studies were carried out in 1- ha apple orchard (5 years old, Granny Smith cv.) of the Uludag University Agricultural Faculty in Bursa (Turkey) from early May to early July 2013. Synthetic formulations of four HIPVs, linalool (L) (97% purity) (Acros Organics, Belgium), benzaldehyde (Be) (99.5% purity) (Merck, USA), methyl salicylate (MeSA) (99% purity) (Acros Organics, Belgium), farnesene (F) (95% purity) (Sigma-Aldrich, USA) and a solvent that was for the most part hexane (Merck, USA) (99.5% purity) were used in this research. Separately (L, Be, MeSA, F) and dual combinations (MeSA+Be; MeSA+F; MeSA+L; F+Be; Be+L; F+L) of these compounds were processed in hexane solutions. Every HIPV was diluted one-to-one in hexane.
Buprestid adults were monitored weekly at every site (involving controls) by yellow sticky cards (28x23 cm, Trece Inc., USA) hanged to an apple tree stem at 2 m above from the ground. Yellow sticky cards that attached to each HIPV were placed 15 m apart (James, 2005). Ten combinations were examined to find out the reaction of the beetles to yellow sticky cards with 5 ml glass vials (consisting 1 ml of applicant HIPV solutions and 1ml of hexane to dilute refined chemicals were left with just 2 ml hexane for control). The glass vials which have volatile compounds were refilled every week and every trap was relocated weekly from May to July in 2013. Three repeats for each of the ten applications and the controls were applied. Buprestids caught in each trap, was counted and recorded weekly in the field and laboratory.
Statistical analysis was performed using analysis of variance (ANOVA) (JMP, version 7: SAS Institute Cary, USA). Mean number of adults in traps were transformed using square root (x + 1), excluding weekly comparison, before ANOVA. The least significance difference test (Fisher’s protected LSD) was used to test for differences among the accession means and the

controls. Means were separated by the least significance difference test (SAS Institute Inc. 1985) (P = 0.05). Likewise the mean insect numbers on traps with each HIPV combination and their control were also compared by a pairwise paired sample *t* test.

Results and Discussion

The Jewel beetle *A.* (*A.*) *anatolica anatolica* was attracted and caught to solo and dual combinations of the synthetic HIPVs in the apple tree orchard (Table 1). A mean number adult *A.* (*A.*) *anatolica anatolica* in the traps baited with the HIPVs varied with caught of 0.2-2.4 adults per trap in the apple tree orchard (Table 1). They were also attracted to the control traps including just hexane with caught of 0.7 adults per week. The highest number of adults caught by HIPVs was a Be (2.4 per trap), followed by F (1 per trap) and the MeSA+F (0.7 per trap) combination and control (0.7 per trap). The lowest adult number was observed in MeSA+L traps, followed by the benzaldehyde+linalool (0.3 per trap) combinations. Among all of the HIPVs, benzaldehyde was highly attracted to the beetle compared with the other baited traps. The highest number of adult captures occurred in the benzaldehyde baited traps. We found significant effects among the different HIPVs and their dual combinations in attracting adults of *A.* (*A.*) *anatolica anatolica* ($F_{10,389}$= 0.03, P= 0.001). These effects were examined in the late May and the first half of June (Figure 1). According to LSD test, among the HIPVs and dual combinations, only benzaldehyde is the most significant HIPV statistically in attracting adults of *A.* (*A.*) *anatolica anatolica* (Table 1). Among the HIPVs except benzaldehyde and control, there is no significant difference statistically between HIPVs and control traps in the Jewel beetle captures. Moreover, when traps has compared with their controls by paired sample *t* test, there were statistically significant more adults of *A.* (*A.*) *anatolica anatolica* was attracted to benzaldehyde baited sticky traps compared with control traps (Table 1).

Other HIPVs traps were not significantly different in captures of adults of *A.* (*A.*) *anatolica anatolica* compared to control traps containing only hexane. Lure of benzaldehyde to natural enemies *Chrysopa sinica* Tjeder (Neuroptera: Chrysopidae), *Aphidius sp.* (Hymenoptera: Braconidae) and *Coccinella septempunctata* L. (Coleoptera: Coccinellidae) was shown in olfactometer and electroantennogram tests (Han and Chen, 2002) and *Stethorus punctum picipes* (Casey) (Coleoptera: Coccinellidae), *Orius tristicolor* (White) (Hemiptera: Anthocoridae), and flies in Tachinidae and Sarcophagidae families in the field study (James, 2005). The same situation was found for Green leaf bug, *Apolygus lucorum* (Meyer-Dür) (Hemiptera: Miridae) and the plum curculio, *Conotrachelus nenuphar* (Herbst) (Coleoptera: Curculionidae). Benzaldehyde baited traps with a pheromone (grandisoic acid) was reported a valuable tool for monitoring of the adult plum curculio move to apple orchards (Leskey and Wright, 2004: Prokopy *et al*., 2004). Benzaldehyde was lured to the Green leaf bug, *A. lucorum* (Sun *et al*., 2014). In the current field study, benzaldehyde attracted the *A.* (*A.*) *anatolica anatolica*. Our result about the attractiveness of the benzaldehyde was similar to those reported by authors above. This result is the first record for *Anthaxia* and is supposed to be the first record for Buprestidae family.

In the apple orchard, the mean seasonal abundances of *A. anatolica anatolica* captured in sticky traps baited with single and dual combinations of synthetic HIPVs are presented in Figure 1. During the experiment, in traps baited with HIPVs and control, the density of adults peaked in 23 May and then decreased rapidly in 30 May. The population density of *A.* (*A.*) *anatolica anatolica* began to increase again beginning June and reached two peaks in 6 and 13 June (Figure 1). After that point, the population began to decline. Significant differences were found among weekly captures of *A.* (*A.*) *anatolica anatolica* in methyl salicylate, benzaldehyde, linalool, farnesene alone, their dual combination (MeSA+Be; MeSA+F;

MeSA+L; F+Be; Be+L; F+L) and control traps during May- July 2013 ($F_{109,290}$ = 5.09, P < 0.01). The highest peak of adult captures occurred in benzaldehyde traps on 23 May (12 per trap), 6 Jun (4 per trap), 13 Jun (5 per trap) and farnesene traps on 23 May (5 per trap) (Figure 1). When the highest numbers of adult captures in traps have a peak, average temperature was 24.6 °C (min 12.8, max 33.2) in May. After 6 June population decreased because of 23 mm

Table 1. Mean captures of *Anthaxia* (*Anthaxia*) *anatolica anatolica* in sticky traps with synthetic HIPVs during early May-early July 2013.

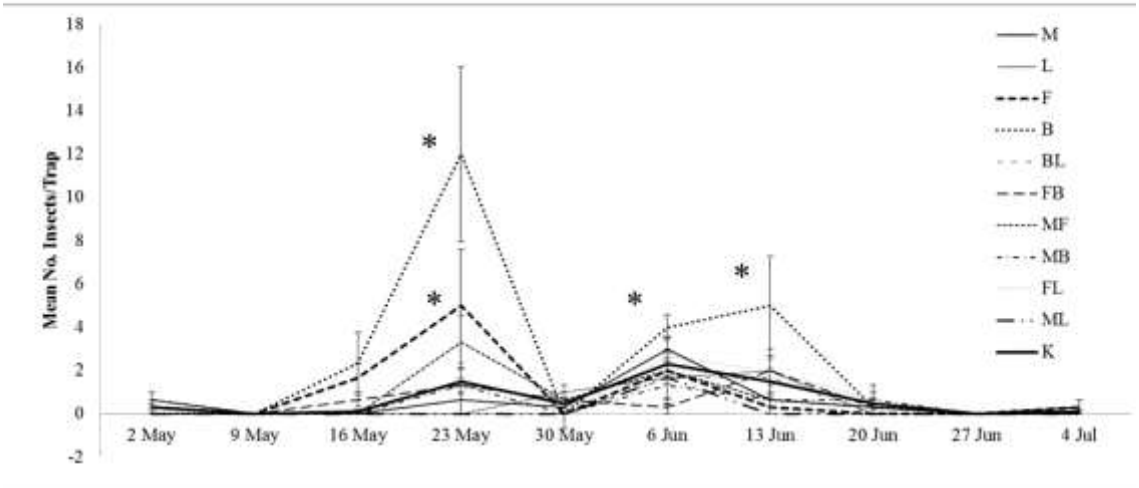

Figure 1. Mean captures per trap of *Anthaxia* (Anthaxia) *anatolica anatolica* in sticky traps with synthetic HIPVs methyl salisylate (MeSA), benzaldehyde (Be), linalool (L) and farnesene (F) alone and their dual combination (MeSA+Be; MeSA+F; MeSA+L; F+Be; Be+L; F+L) during May- July 2013. *Significant P > 0.05 by Student's *t*-test.

heavy rains. Lelito *et al*. (2008) analysed the different ways of trapping emerald ash borers (EAB), *Agrilus planipennis* Fairmaire (Coleoptera: Buprestidae), by testing blue and yellow sticky cards. The lure of *A. planipennis*, to pheromone was showed in field examinations applying baited green sticky traps (Ryall *et al*., 2012). Trap colour is a significant cause effecting capture in traps, by two colours determined as very appealing purple (Crook *et al*., 2008; Francese *et al*., 2008). Purple colored traps are especially appealing to female beetle (Francese *et al*., 2008), while green colored traps are more efficient at trapping male beetle (Lelito *et al*., 2008) monitoring *of A. planipennis*. Traps placed in the mid-canopy of ash trees (13 m) caught significantly more beetles than those placed at ground level, because the most adult buprestids active in the tree canopy (Francese *et al*., 2008). On the other hand, the place of the trap has been already an important issue. In this study, the HIPVs that hanged 2 meters high could be tested by hanging in other altitudes to reach the highest number of captures.

Conclusions

During the experiment, the highest peak of adult captures occurred in benzaldehyde traps on 23 May (12 individual/per trap), 6 Jun (4 individual/per trap), 13 Jun (5 individual/per trap) and farnesene traps on 23 May (5 individual/per trap). This study seems to be quite effective at pulling in *A.* (*A.*) *anatolica anatolica* by benzaldehyde baited traps. This case is promising since benzaldehyde baited yellow sticky traps can be used to collect and monitoring the adult species. May be this combination will be examined for other buprestids of such harmful species *Agrilus* sp. and *C. tenebrionis* whom no effective control methods are currently available and they are important agricultural pests.

Acknowledgements

Our special thanks to Mark Volkovitsh (Zoological Institute, Academy of Sciences USSR GUS-199034 Leningrad, Russia) and Dr. S. Bily (Prague- The Czech Republic) for identifying and confirmation of *A.* (*A.*) *anatolica anatolica.* We thank the Uludag University Scientific Research Project Unit - Turkey (Project Grant No. UAP (Z) - 2010/45) for fund.

Abstract

Non-astringent 'Fuyu' persimmon fruits were harvested at optimal harvest maturity and randomly divided into four groups. Thethree groups of fruitswere treated with 156.25, 312.5 and 625 ppb 1-MCP, respectively at 5°C for 24 h. The fourth group of fruits considered as control fruit. The treated and non-treated (control) fruits were stored at 0±1°C and 90±5% relative humidity for 3 months. After the cold storage,fruits were also kept at 20°C for additional 3 days to simulatetheir shelf-life period. Fruits were removed from different storage conditions at 30 days intervals and weight loss, fruit firmness, skin colour, soluble solids, titratable acidity and decay development during storagewere studied. Furthermore, respiration rate and ethylene production of persimmon fruits were also recorded.The lowest weight loss, decay development, respiration rate, ethylene production andthemaximum titratable acidity, fruit firmness, L*, h°and C* valueswere recorded in the fruits treated with 625 ppb 1-MCP. The fruits treated with the highest 1-MCP dose (625 ppb) showed better performance as compared with other 1-MCP treatments in terms of keeping the best postharvest quality of persimmonfruits during cold storage and shelf life conditions. On the basis of our results it is recommended to use 625 ppb 1-MCP for obtaining better postharvest quality in non-astringent 'Fuyu' persimmon fruits during long term storage.

Keywords: *Persimmon, storage, quality, shelf life, ethylene, respiration*

Introduction

Fruits and vegetables play a vital role in human dietandregular consumption of these commodities help in decreasing the risk of cancer, cardiovascular, Alzheimer diseases and slow down the factors involved in aging (Liu, 2013).According to statistics of 2014, the production of persimmon constitutes 5.190.624 ton/year. China ranks 1st place and South Korea stood at 2nd with share of 73.3% and 8.3% in world production, respectively (Anonymous, 2014a). Researches on how to increase persimmon production in Turkey is still ongoing. According to 2014, the cultivated persimmon growing area in Turkey is 2.062 ha with production of 33.470 ton/year (Anonymous, 2014b). As the production increase it needs to find out the best storage conditions of persimmon fruits to regulate its long term storage and marketing. The main postharvest problems of persimmon fruits are their relatively short shelf-lifeperiod and quality losses (weight loss, bruising, blemishing, fruit softening, etc.) after harvest which decreases the marketing value and shorten its storage period. Like all other horticultural crops, persimmon fruits should be cooled as soon as possible to maintain its postharvest quality. On the other hand, it is also possible to decrease these lossesby using appropriate postharvest applications (Yildiz *et al*., 2002). The storage period of fruits after harvest varies due to the production of ethylene. 1-Methylcyclopropene (1-MCP) that reduces the effects of ethylene has been used on fruits, vegetables and ornamental plants against ripening and senescing. The influence of 1-MCP varies from species, variety and storage conditions (normal atmosphere, modified atmosphere, control atmosphere and dynamic control atmosphere). According to Watkins and Miller (2005), 1-MCP decelerates ethylene production, respiration rate, colour changes, softening, ripening and senescence. Deterioration rate in horticultural crops is closely related to temperature and respiration rate (Kader, 2002). Kilinc and Cakli (2001) reported that, cold storage is the most reliable technique to preserve the quality of fresh produces. Many studies have been conducted regarding temperature conditioning, 1-MCP treatment, MAP and CA storage. But, there still exist the need to know about postharvest physiology of persimmon fruits. So, the objective of this research was to find out the optimum 1-MCP dose during long term storage of persimmon fruit to maintain its postharvest quality.

Materials and methods

'Fuyu' variety of persimmon was used in the experiment. Fruits were harvested at optimal harvest maturity in Denizli, Turkey and immediately transported to Akdeniz University, Department of Horticulture postharvest physiology laboratory for storage operations. After cooling, fruits were randomly divided into four groups. Three doses (156.25, 321.5 and 625 ppb) of 1-MCP (Smartfresh^{TM}) and control groups were tested. For 1-MCP treatment, persimmon fruits of each treatment were kept in gas tight containers of 1m^{3}volume in plastic crates. Fruits were treated with 1-MCPfor 24 hours at 5°C. After treatments, fruit stored at 0-1°C temperature and 90-95% relative humidity for 3 months. Different physiological and chemical analysis was conducted at the interval of 30 days.
For weight losses, persimmon fruits were weighed before storage with the digital scale of 0.01 g sensitivity. During the storage period, fruits were re-weighed again and weight loss was calculated as a percentage of the initial weight. Digital refractometer was used to measure the amount of total soluble solids (TSS) andTSS was expressed as a percentage. For titratable acidity (TA), 2 ml juice+38 ml distilled water titrated with 0.1 N NaOH by using pH meter and calculated as % malic acid/100 ml juice. Fruit firmness was measured by peeling of fruit at three different equatorial sections with the help of Olcweuiz Guss fruit texture analyzer with 7.9 mm plunger. Measured values were expressed in Newton (N). Variations in fruit colour were recorded with the help of Minolta CR-400branded (MINOLTA Camera Co, LTD Ramsey, NJ) instrument. The results were determined as L, Chroma (C*) and Hue angle (h°). Amount of decayed fruits were observed with visual observation and numbers given as percentage.
The respiration rate and ethylene production of fruits were determined at the interval of two days by using a Gas Chromatography (GC) (Thermo Electron S.p.A., Strada Rivoltana, Milan, Italy). For that purpose, fruits of known volume and weight were kept in air-tight containers having a volume of 5 L for 1 hour at 20˚C temperature. Sample of 1ml gas were taken through a gas-tight syringe from the headspace of air tight container and injected into the GC for analysis of ethylene and respiration. External standards were used for the quantification of the resulted peaks. Measurement of quality attributes was done at day 0, 60 and 90. Furthermore, after each storage period, fruits were removed and kept at 20ºC for 3 days to simulate a performance of shelf life. Completely Randomized Design was used with three replications and each replication contained 15 fruits. Duncan's test was conducted for comparing means varied significant or non-significant. Values obtained were evaluated with SAS program.

Results and Discussion

Weight loss

Statistical significance of different doses of 1-MCP on weight losses was recorded. On 30th day of storage 2.46% weight loss was noted which increased to 4.93% after 90th day of storage, means that rises in weight losses occurred in parallel with storage extension. Control fruits had the highest weight loss with 5.51%. 1-MCP treatments decreased the weight losses as compared to control. The use of 625 ppb 1-MCP had the lowest weight loss with 2.61% (Table 1). The similar trend was obtained in shelf-life conditions as well where control group had the maximum weight losses with 6.83% and 625 ppb 1-MCP treatment had the lowest weight loss (3.42%). During storage increases in weight loss occurs due to respirationand loss of water (Yener, 2013). Use of 1-MCP decelerated weight losses in our study. The reason of this could be 1-MCP may have been slow down the respiration of the fruits.

Total soluble solids (TSS)

Effects of 1-MCP treatments on TSSwere found to be statistically significant. Initial value for TSS was 15.39% at harvest. At 30 and 90 days of storage showed decrease to 14.44% and 15.36%, respectively. Comparing to control group 1-MCP treatment slowed down the decrease of TSS. Control group had the lowest amount of TSS with 14.13%. Effects of 1-MCP doses on TSS were found to be statistically significant as well. TSS was 15.39% at harvest and declined to 14.76% at the end of 90+3 days shelf-life period. During shelf life period no statistical differences were found among 1-MCP doses (Table 2). Wright and Kader (1997) reported that the use of 1-MCP played an effective role in preserving amount of TSS which is related to slowing down the respiration rate and water loss. On this aspect, our findings were in agreement with Kuzucu and Kaynas (2002).

Titratable acidity (TA)

The effect of 1-MCP doses on the amount of TA has been found statistically significant. Decreases in TA were observed with the extension of storage duration (Table 1). Initial TA of thefruits at harvest was 0.143% (as malic acid)and reduced to 0.074% at the end of the storage.625 ppb 1-MCP had the maximum TA (0.105%) whereas control group had the lowest amount of TA with 0.098%.Amount of TA at harvest was 0.143% and during the 60+3 days storagethere were a decrease (0.068%) and then an increase to 0.080% of TA was observed at 90+3 days of storage in shelf-life conditions (Table 2). No statistical difference was found among the 1-MCP doses and156.25 ppb dose of 1-MCP had the lowest TA (0.085%)during at shelf-life.Decreases in the amount of TA and decomposition of organic acids during storage due to respiration were observed by Echeverria and Valich (1989). Guillén *et al*. (2006) reported that sugar and organic acids concentration in the fruits and vegetables are affected by ethylene production during storage.The results of these researchers were in agreement with the findings of our study.

Fruit firmness

Initial firmness of fruits at harvest was 108.52 N and declined to 33.49 N after 90 days of storage. Fruits treated with 625 ppb 1-MCP were more firmer (74.13 N) than the control group which recorded 46.3 N (Table 1). Fruit firmness at harvest was 108.52 N and declined to 23.21 N after 90+3 days of shelf-life conditions. 1-MCP dose of 625 ppb had the highest fruit firmness of 60.09 N followed by 312.5 ppb 1-MCP. The lowest fruit firmness of 42.60 N was noted in control fruits (Table 2).The fruit firmness showeda decrease with ripening and prolonging storage duration which showed similarity with the observations found by Ozdemir*et al*. (2009). Karacali (2012) also explained this reduction in fruit firmness and he stated that because of cells enlargement and intercellular spaces, the breakdown of pectin, hemicelluloses and the decrease in resistance of cell wall may have resulted fruit firmness. Significant effect of 1-MCP was found in preservation of fruit firmness. The treatments resulting slowing down the respirationand decreasing the weight loss showed positive effects on maintaining fruit firmness.

Fruit colour (*L, *h*°, *C**)**

Decreases in*L** values occurred with prolonging the storage duration. The *L** values of persimmon fruitsatharvest was 61.55 and declined to 52.28 by 90 days of cold storage. The maximum *L** value of 58.77 was recorded in 625 ppb 1-MCP treated fruit and thecontrol group had the minimum*L** value of 55.63 (Table 1). Extending in storage period resulted in declining*L** values. The *L** value of fruits at harvest was 61.55 and decreased to 51.35 after 90+3 days of shelf life conditions. 625 ppb 1-MCP treatment hadthe highest *L** value which was 56.63 and thelowest *L**was 53.77 in control group (Table 2).

Prolonging storage duration induced a decrease in *h*°. The *h* °at harvest was 79.46°and reduced to 67.46° at 90 days of storage period. 1-MCP dose of 625 ppb gave the highest *h*° value of 74.42° whereas the lowest *h*° wasrecorded in control groupwhich was 69.43 (Table 1). Storage duration and 1-MCP doses had statistically significant on *h*°values. The 1-MCP dose of 625 ppb had the highest *h*°value of71.46° while the lowest *h*°value of 68.01°was noted in control group (Table 2). Storage duration significantly affected *C** values. During storage period, reduction in *C** values occurred and *C**value of 59.03 were noted initially and then decreased to 51.10 by 90 days of storage. 1-MCP dose 625 ppb had the highest *C** value of 56.49 while control group gave the lowest *C**value of 54.26(Table 1). In shelf-life conditions,*C** value of 59.03 were noted initially and reduced to 46.72 by 90+3 days of storage. 625 ppb dose of 1-MCP had the maximum *C** value of 53.42 whereas minimum*C** value of 48.70 was noted in control fruit (Table 2). Extension in storage period resulted in reduction of*L**, *C** and *h*° values of skin colour. During the storage of fruits changes in colour from green-orange to orange was observed. The results reported by Yener (2013) were in parallel with our results regarding the importance of 1-MCP application in maintaining effects of skin colour. Koyuncu *et al*. (2005) reported that darkening in colour was attained by MAP treatment during storage. Kuzucu and Kaynas (2002) stated that different packaging treatments effected the storage duration, ripening and quality of persimmon fruits.They also reported the fluctuations in skin colour during storage. Their findings were in agreement with the results of our study. Besada *et al*. (2010) reported that prolonging the storage duration resulted a decrease in *h*° values of persimmon fruit. According to Woolf *et al.* (1997) L*, C* and *h*° values show a decrease during persimmon storage and our results was in parallel with the findings of their experimental results.

Decay development

Increases in the amount of decayed fruits were observed in the study and decay injury was 10.59% at 90 days of storage. Control group had the maximum decayed fruit of 10.08% followed by 7.19% noted in 312.5 ppb dose of 1-MCP. 625 and 312.5 ppb 1-MCP applications had the lowest deteriorated fruits comparing to control group (Table 1).During shelf-life conditions the effect of 1-MCP doses on decay development was statistically significant. Storage extensionresultedanincreasein the amount of decayed fruits that reached to 8.94% and 16.93% by the end of 60+3 and 90+3 days of shelf-life, respectively. Control group had the maximum (15.89%) of decay, followed by 312.5 ppb dose of 1-MCP with 11.18% (Table 2). Sakaldas (2014) studied the effects of different doses of 1-MCP on postharvest quality in ‘Deveci’ pears and he reported that 625 ppb and 1250 ppb doses of 1-MCP gave better results in terms of preventing decay development inpears.

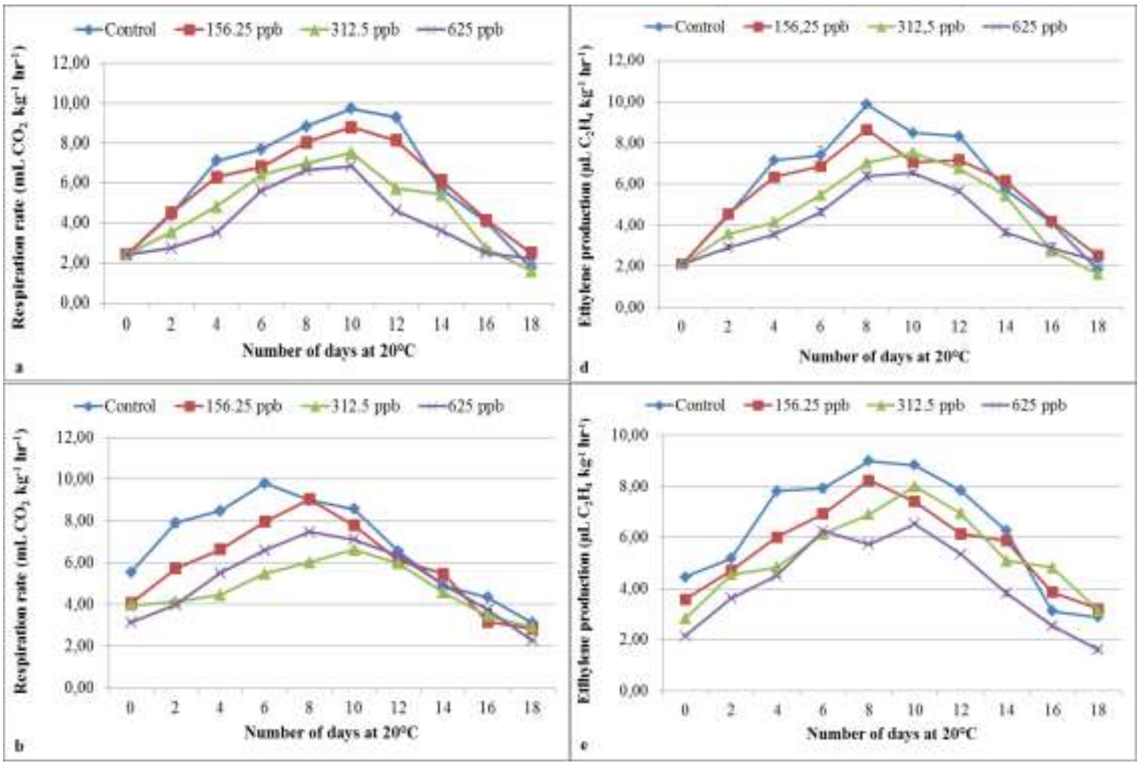
Respiration rate (CO_2 production)

All the treatments reached to maximum climacteric on the 10th day of storage. The control group produced maximum CO_2(9.74 ml CO_2 $kg^{-1}hr^{-1}$) while 1-MCP treatment of 625 ppb had the minimum CO_2 production (6.85 ml CO_2 $kg^{-1}hr^{-1}$) as shown in Figure 1a. Variations in CO_2production occurred at the 60 days of storage at 0°C (Fig. 1b). Control fruit had the maximal respiration on 6th day, 156.25 ppb had maximum respiration on 8th, whereas 312.5 ppb and 625 ppb 1-MCP treated fruits had climacteric maximum on 10th day of storage. The highest respiration rate was calculated in control group. CO_2production in 'Fuyu' fruits treated with different levels of 1-MCP doses and stored at 0°C for 90 dayswere shown in Figure 1c. Control, 156.25 and 312.5 ppb 1-MCP doses attained climacteric maximum on 6th dayof storage whereas 625 ppb dose of 1-MCP had maximum climacteric on 8th day of storage. Control group had the highest respiration rate(9.46 ml CO_2 $kg^{-1}hr^{-1}$) compared to 1-MCP treated fruits. Fruits of 625 ppb 1-MCP dose recorded the lowest respiration rate (7.12 ml CO_2 $kg^{-1}hr^{-1}$). In general, the fruits treated with 1-MCP decreased the CO_2 production. Similarly,1-MCP treatments resulteda decrease in CO_2 production as compared to the control group this means that 1-MCP plays an effective role in increasing the shelf-life of 'Fuyu' persimmons. During storage, 625 ppb 1-MCP exhibited the lowest CO_2 production among the treated groups.

Ethylene (C_2H_4) production

Fruits treated with 156.25 ppb 1-MCP and control group gave the maximum C_2H_4 production on 8th day while fruits treated with 312.5 and 625 ppb 1-MCP doses reached a peak on 10th day. The control group had the highest (9.86µL C_2H_4 $kg^{-1}hr^{-1}$) and 625 ppb dose of 1-MCP had the lowest (6.55 µL C_2H_4 $kg^{-1}hr^{-1}$) C_2H_4 production as shown in Figure 1d. Control and 156.25 ppb 1-MCP treatment groups produced the highest amount of C_2H_4 on 8th day while 312.5 and 625 ppb 1-MCP doses had the highest C_2H_4 productionon 10th day. At 60th day of storage, maximum (8.99 µL C_2H_4 $kg^{-1}hr^{-1}$) C_2H_4 production was in control group and 1-MCP dose of 625ppb had the minimum (6.53 µL C_2H_4 $kg^{-1}hr^{-1}$) C_2H_4 production (Fig. 1e). At 90th dayof storage,C_2H_4 production reacheda peak in control fruits and 156.25 ppb 1-MCP dosereached on 6th day whereas 312.5 and 625 ppb 1-MCP doses had maximumC_2H_4productions on 8th day (Fig. 1f) Control group had maximum C_2H_4 production (6.84 µL C_2H_4 $kg^{-1}hr^{-1}$) while 625 ppb of 1-MCP dose was noted to have minimum (4.29 µL C_2H_4 $kg^{-1}hr^{-1}$) C_2H_4 production.



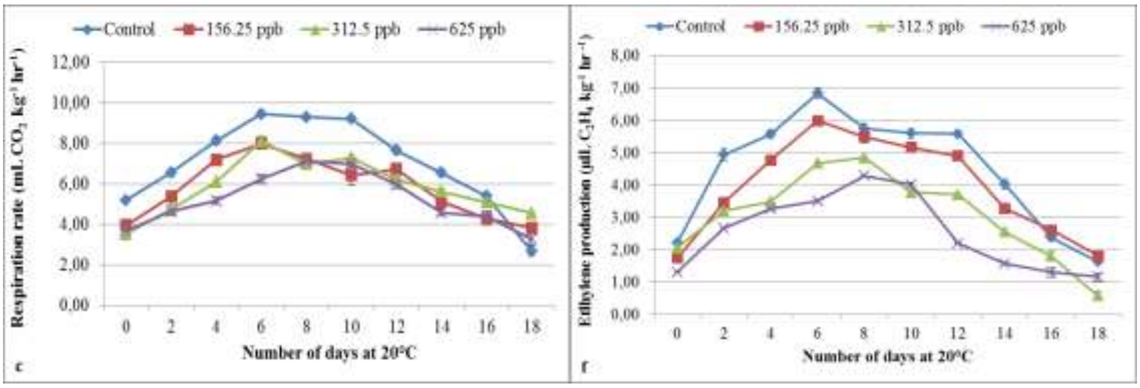


Figure 1. Effects of different 1-MCP doses on respiration rate (a: day 0, b: day 60, c:90 day) and ethylene production (d: day 0, e: day 60, f: day 90) in 'Fuyu' persimmon fruits at different storage periods.

Conclusions

1-MCPtreatments in persimmon fruits reduced weight loss, maintained total soluble solids content, titratable acidity, skin colour and slowed down the rate of respiration and ethylene production. According to the findings obtained, 625 ppb dose of 1-MCP was found to be the most appropriate dose in keeping the best quality of 'Fuyu' persimmons during the long term storage.

Abstract

Astringent 'Hachiya' persimmon fruits were harvested at optimal harvest maturity and divided into four groups for treatment with different 1-MCP doses. The following doses of 1-MCP 0 ppb (control), 156.25 ppb, 312.5 ppb and 625 ppb were tested for postharvest quality of 'Hachiya' persimmons. 1-MCP treatments were carried out at 5°C for 24 h. Treated and untreated (control) fruits were stored at 0±1°C and 90±5% relative humidity for 3 months. Fruits were held at 20°C for 3 days after the cold storage with the aim of determining the shelf-life performance. Fruits were removed from storage conditions at 30 days of intervals and weight loss, fruit firmness, skin colour, soluble solids content, titratable acidity, decay development during storage and shelf-life conditions were noted. Furthermore, respiration rate and ethylene production of persimmon fruits were also recorded.The fruits treated with the highest 1-MCP dose (625 ppb) gave better results regarding the lowest weight loss and decay development. The use of 625 ppb 1-MCP also resulted the highest soluble solids, fruit firmness, L*, h° and C* values, respectively, as compared to the other treatments during the cold storage and shelf-life. Minimum respiration rate and ethylene production were recorded in the fruits treated with 1-MCP dose of 625 ppb. Thus, it can be concluded that 625 ppb 1-MCP can be used for the effective treatment of astringent 'Hachiya' persimmons during 3 months cold storage.

Keywords: *Persimmon, postharvest, ethylene, respiration, 1-MCP*

Introduction

Large number of fruits species can be grown in Turkey thanks to its geomorphologic, topographic and climatic advantages. Turkey is also the origin of many fruits and vegetables. Persimmon growinginTurkey is still in developmental stages concerning its production numbers. Persimmon is cultivated globally on 802.458 ha land with the production of 4.056.987 tonsannually(Anonymous, 2014a). Persimmons are grown on 2.062 ha and its production constitutes 33.470 tons/year by the end of 2014 in Turkey (Anonymous, 2014b). Major importers of persimmon from Turkey are Kuwait, Jordan, Germany and Switzerland (Anonymous, 2012c). Despite increases in the production, persimmon fruits have some problems to overcome during the postharvest stagesuch asstandardization, storage, marketing and transportation. The main postharvest problems of persimmon fruits are the short shelf life and quality losses including weight loss and fruit softening, etc.that decreases its marketing value and postharvest life. These postharvest problems can be reduced or overcomeby using some postharvest treatments (Yildiz *et al.*, 2002).Many factors directly or indirectly contribute to the long or short life span of horticultural produces. Many techniques have been developed to decrease postharvest losses. The use of 1-MCP controls or slows down the negative effects of ethylene on fruit softening and ripening. Effects of 1-MCP vary fromspecies, variety and storage conditions. 1-MCP retards ethylene and CO_2 production, colour changes, softening, ripening and aging (Watkins and Miller, 2005).Cold storage technique have been the most effective and efficient method to maintain the quality offresh fruits and vegetables (Kilinc and Cakli, 2001). Despite of improvement in the cultivation of persimmon, the problems like short shelf life, short marketing period and various factors (weight loss, fruit softening, changes in the skin and flesh of fruit, etc.) decrease its marketing value. Avoiding such problems and increasing the shelf life of this nutritious fruit will provide economic advantages and will allow emergence of new markets. Different studies being conducted on maintaining the postharvest life and preserving the quality of persimmon fruits. However, there is still need of enough research to be done. The objective of this study was to elucidate the postharvest performance of astringent ‘Hachiya’ persimmon fruits by using different 1-MCP doses.

Materials and methods

The fruits were harvested at optimal maturity stage and ‘Hachiya’ persimmon fruits (*Diospyros kaki* L.) were used in the experiment. After pre-cooling the fruits were divided into four groups for postharvest treatments. The first, second and third group of fruits were treated with 156.25 ppb, 312.5 ppb and 625 ppb 1-MCP (SmartFresh^{TM}), respectively. Un-treated fruits were considered as control group. For 1-MCP treatments,the fruits were kept in plastic crates in air tight containers having volume of 1m^3. 1-MCP treatment was carried out at 5°C for 24 hours. After 1-MCP treatments the fruits were stored for 3 months at 0-1°C temperature with 90±95% relative humidity. Quality assessments were carried out at 30-day intervals for each replication of 8 fruits. After each storage period (30-day intervals), 12 fruits out of 24 were removed and kept at 20°C for 3 days to simulate a period of shelf-life and then analyzed. Weight losses of fruits were determined by using digital scale (sensitive to 0.01g) and weight losses were expressed in percentage. Total soluble solids (TSS) content were measured with a digital Refractometer(Hanna HI96801, Hanna Instruments, USA) and means were then calculated in percentage. Titratable acidity (TA) of juice samples was measured with a pH-meter (Inolab pH 720, WTW, Germany). TA was determined by titrating 2 mL of fruit juice in 38 mL of distilled water with 0.1 N NaOH to an end point of pH 8.1 and expressed as % malic acid/100 ml juice. Fruit firmness was measured with the help of fruit texture analyzer (plunger with 7.9 mm diameter) by peeling at three different equatorial sections of the fruit. The measured values were given in Newton (N). The changes in skin colour of the fruits were assessed by the help of Minolta CR-400 (MINOLTA Camera Co, LTD Ramsey, NJ) chromameter. The results were expressed as $L*$, chroma ($C*$) and Hue angle ($h°$). Decaydevelopment of fruits was observed through visual observation and the amount of fruits deteriorated were given in percentage.The respiration rate and ethylene production of fruits were determined at the interval of two days end of the 0, 60 and 90 days of storage by using a GC (Thermo Electron S.p.A., Strada Rivoltana, Milan, Italy). For that purpose fruits of known volume and weight were kept in air tight container with volume of 5 L for 1 hour at 20°C. Sample of 1ml headspace gas were taken through a gas-tight syringe from the atmosphere of air-tight container and injected into the GC for analysis of ethylene and CO_2. Experiment was conducted according to completely randomized design with three replications and each replication had8 fruits. Means were compared by using Duncan’s test to find significant differences. The data obtained was evaluated by using SAS program.

Results and Discussion

Weight loss

Increases in weight losses occurred with the extension of storage duration. Mean value of 2.45% recorded for weight loss after storage of 30 days and increased to 5.98% at 90 days of storage (Table 1). The highest(5.67%)and the lowest(3.23%) mean values for weight losses were noted in control and 625 ppb 1-MCP treated fruits. Similarly, and additional3 days storage at shelf-life conditions resulted an increase in weight loss with maximum mean weight loss of 7.24% recorded in control group and the minimum mean weight loss (4.72%)found in 625 ppb 1-MCPdose (Table 2). Respiration and water loss results an increase in weight losses of fruits and vegetables (Yener, 2013). 1-MCP prevented weight losses in our study which could be because 1-MCP slows down the respiration rate of fruits.

Total soluble solids (TSS)

TSS content increased from 17.57% to 19.02% and then a slight decrease to 15.64% was recorded after 0, 30 and 90 days of cold storage, respectively. Maximum mean (17.80%) of TSS followed by 17.55% was noted in 625 and 312.5 ppb1-MCP treated fruits compared to control (Table 1). Likewise, TSS content increased from 17.57% to 18.04% at 30+3 days, followed by a slight decrease in TSS of 15.25% then to 13.96% in 60+3 and 90+3 days of storage in shelf life conditions, respectively. The highest (17.33%) TSS in 625 ppb 1-MCP andthe lowest TSS (15.45%) wererecorded in control group (Table 2). 1-MCP was effective in maintenance of TSS content during storage and shelf life conditions. In our study the amount of TSS content decreased by the extension of storage period which was in agreement with the results of Kuzucu and Kaynas (2002).

Titratable acidity (TA)

TA of the persimmon fruits declined with prolonging the storage duration. TA of fruits at harvest was 0.184%and decreased to 0.143, 0.111and 0.066% after 30, 60 and 90 days of storage, respectively (Table 1). The highest TA (0.130%) in 625 ppb and the lowest (0.119%) TA was calculated in 156.25 ppb 1-MCPtreated fruits. TA levels of the fruits reduced throughout the shelf life conditions as well. The TA content of the fruits at harvest was 0.184% and exhibit a decline to 0.108% followed by 0.085%, 0.050% 30+3, 60+3 and 90+3 days of storage at shelf-life, respectively. Maximum mean of TA (0.121%) in 625 ppb 1-MCP treatment and minimum TA (0.092%)was calculated in control group (Table 2).In our study, 1-MCP was effective in preservation of TA. Reduction in the amount of TA is related to the decomposition of organic acids during respiration (Echeverria and Valich, 1989). Guillen *et al*. (2006) observed that a rise in the ethylene production of fruits and vegetables affected the amount of sugar and organic acids. Results obtained by these researchers were also in parallel with our study.

Fruit firmness

A decrease in fruit firmness was observed with 70.01 N at harvest and declined to 44.44 N followed by 27.43 N and 12.31 N at 30, 60 and 90 days of cold storage, respectively. The highest fruit firmness of 43.89 N in 625 ppb 1-MCP treated fruits whereas the lowest mean (34.34 N)was recorded in controlgroup (Table 1). In the same way, reduction in flesh firmness occurred with the extension of storage at shelf-life periods.Fruits of 625 ppb 1-MCP treatment were more firmer (30.49 N) thanthe control fruits observed to be less firmer (23.61 N) as shown inTable 2.Reduction in fruit firmness could be because of enlargement in cells, intercellular spaces, breakdown of pectin, hemicelluloses and diminishing resistance of wall (Karacali, 2012). 1-MCP was effective in keeping the fruit firmness. Slow respiration rate and low water loss were maintained in preserving the firmness of fruit.

Fruit colour (*L, *h*°, *C**)**

*L** values of fruits declined with the extension ofcold storage duration. Initial *L** valueof fruits at harvest was 66.88 and decreased to 64.52 followed by 56.04, 50.70 at 30, 60 and 90 days of storage period, respectively. Maximum mean value of *L**was 61.10 in 625 ppb1-MCP treatment while minimum mean value (58.00) was noted in control group. No significant difference was found between 156.25 ppb and 312.5 ppb doses of 1-MCP (Table 1).Similar trend was also found at shelf-life conditions.*L** value of fruits at harvest was 66.88 anddecreased to 55.56,52.52 and 47.57 after 30+3, 60+3 and 90+3 days of storage, respectively. Fruits with 625 ppb 1-MCP had the highest mean value (57.81) of *L** and the lowest mean value(52.92) was calculated in controlgroup (Table 2).

Hue angle (*h*°) declined with the extensionof storage duration. Hue angle value at harvest was 82.99° and declined to 74.56° followed by 71.80° and 69.40° at 30, 60 and 90 days of storage, respectively. The maximum mean value of 76.86° in 625 ppb 1-MCP treatment whereas minimum mean for *h*° was 72.47° noted in controlgroup (Table 1). In the same manner, reduction in *h*° was observed during at shelf-life conditions. Initial *h*° at harvest was 82.99° and declined to 72.49° followed by 68.04° and 66.13° by 30+3, 60+3 and 90+3 days of storage, respectively.The highest mean value (74.41°) was recorded in 625 ppb 1-MCP whereas the lowest (70.46°) for *h*° was measured in control (Table 2).

Decrease in *C** values were noticed as the storage duration prolonged. *C** value recorded at harvest was 65.77 and reduced to 62.17, 50.51 and 40.86 at 30, 60 and 90 days of cold storage, respectively. The highest mean value for *C** was 56.81 in 625 ppb 1-MCP treatment while the lowest (52.22) C* was noted in control group (Table 1). Likewise, decline in the values of *C**occurred in parallel to increase in shelf-life periods. Initial *C** value of fruits at harvest was 65.77 and reduced to 44.69 followed by 39.92 and 34.54 after 30+3, 60+3 and 90+3 days of storage, respectively. The maximum mean value of 49.15 for C* in 625 ppb 1-MCP whereas the minimum *C** was noted in 43.03 in control group (Table 2). In our study prolonging storage duration showed a decline in *C**, *L** and *h*° values and a change in colour from green-orange to orange was noticed. MAP and cold storage treatment with extending storage durations resulted in dark skin colour in fruits (Koyuncu *et al*., 2005). Kuzucu and Kaynas (2002) explained the effects of different types of packaging on storage duration, ripening and quality where they obtained fluctuated skin colour values during the storage.

Decay development

No decay development occurred during the first 30 days of storage while 28.61% of decay was recorded at 90 days of cold storage. Generally, 1-MCP treated fruits had less decay development. Maximum decay percentage was 25.91% in control group whereas minimum decay injury of 5.84% calculated in 625 ppb 1-MCP treatment (Table 1). Increases in decayed fruits were observed in parallel with prolonging shelf-life periods. Mean for number of decayed fruits recorded after 30+3 days of shelf-life was 2.46% and rose to 19.34% followed by 47.82% at 60+3 and 90+3 days of shelf life periods, respectively (Table 2). Sakaldas (2014) reported that 625 and 1250 ppb 1-MCP treatment had a positive effect on preservation of postharvest quality of persimmon fruits.

[1]The values within a column and row with different letters are significantly different at P ≤ 0.05 according to the Duncan's multiple range test.

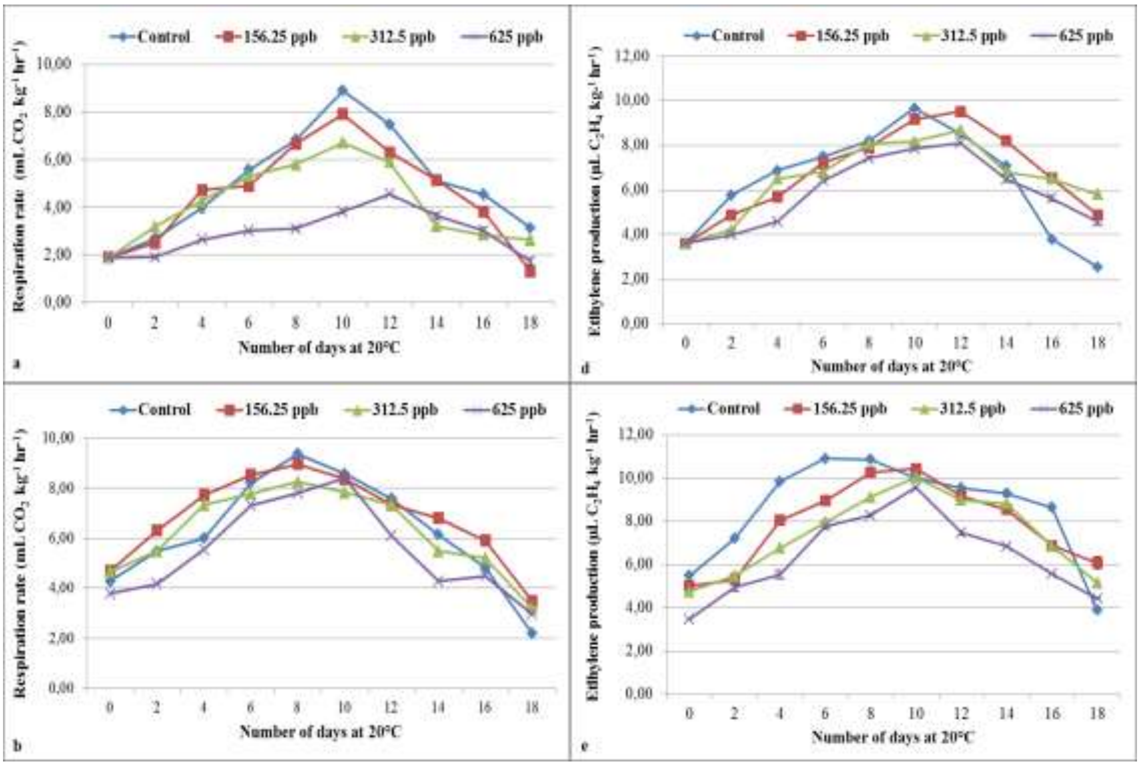
Respiration rate (CO_2 production)

Variations occurred in respiration rate were given in Figure 1a. Control, 156.25 and 312.5 ppb 1-MCP treated fruits reached a maximum climacteric at 10th day. However, fruits treated with 625 ppb 1-MCP had climacteric maximum on 12th day. Maximum CO_2 production (8.90mL CO_2kg^{-1} hr^{-1}) was in control fruits whereas minimum CO_2 production of 4.55 mL $CO_2kg^{-1}hr^{-1}$ was recorded in 625 ppb 1-MCP treatment at harvest. Respiration rate of the fruits at 60 days of storage were illustrated in Figure 1b showed that control, 156.25 and 312.5 ppb 1-MCP treated fruits had maximum climacteric on 8th day. However, 625 ppb 1-MCP treated fruits attained climacteric maximum on 10th day. Control group had the highest CO_2 production (9.36mL $CO_2kg^{-1}hr^{-1}$) compared to 1-MCP treated fruits. The lowest CO_2 production (8.39 mL CO_2 $kg^{-1}hr^{-1}$) was noticed in 625 ppb 1-MCP. CO_2 production of the fruits at 90 days of storage was presented in Figure 1c. Control and 156.25 ppb 1-MCP treatment had maximal climacteric on 4th and 6th day while both 312.5 and 625 ppb 1-MCP had climacteric maximum on 8th day, respectively. The highest CO_2 productions in control group (11.01 mL CO_2 kg^{-1} hr^{-1}) while the lowest CO_2 production was noted in 625 ppb of 1-MCP treatment dose (7.58mL $CO_2kg^{-1}hr^{-1}$).

Ethylene (C_2H_4) production

Ethylene production of persimmon fruits at harvest was presented in Figure 1d. Control group attained maximum C_2H_4 production on day 10th, whereas all doses of 1-MCP treated fruits reached maximum C_2H_4 production on 12th day of storage. The highest value of 9.66µL $C_2H_4kg^{-1}hr^{-1}$was recordedin control group and the lowest C_2H_4 production of 8.10µL $C_2H_4kg^{-1}hr^{-1}$ were recorded in 625 ppb 1-MCPdose. C_2H_4 production at 60 days of storage was given in Figure 1e. Control fruits reached to maximum C_2H_4 production on 6th day while 1-MCP treated groups attained maximal C_2H_4 production on 10th day.



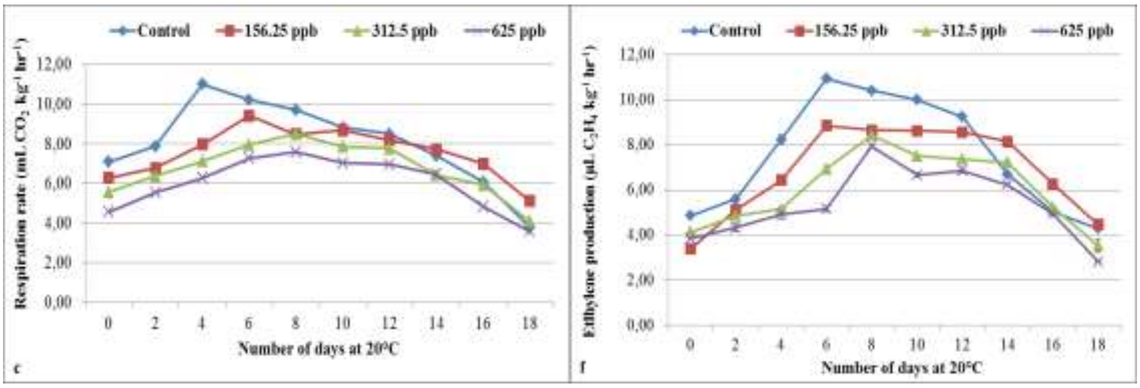


Figure 1. Effects of different 1-MCP doses on respiration rate (a: day 0, b: day 60, c:day 90) and ethylene production (d: day 0, e: day 60 and f:90 day) in 'Hachiya' persimmon fruits at different storage periods.

After 60 days of storage the maximum C_2H_4 production of 10.91μL C_2H_4 $kg^{-1}hr^{-1}$ in control group whereas minimum C_2H_4 production of 9.56 μL C_2H_4 $kg^{-1}hr^{-1}$ was found in 625 ppb 1-MCP treatment. C_2H_4 production after 90 days of storage at 0˚C were exhibited in Figure 1f showed that fruits of control and 156.25 ppb 1-MCP treatment reached to maximum C_2H_4 production on 6th day while fruits with 312.5 and 625 ppb 1-MCP attained maximum C_2H_4 production on 8th day. The maximal amount of C_2H_4 production (10.94 μL C_2H_4 $kg^{-1}hr^{-1}$) in control group however minimal C_2H_4 production (7.95 μL C_2H_4 $kg^{-1}hr^{-1}$) was obtained in fruits treated with 625 ppb 1-MCP. In our study it was found that 1-MCP dose of 625 ppb had the lowest amount of ethylene production and respiration rate. In many fruits and vegetables, 1-MCP generally slows down ethylene synthesis by blocking ethylene action. Furthermore, it decreases CO_2 production, which indicates its positive impact on increasing the storage duration and shelf life period.

Conclusions

Persimmon fruits treated with 1-MCP dose of 625 ppb had minimum weight loss, decay development, respiration rate and ethylene production. Whereas maximum soluble solids content, fruit firmness, *L**, *C** and *h*° values during both cold storage and shelf life were also recorded at 625 ppb 1-MCP treated fruits. On the basis of results obtained it is recommended to use 625 ppb of 1-MCP for keeping the best postharvest quality of 'Hachiya' persimmons during 3 months storage.

IDENTIFICATION OF WEED SEEDS CONTAMINATING WHEAT GRAIN

Sibel UYGUR*

Çukurova University, Agricultural Faculty, Department of Plant Protection, Adana, Turkey
*Corresponding author: suygur@cu.edu.tr

Abstract

The most important feature of weeds compared to cultivated plants, is that they have very high seed output and their longevity in the soil. The first step for the successful management of weeds is using weed-free crop seed. In modern agriculture, separation between weed seed and crop seed was minimized during the seed production and packaging. This study was conducted to identify weed seed contamination in wheat grains between 2014-2016. The wheat samples (average two kg) were taken from randomly selected six (in total 18) wheat grain sellers (crop seed or feed wheat seed) in the Adana province of Turkey. They were brought to the laboratory and examined for any weed seeds. As a method, the wheat grains and weed seed were separated using different sized sieves, then identified using different sources and collections. Corncockle (Agrostemma githago L., Caryophyllaceae) , Goosegrass (Galium aparine L., Rubiaceae), Field bindweed (Convolvulus arvensis L., Convolvulaceae), Jointed goatgrass (Aegilops cylindrica Host., Poaceae), Wild oat (Avena sterilis L., Poaceae), Italian thistle (Carduus pycnocephalus L., Asteraceae), Thistles (Centaurea spp., Asteraceae), Curly duck (Rumex spp., Polygonaceae) were found the most common weed seeds in the samples. Among these important weeds, Field bindweed is only perennial herbaceous weed which reproduces by seeds and rhizomes. On the other hand, some weed seeds are poisonous for both humans and livestocks such as Corncockle.

Keywords: *Weed, Seed, Grain, Wheat, Corncockle.*

Introduction

Wheat is one of the main agricultural products that hold an important place in human nutrition. It is affected by both abiotic and biotic factors (weed, insect and fungus pests) during the cultivation. Weeds are an important pest group in wheat farming. The management of weeds in the wheat field has been particularly difficult in the last two decades because of herbicide resistance.

Adana province is located in the Mediterranean part of Turkey and the center of Cukurova Delta, which is a main agricultural area of Turkey. According to data from TUIK (2015), total agricultural area is 4.891.150 da in Adana. Wheat, citrus, corn, olive, sunflower and watermelon are the main crops. But wheat growing areas has been decreased last couple years. The main reason was herbicide resistant weed species. Wild oat (*Avena sterilis*) and Wild mustard (*Sinapis arvensis*) are two important resistant weeds against ALS and ACCase herbicides (Uygur et al., 2012). So, successful management of wheat weeds are very important including preventation methods. Weed free crop seeds are the first step in the weed management programs. Planting crop seeds containing weed seeds has been the most common methods of spreading weeds for centuries (Wicks et al., 1995).

This study was planned to learn and identify which weed species mixed with wheat grain can be carried to the field. Even wheat grain for animal feeding can be brought these weed seeds to the fields.

Material and Methods

The wheat samples were taken from randomly selected six (in total 18 samples) wheat grain sellers (crop seed or feed wheat seed) in the Adana province of Turkey to identify weed seed contamination in wheat grains between 2014-2016. All samples were taken just after weed harvest. Average weight of each sample was two kg. They were brought to the laboratory and examined for any material. In the first step; soil, straw and stone material, and other pests (especially weevils and snails) were removed by visually. Then wheat grains and weed seed were separated using different sized sieves. Same kind of seeds was collected in a small petri dish, then identified using different sources (Davis, 1965-2000; Hanf, 1990; Lionakis Meyer and Effenberger, 2010) and weed science laboratory collection.

Results and Discussion

Fifty four weed species (14 monocots and 40 dicots) were separated and identified from the samples (Table 1 and Table 2). In general weed species were represented the all geographic regions of Turkey. It means that, some of these wheat grain samples came from different parts of Turkey. The most common weeds in the wheat grains according the frequency (found min. 5 samples) were Jointed goatgrass (*Aegilops cylindrica*), Corncockle (*Agrostemma githago*), Wild oat (*Avena sterilis*), Italian thistle (*Carduus pycnocephalus*), Field bindweed (*Convolvulus arvensis*), Goosegrass (*Galium aparine*), Darnel ryegrass (*Lolium temulentum*), Wild mustard (*Sinapis arvensis*), Johnsongrass (*Sorghum halepense*), Narbon vetch (*Vicia narbonensis*) and Common vetch (*V. sativa*). They are also serious competitor weeds in the wheat fields. *A. githago* and *L. temulentum* were reported as poisonous plant in Turkey (Ozturk et al., 2008).

In another province of Turkey, Kahramanmaras, *Sinapis arvensis* was found the highest number of weed seeds in wheat grain (165.0 seeds /kg). *Hordeum vulgare, Lolium temulentum* , *Boreava orientalis* and *Galium tricornutum* were found as important weeds similarly (Tursun et al., 2006).

Conclusions

Successful management of weeds is not only by using mechanical tools and chemicals. Weed-free crop seed must be the first preventation method during all crop cultivation. In modern agriculture, separation between weed seed and crop seed was minimized during the seed production and packaging. However, some weed seeds are still problematic in the wheat grain. While wheat seeds are being prepared for seed or animal feeding, weed seeds are transported along with them. The weed seeds, which are not in a zone, are transported to other areas. On the other hand, seeds of resistant weed species such as Wild mustard can be carried with grains to the herbicide resistance free wheat fields. As a sample, Guncan (1980), in his large scale project show that, the farmers could be transferred 14500 weed seeds per decares in the case of sowing wheat without being cleaned. Starting from the wheat harvest, the grains must be cleaned using different kind of separator, and, observed by farmers and technical staff in the seed seller and companies.

PRETREATMENT INFLUENCE ON THE DRYING RATE AND BIOACTIVE COMPOUNDS OF DRIED FIGS

Luziana HOXHA*, Renata KONGOLI

Faculty of Biotechnology and Food, Agricultural University of Tirana, Albania

Abstract

Figs are delicious dried fruit consumed, and occupy a special place of importance in nutrition, and have numerous health benefits to offer as well, associated this with the presence of bioactive compounds. The aim of this paper was to investigate the influence of different alkaline solutions used as pretreatment on the drying rate and bioactive compounds content. The selected fig variety was "Roshnik" variety, and was studied in a batch operation in a laboratory dryer, at a preset drying temperature of 60 ^oC and constant air velocity. The constants of drying kinetics and mean apparent diffusivity of moisture for all pretreatment were calculated. Dipping figs in NaCl, $CaCO_3$, K_2CO_3, and lye solution increased the drying rate. Figs dried in 50248-61808 seconds depending on pretreatment for the same drying process parameters. The results showed that figs dipped in a 1% solution of potassium carbonate and sodium chloride to have shorter drying time. Also, application of 0.2 % of $K_2S_2O_5$ resulted to increase the quality of dried products. Applications of pretreatment should be taken under consideration for application to food processors for figs drying as they influenced positively in increasing the drying rate and the quality of the dried figs.

Keywords: *Ficus carica, drying rate, pre-treatment, polyphenols*

Introduction

Figs (*Ficus carica* L.) are a widespread species commonly grown, especially in warm, dry climates, and mainly in Mediterean countries, where they occupy an important role of diet (author).

Figs are widely consumed fresh, as they naturally have a short post-harvest life; also they are very popular as dried fruit. Drying is one of the important preservation methods employed for storage of figs since the dawn of civilization. Fig fruit can be dried either by traditional methods (sun drying) or in conventional hot-air dryers (Babalis *et al*., 2006). However, the research on drying figs is limited (Piga *et al*. 2004; Doymaz, 2005; Xanthopoulos *et al*., 2007, 2009, 2010). Papoff *et al*., (1998) tried to dehydrate figs with an industrial dehydrator, and gained very good results in terms of drying times and microbial stability, but structure collapse occurred and figs have some problems with the sensorial properties.

Drying cause physical, chemical and biochemical changes in addition to some undesirable alterations such as textural and color changes (Xanthopoulos *et al*., 2010). Such changes may be influenced by using pre-treatment, causing a shorter drying time and a reduction in adverse changes that occur during drying compared to untreated fruits (Lewicki, 2006). Several studies have tested various pre-treatment with the aim to reduce peel resistance of the final dried product or to weaken it and to water transfer from the inside of the product to the surface, increasing likewise the drying rate (Doymaz, 2007).

In recent years, several data have been generated on the polyphenol constituents in a variety of food materials, including figs. Ficus species are rich source of naturally occurring antioxidants of which phenolic compounds and flavanoids play a vital role in preventing innumerable health disorders related to oxidative stress including cardiovascular diseases (Sirisha *et al*., 2010). Slatnar *et al*., (2011) compared for the first time the phenolic content between fresh and dried fruit. However, only a few studies have investigated the effect of drying on polyphenols of figs.

The lack of a drying system applicable for figs in industrial level in Albania encouraged us to investigate the influence of different pretreatment in the drying performance and phenolic content of figs (*Ficus carica*), and several drying tests have been carried out in a laboratory dryer, with the attempt to achieve shorter drying time and offering the best quality dried products.

Materials and methods

Plant material

The local variety of *Ficus carica* named "Roshnik" (yellow skin colour and red pulp) was selected for this study. Its cultivation area is Roshnik village (40°42'51.56"N 19°58'48.02"E) in Berat region (Albania) and sun-dried figs are traditional products of this region. Fruits were harvested at the end of August 2017 at optimal maturity and immediately transported to the laboratory. The selection of fruits was done based on weight in order to ensure a uniform size, appearance, maturity, and health conditions.

Sample preparation and drying conditions

Before drying, fruits were pre-treated as: blanching in boiling water with 1% alkaline solution (lye, $CaCO_3$, K_2CO_3, and NaCl) for 1 min, cooling to 25±2 ^oC using tap water (blanching water to fruit ratio was 12:1), also, fruit were dipped in 0.2% $K_2S_2O_5$ (KMS) for 1 min. Also, untreated samples was used as control (sample code C), and only treated with KMS (sample code C-KMS).

Fruits were dried in a laboratory dehydrator. Fruits were placed on three shelves per treatment (the drier can hold ten shelves). Hot air dehydrator was a closed cabinet with a fan inside to blow the air "horizontally" across the shelves (fruits were set on shelve inside the drying chamber). The ambient air temperature was 25^{o}C, while drying air was heated electrically to a 60^{o}C adjusted temperature, with air relative humidity approximately 40% (at the beginning) and 10% (at the end) and flowed to the fruits with a constant speed 1 m/s. Air recycling system allowed the mixing of exhaust air with fresh air, which was then reheated and redirected to the product.

Preparation of extracts

Methanol extracts were prepared by extracting 1 ± 0.001 g grinded fig samples with 10 mL of aqueous methanol 80% (v/v), homogenized for 1 minute using Ultra-Turrax T-25 (Ika-Labortechnik, GR), with speed set 11000 rpm, and centrifuged using centrifuge Eba 21 (Hettich, GR) for 15 min at 4500 rpm. This process was repeated three times and supernatants were collected and analyzed. Extracts of fresh and dried fig samples were prepared separately. All samples were analyzed in triplicate.

Assessments and determinations

The weight of the dried sample was measured using a precision balance with an accuracy of 0.01 g, having a maximum capacity of 3000 g. The weight of the material was measured in fixed time intervals and recorded as a function of drying time. The drying data from the different drying tests were then expressed as moisture ratio MR versus drying time and drying rate DR versus drying time.

The moisture content has been determined both for the fresh and for the final dehydrated products (AOAC, 2000).

pH value was determined using pH meter UB-10 (UltraBasic, Denver Instrument) (AOAC 2000), total acidity (expressed as % citric acid) was determined by titrating with 0.1N NaOH (AOAC 2000).

Total phenolic content of the extracts was determined according to the method of Singleton and Rossi's (1965) with some modification and results were expressed as *gallic acid equivalents* (mg GAE 100 g^{-1} DM^{-1} (dry matter of sample). Total flavonoid content was measured using $AlCl_3$, a colorimetric method (Zubair *et al*., 2013), and results were expressed as *(+) catechin equivalents* (mg CE 100 g^{-1} DM^{-1} of sample). Total anthocyanin's content was measured according to the pH differential method (Cheng and Bren, 1991). Absorbance of extracts was measured at 520 nm and 700 nm in buffers at pH 1.0 and pH 4.5 where absorbance was: $A=(A_{520}–A_{700})_{pH\ 1.0}–(A_{520}–A_{700})_{pH4.5,}$ (with molar extinction coefficient of 26.900 and molecular weight of 449.2). Results were expressed as *cyanidin-3-glucoside equivalents* (mg C3G 100 g^{-1} DM^{-1} of sample).

Results and Discussion

The results are given on Table 1 and Figures 1-5. The weight of pre-selected fig fruits was 14.33 ± 1.25 g, skin colour yellow and red pulp. The drying time took approximately 50248-61808 seconds. The reduction of drying time was attributed to pre-treatment applied. This finding was in accordance with other studies (Piga *et al*., 2004; Lewicki, 2006).

In general the physico-chemical parameters of final dried product were more concentrated due to the drying process, compared to fresh fruit, so the dry matter was 31.34 ±0.19% increased to 75.87±0.19%, The total soluble solids (TSS) of fresh fruit was 27^{o}Brix, and the higher content of total soluble solids make it more suitable for drying. Titratable acidity expressed as citric acid was 0.19 %±0.005 citric acid (CA) increased to 0.61±0.015% CA. Also, the sugar/acid ratio for our selected fresh fig variety was 142.10, and the higher the ratio, the sweeter are the fruits. Accordingly, after drying process the pH values were decreased with increscent of total acidity from 5.01±0.01 to 4.35±0.005. The above data were in the range reported (Piga *et al*., 2004, Slatnar *et al*., 2011) for this fruit species.

On the Table 1 are shown the codes of pre-treated samples, and the drying time for each case:

Table 1. Codification of pre-treated fig fruits samples and drying time

Pretreatment (bleaching in 1% alkaline solution)	Code of pre-treated samples	Drying time (sec)	Code of samples (dipping in 0.2% KMS)	Drying time (sec)
Control	C	60785	C-KMS	61808
Lye	BL	56105	BL-KMS	56452
CaCO3	BCa	57060	BCa-KMS	59651
K2CO3	BK	55965	BK-KMS	56858
NaCl	BNa	50248	BNa-KMS	51965

In the figure 1 are expresed the drying curves, and was noted that the values of moisture ratio decreased rapidly, with consequent increase of the drying rate.

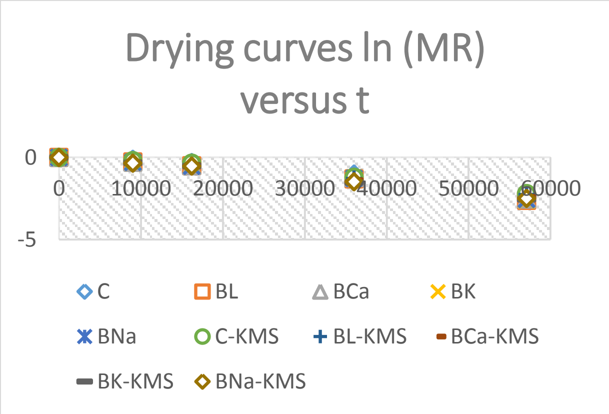

Fig.1: The experimental ln (MR) values against drying time in sec

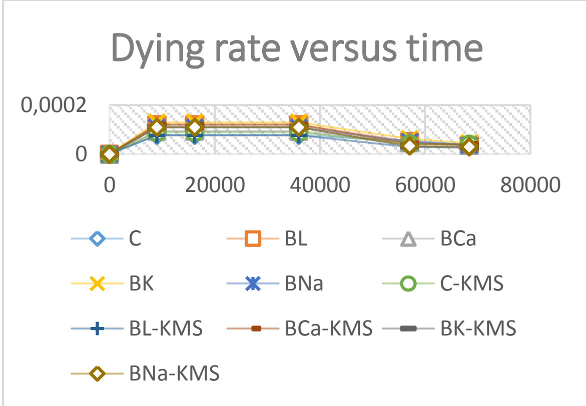

Fig. 2: Figure 2: The values of drying rate against time in sec

Pretreatment favored water mobility and increased drying rates in comparison with those untreated, and BK-KMS and BNa-KMS samples had greater drying rate and the final dried product was the best quality compared to other samples. Also, the untreated dried samples resulted the browning due to high amount of sugars in particular reducing sugars which have the ability to interact with amino acids (nonenzymatic browning reaction). Also, the long drying time for control samples (C) affected more the color compared to C-KMS and other pretreated samples. The application of pre-treatment minimized adverse changes and played a positive role in color retention, shape, and a soft structure according to the order: C<BL<BCa<BNa<BK, and samples dipped in KMS resulted in better color retention, maintained the shape and reduced firmness.

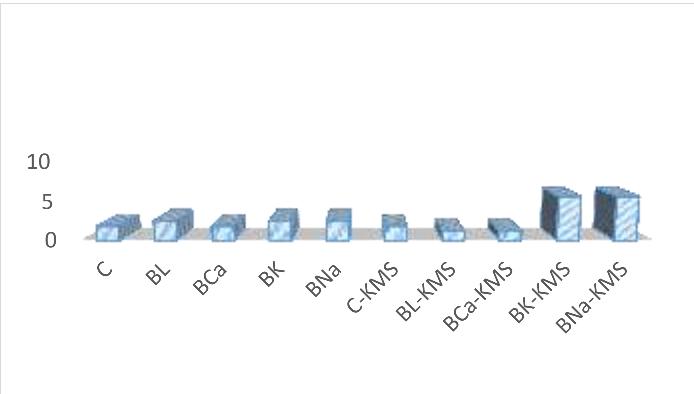

Figure 3: The estimated D*eff* values x 10^{-10} m^2/s for the studied samples

The effective water diffusivity was calculated employing the method of slopes. (Perry,1997; Saravacos, 2001), but the method of slopes can only estimate the initial effective water diffusivity since the shrinkage effect cannot be considered. The calculated D*eff* values varied from 1.25 x10^{-10} m^2/s to 5.62 x 10^{-10} m^2/s for the studied cases. The estimated D*eff* values lie within the general range of 10^{-11} to 10^{-8} m^2/s of food materials (Zogzas et al., 1996).

Bioactive Compounds

A number of studies have shown that the presence of phenolic compounds in food and especially in fruit can be particularly important for consumers, because of their beneficial health properties.

The drying method applied had a depleting effect on anthocyanins content, and the pre-treatment applied did not affect the content of anthocyanins in the dried product.

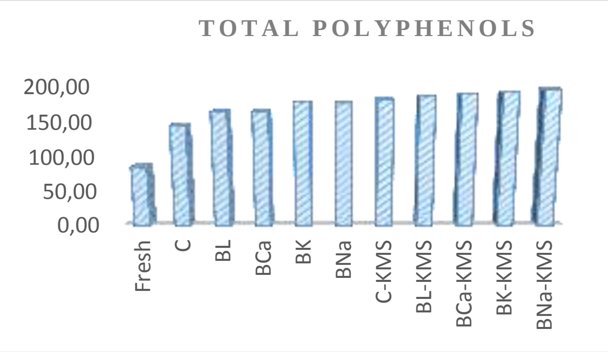

Fig. 4: Total polyphenolic content expressed mg GAE 100 g^{-1} DM^{-1}

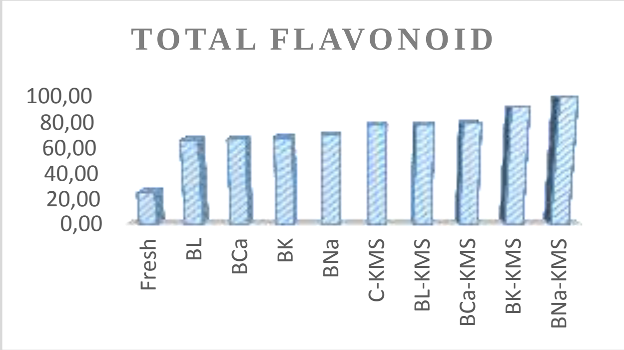

Fig. 5: Total flavonoid content expressed mg CE 100 g^{-1} DM^{-1}

Results showed that figs are rich sources of phenolics, and drying increased their concentration, and between dried samples there were slight differences in values. It was noted that samples dipped in alkaline solution and KMS had greater values than control samples, where BK-KMS and BNa-KMS had the highest values from 192.68 to 196.97 mg GAE 100 g^{-1} DM^{-1} and from 91.24 to 98.63 mg CE 100 g^{-1} DM^{-1}.

Conclusion

From the drying kinetic of figs was seen that drying took place during the falling rate period. The mean effective water diffusivity of whole figs was estimated from drying kinetics. The main advantage of this method was its simplicity and ability to estimate D values. The calculated D*eff* values varied from 1.25 $x10^{-10}$ m^2s^{-1} to 5.62 x 10^{-10} m^2 s^{-1} for the studied cases, that lie in general range for food materials. Pretreatments reduced the drying duration, favoring water mobility and increasing drying rates in comparison with those untreated. The main quality changes were browning of the peel, especially for nontreated figs. The application of pre-treatment minimized adverse changes and played a positive role in color retention, shape, and a soft structure according to the order: C<BL<BCa<BNa<BK, and samples dipped in KMS resulted in better color retention, maintained the shape and reduced firmness. Furthermore, was noted that samples dipped in alkaline solution and KMS had higher total phenolic content than control samples. The results of this work showed that pre-treatment applications reduced drying time and offered better quality of dried fig fruits, and the tested alkaline solution should be taken under consideration for application as pre-drying treatment, to food processors for figs drying in Albania.

WHY *APHIS SPIRAECOLA* (HEMIPTERA: APHIDIDAE) IS BECOMING THE MOST DOMINANT PEST ON CITRUS IN ALGERIA?

Zine Eddine LABDAOUI, Yamina GUENAOUI*

Department of Agronomy, University Ibn Badis of Mostaganem, Algeria

Abstract

In the last few years the aphid *Aphis spiraecola* Patch (Hemiptera: Aphididae) has become the most abundant pest in Algeria. Its population dynamics is connected with favourable factors (young shoots of *Citrus* and suitable climatic factors) or unfavourable factors causing its death as unsuitable natural enemies or high temperatures. The objective of this work was to evaluate the potential of parasitoids associated with *A. spiraecola* for understanding why this aphid species was not efficiently controlled by natural enemies. This study was carried out during the spring leaf-flushing period in 2016 and 2017 in 02 orchards located in 02 sites situated in the Mostaganem region. Sampling of 100 infested young leaves weekly taken from 10 citrus trees in each site showed the predominance of *A.spiraecola* with high densities reaching at least 150 aphids per leaf(10 individuals per cm2).The total parasitism rate remained below 3%.We identified two primary parasitoid species *Lysiphlebus testaceipes* Cresson and *Binodoxys angelicae* Haliday (Hymenoptera: Braconidae) and 6 secondary parasitoid species (hyperparasitoids) with the first record in Algeria of an hyperparasitoid belonging to Charipinae (Hymenoptera: Fitigidae). The parasitism rate in the plantation conducted under a conventional management with sprays of insecticides was by far lower than parasitism rate obtained under ecological management. Protection of *Citrus* from *A. spiraecola* feeding is becoming very difficult because of several factors such as early presence of hyperparasitoids in orchard, relative failure of the development of *L. testaceipes* with a high number of aborted mummies (without adult emergence) and the possible presence of endosymbionts in aphids providing protection against parasitic wasps.

Keywords: *Citrus aphids, Aphis spiraecola, Lysiphlebus , hyperparasitoid abundance, biological control failure.*

Introduction

The green citrus aphid (*Aphis spiraecola* Patch) is among the most damaging aphid species in Algeria, because high populations feed on tender shoots (young leaves, buds, flowers) and spring time attacks are the most deleterious causing distorted foliage an dropping of flowers. It is one of the four main species recorded in Algeria (Mostfaoui et al., 2014; Labdaoui and Guenaoui, 2015). It has a very large indirect impact as it is one of the principal vector of the citrus tristeza virus CTV (Blackman and Eastop, 2000, Addante et al., 2009) with *Toxoptera citricidus* (Kirkaldy) which had been reported in several Mediterranean countries but not yet detected in Algeria. In the Mediterranean region, *A. spiraecola* is one of the most abundant on *Citrus* in Turkey (Satar et al., 2014) and according to Blackman et Eastop (1984) it was found on over 65 plant genera including important crops (*Malus sp*., *Prunus sp.*, *Pyrus sp.*). In Spain, it had displaced the native and previously dominant species *Toxoptera aurantii* becoming the most important citrus aphid species after 1960 (Gomez Marco, 2015); with the rational use of pesticides implemented in Spanish citrus, *A. spiraecola* had become the most abundant and harmful aphid species (Hermoso de 2014; Labdaoui and Guenaoui, 2015). The need of control aphids has always been of central importance in citriculture with an increasing goodwill to promote alternatives measures to chemical control in the framework of sustainable IPM strategies. The objective of this work was to understand why *A. spiraecola* is not enough controlled by its natural enemies. We need to provide more information for a better knowledge about the interactions between native parasitoids and *A. spiraecola* in order to use this information for developing another measure of control without reducing natural biodiversity and in the same time promote the development of sustainability in orchards. We tried to understand the relationships within the the influence of hyperparasitoids appears to be quite complex (Boenisch et *al.*, 1997).

Material and methods

Orchards

This study was carried out in 2 citrus orchards (*Citrus clementina* and *Citrus sinensis* Var. Thomson) grafted on *Citrus aurantium* located in Mostaganem region (northwestern Algeria) where the climate is classified as Mediterranean. The clementina orchard named A (more 30 years old) is located at Mazaghran vicinity (35°53' 30.49"N - 0° 5'7.94"E, 1.12 ha) and belongs to the farm of the university of Mostaganem; the orchard was free of pesticides since at least three years. The orange orchard named B (more 15 years old) is a private crop located at Sirat vicinity (35°43' 34.8"N 0°12' 25.5"E, 2.10 ha); this orchard was conducted according to the conventional system with pesticides sprays against several pests.

Citrus sampling

Both orchards were weekly sampled during the leaf flushing period of 2016 and 2017.Ten trees were sampled per orchard and ten tender leaves per tree were randomly cut and placed in a labelled transparent bag with all needed information on samples. They were brought to the laboratory where visual inspection and observation under a stereo-microscope were made to determine the identity of aphid species and of parasitoids using different keys. Full mummies were singly and smoothly put in a gelatin capsule and kept until emergence of parasitoids (primary or secondary wasps). The parasitized aphids were left in the rearing room until mummification. The mummies without emergence were left and counted as aborted mummies

Results and discussion

Aphids:

The aphid populations inceased rapidly during 2016 in both sites, resulting in crowding with more wigged aphids (alate form) that must alight on citrus with new shoot growth to establish new colonies. We observed the dominance of *A.spiraecola* in both sites and both years with a high percentage varying between 95 and 100% of the total. *A.spiraecola* densities were higher for both sites in 2016.In 2017 mean temperatures were higher, favourating a precocious aphid infestation but keeping aphid densities lowerthan in 2016.

In site A: results (figure 1) showed a maximum number of aphids varying between 75.63 and 78.77 aphids equivalent to about 6 aphids/ cm² during the period from 5th May to 19th May 2016 and a peak of 44.41 individuals equivalent to 4 aphids/ cm² at 17th April 2017.

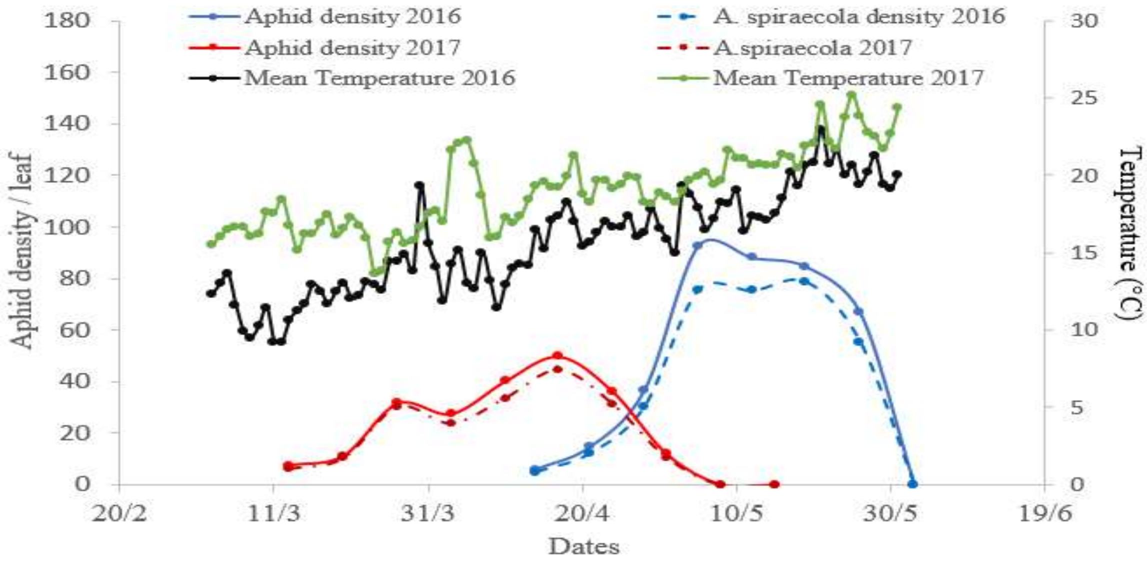

Fig.1: Aphid density/ leaf at Mazaghran location (site A) (2016- 2017)

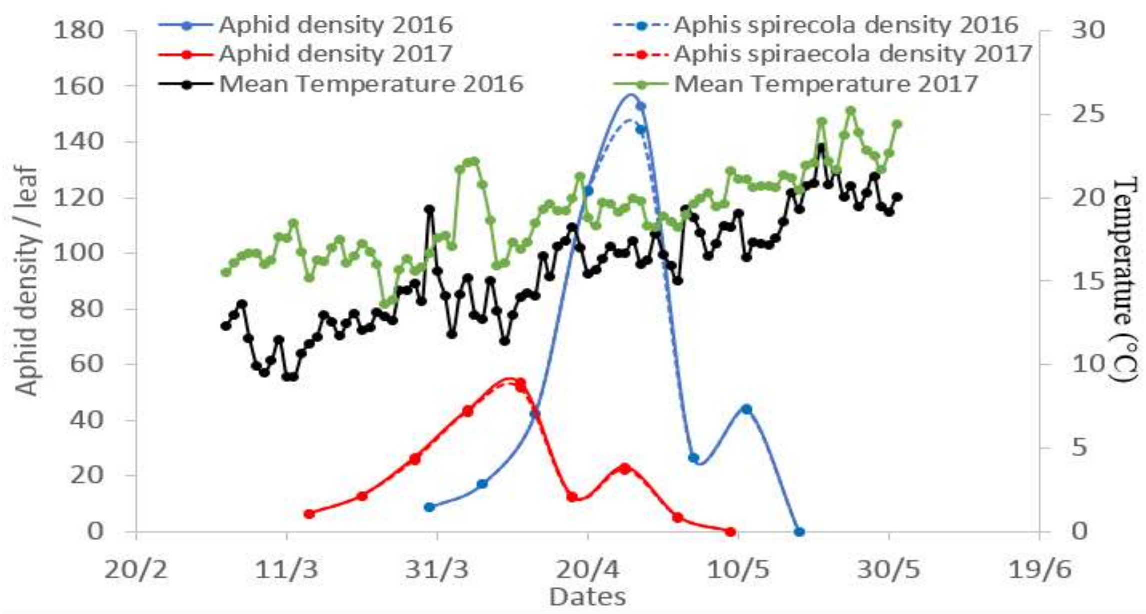

Fig.2: Aphid density / leaf at Sirat location (site B) (2016- 2017)

In site B, the aphid *A. spiraecola* densities reached a peak of 144.38 individuals/ young leaf equivalent to 10 aphids/ cm² in 2016 and to 51.48 individuals/ young leaf equivalent to 6 aphids/ cm² in 20 17 (Fig.2).The difference between years is related to climate. Temperatures in 2017 were higher than in 2016 and more suitable for the beginning of flushing and aphid infestation but aphid density were lower because of high temperatures at mid- April leading to a decline of aphid populations.The optimal range of temperature for *A.spiraecola* population growth was estimated between 20 and 30°C (Wang and Tsai, 2000).

Primary parasitoids

In this study only *Lysiphlebus testaceipes and Binodoxys angelicae (*Hymenoptera: Braconidae: Aphidiinae) were found on *A.spiraecola* with a very low parasitism rate remaining below 3% in both sites, not exceeding 0, 76% in the sprayed orchard during the investigated period (Figure 3).In Spain, on *A.spiraecola* Gomez et al.,(2016) recorded only *B. angelicae*. In Tunisia, during the period 2010-2011 four primary parasitoids of *A. spiraecol*a were recorded (Sellami et al., 2013) and interestingly *L. testaceipes* was found being the predominant primary parasitoid. Initially *L.testaceipes* has been introduced from Cuba to Southern France in 1973 to control *Toxoptera aurantii* (Boyer de Fonscolombe) and *A. spiraecola* as a biological control agent of Citrus in the Mediterranean area (Stary et al., 1988). It has rapidly become widespread and exploited a large number of aphid species in Europe and in Africa Sometimes it could be difficult to identify the species without DNA analyses (Stary et al., 2014). In Algeria it was recorded on several aphid species on diverse host plants (Laamari et al., 2011). The Algerian *L. testaceipes* population recorded in the area of this study is able to complete its development on *A.spiraecola* but a large part of mummies remained full without adult emergence. It is not easy to determine the real causes of this failure.
The figure 3 shows the different rates of the two primary parasitoids, hyperparasitism and mummies remained full without any adult emergence. This last aspect was more dominant varying between 70% to 87%.These results could explain the biological control failure occuring in citrus orchards.
We compared the rate of mummies with adult emergence and without emergence . Analysis by ANOVA showed no significant differences in the ratio of emerged parasitoids at both dates (p = 0,442) . The number of non emerged adults was significant (p= 0,003) on 05/05 may (date before treatment) and was highly significant (p < 0, 0001) on 12/05 may (date after treatment). This could be explained by a more important mortality rate of parasitoids inside the mummy.

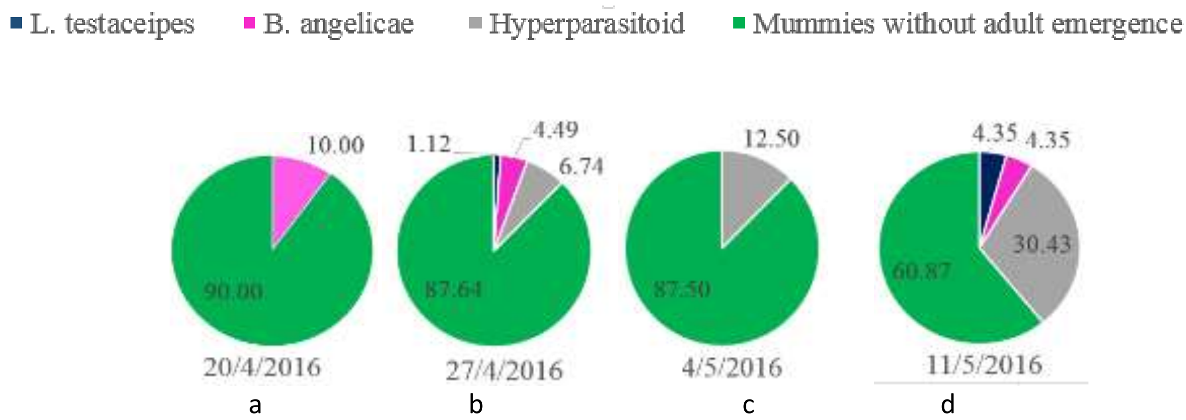

Figure 4 (a,b,c,d): Rate parasitism (site B) 2016

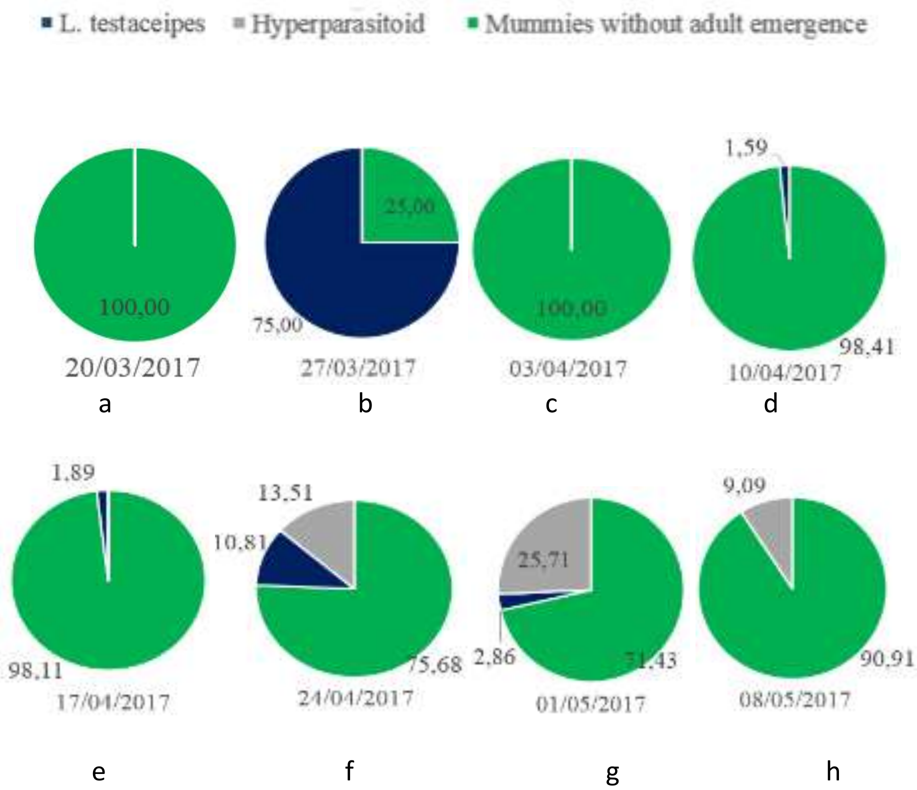

Figure 5 (a,b,c,d,e,f,g): Rate parasitism (site A) 2017

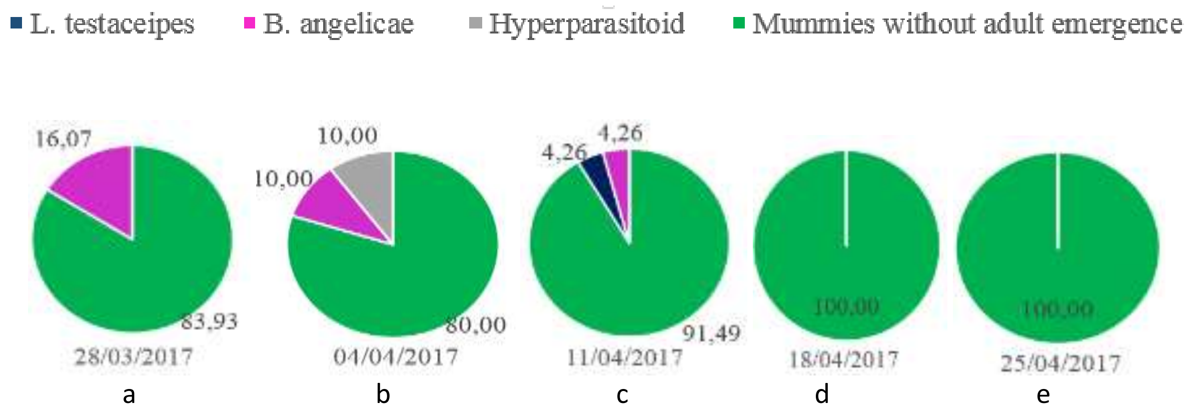

Figure 6 (a,b,c,d,e): Rate parasitism (site B) 2017(Mummies)

Hyperparasitism

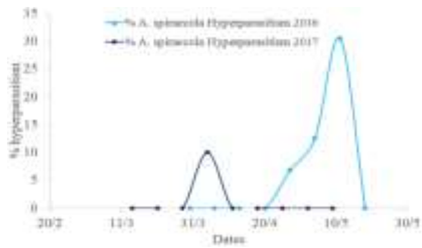

Figure 7 : Hyperparasitism rate (site A)

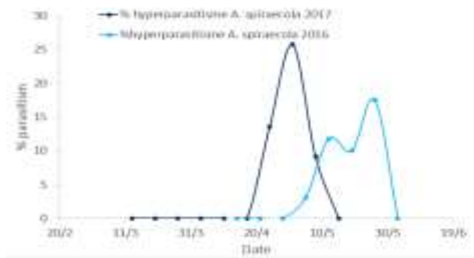

Figure 8 : Hyperparasitism rate (site B).

The hyperparasitim rate on *A.spiraecola* differed between sites and years (Figures 7, 8).In 2016 rate of hyperparasitoids reached 30% at site B and 18% in site A. At least six hyperparasitoid species were recorded from *A.spiraecola* mummies: Two species belonging to *Alloxysta* genus, *Asaphes vulgaris* (Walker), *Pachyneuron aphidis* (Bouche) were recorded in both sites and at site A were recorded *Phaenoglyphis villosa* (Hartig) and a first record from Algeria of *Phaenoglyphis heterocera* (Hartig, 1841) (Ferrer-Suay et al., 2017). A part of hyperparasitoids remained unidentified.
It is well known that the efficiency of primary parasitoids as control agents is affected negatively by high levels of hyperparasitism (Holler, 1993; Sullivan et Volk, 1999).The ecological advantage of the hyperparasitoid presence to an aphid may be due to its negative influence on the primary parasitoids. Hyperparasitoids kill developing parasitoid larvae; their volatils can incite to have escape behaviour in primary parasitoids (Holler et al., 1994). In certain conditions hyperparasitism can impact a parasitoid biological agent and disturb biological control (Schooler et al., 2011).The hyperparasitoid may have a direct effect on the behavioural response of aphids. For instance a single alate *Sitobion avenae* reproduced earlier more offspring in the vicinity of virgin hyperparasitoid females (*Dendrocerus carpenter*) compared with control aphids without hyperparasitoids (Boenisch et al., 1997).Aphids may harbour a wide of variety of facultative bacterial endosymbionts. Several have the ability to protect their hosts against parasitoids (Vorburger, 2014).

Conclusion

The aphid *A.spiraecola* was found highly predominant varying between 95 and 100%.The two primary parasitoid species *L.testaceipes and B. angelicae* are not efficient for control of *A.spiraecola* because they prefer *A.gossypii* or *Toxoptera aurantii* as hosts. Even in orchard free of pesticides the parasitism rate on *A.spiraecola* was very low (3%).The most number of mummies remained full without adult emergence. It is not sure that this biological control failure could be related with presence of defensive symbionts providing aphids with protection against their natural enemies. In addition, these two parasitoid species were early attacked by hyperparasitoids. Because there are few effective parasitoids of *A.spiraecola* in the Mediterranean region it will be interesting to try using another natural enemy with combination with means as providing alternative food for predators by managing the ground cover favouring production of nectar and pollen for natural enemies in early spring with when needed use of chemical control with selective insecticides. In the same time we have to to prevent the occurrence of *Toxoptera citricidus* finding new solutions.

Acknowledgments

We would like to express our gratitude to Dra Mar Ferrer-Suay from Universitat of Valencia, faculty of biological Sciences,(Spain) for the identification of hyperparasitoids from Algeria. We also thank Bernard Chaubet from INRA Rennes (France) for the confirmation of the identity of the primary parasitoids.

Abstract

At present time the new methods are replacing the traditional food technologies which they have potential to reduce production costs. Using infrared irradiation heat for milk pasteurization as a technology with the high thermal efficiency can be a good alternative to traditional methods of milk processing. In addition by replacing potassium chloride instead of sodium chloride in the formula of the salt water of white cheese, the adverse health effects resulting from the consumption of sodium chloride can be prevented.
In this investigation, by using the infrared radiation heat, raw caw milk prepared of Zanjan University animal husbandry was pasteurized and then white cheese produced from it in 2016. The white cheese was placed in four different formulations of brine containing 1) NaCl: KCl, 10:0 percent 2) NaCl: KCl, 7.5: 2.5 percent, 3) NaCl: KCl, 5:5 percent and 4) NaCl: KCl, 0:10 percent for 21 days at a temperature of 8° C. Then the texture characteristics of the cheeses were evaluated. Texture analysis of cheese showed that by reducing the amount of sodium chloride, the strength of cheese texture decreases and there was a significant difference between the strength of two types produced cheeses.

Key Words: *NaCl, KCl, White Cheese, Brine, Infrared pasteurizing*

Introduction

Cheese is the ripened or unripen soft, semi-hard, hard, or extra-hard product, which may be coated, and in which the whey protein/casein ratio does not exceed that of milk (CODEX GENERAL STANDARD FOR CHEESE. 283-1978)[7]. Cheese contains less water than milk, and so has different organoleptic properties and shelf life than milk (Walstra et al., 2006). Cheese is a rich source of protein, fat, calcium, phosphorus, riboflavin and other vitamins. Also it can be more useful than milk in high protein diets, also its proteins are highly digestible (Renner, 1993).
Traditional production of white cheese in brine has been popular for centuries in small-scale caw keeping farms and that way it was difficult to set the standard for the properties and composition of the cheese. Along with the recent developments in dairy product processing industry and with the integration of mechanization and automation, large-scale production of cheese became possible (Ozer, 2014).
Salting is an important stage in the process of cheese. History of salt used as an additive is related to 3,000 years before Christ (Woodin, 1981; Durack et al., 2008). Salt is considered as an additive commonly used in the food industry and plays a vital role in the food processing including food protection, helping to improve the flavor, the impact on proteolysis, water

[7] . www.fao.org/input/download/standards/175/CXS_283e.pdf

activity and strength in the tissue (Reddy and Marth, 1991; Guinee, 2004a; Guinee and Fox, 2004). Salt provides about 90 percent of the sodium in the human diet (He et al., 2012). In the structure of the salt, the sodium intake is very important to control the membrane potential of the cell and absorption of nutrients in the small intestine. In order to maintain the blood volume, osmotic pressure on the cell and also transportation of nervous signals, sodium is essential (Strazzullo et al., 2009; He and MacGregor, 2010).

Although salt plays an important role during food processing, but has been known to be a major risk for diseases such as osteoporosis due to urinary excretion of calcium chloride, kidney stones and high blood pressure (Beumi et al., 2002; Kotchen, 2005 ; Massey, 2005; Heaney, 2006). World Health Organization has recommend food manufacturers to reduce the use of salt (WHO, 2007). Meat, dairy, bakery and other food products, each include a different percentages of sodium uptake by the body in different classes in the world for example, the daily intake of sodium through cheese in England, France, America and Australia, have been reported 7.8, 9.2, 8.2 and 5% namely (Meneton et al., 2009; Anderson et al. , 2010). So many efforts have been made for producing of low-salt cheese using different techniques such as reducing the amount of salt or partial replacement of salt in cheese with other materials (Guinee and O'Kennedy, 2007). Reducing the salt content of the Cheddar cheese and the effects of these changes on the chemical composition, proteolysis, sensory properties and microbial growth were done by Schroeder and colleagues (1988b). Replacing salt with other materials such as potassium chloride, calcium chloride and magnesium chloride may be considered as a successful strategy to reduce the amount of salt (Kilcast and den Ridder, 2007).

Also partial replacement of sodium chloride with potassium chloride revealed that the quality of the cheese has not significantly changed (Guinee, 2004b). Potassium chloride salt is acknowledged as a potential alternative to sodium chloride in cheese making. Increasing potassium intake has been reported as a protection factor for people with hypertension (Fregly, 1981; Reddy and Marth, 1991). A mixture of potassium chloride and sodium chloride has been successfully used in cheese production and no adverse effects have been reported on the quality of the cheese (Fitzgerald and Buckley, 1985). Several studies have been also made on the effect of replacing sodium chloride with potassium chloride on the properties of Cheddar (Reddy and Marth, 1993a), feta cheese (Katsiari, et al., 1997; 2000a), Kefalograviera cheese (Katsiari et al., 2001a), and Fynbo cheese (Zorrilla and Rubiolo, 1994; Zorrilla et al., 1996), but there is not any investigation on white cheese made of IR pasteurized milk and aged in KCl substituted brine.

Infrared heating is an alternative preservation method with higher thermal efficiency which transfers thermal energy in the form of electromagnetic waves. Recent applications of infrared heating indicate this technology is a viable alternate for the pasteurization of liquid foods, in addition it can decontaminate foodstuffs in both liquid and solid foods with retaining higher levels of health promoting compounds (Hagh Nazari. 2014).

The aim of this research is to study the effects of replacement of NaCl with KCl salt on the textural properties of ripened white brined cheese made from pasteurized milk using infrared irradiation.

Materials and Methods

Cheese making method: for the preparation of cheese, raw milk from the dairy farm of Zanjan University was prepared. Raw milk was pasteurized using flavor wave Turbo device that emits infrared waves at 72 ° C for 15 seconds has shown in figure 1. The temperature of the process was checked by a digital thermometer model TES made in China. For comparing and evaluating the effects of the pasteurization methods, the milk was also pasteurized using classic (conventional) methods. After pasteurization of milk, 200 ml of milk was poured in lidded plastic containers of the same shapes in 3 replicates equaled 24 samples.

Figure 1: Flavor wave Turbo device

After the milk temperature reached to 35 ° C; the kefir starter solution to the volume of 2 ml along with calcium chloride to the amount of 0.02% of the milk were added to the pasteurized milk. The samples were transferred to an incubator made in Memmert Company in Germany at 35°C. And 20 minutes after adding the starter, the fungal rennet Valiren made in America was added to the amount of 0. 0025 gr to each container at 35°C.
After clot formation, clots were left without cutting for 12 hours in 18$^{°C}$ to continue fermentation, coagulating and dewatering. The resulting clots were transferred to salt solutions containing: 1) NaCl: KCl, 10:0 percent 2) NaCl: KCl, 7.5: 2.5 percent, 3) NaCl: KCl, 5:5 percent and 4) NaCl: KCl, 0:10 percent for 21 days at a temperature of 8° C. After ripening, tissue analysis was conducted on the cheese.
Chemical tests: measurement of chemical compounds was conducted by AOAC methods (AOAC, 2012). Moisture, fat and protein contents were measured using the oven at 102 degrees Celsius, Gerber method, and Kjeldahl method respectively. PH was measured by Professional portable milk pH Meter HI98162 provided by Hanna Company.
Texture analysis: For this purpose the texture analyzer device TA.HD plus made in Stable Micro Systems Company in England was used for tissue analysis (TPA test).The speed of probe coming down was set on 5 mm / sec.
Statistical analysis: factorial experiments were conducted in a completely randomized design with three replications. The statistical comparison was done using the Mstat-C software via Duncan's method.

Results and discussion

The comparison of the clots formed from pasteurized milk using infrared radiation (1) and Classic method (2) shows that the volume of the Infrared irradiated samples are smaller with higher coherence and solidity.

- Texture analysis:

The results of texture analysis are shown in Figure 2. Description of the charts and data extracted from the analysis are reported in bellow of the tables.

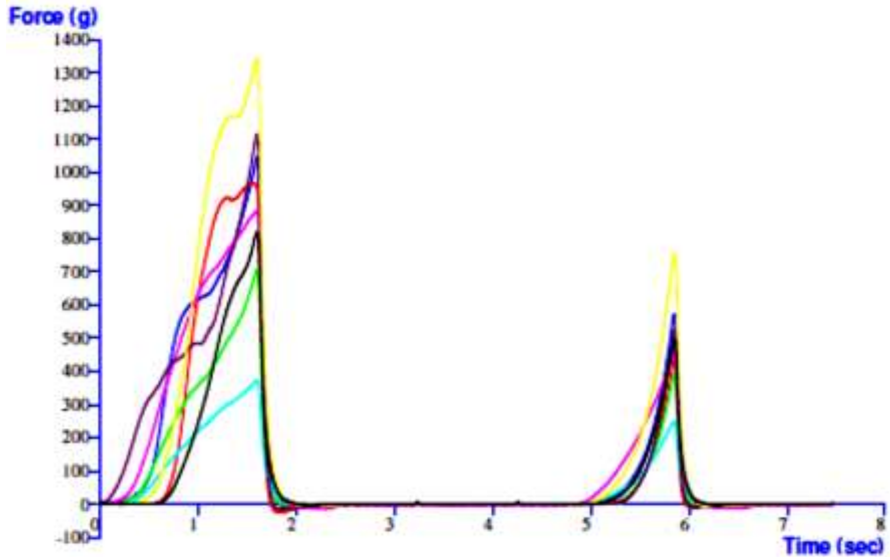

Figure 2: Texture analysis curves of the clots formed from pasteurized milk using infrared radiation (1: left) and Classic method (2: right) at 72° C for 15 seconds. The color description of Texture analysis is as follows:

Number of Formul	Color	Brined Formulations	Methods of Milk
1	Yellow	10% NaCl	IR
2	Violet	7.5:2.5 % – NaCl:KCl	IR
3	Blue	5:5 % - NaCl:KCl	IR
4	Red	10% KCl	IR
5	Pink	10% NaCl	Classic
6	Black	7.5:2.5 % – NaCl:KCl	Classic
7	Green	5:5 % - NaCl:KCl	Classic
8	Sky blue	10% KCl	Classic

Results of the area under the curve of the cheese samples in texture analysis show the difference in firmness and resistance to breakdown between the two methods of milk pasteurization. Data and graph obtained from tissue analysis shows that by reducing the amount of NaCl in the brine formulation, the area under the graph and the force required to breakdown of the texture of cheese is reduced. Also cheeses made from pasteurized milk using infrared radiation are more resistant to breakdown than cheeses made from pasteurized milk using the classic method. The reason of these differences can be due to high calcium concentration in cheese and its role in the increasing the coherence and strength of the cheese texture made from pasteurized milk using infrared radiation than of the classical method product because calcium chloride helps the tissue solidarity.

Overall, comparison of data means resulting from the analysis of the cheese characteristics show that the cheeses made from two types of pasteurized milk and different brine formulations only differ significantly in the firmness and resistance to breakdown between the two cheese preparation methods. Also changing the formula of the brine had no significant effect on the microbial load.

- **The use of potassium chloride in the formula of the cheese brine:**

The reason of the replacement of sodium chloride with potassium chloride, is achieving a product that reduces harmful effects to health caused by the consumption of sodium chloride.

In addition to the fact that the product is supposed to be acceptable in terms of evaluated properties. The results of the analysis showed that the only difference between white cheeses produced in different brine formulas is in their firmness. Reduced sodium salt cheese is very soft, bitter, less salty, and has a strong off-flavor and shorter shelf life (Ying Lu, 2012). Potassium chloride (KCl) has a similar structure and salty flavor as sodium chloride (salt) and partial replacement of salt with potassium chloride can be used to lower salt content in foods. Moreover, potassium can lower the blood pressure and the risk of heart disease or stroke. Thus, potassium chloride is a potential substitution for salt in cheese. In general, from this study it can be concluded that changing the formulation of the used brine only affects the cheese texture and has no effects on other properties.

- **Effects of brine formula on The cheese texture**

in 1998 and 2000, Katsiari pointed out that the changes in the amount of fat, protein and other compounds of cheese occurred by the lipolysis, proteolysis, lactic acid production and other reactions happened during the ripening period not due to brine formula. Although added calcium chloride can effect on cheese density and volume of cheese due to participating in paracaseinate calcium clots which induce the syneresis reaction improve (Fuca, 2012).

The effect of different levels of salt in the brine solution in this investigation shows that at high levels of sodium chloride, the cheese firmness is greater than the other brine formulas. In confirmation of this; results of Katsiari's study in 1998, 2000 and 2001 shows a decrease in firmness by reducing the amount of sodium chloride in cheese. He also showed that by reducing the amount of sodium chloride, the texture becomes softer due to reduction of syneresis and remaining more moisture in the texture of the cheese. In terms of chemical composition, according to the anions of both compounds being the same, cations can be checked on the solubility of the two compounds. The Sodium ion has a smaller radius than the potassium ion. Under the rule of Fajanz rules, the ionic potential of the sodium ion is more than the potassium ion. Sodium ions form a stronger bond with chlorine. By increasing salt in the cheese, the syneresis also increases. Potassium chloride salt is more soluble in the aqueous phase of the cheese and treatments containing potassium chloride salts are softer and have a lower hardness (Katsiari et al., 1998, 2000, 2001). The effect of partial substitution of NaCl with KCl on texture profile and microstructure of Halloumi cheese also was recorded by Ayyash et al., in 2010. They investigate the effect of NaCl substitution with KCl on the microstructure of cheeses. Hardness, cohesiveness, and gumminess of cheese decreased significantly during storage period with the same salt treatment, whereas adhesiveness significantly increased (Ayyash et al., 2010). They resulted that the microstructure of all cheeses became more closed and compact with storage period. Color values and texture parameters of NIR-treated (50-s treatment) ham slices were not significantly ($P > 0.05$) different from those of no treated samples (Won Ha, 2012). Also according to the table 1, due to the lower destruction of the compounds of the milk in the infrared radiation method, there isn't any reduction of dry mass content. In addition this investigation showed that cheeses produced from milk pasteurized using the infrared irradiation was firmer compared to the cheeses produced using the classic method. All above studies confirms this project's results due to the higher efficiency and saving energy consumption via IR assisted systems in comparison of classic method of pasteurization.

Conclusion

In general, from this study it can be concluded that changing the formulation of the used brine only affects the cheese texture and has no effects on other properties.

Effects of brine formula on the cheese texture shows that at high levels of sodium chloride, the cheese firmness is greater than the other brine formulas.
The effect of infrared radiation in cheese production showed no significant difference between the cheeses produced from pasteurized milk using the infrared and classic methods but the pasteurization process of milk is approximately 75% faster than the classic method due to the high heat performance in the infrared radiation.

Abstract

This scientific research determined the impact of indigenous and commercial yeast strain on the production of wine from the grape variety Vranec, grown on Crveni bregovi locality, near Negotino, at an altitude of 250 m. The main objective was to display the correlation between indigenous yeast strains F-8 and F-78 with the commercial strain D-80 (Lallemand). The domestic yeast F-8 and F-78 were previously isolated at the Tikves wine region, Republic of Macedonia. The main purpose of this research is to make a comparison between the wine produced from indigenous yeast strains F-8 and F-78 with the commercial strain D-80. The chemical analysis of the wine, monomeric anthocyanins, polyphenolic composition, and the color intensity of the wine produced from the domestic yeast strains, were compared with the wine produced from the commercial yeast strain. The basic parameters, such as alcohol, sugar, total acids, volatile acids, pH, free/total SO_2, were determined applying international methods of analysis of wines and musts (OIV methods). The correlation value between the main parameters was obtained by using the statistical analysis of the results obtained by applying the software package SPSS 19. The analysis shows that there is a correlation between the analyzed parameters of the wine from the grapevine Vranec, among different strains of yeasts. The Pearson's coefficient of correlation (ρ), between wine Vranec from F-8 and D-80 is (,996) which means high correlation value. Also, the Pearson's coefficient of correlation (ρ), between wine Vranec from F-78 and D-80 is (,999) which means realy high correlation value.

Keywords: *indigenous yeasts, wine, Vranec, anthocyanins.*

Introduction

Vranec is one of the most important red grape varieties in Republic of Macedonia, grown in all vineyards, mostly in the Tikveš wine region. (Ivanova et al.,2014).
In the modern stage of wine production, selected wine yeasts are used, which leads to significant technological progress. The main reasons are: fast and effective controlled alcoholic fermentation of the grape must with a high concentration of sugars, resistance to high concentrations of ethanol and SO_2, and resistance at higher temperatures during fermentation. The increasing use of these commercial yeasts, leads to a loss of indigenous strains of yeasts. The selection of indigenous strains of yeasts with good characteristics, can be successfully shown through the production of quality wines. It would have improved the biodiversity of a region, would be enriched biological heritage, which is of particular importance in the production of wines of controlled origin. (Ilieva et al.,2016).
Domestication of wine yeast, while inadvertent until recent decades, has generated strains that differ considerably from ''wild" *S. cerevisiae* strains. Inoculations of ''wild" *S. cerevisiae* yeasts can influence the process of fermentation and greatly affect the quality of the wine. Isolating strains from successful fermentations for inoculation in subsequent vintages was

being practiced during winemaking in order to avoid unwanted malolactic or acetic fermentation. Largely, the specifics and the most important quality characteristics of the wine are due to the natural microflora of the grape of the viticulture region. (Ilieva et al.,2013). Furthermore, *S. cerevisiae* strains selected from the indigenous population of domestic winemaking enable the alcoholic fermentation to proceed more effectively in comparison with commercial yeast strains. (Settanni et al., 2012).

Polyphenols are large and complex group of compounds responsible for the characteristics, quality and colour of the grape and wines. Polyphenolic constituents are classified as flavonoids and non-flavonoids,which contribute to wine sensory characteristics, especially to colour, flavour and astringency. (Ivanova et al.,2015). Anthocyanins are characterized as 3-monoglucosides, 3-acetylglucosides, 3-p-coumaroylglucosides and 3-caffeoylglucosides of cyanidin, delphinidin, peonidin, petunidin and the dominant, malvidin. (Ivanova et al.,2011).

Yeast interact with phenolic compounds and could influence the wine colour. (Mazauric and Salmon, 2005). At the beginning of fermentation, yeast cell wall can absorb anthocyanins and other polyphenolic compounds, influencing the colour. (Morata et al., 2003).

The main purpose of this research is to make a comparison between the wine produced from indigenous yeast strains F-8 and F-78 with the commercial strain D-80.

Material and method

The newly isolated yeast strains were obtained by spontaneous fermentation of grape must from Vranec and Cabernet Sauvignon varieties collected from ten different micro-regions in Macedonia. The grapevines from both varieties grown in ‘‘Barovo” micro-region were the richest sources of yeast strains. (Ilieva et al., 2016). The isolation of the yeast was previously executed according to the method of KOH (Bambalov et al., 1996).

From this, were isolated 80 new strains, among F-8 and F-78. (Ilieva et al.,2015). These two strains of yeast F-8 and F-78, and the commercial D-80 (Lallemand) were used for this research.

The wines was produced from the grape variety Vranec, grown on Crveni bregovi locality, near Negotino, at an altitude of 250 m. The grapes were harvested at optimal maturity and transported to the winery. Than, grapes were crushed, followed with addition of SO_2 (20 mg/kg). Vranec grapes from harvest 2016 were equally allocated to the lots, in order to make similar fermentation conditions. The destemmed grape grains were crushed with manual crusher. After crushing, 20 mg/kg free SO_2 was added in the must and it was transferred into 20 L PET bottles. After two hours, the must was inoculated with culture of the selected strain F-8 and F-78. Similar to the other bottles grapes must, were inoculated with the other commercial strain of yeast D-80. The period of maceration of wine was 16 days. During the fermentation, wines were be “pumped-over” four times a day. After the fermentation, the wines were transferred to tanks for stabilization and aging.

The determination of the amount of alcohol was performed ebuliometrically with Dujardin - Salleron ebuliometer and for determination of reducing sugars was used Schoorle method.

Determination of titratable and volatile acidity of trial wines was performed by the previous method (Boulton, 1980). The color Intensity (IC) was measured spektrophotometrically at 420 nm (yellow color), 520 nm (red color), 620 nm (blue color) by UV spectrophotometer Shimadzu 1800, Shimadzu Corporation, Kyoto, Japan.

Determination of total polyphenols, anthocyanins, color intensity was performed by applying spectrophotometric methods. Thus, for determination of total phenolics, the Folin-Chiocalteu method was used, measuring the absorbance at wavelength od 765 nm. For anthocyanin analysis, wine was diluted with solution of ethanol/water/HCL=70/30/1 and absorbance was measured on 540.

The monomeric anthocyanins, polyphenolic content, color and other oenochemical characteristics of the wines produced from domestic isolated strains of yeasts were also compared with the wines produced from commercial yeast strain D-80.
The correlation value between the main parameters was obtained by using the statistical analysis of the results obtained by applying the software package SPSS 19. Comparing the Pearson's coefficient of correlation we can see which parameters have higher correlation. If $\rho = 1$, it means that there is a perfect linear correlation, i.e. the growth of the one variable means growth of other variables. If $\rho = 0.5 – 0.9$,there is close correlation. If $\rho = 0.2– 0.5$, then the correlation is weak, but there is still correlation between variables. Of course, negative values, $\rho = -1$ means inversely proportional connection.

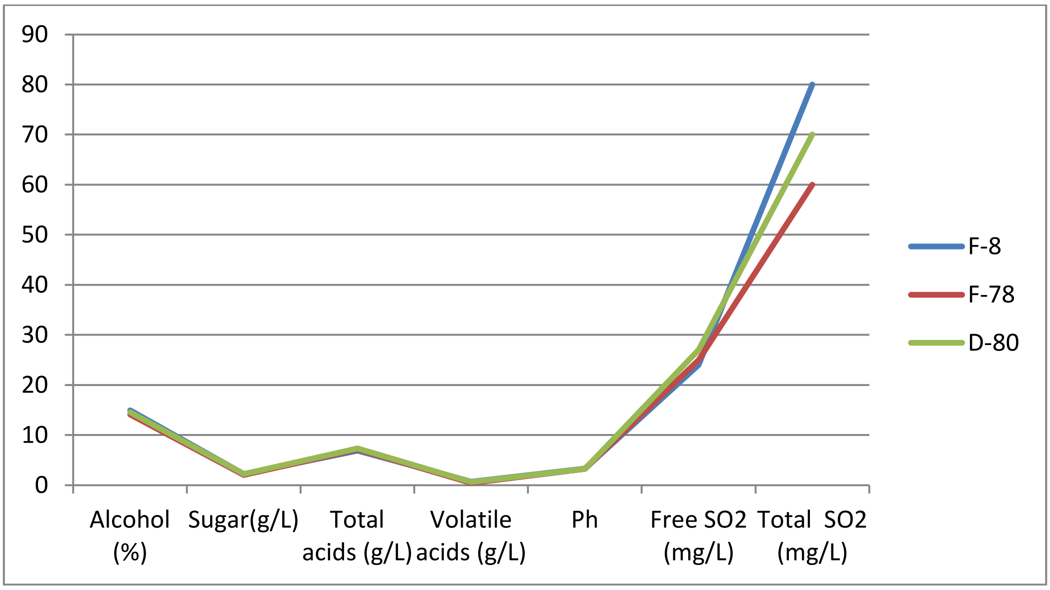
Results and Discussion

The basic parameters, such as alcohol, sugar, total acids, volatile acids, pH, free/total SO_2, were determined applying international methods of analysis of wines and musts (OIV methods). Detailed overview of the main chemical parameters measured for wines produced from three different strains of yeasts is shown in Table 1. The wine Vranec produced from the isolated strain of yeast F-8, has the highest % of alcohol (14,96), but the wine produced from the strain of yeast F-78, smallest % of alcohol (14,11). The wines produced from the strains of yeasts F-8 and D-80 have the same concentration of sugar (2,2 g/L). The highest concentration of total acids has the wine produced from commercial strain of yeast D-80 (7,34 g/L) with pH= 3,24, the smallest concentration of total acids the wine from F-8 (6,89 g/L) with pH=3,32. The wines produced from the strains of yeasts F-8 and D-80 have the highest concentration of volatile acids(0,68/0,61).

Table 1.Chemical characteristic of wine Vranec produced by indigenous strains of yeasts F-8, F-78 and commercial D-80.

Wine	Yeast	Alcohol (%)	Sugar(g/L)	Total acids (g/L)	Volatile acids (g/L)	Ph	Free SO_2 (mg/L)	Total SO_2 (mg/L)
Vranec	F-8	14,96	2,2	6,89	0,68	3,32	24	80
Vranec	F-78	14,11	2,0	7,13	0,43	3,26	25	60
Vranec	D-80	14,53	2,2	7,34	0,61	3,24	27	70

On the graph 1. is displayed the chemical characteristic of wine Vranec produced by indigenous strains of yeasts F-8, F-78 and commercial D-80.
Between three types of wines produced from the different strains of yeasts, we can conclusion high correlation on the chemical characteristic. There is a small difference on the chemical parameters between wine produced from indigenous and commercial strains of yeasts, because the wines were produced from the same grapevariety and locality. The day of maceration was the same (16 days) for the three types of wine. The temperature of fermentation was the same 23-24 ^0C.



Graph 1.Chemical characteristic of wine Vranec produced by indigenous strains of yeasts F-8, F-78 and commercial D-80.

Table 2. Content of total phenolics (TP), total anthocyanins (TA), color intensity (CI) in wine Vranec produced by indigenous strains of yeasts F-8, F-78 and commercial D-80 of three replicates.

		(TA) Total anthocyanins mg/L			(TP) Total polyphenols mg/L			(CI) Color Intensity

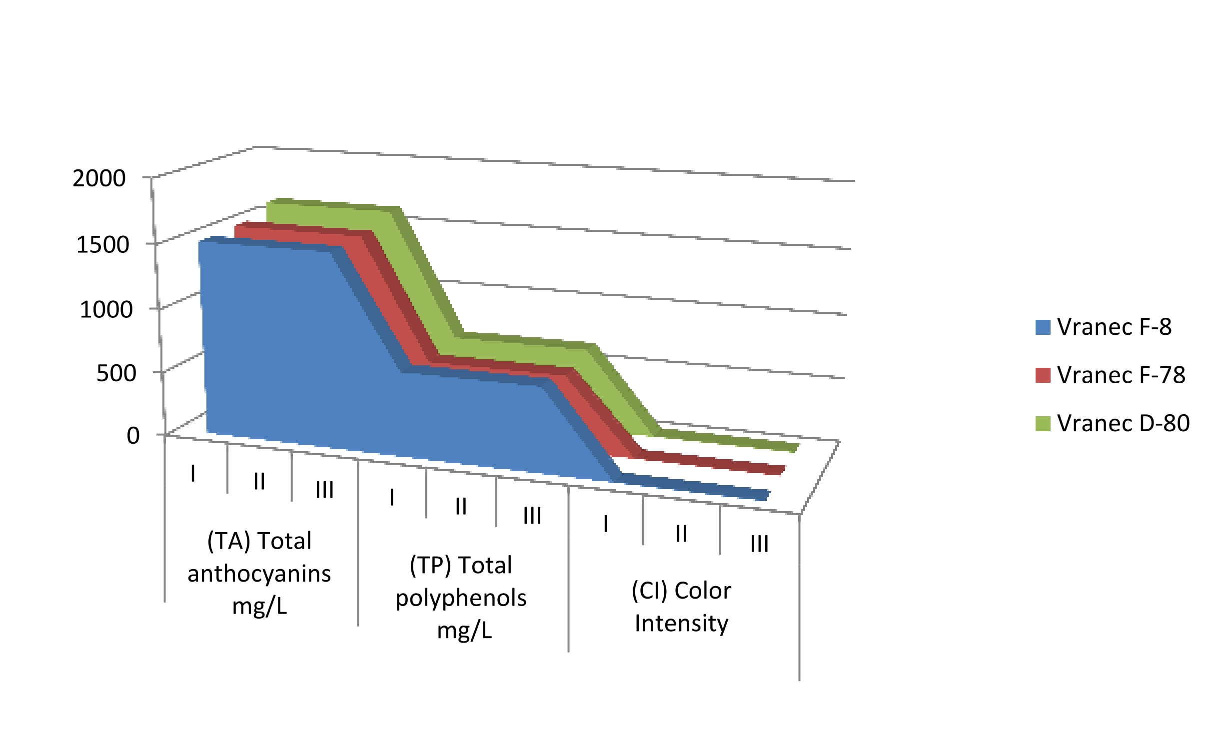
Vranec	F-78	1528,3	1525,4	1523,1	583,2	583,5	584,1	2,1058	2,1026	2,1013
Vranec	D-80	1618,6	1617,0	1615,4	636,2	636,8	637,2	2,3798	2,3657	2,3614

In Table 2, is detailed overview the content of total phenolics (TP), total anthocyanins (TA), color intensity (CI) in wine Vranec produced by indigenous strains of yeasts F-8, F-78 and commercial D-80 of three replicates. The total anthocyanins (TA) have the highest concentration in wine produced from commercial strain of yeast D-80, and the smallest from indigenous strain of yeast F-8. The content of total phenolics (TP) have the highest concentration in wine produced from indigenous strain of yeast F-8, and the smallest from indigenous strain of yeast F-78. The intensity of color was the highest in wine produced from indigenous strain of yeast F-8, and the smallest from indigenous strain of yeast F-78.
There exist a difference on chemical parameters (TA/TP/IC) between three types of wine, but the differences between the three replicates of wines is a small.



Graph 2.The graph shows the content of total phenolics (TP), total anthocyanins (TA), color intensity (CI) in wine Vranec produced by indigenous strains of yeasts F-8, F-78 and commercial D-80 of three replicates.

On the graph 2. is displayed the the content of total phenolics (TP), total anthocyanins (TA), color intensity (CI) in wine Vranec produced by indigenous strains of yeasts F-8, F-78 and commercial D-80 of three replicates.
Between three replicates of wines produced from the same strains of yeasts, we can conclusion a small difference at all parameters. There exist a difference on chemical parameters (TA/TP/IC) between three types of wine.

Table 3. Display of Pearson's coefficient of correlation (ρ) received from corelation between wines Vranec produced from indigenous (F-8/F-78) and commercial (D-80) strains of yeasts.

Correlations

		D80	F78	F8
D80	Pearson Correlation	1	,999**	,996**
	Sig. (2-tailed)		,000	,000
	N	7	7	7
F78	Pearson Correlation	***,999****	1	,993**
	Sig. (2-tailed)	,000		,000
	N	7	7	7
F8	Pearson Correlation	***,996****	,993**	1
	Sig. (2-tailed)	,000	,000	
	N	7	7	7

**. Correlation is significant at the 0.01 level (2-tailed).

The correlation value between the main parameters was obtained by using the statistical analysis of the results obtained by applying the software package SPSS 19. The analysis

shows that there is a correlation between the analyzed chemical parameters of the wine from the grapevine Vranec, among different strains of yeasts.
Display of Pearson's coefficient of correlation (ρ) received from correlation between chemical parameters from all three types of wines produced from indigenous and commercial strains of yeasts is given in Table 3. The analysis indicates that there is a high correlation value between three types of wine (from F-8/F-78/D-80). Because the main objective to this research is to make a correlation between Vranec produced from indigenous strains of yeasts F-8/F-78 and Vranec produced from commercial D-80, we showed that there is a close correlation. The Pearson's coefficient of correlation (ρ), between wine Vranec from F-8 and D-80 is (,996) which means high correlation value. Also, the Pearson's coefficient of correlation (ρ), between wine Vranec from F-78 and D-80 is (,999) which means realy high correlation value.

Conclusion

This scientific research determined the impact of indigenous and commercial yeast strain on the production of wine from the grape variety Vranec, grown on Crveni bregovi locality, near Negotino, at an altitude of 250 m. The main objective was to display the correlation between indigenous yeast strains F-8 and F-78 with the commercial strain D-80 (Lallemand).
A comparison was made between the domestic yeasts F-8 and F-78, previously isolated at the Tikves wine region, Republic of Macedonia and commercial strain D-80. There is a small difference on the chemical parameters between wines, because the wines were produced from the same grapevariety and locality, also the same days of maceration (16 days) and temperature of fermentation 23-24 ^{0}C
The analysis shows that there is a correlation between the analyzed parameters of the wine from the grapevine Vranec, among different strains of yeasts. The main purpose of this research is to make a comparison between the wine produced from indigenous yeast strains F-8 and F-78 with the commercial strain D-80. The Pearson's coefficient of correlation (ρ), between wine Vranec from F-8 and D-80 is (,996) which means high correlation value. Also, the Pearson's coefficient of correlation (ρ), between wine Vranec from F-78 and D-80 is (,999) which means realy high correlation value.
With this scientific research we concluded a very high connectivity between wine Vranec produced from indigenous yeast strains F-8 and F-78 with the commercial strain D-80 (Lallemand).

Abstract

A leaf spot disease was observed in Benue State, Nigeria in the 2013 cropping season. Leaves of infected plants appeared water-soaked. These are usually small, irregular and light brown. These spots increased in size covering the leaf surface and bleaching it. These spots eventually become darkened, necrotic and distorted. Affected leaves last for only three days and dropped off. The pathogen was isolated from infected leaves, seeds, crop debris and soil on potato dextrose agar supplemented with streptomycin sulphate (PDAS). The pathogen was identified as *Coniella musaiensis* var. *hibisci* by the Global Plant Clinic in the United Kingdom (GPCW No. /w 9181). Symptoms were reproduced 24 hours after artificially inoculating wounded leaves of the accessions (Acc_1, Acc_3 & Acc_4) tested. No significant ($p=0.05$) difference was noticed among the accessions with regards to disease severity. The infected leaves were defoliated after 72 hours. It was noticed that the disease did not spread to newly emerged leaves after the dropping of the infected ones. Progression ceases once there is low humidity. This fungus has been previously reported elsewhere in the country but this is its first report in Benue State, Nigeria

Keywords: leaf spot, *Coniella musaiensis* var. *hibisci*, *Hibiscus sabdariffa* L., accession, inoculation.

Introduction

Roselle (*Hibiscus sabdariffa* L.) is an important vegetable crop in Nigeria. It belongs to the family Malvaceae. More than 300 accessions of it can be found now around the world, growing in both tropical and sub-tropical regions. Most accessions are used as ornamental plants, but the swollen red calyces of the sabdariffa type have economic, nutritional and medicinal values (Tindall, 1983; Morton, 1987; Sharoff, 1996; Onyenekwe, 1998; Alegbejo, 2000 and Qi *et al.*, 2005). According to Schippers 2000, Roselle is ranked the third most important vegetable in most Nigerian markets, coming after tomatoes and okra in that order.

Nigeria is not listed among producing nations which is an indication that the production in the country has not been placed on international scale. Nevertheless, meaningful and substantial production has been reported in the country mainly in the Guinea and Sudan savanna zones with major growing areas being Niger, Kogi, Oyo, Kaduna, Bauchi and Kwara States (Alegbejo, 2000).

The crop has not yet attained its full economic potentials in the country yet there are challenges militating against its optimal growth and development. This leaf disease caused by *Coniella musaiensis* var. *hibisci* is a major constraint (Alegbejo, 2000) and management of the disease has to start with ascertaining the pathogenicity of the causal agent.

Therefore the aim of the study was to establish the identity and ascertain the pathogenicity of the causal agent.

Materials and Methods

Isolation of the *Coniella musaiensis* var. *hibisci*

The pathogen was isolated from infected leaves in the 2013 cropping season using the method described by Agrios (2005) in the advance pathology laboratory of University of Agriculture Makurdi, Nigeria. Infected leaves were collected from the field at four locations, placed in envelopes and carried to the laboratory. The infected leaves were thoroughly washed in distilled water. Several small sections ($5mm^2$) were cut, using sterile scissors, from the margin of the infected lesions to contain both diseased and healthy portions of the tissue. The sections were surface sterilized with a dilution of common household bleach (0.5 % active sodium hypochlorite) at the ratio of 1:10 for 1 minute and blotted dry on clean sterile filter papers. The sections were transferred to Petri dishes (4 per dish) containing potato dextrose agar supplemented with 0.1mg/l streptomycin sulphate (PDAS) using sterile forceps. The plates were incubated for seven days at room temperature. Colonies of the organism were sub-cultured by using a sterile needle to remove small portions of the growth and transferring them to fresh PDAS plates, a method described by Collins and Lyne (2004). Subsequent sub-culturing was done until pure cultures were obtained. The pure cultures were sub-cultured into several new plates of PDAS and maintained for use. Characters like color of culture, growth pattern, and type of fruiting structure were examined. Slides were also made from the pure cultures and examined under a stereomicroscope for characterization of the organism. These characters were used in conjunction with reference publications to identify the organism. Cultures of the organism and infected leaves were sent to Global Plant Clinic in United Kingdom for confirmation of the identity of the pathogen. This isolation was done on both red and green Roselle collected from four locations of Katsina-Ala, Gboko, Vandeikya and Makurdi Local Government Areas in Benue State, central Nigeria. The result was used to confirm whether it is the same organism that is causing this disease at these different locations and in these three accessions of the plant.

Preparation of spore suspension

Two weeks old pure cultures were scooped into an electric blender and 250ml of sterile distilled water was added and blended for 15 minutes to expose the spores that were held inside fruiting bodies or the pycnidia. The suspension obtained was filtered using sterile cheesecloth to remove mycelial fragments. The spore concentration was adjusted to 78 $x10^4$ spores/ml of the isolate using a haemocytometer.

Inoculation of healthy plants

Seeds of three accessions were planted on the 20^{th} of July 2013 in polythene bags and allowed to grow for two weeks. They were thinned to two per bag and allowed to grow for additional two weeks. Each accession received four treatments of sprayed intact leaves with water (WIN), sprayed injured leaves with water (WIJ), sprayed intact leaves with inoculums (IIN) and sprayed injured leaves with inoculums (IIJ). This was replicated three times given a total of twelve observations arranged in a complete randomized design (CRD) in the screen house.

The plants were covered for 48 hours with a black polythene sheet to increase humidity and enhance infection. The inoculated plants were observed daily for the development of the symptoms. Disease severity rating was taken after 48 hours and one week. Infected leaves were collected and the pathogens re-isolated and compared with the original isolates. The inoculum was considered pathogenic with the severity rating of between 2 and 5 as described by Mohanan *et al.* (1989) as shown in **Table 1.** In every case, a score of 5 represented total collapse of all leaves and death of the plant.

Table 1: Table of Disease Descriptive scale.

Disease Score	%of leaves with symptoms	Remarks
1	0	No infection
2	1-20	Slight infection
3	21-50	Moderate infection
4	51-70	Severe infection
5	71-100	Very severe infection

Data analysis

All data collected were subjected to analysis of variance using GenStat 5 version 3.2, 1995 (Laws Agricultural trust: Rothamsted Experimental Station, UK)

Results and Discussion

This study identified the causal agent as being *Coniella musaiensis var. hibisci* which was confirmed by the Global plant clinic in the United Kingdom. Cultural characteristics were used in the identification of the causal agent. A pure culture of the fungus on PDAS (Plates 1) is whitish. The mycelia are profusely branched and septate as shown in Plate 2. Old cultures of the fungus produced spiny globolous dark pycnidia (Plate 3) which houses rod shaped spores (plate 4)

Plate 1. Pure culture of *C. musaiensis*

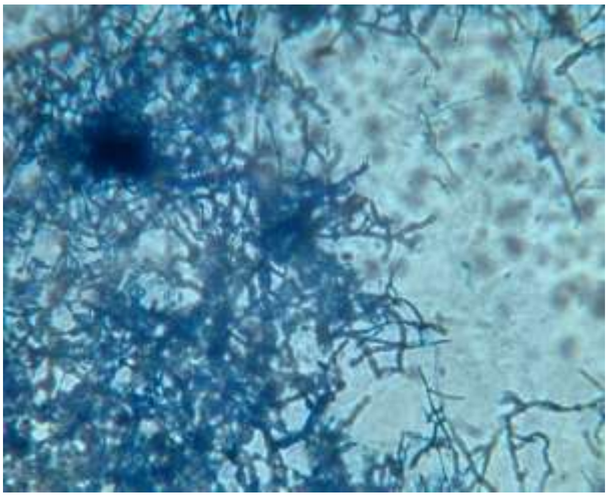

Plate 2: *Coniella* Mycelia (40 x) on Potato Dextrose Agar Supplemented with Streptomycin Sulphate

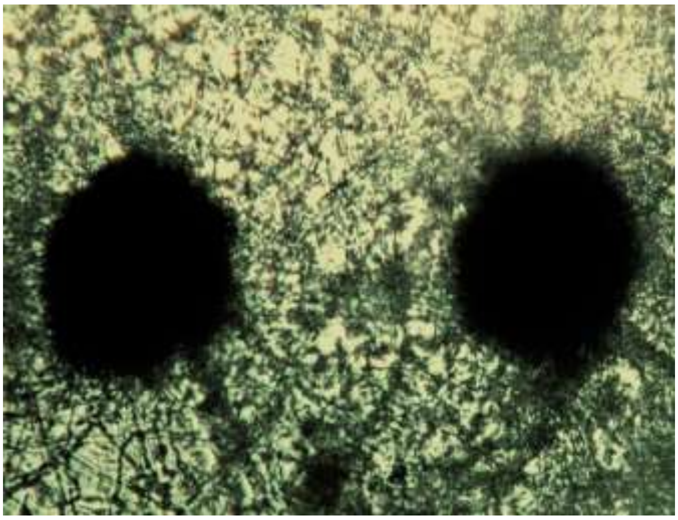

Plate 3: *Coniella* Pycnidia (40 x)

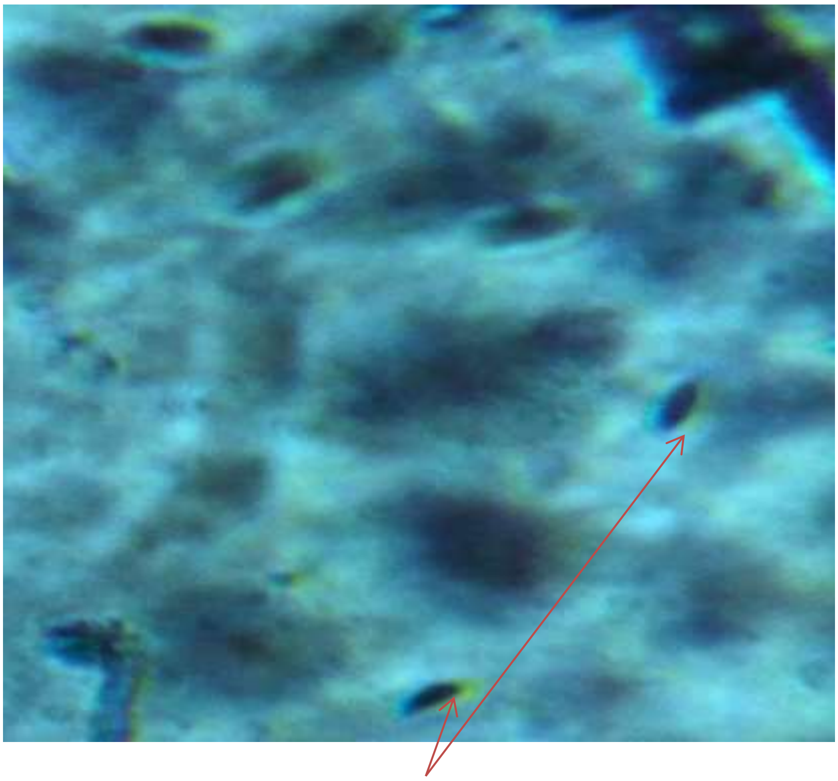

Plate 4. *Coniella* Spores (40 x)

The fungus had uniform radial growth pattern on PDAS with average colony diameter measuring 1.9 mm in a day and reaching 13.5 mm in 7 days.

The fungal colonies causing the observed leaf spot disease of roselle in Benue State was believed to survive in the soil, seeds as well as in debris from infested fields. *C. musaiensis* var. *hibisci* appeared to be ubiquitous as was observed infecting Roselle and causing severe disease in the field. Persad and Fortune (1989) had earlier reported *C. musaiensis* var. *hibisci* as the causal agent of leaf spot and stem canker observed on Roselle in Trinidad and Tobago. Adeoti and Emechebe (1996) reported the same pathogen as being causal agent of leaf spot disease observed in Kenaf (*Hibiscus cannabinus* L.) where it was even tagged the most important disease of the plant in Nigeria.

Pathogenicity Test

Disease severity was rated after 48 hours and 1 week of inoculation and presented in Table 2.The result from this study showed significant difference among the treatments but none was shown between the accessions at both 48 hours and after one week. Disease severity in leaves (Plate 5) injured and treated with the pathogen was significantly (p=0.05) higher than in the rest of the other treatments as shown in Table 2, again for both 48 hours and after one week of treatment. Symptoms manifested within 24 hours of inoculation. Spots were also observed in both the injured and intact leaves treated with water after one week of treatment; however the organism was not re-isolated from the spots. It was also noticed that disease did not spread to newly emerged leaves after the dropping of the infected ones. This points to the fact that the pathogen on its own can't penetrate the plant epidermal wall and relies on external factor(s) to inflict an opening for it to have access to the internal tissue.

Plate 5. Inoculated Plants showing Symptoms on Leaves

Table 2. Disease Severity Rating of three Inoculated Roselle Accessions in the Screen House.

	Inoculation period	
	48 hours	1 week
Treatment		
WIN	1.00	1.22
WIJ	1.00	1.56
IIN	1.00	1.89
IIJ	1.67	3.00
ion		
1	1.08	1.67
3	1.17	2.00
4	1.25	2.08
LSD (P=0.05) Treatment	0.23^{*}	0.49^{*}
LSD (P=0.05) Accession	0.20^{ns}	0.42^{ns}

Where:-

WIN=Intact leaves with water
WIJ=Injured leaves with water
IIN=Intact leaves with Pathogen
IIJ=Injured leaves with pathogen
LSD = least significant difference
ns = indicates not significant at 5%
* =Significant at 5%

Conclusion

Successful identification of disease and causal agent coupled with sources of inoculum are basic efforts towards control of such disease. This study identified the causal agent of leaf spot disease of roselle as being *Coniella musaiensis* var. *hibisci* and it was also found that the pathogen lives in the soil, seeds as well as in debris from infected fields. It also points out that the pathogen is a wound pathogen as it was unable to attack intact leaves.

Abstract

Due to their specific lifestyle, frequency of occurrence, and the damage that they cause on plants, leaf miners have been investigated by many scientists in Serbia. Unfortunately, the overview of research on their fauna in Serbia has not been done yet. Therefore, based on the data from the literature sources and the results of our research, the first overview of leaf miner fauna research in Serbia was made. It was found that 363 species of leaf miners were ascertained in Serbia so far. They are classified as follows: 270 species from 26 families of the order Lepidoptera, 61 species from 5 families of the order Diptera, 21 species from 3 families of the order Coleoptera, and 11 species from 1 family of the order Hymenoptera. The majority of species of the order Lepidoptera belongs to the families Gracillariidae (71), Nepticulidae (61) and Coleophoridae (37), of the order Diptera to the family Agromyzidae (53), and from the order Coleoptera to the families Curculionidae (12) and Chrysomelidae (7). All species of the order Hymenoptera (11) belong to the family Tenthredinidae. Monophagous and Oligophagous species are dominant among the identified species of leaf miners in Serbia. The majority of the species (57%) develop on woody plants. Most of them (30) on the species of the genus *Quercus*, *Prunus* (20), *Malus* (19), and *Populus* (19). The list of 363 species of leaf miners that were identified in Serbia is not definitive. How European leaf mining insect fauna includes about 2500 species, it is certain that new species will be found in the future.

Keywords: *phyllophagous insect, Serbian species list.*

Introduction

Leaf miners are small insects from orders Coleoptera, Diptera, Hymenoptera and Lepidoptera, whose larvae, while feeding on the inside of the leaf, create cavities – mines – of different shape, size, and position on the leaf. These cavities are usually transparent so that when put against a light source, the excrements that the larvae left behind can be seen. They are frequently characteristic of the species that made them so they can be used for their determination. There are about 5500 species of leaf miners in the world (Hering 1957), and approximately 2500 in Europe (Ellis 2007). They are mostly monophagous species from the orders Lepidoptera and Diptera. The species from the order Diptera mostly inhabit herbaceous plants, while those from the order Lepidoptera more often inhabit woody plants. Leaf miners have been studied by many authors in Serbia. Unfortunately, none of them prepared a comprehensive list of Serbian species, so far. Considering that such a list would significantly improve the research on leaf-miners insect guild in Serbia, we compiled and presented in this paper the available data either gathred from the literature or from our researches.

Materials and methods

The work on compiling the list of leaf miners that have been identified in Serbia so far included:

1. Overview of the literature dealing with leaf miners in Serbia,
2. Cataloging of the material that we collected while researching the leaf miner fauna of Serbia.

All the data obtained were entered into a database, from which a list of all the species detected in Serbia was derived.

Results and discussion

Based on the data obtained by reviewing the 98 literature sources, and the data obtained from the inventory that we made while researching the fauna of leaf miners in Serbia, a list of 363 species of leaf miners that have so far been found in Serbia was compiled. They are classified as follows: 270 species from 26 families of the order Lepidoptera, 61 species from 5 families of the order Diptera, 21 species from 3 families of the order Coleoptera, and 11 species from 1 family of the order Hymenoptera. The majority of species of the order Lepidoptera belongs to the families Gracillariidae (71), Nepticulidae (61) and Coleophoridae (37), of the order Diptera to the family Agromyzidae (53), and from the order Coleoptera to the families Curculionidae (12) and Chrysomelidae (7). All species of the order Hymenoptera (11) belong to the family Tenthredinidae. Three hundred and sixty-three species of leaf miners that are listed in this paper were identified on the plants belonging to 205 genera. Monophagous (48%) and Oligophagous (42%) species are dominant among the identified insects. The majority of them (57%) develop on woody plants, most of them on the species of the genus *Quercus* (30), *Prunus* (20), *Malus* (19), and *Populus* (19). Some of them can cause significant damage to agriculture and forestry, and that is why they have been researched by many authors in Serbia. The list of the 363 species of leaf miners presented in this paper is the first faunistic list of leaf miners in Serbia. It surely contains some oversights. However, despite them, it is very useful to us. First of all, because of thanks to the list, we now know which species of leaf miners have been identified in Serbia so far, and how much each species group has been researched. This list will also be useful for researchers from abroad because now they will also know which species of leaf miners are present on the territory of Serbia. Considering that European leaf mining insect fauna includes about 2500 species and that Serbian flora is vibrant with vascular plants, it is certain that new species of leaf miners will be found in the future Leaf miners identified in Serbia, based on the data from the literature sources and the data from our research, are listed in table 1. For convenience, they are all arranged alphabetically within the family to which they belong. Their names are compatible with the names that can be found on the Fauna Europaea website (Van Nieukerken & Karsholt 2016).

Conclusions

Based on the data from the literature sources, and the data from our research, we have found that 363 species of leaf miners, from orders Coleoptera (21), Diptera (61), Hymenoptera (11) and Lepidoptera (270) have been found in Serbia. They were identified on plants from 205 genera, the majority of them on the plants of the genera: *Quercus* (30), *Prunus* (20), *Malus* (19), and *Populus* (19). The number of leaf miners that were identified in Serbia is not definitive. Considering that European leaf mining insect fauna includes about 2500 species, it is certain that new species will be found in Serbia in the future.

Abstract

The use of nuclear energy to peaceful purposes causes contamination of the environment with radionuclides. Therefore, the monitoring of radionuclide levels in the environment in certain region is of vital importance because it creates a basis for providing radiation safety of human population. In this article, basic radiation data such as total beta activity (TbA), potassium-40 activity ($A^{40}K$) and residual beta activity (RbA) in corn-based food samples from different shops in Novi Sad have been measured. Corn-based food plays an important role in traditional Serbian diet and is also very attractive in modern dietary trends. The products, which are most commonly used for human consumption, were selected for the analysis. During spring 2016, the samples of different corn products available on the market in Novi Sad were collected by random selection. In this study, 26 samples in original packaging were collected from the supermarkets. All samples originated from Serbia. The following sample types have been collected: white and yellow corn flour, corn grits, polenta, corn flakes, corn for popcorn, popcorn and corn snacks. Total beta activity was determined from the mineral rest after burning dried samples by the anticoincidental device for measuring low-beta activity, type Omni-Guard (USA). The content of potassium in the samples was determined using atomic absorption spectrometry. Total beta activity ranged from 35.8±1.9 Bq/kg to 224.7±5.4 Bq/kg, and residual beta activity from 4.9–34.8 Bq/kg. Measuring of TbA and potassium-40 activity can serve as a first phase of radiation-hygienic control.

Key words: corn-based food, total beta activity, potassium-40 activity, residual beta activity

Introduction

Peaceful uses of nuclear energy (nuclear weapons testing, nuclear reactor accidents, industrial and medical use of radioactive compounds) and application of phosphate mineral fertilizers in agricultural production lead to substantial environmental contamination (Skipperud et al., 2011). Land contaminated with radionuclides represents the first link in the food chain,, and hence, the radioactive contamination of crop and livestock production (Bikit et al., 1990). The radioactivity released to the atmosphere only during the accident in Chernobyl nuclear plant on 26 April 1986 is estimated to some 12 x 10^{18} Bq. The most important and most hazardous radionuclides that were released into the environment include ^{131}I, ^{134}Cs, ^{137}Cs and ^{90}Sr. Furthermore, the accident in Fukushima dated 11 March 2011 is associated with further increase of radioactive contamination of the environment. Total activity of radioactive particles released from damaged reactors is estimated to 10^{18} Bq. All radioactive particles were transported across the Pacific towards the North-American continent and substantial portion thereof arrived even to Europe (Pantelić, 2016). The plants are an important link in animal and human chain nutrition. Incorporation of radionuclides in plants occurs through leaves (foliated deposit) and root absorption as well. Involvement of particular radionuclides into biological cycle: soil-vegetation-animals-man is associated with plants‘ability to absorb radioactive elements from the soil via their root systems. The amount of radioactive material from the soil absorbed by plants is directly proportional to the pollution emission density at particular territory (Simić, 2001). The highest portion of natural radiation is attributed to natural radionuclide potassium-40 (^{40}K), which is present in the mixture of natural potassium isotopes (^{39}K, ^{40}K, ^{41}K) sharing a mass fraction of 0.0119%, whereas its part in the total beta-activity in bio-communities reaches over 90% (Dželalija, 2006). Radioactive radiation can cause cancer diseases and other health changes of humans and whole living world in general, it substantially influences the changes in the environment (Veriš et al., 2009). Radionuclide transfer through plants or corn-based food affects human population as the last link in nutrition chain posing serious health risks because radiation is a potential cause of somatic and genetic damages. Considering nutritional features, energy value and good digestibility of corn, we are witnessing an increase in production of new corn-based food and feed products (Radosavljević et al., 2002). Consequently, there is a demand for permanent and organized radiation-hygienic control of different food, among which corn-based food takes a significant place.

Material and Methods

Total of 26 different samples of corn-based products were collected including white and yellow corn flour, polenta (3 samples), *Clipsy* popcorn, peanut flips, *Fan* flips, *Jumbo* flips, gold corn flakes, corn flour (5 samples), „*proja*“ (typical bread-like dish made of corn flour), „*Smoki*“ flips and „*Clipsy*“ flips. All analyzed samples were from domestic producers and collected by the method of random selection in several of the largest supermarkets in Novi Sad. The samples differed in view of the type and size of the package and originated from diverse producers and localities. All collected samples were first dried at t=105 ^{o}C and then mineralized at 450±10 ^{o}C in a furnace (MARLAP, 2004). Total beta activity was determined from the mineral rest after burning dried samples, by the anticoincidental device for measuring low-beta activity (IAEA, 1989), type Omni Guard, Tracerlab, company ICN (USA), and its background radiation was less than 1 imm/min. The efficiency of the measuring device is determined by the method of standard sources. As a standard source, ^{40}K in KCl was used (Mitrović et al., 1996). The content of potassium in the samples was determined using emission spectrophotometry on the device Spectr AA-10, Varian, at a wavelength 766.5 nm using cesium as an ion-suppressor. The level of potassium-40 activity in corn-based food samples was determined on the basis of total potassium value of the mass activity of 31.561 Bq/g K (Eisenbud M., 1973). Residual beta activities were determined from the difference between total beta activity and the activity levels of potassium-40. The measured activities and potassium contents are given per kg air-dry matter. The obtained values were statistically processed using statistical software SPSS 17.0 for Windows. The difference between total beta activity and the activity of potassium-40 in samples was analyzed using *t* test.

Results and discussion

Table 1 depicts the results obtained from measurement of total potassium level and total beta activity, the calculated activity of natural radioactive isotope K-40, residual beta activity, the contribution of potassium-40 to total beta activity, as well as the statistically significant differences between the measured total beta activity and the one calculated on the basis of measured potassium concentration. Based on the presented results, the samples can be distributed into three groups according to the statistical significance of the differences between TbA and $A^{40}K$. Statistically significant differences between TbA and $A^{40}K$ were detected in neither samples designated 2,3,5,16,18,22 and 24 at confidence interval(P>0.05) nor in samples designated with 1,4,6,8,9,11,13,14,17,20,21,25 and 26 at confidence level (P>0.01). Since there were no statistically significant differences between measured and calculated values for beta activity (testing of obtained values performed using t-test (Kostić, 2014)), the beta activity of examined samples can be attributed to beta decay of potassium 40. In all aforementioned samples, the contribution of potassium 40 to total beta activity was over 90% in the majority of samples, which corresponds with the data from the literature (Levant, 1996) and the results of our previously reported research (Mihaljev et al., 2011; Ćupić et al., 2005). In the group of samples designated with 7 (corn grits[2]), 10 (corn grits[5]), 12 (corn for popcorn[2]), 15 (flips – peanut), 19 (corn flour [1]) and 23 (*proja*), the t-test results revealed statistically significant differences between measured total beta activity and beta activity calculated based on the measured potassium concentration. This strongly suggests that besides the natural ^{40}K the samples contain some other beta-gamma emitters, which could be identified using more sensitive radio-chemical and spectrometric methods upon comprehensive analysis of radionuclide content.

Table 1. The content of potassium-40, total beta activity (TbA), and residual beta activities (RbA) in different types of corn-based food samples

No. of samples	Sample type	Content of K [g/kg]	Activity of ^{40}K [Bq/kg]	TbA [Bq/kg]	RbA [Bq/kg]	Contribution of ^{40}K [%]	Statistical significance of the difference
1.	White flour	3.98±0.04	125.6±1.3	133.2±8.9	7.6	94.29	P > 0.01

26.	*Clipsy* flips	1.18±0.05	37.2±1.6	42.7±5.0	5.5	87.12	P > 0.01

*-highly statistically significant differences

Apparent variations of potassium levels in the examined samples strongly suggest that incorporation of radionuclides from the soil into the plants (corn) is highly influenced by pedological characteristics, pH and soil management practices (Bikit et al., 2010) as well as conducted agro-technical measures (Mitrović et al., 2011). Measurement of the total beta activity of unstable radionuclides in food and feed is applicable as a very efficient and fast screening method in cases when the activity of individual natural and man-made radionuclides in samples from the food chain is extremely low, that is, almost at the activity level of natural radionuclide K-40. In such cases, if necessary, identification and quantification of individual radionuclides is indispensable.

Conclusion

Total beta-activity (TbA) in majority of investigated samples of different corn products is due to ^{40}K as the most prevalent natural radionuclide. Knowing the potassium concentration and its behavior pattern in the food chain is indispensible in assessing the total radiation load in humans.

In six corn-based food samples, statistically significant difference was determined ($P < 0.01$) between the total beta activity and potassium-40 activity, as following: samples No. 7 and 10 (corn grits[1] and corn grits[5]); sample No. 12 (corn for popcorn[2]); sample No. 15 (flips – peanut); sample No. 19 (corn flour[1]) and sample No. 24 (*proja*). Values of residual beta activity indicate the presence of other beta radionuclides, except potassium-40. The obtained results could serve as a basis for further research in the field of radiation-hygienic control of corn-based food.

It is to be emphasized that activity of radionuclides obtained in the examined corn-based food samples was significantly lower than the maximum permissible values set by relevant legal provisions (Official Gazette of RS, RS 86/2011).

We can conclude that measurement of total beta activity can be considered rapid screening method for selective diagnostics of utility of food and feed.

Abstract

In this study, it was aimed at applying robust factor analysis for an ordinal five-point likert scale data obtained via a questionnaire applied to 385 consumers selected via simple sampling method in Igdir province located in Eastern Anatolia Region of Turkey. As a factor extraction method, Robust Unweighted Least Squares (RULS) was specified together with promin rotation method. Within the scope of explanatory factor analysis, 'FACTOR' software was specified as a remarkable tool in the determination of ideal number of factors and unnecessary items in the EFA analysis. Since use of Pearson correlations are not an advisable option in the violation of the assumption regarding univariate normal distribution of the ordinal variables in the 'FACTOR' software, polychoric correlation was adopted for the likert scale data analysis under investigation. All 29 items prepared on food purchasing preferences of consumers in the present study were included in the EFA analysis within the scope of RULS method. Asymptotic covariance/variance matrix was estimated by bootstrap sampling. Advised number of factors was found to be five. These factors are good reputation of the shop and experience (Factor 1), ease of purchasing (Factor 2), price and properties of product (Factor 3), qualified products (Factor 4) and promotion elements (Factor 5), respectively. Result of Kaiser-Meyer-Olkin (KMO) test was estimated as 0.74. Bartlett statistic was found to be 2541 (P=0.00001). Bias-corrected bootstrap 95% confidence interval for KMO test was found between 0.739 and 0.758. Root Mean Square of Residuals (RMSR=0.0471) was found lower compared with an expected mean value of RMSR estimated based on Kelley`s criterion (0.0510). It was concluded that use of 'FACTOR' software was much more informative and reliable for the ordinal data. Moreover, food sellers and entrepreneurs who aim to improve marketing strategies might be advised to consider the aforementioned five factors that affect food purchasing preferences of the consumers.

Keywords: Robust Unweighted Least Squares, Ordinal data, EFA, Bootstrapping, purchasing preferences.

Introduction

Nutrition is an important part of the human life since human beings need energy to continue living and to perform their daily functions. The quality of the food items from which human beings take necessary required nutritional elements is important to sustain a healthy life. In this respect, the food human beings consume must have certain nutritional and food safety standards. Food safety is one of the essential determinants of food demand (Erturk 2009). Food safety refers to handling, storing and preparing of food to prevent infection and help to make sure that our food keeps enough nutrients for us to have a healthy diet (Anonymous, 2017). Certifications guaranteeing safety in processes of production and distribution of foods not only increase demand for such products but also strengthens customers' loyalty to the brand and the seller (Besch 2002; Erturk 2009). It is reported that emotions (such positive or negative inner tensions as excitement, satisfaction, consciousness, etc.), motivations (being activity-oriented, wishing to be healthy, etc.) and attitudes (product image, positive or negative customer response to a product) are the basic forces that constitute the consumer's drive for buying (Mutlu 2007).

Due to changing lifestyles consumers are now looking for healthy and authentic food products that they can consume. Thus, food safety concerns may be effective in the consumers' demand for any food product. Moreover, it is also important to have an understanding of other factors such as nutritional elements, tastes, ease of consumption, trust and brand respectability (Besch 2002; Erturk 2009).

Erturk (2009) reported that health safety, quality assurance and the product's taste as the most important factors affecting buying decisions of consumers for food products. Personal experiences about the product, certification of quality and packaging might also be effective in consumers' decision to buy. Gender of the consumer may also be effective in buying food products as women who direct household food consumption tend to be more conscious about food safety (Baker 2003). Importance attached to food safety also increases as incomes of the consumers increase (Ozturk 2006).

This study was conducted to determine factors that affect food demand of consumers in Igdir province located in Eastern Anatolia Region of Turkey. For this aim, a questionnaire was applied to 385 consumers selected by simple sampling method and robust factor analysis was applied for an ordinal five-point likert scale data obtained via questionnaire. The results are discussed in the concluding section.

Materials and Methods

The questionnaire study was conducted to determine factors affecting food purchase preferences of 385 consumers from Igdir, Turkey, chosen randomly through simple sampling method.

Formula of simple random probability sampling used in the determination of the required sample size can be written as follows as defined by Karadas et al. (2017).

$n\frac{z^2}{e^2}p.q \ = n\frac{1{,}96^2}{0{,}05^2}0{,}05.0{,}05=385$

n= sample size

z= Standard table value for 95%.

p= proportion of those who prefer potato (0.5)

q=proportion of those who don't prefer potato (q=1-p)

e= proportion of error accepted in sampling method (5%)

All the items ranging from 1 to 5 on the basis of an ordinal 5 point scale data regarding purchasing behavior (29 items) were gathered from the consumers.

Robust Unweighted Least Squares (RULS) extraction method was specified based on Promin rotation method for gaining better solutions in the ordinal data set. Polychoric correlation matrix was used instead of Pearson correlation matrix in the violation of the basic assumption on normal distribution of the ordinal items since null hypothesis of multivariate asymmetric kurtosis was rejected(P=0.000). Four new factors were extracted from all the items on both fresh potato and its products through `Factor` software program, which gives more comprehensive and understandable outputs (Lorenzo-Seva and Ferrando, 2006; Baglin, 2014). Suitability of explanatory factor analysis with the RULS extraction method to the studied data sets was tested with Kelley`s criterion, giving the expected value for Root of Mean Square of Residuals (RMSR). Determinant, Kaiser-Meyer-Olkin (KMO) and Bartlett test values of the polychoric correlation matrix were estimated. Also, Bias-corrected bootstrap 5% confidence interval for the KMO test was found.

Results and Discussion

There are very few studies in the literature on the use of robust factor analysis methods. In the violation of the assumptions on normal distribution of ordinal items, the routine use of explanatory factor analysis may cause biased estimates. With the intention of this problem, a new free software `FACTOR` was developed by Lorenzo-Seva and Ferrando (2006). Very high reliabilities of four rotated factors were determined. Table 1 presents results of Robust Unweighted Least Squares Method for purchasing behaviour.

Advised number of factors was found to be five. These factors are good reputation of the shop and experience (Factor 1), ease of purchasing (Factor 2), price and properties of product (Factor 3), qualified products (Factor 4) and promotion elements (Factor 5), respectively. Result of Kaiser-Meyer-Olkin (KMO) test was estimated as 0.74. Bartlett statistic was found to be 2541 (P=0.00001). Bias-corrected bootstrap 95% confidence interval for KMO test was found between 0.739 and 0.758. Root Mean Square of Residuals (RMSR=0.0471) was found lower compared with an expected mean value of RMSR estimated based on Kelley`s criterion (0.0510), implying that the explanatory factor analysis exposed to 29 items regarding purchasing behavior in the present study gave reliable outcomes.

Abdullah and Asngari (2011) reports that branding, validation and prices, packaging and taste are determining factors of demand for a soft-drink. Majumdar (2015) reports that environmental consciousness, price sensitivity, ınnovativeness in buying products, product ınvolvement and health consciousness are significant factors affecting consumer demand for green cosmetics and food products. Gifford and Bernard (2008) suggests that organic labeling and promotion of organic status of foods may increase demand for non-genetically-modified food. McCluskey (2015) contends that the future of food is about taste, variety, healthiness, natural, authenticity, and freshness. Pícha et al. (2013), found that there is a strong link between quality, locality and environmental friendliness of food and food demand.

Although personal experience is a significant factor, our study showed that food safety is an important factor since the consumers' respect for the outlet and knowing or having been shopped from the same outlet before is an important determinant of demand. This is because the Turkish consumers put a great value on personal relationships with outlets and in Turkish commercial culture regular customers are very welcomed by the sellers. As a result of changes in the use of money, as well as in the consumer preferences and macroeconomic conditions, consumers prefer to use more easy payment methods such as credit cards. In connection with purchasing from well-known outlets, use of layaways and credit cards are also preferred by lower-income or lower-middle income consumers who try to manage their budgets. There is a general tendency to consider the source and originality, thus safety of foods, as such properties as geographical origin, calories, whether the product is organic or not, nutritional elements and quality certification are found to be important for the consumers. Price and discounts are still important determinants for consumers, however, recommendations of close social environment and salespeople are significantly important for consumers than the advertisement campaigns.

Table 1. Results of robust unweighted least squares method for food purchasing preferences

Factor Names	Items	F1	F2	F3	F4	F5
F1 (Recognition of outlet and experience)	According to the demands by family members	0,52				
	According to personal experience	0,64				
	Whether the product is imported	-0,32				
	Whether the product is packaged	0,43				
	Buying from a known place	0,50				
	Buying from commonly-known outlets	0,54				
	The outlet from which the products are bought	0,46				
	Buying products that are not widely-known.	-0,45				
F2 (Ease of purchasing)	Possibility of layaway purchase		0,54			
	Possibility of using credit card		0,74			
F3 (Price and properties of product)	Low price			-0.58		
	Label information			0.45		
	Having a certificate of quality			0,58		
	Being a well-known product			0,41		
	Nutritional elements			0,64		
	Calories			0,67		
	Organic products			0,58		
	Recommended by experts			0,43		
	Discount products			-0,51		
	Product and producer information available on package			0,47		
	Products with promotional gifts			-0,32		
F4 (Specific products)	High price				0.41	
	Local product				0,51	
	New product				0,42	
	Preference of fractional prices				0,47	
F5 (Promotional elements)	Advertisement					0.35
	Recommended by family and friends					0.71
	Recommended by salespeople					0,68

The differences between the results of this study and other studies may have been caused by differences in consumer cultures (tastes and preferences), differences in income levels, whether the products in question are specific products and the statistical approach utilized. Nevertheless, this study presented some informative results for identifying consumers` preferences in food purchases and provided some details that can guide local food producers and sellers in Igdir province, as well as providing clues for further research on the subject using Robust Factor Analysis.

Conclusions

The current results revealed that an application of EFA factor analysis on the basis of ULS extraction method, promin rotation method and polychoric correlations as a dispersion matrix was more effective compared with the traditional EFA applications for the ordinal data. According to the results of our study good reputation of the shop and experience (Factor 1), ease of purchasing (Factor 2), price and properties of product (Factor 3), qualified products (Factor 4) and promotion elements (Factor 5) are found as important factors affecting food purchase by the consumers in Igdir province. Consumers tend to think that well-known outlets are important in food safety. Consumers also choose to seek those outlets which offer them ease of purchasing.

Abstract

Using infrared irradiation heat for milk pasteurization as a technology with the high thermal efficiency can be a good alternative to traditional methods of milk processing. In addition by replacing potassium chloride instead of sodium chloride in the formula of the salt water of white cheese, the adverse health effects resulting from the consumption of sodium chloride can be prevented. In this study, by using the infrared radiation heat, raw caw milk was pasteurized and white cheese produced. The white cheese was placed in four different formulations of brine containing 1) NaCl: KCl, 10:0 percent 2) NaCl: KCl, 7.5: 2.5 percent, 3) NaCl: KCl, 5:5 percent and 4) NaCl: KCl, 0:10 percent for 21 days at a temperature of 8° C. Then the physicochemical characteristics of the cheeses were evaluated. Cheeses produced using two pasteurization methods of classic and infrared irradiation had significant differences in moisture and dry matter content.

Key Words: *NaCl, KCl, White Cheese, Brine, Infrared pasteurizing*

Introduction

Cheese contains less water than milk, and so has different organoleptic properties and shelf life than milk (Walstra et al., 2006). Cheese is a rich source of protein, fat, calcium, phosphorus, riboflavin and other vitamins. Also it can be more useful than milk in high protein diets, also its proteins are highly digestible (Renner, 1993).

Traditional production of white cheese in brine has been popular for centuries in small-scale caw keeping farms. Along with the recent developments in dairy product processing industry and with the integration of mechanization and automation, large-scale production of cheese became possible (Ozer, 2014).

Salting is an important stage in the process of cheese. History of salt used as an additive is related to 3,000 years before Christ (Woodin, 1981; Durack et al., 2008). Salt is considered as an additive commonly used in the food industry and plays a vital role in the food processing including food protection, helping to improve the flavor, the impact on proteolysis, water activity and strength in the tissue (Reddy and Marth, 1991; Guinee, 2004a; Guinee and Fox, 2004). Salt provides about 90 percent of the sodium in the human diet (He et al., 2012). In the structure of the salt, the sodium intake is very important to control the membrane potential of the cell and absorption of nutrients in the small intestine. In order to maintain the blood volume, osmotic pressure on the cell and also transportation of nervous signals, sodium is essential (Strazzullo et al., 2009; He and MacGregor, 2010). Although salt plays an important role during food processing, but has been known to be a major risk for diseases such as osteoporosis due to urinary excretion of calcium chloride, kidney stones and high blood pressure (Beumi et al., 2002; Kotchen, 2005 ; Massey, 2005; Heaney, 2006). World Health Organization has recommend food manufacturers to reduce the use of salt (WHO, 2007). Meat, dairy, bakery and other food products, each include a different percentages of sodium uptake by the body in different classes in the world for example, the daily intake of sodium through cheese in England, France, America and Australia, have been reported 7.8, 9.2, 8.2 and 5% namely (Meneton et al., 2009; Anderson et al. , 2010). So many efforts have been made for producing of low-salt cheese using different techniques such as reducing the amount of salt or partial replacement of salt in cheese with other materials (Guinee and O'Kennedy, 2007). Reducing the salt content of the Cheddar cheese and the effects of these changes on the chemical composition, proteolysis, and sensory properties were done by Schroeder and colleagues (1988b). Replacing salt with other materials such as potassium chloride, calcium chloride and magnesium chloride may be considered as a successful strategy to reduce the amount of salt (Kilcast and den Ridder, 2007). Also partial replacement of sodium chloride with potassium chloride revealed that the quality of the cheese has not significantly changed (Guinee, 2004b). Potassium chloride salt is acknowledged as a potential alternative to sodium chloride in cheese making. Increasing potassium intake has been reported as a protection factor for people with hypertension (Fregly, 1981; Reddy and Marth, 1991). A mixture of potassium chloride and sodium chloride has been successfully used in cheese production and no adverse effects have been reported on the quality of the cheese (Fitzgerald and Buckley, 1985). Several studies have been also made on the effect of replacing sodium chloride with potassium chloride on the properties of Cheddar (Reddy and Marth, 1993a), feta cheese (Katsiari, et al., 1997; 2000a), Kefalograviera cheese (Katsiari et al., 2001a), and Fynbo cheese (Zorrilla and Rubiolo, 1994; Zorrilla et al., 1996), but there is not any investigation on white cheese made of IR pasteurized milk and aged in KCl substituted brine. Infrared heating is an alternative preservation method with higher thermal efficiency which transfers thermal energy in the form of electromagnetic waves. Recent applications of infrared heating indicate this technology is a viable alternate for the pasteurization of liquid foods, in addition it can decontaminate foodstuffs in both liquid and solid foods with retaining higher levels of health promoting compounds (Hagh Nazari. 2014). The aim of this research is to study the effects of replacement of NaCl with KCl salt on the physico-chemical properties of ripened white brined cheese made from pasteurized milk using infrared irradiation.

Materials and Methods

Cheese making method: for the preparation of cheese, raw milk from the dairy farm of Zanjan University was prepared. Raw milk was pasteurized using flavor wave Turbo device that emits infrared waves at 72 ° C for 15 seconds has shown in figure 1. The temperature of the process was checked by a digital thermometer model TES made in China. For comparing and evaluating the effects of the pasteurization methods, the milk was also pasteurized using classic (conventional) methods. After pasteurization of milk, 200 ml of milk was poured in lidded plastic containers of the same shapes in 3 replicates equaled 24 samples.

Figure 1: flavor wave Turbo device

After the milk temperature reached to 35 ° C; the kefir starter solution to the volume of 2 ml along with calcium chloride to the amount of 0.02% of the milk were added to the pasteurized milk. The samples were transferred to an incubator made in Memmert Company in Germany at 35°C. And 20 minutes after adding the starter, the fungal rennet Valiren made in America was added the amount of 0. 0025 gram to each container at 35°C.

After clot formation, clots were left without cutting for 12 hours in $18^{\circ C}$ to continue fermentation, coagulating and dewatering. The resulting clots were transferred to salt solutions containing: 1) NaCl: KCl, 10:0 percent 2) NaCl: KCl, 7.5: 2.5 percent, 3) NaCl: KCl, 5:5 percent and 4) NaCl: KCl, 0:10 percent for 21 days at a temperature of 8° C. After ripening, physic-chemical tests were conducted on the cheese.

Chemical tests: measurement of chemical compounds was conducted by AOAC methods (AOAC, 2012). Moisture, fat and protein contents were measured using the oven at 102 degrees Celsius, Gerber method, and Kjeldahl method respectively. PH was measured by Professional portable milk pH Meter HI98162 provided by Hanna Company.

Statistical analysis: factorial experiments were conducted in a completely randomized design with three replications. The statistical comparison was done using the Mstat-C software via Duncan's method.

Results and discussion

- **Chemical analyses:**

Chemical assessments on raw milk and pasteurized milk using classic method and infrared irradiation are reported in Table 1.

Table 1. Chemical assessments on raw milk and pasteurized milk using classical method and infrared irradiation.

Analysis	Raw Milk	Classic Pasteurized Milk	IR Pasteurized Milk
pH	0.005 ± 6.6866	0.005 ± 6.68	0.005 ± 6.6866
Density	0.0005 ± 1.02867	0.0005 ± 1.02866	0.0004 ± 1.02822
Acidity	0.001 ± 0.1463	0.0015 ± 0.1476	0.0005 ± 0.1476
Fat	0.0082 ± 3.66	0.0032 ± 3.649	0.0074 ± 3.6606
Protein	0.0066 ± 3.2166	0.007 ± 3.2096	0.0065 ± 3.214
Lactose	0.00821 ± 4.8611	4.8483 ± 0.006	0.01 ± 4.8542
Nonfat Dry Mass	0.00356 ± 8.4797	0.0023 ± 8.473	0.001 ±8.4793
Calcium	0.0002 ± 0.122	0.0033 ± 0.120	0.0004 ±0.122

The comparison of data means resulting from the analysis of the cheese characteristics show that the cheeses made from two types of pasteurized milk and different brine formulations only differ in the amount of moisture and dry matter content and there is no significant difference between them. The impact of the brine formulation on the pH of the cheeses: PH of cheeses began to decreasing during preparation and aging in brine formulations and finally reached to 4.02 from 5.3 in beginning stage o aging. Figure 2 shows the pH of ripened cheeses in various ratios of brine and different milk pasteurization methods.

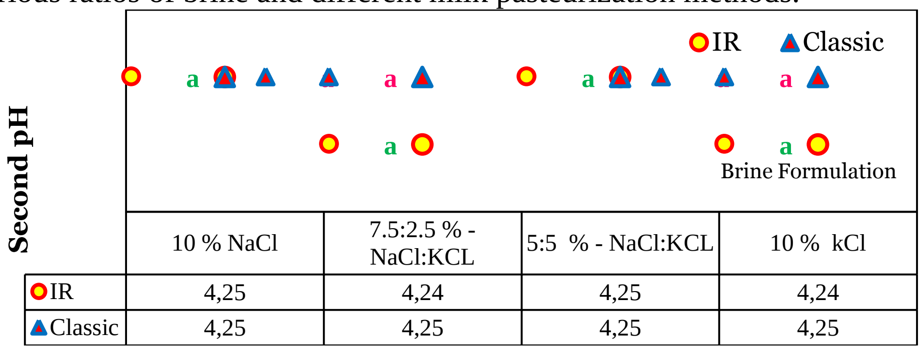

Figure 2: Comparison of the pH of ripened cheeses in various ratios of brine and different milk pasteurization methods

Comparison of cheese samples appearance:

The comparison of the clots formed from pasteurized milk using infrared radiation (1) and Classic method (2) at 72° C for 15 seconds is shown in Figure 3.

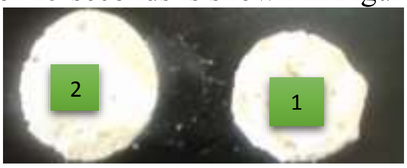

Figure 3: comparison of the clots formed from pasteurized milk using infrared radiation (1) and Classic method (2) at 72° C for 15 seconds.

The comparison of the clots formed from pasteurized milk using infrared radiation (1) and Classic method (2) shows that the volume of the Infrared irradiated samples are smaller with higher coherence and solidity.

- **The organoleptic analysis of cheeses**

The color, flavor and tastes of the cheeses (the organoleptic results) examined by taste panel showed that there is no significant difference between samples.

- **The use of potassium chloride in the formula of the cheese brine:**

The reason of the replacement of sodium chloride with potassium chloride, is achieving a product that reduces harmful effects to health caused by the consumption of sodium chloride. In addition to the fact that the product is supposed to be acceptable in terms of evaluated properties. The results of the analysis showed that the only difference between white cheeses produced in different brine formulas is in their firmness. Reduced sodium salt cheese is very soft, bitter, less salty, and has a strong off-flavor and shorter shelf life (Ying Lu, 2012). Potassium chloride (KCl) has a similar structure and salty flavor as sodium chloride (salt) and partial replacement of salt with potassium chloride can be used to lower salt content in foods. Moreover, potassium can lower the blood pressure and the risk of heart disease or stroke. Thus, potassium chloride is a potential substitution for salt in cheese.

- **Effects of brine formula on Cheese pH:**

At the beginning of ripening period of the cheese samples, the production of lactic acid from lactose reduces the pH and increases the acidity by Lactic Acid Bacteria. With improvement of the cheese ripening, the reduction of lactose continues and lactic acid inhibitory effect begins on the activity of some lactic strains. So, the production of lactic acid is reduced and consequently, the testable acidity remains constant.

Comparing the results of pH shows that differences in the pH in ripened cheese made from pasteurized milk with the two methods is not significant. PH difference between different formulations of salt water is not significant in ripened cheese.

The similar results obtained by Lindsay in 1982, Aly Katsiari in 1985 and in 1998, 2000 and 2001 for cheddar and feta cheeses. The researchers also attributed the reason of the lactic acid produced from lactose causing the initial reduction of pH, while the advancement of proteolysis and lipolysis results an increase in the amount of amino acids and fatty acids during the ripening period induces to final pH decrease.

The researchers also reported that the initial pH of the cheese is specified according to the pasteurization method, the type of milk used to make cheese, the microbial load of the raw milk and the starter culture type. While the pH of the ripened cheese is specified according to the ripening temperature, period length and the type of rennet used (Lindsay, 1982; Aly, 1985; Katsiari et al., 1998, 2000, 2001). Partial replacement of sodium chloride with potassium chloride with different levels of substitution (10:00 percent sodium chloride - potassium chloride, 7.5:2.5% sodium chloride - potassium chloride, 5:5 % sodium chloride - potassium chloride and 10:00 percent potassium chloride - NaCl) had no significant effect on pH values. These results are similar to findings of Katsiari in 1998, 2000 and 2001. This researcher replaced (3% sodium chloride, 1.5:1.5 percent sodium chloride - potassium chloride and 3% potassium chloride) on Kefalograviera cheese and observed no significant change in the pH of the cheese. (Katsiari et al., 1998, 2000, 2001).

- **Effects of brine formula on the chemical properties of cheese**

In examining the impact of different levels of sodium and potassium chloride on cheese chemical properties (including the amount of fat and protein) by infrared or classic method for pasteurization; it became clear that replacement of sodium chloride with potassium chloride in brine have both no significant effect on the fat and protein of the produced cheeses (based on dry weight). Results of the studies of Lindsay in 1982, Aly Katsiari in 1985, 1998, 2000 and 2001 also showed similar results. In addition in 1998 and 2000, Katsiari pointed out that the changes in the amount of fat, protein and other compounds of cheese occurred by the lipolysis, proteolysis, lactic acid production and other reactions happened during the ripening period not due to brine formula. Although added calcium chloride can effect on cheese density and volume of cheese due to participating in paracaseinate calcium clots which induce the syneresis reaction improve (Fuca, 2012).

The effect of infrared radiation in cheese production

Examining properties of the produced cheeses showed no significant difference between the cheeses produced from pasteurized milk using the infrared and classic methods but due to the high heat performance in the infrared radiation, the pasteurization process of milk is approximately 75% faster than the classic method. It is considered a more suitable method for pasteurization of milk compared to the classic method especially due to the heat shock effect on microbial cellular structure. All above studies confirms this project's results due to the higher efficiency and saving energy consumption via IR assisted systems in comparison of classic method of pasteurization.

Conclusion

In general, from this study it can be concluded that changing the formulation of the used brine has no effects on cheese properties.

Effects of brine formula on Cheese pH shows that differences in the pH in ripened cheese made from pasteurized milk comparing with the two methods is not significant.

Effects of brine formula on the chemical properties of cheese shows replacement of sodium chloride with potassium chloride in brine have both no significant effect on the fat and protein of the produced cheeses (based on dry weight).

Abstract

The pear psylla, *Cacopsylla pyri* L. (Hemiptera, Psyllidae) is one of the most important pests on pear in all regions where this fruit species is grown. This species is causing direct and indirect damages, thus reducing the yield and quality of the fruit. In addition, the application of molecular methods confirmed vector function of this species in the transmission of phytoplasma „*Candidatus* Phytoplasma pyri" which causes a dangerous disease, „Pear Decline" (PD) and destruction of pears (Carraro et al., 1998). The survey was conducted in 2011 and 2012 in orchards, in locations Vojkovići, Kula, Tilava, Petrovići and Kasindo (City of East Sarajevo, Bosnia and Herzegovina). Pear orchards were differ in age and growing module as well as in the other environmental characteristics such as altitudes and climate. Pear psylla was collected at different stages of development and examined in the laboratory - Faculty of Agriculture, University of East Sarajevo. Collected species were fixed in 70% alcohol, and preparations of adults and larvae were made in order to determination species. Bionomy of *Cacopsylla pyri* was examined in pear orchards and in laboratory on a sampled infested plant material.

Key Words: *Pear Psylla, development, City of East Sarajevo.*

Introduction

The pear psylla, *Cacopsylla pyri* L. (Hemiptera Psyllidae), is known in Europe for its extended infestations which may cause heavy economical losses to most pear growing regions. The damages that *C. pyri* may induce to pear trees are classified in two main types: 1) direct damages, weakening the plant by subtraction of nutrients; when the pest attack is intense, the plant wastes away with reduced production; 2) indirect damages, due to the production of a large amount of honeydew on which sooty molds develop (russetting fruits, Fig. 2), and also to the possible transmission of phytoplasms (Horton, 1999). In the first case the most damaging stages are the nymphs of all instars because of the high amount of honeydew (produced especially in spring and summer) dripping on everything including fruits. Besides lowering the fruit market value, honeydew favours the growth of sooty molds caused by saprophytic fungi, in turn causing indirect injury to the plant (Pasqualini et. al., 2003; Civolani, 2012).

Thus, in the Czech Republic, *C. pyri* is the most important species in pears, especially since the early 1990´s when enormous damages were registered (Kocourek and Stará, 2006). In Spain and Italy, *C. pyri* also have the first place for damage (Conci et al., 1993; Pasqualini et al., 2002; Sanchez and Ortin-Angulo, 2011; Civolani, 2012). The harmfulnes of *C. pyri* in Greece and Turkey, as well as in other European countries, are confirmed by the data of many authors (Broumas et al., 1989, Stratopoulou and Kapatos, 1995, Souliotis and Broumas, 1998; Erler, 2004).

In the area of the former Yugoslavia, since the beginning of the 80's in the XX century, *C. pyri* has become an increasing problem (Krnjaić and Grujić, 1982). From this period, this species continues to cause damage in pear orchards, and thus represents the most important pest of pears that endangers the survival of pear, in all former parts of Yugoslavia, regarding present countries in the environment (Milenković et al., 1998; Maceljski, 2002; Petrović - Obradović et al., 2007). The number of generations of *C. pyri* during the year is different, depending on the geographic region and the climatic conditions. Thus, this species in southern France, it can develop up to eight generations (Burckhardt, 1994), in Serbia formed five (Jerinić-Prodanović, 2010), and in Slovenia four generations (Vrabl and Matis).

Materials and Methods

The bionomy of *Cacopsylla pyri* was done in 2011. and 2012 in the field and in laboratory of the Agriculture Faculty of East Sarajevo. A field survey was conducted in intensive orchards, in the locations of Vojkovići and Kula, in the semi-intensive orchards in the locations of Tilava and Petrovići, and in extensive orchard in the location of Kasindo. Using entomological methods, such as visual examination of trees, taking a sample of infestation plant organs, collecting preimaginal stadium and adults insects, the bionomy was examined. In this sense, the way of wintering, spring activation, development during vegetation, number of generations, length of developmental stages of life and number of individuals were observed.

Visual examination of trees was done during the vegetation season at intervals of 10-15 days, and during the winter. Winter examination of plants was done by the two samples of two total length of 2 m of two- nor three-year branch were survey (from different places was taken of the 10 branches of length 20 cm) and examined in detail in the laboratory under the dissecting microscope. In all locations, were examined of 20 trees. By method of sampling of 100 diferent plants organs (leaf and flower buds, leaves, fruit) with a randomly selected tree, the presence of this species and development stage, was determined. All sampled infested plant material was observed in laboratory. All collected preimaginal stadium, were reared in the laboratory to adult stadium. The rearing of *C. pyri* was by the method Hodkinson&White, 1979 (cit. Jerinić-Prodanović, 2010). The collected and reared insects were fixed in 70% alcohol; some of them were prepared, and making microscopic preparations or the entomological collection.

The determination of species was based on morfological characteristic of adults and larvae, such as the appearance of genital and anal complex males and females, and the front nervature skirts, as well as the looks of thew fifth larval instar of development. Therefore, temporary and permanent microscopic slides of whole insect body parts important to the determination were made by the method of cold or hot maceration in 10% KOH. Permanent slides were made in Canada balsam by the method Hodkinson & White (1979) and Burckhardt (1989) (cit. Jerinić- Prodanović, 2010).

Considering that the bionomy and the growth cycle of insects in general, depends of the climatic conditions of the external environment, the most of the temperature, relative humidity and precipitation in the area, the meteorological data was followed and obtained from the Federal Hydrometeorological Institute in Sarajevo (Fig. 1, 2).

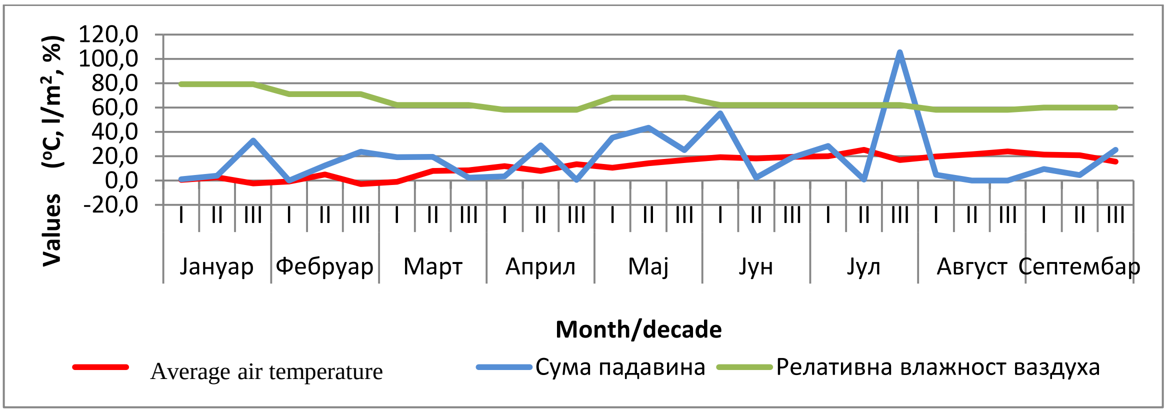

Fig. 1. Meteorological data in 2011

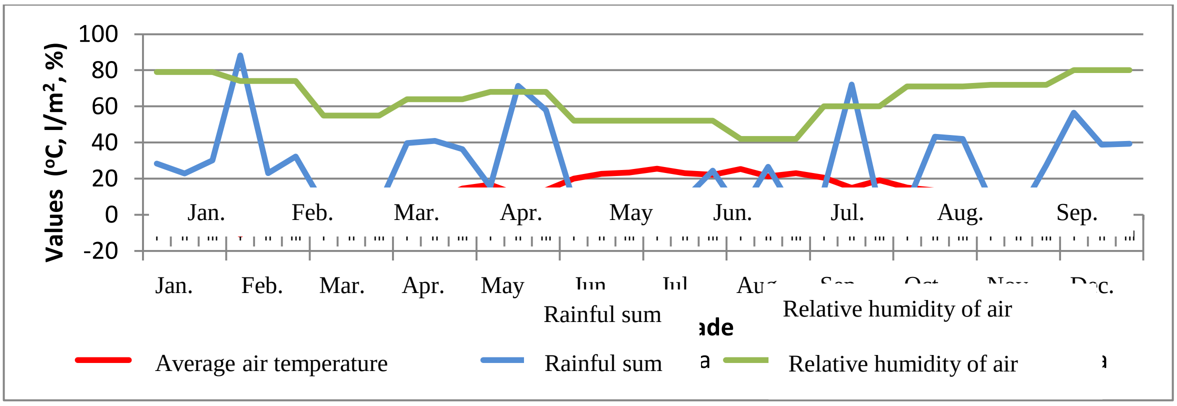

Fig. 2. Meteorological data in 2012

Results and discussions

Average air temperature

In pear orchards of East Sarajevo, during the two examination years, the pear psylla (*C. pyri*) developed four generations during the both years (Table 1), and while according to the data of other authors, in neighboring countries, in Serbia have five generations, in Slovenia four (Vrabl and Matis, 1977, Jerinić-Prodanović, 2010).

Table 1. Development calendar of *C. pyri*

+ overwintering adult; ● eggs; - larvae; + adult new generation; ▬ period of harm

The time of activation of the *C. pyri* depends on climatic factors, especially to temperature. Considering that *C. pyri* overwinter as adult on pear trees, in our research, the first adults were registered at the end of the second decade of March (March 17 in 2011 and March 19 in 2012), with average air temperatures of 7,9 °C in 2011 and 6,8 °C in 2012 (Fig.3,4). According to the data the other authors, the first activity of adult was registered at the beginning of February (Jerinić-Prodanović, 2010), in the winter days when the air temperature is 4-5ºC (Almaši et al., 2004).

Fig. 3. Male of *C. pyri* – winter form

Fig. 4. Female *C. pyri* – winter form

Also, in this period, but also a few days earlier, at the beginning of the second decade of March, on the branches eggs were found, respectively 13 to 41 per sample.
The period of oviposition was very long, about two months, until the beginning of the second decade of May. The highest number of eggs laid, was during the third decade of April, at an average air temperature of 13,3ºC in 2011 and 14,6ºC in 2012, on buds and young leaves, mostly close to the main foliar nerve (Fig. 5). The first larvae were found on April 20 in 2011 and April 21 in 2012. They were mainly concentrated on young leaves or buds, and later found on young shoots (Fig. 6). The larvae have five development stages (Fig. 7,8).

Fig. 5. Eggs *C. pyri* on leaf of pear

Fig. 6. Larva *C. pyri* – L_1

Fig. 7. Larva *C. pyri* – L_4

Fig. 8. Larva *C. pyri* – L_5

The complete development of larvae was 29 days in 2011, and 31 days in 2012. So, the first image of the first generation was determined on May 19 in 2011, and May 22 in 2012. The development of this generation was 55 days. The female of this first generation have laid eggs during the second decade of May and June on leafs and young shoots. The first larvae were registered on June 15 in 2011, and June 16 in 2012. In this second generation, the development of larvae was some longer, 28 days in 2011 and 25 days in 2012.

Feeding on sup from the leaves, larvae *C. pyri* produce a large amounts of honeydew, especially at temperatures higher than 18°C. Our research also confirms the present of honeydew which covering the young shoots of pears, especially in the third decade of June, when air temperature was 19,5 °C in 2011 and 23,4 °C in 2012 (Jerinić-Prodanović, 2010; Almaši et al., 2004). The first adult of the second generation registered on July 13 in 2011, and July 05 in 2012. So, the development of this generation was 55 days in 2011 and 44 days in 2012. The larvae of this generation were registered on July 29 in 2011 and July 21 in 2012. Their development was 22 to 25 days, so the adult of third generation was registered on August 24 in 2011 and August 13 in 2012. The complete development of this generation was 41 days in 2011 and 40 days in 2012. According to the literature data (Jerinić-Prodanović, 2010), the development of the larvae *C. pyri* lasts 20 to 40 days, what is in agreement with our results because the larvae developed from 22 to 31 days, depending on the temperature conditions.

The larvae of third generation have developed in September 08 in 2011 and September 28 in 2012. Their development lasted 30 to 37 days, so adult of fourth generation registered at the beginning of the second decade of October (Oct. 09 in 2011 and Oct. 04 in 2012), what meaning that the complete development of this generation was 47 days in 2011 and 52 days in 2012. This adult *C. pyri* were registered in the orhards of pear by middle November.

According to literature data, generations of *C. pyri* are overlap, what is an agreement with our result of research (Maceljski, 2002; Almaši et al., 2004).

Conclusion

In pear orchards in the area of East Sarajevo, pear psylla (*C. psylli* L.) developed four generations in 2011. and 2012. year.

The first wintering adults were registered at the end of the second decade of March on pear trees to both years. The development of the larvae *C. pyri* was from 22 to 31 days, depending on the temperature conditions. The complete development one generation was from 40 to 55 days, depends from climatic conditions. Generations of *C. pyri* overlappped during both research years.

DISTRIBUTION MAPPING OF SELECTED INVASIVE WEED SPECIES IN NORTH WESTERN AREA OF REPUBLIC OF SRPSKA (BOSNIA AND HERZEGOVINA)

Gordana BABIĆ*, Vojislav TRKULJA

Public institution „Agricultural institute of Republic of Srpska, Banja Luka", Bosnia and Herzegovina
*Corresponding author: brkljacg@hotmail.com

Abstract

Invasive weed species are characterized by rapid spread and successful establishment, occupying different habitats and thus potentially pose a threat to the biodiversity around the world. In recent years, a wide distribution of invasive weed species in north western area of Republic of Srpska (RS) caused irreparable and obviously damage across different habitat type. Considering problems such as their wide spreading and negative ecological, economic and social impact, studies in north western area of RS is addressed to selected invasive weed species. Among many, the most invasive is *Ambrosia artemisiifolia* L., threatening agricultural production and human health. However, a significance importance is placed on other invasive weed species, such as: *Asclepias syriaca* L., *Helianthus tuberosus* L. and *Fallopia japonica* (Hout.) Ronse Decre. Distribution and abundance parameters for selected invasive weed species were done for 62 stands based on Blanque Braun (1964) method and GIS software. Assessment of their occurrence and distribution was taken along the roads in the urban areas, between the settlements in ruderal and less arable land, on the edges of farmland, on arable land, along the rivers and fish pond, in ditches and on the edges of forests. Mapping of above mentioned weed species revealed a wide-spread distribution and renewal potential of selected weed species, thus presenting a real threat to native flora and different habitat type.

Keywords: *distribution, mapping, invasive weed species, Republic of Srpska.*

Introduction

Numerous invasive alien species have become successfully established over large areas in Europe, thus having an increasing invasive potential (Pysek *and* Hulme 2005; Hulme, 2007 *loc. cit*. Lambdon *et al*., 2008; Dumitraşcu *et al*., 2010). The invasive weed species are characterized by rapid spread and successful establishment, occupying different habitats and thus potentially pose a threat to the biodiversity around the world. Thus, biological invasions have been recognized as being one of the main components of global change (Shea *and* Chesson, 2002) that affects populations, communities and even whole ecosystems (Richardson *et al*., 2000). In recent years, a wide distribution of invasive weed species in north western area of Republic of Srpska caused irreparable and obviously damage across different habitat type. Considering problems such as their wide spreading and negative ecological, economic and social impact, studies in north western area of Republic of Srpska is addressed to selected invasive weed species.

Among many, ragweeds (*Ambrosia artemisiifolia* L.) present one of the most invasive weed species in our area (Trkulja *et al*., 2012). However, a significance importance is placed on other invasive weed species, such as: common milkweed (*Asclepias syriaca* L.), Jerusalem artichoke (*Helianthus tuberosus* L.) and japanese knotweed (*Fallopia japonica* (Hout.) Ronse Decre.). Common milkweed is in past few years also in expansion and it is considerd that in the future could present a significant problem in ruderal as well in aglriciltural land (Trkulja *et al*., 2011). According to Babic *and* Trkulja (2014), Japanese knotweed stand occurs in wet grassy lowland areas but is also found on hillsides, sunny sites in coastal areas, wetlands and riparian areas, but predominantly it is found near human settlement, along river banks and in waste areas in the north western part of RS. Also regarding to *H. tuberosus*, the most sever areas are in the river banks of Vrbanja and Sava, as well as areas along the fish pond between Prnjavor and Derventa (Babic and Trkulja, 2015).

Material and method

The current research mainly focuses on the north western part of RS in relation to species habitat requirements and main environmental features. Field survey was conducted during the vegetation period in 2016. Assessment of the occurrence and distribution of invasive weed species were taken along the roads in the urban areas, between the settlements in ruderal and less arable land, and on the edges of farmland, on arable land, along the river Sava and Vrbanja, as well as along the fish pond, in ditches and on the edges of forests. Quantitative distribution, study species density measure was assessed based on Blanque Braun (1964) method. During fieldwork invasive weed species stands were mapped and recorded with GPS, while polygons were digitized using FITO GIS software.

Species habitat requirements

Helianthus tuberosus prefers certain habitat types (Fehér and Končeková, 2001). It is best adapted to rich, moist soil that can be found along roadways, in wasteland areas and gardens (Wyse *et al*., 1986). According to Hartmann *et al*. (1995) *H. tuberosus* is completely naturalized on moist, nutrient-rich, sandy or loamy soils, especially along rivers. The most substantial site of occurrence includes riparian nitrophilic vegetation along watercourses, but also a variety of anthropogenic sites. In the landscape, it spreads very aggressively and settles more and more areas. It is contributed not only by spreading through generative diaspores, but also by vegetative propagation of broken-off parts of corms washed away by water to new sites along the watercourse (Cvachová *et al*., 2002).
Fallopia japonica can usually tolerate a wide variety of environmental conditions ranging from high shade, high temperatures (even drought) to high salinity. In its native range, Japanese knotweed is a pioneer species on volcanic slopes and as invasive it invades disturbed habitats, tolerating a variety of soil structures and textures and pH levels, ranging from 3 to 8 (Pysek, 2006). It frequently occurs in riparian habitats (e.g. along river banks), but because of its invasive nature it also tolerates disturbed habitats, such as railroad tracks and roadsides (Forman and Kesseli, 2003). Other studies undertaken on *F. japonica* also revealed its preference for: boundary walls in farmlands, urban non-industrial land, ruderal habitats, meadows, natural/semi-natural forests, roadways etc. (Tiébré *et al*., 2008). The species usually installs in open places, its growth and abundance being seriously affected by shading. The rhizomes are very resistant to low temperatures, thus permitting its survival in harsh climatic conditions (up to absolute minimum temperature of -30.2° C) (Barney *et al*., 2006).
Asclepias syriaca invades soils due to insufficient cultivation and herbicide use, fertilizers and irrigation measures (Cramer and Burnside, 1981).
Ambrosia artemisiifolia grows best in warm and moist conditions (Deen *et al*., 1998). However according to Trkulja *et al*. (2010) ragweed is present also in dry lands, but can develop in different soil type independently regarding to a quality of soil, and thus often could be seen in very poor or in soil with very bad or damage structure (pH level – 3). Same author stated that ragweed distribution goes to north up to 50 parallels, which why are south parts of

continent and Mediterranean are the most favourable areas for spreading this invasive weed species in Europe.

Results and discussion

Distribution and mapping of selected invasive weed species was observed in the number of municipality of Republic of Srpska, in Banja Luka, Gradiška, Srbac, Vrbanja, Čelinac, Kotor Varoš, Prnjavor and Derventa between the above mentioned municipalities along the roads in populated areas, between settlements in ruderal and less arable land, on the edges of farmland and arable land, near the water sources, along the river Sava and Vrbanja, as well as along the fish pond, in ditches or even in the urban aerias (photo 1-4).

Photo 1. *A. syriaca* in wheat crop

Photo 2. *A. artemisiifolia and F. japonica* in urban area along the roads

Photo 3. *H. tuberosus* on river bank of Vrbanja in Čelinac

Photo 4. *H. tuberosus* along fish pond

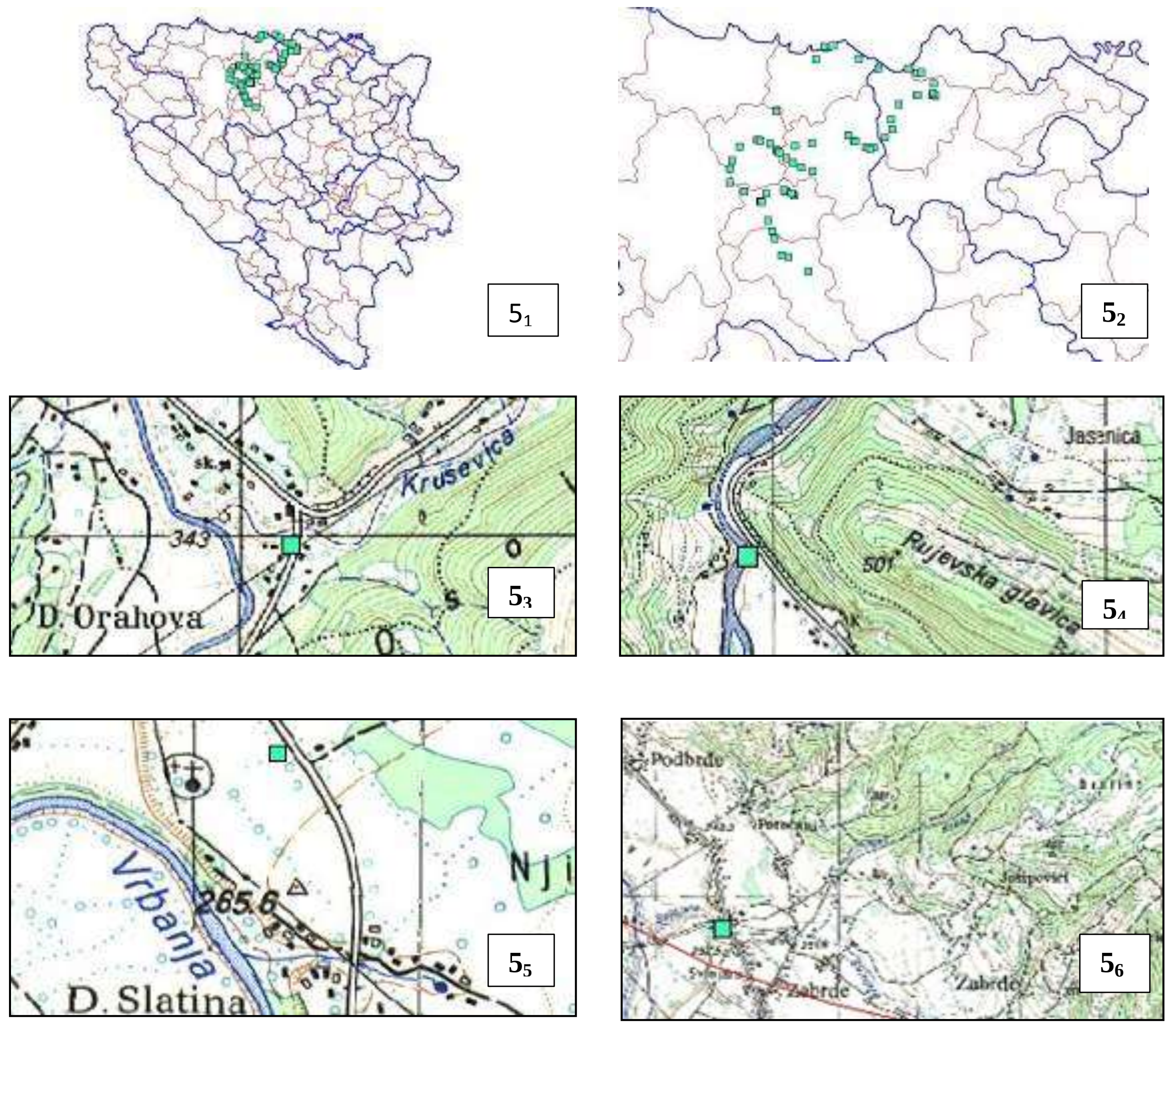
During the research it is noticed that *H. tuberosus* behaves as an invasive weed species in the studied region. Frequent expansion of the species into the surrounding sites inner town, near agricultural lands and the cultivated field is also noticed, beside the expansion on the river bank of Vrbanja and Sava. The abundance of Jerusalem artichoke points to a high density of individuals e.g. up to 60-70/m^2 along the fish pond between Prnjavor and Derventa, as well on river bank of Vrbanja and Sava (up to 30-40/m^2).

The abundance, estimated based on the number of steams, points to a high density of individuals of *F. japonica* on sq.m, e.g. up to 40-50 steams m^{-2} in the Sava river flood plain as well between Srbac and Derventa along the roads in populated areas, in ruderal and less arable land, on the edges of farmland, and on the edges of forests.

In Banja Luka, Gradiška, Srbac, Vrbanja, Čelinac, Kotor Varoš, Prnjavor and Derventa a high density of *A. artemisiifolia* is determineted. It is present in different habitants and in different communities. In some areas density of individuals was over 70 m^{-2} . The highest density is recorded along roads, as well in all type of crops, farmland and less arable lands, stubble fields especially etc. It is noticed that species is highly adjustable to different type of soil, and thus the only place that is not present are forest communities.

The lowest abundance was determinate in case of *A. syriaca*. A highest recorded density of individuals was up to 28 m^{-2} and mostly in wheat crops, less arable lands and along the roads between the urban areas, near the river Sava. Even the species is present and have the invasive potential, outside the wheat crops, and less arable lands, the highest density was no more than 12 individuals m^{-2} .

With current research 62 invasive weed species stand was recorded in the north western part of RS in 8 municipalities. Most of the stands are characterised by presence of two or more weed species together and all of them are recorded in different crops, such as orchards, wheat, corn etc. (Photo $5_{1\text{-}14}$).



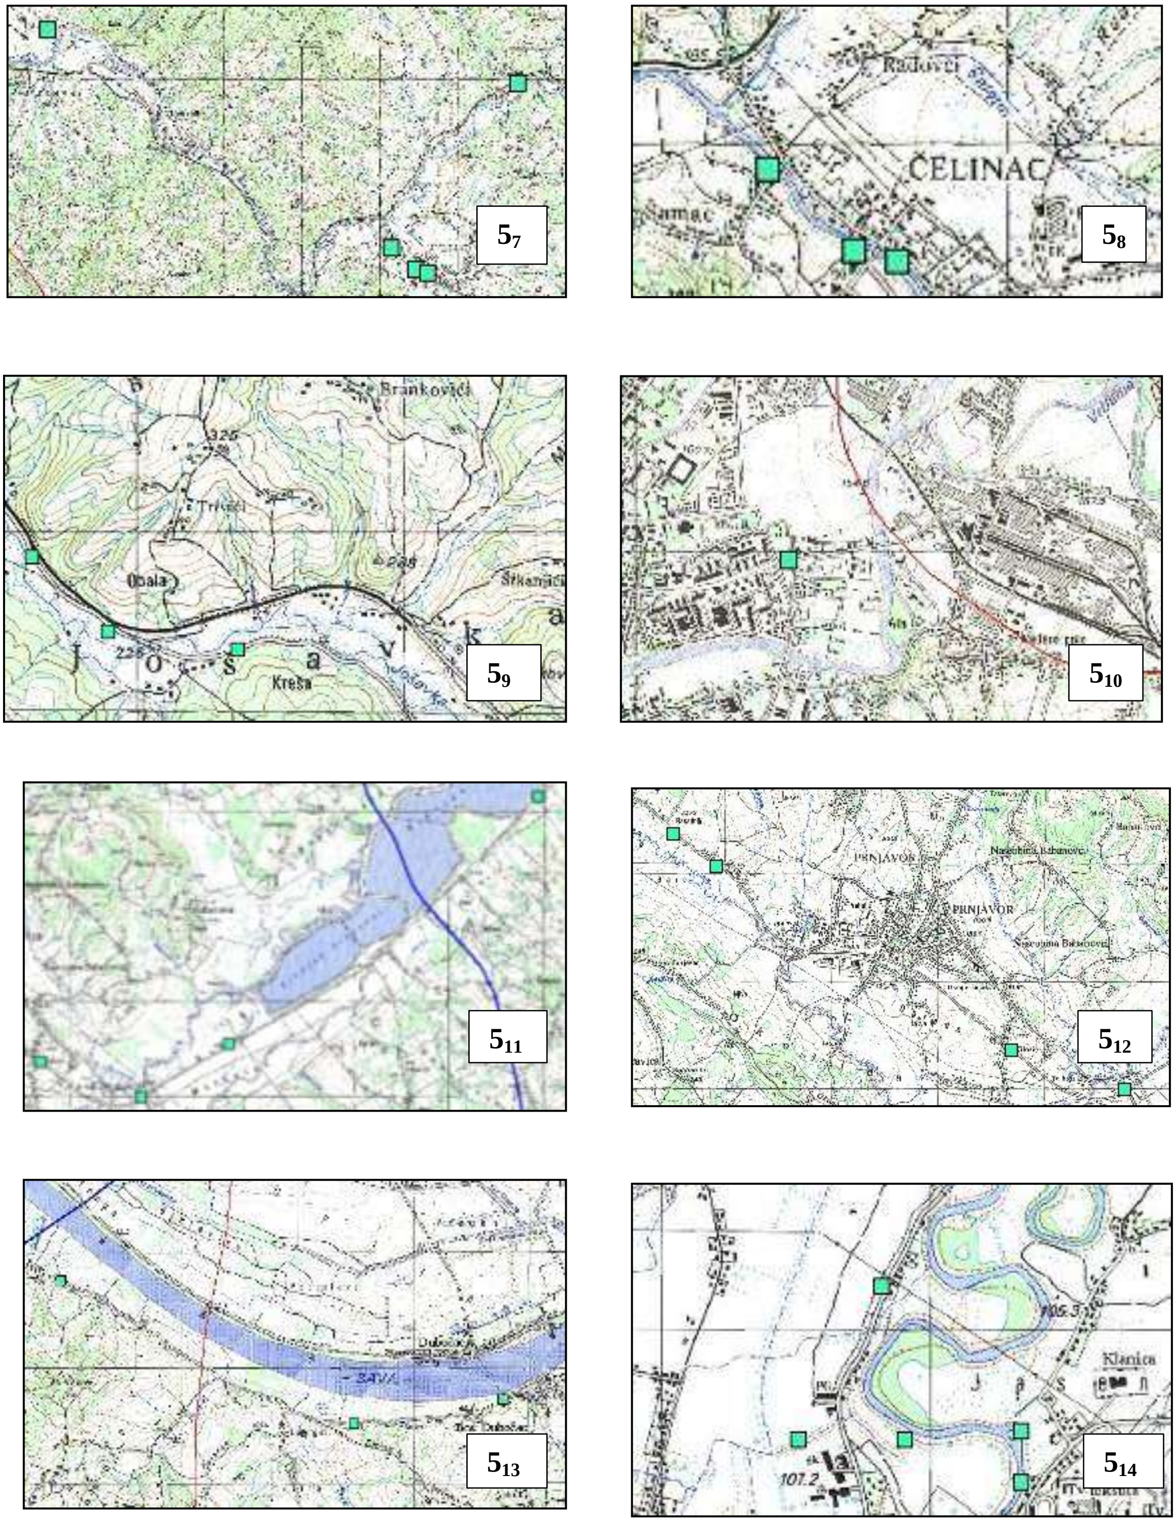


Photo $8_{1\text{-}14}$. Fito GIS distribution mapping of invasive weed species stand in the north western part of Republic of Srpska (along the roads in the urban areas, between the settlements in ruderal and less arable land, and on the edges of farmland, on arable land, along the river Sava and Vrbanja, as well as along the fish pond, in ditches and on the edges of forests).

Conclusion

Mapping of invasive weed species revealed a wide-spread distribution of *A. artemisiifolia*, *H. tuberosus*, *F. japonica* and *A. syriaca.* As expected, the highest abundance is recorded in case of of *A. artemisiifolia* (>70 individuals m^{-2}). However, very high abundance is recorded in case of *H. tuberosus* (60-70 individuals m^{-2}), especially along the fish pond between Prnjavor and Derventa, as well on river bank of Vrbanja and Sava (up to 30-40 m^{-2}). Never the less a high density of individuals of *F. japonica* on sq.m was recorded e.g. up to 40-50 steams m^{-2} in the Sava river flood plain, as well between Srbac and Derventa. However in case of *A. syriaca* the recorded density of individuals was 12- 28 m^{-2} and mostly in wheat crops, less arable lands and along the roads between the urban areas, near the river Sava.
Considering the above mentioned, as well the research in past, among many, the selected invasive weed species present a real threat to native flora and different habitat type in our area.

Abstract

Weed species present a significant limiting factor in soybean production. Their competitivness is more evident in drier years, often resulting in an unfavorable harvest, increased grain moisture and decreased quality and yield of soybean. Thus, a special emphasis is placed on effective weed management programs. Within a cooperative Danube-Soya Program, Public Institution „Agriculture Institute of Republic of Srpska, Banja Luka“ (PI AIRS, BL) from Bosnia and Herzegovina has taken an active role in the effective weed management programs in the production of non-genetically modified soybean. Total 19 herbicide combinations on weed populations in soybean in the Banja Luka region were tested during three-year period. Efficiency test of 5 herbicide combinations during 2014, 6 herbicide combinations during 2015 and 8 herbicide combinations during 2016 was carried out on the experimental fields of PI AIRS, Banja Luka. In 2014, heavy rainfall caused constant emergence of weed species throughout the vegetation period of soybean, resulting in satisfactory efficiency of applied pre. em. herbicide combinations with corrective treatments. High efficiency was only achieved by herbicides applied after sowing and before emergence of soybean with corrective treatment. In 2015, high efficiency was achieved by herbicide applied after sowing and before emergence of soybean with a corrective treatment, while satisfactory efficiency was achieved with post. em. herbicide combinations. In 2016, pre. em. herbicide combinations with corrective treatments achieved high efficiency.

Keywords: *herbicide efficiency, soybean, Danube-Soya Program.*

Introduction

A wide range of broad leaves weed dominate in soyabean, and thus present the limiting factor in production. Heavy weed competition is especially important in the early growth stages and considering that fact, pre-emergence herbicide application can be helpful in controling weeds, but to some extent. Actually, crop-weed competition is minimized by pre-emergence herbicide spray, hence weeds in the early growth stages are more concurent to a young plant of soyabean considering the needs for water, nutrition and if they are robust for light (Hrustić *et al*., 2004.). Their competitivness is more evident in drier years, often resulting in an unfavorable harvest, increased grain moisture and decreased quality and yield of soybean. Not only that they decrease yield, make harvest more difficult, reduce the quality of grain and increase the humidity, but also transmit a variety of diseases and pests. According to Öerke *et al*. (1994) grain yield can be reduced in average 13% or 10% (Maceljski, 1995). Thus a special emphasis is placed on effective weed management programs.

In order to strengthen the competitiveness of the EU market in relation to GMO soy producers, but also to intensify production on domestic manufacturers Public Institution „Agriculture Institute of Republic of Srpska, Banja Luka“ (PI AIRS, BL) took an active role in cooperative Program Danube Soya from 2014. Therefore, to ensure high quality and yield of non-GMO soybean the basic aim of this study was to investigate the efficacy of 19 different herbicides on weed populations in soybean in the Banja Luka area.

Material and method

The herbicide trial was conducted in the experimental field of the PI AIRS, BL according to the European and Mediterranean Plant Protection Organization guidelines (OEPP/EPPO, 1998; OEPP/EPPO, 1999; OEPP/EPPO, 2012). In 2014 herbicide efficiancy trail was set up on 14th April in randomized block design, with elementary plots of 60 m^2 in 3 repetitionin, locality Maglajani. Weed control included one treatment before sowing and immediately after planting (pre.em.), while four others combinations were applied pre. em. (Table 1).

Table 1. Technical data and variants of appleid herbicides in soybean during 2014 in Maglajani

Herbicide variant	Active substances	Time of applications/date	Concentration/Unit
Zanat + Lord + Galolin mono	Pendimethalin +Metribuzin +Linuron	pre. sowing and pre. em	4 L ha^{-1} +0,5 kg ha^{-1} +1,5 L ha^{-1}
Galolin mono +Lord	Linuron +Metribuzin	pre. em	2,5 L ha^{-1} +0,5 kg ha^{-1}
Galolin mono + Lord	Linuron +Metribuzin	pre. em	2 L ha^{-1} +0,75 kg ha^{-1}

The weed population of each herbicide trail plot and untreated control was recorded in terms of numbers with absolute assessment. In terms of absolute assessment individual plants were counted for each weed species. These assessments were made on randomly selected marked quadrats in each plot. Based on the obtained data, the coefficient of efficiency Ce (%) of herbicides is calculated by the formula Dodel *loc. cit.* Janjić (1985) and represents a relative ratio between the number of destroyed weeds compared to the weeds number in the control.

Results and discussion

In 2014 during the evaluations of the herbicide variants efficiency revealed the presence of 11 weed species. Target organisms were *Agropyron repens*, *Amaranthus retroflexus*, *Ambrosia artemisifolia* L., *Cirsium arvense* (L.) Scop., *Convolvulus arvensis* L., *Hibiscus trionum* L., *Matricaria chamomilla* L., *Polygonum aviculare L.*, *Setaria* sp., *Sorghum halepense* (L.) Pers. and *Viola* sp. The total number of weed population in control plots (photo 1) ranged from 109.3-162.4 plants/m^2, and among them the most dominant (63-75 plants/m^2) was *A.artemisiifolia,* which was to be expected given that it is the most invasive weed species in our area. The high efficiency of 92.82% was achieved in the variant applied after sowing and before emergence of soybean (Galolin mono + Lord) at a dose of 2.5 l/ha + 0,5 kg/ha with a corrective treatment (photo 2), while satisfactory efficiency (>80%) was achieved by applying of all other combinations (table 7).

Table 7. Efficiency of different weed control treatments in soybean in 2014

Herbicide variant	**Ce %**
Zanat + Lord+ Galolin mono + post.em. variant	84,17
Galolin mono + Lord + post.em. variant	92,82
Galolin mono + Lord+post.em. variant	88,59
Frontier 900 EC + Lord + post.em. variant	87,25
Lord +Dual gold 960 EC + post.em. variant	86,37

During 2015 the evaluations of the herbicide variants efficiency revealed the presence of 9 weed species. Target organisms were *Ambrosia artemisifolia* L., *Chenopodium album* L.,

Cirsium arvense (L.) Scop., *Convolvulus arvensis* L., *Hibiscus trionum* L., *Polygonum aviculare* L., *Setaria* sp., *Sorghum halepense* (L.) Pers. and *Xanthium strumarium* L.
The total number of weed population in control plots (photo 3) ranged from 125.3-173.4 plants m^{-2} and among them, as in previous year, the dominant species (69-92 plants m^{-2}) was *A. artemisiifolia*. High efficiency (>90%) was achieved in the variant applied after sowing and before emergence of soybeans with a corrective treatment, one of which is a variant Galolin mono + Lord achieved the highest efficiency (94.82%) (photo 4), while satisfactory efficiency (>80%) was achieved by applying both post. em. combinations (Table 8).

Table 8. Efficiency of different weed control treatments in soybean in 2015

Herbicide variant	**Ce %**
Zanat + Lord+ Galolin mono + post.em. variant	90,42
Galolin mono + Lord + post.em. variant	94,82
Lord+Dual gold 960 EC+ post.em. variant	91,36
Lord+Dual gold 960 EC+ post.em. variant	91,06
Pulsar 40	86,35
Dynox+Okvir	86,43

In 2016 during the evaluations of the herbicide variants efficiency revealed the presence of 10 weed species. Among target organisms 7 was annual: *Ambrosia artemisifolia* L., *Chenopodium album* L., *Echinochloa crus-galli* (L.) Beauv, *Hibiscus trionum* L., *Polygonum aviculare* L., *Setaria* sp. and *Xanthium strumarium* L., and 3 was pernial: *Cirsium arvense* (L.) Scop., *Sorghum halepense* (L.) Pers. and *Convolvulus arvensis* L.
The total number of weed population in control plots (photo 5) ranged from 126.7-187.1 plants m^{-2} and among them, as in previous years, the dominant species (52-64 plants m^{-2}) was *A. artemisiifolia*. High efficiency (>90%) was achieved in the variant applied after sowing and before emergence of soybeans with a corrective treatment. However, one of them achieved satisfactory efficiency (>80%). The highest efficiency was achieved with variant Sencor WG 70 + Dual gold 960 EC (92.89%) applied at rate 1 kg ha^{-1}/ha+1,2 L ha^{-1} (photo 6). In case of post. em. combinations, as in previous years, satisfactory efficiency (>80%) was achieved (Table 9).

Table 9. Efficiency of different weed control treatments in soybean in 2016

Herbicide variant	**Ce %**
Sencor WG 70 + Dual gold 960 EC + post.em. variant	91.13

Photo 3. *Control untreated plots in 2015*

Photo 4. *Variant Galolin mono + Lord in 2015*

Photo 5. *Control untreated plots in 2016*

Photo 6. *Variant Sencor WG 70 + Dual gold 960 EC*

Conclusion

During 2014, heavy rainfall caused the emergence of broad-leaves and grassy weed species in a longer period or from the deeper layers of the soil during the entire vegetation period of the soybeans. Thus pre.em. combination with corrective treatments achieved satisfactory efficiency. Compared with the previous year, in 2015, pre.em. combination with corrective treatments showed high efficiency, as in 2016.

Hence the study showed that post. em. combination achieved satisfactory efficiency (75-90%) in every year of testing, this point out the importance of appropriate and timely protection against weeds for agricultural producers as well as significant role in the selection of the most effective combination in the production of non-GMO soybeans in our area.

Abstract

Using infrared irradiation heat for milk pasteurization as a technology with the high thermal efficiency can be a good alternative to traditional methods of milk processing. In addition by replacing potassium chloride instead of sodium chloride in the formula of the salt water of white cheese, the adverse health effects resulting from the consumption of sodium chloride can be prevented. In this study, by using the infrared radiation heat, raw caw milk prepared of Zanjan University animal husbandry was pasteurized and white cheese produced in 2016. The white cheese was placed in four different formulations of brine containing 1) NaCl: KCl, 10:0 percent 2) NaCl: KCl, 7.5: 2.5 percent, 3) NaCl: KCl, 5:5 percent and 4) NaCl: KCl, 0:10 percent for 21 days at a temperature of 8° C. Then the physicochemical characteristics of the cheeses were evaluated. Cheeses produced using two pasteurization methods of classic and infrared irradiation had significant differences in moisture and dry matter content. However, the coliform, yeast and mold counts had not significant difference.

Key Words: *NaCl, KCl, White Cheese, Brine, Infrared pasteurizing*

Introduction

Cheese contains less water than milk, and so has different organoleptic properties and shelf life than milk (Walstra et al., 2006). Cheese is a rich source of protein, fat, calcium, phosphorus, riboflavin and other vitamins. Also it can be more useful than milk in high protein diets, also its proteins are highly digestible (Renner, 1993).

Traditional production of white cheese in brine has been popular for centuries in small-scale caw keeping farms. Along with the recent developments in dairy product processing industry and with the integration of mechanization and automation, large-scale production of cheese became possible (Ozer, 2014).

Salting is an important stage in the process of cheese. History of salt used as an additive is related to 3,000 years before Christ (Woodin, 1981; Durack et al., 2008). Salt is considered as an additive commonly used in the food industry and plays a vital role in the food processing including food protection, helping to improve the flavor, the impact on proteolysis, water activity and strength in the tissue (Reddy and Marth, 1991; Guinee, 2004a; Guinee and Fox, 2004). Salt provides about 90 percent of the sodium in the human diet (He et al., 2012). In the structure of the salt, the sodium intake is very important to control the membrane potential of the cell and absorption of nutrients in the small intestine. In order to maintain the blood volume, osmotic pressure on the cell and also transportation of nervous signals, sodium is essential (Strazzullo et al., 2009; He and MacGregor, 2010).

Although salt plays an important role during food processing, but has been known to be a major risk for diseases such as osteoporosis due to urinary excretion of calcium chloride, kidney stones and high blood pressure (Beumi et al., 2002; Kotchen, 2005 ; Massey, 2005;

Heaney, 2006). World Health Organization has recommend food manufacturers to reduce the use of salt (WHO, 2007). Meat, dairy, bakery and other food products, each include a different percentages of sodium uptake by the body in different classes in the world for example, the daily intake of sodium through cheese in England, France, America and Australia, have been reported 7.8, 9.2, 8.2 and 5% namely (Meneton et al., 2009; Anderson et al. , 2010). So many efforts have been made for producing of low-salt cheese using different techniques such as reducing the amount of salt or partial replacement of salt in cheese with other materials (Guinee and O'Kennedy, 2007). Reducing the salt content of the Cheddar cheese and the effects of these changes on the chemical composition, proteolysis, and sensory properties were done by Schroeder and colleagues (1988b). Replacing salt with other materials such as potassium chloride, calcium chloride and magnesium chloride may be considered as a successful strategy to reduce the amount of salt (Kilcast and den Ridder, 2007).

Also partial replacement of sodium chloride with potassium chloride revealed that the quality of the cheese has not significantly changed (Guinee, 2004b). Potassium chloride salt is acknowledged as a potential alternative to sodium chloride in cheese making. Increasing potassium intake has been reported as a protection factor for people with hypertension (Fregly, 1981; Reddy and Marth, 1991). A mixture of potassium chloride and sodium chloride has been successfully used in cheese production and no adverse effects have been reported on the quality of the cheese (Fitzgerald and Buckley, 1985). Several studies have been also made on the effect of replacing sodium chloride with potassium chloride on the properties of Cheddar (Reddy and Marth, 1993a), feta cheese (Katsiari, et al., 1997; 2000a), Kefalograviera cheese (Katsiari et al., 2001a), and Fynbo cheese (Zorrilla and Rubiolo, 1994; Zorrilla et al., 1996), but there is not any investigation on white cheese made of IR pasteurized milk and aged in KCl substituted brine.

Infrared heating is an alternative preservation method with higher thermal efficiency which transfers thermal energy in the form of electromagnetic waves. Recent applications of infrared heating indicate this technology is a viable alternate for the pasteurization of liquid foods, in addition it can decontaminate foodstuffs in both liquid and solid foods with retaining higher levels of health promoting compounds (Hagh Nazari. 2014).

The aim of this research is to study the effects of replacement of NaCl with KCl salt on the physico-chemical properties of ripened white brined cheese made from pasteurized milk using infrared irradiation.

Materials and Methods

Cheese making method: for the preparation of cheese, raw milk from the dairy farm of Zanjan University was prepared. Raw milk was pasteurized using flavor wave Turbo device that emits infrared waves at 72 ° C for 15 seconds has shown in figure 1. The temperature of the process was checked by a digital thermometer model TES made in China. For comparing and evaluating the effects of the pasteurization methods, the milk was also pasteurized using classic (conventional) methods. After pasteurization of milk, 200 ml of milk was poured in lidded plastic containers of the same shapes in 3 replicates equaled 24 samples.

Figure 1: flavor wave Turbo device

After the milk temperature reached to 35 ° C; the kefir starter solution to the volume of 2 ml along with calcium chloride to the amount of 0.02% of the milk were added to the pasteurized milk. The samples were transferred to an incubator made in Memmert Company in Germany at 35°C. And 20 minutes after adding the starter, the fungal rennet Valiren made in America was added to the amount of 0. 0025 gr to each container at 35°C.

After clot formation, clots were left without cutting for 12 hours in $18^{\circ C}$ to continue fermentation, coagulating and dewatering. The resulting clots were transferred to salt solutions containing: 1) NaCl: KCl, 10:0 percent 2) NaCl: KCl, 7.5: 2.5 percent, 3) NaCl: KCl, 5:5 percent and 4) NaCl: KCl, 0:10 percent for 21 days at a temperature of 8° C. After ripening, physic-chemical tests was conducted on the cheese.

Chemical tests: measurement of chemical compounds was conducted by AOAC methods (AOAC, 2012). Moisture, fat and protein contents were measured using the oven at 102 degrees Celsius, Gerber method, and Kjeldahl method respectively. PH was measured by Professional portable milk pH Meter HI98162 provided by Hanna Company.

Statistical analysis: factorial experiments were conducted in a completely randomized design with three replications. The statistical comparison was done using the Mstat-C software via Duncan's method.

Results and discussion

Chemical analyses:

Chemical assessments on raw milk and pasteurized milk using classic method and infrared irradiation are reported in Table 1.

Table 1. Chemical assessments on raw milk and pasteurized milk using classical method and infrared irradiation.

Analysis	Raw Milk	Classic Pasteurized Milk	IR Pasteurized Milk
pH	0.005 ± 6.6866	0.005 ± 6.68	0.005 ± 6.6866
Density	0.0005 ± 1.02867	0.0005 ± 1.02866	0.0004 ± 1.02822
Acidity	0.001 ± 0.1463	0.0015 ± 0.1476	0.0005 ± 0.1476
Fat	0.0082 ± 3.66	0.0032 ± 3.649	0.0074 ± 3.6606
Protein	0.0066 ± 3.2166	0.007 ± 3.2096	0.0065 ± 3.214
Lactose	0.00821 ± 4.8611	4.8483 ± 0.006	0.01 ± 4.8542
Nonfat Dry Mass	0.00356 ± 8.4797	0.0023 ± 8.473	0.001 ±8.4793
Calcium	0.0002 ± 0.122	0.0033 ± 0.120	0.0004 ±0.122

The comparison of data means resulting from the analysis of the cheese characteristics show that the cheeses made from two types of pasteurized milk and different brine formulations only differ in the amount of moisture and dry matter content and there is no significant difference between them. The impact of the brine formulation on the pH of the cheeses: PH of cheeses began to decreasing during preparation and aging in brine formulations and finally reached to 4.02 from 5.3 in beginning stage o aging. Figure 2 shows the pH of ripened cheeses in various ratios of brine and different milk pasteurization methods.

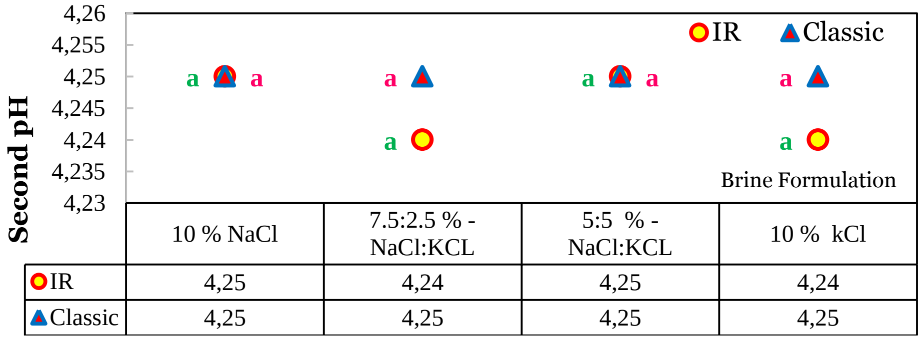

Figure 2: Comparison of the pH of ripened cheeses in various ratios of brine and different milk pasteurization methods

- Comparison of cheese samples appearance:

The comparison of the clots formed from pasteurized milk using infrared radiation (1) and Classic method (2) at 72° C for 15 seconds is shown in Figure 5.

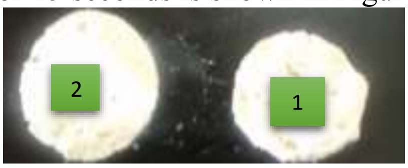

Figure 5: comparison of the clots formed from pasteurized milk using infrared radiation (1) and Classic method (2) at 72° C for 15 seconds.

The comparison of the clots formed from pasteurized milk using infrared radiation (1) and Classic method (2) shows that the volume of the Infrared irradiated samples are smaller with higher coherence and solidity.

- **The organoleptic analysis of cheeses**

  The color, flavor and tastes of the cheeses (the organoleptic results) examined by taste panel showed that there is no significant difference between samples.

- **The use of potassium chloride in the formula of the cheese brine:**

The reason of the replacement of sodium chloride with potassium chloride, is achieving a product that reduces harmful effects to health caused by the consumption of sodium chloride. In addition to the fact that the product is supposed to be acceptable in terms of evaluated properties. The results of the analysis showed that the only difference between white cheeses produced in different brine formulas is in their firmness. Reduced sodium salt cheese is very soft, bitter, less salty, and has a strong off-flavor and shorter shelf life (Ying Lu, 2012). Potassium chloride (KCl) has a similar structure and salty flavor as sodium chloride (salt) and partial replacement of salt with potassium chloride can be used to lower salt content in foods. Moreover, potassium can lower the blood pressure and the risk of heart disease or stroke. Thus, potassium chloride is a potential substitution for salt in cheese.

- **Effects of brine formula on:**

Cheese pH: At the beginning of ripening period of the cheese samples, the production of lactic acid from lactose reduces the pH and increases the acidity by Lactic Acid Bacteria. With improvement of the cheese ripening, the reduction of lactose continues and lactic acid inhibitory effect begins on the activity of some lactic strains. So, the production of lactic acid is reduced and consequently, the testable acidity remains constant.

Comparing the results of pH shows that differences in the pH in ripened cheese made from pasteurized milk with the two methods is not significant. PH difference between different formulations of salt water is not significant in ripened cheese.

The similar results obtained by Lindsay in 1982, Aly Katsiari in 1985 and in 1998, 2000 and 2001 for cheddar and feta cheeses. The researchers also attributed the reason of the lactic acid produced from lactose causing the initial reduction of pH, while the advancement of proteolysis and lipolysis results an increase in the amount of amino acids and fatty acids during the ripening period induces to final pH decrease.

The researchers also reported that the initial pH of the cheese is specified according to the pasteurization method, the type of milk used to make cheese, the microbial load of the raw milk and the starter culture type. While the pH of the ripened cheese is specified according to the ripening temperature, period length and the type of rennet used (Lindsay, 1982; Aly, 1985; Katsiari et al., 1998, 2000, 2001). Partial replacement of sodium chloride with potassium chloride with different levels of substitution (10:00 percent sodium chloride - potassium chloride, 7.5:2.5% sodium chloride - potassium chloride, 5:5 % sodium chloride - potassium chloride and 10:00 percent potassium chloride - NaCl) had no significant effect on pH values. These results are similar to findings of Katsiari in 1998, 2000 and 2001. This researcher replaced (3% sodium chloride, 1.5:1.5 percent sodium chloride - potassium chloride and 3% potassium chloride) on Kefalograviera cheese and observed no significant change in the pH of the cheese. (Katsiari et al., 1998, 2000, 2001).

- **The chemical properties of cheese**

  In examining the impact of different levels of sodium and potassium chloride on cheese chemical properties (including the amount of fat and protein) by infrared or classic method for pasteurization; it became clear that replacement of sodium chloride with potassium chloride in brine have both no significant effect on the fat and protein of the produced cheeses (based on dry weight). Results of the studies of Lindsay in 1982, Aly Katsiari in 1985, 1998, 2000 and 2001 also showed similar results. In addition in 1998 and 2000, Katsiari pointed out that the changes in the amount of fat, protein and other compounds of cheese occurred by the lipolysis, proteolysis, lactic acid production and other reactions happened during the ripening period not due to brine formula. Although added calcium chloride can effect on cheese density and volume of cheese due to participating in paracaseinate calcium clots which induce the syneresis reaction improve (Fuca, 2012).

- **The effect of infrared radiation in cheese production**

Examining properties of the produced cheeses showed no significant difference between the cheeses produced from pasteurized milk using the infrared and classic methods but due to the high heat performance in the infrared radiation, the pasteurization process of milk is approximately 75% faster than the classic method. It is considered a more suitable method for pasteurization of milk compared to the classic method especially due to the heat shock effect on microbial cellular structure. All above studies confirms this project's results due to the higher efficiency and saving energy consumption via IR assisted systems in comparison of classic method of pasteurization.

Conclusion

In general, from this study it can be concluded that changing the formulation of the used brine has no effects on cheese properties.
Effects of brine formula on Cheese pH shows that differences in the pH in ripened cheese made from pasteurized milk comparing with the two methods is not significant.
Effects of brine formula on the chemical properties of cheese shows replacement of sodium chloride with potassium chloride in brine have both no significant effect on the fat and protein of the produced cheeses (based on dry weight).

SEASONAL DYNAMICS OF AERO-ALERGENIC RAGWEED POLLEN IN BANJA LUKA (BOSNIA AND HERZEGOVINA) DURING 2012-2016

Gordana BABIĆ*, Bojana ĆURKOVIĆ, Vojislav TRKULJA

Public Institution „Agricultural Institute of Republic of Srpska, Banja Luka“, Bosnia and Herzegovina
*Corresponding author: brkljacg@hotmail.com

Abstract

The problem of human sensitivity to ragweed pollen in our country lately is characterized by increasing trend. This is corroborated by the results of the population analysis (late adolescence patients) by skin prick test to pollen from Clinical Center Banja Luka (Entity of Republic of Srpska, Bosnia and Herzegovina). Research conducted in the ten-year period (2001-2010) showed that from the individual weed pollen in the total sample and by groups of respondents prick test is mainly positive to ragweed. Considering the above mentioned and the fact that *Ambrosia artemisiifolia* L. is widespread in the area of Banja Luka, the main aim of this study was to analyze the seasonal dynamics of ragweed pollen during a five-year monitoring (2012-2016). Sampling of ragweed pollen during the pollination period 2012-2016 was conducted in urban, industrial part of Banja Luka in Public Institution „Agricultural Institute of Republic of Srpska, Banja Luka“ with Hirst sampler using the method defined by the International Association for Aerobiology (IAA). During the five-year monitoring, the highest annual total concentration of *Ambrosia* pollen grains was recorder during 2012 (8.983 pm^{-3}). Lower annual total concentration of *Ambrosia* pollen grains was recorder during 2013 (5.004 pm^{-3}), 2014 (4.970 pm^{-3}), 2015 (5.478 pm^{-3}) and 2016 (5.256 pm^{-3}). However, considering clinical thresholds that lead to the symptoms of allergy can be as low as 1-3 pm^{-3} of air for hypersensitive patients and 10-50 pm^{-3} for the majority of the patients, conducted monitoring pointed out on *Ambrosia* pollen as a growing health and social problem in our country.

Keywords: *seasonal dynamics, aero allergen, ragweed, Banja Luka.*

Introduction

A number of authors like Makovcová *et al*. (1998), Dahl *et al*. (1999), Rybnícek *et al*. (2000), Laaidi *et al*. (2003), Makra *et al.* (2004), Peternel *et al*. (2005) and Taramaracaz *et al*. (2005) stated Bosnia, amoung many countries, as one of the most contaminated place in Europe with *Ambrosia artemisiifolia* L., the highly allergenic plant. This species is considered a biological pollutant responsible for severe allergic diseases (Déchamp and Méon, 2003), that are clinically manifested as rhinitis, rhinoconjunctivitis and bronchial asthma (Gioulekas *et al*., 2004; Trkulja *et al*., 2010). In the area of Banja Luka, ambrosia is very widespread and it is in expansion (Pušić *et al*., 2012). Thus the problem of human sensitivity to allergenic ragweed pollen in our country lately is characterized by increasing trend. This is corroborated by the results of the population analysis (late adolescence patients) by skin *prick* test to pollen from Clinical Center Banja Luka. Research conducted in the ten-year period (2001-2010) have shown that from the individual weed pollen in the total sample and by groups of respondents *prick* test is mainly positive to ragweed (Balaban and Balaban, 2012). Never the less, ragweed presents one of the most invasive weed species in our area (Trkulja et al., 2012) and to polinosis as an additional problem indicate data that this aeroallergen with a favorable wind can move at up to 300 km (Jones, 1953; Comtois, 1998; Deen et al., 1998, Genton et al., 2005) to large distance of 10 to 100 km. Considering the above mentioned, the main aim of this study was to analyze the seasonal dynamics of ragweed pollen during five year monitoring (2012-2016).

Material and method

Monitoring the concentration of ragweed pollen during the pollination period (2012-2016) was conducted at the PI Agricultural Institute of Republic of Srpska, Banja Luka (N 44º47`41.0``, E 017º12`22.6``), by Hirst's type pollenometar (Hirst, 1952). Sampling of aeroallergenic ragweed pollen was conducted in urban, industrial part of Banja Luka, using the method defined by the International Association for Aerobiology (IAA). The trap brand Burkard (Burkard Manufacturing Co., Uxbridge, Middlesex, England) is calibrated for sampling 10 liters of air per min through a hole 14 x 2 mm diamtear, which always faces the wind direction and it is protected from direct rainfall. As air passing through the orifice, pollen grains are fixed on glass slides coated with silicone gel, which moves at the rate of 2 mm h^{-1}. Visual identification, or qualitative and quntitative assessment, of sampled ragweed pollen grains was carried out on a daily basis after 24 hours, based on the morphological characteristics under a light microscope Olympus BX51 at magnification x400, according the International Association for Aerobiology and converting the obtained results in the concentration of pollen grains per m^3 of air. Immediately prior to screening, microscopic slide with 24-hour segment, is prepared by placing polyvinyl alcohol substrate (Gelvatol), phenol, and glycerol, which allows color fuchsin staining of pollen grains and easy separation of the same from dust particles and fungy spores. After preparation and drying microscopic slide determining the number of pollen grains is carried out by the method of longitudinal lines in two-hour intervals and reviewing the 3 horizontal lines. At the end of the analysis, the obtained values are converted to daily concentrations determined by multiplying the number of pollen grains by a factor F, depending on the characteristics of the device for sampling, surface of 24 hour segment, characteristics of the microscope and the surface of the inspected sub-sample. Concentration of the pollen grains per m^3 of air is important for symptoms occurence of allergic reactions. Thus the monitoring results are presented to the public in the form of daily aeropallinological reports or so called "Pollen traffic light" on the official web site of City of Banja Luka (Table 1).

Table 1. Number of ragweed pollen grains in the air with the corresponding percentage of persons in whom is possible occurrence of symptoms of allergic reactions (Forsyth County Environmental Affairs Department Pollen Rating Scale, PRS)

Level of pollen	*Number of pollen grains /m³ air*	*Occurrence of symptoms of allergic reactions*
	Weeds	
Not present	0	No symptoms
Low	1-10	Only in extremely sensitive individuals
Moderate	11-50	In 50% of sensitive individuals
High	51-500	Almost all allergic people
Very high	>500	In all allergic people

Results and discussion

During the five-year sampling (2012-2016) of aeroallergen ragweed pollen in the city of Banja Luka dynamics, i.e. the beginning, duration and end of the pollination period with presenting daily low, moderate, high or very high concentrations (p pm^{-3}) as well as a total weed pollen number on annual level (p pm^{-3}) was monitored. Annual total concentrations of *Ambrosia* pollen grains was 8993 p pm^{-3} in 2012, 5004 p pm^{-3} in 2013, 4970 p pm^{-3} in 2014, 5478 p pm^{-3} in 2015 and 5256 p pm^{-3} in 2016 (Figure 1). In addition, high to very high concentrations in all five years of monitoring were recorded from third decade of August to the second decade of September.

The first ragweed pollen grains in 2012 were registered in early July. Occurrence of low concentration or absence of ragweed pollen grains retained until the second decade of August. Since mentioned period moderate concentration trend was registered until the second decade of August. Increased tendency starts from second decade of August, and is characterized by high concentrations. Maximum concentration of 476 p pm^{-3} was recorded on September 1st. High concentration retained until the second decade of September with a few occurrence of moderate concentration. Until October moderate concentrations were registered which remains for a shorter period of time, followed by low concentrations that remain until the end of the pollination season (Figure 2).

In 2013 the first ragweed pollen grains were registered in the third decade of June, with very low concentration or even absence of ragweed pollen grains in the atmosphere until third decade of July. Low concentrations were registered until the second decade of August, with moderate concentrations registered only during two days. From that period increased tendency ragweed pollen concentration, with moderate and high concentration start and last until the end of September. Maximum concentration of ragweed pollen grains, 199 p pm^{-3} respectively, was registered on August 8th. Low concentrations were registered until the end of the pollination season (Figure 3).

Similarly to previous year, seasonal dynamic of ragweed pollen in 2014 was almost identical with the pervious one, starting from the end of June with low concentrations until the first decade of August. Moderate to high concentration remain until the end of September, while the maximum concentration, 197 p pm^{-3} respectively, was registered on August 8th. Low concentration remains until the end of season (Figure 4).

In 2015 the first ragweed pollen grains were registered in the third decade of June. Low concentrations remain until the third decade of July. However moderate concentration last just a few days. Increasing trend starts from the first decade of August, and moderate to high concentrations remain until the end of September, however the maximum concentration (220 p pm^{-3}) as in 2012 was registered in first decade of September, on September 8th respectively. Trend of low concentration lasts until the end of the pollination season (Figure 5).

Starting from the end of July until the almost second decade of August 2016, low concentrations of ragweed pollen grain were recorded. Moderate concentrations remain until the end second decade of August, followed by high concentrations until second decade of September. Moderate concentration last a few days, followed by low concentration until the end of season, the end of October. In 2016 the maximum concentration, 389 p pm^{-3}, was recorded on September 4th (Figure 6).

Conclusion

Although in Banja Luka in last five years very high concentrations (>500 p pm^{-3}) were not registered, conducted monitoring pointed out on *Ambrosia* pollen as a growing health and social problem in our country. This is also corroborated by the past results of the population analysis from Clinical Center Banja Luka, as well by fact that patient sensitivities to the symptoms of allergy can be as low as 1-3 p pm^{-3} for hypersensitive patients and 10-50 grains for the majority of the patient.

Abstract

The aim was to study life cycle, biological and morphological characteristics of the pest Pear Shoot Sawfly (*Janus compressus Fabricius*) .Field trial was carried out in pear orchard area during 2011 and 2012 at locality Jablan (Laktaši Municipality, Bosnia and Hercegovina). The emergence of adults was monitored with yellow sticky traps produced by BioPlantella and by visual inspection. Biology and morphology of pear sawfly was studied by monitoring and observation of different stages. Life cycle of the pest was monitored by direct observation in natural environment. Morphological characteristics of different stages were observed and studied using a laboratory stereomicroscope. Pest is univoltine in climatic conditions of Banja Luka's region. Pear shoot sawfly emerges from the end of April until the end of May with the peak population around May 1st. Adults have elongated body and sexual dimorphism is present. Female lays eggs in very specific way by making punctures with ovipositor on young shoots spirally from the top to the bottom of the shoot. Egg is whitish or light yellow. Embryonic development lasts from 12 to 14 days. Fully grown larvae are about 10 mm long and have characteristic shape of letter "S". During September larvae finish their development and make hibernation chamber where they overwinter. Larvae spend its whole life in infested shoots. Pupa is found in spring, at the end of March and beginning of April. Pupa is exarate and pupal stage lasts 4-5 weeks.

Key words: *Pears shoot sawfly, biology, morphology, Banja Luka's region*

Introduction

In the last decades fruit production in Republic of Srpska has been characterized by extremely dynamic and fast changing technology. However, pear production and yields are such that they put us in an inferior position in relation to the developed European countries and world. There are many reasons for this situation, and one of the most important is pests and diseases of pear. Pear shoot sawfly has been considered an important pest in recent years, although it is a periodic pest. Validžić *et al*. (2010) state that *.J. compressus* gets on the significance in the area of Eastern Slavonia in recent years and that the most severe damage is on the pear, but the pest also attacks apple, quince and medlar, although rarely. On young fruit trees, even if it's low population density of the pest, the damage is very noticeable although there is only one generation per year. Adult, that is, female, adversely affects the proper formation of the tree crown by destroying young pear shoots, but also tree productivity (Maceljski, 1999). It is especially dangerous in fruit tree nurseries because it destroys and stops the growth of young branches, and complicates the production of fruit trees (Balachowski *et* Mesnil, 1935). Literature data about this pest are insufficient in the territory of the former Yugoslavia as well as in Europe. The oldest data about pear shoot sawfly are published by Jablanowski in 1904 and Balachowsky and Mesnil in 1935.

The aim of the research was to study the biology, that is, the life cycle of the pear shoot sawfly and to study the morphological characteristics of different development stages of the pest.

Material and method

Field trial was conducted in pear orchard area during 2011 and 2012 at locality Jablan (Laktaši Municipality). In this orchard there is no intensive spraying against pear pests and diseases and pesticides are applied only periodically and if economic threshold is exceeded. A great number of pear orchards in Banja Luka and Gradiška in which pesticides are applied regularly were checked in order to choose the location for setting up a trial but pear shoot sawfly was not detected there. The adult emergence and flight activity was monitored in 2011 by yellow sticky traps produced by BioPlantella and by visual method. Traps are placed inside the tree crown so that both sides of the trap are exposed to insect flight as much as possible. Traps were changed weekly, and the traps were placed on the selected trees 7 days before the expected pest flight in 2011. Population level was determined every week after changing the traps. Data on adult emergence and flight are compared with climate factors (precipitation, minimum, maximum and mean daily temperature). At the same time, typically damaged shoots were isolated with “cages” made of thin transparent material (marquisette) in order to monitor adult emergence, but also in order to mark the shoots so that they could be easily found on the trees during the whole year. The biology and morphology of pear shoot sawfly were studied by monitoring and observing different developmental stages of the pest, that is, the morphological characteristics of eggs, larvae, pupa and adults as well as egg- laying, the shape and number of punctures made during laying eggs, embryonic development and time of occurrence of different stages. A total of 240 young shoots were checked. The pest life cycle was studied by direct observation in the natural environment. The morphological characteristics of different development stages of the pest were observed and studied using a laboratory binocular (stereomicroscope) Olympus SZX7, while photographs were taken using the digital camera Olympus DP12 and measurements were done by Olympus Camedia Micro Imaging software in Agricultural Institute of the Republic of Srpska, Banja Luka.

Results and discussion

Damage

Female damages young shoots that soon afterwards wilt and curve. After that, damaged shoots decline and the leaves turn black (fig. 1).

Fig. 1. Young pear shoot damage by pear shoot sawfly. (Photo: original)

Fig. 2. Pear shoot sawfly adult. (Photo: original)

The damage can be particularly significant in nurseries. These symptoms can be confused with symptoms of fire blight caused by *Erwinia amylovora*. However, there is no spirally arranged series of punctures on shoots with fire blight symptoms. Sometimes the infested shoot regenerates and continues to grow. These shoots are easily recognized by their leaves that haven't turned black and there are no punctures. We can conclude that female has attacked these shoots but didn't lay an egg or larvae didn't develop from some reason. During the orchard check on 10th May a young pear fruit with characteristic spirally arranged series of punctures on stalk was found. The infested fruit decline and turned black. The female also laid an egg in the fruit stalk. Detected shoot damage corresponds to literature data (Jablanowski, 1904; Kovačević, 1961; Tanasijević i Simova-Tošić, 1987; Kišpatić i Maceljski, 1989, Pollini, 1992).

Morphological and biological characteristics of pear shoot sawfly adult

Morphological characteristics of adult

Pear shoot sawfly adult has elongated body and antennae (fig. 2). All Hymenoptera are parthenogenetic and that results in sexual dimorphism (Gardner *et al*., 2011; Ivezić, 2008; Kovačević, 1950; Jablanowsky, 1904;). Females are 9-12 mm long, while males are smaller and 6-9 mm long. Basic color of both male and female is black. The head is black except the mandibles that are yellow. There is a pair of compound eyes on the front part of the head as well as three simple eyes. Antennae are filiform. Thorax is black and three-segmented. Abdomen in males is yellowish-orange to orange, while females have red to dark red abdomen. The last abdominal segment is black and ends with protuberance that serves to protect the ovipositor (Goulet, 1992). Ovipositor is short and denticulate. Legs of male are yellow, while those in female are darker (brown). Although the wings are transparent, folded wings have purple glow. Literature data on morphology of adults vary depending on the author.

Pear shoot sawfly adult flight monitoring

Pear shoot sawfly adult flight activity was monitored for eight weeks during 2011 (18th April – 12th June). Data on average number of adults per trap are shown on chart 1.

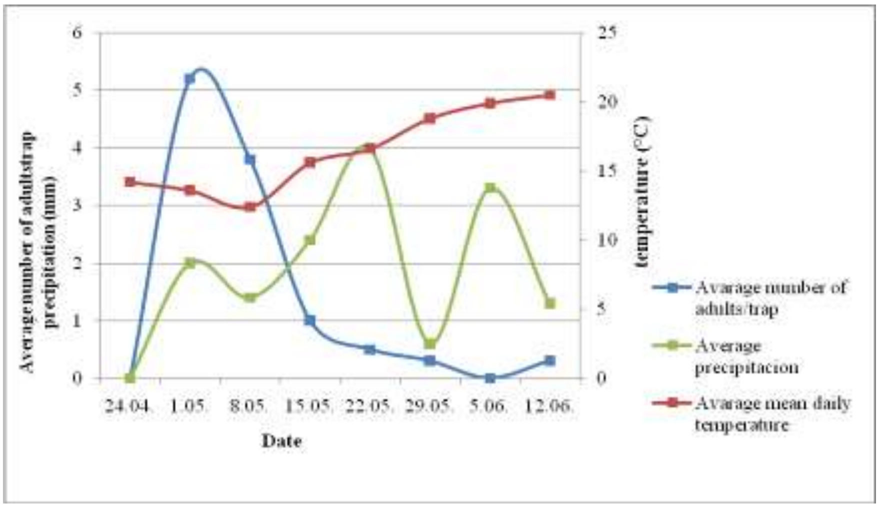

Chart 1. An average number of pear shoot sawfly adults per sticky traps and meteorological data for the monitoring period.

According to flight monitoring, adult flight activity was detected from 25th April till 29th May, and the largest number of adults was caught in the second and third week of monitoring, that is from 25th April till 8th May (Kovačić, 2015). In the fourth, fifth and sixth week of monitoring, four, two, and one adult were caught, respectively, while in the seventh week no adult was caught. It is interesting that on June the 12^{th}, that is, in the last week of monitoring, one adult was found on sticky trap indicating a very prolonged period of adult flight or the appearance of the adult was postponed due to climate factors. When compared with climate factors (precipitation, minimum, maximum and mean daily temperature) these data show that adults flight is the most intensive during warm spring days, when mean daily temperatures are above 12°C. Adults are frost-sensitive.

Egg-laying

Female lays eggs in a very specific way that is not seen in other insect families. Eggs are laid in 10-20 cm long young shoots and the female is making a spirally arranged series of punctures from the top to the bottom of the shoot. The smallest found number of punctures on 40 checked shoots is eight, while the largest number of punctures is 39 (Kovačić, 2015). The number of punctures on single shoot ranges between 10 and 30 (an average of 22). Reasons why female makes the punctures aren't studied enough and some authors (Kišpatić and Maceljski, 1979; Maceljski, 1999) state that in this way female creates favorable conditions for larval development. At the site of the punctures shortly after attack dark dots are created. Size of the puncture hole is an average of 0.35 x 0.12 mm.

Morphological and biological characteristics of the egg

The egg is whitish to light-yellow, oval or elongate and slightly curved along the longitudinal axis (fig. 3). Eggs are laid singly in young pear shoots. The egg was found in 37 out of 40 (92.5%) checked shoots. The average size of measured eggs is 1 x 0.32 mm. Embryonic development was observed in natural conditions by checking the damaged shoots 10-15 days after the most intensive attack. First larvae were found on 12^{th} May, and considering that damaged pear shoots were noticed on 29^{th} April and that till 01^{st} May there was very large number of infested shoots it can be concluded that embryonic development lasts 12-14 days.

Fig. 3. Pear shot sawfly egg (Photo: Kovačić Jošić, D.)

Morphological and biological characteristics of larvae

Larva is white to light-yellow, about 10 mm long. Larva has characteristic letter "S" shape (fig. 4). Head is well developed as well as mouth parts that are dark. The body consists of segments that are narrowed laterally along the whole body and look like "stitches". Thoracic legs are reduced and hardly visible while abdominal legs are absent. On the last abdominal segment there is dark protuberance with dark hair. In the beginning of June 40 marked pear shoots were checked and in 27 out of 40 (67.5%) larvae were found. The reason for such high mortality of larvae might be climatic factors. On May 6^{th} there was a frost with minimal daily temperature 0.5°C and after that adult flight activity was severely reduced as well as number of adults caught on sticky traps. This low temperature surely affected the eggs, too and embryonic development lasted longer. Validžić (2013) states that there are also other reasons for this, that is regeneration of some shoots after the attack as well as parasitoids and entomopathogenic fungi. Larvae spend its whole life within the shoots and feed with the pith of the shoot. During the feeding larvae move from the top to the bottom of shoot and the shoot pith is completely destroyed and turned to frass-filled gallery (fig. 5). In the beginning of September larvae stop to feed and end their development and then make hibernation chamber at the end of the feeding gallery in which they overwinter in translucent cocoon. Before changing into the pupal stage larvae make an exit hole for adults, leaving just the thin layer of bark.

Fig. 4. Different larval stages photographed in the beginning of June and beginning of September; visible letter “S” shape (Photo: Kovačić Jošić, D.)

Fig. 5. Pear shot sawfly larvae frass-filled feeding gallery (Photo: Kovačić Jošić, D.).

Morphological and biological characteristics of pupa

Pupa is exarate, which is typical for suborder Symphyta, 7-9 mm long. Pupal stage occurs in spring from the last decade of March and in the beginning of April. Pupal stage lasts 4-5 weeks. Pupation is finished in the middle of April and adults emerge from the end of April. Pupa was found in 57.5% of checked shoots.

Conclusions

Pear shoot sawfly has been considered an important pest in the last decades. Damage is very specific and can't be confused with any other pest. Adults in Banja Luka's region emerge earlier than the literature data state. There is sexual dimorphism present. Adult flight activity lasts very long and the peak population is around 1st May. Eggs are laid singly in young pear shoots. The egg is whitish to light-yellow, oval or elongate and slightly curved along the longitudinal axis. Embryonic development lasts 12-14 days in climatic conditions of this region. The female can also lay an egg in young fruits that desiccate and turn black. Larvae spend its whole life within the shoots and feed with the pith of the shoot. Larva is white to light-yellow and has characteristic letter "S" shape. Larval stage lasts from May till September. Larvae overwinter in the shoot. Pupa is exarate and pupal stage lasts 4-5 weeks.

Abstract

During April, May and June 2014 frequent and extremely heavy rainfall and floods in area Banja Luka caused high occurrence of *Fusarium* species in winter wheat. Fusarium head blight (FHB) presents a worldwide problem and it is the most important disease in wheat In the last few years great attention is particularly focused on the risk of FHB of various types of small grains, not only because they cause yield reduction which reaches 10-70%, but primarily due to the production of mycotoxins. The main objective of this study was to determine the intensity occurrence of FHB and make the identification of *Fusarium* species in the area of Banja Luka, as well as to consider the possibility of effective chemical control. Efficiency of prothioconazole + tebuconazole was carried out on two winter wheat varieties (Orion and Nova Bosanka) in the experimental fields of PI AIRS, Banja Luka (Entity of Republic of Srpska, Bosnia and Herzegovina) according to EPPO broj standards. Visual assessment of FHB intensity was made according to Miedaner and Perkowski (1996) scale. The identification of sampled ears pointed out the presence of two *Fusarium* species, *F. culmorum* and *F. graminearum,* respectively. Considering the environmental conditions in 2014, high intensity of *Fusarium* species in both varieties of winter wheat was observed. However, applied fungicide showed high efficiency (>90%), with a small difference in coefficient of efficiency Ce (%) between treated varieties.

Keywords: *FHB, natural infection, F. culmorum, F. graminearum , fungicide protection.*

Introduction

Fusarium head blight (FHB) in wheat is a widespread disease around the world including all European cereal-growing areas (Bottalico *et* Perrone 2002). Nineteen species of *Fusarium* are reported to cause wheat FHB disease (Stepień *et* Chelkowski, 2010). In general, the causal agents of FHB in Europe are primarily *F. graminearum* (teleomorph *Gibberella zeae*), *F. culmorum* and *F. avenaceum* (teleomorph *Gibberella avenacea*). Less frequently represented species are *F. poae, F. cerealis, F. equiseti, F. sporotrichioides, F. tricinctum* and, to an even lesser extent also *F. acuminatum, F. subglutinans, F. solani, F. oxysporum, F. verticillioides, F. semitectum* and *F. proliferatum* (Bottalico *et* Perrone, 2002; Lemmens *et al*., 2004; Stepieň *et al*., 2008). Disease is favored by extended periods of moderately high temperature (15–30°C), high moisture (relative humidity > 90%), and frequent rainfall (De Wolf *et al*., 2003; Lemmens *et al*., 2004; Xu *et al*., 2008; Sadowski *et al*., 2011; Lenc, 2015). Their distribution in almost all agro climatic areas is conditioned by high adjustment to different extreme environmental conditions. However, FHB occurs primarily in warm and humid climatic conditions during the flowering stage (Parry *et al*., 1995; Walter *et al*., 2010). Anderson (2007) research pointed out how much the appearance and development of this disease is closely related with the temperature. According to the above mentioned research incidence increases as temperature increases from 20˚C to 30˚C, and little or no infection occurred under 15˚C. But humidity is as important as temperature for the occurrence of wheat scab (Xu *et* Nicholson, 2009; Horberg, 2002).

In the last few years great attention is particularly focused on the risk of FHB of various types of small grains, not only because they cause yield reduction which reaches 10-70% (Matthies *et* Buchenauer, 2000), but primarily due to the production of mycotoxins. Frequent occurrence of extremely heavy rainfall and floods, as one of climate extremes recorded in area Banja Luka during April, May and June 2014, resulted in the occurence of an severe infection of winter wheat with *Fusarium* species. The main objective of this study was to determine the intensity occurrence of FHB and make the identification of *Fusarium* species in the area of Banja Luka, as well as to consider the possibility of effective chemical control.

Material and method

A field experiment was conducted in 2013/2014 according to European and Mediterranean Plant Protection Organization guidelines (EPPO/OEPP 1999; EPPO/OEPP 2012) in the experimental field of the PI AIRS, BL. The experiment was designed as a randomised block, with 12,5 m^2 (2,5 x 5 m) elementary plots in 4 repetition in locality Ekonomija. Winter wheat, cv. Orion i Nova Bosanka are sown and grown according to standard farm practice in our area. Fungicide Prosaro 250 EC (prothioconazole + tebuconazole) was applied according to a recommended dose of producer Bayer CropScience (1L ha^{-1}) during the early flowering stage. Fungicide was applied with sprayer "Solo 425" and šta. The experiment was conducted under the conditions of conventional technology, with the application of a certain quantity of mineral fertilizers that in our conditions can provide a yield between 6 and 7 t ha^{-1}, as follows: 300 kg NPK 15:15:15 in stage of cultivation, followed by first fertilization with 200 kg KAN - 27% at the stage of the start of tillering, and the second fertilization of 180 kg in the phase of tillering or intensive growth.

Visual assessment of FHB intensity was made following the manifestation of a clear difference in the intensity of the disease between the control (untreated) and treated varinats. For disease assessment wheat heads were rated at the hard dough stage. One hundred wheat heads from each replication were harvested by hand and subsequently analyzed in the laboratory for disease incidence (DI; percentage of diseased ears) and disease severity (DS) on a 1 to 9 scale in which 1 – no symptoms, 2 – < 5%; 3 – 5-15%; 4 – 16-25%; 5 – 26-45%; 6 – 46-65%; 7 – 66-85%; 8 – 86-95%; 9 – 96-100% (Miedaner *et* Perkowski, 1996).

For isolation of *Fusarium* species, kernels with visible symptoms were collected directly during the visual analysis from the wheat ears. Each sample was subjected to a stereomicroscope (Olympus SZX7) and a microscope (Olympus BX51) examination with photo documentation. Samples were 45 minutes washed under running water, surface-sterilised in 1 % NaOCl, 3 time washed in sterile water, air dried and transferred onto PDA (Potato Dextroze Agar, Difco pH 6,5) supplemented with antibiotics streptomycin sulphate. After 5-7 days incubation in an incubator (temperature 25°C and humidity 80%, illumination with dark UV light), a single spore technique was used to obtain pure cultures for identification (Photo 1a-1f). In further assessment Potato dextrose agar (PDA) (Difco) medium was used to assess colony characteristics such as pigmentation and growth rate. SNA medium, supplemented with a piece of filter paper to promote sporulation, was used to examine conidial morphology and to detect the presence of chlamydospores. Individual *Fusarium* species were identified (Booth 1971; Nelson *et al*. 1983; Lević, 2008).

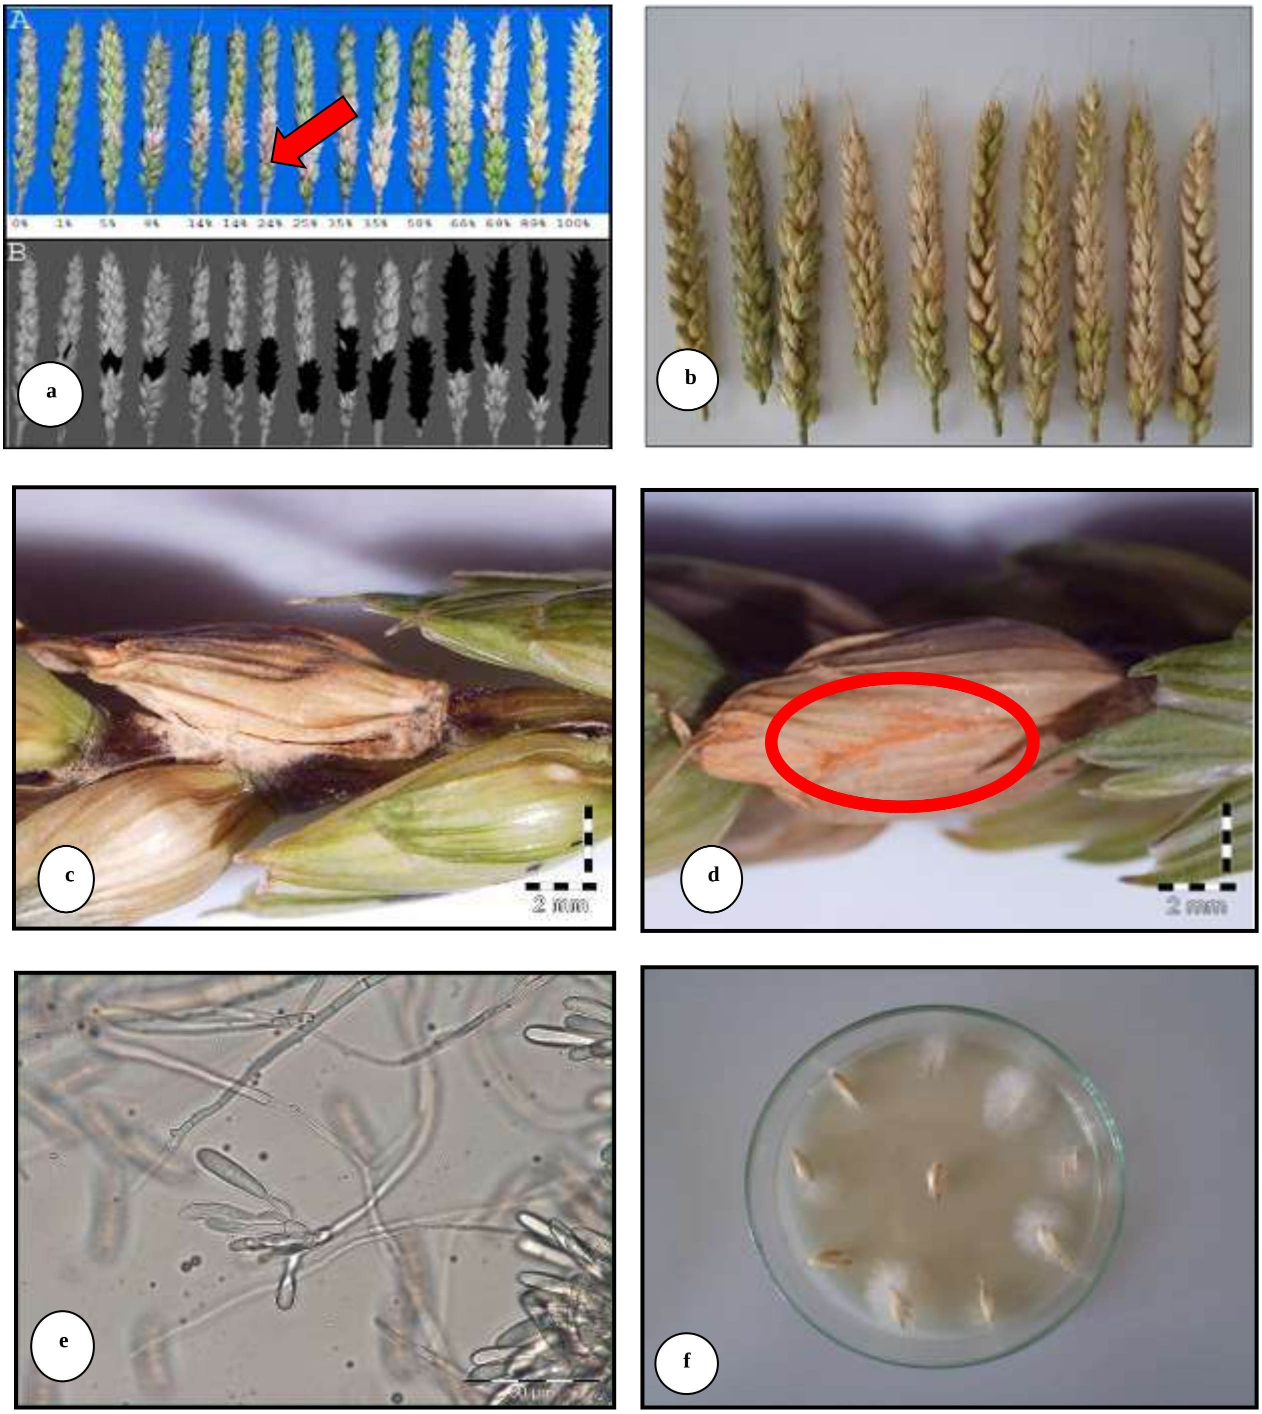

Photo 1. *FHB of winter wheat: a) Scale for disease incidence; b) Typical symptoms of FHB (natural infection); c) Typical symptoms of FHB on wheat grain (natural infection); d) Sporodochium on infected wheat grain; e) Conidiophore from infected wheat grain; f) Colony development on PDA.*

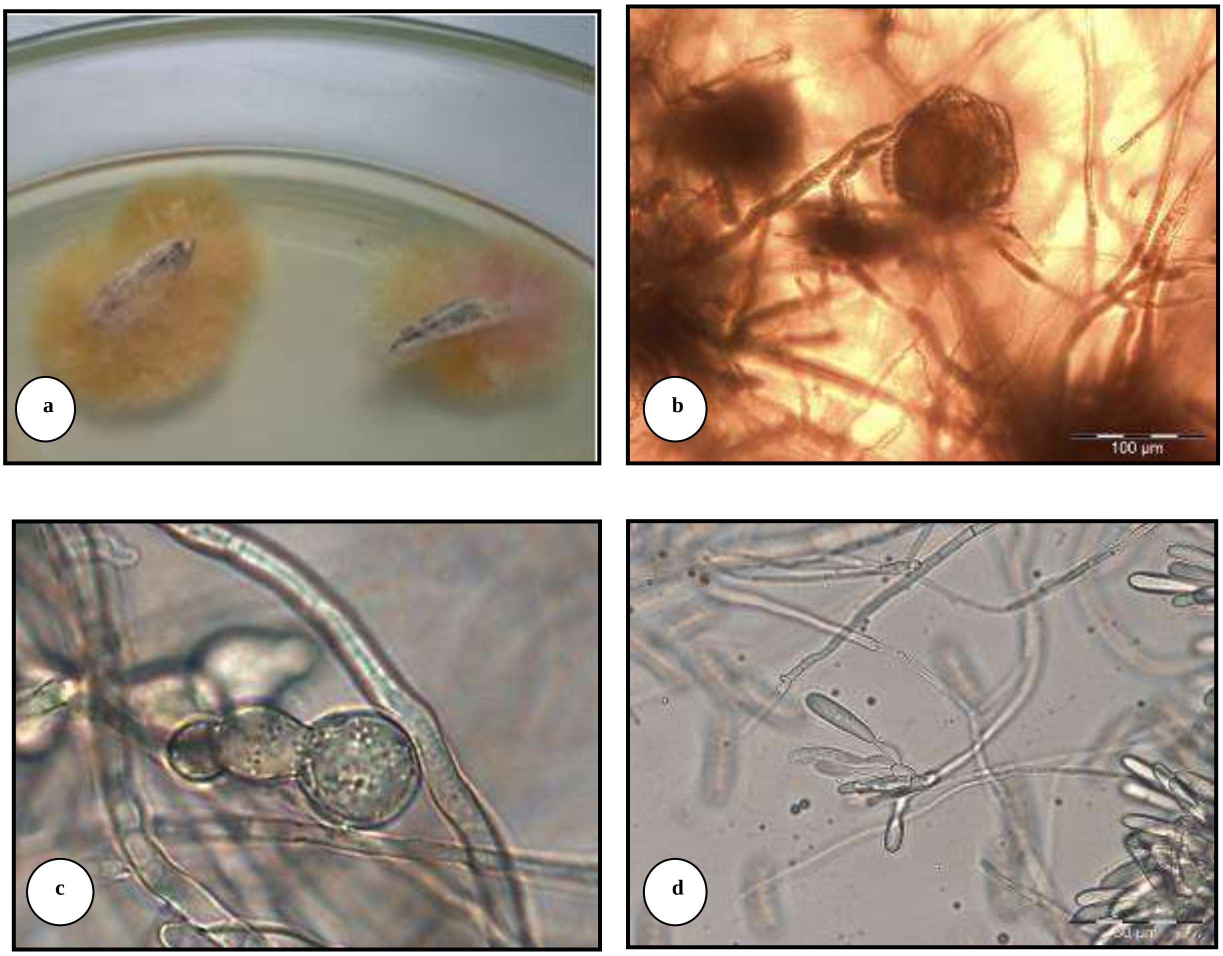
Results and discussion

During 2014, in the experimental field of the PI AIRS, BL after two evaluations of the fungicide in untreated control plots a significant disease, FHB respectively, was observed in both varieties. However, applied fungicide achieved a high efficiency (table 1). Statistical analysis and standard test of low significant difference (LSD) was performed, wherein all statistical analyses were performed for the risk level 0.05 (P=0.05). Data processing using standard statistical methods has found that there are significant differences between treated and untreated variants.

Table 1. Efficiency of applied fungicide in varieties Orion and Nova Bosanka

Variant	Active substances	Concentration/Unit	Variety	Ce %
Prosaro 250 EC	prothioconazole + tebuconazole	1 Lha^{-1}	Orion	90,30
			Nova Bosanka	91,04

Identification and determination of *Fusarium* sp., the development of phytopathogenic fungi under controlled conditions and the identification of all microscopic and macroscopic characteristic of the target species was carried out after isolation and obtaining of two pure culture groups. The first group is determinated as *Fusarium culmorum* (W.G. Smith) Sacc. (syn. *Fusarium culmorum* (W.G. Smith) Sacc. var. *cerealis* (Cooke) Wollenw.) (photo 2a-e). Mycelium on PDA is aerial, abundant, cottony textured, light yellow formed after five days at 25°C. Sporodochium is light orange to golden yellow, 1.2-2.0 in diameter. Conidiophores are monophialide type (15.00-20.00 x 3.5-5.0 µm). Microconidia's and mesoconidias are not determined. Macroconidia's are bent on dorsal side, straight or light bent on ventral side, thick walls, short, large, mostly with five (23.0-74.0 x 4.0-9.0 µm), rare with 3-4 (18.0-44.0 x 3.7-8.5 µm) transversely partition. Apical cells are obtuse or rounded, sometimes with a poorly expressed nipple, basal, comma shape or unexpressed foot. Chlamidiospores are rounded or oval (8.0-16.0 µm), smooth walls, brown, individual, in a chain and groups in hyphae and conidia. Sclerotia are not determined.



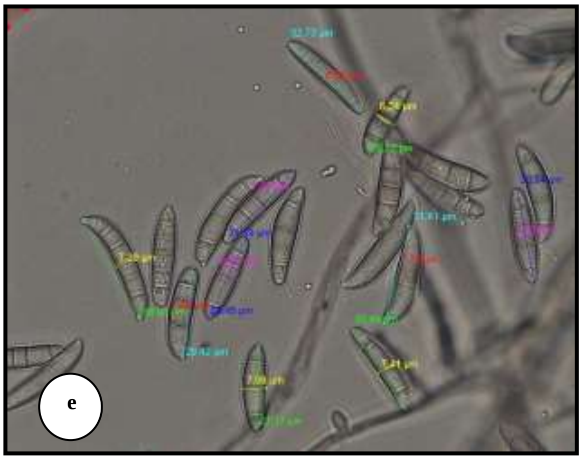


Photo 2. *Fusarium culmorum: a) Colony development on PDA; b) pure culture in situ; c) Chlamidiospore in chain; d) Conidiophory – monophialide type; e) Fusarium culmorum macroconidia's.*

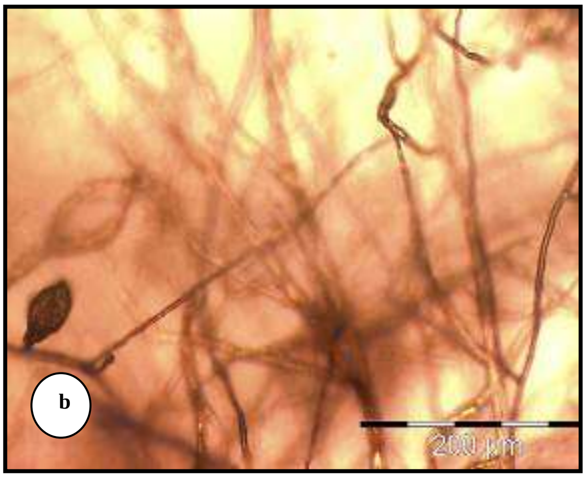
The second group is determinated as *Fusarium graminearum* Schwabe (syn. *Fusarium graminearum* Schwabe grupa 2 Burgess, Wearing & Toussoun; *Fusarium roseum* Link Snyder & Hansen var. *graminearum* (Schwabe) Snyder & Hansen) (photo 3a-e). Mycelium on PDA is aerial, dense, cottony textured, red to minium red, formed after five days at 25°C. Sporodochium are yellow, orange or red-brown. Conidiophores are monophialide type (15.00-25.00 x 2.5-3.5 µm). Microconidia's and mesoconidias are not determined. Macroconidia's are straight to moderately sickle, uniformly bent on dorsal side, thick walls, with 5-6 transversely partition (28.0-72.0 x 3.2-6.0 µm), rare with 3 (21.0-66.0 x 3.0-6.0 µm) or 4 partition (23.0-59.0 x 3.0-5.8 µm) mostly with 5 (41.0-60.0 x 4.0-5.0 µm). Apical cells are cone-shaped or constricted as a snout, while basal are characteristic foot shape. Chlamidiospores are rounded (8.0-12.0 µm), smooth walls, with no or light brown colour, in chain and exceptionally in group, more often in conidia than in hypha. Sclerotia are small, light brown to red.



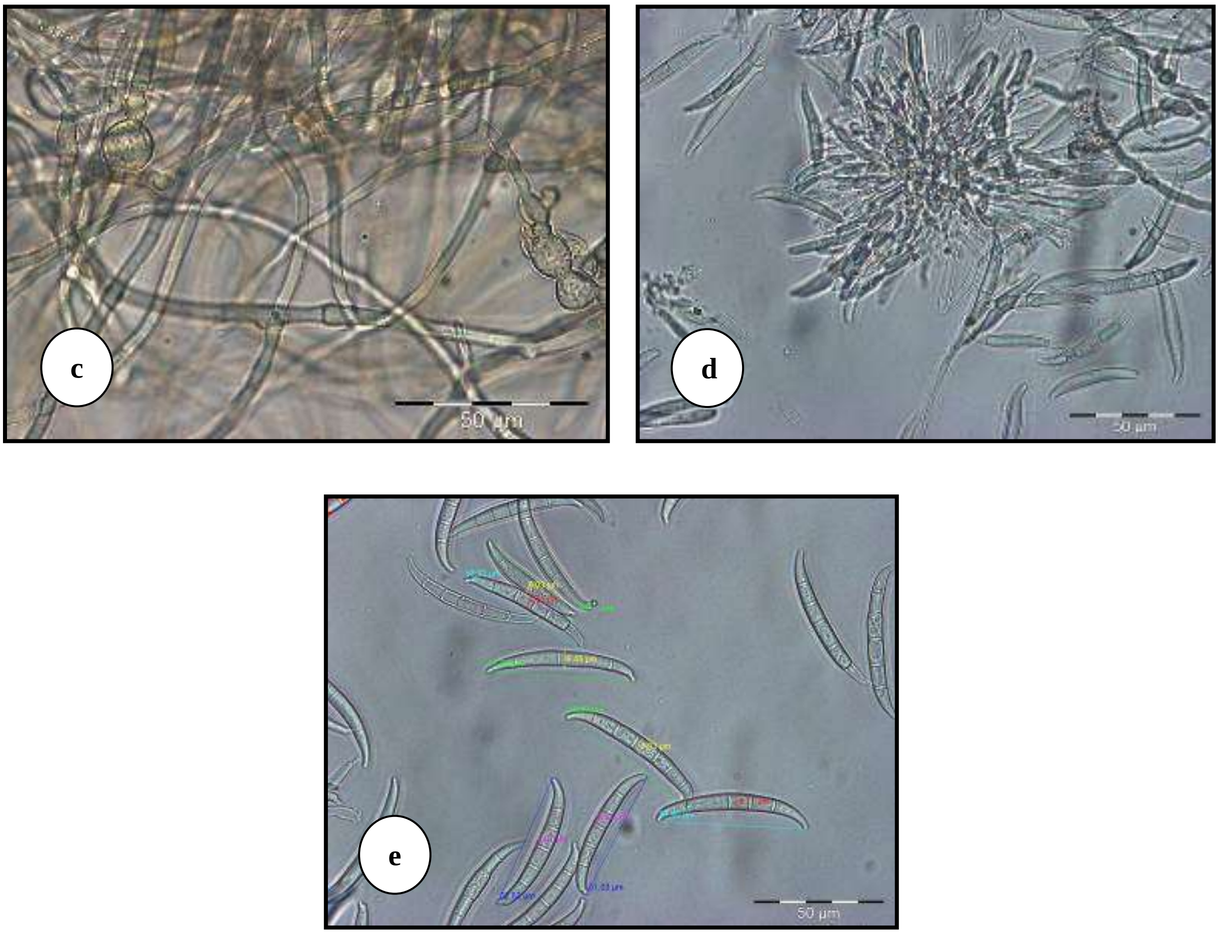


Photo 3. *Fusarium graminearum: a) Colony development on PDA; b) pure culture in situ; c) Chlamidiospore in chain; d) Conidiophory – monophialide type; e) Fusarium graminearum macroconidia's.*

Conclusion

During 2014 high percentage of disease incidence (DI; percentage of diseased ears) and disease severity (DS) of FHB was recorded in the experimental field of the PI AIRS, BL on both varieties (Orion and Nova Bosanka). Mycological analyzes confirmed that the tested varieties in the conditions of natural infection was in high % infected by two *Fusarium* species, *Fusarium graminearum* and *F. culmorum*, respectively. A significant impact on the high-intensity infection of wheat with FHB had extreme rainfall in the spring and floods. However, timely treatmen showed high efficiency (>90%), with a small difference in coefficient of efficiency Ce (%) between treated varieties, while higher efficiency was achieved in variety Nova Bosanka.

Abstract

The research was conducted during 2013 - 2015 on pellic vertisol soil type. The subject-matter of this research was Bulgarian milk thistle cultivar Silmar (*Silybum marianum* Gaertn.). Factor A included no treated check, 6 soil-applied herbicides – Tender EC (S-metolachlor), Sharpen 33 EC (pendimethalin), Merlin flex 480 SC (isoxaflutole), Smerch 24 EC (oxyfluorfen), Raft 400 SC (oxidiargil), Eagle 75 DF (chlorsulfuron) and 5 foliarly-applied herbicides – Kalin flo (linuron), Eclipse 70 DWG (metribuzine), Sultan 500 SC (metazachlor), Granstar super 50 SG (tribenuron-methyl + tifensulfuron-methyl), Starane 250 EK (fluroxypyr). Factor B included no treated check and 1 antigraminaceous herbicide – Tiger platinium 5 EC (quizalofop-P-ethyl). Combinations of antigraminaceous herbicide Tiger platinum with soil-applied herbicides Tender, Sharpen, Merlin flex, Smerch, Raft and Eagle and foliar-applied herbicides Kalin flo, Eclipse, Sultan, Granstar super and Starane do not reduce herbicide efficacy. Volunteer durum wheat crops in milk thistle crops are successfully controlled with the foliarly-applied herbicide Tiger platinum. The tank mixtures of the antigraminaceous herbicide Tiger platinum with foliar herbicides Kalin flo, Eclipse, Sultan, Granstar super and Starane lead to high seed yield of the milk thistle. High seed yields are also obtained with the foliar treatment with Tiger platinum after soil-applied herbicides Raft, Sharpen and Eagle. The use of the soil-applied herbicides Smerch, Merlin flex and Tender does not increase the seed yield, due to higher phytotoxicity of Smerch and Merlin flex to milk thistle and lower herbicide efficacy of Tender. Sole use of soil-applied or foliarly-applied herbicides leads to lower yields due to the fact that they must be combined for full control of weeds in milk thistle crops.

Key words: *Milk thistle, Herbicides, Efficacy, Selectivity, Seed yield*

Introduction

Although the growing technology is known from 70^{-s} and 80^{-s} years of XX century, it was never solved in complex including the plant protection. There is little plant protection products are registered for milk thistle (Khan at al., 2009). Milk thistle has good weed-removing qualities thanks to quick growth and high leaves cover, but decreased competitive ability during germination to extensive growth. Milk thistle itself is often an unpleasant weed for next crops, especially for winter cereals and winter oilseed canola (Delchev, 2015, Delchev and Georgiev, 2015a,b). The most frequent weeds in milk thistle fields are *Sonchus arvensis, Elytrigia repens, Cirsium arvense, Chenopodium album, Raphanus raphanistrum, Sinapis arvensis, Galium aparine, Mentha crispa, Convolvulus arvensis* и *Atriplex patula* (Czyž, 2008). Weed control is based on mechanical cultivation. Herbicides can be given as soil-applied after sowing before emergence or as foliar-applied during rosette stage of milk thistle (Drapalova and Pluhackova, 2014). The purpose of this investigation was to establish the efficacy and selectivity of some herbicides, herbicide combinations and herbicide tank mixtures on the milk thistle by influence of different meteorological conditions.

Materials and methods

During 2013 - 2015 on pellic vertisol soil type was conducted a field experiment. It was carried out a two factor experiment as a block method in 4 repetitions, on a 15 m^2 crop plot. Under investigation was Bulgarian milk thistle cultivar Silmar (*Silybum marianum* Gaertn.). Factor A included no treated check, 6 soil-applied herbicides – Tendar EC, Sharpen 33 EC, Merlin flex 480 SC, Smerch 24 EC, Raft 400 SC, Eagle 75 DF and 5 foliar-applied herbicides – Kalin flo, Eclipse 70 DWG, Sultan 500 SC, Granstar super 50 SG, Starane 250 EK. Factor B included no treated check and 1 antigraminaceous herbicide – Tiger platinium 5 EC. Active substances of herbicides and their doses are shown in Table 1.

Table 1. Investigated variants.

№	Variants	Active substance	Doses	Treatment period
Antibroadleaved herbicides				
1	Check	-	-	-
2	Tendar EC	S-metolachlor	1.5 l/ha	ASBE
3	Sharpen 33 EC	pendimethalin	5 l/ha	ASBE
4	Merlin flex 480 SC	isoxaflutole	420 g/ha	ASBE
5	Smerch 24 EC	oxyfluorfen	1 l/ha	ASBE
6	Raft 400 SC	oxidiargil	1 l/ha	ASBE
7	Eagle 75 DF	chlorsulfuron	20 g/ha	ASBE
8	Kalin flo	linuron	2 l/ha	rosette
9	Eclipse 70 DWG	metribuzine	500 g/ha	rosette
10	Sultan 500 SC	metazachlor	2 l/ha	rosette
11	Granstar super 50 SG	tribenuron-methyl + tifensulfuron-methyl	40 g/ha	rosette
12	Starane 250 EK	fluroxypyr	300 ml/ha	rosette
Antigraminaceous herbicides				
1	Check	-	-	-
2	Tiger platinium 5 EC	quizalofop-P-ethyl	2.5 l/ha	rosette
ASBE – after sowing, before emergence				

All of the herbicides, herbicide combinations and herbicide tank-mixtures were applied in a working solution of 200 l/ha. Mixing of the foliarly-applied herbicides was done in the tank on the sprayer. The soil-applied herbicides were used in the period between sowing and emergence. The foliarly-applied herbicides were used at the rosette stage of the milk thistle. Introduction of herbicide combinations during rosette stage is done as herbicide tank mixtures – the mixing is done in the spray tank. It was investigated efficacy and selectivity of herbicides and their tank mixtures. It was established their influence on seed yield. Efficacy of herbicides against weeds was appointed according to 100 % scale of EWRS (European Weed Research Society). Selectivity of herbicides to milk thistle plants was followed according to the 9-rate scale of EWRS (rating 1 - without damages, rating 9 - crop is completely destroyed). The mathematical processing is done with analysis of variance method.

Results and discussion

Annual broadleaved weeds in the experiment are represented by *Anthemis arvensis* L., *Chamomilla recutita* Rauchert, *Galium aparine* L., *Sinapis arvensis* L., *Raphanus raphanistrum* L., *Capsella bursa-pastoris* L., *Falopia convolvulus* Leve, *Lithospermum arvense* L., *Papaver rhoes* L., *Consolida regalis* Gray, *Viola tricolor* L., *Myagrum perfoliatum* L., *Lamium purpureum* L., *Veronica hederifolia* L., *Stellaria media* Cyr. Annual graminaceous weeds are *Avena fatua* L., *Avena ludoviciana* Durien., *Alopecurus myosuroides*

L., *Apera spica-venti* P.B., *Lolium temulentum* L., *Lolium multiflorum* L., *Bromus arvensis* L. Perennial broadleaved weeds are *Cirsium arvense* Scop., *Convolvulus arvensis* L., also single plants of *Cardaria draba* L. and *Sonchus arvensis* L. Perennial graminaceous weeds are represented by *Sorghum helepense* Pers., *Cynodon dactylon* Pers. and more rarely *Agropyrum repens* L. Volunteers are represented by durum wheat (*Triticum durum* Desf.), was grown as predecessor. Soil-applied herbicides Tendar, Sharpen, Merlin flex, Smerch and Raft applied in autumn, during the period after sowing before germination of coriander, are inefficacy against *Cirsium arvense* Scop., *Convolvulus arvensis* L., *Cardaria draba* L. and *Sonchus arvensis* L., because these perennial broadleaved weeds germinate in spring (Table 2). Herbicide Eagle has weak efficacy of 50 % against these weeds. Foliar-applied herbicides Kalin flo, Eclipse and Sultan applied in spring, during the rosette stage of milk thistle, are also inefficacy against perennial broadleaved weeds *Cirsium arvense* Scop., *Convolvulus arvensis* L. and *Sonchus arvensis* L. Foliar-applied herbicide Granstar super is inefficacy only against *Convolvulus arvensis* L., because this perennial broadleaved weed germinate later, after treatment with the herbicides. Herbicide Starane is efficacy only against *Convolvulus arvensis* L. but is inefficacy against other perennial broadleaved weeds.

Table 2. Efficacy of some herbicides against broadleaved weeds at milk thistle according to the 100 % visual scale of EWRS (mean 2013 - 2015).

Tendar has the weakest efficacy against annual broadleaved weeds. It controls of 100 % only *Chamomilla recutita* Rauchert and *Capsella bursa-pastoris* L. Tendar controls of 85 – 95 % weeds as *Galium aparine* L., *Papaver rhoes* L., *Sinapis arvensis* L., *Raphanus raphanistrum* L., *Anthemis arvensis* L. Soil-applied herbicide Eagle has weaker efficacy of 60 % against *Galium aparine* L. and is inefficacy against *Raphanus raphanistrum* L. Other four soil-applied herbicides - Sharpen, Merlin flex, Smerch and Raft have 100 % efficacy against all annual broadleaved weeds, which are represented in the experiment. Foliar-applied herbicides Kalin flo, Eclipse and Granstar super are weaker efficacy against *Galium aparine* L. They control this weed from 15 % at Eclipse to 65 % at Granstar super. Herbicide Sultan is inefficacy against *Sinapis arvensis* L. and *Raphanus raphanistrum* L. and has weaker efficacy against *Galium aparine* L. and *Anthemis arvensis* L. Herbicide Starane is inefficacy only against *Chamomilla recutita* Rauchert, and *Anthemis arvensis* L. and has weak efficacy of 10 % against *Raphanus raphanistrum* L.

*- volunteers of durum wheat (*Triticum durum* Desf.)
(50) – against *Sorgum helepense* Pers. from seeds only, without *Sorgum helepense* Pers. from rhizomes

Soil-applied herbicides Tendar and Eagle are inefficacy against annual graminaceous weeds *Bromus arvensis* L., *Avena fatua* L., *Avena ludoviciana* Durien. and against perennial graminaceous weeds *Sorghum helepense* Pers. and *Cynodon dactylon* Pers. (Table 3). Tentar has weak efficacy of 40 % against volunteers of durum wheat (*Triticum durum* Desf.) and Eagle is inefficacy against these volunteers. Herbicides Merlin flex and Raft are efficacy against all annual graminaceous weeds except *Bromus arvensis* L. Herbicides Sarpen are efficacy against all annual graminaceous weeds except *Bromus arvensis* L. and volunteers of *Triticum durum* Desf. Herbicides Smerch, Kalin flo, Granstar super and Starane are inefficacy against all annual and perennial graminaceous weeds and volunteers of durum wheat. Herbicides Tendar, Sharpen, Merlin flex and Raft are efficacy against *Sorghum helepense* Pers. by seeds, but are inefficacy against *Sorghum helepense* Pers. by rhizomes. Herbicide Sultan has sufficient efficacy against annual graminaceous weeds and volunteers of durum wheat but it is not efficacy against perennial graminaceous weeds. Herbicide Eclipse has antigraminaceous effect only against *Alopecurus myosuroides* L. Annual graminaceous weeds are *Avena fatua* L., *Avena ludoviciana* Durien., *Alopecurus myosuroides* L., *Apera spica-venti* P.B., *Lolium temulentum* L., *Lolium multiflorum* L., *Bromus arvensis* L., Perennial graminaceous weeds *Sorghum helepense* Pers., *Cynodon dactylon* Pers. and *Agropyrum repens* L., as well as volunteers of *Triticum durum* Desf. are controlled successfully by foliar-applied antigraminaceous herbicide Tiger platinium. Combinations of Tiger platinium with soil-applied herbicides Tendar, Sharpen, Merlin flex, Smerch, Raft and Eagle and with foliar-applied herbicides Kalin flo, Eclipse, Sultan, Granstar super and Starane do not reduce herbicide efficacy. From those herbicides included in the experiment the use of soil-applied herbicide Smerch and herbicide combination Smerch + Tiger platinium leads to phytotoxicity on milk thistle - rating 3 by scale of EWRS (Table 3). The use of soil-applied herbicide Merlin flex and herbicide combination Merlin flex + Tiger platinium also leads to phytotoxicity on milk thistle - rating 2 by scale of EWRS. Signs of phytotoxicity overcome difficult from milk thistle plants and lead to decrease of seed yield. Soil-applied herbicides Tendar, Sharpen, Raft and Eagle and foliar-applied herbicides Kalin flo, Eclipse, Sultan, Granstar super, Starane and Tiger platinium have high selectivity - rating 1 by scale of EWRS. Experiment data show that the lowest seed yields are obtained by alone application of herbicide Smerch, followed by herbicide Merlin flex and by the untreated control (Table 4). The use of soil-applied herbicides Smerch and Merlin flex do not increases seed yields despite their very good herbicidal effect against both graminaceous and broadleaved weeds. The reason for this is their higher phytotoxicity against milk thistle.

Table 4. Influence of some herbicide combinations on seed yield of milk thistle (2013 - 2015).

The alone application of soil-applied herbicides Tendar, Sharpen, Raft and Eagle and foliar-applied herbicides Kalin flo, Eclipse, Sultan, Granstar super and Starane increases seed yields because the big numbers of weeds are destroyed by these herbicides. The increases of the yield by alone application of antigraminaceous herbicide Tiger platinium is less than the increase by other herbicides, because prevailing weeds in the trail are broadleaved. Tank mixtures of Tiger platinium with herbicides Kalin flo, Eclipse, Sultan, Granstar super and Starane lead to bigger increase in seed yields compared to yield at alone application of respective herbicides. Foliar treatment with Tiger platinum after soil-applied herbicides Tendar, Sharpen and Raft also increases the seed yields during the three years of the investigation. Herbicide combinations Smerch + Tiger platinum and Merlin flex + Tiger platinum increase seed yields compared to alone application of Smerch and Merlin flex, but not proven increase yields compared to no treated control.

Conclusions

Combinations of antigraminaceous herbicide Tiger platinum with soil-applied herbicides Tender, Sharpen, Merlin flex, Smerch, Raft and Eagle and foliar-applied herbicides Kalin flo, Eclipse, Sultan, Granstar super and Starane do not reduce herbicide efficacy. Volunteer durum wheat crops in milk thistle crops are successfully controlled with the foliarly-applied herbicide Tiger platinum. The tank mixtures of the antigraminaceous herbicide Tiger platinum with foliar herbicides Kalin flo, Eclipse, Sultan, Granstar super and Starane lead to high seed yield of the milk thistle. High seed yields are also obtained with the foliar treatment with Tiger platinum after soil-applied herbicides Raft, Sharpen and Eagle. The use of the soil-applied herbicides Smerch, Merlin flex and Tender does not increase the seed yield, due to higher phytotoxicity of Smerch and Merlin flex to milk thistle and lower herbicide efficacy of Tender. Sole use of soil-applied or foliarly-applied herbicides leads to lower yields due to the fact that they must be combined for full control of weeds in milk thistle crops.

Abstract

Aphidophagous hoverflies are one of the most important predators of *Myzus persicae*. The relationship between laid eggs of hoverflies, up to new emerged adults is very variable factor. Besides abiotic conditions, biotic interactions with other parasites can affect the survival of hoverflies. During tobacco vegetation, in the Prilep area, we applied the following methods: survey of 20 tobacco stalks and survey of 100 tobacco leaves, in 10 days interval. The prime material collected from the nature, further is cultivated and analysed in laboratory.
Were identified seven parasite species from superfamily Ichneumonoidea, emerged from pupae of hoverflies: *Diplazon laetatorius* Fabricius, 1781, *Diplazon* sp. 2, *Diplazon* sp. 3, *Homotropus* sp. 1, *Homotropus* sp. 2, *Sussaba* sp. 1, and *Promethes* sp. 1. The most numerous is the parasitic specie *D. laetatorius*. It was registered as a parasite on: *Sphaerophoria scripta*, *Sphaerophoria rueppelli*, *Episyrphus balteatus*, *Scaeva pyrastri* and *Eupeodes corollae*. *Diplazon* sp. 2, *Diplazon* sp. 3 and *Homotropus* sp. 2 are parasites only on *S. pyrastri*. *Homotropus* sp. 1 is a parasite on: *S. scripta S. rueppelli*, *S. pyrastri* and *E. corollae. Sussaba* sp. 1 and *Promethes* sp. 1 are parasites on *S. scripta* and *S. rueppelli*.
From the pupa of Syrphidae is emerges one imago of parasite, that biting hole on rounded side of the pupa. The annual activity of these parasites is synchronized with the maximum availability of the larvae of their hosts. Parasitism occurs later in August, and during September. This data could be useful in implementation of Integral pest management.

Keywords: *aphids, Syrphidae, parasites, Ichneumonoidea*

Introduction

Ichneumonoidea is one of the largest superfamilies and they are found almost in all continents and they are important parasitoids of other invertebrates.
The family Ichneumonidae is highly diverse and abundant, with more than 60000 species and it is cosmopolitan, richer in species in the northern hemispheres than in the tropics. Members in this family have long and thin body, with narrow waist like wasps. Some species are colourful. Adults are active in day time and feed on flowers. Their larvae are either parasitic or hyperparasitic (living parasitically upon a parasite). Many species are parasites (endoparasites and ectoparasites) of plant pests. Some species attack a variety of hosts, they are internal or external parasitoids of insects (lepidopterous, coleopterous and hymenopterous larvae), some species in this family attack spiders.
The species of subfamily Diplazontinae are spread all over the world, and most of it in the Holarctic region where there are 19 genera. Generally stated genera are: Diplazon, Promethes, Sussaba, Homotropus, Syrphoctonus and others. They are koinobiont endoparasites of Diptera, especially Syrphidae.

According to Gilbert (1986), approximately all the parasites of the hoverflies are wasps and the most of them belong to the subfamily Diplazontinae. The parasite placed egg in either the egg or the larva, and the adult parasitoid emerges from the puparium. Depending on whether the host is uni, oligo or polyvoltine, the parasites synchronize their development with the host's development cycle - the hoverfly.

The wasps can be kept alive for weeks by feeding on a sugar solution. Older animals devour eggs and young syrphid larvae, squeezing them out and sucking up the contents. This uptake of protein food, as in other parasitic hymenoptera, is probably necessary for continuous egg production (Schneider, 1950).

These parasites have great economic significance in the biological struggle from plant pests.

According to Jankowska (2004), the parasitization of hoverflies varied within the years of observation and oscillated from 14.4% to 46.4%. The parasitization by *D. laetatorius* reached 21.7%. Krsteska (2007), state that in the parasitic complex, the parasites of the genus Diplazon, during 2003-2005, were represented with 41.46% of *D. laetatorius*, 16.09% of *Diplazon* sp. 2 and 8.78% of *Diplazon* sp. 3.

Wnuk and Wojciechowicz (1993) noted that syrphid larvae which attack *Brevicoryne brassicae* L. were infested from 27% to 40% cit. Jankowska (2004).

Bombasch (1963), state that the parasites of hoverflies destroy from 5 %, to 48 % of their population. According to Adaskkevch (1975), in Moldavia on a cabbage, from May to July, the parasites attacked the hoverflies 30%, but from September to October the percentage increased to 72.78%. On lupine and bean the percentage of parasitization is lower (5.4%).

Pek (1981) noted that larvae of hoverflies are often parasitized, especially from Ichneumonidae 18-70%.

According Resende et al., (2006), the percentage of parasitization of the aphidophagous hoverflies is 27.5%, and according Cheek et al. (1974) it is 50%.

Material and Methods

Field research

a. Method of survey of 20 randomly selected tobacco stalks infested with aphids. Tobacco stalks were sampled from the whole area of the trial at 10-days interval, starting from June 1, up to the end of September. The tests were performed on targets tobacco (leaves, tobacco flower and flower seed capsules). 10 checks were made by this method in each of the three years of investigations, i.e. 200 stalks per year, or 600 stalks in total. During investigations, 5813 tobacco leaves were examined in 2003, 5851 in 2004 and 5944 in 2005 or 17608 tobacco leaves in total.

b. Method of Davies- survey of 100 randomly selected tobacco leaves infested with aphids. Tobacco leaves were sampled from the whole area of the trial at 10-days interval, during tobacco vegetation. 10 checks were made by this method in each of the three years of investigations, i.e. 1000 leaves per year, or 3000 leaves in total.

These two methods of analyses are simple and secure to be performed; the advantage of this method is that the data can be collected by one person only.

Laboratory research

The prime material is collected in the nature, after which it is further nourished, cultivated and analysed under laboratory conditions. The eggs, larvae and pupae of Syrphidae, are placed in special containers and raised until adult eclodes. Larvae were reared on tobacco leaves infested with *M. persicae* in Petri- dishes.

The pupae which were brought up and those collected were separately placed in test-tubes. Later we have monitored the internal modifications of the pupae, the length of its developing

stadium, the degree of eclosion of imago, the percentage of parasitism and the eclosion of different types of parasites.
Among ecloded parasites derived from the Syrphidae, we have determined their species and their morphological characteristics.

Results and Discussion

Aphidophagous hoverflies are attacked by a wide range of hymenopterous parasites.
During investigations seven species of parasites were identified in the order of Hymenoptera, suborder Apocrita, superfamily Ichneumonoidea, family Ichneumonidae, subfamily Diplazontinae, ecloded from pupae of various hoverflies species:
-from genus *Diplazon* Nees (1818) we have detected: *Diplazon laetatorius* Fabricius (1781), *Diplazon* sp. 2 and *Diplazon* sp. 3.
-from genus *Homotropus* Förster (1868): *Homotropus* sp. 1 and *Homotropus* sp. 2.
-from genus *Sussaba* Cameron (1909): *Sussaba* sp. 1.
-from genus *Promethes* Förster (1868): *Promethes* sp. 1.
The largest group of reared parasitoids belonged to the genus *Diplozon*, of which the most frequent was *D. laetatorius*.
According to Adashkevich (1975), four species of syrphid parasites have been observed in the USSR from the genus *Diplozon*, including *D. laetatorius*, 3 from the genus *Homotropus* and 3 from the genus *Promethes*.
Harizanov, Babrikova (1990), identified seven species of hoverflies parasites in Bulgaria, including *D. laetatorius*.
Resende et *al*. (2006) and Sánchez (2000), identified three species of hoverflies parasites, including *D. laetatorius*.
G r e c o (1998), also listed *D. laetatorius* as parasites of aphidophagous hoverflies in Argentina.
Adashkevich (1975), investigate that in Moldava the most numerous parasites of hoverflies is *D. laetatorius*. Also in investigation of Jankowska (2004), the most frequent parasitic species, was *D. laetatorius*.
These parasites are effective enemies of predatory hoverflies. They use koinobiont parasitising strategies. The female insert egg into the host body. We should have in consideration that aphidophagous larva still feeds with aphids and perform its bioregulatory role in the destruction of aphids. Parasite species is activated after the larva of hoverflies is transformed into a puppet stage. Then it destroys the host-hoverfly and ichneumonid adult emerges from the syrphid pupae. In the beginning the pupa of the hoverfly has its specific larval color. Few days later its color becomes more whitish and dull.
If you carefully cut the hoverfly pupa, inside you will notice a one small white larvae of the parasitic specie. Then the pupa turns dark and it is a sign of a parasitism. When the adult of parasite flies (emerge), it chewed large, curved hole in the rounded side of the hoverfly pupa.
These parasites reduced the number of hoverflies larvae. During tobacco vegetation, the number of the parasitized hoverflies was small in July. As the number of larvae feeding in tobacco aphid colonies was increasing, the percentage of parasitized larvae increased. The majority of infested hoverflies larvae were found during September.
D. laetatorius is a widespread species of parasite, ecloded from the Syrphidae pupae. It is polyphagous specie and parasitized five species of hoverflies. During investigations, *D. laetatorius* was identified as a parasite on *S. scripta, S. rueppelli, S. pyrastri* and *E. balteatus* in 2003; *S. scripta, S. rueppelli, S. pyrastri, E. balteatus* and *E. corollae* in 2004; *S. scripta, S. rueppelli, S. pyrastri* and *E. balteatus* in 2005.
Jankowska (2004) reared *D. laetatorius* from 8 syrphid species.

Adashkevich (1972), reported that the parasite *D. laetatorius* emerged from the pupae of *S. scripta*, *Syrphus corollae* and *Syrphus balteatus.*
Feraru et al. (2004) stated that the parasite *D. laetatorius* emerged from the pupae of *S. scripta.*
After the hoverfly will reach the pupation stage, the parasite *D. laetatorius* emerges in average 10 days in *S. scripta* (5 to 15 days), average 12 days in *S. rueppelli* (7 to 21 days), average 11 days in *E. balteatus* (10 to 14 days), 11 days in *E. corollae*, and 10 days in *S. pyrastri*.
In tobacco fields, appearance of parasitised larvae was first determined on the 3th of August. They were most frequently recorded from 20th August to 15th September and then their number gradually decreased. During our ivestigations, the earliest registereded pupae parasitised with *D. laetatorius* was the pupae of *S. scripta*, on 16.07.2004, and the last one was that of *S. scripta* on 17.09.2004.
During the examination, we found out that from the pupa of the hoverfly flies (emerge) out one parasite which is also found in examination of Resende et al. (2006).
We conclude that the length of the body of the imago is from 4 to 6 mm (Figure 1). Ma et al., (1986), states that the length of the body is 5-6 mm.
***Diplazon* sp. 2** in three years investigations it was identified as a parasite of *S. pyrastri*. Development of the parasite from pupation until eclosion lasts 11 to 17 days, in average 14 days. The first occurrence of parasitised larvae was recorded in August 20 and parasitism could be observed until September 17. We conclude that the length of the body of the imago is from 5 to 6.5 mm (Figure 2).
***Diplazon* sp. 3** in three years investigations it was identified as a parasite of *S. pyrastri*.
Development of the parasite from pupation until eclosion lasts 11 to 22 days, in average 13 days. The first occurrence of parasitised larvae was recorded in August 20 and parasitism could be observed until September 19. We conclude that the length of the body of the imago is 4 mm (Figure 3).
***Homotropus* sp. 1** is polyphagous species and during our trials it was registered as a parasite of four hoverflies species. In tobacco biocenosis it was identified as a parasite on: *S. scripta, S. rueppelli, S. pyrastri* and *E. corollae* in 2003 and 2004; *S. pyrastri* and *E. corollae* in 2005.
After the hoverfly will reach the pupation stage, the parasite *Homotropus* sp. 1 emerges in 10 to 11 days in *S. scripta* and *S. rueppelli*, 13 days in *S. pyrastri,* and 14 days in *E. corollae.*
The first occurrence of parasitised larvae was recorded in August 18 and parasitism could be observed until September 9. We conclude that the length of the body of the imago is from 4 to 5 mm (Figure 4).
***Homotropus* sp. 2** in our investigations it was identified as a parasite of *S. pyrastri* in 2003 and 2004. Development of the parasite from pupation until eclosion lasts 11 to 19 days, in average 14 days. The first occurrence of parasitised larvae was recorded in August 16 and parasitism could be observed until September 7. We conclude that the length of the body of the imago is from 5 to 5.5 mm (Figure 5).
***Sussaba* sp. 1** was registered as a parasite of two hoverflies species. In tobacco biocenosis it was identified as a parasite on: *S. scripta* and *S. rueppelli* in 2003 and 2004.
After the hoverfly will reach the pupation stage, the parasite emerges in 12 days in *S. scripta* and *S. rueppelli*. The first occurrence of parasitised larvae was recorded in July 20 and parasitism could be observed until August 15. We conclude that the length of the body of the imago is from 3 to 4 mm (Figure 6).
***Promethes* sp. 1** was registered as a parasite of 2 hoverflies species. In tobacco biocenosis it was identified as a parasite on: *S. scripta* and *S. rueppelli* in 2003 and 2004.
After the hoverfly will reach the pupation stage, the parasite emerges in 11 days in *S. scripta* and *S. rueppelli*. The first occurrence of parasitised larvae was recorded in August 20 and

parasitism could be observed until September 4. We conclude that the length of the body of the imago is from 3 to 4 mm (Figure 7).

Figure 1 *D. laetatorius* Figure 2 *Diplazon* sp. 2

Figure 3 *Diplazon* sp. 3 Figure 4 *Homotropus* sp. 1

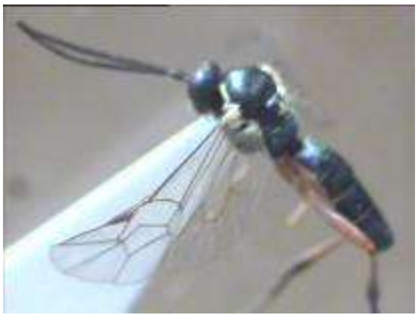

Figure 5 *Homotropus* sp. 2 Figure 6 Sussaba sp. 1

Figure **7** *Promethes* sp. 1

Conclusions

Aphidophagous Syrphidae are attacked by a wide range parasitic *Hymenoptera.*
During investigations seven parasitic Hymenoptera: *D. laetatorius*, *Diplazon* sp. 2, *Diplazon* sp. 3, *Homotropus* sp. 1, *Homotropus* sp. 2, *Sussaba* sp. 1 and *Promethes* sp. 1 were identified. The dominant species was *D. laetatorius.*

They lay their eggs in the host's body. They are activated after the hoverfly larvae is transform into the pupa, then the ichneumonid larva eats its host alive. The imago of the parasite flies (emerge) from the puparium of the hoverflies.

The occurence of parasite depends on the occurrence of host-hoverflies, while the occurence and development of aphidophagous hoverflies depends on the appearance of green peach aphid on tobacco and climate conditions in the region of Prilep.

Abstract

Plant exudates and secondary metabolites have a variety of biological actions. This is measurable through allelopathic, herbicidal, toxic (human and animal) and insecticidal activity. Allelochemicals are products of plants, algae, bacteria and fungi and affect the growth and development of agricultural crops. Positive and negative effects of plants depend on the allelochemicals' chemical composition, i.e. different compounds released from different plants part (leaves, roots, and stem) with different mechanisms. The aim of this study was to determine the potential allelopathic effects of three widespread invasive species in area of the Čačak city *Ailantus altisima, Portulaca oleracea* and *Ambrosia artemisiofolia* on the seed germination under laboratory conditions. The crude ethanolic extracts *A. altissima, P. olerace* and *A. artemisiofolia* were prepared in aqueous solution concentration 0.1%, 1% and 5%. Allelopathic effects were measured by determining of seed germination % of barley and wheat in the exposition to plant extracts. After 96h allelopathic effect of *A. altissima* and *P. oleracea* extract was observed. Extracts of these herbs have demonstrated an inhibitory effect on germination of wheat grains and stimulating the germination of barley grains. Ethanol plant extract of 5% solution *P. oleracea* at the same time had the strongest inhibitory effect on germination of wheat grains and strongest stimulating effect on germination of barley grains. Extracts of *A. artemisiifolia* did not have allelopathic effect in any concentration.

Keywords: *Invasive plants,* allelopathy, barley, wheat.

Introduction

Allelopaty is defined by the Austrian botanist Hans Molisch (1937) and describe the interaction of plants and microorganisms (Siddiqui *et al*., 2009). This term is origin Greek words: allélon - mutually; pathos - pain. Chemical compounds (allelochemicals) are released from the plants by various mechanisms, from different plant parts as the roots, stem, leaf, and flower. Allelochemicals have their positive and negative effects at environment (Rice 1984). It has been found that the substances that cause allelopathic biochemical interactions between plants represent the products of secondary metabolism (Einhelling, 2004). Allelochemicals has low molecular weight, relatively simple structure and represents volatile substances. They belong to phenolic compounds free-phenols and terpenoids (monoterpenoids, sesquiterpenoid lactones, diterpenes quassinoids, etc.). It is often said that the free phenols have alleopathic effects (Einhelling, 2004). Muller (1966) believes that the sage bushes and diapers produce essential oils that inhibit vice herbaceous plants in the immediate environs. Benzoic and cinnamic acid are commonly referred to as compounds having a primary allelopathic effect in forest ecosystems (Muscolo, 2004), but in asparagus and coffee they have an autoallelopathic effect (Songh et al., 1999; Miller *et al*., 1991). In plants *Ceratiolia ericoides* Michx, *Centaurea trifolii* Lam., *Robinia pseudoacacia* L., have been found allelopathic flavonoids which inhibit germination (Williamson *et al*., 1992; Sorbo *et al*., 2004). Monoterpenes are volatile compounds and as the main constituents of essential oils exhibit allelopathic effect particularly with aromatic plants in the arid and semi-arid zones (Angelini *et al*., 2003; Williamson *et al*., 1989). Several monoterpenes such as camphor, pinene and cineol in pure form or in the essential oil mixtures inhibit the germination or exhibit some other physiological functioning (Angelini *et al*., 2003; Vokou *et al*., 2003).

Ailanthus altissima (Mill.) Swingle 1916, one in five plant species belonging to the genus Ailanthus (Nooteboom, 1962). It is used traditionally in Chinese folk medicine as an astringent, antispasmodic, antihelmitik, narcotic, anti-diarrhea and dysentery, epilepsy, ophthalmic diseases, acne (Hu, 1979; Howard, 2004). *A. atissima* tree produces substances that show inhibitory effects on seed germination and seedling growth (Heisey, 1990). The strongest inhibitory effect shows the bark, especially the root, on the other hand the leaves show moderately (Heisey, 1990). From the root of *A. altissima* has been isolated aylantone, heparin, alantion B and other substances with alleopathic and the phytotoxic effects (Dayan *et al*., 1999; Callaway, 2000; De Feo *et al*., 2003). *P. oleracea* belongs to the family Portulacaceae which beside her has another 120 plant species (Azuka *et al*., 2014). This annual plant is presence around Europe (Movahedian *et al*., 2007). It is believed that the name of this species comes from the Latin word „porto" meaning wear and „lac" which means milk. *P. oleracea* can be grown in gardens (Loutfy and el Hadidi, 1984). The use of this plant as a vegetable, spice and for medicinal purposes has been known since the ancient Egyptians and was very popular during the middle Ages in England (Azuka *et al.*, 2014). It is characterized by a high nutritional value consisting of vitamins, minerals, fat, carbohydrates, proteins and water (Azuka *et al.*, 2014). It is also used as a vegetable, especially in the Mediterranean area. Its stem and leaves are edible, and have the taste similar to spinach (Liu *et al*., 2000). *P. oleracea* has wide application in the pharmaceutical industry through the microbiological quality, an antioxidant, an immunological and neurological activity (Azuka *et al*., 2014). *A. artemisiofolia* is an annual plant species originating in the prairie regions of North America (Brandes and Nitzsche, 2006). It is one of the leading allergens and causes very serious health problems in the human population and significant economic impact on the agricultural yield (Genton *et al*., 2005). On the territory of Europe considered the weed plant species that causes severe yield losses of sunflower, corn, sugar beets, soybeans and grains (Kazinczi *et al*., 2008).

The aim of this study was detect effect of plant ethanol extracts of *A. atissima*, *P. oleracea* and *A. artemisiofolia* in different concentration on the germination of wheat and barley in laboratory conditions.

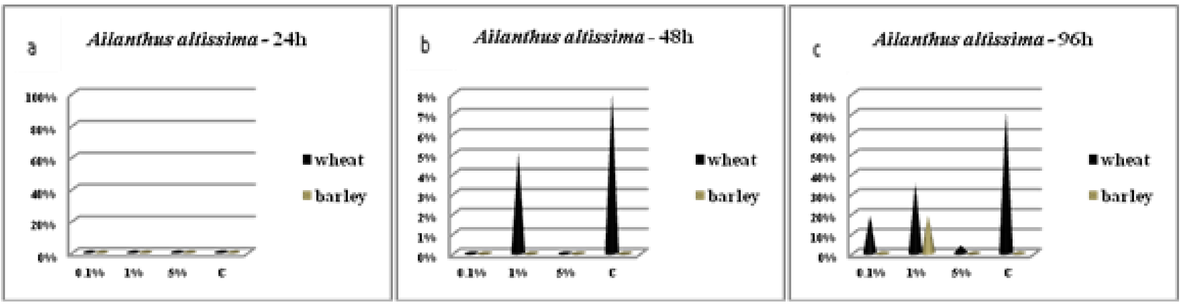
Material and methods

For the experiment plant ethanol extracts prepared from *A. altissima, P. oleracea and A. artemisiofolia.* The extracts used were obtained by the process of maceration with ethanol as the solvent. For the preparation of the extract was used 10 g of air dry plant material overflow with 100 mL of ethanol. After 24 hours the solvent was decanted. From initial extract concentration were prepared 0.1%, 1%, and 5% dilution in distilled water and used in the experimental work. For the experiment used a total of 800 seeds per plant crop or 100 seeds per Petri dishes. On the bottom of each jar placed filter paper (Wattman no 1) and 5 mL of extracts or distilled water injected, and Petri dishes filled with seeds of wheat and barley. Inspection of seed germination was done after 24^h, 48^h and 96^h from the experiment settings.

Results and discussion

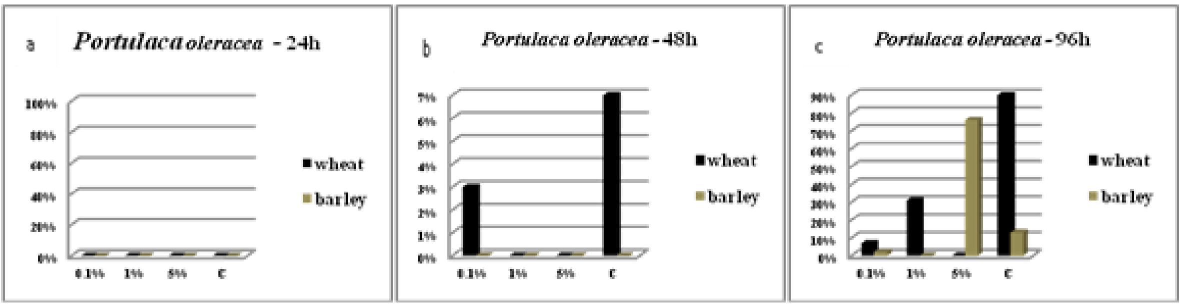
In investigation of seed germination of wheat and barley, during the first inspection after 24^h (Graph 1a), plant extracts of *A. altissima* showed an inhibitory effect at all three concentration

(0.1%, 1%, 5%). During the second inspection, germination was recorded only on wheat seed. After 48^h germination of 5% was recorded in the exposure of 1 % of plant extract *A. altissima*. The biggest germination (8%) was recorded in control (Graph 1b). In the last inspection after 96^h germination was recorded at booth, and wheat and barley seed (Graph 1c). In the exposure 1% *A. altissima* extracts was recorded germination of 35% for wheat and 19% for barley seed. The wheat germination of 19% and 4% was recorded also in exposure 0.1% and 5%, respectively. The plant extracts 0.1% causes germination of 1% at barley seed. The seed germination of 71% and 1% of wheat and barley was recorded in control, respectively.



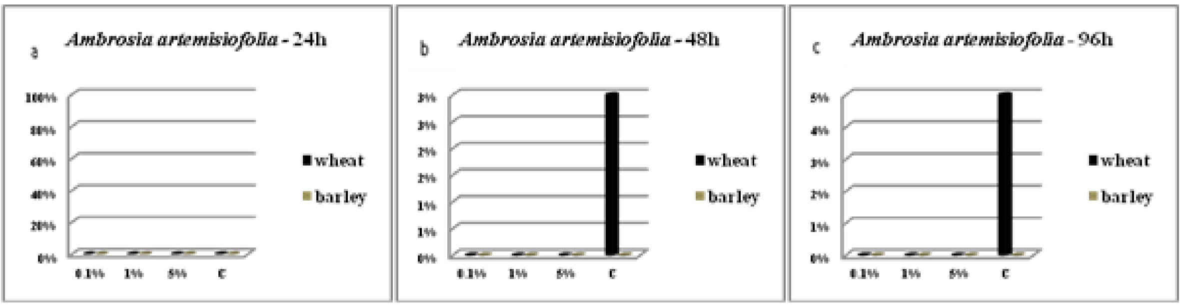
Graph 1. (a, b, c). The influence of plant extracts *A. altissima* (0.1%, 1%, 5%) on the germination of wheat and barley seed

In investigation of seed germination of wheat and barley, during the first inspection after 24^h (Graph 2a), plant extracts of *P. oleracea* showed an inhibitory effect at all three concentration (0.1%, 1%, 5%).



Graph 2. (a, b, c). The influence of plant extracts *P.oleracea* (0.1%, 1%, 5%) on the germination of wheat and barley seed

During the second inspection (48^h) seed germination of 3% was recorded only on wheat seed (Graph 2b), in exposure of 0.1% *P. oleracea* plant extracts. The biggest seed germination (7%) of wheat was recorded at the control. During the last inspection after 96^h seed germination was recorded on both wheat and barley (Graph 2c). In exposure 0.1% and 1% was recorded seed germination on wheat seed of 7% and 31%, respectively. Barley seed germination of 2% and 76% was recorded in exposure 0.1% and 5% , respectively (Graph 2c). The seed germination of 83% and 13% on wheat and barley was recorded in control, respectively.



Graph 3. (a, b, c). The influence of plant extracts *A. artemisiofolia* (0.1%, 1%, 5%) on the germination of wheat and barley seed

In investigation of seed germination of wheat and barley (Graph 2a, b, c), during all three inspection after 24^h, 48^h and 96^h plant extracts of *A. artemisiofolia* showed an inhibitory effect at all three concentration (0.1%, 1%, 5%). The barley seed germination of 3% and 5%, was recorded after 48^h and 96^h in control, respectively.

Conclusion

After 96h allelopathic effect of *A. altissima, P. oleracea* and *A. artemisiifolia* extract was observed. Extracts of *A. altissima* and *P. oleracea* have demonstrated an inhibitory effect on germination of wheat grains and stimulating the germination of barley grains. Extracts of *A. artemisiifolia* did not have allelopathic effecs in any concentration.

Abstract

Spain has a long cheese making tradition and a wide variety of traditional cow, goat and ewe cheeses. The dairy sector is strategic in the Spanish agri-food industry due to its economic relevance and its contribution to the development of the rural population. Afuega'l Pitu is a popular artisan cheese from Asturias (northern Spain) protected with PDO (Protected Designation of Origin) since 2004. It is made with pasteurized milk from Friesian and Asturian Valley breeds, and their crosses, fed by traditional diet. The aim of this study was to analyze biochemical and thermo-rheological characteristics of *Roxu* variety of Afuega'l Pitu ripened for 30 days. Eight batches (R1-R8) of PDO cheesemakers were studied. From stress sweeps at 1Hz and 20°C, the highest significant differences in stress (σ_{max}) and strain (γ_{max}) amplitude values were between R5 and R8 (σ_{max}=885±89 *vs* 177±18 Pa; γ_{max}=0.283±0.035 *vs* 0.347±0.022%), respectively. This could be explained based on the moisture-protein ratio (MPR), being the lowest for R5, resulting in a more brittle network due to a greater casein packing, and the highest for R8, producing a weaker and more deformable casein gel. Thermal profiles, obtained using dynamic thermo-mechanical analysis, showed casein matrices with a solid-like character ($G' > G''$) from 20 to 90ºC. Specifically, from T>60ºC $\tan\delta$ decreased with increasing temperature for all samples, showing a specific heat-induced gelation, compatible with the softening of cheeses at high temperature.

Key words: Compositional parameters, Thermo-rheological properties, Afuega'l Pitu cheese, Spain.

Introduction

Afuega'l Pitu cheese is made in the north of Spain (Asturias) from pasteurized cow's milk by predominantly acid coagulation. It is protected with a Denomination of Origin (PDO) since 2004 (Commission Regulation (EC) No. 723/2008). There are four varieties according to its form, troncoconic (*atroncau*) or pear shape (*trapu*), and its colour, with (*roxu*) or without (*blancu*) paprika added. The elaboration is a slow process resulting in a soft paste which becomes gradually harder during ripening. The milk used is obtained from healthy cows of Friesian and Asturian Valley breeds and their crosses, belonging all of them to the region of the Principado de Asturias. Feeding of livestock is based on traditional practice, grazing of dairy herds throughout the year and supplementing with fresh grass, hay and silage from the farms themselves. The delimited territory is characterized by large areas of natural meadows due to abundant rainfall and soft temperatures throughout the year. Management is based mainly on a semi-stabling system, in which the animals remain in the pasture during most of the day and in the evening are collected for milking (MAPAMA, 2016).
This type of cheese is an acid milk gel made at pH near to the isoelectric point of caseins, resulting in a particulate gel (coarse-structured) formed by aggregation of casein micelles of heterogeneous size distribution (Fox *et al.*, 2000; Rao, 2007). The structure of the gel may be

affected by different cheesemaking conditions during manufacturing (rennet dose, coagulation temperature, consistency of the curd, kneading time, etc.) (Lucey *et al.*, 2005). The rheological properties of cheese are quality attributes that are important to the manufacturer and consumer (Fox *et al.,* 2000). Previous studies have analyzed microbiological and biochemical changes during ripening (Cuesta *et al.*, 1996). However, to date no research has been reported regarding rheological parameters of Afuega'l Pitu cheese (PDO). The aim of this work was to analyze the viscoelastic and biochemical parameters of *Atroncau roxu* variety of Afuega'l Pitu cheese (PDO) made by different manufactures at fixed ripening time.

Material and Methods

Sampling

Two batches of cheese were produced by eight different farms of Asturias following the PDO indications and ripened for 30 days. Each sample was split into two halves; one was ground and held in an air-tight container at -40 ºC until biochemical analysis, while the other was directly subjected to the rheological test on the same day.

Biochemical determinations

Moisture, ash, fat and protein content and pH were analyzed according to the standards described by Bargiela *et al.* (2012).

Rheological determinations

The viscoelastic tests were performed with a Haake RS600 controlled stress rheometer (Thermo Electron, Corp. Germany) using parallel-plate geometry (20 mm diameter and 1 mm gap). The samples were tempered at 20 °C and allowed to rest for 15 minutes to achieve thermal and mechanical equilibrium prior to the start of the measurement. The temperature was controlled to within 0.1 °C using a Peltier element on the lower plate. Viscoelastic parameters in the linear viscoelastic (LVE) range were obtained from stress sweeps at 1Hz and 20 °C from the initial shear stress (σ_i= 75 Pa) to final stress (σ_f= 4,700 Pa). Temperature sweeps were performed at 0.1 Hz at fixed strain γ= 0.1% within the LVE range at 1 ºC/min from 25 to 90 ºC.

Statistical analysis

Biochemical data were subjected to an analysis of variance (ANOVA) using the General Linear Model procedure of the computer programme Statistica© 8.0 for Windows (Statsoft Inc., Tulsa, OK, USA). A Tukey HSD test (significance level of P<0.05) was performed to compare the mean values by the different cheeses. Statistical correlations between the biochemical and viscoelastic parameters were determined by multiple regression with confidence intervals of 95% (P<0.05), 99% (P<0.01) and 99.9% (P<0.001), by the use of the same statistical program. Stress sweeps were shown as mean values of five independent measurements and the expanded uncertainty limit (EUL) was calculated as the maximum and the minimum deviation from the mean value. Temperature sweep were presented as the mean values of at least three independent measurements.

Results and Discussion

Biochemical parameters

The values of the physicochemical parameters for the eight samples (R1–R8) (Table 1) were within the specification for the Afuega'l Pitu PDO, and similar to the obtained for Cuesta *et al.* (1996) for the same type of cheese. However, slight differences were found among samples as a consequence of the different cheesemaking conditions during manufacturing (rennet dose, coagulation temperature, consistency of the curd, kneading time, etc.). These factors could influence in the curd moisture content and pH (Lucey *et al.*, 2005). All samples showed pHs near to the isoelectric point (pI~ 4.6) (Table 1), thus, a significant demineralization of the casein micelles was produced (Le Graët and Gaucheron, 1999; Phadungath, 2005). Differences among samples in the pH attained may be affected by the buffering capacity of the milk and curd (Fox *et al.*, 2000). As regards to moisture content, samples R4 and R5 showed a significant (P<0.05) lower amount and R8 had the highest moisture content (Table 1). These changes could be caused by different conditions of drainage time between cheesemakers. Ash, fat and protein contents were similar than those reported by Cuesta *et al.* (1996) and for other cow's milk acid coagulated cheeses (Arenas *et al.*, 2014).

Table 1. Biochemical parameters of Afuega'l Pitu cheese.

Sample	pH	Moisture[1]	Ash[2]	Fat[2]	Protein[2]	MPR

[1] g/100 g cheese; [2] g/100 g TS; MPR: moisture:protein ratio; [a-g] Different letters in the same column indicate significant differences (P<0.05).

Linear viscoelastic range

Stress sweeps were carried out to determine the LVE range in terms of stress (σ_{max}) and strain (γ_{max}) amplitudes. As consequence of slow acid-induced gels the colloidal calcium phosphate (CCP) was solubilized thus, the casein micelles were destabilized. Moreover, the production of lactic acid (pH decrease ~ pI) reduced the intermicellar repulsive forces promoting the micellar aggregation into a more compacted system (Fox *et al.*, 2000). In all samples, the loss of Ca^{2+} ions produced a less cohesive micellar network (Hui *et al.*, 2006) which explains the low values of γ_{max}< 0.35% (Table 2) comparing with those obtained by rennet-induced coagulation (γ_{max}> 0.60%) at similar ripening time (Bargiela *et al.*, 2012). Thus, the resulting acid gels exhibited a lower conformational flexibility (low γ_{max}). This fact is consistent with the high values of complex modulus (G*) for R1–R7 samples (Table 1), indicating a greater cross-linking density in the casein network.

Table 2. Viscoelastic parameters in the linear viscoelastic (LVE) range for different commercial producers (R1− R8) at 1Hz and 20 °C.

Sample	σ_{max} **(Pa)**	γ_{max} **(%)**	***G** (kPa)**	δ **(º)**
R1	571 ± 57^{e}	0.180 ± 0.018^{e}	314 ± 27^{e}	16.00 ± 0.21^{ab}

R8	177 ± 18^{a}	0.347 ± 0.022^{c}	51 ± 3.1^{a}	15.87 ± 0.13^{a}

[a-f] *Different letters in the same column indicate significant differences P<0.05 among samples.*

The only exception was the R8 sample, which exhibited the lowest rigidity in the micellar network (minor *G**) in line with the lowest conformational stability (minimum σ_{max}) (Table 2). This result could be related with the greatest moisture content and the subsequent highest MPR (Table 1). Thus, the R8 gel network showed a more hydrated structure preserving similar solid-like character (~ phase angle, δ**)** than the other samples (Table 2). These trends were assessed by bivariate Pearson correlation coefficient, that showed high negative correlations between MPR–σ_{max} (-0.81***) and MPR–*G** (-0.86***). In addition, R8 sample showed the highest fat content (Table 1), which might act as a filler phase disrupting the characteristic continuity of the solid phase in the casein matrix, that could also explain the lowest *G** and σ_{max} values (Table 2).

Temperature sweeps

The thermal response of the viscoelastic modulus was obtained by dynamic-mechanical thermoanalysis (DMTA), to study the thermal profile. All samples exhibited the same thermal pattern showing a solid-like character (storage modulus, *G'* > viscous modulus, *G''*) from 20 to 90ºC (Figure 1).

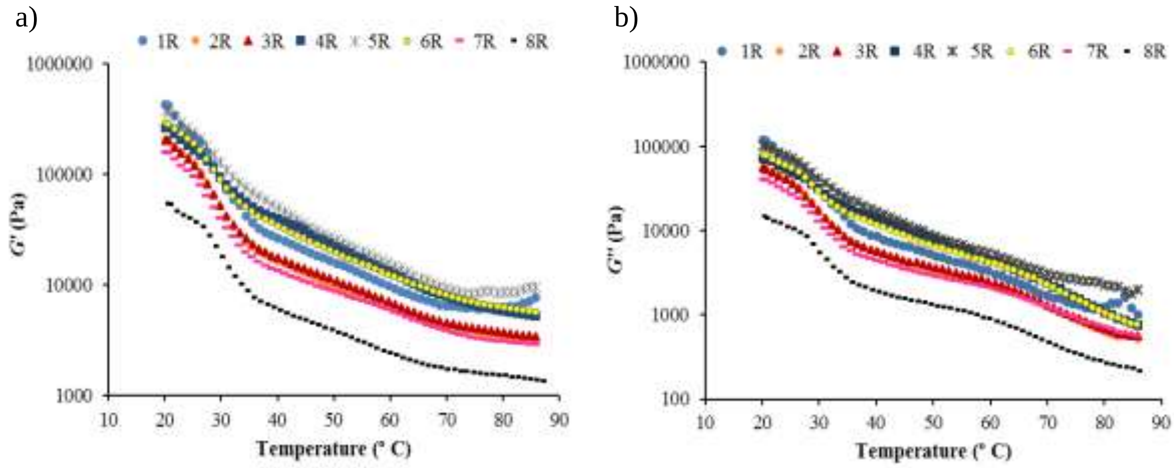

Figure 1. Thermal profile of Afuega'l Pitu samples (a) storage modulus (*G'*), (b) loss modulus (*G''*).

It was observed that *G'* decreased more remarkably up to 75 ºC, and at T> 75 ºC it decreased more slightly (Figure 1a). However, *G''* decreased almost continuously up to 90 ºC (Figure 1b). This result could be explained considering the breakage of polar interactions and hydrogen bonds in the micellar network, and at the same time the melting of the fat (20-40 °C). At high temperature the reinforcement of hydrophobic interactions could explain the minor decrease of *G'*. The greater weakness of R8 casein matrix, analysed above, was reflected in the notably lower values of both *G'* and *G''* in all temperature ranges (Figure 1), without changes in the thermal profile pattern. This thermal response was also visible in the behavior of loss factor (*tanδ*) by increasing the temperature (Figure 2), whose pattern was similar for all samples. According to the higher decrease of *G'* respect to *G''* from 20 to 35 °C, *tanδ* increased up to ~ 35 ºC (Figure 2), indicating some weakening of the overall elasticity in the protein network because of the increase in the viscous component. From 40 to 60 °C there was found a plateau zone, consequence of the similar thermal decrease of both *G'* and *G''*, which reflects the increase in the internal mobilization of the casein fragments in the micellar network (Tunick, 2010).

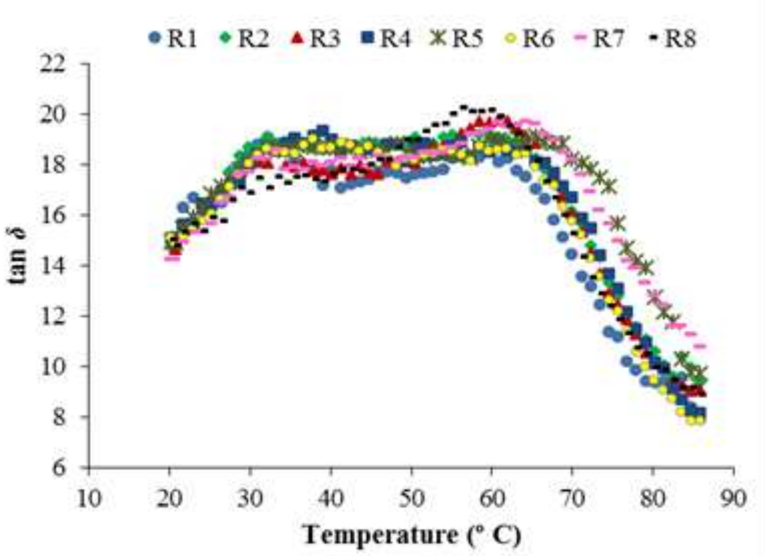

Figure 2. Thermal profile of Afuega'l Pitu cheese. Changes in *tanδ.*

Finally, from T> 60 ºC *tanδ* decreased with increasing temperature for all samples (Figure 2), indicating that the viscous component (*G''*) decreased to a greater extent than the elastic component (*G'*) (Figure 1). This fact indicates that an increase of the fluidity combined with the high hydrophobic resistance, produced a net reinforcement of the gel-like property at high temperature.

Conclusions

In general, Afuega'l Pitu cheeses exhibited a firm and low deformable texture. The moisture and fat contents were determinant to distinguish the lower conformational stability and the higher softness in the R8 micellar network comparing with R1–R7. At high temperatures all samples exhibited a notable increase in the solid-like character up to ~90 ºC, showing a peculiar heat-induced gelation, compatible with the thermal softening of the heated cheeses.

Aknowledgement

This work was financially supported by the Xunta de Galicia (Consolidation and Structuring of Competitive Research Units-Strategic Groups Mode, 2009/060). The authors would like to thank to the cheese makers of Afuega'l Pitu for their contribution to the study.

Abstract

The European eel (*Anguilla anguilla*) is of great commercial importance in Spain and Portugal, as part of their traditional gastronomy. However, it can also be found in different European areas, from Norway to the Mediterranean coast. The protein content of fish can change according to the species, sex, age, nutritional status, season, among others. Protein provides nitrogen and amino acids necessary for the synthesis of new proteins and other important compounds. In any case, fish is considered a good source of high-quality protein. This quality is measured as a function of the proportion of essential amino acids that form them. Several authors write about amino acid profiles of different species. However, there are not enough data about the nutritional value of eels. The aim of this work was to determine the amino acid composition in the muscle and skin of the European eel. All samples weighed between 10 to 100 g. The head and the thorn were removed. The skin and muscle were used to measure the protein content and amino acid profile. The protein content was assessed by the Kjeldahl procedure, and the total amino acids were determined according to Franco *et al.* (2010). Significant differences ($P < 0.001$) were found in the protein content between the muscle and the skin (19.54 ± 0.54 % and 23.42 ± 1.50 %, respectively). The major essential amino acid in both the muscle and skin was leucine. The major non-essential amino acids in the muscle and the skin were glutamic acid and glycine, respectively, and the minor amino acids were proline and methionine.

Key words: *Food composition, European eel, Protein, Amino acid profile, Nutritional value.*

Introduction

European eel (*Anguilla anguilla*) belongs to the anguilliform order. It is present in European and African rivers and oceans. Eel is a very valued fish and very important economically and ecologically. In the last decades its production decreased, because of this sometimes it get an enormous price. The populations of eel have declined and it is now classified as 'critically endangered' according to the International Union for Conservation of Nature. The composition of the fish varies between individuals of the same species. It depends on the age, sex, environment and season of the year (Ordóñez and la Hoz, 1999). The nutritional value of the fish is given by the quantity and quality of protein. It is therefore important to know the amino acid composition of the European eel. The European eel can be consumed in different forms. Sometimes, with skin and sometimes only the muscle. It is therefore important to know the composition of amino acids in both, muscle and skin.

Fish proteins have got a good nutritive value because of their content in essential amino acids. These are useful in maintaining health and prevention of cardiovascular, immune and others diseases (Venugopal, 2008). Amino acids are synthesized in the liver except the essential amino acids. These have to be supplied by the diet (Gökoğlu and Yerlikaya, 2015). Amino acids are important for the nutritional value but they are also important for sensory quality of seafood (Aristroy and Toldrá, 2009). The relationship between essential and non-essential amino acids determines the nutritional value of a food (Ibegbulem *et al.*, 2013). The amino acid content of fish has a higher nutritional value than amino acid content of beef or milk (Belitz *et al.*, 2009). European eel is a good source of glutamic acid and aspartic (Banca Dati di Composizione -BDA-, 2017; United States Department of Agriculture -USDA-, 2017). The aim of this work was to determine the amino acid composition in the muscle and skin of the European eels.

Material and Methods

Samples and analytical methods

Eels were captured in the Pontecesures region (Galicia, northwest of Spain). The eels used for this study were 10-100 g weighting. They were stored at -20 °C until their analysis. The head and the thorn were removed. The muscle and skin were analysed to measure the protein content separately. Protein content was evaluated by Kjeldahl method, according to AOAC method (Horwitz, 2000), using 6.25 as a factor to convert percent N to percent crude protein. The hydrolysis of the proteins was carried out by Franco *et al.* (2010) method. The identification and quantification of amino acids were carried out by HPLC, using the conditions described by Alonso *et al*. (1994) with some minor modifications. The conditions of the method are shown in Table 1. The liquid chromatography equipment consisted of TermoFinnigan chromatograph with UV/VISIBLE detector by photodiode matrix Spectrasystem UV6000LP. The column used was a reversed phase C18 Ultrasphere 5–ODS (diameter of 4.6 mm and 25 cm of length) from Beckman (Fullerton, EE.UU). The temperature of the column was controlled to 50 ± 1 °C with a column heater (Spectrasystem 3000). The wavelength of the detector was at 254 nm. Standards of the 22 different amino acids were supplied by Sigma Chemical Co. (St Louis, MO). All the samples and standards were injected at least in duplicate. Repeatability tests were performed by injecting a standard and a sample consecutively six times in a day. Reproducibility tests were also carried out by injecting the standard and the sample twice a day for three days under the same experimental conditions. Significant differences ($P < 0.05$) were not found between the results obtained in these tests.

Table 1. Conditions of the chromatographic method.

Time (min)	**Flow (mL/min)**	**% A**	**% B**
0.00	0.90	100	0

43.00	1.00	0	100
44.00	1.00	100	0
46.00	1.50	100	0
47.00	0.90	100	0

Statistical analysis

Mean and standard error of the mean values were determined for all the parameters and the results were expressed as mean and standard error of the mean. Analysis of variance (ANOVA) was carried out in order to compare the value of each parameter and the significance is given as $P<0.05$, $P<0.01$ and $P<0.001$. Means were compared by the least-square difference test (LSD), using the computer programme Statistica© 7 for Windows (Statsoft Inc., Tulsa, OK, USA). A factor analysis was made to obtain a reduced number of principal components to explain the variability of the selected variables. The relationship among the variables was represented by a principal component analysis (PCA). Using a new matrix of data integrated by the standardised reduced original variables, which were selected from the previous factor analysis, a discriminant analysis was developed to assess the fish according to muscle and the skin.

Results and Discussion

The Figure 1 represents the different composition of protein obtained. The major percentage of protein was found in the skin of the eel. There are significant differences between protein content of muscle and skin. The results are inside the range of normal protein content of fish. The amount of protein of the fish can vary between 12 to 23% (Badui, 2006). The results are normal for fish, being higher than other fish species like cod (Thorarinsdottir *et al*., 2002) or the sea trout (Etienne *et al*., 2000).

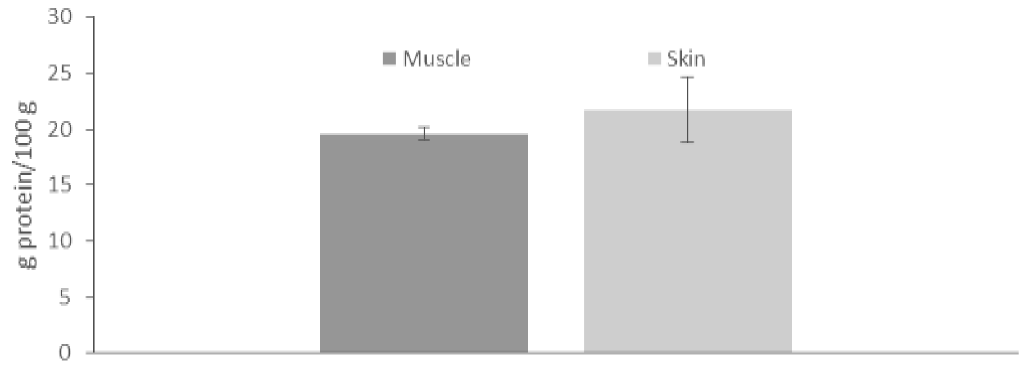

Figure 1. Protein content (expressed as g/100 g) in muscle and skin of eel.

The results, expressed as amino acid g for 100 g wet weight are shown in Table 2. Seventeen amino acids were studied in this work. The different amino acids were classified according essential or non-essential. The major essential amino acid obtained in muscle and skin eel was leucine (Leu) with 1.65 and 1.29 g/100 g, respectively. On the other hand, the major non-essentials amino acids found were glutamic acid (Glu) (2.00 g/100 g) in muscle and glycine (Gly) (2.98 g/100 g) in skin. The minor essential amino acid in muscle and skin was methionine (Met). In muscle, the minor amino acid was the hidroxyproline (Hyp). Proline (Pro) was the minor amino acid found in skin eel. There are more non-essential amino acids than essential in muscle and skin eel. The comparison between muscle and skin shows a higher content in essential amino acids in muscle than skin. Furthermore, significant differences were obtained in amino acid concentration between muscle and skin in most cases as can be seen in Table 2.

Significant differences between muscle and skin were not found for valine (Val), isoleucine (Ile), phenylalanine (Phe), aspartic acid (Asp) and proline. The hidroxyplroline was the amino acid with highest content, as it could be saw on Figure 2.

The relationship between essential and non-essential amino acids studied in this work was 0.80 for muscle and 0.49 for skin. This relation determine the nutritional value of the eel. The muscle has a better relation essential/non-essential amino acid than skin. This relation in muscle is major than in other fish species, like grey mullet (*Mugil cephalus*) or Gilthead seabream (*Sparus aurata*) (Cobas *et al*., 2016).

n.s: no significant differences. Significant differences * ($P < 0.05$) ** ($P < 0.01$) *** ($P < 0.001$). SEM: Standard Error of Mean.

With the objective of discrimination between muscle and the skin of eel, multivariate statistical techniques were applied. All variables studied were used for the analysis and a factorial analysis was previously performed to obtain the variables which contributed the most to the classification. A Varimax rotation was carried out to minimise the number of variables that influence each factor, and so facilitate the interpretation of the results. The first principal component (PC1), which explained 48.97% of total variance, was positively correlated with the E/NE relation, total esential amino acids, Tyrosine (Tyr) and Val and inversely related to Hyp, Gly and total non essential amino acids. Principal component 2 (PC2), which explained 30.81% of the total variance, was positively related to E/NE relation. Finally, a canonical analysis was developed to assess the fish units. From the data set subjected to discriminant analysis, 4 variables were retained at the end of the stepwise discriminant analysis and were linearly combined to form canonical discriminant functions. When canonical discriminant analysis was performed for their selected variables, the percentage of classification was of the 100% for all fishes. The variable with the highest discriminating power were E/NE relation.

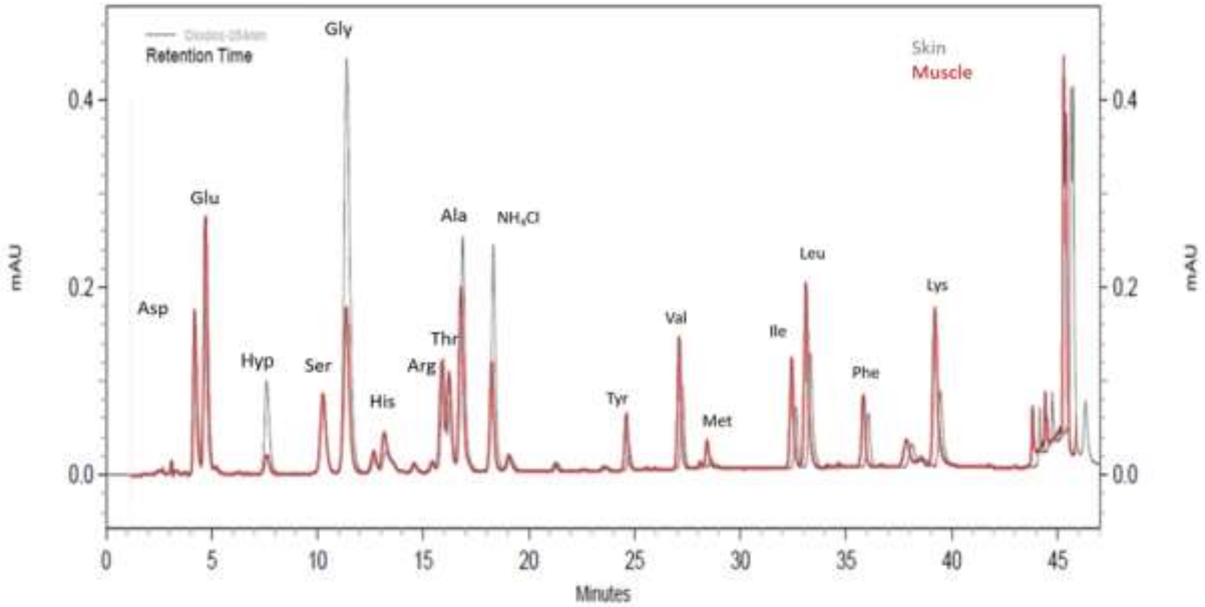

Figure 2. Chromatogram of muscle and skin eel amino acid contents.

The data obtained show that the European eel is a good source of amino acids. Even they supply the recommended daily allowance of some essential amino acids. The Table 3 describes the requirement of different amino acids and the percentage supply by eel.

Table 3. Amino acid requirements and the percentage supply by eel.

Source: Williams (2002) and World Health Organization (WHO) (2007). * Data calculated based in results obtained for male adult weighing 70 Kg. RDI: Recommended Daily Intake.

Conclusions

The results achieved in this study show that the European eel is a good source of protein. The consumption of 100 g of meat eel supplies the requirement of amino acids for histidine, isoleucine, leucine, lysine, threonine and valine. To conclude, present results indicate that European eel (*Anguilla anguilla*) is a good source of amino acid. It composition has a great nutritional value and the relation between essential and non-essential amino acid was optimum. The muscle has more content in essential amino acid than skin. The consumption of muscle and skin provides a good ingest of essential amino acid.

Abstract

Annually, around 300 tons of saffron is produced worldwide in a belt of lands ranging from the Mediterranean in the west to Kashmir in the east. Iran produces about 76% (230 tons) of the entire world production of saffron. Due to the long experience of Iran in cultivation, consumption and cultural influencing of this plant on their life; it has been used in many directions as a hair and clothes dyes, perfumes, flavoring foods, food ingredient for organoleptical properties and medical purpose for curing disease which with all specifications it nowadays called as a functional food. On the other hand, at present time one of the main areas of research in food Science and technology is the extraction and characterization of new natural food ingredients with biological activity can contribute to consumer's health as part of new functional foods. So the number of investigation that is designing on various aspects of food Science pertaining to functional foods has increased dramatically especially on saffron which is Iranian national plant. Also, in recent years there has been increased public interest in unconventional medicine such as homeopathy. At the same time, however, all countries have experienced the need to reduce public spending and cut back on expenses for a refundable treatment. As a result in this article the various researches and scientific reference will be surveyed.

Key Words: *gold plant, saffron, Homeopathy, functional food*

Introduction

The world's most expensive spice by weight is Saffron which is derived from the flower of the saffron crocus (*Crocus sativus*). Its flower bears three stigmas that are dried and used in cooking as a seasoning and coloring agent. Saffron's taste and fragrance result from the chemicals picrocrocin and safranal. A rich golden-yellow hue is produced from a carotenoid dye, named crocin, which is imparted as a dishes and textiles colorant. It takes roughly 150,000 flowers and 400 hours' work to make 2 lb (1 kg) of dried saffron, making it the most costly spice in the world.

Due to the long experience of Iran in cultivation, consumption and cultural influencing of this plant on their life; it has been used in many directions as a hair and clothes dyes, perfumes, flavoring foods (Hagh Nazari and Keifi, 2007), food ingredient for organoleptical properties and medical purpose for curing disease which with all specifications it nowadays called as a functional food.

History: The history of saffron cultivation reaches back more than 3,000 years ago. Ancient Persians cultivated Persian saffron in Derbena, Isfahan, and Khorasan by the 10th century BC. At such sites, saffron threads were woven into textiles. Alexander the Great used Persian

saffron in his infusions, rice, and baths as a curative for battle wounds. Alexander's troops mimicked the practice and brought saffron-bathing back to Greece [2].
Most saffron is grown in a belt of land ranging from the Mediterranean in the west to Kashmir in the east. Annually, around 300 tones of saffron are produced worldwide [3]. Iran, Spain, India, Greece, Azerbaijan, Morocco, and Italy, in decreasing order of production, are the major producers of saffron. Iran with its cultivation of different varieties is the largest producer of saffron with 93.7% of the world's total production [4].

Medicinal applications of saffron:

Saffron has a variety of uses in the world for healing a variety of diseases ranging from Arthritis to Impotence and Infertility. It is known to have aphrodisiac properties and is widely used in Asia and the Middle East as such. It has also been used in traditional Persian medicine to relieve stomachaches, ease the pain of kidney stones, and treat depression. Chinese and Tibetan Medicine also find many uses of this exotic herb. In traditional Chinese system, saffron was used as an agent to improve blood circulation and cure the bruise [5].
Saffron is used in Ayurveda medicine to treat conditions such as asthma, coughs, and alcoholism, acne and skin diseases. Also, in Greek medicine, it has been used in the treatment of liver, kidney and urinary infections. Saffron has been used to help cure menstrual disorders in women, to strengthen the heart and also as a coolant for the brain. Meadow saffron was used from the 2nd century BC for the treatment of joint disease and gout [6].
Ancient Romans hoped to benefit from its reputed ability to prevent hangovers by steeping the spice in their wine, or wearing it on their heads. It was also regarded to have sedative, antispasmodic, expectorant and aphrodisiac properties. Saffron was official in the pharmacopoeias of many countries in the seventeenth and eighteenth centuries, but by the beginning of the nineteenth century its therapeutic activity was beginning to be researched.

New attention to saffron:

In the last decade, much attention has been focused on the biological and medical properties of saffron and its ingredients and the most striking evidence for the written records from many countries about the use of saffron in 90 illnesses over four millennia [7].
Saffron has further medicinal applications which are derived from its chemical composition about more than 150 volatile and several nonvolatile compounds of it based on these data, It can conclude that saffron contains three main pharmacologically active metabolites: 1.) Saffron-colored compounds are crocins, which are unusual water-soluble carotenoids (mono and diglycosyl esters of a polyene dicarboxylic acid, named crocetin). The digentiobiosyl ester of crocetin - α-crocin is the major component of saffron. 2.) Picrocrocin is the main substance responsible of the bitter taste in saffron. 3.) Safranal is the volatile oil responsible of the characteristic saffron odor and aroma. Furthermore, saffron contains proteins, sugars, vitamins, flavonoids, amino acids, mineral matter, gums, and other chemical compounds [8 & 9].
The medicinal uses of saffron are diverse. Saffron extracts have shown various pharmacological properties in laboratory tests, including lowering blood pressure and heart rate, and stimulating respiration [10].
Recent scientific findings have been encouraging, uniformly showing that saffron and its components can affect carcinogenesis and currently have been studied extensively as the most promising cancer chemo preventive agents. The spectrum of tumors which saffron is against is wide including leukemia, ovarian carcinoma, colon adeno-carcinoma, rhabdo-myo-sarcoma, papilloma, squamous cell carcinoma, and soft tissue sarcoma [5].
Saffron extract has been shown capable of inhibiting and/or retarding tumor genesis in a variety of experimental models in vivo [11]. Topical application of saffron extract (100 mg/kg

body wt) inhibited two-stage initiation/promotion dimethylbenz anthracene (DMBA)-induced skin carcinogenesis and oral administration of saffron extract in the same dose restricted 20-methylchloanthrene (MCA)-induced soft tissue sarcomas in mice [12].

Saffron delayed ascites tumor growth and increased the life span of the treated mice compared to untreated controls by 45-120%. In addition, it delayed the onset of papilloma growth, decreased incidence of squamous cell carcinoma and soft tissue sarcoma in treated mice. A study indicated significant inhibition in the synthesis of nucleic acids but not protein synthesis. It appears now that saffron (dimethyl-crocetin) disrupts DNA-protein interactions e.g. topoisomerases II, important for cellular DNA synthesis [13].

The results of the study by Agha-Hosseini *et al* (2008), indicate the efficacy of *C. sativus L.* in the treatment of PMS. However, a tolerable adverse effects profile of saffron may well confirm the application of saffron as an alternative treatment for PMS. These results deserved further investigations. [14].

In recent years there has been increased public interest in unconventional medicine, especially homeopathy. At the same time, however, all countries have experienced the need to reduce public spending and cut back on expenses for refundable treatment [15]. Homeopathy is the branch of medicine which cures on the basis of similarity to the whole healthy condition of the patient, rather than addressing symptoms in isolation. It is a powerful and effective therapy, but it also demands a great deal of the patient. The patient must learn to observe areas of life which are ordinarily ignored by most people, and this observation must be done objectively and dispassionately [16].

Homeopathy is extremely effective curing. When the correct remedy is taken, results can be rapid, complete and permanent. It is completely safe. Even babies and pregnant women can use Homeopathy without the danger of side effects. Homeopathic remedies can also be taken alongside other medication without producing unwanted side effects. Homeopathy is natural treating normally based on natural ingredients. Homeopathy works in harmony with human immune system, unlike some conventional medicines which suppress the immune system. For example, cough medicines suppress the cough reflex, which is your body's attempt to clear the lungs. Homeopathic remedies are not addictive - once relief is felt, man should stop taking them. If no relief is felt, you are probably taking the wrong homeopathic remedy. Homeopathy is holistic. It treats all the symptoms as one, which in practical terms means that it addresses the cause, not the symptoms. This often means that symptoms tackled with Homeopathy do not recur.

The first law of Homeopathy is known as the Law of Similarities, or “like cures like.” This law states that “a substance that produces a certain set of symptoms in a healthy person has the power to cure a sick person manifesting those same symptoms.” The second law, or Law of Infinitesimals, states that diluting a remedy makes it more powerful [17].

Recent meta-analyses of randomized controlled trials in homeopathy have suggested that the homeopathic strategy appeared to be more medically effective and to be associated with a better quality of family life in the treatment of recurrent acute infantile rhino-pharyngitis than the antibiotic strategy incurring the Social Security significantly lower direct medical costs and producing fewer sick-leaves. Homeopathy could thus constitute a cost-effective alternative to antibiotics, providing an economical and ecological solution to public health problems caused by antibiotics (over-consumption and bacterial resistance respectively) [18].

Saffron as a useful remedy in Homeopathy

In Homeopathy saffron is used as an effective remedy for patients with symptoms similar of saffron overdose. It is a remedy often useful in Hemorrhages that are black and stringy, Tingling in various parts, Chorea and hysterical affections, Frequent and extreme changes in sensations and mental conditions, Anger with violence followed by repentance, Laughing mania, Drowsiness and Lassitude which get better by literary labor in open air, Get worsted by lying down, hot weather, warm room, in morning, fasting, before breakfast, looking fixedly at an object. Other symptoms which help to diagnose saffron needed for treating patient are:

- ✓ Vacillating; pleasant mania; sings and laughs
- ✓ Vivid recollection from music heard
- ✓ Sudden changes from hilarity to melancholy
- ✓ Happy and affectionate; then angry
- ✓ Throbs, pulsates, during climacteric; worse during menses.
- ✓ Threatened glaucoma; embolism of arteria centralis retinal.
- ✓ Sensation as if cold air was rushing through eye. Asthenopia with extreme photophobia
- ✓ Cleary neuralgia, pain from eyes to top of head
- ✓ Lids heavy
- ✓ Appearances as of electric sparks
- ✓ Must wipe eyes as if mucus or water were in them
- ✓ Feeling in eyes as after violent weeping
- ✓ Sensation as if she had been looking through too sharp spectacles
- ✓ Eyes feel as if in smoke
- ✓ Pupils enlarged and react slowly
- ✓ Vision; exertion of vision; foggy;
- ✓ Nose; nose bleed stringy blood; in hot weather,
- ✓ Strings of dark blood hanging down the nose, clotted
- ✓ Face skin discolors to pale during heat
- ✓ Abdomen as if something was in abdomen (movements, lumps, etc.) and feels movements in abdomen;
- ✓ Genitals; female; metrorrhagia (non-menstrual bleeding)
- ✓ Spasmodic contractions and twitching of single set of muscles
- ✓ Generalities; numbness; internally; in single parts

When these symptoms peculiar to the individual patient are known the homoeopathic remedy can be selected that will surely cure every curable disease, whether the disease be tumors, morbid growths, cancer or other skin diseases, or any form of chronic or acute disease peculiar to man, woman or child.

Remedy Preparation: The dried stigmas of the plant are macerated in alcohol. Remedies are made by the process of dilution and succession.
The mother tincture is usually diluted in a mixture of pure alcohol and distilled water according to one of several scales. The ratio of alcohol to water varies depending on the base substance of the mother tincture. To produce 1c potency, one drop of the mother tincture is added to 99 drops of an alcohol-and-water mixture and successes. To produce 2c potency, one drop of the 1c mixture is added to 99 drops of an alcohol-and-water mixture and successes. To manufacture the 6c potency illustrated in figure 1, this process is repeated a further four times. Once the mixture has reached the required strength and potency, a few drops of it are added to lactose tablets, granules, or powder, to impregnate them with the remedy. These are then stored in dark glass bottles.

Figure 1**:** The mother tincture dilution in a mixture of pure alcohol and distilled water according to one of several scales**.**

Figure:

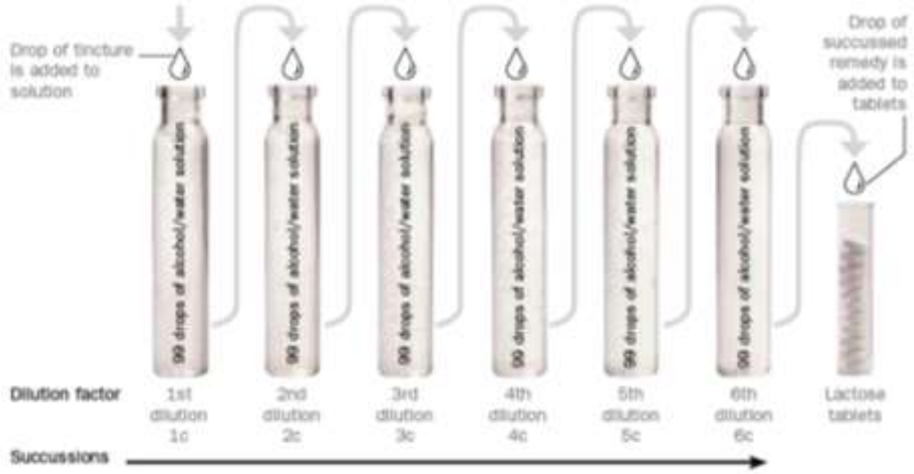

Figure 1: The mother tincture dilution in a mixture of pure alcohol and distilled water according to one of several scales

Conclusion

Saffron has a long history of use in natural medicine for example in Homeopathy. Homeopathy appeared to be at least as effective as conventional medical care in the treatment of patients.

As a summary, the range of key symptoms for which *Crocus* is generally prescribed includes nervous excitement, alternating moods, sensation as if something is moving inside the abdomen, and hemorrhages with dark, clotted, stringy blood, usually in the form of nosebleeds or uterine bleeding.

Crocus is taken for rapidly alternating mental and physical states. The nervous system is overexcited, causing mood swings and hysterical, excited behavior. The feeling that something is moving inside the abdomen may be linked to a false pregnancy. Symptoms better for open air; for yawning and after breakfast. Symptoms worse for movement; during pregnancy; with puberty, fasting and in a warm room [19].

Abstract

Perfection of the soil fertility systems under agrocenosis cultures promotes an improvement of nutrient dynamics in the soil, preservation of preserves the agronomical valuable soil aggregates, influences on structural coefficients in arable and under arable layers of soils, improve sand improves aggregate composition, by increasing a measure of the agronomical valuable aggregates. The researches in connection with the investigation of the studies on the impact of different fertilisation systems impact of fertilizer on soil the mineral part of soil present a definitely raise interest, so allow to study particularly studies on anthropogenic factors influencing on soil fertility change, as soil irrigation, cultivation, sowing of the annual and perennial fodder crops. Supporting providing favourable physical conditions in soil permits allows us to create favourable situations for preservation of agronomical valuable water-stable fine-granular structure in it of soil. So many of its quality as factors, such as water, air, biological and nutritious regimes depend on soil structural character structure providing the life living conditions of higher plants and microflora. The soil conditions side by side with the soil density and supplies of the amount of the productive moisture determine such parameters as a coefficient of structure quantity in the agronomical valuable aggregates. A totality of microorganisms, soil particles in different forms and measures more than 0,25mm forms soil aggregate compositions which that can be examined as an object, not only reflecting results of soil-forming processes, but also the man᾽s human activities on land activity. Change of in the aggregate composition and structural coefficient in the alluvial meadow-forest soils under vegetable (tomato) cultures depending on caused by different fertilizer systems showed that an application of the fertilizer organic (manure of-horned of horned cattle) systems improves improved the soil structural condition of the soil. The use of the organic-mineral (manure + nitrogen, phosphorus and potassium fertilizer) systems of fertilizers positively influence don the structural condition in of the alluvial meadow-forest soils under vegetable cultures, in comparison with the control versions variants. In the fertilizer organic-mineral fertilizer system under version of($N_{60}P_{90}K_{120}$ + 20 t/h manure), also improved the aggregate composition of the soil, i.e. an the importance, of the agronomical valuable aggregates rose on the arable and under arable layers of soil (10-0,25 mm) in comparison with the control (without fertilizer) version is accordingly till 14,1 and 9,8%. The investigations study allow us to establish the best index of improvement and preservation of ergonomically agronomical valuable soil aggregates which are revealed under the version where an the organic system of fertilizers was applied (40 t/h of manure). More over, the significance of the structure coefficient on the arable and under arable layers in the soil are equal accordingly to 1,6 and 1,4.

Key words: *soil structure, physical chemical peculiarities, nutritious regime, fertilizer, fertilizer systems.*

Introduction

A rich material of the world farming practice influences the important change of soil fertility under an impact of the organic and mineral fertilizers, irrigation and cultivation, seeding of the annual and perennial fodder plants, freshening and drainage of salinized and marshy lands and etc (Gorbileva, Lalomova, 2002; Mammadov, 2007). The soil change structure under an influence of mineral and organic fertilizers has been studied a little. An analysis of the aggregate composition the methods of the moist sift in on the sieve give very indefinite results which largely depend on growing cultures, cultivation, fertilizer application (Hummatov and Pachepsky, 1991). The numerous investigations maintain that the soil structure changes tempo and direction of the physic-chemical and biological processes in it, affects on growth character and plants development and crop quality (Mammadov, 1989), (Kachinsky, 1970; Mammadov, 1989, Guliyev, 2014). The structural soils are distinguished by the favorable physical peculiarities and good nutritional regime, the water and air easily penetrate into them (Gregory, 2006). As a result of the good water permeability the whole water falling on structural soil surface is absorbed, sucked and isn't lost (Barthes, 2002). These soils are able to provide a solid supply of water in the soil forming 80-85% of the yearly quantity of precipitations (Barber, 2000).

Material and Methods

The researches have been performed on generally accepted methods under different agrocennosis: in the apple garden and under vegetable cultures (tomato) in the alluvial meadow-forest and meadow-brown soils under conditions of the soil irrigation from Guba-Khachmaz zone of Azerbaijan. The agrotechnical measures corresponded to the generally accepted agrorules for the region (Beluchenko, 2014; Mammadov, 2016). An aggregate composition of soils by N.I.Savinov, general porosity-calculation method, specific gravity-bottle by S.I. Dolgov granulometric composition - pipette method with the application of dispergator-pyrophosphate of Na, hygroscopic moist-dried at 10^{o}C temperature. Calcareous ($CaCO_3$) - calcimetric by Sheibler's method absorbed with calcium and magnesium-"trilon B" (depletion 3n NaCl by Ivanov's method: ammiac nitrogen-by help of Nesler's reactive, by Matchigin, nitrate nitrogen, P_2O_5 and K_2O kilometric in apparatus "Palintest". The obtained materials were exposed to the mathematic processing by B.A. Dospekhov method Na+P_c, K_x were applied as mineral fertilizers (Arinushkina, 2009) The cow manure serves as organic fertilizer under 65% of moisture maintain on average 0,5% n 0,25%-P_2O_5 and 0,45%-K_2O.

Results and Discussion

At present search of the ways and methods in soil ecological functions restoration, its physical condition improvement and structural-aggregate composition which lead to the soil favorable characteristics, formation as the in- habitation environment. Optimization of the soil physical condition and namely an improvement of its structural-aggregate composition, preservation of the grain structure in chernozem is the first-degree in soil fertility at high horizons. The soils in Azerbaijan arid subtropics in limits of the Guba-Khachmaz zone are mainly used under agricultural plants, weakly provided by the main nutrient, as in alluvial meadow-forest soils-at horizons 0-115cm, a content of the mobile forms in humus, nitrogen, phosphorus and potassium varies accordingly in limits of 0,41-3,95% (humus); 0,01-0,24% (N); 0,03-0,16% (P_2O_5) and 1,43-3,66% (K_2O). At the same time these indices in the irrigative meadow-brown soils form: humus-0,64-3,12; gross (total) nitrogen 0,06-0,29; phosphorus 0,07-0,26 and potassium-1,65-3,07% on soil profile (0-115 cm) that is more in comparison with the alluvial meadow-forest soils (table 1, 2). Wholly, the investigations of the arid subtropical soils in the

Guba-Khachmaz zone are characterized as weakly provided on mobile forms content of nitrogen, phosphorus and potassium. The problems of the structure impact on soil characteristics, its fertility, and plant crop attracted the soil scientists, agrochemists and agronomists attention long since. The soil structure is formed as a result of the long active soil forming processes proceeding under some or other conditions. The soil structure develops and changes with the soil development. The research results of the agrochemical, agrophysical, chemical and water-physical parameters their productivity increase in these soils showed that it is necessary to perform the following measures; application and improvement of the mineral and organic fertilizer systems, large application in the correct crop rotation, observation of the land rational usage. The soil conditions besides soil density and productive moisture supply determine such indications as a coefficient of structure and quantity in agronomic valuable aggregates. Joint of macroorganisms, soil particles of the various forms and sizes more than 0,25 mm, form soil composition, it can be examined as an object, and the reflecting consequences aren't only soil forming processes but also the man's farming activities. Change of the aggregate composition and structure coefficient in the alluvial meadow-forest soils under vegetable (tomato) cultures and dependence on fertilizer systems (mean data for 2014-2016) is given on the table 1.

Table 1. Aggregate composition and structure coefficient in the alluvial meadow-forest soils under vegetable (tomato) cultures and dependence on fertilizer system (Guba-Khachmaz zone 2014-2016)

Fertilizer system	Fertilizer norm	Soil layer, cm	Size of the soil aggregates, mm maintain %			Structure coefficient (K)
			>10	10-0,25	<0,25	
Unfertilized (control)	------------------	0-20	0,1	53,7	46,2	1,6
		20-40	0,3	59,1	40,6	1,4
		40-60	0,4	60,2	39,4	1,5
Organic	40 t/ha manure	0-20	--	71,3	28,7	2,4
		20-40	--	67,8	32,2	2,1
		40-60	0,1	61,2	38,8	1,6
Mineral organic (joint application)	$N_{60}P_{90}K_{120}$ +20t/ha manure	0-20	0,2	67,8	32,2	2,1
		20-40	0,4	68,9	30,6	2,2
		40-60	--	63,8	36,2	1,8
Mineral organic (joint application)	$N_{90}P_{100}K_{140}$ +20t/ha of manure	0-20	0,2	66,2	33,4	1,9
		20-40	0,1	62,5	37,4	1,6
		40-60	--	58,6	41,2	1,4
Mineral	$\mathbf{N}_{120}P_{160}K_{180}$	0-20	0,4	59,4	40,2	1,4
		20-40	0,2	61,1	38,7	1,5
		40-60	0,5	57,2	42,3	1,3
SED$_{0.95}$ (the smallest essential difference)						**0,18**

An analysis of the obtained data shows that an application of the organic (cow manure) improves the soil structural condition. The utilization of the organic-mineral (manure+nitrogen, phosphorus and potassium fertilizer) systems of fertilizer positively affected the structural state in the alluvial meadow-forest soils under vegetable cultures in comparison with the control variants.

On average for 3 years under organic fertilizers application (cow manure 65% of moisture) decrease of the valuable range fraction sums (0,25-10,0 mm) at 0-60cm of soil layer where the structure coefficient (K_{st}) rose 9,1% on average in comparison with the control, accordingly

increased and formed 0,46-on control (at 0-20 cm of soil layer) 1,6 under the version with the organic fertilizers application at 0-20 cm it is equal to 2,4%.
Preservation of the unique gluey-granular structure and well-distinguishing soil clods and aggregates after water impact is the soil important function. The consequences of the water-stability definition in structural aggregates showed that the given character in soil with the application of the organic, also organic-mineral (manure-mineral) fertilizers was more than the variant control. Maintain of the soil aggregates with a quantity of 0,25mm under the control variant at 0-60 cm of layer of soil formed 42% on average, then as under the version where a system of organic fertilizers (40 t/h of manure) and organic-mineral (20 t/h of manure+$N_{60}P_{90}K_{120}$) fertilizers is applied these significances approximately formed 33%. For all that under these variants the maintain of the agronomic valuable aggregates (particle size 10-0,25 mm) gets increased. Change of aggregate composition and structure coefficient in irrigated meadow-brown soils under fruit (apple) cultures depending on fertilizer system is performed on Table 2.

Table 2. Aggregate composition and structure coefficient in the irrigative meadow-brown soils under fruit (apple) cultures depending on fertilizer systems (Guba-Khachmaz, 2014-2016)

Fertilizer system	Fertilizer norm	Soil layer, cm	Size of the soil aggregates, mm			Structure coefficient K(st)
			>10	10-0,25	<0,25	
Unfertilized (control)	--------------	0-20	2,6	52,6	45,4	1,1
		20-40	2,1	57,0	40,9	1,3
		40-60	4,3	72,7	23,0	2,6
Organic	40 t/h manure	0-20	1,8	66,2	32,0	1,9
		20-40	1,4	70,5	28,1	2,3
		40-60	3,9	67,8	28,3	2,1
Mineral organic (joint application)	$N_{60}P_{90}K_{120}$ +20t/h of manure	0-20	2,0	63,5	34,5	1,7
		20-40	1,7	67,8	30,5	2,1
		40-60	2,2	69,1	28,7	2,2
Mineral organic (joint application)	$N_{90}P_{100}K_{140}$ +20t/h of manure	0-20	1,7	61,8	36,5	1,6
		20-40	1,5	63,7	34,8	1,8
		40-60	2,6	66,8	30,6	2,0
Mineral	$\mathbf{N}_{120}P_{160}K_{180}$	0-20	2,7	50,7	46,6	1,0
		20-40	2,3	54,8	42,9	1,2
		40-60	3,8	69,6	26,6	2,6
SED$_{0,95}$ (the smallest essential difference)						**0,27**

An analysis of the obtained data shows that an application of the organic and organic-mineral systems in fertilizers in irrigated meadow-brown soils under agrocenosis positively affected the soil structural state in comparison with the control version. Maintain of soil aggregates with the size 0,25 mm under the control variant forms 46,2%, then as while the organic fertilizers (40 t/h of manure) is applied, these indices get the agronomic valuable particles rose till 71,3% at 10-0,25 mm. Under an application of the organic-mineral system in fertilizer (joint application) the maintain increase of the particle sizes is also established (10-0,25mm). Soil aggregates content (10-0,25 mm) on the arable layer is 63,5%, but it reaches 67,8%, a coefficient of these parameters structure is accordingly 1,7 and 2,1 under an application of mineral fertilizers at a norm of $N_{60}P_{90}K_{120}$+20 t/h manure (cattle) on the arable layer. An application of only mineral systems of fertilizer at a norm of $N_{120}P_{160}K_{180}$ in maintain of soil aggregates at a size of 1-0,25 mm (agronomic valuable) in comparison with the control version the positive actions aren't established, but a content of the particles with a size of < 0,25mm increases a little, that leads to the aggravation of the water-physical indications in the soils. So, the best indications of the fertilizer organic systems (cow manure 40 t/h) on maintain of the agronomic valuable particles with a size of 10-0,25 mm. Under an application of the organic systems in fertilizers (cow manure 40 t/h) the high significant on structure coefficient is established. On the arable and subsurface layers of the soils these indices accordingly form 1,9 and 2,3. If the middle maintain of soil aggregated with a size of particles is 10-0,25 mm at 0-60 cm layer of soil forms 57,6%, then these parameters are accordingly equal to 20t/h of manure +$N_{60}P_{90}K_{120}$, at 0-60 cm layer of soil this significant is equal to 66,8% on average. An analysis of these data shows that on average for 3 years while performing researches with an application of organic-mineral systems in fertilizers of the irrigated meadow-forest soils under tomato plant at the end of vegetation a quantity of the agronomic valuable aggregates (with a size of particles 10-0,25 mm) increases till 9,2%. These parameters were the best in the performed experiment. It is established that with the increase of the mineral doses and doses of organic fertilizers the maintain of soil aggregates with the particles size (10-0,25 mm) is gradually became diminished i.e. decrease fertilizer doses negatively affected the content in the agronomical valuable aggregates. The structure coefficient under the control variant (unfertilized) at 0-60 cm layer formed 1,5 on average, under an organic system of fertilizer (40 t/h of manure) the average significant (at 0-60 cm layer) was 2,03, but under the version where the organic-mineral system of fertilizer is applied, a quantity of the structure coefficient was analogical organic system of fertilizer on soil profile. Increase of the mineral fertilizer, doses and application of organic-mineral system in fertilizers under corresponding growth of the mineral fertilizer doses ($N_{90}P_{100}K_{140}$) and reduction of the organic (10 t/h of manure) fertilizers negatively affected the soil structure in comparison with the fertilizer organic system that rendered an influence on structure coefficient significant (K_{st}). On average this quantity at 0-60 cm of soil layer is 1,6. It is revealed that an application of the mineral system in fertilizer reduces the structure coefficient which reaches 1,4 on soil profile on average (at 0-60 cm of soil layer). For all that they maintain of soil aggregates with a size of particles <0,25mm rises, that aggravates the soil structure and negatively affects chemical soil environment. While studying the aggregate composition and structure coefficient in the irrigated meadow-brown soils under fruit plants the analogical consequences are obtained.

Conclusions

The best parameter of the improvement and protection in the agronomical valuable soil aggregates in the alluvial meadow-forest soil is revealed under the version where the organic system of fertilizers (40 t/h of manure) is applied. For all that a significant of the structure coefficient in the tillage and under tillage arable layers is accordingly equal to 1,6 and 1,4.
White an application of organic-mineral system of fertilizer under vegetable cultures in the variant of $N_{60}P_{90}K_{120}$+20 t/manure the aggregate composition is improved, i.e. a significant of the agronomic valuable aggregates rose in tillage and under tillage layers (10-0,25 mm) in comparison with the control (unfertilized) variant till 14,1 and 9,8%.
The structure coefficient grows under organic-mineral systems of fertilizers in comparison with the control 1,5 times approximately.
A positive influence of organic system in fertilizers on increase of soil aggregates at a size of 10-0,25 mm is established under the fruit cultures in the irrigated meadow-brown soils. The

agronomical valuable aggregates rose under an application of the organic systems of fertilizers (40 t/h) in comparison with the control one in the tillage and under tillage layers 13,55% on average.

Abstract

The paper describes testing the impact of a special herbal preparation (SHP), in the capacity of a plant growth regulator (PGR) and a mild organo-mineral fertilizer, on yield of cabbage and lettuce. Field experiment was carried in two greenhouses situated at the location Gadid in Gaza Strip, under specific site conditions - sandy soil, low organic matter content, increased concentration of salts in irrigation water. SHP was based on herbal extracts from comfrey, dandelion, horsetail, lavender, nettle, yarrow and wormwood, enriched with major macronutrients and essential micronutrients. The production trial was executed as per following conditions. There were four treatments (T_i): T1 - SHP, standard rate, T2 - SHP double rate, T3 - SHP, standard rate + NPK (25 % of commercial rate), T4 - NPK (25 % of commercial rate) and control group - NPK, commercial rate. Planting density of cabbage was 6,500 plants/dunam (1000 m^2) and that of lettuce – 7,800 plants/dunam. Experiment layout was the random block system with four replications (blocks). The achieved results had shown that it is possible to produce cabbage and lettuce on sandy soils using SHP enriched with low mineral inputs. Also, it is obvious that applied commercial production of cabbage and lettuce on sandy soils was based on the huge input of fertilizers.

Key words: *special herbal preparation, cabbage, lettuce, sandy soils, yield*

Introduction

The production of special herbal preparation (SHP) intended for commercial use in agriculture is grounded on natural raw materials – wild growing medicinal herbs. The initial set of species was determined on the bases of previous knowledge and large scale experiments under controlled conditions. In order to extract the active matter without application of chemical means, an original production process has been developed. The foundation of this process is a unique combination of water extraction and biofermentation supported by continual oxygen enrichment (Ljubojević, 2015). Subsequently, extensive field experiments have been undertaken on various agricultural crops, including cucumber, pepper and tomato in greenhouses in the south of Urals (Ljubojević and Eliseev, 2016). Original SHP was designed to act as a plant growth regulator and as an uptake improver, behaving as a kind of catalyst and an accelerator of complex relations in the plant-soil system. As such, SHP cannot provide a sufficient amount of nutrients for crops. It is only an auxiliary mean which helps existing stocks of nutrients to be of better used and faster utilized by crops. However, since the experiment is realized on sandy soil, poor with organic matter and mineral nutrients, SHP was designed to act in the capacity of a PGR and as a mild organo-mineral fertilizer. In addition, field trials were performed in stressful conditions - increased salinity of soil and water for irrigation, drought and heat. From Physiology it is known that the consequences of salinity manifest as: water potential reduction, cell dehydration and ion cytotoxicity, while the high temperatures lead to membrane and protein destabilization (Taiz *et al*., 2014). Thus, apart from analyzing yields, this paper tries to answer the question - is it possible for a SHP to positively influence plant response to stress ?

Material and method

Special herbal preparation and its production

SHP was based on herbal extracts from comfrey (*Symphitum officinale*), dandelion (*Taraxacum officinale*), horsetail (*Equisetum arvense*), lavender *(Lavandula angustifolia*), nettle (*Urtica dioica*), yarrow (*Achillea millefolium*) and wormwood (*Artemisia absinthium*) enriched with major macronutrients (N,P,K) and essential micronutrients (Mg, Fe, Mn, Zn, Cu, B, Mo). The presence of herbal extracts were the following: comfrey and nettle by 30 % each, dandelion, horsetail and yarrow by 10 % each and lavender and wormwood by 5 % each. Participation of NPK 28-14-14 was 8,4 g/l of SHP (it was used "Solinure 5" soluble fertilizer) and of micronutrients 5,0 g/l of SHP (it was used "Nutriplex Chelated Micronutrient Fertilizers"). Chemical composition of micronutrients was the following: Mg (MgO_9) – 5.43 %, Fe (EDTA) – 4 %, Mn (EDTA) – 4 %, Zn (EDTA) – 1.5 %, Cu (EDTA) – 1.5 %, B – 0.5 %, Mo – 0.1 %. SHP was produced at the Agyos Athanasios Industrial Estate, Limassol, Cyprus, according to the author's prescription (Ljubojević and Eliseev, 2016).
From the standard set of species in SHP (comfrey, dandelion, horsetail, lemon balm, nettle, yarrow and valerian) were excluded lemon balm and valerian and included instead lavender and wormwood. Previous research has shown that extract of lemon balm has significant impact on the growth of above ground portions of leafy plant (Ljubojević, 2015), so the concern was that there might be a gap between growth and the resources available. On the other hand, to raise plant tolerance to abiotic stresses, lavender and wormwood were included (based on personal findings).

Field trial

The experiment was designed by the author and was commissioned by Agronomy Services from Maccabim, Israel. Sample of SHP taken from the regular production was brought to the greenhouses in Gadid settlement in the Gaza Strip. Field trial lasted from July 7th to September 15th in year 1996 for cabbage (photo1) and from July 7th to September 15th in year 1996 for lettuce (photo 2), with single harvest for both cops. The results of the experiment were considered as a kind of trade secret and have not been published earlier.
Gadid is located in the southern part of the Gaza Strip, about 2 km away from the Mediterranean Sea. There is no surface water and the rainfall is below 200 mm (Dudeen, 2001). Soli type is Arenosolic (sandy) Rhegosol without a marked profile. The soil is poor with organic matter (o.m: 0.0 - 0.5 %) and has low nitrogen content (N as NO_3: 15 - 30 mg/kg); pH 7.3 - 7.5. Here salinity has a huge impact on the structure of soils, affecting permeability and infiltration. Saline irrigation water, low soil permeability, inadequate drainage, low rainfall, high potential evapotranspiration, and poor irrigation management all have caused salts to accumulate in soils, which deleteriously affects crop growth and yields (cit., Sparks, 1995). According to the greenhouse owners in which the experiment was realized, "this land has the only function to hold the plant upright, and nothing else."
High input agriculture, practiced in the Gadid area at the time of the experiment, led to increased and cumulative effects of chemically based fertilizers, pesticides, and herbicides. However, high sand content of the soil pertains no toxic metals in the upper layer, but there is a risk of toxic elements leaching to the groundwater (Al-Khatib and Al-Najar, 2011).

Photo1 : Experimental parcel with cabbage, variety `Tasty` (taken by S. Ljubojević)

Photo 2 : Experimental parcel with lettuce, variety `936` (taken by S. Ljubojević)

The subject of research were two types of leafy vegetables: cabbage (*Brassica oleracea* L.), variety `Tasty` and lettuce (*Lactuca sativa* L.), variety `936`. The planting density of cabbage was 6,500 plants per dunam (1 dunam = 1,000 m^2) with spacing 45 cm x 34 cm and of lettuce 7,800 plants per dunam with spacing 40 cm x 32 cm. There were four treatments and a control group.

Treatments (T_i) were as follows:
T1. SHP, standard rate
T2. SHP, double rate
T3. SHP, standard rate + NPK
T4. NPK, at a concentration of 25% of the commercial input
Control: NPK in the commercial concentration.

Compared to the classic experimental design, the control group was not with zero inputs, due to the specific conditions of the environment, in which plants would have poor opportunity for growth and development. Instead, an agrotechnic that is applied in regular (commercial) production was taken as a rapper.
Treatments T1-T4 were applied by direct drench of the root system once a week, while in the control group NPK was injected through drip irrigation system during the entire week 3-4 times a day; fertilization inputs are given in table 1. Each treatment was repeated four times with random allocation on 20 m^2 rectangular sample blocks. From each sample block 40 heads for weighing were taken, in a systematic manner, given a total of 160 head for each species.

Table 1: Fertilization inputs

Treatments	Cabbage			Lettuce		
	SHP	NPK (7:3:7)	Number of applications	SHP	NPK (7:3:7)	Number of applications
	liters/dunam per season			liters/dunam per season		
T1	**8,5**	**-**	**7**	**8,5**	**-**	**4**
T2	**17.0**	**-**	**7**	**17.0**	**-**	**4**
T3	**8.5**	**950**	**7**	**8.5**	**430**	**4**
T4	**-**	**950**	**7**	**-**	**430**	**4**
Control	**-**	**3.800**	**many(*)**	**-**	**1720**	**many(*)**

(*) During the whole week 3-4 times a day

At this point it should be emphasized that during the application, treatments with SHP were somewhat unequal in relation to the control group because its NPK was continuously applied through microfertigation and SHP only at certain moments. According to the contractor's explanation, this was done on the concern of clogging of the drains/sprinklers, despite the assurance that each drop of SHP was filtered to 80 microns.

Results and discussion

The average weight of fresh cabbage head is convincingly the largest in the control group, benefiting from a huge input of fertilizer. At a given density of 6,500 plants per dunam, the expected yield is 71.5 t/ha, which is considered to be a very high yield in world relations (Sadowski and Kole, 2011). Double dose SHP (T2) achieved a solid yield of 29.9 t/ha and was significantly higher than treatment with NPK (T4). The standard dose SHP (T1) also achieved a solid yield of 26 t/ha. In both treatments with SHP, lower variability (lower C.V.) was observed in relation to the treatments with NPK (T3 and T4). The comparison of T1 and T3 treatments suggests that there was no increase in the average weight of fresh cabbage head in spite of the additional NPK imputations. Aforementioned can be explained by the discontinuous way of application, when plants, due to the poor retention capacity of sandy soil, are unable to use all that is provided through drench. Plants in the control group did not have such problems since they were continuously supplied with mineral substances dissolved in irrigated water. No signs of drying or damage to disease and pests have been registered during the experiment with cabbage.

Table 2: Cabbage performances

Parameters	Treatments				
	T1	T2	T3	T4	Control
Average weight of fresh head (g)	400	460	370	320	1100
Standard deviation (+/- g)	110	130	120	100	170
C.V. (%)	27.5	28.3	32.4	31.2	15.4
F-test	↗ 95 % $F_o = 96.68 > F_1 = 3.06$ ↘ $n_1 = 4$; $n_2 = 15$				
LSD (0.05)	98.9 g				
Expected yield (t/ha)	26	29.9	24	20.8	71.5

The average weight of fresh lettuce head is also the largest in the control group, but the differences compared to the treatments are less pronounced than to cabbage. In a given density of 7,800 plants per dunam, the expected yield is 42.9 t/ha, which is considered to be a good yield in world relations (Simko *et al*., 2014). Double dose SHP (T2) achieved a solid yield of 25 t/ha and was significantly higher than the NPK treatment (T4). The standard dose SHP (T1) also achieved a solid yield of 21.1 t/ha. In the double dose treatment of SHP, there was a lower variability (lower C.V.) in relation to treatments T1, T3 and T4. The comparison of T1 and T3 treatments suggests that there was no increase in the average weight of fresh lettuce head in spite of the additional NPK imputations. Full explanation of this has already been given to cabbage. No signs of drying or damage to disease and pests have been registered during the experiment with lettuce.

Table 3: Lettuce performances

Parameters	Treatments				
	T1	T2	T3	T4	Control
Average weight of fresh head (g)	270	320	270	210	550
Standard deviation (+/- g)	85	85	85	80	50
C.V. (%)	31.5	26.6	31.5	38.1	9.1
F-test	↗ 95 % $F_o = 17.15 > F_1 = 3.06$ ↘ $n_1 = 4$; $n_2 = 15$				
LSD (0.05)	96.2 g				
Expected yield (t/ha)	21.1	25.0	21.1	16.4	42.9

Conclusions

The results of the experiments show that the organo-mineral variant of SHP can be easily used in the production of leafy vegetables on sandy soil, under the low input agriculture. By applying only about 2.6 and 2.2 ml of the means per plant and season, without side assistance except watering, cabbage yields of about 30 t/ha and lettuce of about 25 t/ha can be achieved. No signs of drying or damage to disease and pests have been registered during the experiment with leafy vegetables, which means that abiotic stresses did not limit crop productivity and that selected SHP have been shown to mitigate unwanted phenomena. Experiences from other experiments indicate that even better results could be achieved with the foliar application of SHP or by microfertigation. Also, it is apparent that applied commercial production of cabbage and lettuce on sandy soils (control group) was based on the huge input of fertilizers – 3,800 liter of NPK (7-3-7) per dunam of cabbage in a growing season of 65 days, and 1,720 liter of NPK (7-3-7) per dunam of lettuce in just 30 days of growing season. In other words, for one head of 1,100 g of cabbage, 585 ml of NPK is consumed, and for one head of 550 g of lettuce 220 ml of NPK. If we put aside the direct threat to a groundwater contamination, the question arises - who really needs such “fresh, crunchy green vegetable”.

THE EFFECT OF APPLYING A TARGETED POLICY FOR DEVELOPMENT OF ORGANIC FARMING IN BULGARIA

Monika SABEVA*

University of National and World Economy (UNWE), Sofia, Bulgaria
*Corresponding author: monikasabeva@abv.bg

Abstract

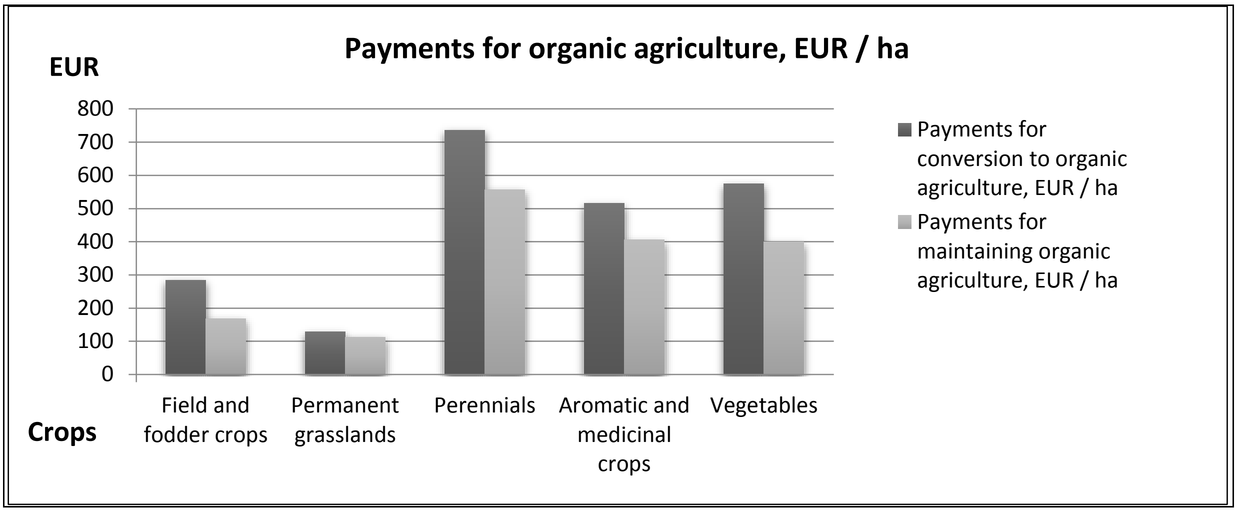
Organic farming is an important priority for agriculture policy in Bulgaria and one of the key components of the Common Agricultural Policy (CAP) for the period 2014-2020. Encouraging farmers to switch to or to maintain organic farming contributes to both: (a) conservation environment – strengthening agro-ecosystems, protect biodiversity and enable future generations to benefit from the preserved nature; (b) production of healthy food – this form of agriculture meets the needs of the growing number of users because it uses safe and transparent methods of production; (c) social impact – creating rural employment and more jobs compared to conventional agriculture. In recent years, the awareness of consumers about the qualities of food products they consume and for the environmental protection is increasing. This leads to increased demand for organic products. The growing demand for organic agricultural production requires the introduction of specific policy measures to support and facilitate organic farming. The main objective of the paper is to analyze the overall impact of the implementation of policy measures targeted to stimulate organic production in Bulgaria in last ten years.
Keywords: *organic farming, Policy measures, CAP, Bulgaria*

Introduction

Practices of organic farming have low impact on the environment, as they avoid or drastically restrict the use of synthetic chemicals, which leads to reducing pollution of soil and water resources and the pressure on biodiversity. This improves the state of ecosystems, animal and human health, increases revenue generated, and the self-confidence of communities (Ordinance No. 1, 2013; Ordinance No. 22, 2001; Regulation (EC) No 834/2007). In Bulgaria the first steps for development of organic farming date back to the 60s years of 20th century, but only in the last 15 years the interest in this type of production has increased. The first systematic studies of the possibilities for substitution of chemical agents in agriculture date back to 1965, when in the Institute for Plant Protection the first section for exploration of biodiversity of agro-ecosystems was established (NPDOP, 2004). However, until the end of 2004 no financial support was provided to organic farmers in Bulgaria. The actual efforts to support organic farming start with the preparation of the National Plan for Development of Organic Production (NPDOP), which is in accordance with the European Plan for Organic Food and Agriculture of 2004 and was in place until 2013 (NPDOP, 2004). Organic farming is an important priority for agriculture policy in Bulgaria and one of the key components of the Common Agricultural Policy (CAP) for the period 2014-2020. Encouraging farmers to switch to or to maintain organic farming contributes to both: (a) conservation environment – strengthening agro-ecosystems, protect biodiversity and enable future generations to benefit from the preserved nature; (b) production of healthy food – this form of agriculture meets the needs of the growing number of users because it uses safe and transparent methods of production; (c) social impact – creating rural employment and more jobs compared to conventional agriculture (RDP 2014-2020). In recent years, the awareness of consumers about the qualities of food products they consume and for the environmental protection is increasing. This leads to increased demand for organic products. The growing demand for organic agricultural production requires the introduction of specific policy measures to support and facilitate organic farming. The **main objective** of the paper is to evaluate the overall impact of the implementation of policy measures targeted to stimulate organic production in Bulgaria in last ten years.

Materials and methods

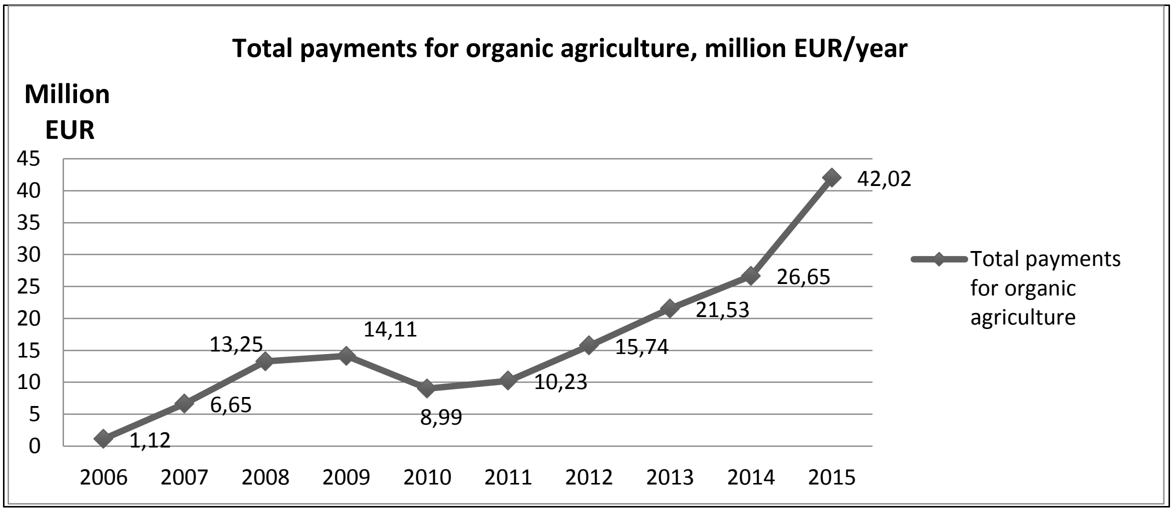
The paper is based on thorough review of reports, analysis and official documents as Agrarian reports, Rural Development Programs (RDPs), the National Plan for Development of Organic Production (NPDOP) , regulations and statistical data relating to organic farming and agricultural policy in Bulgaria. Organic production is a new branch of agricultural production and time series related to it are missing. There are data for the last 15-16 years but we can not rely on an exhausted statistical data panel. Thus the analysis is based on n available official documents and statistical information provided by the Ministry of agriculture and forestry. Data related to changes in size of areas with organic crops (as a % of UAA and as a total area), in number of operators and in total annual payments for organic farming were reviewed and, on that basis, the main effects for this sector are indicated. In the last years, organic farming is one of the sectors that is rapidly developing, as the areas and the number of operators involved in a control system are constantly increasing. This is what the targeted government policy for the sector contributes to. After the entry into force of The National Plan for Development of Organic Production (NPDOP), the targeted support of farmers applying the practices of organic farming begins. The NPDOP has 5 strategic objectives: (1) Development of the market of organic products; (2) 8 % utilized agricultural areas (UAA) to be managed organically by 2013; (3) Establishing an effective regulatory framework for the development of organic farming by 2007; (4) Practice-oriented research, educational, training and consulting activities in the field of organic farming and (5) Establishing an effective system of control and certification. For their implementation, annual financial support is provided, as for the period 2006-2013 a total of 164 544 000 BGN or 84 036 772 EUR are paid (NPDOP, 2004). The support for organic farming under the Rural Development Program 2007 – 2013 is a part of Measure 214 "Agroecological payments", aimed at supporting organic plant growing and organic beekeeping. The measure has a total budget of 435 340 701 BGN or 222 339 479 EUR (RDP 2007-2013). The reformed CAP, applicable after 2014, includes new or revised measures for support which would be applied to organic farmers. It is foreseen that 30% of the direct payments will be allocated to the so-called "green direct payments" (Regulation (EU) No 1307/2013, Article 9). During the current programming period 2014-2020, under the Rural Development Program the support for organic farming will be provided by a separate measure (Regulation (EU) No 1307/2013, Article 9) – Organic Farming comprising two sub-measures (1) Payments for conversion to organic farming per hectare UAA and (2) Payments for maintaining organic farming per hectare UAA. The support is provided under the form of annual payments per hectare of UAA (Agrarian Reports, MAF, 2013, 2014, 2015). For the current programming period payments for organic farming are provided for 5 groups of crops: (1) field and fodder crops; (2) permanent grasslands; (3) perennials (orchards and vineyards); (4) aromatic and medical crops and (5) vegetable crops from open areas (Graph 1) (RDP 2014-2020).



Graph 1: Payments for organic agriculture, (EUR/ha)
Source: RDP 2014-2020

Results and discussion

The total payments for conversion to or maintenance of organic farming are calculated in euro on the basis of data for the annual payments under the NPDOP and data for payments per hectare by crops under the RDP 2014-2020 and the Annual Agrarian Reports of MAF. On this basis, the following values were obtained (Graph 2):



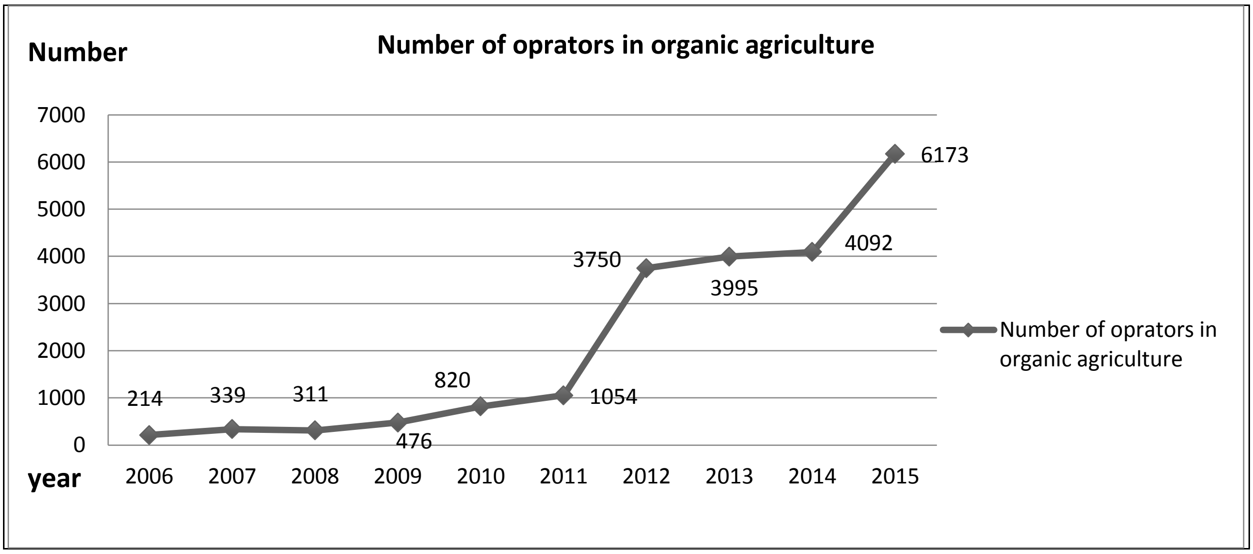
Graph 2: Total payments for organic farming, (Million EUR/year)
Source: Adapted from data from the NPDOP, 2004 and Annual Agrarian Reports, MAF, 2006 – 2016

The data indicate that for the considered period, **one of the first effects** of implementing the targeted measures is that payments for organic production are constantly growing, with the exception of the period right after the beginning of the economic crisis, but after that the trend of growth remains. This is a result of the state's clear willingness to support the development of the sector, which in turn would contribute to the overall improvement of environment and improvement of the quality of life in the rural areas of the country.

The total annual payments for organic farming increased from 1,12 million EUR in 2006 to 42,02 million EUR in 2015, which is over 35 times increase for the period. As a result, by the end of 2015 the number of operators in organic farming, the size of areas in the control system and the species diversity of organically grown crops are constantly increasing.

The second effect of the targeted state policy to support organic farming is that the number of registered operators (producers, processors and traders) in the control system for 2006-2015 also marks a significant increase (Graph 3) – from 214 in 2006 to 6173 in 2015. This indicates that the number of registered operators in the control system has increased over 25 times over the period.

The number of operators almost stagnate between 2012 and 2014 as this is the transition period between two planning periods. This phenomenon is observed and could be traced in years before. During this time, no new calls were announced and open, consequently no possibilities for producers to diversify the funding portfolio and to enter in new areas like organic production.

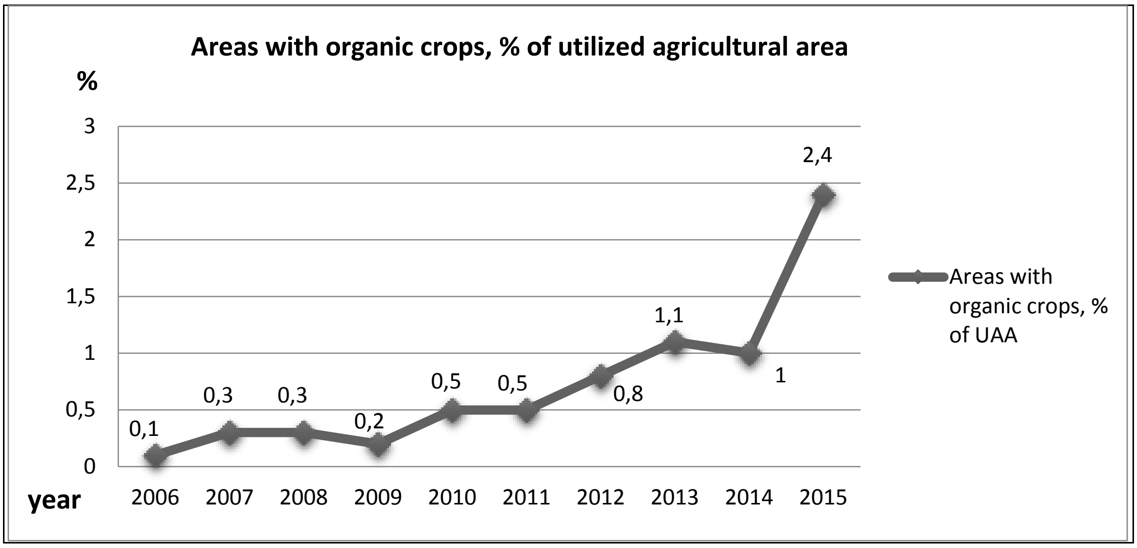


Graph 3: Number of registered operators in the control system of organic farming (producers, processors and traders, incl. subcontractors)

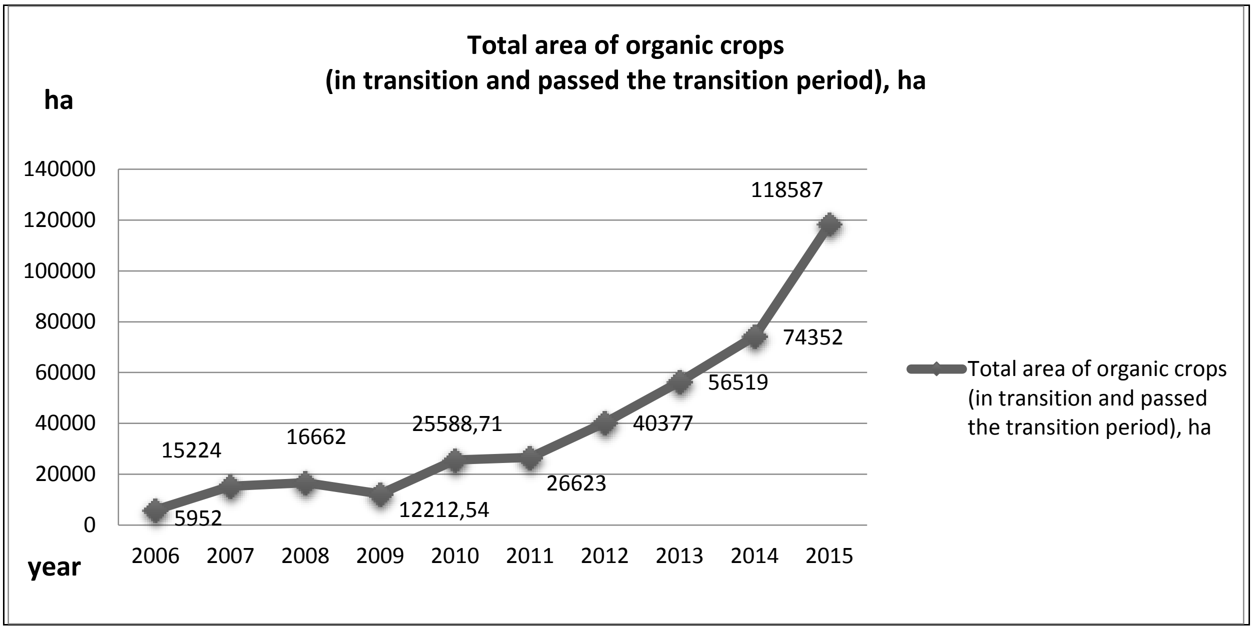
Source: MAF, based on data from the annual reports of the controlling authorities of organic production, 2006 – 2016

The third effect of the measures applied is the constant growth in the size of areas (in % of UAA and in absolute value) occupied by organically grown crops (Graphs 4, 5).

At the beginning of the period, the areas occupied with organically grown crops are 5952 ha, which is only 0,1% of the country's UAA. By the end of 2015 they have increased to 118 587 ha or 2,4% of UAA.



Graph 4: Areas with organic crops, % of UAA
Source: Eurostat



Graph 5: Total area of organic crops, ha
Source: MAF, based on data from the annual reports of the controlling authorities of organic production, 2006 – 2016

Conclusion

Bulgaria has favorable opportunities for developing organic farming and taking a decent place in the still unsatisfied market niche of organic products in the EU and in the world. The targeted policy of the government over the last decade to support organic farming, in line with global efforts contributes to developing of the sector at a rapid pace. Annual payments for the period 2006-2015 increase more than 35 times. There is also a tendency of increasing in both the number of operators and in the areas and the number of animals involved in the control system. Organic production has grown significantly over the period 2006-2015. It is still oriented mainly to export of raw materials, due to poor development of both the market of organic products and the processing facilities in the country. Increasing the share of organic farming will reduce the use of mineral fertilizers and pesticides and will reduce water pollution. This in turn contributes directly to reducing the pressure on the environment – stabilizing ecosystems, preserving and restoration of natural resources, development of rural areas and preventing land abandonment. Organic farming also leads to stabilizing farmers' incomes by entering new, emerging and developing markets for healthy food products. The main problems of organic production are associated with lower yields and high production costs, the lack of specialized equipment to maintain soil fertility and the low cost of products in transition.

EVALUATION OF GENETIC POTENTIAL FOR ENVIRONMENTAL PLASTICITY OF MALTING BARLEY BREEDING LINES

Marina MARCHEVA*, Silviya VASILEVA, Nevena GANUSHEVA

Agricultural University, Dept. Genetics and Plant breeding, 12 blvd., Mendeleev, 4000 Plovdiv, Bulgaria

Abstract

Climate changes impose different environmental stress, which limits plant's growth and development, the formation of yield and quality of production. Lack of sufficient moisture and lower temperature during the crops vegetation are more challenging and requires the establishment of stress-tolerant varieties with high quality and yield. Evaluation in field condition of the reaction to different abiotic stress factors is sometimes difficult due to the lack of such. Therefore, application of reliable laboratory methods for quick screening of a large amount of breeding materials on these indicators is necessary. The cold and drought resistance of 15 high yielding two-row barley breeding lines has been investigated in laboratory conditions. The laboratory trials have been conducted in Agricultural University of Plovdiv, Bulgaria by express methods of Bozhanova (1997) and Bates (1973). The evaluation of shoot and root response to osmotic stress and low temperatures as well as the accumulation of free proline in stressed young plants allows the identification of the most adaptive genotypes to unfavorable abiotic factors. The stress reaction of breeding lines 5, 13 and 45 defines them as the most cold resistant and drought tolerant, and therefore suitable germplasm in new breeding programs of winter barley.

Keywords: *Cold resistance, Drought tolerance, Malting barley, Osmotic stress, Plant breeding.*

Introduction

Barley *(Hordeum vulgare* L.) is one of the main cereal crops worldwide next to the wheat, rice and maize. It is one of the multipurpose plants suitable for human food and animal feed, primary ingredient for beer and whiskey production. Barley has been cultivated for a long time in various soil and climate conditions and has been proven as the most tolerant to drought and salinity stresses among the cereals (Bornare et al., 2012). Despite this plant's growth and development, the yield stability and quality of production have been limited in the last decades by climate changes. Winter air temperatures below -16^{0}C to -18^{0}C and reciprocal raising back with amplitude more than 20^{0}C can be very risky for winter survival of the crop. Even with normal hardening in the early winter, modern barley varieties hardly survive temperatures below 14^{0}C at the tillering node for 24 hours without snow cover. Frost injury in barley fields is common problem for grain producers in Europe. Increasing the winter survival skills by improving the cold tolerance is still one of the main challenges for barley breeders (Marcheva and Koteva, 2014).
The lack of available water for the plant during the stages of its development remains a major limiting constraint to its productivity. Drought escape and drought avoidance are related to early maturity and maintenance of relatively high tissue water potential in poor soil humidity percentage. Survival of water deficit condition with low tissue water potential of the plant is referred as drought tolerance. It can be estimated by various physiological and biochemical

traits as proline content, soluble carbohydrates, transpiration efficiency; and morphological traits as leaf and root emergence and development, waxiness, stomatal density etc. However, the primary parameters for drought tolerance are grain yield and its stability in stress conditions. Selection on this criterion can be made under favorable or drought conditions using indices as stress tolerance index, yield stability index, and geometric mean productivity (Sio-Se Mardeh et al. 2006, Khalili et al., 2016). In the earlier stages of barley breeding evaluation of large collection of genotypes with small sets of seeds, requires reliable, quick, easy to perform and repeatable laboratory method which results represent the reaction of the adult plant in field stressed condition. Optimizing the early selection of breeding lines with good tolerance to abiotic stress factors is a precondition for improving the environmental plasticity of the next generation malting barley varieties (Blum, 2005).
The climate changes in Bulgaria imposed the necessity of breeding high yielding and adaptive to various environments genotypes. The weather conditions in the last vegetation seasons were relatively good for barley production and no risky low temperatures of droughts were presents, so breeding for abiotic tolerance was impossible in field trials. The aim of this study is quick screening by laboratory methods of the genetic potential for cold and drought resistance of malting breeding lines.

Materials and methods

The investigation is part of a large-scale project of plant breeding of malting barley. Fifteen breeding lines (BL) of *Hordeum vulgare ssp. distichum L.* with genetically distant pedigree, created in the Department of Genetics and Plant breeding of Agricultural University Plovdiv in Bulgaria, have been evaluated in order to determine the genetic potential for yield and ecological plasticity. The genotypes are winter type, 2 rowed, awned, husked, with good productive tillering, medium height of the stem with good lodging and shattering resistance (unpublished data). Five of them have stable and higher yields of grain than the standard variety Obzor (unpublished data). The lack of limiting environmental factors as low temperatures and drought during the vegetation period of barley in the project duration imposed the necessity of laboratory testing under controlled conditions. It has been proven reliable correlation in barley plant response to stress at shoot stage and adult plant (Marcheva and Koteva, 2014). The laboratory trial has been conducted in 2015 at the laboratory of the Department of Genetics and Plant breeding of Agricultural University - Plovdiv. Each accession has been cultivated in four replicas, each with 30 seeds, under stress and with standard conditions. As a standard is used Obzor variety (one of the official standards for 2-row winter barley in Bulgaria) with cold resistance and winter hardiness group 3 by International scale Seeds were with similar size and were collected above sieve 2.0 mm. They were soaked with distilled water and let to germinate at 24^0C for a week. The cold resistance has been estimated as depression in the length of shoot and roots at the plantlets, transferred at 8^0C for a week (Bozhanova and Petrova, 2000). The control has been maintained at 24^0C. The osmotic stress tolerance evaluation is made on the bases of the shoot and root length depression after one-week cultivation on 1M solution of sucrose. The control is cultivated on distilled water. Coefficient of depression of shoot and root development has been calculated by the formula of Blum et al. (1980) as $D_{\%} = [(A-B/A] \times 100$, where A is average shoot/root length in control at 26 ^{0}C, - B is average shoot/root length in stress at 4^0C. The accumulation of free proline by Bates (1973) in barley plants, cultivated in osmotic stress conditions has been estimated. The coefficient of increase (I) is calculated as $I = A * 100/B$, where A is the proline content in control plant, B is the proline content in plants, cultivated under osmotic stress.
Results are analyzed by dispersion analyses.

Results and discussion

The mild winter conditions and relatively favorable temperatures and soil humidity during the vegetation period of malting barley in three successive years of our project didn't cause any injuries of frost or drought stresses. In field trials winter survival of all breeding lines was excellent and any selection on this criterion couldn't be implemented. Drought tolerance also couldn't be evaluated in field plots in any of the years and laboratory testing of the reaction to both factors was necessary.

In our previous researches (2013 and 2014) and in many others scientific publications (Marcheva et. al., 2013; Moud and Maghsoudi, 2008) correlation of young plants reaction to low temperatures in laboratory conditions with their cold-resistance in bigger plots, cultivated in field conditions has been proven. Roots and shoots length depression of 2-row winter barley genotypes is stronger in more adaptive genotypes to the decreasing temperatures in the late autumn which stop their vegetation quickly in order to prepare for the coming winter weather. The analyze of results, obtained from the experiments conducted in the Laboratory of Genetics and Plant breeding Department, reveals serious differences regarding this indicator (Table 1). Generally, the roots reaction to low temperatures is slower than the shoot and the length decrease of the upper part of the plant is expressed more clearly in all of the observed barley breeding lines. The depression of the standard variety Obzor for root and shoot length is 11.6% and 38.3% respectively. Stronger depression of the length of the roots is observed in 4 breeding lines and for the shoots length – 7 lines. In most control plants from each genotype, cultivated in 24^{0}C, the ratio between roots and shoots length is close to 1, with the exception of lines 17 (the length of the roots exceeds the shoots one), 29 and 77 (with more developed upper part of the plant). After cultivation for a week under temperature stress, the ratio of the roots to the shoots lengths is changed and its values are stable above one. The low-temperature protection mechanisms of the studied two-row winter barley breeding lines at this level are expressed in a strong delay in the development of the upper part of the plant and a slower decrease in root growth. By this indicator, breeding lines 5, 13 and 45 can be distinguished as the most responsive to low temperatures stress.

Statistically significant differences: GD 5% - *, GD 1% - **, GD 0.1% - ***

Unlike the temperatures stress reaction in the osmotic one, it is evident that the individual part of the young barley plantlets reacts in a similar way and the ratio between the root lengths and the growth rate are kept close in the control and stress scenarios. In almost all accessions, except for breeding lines 5, 11 and 17, the upper part of the plants slightly exceeds the underground in both variants. Cultivation under osmotic stress slows the growth the standard variety Obzor by 20.2% and 18.5% of roots and shoots respectively. The significant difference is roots depression is marked for 8 genotypes, and for shoots – 9 genotypes. The smallest depression in the development of all plant shows genotypes which are tolerant to water deficit. Breeding lines 5, 13, 33 and 45 can be outlined as such (Table 2).

Another biochemical trait for estimation of drought tolerance is accumulation of free proline in plants cultivated under water stress. On drought, the increase in the amount of stress proteins in plant cells can reach up to 100 times. Due to their hydrophilic groups, the proline can bind to the hydrophilic residues of the proteins and form aggregates that are hydrophilic colloids. Thus, it acts as an osmotically active substance, favoring the retention of water in the cells, while protecting the proteins from denaturing. Additionally, it also appears as an organic nitrogen reserve to overcome the effects of drought.

In a laboratory test carried out in December 2014 at the Department of Plant Physiology and Biochemistry in Agricultural University Plovdiv, the measurement of free proline content (Bates et al., 1973) was determined in young barley plants placed under osmotic stress conditions. In winter barley breeding lines, its content varies widely in both control and stress conditions (Table 3). The genotypes studied have a different response to applied stress, with levels of free proline changing in a different way. The control plants of line 18 have nearly three times more proline in their leaves compared to line 23 and twice then the standard variety Obzor. On osmotic stress BL18 increases the synthesis of this amino acid only 7 times. For comparison, in the stressed plants, the majority of the samples recorded values exceeding 13 to 37 times those of the control variant from the same genotype. Six of our breeding lines have bigger increase of free proline content in stressed plants than the standard Obzor. The response of lines 5, 13 and 45 on this indicator is particularly strong and determines them as drought-tolerant and suitable for inclusion in selection programs in this direction.

Table 3. Free proline content in two-row winter barley breeding lines (BL) cultivated under osmotic stress in laboratory conditions, compared with standard variety Obzor (St).

Proline content, μg/g FW				Proline content, μg/g FW			
BL	Control	Osmotic stress	I*	BL	Control	Osmotic stress	I*
St	67.3	1535	23	24	54.5	417	8
5	67.4	2947.1	**44**	29	49.7	872.1	18
11	61.3	1843.5	30	31	57.5	1573.6	27
13	58.1	1924.5	**33**	33	84.6	1668.3	20

18	**119.8**	850.8	7	47	87.6	670	8
23	46.1	603.8	13	77	82.5	1042.8	13

* The coefficient of increase (I) is calculated as I = Control * 100/Osmotic stress.

Conclusion

Analyses of date from laboratory testing of cold resistance and drought tolerance in quick screening methods of Bozhanova (2000) and Bates (1973) of 15 breeding lines of 2-row winter barley *Hordeum vulgare ssp. distichum L.* emphasizes the good genetic potential for ecological plasticity of three genotypes – BL 5, BL 13 and BL 45. Also taking into account other results of the studies of the elements of the productivity, disease resistance of productive potential under different environmental conditions, we can distinguish these genotypes as suitable for further breeding studies.

Acknowledgement

Financial support from the by Scientific research center of the Agrarian University - Plovdiv of the project "Plant breeding evaluation of the genetic potential of productivity and ecological plasticity of 2-row barley breeding lines in accordance with the global climate changes" is gratefully acknowledged.

Abstract

Acceptance of technology innovations is complex issue. Moreover, there is little known on farmer's perceptions and attitudes towards acceptance of organic agricultural practices. This paper investigates the behavioral drivers of farmers with respect to the adoption of organic practices by comparing conventional and organic farmers. The attitudes of farmers in relation to adoption of organic farming practices are examined by comparing Turkish organic (N=131) and conventional (N=144) growers. The modified model from related models which are proposed in the context of the study has adapted and used to enhance a comprehensive analysis of the farmers' adoption decisions. The partial-least squares-structural equation modelling based multi-group analysis was performed in order to investigate group differences. The estimation results showed significant differences between the groups. The group comparison indicated that perceived output quality, perceived costs, and perceived usefulness have influences on the attitudes of farmers' decisions with respect to organic farming practices.

Keywords: *Adoption, organic farming, attitude, adoption, partial least square, structural equation modeling*

Introduction

Individual's adoption behavior is considered as an important parameter to accept new technologies. In addition to the adoption theory by Rogers (1983), behavioral approaches have also been investigated for analyzing adoption processes. Whereas the studies based on Rogers' adoption theory dealt with the technical view, behavioral research approaches focus on unobservable determinants of adoption. From the latter perspective, the most popular theoretical approaches are known as Theory of Reasoned Action (TRA) (Ajzen, 1991) and an extended version of the Theory of Planned Behavior (TPB). The TPB, developed by Fishbein and Ajzen (1975), consider the impact of subjective norms, attitudes, and perceived behavioral control on the intentional and observable characteristics towards adoption of an innovation. There have been vast studies explain adoption process with TPB (Herath and Wijekoon, 2013; Hattam, 2006). However, several difficulties in applying TPB and explaining the behavioral drivers directed researchers to apply different models to understand farmers' perceptions and attitudes on the organic production and certification system, such as Technology Acceptance Model (TAM) (Davis, 1989), as it is a well-known modification of the TPB and TRA models (Jahn and Spiller, 2005; Schulze et al., 2007).

An extensive organic conversion literature also addresses the motivational aspects such as financial motives, farming related motives, as well as personal motives. For instance, some adoption literature led to a general outcome that financial motives such as price premiums, subsidy payments, cost saving are the main reasons for farmers to convert to organic agriculture (Vogtmann et al., 1993). However, studies advise caution against generalizations on the economic reasons in conversion decision, since much research identified non-profit aims and the importance of other motivational factors (Fowler et al., 2000; Offermann and Nieberg, 2000).

Understanding factors influence adoption, in terms of acceptance of a new technology, has been a long-standing issue in agricultural economics and social development research. The wide range of studies on the farmers' decision making attitude shows that it is still challenging to understand concept of technology adoption. This may get more complex in developing countries, since many farmers have been scaled as small adopters (Herath and Wijekoon, 2013). Therefore, the concept of farmers' attitude and intentions is an important research area in agricultural literature. On the base of this literature background, we suggest that innovations can be adopted more easily if they correspond not only with the financial, economic and demographic factors, but also link to the main aspects of the farmers' perception and their attitudes. In this respect, it has an essential role to understand farmers' intentions towards organic farming.

The present study is designed to examine farmers' technology acceptance towards organic agriculture, by comparing Turkish organic and conventional growers. In order to identify what factors might lead to formation of attitudes towards behavioral intentions we use a modified model of the TPB and the TAM, which are proposed in the context of the study. A comprehensive analysis of the farmers' attitudes and intentions are employed using the partial-least squares (PLS) structural equation modelling. The multi-group analysis (MGA; Sarstedt et al., 2011) is performed in order to investigate group differences.

Materials and Methods

Research framework and hypotheses

The conceptual framework introduced in the study is based upon the TPB and the TAM theoretical frameworks. Behavioral intention (to continue to use, or to adopt), that is, the explanandum in the TPB and the TAM, is replaced by intention to adopt/intention to continue in our framework. Perceived ease of use, as a construct from the TAM is replaced by perceived costs which can be considered relevant for both economic and bureaucratic costs. Subjective norm is replaced by perceived internal pressure. We take into consideration not only social pressures but also other type of pressures that might take place in farmers' environment. Therefore, the external environment takes place as perceived external pressure in the model. Perceived usefulness, perceived output quality, and result demonstrability are adapted from TAM model. The model is illustrated in Figure 1 and explained below in detail.

In our perception-based research framework the basic assumption is that organic adoption behavior is influenced by the attitudes of farmers. Attitudes may depend on subjective perceptions, cost and benefit evaluations of the farmers concerning the usefulness of organic production. Perceived social influence show to what degree normative beliefs can be significant on the performance of attitude. This construct corresponds to the perceived social belief of a person, who anticipates being approved or supported by a person or surrounded group of people with respect to specific attitude (Ajzen, 1991). The influence of others such as family members, neighbors, relatives can influence social pressure of the individuals about a given behavior (Park, 2000). Therefore, we assume that perceived internal pressure has a positive influence on attitude (*H1*). Apart from the internal subjective norms, the external interested group effect on the attitudes is measured subjectively from the viewpoint of perceiver. Different adopters might perceive the primary features of an adoption in different ways and this eventually might lead different attitudes and behaviors (Kossahl et al., 2012). Thus, it is important to measure potential pressure from these groups to consider the different subjective behaviors of the adopter. In this regard, we propose perceived external pressure has a positive influence on attitude (*H2*). Perceived usefulness (Venkatesh and Davis 2000)

explains the degree to which an individual believes that using the system will help to attain gains in job performances. The farmers perceive improvements in performance through implementing certified organic production. To see whether organic produce enhance farmers' success and competitive power, we hypothesize that 'the greater the perceived benefit (usefulness) of organic agriculture, the more pronounced in the attitudes towards the organic adoption (*H3*). The perceived costs construct is defined as the effort which a farmer perceives by fulfilling the requirements for organic certification. The definition of the cost primarily refers the costs necessary for formalization procedures in enterprises. For instance, certification process in organic production deals with several steps such as documentation, registration, process modifications, and organizational adaptation to the procedures, which might all brings bureaucratic burden (Jahn and Spiller 2005). Against this background, we assume the two following two hypotheses; Perceived costs has a negative influence on perceived usefulness (*H4*), Perceived costs has a negative influence on attitude (*H5*). The TAM model proposes that the perception of benefits of a technological innovation is positively influenced by the demonstrable results that encompasses the degree of the tangibility of the results by using the innovation (Moore and Bensabat, 1991). To this, we hypotesize that result demonstrability has a positive influence on perceived usefulness (*H6*). The perceived output quality (Venkatesh and Davis, 2000) explains how well a system realizes its technical capability, that is, the degree to which a farmer believes that the system performs related activities well. For the acceptance of a technology innovation, it is also important to know whether problems associated with the use of technology improvements are only internally visible, or also they are recognized by externals (Agarwal and Prasad, 1997). We assume that, the visible performance from the organic production resulting positive effect and impact on the perceived usefulness of practicing organic agriculture. Therefore, we propose that perceived output quality has a positive influence on perceived usefulness (H7). According to the TAM model explained by Venkatesh and Davis (2000), we presume adoption or continuity of organic farming is the result of the attitudes in this particular object. The TPB also states that, the more a person tends to perform behavior, the greater the likelihood that the behavior will actually performed (Ajzen, 1991). To this, we hypothesize attitude has positive influence on behavioral intention (*H8*).
Research framework is given as Figure 1.

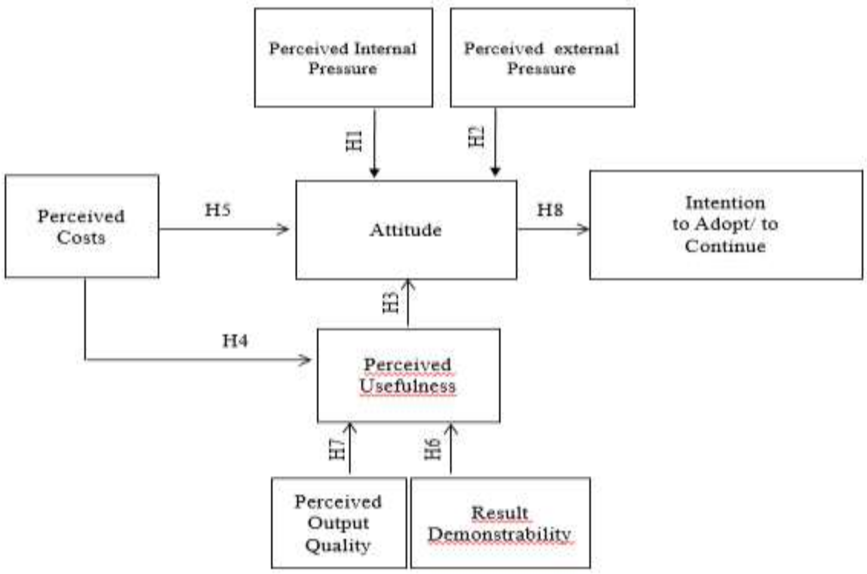

Figure 1: Research Model (Authors' illustration)

Sample and Methodology

The cross-sectional data employed in the study was collected during a comprehensive survey of farmers via face-to face interviews in 2015. The number of questions (cf. Table 1) eliciting farmers' perceptions, attitudes, and intentions were included and measured with five-point Likert scales. The full sample after data cleaning consisted of observations from 144 conventional and 131 organic producers. The research model used in the study (cf. Figure 1) has structured as an extended from different model frameworks, the TPB and the TAM, which are developed and used to identify the factors influencing adoption of, not only technologies in information sytems but also choices of alternatives in agriculture and food technologies. The data was analyzed by applying structural equation modeling methods in the SmartPLS 3 (Ringle et al., 2015) statistical software. The analysis of PLS models entail two-stage approach which are an assessment of the reliability and validity of the measurement model, and an assessment of the structural model (Hair et al., 2013). After the research model was built into SmartPLS, the PLS Algorithm, bootstrapping procedures and the MGA were employed in the software.

Results and Discussion

Assessment of the measurement model

The constructs indicated in our model are used and each construct is measured by assigned observable items. Before starting the analyses, a confirmatory factor analysis are employed to identify the relevant items for each latent variable (construct). Afterwards, we checked costruct reliability and internal consistency with the help of Cronbach's alpha and composite reliability (CR) (Hair et al., 2013). The suggested values of Factor loadings (≥.70), Cronbach's Alpha (CRA) (≥.70), composite reliability (CR) (≥.70) are met. In order to measure the discriminant validity, the average variance extracted (AVE) with the Fornell-Larcker criterion was tested (Fornell and Larcker, 1981). The suggested value of AVE (≥.50) (Chin, 1998), and for AVE was reached for all constructs. The measurement model was proven by having satisfactory results with respect to all above mentioned parameters. CR and AVE results were given in Table 1 for both organic and conventional farmer groups. Data analysis also revealed that there was no eviedence of any cross-loadings and multicollinearity.

Table 1 Results of the evaluation of the Measurement Model

Construct (latent variable)	Indicator variable (OF=organic farming)	Organic CR (≥0.7)	Organic AVE (≥0.5)	Conventional CR (≥0.7)	Conventional AVE (≥0.5)
-Perceived Internal Pressure (PIP)	Family members encourage farmers to practice OF.	0.954	0.838	0.939	0.794
	Family members support farmers to fulfill the requirements of OF.				
	Organic farmers convert because their neighbors also do OF.				
	Local community prefers organically farmed food.				
-Perceived External Pressure (PEP)	The buyers control the farmers whether they keep close to guidelines.	0.932	0.775	0.911	0.719
	NGOs motivate farmers to convert to OF.				
	Consumers prefer organically farmed food.				
	Government support accelerates adoption of OF.				
-Perceived Costs (PC)	Organic farms have higher input costs than conventional farms.	0.941	0.800	0.918	0.737
	The expenditures for land preparation in OF is high.				
	The costs for the organic certificate are high.				
	The certification control system is very bureaucratic.

Hypotheses testing, results of the multigroup analysis

In order to evaluate group differences on the base of the proposed research model, we tested the hypothesized relationships for both subsamples. In the model each path is characterized by each hypothesis and path coefficiensts. The path coefficient values can be interpreted as follows: >0.35 strong influence, >0.15 moderate influence, >0.02 weak influence (Cohen, 1988). Correspondingly, the t-values as the other indicator values of a good structural model are calculated using bootstrapping method. The final results of the calculations for the path coefficients, t-values, and p-values are depicted in Table 2. With respect to the analysis of the group differences, the bootstrap results for PLS-MGA show significant differences in the path coefficients for perceived output quality and perceived cost on the perceived usefulness show significant differences between the groups (IdiffI=0.197** and IdiffI=0.337*** respectively). Similarly, path coefficients for perceived cost and perceived usefulness on the attitude show significant differences between the groups (IdiffI=0.305** and IdiffI=0.328*** respectively). These significant differences confirm the hypotheses H3, H4, H5, and H7. Similar correlations regarding organic agricultural adoption have been resulted in the studies of Schulze et al. (2007) and Bravo et al. (2012), but the finding is not supported by the studies of Herath and Wijekoon (2013) which investigates behavioral differences between organic and non-organic coconut growers.

Conclusions

In the foregoing research, the examination of perceptions and attitudes of conventional and organic growers was carried out by use of an extended acceptance model of TPB and TAM. As a consistent result to our expectations, perceived cost and perceived usefulness are significant challenges impeding technology adoption. Suprisingly but very possible to the current market and certification process of the organic products (Demiryürek, 2008), cost is not perceived highly significant influence factor for conventional farmers comparing to organic farmers. Additionally, conventional farmers perceive greater usefulness of the organic systems than organic farmers. this is one of the important conclusion that, in the line with the growing economic pressure and the propagation of organic production (Aksakal, 2016), these results can be further considered by practitioners and policy makers. To this, implementing solutions to improve and expand organic agricultural adoption shall be addressed and maintained not only convince farmers to convert their land into organic farming system, also to keep organic farming as a continuous production.

Abstract

Sage herb (*Salvia officinalis* L.) comprises an important medicinal and aromatic plant, well-known for its various uses in medicine, as well as in cosmetic and food industries. The present work focuses on the productivity of a biologic cultivation of sage, obtained in the first growth (establishment) year under different water and nitrogen inputs and plant populations on a SL soil in central Greece. A split-split plot field experiment was established in three replicate blocks in November 2016. Rainfed and irrigated condition applied comprised the main plots with the irrigated plots receiving 100% of ETo (100 mm) until the harvest of the crop in late May 2017. Plant population in two levels (D1: 20x50cm, D2:40x50cm) comprised the subplots and in the sub-sub plots nitrogen fertilization in three levels (N0:0, N4:40, N8:80 kg Nha^{-1}). The results showed the positive effect of irrigation on yield traits such as plant height, chlorophyll content and dry matter produced, especially for the denser plant population. Actually, irrigation increase sage yields in half: from 900 kg dm ha^{-1} (rainfed crop) to over 1500 kg ha^{-1} for the plants receiving 100 mm of irrigation water. The positive effect of irrigation was significantly more pronounced to the denser population, whereas nitrogen fertilization did not show a significant effect on productivity, apparently due to the high fertility status of the studied soil. Such results are important and may assist future cost/benefit analyses concerning the introduction of sage as an important aromatic/medicinal plant in crop rotation schemes in near future in Greece and more generally in Mediterranean places.

Keywords: *Sage, irrigation, fertilization, plant density, aromatic plants, medicinal plants.*

Introduction

The genus Salvia belongs to the family of Lamiaceae and it is a perennial woody shrub which it is native to the Mediterranean countries. The commercial value of the plant is its leaves that are used as a raw materials in perfume, in food industry and in medicine (Bruneton, 2001).Water is one of the most valuable sources of our planet and its consumption in many area of Mediterranean countries which are characterized by rainy winters and dry, warm summers is an important tissue. Species of sage are characterized as xerophytes and especially *Salvia officinalis* L. is a drought-susceptible species which means that its demands on water is low (Munne-Bosch *et al.*, 2001). Optimum planning density is the key for obtaining the maximum crop production especially, in case of deficiency in water as it happens in Mediterranean countries. Better understanding of relationship of irrigation and plant density is the key to schedule better irrigation system in order to have the optimum yield (Khazaie*et al.*, 2008). Biofertilizers considered as more eco-friendly comparison to chemical fertilizers and it is thought to enhance soil fertility and to enhance crop production. As far as it is concerned medicinal and aromatic plants, there is an interest to produce chemical-free plants for growers in order to ensure good quality and safe plant products for both human and environment. This study aims to examine production of sage in relation to cultivation practices of irrigation, plant density and nitrogen fertilization at the first year.

Materials and methods

The field experiment was carried out in the experimental field of University of Thessaly which is located in Velestino, Magnesia, Greece (Latitude 39°23' North, Longitude 22°45' East) and elevation 70 m above the sea level. The means of temperature during experiment was 10.4°C, Relative Humidity was 54.4% and the sum of rain was 195.7 mm. The experiment was a split-split-plot and was established as complete randomized in three replicate blocks with three factors and twelve treatments. The main factor was irrigation in two levels: 0%(I1) and 100% of Evapotranspiration (I2), the sub-factor was plant density 20cm x 50cm (D1), 40cm x 50cm D(2) and the sub-sub-factor was N fertilization in three levels: (N0)0 kg ha^{-1}, (N4)40 kg ha^{-1} and (N8)80 kg ha^{-1}. Plant material wasseedcuttings which were approximately 20cm and were transplanted in November 2016 in a depth of 10 cm. Plant density was 20cmx50cm (plant to plant x row from row) and 40cmx50cm, respectively. According to soil analysis our soil consisted of 47% loam, 14% clay and 39%sandand characterized as SL. Soil pH was 7.7 (Table 1).

Table 1. Physical and chemical composition of experimental soil in two depths.

Depth	Sandy %	Clay %	Loam %	pH	ECμS/cm	% $CaCO_3$	% O.M.	Pmg/kg	K mg/kg	N(%)
0-30 cm	39	14	47	7.7	302	12.5	2.5	42	1118	0.08
30-60 cm	42	12	46	7.7	378	13.0	2.1	35	1077	0.11

As irrigation system was used the drip irrigation with water supply per dripper 4 l h^{-1} and the total supply to field was 280,000 lha^{-1} or 280 m^3ha^{-1} or 28mm per hour. Irrigation was calculated to field using an atmometer close to experiment and irrigation until first cut was totally 100 mm. Fertilization was organic with 6% total Nitrogen, 0.5% P_2O_5, 0.3% K_2O and 85 % organic matter. In order to cover the needs of 80 $kgha^{-1}$ was imposed 540 gr per plot and for 40 $kgha^{-1}$ was imposed 270 gr per plot. Fertilizer was applied in early March after the soil's analysis. Cutting is programmed to be in early May (40% of the anthesis stage). In the sampling, for each plot ($2x2m^2$) we harvested 1m in the inner plot rows to avoid any border effect. In the field we measured plant height and chlorophyll content index with CCM-200. Plant height was determined as the average for all harvested plants per plot. The plant material was weighted fresh and divided into the various plant components: leaves, stems and flowers. Then the plant fractions were oven-dried at 45°C until equal weights (8 days) and weighed again to determinate the respective dry weights (Sellami et al., 2012). Also, before drying, leaf area (green leaf lamina) was measured usingan automatic LI–COR model LI–3000A portable leaf area meter. Leafarea index (LAIm^2 green leaf m^{-2} ground) was determined as theproduct of green leaf dry weight (kg m^{-2} ground) times the specific leaf area (SLA in m^2 leaf kg^{-1}). All measured and derived data were subjected to analysis of variance (ANOVA), using Excel program.

Results and discussion

Fig. 1 illustrates how the plant height,in sage (*Salvia officinalis* L.) is affected by irrigation,N-fertilization inputs and plant densities and have found that irrigation and D2 plant density caused a slight increase to height.Bettaieb*et al.* (2011), claim that water stress causes a decrease in plant's height and our results agree with this statement and as far as it is concerned plant density, Kumar *et al.*, (2013) resulted in the same conclusion since the maximum height, was in case of plant density of (45x45) cm in *Salvia sclarae* 30cm. Plant height ranged from 28,1cm to 32,6cm which is in accordance with previous studies before flowering in a conventional system production with plant spacing 30x40cm (Dzida*et al.* 2015). No Significant differences ($P < 0.05$) of plant height were observed for the different plant densities, N-fertilization rates and irrigation inputs for the establishment year. Also, our results show that half of the N fertilization treatments (N4) had greater height than N8 and N0 treatments.

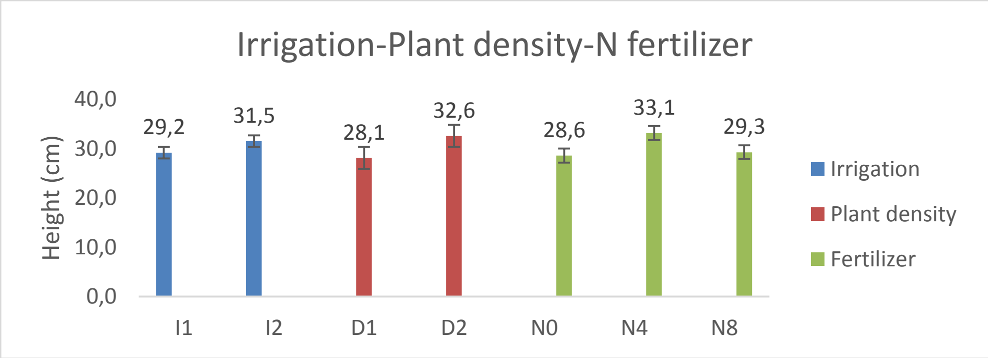

Figure 1. Average plant height measurements (cm) in relation to I- irrigation treatments (I2:Irrigated I1:Control, D- plant densityD1: 20x50cm, D2: 40x50cm, N- fertilization N0: 0 $kgha^{-1}$, N4: 40 $kgha^{-1}$, N8:80 $kgha^{-1}$. Vertical bars indicate Standard Errorat $p<0.05$.

Chlorophyll content index (CCI) was in average more in rainfed conditions and in D2 treatments (Fig. 2). Our results are shown that average of CCI was higher in the case of rainfed condition (CCI=22.9) than in irrigation (CCI=19.4) treatments and in case of plant density we found that CCI was higher in case of D2 (26.7) rather than D1 (25.1). As far as it is concerned the nitrogen fertilization, average of CCI was higher in case of 0 $kgha^{-1}$ (CCI=21.7) following the 80 $kgha^{-1}$ (CCI=21.4) nitrogen and 40 $kgha^{-1}$ (CCI=20.7). Amador *et al.* (2014), measuring chlorophyll in sage with SPAD-502 meter found that leaf SPAD of sage had a mean value of 20,valuesimilar to ours.

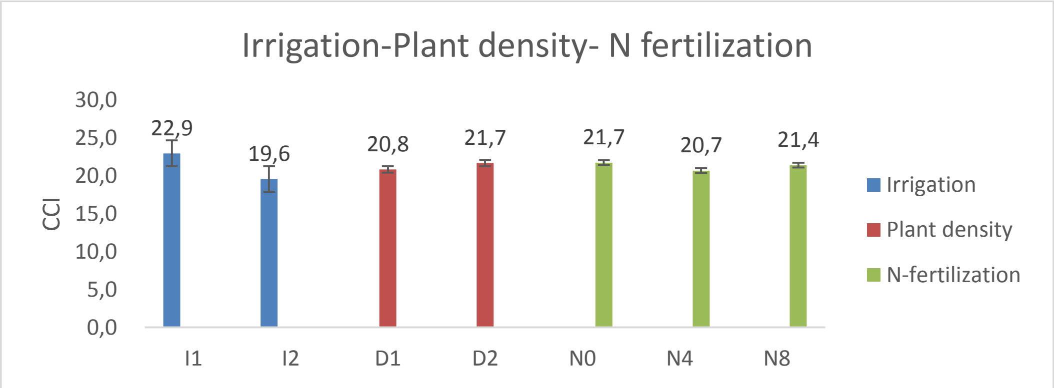

Figure 2. Average of Chlorophyll Content Index (CCI)in) in relation to all treatments (I2:Irrigated I1:Control, plant density D1: 20x50cm, D2: 40x50cm, N- fertilization N0: 0 $kgha^{-1}$, N4: 40 $kgha^{-1}$, N8:80 $kgha^{-1}$). Vertical bars indicate SD at $P < 0.05$.

LAI comprises a very important index for assessing biomass accumulation, whereas accurate estimation of the dynamic pattern of LAI is central in crop modelling (Goudriaan and van Laar, 1994). Leaf Area Index (LAI) had the bigger value in treatments of irrigated (100 of ET_0) and in D1 (Graphs 3). Obviously, average of LAI from irrigation and narrow plant density caused an increase on leaf surface. In case of fertilization it seems that N8 treatments had a slight increase instead of N0 and N4 indicated that fertilizer could increase LAI. No statistically differences were found between irrigation and N fertilization treatments while plant density treatments had significant difference (Fig. 4).

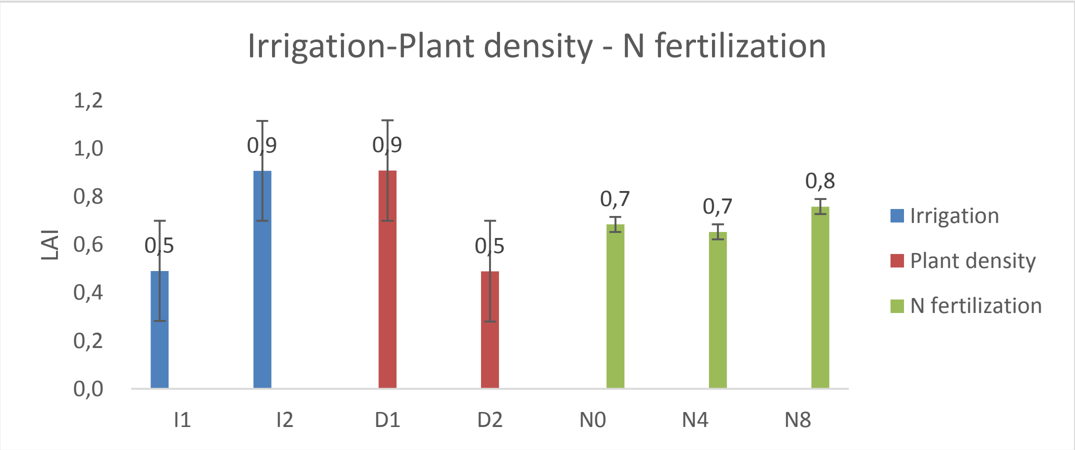

Figure 3. Average of Chlorophyll Content Index (CCI)) in relation to all treatments (I2:Irrigated I1:Control, plant density D1: 20x50cm, D2: 40x50cm, N- fertilization N0: 0 $kgha^{-1}$, N4: 40 $kgha^{-1}$, N8:80 $kgha^{-1}$). Vertical bars indicate SD at $P < 0.05$.

According to statistical analysis of ANOVA, there are significant differences between irrigation treatments and between plant density treatments. Means of Irrigated treatments is 1569 $kgha^{-1}$ while rainfed treatments is 907 $kgha^{-1}$ (Fig. 4) indicating that irrigation increase significant production by increasing leaves' weight comparison to non-irrigated plants. Govahi*et al.* (2015), found that yield of dry matter of sage is 2,702 tha^{-1} in irrigated conditionsand plant density 60x30cm.

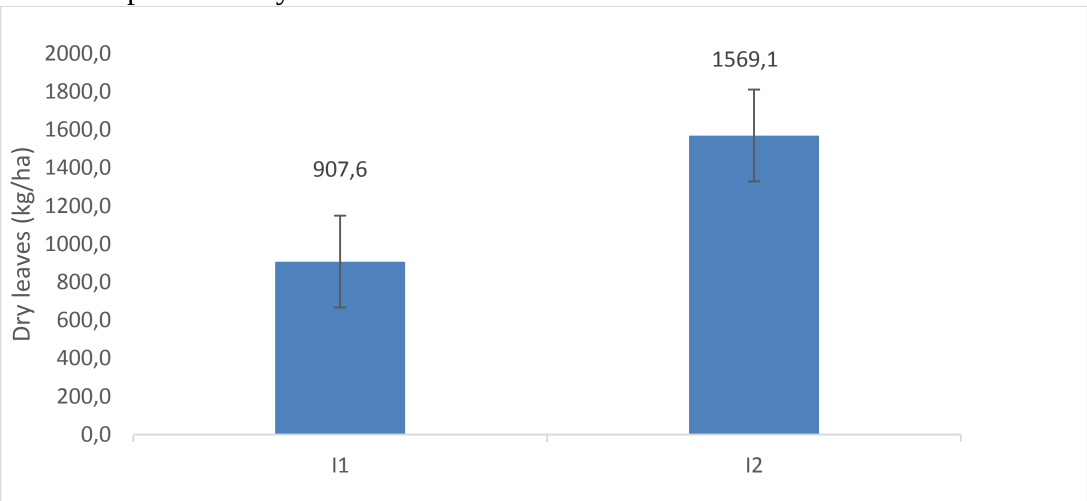

Fig. 4. Means of dry leave weight (kgha-1) in relation to irrigation treatments (I2: Irrigated I1: Control). Vertical bars indicate LSD, 05.

In addition, plant density play a significant role in our production indicating that narrow plant density increase production per unit (1500 $kgha^{-1}$) comparison to D2 (978 $kgha^{-1}$) (Fig. 5).

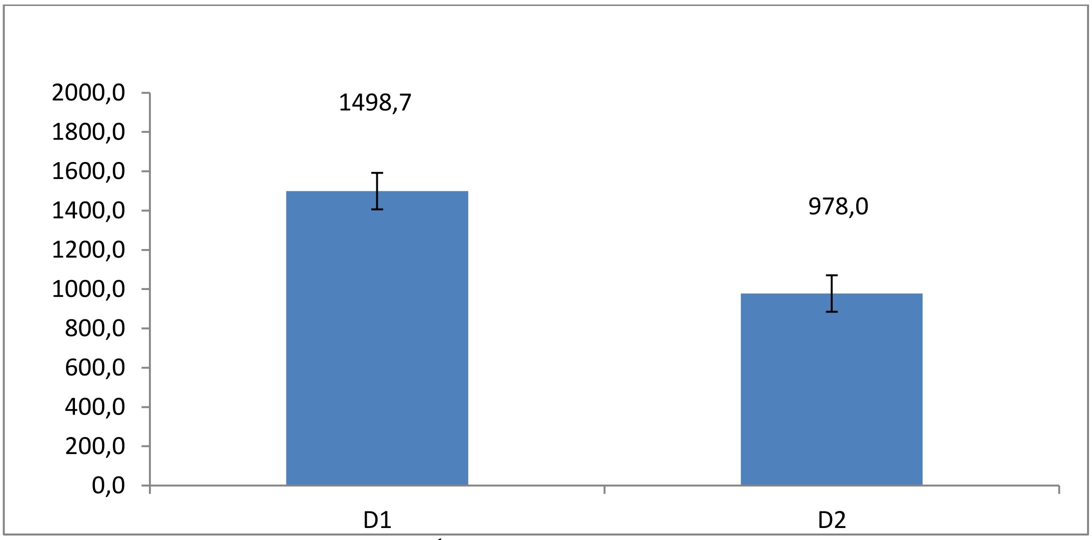

Fig. 5. Means of dry leave weight (kgha^{-1}) in relation to plant density treatments (D1: 20x50cm, D2: 40x50cm). Vertical bars indicate LSD$_{,05}$.

As far as N fertilizationis concerned, there is not significant differences between the treatments and seems that fertilization have no influence on production. Our results agree with Nadjaf*et al.* (2014), who claim that biofertilizer have no effect on plant growth and yield in sage (*Salvia officinalis* L.). Corell*et et al.* (2012), found that the dry matter yield of *Salvia officinalis* L. is 1.27 t ha^{-1} in rainfed conditions and 4,57 t ha^{-1} by applying water 100% of ETo, in a two year cultivation, with applying 80 kgha^{-1} N, plant density (35x75) cm and with three cuttings (first autumn, second autumn and third spring).

Conclusion

Our results have shown that irrigation increase plant height, leaf production and leaf area index. Narrow plant density increase LAI and leaf production in both irrigation and rainfed systems. Unexpectedly, dry leaf biomass of sage was not influenced by N fertilization ($P > 0.05$) in the range of 0–80 kg Nha^{-1}. This is apparently due to the low nitrogen needs of the crop and the relatively high fertility status of the study soil. Thinking about productivity, the best combination in irrigated and in rainfed systems is the narrow plant density with 80 kgha^{-1} nitrogen fertilization. Finally, our first year results are encourage and show the important role of irrigation, in combination to plant density on sage productivity. Such results are important and may assist future cost/benefit analyses concerning the introduction of sage as an important aromatic/medicinal plant in crop rotation schemes in near future in Greece and more generally in Mediterranean places.

Abstract

The effect of geochemical state of the moraine-erosion landscape, caused by the relief, and fertilization on agrophysical and agrochemical parameters of sod-podzolic heavy loam soil and spring wheat yield was studied in a stationary experiment in the Ural Region. Fertilizers application was studied on three landscape types: eluvial, transit and accumulative. In the control treatments (no fertilizers: organic or mineral) degradation processes in sod-podzolic soils and irrational use of arable land as a result, were evident. That was confirmed by deterioration of soil fertility parameters, hydrolytic acidity raising for 0.2-0.3 mmol/100 g of soil, total exchange bases (S) decline. Microbiological soil activity decreased by 8.2-8.8%, humus content in arable layer- by 0.14%, labile forms of phosphorus and potassium - by 19-26 mg /1000 g. Degradation processes were mostly developed in the transit landscape. Stabilization of soil fertility at the initial level was provided by farmyard manure application in rate 60 t ha^{-1} combined with the use of mineral fertilizers $N_{60}P_{60}K_{60}$. The close inverse correlation (r=-0,85) between humus content and soil density was determined. Accumulation of mobile phosphorus, exchange potassium and mineral nitrogen is observed down the slope towards accumulative landscapes and reaches the maximum values in the inter-hill depression (accumulative landscape). The influence of the geochemical state and landscape heterogeneity, caused by relief, was more important for agrophysical and agrochemical properties of the soil compared with fertilizers application. The accumulative landscape is characterized by favorable soil conditions, in transit landscape the worst fertility parameters were noted.

Key-words: *agromicrolandscape, sod-podzolic soil, mineral fertilizers, farmyard manure, humus, soil density, spring wheat, soil acidity, labile phosphorus, exchange potassium.*

Introduction

The country's food security, stable development of society are possible only in harmony with natural forces. Mankind must successfully engage in biogeochemical cycles of the biosphere and rationally take into account landscape features (Gardner, 1990; Nazaryuk , 2002; Lykov, 2006).

Soil is the important component of any landscape. Sod-podzolic soils are most common in Ural region and have unfavorable agrochemical properties: high acidity, low content of phosphorus and potassium mobile forms. Technological load on the soil cover increases as a result of agriculture intensification and caused the degradation processes intensification. (Demidov, Shiryaeva, 2004; Dobrovolsky, 2004; Kesavan P.C., Swaminathan M.S., 2008). Soil degradation is intensified due to the peculiarities of landscape conditions, because fertility parameters vary according to distribution of material and energy flows in agromicrolandscapes. Soil fertility indicators within landscapes vary, primarily, according to altitude and slope exposure. At present time erosion processes on the slopes of different exposures are studied sufficiently. The processes of natural, geochemical differentiation of nutrients in different elementary landscapes, their influence on the crops productivity are characterized to lesser extent. The purpose of given work – to study the influence of landscape conditions: geochemical state of the moraine-erosion landscape, caused by the relief, on agrophysical and agrochemical parameters of sod-podzolic heavy loam soil and spring wheat yield.

Materials and methods.

The studies were carried out during 1996-2000 and 2013-2016 years in short-term experiment, located on the central experimental farm of Perm Agricultural Research Institute on sod-podzolic heavy loam soil with following agrochemical properties: humus content 2.21%, pH_{KCl} = 5.4, H_A- 2,8; S- 14.2 mmol/100 g of soil, labile phosphorus (P_2O_5), exchange potassium (K_2O), respectively 100 and 134 mg/kg.

Scheme of the experiment: factor A – Landscapes: 1. Eluvial, 2. Transit. 3. Accumulative; Factor B: – Fertilizers: 1. Control (without fertilizers), 2. NPK - each of 60 kg ha^{-1}, 3. FYM - 60 t ha^{-1}, 4. NPK - 60 kg ha^{-1}+ FYM 60 t ha^{-1}.Treatment placing is serial, each treatment has four replications, according standard methods (Dospehov, 1979).

NPK were applied for spring wheat, FYM - in a fallow field, after-effect was accounted. The objects of research were eluvial, transit and accumulative agromicrolandscapes. The studied crop – spring wheat (Triticum aestivum L. var. milturum, cultivar Irgina), the preceding crop – winter rye after bare fallow.

Observations and studies were carried out according to accepted methods (Mineev, 2001). Soil and plant chemical analyses were fulfilled in analytical laboratory of Perm Agricultural Research Institute according national standards: humus content – GOST 26213-84 (Tyurin method); pH_{KCl} – GOST 26483-85 (potentiometrically); hydrolytic acidity - GOST 2 OST 26207-91 (Kappen method); total exchange bases – GOST 27821-88 (Kappen-Gilkovits method); content of mobile phosphorus and exchange potassium – GOST 26207-91 (Kirsanov method). Data processing included analysis of variance and correlation coefficients determination, using the program SPSS (v.18).

Meteorological conditions during the years of the experiment were typical for the Ural Region and favorable for growth and development of spring wheat.

Results and discussion

Irrational use of arable land without mineral fertilizers application adversely affected on soil agrophysical and agrochemical properties. One of the important factors determining crops productivity is soil density.

The soil became very compact in the control treatment on all types of landscapes (Fig.1). The highest soil density 1.54 g/cm^3 was noted in the transit landscape, which was due to flushing of structural soil particles. The soil density decreased with fertilizers application, especially organic.

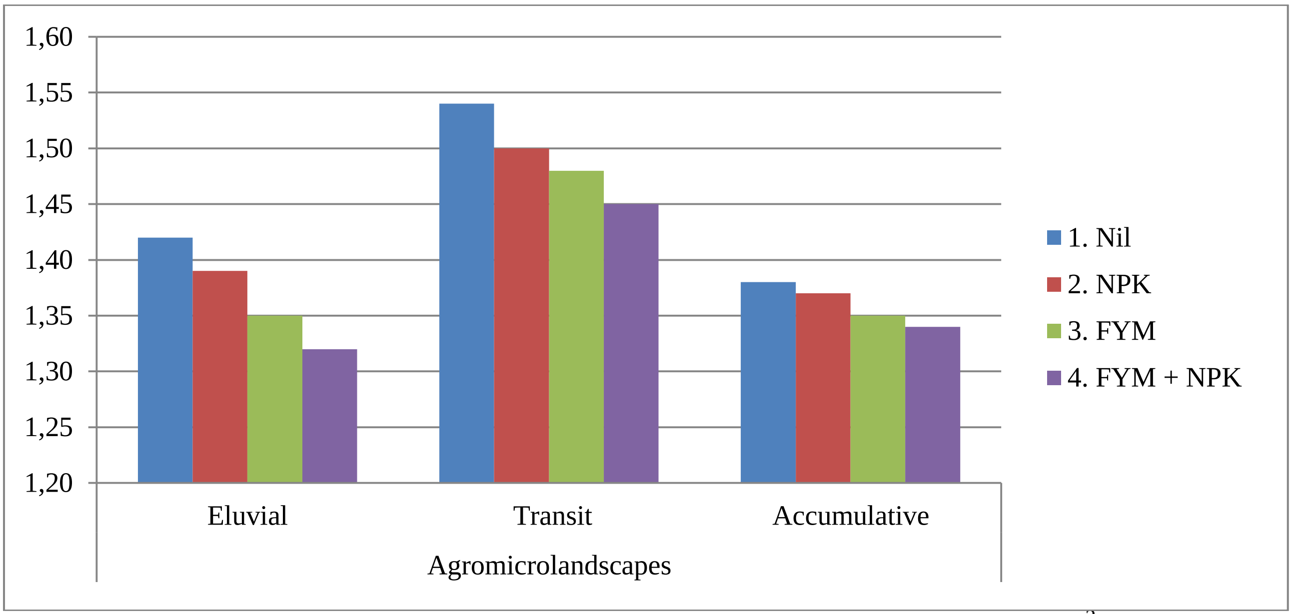

Fig.1 Soil density by the time of wax ripeness phase of spring wheat, g/cm^3
(average for 2013-2016).

Soil erosion phenomena are sufficiently highlighted in modern literature (Dobrovolskiy 1997; Kuznetsov and Glazunov, 1996; Lobosova and Goneev, 2015). The processes of natural geochemical differentiation of nutrients, agrophysical properties in various elementary landscapes and their influence on the productivity of agricultural crops are studied much worse.

Geochemical subjection of landscapes was demonstrated in parameters of soil absorbing complex and mobile nutrition elements. So, monitoring of agrochemical soil indicators showed the accumulation of exchange bases sum on the catena and their maximum values in the inter-hill depression (accumulative landscape), which is associated with the advantage of lateral runoff, as well as within the profile migration. Accumulation of labile phosphorus, exchange potassium and mineral nitrogen was gradually raised down the slope towards accumulative landscapes (Table 1).

Table 1– Influence of fertilizers and landscapes on agrochemical soil indicators
(average for 2013-2016).

Treatment	Humus, %	pH	H_A *	S	NH_4	NO_3	N_{A-H} **	P_2O_5	K_2O

4. FYM + NPK	3.99	5.8	2.1	16.2	5.5	2.9	13.6	194	178
HCP_{05}	0.12		0.5	1.4	0.3	0.2		12	14

Notes:
*-H_A – Hydrolytic acidity;
** - N_{A-H} – Alkali-hydrolysable nitrogen

The minimum content of these elements was noted in the transit landscape, as affected by their elution by melt- waters during the snowmelt period and rainfalls during the growing season.

$N-NH_4$ prevailed in all forms of the landscape because the nitrate form is flushed from plowing horizon to the underlying layers with a natural runoff and, on the contrary to ammonium ions, does not form any hardly soluble salts, and it is not absorbed by negatively charged soil colloids.

The content of alkali-hydrolysable nitrogen was closely correlated with humus content (r = 0.89) and reached maximum in the accumulative landscape.

Total humus content was also closely correlated to relief elements, the correlation coefficient was 0.91. The highest humus content was noted in arable layer 3.65% (average meaning for factor) in the accumulative landscape, which was 1.55% more than in the eluvial landscape and on 2.32% higher compared the transit landscape. Changes in humus content, depending on the landscape conditions, are associated with material and energy flows vectors.

The use of mineral and organic fertilizers promoted increasing of humus content, mobile forms of nitrogen, phosphorus and potassium.

Thus, the landscape heterogeneity and geochemical state of the moraine-erosion plain (plain landscape), caused by relief, was more important to the agrophysical and agrochemical properties of the soil compared with fertilizers application. The accumulative landscape (inter-hill depression) is characterized by favorable soil conditions, eluvial landscape (watershed) conceded the accumulative one in this relation.

Degradation processes are most intensively revealed in the transit landscape, due to the flushing of the most valuable structural soil particles and nutrients.

Fertilizers in sufficient rates restrain degradation processes in the soil. The joint application of organic and mineral fertilizers promotes the accumulation of humus, nutrients and improves agrophysical properties of the soil.

Conclusion

The influence of the geochemical state and landscape heterogeneity of moraine-erosion plain, caused by relief, was more important for agrophysical and agrochemical properties of the soil compared with fertilizers application.

Fertility parameters differed significantly in various landscape types, relatively favorable soil conditions were noted for accumulative landscape (inter-hill depression), eluvial landscape (watershed) conceded the accumulative one in this relation. Degradation processes are most intensively revealed in the transit landscape, due to the flushing of the most valuable structural soil particles and nutrients.

Fertilization restrains degradation processes in the soil. The joint application of organic and mineral fertilizers promotes the accumulation of humus, nutrients and improves agrophysical properties of the soil.

Abstract

Spelt wheat (*Triticum aestivum* sub sp. *spelt*) is an old crop. That is a low input plant, sutible for growing without the use of pesticides in harsh ecological conditions and in marginal areas of cultivation. Spelt pasta is produced without additives, food colours and it doesn't contain genetically modified materials, thus meets the requirements of an organic product. Organic food can be rated from satisfactory to good, because it contains much higher levels of nutrients. Spelt wheat is suitable organic raw material for extruded products with modified nutritional characteristics. During the process of extrusion, spelt is exposed to high temperature and high pressure, during which raw material is also mechanically treated by shear forces. This paper investigates chemical and mineral characteristics of three spelt flours cultivars (Nirvana, Austria and Eco) and their influence on technological quality of spelt pasta. The significant differences between spelt flour was confirmed by application of Post-hoc Tukey's HSD test at 95% confidence limit. Calculation of standard scores (SS), based on assigning equal weight to applied parameters (chemical, mineral and technological) has been conducted and the obtained values compared. Data point at good indicators of spelt pasta technological quality with improved chemical and mineral characteristics. Pasta obtained from spelt flour may contribute to variety of organic safe products at the market.

Keywords: *Organic raw material, spelt, chemical characteristics, mineral characteristics, technological quality*

Introduction

Wheat is one of the most widely grown crop in the word because of its unique protein characteristics. While most of the world wheat crop arises from production of common and durum cultivars, there is increasing interest in ancient wheat species, especially spelt (*Triticum aestivum* sub sp. *spelt)* ones, particularly with regard to use in special bakery and pasta products, health and organic foods (Gálová and Knoblochová, 2001, Abdel-Aal *et al.*, 2008). Spelt pasta is produced without additives, food colours and it doesn't contain genetically modified materials, thus meets the requirements of an organic product. Spelt is valued due to its high nutritional value, health-promoting qualities and agronomical advantages, such as high pest resistance and the fact that it can be cultivated on low fertility, poorly drained soils (Koenig, *et al.,* 2015, Biel, *et al.,* 2016). The nutritive value of spelt wheat is high and contains all the basic components which are neccessary for human beings such as starch and nonstarch carbohydrates, proteins, lipids, vitamins and minerals (Bojanski and Frančakova, 2002). Some of spelt cultivars have very high protein content and even 30 to 60% higher concentration of mineral elements (Fe, Zn, Cu, Mg and P) compared to *Triticumaestivum* (Bonafaccia *et al.,*2000, Filipović *et al.,* 2013,).
This paper investigates the basic chemical components (protein, starch, fat, cellulose, ash, and moisture) and mineral content of (Ca, Zn, Cu, Mn, Fe) of three spelt cultivars (Nirvana,

Austria and Eco) as a raw material for pasta. Beside chemical and mineral content the convenience of spelt flour for pasta is evaluated based on the data concerning pasta texture.

Material and Methods

Three spelt cultivars: Nirvana, Austria and Eco 10, (particle size of whole meal flours ranged between 200 and 300 μm) representing the average quality from producing areas grown in Serbia are tested. Basic chemical analyses (protein, starch, fat, cellulose, ash) of spelt flour are tested according to the Regulations onthe physical and chemicalmethods ofanalysisfor quality controlof grain, milling and bakery products, pasta and deep frozen dough (1988). The content of calcium, zinc, copper, magnesium and iron was determined by atomic absorption spectroscopy using standard procedure (No. 985.29) given by AOAC (1990). Pasta is made on the device "La Parmigiana D45" MAC 60, La Parmigana Italy, procedure described by Filipović *et al.,* (2013). Method of cooked texture pasta was described by Filipović *et al.,* 2015. Descriptive statistical analyses for all the obtained data were expressed as the mean ± standard deviation (SD). The evaluation of one-way ANOVA analyses of the obtained results was performed using StatSoftStatistica 10.0® software. Collected data were subjected to one-way analysis of variance (ANOVA) for the comparison of means, and significant differences were calculated according to post-hoc Tukey's HSD (honestly significant differences) test at $p<0.05$ significant level, 95% confidence. Score analysis uses min-max normalisation of flour and pasta quality parameters transforming them from their original unit system in new dimensionless system where further mathematical calculations with different types of quality parameters were applicable (Jayalakshmi and Santhakumaran, 2011). Individual score for following attributes (*Ki*): Crude protein content (CP), Cellulose content (C), Fat content (F), Ca, Zn, Cu, Mn, Fe, Hardness (HAR), Work of Shear (WOS) is calculated according following equation:

$$S_{ki} = \frac{(x_{ki} - x_{k\min})}{(x_{k\max} - x_{k\min})} \qquad k = 1\text{-}10 \qquad (1)$$

For moisture content (M), ash content (A), starchcontent (S), Adhesiveness (ADH) individual score are calculated according following equation:

$$S_{ni} = 1 - \frac{(y_{ni} - y_{n\min})}{(y_{n\max} - y_{n\min})} \qquad n = 1\text{-}4 \qquad (2)$$

Segment score for chemical content, mineral content and texture attributes equations (3) (4) and (5) respectively are calculated as arithmetic means of individual scores:

$$Chemical\ content\ Score_i = \frac{S_{M\,i}+S_{A\,i}+S_{CP\,i}+S_{C\,i}+S_{S\,i}+S_{F\,i}}{6} \qquad (3)$$

$$Mineral\ content\ Score_i = \frac{S_{Ca\,i}+S_{Zn\,i}+S_{Cu\,i}+S_{Mn\,i}+S_{Fe\,i}}{5} \qquad (4)$$

$$Texture\ attributes\ Score_i = \frac{S_{HAR\,i}+S_{ADH\,i}+S_{WOS\,i}}{3} \qquad (5)$$

Total score is arithmetic mean of three segment score:

$$S_i = \frac{Chemical\ content\ Score_i + Mineral\ content\ Score_i + Texture\ attributes\ Score_i}{3} \qquad (6)$$

$$\max[S_i] \rightarrow optimum \qquad (7)$$

Results and Discussion

Quality of l spelt flour of three different varieties is presented in Table 1.There are statistically significant differences between Nirvana and Eco 10 concerning moisture and ash content. Investigated spelt cultivars are characterized by high protein content (Table 1), which qualifies this raw material as a suitable for pasta production. The highest value for crude protein (17.02±0.15) is observed for Nirvana and statistically significantly different from cultivar Austria and Eco 10. The content of cellulose, starch and fat are relatively uniform in all cultivars, with some statistically significant differences between values. Data concerning content of individual mineral elements statistically significantly vary depending on the cultivar with the greatest difference in Ca (cultivar Eco 10) and Fe content (cultivar Austria). The high mineral content experienced in spelt cultivars point at the improved bioavailability of those elements, due to low phytic acid content reported by and Ruibal-Mendieta *et al.*, (2005).

Table 1. Parameters of quality of spelt flour cultivar

Characteristics	Spelt cultivar		
	Nirvana	Austria	Eco 10
Moisture content (%)	13.26 ± 0.04^{ab}	13.34 ± 0.03^{a}	12.72 ± 0.05^{b}
Ash content (% d.m.)	1.08 ± 0.02^{a}	1.20 ± 0.03^{b}	1.18 ± 0.02^{b}
Crude protein content (% d.m.)	17.02 ± 0.15^{a}	15.81 ± 0.21^{b}	15.42 ± 0.18^{b}
Cellulose content (% d.m.)	0.87 ± 0.07^{a}	1.47 ± 0.11^{b}	1.05 ± 0.09^{a}
Starch content (% d.m.)	62.77 ± 0.35^{a}	61.62 ± 0.29^{b}	60.75 ± 0.25^{c}
Fat content (% d.m.)	1.91 ± 0.04^{a}	1.66 ± 0.02^{b}	1.93 ± 0.04^{a}
Mineral content			
Ca content (mg/kg)	170.04 ± 2.81^{a}	147.94 ± 1.35^{b}	212.33 ± 2.21^{c}
Zn content (mg/kg)	14.10 ± 0.48^{a}	18.27 ± 0.56^{b}	18.15 ± 0.52^{b}
Cu content (mg/kg)	2.30 ± 0.05^{a}	2.18 ± 0.05^{b}	1.34 ± 0.04^{c}
Mn content (mg/kg)	17.26 ± 0.31^{a}	13.91 ± 0.25^{b}	20.58 ± 0.28^{c}
Fe content (mg/kg)	21.83 ± 0.54^{a}	60.15 ± 0.88^{b}	22.60 ± 0.67^{a}

The results are presented as mean±SD; different letter within the same row indicates significant differences ($p<0.05$), according to Tukey's test, number of repetitions: n=4.

The texture attributes of pasta are important quality characteristics of product and very important for consumers. Statistically significant differences in adhesiveness between pasta cultivar Niravna and Austria were not observed, contrary to statistically significant reduce of the adhesiveness of pasta in cultivar Eco 10 (Table 2). The difference in work of shear was statistically significant for cultivar Austria and Eco 10. The maximum value of work of shear was observed in Eco 10 (148.42±8.19) and the lowest value of work of shear was found in Austria (120.83±9.60).

Table 2.Texture attributes of cooked pastas cultivar

	Spelt cultivar		
	Nirvana	Austria	Eco 10
Hardness (g)	2496.47 ± 85.10^{a}	2185.67 ± 35.28^{b}	2678.64 ± 75.18^{c}
Adhesiveness (gsec)	17.25 ± 1.47^{a}	21.23 ± 0.76^{a}	12.38 ± 2.50^{b}
Work of shear (gsec)	130.67 ± 5.01^{ab}	120.83 ± 9.60^{a}	148.42 ± 8.19^{b}

The results are presented as mean±SD; different letter within the same row indicates significant differences ($p<0.05$), according to Tukey's test, number of repetitions: n=4.

Table 3.Spelt flour and pasta score values

Spelt cultivar	Segment Scores			Total Score
	Chemical content Score	Mineral content Score	Pasta texture attributes Score	
Nirvana	0.51	0.37	0.48	0.45
Austria	0.30	0.58	0	0.29
Eco 10	0.58	0.60	1	0.73

By means of Score analysis, 14 different flour and pasta quality parameters were quantified further calculated in three Segment Score values, and one Total Score value, which were comparable between the different flour and pasta samples. In that way score values of flour and pasta samples allowed the possibility of comparing segment and total quality of the analyzed samples. Table 3 shows score values of spelt flour and pasta attributes. It can be seen that Eco 10 achieved the best Score values in all tested segments (chemical, mineral and texture attributes score; 0.58, 0.60 and 1, respectively). The highest total score value of 0.73 was also determinated for spelt flour Eco 10, indicating on the best technological quality between tested spelt flour samples.

Conclusions

Quality of three spelt cultivars differs in chemical, mineral content and texture quality. By using the standard score analysis cultivar Eco 10 has highest score (0.73) while cultivar Austria gained lowest score (0.29) characteristics. Chemical and mineral content vary upon the cultivar score analysis is a usefull tool in characterizing spelt as a raw material for pasta. Pasta obtained from cultivar Eco 10 prove to be a new organic safe product on the market with good technological quality with improved chemical and mineral characteristics.

Abstract

Owing to the content of hormones, vitamins and enzymes, brown algae extract, *Ascophyllum nodosum* L. (ANE) has plant growth promoting effect despite the small content of the major plant nutrients (N, P, K etc.). In addition, due to its natural content of physiologically active substances, ANE can alleviate the effects of stress in treated plants. This may have a particularly great importance for the winter production of vegetables in greenhouses in which the soil is usually highly saturated with nutrients. In order to determine the plant growth promoting effects of three different ANE, the experiment was conducted in the greenhouse of the Institute of vegetable crops in Smederevska Palanka, Serbia, on the vertisol soil type. The low-temperature tolerant species radish (*Raphanus sativus* var. *radicula* L.), spinach (*Spinacia olerace* L.) and garlic (*Allium sativum* L.) were sown in late autumn and treated with three different ANE. Plant height, plant mass, the number of leaves per plant and yield were measured. Comparing to untreated plants, examined traits on radish treated with ANE were not significantly different. However, ANE enhanced the plant mass and yields of spinach and onion. The application of ANE for vegetable cultivation in greenhouses during the winter can be recommended for conventional as well as for organic production systems.

Keywords: *Greenhouse cultivation, Sustainable production, Fertilizers*

Introduction

During the last few decades, the awareness for environment and ecosystems preservation was increased. Due to application of heavy doses of mineral fertilizers, contamination with nitrogen, phosphorus and some accompanying heavy metals became serious problem in some agricultural soils and ground waters (Stojanović et al. 2006; Huang et al. 2007; Sebilo et al. 2013). Eutrophication of rivers, lakes, water-ways and water accumulations is another great problem caused by excessive application of mineral fertilizers (Carpenter 2005). Many trials highlighted the necessity of precise and reasonable fertilizer utilization management, as well as the use of some biostimulants and plant growth promotion matters in agricultural practice (Khan et al. 2009; Diacono et al., 2013).

Brown algae or rockweed, *Ascophyllum nodosum* L., is an important member of marine ecosystems which provides habitat, nitrogen and carbon storage services (Schmidt et al. 2011). It is used as a raw material in a foodstuff and pharmaceutical industry (Khan et al. 2009). Due to content of certain organic acids, polysaccharides, phenols, enzymes and hormones, brown algae have application in agricultural production (Audibert et al. 2010; Craigie 2011; Yuan and Macquarrie 2015).

Recent studies, showed the effects of *Ascophyllum nodosum* L. extract (ANE) as a plant growth promoter (Khan et al. 2009; Zodape et al., 2010; Alam et al., 2013). The application of ANE on some plant species is also connected with increment of phenolic antioxidant content (Fan et al., 2011). The findings of Vera et al (2011), as well as Abkhoo and Sabbagh (2016) suggested the possibility of application ANE as a stimulant and protection against plant pathogens. The most interesting issue of ANE is the improvement of stress tolerance of cultivated plants (Guinan et al 2012; Nair et al 2012). Particularly important is the increase in tolerance to low temperatures (Nair et al 2012).

In this experiment our main goal was to evaluate biological nutritional value (growth promoting effect) of three different ANE and to determine their usefulness for the winter vegetable production in the greenhouses without additional heating.

Materials and Methods

The experiment was conducted in the experimental glasshouse of the Institute of vegetable crops, Smederevska Palanka (44^o 22' N, 20^o 57' E, altitude 101 m above sea level), in Serbia. The experiment was set up as a completely randomized block design with three replications. The soil type was vertisol with pH 6.6, 3.83% of organic matter, 0.19% of nitrogen, 1.29% of calcium carbonate, 838.8 ppm of available phosphorus and 392.6 ppm available potasium.

The previous crop was tomato (grown as monoculture; more than 8 years). Plant residues were removed following the tomato fruits harvest. Soil was watered by sprinklers and tilled by rototiller. During the first decade of December 2016, radish (*Raphanus sativus* var. *radicula* L. cv. *Saksa*) and spinach (*Spinacia olerace* L. cv. *Matador*) seeds were sown at the high rate density in rows separated 20 cm from one another and the garlic bulbs (*Allium sativum* L. cv. *Domaći jesenjak*) were planted in similar distance rows with 7.5 cm distance between bulbs inside the row. Each plot measured $4m^2$. After sowing and planting, the drip irrigation system was installed and the plots were cowered by agro textile tiles in order to accumulate heat in rhizosphere and speed up emergence of crops.

When each crop emerged, excessive plants were removed and crop densities were decreased to terminal number of plants (80, 50 and 60 plants/m^2 of radish, spinach and onion respectively).

At the stage of two regular leaves, each crop was watered with three different ANE solutions, according to producers' instructions (Table 1.). The fourth treatment was water (control). Different ANE solutions were prepared as follows: four barrels (20l) were half filled with water. In three barrels, the ANE extracts were added (20, 40 and 40 ml of Biocomplex, ASCO Forte and SIB AF respectively) and the barrels were mixed by hands. Each ANE solution (10l) was sprinkled by hand-can with sieve as well as water used for control treatment. The experimental plots were previously watered by drip irrigation system. The can and sieve were carefully washed after each treatment. The same treatments were repeated after ten days.

During the experiment it was not noticed any pest or plant diseases appearance on experimental plants so the usual treatments with pesticides were not applied and all other measures of vegetable growing practice were in accordance with organic principles.

Table 1. Basic chemical properties of examined ANE and their concentration of application

Parameter	Biocomplex	Asco Forte	SIB AF 1/17
pH	4.1	6.4	8.4
Dry matter (%)	15.2	15.5	15.1
Organic matter (%)	9.2	11.2	11.6
N total (%)	0.27	0.22	0.24
C total (%)	4.5	5.5	5.7
Concentration of application (%)	0.2	0.4	0.4

When the crops reached commercial maturity, samples of 20 plants of radish, spinach and onion were taken and measured for examined parameters via analytical and technical scale (yields); radish (9.02.2017.): fresh plant mass, number of leaves per plant, hypocotyl mass and biomass yield per plot; spinach (14.03.2017.): fresh plant mass, number of leaves per plant, leaves mass and biomass yield per plot; onion (21.03.2017.): fresh plant mass, number of leaves per plant, plant height and biomass yield. Hypocotyl index (radish) was calculated and used for calculation of radish hypocotyl yield per area unit (Hypocotyl yield = Hypocotyl index * biomas yield per ha; Hypocotyl index = average hypocotyl mass/fresh plant mass). Spinach commercial yield per unit area (ha) was calculated via average fresh plant mass, leaves mass and biomass yield per plot i.e. Spinach commercial yield (ha) = (average leaves mass / average fresh plant mass) * biomass yield per plot * 2.500.
One way ANOVA was performed for each examined parameter of both crops. The differences between average parameter values were compared by Duncan-test ($p < 0.05$).

Results and Discussion

The average temperature in December was 0.2°C and the sum of sunshine hours was 103, which slowed down the sprouting and initial growth of plants. In January, the average temperature was -4.3°C with 12 days with temperatures below 0°C throughout the whole day, and sum of 99 hours of sunshine, which additionally slowed down the growth, but also caused the freezing and decaying of plants that were not at appropriate stage of development. In February, average temperature was 5.1°C with sum of sunshine being 114 hours, which influenced the growth and development of crops very favorably. In March, average temperature was above average, 10.4°C and the sum of sunshine was 184 hours. All this influenced the growth and development of plants beneficially.
In case of radish plants treated with ANE, recorded were the average larger plant weight, higher number of leaves per plant, higher hypocotyl mass, higher hypocotil index and higher yield of hypocotyl per unit area compared to the control group of plants. However, only in the yield of the hypocotil per unit area in ASCOforte and SIB AF treatments, this difference was statistically significant (Table 2).

Table 2. Average plant mass, number of leaves, hypocotyl mass, hypocotyl index and radish hypocotil yield, recorded in control treatment and in treatments of the tested ANE.

Treatment	Plant mass^{ns} (g)	Number of leaves^{ns}	Hypocotyl mass^{ns} (g)	Hypocotyl index^{ns}	Hypocotyl yield (t/ha)*
Control	24.47	7.87	10.82	0.44	4.81^{a}
Biocomplex	25.51	8.2	12.07	0.47	5.23^{ab}
ASCOforte	26.62	8.01	11.79	0.44	5.42^{b}
SIB AF 1/17	25.28	7.91	11.57	0.46	5.57^{b}

Values within the same column followed by the same letter do not differ significantly (p<0.05)

Compared to the control of ANE treated spinach plants, larger plant mass, higher number of leaves, higher root mass, higher mass per plant, and higher market yield was recorded. In the ASCOforte and SIB AF treatment, mass of the plant, root mass and market yield, and in regards to the control, the difference was statistically significant (p<0.05). Regarding the control treatment but also the other two ANE, there was no statistically significant difference in yield in the Biokomplex treatment (Table 3).

Table 3. Average plant mass, number of leaves, root mass, laves mass, yield imdex and market yield of spinach, recorded in control treatment and treatment of tested ANE.

Treatment	Plant mass (g)*	Number of leaves^{ns}	Leaves mass (g)^{ns}	Root mass (g)*	Commercial yield (t/ha)*
Control	12.54^{a}	7.93	6.85	1.62^{A}	2.58^{a}
Biocomplex	15.79^{ab}	7.97	7.96	2.06^{AB}	3.25^{ab}
ASCOforte	17.55^{b}	8.38	8.87	2.37^{B}	3.89^{b}
SIB AF 1/17	15.73^{ab}	8.22	8.38	2.2^{B}	3.91^{b}

Values within the same column followed by the same letter do not differ significantly (p<0.05)

In garlic plants treated with ANE, comapred to the control, noted were the higher plant mass, greater number of leaves, larger plant height and higher yield. In all three ANE treatments, difference was statistically significantly higher (Table 4)

Table 4. Average plant mass, number of leaves, height of plants and garlic yield, recorded on the control treatment and the treatment of the tested ANE.

Treatment	Plant mass (g)*	Number of leaves^{ns}	Plant height (g)^{ns}	Yield (t/ha)*
Control	7.33^{a}	5.40	36.9	3.08^{A}
Biocomplex	9.77^{b}	5.95	40.74	4.4^{B}
ASCOforte	10.23^{b}	5.49	40.55	4.39^{B}
SIB AF 1/17	9.18^{b}	5.73	37.15	4.11^{B}

Values within the same column followed by the same letter do not differ significantly (p<0.05)

Many studies indicate that application of seaweed increases the yield of vegetable crops (Jayaraman et al 2011; Jannin et al 2013; Đurić er al 2014; Abkhoo and Sabbagh, 2016) but there is also a number of studies with opposite results (Lola-Luz et al 2013; Yusuf et al 2015).

Testing the effects of ANE foliar application on cabbage, Lola-Luz et al (2013) determined qualitative improvements i.e. increase in phenol and flavonoid compounds, however, no significant increase in yield relative to control was found. The absence of effects in the above case could be attributed to the method of ANE application, since it was noticed that watering had better effects than foliar application of ANE (Abkhoo and Sabbagh, 2016).

Increase in growth of plants treated with ANE is associated with better health conditions and greater resistance to plant diseases (Jayaraman et al 2011). In our study, no harmful insects or diseases were observed, both on plants treated with ANE and on control treatment.

Đurić et al (2014) and Yusuf et al (2015) have found that ANE can influence the increase in vegetative mass of the plant, in particular the increase in root mass, i.e. Hypocotyl. The effect on treated plants seems to depend on the type of ANE used. By examining different ANE on Brassica napus, no statistically significant increase in root biomass and overheads was observed in all ANE treatments (Jannin et al 2013).

Our results are in accordance with experiments of Janin et al. (2013), Đurić et al (2014), Yusuf et al (2015), especially when it comes to garlic and spinach where statistically significant increase in average root mass and average plant mass was determined.

On the other hand, the absence of a statistically significant effect of the ANE application in the observed properties in radish is most likely due to short vegetation period of the investigated species, and in particular due to the short period of time, since the moment of treatment with the investigated agents, until the moment of harvesting.

An increase in yield of radish could be attributed to a larger number of plants that survived negative temperatures, which is in accordance with results of Nair et al (2012), which confirmed the increase in tolerance to low temperatures on Arabidopsis talian plants.

Conclusion

Based on the results of the experiment, use of the tested ANE can be recommended for winter vegetable production in greenhouses. All three investigated ANE showed positive effects on yield and observed properties. Given the relatively low content of the main nutrient macroelements in ANE and relatively small dose of application, it can be concluded that the cause of increased growth and yield of treated plants, is not the main macroelements, but some physiologically active substances found in ANE. The obtained results on radish, spinach and garlic lead to assumption about the effectiveness of ANE on other plant species during the winter production season in greenhouses. The special benefit of ANE is that their production is renewable and can be applied both in conventional production and in organic farming systems.

Abstract

The experiment was conducted in 2014 in the experimental plantations of Japanese quince (*Chaenomeles sp.*) at RIMSA in Troyan, in cooperation between RIMSA-Troyan and FRDI-Plovdiv, Bulgaria. The influence of the organic fertilizer Tekamin Brix (in two concentrations 0.2% and 0.3%), NH_4NO_3 and manure on the biochemical composition of fresh and dried fruits of Japanese quince were studied. The effect of drying process on the biochemical indicators was reported. Fertilization influenced on the values of tannins, total and inverted sugar in fresh fruits. After the drying process the amount of ascorbic acid was better preserved in fruits fertilized with Tekamin Brix 0.2 %. - 40.48 mg/% and the control - 42.24 mg/%. In dried fruits the total sugars have a higher content than the variant with Tekamin Brix 0.2%. The highest amounts of tanning substances and pectin in dried fruits are found in fruit fertilized with Tekamin Brix 0.3% and mineral fertilizer. The highest acidimetric coefficient for the fresh and dryied fruits is found in the variant with the mineral fertilizer.

Key words: *Japanese quince (Chaenomeles sp.), Fresh fruit, Dry fruit, Bio chemical compounds, Organic fertilizers.*

Introduction

Under the changing climate, *Chaenomeles* deserves great attention because of its increased cold and drought resistance. Chemical additives in food production have been continuously increasing worldwide in recent years. In response to the increased interest in pure agricultural products, Japanese quince is an appropriate culture for inclusion in organic production and sustainable agriculture in Bulgaria.

The fruits of *Chaenomeles japonica* are used in the food industry for processing because of their high content of biologically active compounds: organic acids, vitamin C, phenolic compounds, pectin and aroma components (Lesinska *et al.*, 2006). Vitamin C content in fruits differs from 41.2 to 105.8 mg 100 g -1 , phenolic compounds range from 523.9 to 1271.7 mg 100 g (Krasnova *et al.*, 2007). Another property of great interest is its presumed high antioxidant capacity due to the content of vitamin C and phenolic compounds. The content of vitamin C is 45 to 109 mg 100 ml -1 and phenolic compounds in juice of the *Chaenomeles japonica* was 210 – 592 mg 100 ml -1 (Hellin *et al.*, 2003).

Drying is a method that has been applied as a way to preserve fruits. The process includes different variants of application in order to obtain the finished product. It is opened, as it is being improved all the time in the different stages and elements of technology. An important element in the different drying technologies is to follow the changes in biochemical compositions of fruits (Mezhenskii, 2004; Mondeshka, 2005; Graeme *et al*., 2007; Rupasova *et al*, 2008; Figueiredo, 2009;; Zhu *et al*., 2012; Zhang *et al*., 2014). Dried fruits in the form of a powder

are a dietary supplement used as a health prevent atherosclerosis and have antioxidant effects (Tang *et al.*, 2000; Dharmananda; 2005; Malgorzata *et al*, 2007; Tang *et al.*, 2010).
Dried fruits from *Chaenomeles sp*. are used from thousands of years in Chinese medicine. Japanese quince is a valuable remedy in China, and occupies a significant component of their prescriptions (Chace *et al.*, 1997; Dharmananda S., 2005; Sagar *et al.*, 2010; Figueiredo, 2009).

Material and Methods

The experiment was carried out in 2014 in a demonstration plantation of the Research Institute of Mountain Stockbreeding and Agriculture – Troyan (Bulgaria). Five genotypes of *Chaenomeles* were included in each variant. Different fertilization types were used, such as the organic fertilizer Tekamin Brix, mineral fertilizer (ammonium nitrate - NH_4NO_3) and manure. The results are presented as averaged values of each variant and compared with the control. The planting scheme is 2.50/1.50 m. Cultivation technology includes grassed inter row spacing. The intra row spacing is kept in black fallow under non-irrigating conditions. The crop is grown according to its agro-technical requirements.

The following fertilization variants have been applied in the experiment:

- Tekamin Brix - 0.2 % - foliar treatment, applied two times during the period of vegetation
- Tekamin Brix - 0.3 % - foliar treatment, applied two times during the period of vegetation
- Ammonium nitrate (NH_4NO_3) - 0.200g/bush (before the period of vegetation)
- Manure - 5 kg/bush – (before the period of vegetation)
- Control.

Fruits reached their ripening stage in October. Drying process was fulfilled in FRDI-Plovdiv, and the biochemical composition was determined at a chemical laboratory at RIMSA-Troyan.

Results and Discussion

Data from the biochemical composition results of fresh and dried fruits of *Chaenomeles* are presented in Table 1 and Figure 1.
The dry weight of fresh fruits of the variants ranges from 11.96% (control) to 14.15% (manure variant) (Table 1). The fertilization factor affects the values of the indicator. In terms of refractometric dry substances, the lowest values were found again in the control - 8.38% and the highest in fruit treated with the organic fertilizer Tekamin Brix - 12.17%. An increased content in the amount of sugars was reported in the variant with fertilization compared to the control (Figure 1).
There is no significant variation in the total sugar content, which is slightly above five percent in the variant with fertilization. It is 4.40% in the control. The highest amount of invert sugar is found in manure variant - 4.40% and the mineral fertilizer - 4.13%. For comparison, it is 3.50% for the control. This is not the trend in the sucrose content of fruit. The highest content is found in the variants with a higher concentration of the organic fertilizer - 1.50%, followed by those with a lower concentration - 1.13% of the same fertilizer. Organic acid values are in close range between variants, more than two percent. Fertilization did not significantly affect the amounts of ascorbic acid, which is 99.44 mg /% in fruit fertilized with 0.2% Tekamin Brix and its content is very close in the control 98.12 mg /%.

Table 1. Biochemical composition of fresh and dried Chaenomeles fruits in different variants of fertilization.

Fertilizer	Type of fruits	Dry weight	DM in %	Organic acids %	Ascorbic acid mg/%	Tannins %	Pectin %
Tekamin Brix 0.2%	Fresh fruits	13.02	8.43	2.33	99.44	0.503	0.437
	Dry fruits	90.02		10.08	40.48	0.865	0.987
Tekamin Brix 0.3%	Fresh fruits	13.29	12.17	2.17	95.63	0.558	0.777
	Dry fruits	90.66		9.40	29.33	1.305	3.095
NH4NO3	Fresh fruits	14.02	9.33	2.14	92.11	0.361	0.830
	Dry fruits	90.46		7.92	27.57	1.195	3.050
manure	Fresh fruits	14.15	9.50	2.44	87.41	0.440	0.770
	Dry fruits	90.03		9.48	30.51	0.904	1.233
Control	Fresh fruits	11.96	8.38	2.24	98.12	0.442	1.030
	Dry fruits	90.45		10.26	42.24	0.992	1.500
V%	Fresh fruits	6.52	12.86	8.25	10.75	20.16	34.22
	Dry fruits	0.80		10.77	22.88	16.99	79.43

As far as tanning substances are concerned, they are clearly higher in the variants with the organic fertilizer Tekamin Brix with values of 0.558% at the higher fertilizer concentration and 0.503% at its lower dose. The smallest amount is found for fruits fertilized with ammonium nitrate - 0.361%. The results of pectin amounts indicate that fertilization does not affect its content in fruits. It reaches up to 1.030% in the control variant, and the lowest amount is found in the fertilization variant with with Tekamin Brix - 0.2% - 0.437%.

The analyzed organic acids of which *Chaenomeles* fruits are rich. There are not significant differences between the variants in the amount of analyzed organic acids, which *Chaenomeles* fruits are rich in. However, the fruits fertilized with ammonium nitrate have the smallest amount of organic acids - 7.92% and more in the control - 10.26%. The drying process had an effect on ascorbic acid values. In comparison with fresh fruits are reported two to three times lower amounts, while it is better maintained in the variants with Tekamin Brix - 0.2% - 40.48 mg/% and the control - 42.24 mg/%. A significant increase in tanning substances has been registered. The most significant increase is found in the mineral fertilization variant up to 1.195%. The amount of pectin is most significant in the variants with Tekamin Brix 0.3% - 3.095% and with the mineral fertilization - 3.050%. The lowest content is found in the variant with Tekamin Brix 0.2% - 0.987%.

The variation of values in dry weight, dry refractometric, organic acid and ascorbic acid for fresh fruit is low to medium high and high for tannins and pectin. The highest variation in ascorbic acid and pectin for dried fruits ratios is the highest.

LSD there is no statistical significance of fresh and dried friuts.

	Fresh fruits						Dry fruits				
	Tekamin Brix 0,2%	Tekamin Brix 0,3%	NH4NO3	manure	Control		Tekamin Brix 0,2%	Tekamin Brix 0,3%	NH4NO3	manure	Control
Total sugar %	5,18	5,18	5,02	5,23	4,40		17,35	13,25	13,43	14,88	13,47
Inverted sugar%	3,98	3,60	4,13	4,40	3,50		16,48	12,68	12,40	14,15	11,32
Sucrose %	1,13	1,50	0,84	0,79	0,86		0,83	0,54	0,98	0,70	2,05

Figure 1.Total sugar, inverted sugar and sucrose in fresh and dried Chaenomeles fruits in different variants of fertilization, (%).

The drying process has had an effect on the total sugar content of fruits in some of the variants, in relation to its values in fresh fruit (Figure 1). The largest amounts were reported in the variants with the application of Tekamin Brix - 0.2% - 17.35% and significantly less are in the other variant with the application of organic fertilizer with a higher concentration - 13.25%. When invert sugar is analyzed, the trend remains as in the case of fresh fruit. The fertilized variants have higher values of the indicator, the most striking being the difference between the first variant - 16.48% in comparison to the rest.
The drying process also affects the amounts of sucrose. Unlike fresh fruit, the largest amount in dried fruit is found in the control variant - 2.05%. In the other variants, sucrose is present in amount below one percent.

For dry fruits, the dry weight is almost equal in the variants - about and above 90% (Table 1).

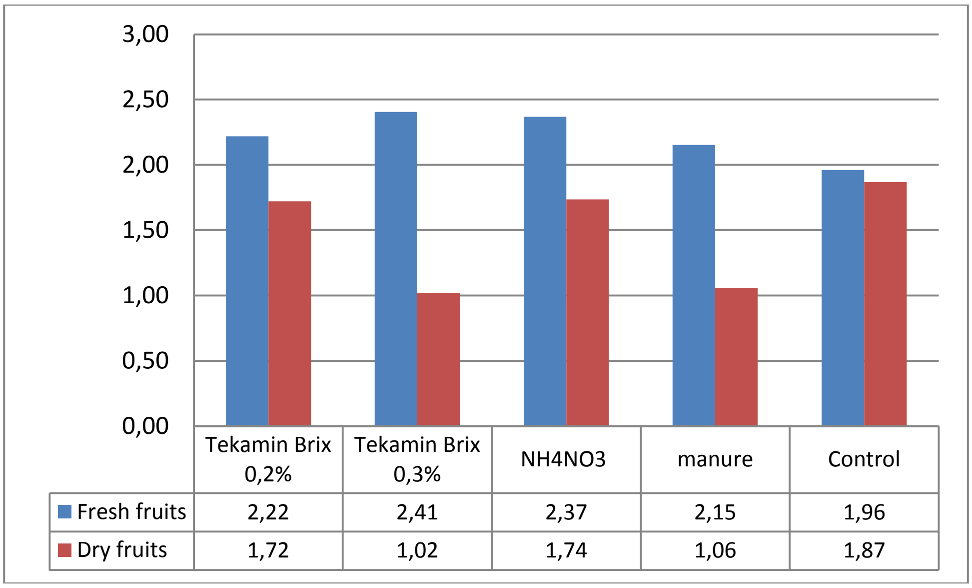

Figure 2. Acidimetric (sugar-acid) coefficient of fresh and dried Chaenomeles fruits in different drying variants.

The acidimetric coefficient determining the taste properties of fruits is presented in Figure 2. Generally, it is higher for fresh fruit. Its values are most significant for fruits in the variants with Tekamin Brix 0.3% and the mineral fertilization. The lowest value is found in the control. The highest acidimetric coefficient is reported for dried fruit in the control variant and the mineral fertilization. Its values are almost the same for the Variants with Tecamine Brix - 0.3% and for manure variant.
For fresh fruit, the variation in dry weight, dry refractometric, organic acid and ascorbic acid values is low to medium high and high for tannins and pectin. For dried fruits, the highest variation in ascorbic acid and pectin ratios is the highest.
LSD there is no statistical significance of fresh and dried friuts.

Conclusion

The influence of fertilization on the biochemical composition of fresh and dried fruits of *Chaenomeles* fruit has been reported.
The effect of drying process on the individual biochemical parameters is monitored.
Fertilization of fresh fruit has been influenced by the values of tanning substances, total and invert sugar.
After the drying process, the quantity of ascorbic acid is better maintained in fruit that were fertilized by Tecamin Brix with 0.2% - 40.48 mg /% and the control - 42.24 mg /%.
In dried fruits the total sugars have a higher content than the variant with Tecamin Brix 0.2%.
The highest amounts of tanning substances and pectin in dried fruits are found in fruit fertilized with Tekamin Brix 0.3% and mineral fertilizer.
The highest acidimetric coefficient for fresh fruit is found in the variants with Tekamin Brix 0.3% and mineral fertilizer, and for the dried fruits – with NH_4NO_3 and the control.

Abstract

The aim of this study was to evaluate irrigation and fertilizer requirements of broccoli (*Brassica oleracea* L. var. *italica*) in Tekirdağ region. For this purpose, using fertigation techniques, growing possibilities of broccoli and the effects of soil and plant to fertilizer concentrations have been established and compared with applied fertilizer rates and irrigation water volumes. Field trials were conducted in a greenhouse during the year 2016 spring and autumn periods. Experiment was applied at two different irrigation levels and four different fertilizer with the randomized complete block experimental design and three replicates. Irrigation water ratio was, depending on the greenhouse soil moisture monitoring; the irrigation application was started when available soil moistures drops to 60%and deficit soil water was completed at 50(I_2) and 100% (I_1) percent. Fertilizer applications was performed as vermicompost, two different doses of liquid worm-fertilizer and ammonium nitrate.Generally, the effects of irrigation and fertilizer amounts on yield and macro and micro nutrient content of plant and soil were statistically significant. The greatest broccoli yield was obtained in the spring period from I_1G_4 treatment as 1665 kg da^{-1} and in the autumn period yield did not obtained. It was observed that fertilizer activity increased with irrigation practices, chemical fertilizer applications contributed to yield; also, vermicompost applications have been shown to contribute to soil in respect of soil and leaf nutrients.

Key Words: *Broccoli, vermicompost, fertigation, organic fertilizer, chemical fertilizer*

Introduction

In order to meet the rapidly increasing food needs of humans, it is necessary to increase the yield and quality obtained from the unit area. Cropping systems involves studies about determining when and how much irrigation and also which fertilizers to apply to a plant during its growing period. Within this scope; it is first needed to choose proper irrigation and fertilizer scheduling, which allows efficient use of available water and fertilizer will not cause yield decrease. Decreasing water resources and water demands have enabled the development of irrigation technologies. Today, with controlled irrigation water, removing the problem of drainage and salinity in the soil, the use of organic fertilization and irrigation systems that will increase yield-quality gains more and more importance (Çetin *et al*., 2006). Organic fertilizers, which are becoming more and more popular, are at the forefront of organic worms called vermicompost. In previous studies relating to vermicompost, they reported that the earthworm for agroecosystems have a very significant impact on the quality of soil (Edwards and Bohlen, 1996; Çıtak *et al*., 2011; Bellitürk and Görres, 2012; Jahan *et al*., 2014; Adiloğlu *et al*., 2015). The aim of this study was to evaluate irrigation and fertilizer requirements of broccoli (*Brassica oleracea* L. var. italica) in Tekirdağ region (Turkey). For this purpose, using fertigation techniques, growing possibilities of broccoli and the effects of soil and plant to fertilizer concentrations have been established and compared with applied fertilizer rates and irrigation water volumes.

Materials and Methods

Field trials were conducted in a greenhouse during the year 2016 spring and autumn periods in the city of Tekirdağ (Turkey). Each plot covered an area of 9.00 m^2 and contained 42 plants with 0.50 m x 0.40 m spacing. The soil type is deep, heavy textured, well-drained and the available water holding capacity within 0.60 m of the soil profile is approximately 80 mm. The electrical conductivity (EC) of irrigation water was classified as C_2S_1 according to U.S. Salinity Lab. (US Salinity Laboratory Staff, 1954). Experiment was applied at two different irrigation levels and four different fertilizer with the randomized complete block experimental design and three replicates. Irrigation water ratio was, depending on the greenhouse soil moisture monitoring; the irrigation application was started when available soil moistures drops to 60% and deficit soil water was completed at 50(I_2) and 100% (I_1) percent. Fertilizer applications was performed as vermicompost, two different doses of liquid worm-fertilizer and ammonium nitrate. In the research, soil moisture levels was monitored gravimetrically. Irrigation system was composed of water source, fertilizer tank, screen filter, pipelines and drippers, respectively. In the research greenhouse, climatic elements were monitored throughout the cultivating period from the meteorology station that was placed into the greenhouse. Irrigation water was applied to plots with drip irrigation. Effective root depth was 30-60 cm and evapotranspiration rates were calculated with respect to 60 cm soil depth, according to water budget approach (Walker and Skogerboe, 1987). Rumba F1 seedlings were planted by hand into the parcels of which the field preparation was completed on April 15th, 2016 (DOY 106) in spring and on October 01st, 2016 (DOY 274) in autumn. Yield harvest was completed on June 27th, 2016 in spring season. Plants have not reached the harvest maturity due to the negative weather conditions in autumn. Produce leaf and soil samples taken from each parcel were taken to the laboratory, physical measurements and also chemical analyzes were completed according to methods of Sağlam (2012), Kacar (2009), Lindsay and Norvell (1978). Irrigation water use (WUE) and water use efficiency (IWUE) rates were calculated based on the irrigation water applied to trial subjects, measured evapotranspiration and harvest efficiency values (Zhang *et al.*, 1999). The variance analysis of the data obtained from the research, the significance control of the variations between the averages, the correlations between the characters studied were determined according to the principals stated in Yurtsever (1984) using SPSS 8.0.

Results and Discussions

The maximum interior temperature value was measured as 30°C in the month June while the minimum interior temperature value was measured as 17°C in the month April in spring according to the meteorology station. These values changed between 22 and 2.4 °C in autumn. The growth periods and growing season lengths for the year 2016 is shown in Figure 1. Seasonal total evapotranspiration, the amounts of applied irrigation water, yield and yield parameters for all treatments during the spring periods, are summarized in Table 1. Treatments were irrigated using fertigation method nine times in the spring and autumn growing periods at varying day intervals. The macro and micro element quantities obtained from broccoli leaf samples and soils taken in the all plots, also ANOVA results of each element are studied for the spring and autumn periods, but only the spring period results are presented in Table 2,3.

Generally, the effects of irrigation and fertilizer amounts on yield and macro and micro nutrient content of plant and soil were statistically significant. The greatest broccoli yield was obtained in the spring period from I_1G_4 treatment as 16.65 t ha^{-1} and in the autumn period yield did not obtained. Some of parameters measured on the leaf have remained within the desired limits, parallel to the work carried out previously (Jones *et al.*, 1991; Alpaslan *et al.*, 1998; Bergmann, 1992; İbrikçi *et al.*, 2004). The fact that the Ca, P, Mg, N contents of soil samples are below the limit values is "insufficient" and that the Fe, Cu, Ca, K elements are more than the limit values is "sufficient" (Lindsay and Norvell, 1978; Tovep, 1991; Güneş *et al.*, 2010; Kacar, 2009). In particular, vermicompost applications cause enrichment of the soil in terms of Fe, Zn, K elements (Preetha *et al.*, 2005; Chamani *et al.*, 2008; Sinha *et al.*, 2010).

The highest IWUE values for the adequate water applied treatment were obtained from subject G_4 and G_1 as 4.23 kg m^{-3} and 3.44 kg m^{-3}, respectively.

Conclusion

The fact that yield values obtained from the fully irrigated subject I_1 were considerably greater than those obtained from subject I_2, which was subjected to maximum limitation, clearly exhibits the importance of irrigation for broccoli cultivation.

It was observed that fertilizer activity increased with irrigation practices, chemical fertilizer applications contributed to yield; also, vermicompost applications have been seen to contribute to soil in respect of soil and leaf nutrients. According to Bellitürk (2016),

vermicompost expression is a word which is used for the final product (humus-like material) of composting procedure of organic waste materials by soil worms.
Vermicompost increases flowering and soil organic matter compared to chemical fertilizer, although the growing of the plants in the chemical fertilizer applied plots is better; it was determined that plants in vermicompost applied were matured early and their heads were tighter. In the light of the results obtained from this study, it is thought that this fertilization, especially 200 kg da^{-1} dose, may be "sufficient" to grow plants rich in quality, fertile and mineral nutrients.
To avoid low yield values in agricultural production and to contribute to the improvement of intensive farming soil, coexistence of chemicals and vermicomposts in fertilization programs will lead to more beneficial results.

GEOMORPHOLOGY AND WATER QUALITY OF THE COASTAL LAGOONS OF ALBANIA

Elvin ÇOMO*, Albana HASIMI, Jakup HOXHAJ, Bashkim LUSHAJ

1Institute of Geosciences, Energy, Water and Environment, Polytechnic University of Tirana,

Abstract

Coastal lagoon ecosystems are typical habitats of the Mediterranean Region. The Albania coastline has a total length of about 380km, two third of which border the Adriatic Sea and one thirds the Ionian- Sea. This coastline is characterized by an extremely active sedimentary regime. The sediments discharged by the rivers Shkumbini, Semani and Vjosa have built up the coastal plain, where at present the two largest lagoons of Albania, Karavasta and Narta, are found. Karavasta lagoon (Ramsar site) is included on the most various mosaics of coastal habitats in Albania that extend between Shkumbini and Semani river, in the central part of the Albanian Adriatic coast. Karavasta Lagoon is included in Karavasta complex area with Godulla lagoon, and irrigation collectors of Myzeqe and Terbufi, Kulari area and Semani and Shkumbini River at both sides of the lagoon. The coastal zone of the Vlora Bay, including that of the Treport, is one of the most active one from the geomorphologic point of view, as well as related to the environmental issues. The coastal lagoons have attracted man’s interests for their biological resources richness. Over the centuries, fishing and hunting, more recently nature conservation, have concentrated man’s interests on these environments. Such activities have determined the interventions for maintenance of hydraulic circulation within the lagoon, the stabilization of the inlets (channel connecting sea- lagoon), the attempt to control and regulate freshwater input in quantity and quality.
Keywords: *lagoon, wetland, shelf, littoral, spaces, erosion*

Introduction

Coastal lagoon ecosystems are typical habitats of the Mediterranean Region. The Albania coastline has a total length of about 380km, two third of which border the Adriatic Sea and one thirds the Ionian- Sea. (Lushaj, 1996 & 2006). Wetlands provide important services to human societies, such as water supply, sanitation, flood control and food resources. All over the world, management of water the key component of wetlands will be an issue of crucial importance in the 21st century, affecting the daily lives of millions of people. Furthermore, wetlands are cradles of biodiversity, providing the water and primary productivity upon which countless species of plants and animals depend for survival. Coastal lagoons located between land and seas are influenced by both the marine and terrestrial environments. Coastal lagoons are naturally enriched areas with very unstable environmental conditions due to their position from the open sea and to their shallowness. In this sense they are considered as naturally stressed environments. Furthermore, being close to land, they are vulnerable to human disturbance. Adriatic and Ionian coastal lagoons, constitute16 complex area with 40 smaller wetlands as part of their stretch starting in the north, as Velipoja, Viluni, Kune-Merxhani, Vaini-Ceka, Patok, Rushkulli, Karavasta-Divjakë, Narta, Orikum and Butrinti. Space representing shelf deposits, the littoral, alluvial and other older places; mollas, terrigenous, flyschand carbonates.(Hoxhaj et al., 2010).

Material and Methods

In the framework of the implementation of the project “Monitoring of the quality of surface waters", the monitoring program of the waters quality of the lagoons system have been developed. According to this program, the sampling has been conducted in 4 fixed stations inside the lagoons during time interval 2010-2014 with a frequency of 4 times per year. Water samples are taken in surface respecting the sampling procedure for the shallow waters. Basic parameters analyzed are pH, transparency, temperature, Salinity, BOD, COD, NO_3-N, NO_2-N, NH_4-N, P-PO_4 and P total. The basic parameters level has been analyzed using standard methods prescribed in ISO and EU standards and from the APHA methods for analyzing water and wastewater (APHA 20-th edition).

The geographic extent of the Karavasta Lagoon

The Karavasta lagoon located along the Adriatic coast, between the Shkumbini river, in north, and the Semani river, in the south. Lagoon is largest of our country and the entire southern coast of the Adriatic with an area 4330 ha, length 10.6 km, width 4.3 km and a depth of up to 1.5 m. Separated from the sea through a broad belt of sand, covered by dense forest. Connected with the sea by three channels, one of which is open to fishing needs.The area is bordering the Adriatic Sea and the western hillside of Divjaka hills, and is composed mainly of Quaternary sandy and clay deposits. South of Shkumbini mouth parallel with sandy and sub sandy area Quaternary deposits occur, and round Karavasta lagoon, with find seamy deposits with clay, and sub clay, sub sand and peat of Quaternary age. Between the Divjaka hills, the Shkumbini river in the north and Semani river in the south, there are deposits of alluvial clay and sand. The area is poor in underground water. The Karavasta lagoon is connected to the sea via three channels: Northern - 700m long, 17m wide and 0.75m deep: Central - 1200m long, 26m wide and 1.55m deep: Southern - 500m long, 23m wide and 0.61m deep. Only the northern channel is connected directly with the sea, but to maintain this connection, regular dredging is necessary. The others communicate with the Godulla lagoon, west of Karavasta lagoon, with an area of 650 ha, 5 km length, 3,8 km width and a maximum depth of 1.7 m, connected to the sea by two other channels (fig. 1).

Figure 1.Geographical situation of the main lagoons of Albania

The geographic extent of the Narta Lagoon

Narta Lagoon is one of the largest and the most important coastal wetlands of Albania. It is situated about 14 km in the northern part of Vlora town. The lagoon has a surface of 42 km^2, where 13.8 km^{2}of the northern part are used as saline (Skrofotina Salt Pan). This is formed from a coast bay, which is divided from the sea as result of soil accumulation from Vjosa River is transported in this bay(Lami.S 2004).The average depth is 1.26 m. It is connected with the Adriatic Sea by two artificial channels; the southern channel is 200 m long and 6.48 m wide; the northern channel is 800 m long and 11.60 m wide (Pano, 2009). At its north extend the bottom part of Vlora Myzeqeja, while in south and in its south western Narta lagoon border with picturesque hills of Zvërneci. There are two small picturesque islands in this side. There is the monastery of Zvërneci in the big island. The east coastline of Narta Lagoon represent from the western face of Vlora hills area, which are dressed with olive trees and vineyards. The hydro-morphologic processes in the lagoon are related with the adjacent hydrographical network, with a contribution of solid alluvium materials from different small rivers, mainly during winter period, and the detritions from the Adriatic Sea wave refraction. Despite relatively big surface the lagoon is characterized by a short time of water circulation, firstly because of huge water inflow and outflow through water exchange between lagoon and sea, and secondly, because of its small depth (Selenica. A 2008). At the same time, water movements in lake can be affected by many factors, such as wind, air temperature, and pressure and bottom friction.

Lagoons morphology

Geology, its dynamics, structure of hydric system and climate have conditioned the morphology of Narta Lagoon Vlora bay and Vjosa river mouth. Narta Lagoon was formed in e sea bay, which is closed by solid sediments transported by Vjosa River to the sea. The neotectonic phenomena also characterize the lagoon area. At southwestern direction, the Tortonian molasses Zvërneci hills chain from the isle separated Narta Lagoon from Adriatic Sea. Geological section is extended from the beach to the northern direction and by erosion abrupt slope has been formed rising over the seaside. These characteristics make Zvërneci a rare geo-monument, with great international scientific and touristic interest. Around the Narta Lagoonside the lagoon Quaternary deposits (Q_4^1)are extended. These deposits are represented by sky-blu-gray color silt, with siltstone interbreeds of gray color. Thickness of these deposits varies from 0.5-1 m up to 20-30m. Lagoon deposits have covered marine Quaternary deposits (Q_4^m). Marine deposits are represented by arkoses sand, with green silky clay and gray siltstone interbreeds. Quaternary deposits thickness is more than 100m. The dominant geomorphologic processes acting in the Karavasta lagoon area, consist in a notable discharge of solid alluviums from the Semani and Shkumbini rivers and wave transformation processes around the delta cusps and the bayed beach enclosed between them (Ciavola et al., 1999; Phare, 2002). This area is composed mainly of sandy and clay deposits of Quaternary age. South of the Shkumbini mouth, parallel with the shore sandy Quaternary deposits occur as beach ridges, while around the Karavasta lagoon, swampy deposits are found consisting of clay, silts, fine sand and peat (turf) of Quaternary age. Between Divjaka hills, Shkumbini River in the north and Semani River in the south there are deposits of alluvial Quaternary clay, silts and sand. The western sides of the Divjaka hills are formed by mudstones, sands and conglomerates of Pliocene age. The central part of Karavasta lagoon is characterized by a slimy layer that in the peripheral zone is bordered by peat, sand, sub-sand and sub-clay (Ciavola et al., 1995). Landscape changes in this lagoon take place as accumulation and deposition of sand mostly with dramatic coastal changes, creation of lagoons, moderates to strong erosion affecting low-lying shores and sand spits. To note that the magnitude of coastal changes is unusual for Mediterranean environments, normally altered by man because of development pressures. Due to the sedimentation of the alluvium of the Semani and Shkumbini rivers, the mouth of the deltas is constantly shifting on the coastal plain in an endless search for an equilibrium position. The sediments discharged by the rivers Shkumbini, Semani and Vjose have built up the coastal plain where at present the two largest lagoons of Albania, Karavasta and Narta, are found (Ciavola et al., 2000). Data from (Pano. N 1992) for the period 1948-1990, indicate that the mean total sediment discharge of Albanian rivers was in the order of 65.7 million tons per year. It is quite likely that in recent years the sediment load decreased because of sand and gravel extraction and dam construction (Simeoni et al., 1997). Values of water and solid discharges of Shkumbini, Semani and Vjosa rivers are summarized in Table 1.

Table 1: Mean annual water discharges and sediment load of Shkumbini, Semani and Vjosa rivers.

River	Catchment (km^2)	discharge (m^3/s)	sediment discharge (tons/year)
Shkumbini	2444	61.5	7.20×10^6
Semani	5649	95.7	16.5×10^6
Vjose	6706	195	8.30×10^6

The coastal morphology of Karavasta lagoon has been highly dynamic for the last 135 years because of the changes which occurred to the two river deltas. The major events occurred when the Semani river changed its course moving northwards in the 1950s, then again southward in the late 1970s. Then the erosion of its abandoned delta progressively created a spit growing northward of the most recent mouth, which eventually closed in a few years to form the Godulla lagoon. At the moment, it seems that this Godulla barrier-island system is being eroded and will tend to disappear within years (Technical, 1995; MedWetCoast2005).

Climate

The area is situated in the coastal plateau, which according climate regionalization of Albania, belongs to the Central Mediterranean field climate. It is characterized by mild winters with abundant precipitation and hot-dry summers. Precipitations are mainly in the rain form, while the snow layer is of very short duration. Solar radiation, as one of the principal factor ofclimate, is very uniform over the area under the study. The annual solar radiation for the area is about 1540 kwh/m^2. The highest value is observed in July and the smallest one in December

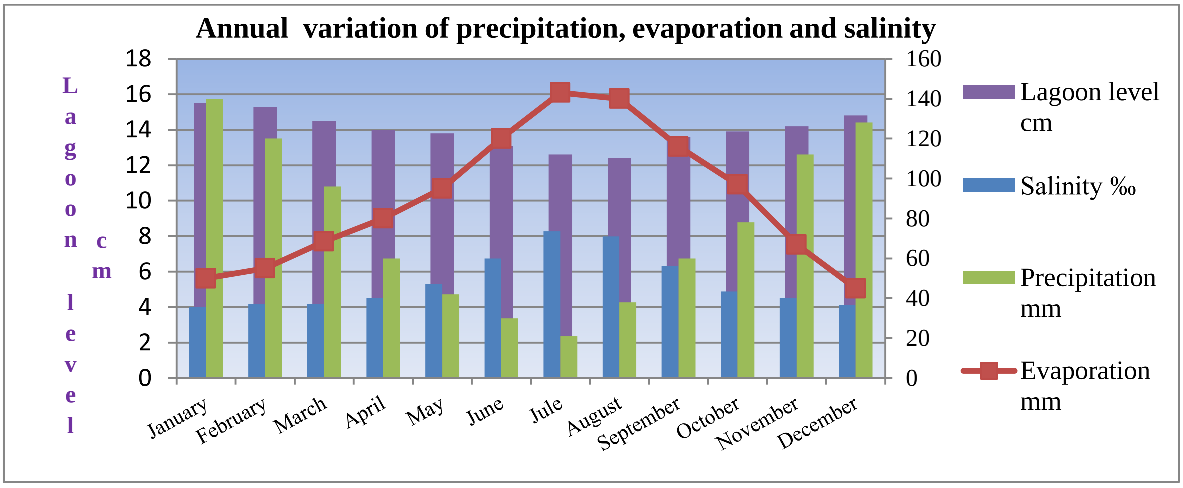

Figure 3. Relation between precipitation, evaporation and salinity of Narta Lagoon.

The annual average of air temperature varieties from 15.4 ^{0}C up to 16.3 ^{0}C. The maximal air temperature is reached in July/August with 30.0 ^{0}C and the minimal in January with 4.8 ^{0}C. The climate in coastal area of Karavasta Lagoon is typically Mediterranean, with average precipitations of 893 mm in Divjaka, 70 to 75 % of the rain occurring from October to March. Evaporation estimated from climatologically data of Vlora station (Hydro meteorological Institute, 2001) reach an annual value of about 1,200mm, evaporation calculated from data temperature in the Karavasta area (Technical, 1995, 2003) is of the same order. Although there is a hydro- climatic deficit, it is not as important as in other western Mediterranean areas. Nevertheless, during the summer month, with monthly evaporation values reaching 150 mm, and low precipitations the water deficit is severe for the Karavasta lagoon (fig.4). This implies that even with its original drainage basin, the lagoon has always faced strong seasonality in its water and salinity regime, as it is generally the case for Mediterranean coastal lagoons. Another important climatic variable for lagoon hydrology is the wind, which allows mixing of waters and enhances or counteracts the tidal effect on water exchanges with the sea. (Lowry, J. 2006).

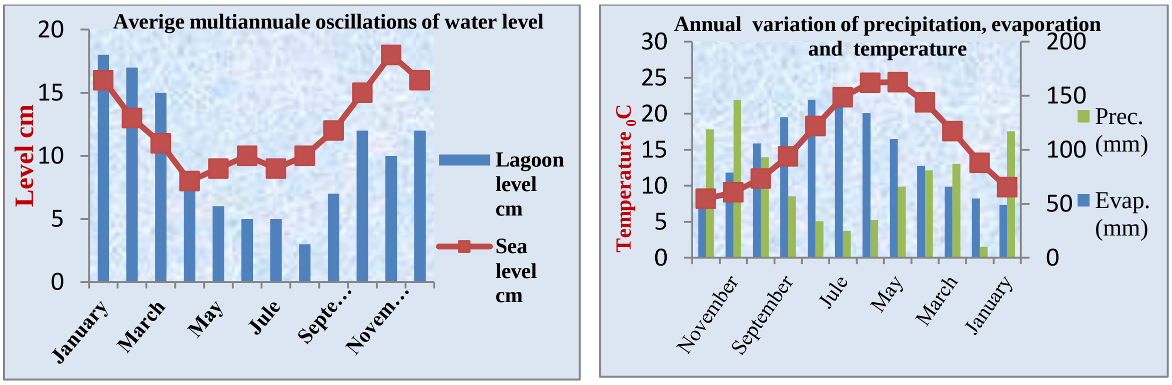

Figure 4. Monthly average temperature, rainfall and evaporation in the Karavasta.

Air humidity is regularly linked with air temperature. Monthly mean of the relative humidity in this zone variate from 62 to 69 %, while the annual mean is 66 %. Wind is mainly represented by sea breeze. The sea breeze phenomenon here is very evident especially during the summer. Winter is dominated by eastern winds with an average speed of 3.5 m/s. The mean velocity is respectively 4.4 m/s and 5.2 m/s. Due to its limited water depth, the thermal regime of lagoon waters is similar to the air temperature regime. The seawater that penetrates in lagoons has a great influence on its thermal regime, particularly near the communication channels. The lowest water temperatures in the lagoon are in December-January period and highest in July-August period. The average annual temperature is 14.9 ^{0}C.

Results and Discussion

Narta lagoon

The lagoon is hyper saline especially during summer with salinity up to 78.0$^0/_{00}$. The eastern part of the lagoon which is less influenced by sea water, shows high oscillations of salinity (fig.3). The high value of the salinity of Narta Lagoon water can be explained by the highest evaporation of water in this lagoon. Lagoon waters are slightly alkaline (pH 8.4-8.8). The content of dissolved oxygen oscillates between 7-10 mg/l. The level of orthophosphate varies from 0.005 to 0.025 mg/l P (Çomo *et al.*, 2014). Nitrogen concentration as ammonium, nitrate or nitrite is linked closely with nitrogen cycle. The time distribution of this indicator in the lagoon water follows that of water circulation from the water exchange between sea and lagoon, accompanied with organic development during the summer period (Kane S et al., 2015). The levels of nitrates in the water samples ranged from 0.1 mg/l to 0.66 mg/l. The analysis reveals that BOD_5 values variation with a range from 1 to 6 mg/l $O_{2.}$ Narta Lagoon water is saturated with oxygen; even there inflow domestic and some industrial wastewaters. This indicator varies from 7.17 to 10.07 mg/l. These indicates that the lagoon water have a rapid mix with fresh water coming from inland channels or from sea water exchange in communication channels.

Karavasta Lagoon

Salinity analyzes, showing its values extending within range 49.59-56.46 $^0/_{00}$ (gr/kg). The highest value is observed 55.67$^0/_{00}$and the minimum value is observed, 55.03$^0/_{00}$. The level of salinity in the lagoon depends heavily on the tidal flow regime. The total phosphorous oscillation values lay within the range 0.05-0.074 mg/l. The highest value is 0.074 mg/l, due to discharges from the hydropower channel and the lowest value is 0.051 mg/l, due to the impact of the canals connecting the lagoon to the sea. The content of $N\text{-}NH_4^+$ in the lagoon is different and lies in the range of 0.014-0.027 mg/l. The amount of nitrite fluctuates in 0.001-0.0025 mg/l. While nitrates fluctuate in the values: 0.12-0.18 mg/l. Oxygen content is relatively low. Its values range from 5.02-6.1 mg/l. The COD values fluctuate in the range 7.3-8.2 mgO_2/l, while the values of BOD_5 are in the range of 3.54-3.81 mgO_2/l. Likewise; the displayed values of these parameters indicate the relatively high presence of organic matter and biological load due to industrial, agricultural and urban pressures.

Conclusions

The communication between Narta Lagoon and the See, during the period under the study, has been weak which influences in increasing of the time interval of water lagoon full change. Hydrologic common feature for the lagoon is sea water supply during the period tides and discharge water during low tide. Narta Lagoon stands for a highly unstable limnological regime characterized by large variations in physical and chemical characteristics in time and space. This had a negative impact on utilization of the lagoon for fishing purposes. Communication of waters between the processes is weak due to the small size of the communication channels. This allows the amount of water that enters the lagoon long as the tide small compared to the water mass itself lagoon.High water channel that discharge into Narta Lagoon contain big amount of organic substance. Phosphor is a restriction factor of water eutrophication of Narta lagoon. Based on the trophic state index (TSI) (Carlson & Simpson, 1996), and phosphorus contents total transparency (Secchi disk), it was observed that the waters belong mesotrophic state for the Karavasta Lagoon and oligotrophic state for Narta Lagoon. In the Karavasta Lagoon as a water facility closed with insufficient communication with the sea, feels more human intervention. Karavasta Lagoon is under constant pressure from industrial, urban and agricultural pollution.

Abstract

This work is to examine whether the soil moisture gradient creates in soil physicochemical characteristics and how variation in soil physicochemical characteristics influences species composition, and the response to herbaceous vegetation species composition, and vegetation to heavy grazing pressure on native rangeland in Northeast Algeria, is reducing the diversity of herbs and shrubs in the areas. Adverse effects of overgrazing may include the trampling and removal of plant structural materiel critical for persistence of the plant with in the environment. Some species have disappeared; with others have survived or other adaptation. . Differences in grazing pressure may modify the relation between richeness and fertility. In whole of pasture, the soil moisture was the major factor effecting plant species and, it seems to be influenced by competition. Soil physicochemical characteristics have not varied considerably and this situation is partly due to lack of management and applications of nutrients. our study, livestock population have negative effects on soil fertility in degraded land in the shoreline lake, because the habitat has deteriorate seriously due to heavy trampling and soil erosion, Compared with some results, our study showed similar changes in composition.under high grazing pressure, the tender palatable genra such as *Trifolium subterranuim* and *Medicago arabica L*. diminished rapidly because of their sensitivity to herbivory, and later they were replaced by the inpalatable genera

Keywords: *shorelake, grassland, overgrazing, species composition, soil physicochemical*

Introduction

The Wetlands of the Mediterranean basin are known for their multiple values for man and nature (Skinner and Zalewski, 1995), one of these values is food for grazing animals. In fact, most fresh water wetlands in Algeria have involved with the presence of grazing farm animals. Mediterranean rangelands have been shaped by high degree of natural disturbance (Archibold, 1995; Allen, 2001), and the early impact of humans which continue to the present, (Allen, 2003).These activities have created a mosaic of ecosystems such as woodlands, marquis, tree-shrub communities, low shrub-lands and grassland (Naveh and Whittaker, 1979). Over a long period of time intensive grazing, fire and periodical ploughing in conjunction with variable precipitation and heterogeneity which is dominant feature of the Mediterranean vegetation (Naveh, 1982, Trabaud, 1982).

Heavy grazing pressure on native rangeland in Northeast Algeria is reducing the diversity of herbs and shrubs in the areas. Due to overgrazing, the vegetation species composition, richness and productivity has changed overs past few decades (Gehu et al, 1993). Some

species have disappeared; where others have survived using of morphological or other adaptation forms (Hustings and Dukroon, 1994).
Moreover, low-lying areas around lake regions, in the National Park of El-kala (Northern east Algeria), are frequency convoyed by man and animal. These areas with ground water table is high enough to enable the growth of herbaceous plants and crops during the growing season. Plant species composition and primary productivity of wet meadow are determined both by management practices such as plowing, fertilizers application, grazing by farm animals and abiotic factors like soil type and water system. Furthermore, trampling by farm animals create disturbed patches where species with high dispersal ability are able to be formed (Somers, et al, 2000).
For instance, plants growing in infertile environments adapt to low levels resources by lowering their growth rate and regulating their plasticity degree to resources disposal (Grime, 1979). In fact, a case study in Africa showed that plant community response to heavy grazing near stock pests was reduction of palatable grass species sensitive to heavy grazing and replacement with ones of lower palatability, thus lowering grazing pressure (Hendricks et al., 2005). In addition, some native populations of perennial grass in central semi-arid Argentina subjected to heavy grazing were typically shorter and more prostate than ungrazed or lightly defoliated population of the same species (Tomas et al., 2000). In Mongolian steppe, *Artemisia frigita* responds to heavy grazing by increasing branch number and reducing foliage biomass (Li et al., 2005).
The research has not yet revealed how resistance to heavy grazing pressure progresses in vegetation. Grazing is understood as a biotic form of disturbance. Differences in grazing pressure may modify the relation between richness and fertility. Some spatial changes of grassland vegetation (herbaceous communities) around the lake area provided an opportunity for us to study the response of vegetation to grazing turbulence. Our study was conducted in a pasture next to the shore of Oubeira lake which is a part of El-Kala's National Park. Consequently, objectives of our studies were: (1)first, to investigate whether the soil moisture gradient creates in soil physicochemical characteristics and how variation in soil physicochemical characteristics influences species composition, then and (2) to observe the response of herbaceous vegetation and species composition to heavy grazing.

Materials and methods

Study area

The studied area is a pasture, situated 5km Southeast of El–Kala and 54 km East of Annaba (Algeria) at 25 km altitude. It is a part of the Nationl Park of El Kala (PNEK), located at the extreme East of Algeria (36°, 49' 01" N; and 8° 24'47"E). The Oubeira Lake is endorheic mésoeutrophe with water and 25 meters above sea level.. This lake undergoes the most intense human pressure throughout the year. Primary productivity and species composition are both influenced by abiotic factors, such as extend and duration of flooding, substrate type. The site is characterized by a moderate salinity (≈ 1%, the soil is alluvial and originates from the surrounding hills where the parental rock is mainly with limestone and sand, its maximum water (sweet) level at 157 m asl,which is reached in late winter. Draining waters also contribute to the creation of gradients in various soil physicochemical characteristics by depositing fine soil particles closer to the lake (Thornton and Dise 1998. The climate is continental Mediterranean with an average of 750 mm (over 30 years) annual rainfall and heavy internal fluctuations (standard deviation 80, 41) 81% of falls between November and March period.

The area shores is mainly covered by, *Agrostis stolonifera*, *Cynodon dactylon*, competing with the *Juncus articulatus* L., and *Juncus maritimus lam.*.The floating mats are made by hydrophytes, *Chestnut Trapa natans water, Myriophylle and Potamots potamgeton sp*, these formation occupy the large open water area essential nesting waterbirds in this Lake.
Considering the relationship between grazing pressure and the distance from the shoreline. The field investigation was carried out in two summer seasons 2011 and 2015 at the end of May, June, July and August, which corresponding to no grazing periods.
This Shore Lake have been experienced a long history of human use and impact, including traditional gazing by cheep, sheep and plowing activities. The grazing activities occur primarily from March to June, and from September to November (stocking density: 50 sheeps ha^{-1} and 60 sheeps ha^{-1}). Although the number of plant species, or density in the whole pasture is relatively low. Due to policy change in the mid-2008s, lands that were once owned by the state were contracted out to the riparian for 30 years. The change in land-use policy dramatically increased animal productivity, but caused severe degradation of rangeland areas. For instance, from 2011 to 2015 the amount of livestock increased from 13 546 to 35 241 sheeps (local specie a 40 kg weight standard sheep unit) (table I). All data comes from the Directory of Agriculture Service. + (surplus) means the total numbers of livestock are below the grazing capacity, and – (deficiency) implies the contrary.
At the same time, grazing capacity for livestock on the rangelands had changed from self-sufficiency to serious deficiency. As the livestock increases, the rangeland is serious decline under the huge stresses of overgrazing.

Table 1**.** Changes of livestock population in the winter spring and autumn pasture of the shore Oubeïra Lake

Year	Item	Livestock population	Grazing days	Grazing pressure	sheep unit
2011	Total numbers	13253	134	Moderate grazing	
	Movement of livestock	+ 1841 (+13, 9%)			
	Balance (+ surplus - deficiency)	16094			
2013	Total numbers	29357		Overgrazing	
2015	Total numbers	35241	110	Serious overgrazing	
	Balance (reference)	– 29147 (–181, 4%)			

Methods
In April 2015, 31 (1x1m) quadrates were laid out in the shore lake; the stations were installed at distances of about 50, 100, 150 and 200 m from the shoreline of the lake. Because of unequal surfaces sizes of this zones shore lake. Distances of quadrates were measured from the shoreline lake (Fig.1). From the center of each quadrate, soil cores were taken to a depth of 10 cm at each of the 31 stations soil, then was analyzed for pH, organic matter total, total N, P, K, Mn and total $CaCo_{3,}$ coarse and fine sand fractions, silt and clay. The soil pH aqueous (NF ISO 10693) measured in 0,01 M $CaCl_2$ (1:1 w/v). Organic matter was evaluated from dry soil weight difference before and after oven drying at 450°C for 4h and using

limestone correction. The total “N” was determined by Kjeldahl method**,** 2300 Kjeltec Analyzer, Foss Testator Höganäs, and Sweden. The total “P” was determined by Jeret-Hébert method, exchangeable K and Mn extracted with 0.5 M ammonium acetate and total Calcium determined by NF ISO 10693 in Arras soil laboratory (INRA France).

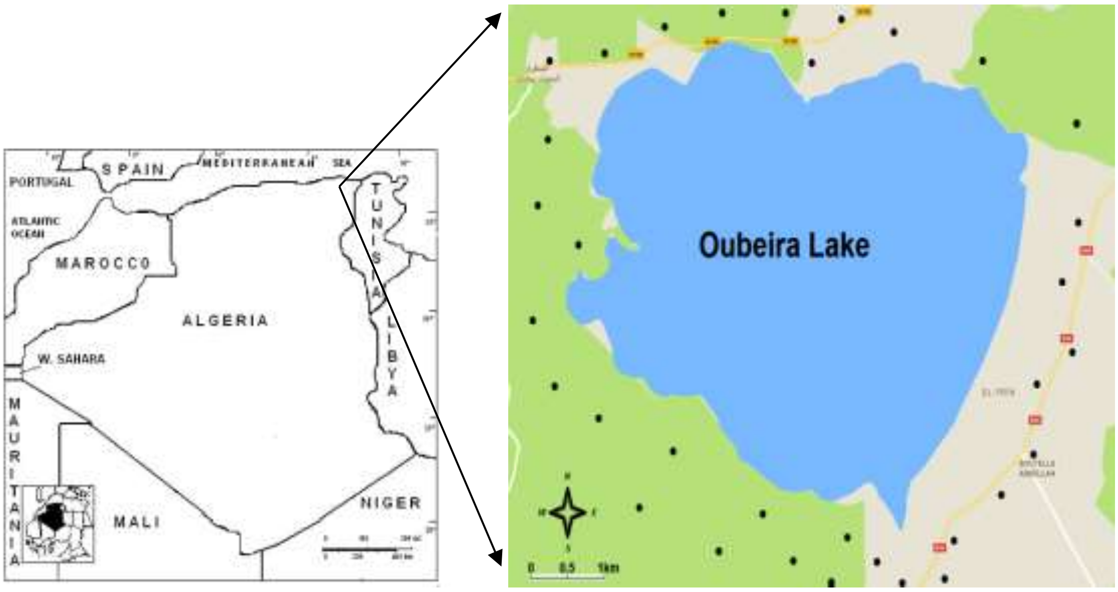

Fig. 1. Above: location of study area showing one of the three lakes in the National Park of El-Kala in the northeast part of Algeria. Below: location of study area with sketch of the layout showing the distribution of 31 stations in the shore Oubeira Lake (black dot).

Species richness and aboveground plant biomass, harvested at end of June, was measured in each quadrate. All stems and leaves above the root collar and measuring their fresh weight, respectively, than taking a part of them to the laboratory and dried at 75°C for 24 h. Dry matter biomass (DM/m^2) was calculated after oven-drying. The measures of species composition estimated depends on the used presence scale (Dupré and Diekmann, 2001). Presence/absence of each species.

Also multivariate analyses were performed; every vegetation component (aboveground biomass, number of species / 1m^2) or relative abundance of species of every functional group of species (annual and perennial grasses and legumes, forbs and sedges) was used as the dependent variable and independent variables were the distance of quadrates from the shoreline and all the measured soil physicochemical parameters.

Results and discussion

Soil texture % of sand, silt and clay was similar in zones (I –II) (table II). Zones III and IV are quite different consisting almost exclusively of sand. The groundwater level became progressively deeper, in shore Lake as expected during the growing season, from zone 1 to zone 4. Table II, shows that soil texture (% of sand, silt and clay) was similar in East and South sides. Side Ouest is quite different consisting more Clay. As expected level of water became progressively higher through the growing period and from South side to North side (Fig II). It is obvious that the characteristics of the soil vary along to the gradient of moisture.

Soils characteristics varied along the moisture gradient the distance from the shoreline affected the measured soil characteristics. The pH values was not related to distance (Fig.II),

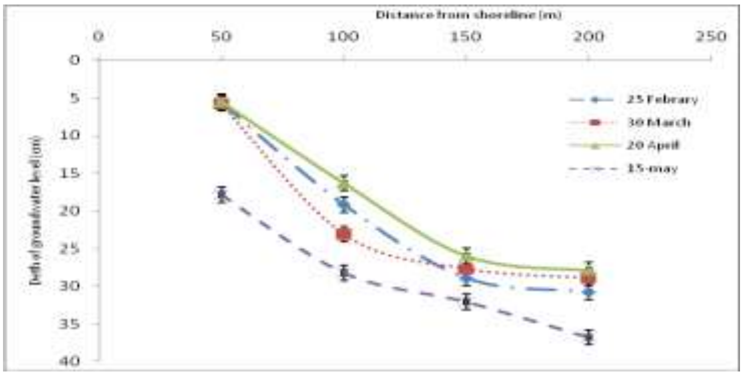

Fig.II. Depths to groundwater in relation to distance from the shore lake during the growing season (February, Marsh, April, may (means ± S.E, *n=3*)

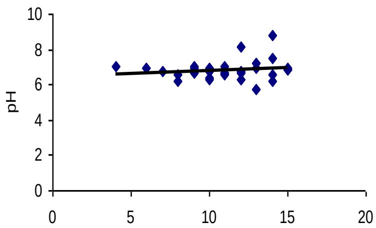
The distance from the shoreline affected the other measured such as, total organic matter, total N, extractable P and extractable K (Fig.III.(a) (b) (c) (d) and (e)). Since Organic matter K and P extractable had the lowest values in the first wettest zone. The best curve in relation to distance from the shoreline were the curvilinear, the total N was related to distance the amount of N tended to increased from the wettest zone to the dried zone it was positively related to distance ($P < 0.05$). Hence, the upper slope zone was richer in sand and phosphorus that the zone. The latter, however had more clay, organic matter, nitrogen total and water retention capacity than the zones 3 and 4.

Table II. Soil texture (means ± 1S.E) in the four pasture sides

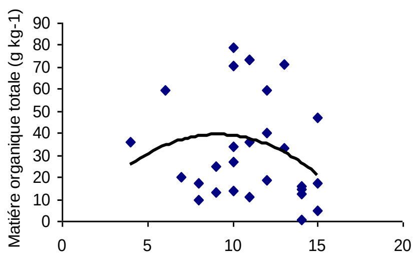
Sides		samples	sand (%)	Silt (%)	Clay(%)
East (1)	zone 1	6	61, 7±5,6	20,1±4.8	8,2±3.1
Ouest (2)	zone 2	5	61, 3±5,4	22,4 ± 5.7	16,3±2.4
South (3)	zone 3	10	93, 9±8.5	4.7±1,5	3.4±0.6
North (4)	zone 4	10	89, 1±7,3	5,7±1.1	6,2±1.5

Table III, shows that the palatable species diminished while unpalatable species increased from (I) East to North (IV) *Festuca arundinacea*, *Paspalum sp.* and *Medicago arabica L*. disappeared in (III) and (IV), and *Trifolium subterranuim* disappeared in (IV). The unpalatable species *Conipodium glaucum* started accuring in (II), and indelible species Asphodelus *cerasiferus* in (IV).palatable species *Agrostis stolonifera*, *Cynodon dactylon*, and unpalatable species *Juncus articulatus L* remained unchanged through four sites.
The statistical analysis indicated that the number of species/1m^2 as well as almost every functional group of species seems to be ordered along the distance from the shoreline. The first group of the abundance species that has formed was present in the four zones and all distances from shoreline: *Agrostis stolonifera*, *Cynodon dactylon*, *Juncus articulatus L*, the second group of three species is recorded in the first two wetter zones, and the abundance species of *Juncaceae* and *Sedges* were highest at intermediate distances from the shoreline, while *Asphodelus* decline with distance, and abundant at 200 m and more.

(a) R^2= 0,29

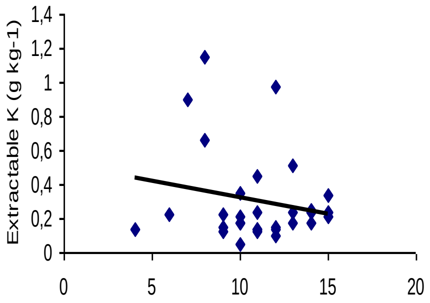


(b) R^2= 0,34

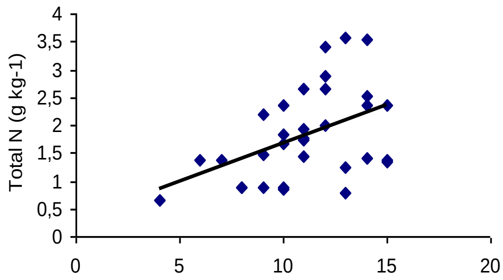


line 10-1

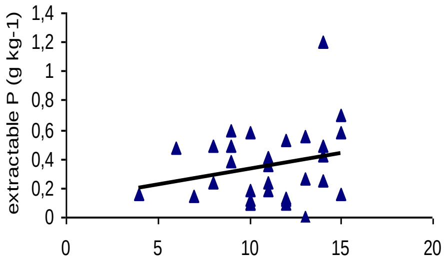
(c) $R^2 = 0.43$



(d) $R^2 = 0.55$



(e) $R^2 = 0{,}51$



Fiq 4. Relationships of five physicochemical soil characteristics ((a) pH, (b) organic matter, (c) extractable P, (d) extractable K, and (e) total N) with the distance from the Lake ‘shoreline. Lines or curves are the best fitted to data *P <0.05 ;**P <0.01.

Table III. shows that the palatable species diminished while three unpalatable species increased from zone 1 to IV. *Trifolium subterranium* and *Medicago Arabica* disappeared in II, III and IV, and *Festuca arundinuim* and *Paspalum sp*. Disappeared in IV. The unpalatable species *Juncus articulatus L.*, and *Juncus maritimus lam.*, started to appear in II, while *Conipodium glaucum* begins to occurring from III, and indelible species *Asphodelus cerasiferus* in IV. The palatable *Agrostis stolonifera* and unpalatable *Juncus articulatus* L.. Species remained unchanged from I to IV sites.

The cover of palatable species mainly Agrostis stolonifera declined as the distance increased from the shoreline lake Agrostis stolonifera accounted for 78,6% of the total biomass in I. the proportion of others palatable species decrease from I to IV .

Total aboveground biomass ranged from 180 g m^{-2} and 48 g m^{-2} (Fig.IV.) and it related to the distance from the shore line, but not related to any variable physicochemical parameters measured.

The main differences in the soil parameters are linked to a topographic gradient in which the low slope zone 1 and 2 have higher proportion of clay , organic matter total nitrogen and water available Although the main factor explaining changes in the floristic composition of the studied communities was the greater water and nutrient availability in the Mediterranean environments. Grazing pressure is difficult to evaluate. Still, indirect methods have been developed from which scales are valid for comparisons (Helle and Aspi 1983). The main factor explaining changes in floristic composition was the presence of grazing farm animals (Papanastasis, 1992).

Table III. Species composition and biomass in fourth zones

Forage selection	species	East zone (I)	West zone(II)	South zone(III)	North zone(IV)
		Distance from the shore			
		50m	100m	150m	200m
Palatable	*Agrostis stolonifera*	1	1	1	0
	Cynodon dactylon	1	1	1	0
	Trifolium subterranuim	1	0	0	0
	Festuca arundinacea	1	1	0	0
	Paspalum sp.	1	1	0	0
	Medicago arabica L.	1	0	0	0
Unpalatable	*Juncus articulatus L.*	1	1	1	1
	Juncus maritimus lam.	0	1	1	1
	Conipodium glaucum	0	0	1	1
Indelible	*Asphodelus cerasiferus*	0	0	0	1
Total species number		7	6	5	5

A total of species were classified in relation to grazing in the fourth zones (table III). Only one species appeared simultaneously in zone I to IV. *Agrostis stolonifera*, which always appeared in the palatable group with higher level, and *Cynodon dactylon*, *Trifolium subterranuim*, *Festuca arundinacea*. *Paspalum sp.*, and *Medicago arabica L.* are present at the shoreline zone 1 and decrease in II, III and IV is thus a grazing decreaser in II to IV but indifferent in shoreline zone We found significant differences in soil parameters for grazing and zone (table IV.). Grazing produces an increase in the percentage of sand in all zones and an increase in the percentage of silt and clay in II and III zones only. There was no significant effect in total nitrogen levels, but not in the organic matter/ finally grazing had a significant effect in the fourth zones. Even in available water. The topography of the shoreline allows the circulation of waters without obstacles of the slopes. The floristic composition tends to change with the water level and it will be greater in moister zones, ($P<0.001$), which does corroborate the hypothesis of Milchunas et al., (1988).

Table IV. Two way-ANOVA for soil parameters

Parameters	Zone		Grazing		Zone x Grazing	
	F	P	F	P	F	P

Organic matter	54.11	***	5.32	n.s	1.17	n.s
Available water	89.50	***	49.23	***	21.12	**

n.s: non significant ** $P<0.01$ *** $P<0.001$

In whole of pasture, soil physicochemical characteristics have not varied considerably and this situation is partly due to lack of management and applications of nutrients Organic matter and total Nitrogen P<0.001. Unlike results in Spain (Peco et al., 2006), our study, livestock population have negative effects on soil fertility in degraded land in the shoreline lake, because the habitat has deteriorate seriously due to heavy trampling and soil erosion, and it is difficult for plants to resettle on the bare soil, the few tender palatable species have disappeared and unpalatable species have successfully invaded, which is in agreement with the results of Al Mufti et al., (1977). However, water availability has an important contribution to this variation. The significant relationship between the ground depth of water and the distance from the shore indicated that approaching the lake the water availability increases P<0.001. This situation does not coincide with increased accumulation of total of nitrogen as well as of phosphorus. Again, during the wet period (winter and spring) zones I and II are exposed to waves on lakeshore which are loaded that has high amount of sand and low percentage of organic matter, nitrogen and phosphorus (Spence 1982). Vegetation did not cover all the ground, bare soil covers 35%. In this study, the four zones (I, II, III and IV) can be generally regarded as typical representative of four degrees of grazing pressure increasing from I to IV. Similar work in others countries has been conducted and attributed to the change in over grazing. Although productivity of the pasture was the lowest at the different distances from the lake. There is relation to any of the various physicochemical characteristics and not correlated with soil moisture gradient as was found by Grace and Wezel (1981); keddy (1989); and Gaudet and Keddy (1989), and Gaudet and Keddy (1995), Tzialla et al., (2006), and Zhao et al., (2007). The values of biomass 180 g m^{-2} and 48 g m^{-2} are very low (Fig 4) compared to those reported by Puerto et al.,, (1990) and ; Peco et al., (2006) in Spain and Greece having a similar climate. Heterogeneously distributed grazing pressure was an important factor in generating differences in patch structure (Augustine, 2003). In our study, continuous overgrazing in restricted not only reduced species composition and productivity (R^2 = 0,88) but also change the structure of species by shortening tender stem sections and diminishing of the leaves (leaf and flower).

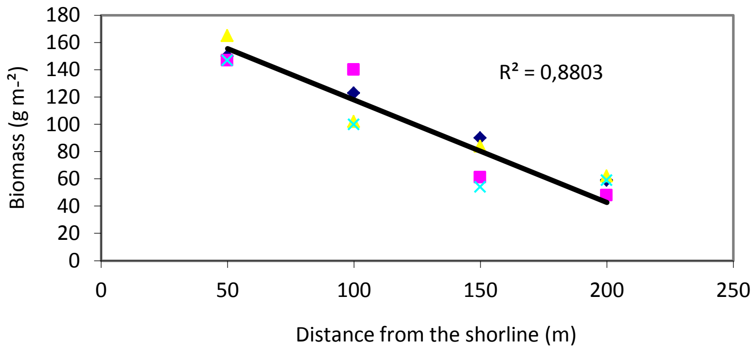

Fig. 4. Relationship of aboveground biomass (gm-²) per 1m² and relative with distances from the lake's shoreline. Line are the best fitted to data. ***P<0,001.

A previous study of 4 years' grazing trial in *Agrostis* and *Cynodon* communality revealed a declining trend of palatable species with increasing grazing pressures. *Trifolium subterranuim* and *Medicago arabica* L. and declined first and *Festuca arundinacea* later , while *Paspalum sp*. (Li and Jiang, 1997; Peco et al., 2006), the dominant species did not changes. Compared with some results, our study showed similar changes in composition. From this it can be deduced that under high grazing pressure, the tender palatable genra such as *Trifolium subterranuim* and *Medicago arabica L*. diminished rapidly because of their sensitivity to herbivory, and later they were replaced by the inpalatable genera such as *Juncus articulatus L* and *Juncus maritimus lam*. This case demonstrated a fluctuation of palatable species clearly responding to the grazing pressure in the shoreline. There is difference in biomass between the zone I and zone II and III, the productivity of the pasture was highest at zone I and lowest at the zone VI, this relatively productivity for Mediterranean pastures seems to be result of adequate soil moisture during the growing period, and probably to high fertility of alluvial soil. Characteristics of the plant community were not influenced by soil heterogeneity. The soil moisture was the major factor effecting plant species. Although the vegetation zonation seems to be influenced by competition. Here, grazing by large herbivores seems to also effect the vegetation of the shoreline.

Conclusion

A previous study of 4 years in the whole of the overgrazing pasture, have showed que the physicochemical characteristics of the soil did not vary considerably; and the soil texture is of the sandy-loam-clay type, with low fertility exept the nitrogen. However, The statistical analysis indicated has showed the functional group of species seems to be ordered along the distance from the shoreline. The group of the palatable species diminished while unpalatable species is increasing indifferently of the richness of the soil. The species productivity is well below average compared to other Mediterranean area

Abstract

The objective of this study is to evaluate the physico-chemical and bacteriological quality of water from some watering sources of dairy cattle in the wetlands of El Tarf. Our study was carried out on water samples from different dairy cattle farms. Water samples were analyzed during the period from January to June of 2016. The study implies physico-chemical and bacteriological analyzes of various parameters related to the control of water quality in dairy farms. The results obtained have shown that the water has a satisfactory quality in terms of pH, temperature, salinity and can be considered as eligible and does not pose any threat for ruminant's consumption. However, nitrite concentrations exceed the drinking water standards recommended for dairy cattle. The bacteriological quality of the waters is poor and reveals groundwater table contamination by nearby pollutions (agricultural land, cattle breeding, existence of septic tanks), which presents a real threat to dairy cattle.

Key words*: Water, quality, physico-chemical, bacteriological, dairy cattle*

Introduction

Water quality has been a topic for many years, covering many aspects, such as the environment, human health and breeding.Water is one of the essentials of biological life, not only itis a vital nutrient, but also it participates in many basic physiological functions such as digestion, absorption, thermoregulation, waste disposal and Others (Olkowski, 2009). Its availability and quality are key parameters in the health and livestock production (Houd and Slimani, 2014). Multiple qualitative parameters, such as pH, salinity, odor, etc, can have an impact on the taste of the water. A decline in livestock food consumption due to poor water quality can have a negative impact on the performance (Weeth, 2001). All surface or ground raw water, holds microorganisms. The main health risk of drinking water is probably the microbiological contamination, but the total count, which represents an estimate of the total number of bacteria contained in water, is not sufficient to assess the threat, all depends on The nature of germs (Chevet, 2000).The objective of our contribution is to define the quality via the physico-chemical and bacteriological composition of the main sources used for dairy cattle watering in the town of Boutheldja and El Tarf in order to assess opportunities and risks associated with the use of such sources.

Materials and methods

The study was conducted in a dairy pool in the area of El Tarf, which is located to the north-east of Algeria (8 ° 11 'longitude and 36 ° 47' latitude). Climatically speaking, the region is located in the bioclimatic stage in sub-humid to warm-dampclimatic zone, with mild winters and dry summers. Climatic surveys over the last 10 years indicate an average annual rainfall of 800 to 1200 mm, characterized by a great intra-annual irregularity. Monthly precipitation varies between a maximum in December and January (134.34mm and 136.42 mm respectively) and a minimum in July and August (3.97mm and 13.34mm). The average annual temperature is 19.24 ° C with a maximum in August (27.35 °C) and a minimum in January (12.96 °C) (Mibirouk-Boudechiche *et al.,* 2011).

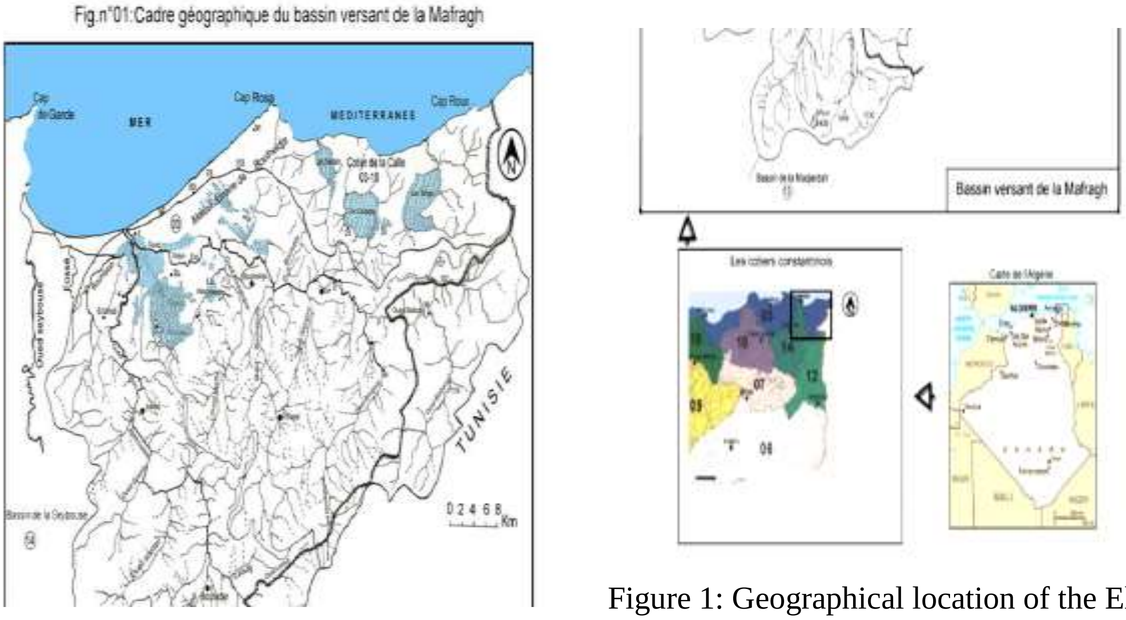

Figure 1: Geographical location of the El Tarf city and the study area (Boutheldja and El Tarf)

Among the most responsive breeders who have agreed to cooperate with us in the town of El Tarf and Boutheldja, we have selected different watering sources such us: well, source, wadi, public drinking water supplies and borehole water. Three selected breeders were visited for dairy cattle watering withdrawal from January until June 2016. This period coincides with the most important phase of milk yield in lactating cows (peak lactation).The samples taken from the seven selected different watering sources: two wells, one natural source, one public drinking water supplie, one wadi and two boreholes, were filled in 500 mL glass vials. Temperature, pH and salinity were measured in situ at each sampling using a multi parameter water quality analyzer. The pollution parameters were analyzed at the laboratory according to the analytical methods recommended by (AFNOR, 1997) and (Rodier, 2009). The microbiological parameters analyzed in this contribution are: total coliforms; Thermotolerant coliforms; *Escherichia coli* and faecal streptococci, the latter were analyzed in the laboratory followingthe analytical protocol of Rodier et al. (2009). The results are presented on average ± standard deviation (SD), all the obtained results of the water quality were subjected to one-way analysis of variance (ANOVA) with the SAS system for generalized linear model (15) at thep <0.05level of statistical significance. The Student-NewmanKeuls test (SAS) (15) made it possible to seek homogeneous groups of averages.

Results and discussion

The turbidity of the water sources analyzed is not hight; the waters are generally colorless or slightly colored except for the two wells and El Kebir wadi where the waters are turbid. Vegetation cover is one of the factors capable of increasing the turbidity (Harrat and Achour, 2010). This turbidity would then be partly organic and may lead to a significant increase in chlorine doses during water treatment (Harrat and Achour, 2010). The pH depends on the origin of the water, the geological nature of the substrate and the watershed crossed. This parameter can have more significant impacts on animals. In ruminants, consumption of water with a pH less than 5.5 is associated with metabolic acidosis, whereas alkaline water with a pH above 8.5 may be the source of an increased risk of metabolic alkalosis. Nevertheless, observed values indicate that the pH of all analyzed sources is neutral and therefore remains within drinking water standards for dairy cattle, except for the second well where the trend is alkaline. These values could be explained by the shallow depths of the wells and the geological characteristics of the terrain. Conductivity is proportional to the amount of dissolved ionizable salts and is a good indication of mineralization of the water. The measured range from 130.4±4.8 µS/cm to 2515±35µS/cm. This reveals a significant variation between watering sources with strong mineralization associated with high salinity for certain points (borehole 2 and Well 2). Nevertheless, our results can be considered acceptable from conductivity and salinity points of view. Moreover, the analyzed waters are too hard, for all the points analyzed. Analysis of the variance shows highly significant differences ($p < 0.001$) in terms of pH, turbidity, conductivity, salinity and hardness in the different analyzed sources, however, a significant difference ($p = 0.023$) is found in the sampling points in terms of temperature.

Table 1. Results of physicochemical watering parameters

Parameter	Turbidity	pH	Conductivity	Salinity	Temperature	Hardness

The results of the nitrate analyzes show that their contents range from 1.5 ± 0.2 mg /l to 15.23 ± 2.3 mg / l during this study period with highly significant differences (p <0.001). All stored values do not exceed the recommended standards of 50mg /l. The quantities of nitrates in well water can vary abruptly, and depend on many climatic, environmental and agricultural factors; these results are consistent with those found by (Merzoug *et al.,* 2010). On the basis of the results achieved, nitrite concentrations show highly significant differences with values ranging from 0.01 ± 0.006 mg / l to 3.83 ± 0.8 mg / l for the second well water. However, the concentration of this element remains high compared to the standard of 0.1 mg / l and this for a significant number of our sampling points, which foretells an anthropogenic pollution.
A high nitrite content in ground and surface water is often associated with excessive use of nitrogen fertilizers, excessive manure application, runoff from livestock collecting areas. It often happens that water sources close livestock farms contain high levels of nitrite. Generally, high concentrations of nitrite are found only when the source is polluted with organic waste and very low oxygen levels (AAVL, 2000). For phosphorus, all recorded values do not exceed standards (p =0.637), these results are consistent with those found by (Merzoug *et al.,* 2011). Excess sulphates and chlorides cause corrosion but also give an unpleasant taste to water with a risk of under-consumption and can cause diarrhea (Gadin-Goyon, 2002). According to the results of the samples analyzed, the concentrations of sulfate ions range from 82.92±31.5 mg / l to 188.3±40.2 mg / l. These values remain below the OMS value (VG = 500mg/l) of the water quality standards for livestock watering and don't constitute any danger. A similar result was observed for chlorides except for the second well and the second borehole where concentrations exceed international recommendations by 400mg / l. The analysis of variance shows very significant differences (p=0.003) for sulphates and highly significant for chloride between sampling points.

Table 3. Results of bacteriological parameters of drinking water

The evaluation of the bacteriological quality of ruminant wateringis based on the concept of germs known as indicators of fecal contamination (Dermaux, 1999). The more there is fecal bacteria in the water, the greater the risk of the presence of pathogens organisms is real (Chevet, 2000). Table 3 shows that the second wells as the most contaminated source of water with a total of 840 ± 160UFC/100ml, however, the least contaminated watering point with a total of 7±6,1UFC/100ml in the second drilling. Nevertheless, the second well is characterized by the most important bacteriological loads, and this for all the bacteria. However, the results of *E. coli* reveal an absence of this bacterium in all the points except the waters of wadiofkebir and the second well.
Analysis of the variance shows highly significant differences (p = 0.000) in the bacterial load of the studied sources.The high bacteriological contamination of the waters analyzed could be due to: poor protection of wells (open pits). Moreover, the waters of the study area have a

high fecal contamination, which is in line with those found by (Boutin and Dias, 1987) for the Marrakech aquifer. The surface watersladen with microorganisms seep through the soil into groundwatertable without having hadan efficient filtration, and causes many differentpoint sources of pollution. (Boutin, 1987) also mentioned that water from undergroundreservoir is all the more vulnerable as the top ofthe underground water table is close to the surface of the ground, that the landabove aquifers is permeable and surface sources of pollutionare important. In addition, shallow aquifers, with accessvia wells, appear to be highly contaminated with organic materials of human and animal origin.

Conclusions

This study reveals that the waters of the sources analyzed are highly mineralized, characterized by high salinity and high hardness; With detected nitric pollution. In addition, bacteriological analysis shows that the majority of our sources are highly contaminated with at least two bacteria, hense, the majority of the sources studied are unfit for dairy cattle consumption.

Abstract

To assess the heavy metals in soil and coal used in Brick kilns and to monitor the air pollution awareness at Madhupur union in Rangpur district in Bangladesh a study was conducted from January 2015 to June, 2017. Soil and coal samples were randomly collected from six brick kiln areas followed by analysis using Atomic Absorption Spectrophotometer. The farmers' awareness on metal impact on health nearby the investigated brickfield areas was surveyed using questionnaire and personal interview. The results revealed that the deposition of fly ash or residues after combustion of coal burning produced notice worthy effects on the soil quality. The mean concentrations of Cr and Pb in the soil of the brick kiln area were 59.54 and 25.84 mg/kg, respectively and the mean concentrations of the Cr and Pb in the coal were 27.15 and 45.87 mg/kg, respectively. The concentrations of Cr and Pb in soil were found in uncontaminated in nature but Pb of coal were high in UBC-3 brick kiln area and higher than permissible limit. This would negatively impact on human health and crop production. The survey findings revealed that majority of the farmers had medium level of awareness on health impact and air pollution nearby the brickfield areas. Farmer characteristics like academic qualification, extent of media contact, knowledge and vulnerability on air pollution had significant positive relationship with their awareness on air pollution. So, awareness should be built up against traditional brick making industries through adopting energy efficient clean technology in brick kilns.

Keywords: *Heavy metals, soil and coal, brick kiln, air pollution, deposition of fly ash, Bangladesh.*

Introduction

Bangladesh has about 6,000 authorized brickfields and numerous illegal ones (Bayron, 2009). In Bangladesh there are three major sources of air pollution; brick kiln is one of them. The prominent cause of this pollution is using coal as fuel in maximum brick kilns. In manufacturing seasons of brick, pollution goes to the peak in and around the brick kilns situated area depending on the monsoonal rains. One investigation says that Bangladesh uses about 23 tons of coal to produce 100,000 bricks, where China which uses 7.8 to 8 tons of coal to produce the same amount (Maksuda and Abdullah, 2012). Using low quality coal seams to have much Cd, Hg, Pb, Cr, As compared to typical basalt. Heavy metals accumulation observed and reported in Brick Kiln surroundings in Pakistan (Ishaq et al., 2010). So Bangladesh has a probability to show more toxicity comparing with other countries of the world.

Various particulate and gaseous matters also released from brick industry which badly affect our environment (Banglapedia, 2007). It is necessary to know their awareness on health impact and air pollution due to brickfields. There is a few research has been conducted on analysis of soil, water, fish and plant accumulation in Bangladesh but limited reports observed on metal contents in soil and coal used in brick kiln (Rahman et al., 2016, Uddin et al., 2016, Khan et al., 2007, Khan et al., 2004). There were about 8 brick kilns in the *Madhupur Union* of target area in Bangladesh and most of the brick field owners use low quality coal for saving extra cost (Talukder et al., 2015) and so, the probability of toxic pollutants entering into ecosystem is pretty high. As there are still some limitations due to their not considering heavy metal analysis, such kind of effective works including of heavy metal analysis have been undertaken by this present study. Also soil contamination and coal burning is a major problem undergone only a little effective research for what the present study was undertaken to compare heavy metals (Cr and Pb) status of soil and coal used near the brick field areas and to investigate the farmers awareness on health impact as well as air pollution nearby the brickfield areas.

Material and Methods

Study area & sample collection: Soil and Coal samples were collected from *Madhupur Union* of *Badargonj Upazilla* which is situated in the northern part of the *Rangpur* district in Bangladesh. Geographically it is laying from 25.667°N Latitude to 89.050°E Longitude. Soil samples (0–20 cm depth) and coal samples were collected from 3 brick kilns: (a) RBL-2 (b) UBC-3 and (c) PBM separately. From each location, three soil samples were collected as replications. Samples were kept separately on a brown paper and then collected samples were air-dried and external substances were removed. Samples were sieved using sieving apparatus consisting of different sieve sizes. Sieved samples (>2mm) were preserved for laboratory analysis. Samples were placed in sealed plastic bags and labeled appropriately. The collected coals were thoroughly mixed, air dried over night and crushed. After sieving samples were placed in sealed plastic bags and labeled appropriately. After that the samples were carried to the Laboratory of Soil Science Division, BINA, Mymensingh for measurement and analysis.
Digestion of soil & coal samples: The samples weighing 1.0 g was taken into a dry clean digestion vessel. 5 ml nitric acid (HNO_3) was added to the vessel and allowed to stay it overnight with covering the vessel to vapor recovery device. On the following day, the digestion vessel was placed on a heating block and was heated at a temperature slowly raised to 120° C for two hours. After cooling 2 ml Hydrogen per oxide (H_2O_2), it was added and waited to minimize the reaction with organic matter for 30 minutes. Heating was normally stopped when the dense white fume emitted, after which the volume was reduced to 3-4 ml. The digestion was cooled, diluted to 50 ml with deionized water and filtered through Whatman No. 42 filter paper into plastic bottle. The soil/coal sample was digested at laboratory of the soil science division, BINA, Mymensingh.
Determination of total Pb and Cr**:** Total Pb and Cr were determined at the Laboratory of Soil Science Division, BINA (Bangladesh Institute of Nuclear Agriculture) by using the SHIMADJU AA 7000 Atomic Absorption Spectrophotometer (AAS) (PG 990, England) by following the methods of Haq and Alam (2005).
Statistical analysis of analytical data**:** Statistical analysis of the data generated out of analysis of soil and coal samples was done. Microsoft Office Excel 2007 software was used for data analysis and presentation. Various descriptive statistical measurements such as Range, mean and standard deviation of the contents of heavy metals of soil and coal were calculated for categorization and describing the variables.

Data collection for focusing health impact and metal pollution: Data were collected through focus group discussion (FGD) and personal interview schedule from the farmers of the selected sites. Measurement of vulnerability of air pollution faced by the farmers nearby the brickfield areas and measurement of dependent variables (awareness), data processing and statistical tests were done accordingly. Pearson's Product Moment Coefficient of Correlation (r) was used. The analysis of the data was performed using software.

Results and Discussion

Heavy metal status in soil samples of brick kiln area

Chromium: The total Cr content in the study area ranged from 57.23 to 61.83 in soils with a mean value 59.54 mg/kg (Fig. 1a), when these concentrations were compared with U.S. EPA standards. The permissible range of chromium in soil is 1 – 1000 mg/kg. The maximum concentration of Cr in soils was recorded 60.83 in UBC-3 brick kiln area where coal was burned to making the bricks. So, the unburned coal and its combusted residual waste was highly polluted in soil and this location, Cr concentration were increasing while at RBL-2 brick kiln area from chimney it was 120 feet high, that is 58.25 mg/kg. The difference in the concentration of metals with distance might be attributed to the fallout of pollutants a few meters away from the source depending upon the direction and velocity of wind. Results of this study indicated that Cr concentration of that locality was highly related to brick kilns. Piwnik (2008) reported that the chromium concentration in the soil samples ranged from 1.67 to 10.005 mg/kg in the brick kiln area of Kathmandu-Bhaktapur road section of Araniko highway. Shorove (2013) estimated that the Cr concentration in the soil samples ranged from 122.56 mg/kg to 60.76 mg/kg with an averaging value 79.67 mg/kg, respectively nearby the brick kiln areas in Burera union, Mymensingh.

Lead: The Pb content of soil in the brick kilns ranged from 22.95 mg/kg to 29.95 mg/kg (Fig. 1b), when these concentrations were compared with U.S. EPA standards, it was found within the permissible limit of lead in soil (2–200 mg/kg). Presence of lead in this environment may have been due to the coal combustion. Across all locations of brick kilns, Pb concentration was the highest in PBM brick kiln area that is, 29.28 mg/kg, which may be due to the burning of coal during the baking of bricks and mainly its combusted residue polluted in soil and increase in Pb concentration while in RBL-2 brick kiln was 23.92 mg/kg. Sikander et al. (2014) revealed that Pb concentration ranged from 5.45 to 11.82 mg/kg in brick kiln area of western India. According to Kabata and Pendias (2001), the Pb status of the soils was lower than the maximum acceptable limit of 150mg/kg for crop production.

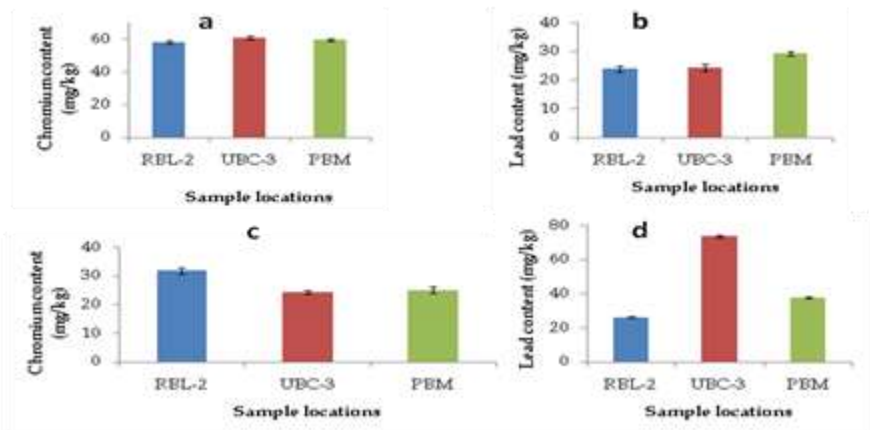

Fig. 1: Metal contents in soil (a,b) and coal (c,d) used in different brick kilns

Heavy metal status in coal samples of brick kiln area

Chromium: Cr content of coal samples used in different brick kilns in the study area ranged from 23.95 mg/kg to 33.03 mg/kg with a mean value of 27.15 mg/kg. The maximum concentration of Cr in coal was recorded 31.83 mg/kg in RBL-2 brick kiln area and the lowest concentration of Cr in coal was recorded 24.51 mg/kg in UBC-3 brick kiln area (Fig. 1c). The permissible value of Cr in coal was 33.1 mg/kg (Bieniek, 2005). According to Kudesia (2009) using low quality coal seams to have high Cr concentration may also be the cause of plant growth reduction, soil fertility loss and also some hazardous diseases of human being. Ram *et al.* (2015) estimated that concentration of Cr 7.976 mg/kg in brick kiln area of central India. An extremely high dose of chromium compounds by humans has resulted in severe respiratory, cardiovascular, renal and neurological effects as part of the sequelae leading to death or in patients who survived because of medical treatment (Hanna *et al*. 2000).

Lead: The Pb content of coal samples used in different brick kilns in the study area ranged from 26.03 mg/kg to 74.40 mg/kg with a mean value of 45.87 mg/kg (Fig. 1d). The maximum concentration of Pb in coal was recorded 73.65 mg/kg in UBC-3 brick kiln area where air pollution were increasing due to the burning of coal. So, the result it is negatively impact on human health and crop production. The lowest concentration of Pb in coal was recorded 26.27 mg/kg in RBL-2 brick kiln area. The Health Risk Level of Pb content of coal was 4 (Ezemokwe, 2015). The permissible value of Pb content of coal was 56.83 mg/kg (Bieniek, 2005). Ram *et al.* (2015) reported that Pb concentration in coal was observed as 4.117 mg/kg in brick kiln area of central India. Lead is a highly toxic metal whose widespread use has caused extensive environmental contamination and health problems.

Table 1: Salient features of the selected characteristics of the respondents and their awareness on air pollution

Characteristics	Unit of measurement	Range		Categories	Farmers (n= 50)	
		Possible	Observed		Number	(%)
Age	Year	Unknown	25-65	Young aged (25-36)	25	50
				Middle aged (37-50)	17	34

Farm size	Hectare	Unknown	0.028-2.02	Marginal (up to 0.04)	10	20
				Small (0.041-1.0)	28	56
				Medium (1.01-2.00)	9	18
				Large (above 2.00)	3	6
Annual income	'1000' Tk	Unknown	40-130	Low income (below 80)	18	36
				Medium income (81-100)	21	42
				High income (above 100)	11	22
Extension media contact	Score	0-8	0-7	Low contact (0-2)	19	38
				Medium contact (3-5)	25	50
				High contact (above 5)	6	12
Knowledge on air pollution	Score	0-50	16-43	Low knowledge (below 20)	11	22
				Medium knowledge (20-40)	33	66
				High knowledge (above 40)	6	12
Awareness	Score	0-14	3-9	Low awareness (0-4)	12	24

				Medium awareness (5-7)	32	64
				High awareness (above 7)	6	12
Vulnerability	Score	0-21	8-17	Low vulnerability (below 10)	11	22
				Medium vulnerability (10-14)	29	58
				High vulnerability (above 14)	10	20

Assessment of health impacts and air pollution around the brick kiln areas: The different characteristics of the respondents and their awareness on air pollution in brick kiln surrounding areas were enlisted in Table 1. The highest proportion (66%) of the respondents had moderate air pollution knowledge compared to 22% had low air pollution knowledge and 6% had high air pollution knowledge (Table 1). Hossain & Ijaz (2008) reported that the highest proportion (49.20%) of the respondents had moderate air pollution knowledge compared to 7.7% low air pollution knowledge and 43.1% having high air pollution knowledge nearby the brick kiln areas at *Bogra* district.

Awareness of respondents on air pollution nearby the brickfield areas: The highest portion (64%) of the farmers had (5-7) medium awareness on air pollution due to establishment of brickfield compared to 24% low (0-4) and 12% high (above 7) awareness on air pollution due to establishment of brickfield (Table 1). The value of the mean indicate that the farmers of the study area have medium awareness on air pollution. Parveen (2006) reported in a study on awareness of farmers on air pollution due to brick field areas found that 60% farmers had poor awareness, while 34% had medium and 6% had high awareness on air pollution.

Vulnerability of air pollution faced by the farmers nearby the brickfield areas: The majority of the respondents 58% put their opinion towards medium vulnerability, 22% had low vulnerability and 20% had high vulnerability of air pollution nearby the brickfield areas (Table 1). Badrul (2012) reported that the majority (57%) of the respondents expressed their opinion towards medium vulnerability, 15% low vulnerability and 28% high vulnerability of environmental pollution nearby the brickfield areas at *Trishal Upazila* in Mymensingh district.

Relationship between respondent characteristics and farmer's awareness on air pollution: The age of the farmers had no relationships with their awareness on air pollution nearby the brickfield areas (Table 2). Hossain & Ijaz (2008) reported that age of the farmers had no significant relationship with their awareness on air pollution nearby the brick field areas in *Bogra* district. The findings indicate that the academic qualification had a significant and positive relationship with their awareness on air pollution nearby the brickfield areas. The findings also indicate that more education of the farmers leads to a tendency towards more awareness on air pollution because more educated farmers know the various adverse effects of brickfield (Table 2). Hossain & Ijaz (2008) found that academic qualification of the farmers had significant relationship with their awareness on air pollution nearby the brick field areas in Bogra district. It was found that family size of the farmers had no relationships with their awareness on air pollution due to establishment of brickfield (Table 2). Kashem (2001) found that family size of the farmers had no significant correlation with their awareness, in the study on farmer's awareness on air pollution nearby brick kiln areas in *Kalihati, Tangail*.

Table 2: Relationship between the selected characteristics of the farmers and their awareness on air pollution nearby the brickfield areas (N=50)

Depended variable: Farmers awareness									
Independent variables								LSD*	
Age	Academic qualification	Family size	Farm size	Annual income	Extension media contact	Know-ledge	Vulne-rability		
Computed 'r' values								0.05	0.01
0.261ns	0.907**	0.237ns	0.349*	0.837**	0.899**	0.723**	0.966**	0.277	0.358
* Table value of 'r' at 48 df; Correlation is significant at 0.01 levels of probability (Table value 0.358) Correlation is significant at 0.05 levels (Table value 0.277), ns = non significant									

The result also showed that the farm size of the farmers had a significant positive relationship with their awareness on air pollution nearby the brickfield areas (Table 2). Kashem (2001) found that farm size of the farmers had positive and significant correlation with their awareness, in the study on farmer's awareness on air pollution nearby brick kiln areas in *Kalihati, Tangail* districts. The findings indicate that the annual income of the farmers had a significant and positive relationship with their awareness on air pollution. The farmers who had high annual income also had more awareness on air pollution because he was able to invest more money to eco-friendly activities (Table 2). Hanif (2000) reported that there was a significant relationship between annual income of the respondents and their awareness on air pollution nearby the brick kiln area in *Dhaka Aricha* road. The extension media contact of the respondents had a significant positive relationship with their awareness on air pollution (Table 2). A respondent with more extension media contact has more awareness on air pollution. Kashem (2001) found that extension media contact of the respondents had a significant and positive relationship with their awareness on air pollution nearby brick kiln areas in *Kalihati, Tangail* which is similar to the present study.

The air pollution knowledge of the respondents had a significant positive relationship with their awareness on air pollution (Table 2). Kashem (2001) found that agricultural knowledge of the respondents had a significant and positive relationship with their awareness on air pollution nearby brick kiln areas in Kalihati, Tangail which is similar to the present study. The air pollution vulnerability of the respondents had a significant positive relationship with their awareness on air pollution (Table 2). In the study area, most of the respondents expressed their views that the smokes released from brickfield hampered the production of crops, vegetables and fruits and increase disease on human health, soil fertility decreases etc which was ranked at the top considering the air pollution vulnerability. Dixon *et al.* (2002) reported that vulnerability of air pollution had significantly related with farmers awareness nearby the brick kiln areas in Gujarat, India.

Conclusions

To evaluate the quality of soil and coal used in brick kilns and farmers awareness on air pollution caused by brick kilns the present study was conducted. Results indicated that the soils were slightly contaminated due to fly ash or combusted residues after coal burning in brick kilns which contain toxicants including heavy metals. Heavy metal of coal was higher in brick kiln area which is harmful for human and environment. Heavy metals from brick kilns and their contamination is not a familiar term in Bangladesh, even people actually aren't aware of any of these kinds of contaminations or pollutions that can reduce their crop production as well as their health. So, at first awareness should be built up about this contamination so that they themselves can protest their hazards. Strict law should be enforced to adopt energy efficient clean technology in brick kilns against traditional brick system in all over the Bangladesh. However, findings of this study indicated that no element exceeded the maximum acceptable concentration (MAC) for crop production. Survey report illustrated that air pollution vulnerability of the respondents had positive and significant relationships with their awareness on air pollution. On the other hand, age and family size had no significant relation with their awareness on air pollution nearby the brick field areas. So, it can be concluded that the findings of the work are not alarming yet but still care should be taken properly so that it cannot exceed the critical level.

Abstract

Soil represents a very complex and sensitive component of the environment that could easily be compromised by irrational exploitation, industrialization, mining operations, erosion and various other activities. Soil pollution is a globally growing problem, while among numerous resistant pollutants, heavy metals are the most dangerous. This group of pollutants is considered the most significant cause of degradation the soil quality, surface and underground waters as well as an immediate cause of the harmful impact on the living world.
Although heavy metals are naturally present in the soil in low concentrations, and some of them are even essential for the living world, anthropogenic activities may lead to increase of their concentration above allowed limits, which produces numerous unwanted impacts. When it comes to negative characteristics of heavy metals, it is significant to emphasize durability, toxicity, carcinogenicity, and inclusion in the food chain. The most important anthropogenic sources of heavy metals in the soil are wastewater from some industrial processes (production of metals and alloys, electroplating, production of batteries), mining activities, burning of fossil fuels, municipal waste waters, incineration and disposal of waste, sludge stemming from waste water treatment, fertilizer and pesticides usage in agriculture, military activities. The most significant heavy metals present in the soil as a consequence of these activities, are: Cu, Zn, Pb, Ni, Cd, Hg, As. In order to determine the impact of these pollutants on the environment and human health, it is necessary to determine their concentrations and form in the soil. Generally speaking, only mobile fractions are dangerous. From the health and ecological aspects, knowing the mobility of heavy metals is of great importance. This study addresses the impact of anthropogenic activities on soil contamination with heavy metals, the form in which they are present, and the negative effects caused by their presence.

Keywords: *Pollution of soil, Heavy metals, Mobility, Speciation, Effects.*

Introduction

Soil and water are the most important natural resources for the existence of living species. Since the soil is practically non-renewable natural resource, conservation of this resource is becoming increasingly important. The basis of the soil is the rooting and growing of plants. It is therefore a habitat for a wide spectrum of the living world, micro and macro organisms that spend all their lives in it. If the effect of human activities disturbs the natural dynamic equilibrium established in the soil, it comes to its degradation and pollution. Contaminated soil becomes a long-term source of pollution of water systems and crops that exist in it, which has an unfavorable impact on the entire ecosystem in the surrounding area. Heavy metals represent polluting substances which exhibit extremely harmful effects on the environment and living world, if their concentration in an ecosystem exceeds the allowed quantities. The processes of soil and water contamination with heavy metals present a growing problem today in many countries. This group of pollutants is considered the most significant cause of degradation the soil quality, surface and underground waters as well as an immediate cause of the harmful impact on the living world. In order to determine the impact of these pollutants on the environment and human health, it is necessary to determine their concentrations and form in the soil. Generally, only mobile fractions are dangerous. From the health and ecological aspects, knowing the mobility of heavy metals is of great importance.

Soil pollution with heavy metals

Soil has production value with limited scale and represents a very complex and sensitive component of the environment that could easily be compromised by irrational exploitation, industrialization, mining operations, erosion and various other activities (Maksimović et al., 2009). Soil pollution occurs when the superficial layers are loaded with large quantities of waste materials which could not be decomposed under normal conditions of self-purification (Kastori, 1995). Soil pollution is a globally growing problem, while among numerous resistant pollutants, heavy metals are the most dangerous. This group of pollutants is considered the most significant cause of degradation the soil quality, surface and underground waters as well as an immediate cause of the harmful impact on the living world. Some of these heavy metals i.e. Mn, Zn, Cu, Fe, Mo, Ni, B are, in low concentrations, necessary for plants growth and they are called microelements (trace elements). In larger quantities, Mn, Zn, Cu, Fe, Mo, Ni are a burden for the environment. Other elements (Cr, Cd, Hg, Pb), that could be find in traces of soil, but are not necessary for plants growth, are mainly typical toxic pollutants and they are significant from the point of view of soil contamination (Manojlović et al., 2014).

In addition to toxicity, heavy metals are characterized by their great mobility, which causes entering the food chain so they could reach to the human body causing many negative effects on life and health (Tyteca, 1999; Gevorgyan et al., 2015). All heavy metals have a tendency of unlimited accumulation in the organism or plant tissue, which is particularly dangerous on contaminated habitats and in cultivation of plants that have high affinity for these elements (example of vegetables) (Jug, 2016). Deposition of heavy metals in the human body causes intoxication and numerous negative consequences. Long-term exposure to contaminants causes poisoning, diseases of the central nervous system, hepatitis, leukemia, diseases of cardiovascular system, kidneys and other serious disorders (Tyteca, 1999). By entering the heavy metals into the soil, a whole series of reactions are triggered, that cause changes in the quality of soil, water and atmosphere, what necessarily reflects on changes in the structure of living organisms that inhabit the contaminated area.

Source and content of heavy metals in the soil

Metal in the environment arises from both natural sources and human activities. In natural systems, potentially toxic heavy metals can originate from rocks, ore minerals, volcanoes and weathering releases of metals during soil formation transported to the surface and /or aquifer waters (Szyczewski et al, 2009), forest fires, radioactive dust, etc. (Trierry et al., 1995). In most cases, the natural content of heavy metals in the soil is low and there is no significant impact on the pollution of agroecosystems. Exceptions are soils near the mine or metal deposits, in which heavy metals concentrations could be very high (Manojlović et al., 2012). Long-term input of pollutants into the soil can lead to a reduction in its buffer capacity, and that may result in permanent contamination of soil and groundwater (Thierry et al., 1995). The development of agricultural, industrial and urban activities has led to an increase in many ecological problems due to presence of heavy metals in the soil. The most important anthropogenic sources of heavy metals in the soil are wastewater from some industrial processes (production of metals and alloys, electroplating, production of batteries), mining activities, burning of fossil fuels, municipal waste waters, incineration and disposal of waste, sludge stemming from waste water treatment, fertilizer and pesticides usage in agriculture, and military activities. The most significant heavy metal presences in the soil as a consequence of these activities are: Cu, Zn, Pb, Ni, Cd, Hg, As. Heavy metals exist in different chemical forms in the soil, differently linked to the soil particles. In ecological research, determination of these forms gives more information about the mobility of trace metals, as well as their availability and toxicity, compared to the total content of heavy metals (Pueyo et al., 2004). The presence of these toxicants has negative impact on biodiversity, productivity of the soil and overall functioning of the agroecosystem. The net balance of the average content of heavy metals in agroecosystem is obtained by direct laboratory measurement or using calculation of their entry (industry, fertilization, etc.) and exit in the form of agricultural products (crops, content in the animal tissues). Due to the complexity of interactions in the agroecosystem, the ecological impact of these pollutants is far more complex than in industrial processes (Pettersson, 1993). Determination of concentration of input and output of heavy metals in soil, knowing the possibilities of their immobilization, binding, precipitation or inactivation, is an essential prerequisite for sustainable management of these toxicants in agro-systems. The total content of heavy metals in the soil is a result of input of metals from multiple sources: the parent material, the atmospheric deposition, the fertilizer sources, the agrochemicals, the organic and inorganic pollutants reduced by removal of metal with crops as well as leaching and volatilization. This can be expressed as follows (Raymond and Felix, 2011; Kastori, 1997):

$$M_{total} = (M_p + M_a + M_f + M_{ag} + M_{ow} + M_{ip}) - (M_{cr} + M_l) \quad (1)$$

where “M” is the heavy metal, “p” is the parent material, “a” is the atmospheric deposition, “f” is the fertilizer sources, “ag” are the agrochemicals sources, “ow” are the organic waste sources, “ip” are other inorganic pollutants, “cr” is crop removal and “l” is the losses by leaching and volatilization.

The level of soil contamination with heavy metals and potentially polluting elements (*Lsk (%)*) can be evaluated using the expressions:

$$Lsk(\%) = \frac{Total\ content\ of\ heavy\ metal}{Treshold\ Limit\ Values} \times 100 \quad (2)$$

The following criteria are used for the interpretation of pollution (Jug, 2016): clean, unpolluted soil to 25%, soil with increased pollution 25-50 %, soil of great pollution 50-100%, polluted soil 100-200% and polluted soil more than 200% of the limit values.

Heavy metals have a normal biogeochemical cycle and their entrance into the soil can be retained shorter or longer time, depending on their physical and chemical properties. They are disappearing slowly by leaching and removal with crops. Therefore, they can accumulate in the soil in large quantities and then can disrupt natural physical-chemical properties, fertility and filtration ability. Because of this, it is of great importance to know the factors that have the influence on behavior of heavy metals in the soil and their accessibility to living organisms (Goletić, 2005).

Mobility and ways of binding heavy metals in soil

Numerous studies in the last decades have shown that data on the total content of metals in the environment do not give a clear picture of their geochemical properties, such as mobility and reactivity or biological properties (accessibility, toxicity) (Kabata-Pendias, 2004; Menzies et al., 2007). Mobility and accessibility of metals in the soil are influenced by various factors that can be geochemical, climatic and biological source (Kabata-Pendias, 2004).

Heavy metals that came into the soil as a result of anthropogenic activity are most commonly found in mobile fractions and plants can absorb them in increased concentrations. In the case of unpolluted or low-polluted soils, the metal content is uniform in the depth of the profile or slightly elevated in the plowing layer due to the biological circulation of the elements. Soil that is heavily exposed to anthropogenic pollution by heavy metals, and since metals from anthropogenic sources are retained in surface layers of soil, they usually have a higher concentration of mobile forms of heavy metals in the zone of rooted plants (Antić – Mladenović, 2004). Heavy metals in soil can exist in several forms that primarily depend on the pH of the soil, its chemical and mineral composition, and properties of the heavy metals. The mobility of heavy metals from anthropogenic pollution depends on the acid reaction, the mineral composition, the content of organic matter and humus, the granulation, the temperature and the humidity of the soil. Metals in soil can be found in one or more of several fractions (Hlavay et al., 2004; Pertsemli and Voutsa, 2007): 1) dissolved in a soil solution, 2) occupy interchangeable places on inorganic soil constituents, 3) specifically adsorbed on inorganic soil constituents, 4) related to the insoluble organic matter of the soil, 5) precipitated as pure or mixed matter, 6) present in the structure of secondary minerals and / or 7) present in the structure of primary minerals. In situations where the metals get into the environment due to human activities, the metals are associated with the first five basins. Natural metals can be connected to any of the basins depending on the geological history of the area. Depending on the phase to which they are bound, metals exhibit a different degree of mobility. The method of sequential extraction is used to determine these fractions. There are several modifications of this method, but the most common method is that the metals are classified into 5 factions: exchangeable, carbonate, oxide (Fe-Mn oxide), organic (organic / sulphide) and residual. Sequential extraction techniques are based on the successive application of various chemical extracts on the same sample. Each subsequent extraction step involves a different type of chemical reaction (Tessier et al, 1979; Tessier and Campbell, 1987; Jain, 2004). It is shown that the heavy metals in contaminated sediments significantly accumulate in a removable, carbonate and oxide fraction. In uncontaminated sediment, heavy metals are usually found in the residual fraction (Jain, 2004). According to Zeien, mobile fractions of heavy metals (which are accessible to plants) include: metals soluble in water (in the form of ion in the soil solution), exchangeable fraction and easily soluble metal - organic complexes. There are potentially affordable metal fractions that form part of organic compounds with low-stability and metals related to carbonates. Residual fraction and fractions in which metals are bound to Fe and Mn oxides and organic matter are not accessible to plants because they are practically immobilized in them (Zeien, 1995). A. Kabata-Pendias and A. B. Mukherjee state that the heavy metals in the soil originate from several sources and therefore are determined their accessibility (Table 1). Given the uncertainties that exist in the scientific literature regarding the mentioned term of accessibility, the current division is due to its systematic approach very useful and easily applicable (Kabata-Pendias and Mukherjee, 2007).

In a natural environment, where typically exists a complex mixture of compounds that are able to bind metal ions in complexes, they precipitate into insoluble compounds or strongly adsorbed on the surface of the particles (Nieboer, 1999). Heavy metals can be deposited in soil by processes such as precipitation, complexing and sorption on various minerals. Natural deactivation of heavy metals in the soil is limited and mainly takes place their sorption by soil minerals, or conversion into insoluble compounds. Oxides of iron and manganese, to lesser extent minerals of clay, are the most important sorbents of heavy metals in the soil (Bowman et al, 1981), and besides them, it is also important to mention organic matter (Kerndorff and Schnitzer, 1980).

Table 1. Fractions and accessibility of heavy metals depending on their source in soil (Tessier et al., 1979; Kabata-Pendias and Mukherjee, 2007)

Source	Bound to	Phase of soil	Fraction	Accessibility
From the lithosphere - originating from the parent substrate	mineral	solid	residual	very weak
From the pedosphere - originating from the parent substrate but during the process of genesis of soil changes the original shape of these elements, whereby climate conditions have dominant influence	clay particles, organic matter of soil and oxides and hydroxides ---------------------- individual and complex ions	solid ---------- liquid	bound to organic matter of soil and oxides and hydroxides ------------- free ions and atoms	weak ---------- weak
Anthropogenic - elements are deposited on soil and / or into soil as a result of different human activities	mineral, organic matter of soil and the particle surface of soil	solid	mostly interchangeable and chelated	medium and weak
From the pedosphere + anthropogenic	individual and complex ions	liquid	free ions and atoms	weak

Conclusion

The important issue today is the preservation and protection of the soil from damage and permanent destruction. In most cases, uncontrolled use of soil leads to its permanent destruction. Such processes reduce the areas for agricultural production, but also for other uses, thus reducing the possibility of food production.
Total content of an element is a very poor indicator of its bioavailability. Toxicity of an element is dependent on the mobility, transformation and potential bioavailability to plants and so into food chain. The separation of various chemical forms of heavy metals in soils is very important. The chemical and physical properties of the soil are essential parameters that have effects on metal forms in soil and its mobility. Toxic metals are widespread in the environment and their early detection is the basis for the prevention or control damage to people or the ecosystem. High concentrations of heavy metals have a harmful effect on the living world so this is of great importance to monitor these toxicants.

ENVIRONMENTAL ASPECTS IN CULTIVATION OF PAULOWNIA IN BULGARIA

Avgusta STEPCHICH

Institute of Soil Science, Agrotechnology and Plant Protection "N. Poushkarov", Sofia, 7 ShosseBankya Str., Bulgaria
*Corresponding author:astepchich@yahoo.com

Abstract

Paulownia is a relatively new plant species grown in Bulgaria. It is primarily associated with the extraction of timber. The tree is characterized by rapid growth in height, but also with high value of the manufactured wood. The species is of great ecological importance. There are large, bright and fragrant flowers and the big leaves facilitating the absorption of carbon. It is suitable as a honey culture and the most suitable type is Paulownia tomentosa. The plant is propagated in different ways – by seeds, by cuttings and in-vitro method. The most popular method is by cuttings. The seeds are light and easily propagated by wind, but difficult to intercept alone. Because of the large amount of seeds in the seed pod, species is considered invasive for the territory of Bulgaria. The studies aimed at establishing risk of invasiveness and the possible usage of the species in Bulgaria. The studies, based on field measurements, showed that the soil and climatic conditions of the country do not premise invasiveness of the species. The species Paulownia is suitable for cultivation on reclaimed land, as well as for soil erosion control. Based on information collected from different experimental sites it is concluded that Paulownia has a great ecological importance and can be used in different areas.

Keywords: *Paulownia, environmental impact, cultivation, Bulgaria*

Introduction

The ecological significance of individual plant species varies on soil and climatic conditions. The plant species Paulownia spp. has gained popularity in recent years. Cultivation is related to the possibility of using the species for different purposes. It is known for its rapid growth and decorative qualities. Paulownia best develops on light, well-aerated soils with a pH of 5.5 to 8.9. In clay or swampy soils the development of the root system is difficult and the growth is insignificantly. Intensive Paulownia cultivation is optimal to an altitude of 700-800 m and temperatures at which maximum growth is observed in the range of 24-33 °C. Regarded to wind, it is recommended that plantations be established in locations with a wind speed of not more than 28 km/h. The plant is propagated in different ways - by seeds, cuttings and in-vitro method. The most popular method is cuttings. Due to the presence of a large quantity of seeds in the seed pod, the species was considered invasive for the territory of Bulgaria. The seeds are light and easily transported by wind, but are difficult to strike root on their own. The flowers are large, bright and aromatic, hanging on long 15-30 cm thick twigs. The planting pattern is determined depending on what the resulting timber will be used for. Lawrence (2011) gives an example with plantations from Western Australia, Queensland, where the scheme used ranges from 6x5 m to 6x7 m, rarely 7x7 m. Kalmukov (2009) indicates the use of two distances between adjacent rows- 1.5 m and 2.0 m three densities between each two plants within the row - 0.5 m, 1.0 m and 1.5 m. Paulownia wood is suitable for both biomass and wood production. The price of wood is high, as the World Paulownia LLC proposed for

m^3 wood is US $ 275. Diseases of Paulownia are most often caused by fungi, viruses, sunburn or over-wetting, which mainly affect the root, the trunk and the leaves. There are also a number of pests.

Materials and methods

The article is based on a review of primary and secondary data. Field experiments have been set up under different soil conditions. The trials were carried out on the territory of village of Pravda (Dulovo municipality) and village of Lyulin (Pernik municipality). To determine the morphological structure, composition and soil properties, soil profiles were made and soil samples were taken from the two sites. The climate is tracked according to the National Institute of Meteorology and Hydrology.

For the village of Pravda, plantations have been observed since 2012. The planting pattern is 3x3 m in chess scheme. This scheme is widely used for growing timber. Plantation in Lyulin is made 2013. The planting pattern is 3x3 m in straight rows. Measurements of the height of individual plants for each site were carried out.

Three maps have been created using soil, climate and irrigation data to produce maps showing the appropriate areas for paulownia, meeting the requirements of culture. The first map shows territories that cover all the required factors (soil, climate and irrigation). The second map limits places with an average temperature of up to +13.5 °C, and the third indicates places with irrigated mode. Observations have also been carried out on invasiveness of the species.

Results and discussion

The reason why the plant has gained great popularity in recent years is the extremely fast growth. Various sources describe the growth of the tree, which in 8 years reaches over 20 m. The height of a 3 year old poplar is from 9 to 12 m, while in paulownia it is from 10 to 15 m. Plant development is traced under different soil and climatic conditions on the territory of two plantations in different parts of Bulgaria. The first site is in the village of Pravda (Dulovo municipality). From the soil profiles made on site, it was found that the soil is Luvic Chernozems, heavy sandy-clay (Clayic). By mechanical composition the soil is characterized as heavy sandy clayey (54.3% physical clay in the surface horizon). The humus content in the surface horizon is 2.20%, which characterizes it as low humus soil. The nitrogen content of the soil is very low - 17.9 mg / kg. The phosphorus content is 12.8 mg/kg, and with potassium content of 20.2 mg/kg the soil is considered as well stocked. The reaction of the soil is very strongly acidic (pH in water 4.9), and carbonates are not found at the depth of the profile. In climatic terms the territory of Pravda is characterized by temperatures of 12.7 to 13.1 °C. High annual precipitation values are reported - from 789 mm to 813 mm. No frost for the studied period was recorded at the plantations in Pravda.

Plants show a significant growth since the first year of planting. The average growth in height of the plants is shown in Table 1.

Table 1. Average height (m) of plants in village of Pravda

Year	2012	2013
Average height	2.4 m	4.7 m

The data from the measurements made indicate the possibility of the species to develop rapidly in the soil-climatic conditions of the village of Pravda. For 2012, the average height increase is 2.4 m. For 2013 - is 4.7 m, which is double compared to the previous year. No tree pruning was performed for the observed period. This allows tracking their growth from the planting period.

The second site is village of Lyulin. From the soil profile made on site, it was found that the soil is anthropogenic, light loam. By mechanical composition soil is slightly clayey (65.44% physical clay in the surface horizon).
The humus content in the surface horizon characterized it as humus soil - 6.12%. In nitrogen content – 37.7 mg/kg and in phosphorus content – 4.5 mg/kg the soil is poorly stocked. But in potassium content - 23,6 mg / kg, it is well stocked. The soil reaction is slightly alkaline (pH in water 8.1) and carbonates are established over the entire depth of the soil profile. In climatic terms the territory of Lyulin is characterized by temperatures of 10.0 to 10.4 °C. The annual rainfall in 2013 is 433 m and in 2014 it is twice the amount (808 m). As a result of the reported frost in 2013 the leaves froze, which led to their subsequent fall.
Plants in the village of Lyulin are also characterized by rapid growth during the years. The pruning has been performed for the measurement period. The average height increase for 2013 is 0.72 m and for 2014 - 0.24 m. After the pruning at the end of 2013, the plants begin their development from the root. This is also the reason for the lower results during second year of their planting (Table 2). Pruning has been done to ensure faster growth. This is a commonly used method for growing the species for the needs of the forestry industry.

Table 2. Average height (m) of plants in village of Lyulin

Year	2013	2014
Average height	0,72 m	0,24 m

To compare the results, Gyuleva (2010) gives data about the first year of planting the species in different regions of the country. For the territory of Svilengrad there is an average height of one year old plants of 0.57 m. For Karlovo is 0.67 m and for Lukovit is 1.19 m. From the data shown above it is obvious that the increase of the plants in Lyulin is very good. The impression is made by the much larger increase in the village of Pravda, due to the soil and climatic conditions.
Trees planted in 2009 are used for the calculation of the volume of the wood planted in the territory of Dulovo municipality. The main reason for this is that by the third year the trees have a hollow core, making them extremely susceptible to strong winds. The plants from the village of Lyulin have not been calculated because of the pruning at the end of the first year. The average volume of wood was calculated per cubic meter per year per hectare (m^3/y/ha). Plants are measured over a three year period (2012-2014). For 2012 the values are 29.0929 m^3/ha. For 2013, the volume is calculated at 27.8820 m^3/ha and for 2014 it is 84.1009 m^3/ha.Some sources point out that under perfect conditions Paulownia starts to give 1 cubic meter of tree wood growth after the seventh-eighth year.
With the help of the observations and the information gathered, three maps were prepared for the territories in Bulgaria suitable for Paulownia breeding. (Figures 1, 2 and 3).

Figure 1. Map of soil-climatic areas with optimal, natural conditions for the development of Paulownia

With all the factors for the development of the plants, the lands along the Struma River and parts of the Sakar Mountain, part of the Arda River and the southern parts of the Black Sea coast.

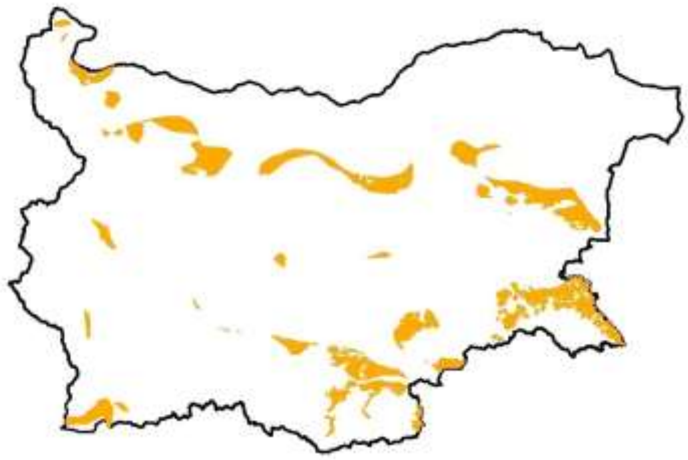

Figure 2. Map of the territories with optimal annual temperature +13,5 °C

When temperature is reduced, there is a greater fragmentation of the Paulownia growing areas. There are parts of southern Bulgaria overlapping with the territories from the first map. Besides them, parts of the Balkan Range and the eastern parts of Stara Planina are also suitable.

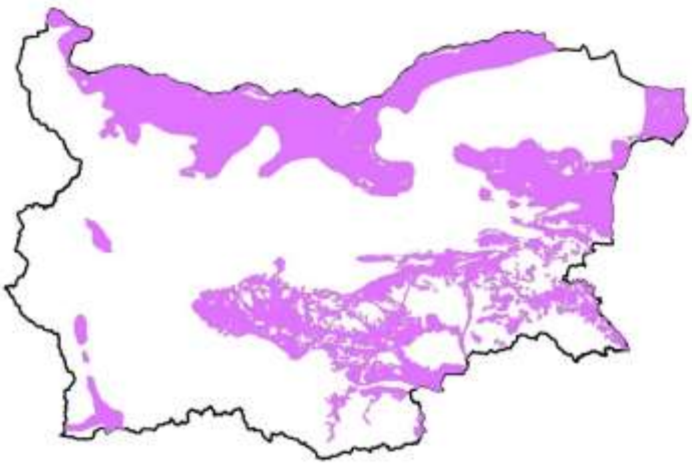

Figure 3. Map of the territories with irrigated conditions

Unlike the first two maps, on the third map there are more territories suitable for Paulownia breeding. Impressive is the territory along the Danube River, as well as the valley of the Osam River. The lands located in the Maritsa and Tundja rivers, as well as almost everywhere along the Black Sea coast, are suitable.
Determining a crop as a honey is dependent on climatic conditions. Higher temperatures allow for a longer flowering period and vice versa - shorter blooms. Nectar in a paulownia color is significantly higher than that in one acacia white color, which is from 1,662 to 8,130 mg (Vachev, Kalmukov, 2005) and from lime-tree is from 1,414 to 10,53 mg (Tsocheva, Vachev, Karmukov , 2007). Plants begin to bloom in the third year. From an economic point of view, it is better to plant the plantations to be used as honeycombs in areas with higher air temperatures (Kalmukov, Vachev, Kanchev, 2016).
From an erosion point of view, it is noted that at the beginning of its development, the culture has poor erosion protection, due to the slow increase in area coverage. When cultivating the species for the harvesting of wood is not allowed the shaping of a powerful crown. The trees are allowed to grow only at a height, thus the only area coverage is from the single leaves located on the stem. Upon growth, these leaves drop and reduce the anti-erosion effect of the culture. Unlike other species paulownia, it can also be grown as a bush species. This allows the formation of more branches and consequently increases the area coverage. An important condition for growing the species for anti-erosion purposes is that the terrain should appropriate with the requirements of the culture. The lack of key factors for its development could lead to the extinction of planted plants.
In some areas, Paulownia is considered an invasive species. In Europe, it is predominantly limited in man-made habitats (Essl 2007). For the territory of Bulgaria, the species is not defined as invasive. A small pod of Paulownia contains hundreds of small seeds, and since their vitality is always high, only a few pods are required to produce a large number of seedlings. However, climate conditions in Bulgaria do not allow these seeds to spread and set off independently, which is why it is not to be described as invasive.

Conclusion

From the measurements and observations made, it can be noticed that the fast-growing species of Paulovnia can be cultivated for different purposes on the territory of Bulgaria. With its honey-like properties it is suitable for planting near hives. The formation of a large crown and exceptionally beautiful colors are a prerequisite for its cultivation as park vegetation. Its rapid growth, under appropriate conditions, allows it to be cultivated for the forestry industry, and thus could replace slower growing species. The increase in the volume of wood is increased every year, with the average volume of six years of planting being 84.1009 m^3/ha. From the maps, a repeat of the territories suitable for paulownia cultivation in Bulgaria is observed. Under optimal conditions the lands along the Danube River and the rivers Maritsa and Struma are distinguished. It is precisely this restriction of the appropriate territories that it does not allow it to be included in the list of invasive species for the country. Depending on the way of cultivation, paulownia has the potential to protect the soil from erosion. Its growing in the form of a bush increases the area coverage, thus increasing its protective effect. The species is relatively new and unexplored for the territory of Bulgaria and this necessitates the need for further in-depth research.

Abstract

The present study examines the medical plants in the protected zone “Yazovir Konush”, Konush village in the region of Plovdiv in Bulgaria. Eco-biological characteristic of the medical plants is made, and the species are categorized by biological groups, by life forms, by floral elements, and by time of flowering. The plants are classified by ecological groups according their regard towards the water, the light and the heat as a factor. Conclusions for the presence by percentage of medicinal flora in the protected zone are made. The research held in the period 2012-2014 of the medicinal plants in protected zone “Yazovir Konush” shows that there are 100 species plants from 82 genera and 40 families. Among these plants the majority are the perennial herbaceous species, the hemicryptophytes, the species with European and Mediterranean origin, the thermophytes, the mezophytes and the heliophytes.

Keywords: *Protected zone “Yazovir Konush”, NATURE 2000, medical flora.*

Introduction

The subject of the research is the medical plants in the PZ “Yazovir Konush”, village of Konush, municipality of Asenovgrad (0.376 ha), located in the Upper Thracian Plane in Bulgaria. The protected area is stated with Order № RD-367/ 16.06.2008 from Ministry of Environment and Water (MOEW) aiming to protect and support the habitats of the bird species, included in the Law for the biological diversity and restoring the habitats of these species. The protected zone is located in the field of Plovdiv of the Upper Thracian Plain. According to phytogeographical subdivision (Bondev 1991) the territory of the commented object is at the borders of the floristic region Thracian Plain. According to the physiographic division of Bulgaria (Galabov 1982) the examined territory falls in the Kraishtensko – Tundjanska (transitional) zone, region of the upper Thracian Plain, in the Western sub-region which is in the field of Plovdiv. Based on the climatic zoning of the country (Galabov 1982) the territory of the PZ “Yazovir Konush”, is in the Eastern Thracian sub-region of the climatic region of Eastern Central Bulgaria, Transitional – continental climatic sub-region of the European –continental climatic region. It is characterized with relatively mild winter and hot summer, with well-defined drought especially in the months August-September, which are the driest months of the year. The average annual rainfall is 551 l/km^2, which defines the area as a place with little annual rainfall (Galabov 1982). The average annual temperature is around 12.1 °C, which matches the indicated temperature for the country between 11 and 12 °C (Galabov 1982). The average air humidity is 72% and matches the average for the country (Galabov 1982). The soils are mainly alluvial meadows, where at some places are mixed with clay and black resinous.

The purpose of the current research is to create a list and to make floristic analysis and ecological and biological characteristic of the medical plants (MP) within the borders of the protected zone (PZ) “Yazovir Konush”, village of Konush in the region of Plovdiv.

Material and Methods

The diversity of medicinal flora in PZ “Yazovir Konush” is studied by systematic observations and collecting of material during the vegetative seasons of 2012-2014. The periodicity of the visits is conformed to the climatic conditions in the region and the determined by their phyto-rhythmic. The earliest aggregates are form the beginning of February 2012, and the latest – from the end of September 2014. This allows the most complete taxonomic diversity of the medicinal flora in the reserve and its seasonal dynamics. .The determination of the species is made by means of Flora of Bulgaria (Yordanov, edit. 1963-1979; Velchev, edit. 1982-1989), Flora of Bulgaria (Kozhuharov 1995), and Flora of Bulgaria (Stoyanov et al. 1966-1967, Identifier of Trees and Shrubs in Bulgaria (Gramatikov 1992), Identifier of Plants in Bulgaria (Delipavlov, Cheshmedzhiev edit. 2011). The processing of herbarium materials and characteristics of medicinal flora were carried out by standard methods (Gusev et al., 2004). Characteristic of medicinal plants was done according to biological types and life forms of Raunkiaer (1934). Floral elements were characterized by the classification of B. Stefanov (1943) and the adapted to the flora of Bulgaria classification of Walter (Asyov, Petrova 2012). The identified taxa are divided into ecological groups in terms of the most important ecological factors – water, temperature and light. An account and analysis of the flowering period for all identified species were done. The names of the plants are by The Euro + Med PlantBase – the information resource for Euro-Mediterranean plant diversity (2011), Identifier of Plants in Bulgaria (Delipavlov, Cheshedzhiev 2011).

Results and Discussion

The results from the resent analysis summarize the data from the terrain researches according to the project “ Suggestion for preparing a plan for control of the protected zone “Yazovir Konush” (Contract № 5113123-C-001 for grant by Operative Program “Nature 2007 – 2013”, Co-financed by the European fund for regional development and by the Cohesion fund of the European Union). Based on the literature analysis of publications for medical plants of Bulgarian flora (Annex 1 to the Law for medical plants, 200, 2006; Nikolov, 2007; Tashev, Tsavkov 2008, Landjev, 2010; Delipavlov, Cheshmedjiev edit. 2011), was established that in PZ “Yazovir Konush” there are 100 species of medical plants from 82 genera and 40 families, which is 2.8% from the species, 9.8% from the genera and 33.3% from the families in the Bulgarian flora (Asiova, Petrova 2012). Systematic list of the medical plants in PZ “Yazovir Konush”

Liliopsida

Alliaceae: *Allium rotundum* L.; *Butomaceae*: *Butomus umbellatus* L.; *Iridaceae*: *Iris pseudacorus* L.; *Poaceae*: *Cynodon dactylon* (L.)Pers.; *Typhaceae*: *Typha angustifolia* L., *Typha latifolia* L.

Magnoliopsida

Aceraceae: *Acer tataricum* L.; *Apiaceae*: *Eryngium campestre* L.; *Asteraceae*: *Achillea millefolium* L., *Arctium minus* (Hill) Bernh., *Artemisia vulgaris* L., *Carduus acantoides* L., *Carlina vulgaris* L., *Centaurea calcitrapa* L., *Centaurea solstitialis* L., *Chamomilla recutita* (L.) These plants resemble 13.4% from all species included in Annex 1 to the Law for the medical plants (200, 2006). All species belong to Magnoliophyta division. From the seed plants in the area 6 species belong to Class Liliopsida, distributed into 5 genera and 5 families, and the rest 96 species belong to Class Magnoliopsida, distributed into 77 genera and 35 families. Richest in medical species families in the PZ are: Asteraceae and Lamiaceae with 15 species, Fabaceae with 8 species and Rosaceae with 7 species. The distribution of the taxon according to biological types shows that with the most significant presence are the perennial herbaceous species – 51 or 51. 0% of all the medical plants, followed by the annual- 18 species (18. 0%), trees and shrubs with 4 species (4.0 %) each. The rest of the species belong to the transitional biological types (Table 1).

Table 1. Distribution of the medical plants from PZ "Yazovir Konush" according to biological types

Biological type	Number of taxa	% from MP in PZ "Yazovir Konush"
tree	4	4
tree-shrub	1	1
shrub-tree	2	2
shrub	4	4
perennial	51	51
biennial-perennial	5	5
biennial	5	5
annual-perennial	2	2
annual-biennial	9	9
annual	18	18
Total	100	100

According to the biological spectrum of the studied species, most are hemicryptophytes (H) – 46 species or 46.0 % of the total number of plants in the protected area, followed by therophytes (Th) – 18 species (18.0 %) , phanerophytes (Ph)– 10 species (10.0 %), cryptophytes (Cr) – 5 species (5.0 %) and chamephytes (Ch) which are only 1 species (1.0 %). The remaining species are of transitional life forms – among them the most – 12 species (12.0 %) are these which can be hemicryptophytes or therophytes (H-Th), depending on the habitat conditions. The distribution of medical plants in phytogeographic centers according to the classification of B. Stefanov (1943) shows that the greatest part – 45.0 % are thermophytes from the Southern Continental Center, followed by the thermophytes from the Northern Continental Center – 28.0%, the mesotherms of Silvo boreal Center - with 13.0%, thermophytes and mesotherms from the Mountainous Center – 11.0 %, plants from other phytogeographic centers – 2.0 %, and least are the thermophytes from Mediterranean Centre – 1.0 %. According to their mobility the analyzed plants are distributed as follows: the stationary species 12 (12.0 %), the moving ones with secondary expanded areas – 33 species (33.0 %) and the species that have appeared by secondary displacement – 55 plants (55.0 %) (Stefanov, 1943). These data is evidence of significant anthropogenic interference within the territory of the reserve in the past. Analyzing medical plants by floral elements, distributed according to the classification of Walter, shows that geo-elements with European component – 51 species or 51.0 % are the greatest part, as among them most are Euro-Asian (*Eur-As*) –22 species (22.0 %), Euro Mediterranean (*Eur-Med*) – 16 species (16.0 %), Euro-Siberian (*Eur-Sib*) with 6 species (6.0 %), European (*Eur*) – 5 species (5.0 %) and Euro-Tuman – 2 species (2.0 %). Second is the group of species with Mediterranean component - 34 species or 34.0 %, among them most are Euro Mediterranean (*Eur-Med*) with 16 species (16.0 %), followed by sub-Mediterranean (*subMed*) with 11 species (11.0 %), Pontic-Mediterranean (*Pont-Med*) – 4 species (4 %), and Mediterranean (*Med*) – 3 species (3.0 %). There is a large amount of Cosmopolitan (Kos) plants – 15 species (15.0 %) (Table 2).

Table 2. Distribution of the medical plants from PZ “Yazovir Konush” by floral elements according to the adapted classification of Walter (Asyov and Petrova 2012).

Floral elements by Walter (2012)	Number of taxa	% from MP in PZ “Yazovir Konush”
Adv	2	2
Boreal	5	5
Eur	5	5
Eur-As	22	22
Eur-Med	16	16
Eur-OT	2	2
Eur-Sib	6	6
Kos	15	15
Med	3	3
Pont	1	1
Pont-Med	4	4
subBoreal	8	8
subMed	11	11
Total	100	100

The distribution of the studied plants according to their period of flowering shows that the most active period is from May to July. During this period 95 taxa blossom, 95.0 % of all the plants. Among them, most species blossom in June-August – 17 species, May-August and June-September – 13 species each, May-June and May-September – 7 species each etc.

The fact that the grater part of PZ “Yazovir Konush” is watercourse determines the presence of waterfowl species. So among the medical plants in the explored area dominating are the mezophytes with 54 species (54.0 %), followed by the hygrophytes and xerophytes with 12 species (12.0 %) each, xeromezophytes – 7 species (7.0%), hygromezophytes and mezohygrophytes with 6 species each (6.0%). 3 species (3.0 %) can be related to the hydrophytes.
The analysis of the medical plants distribution in terms of the light factor shows prevalence of heliophytes that are most of the species (96 %), and the rest are hemi-scyophytes (6.0%) as there are no schyophytes.
According to their relation to heat the species are divided into only 2 groups. Thermophytes go to the bigger group with 84 species (84.0 %), and the rest 16 species (16.0 %) refer to the group of mesotherms. The dominance of thermophilic species is directly related to the influence of the Mediterranean climate, penetrating along the Maritsa River (Galabov, 1982).

Conclusion

The research held in the period 2012-2014 of the medicinal plants in PZ “Yazovir Konush” shows that there are 100 species plants from 82 genera and 40 families. Among these plants the majority are the perennial herbaceous species, the hemicryptophytes, the species with European and Mediterranean origin, the thermophytes, the mezophytes and the heliophytes which mainly blossom in the period May-July. The comparatively big participation of secondary and cosmopolite plants within the borders of the examined area is evidence for the considerable anthropogenic interference in the processes occurring in the plant cover of the protected area. There are plenty different plant groups according to the water as a factor, which is evidence for the existence of different types of habitats within the borders of the examined territory. This fact increases the ecological importance of the PZ “Yazovir Konush”.

Abstract

This study aimed to compare four different regression methods, including partial least squares regression (PLSR), principal component regression (PCR), boosted regression trees (BRT) and support vector machines regression (SVMR) for predicting organic carbon content in soil samples with visible-infrared (Vis-NIR) diffuse reflectance spectroscopy (DRS). The reflectance spectra of a total of 238 topsoils (0-25 cm) heterogeneous samples were measured in a laboratory using a portable Terra Spec 4 Hi-Res Mineral Spectrometer with a wavelength range of 350-2500 nm. The analysed soils belong to various soil types used in agricultural production with SOC content ranging from 0.29 to 37.50 g C kg^{-1}. The estimation accuracy was determined with the coefficient of determination (R^2), the ratio of performance to deviation (RPD) and the root mean square error of prediction (RMSEP). The results of this study showed that the SVMR and the PLSR models obtained good predictions for soil organic carbon with R^2 values of 0.87 and 0.86, RMSEP 2.48 and 2.58 g C kg^{-1} and RPD values of 2.5 and 2.4, respectively. The PCR and BRT showed a noticeable decrease in prediction accuracy with R^2 values of 0.77 and 0.72, RMSEP 3.49 and 3.71 g C kg^{-1} and RPD values of 1.6 and 1.5, respectively indicating fair predictions. Our study confirmed the potential of Vis-NIR spectroscopy for estimation of SOC content and showed that the estimation accuracy of the analysed calibration methods decreased in the following order: SVMR>PLSR>PCR>BRT.

Key words: *BRT, Chemometrics, PCR, PLSR, SVMR*

Introduction

Soil organic carbon (SOC) has a leading part in maintaining soil quality since it affects the chemical, physical and biological processes in soil. Thus, there is growing need for a large amount of precise data on its content, in order to improve soil/land management. Classical analytical methods are expensive, time-consuming and resulting in the disposal of toxic chemicals harmful to the environment. Diffuse reflectance spectroscopy (DRS) is a rapid, non-destructive and eco-friendly method, which offers a cheaper solution in the estimation of SOC content. The most commonly analysed part of reflectance spectrum is visible and near-infrared (Vis-NIR, 350-2500 nm). Diffuse reflectance measurements of soil have spectral activity throughout the entire spectral region and it characterises complex absorption patterns. The soil spectra hold large numbers of the predictor variables that are highly collinear and therefore analyses of diffuse reflectance spectra require the use of multivariate calibrations (Martens and Naes, 1989). The correlation between SOC content and reflectance measurements have been investigated using various multivariate chemometrics techniques and pre-processing transformations.

The selection of a calibration method is one of the main factors influencing measurement accuracy with Vis-NIR spectroscopy (Gao et al. 2014). The most common calibration method for analyses of soil spectra is partial least square regression (PLSR), developed by Wold

(1985). However, other widespread regression methods have been used, i.e. principal component regression (PCR) by Chang et al. (2001) and Viscarra Rossel and Behrens (2010), support vector machines regression (SVMR) by Stevens et al. (2010 and 2013), Viscarra Rossel and Behrens (2010) and Gao et al. (2014), boosted regression trees by Brown et al. (2006), Viscarra Rossel and Behrens (2010) and artificial neural networks (ANN) by Brown et al. (2006) as well as many others.
The aim of this study was to compare four different regression methods, including partial least squares regression (PLSR), principal component regression (PCR), boosted regression trees (BRT) and support vector machines regression (SVMR) to find the most accurate method for SOC prediction in sample set collected in the various agricultural soils from Mediterranean part of Croatia.

Material and methods

In this paper, we used the SOC content determined with the Kotzman method (JDPZ, 1966) and Vis-NIR reflectance measurements for a total of 238 topsoil samples selected from a Soil Spectral library from Dalmatia (Miloš, 2013). Soil samples were collected in the agricultural areas of Split-Dalmatia County centred at 43° 30'N and 16° 26'E. According to the World Reference Base for soil resources (IUSS, WRB 2014), selected soils are classified as Calcic, Chromic and Rhodic Cambisols, Rendzic Leptosols and Regosols (not Lithic). The climate of this area is characterised by dry, hot summers and mild, moderately rainy winters. Agricultural areas are typical Mediterranean including olive groves, vineyards, fruit orchards and abandoned agricultural land. The reflectance spectra of soil samples were measured in a laboratory using a portable Terra Spec 4 Hi-Res Mineral Spectrometer (Analytical Spectral Devices, Boulder, CO, USA) with a wavelength range of 350-2500 nm. The original soil spectrum recorded at 1 nm interval wavelengths was resampled at every 5 *nm* over the „full“ spectral range. Pre-processing transformations of the original spectra were performed using Savitzky-Golay first derivative and smoothing (Savitzky and Golay, 1964) with a second order polynomial fit.
We compared four methods to derive SOC calibration and validation predicting models including partial least squares regression (PLSR), principal component regression (PCR), boosted regression trees (BRT) and support vector machines regression (SVMR). The PLSR and PCR are a multivariate regression analysis technique used to construct predictive models when there are large numbers of predictor variables that are highly collinear. These methods are based on a linear transition of a large number of original descriptors to a small number of new predictors (components or orthogonal factors). In contrast to PCR, the PLSR creates components taking into account the response variable resulting in models that are able to fit on the response variable with fewer components. So, the PLSR, introduced by Wold (1985), has become a standard tool in chemometrics and the most commonly-used calibration method for estimation soil properties using diffuse reflectance spectroscopy. We used the PLSR and PCR with leave-one-out cross-validation method (Efron and Tibshirani, 1994) for calibrating the reflectance spectra and construction of SOC prediction model. For more details on the PLSR see eg. Martens and Naes (1989), Wold (1985), Wold et al. (2001) and for the PCR Jackson (1991).
The boosting regression tree (BRT) is a machine learning technique developed by Friedman (1999a and 1999b). The general idea of this regression method is to compute many very simple models (trees) and derives weights for combining simple models into a single highly accurate prediction model. The support vector machines regression (SVMR) is regression method based on statistical learning algorithms (Vapnik, 1995). Detailed discussions of these techniques are given in Hastie et al. (2001).

The accuracy of the SOC models was evaluated by calculating the root mean square error (RMSE), the ratio of performance to deviation (RPD) and the coefficient of determination (R^2). The RMSE is defined as the square root of the average of squared differences between predicted and measured Y values and evaluated with equation:

$$RMSE = \sqrt{\sum_{i=1}^{N} \frac{(\widehat{y_i} - y_i)^2}{N}}$$

where y_i and $\widehat{y_i}$ are the measured and predicted values of sample *i*, respectively, and *N* is the number of samples. The RPD was initially used by Williams (1987). It represents the division between the standard deviation (SD) of the validation dataset and the standard error of the prediction (SEP) and deduced with relation:

$$RPD = SD \;/\; SEP$$

To interpret RPD values we adopted the interpretations given by Chang et al. (2001) as follows: models with RPD ≥ 2 are considered as ‘good’, models with 1.4 ≤ RPD< 2 predict „fairly“, while models with RPD < 1.4 predict „poorly“. To interpret R^2 values we adopted threshold values given by Saeys et al. (2005) as follows: a value for R^2 between 0.66 and 0.81 indicates approximate quantitative prediction, R^2 between 0.82 and 0.90 reveals good prediction and R^2 >0.91 is considered to be an excellent prediction.

Results and discussion

The descriptive statistics for the reference dataset (SOC content analysed using conventional laboratory method), calibration and validation datasets for different regression methods is given in Table 1. The SOC content for the reference dataset varies from 0.29 to 37.50 g C kg^{-1} with an average value of 17.74 g C kg^{-1} (Table 1). The negatively skewed distributions for the reference, BRT and SVMR calibration, and BRT validation datasets indicate approximately symmetrical distributions. The PLSR and PCR regression models indicate a slightly asymmetrical distribution with a long tail to the left.

Table 1 Statistical description of the soil organic carbon content (g kg^{-1}) for the reference, calibration and validation datasets for different regression methods

Statistics	Reference	Calibration				Validation			
		PLSR	PCR	SVMR	BRT	PLSR	PCR	SVMR	BRT
Mean	17.74	17.74	17.75	17.92	16.65	17.76	17.78	17.65	17.39
Minimum	0.29	0.50	0.22	1.95	3.65	0.51	0.61	0.35	4.22

PLSR - partial least squares regression, PCR - principal component regression, BRT - boosted regression trees, SVMR - support vector machines regression

Figure 1 shows the mean reflectance spectra and the mean first-derivative spectra of 238 soil samples that were used to develop SOC models. The mean reflectance spectra (Figure 1a) in the visible spectrum shows a continual increase in reflectance with increasing wavelength, while in the NIR spectrum has several characteristic adsorptions around 1400, 1900 and 2200 nm due to water molecule vibrations and OH^- groups (1400 nm), water (1900 nm) and mineral influences (2200 nm). The mean first-derivative of the SOC reflectance spectra (Figure 1b) is characterised with a broad spectral range from 540 to 580 nm, with the maximum peak at 565 nm in the visible range due to chromophorous constituents, mainly iron oxide (Ben-Dor et al.

1999). Furthermore, this spectrum shows several important absorptions around 1400 nm, 1900 nm, a broad adsorption region between 2165 nm and 2200 nm and the absorption peak located around 2340 nm corresponding to CO_3 overtone vibrations (Viscarra Rossel and Behrens 2010).

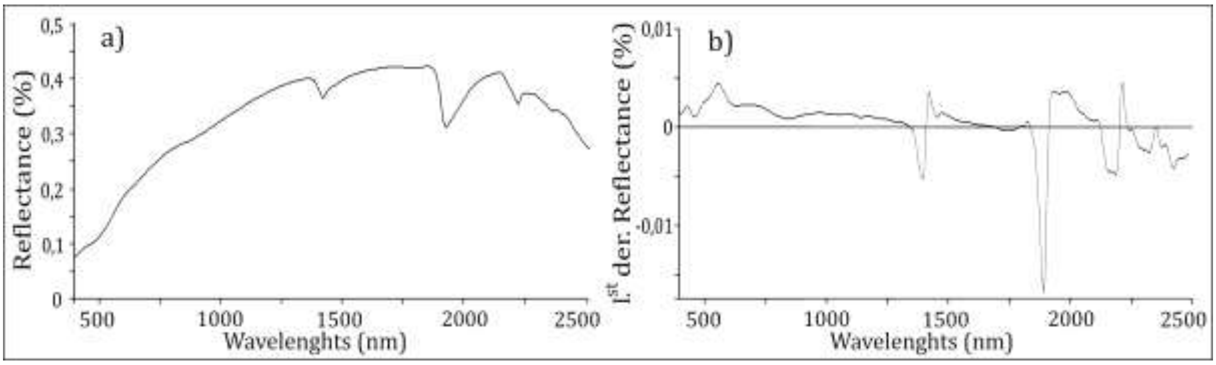

Figure 1. Original (a) and first derivative (b) Vis-NIR spectra of the 238 soil samples

Calibration and validation results of the SOC models diagnostics for the different regression methods are given in Table 2. The best prediction of the SOC was obtained using the SVMR method which revealed the highest R^2 and RPD values of 0.87 and 2.5 respectively, as well as the lowest RMSEP of 2.48 g C kg^{-1}. The PLSR model showed similar performances with slightly higher RMSEP and lower values of R^2 and RPD (Table 2).

Table 2 Calibration and validation results of the SOC models diagnostics for the different regression methods

Regression method	Calibration		Validation		
	R^2	RMSEC	R^2	RMSEP	RPD
PLSR	0.90	2.32	0.86	2.58	2.4
PCR	0.81	3.27	0.77	3.49	1.6
SVMR	0.92	1.97	0.87	2.48	2.5
BRT	0.87	2.51	0.72	3.71	1.5

Two other methods (PCR and BRT) showed a noticeable decrease in prediction accuracy compared to the best accurate method (SVMR), with the PCR performing somewhat better than the BRT. The performance of the SVMR SOC prediction model was much better than the BRT, as R^2 was increased for 20.8% and RPD for 60.0%, while RMSEP was decreased for 1.23 g C kg^{-1}, Table 2. According to the threshold values for the coefficient of determination (R^2) given by Saeys et al. (2005), the SOC models developed using the SVMR and PLSR reveal good prediction, while the PCR and BRT models indicated an approximate quantitative prediction of the SOC. According to Chang et al. (2001), the RPD values >2.0 for the SVMR and PLSR methods (Table 2) indicate good prediction, while RPD values between 1.4 and 2.0 for the PCR and BRT indicate "fairly" prediction.

Our results are consistent with the study of Viscarra Rossel and Behrens (2010) that found the decline of prediction accuracy for the SOC content in the following order: SVMR>PLSR>BRT with R^2 values of 0.84, 0.82 and 0.62 respectively. Gao et al. (2014) showed that the SVMR model with an average RMSE of 2.45 g C kg^{-1} provided a more robust performance than the PLSR which had a larger average RMSE of 2.95 g C kg^{-1}. Peng et al. (2014) also found that SVMR model was superior to PLSR model. The both their models (SVMR and PLSR) have achieved lower accuracy compared to our results (R^2 0.73 and 0.62; RPD 1.89 and 1.63 respectively). Luca et al. (2017) showed that SVMR model outperformed PCR and PLSR models with higher R^2 and lower RMSEP. Contrary, Nawar et al. (2016)

found better prediction accuracy for SOC content with PLSR method (R^2 0.72 and RPD 1.70) compared to SVMR (R^2 0.64 and RPD 1.67). Vohland et al. (2011) established rather small differences between SVMR and PLSR models which both provided reliable estimates with R^2 above 0.85 and RPD above 2.5. Stevens et al. (2010) compared the PLSR and SVMR methods for the SOC predictions on the global and regional scale and showed that SVMR performed better for the global dataset, while the PLSR achieved better accuracy for the regional datasets. Vasquez et al. (2008) established that PLSR method outperformed PCR based on mean R^2 (0.82 and 0.76 respectively) and RPD values for 30 different pre-processing techniques (2.37 and 2.08 respectively).

Conclusion

The SVMR and PLSR models obtained good SOC predictions with similar R^2 values of 0.87 and 0.86 and RPD values of 2.5 and 2.4 respectively. The PCR and BRT models with $1.4 \leq$ RPD<2 indicated „fairly" SOC content prediction. Our study (i) confirmed the potential of the Vis-NIR spectroscopy for estimation of SOC content in the various agricultural soils from Mediterranean part of Croatia and (ii) showed that the estimation accuracy of used calibration methods for the prediction decreased in the following order: SVMR>PLSR>PCR>BRT.

Abstract

Croatia has about 2.3 million hectares of agricultural land, of which one third is state owned. About 167 thousand hectares of agricultural land in Croatia are covered by pipe drainage. Revitalization of pipe drainage and construction of new drainage systems are important potentials for improvement of agricultural production in Croatia. Intensification of drainage was carried out mainly from 1976 to 1990, mostly on agricultural land belonging to state owned farms. Eastern Croatia accounts for 30% of agricultural land at state level and pipe drainage is installed on 122,390.5 ha or 73% of total drained area in Croatia and 17% of agricultural land of the region. More than 20% of agricultural land is drained in three counties of the region (Vukovar and Srijem, Brod and Posavina, Virovitica and Podravina Counties). In general, maize and wheat yields in Eastern Croatia are by about 30% higher compared to the state average. In this regard, we presume that pipe drainage has given a considerable positive contribution, particularly under wet year conditions. Current status of pipe drainage functionality is mainly inadequate and reconstruction and regular servicing are needed. In spite of soil reclamation and pipe drainage management, yields of main field crops mainly in the southern lowland part of the region were accompanied with inadequate supplies of phosphorus and potassium. These problems were eliminated by adequate agroamelioration, for example, ameliorative fertilization. Nutritional problems could be also alleviated by selection of more tolerant field crop genotypes.

Keywords: *underground drainage system, pipe drainage, current status, reconstruction*

Introduction

Underground pipe drainage has been applied on 167,174 ha of agricultural land in Croatia since 1976. The largest part of this system - above 95% - was developed by open ameliorative canals of third and fourth orders during the period 1976-1990 (Marusic, 2003; Petosic et al., 2015; Sostaric et al., 2016). Current status of pipe drainage functionality is unsatisfactory because as much as about 63% at country level and about 53% in Eastern Croatia have the status of a low degree of functionality. Main reasons for the low drainage system status in Croatia are improvisation in construction, inadequate servicing and its devastation during the reconstruction of third and fourth order canals (Petosic, 2003; Petosic et al., 2015). Improvement of plant production on drained agricultural land will be achieved by revitalizing pipe drainage (Petosic et al., 2015), while some drained soils require correction of their chemical properties (Kovacevic and Basic, 1997; Kovacevic et al., 1988, 2005; Petosic et al., 2003) due to very acid soil reaction and low levels of available nutrients, particularly potassium (K) and phosphorus (P).
The aim of this study was to survey the current status of the pipe drainage system in Eastern Croatia and present the possibilities of improving plant production on drained soils.

Material and methods

Until the end of 1992, Eastern Croatia was territorially divided into 14 municipalities of a total area of 11,090 km^2 or 19.6% of the state territory (Vukovar, Beli Manastir, Osijek, Zupanja, Vinkovci, Djakovo, Slavonski Brod, Valpovo, Nasice, Slavonska Požega, Nova Gradiska, Donji Miholjac, Orahovica and Podravska Slatina). Since 1992, according to the new territorial division, Eastern Croatia includes five counties of a total area of 12,452 km^2 (22.0% of the state territory) as follows (Fig 1): Vukovar and Srijem County (15), Osijek and Baranja County (12), Slavonski Brod and Posavina County (14), Pozega and Slavonia County (10) and Virovitica and Podravina County (11). Control drainage units (Fig 1) were selected in each county of the region with the aim to test the status of the drainage system: Stara Sela (15),Trnava III (12), Veliki Crnac (14), Siljkovac (10) and Beljevina (11).
Publications of the State Bureau of Statistics (Statistical Yearbook of Croatia) were used as sources of maize and wheat growing area and yield data (Table 1).

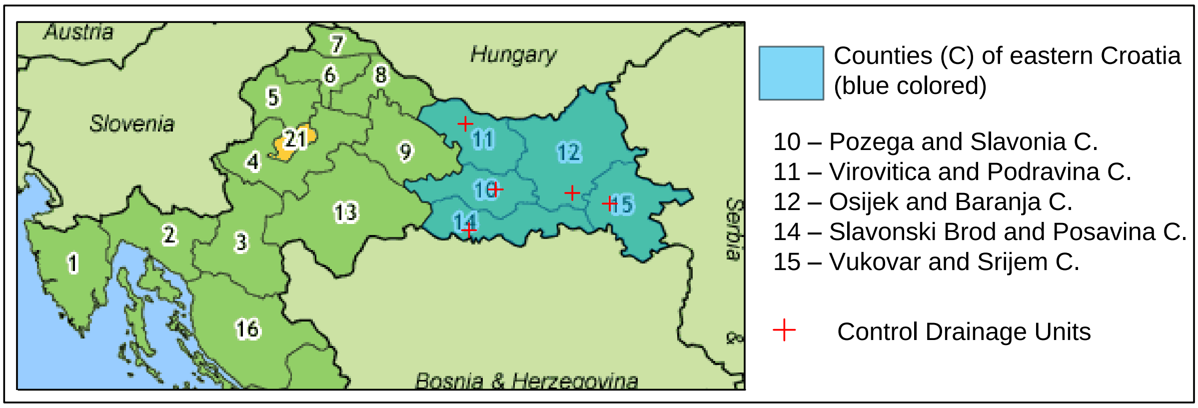

Fig 1. Location of the five counties of Eastern Croatia and control drainage units.

Results and discussion

Croatia has about 2.3 million hectares of agricultural land, of which one third is state owned. About 7% of agricultural land of the country is covered by the drainage system. Eastern Croatia accounts for 30% of agricultural land at state level and pipe drainage is installed on 122,390.5 ha or 73% of total drained area in Croatia and 17% of agricultural land of the region. More than 20% of agricultural land is drained in three counties of the region (15, 14 and 11) (Table 1). In general, maize and wheat yields in Eastern Croatia are by about 30% higher compared to the state average. In this regard, we presume that pipe drainage has given a considerable positive contribution, particularly under wet year conditions. However, alkalization of the soil surface layer is a negative soil property closely associated with drainage.
Higher yields in Eastern Croatia (maize 5.94 and 4.68 t ha^{-1}, 6.06 and 5.17 t ha^{-1}; wheat 5.02 and 3.87 t ha^{-1}, 4.51 and 3.92 t ha^{-1}; for 1980-1989 and 2000-2005, respectively) compared to the state averages can be partially attributed to systematic hydroamelioration (Table 1).
Basic elements of pipe drainage in Eastern Croatia were in the following ranges: depth from 0.9 to 1.1 m, pipe spacing from 15 to 40 m, diameter of drainage pipes from 50 to 65 mm and length of drainage pipes from 60 to 290 m (Table 2).
Basic parameters of open canals of third and fourth orders were from 2.0 to 2.7 m and from 1.5 to 2.2 m (depth), from 800 to 1000 m and from 175 to 320 m (spacing), from 9.2 to 11.4

m^2 and from 7.42 to 9.92 m^2 (cross-section), from 800 to 2000 m and from 350 to 850 m (length of canals), respectively (Table 2).

In Eastern Croatia, 3165 km or close to 48% of the existing ameliorative canals of third and fourth orders were fully reconstructed. Good pipe drainage functionality was found on 39,059 ha or close to 32%, on average on 14,390 ha or close to 12%, and poor on the remaining 68,940 ha or about 56% of the existing canals (Table 3).

Despite soil reclamation and pipe drainage management, yields of main field crops, mainly on hydromorphic soils in the southern lowland part of the region, sporadically remained low due to inadequate P and K supplies (Petosic et al., 2003; Kovacevic, 2002; Kovacevic et al., 2005). Nutritional unbalance and maize and soybean yields were considerably improved by adequate ameliorative K fertilization (Table 4). Survey of K nutritional problems and responses of main field crops to K fertilization were elaborated by Kovacevic and Basic (1997). Both inadequate P and K status were found in some drained gleysols of the Sava Valley area and ameliorative fertilization resulted in considerable maize yield increases of 87% (K effect) and 41% (P effect) as well as in alleviation of nutritional unbalance due to lower P and particularly K uptake by plants (Table 5).

Table 4. Response of maize and soybean to ameliorative K fertilization on drained gleysol of the Vinkovci State Farm (Kovacevic and Vukadinovic 1992)

* K. Mg and P in three developed lowest stalk nodes at maturity (% in dry matter); SL=stalk lodging

Nutritional problems can be alleviated also by selection of more tolerant genotypes (Kovacevic and Vujevic, 1994; Simic et al., 2003; Kovacevic et al., 2011). Fourteen maize hybrids were grown under the K deficiency and Mg oversupply conditions. Seven hybrids of the Os1-48 male parent (group A) were more tolerant to this type of soil stress conditions compared to the hybrids of the Os87-24 male parent (group B), particularly regarding stalk lodging resistance at maturity. The higher K and lower Mg and particularly P concentrations in the stalk base were associated with lower stalk lodging (Table 6).

Conclusion

Soil reclamation by pipe drainage and construction of appropriate ameliorative canals had a considerable effect on the yields of main field crops in Eastern Croatia, particularly under hydromorphic soil conditions. However, improvisation during construction and inadequate servicing of drainage systems during exploitation resulted in their mainly low functionality. For this reason, their urgent revitalization is required. Some soils of the region have less favorable chemical properties and appropriate agroamelioration is required to improve their productivity, for example, ameliorative potassium and phosphorus fertilization.

Abstract

Ground invertebrate fauna is the most diverse and important group to maintain the soil health. Suez Canal is the Egyptian water corridor connecting Red Sea in the south and Mediterranean in the north. The Suez Canal region has a unique status in Egypt. Since the opening of Suez Canal for international navigation in 1869, population in the Canal region increased and green areas expanded. The expanded cities have initiated new habitats and attracted some taxa from Nile valley to the west bank of Suez Canal. The distribution pattern of ground-macro invertebrates has been investigated in correlation with the selected land-use forms along the west bank of Suez Canal in a considerable region. The faunal samples were collected using pitfall traps in nine sites belonging to three stations in the study area; Abusultan, Fanara and Geneifa, with different land use practices (natural desert, agricultural areas and urbanized coast). A total number of 3502 individuals of insects, malacostracans, gastropods and arachnids belong to 129 species were found. The highest species richness was shown by Coleopterans, while the most abundant group was Hymenoptera. The agricultural and the urbanized coastal sites have shown significantly lower abundance of ground macro-invertebrates in comparison with the natural desert habitats. It was concluded that urbanization and agricultural practices have altered soil properties, thus they adversely affected the abundance of ground invertebrate assemblage.

Key words: *Ground invertebrate fauna, Suez Canal region, Distribution pattern, Urbanization, Agricultural practices.*

Introduction

Suez Canal region is a special habitat in Egypt and has a unique status. Suez Canal was opened for international navigation in 1869, with a freshwater canal (Ismailia canal) originating at the River Nile (established in 1862) and running parallel to the Suez Canal to supply drinking water (Arnous et al, 2011). At that time, the Suez Canal area was almost uninhabited. After several years, the Suez Canal population has greatly increased. According to census of 2010, population of Suez Canal region is roughly 2.5 million people (Ibrahim, 2013).

This region was a stage of military actions for decades starting with First World War and ending in the war of October 1973. Since the end of war October, 1973, the Suez Canal cities have greatly expanded and doubled in size, in addition to many lands which are irrigated and cultivated recently (Ibrahim, 2013). Surveys and ecological studies to the biodiversity of the Suez Canal region were neglected during the wars periods. After the end of wars, ecological studies had a great attention. According to the studies, the left bank of Suez Canal was found to be an important eco-zone for some faunal groups such as butterflies, amphibians, reptiles and mammals (Baha El Din, 2006; Basuony et al., 2010; Gilbert et al., 2007).

A considerable number of fauna species were newly discovered in the region (6 spider species (Medany, 2013). Thirty-three species of reptiles and amphibians were recorded from the west bank of Suez Canal zone between 1999 and 2012 (Ibrahim, 2013) out of the ninety-nine terrestrial reptiles and eight amphibians found in Egypt (IUCN, 2000), i.e about one third of reptiles and amphibians found in Suez Canal area. About 55 species of bees have been collected and identified around the Suez Canal Region, in addition to 17 species of Hymenopteran wasps. This number is equal to the species number collected from all over Egypt by the former projects during the 1970s (Shebl et al, 2013).

Human impacts are continuing to drive natural systems to the direction of increasing patchiness and variability. These patchy habitats can affect ecological patterns and processes (MacArthur & Wilson's, 1967). The urbanization was found to be a matter of debate in the field of soil ecology. General ecologists consider it as a global problem with negative impact on natural ecosystem and whole biodiversity. Some of them believe that urbanization has recently been the master land use that make changes in species richness, diversity and distribution of species in many ecosystems, leading to the threats on biodiversity (El Surtasi, 2012). Several studies proved this belief especially those used pollinators as an indicator for the effect of urbanization on biodiversity.

Soils in urban areas are generally considered as highly disturbed and heterogeneous, with little systematic pattern in their characteristics (Pouyat et al, 2010). The urban soils have been viewed as drastically disturbed and of low fertility (Craul, 1992). There is always hypothesis that urbanization, as a change in land use, will alter the physical and chemical properties of the soil. This will lead to a habitat disturbance for micro-, meso- and macro-fauna of the soil. Changed soil conditions can affect the functionality of individual soil biota, as well as determine their presence or absence in a community (De Ruiter et al., 2002).

Agricultural activities have either positive or negative influence on diversity, abundance and activity of soil fauna according to the chemical properties of soil and the alteration of natural habitat to agricultural land. Agricultural practices can be both beneficial and detrimental to soil invertebrates. The various management practices that influence populations and activity of soil biota include: tillage, stubble retention, and crop rotation, application of fertilizer, pesticides, irrigation and soil compaction, indicated that population size and community structure of soil fauna are strongly influenced by agriculture practices (Rizk and Mikhail, 1999). The different fertilization regimes can impact significantly on the soil's physical and chemical properties (Zhu X. and Zhu B., 2014). Long-term fertilization can led to the reduction of some arthropod species and the increase in some soil biota groups (e.g., Collembola and Acarina) (GuÐleifsson, 2002). Sludge application had a significant influence on some soil microarthropods and the intensity of the effect was highly correlated to sludge doses (Al-Assiuty et al., 2000).

The aim of this work is to illustrate the impact of agricultural and urbanization practices on the soil fauna through analyzing the effect of soil parameters on the abundance of the collected ground fauna invertebrate species in that study from the study area located on the west bank of Suez Canal.

Material and methods

The study area

The study was conducted in Suez Canal region along the west bank of Suez Canal and includes the northern part of Suez Governorate and the southern part of Ismailia Governorate (at N30.41046, E32.32851 - N30.23229, E32.45744) (Figure 1). This region is characterized by an arid climate with a maximum temperature of 36.1°C in July and a minimum temperature 7.8°C in January. The average annual temperature is about 21.5°C. The average annual precipitation is 33.3 mm (Golani, 1993).

The study was conducted in 9 sites varied in their land use intensity and classified into 3 main habitats: desert (natural), agriculture and coastal (urbanized) habitats. Each one of the three habitats is represented by three sites which are sharing the main characteristics of desert, agriculture or the coastal habitats, but differ slightly in the human activity pressure affecting them. In the selected study area, 3 stations were chosen to trap ground-dwelling fauna: Abu Sultan, Fanara and Geneifa (Figure 1). Each one of them contains the 3 required types of habitats. Three sites were chosen in each station to put the traps which are representatives to natural desert, agricultural, and urbanized coastal habitats. Two of the agricultural lands were typical cultivated lands while the third one was reclaimed land. The coastal sites were affected by the urbanization activities and military camps.
The 9 sites within the different 3 stations were chosen according to: Accessibility, Out of reach, Sustainability and representativeness (costal, agricultural and desert sites). The pressures were mainly identified in the presence of high pressure poles, large heaps of rubbish, as well as some grazing activities and the interruption by train railway which appeared on desert lands.

Fig. 1: Study area (the area marked with red)

Methods

The collection of these sample fauna was done by pitfall trapping method. A number of 54 jars were used as pitfall traps, 6 for each site compromising 18 for each station. Traps were put in dug holes in the ground deep enough to take the whole jar. They were kept open for 3 days in the soil then they were collected. After collecting the traps, the collected specimens were separated, counted, preserved and then identified.
Ground macro-fauna were collected seasonally, from autumn 2010 to summer 2011. The field trips have been conducted every three months, in October, January, April and July.
Soil samples in the study extend down to about 20 cm depth, as samples from soil surface layer only are needed. Samples were put in clean plastic bags with labels describing each subsample. Subsamples were mixed thoroughly to make a composite soil sample. Before air-drying samples, a little portion of each was separated to measure moisture and pH in soil. Afterwards, soil samples were spread over clean paper sheets for 2 days to dry then they were put in cooler until being analyzed. The collected soil samples were air-dried, crushed and sieved to pass through a 2 mm sieve and kept in plastic containers for analyzing physical and chemical properties. Soil moisture was determined by drying the soil samples at 105 °C, and calculated on oven dry weight basis.
Physical and chemical analyses of the soil were carried out according to standard methods (Page *et al*., 1982). Twenty five physical and chemical properties of soil samples were measured during the study. These properties were as follows:
Chemical: [pH, Electric conductivity (E.C dsm^{-1}), Sodium Adsorption Ratio (SAR), Soluble Cations {Calcium (Ca^{2+}), Magnesium (Mg^{2+}), Potassium (K^{+}), Sodium (Na^{+})} in meq/L (soil paste), Soluble Anions {Chloride (Cl^{-}), Carbonates (CO_3^{-2}), Bicarbonate (HCO_3^{-}), Sulfate (SO_4^{-2})} in meq/L (soil

paste), Calcium Carbonate ($_{CaCO3}$%), total soil Nitrogen (N), total Phosphorus (P), total Potassium (K), total Soil Organic Matter (SOM), total Organic Matter, Carbon/Nitrogen ratio (C/N) and Carbon/Phosphorus ratio (C/P)].

Physical: [Sand %, Silt%, Clay%, soil type and soil moisture]

Data analysis: The resulted data, corresponding the faunal species and soil samples which were collected during the practical work of the study, were manipulated and analyzed using Microsoft Excel 2010, SPSS "14" and PC-ORD "5" programs. Charts using Microsoft Excel were conducted to show the difference in values of species abundance and ANOVA test was applied to show the significance of the difference among spatial abundance. Multivariate analyses using Two Way INdicator SPecies ANalysis (TWINSPAN), Detrended Correspondence Analysis (DCA) and Canonical Correspondence Analysis (CCA) were carried out for the 9 sites of this study in the view of ground faunal species and soil chemical and physical properties. PC-ORD 5 program was used to complete all the multivariate analyses. (Hill et al., 2013; McCune and Mefford , 1999).

Results and discussion

This study focuses on the ecology and distribution pattern of ground-dwelling macro invertebrates in one of the natural habitats which exposed to habitat alteration in the previous few decades, the Suez Canal region. It was illustrated that the most important groups are Order Hymenoptera (especially family Formicidae), Order Coleoptera and Order Araneae (spiders). They are represented by large numbers of both species and individuals. Among 129 species found during this study, 38 species were belonging to Coleoptera, 30 species of Spiders and 23 species of Hymenopterans (from which 14 species are formicids). The total number of individuals collected was 3502 from which 2322 Hymenopterans, 245 Coleopterans and 208 spiders.nThe total abundance of the collected soil arthropods was relatively low (3502 individuals), but the species richness is relatively high (129 species). Generally, the high diversity within the insect communities of a habitat is an important factor reflecting the richness of the overall quality of that ecosystem and can be a useful tool in ecosystem conservation (Semida et al., 2001). Although gardens in arid environments may be a home for ground arthropods with having an enhanced abundance of them (Norfolk et al., 2012), agricultural sites in this study showed significantly low ground fauna abundance ($p < 0.01$) in comparison with natural desert habitats followed by urbanized sites (Fig. 4). The reason for these results could be explained by the unfavorable changed soil conditions according to urbanization and agricultural practices.

The Multivariante Analysis

The application of the Detrended Correspondence Analysis (Figure 5) to the study sites showed the tendency of the agricultural sites then the coastal sites to the coordination axis 2. When the Canonical Correspondence Analysis (Figure 6) is applied to the soil parameters against the ordination sites, it showed that the most effective soil parameters were total Soil Organic Matter (Tot SOM) and total organic matter (Tot Org) which characterize the agricultural sites. Other effective factors are clay, moisture, the ratio of Carbon/Nitrogen (C/N) and the ratio of Carbon/Phosphorus (C/P). Coastal and desert sites are characterized by sandy soils, however, the coastal sites are characterized by the effect of potassium. The desert sites are affected by high levels of calcium carbonate ($CaCO_3$).

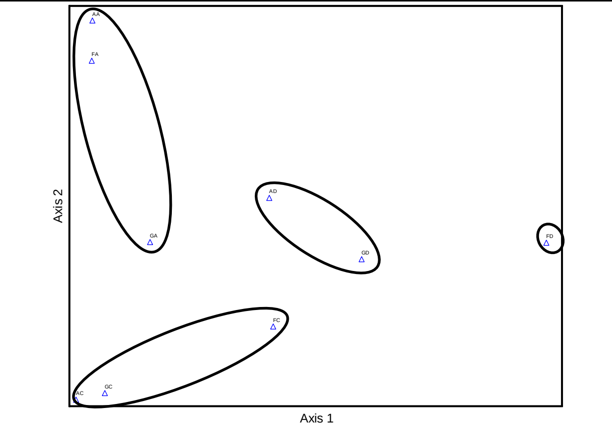

Fig. 5. A graph resulted from Detrended Correspondence Analysis (DCA or DECORANA) for the ordination of the study area site

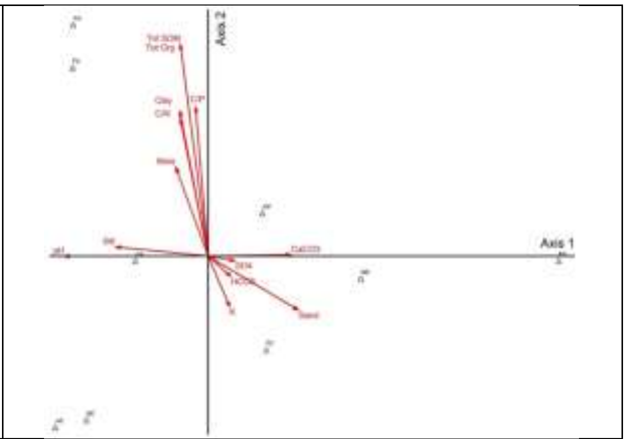

Fig. 6. The effect of soil physical and chemical parameters on the nine sites of the study area

The variation in ecoregions in Egypt and in land use practices has been proven to affect ground fauna density and, in consequence, species diversity and biological functional groups.

Changing the use of land will has either negative or positive impact on the soil structure, which is the shelter of many groups of arthropods. The impact of land use changes can lead to a favorable conditions for certain ecosystem services or to the degradation and even loss of soil (Defra, 2009). TWINSPAN analysis and Detrended Correspondence Analysis (DCA) have differentiated among the sites of the same habitat with each other. The classification process proceeded in 3 levels. The first level separated the site (4) community than the other 9 sites. This site is Fanara desert which is characterized by a significant higher abundance of ground invertebrate fauna. It was also the lowest site in human pressure, land use and habitat alteration. The second level of division have separated the coastal sites in one group from the other group which included agricultural and desert sites. The result of this separation illustrates that natural ecosystems represented by the desert habitats are similar to each other and more similar to the agricultural sites than the urbanized coastal ones. Earlier studies supported this conclusion (e.g., Ghabbour and Mikhail 1993a, 1993b and Hanna et al, 2012). The third level of division resulted in separating the remaining desert sites from the agricultural sites. According to Detrended Correspondence Analysis, Abu Sultan and Fanara agriculture (sites 2, 5) are more similar to each other in the view of ground fauna community. However, Geneifa agriculture (site 8) is less similar to them and far from them. It is not strange result because Abo Sultan and Fanara agriculture are typical cultivated lands, while Geneifa agriculture is a newly reclaimed land. On the other hand, the communities of Abu Sultan and Geneifa coastal sites (sites 3, 9) are more similar and closer to each other than Fanara coastal site (site 6), which is less effected by urbanization. This is also normal because Abu Sultan and Geneifa coastal sites are urbanized sites, but Fanara coastal site is a military place with less urbanization impact. Canonical Correspondence Analysis (CCA) showed that the most effective soil properties that affect the differentiation of the sites are those associated with the agricultural practices, especially the soil organic matter (SOM) and the total organic matter. They were greatly increased in the agricultural land, in particular in Abu Sultan and Fanara. As a consequence, the factors of SOM total organic matter are accompanied by related factors such as clay percentage, moisture, the ratio of Carbon/Nitrogen and the ratio of

Carbon/Phosphorus. Soil organic matter (SOM) has a great effect on soils. It increases the capacity of soils to bind chemicals, improves soil structure and water infiltration and retention, buffers the releases of pollutants, regulates the supply of nutrients and makes the soil more resistant to drought and erosion (Defra, 2009). Soil structure was one of the most important factors. Geniefa agricultural site is the sandiest agricultural one, desert sites are affected by the sandy texture, as well as coastal sites. Coastal sites are characterized by the effect of decreased levels of potassium, however the desert sites are affected by the higher levels of calcium carbonate (CaCO3). pH increases in two of the agricultural sites (Abu Sultan and Fanara), and also the coastal sites (especially those in Abu Sultan and Geneifa), exceeding the edge of 8. Plant growth and most soil processes, including nutrient availability and biotic activities, are favored by a soil pH ranging from 5.5 to 8 (Bolland et al, 2004). Over or below these range, soil begins to be unhealthy. These results indicate that each type of habitat has its own soil composition with different factors affecting them. This difference has been resulted in the variation of ground fauna abundance with the greatest values in natural desert habitats and diminished values in the other impacted sites, especially agricultural habitats.

Conclusion

According to the present study, Suez Canal region is rich in ground invertebrate fauna that may include undiscovered species. Data available about ground invertebrates in Suez Canal region is still poor. This area is also under the pressure of the continuous development and increased human activities. Urbanization and agricultural practices showed an adverse effects on ground fauna abundance in the study area. Therefore, more ecological studies concerning ground invertebrate fauna and their response to habitat alteration in Suez Canal region are required.

EFFECT OF HIVE BUILDING MATERIAL ON BEE COLONIES

Mohamed Ali Ibrahim AL-RAJHI

Agriculture Engineering Research Institute, AEnRI, ARC. El-Dokki - Egypt.
Corresponding author: moh.elrajhi@yahoo.com

Abstract

This study was carried out in a private apiary at Meet Salseel, Eldaqahliyah Governorate, Egypt for four months to compare foam, clay, cement and white brick with common material (wood), in the construction of *Langstroth* beehive model in a completely randomized design. The evaluation also included three thicknesses of hive sides and three sizes of hives. There were primary measurements on the building materials such as: density, thermal conductivity, water absorption, and rate of water loss. The secondary measurements including: inside hive temperature, bee colony strength (number of occupied frames), productivity (net colony weight, kg.), and the production cost. Results indicated that the mean density of foam, clay, cement and white brick samples were about 49, 2650, 952, and 811 kg/m^3, respectively, while it were 528 kg/m^3 for wooden hives. The mean values of thermal conductivity were 0.93, 0.33, 0.28 and 0.01 Wm^{-1}°C for clay, cement, white brick, and foam samples, respectively, while it were 0.18 Wm^{-1}°C for wooden hives. The cement, white brick and wood samples absorbed 24, 18, and 14 % of water, while the foam simple didn't absorb any water. Cement and white brick samples absorbed more water and lost water faster than wooden one. The maximum inside hive temperature was recorded in foam hive, while the minimum was recorded in white brick hive. The mean number of occupied frames were increased 20.45 and 13.64 % than it in wooden hives for foam and clay hives, respectively, but it were decreased 11.36 and 15.91 % when using cement and white brick hives, respectively. The mean colony net weight, kg were increased about 24.85 and 10.82 % than it in wooden hives for foam and clay hives, respectively, but it were decreased about 11.7 and 7.41 % when using cement and white brick hives, respectively. There was an increasing in mean internal hive temperatures, number of workers/ 5 min, number of occupied frames and colony net weight by decreasing hive size and increasing side thickness. Foam, clay, cement and white brick cost requirements were 80, 73.3, 40 and 63.3 % cheaper than the wooden beehive (150 L. E. without the price of the nest). In general, the foam, clay, cement and white brick hives can be easily constructed with a low cost and with similar characteristics as traditional wooden hives.

Keywords: *Hive building materials, Thermal conductivity, Temperature, Colonies strength and productivity.*

Introduction

Normally honeybees build their nest in different places like mountains, hollow trees, ground holes and others, trying to protect themselves from wind, rain and enemies. Honeybees are known to control their hive environment to survive drastic changes in the field environment (Jones and Oldroyd, 2007). Bees consume honey to rise inside hive temperature and worker bees contribute to the regulation of brood nest temperature by producing heat while sitting motionless on the caps of brood cells (Marco Kleinhenz, et al., 2003). Several investigators as (Jevtic, et al. 2009), has proved positive correlation between stored pollen, brood production and honey yield.

The wooden Langstroth beehives offers acceptable conditions, allowing their dispersion worldwide (Wiese, 1974; Dadant and Sons, 1975). But, the Langstroth wooden hive cost is high at the beginning of the honeybee project and didn't encourage the production, especially for small beekeepers at the developed countries. Also the expected life of wooden hives is short and it can be burned. (Hobson, 1983) suggested the ferrocement hive that is more resistant and cheaper than the wooden hive. (Soares and Banwart, 1989), used the Fibercol hive that made of fiberglass despite of its high cost. (Neves, 2002), verified that the brood nest temperature were similar in a cement vermiculite mortar and wooden hives. (Padilha, et al. 2001), obtained that the thermal conductivity of 0.16 to 0.44 Wm-1˚C in cement-vermiculite mortar (CVM) boards. According to (Stangenhaus, and Paredes 1992), the thermal conductivity of concrete is 1.5 Wm-1˚C and the mortar cement is 1.15 Wm-1˚C. Also, it found out that clay hives are easily available and very cheap compared to wooden hives and also more environmentally friendly (F.A.O., 1990).There aren't any researches about the effect of hive building materials on bee colonies under Egypt conditions. So, this research was carried out for testing the hypothesis that the new hive build materials such as: clay, with white brick and foam shows similar results to the wooden hive.

Material and Methods

Langstroth beehives is the most widely used hive in the world (Ojeleye, 1999). To conduct the experimental work, a new *Langstroth* bee hives were constructed from a local and a valuable cheap materials such as: foam, clay, cement and white brick as illustrate in Fig. (1) and compared with common material (wood). Honeybees (hybrid Carniolan, *Apis mellifera carnica carniolan*) are a single honeybee species adopted by the farmers in Egypt. The honeybees that had been established 8 months prior to the beginning of the experiment were placed on a sunny site in the bee yard, with their entrances far from the common wind direction and rain. Bees were about equal in the strength, food stores (Honey and pollen), queen's age (about 8 months old) and number of combs covered with bees from both sides (5 combs). Colonies were fed with sugar: water solution at 2: 1 percentage during the duration of the study. *Nosema apis and Varroa* destructor were monitored every 12 days throughout the study period, and treated whenever necessary. A total of 45 *Langstroth* enclosure bee hives were constructed as following: foam was cut to boards with a suitable dimensions. The foam boards were joined together using adhesive material. Clay beehives were made by using clay grains (from 4 to 5 mm) and water. To prepare the mixture, some water was added little by little, until the fingers marked the mixture. The mortar was shaped around a wooden mold. The upper edge of the two longitudinal sides were formed to suit the dimensions of *Langstroth* frames. The clay hives were left to dry in a shaded place for two days. The wooden beehives were obtained from a local workshop. Cement beehives were built by preparing molds. These molds were easily made, but should followed the dimensions of *Langstroth* model in its width. Before receiving the cement, the molds were previously moistened and coated with oil to facilitate the removal of boards. The cement was gradually filling and compacted in the molds and left to dry for two days without sprinkling water and in the next three days it was sprinkled water twice a day. On the ninth day, it were carefully removed. White brick beehives were made by cutting a valuable and cheap kind of white brick. The boards were joined together by cement, as shown in fig. (1). The slides have to be polished for a better finishing. The *Hoffman* Bee frames were made of wood. There was a removable top on all of them. There was a piece of sackcloth located under the cover to prevent any foreign insect to inter the hive and absorb vapor from the evaporation process. These hives were painted blue as the wooden ones. Beehives standing about 0.5 m above the ground on individual stands. The hives were opened every 12 days to verify possible damages due to the environment and to manage them. The distances between each beehive was 2 meters.

Fig. (1): Different types of beehives

Measurements including: five types of hive building materials (clay, white brick, foam, cement and wood), three thicknesses of beehive sides (1, 2, and 3 cm) and three hive sizes (0.057, 0.086 and 0.114 m^3) were studied. The present study carried out from 1 December until 30 March. To determine thermal conductivity: three parts of each of foam, clay, wood, cement and white brick were cut and taken as samples. The samples were weighted with electronic balance, with an accuracy of 0.01 grams and the mean mass was obtained. The volumes of white brick, foam, cement and wood were estimated by putting the weighted sample in a measuring flask (250 ml) filled to its a half with water and estimate the variance of water volume. The mean volume of clay samples was estimated by the same method, but after coating with fused beeswax. According to (Rodrigues, 1998) the following equation used to determine thermal conductivity

$$k = 0.0003545\,\rho - 0.007146,\ \mathrm{Wm\text{-}1°C} \rightarrow \quad (1)$$

Where: k is thermal conductivity and ρ is the density of samples, which was determined by the following equation,

$$\rho = \frac{m}{v} \quad , kg/m^3 \qquad \rightarrow (2)$$

Where: m is the mass of broad material in kg and v is the volume of it in m^3.

The mass of samples were determined before and after soaking them in water for 30 minutes, the variation between mass indicated water absorption by each material. The simples were dried in an oven at 30˚C. The test began at 9:30 a.m. and the mass measurements were taken at 10:00 a.m., 11.00 a.m., 01:00 p.m., 05:00 p.m. and 08:00 a.m. The mean masses for each tested material were obtained and the results were applied by the following equation (Lorenzon, *et al* 2004),

$$W.L.R. = \frac{S.M._{sat.}}{S.M._{dry}} x100 \qquad \rightarrow (3)$$

Where: W. L. R.: water loss, %.
$S.M._{sat}$: saturated sample mass in gram.
$S.M._{dry}$: dry sample mass at a given time in minutes.

A digital thermometer with an accuracy of 0.1 ˚C was used to determine internal hive temperatures and in the bee yard. Air temperature outside the hives was taken by a thermometer placed in in a shaded place in the apiary. The number of combs covered with bees from both sides was investigated every 12 days throughout the winter season for adding empty new combs. Bees or adult population was estimated at the rate of 2000 adult bees which can cover a comb from both sides (Hauser and Lensky, 1994). This investigation was carried out every 12 days throughout the winter season of 12 December, 24 December, 5 January, 17 January, 29 January, 10 February, 22 February, 6 March, 18 March and 30 March. After assembling all types of boxes the empty weight was determined by an electronic balance. The balance had a maximum capacity of 100 kg with an accuracy of ± 30 gram as described by (Meikle et al., 2006). The nearest colonies net weights were determined by the following equation every 12 days.

Colony net weight= whole hive weight – empty box weight, kg. $\rightarrow (4)$

The cost for the model *Langstroth* clay, white brick, foam and cement beehive was estimated and compared with the wooden one.

Results and Discussion

The densities of foam, clay, cement and white brick samples were about 49, 2650, 952 and 811 kg/m^3, respectively, while it were 528 kg/m^3 for wooden hives. The lowest density was obtained with foam material and the highest with clay material. The thermal conductivity of samples were about 0.01, 0.93, 0.33 and 0.28 Wm^{-1}°C for foam, clay, cement and white brick samples, respectively, while it were 0.18 Wm^{-1}°C for wooden hives. The lowest thermal conductivity was obtained with foam material and the highest with clay material. In general, the thermal conductivity was decreased by decreasing the density of materials.

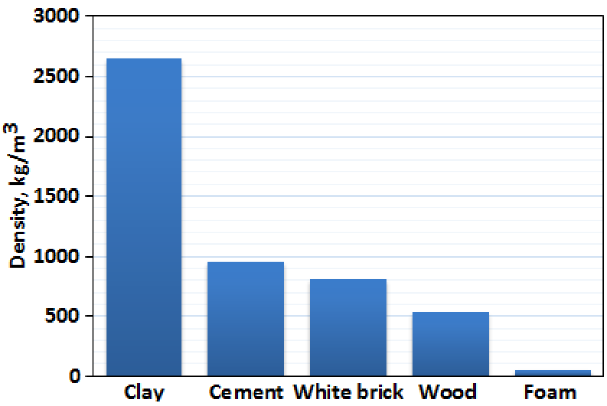

Fig. (2):The density of the used materials

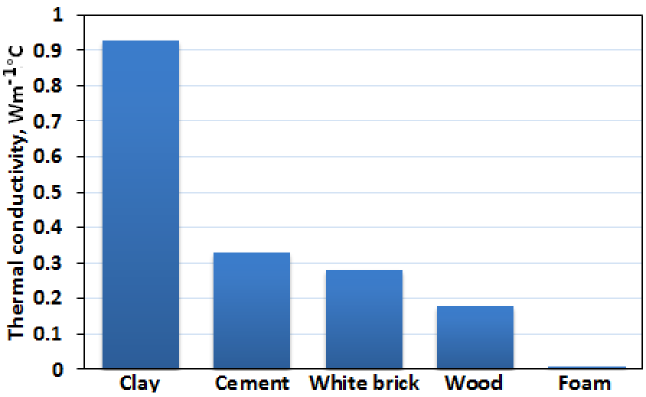

Fig. (3):The thermal conductivity of the used materials

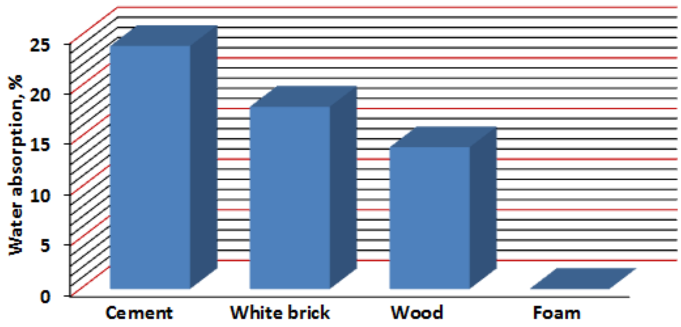
The wood, cement and white brick, samples absorbed 14, 24, and 18 % of water, while the foam simple didn't absorb any water. The cement and white brick samples showed greater loss than wooden sample during the most of the drying time. At the end of the drying process the wooden samples lost much water because the cement and white brick samples were already dried. Generally, cement and white brick samples absorbed more water and lost it faster than wooden one.



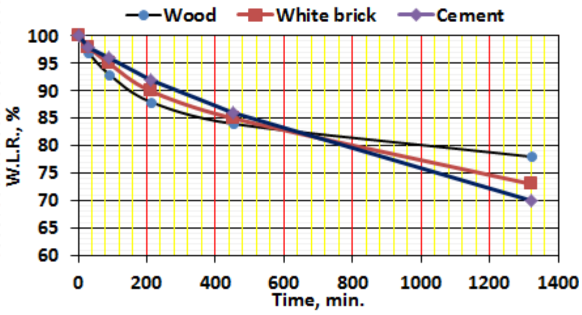


Fig. (4): The water absorption, % of the used materials Fig. (5): Water loss from white brick and wooden simples

Factors affecting inside hive temperature, °C: The main inside hive temperature was increased 52.45% than the outside air temperature, because honeybee colonies rise the inside hive temperature to regulate the brood nest temperature.

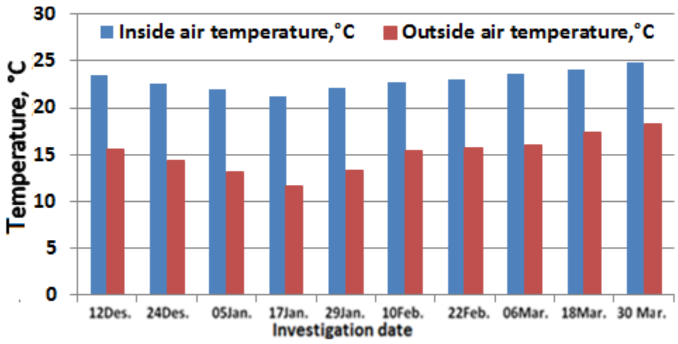

Fig. (6): The inside and outside air temperature, °C during the experiment period

The mean inside hive temperatures were increased 8.24 and 2.91 % than it in wooden hives for foam and clay hives, respectively, but it were decreased 4.34 and 8.29 % when using cement and white brick hives, respectively. There was a little difference in inside hive temperature, °C with reference to the type of material, because honeybee colonies regulated the brood nest temperature all of foam, clay, wood, cement and white brick hives. This result agrees with (Myerscough, 1993). The mean inside hive temperatures were increased from 21.79 to 24.04 °C when increasing side thickness from 1 to 3 cm, because the rate of heat flux through the hive sides decrease by increasing the sides thicknesses. The mean inside hive temperatures were increased from 21.23 to 24.78 °C when decreasing hive size from 0.114 to 0.057 m^3. This due to the small internal environment needed to regulate by the bee worker.

Factors affecting number of occupied frames: The maximum mean number of occupied frames was 8 for foam and clay beehive at the end of March. The minimum number of occupied frames was 2 frames in the middle of January for wood, cement and white brick beehives. The main number of occupied frames for foam and clay were increased 20.45 and 13.64 % than it in wooden hive and decreased 11.36 and 15.91% for cement and white brick, respectively. This is due the higher internal temperature, which improve the colony performance and decrease mortality of worker bees. The mean number of occupied frames were increased from 4 to 5 frames. when increasing side thickness from 1 to 3 cm, due to the improve of the inside hive temperature by increasing the sides thicknesses. The mean number of occupied frames were increased from 4 to 5 frames when decreasing hive size from 0.114 to 0.057 m^3. This due to the improve of inside hive temperature and consequently, of the colony performance by decreasing the hive size. Factors affecting colony weight, kg: The mean net colony weight were increased 24.85 and 10.82 % than it in wooden hives for foam and clay hives, respectively, but it were decreased 10.48 and 17.89 when using cement and white brick hives, respectively. This is due the improvement of colony performance and productivity. The mean net colony were increased from 5.40 to 6.90 kg when increasing side thickness from 1 to 3 cm, due to the improve of the inside hive temperature by increasing the sides thicknesses. The mean net colony weight, kg were increased from 5.43 to 6.75 kg when decreasing hive size from 0.114 to 0.057 m^3. This due to the small internal environment needed to regulate by the bee worker.

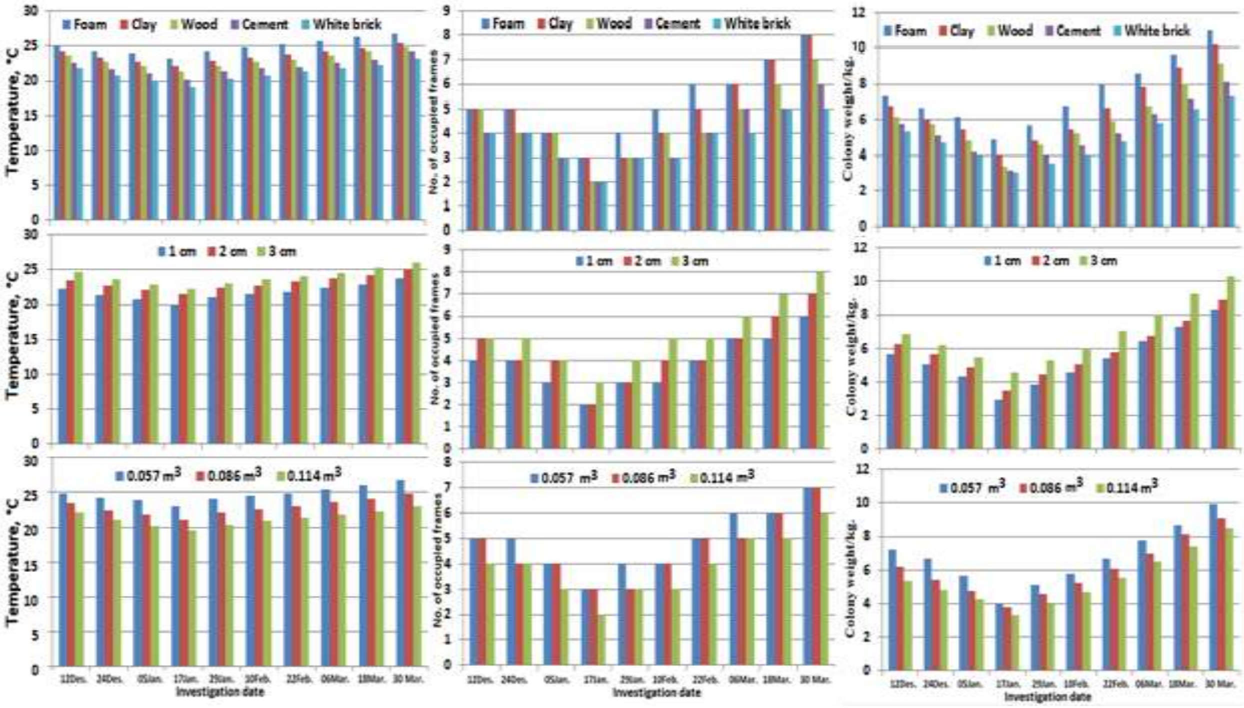

Fig. (6): Factors affecting hive temperature, number of occupied frames and colony weight

It was noticed that the main inside hive temperature, number of occupied frames, and net colony weight, kg increased; with hive building materials, hive sides thicknesses and hive sizes, according to the following descending order (foam > clay > wood > cement > white brick); (3 cm > 2 cm > 1 cm) and (0.057 m^3 > 0.086 m^3 > 0.114 m^3), respectively. In general, the main inside hive temperature, number of occupied frames, and net colony weight, kg were decreased for each type of material all levels of hive thicknesses and sizes from, the first day of the experiment (12 December, 2014) up to the nearly middle of January (17 January, 2014) and started to increase from the end of January (29 January, 2015) up to the end of the experiment (30 March, 2015). This is due the effect of changes in ambient temperature during the study. Factors of external ambient conditions are very important to the productivity of honeybees (Cetin, 2004). The main theory to explain why brood production reduces during cold periods is that workers spend more energy in heating the colony than with tasks related to brood production (Engels et al., 1995). Also, ambient temperature has a great effect on foraging activity (Al-Qarni 2006 and Blazyte-Cereskiene *et al.* 2010). In regards to inside hive temperature, number of occupied frames, and net colony weight, kg, there was no significant difference between hive material types, hive side thicknesses and hive sizes (P> 0.05). During management clay model was the most breakable especially after rainy days.

The wooden and foam model could be burned during sterilization by scorching them with a blow lamp compared with clay, cement and white brick model. Wooden and clay hives are more attractive to wax moth (*Galleria mellonella and Achroia grisella*). Foam hives are more attractive to rodents and more susceptible to environmental conditions. Cost estimation: The following table represents a comparison between a complete *Langstroth* beehive made of wood and foam, clay, cement and white brick hives with a thickness of 2 cm and a size of 0.57 m^3.

Table (1): Production cost of foam, clay, wood, cement and white brick hives for one super.

Specification	Price				
	Foam	Clay	Wood	Cement	White brick
- Super	15	20	85	65	45
- Nest from 5 frames	350	350	350	350	350
- Cover and bottom board	15	20	65	25	10
- Total hive cost	380 L.E.	390 L.E.	500 L.E.	440 L.E.	405 L.E.
- Total hive cost without the price of the nest	30 L.E.	40 L.E.	150 L.E.	90 L.E.	55 L.E.

The construction of the new hives (foam, clay cement and white brick) after subtracting the price of the nest were 80, 73.3, 40 and 63.3 % reduction in cost relative to the price of wooden hive, that is due to the higher costs of wood Compering with foam, clay, cement and white brick, respectively.

Conclusions

Foam is a light-weight, cheap and a valuable material. Cement and white brick materials could be resistant to burnings. The white brick hives needed a certain care while cutting of boards and assembly of it. The disadvantages of clay consist in the more occurrence of fractures in some parts or carelessness during assembly. Some parts like cover and bottom could be cracked by rains or broken during handling, that require more care. Also clay and foam hives have presented gaps, damaging and they were more susceptible to environmental conditions. The expected life of foam hives was about one season, due to the effect of environmental conditions and rodents especially rats. The clay, cement and white brick hives are almost twice as heavy as the mass of wooed one, but it is lighter than the hive constructed by (Lengler *et al*., 2003) with a mass of 43.55 kg. Even if the white brick presents higher water loss, the internal moisture stability in the colony should be a critical point. wooden hives were more suitable for rearing of honeybee than other hive types, but the absorption of water increase during the periods of rain, so we should protect the outsides of it with a moisture resistant product like foam (figure 1) and the upper cover with a sheet of galvanized steel or put the hives under a shelter during winter season. It was observed that during the studied months, the maximum values of inside hive temperature, flight activity, number of occupied frames and net colony weight were achieved by using foam and clay materials, but they have a less expected life and foam can't be sterilized from almost all microorganisms like fungi, bacteria, viruses, and spores by flume without burning hazard. Foam, clay, cement and white brick *Langstroth* beehive models were cheaper than the wooden beehive cost. In general, foam, clay, cement and white brick hives can be used by small or poor beekeeping in the cities that imports wood by forging currency like Egypt. On the other hand clay, cement and white brick could provide evaporative cooling by honeybees in the dry period, thus favoring honey maturation and temperature control. Thus, new hives could be performed better in dry climates than humid.

RECOLONIZATION OF CULTURAL LANDSCAPES BY LARGE PREDATORS: CHALLENGES AND RECOMMENDATIONS USING GREY WOLF (*CANIS LUPUS*) AS AN EXAMPLE

Sven HERZOG

Dresden University of Technology, Chair of Wildlife Ecology and Management, PiennerStrase 8 D-01737 Tharandt, Germany, herzog@forst.tu-dresden.de

Abstract

The present paper deals with the question as to how the re-colonization of Central Europe by large predators, i.e. Brown bear (*Ursus arctos*), Lynx (*Lynx lynx*) and especially Grey wolf (*Canis lupus*) has to be supported by active management efforts. It defines some important future needs of active management based on an analysis of the last decade of re-migration in Germany. Whereas Brown bear and Lynx are spontaneously re-migrating only sporadically, and for Lynx we find some more or less successful re-introduction projects, the actual situation of Grey wolf in Central Europe is characterized by a high rate of re-colonization, establishing local packs and reproducing successfully. In Germany, an exponential population increase (clearly at the actually still low level) is to be observed actually. As a consequence, conflicts between different stakeholders with respect to the wolf management are also increasing. Over the last 15 years the core business area of large predator management was to avoid or to reduce those conflicts. However, conflicts between different stakeholders are increasing, and management has failed to a large extent. It is shown that existing management plans e.g. by several German states are not sufficient to guarantee an adequate management of the species, minimizing the existing conflicts between different stakeholders. The existing management plans and protective legislation are to be exempted from bureaucratic restrictions and improved on a scientific basis. It is further shown that participatory processes involving all relevant stakeholders are required in development of management plan as well as in conservation legislation. In addition, there is a lack of fundamental knowledge concerning the development of wolf-man interactions in densely settled and urban environments. So, the actual situation requires also intensive research on questions as predator-prey-relationships, dynamics of re-colonization by the wolf, disease management, hybridization, development of repellent techniques and, last but not the least, research on the question as to how we can maintain timidity against man.

Key words: *large predators, Canis lupus, re-colonization, conflicts, management*

Introduction

Large Predators are actually re-colonizing huge parts of Central Europe. In addition, they are subject of several reintroduction programs.

The story of extinction of large predators, especially wolf and brown bear is by far a story of socio-cultural and socio-economic structures in this region. If we recall that until the 19th century Central Europe was characterized to be an agricultural region, dominated by small family farms of few hectares. The property of a cow or some sheep or goats symbolized significant economic wealth. Thus, the loss of a sheep or even a cow by large predators did mean the loss of the livelihood of the farmer and his family. The extinction of large predators, in that context, was consequent from the former point of view.

However, in several parts of Europe, the extinction was not complete, so wolf, lynx or even brown bear survived in some regions (e.g. Italy, France, Spain or the Balkans) as small, isolated populations. In other parts of Europe such as Germany, the “Benelux” region or Switzerland, the extirpation was performed more consequently.
Beside this situation, in major parts of the Palaearctic Grey wolf is regularly to be killed not only based on sustainable hunting, but also by so called „population control“ or “predator control“ measures, often being an euphemism for efforts to exterminate the species locally. North America, Eastern Europe or Central Asia provide examples. In the European Union, the management of large predators ranges from a sustainable utilization by regular, controlled hunting (as e.g. for the wolf in Estonia) to a more or less uncritical total protection (as e.g. in Germany or Austria, see also Guber and Herzog 2017).

Results and discussion

Goals

From a wildlife management point of view, the goal should be to establish viable, adaptable populations in suitable habitats, which is accepted by the local land users and by the local human population (Herzog, 2016).
Whereas Brown bear and Lynx have particular habitat requirements, Grey wolf is a generalist, able to live nearly everywhere: absence of persecution and presence of food are the only preconditions. This means that Grey wolf will be the most important target species of large predator management in Central Europe.
Thus, in the present paper, the challenges and recommendations for a large predator management in Central Europe will be compiled using the Grey wolf as an example.

Population dynamics

There was an intensive discussion in the past, if anthropogenic mortality in large mammal species is tending to be either additive or compensatory (see e.g. Ellenberg 1978, Lebreton 2005). Today we recognize that this question has to be differentiated concerning species as well as concerning the actual status of a (sub)population. Compensatory mechanisms might be especially a higher reproduction rate, and/or a reduction of other anthropogenic and/or natural factors influencing mortality.
Many studies on Grey wolf (see e.g. Jędrzejewska *et al*., 1996; Mörner *et al*. 2005, Lovari *et al*. 2007, Brainerd *et al*. 2008, Creel and Rotellea 2010, Liberg *et a*l. 2011, Sparkman *et al*. 2011) are dealing with anthropogenic mortality. However, the problem is that they look at “anthropogenic mortality” *in toto.* For management purposes, it should be clear that the factor “antropogenic mortality” has to be analyzed in more detail. So, for example, it should be assumed that the consequences of a controlled, sustainable utilization are different from those of “predator control” measures or even poaching. In addition, there is no doubt that the effects of those measures are different for a very small, just founded (sub)population of only one or few wolf packs, compared to a well-established, constantly growing subpopulation.
Thus, as a first result, we have to state that anthropogenic mortality hast to be considered more differentiated as previous papers do. Generally, we can subdivide the topic into different categories (see Table 1).

For Germany, Grey wolf population dynamics during re-colonization has been studied by Herzog (2014). Although a precise data base is lacking, road kills are assumed to be the most important mortality factor.

However, the German subpopulation, regarded as the westernmost part of the huge Baltic-Eastern European wolf population, actually shows an unbowed exponential growth. This would mean that even road kills either are of compensatory character or at the most resulted in a slight shift of the growth function.

Table 1. Categories of anthropogenic mortality in large predators (following Herzog, 2014)

Category	**Examples**
Predator control	Intentional, more or less controlled reduction of population size. Actually not practiced in Central Europe
Sustainable hunting	Controlled, planned wolf hunting for utilization e.g. in Baltic states
Illegal hunting, not sustainable hunting, poaching	Killings from different reasons without (legal) control
Accidents (unintentional)	Collisions along roads or railroad tracks, strangulation in fences

As a consequence, it should be clear that differentiation only between anthropogenic and natural mortality is not sufficient. Anthropogenic mortality should be differentiated into

- compensatory mortality (balanced by other natural or anthropogenic mortality factors)
- additive mortality (with care and attention of sustainability criteria)
- additive mortality (without care and attention of sustainability criteria)

Thus, it should be easily possible to differentiate intended from unintended effects of management measures or other influences. This is an indispensable basis for serious management recommendations.

Regardless of the presumably low impact of wolf road-kills on population dynamics, management in the special situation of a densely inhabited landscape with huge urban region and a close-meshed network of roads and railroad tracks calls for particular solutions (see also Polster et al. 2014, Polster and Herzog 2014).

Actual major problems

As the actual discussion about re-colonization of Grey wolf shows, there are a lot of unsolved or even unknown conflicts existing between different stakeholders. The fact that these conflicts persist since more than 15 years points to some serious failings of wolf management. The present chapter gives an overview on some actual problems and highlights some potential ways to solve these problems.

Predation of wildlife

In Central Europe, wolf prefers Roe deer (*Capreolus capreolus*) and Red deer (*Cervus elaphus*) as prey species, whereas Wild boar (*Sus scrofa*) is subordinated (Wagner *et al*. 2012). We have actually no reliable scientific data, but it seems that local subpopulations of these species are slightly influenced by lowering their abundance. However, a serious threat

could not be observed. Reports of significant reductions of population size concern fallow deer (*Cervus dama*), and, especially, mouflon (*Ovis ammon musimon*). The latter species will be supposedly exstirpated by large predators such as wolf or even lynx. This is a very particular conflict of different species conservation goals. This wild sheep subspecies is highly endangered and close to extinction in itsnatural habitats in Corsica and Sardinia. The Central European populations represent the majority of the gene pool of he subspecies and might be regarded as a very effective *ex-situ* gene conservation measure (see e.g. Piegert and Uloth 2000, Herzog and Schröpfer 2016).
As long as we have no well established, active wolf management in many European countries, we have to bridge this period with conservation measures designed especially for the mouflon.
Another problem, especially in Germany, is that the question of an area-wide occurrence of prey species in adequate densities is completely disregarded. Due to forest economic and agricultural concerns, especially red deer is not tolerated in huge parts of the potential wolf areas. This shows once more the weak performance of actual wolf management.

Predation of livestock

Predation of livestock is actually the most critical area of conflicts.

Actually, the focal point is the predation of small livestock such as sheep, goats, alpacas or farmed fallow deer. The economic impact of this phenomenon is from a viewpoint of nature conservation authorities, being responsible for the wolf management, quite low. Thus, the idea of compensation payments as well as some financial support of protective and repellent measures, is favored by administration and politics. However, an increasing period of total protection of wolves will certainly lead to a significant loss of timidity. This will result in a decreasing efficiacy of protective measures and, as a consequence, an increased rate of livestock predation.

Additionally, more reports of predation of larger livestock such as cattle or horses show up. Apart from economical or non-material value of these animals, the risk of traffic collisions with animals brought into panic by wolf attacks will increase. This bears the risk of immense economic impact and body-injuries indirectly resulting from wolf attacks on livestock in the future.

Also from a nature conservation viewpoint, we will get roped into serious conflicts. Grazing with livestock is an important and relatively cost efficient method of keeping landscapes open and prohibit special protected plant societies from succession. If livestock farming is becoming uneconomical by presence of the wolf, these conservation concepts in open landscape protection will fail at a long-term scale.

Hybridization

The question of hybridization between wolf and domestic as well as between wolf and jackal (*Canis aureus*) in Central Europe is still open. Dependent on the role of hybridization in the past, especially in the abruzzo-alpine wolf population, beeing over centuries in more or less narrow contact to domestic dogs, we have actually no clear evidence if molecular markers are discriminative or not (see *e.g.* Tsuda *et al*. 1997, Randi *et al*. 2014). As recent studies show, admixtures of canid taxa, previously regarded as different species, are regularly occurring (vonHoldt *et al*. 2016).

The central problem of hybrids between domestic dog and wolf is the problem of maintainance of timidity (Herzog 2016). Decades of dog breeding contributed to a reduced timidity against man. Hybridization is assumed to increase the risk of wolf attacks against man and thus it bears an immense risk of increasing conflicts.
In this context, we have also to ask, if the renouncement of re-introduction of single wolf individuals will be helpful to avoid hybridization. Maybe, active release of a male or female might help to reduce the risk of hybridization, if a single wolf is to be observed in a region over a longer period (see Herzog 2016).

Diseases

Out of the number of diseases wolf can suffer from, only a few are relevant for active wolf management.
Maybe not most important, but for avoidance of conflicts most relevant is rabies. We know that wolf was a major factor for transmission of this zoonosis to man in the past. The extinction of wolf in the 18th and 19th century made red fox (*Vulpes vulpes*) increasingly important in that context.
Actually, responsible authorities have no concept of prevention, especially no vaccination concept, neither for the wolf, nor (especially in Saxony with the highest wolf abundances in Western Europe) for the fox.
In addition, distemper, aujeszky´s disease and (with increasing abundances of wolf) scabies will maybe also play a major role in the future. However, these diseases will be not so controversial, but maybe they will be able to reduce abundance significantly.

Public relations

The actual public relations campaigns on wolf are focused on an urban population, and can be summarized (with a little simplification) that the big bad wolf is a nice and cosy animal that never has predated neither Little Red Riding Hood nor the grandmother.
The problem is: no one is still believing these stories, and the urban population yet has by trend a very positive image of wolf.
The real resentments against wolf come from highly professional groups of stakeholders, such as small livestock farmers, with real problems, that are not to be sugarcoated by some high-gloss flyers. These people need feasible solutions and a legislation incorporating their needs.

Conclusions

Actually, most Central European countries are tending to a total protection concept with no active influence on the population. What is called "wolf management" in Germany and Austria, is a kind of passive observation of the ongoing situation. This might be a proper approach in an early state of a re-colonization process. To avoid major risks for the future, this concept has to be replaced by a more sophisticated approach, defining clear goals and taking different measures of management into consideration.
Good examples of e.g. Slovakia or Baltic countries should be taken into consideration. A local differentiation and a combination of different management measures, as e.g. total protection, sustainable utilization, prevention of diseases, herd protection measures and a management concept, developed from a participatory process should be a solution.
The present paper might have been shown in short that an active wolf management is needed especially in Central Europe with the particular civilisatory situation. A passive "wait and see" strategy is bound to fail, and failure of wolf management would mean huge problems for the wolf as well as for man in the future. Thus, we should focus on a foresight strategy,

including a sophisticated concept of management measures, covering the whole spectrum of management methods in the near future to prevent conflicts are getting out of hand.

EVALUATION OF AN INDICATOR FOR THE RISK OF DIFFUSE PHOSPHORUS LOSSES IN NORTHEAST GERMANY

Uwe BUCZKO

Landscape Ecology and Site Evaluation, University of Rostock, Rostock, Germany
*Corresponding author: uwe.buczko@uni-rostock.de

Abstract

For the assessment and mitigation of diffuse Phosphorus (P) losses from agricultural fields into surface waters, knowledge of P contents in soils and P application rates are not sufficient, because diffuse P losses depend also on transport factors such as erosion, runoff and subsurface drainage. The “Phosphorus Index” (PI) is a risk assessment tool for diffuse P losses from agricultural fields which is based on a simple algebraic combination of source (soil test P, fertilizer, and manure additions) and transport factors (e.g., erosion, runoff, subsurface drainage, riparian buffer strips). The objectives of this study were to develop and evaluate a PI for NE Germany. This PI is based on the Pennsylvania and Danish P Indices but accounts in addition for wind erosion, soil leaching potential, and groundwater influence. A sensitivity analysis showed that soil test P, manure application and the riparian buffer factor have the largest impact on PI values. An application in two mesoscale catchments revealed different area-averaged PI values, which largely correspond to measured P losses by riverine flow at the catchment outflow. The results show that the proposed P index is a good indicator for P loss at the catchment scale. More detailed studies to evaluate the P Index at the field scale are currently underway.

Keywords: *agricultural nutrient management, non-point source pollution, phosphorus export, phosphorus index, water quality*

Introduction

Although P is an essential nutrient for plant growth, excessive amounts in surface waters are a major factor causing eutrophication. Whereas until recently, point sources of P (like sewage treatment and/or water purification plants) were the major source of P loading into surface waters, P loadings from diffuse sources, mainly agriculture, are a major focus of concern since the 1990’s (Behrendt *et al.*, 2003; Sharpley *et al.*, 2003; Delgado and Scalenghe, 2008; Nausch *et al.*, 2011). For effective control of P losses into surface waters, an assessment of the susceptibility for P loss at the field scale is necessary. Many studies (see Buczko and Kuchenbuch, 2007) have shown that P losses from fields into surface waters depend not only on soil P contents and fertilizer applications, but also to a large degree on transport factors such as erosion, surface runoff, and subsurface drainage. This knowledge is incorporated into simplified risk indicators for P export from agricultural fields which have been developed since the 1990’s (Lemunyon and Gilbert, 1993; Sharpley *et al.*, 2003; Buczko and Kuchenbuch, 2007). Such "Phosphorus Index" (PI) approaches account for different source and transport factors and the resulting PI values are a measure for the risk of P export from a single field. The PI approach is routinely applied in the USA (Sharpley *et al.*, 2003) and it has been adopted in several European countries, especially in Scandinavia (e.g., Heckrath *et al.*, 2008).

The PI is a simplistic and pragmatic approach, which largely neglects or simplifies several processes and factors at the small scale, which are possibly relevant for P losses. However, it has been shown that this approach is suitable for delineating fields with a high risk for P export within watersheds and of defining best management practices to mitigate P losses from those fields (Sharpley *et al.*, 2003). Thus, it seems useful to test or to adopt a similar approach also in countries in which risk of P loss is evaluated until now based on soil test P values mainly, as for instance in Germany.

In the Mecklenburg-Vorpommern (MV) state, diffuse (non-point-source) P losses are comparatively low for most regions. However, there are few hot spots with elevated P concentrations and large input of manure P, mostly near cattle feeding operations and dairy farms. Thus, our objective was to review the factors contributing to P loading from agricultural land into surface waters in NE Germany and to present an index for the assessment of the risk of diffuse P losses for this region. This PI will allow the more accurate adjustment of manure and fertilizer additions in "hot spot" regions at the field scale based on a relatively simple modelling approach which incorporates all important source and transport factors.

Material and Methods

Diffuse phosphorus losses from agricultural fields in NE Germany are characterized by a high proportion of wind erosion, widespread occurrence of tile drainage, many peat soils and large areas with shallow groundwater tables. Based on these factors and a review of existing P indices (Buczko and Kuchenbuch, 2007), a PI is proposed for the MV state in which source and transport factors are grouped into two major separate terms, which are multiplied to calculate the final PI value, "PI(MV)" (Fig. 1).

Source factors encompass soil test phosphorus (STP), mineral fertilizer and manure:

Plant-available soil P contents are assessed in Germany using the CAL or the double-lactate (DL) extraction method. The resulting STP values are divided into five nutrient content classes, A - E. For calculating the PI(MV), these STP classes are assigned the numerical values A = 10, B = 20, C = 30, D = 40, E = 50.

Phosphorus additions in form of organic or mineral fertilizer form a distinctly separate P pool besides soil P. The proportion of soluble P components in manure or fertilizer is usually higher compared to those in the soil (Kleinman *et al.*, 2005). A further distinction is made between organic and mineral fertilizer additions, because they exhibit differences in solubility, P content, availability to runoff and physical properties (Withers *et al.*, 2001; Kleinman *et al.*, 2002).

Manure availability accounts for the availability of P to be lost directly from the manure to runoff. This availability is not identical with crop availability of manure P. Values range from 1.0 for swine slurry to 0.2 for heat-dried or advanced-alkaline stabilized biosolids.

Transport factors: In general, water erosion is the main transport process for phosphorus loss from arable fields (Sharpley *et al.*, 2003). Since maps of potential risk of water erosion are available for the whole of MV, those risk ratings rather than estimated soil losses are used in the PI(MV). The risk ratings are categorized into 5 classes and based on the type and texture of the soil and morphological properties (slope steepness and length). In terms of the universal soil loss equation (USLE), the potential risk of soil erosion encompasses the soil erodibility factor ("K"), the slope length factor ("L") and the slope steepness factor ("S"). Calculation of erosion rates based on these risk ratings with the USLE or RUSLE is straightforward provided data on vegetation cover, management practices and rainfall erosivity are available. Similar as water erosion, wind erosion is assessed in the PI(MV) using erosion risk classes with ratings between 0 ("none") and 5 ("very high"). It has been shown in many field studies that riparian buffer strips can cause a marked reduction (up to 90 %) of phosphorus loads into receiving

waters (e.g., Dorioz *et al*., 2006). This reduction depends on buffer width (Hook, 2003; Kronvang *et al*., 2005), vegetation type and density (Schoonover *et al*., 2006), magnitude of erosion or flow rate (inversely related, Kronvang *et al*., 2005), time scale (Dorioz *et al*., 2006), and slope gradient (Hook, 2003).
In most studies, it was found that buffer widths had a greater effect on the reduction of P loads, compared with the other factors (Hook, 2003; Kronvang *et al*., 2005). Because of this, and since buffer widths are relatively easy to quantify, it is assumed in the PI(MV) that the effectiveness of riparian buffer strips is solely a function of their width, with the following classes for the buffer factor: < 2 m: 1.1; 2 – 6 m: 1; 6 – 20 m: 0.7; > 20 m: 0.5.
Besides riparian buffers, the connectivity between fields and receiving waters depends on the distance between field and stream (Buczko and Kuchenbuch, 2007). The "contributing distance" factor used in many recent P indices is thus a measure for the probability that a field within a specified distance to the stream contributes to P loss. In the PI(MV), a threshold value of 50 m was adopted from the Denmark and Norway P indices.
Transport through artificial tile drains can be an important factor of P loss from agricultural fields (Sims *et al*., 1998), small watersheds (Gelbrecht *et al*., 2005), and even at the scale of large catchments (Behrendt *et al*., 2003; Deumlich and Völker, 2004). The soil type has a pronounced influence on the propensity for subsurface P leaching. The especially high disposition for subsurface P leaching of organic soils with low contents of sesquioxides (Fe and Al oxides) has been known for a long time (Larsen *et al*., 1958; Cogger and Duxbury, 1984). More recently, high P leaching has been documented for sandy soils (Sims et al., 1998), but even more in well-structured, fine-textured soils with macropores (Djodjic *et al*., 2004). Based on several comparative studies of differently textured mineral and organic soils (Larsen *et al*., 1958; Djodjic *et al*., 2004) the following general order for the susceptibility of soils for vertical P leaching is incorporated in the PI(MV): organic soils > macroporous clay soils > sandy soils > loam soils.
Transport of P via groundwater can be important (e.g., Behrendt *et al*., 2003; Gelbrecht *et al*., 2005). P loss from surface soils into groundwater and concomitant lateral saturated flow is often inversely proportional to the depth of the groundwater table, i.e., shallow groundwater bodies favour P loss by groundwater flow (Stämpfli and Madramootoo, 2004). Further, shallow groundwater tables create reducing conditions in shallow soil depths which favour the P mobility in the soil (Rupp *et al*., 2004). When no data on groundwater (GW) depths are available, the GW-factor can be estimated from soil surveys.
The sensitivity of the PI model was evaluated using both absolute and relative sensitivity coefficients (Jesiek and Wolfe, 2005).
The PI(MV) was tested in two catchments: the Beke near Rostock, and the Zarow in the eastern part of MV. The Beke catchment is dominated by arable land use. A large proportion of the area exhibits high erosion risk (both by water and wind). In the Zarow catchment, the proprotion of forest land use is considerably higher. Erosion risk is lower than in the Beke catchment, whereas the proportion of organic soils and soils with shallow groundwater tables is markedly higher.

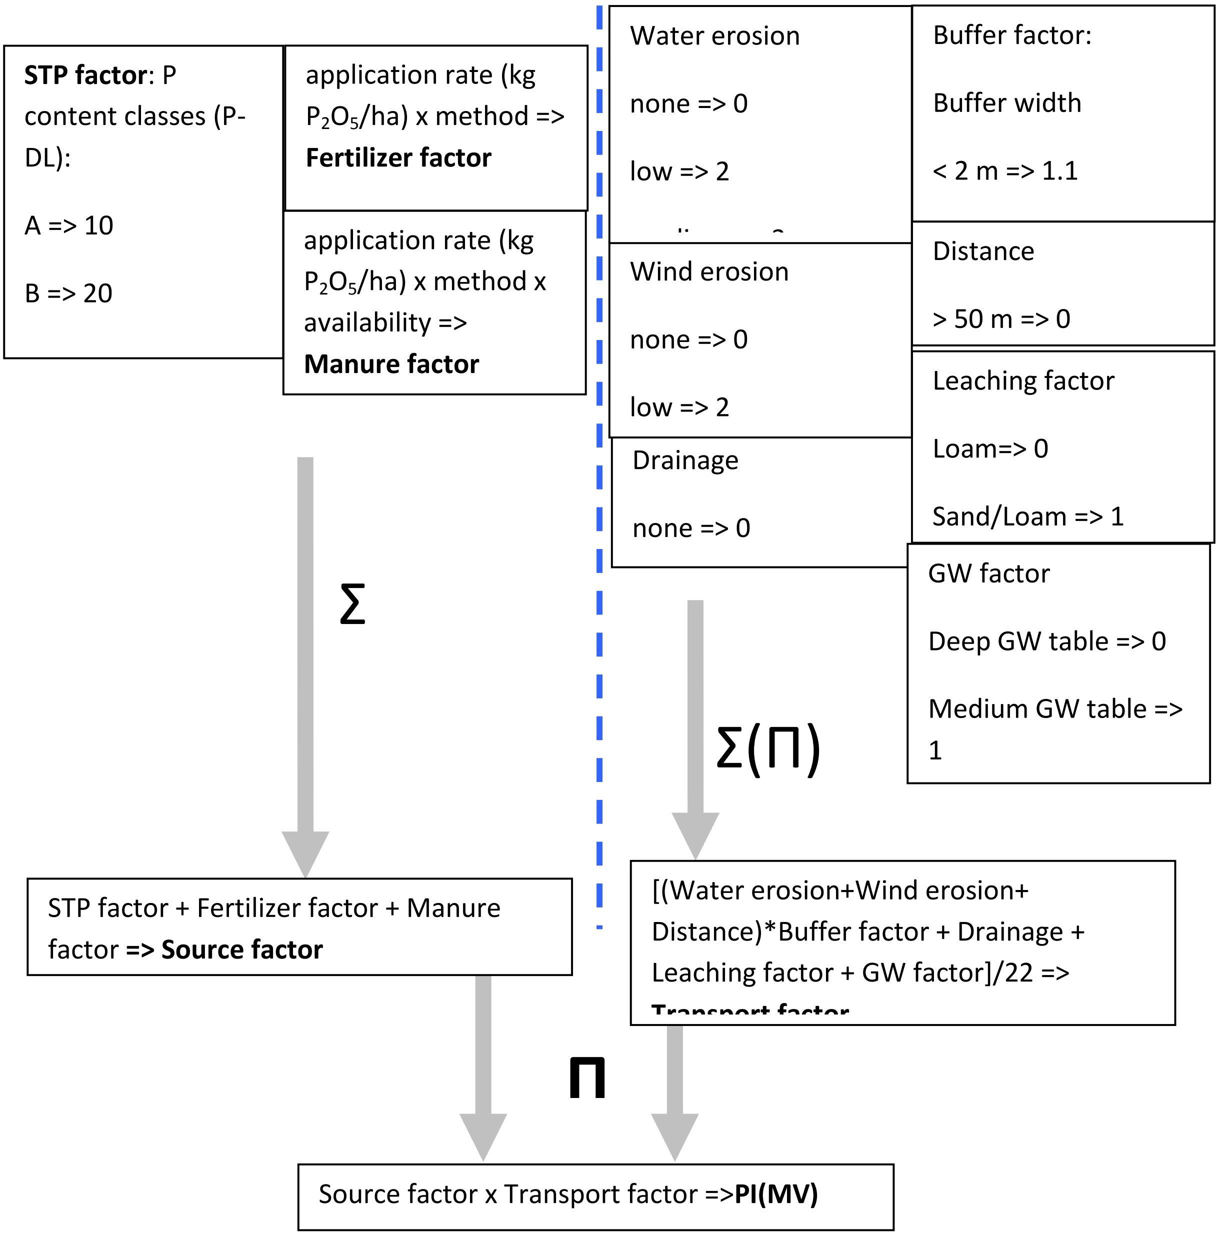

Figure 1. Structure and components of the Phosphorus Index (PI(MV)).

Results and Discussion

The sensitivity analysis revealed the following:

1. The STP has a large sensitivity in the proposed PI(MV). This is in line with experimental results which revealed a strong dependency of P loss from the P content of the soil (e.g., McDowell and Sharpley, 2001).
2. Also, manure application rate and method have a great impact on calculated PI values, which agrees well with experimental studies of P loss with high manure applications (e.g., Kleinman *et al*., 2002).
3. Among the transport factors, the buffer factor exhibits the highest relative sensitivity, similarly as reported by Brandt and Elliott (2005). This is supported by many field studies, which reported a huge influence of riparian buffer strips on P loadings from fields to surface waters.

4. The sensitivity of water (T1) and wind (T2) erosion seems relatively low, in view of the purported great impact of erosion on P loss in NE Germany (Behrendt *et al*., 2003; Deumlich and Völker, 2004), but it has to be taken into account that two separate erosion factors are considered here. The area-averaged PI values are 26.6 for the Beke and 11.2 for the Zarow catchment. The distribution of PI values calculated for single fields into separate classes (not shown here in detail) reveals for the Zarow catchment a bimodal distribution with most fields exhibiting PI values < 20, but also a large proportion of fields with PI values between 40 and 100. On the other hand, PI values for the Beke catchment show a unimodal distribution with the highest proportion in the range 20 – 40. The relatively low calculated PI values are overall in line with measured P concentrations in streamwater and total P loss at the catchment outflow for the period. In both catchments, overall P loss is relatively low, but slightly higher for the Beke than for the Zarow catchment. For comparison, Gelbrecht *et al*. (2005) reported for two 37.8 and 48.9 km² catchments in Brandenburg total P losses of 4 – 25 kg km^{-1} yr^{-1}. Higher TP losses than measured in the Beke and Zarow catchments were also reported by Kronvang *et al*. (2003) for several European catchments with areas < 100 km².
Overall, the mean PI values for the whole catchments largely reflect the P losses from both catchments, but more detailed studies and comparisons at smaller scales (sub-catchment or field-scale) are necessary to confirm this assertion. Moreover, the spatial distribution of fertilizer and manure input has to be refined based on data for separate fields.

Conclusions

The P index as a risk assessment tool for diffuse P loss from agricultural areas into surface waters presented here for NE Germany, especially for the federal state of Mecklenburg-Vorpommern, could possibly also applied in a similar form in other regions of Germany.
The novelty of this PI is the incorporation of wind erosion and a factor for the groundwater influence. A sensitivity analysis revealed that STP, manure input and riparian buffers have the greatest impact on PI values. A comparison of area-averaged PI values and measured P export for two 321 and 720 km² catchments revealed correlation, but evaluation on a smaller scale (sub-watershed and field-scale) is necessary. Such investigations are currently underway.

Abstract

Increasing the yield of energy crops is of key importance for Greece and other European counties in order to achieve the European Community's targets for substitution of imported fossil fuel with locally produced renewable energy. However, in order the cultivation of energy crops to be viable, high yields should be achieved at the lowest possible inputs. Reduced tillage and reduced levels of fertilization reduces crop production inputs. The present study investigates the effects of three soil tillage methods (conventional tillage, reduced tillage and no-tillage) along with three levels of fertilization on yields of six energy crops (pea and triticale intercropping, sunflower, rapeseed, sorghum, oat and vetch intercropping and soybean), cultivated in a rotation system in central Greece. Increasing levels of nitrogen fertilization led to increased rapeseed and sunflower seed yields. The yields of sorghum and soybeans were not affected by the applied fertilization rates. The yields of sorghum, and pea and triticale intercropping, were not affected by the soil tillage methods. The no-tillage method, although it resulted in the highest yield in the case of vetch and oat intercropping under high soil moisture conditions, it gave lower yields in the case of rapeseed, sunflower seed and soya seed. The reduced tillage resulted in yields similar to the yields obtained with the conventional treatment in the case of rapeseed and vetch-oat intercropping. However, it gave a higher yield in the case of sunflower seed, and only in the case of soybean seed, the yield was lower, compared to the conventional tillage. The results of this study indicate that reduced tillage (with a heavy cultivator) can lead to increased production of energy crops, whilst contributing to energy savings, compared to the conventional method (plowing).

Introduction

The European Community encourages the production of energy from renewable sources, aiming to achieve reductions in greenhouse gas emissions and to reduce its dependence on imported oil in the transport sector. The target for energy share from renewable sources in Greece in 2020 amounted to 18% of gross final energy consumption (Directive 2009/28/EC). It has also been adopted as a mandatory minimum target, which must be achieved by all Member States, 10% share of biofuels in petrol and diesel consumption for transport by 2020.
Up until now, there have been significant efforts in Greece for substitution of imported fossil fuels with locally produced renewable energy. The only feasible solution today for the production of liquid fuel seems to be the production of biomass (Gemtos *et al*., 2009). The crops that produce biomass for the production of biofuel are called energy crops. The cultivation of energy crops is therefore of strategic importance for the Greek agriculture as it can contribute both to energy production and liquid fuels, ensuring or even improving farm

income, and also to environmental protection. Among the energy crops that give high yields of biomass are sweet sorghum and sunflower (Vakakis, 2007; Gemtos *et al.*, 2009).
However, in order the cultivation of energy crops to be viable, high yields must be achieved at the lowest possible inputs. The reduction of soil tillage is a method of reducing production inputs (Hernanz et al., 2014), while at the same time contributes to improving soil quality by increasing the organic matter content (Holland, 2004; Gemtos *et al.*, 2013; Küstermann *et al.*, 2013). Soil moisture is a key factor for plant growth. Soil moisture is affected by soil tillage methods and research has shown that in cases of reduced or zero tillage is generally higher due to increased soil water holding capacity and reduced evaporation (Bescansa *et al.*, 2006).
The objective of the present study is to evaluate the effects of soil tillage methods and nitrogen fertilization levels on yield of six energy crops cultivated in Thessaly, central Greece.

Materials and methods

A field experiment was undertaken at TEI of Thessaly university farm in Larissa, central Greece (39° 37.12' B, 22° 23.05' A). The total area of the experimental plot was 1 ha. The soil in the field was sandyclayloam and was classified according to the Soil Taxonomy system (Soil Survey Staff, 1999) as Inceptisol (suborder: Ochrept, Typic Xerochrept subgroup). The climate of the area is semiarid.
Six energy crops were cultivated in rotation, starting from December 2012 till November 2015, as it is presented in Table 1.

Table 1. Energy crops installed in rotation in the field experiment in TEI of Thessaly, Greece.

Crop	**Sowing**	**Harvest**
Pea (*Pisum sativum* L.) & Triticale (*x Triticosecale*)	Dec-12	May-13
Sunflower (*Helianthus annuus*)	Jun-13	Oct-13
Rapeseed (*Brassica napus* L.)	Nov-13	Jun-14
Sorghum (*Sorghum bicolor* L.)	Jun-14	Nov-14
Vetch (Vicia *sativa* L.) & Oat (*Avena sativa* L.)	Dec-14	May-15
Soybean (*Glysine max*)	Jul-15	Nov-15

The soil tillage methods used include: (1) Conventional tillage: plowing at a depth of 25-30 cm and seedbed preparation with a seedbed cultivator, (2) Reduced tillage using a heavy cultivator: primary tillage with a heavy cultivator at a depth of 15-20 cm and seedbed preparation with a seedbed cultivator, and (3) No-tillage: direct sowing on the undisturbed soil surface using special seeders, for summer or winter crops, respectively. The three tillage methods were replicated four times. Also, three levels of nitrogen fertilization were applied to each crop (F1, F2 and F3). The total amount of fertilizer applied to each crop is summarized in Table 2. Each fertilization treatment was replicated three times. For the summer crops irrigation was required, which was determined on the basis of crop evapotranspiration (ET_c). All treatments received the same amount of irrigation water. The ET_c was estimated using the revised FAO-56 Penman-Monteith method (Allen et al., 1998), based on the meteorological data collected from the weather station at TEI of Thessaly farm. At the completion of plant development, biomass was collected in a hanging basket at the back of a 1.5m-wide harvesting combine (HEGE 125c), and biomass fresh weight was determined. Subsequently, a representative sample was taken. Sample's moisture content was determined and based on this result biomass dry matter (DM) yield was calculated. In the case of sunflower, rapeseed and soybean, the DM yield of the seed and stem were determined separately, using the same procedure described above. Crops DM yields were analyzed by two factors ANOVA, with fertilization as main factor and soil tillage as secondary, based on the SPSS10 statistical program (SPSS Inc., Chicago, USA).

Table 2. Application rates of N - P_2O_5 - K_2O (in kg/ha) to the energy crops for each one of the three fertilization levels used: F1, F2 and F3.

Crop	**Fertilization**		
	F1	**F2**	**F3**
Pea & Triticale*	33 - 45 - 45	33 - 45 - 45	33 - 45 - 45
Sunflower	100 - 50 - 0	120 - 50 - 0	140 - 50 - 0
Rapeseed	80 - 0 - 0	100 - 0 - 0	120 - 0 - 0
Sorghum	100 - 0 - 0	200 - 0 - 0	300 - 0 - 0
Vetch & Oat*	64 - 80 - 0	64 - 80 - 0	64 - 80 - 0
Soybean	64 - 80 - 0	83.2 - 80 - 0	102.4 - 80 - 0

*In the case of legume crops, there was no differentiation in the nitrogen fertilization levels applied.

Results and discussion

The biomass DM yield of the pea and triticale intercropping ranged between 3600 and 3880 kg per ha within the different treatments. The effect of the three tillage methods on the biomass DM yield was not statistically significant. It should be noted that nitrogen fertilization levels were not differentiated in the case of the pea and triticale intercropping, as in all cases of legume crops. The nitrogen fertilization rates used significantly increased sunflower DM yields. As a matter of fact, there was a linear increase in sunflower DM yield with increasing rates of fertilization (Fig. 1). The lower fertilization application rate (F1) resulted in significantly lower DM yield compared to the medium rate (F2), and F2 resulted in significantly lower DM yield compared to the higher rate (F3), for both seed and stem.

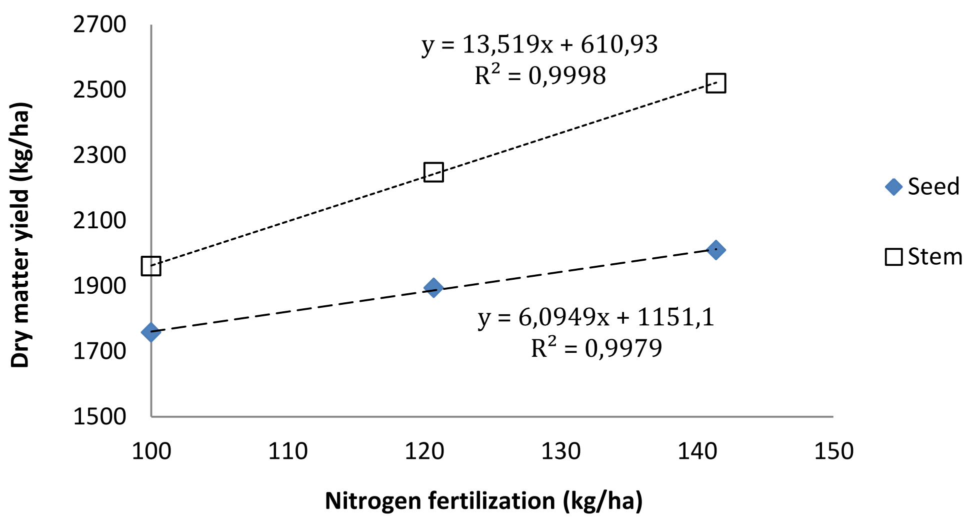

Figure 1. The effect of nitrogen fertilization rates on the DM yield of sunflower seed and stem.

The different soil tillage methods significantly influenced sunflower seed DM yield, but not the sunflower stem DM yield. On average, sunflower stem DM yield was 2236 kg/ha for the conventional tillage, 2218 kg/ha for the reduced tillage and 2274 for the no-tillage. On the other hand, reduced tillage resulted in the highest sunflower seed DM yield, followed by conventional tillage, whereas no-tillage resulted in the lowest yield (Fig. 2).

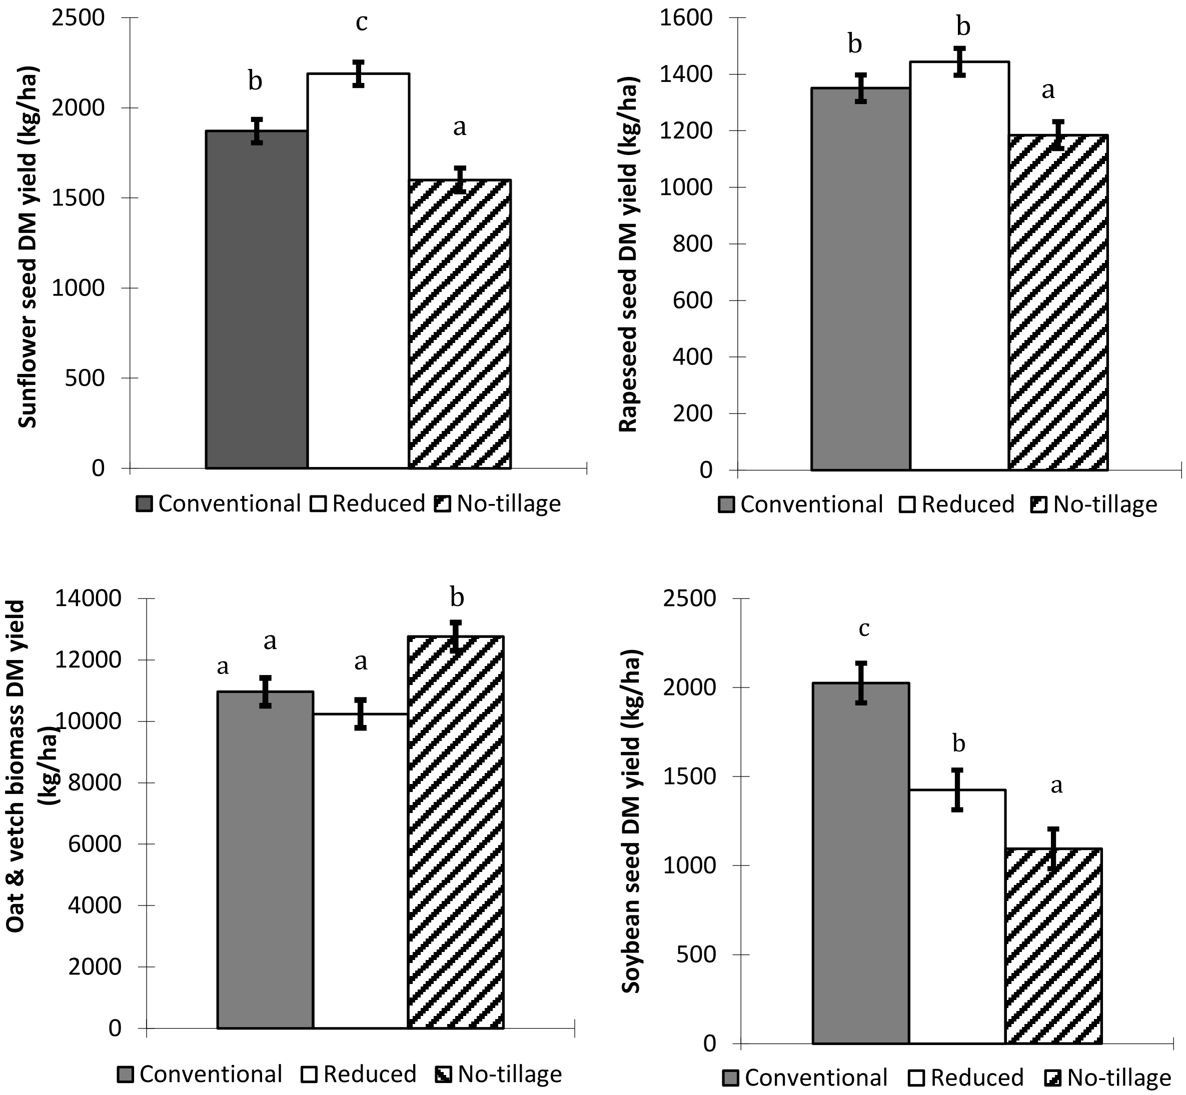

Figure 2. The effect of the three soil tillage methods used: conventional (plowing), reduced (with a heavy cultivator) and no-tillage, on the DM yield of sunflower seed, rapeseed seed, oat & vetch biomass and soybean seed. Columns labeled with the same letter are not significantly different (P>0.05).

Rapeseed seed DM yield was also affected by the different soil tillage methods. Reduced tillage resulted in an average of 1444 kg/ha rapeseed seed DM yield. Conventional tillage ranged in similar levels, whereas no-tillage resulted in the lowest yield (Fig. 2). The application of nitrogen fertilization at the highest rate (F3) significantly increased rapeseed seed yield, in comparison to the other two rates used, which resulted in similar DM yields. The increase in rapeseed seed DM yield with increasing rates of nitrogen fertilization followed a linear trend (Fig. 3). Sorghum DM yield was not significantly affected either by the nitrogen fertilization rates applied, or the soil tillage methods used, under the conditions of our study. On average, sorghum DM yield was 18290 kg/ha for the conventional tillage, 16322 kg/ha for the conservation tillage and 15574 for the no-tillage. The increase in nitrogen fertilization application rate did not increase sorghum DM yield. In detail, the lower application rate (F1) resulted on average in 17248 kg/ha, the medium rate (F2) in 17009 kg/ha, whereas the higher rate (F3) in 15929 kg/ha. These results indicate that there was no advantage in increasing the nitrogen fertilization rate under the conditions of our study.

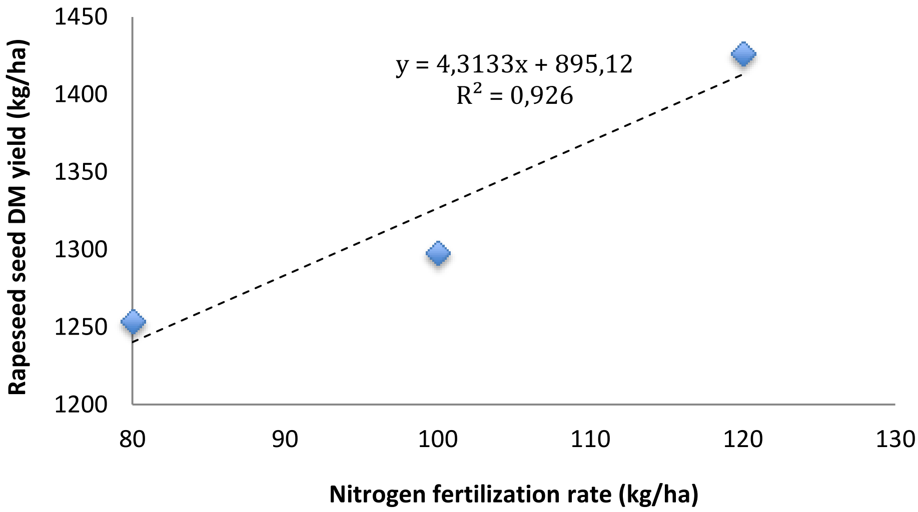

Figure 3. The effect of nitrogen fertilization rates on rapeseed seed DM yield.

In the case of the oat and vetch intercropping, nitrogen fertilization levels were not differentiated, as in all cases of legume crops. The effect of the soil tillage method on biomass DM yield is presented in Figure 2. As it can be seen in Figure 2, the no-tillage method significantly increased biomass DM yield, in comparison to the other two methods, which resulted in similar DM yields. It should be noted that during the experimental period of soil tillage and seeding of oat and vetch intercropping, soil moisture content was quite high, due to the on-going rainfall. This fact most probably led to soil compaction, especially in the treatments of conventional and reduced tillage, and therefore biomass yield in these treatments was reduced in comparison to the no-tillage method. Finally, as far as the soybean seed DM yield is concerned, it was not significantly influenced by the nitrogen fertilization rates applied. On the contrary, soil tillage methods significantly affected soybean seed DM yield, as it can be seen in Figure 2. Conventional tillage resulted in significantly higher yield, followed by conservation tillage, whereas the no-tillage resulted in the lower yield. The effect of fertilization and soil tillage methods on soybean biomass DM yield was not significant, due to the high variation observed. However, a tendency for higher yields with the conventional tillage and the two higher nitrogen fertilization rates was observed (Table 3).

Table 3. Soybean biomass DM yield (kg/ha) for the different treatments. Average values labeled with the same letter are not significantly different (P>0.05).

Soil tillage methods	**Nitrogen fertilization rates**			***Average***
	F1	F2	F3	
Conventional	3014.8	5439.5	5344.0	***4599.4***[a]
Reduced	2610.0	3472.3	3449.5	***3177.3***[a]
No-tillage	3291.5	2506.3	2940.5	***2912.8***[a]
Average	***2972.1***[a]	***3806.0***[a]	***3911.3***[a]	

Conclusion

The present study investigated the effects of three soil tillage methods along with three levels of nitrogen fertilization on yields of six energy crops cultivated in a rotation system in central

Greece. The experimental results provided evidence that reduced tillage (with a heavy cultivator) can lead to increased production of energy crops, whilst contributing to energy savings, compared to the conventional method (plowing). The no-tillage method was advantageous under high soil moisture content conditions. Increasing levels of nitrogen fertilization led to increased yields only in the case of rapeseed and sunflower. Reducing levels of nitrogen fertilization to the rest energy crops resulted in high yields, whilst lowering crop production inputs.

UNLIMITED USE OF IRRIGATION WATER RESOURCES IN ARID AND SEMI-ARID REGIONS OF IRAN: NO-WIN COMPETITION

Marzieh KESHAVARZ

Department of Agriculture, Payame Noor University, Tehran, Iran
*Corresponding author: keshavarzmarzieh@pnu.ac.ir

Abstract

Water shortage as a virtually common feature is a major limitation for agricultural development, in Iran. Climate change is also expected to put extra pressure on Iran's water resources through making the region hotter and drier. These extreme environmental conditions require flexible and adaptive utilization of water resources. However, the average irrigation efficiency is low and the crop pattern, e.g. rice production, does not match the regional water availability conditions. Using qualitative research method in three rice growing villages of Firuzabad County, southwest Fars province, this study aims to identify the main causes of unlimited use of water resources in water scarce regions of Iran. Results indicated that Fars has experienced significant reduction in rice production since 2007. Some rice farmers have modified their cropping systems by growing drought resistance crops. However, some others are still cultivating irrigated rice which is causing the looming water crisis. Finding revealed that personal, financial, institutional, legal and regulatory issues and socio-psychological drivers have constrained sustainable use of scarce water resources. Recommendations are offered to increase the efficiency of water resources and modify cropping system in water scarce regions.

Keywords: *Agriculture, climate change, scarce water resources, rice producers, sustainable management*

Introduction

Agriculture as the dominant sector in Iranian rural economy accounts for almost 13% of GDP, 20% of the employed population, 20% of non-oil exports, 85% of raw materials used in the food processing industry and 93% of water withdrawals in Iran (Ardakanian, 2005; IRNA, 2015). However, this country is not well-endowed with water; the per-capita water endowment is approximately one-quarter of the world's mean value (Alyasin, 2005) and lack of adequate water is a major limitation for agricultural development in Iran. Meantime, the demand for water consumption has increased during the recent severe sustained droughts (e.g. 2007–2014). The 2007-2014 drought has led to completely drying up of many internationally renowned wetlands and lakes, significant reduction of river flows and depletion of groundwater resources (Keshavarz et al., 2013; Keshavarz and Karami, 2016). Furthermore, climate change is expected to put extra pressure on Iran's water resources by making the region hotter and drier (Abbaspour et al., 2009; Jamali et al., 2012). For instance, it is estimated that the average annual runoff in Pishin (southeast Iran) and Zayandeh-Rud (center of Iran) basins will decrease by 33% and 40 to 70% around 2040, respectively (Massah Bavani and Morid, 2005; Mohammadnejad, 2010). Moreover, it is projected that the demand for irrigation water will rise soon (Shahkarami et al., 2011), having major implications for agricultural production (Gohari et al., 2013; Moradi et al., 2013). These variable, unpredictable and extreme environmental conditions require flexible and adaptive utilization of irrigation water resources (McAllister et al., 2006; Schmidt and Pearson, 2016). Moreover, Iran has always suffered from an inefficient agriculture that has heavily relied on limited irrigation water resources (Seyf, 2006). Currently, the average irrigation efficiency is less than 35% and only 5% of the cultivated area is under pressured irrigation. Also, the crop pattern does not match the regional water availability conditions and follows the traditional crop choices and farming practices (Madani, 2014). For instance, high water requirement crops such as rice are still grown in some arid and semi-arid regions of Iran. While 277 out of 609 plains of Iran suffer critical conditions (Forootan et al., 2014). This study aims to identify the main causes of the unlimited and irrational use of the irrigation water resources in water scarce regions of Iran.

Material and Methods

This study was conducted in Firuzabad county, southwest Fars province, Iran. While the average annual rainfall in this area is 434.8 mm (1971–2016), the mean precipitation decreased to 238.6 mm in 2014. Due to unavailability of sufficient surface water, the agricultural sector has consumed a lot of groundwater. This county was further confronted with a 20 to 30% drop in its water-table and about 140 meters increase of the well depth (Fars News Agency, 2015). Despite groundwater degradation and water scarcity, rice production is still prevalent in the region. This is while the typical amount of water required for irrigated rice in Iran is around 30000-35000 m^3 per hectare. Qualitative research was conducted in three rice growing villages of the county. With this regard, a purposive sample of 19 rice producers were interviewed to identify the main causes of producing rice in the water scarce environment.

Results and Discussion

Past and present status of rice production in Fars province and Iran

Rice production in Iran has more than tripled in the last 37 years (from 741 to 2347.7 thousand tons; Jihad-Agriculture ministry, 2015) mainly due to the increased grain yield rather than enhanced cultivation area (Fig. 1). This increase is resulted from development of high-yielding varieties and improved nitrogen fertilization. For instance, the average rice yield of Fars was 5.4 tons per hectare in 2009 that was higher than the world average (Fig. 2).

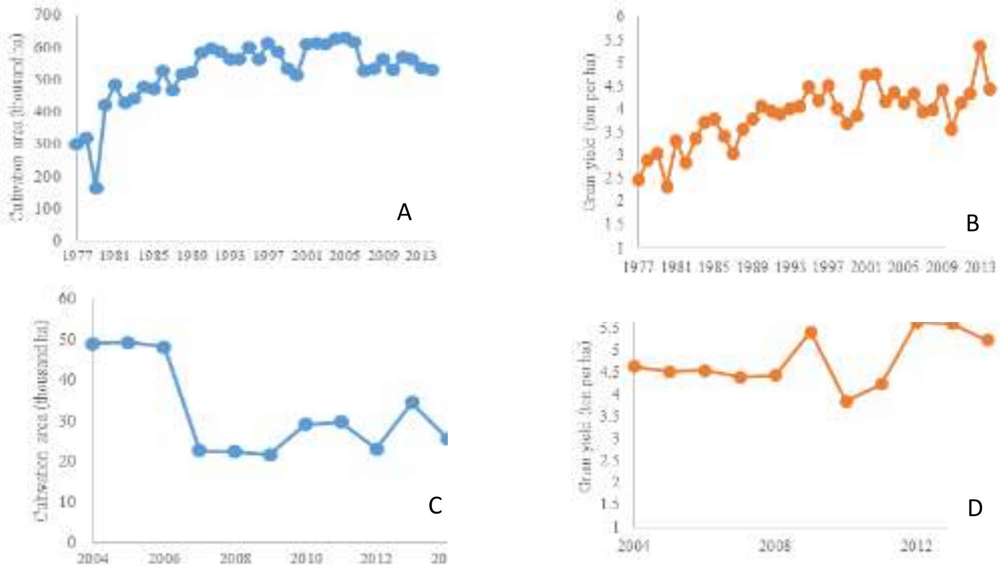

Fig. 1. Rice cultivation area (A, C) and grain yield (B, D) in Iran and Fars province, respectively (Jihad-Agriculture ministry, 2015)

While rice production is promoting in some regions of Iran, i.e. Gilan and Mazandaran provinces, Fars has experienced its significant reduction since 2007 (Fig. 1). The annual total rice cultivation area has decreased from 49.3 to 22.7 thousand hectares from 2005 to 2007 and stagnation of rice production has been observed in the past ten years. The major constraints of the sustainable rice production in many rice growing areas of Fars include drought stress and scarcity of freshwater resources, deterioration of water quality and global warming that reduces rice yield by increasing grain sterility and decreasing biomass production (Madani, 2014). While some rice farmers have modified their cropping system by growing drought resistance crops, some others still cultivate irrigated rice which causes further water crisis.

Main causes of rice production in water scarce regions of Fars

A complex set of factors are considered as the main drivers of rice production under water stress (Table 1). As illuminated in Table 1, low education level and lack of knowledge about many water related issues pose powerful effects on farmers' behavior. Comments indicated that greater awareness and education is needed about water conservation actions, water consumption rates and the possibility of water scarcity. However, Iran has failed to provide a comprehensive plan for empowerment of farmers. Some failure reasons are attributed to low effectiveness of extension services due to poor linkages between extension agents and local people, lack of practical relevance of educations to local and community demands and lack of continuity between different levels of education (Table 1).

Table 1. Drivers of rice production in water scarce regions

Themes	Formulated concepts	Significant statements
Personal	Low level of education	*- We're illiterate people. We don't know what's good for society and environment.*
	Lack of knowledge about water issues	*- I heard from one expert that it takes about 9000 liters of water to produce one kilogram of rice. It is unreal.* *- I heard that there's a new rice verity that requires only 12000 m^3 water per hectare but I don't know more.*
Financial	Poverty	*- Our poverty is the root of water crisis.* *- If we want to change our copping pattern effectively, our farmed area should be under pressured irrigation. We don't have enough money to improve our irrigation system.*
	Lack of income diversification	*- How other people can understand our situation? Agriculture experts, public media and even urban people blame us for over-use of water and always talk about conservation of environment. What should we do when we don't have any other income resource?* *- We have no serious job alternative than farming.*
	Access to local markets	*- Agriculture experts recommend us to cultivate low water requiring crops such as safflower. No one buys this crop in Fars. We prefer to produce rice which has many consumers in Firuzabad and Shiraz.* *- Although the process of rice production is difficult but it's market is safe. Everyone likes to buy our rice.*
Institutional, legal and regulatory	Inequitable access to low-interest loans	*- Banks argue that they don't have enough funds to give us loans. Iran is a rich country, how is it possible?* *- Even if I want, I can't get a loan. The guarantor has to be a government worker, and I don't have any relatives working for the government.*
	Inadequate extension services	*- We don't know which cropping system is better for our farm. This is extension agents' fault. Why they never hold water management classes for us?* *- Agricultural extension service centers don't pay any attention to small scale farmers. They just support famous farmers with more arable lands.*
	Uneven geographical distribution of welfare	*- All capitals and budgets are spent for urban not rural people. Urban people have everything, but we don't have anything. We think the blame is on the government for our rice production behavior, not us.*
	Lack of government control	*- We didn't find any policy plans to improves water efficiency in the region or prevent misuse of water resources.* *- All of us should be restricted, otherwise one farmer obeys the restrictions*

		while others use the entire amount of water.
Social- psychological	Distrust in governmental organizations	*- Officers and extension agents almost always say there's no enough water in the region. They are liars. There is no water scarcity. They want to give our water to other regions. It's better to use water by ourselves.* *- Governors told us if you avoid rice production we will give you salary for almost three years. No one has received such money.*
	Tragedy of the commons	*- We own common irrigation wells. If I avoid growing rice others use more water and increase their rice cultivation area.* *- We always have water competition! Who can ensure if I ignore rice production benefits, others ignore it?*
	Lack of deferred gratification	*- Folks are saying that rice growers are somehow responsible for this water crisis. My question is who can delay short term gratification for long term sustainability?*
	Cognitive misperceptions	*- Water management is an engineering issue. How can we improve water use in our small farm?* *- We have water right and private borehole. It allows us to use water, freely. Does anyone ask you about what you do in your house?*
	Risk aversion	*- We as small scale farmers are risk averse. Modifying cropping system from rice to other crops is risky. We're afraid if we lose our subsistence.* *- Who can insure our sustainable livelihood if we avoid production of rice?*

Also, poverty and lack of income diversification are the main drivers of unlimited irrigation water use (Table 1). Although Iran is implementing poverty reduction programs in rural areas, findings revealed that governors have failed to reduce poverty in the area. Poor farmers often lack the financing capacity to improve water use efficiency. Enhancing equity within irrigation systems to support poverty reduction and efficiency through equitable welfare distribution mechanisms is imperative. However, most respondents did not receive any subsidized loans. Budget limitation and farmers' inability to provide a guarantor were the main reasons for refusal. Furthermore, uneven geographic distribution of welfare and lack of access to markets have put extra pressure on water resources and created a no-win competition between rice growers and no-rice grower farmers (Table 1). To prevent further water loss, the government should provide a robust action plan and prohibit overuse of water resources (Table 1). Recently, the government has installed smart groundwater monitoring devices in some regions but effectiveness of this action is unknown and many believe that water crisis in Iran is the result of decades of government mismanagement (Madani, 2014).
As illustrated in Table 1, water use reduction was not considered as an option by farmers due to their distrust in the governors. Building trust and confidence through dialogue among all stakeholders is required for effective regulation of water management issues and averting tragedy of the commons (Table 1), where common groundwater resources are depleted and destroyed through the unregulated and self-interested activities of countless consumers. Risk aversion, lack of deferred gratifications and misperceptions about water rights constraint efficient use of irrigation water, too.

Conclusions

This study indicated that the roots of water use crisis can be traced back to lack of knowledge, poverty, unequal access to markets, loans and government welfare programs, government mismanagement, as well as social-psychological factors. This problem is normally the product of rapid growth of agriculture sector without considering its dynamic relation to water resources. If water resources are to be sustainable, Iran needs serious control of aggressive groundwater withdrawals, modify the inappropriate crop patterns and reduce irrigation water consumption through empowering farmers. If timely regulatory actions are not taken in these issues, the unintended damages can become fully irreversible (Madani, 2014).

PROMISING AMMONIA MITIGATION OPTIONS IN LATVIA'S AGRICULTURE

Ligita MELECE

Institute of Agricultural Resources and Economics (AREI), Latvia
Corresponding author: ligita.melece@arei.lv

Abstract

The revised Gothenburg protocol and EU National Emission Ceilings Directive establish ammonia emission reduction targets. Taking into account that the agricultural sector remains the major source of ammonia emissions in both EU and Latvia (86%), the huge effort should be made by agriculture sector to achieve ammonia mitigation. The aim of the paper is to provide the most promising ammonia emissions reduction and mitigation options in Latvia's agricultural production. Following tasks have been covered in the study: 1) to determine the main sources of ammonia emissions in the each of livestock species (dairy cattle, pigs, poultry) and farms' size; 2) to evaluate and to identify the most promising mitigation measures, taking into account the reduction potential, effectiveness and potential costs. The largest proportion of ammonia emission comes from the livestock production: 45.6% from manure management and 19.6% from manure application. The results show that the milk production, pig and poultry industry are the target branches of agricultural production. The most promising emission reduction and mitigation measures have been proposed, out of which the animal feeding strategy and manure application techniques are distinguished as the most effective.

Keywords: *Ammonia mitigation, agriculture, feed, manure, Latvia*

Introduction

Ammonia (NH_3) emissions are contributing to several different negative effects to human health and ecosystems (Sutton et al., 2011). The Convention on Long-Range Transboundary Air Pollution (CLRTAP) is the main international framework for cooperation and measures to limit, to reduce and to prevent air pollution. CLRTAP Protocol, which is also known as the Gothenburg Protocol, was revised in 2012. Based on the revised Protocol the EU National Emission Ceilings Directive - Directive (EU) 2016/2284 on the reduction of national emissions of certain atmospheric pollutants, including NH_3, has set national emission reduction commitments (EC, 2016). The reduction target of NH_3 emissions for Latvia should be one per cent – 1% for any year from 2020 to 2029; and 1% from any year from 2030, compared with a 2005 baseline. The agricultural sector remains the major source of NH_3 emissions in both EU and Latvia, e.g. 94% and 86%, respectively in 2015 (Eionet, 2017). Therefore the huge effort should be made by agriculture sector to achieve the reduction commitments.

The aim of the paper is to provide most promising NH_3 reduction options in Latvia's agricultural sector. Following tasks have been covered in the study: 1) to determine the main sources of NH_3 in the each of livestock species and farms' size; 2) to identify and to evaluate the most promising mitigation measures, taking into account the reduction potential, effectiveness and potential costs.

Material and Methods

The literature review seeks to identify the main ammonia emission mitigation and reduction goals and especially the measures to achieve them. The principal materials used for literature review are as follows: different primary and secondary sources of literature, e.g., scholars' articles, research papers and the reports; as well as legislative acts, guidelines and recommendations of both international institutions (EMEP, UNECE) and EU (European Commission, EEA). The main selection criteria of literature were: the most recent ones, peer-reviewed, with similar climatic conditions or technologies, of Latvian origin etc. In order to identify the main sources of ammonia emissions in Latvia, particularly from agriculture, the following secondary data were used: published and unpublished data from Central Statistical Bureau of Latvia (CSB, 2017), as well as the data from CLRTAP (Eionet, 2017). The reference or baseline year – 2005 was chosen in accordance with the EU legislation (EC, 2016). The literature review was conducted, in which systematic review approach was applied, and the descriptive and comparative methods were used. The quantitative estimation of NH_3 emissions trends and main sources was performed using data analysis methods, including simple regression.

Results and Discussion

Main sources of ammonia emissions in Latvia

The main share (86%) of NH_3 emissions in Latvia was originated by agriculture. In Latvia, total NH_3 emissions show significant growing trend from 2005 to 2015, where coefficient of determination is - $R^2 = 0.8141$ ($y = 0.2165x + 16.086$; p-value is 0.000145). NH_3 emissions from agriculture significantly increased from 2005 to 2015, but from other sectors significantly decreased in the same period (Figure 1).

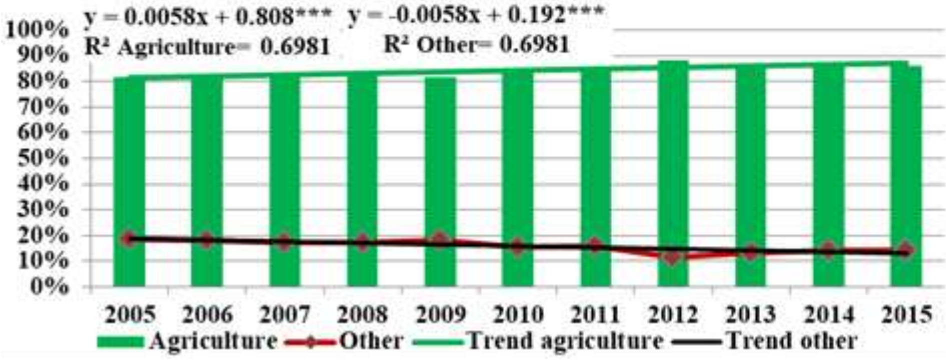

Figure 1. Trends of NH_3 emissions (NH_3 kt) in Latvia, 2005-2015

Source: author's calculations based on data of CLRTAP Data Repository (Eionet, 2017).

The share of NH_3 emissions from manure management was 45.6% in 2015, where 20.7% came from dairy cattle (Table 1). NH_3 emissions from manure management cover emissions from animal housing, grazing and manure storage (EMEP/EEA, 2016). Application of inorganic nitrogen (N) fertilizers, which accounts for 31.6%, is the second main source of NH_3 emissions from agriculture sector (Table 1).

Table 1. Agriculture origin NH3 emissions in Latvia by source, from 2010 to 2015

Source		2010	2011	2012	2013	2014	2015	% of total
Manure management	Dairy cattle	3.44	3.44	3.46	3.47	3.51	3.34	20.7%
	Non-dairy cattle	0.63	0.65	0.67	0.7	0.73	0.74	4.6%
	Swine	1.90	1.81	1.72	1.77	1.67	1.55	9.6%

Source: author's calculations based on data of CLRTAP Data Repository (Eionet, 2017).

In Latvia NH_3 emissions have increased substantially since 2005 by 20.1% - Table 2). Moreover, the emissions from inorganic N fertilizers application have almost doubled (by 96.2%), but manure application grew by 19.2%.

Table 2. Changes of NH3 emissions from main sources in Latvia, comparing 2005 and 2015

Source		2005	2015	Changes
		NH3 emission, kt		2015/2005, %
Manure management	Dairy cattle	3.87	3.34	-13.7%
	Swine	2.23	1.55	-30.5%
	Laying hens	0.47	0.49	4.3%
	Broilers	0.16	0.24	50.0%

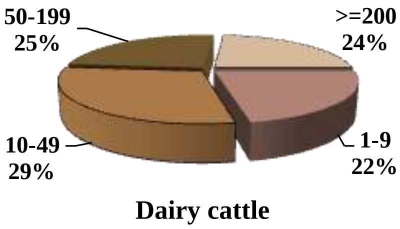
	Animal manure	2.66	3.17	19.2%
Other		1.45	2.25	55.2%
Total:		13.44	16.14	20.1%

Source: author's calculations based on data of CLRTAP Data Repository (Eionet, 2017).

Despite the farms with more than 50 cattle have been distinguished as intensive (EC, 2013), currently those are not recognised as industrial source (EC, 2017). EU Directive 2016/2284 states that the EU Member States could protect small farms and could ensure that impacts (i.e. economic) on small and micro farms are taken into account (EC, 2016). The dairy cattle holdings with more than 50 animal places account for 48.5%, but non-dairy cattle for - 62.1% (Figure 2). Since 2004 the proportion of dairy cattle in the small holdings (fewer than 10 animals) has dropped sharply from 61% to 23%, and this trend could continue. The cattle grazing are less NH_3 emissions originated and more difficult managed stage of rearing. Accordingly, the low-protein feeding for non-dairy cattle is not a priority in Latvia, particularly in mid-term. Consequently, the target holdings should be dairy cattle with 50 and more cattle.



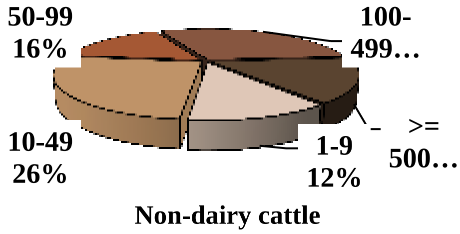


Figure 2. Share of number of livestock by holding size in Latvia, 2016

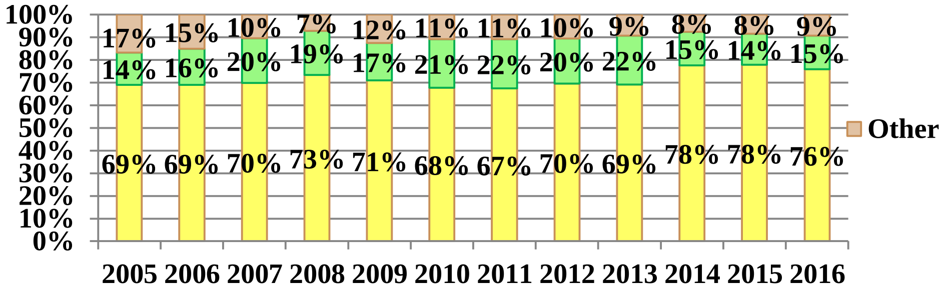
Source: author's calculations based on published and unpublished data of CSB, 2017.

Directive 2010/75/EU on industrial emissions includes as industrial installations intensive livestock holdings with more than 40,000 places for poultry; with more than 2,000 places for pigs (over 30 kg); with more than 750 places for sows. In Latvia the pig and poultry rearing is concentrated in large holdings, where 76.6% of sows are placed in 15 holdings with more than 500 animals, 78.5% of pigs are fattened in 17 holdings with more than 5,000 animals, but 91.0% of poultry are located in ~ 3-4 holdings with more than 5,000 birds (CSB, 2017). Consequently, the NH_3 reduction measures will cover the major part of livestock, but will affect smaller number of farms, which will facilitate the implementation and support.

The intensive rearing of poultry and pigs is regulated by EU Decision 2017/302, which establishes best available techniques (BAT): nutritional management; feed preparation; housing; collection, storage and processing of manure; and manure land spreading.

The main sources from application of inorganic N fertilizers were cereals and rape areas (Figure 3). Since the large holdings (more than 150 ha) accounted 60.4% of the total sown area, 64.8% of cereals area (45% of farms with more than 300 ha), 77.2% of winter wheat area, and 89.1% of rape area (CSB, 2017), the main target group of agricultural holdings could be large ones.



The share of inorganic N fertilizers' application by crop in Latvia, 2005-2016

Source: author's calculations based on published and unpublished data of CSB, 2017.

Main NH_3 emissions abatement measures

ECE Guidance suggests NH_3 emission abatement measures in the following areas: nitrogen (N) management, taking into account the whole N cycle; livestock feeding strategies; animal housing techniques; manure storage types; manure application and fertilizer application techniques (UNECE, 2014).

N management provides to establish an N input-output balance at the farm level that is aimed to increase the N use efficiency (NUE). Taking into account high implementation and maintenance cost (~ 200-500 EUR/farm/year) this measure could not be as priority for Latvia.

Livestock feeding strategies are implemented through: phase feeding; low-protein or low crude protein (CP) feeding (Bittman et al., 2014; UNECE, 2014). Low-protein feed as one of the most cost-effective measure decreases NH_3 emissions in both housing and storage, and following application to land (Hou et al., 2016; Loyon et al., 2016). The low CP diet does not negatively affect the milk quality, but increases NUE, significantly decreases NH_3 emissions, and N output (Bittman et al., 2014; UNECE, 2014; Hristov et al., 2015). Accordingly, producers have financial benefits, because the feed cost is reduced, the need of inorganic fertilizers decreases, and farm profitability increases.

Manure storage and application, particularly slurry, is a significant source of emissions. Cover slurry or solid manure during storage is proposed by many scholars (Bittman et al., 2014; EC, 2017). Slurry storages covered by chopped straw, granules, artificial film, peat have significantly decreased NH_3 emissions. Moreover, only natural crust significantly decreases NH_3 emissions by 65% (Hou et al., 2015). The application techniques for slurry (shallow injection, band spreading and trailing shoe), reduces NH_3 emissions by 70-95% (Misselbrook et al., 2016). Some researchers reported lower reduction levels, for example, Hou et al. (2015) argue that reduction by band spreading is 55% (37–67%), incorporation -

70% (50–82%), and injection - 80% (72–86%). Higher reductions could be achieved when incorporation takes place immediately after land spreading (UNECE, 2014; Santonja et al., 2017). Promising manure management techniques such as composting and compacting are not the subject of the evaluation, because there is no previous experience for it in Latvia.

Application of inorganic N fertilizer is significant source of N-based emissions (NH_3, N_2O) and nitrate leaching. Even though alternative N fertilizers to urea decreased NH_3 emission by 22–55% (UNECE, 2014; Misselbrook et al., 2016; Pan et al., 2016), the urea is commonly used due to high content of N. Recommended NH_3 reduction measure is the use of urease inhibitors (Bittman et al., 2014; Misselbrook et al., 2016; Oenema, 2016), which significantly decreased NH_3 volatilization (UNECE, 2014; Misselbrook et al., 206; Pan et al., 2016). NH_3 reduction potential is variable; for example, Abalos et al. (2014) reported reduction by 58%, but Ni et al. (2014) indicated wider range - 26–89%. Despite largely proposed use of urease inhibitors as a method for NH_3 mitigation, some evidence indicates that more effective is urea and ammonium based fertilizers' injection and incorporation, compared with urease inhibitors or coating use (Table 4). Due to variability of the reduction efficiency of urease inhibitor, the recommendations should be assessed under different (specific) climatic and soil conditions (Ni et al., 2014), as well as to clarify the financial benefits and to compare another options in certain circumstances (Abalos et al., 2014).

Table 4. NH3 emissions reduction measure efficiency (reduction potential and costs) for urea and ammonium based fertilizers

Fertilizer	Application technique	NH3 reduction, %	Cost, EUR/ kg NH3-N saved
Urea	Injection	> 80	-0.5–1
	Incorporation	> 50	-0.5–2
	Urease inhibitors	> 30	-0.5–2
	Coating	~ 30	-0.5–2
Ammonium carbonate	Ban	~100	-1–2
Ammonium-based fertilizers	Injection	> 80	0–4
	Incorporation	> 50	0–4

Source: based on Bittman et al., 2014; Oenema, 2016.

Considerably, the most promising mid-term measures in Latvia could be incorporation of urea and ammonium based fertilizers, as well as choosing the appropriate application conditions (soil conditions, weather conditions, i.e. temperature etc.).

Conclusion

Taking into account that NH_3 emissions from the Latvian agriculture have significantly increased since 2005, the selection of effective reduction measures and their implementation in order to reach mitigation goals is a major challenge. The reduction measures in pig and poultry production should be aimed at larger or industrial farms according to the latest EU regulations. Besides, a major part of livestock is placed in large holdings. In general, the most promising NH_3 emission reduction measures in Latvia could be the following: balanced and low-protein content feeding strategies for intensive breeding of dairy cows, pigs and poultry; low-emissions manure (i.e. slurry) storage and application, including manure incorporation; and urea incorporation. The main tasks or priorities of further research are: 1) the selection of priority measures; 2) identifying the need for state supporting tools and instruments, including EU funds (e.g., Rural Development Plan 2014-2020); and 3) the determination of the necessary studies in the field of livestock husbandry and crop production mainly oriented to the nitrogen use efficiency improvement. The involvement of experts and stakeholders (i.e. farmers) is essential. Besides, future research needs to develop models for forecasting impact of NH_3 reduction measures. At the same time, the cost-benefit analysis of chosen most promising abatement measures should be performed.

Abstract

Discarded cigarette butts are toxic, non-biodegradable, waste that create environmental health risks and an economic burden. It is estimated that 1.69 billion pounds of cigarette butts end up as toxic waste annually. In areas with substantial amounts of butts, environmental hazards may arise as nicotine and other chemicals, heavy metals, additives, pesticide residues are leached from the filters and tobacco. The aim of this study was to optimization of qualitative analysis of nicotine in discarded cigarette butts using chemical test (Dragendorff's reagent). Orange colored precipitation with Dragendorff's reagent indicated the presence of nicotine which was confirmed by gas chromatographic (GC-FID) method with liquid-liquid extraction of butts. Ten samples of most popular cigarette brands were selected to cover the low, medium and high range of nicotine yields had to be consistently smoked down to about 1 cm from cigarette filters. The nicotine content in smoked cigarette butts (CBs) with and without remnant tobacco was measured using Dragendorff's test and ISO 10315. Our results confirm the nicotine concentration of orange colored precipitation obtained with Dragendorff's reagent with nicotine concentration measured by GC-FID. The nicotine concentration in littered butts without remnant tobacco was range from 0.24 to 1.36 mg per butt and with remnant tobacco was higher about 20 to 25 %. An accurate analytical method for determining nicotine in littered cigarette butts (CBs) has been developed. This method is found to be low-cost, quick and valuable for analysis of moderate and significant levels of nicotine in cigarette butts (CBs).

Keywords: *cigarettes, butt, nicotine, environment, Dragendorff's reagent*

Introduction

Filters are recognized as an integral part of cigarette design and are used extensively to meet range of product parameters such as draw resistance, and more importantly reduction of tar and nicotine yields. Manufactured cigarettes are the most commonly used form of tobacco, accounting for 92.3% of tobacco product sales worldwide, and most of them are filter-tipped (Euromonitor). With 5.8 trillion cigarettes consumed worldwide in 2014, and nine trillion expected by 2025, the global environmental burden of cigarette waste is also significant (Thomas *et al.*, 2014; Eriksen *et al.*, 2015).The impact that tobacco has on the environment is less well recognized. The World Health Organization (WHO) and Framework Convention on Tobacco Control (FCTC) address the environmental concerns regarding tobacco in Article 18. Both cigarettes smoke itself and the post-consumption waste from cigarettes represent potential point sources for environmental contamination.
Cigarette butts (CBs) are the single most collected item in urban and environmental trash cleanups. An estimated 4.5 trillion of the annual 6 trillion cigarettes sold do not end up in a

dustbin or ashtray, but are deposited somewhere into the urban and environment area as post-consumption waste. Assuming that each filter weighs 170 milligrams, the weight of all butts discarded annually is about 175 200 tonnes (Novotny *et al*., 2015). Cigarette butt (CBs) littering is very often in urban area. Many smokers who do not properly dispose of their butts, lighting material, and packaging do not consider their behavior littering (Rath *et al*., 2012). Studies have consistently found that a great majority of smokers litter cigarettes after smoking (76.7% reported by Patel *et al.* (2013), and 84% by Wilson *et al.* (2014)). The problem has increased in recent years with government legislation for smoking restrictions in public buildings and restaurants forcing smokers outside, where butts are often littered. Typically, discarded cigarette butts consist of three components: unsmoked remnant tobacco (including partially smoked/charred tobacco on the end), the filter of a filtered cigarette and a paper wrap. Each of these components of the discarded cigarette butt presents its own concerns. Cellulose acetate is used in the majority of commercial filters but some filters are also made from either paper or polypropylene. The cellulose acetate fibers are a slowly degradable plastic in the environment, with an estimated degradation of 18 months or longer in ideal conditions (Ach, 1993). These fibers, each about 20 μ in diameter, are treated with titanium dioxide and over 15,000 of them are packed tightly together, using triacetin as a binding agent, to create a single filter (Norman, 1999). Most cigarette filters are surrounded by two layers of paper and rayon wrapping, the porosity of which acts to control the airflow through the filter. Cigarette paper also has many chemicals, including glues to hold the paper together and alkali metal salts of organic acids such as sodium acetate to keep the cigarette burning while smoking (Norman, 1999). Although the environmental impact of this waste has not yet been quantified, the large quantity of discarded butts may allow leachates to affect the quality of aquatic environments and soil. Few studies have investigated nicotine and chemical components in CBs by different chromatographic methods (Moriwaki *et al*., 2009; Slaughter *et al*., 2011; Novotny and Slaughter, 2014). There are a wide range of factors that can impact the chemicals retained in cigarette butts. These include the brand of the cigarette, the length of the cigarette butt, the temperature during the aging process, the number of puffs taken while the cigarette was being smoked and the degradation of the cigarette butt. The nicotine content released in smoke and retained in filters depends from cigarette design, consumers smoking behavior and filter efficiency. In commercial filter-tipped cigarettes nicotine normally constitutes from 1.0 to 1.5 percent of the tobacco weight, so that each cigarette contains an average of 10 to 15 mg per gram of nicotine. The amount of nicotine, chemically transformed during smoking, is unforeseeable and depends on the burning temperature. The rate of deposition of nicotine depends on the chemical composition and the size of particles in the tobacco smoke (Pankow *et al.,* 2003; Kibet *et al.,* 2016). If we assume that the 20% of this amount goes into smoke and 50% is decomposed during combustion. In this case the amount of nicotine remaining in the single butt is not significant. What multiplies the problem is a large number of discarded CBs. Here we propose a simple and rapid chemical test using Dragondorff's reagent (potassium iodide-bismuth nitrate), which is widely used in routine detection of alkaloids. The aim of this study was to optimization of qualitative analysis of nicotine in discarded cigarette butts using chemical test (Dragendorff's reagent). Orange colored precipitation with Dragendorff's reagent indicated the presence of nicotine which was confirmed by gas chromatographic (GC-FID) method with liquid-liquid extraction of butts.

Material and methods

Sample preparation

Sampling and analysis were conducted during May/June of 2017. Ten samples of most popular cigarette brands filters were purchased in a convenience store to cover the low, medium and high range of nicotine yields.

The cigarettes are chosen to have the same type of filter and filter length and therefore similar filtration efficiency. Cigarettes are conditioned at 22°C and at 60% relative humidity according to ISO 3402: 1999. In order to minimize variability between cigarettes, they were weight (±3% of mean weight) and pressure drop (±3% of mean of pressure drop) selected.

All cigarette samples was smoked in smoking machine Borgwaldt RM 20/CS under ISO smoking regime (ISO 3308:2012) (*35 ml* volume and 2 s duration every 60 s, without blocking of filter ventilation) to about 1 cm from cigarette filters. The resulting CBs after machine smoking were collected in in zipped plastic bag and stored in the dark at room temperature.

Materials

Acetonitrile, 25 mM phosphate buffer (pH 7.8), ethanol, *n*-heptadecane, bismuth subnitrate, glacial acetic acid, potassium iodide, sodium hydroxide, and hydrochloric acid. All reagents are analytical grade. Dragendorff's reagent was prepared according of the directions in The International Pharmacopoeia - Sixth Edition from 2016.

Dragendorff test

In order to qualitatively determine the nicotine in the CBs (with and without remnant tobacco) the cellulose acetate is dissolved in acetonitrile to release any trapped nicotine.

The filter butts from five to seven cigarettes are placed in a 125 ml Erlenmeyer flask and added 50 ml of acetonitrile. The flask is shaken on a mechanical shaker about 30 min until the cellulose acetate is dissolved. The cellulose acetate is precipitated from solution by addition of 50 mL of 25 mM phosphate buffer (pH 7.8) in water. The aqueous extract was filtered twice through filter paper.

In the tube was added 5 mL aqueous extract, then 0.5 mL of methanol and 0.5 mL of 8M sodium hydroxide (NaOH). The tube was closed and vigorously shaken. The contents are filtrated in another test tube. In another test tube, weigh 2 mL of the extract after alkalization, and then add 2 mL of 2M hydrochloric acid (HCl) and 1.0 mL of the Dragendorff's reagent. The tube is closed and vigorously shaken. Leave to stay for a few minutes. It is observed obtaining orange staining of the solution and simultaneous precipitation.

Gas chromatographic (GC-FID) procedure

The CBs were extracted into 20 mL of a methanol solution containing 1 mg/mL sodium hydroxide and 0.24 mg/mL *n*-heptadecane internal standard. The flask containing the extraction solution was stoppered and shaken on a flat-bed orbital shaker at medium speed for a minimum of 40 min. The nicotine content of the extract was determined by using an Agilent 7890B gas chromatograph with a Varian CP Wax 52 CB, 0.53 mm × 2 m × 25 m, fused silica column and flame ionization detector (FID) using ISO 10315 with modification.

Results and Discussion

The amount of retained nicotine in the filter tip after smoking depends on the filter design, the types of tobacco mixture, how the cigarette was smoked, and the mass transfer behavior of combustion products along the cigarette. The smokers have a wide range of smoking habits that can impact emission and deposition of nicotine on filter tip. Regarding the sample preparation we perform machine smoking allows controlling variables such as the size and duration of puffs taken on the cigarette and reproducible generating mainstream smoke.

Although there may be differences in cigarette emissions using a smoking machine compared to a human, we consider that machine smoking obtained reproducible deposition of nicotine on filter tip. Qualitative analysis of nicotine in CBs was carried out using chemical test (Dragendorff's reagent) The heavy metal atom (BiI4) combines with the nitrogen in the alkaloid to form ion pairs. This ion pair forms insoluble orange red colored complex (Pederson 2006). The first step is to dissolve the cellulose with acetonitrile to release the trapped nicotine on the filter butts. After the filter is dissolved, the cellulose acetate is precipitated by addition of phosphate buffer and an aliquot of the filtered solution is tested for alkaloid presence. First we optimize Dragendorff'test for determination of presence of nicotine in aqueous extract of CBs (Pharmaceutical Chemical Analysis: Methods for Identification and Limit Tests). Extraction of retained nicotine from CBs (with and without remnant tobacco on) carried out as follow: in 5 mL aqueous extract was added 0.5 mL of methanol and 0.5 mL of 8M sodium hydroxide (NaOH). Without the addition of methanol during the extraction, the extraction efficiency was less, but was highly variable. The addition of methanol helps to increase efficiency. Free-base nicotine is also the dominant form of nicotine on the cigarette filter when freshly smoked and addition of sodium hydroxide leads to deprotonation of the present monoprotonated and diprotonated form of nicotine. The extract was found to be very efficient when 0.5 mL of 8M sodium hydroxide (NaOH) was added to the solution, but less led to inefficient recovery of nicotine. Alkaloid detecting reagents are solutions of the salts of heavy metals such as Dragendorff"s (potassium iodobismuthate solution KBiI4). The mechanism of action is proposed to occur via coupling of the reagent's heavy metal atom in the reagent with the nitrogen in the alkaloids to form ion pairs. The nitrogen of pyrrolidine ring of nicotine is protonated due to the acetic acid in present of Dragendorff's reagent and the ion pairs to form insoluble orange red colored precipitate. Color disappears with alkaloid's solution in extremely low concentration (Picture 1).

Picture 1. Dragendorff test for nicotine detection in cigarette buts

Confirmation of the nicotine in CBs with and without remnant tobacco also is carried out with GC-FID after extraction of nicotine retained in CBs with methanol solution containing 1 mg/mL sodium hydroxide. Table 1 summarizes mean concentrations of measurement of nicotine retained in the CBs with and without remnant tobacco for of each cigarette samples analyzed by gas chromatography

Table 1. Concentrations of measurement of nicotine retained in the CBs with and without remnant tobacco (n=3, mean±SD)

Sample No.	**Labeled nicotine concentration (mg/cig.)**	**Determined nicotine concentration without tobacco (mg/butt)**	**Determined nicotine concentration with tobacco (mg/butt)**
1	0.3	0.24±0.1	0.28±0.0
2	0.3	0.26±0.1	0.31±0.1
3	0.4	0.61±0.3	0.73±0.4
4	0.4	0.54±0.2	0.67±0.5
5	0.4	0.50±0.4	0.59±0.4
6	0.6	0.91±0.2	1.07±0.7
7	0.6	0.79±0.6	0.99±0.6
8	0.6	0.89±0.7	1.09±0.3
9	0.8	1.24±0.6	1.50±0.3
10	0.8	1.36±0.3	1.61±0.4

Our results confirm the nicotine concentration of orange colored precipitation obtained with Dragendorff’s reagent with nicotine concentration measured by GC-FID. The nicotine concentration in littered butts without remnant tobacco was range from 0.24 to 1.36 mg per butt and with remnant tobacco was higher about 20 to 25 %.

Conclusions

Given the frequently littering of cigarette butts, and the release of nicotine, cigarette butts are assessed to be a relevant threat to the quality of urban environment. While most smokers and nonsmokers today understand that cigarette butt is an environmental problem, a minority of smokers still do not recognize discarded cigarettes butts as waste.

Our results demonstrate that the Dragendorff test can be a useful and simple qualitative method for determine of amount of nicotine retained in in littered cigarette butts (CBs).

Comparison suggests that, for the measurement of nicotine, which is normally conducted by GC with internal standardization, the reproducibility is visible than that observed in Dragendorff test.

Dragendorff test is found to be low-cost, quick and valuable for analysis of moderate and significant levels of nicotine in cigarette butts (CBs). Additionally, the pathways of nicotine released from cigarette butts to urban environment are in need of investigation.

CONSEQUENCES OF FUTURE EXPANSION AT THE ARCTIC TREELINE IN NORTHERNMOST NORWAY

Oddvar SKRE[1*], Stein Rune KARLSEN[2], Jan Åge RISETH[2], Frans E. WIELGOLASKI[3]

Abstract

Seedlings of mountain birch (Betula pubescens var. tortuosa), were transplanted to a site close to the town Vardø, in the arctic part of the Varanger area in northernmost Norway. The site is partly snow-free, sheltered by a willow thicket, and partly on an exposed ditched peat bog with thick snow cover from a nearby snowfence. Annual measurements were carried out on survival and growth parameters. The objective of this review study is to evaluate the consequences of future climate and land-use changes on the birch treeline and local communities on the basis of earlier studies. The preliminary conclusion from this study is that local climate may be more important than the overall climatic variation in the adaptation and reforestation process in northernmost Fennoscandia. In this process, the subarctic willow and shrub vegetation seems to be an important factor influencing the microclimate and seedling establishment. Species and provenances originating from areas with similar latitudes and climatic conditions as the reforestation area, seemed to be most successful. The Varanger area has always been a meeting place between different cultures, i.e. the Sami, Norwegian, Finnish and Russian population. The study indicates that in a changed climate the birch forest area would expand because there will be more willow growth and consequently more safe sites for birch seedling establishment and growth, which would also create a better local climate for the human population. In this process, local birch populations that are adapted to a more coastal climate, would have an advantage. Since birch has been shown to be an important resource for all these cultures, this would decrease the level of conflicts between the different groups of stakeholders about the resources in the area.

Keywords: *Northernmost Norway, mountain birch, Arctic treeline,* treeline.

Introduction

The Varanger peninsula west of the city of Vardø (Fig 1) and the coastline along the adjoining Varanger fjord, is located in the arctic-boreal transition area, between 70-71°N, and 27-31°E in northeasternmost Norway. Most of the area is a true arctic tree less undulating inland plain at 2-300 m altitude, where the highest mountain peak reach 636 m altitude. The dominant treeline species is mountain birch (*Betula pubescens* var. *tortuosa*) with patches of rowan (*Sorbus aucuparia*) and abundant growth of willow species (mostly *Salix phylicifolia and S. glauca*) outside the tree line (Karlsen *et al*., 2005). In the southern and eastern part of the peninsula there are large areas of wetlands and willow thickets. The mean annual precipitation is in the range 365 to 550 mm and mean July temperatures between 9.8 and 12.3°C. The first immigrants after the deglaciation 12 000 years ago were hunters and fishers, mostly on the rich populations of reindeer and marine resources (fish, whale and seal), and there are numerous remains of ancient settlements along the coast (Slettjord, 1993). These are believed to be the forerunner of what was later defined as the Sami population in the area. However,

from about 700 A.C. immigrants from southern Norway started to settle along the coast, where they were living of fishing and fur trade with Russia. The oldest city in northern Norway, Vardø, at the easternmost coast of the peninsula, was established around Vardøhus castle in 1307, to protect Norway/Denmark from Russian and Swedish influence. Around 1500 the wild reindeer population had decreased to a minimum due to overexploitation, and part of the native Sami population in the area then turned partly to a nomadic life form where they started to keep reindeer as domestic animals, travelling up to 200 km between summer pastures at the coast and winter pastures with lichen (*Cladonia* spp.) in the inland areas. Another part continued their fishing and hunting activities and combined this with a small livestock. Their winter settlements were located in the inner part of the fjord, while the summer settlements were located further out along the seaside (Schanche, 2002. Over-grazing and excessive clear cutting have permanently damaged the ecosystems of the outermost coast of the Varanger peninsula more than ecosystems further inland. Currently, reindeer herding has been restored and have grown to be a viable and prosperous industry. However, climate change with milder winters causes ice formation after thawing periods. This makes the lichen difficult or impossible to reach by the animals (*cf.* Tømmervik *et al*., 2004; Tømmervik *et al*., 2005; Riseth *et al*., 2011).
The ecosystems of these coastal districts are now characterized by low regrowth due to the harsh climate with an average tetratherm temperature of June, July, August and September just below 8ºC in recent years. Hovewer, it should be possible to get an "Environmental forest" to survive in the Vardø area, particularly by the present climate change (Skre *et al*., 2002; Skre *et al*., 2005), by choosing the right tree species and provenances and by protection and good shelter especially to the young seedlings (Skre *et al*., 2017). This is true especially for the dominant treeline species *Betula pubescens* var. *tortuosa*, but also for other low tetratherm temperature requiring deciduous trees like *Populus tremula, Prunus padus, Alnus incana, Sorbus aucuparia*. Re-vegetation of most coastal districts in Finmark county today, therefore, probably will require both shelterbelts, protection of populations from grazing, and species adapted to local climate and soil. Indigenous willows, such as *Salix lanata* and *Salix phyllicifolia* grow rapidly and form natural shelterbelts on the coast, often up to 5 m high. As the willow thickets grow older, hardy genotypes of larger and less wind-tolerant species can be transplanted into the natural shelterbelts formed by the willows (without too strong shading) and in small ditches in the lee of furrowed soil ridges on a mixture of mineral and organic soil (Slettjord, 1993).
With this background, the aim of this review study is to evaluate the consequences of the expected climate and land-use changes on the treeline at different scales and their implications for local communities, by summarize some recent results from transplanted birch provenances, and discuss the implications for local communities.

Background

Seedlings from 8 populations of mountain birch (*Betula pubescens* var. *tortuosa*), Fig 1 and Table 1, were transplanted to a subalpine site in Kilpisjärvi (510 m altitude) and an Arctic site in Vardø (15 m altitude). Fig 2 shown a view of the Vardø site. In Table 1 the position and altitudes of the seed populations are shown with the mean January (t_1) and July temperatures (t_7) in °C. The continentality is determined mainly by the amplitude between t_1 and t_7 (Ovaska *et al*., 2005). As a result, populations from Utsjoki (FU), Kevo (FJ and FK), Kilpisjärvi (FKi) and Abisko (SAb) were classified as continental and those from Narsassuaq (GNa), Hafnarskogur (IHa), Blefjell (NB), Melbu (NMe) and Hammerfest (NHa) as oceanic (*cf.* Fig. 1). The seedlings were raised in the greenhouse at University of Tromsø, and transplanted in 2002 to the Vardø and Kilpisjärvi sites as five replicates with 1 m^2 plots and 20 plants per population and replicate (Ovaska *et al*., 2005). The results from this extensive long time study was recently analysed and published (Skre *et al*., 2017).

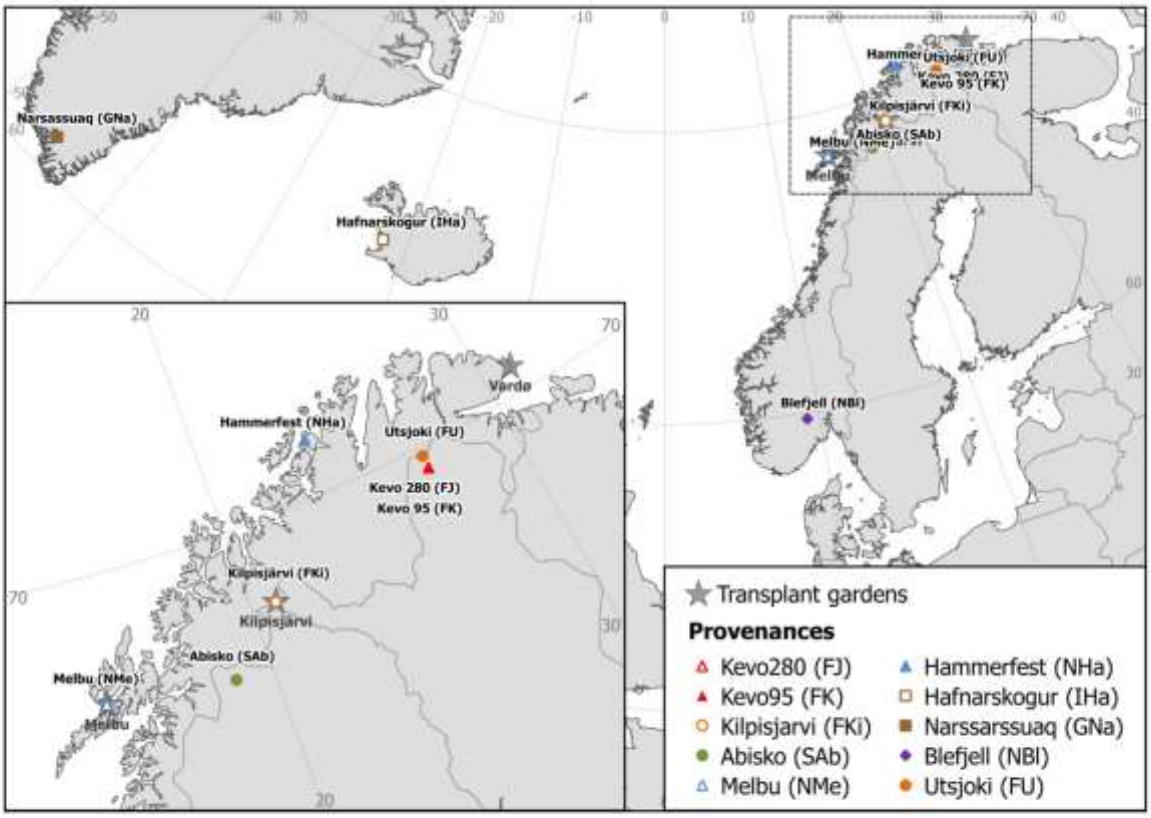

Fig 1. Location of the transplanted gardens at Vardø and Kilpisjärvi (Skre et al. 2017). The map also shows the location of mountain birch provenances transplanted to Vardø and Kilpisjärvi. The Varanger peninsula is located just west of the city of Vardø.

Results and Discussion

Birch ecology. Recently, Skre *et al*. (2017) analysed the extensive dataset of transplanted birch at the Vardø and Kilpisjärvi site (Fig. 1). The survival rates during 2010-14 at Vardø and Kilpisjärvi (planted in 2002) are shown in Fig. 3. At the continental Kilpisjärvi site there was a strong latitudinal effect where the three southernmost populations (NBl, GNa and IHa) were less successful than their northern relatives, but also a certain effect of different oceanity. At the Vardø site, the northern oceanic plants from Hammerfest (NHa) were the most successful in terms of survival rates at both sites. Skre *et al*. (2017) also found that measurements on total living height partly confirmed the results of the survival rates, but with generally much lower growth rates in the plants growing at the Vardø site than at the Kilpisjärvi site, in agreement with summer temperatures (Table 1).

In contrast to the relatively small macroclimatic differences between Vardø and Kilpisjärvi, a clear difference was found within the Vardø site, between the two different parts of the site (Skre *et al*., 2017), illustrating the effect of different snow cover and growing season (*cf*. Holtmeier and Broll, 2005). In this respect the three continental populations (FK, FKi, SAb) seemed to be most sensitive. Negative height increments due to dieback were found in all populations at the four cold and wet plots (Skre, unpubl.). In terms of survival rates and height increment, the warm and dry plot at the Vardø site was comparable to the Kilpisjärvi site (Skre *et al*., 2017).

Table 1. Origin of seed populations, with position, altitude (m), mean temperatures 1961-90* in °C of January (t_1) and July (t_7), The localities are classified as oceanic (-) when the difference between t_7 and t_1 is below 20°C (Ovaska *et al*., 2005).

Fig 2. View of the Arctic Arboretum in Vardø September 2010. In front the cold and wet birch replicates, in the background to the left the warm and dry replicate, sheltered by the willow thicket and the conifer plantation behind. Photo Oddvar Skre.

It is interesting to notice that plants from Iceland (IHa) showed relatively high survival rates in spite of its southern origin (*cf*. Table 1). This adaptation may be partly climatic (Myking, 1999) but also genetic as a result of inbreeding with *B nana* (Anamthawat-Jonsson *et al*., 1993; Thorsson *et al*., 2001).

The present study supports studies on birch ecology as influenced by climate change (*e.g*. Tømmervik *et al*., 2005; Ovaska *et al*., 2005; Johansen and Karlsen 2005; Bjerke *et al*., 2014; Bjerke *et al*., 2017; Skre *et al*., 2017) indicating that climate change with milder winters and longer growing season as well as increasing precipitation may favour mountain birch plants adapted to an oceanic climate, that are less sensitive to frost and insect damages than continental populations. This strongly indicates that mountain birch would be a good indicator for such changes in the future. As expected, the various birch provenances seem to be best adapted to survive and grow in the climate of their origin, while transplantation to a different climate, makes the plants less adapted, Plants with high demands for dormancy breaking (Myking and Heide, 1995), *i.e*. southern and oceanic provenances would have an advantage (Vitasse *et al*., 2014), since also spring frosts caused by premature dehardening would be more common (*cf*. Myking, 1999).

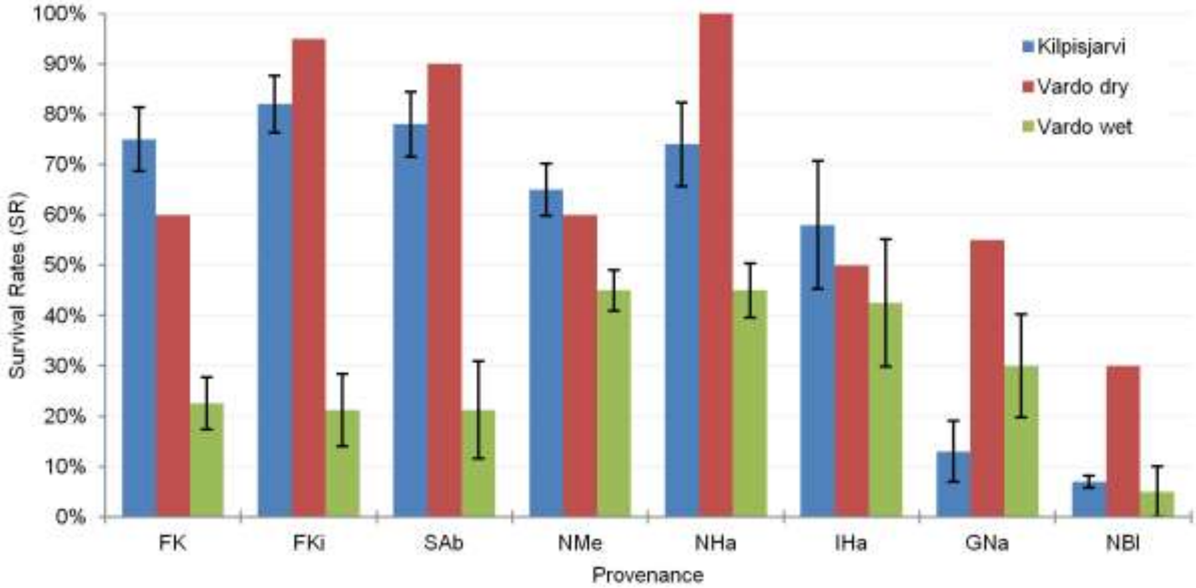

Fig 3. Mean survival rates (%) with confidence limits 2010-14 in birch seedlings from birch provenances (cf. Table 1 and Fig 1) at the cold and warm parts of the Vardø site and in Kilpisjärvi. See Table 1 for acronyms and locations of seed populations. After Skre *et al*., (2017).

Further, predictions for the Varanger region (Hanssen-Bauer *et al*., 2017) indicate an annual temperature increase of 2.1-6.7°C (depending of the scenario used) comparing 1971-2000 with 2071-2100, and 11-17% increase in annual precipitation,. These scenarios towards a more oceanic climate along the coast of northern Scandinavia, is associated with increased risk of insect attacks (Jepsen *et al*., 2011). Polycormic birch with high degree of inbreeding with *B. nana* would then have an advantage (Nilsen and Wielgolaski, 2001). Similarly, oceanic birch provenances (IH, NMe, NHa) would be expected to expand at the expense of continental relatives (FKi, FK, SAb) because they are more adapted to spring frosts (*e.g*. Skre *et al*., 2005). Similar relationships may be used to predict future changes on species level. Scenarios of future forest in northernmost Norway indicate reduction of the continental lichen rich alpine heaths, and such changes would have consequences for the reindeer grazing system, as the predicted changes would lead to a decrease in the vegetation types that have high winter grazing accessibility for reindeer (Karlsen *et al*., 2017).

Mountain birch as a socio-ecological factor in northernmost Norway. Earlier investigations seem to indicate that in addition to climate, land-use change like overgrazing by reindeer and abandonment of farmland is an important driver of change (*cf*. Körner and Paulsen, 2004, Bryn, 2008; Aune *et al*., 2011). The frequent insect attacks by geometrid moths are also related to climate change. Increased reindeer grazing as well as insect attacks would be expected to slow down treeline advance as stated by Neuvonen et al. (1999) and Jepsen *et al*.

(2008), while reduced reindeer grazing would enhance treeline advance (Neuvonen *et al.*, 1999). The study also indicated that local climate may be equally important than the overall climatic variation in the adaptation and reforestation process in northernmost Fennoscandia. In this process, the subarctic willow and shrub vegetation seems to be an important factor, influencing the microclimate and seedling establishment. Different snow and temperature conditions are the main selective factors, and the northern Hammerfest population (NHa) seemed to be most successful at this site. Finally, birch plants growing close to treeline seem to be subjected to frequent frost damages causing dieback of annual shoots and negative height increment. The birch forest has traditionally been used by the Sami for different purposes (*e.g*. Aikio and Müller-Wille, 2005) i.e. firewood heating, building material and handicrafts, and is a valuable resource for the aboriginal Sami population, but have also been very important for the Norwegian settlements along the coast (Slettjord, 1993). As a result, large areas along the eastern coast of the Varanger Peninsula were deforested. During the last centuries, there have also been many conflicts between the different cultures and life forms in the Varanger area, i.e. between Sami reindeer herders and Norwegian and Finnish («kvenish») sheep farmers about summer pastures and birch forests (Riseth 2007). The central part of the Varanger Peninsula is since 2006 a national park area, where construction and roadbuilding activities are restricted because of the wildlife and vegetation (Riseth, 2007). Altogether, this mixture and interactions between different cultures and life forms makes the Varanger peninsula a very good example of commitment of local communities to their environment, including the relationship and partnership between different stakeholders about sharing resources and ecosystem services. The main traditional products from the farmers in the area is sheep and cattle meat and milk products, while the reindeer herders produce reindeer meat and handicrafts, e.g. hide, carved reindeer horn and birch wood products. The sheep and reindeer husbandry in the study area is providing a number of ecosystem services, like landscape protection and biodiversity, and preserving cultural and spiritual values, as well as income and employment. During the recent decades, the economy has gradually changed from primary to secondary sector activities like agrotourism (small restaurants, farm shops and hotels) where tourists can stay overnight with breakfast, taste local food and buy locally produced handicrafts, as well as performing guided tours and hiking trips in the national park and along the coast for recreation, and visits to bird cliffs and fishing villages.

Conclusion

Studies on traditional sustainable and balanced use of ecosystem services by different stakeholders/cultures, e.g. reindeer herders, sheep farmers, local enterprises (*e.g.* Müller-Wille *et al*., 2005), indicate how to make use of them in a sustainable way in an arctic environment and how possible conflicts between user groups has been solved in a successful way. The present study seem to indicate that although local birch provenances seem to be best adapted at present, more oceanic provenances may have an advantage in the future, and in a future climate with extended birch and willow growth along the Arctic coast of Norway, balanced use of grazing areas by sheep farmers and/or reindeer herders would be easier to achieve. With better grazing conditions, good relationships between reindeer herders and conservationists and ecotourism in the national park area in the inner part of Varanger peninsula, would also be expected. However, because the lichen is a limiting factor for reindeer grazing in winter, the changed climate would represent a challenge for reindeer herders, and compensation measures like strict population control and/or supplementary winter food would be necessary. In this respect, the increased birch and willow growth would represent a valuable resource – not only for reindeer herders, but also for sheep farming, sustainable tourism and the well-being of the local population.

Abstract

The tests aimed at the determination of the influence of granulation, compaction and the shear rate on the shear strength parameters, which is the angle of internal friction and cohesion of the unburnt coal mining waste from the mine "Anna" from Upper Silesia (Poland) with grain sizes less than 10 and 40 mm. The tests were conducted in a standard (sample size 12×12×7.5 cm) and a medium size (sample size 30×30×13.6 cm) direct shear apparatus respectively for finer and coarser material. The shear rate was 0.1 and 1.0 mm·min^{-1}, and the maximum value of the shear stress in the range of relative deformations up to 10% was assumed to be the shear criterion. The test samples were formed at the optimum moisture content to achieve a degree of compaction I_S = 0.90 and 1.00. According to the geotechnical nomenclature, the examined waste was classified as multi-fractional medium sand gravels (d < 40 mm) or fine sand gravels (d < 10 mm). The carried out research revealed a significant effect of granulation on the values of the shear strength of the coal mining waste – as the grain thickness increased, the angle of internal friction decreased and cohesion increased. There was a similar effect of compaction and shear rate on the shear strength parameters for both grain sizes of the examined waste. The increase in compaction caused an increase in the angle of internal friction and cohesion, and the increase in shear rate resulted in a slight increase in the angle of internal friction and a noticeable reduction in cohesion.

Key words: *Coal mining wastes, Earth structures, Angle of internal friction, Cohesion.*

Introduction

The use of industrial waste for earth structures, in particular for road construction, has become of major importance in recent years. This is due to, among others, the shortage of masses of soil used for the construction of motorways, expressways, city bypasses and other investments. In addition, industrial waste is cheap and can compete effectively with mineral raw soil materials.

Coal mining waste used in the broadly understood earth structures is mainly produced in the mining industry (gangue in the case of hard coal mining) but also in mineral processing (mineral waste) (Gruchot, 2016; Skarżyńska, 1997). Utilization of the waste for road construction requires assessment of their usability, which is based mainly on their geotechnical properties, and in particular the parameters of shear strength (angle of internal friction and cohesion). The values of these parameters influence the stability of the embankments or the bearing capacity of the subsoil. It is therefore important to define them correctly by applying the appropriate test method (test apparatus) to the planned working conditions after incorporating the waste into the structure.

For the purposes of engineering practice, direct shear apparatus is used to determine the angle of internal friction and cohesion of coarse-grained soils, such as the coal mining waste (Gruchot, 2016; Zadroga, 1994). The general principle of the test consists in measuring the limit of soil resistance at a known normal load, and the sample shearing occurs in the plane or zone forced by the construction of the apparatus. In the case of the coarse-grained materials, there is a problem of selection of the grain size to the dimensions of the sheared sample. According to Pisarczyk (2004) the width of the apparatus box should be at least 4 to 6 times greater than the maximum diameter of the sheared material grains. That is why it is recommended to use the medium-sized apparatus where the research can be done on a material with a particle size similar to the natural.

The study aimed at the determination of the effect of granulation, compaction and shear rate on the shear strength parameters of the selected coal mining waste. For the research, there was used unburnt coal mining waste from the Coal Mine "Anna" in the Upper Silesian Coal Basin in southern Poland, with natural granulation as well as the granulation less than 40 and 10 mm.

Tests methods

Basic physical properties and compactibility parameters of the tested coal mining waste were determined by standard methods. Granulometric composition was determined by sieve method for particles coarser than 0.063 mm and areometric method for finer particles, and the density of solid particles by means of a volumetric flask in distilled water. Optimum moisture content and maximum dry density of solid particles were determined in a Proctor's apparatus in a cylinder with a volume of 9.8 and 2.2 dm^3 for the waste with a grain size finer than 40 and 10 mm respectively, at the compaction energy 0.59 $J \cdot cm^{-3}$.

Determination of the shear strength parameters of the material with grains finer than 40 mm was performed in a medium-sized direct shear apparatus for samples of the cross-section dimensions 30×30 cm and the height of 13,6 cm. Whereas, the tests of the material of the granulation finer than 10 mm were conducted in a standard direct shear apparatus for samples of the cross-section dimensions 12×12 cm and the height of 7,5 cm (Cisek, 2004). Intermediate frames were used to limit the impact of interlocking the grains on the cohesion values in both pieces of apparatus, which led to obtaining a 3.0 cm thick (6 intermediate frames) and 1.0 cm thick (5 intermediate frames) shear zone, in the standard and medium-sized shear apparatus, respectively. It was assumed, that the thickness of the shear zone should be equal or close to the maximum diameter of the tested material grain. The samples were formed directly in the box of the apparatus, at the moisture content close to the optimum one, until the degree of compaction I_S = 0.90 and 1.00. Consolidation and shearing of the samples were performed at normal stresses of 50, 100 or 110, 200, 300, 400, 600 kPa. The shear rate was 0.1 and 1.0 $mm \cdot min^{-1}$, and the maximum value of the shear stress in the range of relative deformations up to 10% was taken as a shear criterion.

Results and discussion

Petrographic composition

The petrographic composition of the investigated coal waste was dominated by claystone, which accounted for 82%, mudstone interlayers being adjacent to claystone were 14%. The content of the carbon shale together with the coal chips was low and amounted to 3%. Sandstone chips were also present in the tested material in an amount of 2% (Fig. 1).

Physical properties

In the coal mining waste with the natural granulometric composition, the gravel was the dominating fraction that amounted to 68%, sand fraction was 16%, cobbles 8%, and silt and clay fraction – almost 8%. In the material with the granulation finer than 40 or 10 mm, the gravel fraction also dominated, and amounted to 71 and 58%, respectively, the sand fraction, was 28 and 20%. Whereas the content of the finest fractions, i.e. silt and clay was 9% in the material of the granulation finer than 40 mm and over 14% in the material of the granulation finer than 10 mm (Fig 2). According to the geotechnical nomenclature (PN-EN ISO 14688-2:2006), the tested waste of the natural granulation was classified as multi-fractional medium gravel with a small content of cobbles, and sandy medium gravel (d < 40 mm) or sandy fine gravel (d < 10 mm) (Tab. 1).

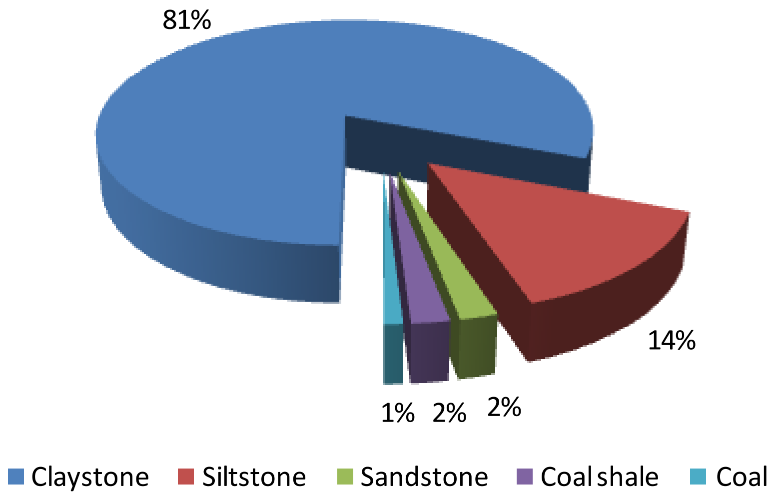

Fig. 1. Petrographic composition of the tested material

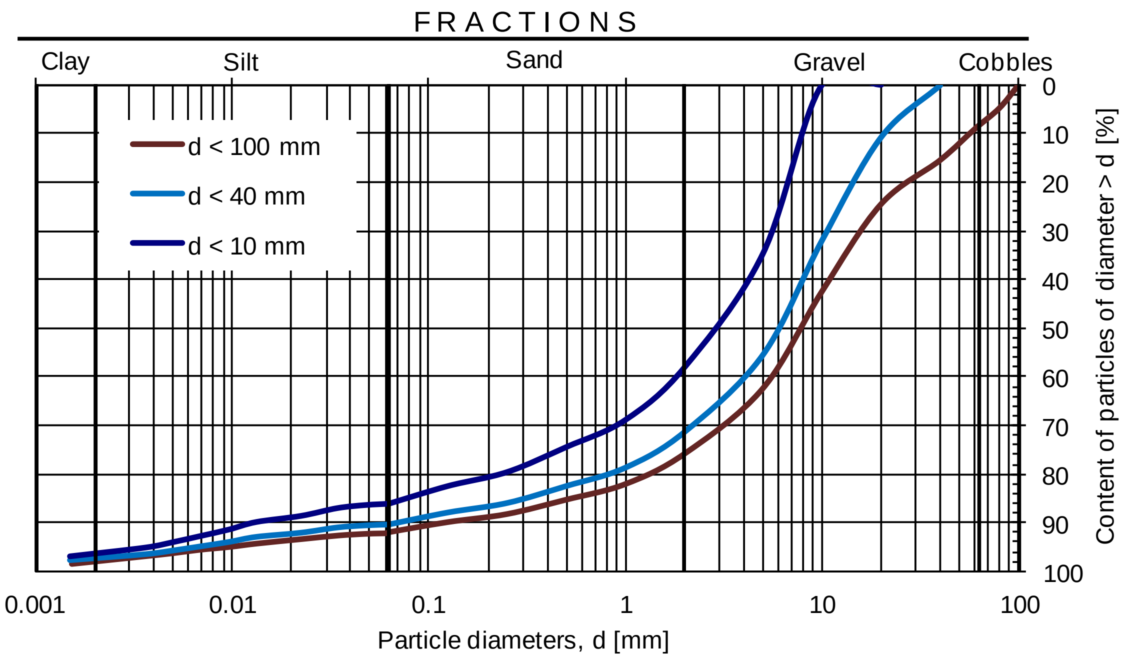

Fig. 2. Grain size distribution curves of the tested coal mining waste

Density of solid particles of the coal mining waste was equal 2.39 $g{\cdot}cm^{-3}$. Maximum dry density of solid particles of the waste finer than 10 mm was 1.76 $g{\cdot}cm^{-3}$ and increased up to 1.86 $g{\cdot}cm^{-3}$ with increasing thickness of the grain size up to 40 mm, at the moisture content decreasing with the increase of the grain size and amounting to 12 and 8.5%, respectively.

Table 1. Geotechnical characteristics of the tested coal mining waste

Parameter	Grain size distribution		
	d < 100 mm	d < 40 mm	d < 10 mm
Fraction content (%): - cobbles, Co (> 63 mm), - gravel, Gr (2–63 mm), - sand, Sa (0.063–2 mm), - silt, Si (0.002–0.063 mm), - clay, Cl (< 0.002 mm).	 8.1 67.9 16.2 5.3 2.5	 0.0 70.7 20.3 6.0 3.0	 0.0 58.0 27.5 10.3 4.2
Uniformity coefficient [–]	85.7	106.7	300.0
Coefficient of curvature [–]	6.1	8.8	13.8
Content of grains greater than 10 mm [%]	42	32	–
Soil name according to (PN-EN ISO 14688-2:2006)	medium gravel with a small content of cobbles (coMGr)	sandy medium gravel (saMGr)	sandy fine gravel (saFGr)
Density of solid particles [$g \cdot cm^{-3}$]	2.39		
Optimum moisture content [%]	–	8.50	11.95
Maximum dry density of solid particles [$g \cdot cm^{-3}$]	–	1.855	1.76

Shear strength parameters

The obtained values of the angle of internal friction were high and ranged from 33 to 40° and cohesion ranged from 22 to 39 kPa for the coarser waste (d < 40 mm). For the finer waste (d < 10 mm) the same parameters values ranged respectively from 37 to 41° and from 15 to 38 kPa (tab. 2). There was a clear effect of compaction and grading on the values of the angle of internal friction and cohesion at both shear rates.

The increase of the value of the angle of internal friction together with the increase of the compaction from I_S = 0.90 to 1.00 for the waste of the granulation finer than 40 mm was by 2 and 4° (by 5 and 12% relatively), and for the waste of the granulation finer than 10 mm was smaller and was by 1 and 2° (2.5 and 5% relatively) (Fig. 3a). The smaller values from the given increment range were obtained at the higher shear rate, i.e. 1.0 $mm \cdot min^{-1}$. The increase of the shear rate from 0.1 to 1.0 $mm \cdot min^{-1}$ resulted in an increase in the angle of internal friction by 5 and more than 2° for the coarser waste, and by about 2 and 1.5° for the finer waste, with larger increment of these parameters occurring at smaller compaction (I_S = 0.90).

The increase in the compaction resulted also in the increase in the cohesion of the tested coal waste. For the waste of the granulation finer than 40 mm, the increase amounted to by about 7 and 13 kPa (by 20 and 58 % relatively), and for the waste of the granulation finer than 10 mm – by 14 and 9 kPa respectively at the shear rate 0.1 i 1.0 $mm \cdot min^{-1}$ (Fig. 3b). The increase in the shear rate caused the decrease in cohesion by 5 and 11 kPa for the coarser waste and by 9 and 15 kPa for the finer waste, at the compaction I_S = 0.90 and 1.00 respectively.

An analysis of the impact of the grain size revealed that the highest values of the angle of internal friction were obtained for the waste of the granulation finer than 10 mm, and they were higher by 4 and 2°, at the shear rate 0.1 $mm \cdot min^{-1}$ and by 2 and 1°, at the shear rate 1.0 $mm \cdot min^{-1}$ in relation to the coarser waste (Fig. 3a) at the compaction I_S = 0.90 and 1.00 relatively.

The highest values of the cohesion were obtained for the coarser waste. The increase in the grain size of the tested materials caused the decrease in cohesion by 8 and 1 kPa at the shear

rate 0.1 mm·min^{-1}, and by 6 and 11 kPa at the shear rate 1.0 mm·min^{-1}, at the degree of compaction I_S = 0.90 and 1.00 respectively.
Hence, it can be concluded that the increase in the compaction were followed by the decrease in differences between the values of the shear strength parameters of the waste of different granulation.

Table 2. Values of angle the of internal friction (ϕ) and cohesion (c) of the selected coal mining wastes

Shear rate	Degree of compaction	Grain size distribution			
		d < 40 mm		d < 10 mm	
v_s [mm·min^{-1}]	I_S [–]	ϕ_{40} [°]	c_{40} [kPa]	ϕ_{10} [°]	c_{10} [kPa]
0.1	0.90	33.4	32.3	37.4	24.1
	0.95	36.1	34.9	38.5	32.8
	1.00	37.4	38.8	39.2	37.9
1.0	0.90	38.0	21.6	39.6	15.1
	0.95	39.3	29.9	40.0	18.3
	1.00	39.8	34.1	40.6	24.0

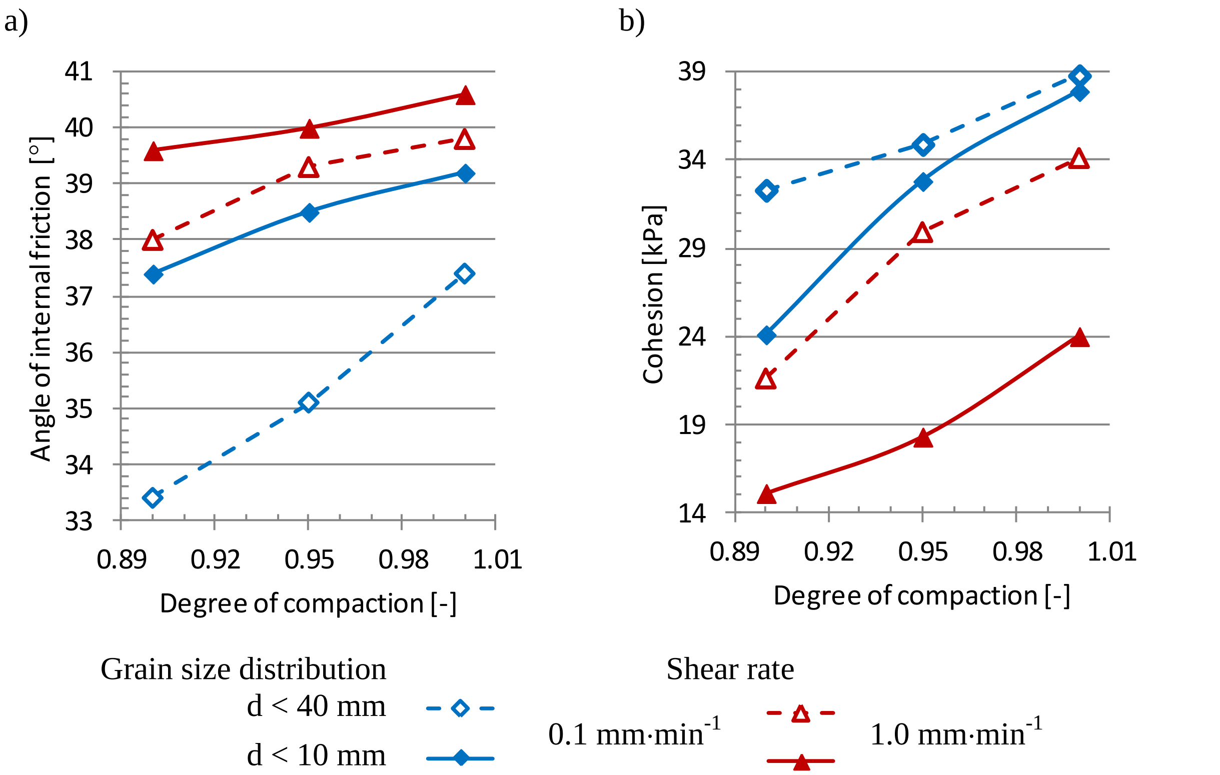

Fig. 3. Influence of compaction on the angle of internal friction (a) and cohesion (b)

Conclusion

The conducted research showed the impact of the granulation on the angle of internal friction and cohesion of the coal mining waste from the coal mine "Anna". The effect of compaction and shear rate on the shear strength parameters for both tested ranges of the waste granulation was also found. The increase in compaction caused the increase in the angle of internal friction and cohesion, and the increase in the shear rate resulted in the slight increase in the angle of internal friction and the significant reduction in cohesion.

It should be noted that the coal mining waste is characterized by geotechnical properties, which largely depend on their petrographic composition and grain size distribution as well as the time of their storage. Sifting thicker fractions can cause significant changes in petrographic and granulometric composition. Therefore, it is recommended to carry out tests in medium-sized apparatus, on the material with the granulation close to the natural one.

Abstract

Natural values are the main potential aspects for development of rural communities. It was presented natural evaluation method focused on classification values of landscape. The whole stages of natural evaluation depend on the main purpose of research. The main question is: it will be doing for example for toursim or protection aspects? Proper selected criteria of natural evaluation are first success of this method. The purpose of this paper was to classify natural values of Nasielsk commune and to formulate directions for protection and touristic aspects.
Nasielsk commune is located in the north-east part of Poland. It was recognized natural elements and prepared selected criteria of evaluation as diversity of plant communities, naturalness of vegetation, protected forms, water surface, Natura 2000 habitats, vegetation availably for recreation. Natural evaluation included division of study area into landscape special units, formulated criteria to assessment, scale of values. Scale of values was characterized by points from 1 to 5 points. Areas with different natural values were distinguished. Areas were classified into three groups: areas with high natural values, areas with medium natural values and areas with low natural values. The last stage of work was formulating directions for protection and tourism on studied area.

Keywords*: Evaluation, Rural areas, Landscape management.*

Introduction

Natural evaluation is very important and usefulness method for characteristic of biotic and abiotic values of landscape elements (Mazurski, 2012, Myga-Piątek 2007, Żarska 2011, Żarska et.al. 2014). There were presented many evaluation methods focused on quality of landscape elements as LANDEP method (Landscape Ecological Planning), GEM (*General Ecological Model).* The whole stages of natural evaluation depand of the main purpose of research. Is it will be doing for toursim or protection aspects? Natural evaluation is most often done with the addition of bonitation assessment, which takes into account the different characteristics of the environment. So far, no universal method has been developed for natural evaluation. The most appropriate way is to mix and modify the various methods to adjust the evaluation criteria to the area being analyzed. The basic problem of preparing natural evaluation is the selection of the proper basic field. For the implementation of the evaluation of the landscape, the division of the examined area into the "basic assessment" fields is used. Using the term "basic field" we mean a unit of space, which can be uniquely attributed to a certain value obtained in the evaluation of the environment(Bajerowski 2007). There are three basic criteria for determining the shape and size of the basic fields: separation of units corresponding to administrative fields, artificial separation of homogeneous geometric fields, the unmistakable advantages of which are equal surfaces, which makes them comparable. Often within the boundaries of one field there are areas of varied nature, the separation of natural units - geocomplexes, which are homogeneous internally and characterized by uniform features and values of the landscape, but they have uneven surfaces (Balloon 2007). The next ste is to formulated proper criteria of natural evaluation for example for landscape management.The main purpose of this article is natural evaluation for tourism aspect on example of Nasielsk commune in Poland.

Material and Methods

Nasielsk commune is located on central part of Poland covering an area of 205,77 square kilometers. It is a typical agricultural commune with mosaic parts where natural plant communities are growing. Forests are represented by few communities as: *Peucedano-Pinetum* on upper sandy habitats, *Tilio-Carpinetum* on fresh soils and *Fracino-Alnetum* along the river valleys. It was observed here many local depressions where wet meadows (*Molinion*) are occurred. Water and rushes plants are strictly connected with the rivers and local small natural ponds. It was also recognized fresh meadows and pastures. Synatropical plants (*Artemisetea vulgaris*) are growing mostly on fields and settlements.

Methodology is included fields and indoor studies. It was recognized natural elements and prepared selected criteria of evaluation as diversity of plant communities, naturness of vegetation, protected forms, water surface, Natura 2000 habitats, vegetation availably for recreation.

Natural evaluation was included division of study area into landscape special units, formulated criteria to assessment, scale of values. Scale of values was characterized by points from 1 to 5 points.

Bonitation points:

5 point – very high values/occurring
3 - 4 points – high values/occurring
2 points – medium value/occurring
1 point – low value/occurring

The last stage of analysis was distinguished areas with different natural values. Areas was classificated into three groups: areas with high natural values (10 and above 10 points), areas with medium natural values (from 5 to 9 points), areas with low natural values (from 1 to 4 points).

Results and discussion

Different types of special-landscape units were distinguished in Nasielsk commune. They are represented by forests (59 units), river valleys (2 units), settlements (14 units) and agriculture units with mosaic of fields, pastures and meadows (29 units).

Forest unities are represented by coniferous community (*Peucedano-Pientum*) and decidious communinity (*Tilio-Carpinetum*).

River valley unities – are chercterised by riperian forests, rushes and water plants and wet meadows (*Molinetalia*).

Settlement units– are included villages and small towns with accomanio vegetation (gardens, orchards, alloments).

Agriculture unities – have mosaic structure with fields, fresh meadows and pastures.

The most valuable special-landscape units are represented by river valleys, forests and one agriculture unit (A23) with share of groups of trees and small agriculture ponds with water and rushes vegetation. Riparian forests, water and rushes plant communities are dominated in river valleys. These units are the most valuable in studded area. Only one protected form as ecological ground is located on the south part of Nasielsk commune (A23).

S – settlement units
RV – river valley units

<u>Areas with different values and availability for touristic aspect:</u>

I – areas with high natural values for protection and tourism aspects(10 and more points) – 62 special-landscape units
II- areas with medium natural values for protection and tourism aspects (from 5 to 9 points) – 43 special landscape units
III–areas with low natural values for protection and tourism aspects (from 1 to 4 points) – non
It is observed landscape fragmentation and human pressure on natural elements in Polish rural areas (Orłowski and Nowak 2007). Agricultural communes as Nasielsk are dominated in Poland. That's why proper management is demanded for keeping existing natural values. It is a priority in political strategy of commune how to shaping the landscape for touristic of protection aspects. Evaluation is very easy and usefulness method which help to classificated landscape values (Żarska et al. 2014). Natural vegetation is the most valuable element in ecological corridors because of high biodiversity of plant species (Żarska et al. 2014). Polish river valleys are not melioratied yet and characterised by rare vegetations as riperian forests, water and rushes vegetation (Żarsak B. et al. 2014). Moreover old forests do not take a large areas too so small group of plantings and small forests should be keeping in good condition in rural landscapes (Liro and Szacki 1993, Shields et al. 2000). These whole presented reasons describe the purpose of natural evaluation on rural areas

Conclusions

1.Natural evaluation is very useful and important stage of landscape analysis for proper management, for example for touristic and protection aspects of Nasielsk commune.
2. It was achieved 52 special landscape units with high natural values and 43 special landscape units with medium values. It was no areas with low landscape values.
3. The preparation of the evaluation of the area for tourism and recreation is an indispensable process indicating the potential of the municipality's tourism.
4. It is important to emphasize the importance of drawing up such studies by local governments interested in the development of tourism in their region.

Abstract

The landscape reserve „Skarpa Ursynowska" is one of the 12 nature reserves situated in Warsaw (Poland). It was created in 1996 to protect piece of the high Vistula escarpment along with meadows and peat bogs of high natural values, which are located at the foot of Vistula escarpment. Cessation of management (from 1998 year) and the neglected, non-functioning drainage system for many years, as well as the storm canal banks covered with the concrete, have contributed to changes in habitat conditions and in botanical composition of post-marsh meadow communities. Floristic impoverishment of meadow communities, development of herbaceous (mainly willow) communities and invasive, arable land weeds and ruderal plants were demonstrated. These communities were characterized by small natural values, which reduced the aesthetic and landscape value of the reserve. The inadequate protection status of the meadow communities of the "Skarpa Ursynowska" reserve obliges to take action to stop the above mentioned processes and to restore the multi-species meadow communities. For this purpose, seedlings of wild flowers, dicotyledonous plant species (grown in laboratory conditions from seeds obtained from natural sites) were planted. The studies were carried out during 2015–2016. The growth and development of plants, the condition and range of the populations and the threats of 22 plant species were determined. It was found that most populations of species from drier habitats survived and unsuccessful were especially species with higher water requirements. On that basis, further protective measures were established.

Keywords: *Restitution of meadow species, wild flowers, post-marsh meadow, „Skarpa Ursynowska" nature reserve, Poland.*

Introduction

The flora of the meadows and pastures is one of the most endangered elements of the vegetation. The impoverishment of the floristic diversity is being observed in the whole world, in various types of grassland communities (Pärtel *et al.*, 2005). The threat to the Polish flora, although lesser than in Western Europe, increases rapidly (Trąba *et al.,* 2006; Warda and Kozłowski, 2012; Kucharski, 2015). The community of floristic-rich "lowland hay meadows" *Arrhenatherion elatioris* (6510-1), for example, becomes more and more sparse. It is typical for the areas outside the rivers' floods, on the eutrophic and mesotrophic habitats, not especially humid or dry. Thanks to colourfully flowering plants these meadows belong to the most decorative elements of the landscape (Kozłowski, 2002). The most important reasons of the decreasing in floristic diversity of the meadows are the habitats' fragmentation and their degradation, caused mainly by the irrational human activity (Plantureux *et al.,* 2005; Winter *et al.,* 2008). More than 1/3 of the threatened species in Poland dies because of too small ranges of the local plant populations (Falińska, 2004). The excessive drying of the habitats, especially on the organic soils, influences the intensification of the decomposition process, the mineralisation of organic substance and the decreasing in physicoaquatic properties of the soils (Kozłowska, 2005). These changes are progressed due the abandonment of management, what causes negative changes in the species composition of the meadow communities (Zarzycki and Misztal, 2010; Sienkiewicz-Paderewska *et al*., 2012; Janicka *et al*., 2016). It is being evaluated that the half of grassland in Poland is neglected or degraded, and the part – excluded from use. The improvement of the floristic diversity of the meadows' communities requires the active protection and the restoration of the flora. The choice of the method depends on the species, the restoration area and financial possibilities (Hedberg and Kotowski, 2010; Scotton *et al*., 2012). The seedlings' production and planting is the best method of the rare and threatened species' introduction, which dispersal is limited, and the species of low light, nutrients and water-competition, what effects the low survivability of the seedlings and young plants in the presence of primary sward (Walker *et al*., 2004; Wallin *et al*., 2009). The aim of the studies was the evaluation of the possibilities of increasing in meadow communities' floristic diversity as the result of species introduction to the impoverished meadow-patches dominated by *Arrenatherum elatius* in the landscape reserve "Skarpa Ursynowska" and the restoration of its environmental values, basically the landscape and aesthetical functions.

Material and methods

The study area. The landscape reserve "Ursynowska Slope" is one of the twelve natural reserves in Warsaw (Poland). It was established in 1996 to protect the part of the high Vistula Slope (the highness of the slope in the reserve area – 5-18 metres, gradient 24-60^0) with the meadows and peatlands of high natural value at its background (20,8 ha, the insulation cover 155,35 ha) (The Edict, 1996; 2011). That area is the part of Warsaw Area of the Protected Landscape (The Edict, 2007). It is characterised by the presence of 126 taxa of the vascular plants, including *Dryopteris cristata*, the threatened species (Category V according to Zarzycki *et al*., 2002) (Wysocki and Budzikowski, 1996; Grabowska, 2016). Amongst the mycobiota three species from The Red Book of Polish Plants and Fungi are being noticed (Snopek 2016). The reserve serves as the migration corridor, provides the nesting or breeding sites for the amphibians, birds and mammals. It is the refuge for the invertebrates with many rare species, including daylight butterflies, such as *Lycaena dispar*, *Polyommatus bellagrus* and *Cupido argiades* (Kozłowski and Sielezniew, 1996; Snopek, 2016).

The meadow site covers 12 quarters (10.7 ha). It was drained and managed in the years 1952-1953. In the seventies and eighties of XX century the intensive pasture-meadow management was carried out on that area. After the system transformation the management was limited to the one, summer cut. Since 1998 the meadow communities are not being mowed.

The water conditions are being shaped with constant groundwater inflow from under the slope and frequent surface runoff. As the result the low peats on the loose sands were developed (Pawłat *et al*., 1996). On the majority of the meadow area the muck soils, subtype peaty-muck (30-40 centimetres of muck layer) with strongly decomposed peat (25-50 centimetres) are present. Below the sandy formations and locally gyttja occur. The soils in the root layer characterise themselves by very large amounts of phosphorus (more than 1050 mg P·kg^{-1} d.m. of the soil), very small amounts of potassium (85-228 mg K·kg^{-1} d.m. of the soil) and pH in the range from 5.5 to 6.8 (Janicka *et al*., 2016). The groundwater level maintains during the vegetation period at 60-90 (120) cm.

The surveys were carried out in the years 2015-2016. The vegetation period in 2015 was unusually warm and dry, the Vinczeffy hydrothermic index was equal only to 0.091 mmC^{-1}. The July, August and September were described as extremely dry (Vinczeffy, 1984). The winter period 2015/2016 characterised itself by low temperatures and the lack of snow coverage. In 2016 the summer was not such hot as in 2015 and the hottest month was June. The water supply for the plants was generally good.

The methods. In the spring of 2015 (after the previous cutting of sward) twenty two native plant species were introduced to the *Arrhenatherion elatioris* community (Tab.1). The diasporas were collected on the meadows of PLH 140016 protection area near Mniszew (Kozienice county, Mazovian voivodeship) in 2014. The seedlings from the laboratory were planted in the northern part of the reserve (geographical coordinates 52°16’ N; 21°05 E). The following parameters were being determined: (1) the plants’ growth and development – once a month the heights were measured, in three points on the diagonal of the area covered by peculiar species and the developing phase was determined, (2) the community range (in cm^2), (3) the community condition in the 5-points scale:

very poor condition, more than 80% of the plants wither or yellow,
poor condition, 50-80% of the plants wither or yellow,
average condition, 30-50% of the plants wither or yellow,
good condition, 5-30% of the plants wither or yellow,
very good condition, plants brightly green, traces of withering or yellowing.

The results were analysed statistically with use of the variance analyses (ANOVA) and the Tukey test with significance level 0.05.

Results and Discussion

In the literature dedicated to the aim of the study the risk of meadows' disappearing in the "Ursynowska Slope" reserve due to secondary succession connected with the lack of regular use was considered many times (Wysocki and Budzikowski, 1996; Rutkowska *et al.*, 1999; Janicka, 2000; Janicka and Kwiecień, 2004; Grabowska, 2016). The environmental evaluation of the *Arrenatherion elatioris* communities, carried out in the years 2013-2015, shown the significant dumbing down of the species composition of the meadow communities, the development of the *Filipendulo-Petasition* communities and the invasive, segetal and ruderal plants. These communities are characterized by low natural values, what is being denoted by the low values of Shannon-Wiener coefficient (0.34-0.95) and the natural valorisation index (1.8-2.1) (Janicka *et al.*, 2016). The significant share of *Urtica dioica*, dominating on 1/3 of non-forest communities' area, impacts the decreasing the aesthetic and landscape values of the reserve. Furthermore, that species indicates the mineralisation of the organic substrate and permanent drying and softening of the outer layer of the soil. The condition of the meadow communities in the reserve is the result of abandonment of management and neglected, non-functional for many years reclamation system and the covering with concrete the banks of the storm channel. The improper state of these communities protection obliges to perform the activities up to stop of the sward degradation processes. Twenty two species of wild flowers were introduced for that purpose.

The hierarchic data clustering for two estimated parameters (the range and conditions of the community) of the introduced species made possible to set apart two basic groups of different probability level (Fig.1). In the first one the fast developing and systematically increasing their ranges species, which may be used for the introduction to the reserve area, were placed. Four of them should be distinguished: *Achillea millefolium*, *Veronica longifolia*, *Dianthus deltoides* and *Inula britannica*. These species underwent the unfavourable weather conditions as well as the competition of the old sward vegetation. The ranges of their communities in the second year of the surveys were about 4-10 times larger than in the previous year (Tab.2). Additionally, four species (*Tragopogon pratensis*, *Verbascum thapsus*, *Centaurea stoebe* and *Plantago lanceolata*), which communities developed rapidly and were characterised by the widest ranges in the first year, but the next year, after forming the flower buds and setting up the seeds, died out or their ranges decreased significantly, were included to that group. The prime three of the mentioned species are biennial, well tolerated the droughts. They may develop successfully in the following years from the seeds of the soil seed bank. *Plantago lanceolata*, on the other hand, is the low, rosette species, shade-sensitive species. It was present in the reserve area in the former period, when the sward was partially grazed. Introducing that species, one has to remember about systematic sward cutting-off.

In the second, assigned with the use of data clustering method, group of the species the ones characterized by poor development after planting and quick coming out of the sward, were placed. The following four shown poor conditions in the short time after planting: *Armeria maritima*, *Lythrum salicaria*, *Sanguisorba officinalis* and *Thalictrum flavum* (Tab.2). The strong drying out of the habitat, long-lasting summer drought in 2015 or too strong competition of the primeval sward species could be the reasons of their elimination. The disappearance of *Armeria maritima* was the effect of serious harms of the leaves, caused by the birds. It is worth stressing that from the species mentioned above *Sanguisorba officinalis* and *Lythrum salicaria* were present before in the reserve area, but they cannot be recommended at present habitat conditions.

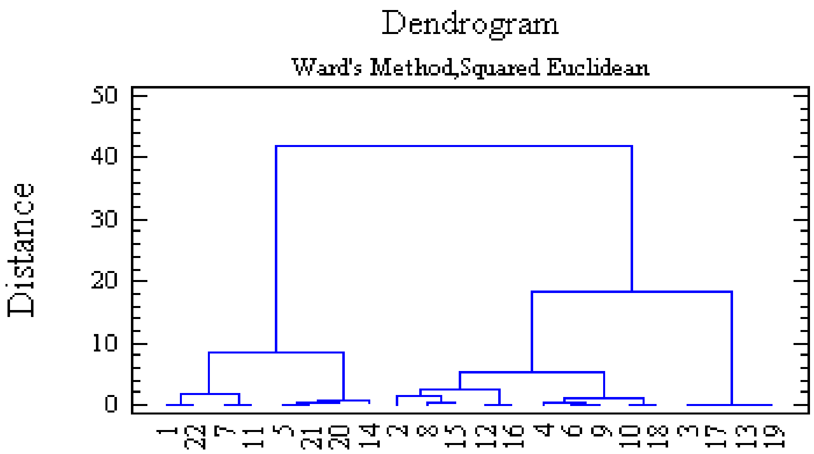

Fig. 1. The dendrogram and the groups of the species of similar range and community condition (the average from the study period). The numbers of the species are in accordance with the ones in the tables.

Table 2. The state of the populations of planted species during first two years of the vegetation (September 2015 and 2016)

- eliminated, * shorter vegetation, ** destroyed by the animals

Conclusions

The results of the study denote the efficiency of the species introduction (especially the ones of drier habitats) to the *Arrhenatherion elatioris* communities and improving their floristic diversity. The planted species will be monitored during next years. The stabilisation or increase in population size of the species, affirmed by multi-years observations, will be able to consider as the full success. The authors seem that the steps to the right direction, encouraging to the next tries of another plant species introduction, occurred before in the reserve or in similar meadow habitats of the same geobotanical region, were made. The detailed cognition of various plant species reactions in changed habitat conditions will allow for the working out the strategy of restoration the meadow communities of high species richness, and in consequence the improving of landscape and aesthetical functions of the reserve. To secure their long-lasting the regular management (twofold mowing) is recommended.

Abstract

The aim of the research was the valorization of farms with different areas, specialization and intensity of production using a comprehensive evaluation method. The scope of work covered 404 farms with data from 2008-2014. The area of the farms ranged from 1 to 1001 ha. The elements subjected to the bonitational assessment were divided into two modules - production and environmental modules. The production module included: the share of selected agricultural land and crop groups, the use of mineral nitrogen and phosphorus fertilizers, industrial feed consumption and animal stocking. The following elements were evaluated in the environmental module: dates of application of manures and number of days to be mixed with soil, method of preparation of silage, management of domestic sewage, size of buildings for storage of solid and liquid manures, year of construction of slabs for solid manure, tanks and cesspool. The points received in individual farms ranged from 49 to 148. Three groups of farms were identified on the basis of cluster analysis. The results showed that such elements as specialization, farm size, a share of arable land and grassland, stocking density, mineral fertilizers and industrial feed consumption were important for the identification of potentially hazardous farms. Differences in nitrogen fertilizer consumption varied in particular groups of farms from 16 to 169 N $kg \cdot ha^{-1}$. Nitrogen equivalent in industrial feeds indicated the consumption even at 500 N $kg \cdot ha^{-1}$.

Keywords: *rapid identification system (RIS), comprehensive assessment of farms, non-point pollution*

Introduction

Agricultural production is a branch of the national economy, which operates on very large areas. Farms use natural resources to achieve productive effects. Agro-ecosystems are not an isolated part of the area. They are strongly interconnected and interact with biogeosystems. Their condition often depends on the quality of agricultural production in the region. The problem of non-point pollution has been present for several decades. A particular risk for the environment is the dissipation of unused nutrients in agricultural production. The emission of macronutrients into natural ecosystems can cause unfavorable physical, chemical and biological changes. That is why the monitoring and control system on farms is so important. The only tool for controlling agricultural production is the balance of nutrients (Kupiec 2015). In the EU and OECD countries it is mandatory (Regulation... 2002, Kopiński 2005). However, the lack of standardization of the method makes that the results are often unreliable and incomparable. Such an approach may result in an incorrect assessment of the facts. However, the balance of nutrients only estimates the part of agricultural production. The problem is the lack of a comprehensive farm assessment methodology for their potential environmental impacts, which will take into account, in addition to the nutrient circulation, several other equally important parameters that may contribute to the deterioration of environmental indicators. The purpose of the research was a comprehensive analysis of potential risks of the environment from a representative group of farms characterized by large diversity in terms of area, specialization and intensity of land management.

Material and Methods

The research was partially financed by the National Science Centre Research Project No: N N305 372238. There 404 farms located in 294 towns, 161 communes and 10 provinces (Dolnośląskie, Kujawsko-Pomorskie, Lubelskie, Lubuskie, Łódzkie, Mazowieckie, Pomorskie, Warmińsko-Mazurskie) have been selected for the research. The average size of the farm was 47.6 ha. Among the analyzed farms, 15% had no animals and among the selected farms, the largest group was medium-sized farms in the range of 11-50 hectares (75%).
The potential environmental hazard assessment from the surveyed farms were made on the basis of a comprehensive method based on basic production and environmental parameters that could have a negative impact on soil, water, atmospheric environment and biodiversity. The selected elements were quantified with the use of point bonitation (Kupiec 2017). The rapid identification system (RIS) allows to identify farms that may be a potential threat to the quality of the environment and can be used in order to monitor and control agricultural units. The essence of this system is two modules: production and environment (Figure 1).

Production module

It includes elements directly linked to the production process, i.e. plant and animal production:
share of arable land and permanent grassland [%],
share of selected groups of plants that most influence on the process of reproduction or degradation of organic matter in soil (cereals, industrial crops, roots, vegetables, intensive orchards, smallseed papilionaceae, leguminous, pasture crops and green manure) [%],
livestock density calculated on the basis of the Regulation of the Council of Ministers (Journal of Laws 2005, No. 92, item 769) [LSU·ha^{-1}],
consumption of nitrogen and phosphorous mineral fertilizers [kg N and P·ha^{-1}],
consumption of industrial feed - calculated on the basis of nitrogen equivalent (0.043) - average nitrogen content in industrial feeds most frequently registered on farms (Kupiec 2008):

$$Npp = \Sigma pp \times 0.043$$

where: *Npp - nitrogen in industrial feed, Σpp - sum of industrial feed calculated per the area of agricultural land [kg N·ha^{-1}]*.

Environmental module

This module is based on the practices of organization and management on the farm:
the date of application of solid and liquid manures was assessed on the basis of the months in which the farmers applied them on the fields.
the lack of buildings for the storage of manures were calculated according to the formula:

$$B_b = Z - S$$

where: *B_b – the lack of building, Z – demand for: concrete plate (m^2) or tank (m^3), S – current state: concrete plate (m^2) or tank (m^3)*
The 5% tolerance threshold was applied due to changes of inventory strength over the year. The lack of building was converted into percentages and the score was assigned according to the following divisions: scores by compartments.
age of the building [year of construction],
period from application to plough manures [number of days],

the way of preparing silage - variants: concrete floor with drainage tank, foil sleeves, concrete floor without drainage tank, on the ground isolated with foil, on the ground without isolation, the way of water waste management - variants: domestic wastewater treatment plants, sewerage system, waste water treatment plant or reception by municipal services, agricultural using.
The minimum number of points for a particular feature is 0 and a maximum number of points is 16.

Results and Discussion

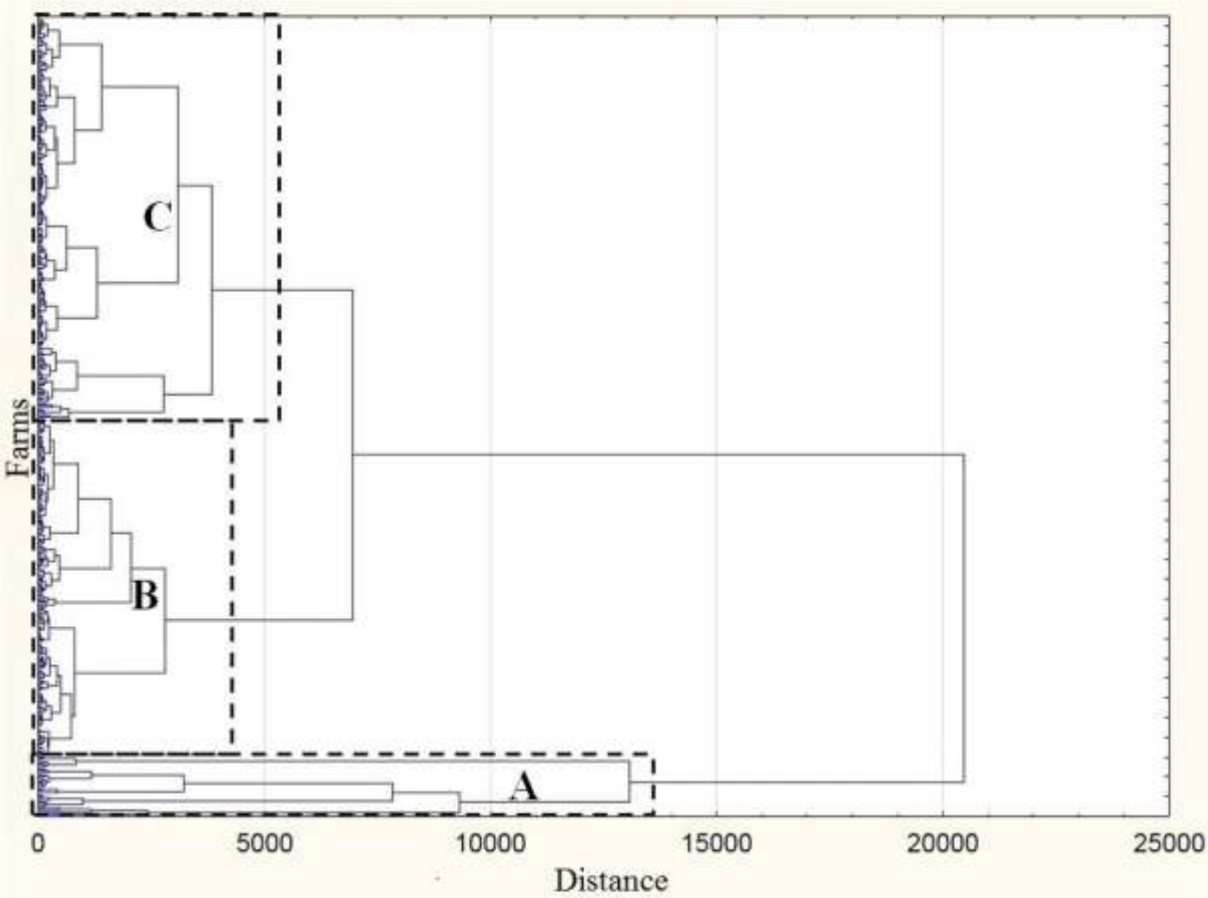
The total number of points awarded in individual farms ranged from 49 to 148 (average 96). The smallest of them received farms without animals and the largest ones with pigs (Table 1), indicating a potentially higher level of environmental standards in this group of farms. Breeding swine is a serious environmental hazard resulting primarily from the production of excrements (Marszałek et al. 2011) and the emission of various gases into the atmosphere (Tofant et al 2003). The high level of the consumption of industrial feed has also been recorded in pig farms. In Poland in the years 2000-2014 their production increased by about 101%. Breeding swine is in the second place after the poultry in terms of consumption of this type of feed (Urban 2015).

Table 1. The score assessment according to specialization group

The scope of points	The share of farms [%]	The share of specialization groups [%]								
		F	F < 0,15	CF	SF	CF/SF	SF/CF	PF	HF	EE/SF
<60	4	88	6	6	0	0	0	0	0	0
61-80	21	49	6	34	5	2	2	1	1	0
81-100	34	14	4	35	28	11	7	1	0	0
101-120	29	0	5	41	35	8	9	1	0	1
>120	12	0	0	23	64	6	2	4	0	0

F – farms without animals, F < 0.15 – farms with the livestock density below 0.15 $LSU \cdot ha^{-1}$, CF – farms only with cattle, SF – farms only with pigs, CF/SF – farms with cattle > 50% of share and with pigs > 30% of share, SF/CF – farms with pigs > 50% of share and with cattle > 30% of share, PF – farms only with poultry, HF – farms only with horses, EE/SF – farms with sheep > 50% of share and with pigs > 30% of share
Source: own research

Farms carrying out only plant production can pose a threat mainly from the production module. Only the management of the purchased manures (field application and application to plow) was considered in the environmental module on these farms, but it was rarely quoted. An additional parameter evaluated in the environmental module on non-livestock farms was the management of domestic waste water. There are still cases of agricultural use of domestic sewage in which there may be several types of pollution. The conditions of agricultural waste water use are specified in the Water Law (Journal of Laws of 2001, No. 115, item 1229), Regulation of the Minister of the Environment of 2006 (Regulation… 2006; Journal of Laws No. 137, item 984, as amended) and Code of Good Agricultural Practice (Code… 2004). Among the surveyed farms, 12% of them applied the sewage into the fields.
The analyzed features of the farms were analyzed statistically using cluster analysis on the basis of which three groups of farms (A, B and C, Figure 1) were distinguished.



Source: own research

Fig. 1. The hierarchical tree for analyzed farm features made by the agglomeration method

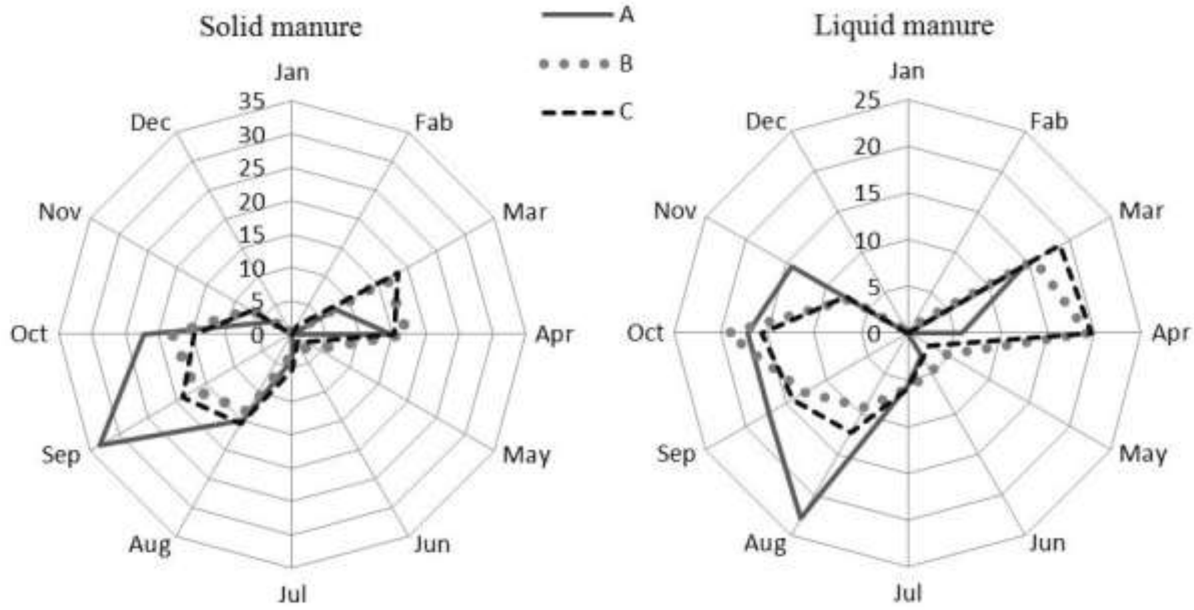
Group A consisted of farms in large areas targeted at fattening pigs. The intensity of production in these farms was mainly attributed to the high consumption of industrial feed which was 19 times higher than in farms of group B and with livestock above 4 $LSU \cdot ha^{-1}$ (Table 2). These farms also received the highest number of points according to the rapid identification system.

Table 2. The differences between groups of farms on the basis of the most discriminating characteristics and results of point bonitation in the groups

Group	Farm area	Arable land	Grasslands	N min[1]	P min[2]	N of feed[3]	The livestock density	The rapid identification system	
	[ha]			[$kg \cdot ha^{-1}$]			[$LSU \cdot ha^{-1}$]	mean	median
A	220.9	92.2	8.5	87	15	500	4.3	105	109
B	41.5	77.0	18.7	16	3	27	1.3	87	88
C	33.5	81.6	11.8	169	21	40	1.4	101	102

[1] nitrogen from mineral fertilizers, [2] phosphorus from mineral fertilizers, [3] nitrogen from industrial feed
Source: own research

The farms of the group B are five times smaller than those belonging to group A and the largest share of grassland was in farms, which was related to the predominance of dairy farms (Table 3). The consumption of fertilizers and industrial feeds was at the lowest level, as was the stocking density which was the lowest in comparison to the other analyzed groups. These farms received the lowest score of the rapid identification system (Table 2). The differences were also observed in the dates of application of manures (Figure 2). Farms of group A preferred September and October for solid manures and the period between August and November for liquid manures. In the other two groups (B and C) the differences in the time were not significant.



Source: own research
Fig. 2. The preferred dates of application of manures in analyzed farm groups [%]

Group C is the smallest, most equitable share of cattle and pigs (Table 2). They consumed the largest amount of mineral fertilizers - in the case of nitrogen it was ten times more than in farms of group B. The consumption of fertilizers in groups A and C was significant, more than a mean in Poland. The average consumption in the country for the years 2006-2016 was 65-81 kg $N \cdot ha^{-1}$ and 9-12 kg $P \cdot ha^{-1}$ (Central… 2017). The number of points based on the rapid identification system was also high and exceeded 100 points.

Table 3. The differences between farms on the basis of specialization of production

Group	The share of specialization group* [%]

Conclusion

The comprehensive approach to assessment of farms in terms of their impact on the various components of the ecosystem is justified in the context of conservation of natural resources and improvement of environmental standards in agricultural enterprises. The implementation of the assumptions of the Nitrates Directive (91/676/EEC), the Water Framework Directive (2000/60/EC) and the Sewage Directive (91/271/EEC), but also the obligations resulting from Poland's membership in the OECD, HELCOM or the sustainable development principles is the requirement that Poland must consistently implement. The rapid identification system has been focused primarily on aspects related to dispersion of nutrients. And, the particular importance in this case is attached to the means of production containing nitrogen and phosphorus used in crops and livestock breeding. These two macronutrients have the greatest impact on adverse changes occurring in natural ecosystems. Currently the only tool for monitoring agricultural production is the nutrient balance. The calculated balances on farms of different specializations show unequivocally, as in this study, that the highest risk is intensive animal production, especially fattening of pigs (Goulding et al. 2008, Kopiński 2012). This is mainly due to the production of large quantities of manures and high fertilization. Pig farms have potential environmental risks because of high farm nitrogen imbalances. With more than a 2:1 ratio of N inputs to outputs, N inputs were 50 percent higher than outputs (Yue et al. 2006). Another problem is the large consumption of industrial feed in such farms, which negatively affect balance sheet balance (Tagliapietra et al. 2004). The balances only cover the circulation of nutrients on the farm. These studies have also highlighted other issues in agricultural holdings, such as large deficiencies in the construction of manure storage, inadequate land pattern or to high livestock density. According to some authors, should seek to seal the agro-ecosystem (Sosulski and Łabętowicz 2007). It is also very important to remember about the internal sources of biogenic pollutants arising from wastewater management, manures or feed preparation (Myczko et al. 2009, The Agricultural… 2012, Kupiec et al. 2015). A detailed analysis of selected farms has shown that large farms with high livestock density, especially the farms specializing in pig breeding, pose the most significant problem in the context of environmental impacts. The biggest deficiencies are found in buildings for the storage of manures and the highest use of industrial feed in farms with pigs. These kind farms received the highest number of points according to the rapid identification system. In the group of medium-sized farms (34 ha) the highest use of N and P mineral fertilizers was recorded. Nitrogen fertilization was sometimes even 10 times higher than in the other groups of farms. These farms also received a large number of points of the rapid identification system. The research has shown that the rapid identification system allows the selection of farms that may have potentially negative impacts on the environment, including water quality. Farms with the high consumption of selected means of production and inappropriate agricultural practices received the highest number of points.

Abstract

Recent concerns regarding environmental safety have drawn attention to the risks of petroleum hydrocarbons (PHC) contaminants. These pollutants are highly toxic mostly because of their persistence in the environment, and long range of toxicological effects. Therefore, we considered that accidental PHC field contamination when using agricultural mechanical systems is an issue that should be suppressed. In these regard we focused on the isolation of potential PHC decontaminating microorganisms. The lignocellulosic fibers are known as good absorbents of PHC, and also they are abundant materials in agricultural lands. From such lignocellulosic fibers, we isolated several bacterial strains, one expressing PHC decontaminating abilities. The new isolated strain BBp1 revealed PHC emulsification ability and was able to disperse the diesel fuel. The BBp1 bacterial strain also showed several plant beneficial traits. The phosphate solubilizing activity of this strain could improve soil fertility, thus contributing in plant growth stimulation. Arginine metabolism revealed in this strain could improve the efficiency of plant nitrogen use, thus regulating plant developmental processes as well as plants response to biotic and abiotic stress. The selected strain can contribute to plant growth stimulation through phytohormones synthesis, as it produces 9.6µg IAA/ml in the culture supernatant (LB broth supplemented with 2.5mM tryptophan).

Keywords: *PHC, Bacterial strain, Emulsification, Plant growth stimulation.*

Introduction

The worldwide concern for human health and environmental protection considered the pollution derived from the diesel oil and its refined products is highly damaging for the soil structure and ground water quality, and highly toxic due to its persistence in the environment and long range of toxicological effects (Hussain et al., 2016; ATSDR, 1999). Soil pollution with petroleum hydrocarbons causes extreme harsh surroundings as it creates hydrophobic conditions, diminish the microbial diversity and growth, produces soil infertility that finally lead to less plant growth, with serious consequences for agriculture. For soil decontamination, bioremediation is a promising biological method, with both technical and ecological benefits (Hussain et al., 2016). The environmental biotechnology improves the negative effects caused by hydrocarbon pollution by using specialized microorganisms or microbial consortia capable of bioremediation of PHC contaminated soil (Onwurah et al., 2007). Several authors demonstrated bioremediation of PHC contaminated soils using native or exogenous microorganisms, usually improving soil aeration, moisture and nutrient content to increase microbial activity (Kulkarni, 2014). As in these study we considered only the accidental PHC field contamination when using agricultural mechanical systems, we focused on the isolation of potential PHC decontaminating microorganisms with plant beneficial applications as agro-inoculants.

Material and Methods

The present study was performed at the RDIPP, Bacteriology laboratory, during 2016 and 2017. The study is focused on beneficial bacteria with PHC decontaminating potential and other traits involved in the improvement of agricultural land. In these regard we focused on the isolation of potential PHC decontaminating microorganisms. With this purpose we isolated some bacterial strains from lignocellulosic fibers, an abundant material in the agricultural lands, known as good absorbents of PHC. For microbial isolation, 1% of lignocellulosic fiber was immersed in distilled water and homogenized by vortex at 2000rpm for 1 minute, incubated for 15 minutes at room temperature and than displayed on Luria Bertani (LB) medium. The obtained bacterial growth was purified using the streak plate method for several sub-culturing on the same medium. During the isolation, there were maintained only the cultures with different colony morphology. The bacterial isolates were microscopically analyzed for their gram reaction and cell morphology. To establish the colonization potential the isolates were analyzed for swimming and swarming motility on LB with 0.3 and 0.5% agar, respectively, as mentioned by (Constantinescu et al., 2010). The bacterial respiratory type was determined by analyzing their growing in LB broth after static incubation. The emulsification potential of the isolated bacteria was evaluated on diesel fuel and engine oil as PHC substrates. Two methods were used to evaluate the emulsification activity of the bacterial strains. In the first method the bacteria were grown in LB broth at 150rpm orbital shaking and 28°C, until 10^8cfu/ml. The cultures were centrifuged and only the supernatant was used in the emulsification test. The cell free supernatant was mixed with distilled water and PHC substrate in a ratio of 2:2:1 (v/v/v). As a negative control we used un-inoculated LB medium instead of bacterial supernatant. The samples were vertex for 2 minutes at 3000rpm and allowed to rest for one hour before analyzing. Emulsification activity was determined by measuring the optical density at 540 nm (Patel and Desai, 1997; Olteanu et al., 2011). For the second method, the bacterial strains were grown in LB broth and modified McKeen medium (Olteanu et al., 2011) for four days in orbital shaking at 150rpm and 28°C. The cultures were centrifuged and the free cell supernatant was used in the emulsification test. Equal volumes of bacterial supernatant and PHC substrate were mixed together at 3000rpm for two minutes and allowed to rest for one day at room temperature before analyzing (Priya and Usharani, 2009). The emulsification index (E_{24}) was calculated based on the emulsion layer height (H_{EL}), and total height of the sample (TH), using the algorithm mentioned by Satpute et al. (2008):

$$E_{24} = \frac{H_{EL}}{TH} \times 100$$

The oil spreading technique was carried out in order to detect the biosurfactant production and potential of hydrophobic PHC solubilization. For this test 40 ml of distilled water were added to a Petri dish of 10cm in diameter, 300 µl of used engine oil were slowly added to the surface of water. After 5 minutes, when the oil stain has spread in a thin layer on the water surface 60 µl of cell free supernatant from 4 days old cultures obtained in modified McKeen medium were slowly added to the surface of the oil. The diameter of clear zone formed by oil dispersion was measured and compared to a negative control of distilled water, and a positive control of 1% SDS (sodium dodecyl sulfate) solution, similarly prepared. The occurrence of clear zone is an indication of biosurfactant production.

Bacterial potential to produce several enzymes, like amylase, arginine dihydrolase, arginine decarboxylase, phosphatase, cellulase, chitinase, and gelatinase, and phytohormones (indole acetic acid, IAA) involved in plant growth promotion were analyzed according to Sicuia et al. (2015 a,b, 2016).

Results and discussion

The analyzed lignocellulosic material revealed a load of 1.5 $\times 10^4$ cfu/g. Two bacterial isolates, BBp1 and BBp2.1, were selected considering the differences in their colony morphology. The isolated bacteria were aerobic, gram positive, with rod shaped cells. Only BBp1 strain revealed swimming and swarming motility (figure 1), these indicating a good colonization potential.

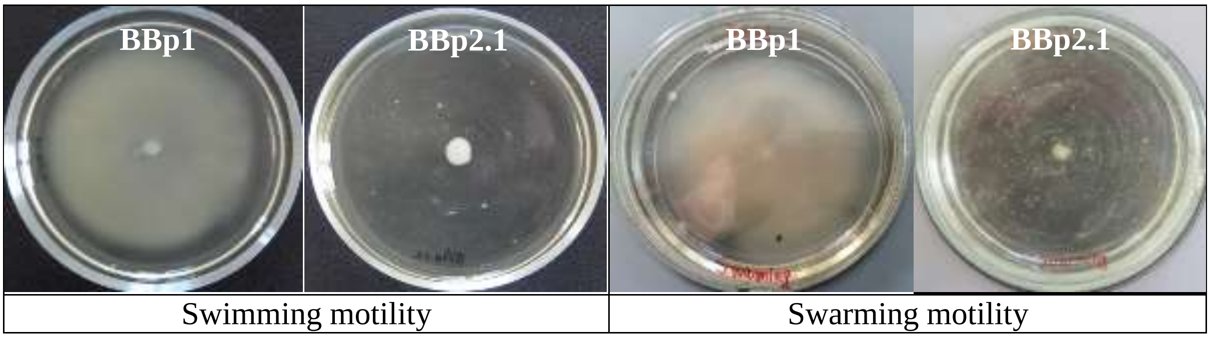

Figure 1. *In vitro* motility of BBp1 and BBp2 bacterial isolates

The emulsification potential expressed on the diesel fuel and engine oil revealed that BBp2.1 was more competitive than BBp1 strain, when cultivated on LB medium. However, both strains expressed a better emulsification of the engine oil than the diesel fuel (table 1, fig. 2).

Table 1. PHC emulsification activity of the isolated bacterial

PHC substrate	Emulsification activity at 540nm	
	BBp1	BBp2.1
Diesel fuel	0.041	0.121
Engine oil	0.301	0.532

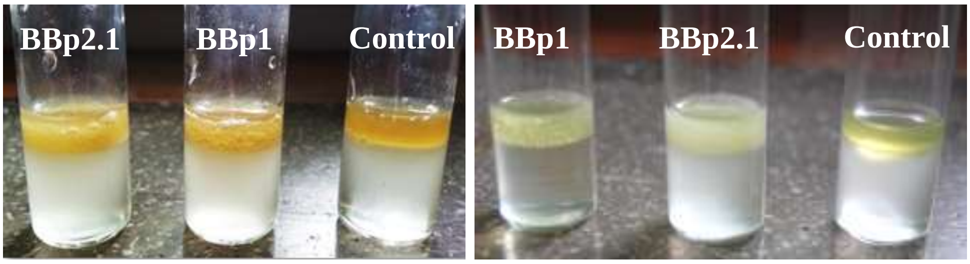

Figure 2. Emulsification activity of engine oil (a) and diesel fuel (b) by LB broth bacterial cultures

In the second method the bacterial strains were grown not only in LB broth, but also in McKeen medium, known to stimulate biosurfactant production in bacterial cultures. This aspect was better noticed on diesel fuel, when, after 24h of static incubation, both strains expressed low to medium emulsification index values when grown in McKeen medium compared to the emulsion stability revealed by the LB cultures supernatant (table 2). However, when the emulsification stability was calculated for the engine oil, no significant differences were revealed among strains activity when cultivated in McKeen or LB broth, and both strains (BBp1 and BBp2.1) revealed similar emulsification index values (table 2).

Table 2. Emulsification stability after 24h of incubation

Sample type	BBp1		BBp2.1		Control	
	McKeen	*LB*	*McKeen*	*LB*	*McKeen*	*LB*
Emulsification index - E_{24} (%)						
Diesel fuel	15.4	0	7.7	0	0	0
Engine oil	46.2	50	50	42.3	7.7	3.8

Biosurfactant activity of BBp1 and BBp2.1 in McKeen broth was evaluated trough oil dispersion technique on engine oil (figure 3). Performing this test, BBp2.1 revealed poor oil dispersion ability of only 4mm in diameter. The BBp1 strain cleared the engine oil over an area of 18mm in diameter, which represent a quarter (25.7%) of the dispersion potential of the SDS control solution (that revealed a dispersion spot of 7cm in diameter).

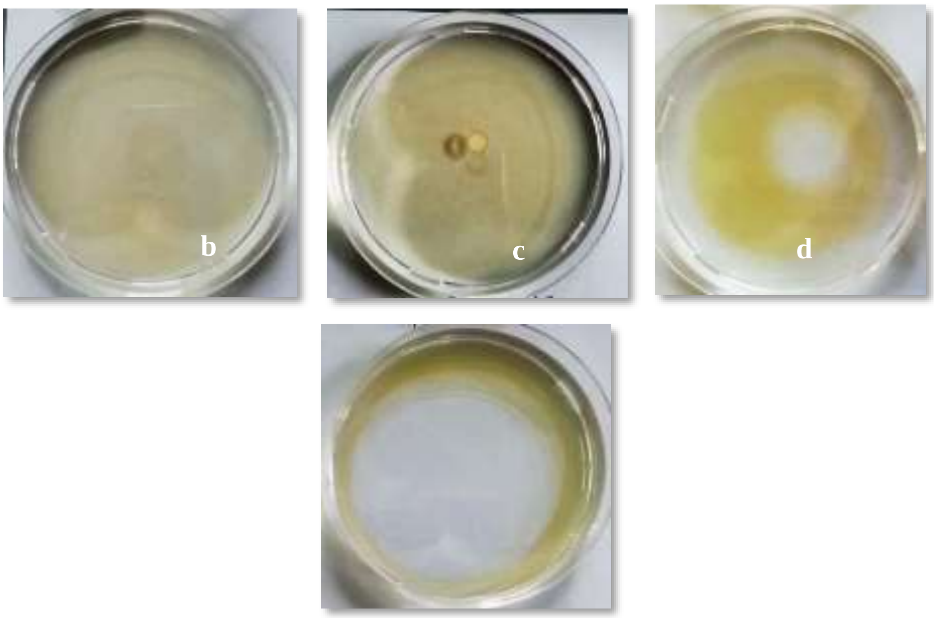

Figure 3. Clear zones of engine oil dispersion: a. negative control with distilled water, b. BBp2.1. strain, c. BBp1 strain, d. SDS 1% as positive control

Plant beneficial traits were analyzed only for BBp1 strain. This strain revealed arginine decarboxylase, phosphatase, and gelatinase activity (figure 4). However, no amylase, arginine dihydrolase, cellulase and chitinase were detected.

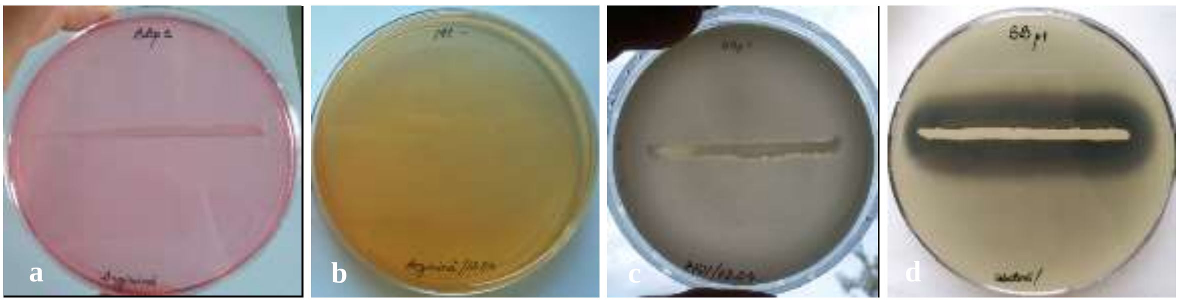

Figure 4. *In vitro* trials for BBp1 enzymes production.
Anginine decarboxylase production (a), compared to the negative control (b);
clear halo of substrate hydrolysation revealing phosphatase (c) and gelatinase (d) activity.

Arginine decarboxylase triggers one of the pathways of polyamine synthesis. This increases plant growth and development, and plant tolerance to biotic (Rossi et al., 2015) and abiotic stresses (Gupta et al., 2016).

Regarding phosphate fertilizers, many such compounds have poor solubilization in water. However, using plant beneficial microorganism with phosphatase activity could contribute to a better absorption of such nutrients in plants, increasing the efficiency of phosphate fertilizers.

Analyzed for IAA production potential, BBp1 strain revealed 5.3μg IAA/ml of culture supernatant when grown in usual LB broth medium. However, when IAA precursor was added into the medium, BBp1 produced 9.6 μg IAA/ml of culture supernatant of LB supplemented with 2.5mM tryptophan.

Conclusions

A microbial load of 1.5×10^4 cfu of cultivable microorganisms was determined per gram of lignocellulosic fiber experimentally used as PHC absorbent in contaminated areas. From this microbial growth, two gram positive bacteria, BBp1 and BBp2.1, were analyzed for their emulsification and dispersion ability of two petroleum hydrocarbons: diesel fuel and engine oil. Although, BBp2.1 revealed a better emulsification activity after one hour of incubation with the PHC substrate; BBp1 revealed that the emulsification activity is more stabile after 24h. BBp1 bacterial strain also expressed oil dispersion activity and a better colonization capacity. Therefore, it was also analyzed for plant growth stimulation ability, revealing phytohormones production (9.6μg IAA/ml LB with 2.5mM tryptophan) and several plant beneficial enzymes such as arginine decarboxylase, phosphatase, and gelatinase.

Abstract

In the period 2014-2015 were made observations on mining moth chestnut *Cameraria ohridella* Deschka Dimic, in parks and chestnut zone alignments in Huşi from Vaslui County. For observations in each year are purchased the pheromone traps type atra-CAM at the Institute of Chemistry "Raluca Ripan" from Cluj. In each of the two years of observations and proceeded to the systematic recording of data on the occurrence and flying insect oviposition, completing the larval stage, the pupa stage and replay each generation cycle.Since visual observations in the field are difficult to track in the number of generations, thanks to the emergence staggered butterflies and then deposit eggs, emergence of larvae of the first egg, so to establish better during each stage in the field I doing so: - I chose trees that have branches below, so that they can get to them from these branches have chosen 10 leaves that we signed with a thread and on them we followed all stages from egg to pupa and adult.On these leaves observation of 3 in 3 days, I followed and noted laying and still other stages: larva, pupa and adult.Basically, I followed the stage of egg, larva, pupa to butterfly leaving the mine by the same leaves and leaflets.With the help of Agroexpert system was calculated sum of effective temperatures required at each stage of development.

Keywords: *mining moth, Chestnut, life cycle, stages of development*

Introduction

The ornamental chestnut, *Aesculus hippocaslanum* L, originated in the Balkan Peninsula, is a tree, which in our country is spread everywhere, being a decorative element in green spaces, parks, botanical gardens, institutions, and leaves and especially fruits are of phytopharmaceutical importance , The seeds are used in the production of technical soap, technical oil and glue, and starch extracted from chestnuts is used for the preparation of color pastes and for printing fabrics. Soft, lightweight, slightly resistant wood, impregnates well, good groundwork is used for use as a panel veneer for orthopedic articles. Chestnut is also a honey-like species, its flowers being extensively visited by bees for picking nectar and pollen However, the ornamental chestnut is to be cultivated mainly as a decorative species in parks, public gardens, on the alignments of the stalls and the boulevards, and is marked by the symmetry of the crown, the early flowering and the display of beautiful flowers, and then through the rich and very elegant foliage Also supports the trimming of the crown).

Although, in general, the ornamental chestnuts to which we refer do not require special measures to combat plant phytosanitary organisms, the trees being vigorous and tolerant to possible damage to various organs, vegetative and reproductive, are more or less affected by many phytopathogens. (Prodan, 1915, quoted by Oltean 2015). However, we can say that for a long time there has been a balance of these harmful organisms, the trees generally growing in the proper way.

This biochemical balance of the ornamental chestnut has been disturbed in recent years by the presence and activity of a new pest - the leaf mining moth - *Cameraria ohridella* (DESCHKA-DIMIĆ, 1986), recently reported in the entomofauna of the countries in Europe, (Beratlief C., 1998) including in our country. Chestnut with white flowers called popular wild or ornamental chestnut (*Aesculus hippocastanum* L.) is preferred by the harmful species occurring in our country and causing premature defoliation.

Material and method

In the agricultural year 2014-2015, observations were made on the chestnut moth *Cameraria ohridella* Deschka Dimič in the chestnut parks and alignments in the county of Vaslui. For ease of observation every year, trap-atract pheromones are purchased from the Raluca Rîpan Institute of Chemistry in Cluj.bIn each of the two years of observations, systematically recorded data on the occurrence and flight of the insect, the pond deposition, the larval stage, the cycle and the resumption of the cycle of each generation. Since visual observations in the field are difficult to track in terms of the number of generations(Perju, T., 2004), due to the gradual occurrence of butterflies and then the laying of eggs, the appearance of larvae in the first eggs, so in order to best determine the duration of each stage in the field Proceed as follows: The trees that have the branches below, so that they can reach them, from these branches, I chose 10 leaves that I have a thread of thread and I followed all the stages from egg to stern and adult (Oltean I., 2015) .On these observation leaves, from 3 to 3 days, I watched and noted the laying of the eggs and then the other stages: larva, stern and adult.Basically, I watched the egg, larva, sternum stage until the butterfly leaves the butterfly on the same leaves and foliage. With the Agroexpert program the sum of the actual temperatures required for each stage of evolution was calculated.

Results and Discussion

The research carried out during the year 2014 aimed at studying the biological cycle, the dynamics of adult flight and the influence of climatic factors on *Cameraria ohridella* Deschka Dimič, in order to issue warning bulletins by proposing chemical treatments as measures to limit the population in climatic conditions of Vaslui County.
For the pursuit of *Cameraria ohridella* adult flight, were used the pheromone traps, atra-CAM type. Thus, a trap / location was used, and baits were changed monthly from May to September. Adult flight rating grades were made 3 times a week. In order to correlate the data obtained with the meteorological data, the sums of the actual temperature ranges (over 12°C) were calculated for each stage of evolution.In terms of climatic characterization, the year 2014 recorded a series of higher temperatures in spring compared to the normal multiannual period with values between 1.9-3.9°C (March - May), precipitation (11.2 mm (March) and 10.3 mm (m) and were below normal in April with a 11.3 mm deficit, and the monthly average relative humidity had values Between 74% (March) and 69% (April - May). In the summer, temperatures were higher than the normal multi-annual, with values ranging from 0.7 to 2.1°C, and the rainfall had a deficit in July and August between 14.22 and 22.3 mm, and in June Exceeded normal by 52.6 mm. September has recorded temperatures that exceeded the multi-annual by 1.1°C and rainfall by 46.3 mm. The absolute minimum temperature was -12.7 °C, recorded on January 12; The absolute maximum was + 35.5 °C recorded on July 29, and the last spring frost was on March 29, -2.0°C.
The biological cycle of the chestnut moth in the Vaslui area (Table 1) has observed field conditions with the appearance of adults, pond deposition, larva and pup, the duration of each stage of the insect and the sum of actual temperatures for all generations of the insect.

Under the ecological conditions in the Vaslui area, the mining chest of *Cameraria ohridella* Deschka Dimič, chewed as a snout in the leaves fallen on the ground.
Adults of the third (hymnal) generation appeared on 05.05, at a Σ (tn - to) = 118.06°C (Table 1). After sexual maturation and mating, which has tree trunks, especially in the morning, 7 days after the appearance of the first butterflies, the females started pond deposition. The first eggs were deposited on 12.05, at a Σ (tn - to) = 170.69°C. Ponta is deposited throughout the flight of the insect, the last eggs were observed on 19.06. The incubation lasted 6 days, at a mean decade temperature of 200°C and a relative humidity of 62%.
The first V1 larvae occurred on 18. 05, at a Σ (tn - to) = 209,18°C. The duration of the larval stage was 22 days at a mean decade temperature of about 20.9°C and relative humidity of 62-70%. The kernel stage was observed on 09.06, at a Σ (tn - to) = 348.51°C, and after 8 days, the first butterflies of the generation - a, on 17.06, appeared at Σ (tn - to) = 446, 8°C.
Generation I lasted 36 days (from the first eggs to the first butterflies).
Approximately 10 days after the appearance of the first generation butterflies, the first new eggs on the leaves were observed on 29.06, at a Σ (tn - to) = 553.71°C.
The incubation lasted about 5 days, the first larvae appeared on 03.07, at a Σ (tn - to) = 577.7°C. The duration of the larval stage was 22 days, at a mean decade temperature of 21.80C and a relative humidity of 67-74%.
The registration of the first knuckles took place on 25.07., At a Σ (tn - to) = 785.46°C, 10%, and on 28.07 the percentage of the umbilions was 80%, at Σ (tn - to) = 816.77°C.
The duration of the pupal stage was 10 days, so on 04.08, the first butterflies of the second generation began to appear on a Σ (tn - to) = 891,91°C.
The second generation lasted 35 days (from the first eggs to the first butterflies).
The butterflies of the second generation began to plow on 08.08, at a Σ (tn - to) = 939.23°C. Massive egg deposition was recorded on 12.08, 60%.
Approximately 5 days after the pond deposition, the first larvae (V1) occurred on 14.08, at a Σ (tn - to) = 1002.09°C.
The duration of the larval stage was approximately 23 days at an average temperature of 23.0°C and a relative decade humidity of 55%.
Complete development of stern transforming larvae. The first knuckles were observed on 07.09, at a Σ (tn - to) = 1190.71°C, at a rate of 3-4%.

Table 1. The emergence of the first stages of development of Cameraria ohridella Deschka Dimič mining moth in 2014

Generation	**Stage**	**Date of first appearance**	**Stage duration (days)**	$\sum(t_n - t_o)$
G3 (hiemal)	Adults	05.05	38	118,06^{0}C
G1 36 days	egg	**12.05**	6	170,69^{0}C
	larvae	**18. 05**	22	209,18^{0}C
	pupae	**09.06**	10	348,51^{0}C
	adult	**17.06**	-	446,80^{0}C
G2 35days	egg	**29.06**	5	553,71^{0}C
	larvae	**03.07**	22	577,75^{0}C
	pupae	**25.07**	10	785,46^{0}C
	adult	**04.08**	38	891,91^{0}C
G3 up to 10 may	egg	**08.08**	5	939,23^{0}C
	larvae	**14.08**	23	1002,09^{0}C
	pupae	**07. 09**	212	1190,71^{0}C

On 20.09, at a Σ (tn - to) = 1237,79°C, more than 50% of the larvae were recorded, and on 26-28.09 they were about 91%, at a Σ (tn - to) = 1243,35°C. At this stage, the insect hibernates until May next year for 8 months.

Fig.1. Graphical representation of the first occurrences of the development stages of the chestnut moth in 2014

Table 2. The biological element of the chestnut moth Cameraria ohridella Deschka Dimič, In 2014

Year	**Generation**		
	I	**II**	**III**
2014	12 may – 17june	29 june – 04 august	08 august – 10 may

In ecological conditions in the Vaslui area in 2014 (Table 2), the species *Cameraria ohridella* Deschka Dimič has 3 generations, namely: 1st generation (G1) evolved during May 12 - June 23, for 40 days; The second generation (G2) that evolved from June 30 to July 01 for 35 days and the second generation (G3) that evolved from August 8 to May 10, hibernating in the stern stage in fallen leaves on the ground.

The biological cycle of the chestnut moth in the Huşi-Vaslui **in 2015**, area has seen parks and alignments, looking for the appearance of adults, pond deposition, larva and hoop, the duration of each stage of the insect and the sum of effective temperatures for all insect generations.

Adults of the third generation (hyeml) appeared on 10.05, at a Σ (tn - to) = 85.25°C (Table 3).

The butterfly flight and the moonlit moon in May was made heavy by heavy rainfall for 16 days when 179 mm precipitation was recorded, the average deviation was 118.9 mm and the average daily temperatures were relatively small, up to 18 .between 9.6 and 16.20 °C.

After mating and sexual maturation, females began pond deposition on 20.05 at a Σ (tn - to) = 100.25°C and hatched after about 8 days at a mean decay temperature of 20.0°C. Ponta is deposited throughout the flight of the insect, the last eggs were observed on 21.06.

The first V1 larvae appeared on 28.05 on a Σ (tn - to) = 147.49°C, and the stage lasted 24 days at a decade average temperature of approximately 20.0°C. Stage stage was observed on 21.06, at a Σ (tn - to) = 324.88°C, and after 8 days the first butterflies of the generation I appeared on 29.06, at Σ (tn - to) = 378.77°C.

Generation I lasted 40 days (from the first eggs, until the first butterflies).

After sexual maturation and mating, the first generation butterflies deposited the first eggs on the leaves on 05.07, at a Σ (tn - to) = 427.78°C. The incubation lasted about 5 days, the first hirsute larvae appeared on 10.07, at a Σ (tn - to) = 484.01°C. The duration of the larval stage

was 22 days at a decade average temperature of 21.6 - 22.5 °C and a relative humidity of 74%. Starting with 03.08. The first knuckles were recorded, at a Σ (tn - to) = 736,70°C, in the percentage of 20%, and on 05.08 the percentage of the umbilions was 55%, at Σ (tn - to) = 723,09°C. The duration of the pupal stage was 8 days at a mean decay temperature of 24.2°C, so on 11.08, at a Σ (tn - to) = 833.96°C, the first butterflies of the 2nd generation .
The butterflies of the second generation began to plow on 17.08 at a Σ (tn - to) = 906.95°C. The mass deposition of eggs was recorded on 20.08, over 50%. The incubation lasted 5 days, and the first V1 larvae appeared on 22.08, at a Σ (tn - to) = 949.95°C. The duration of the larval stage was approximately 25 days at a decade average temperature of 19.6 ° C.
The first knuckles appeared 15. 09, at a Σ (tn - to) = 1143,25°C. Transformation in excess of 50% took place on 20.09, at a Σ (tn - to) = 1160.19°C.

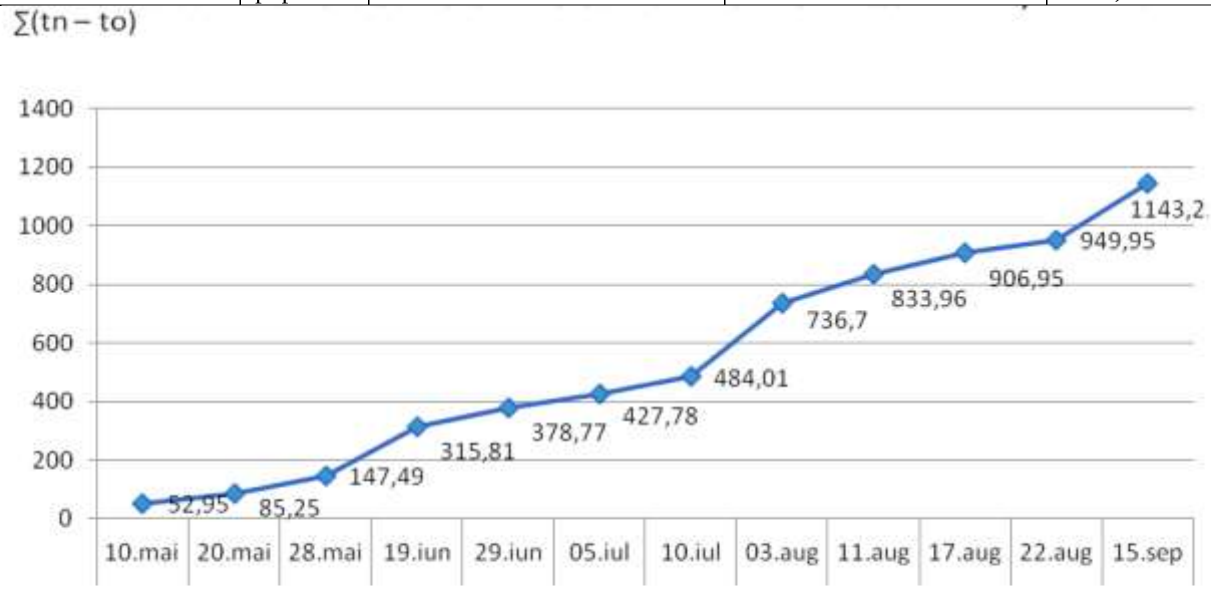

Fig. 2. The graphical representation of the first occurrences of the development stages of the *Cameraria ohridella* Deschka Dimič mining mould in 2015

Table 4.The biological cycle of the chestnut moth *Cameraria ohridella* Deschka Dimič in 2015

Year	**Generation**		
	I	**II**	**III**
2015	20 may – 29 june	05 july – 11 august	17 august – 08 may

Under ecological conditions in the Husi - Vaslui area in 2015, the species *Cameraria ohridella* Deschka Dimič has three generations, namely: the 1st generation (G1) evolved during May 20 - June 29, for 40 days; The second generation (G1) that evolved between July 5 and August 11, for 37 days and the second generation (G1) that evolved during August 17 - May 8.

Conclusions

In the Husi area, in the four years of observation, the species *Cameraria ohridella* Deschka Dimič shows that every year the insect presents three generations per year and ate in the aft stage in a silky cocoon: generation I - May - June; 2nd generation - July - August Generation II - August - May.

The duration of one generation ranged from 40 days to the first generation and 33 to 35 days to the second generation.

The period from the appearance of the first butterflies to the first eggs is 7 to 10 days, during which sexual maturation and copulation take place.

Eggs are always deposited on mature, mature leaves, never on the barely emerging leaves; The sum of actual temperatures, Σ (tn - to), required for the pint deposition is above 100°C;

The mining mine needs the spring for butterflies with a lower threshold of t0 = 12°C and a sum of effective temperatures, Σ (tn - to) => 70ºC.

Incubation takes 3 to 10 days depending on temperature and relative air humidity.

Stage of larvae lasts between 20 and 25 days, depending on the temperature and relative air humidity, and the aft stage is 8 to 10 days.

Under the conditions of the Huşi area, hibernates from September to May next year for 8 months.

Abstract

The effect of simazine (62, 125, 250 and 500 μg/g soil), paraquat (37, 75, 150 and 300 μg/g soil) and 2,4 D (87, 175, 350 and 700 μg/g soil) on cellulose decomposition in two soils (sandy soil and chernozem) was studied. Simazine and 2,4 D were mixed with soil and cellulose (2% powdered cellulose) before humidification, whereas paraquat was introduced into the soil along with water during humidification. The soil receiving no pesticide treatment was the control. The modelled soil samples were incubated in a thermostat at 28 ˚C for 12 weeks. The amount of water that vaporized was added to the soil on a weekly basis.
Results showed that simazine rates had a slight inhibitory effect on cellulolytic activity in the tested soils. Only the highest rate of 2,4 D caused a considerable degree of inhibition of cellulose decomposition. Paraquat exhibited a higher level of toxicity compared to simazine and 2,4 D. As even the lowest application rates were several times greater than the rates commonly used in agricultural practice, the herbicides tested, when applied at recommended rates, cannot be inhibitory factors in cellulose transformation in these soils.

Key words: *herbicides, cellulolysis, soil, microorganisms*.

Introduction

Research on the effect of different chemical crop protection agents on microbial communities in the soil is of high theoretical and practical importance. Effects of pesticides under soil conditions are quite different from those under laboratory conditions.
On the one hand, some microbial populations have the ability to degrade pesticides and use them as sources of biogenic elements and energy required for physiological processes (Janjić et al., 1996; Regno et al., 1998; Singh, 2008). On the other hand, pesticides can change the biodiversity, activity and rhythm of reproduction of microorganisms (Johensen *et al*., 2001).
In agricultural ecosystems, herbicides are subjected to transformation and degradation processes, and constantly interact with soil microorganisms. Increasing consideration has been given to the quantitative and qualitative composition of microorganisms and their enzymatic activity as soil quality indicators which are, in agricultural soils, correlated with the herbicide application rate (Zain *et al*., 2013).
Many authors have studied the effect of pesticides on cellulose decomposition (Szegi, 1972; Malkomes, 1977; Mandić and Đukić, 2007; Baldrian *et al*., 2011). The application of Paraquat above its recommended label rate reduced cellulose degradation and soil respiration by 39-58%. The degree of inhibition decreases with increasing content of organic matter in the soil i.e. its increasing sorption (Bromilow, 2003). In study on the effect of herbicides (butachlor, pyrozosulphuran, paraquat and glyphosate) on the organic carbon content of the

soil, microbial biomass and activities of the enzymes (amilase, invertase, protease, urease and dehydrogenase), Baboo *et al*. (2013) found a decrease in organic carbon content and microbial biomass in the soil. Many studies have proven that paraquat is active only when it comes in direct contact with the plant, while in the soil it occurs in a strongly bound form (Bromilow, 2003). In field trials, normal rates of paraquat increase the numbers of bacteria, fungi and actinomycetes, whereas high rates are toxic to fungi (Camper *et al*., 1973). Simazine can lead to changes in the bacterial community structure; however, some bacteria can become involved in simazine biodegradation, and autochthonous microbial communities can metabolize high rates of simazine in agricultural soils (Wan *et al*., 2014).

The transformation of the cellulose incorporated in the soil in the presence of crop protection agents is dependent on soil texture, humus content, soil pH, the amount of uptakeable nutrients and other factors (Schröder, 1979; Malkomes, 1993). This finding has been confirmed by Ayansina and Oso (2006) through their analysis of the effect of atrazine on organic matter content, soil pH and microbial numbers in the soil.

Manure stimulates cellulose decomposition and detoxification of the abovementioned pesticides as it provides sufficient amounts of nutrients for the massive reproduction of soil microorganisms. Compost and biohumus are additional sources of simazine-degrading microorganisms (Błaszak *et al*, 2011).

Therefore, non-judicious use of pesticides can affect transformation processes in the soil, primarily the degradation of crop residues. Fresh organic residues originating from plants, animals and microorganisms (biomass) undergo transformation, leading either to their complete mineralization or partially degraded substances which directly or indirectly make up humus. The degree of transformation is dependent on the type of plant material, temperature, water content and the activity of the microbial populations present in the soil. Cellulose, lignin and chitin are the three most common soil biopolymers. Micromycetes exhibit pronounced cellulolytic and chitinolytic activities which make them actively involved in the transformation of cellulose and dead biomass of different soil organisms, which are important sources of soil carbon (Baldrian *et al*., 2011).

The aim of this study was to examine the effect of herbicides (simazine, paraquat and 2,4 D) on cellulose decomposition in sandy and chernozem soils.

Material and methods

A model trial was established to determine the effect of pesticides on cellulose transformation in the soil. In the experiment, 2% powdered cellulose was homogenously mixed into 200 g sandy soil (pH_{KCl}- 6.4; humus-1.7%; N-0.1%; P_2O_5-0.068 mg g^{-1}; K_2O- 0.1 mg g^{-1}) and chernozem (pH_{KCl}- 7.2; humus-3.07%; N-0.2%; P_2O_5-0.37 mg g^{-1}; K_2O- 0.22 mg g^{-1}), and then the treated soil sample was humidified to a moisture content of 60% of maximum water holding capacity. The effect of the herbicides simazine (2-chloro-4,6-bis(ethylamino)-s-triazine), paraquat (dichloro-1,1-dimethyl-4,4-bipyridine) and 2,4 D (2,4-dichlorophenoxyacetic acid) was evaluated. Simazine was applied at 62, 125, 250 and 500 μg/g soil, paraquat at 37, 75, 150 and 300 μg/g soil, and 2,4 D at 87, 175, 350 and 700 μg/g soil in three replicates. Simazine and 2,4 D were mixed with the soil and cellulose before humidification, whereas paraquat was introduced into the soil along with water during wetting. The soil without pesticide treatment was the control. The modelled soil samples were incubated in a thermostat at 28 ˚C for 12 weeks. The amount of water that vaporized was added to the soil on a weekly basis. The amount of transformed cellulose was determined by the method described by Petkov and Markova (1969). The results obtained were subjected to an analysis of variance. The importance of differences in the level of cellulose degradation (%)

for each individual soils, as dependent on the herbicide application rate, was assessed by LSD test (Statistica SPSS 5).

Results and Discussion

As shown in Table 1, the three herbicides affected the percent decomposition of powdered cellulose mixed with soil samples, and different results were obtained. No simazine application rate had a significant inhibitory effect on cellulase activity. Similar findings were recorded for 2,4 D, although its highest rates (700 μg/g) inhibited cellulose decomposition by about 17% compared to the control. Paraquat was much more toxic than the other herbicides. The two highest rates (150 and 300 μg/g soil) had a significantly depressive effect on cellulose decomposition. The rate of 300 μg/g soil caused a reduction in cellulose decomposition by about 20% compared to the same process in the control soil. The two lowest rates (37 and 75 μg/g soil) did not prevent cellulose decomposition. Although even the lowest application rates were several times greater than the rates commonly used in agricultural practice, the recommended rate of paraquat in the soil is not an inhibitory factor in cellulose transformation processes. In this regard, as reported by Bromilow (2003), paraquat applied at high rates (1300 mg kg^{-1}) had no detrimental effect on cellulose decomposition in the soil; when used at recommended rates, it had no effect on bacterial and fungal activities in the soil. The adverse impact of paraquat on soil organisms is minimized through its high sorption by soil particles. Whitelaw-Weckert *et al.* (2004) observed that it is impossible to determine whether changes in soil microbial population are directly associated with pesticide use or with the indirect effect of pesticides manifested through reduced amounts of organic matter and rhizosphere exudates.

In contrast, Adomako and Akyeampong (2016) found significant changes in the growth and development of soil microorganisms as induced by atrazine, 2,4 D, glyphosate and paraquat applications. The toxic effect of some herbicides was observed immediately after their use, and paraquat treatment had a long-lasting effect on most microorganisms. Microorganisms respond to herbicides in a variety of ways, depending on herbicides themselves, their concentrations, exposure time, chemical and physical soil characteristics, and properties of the microbial populations present in the soil.

Tab.1. Effect of some herbicides on cellulose decomposition in the soil

Herbicides	**μg active ingredient per 1g soil**	**Cellulose decomposition, % relative to the control**	
		Sandy soil	**Chernozem**
Control	-	100 ab	100 ab
Simazine	62	105 a	97 c-f
	125	94 b	92 ef
	250	98 ab	96 def
	500	97 ab	94 def
Paraquat	37	97 ab	105 abc
	75	98 ab	108 a
	150	84 c	90 f
	300	79 c	71 g
2,4 D	87	100 ab	101 a-d
	175	99 ab	107 ab
	350	94 b	99 b-f
	700	83 c	91 f

Means followed by the same lowercase letters in rows are not significantly different ($p > 0.01$) according to LSD test

As the herbicide rate increased, the percentage of cellulose decomposition slightly decreased relative to the control in both soils (sandy soil and chernozem), which was consistent with the reports of many authors on the inhibitory effects of triazine, dinitroaniline and phenoxycarboxylic acid derivatives on total microbial count, bacterial biodiversity, microbial biomass and enzyme activity (Ayansina and Oso, 2006; Šantrić *et al*., 2015).

The percentage of cellulose decomposition slightly decreased with increasing simazine rate in both sandy soil and chernozem, most likely due to the effect of simazine on soil microorganisms (Harden *et al*., 1993; Kodoma *et al*., 2001).

Conclusion

The results of this research suggest the following:

- simazine application rates had a slightly inhibitory effect on cellulolytic activity in the soils tested;
- only the highest rate of 2,4 D was significantly inhibitory to cellulose decomposition in both soils;
- paraquat showed a much higher level of toxicity compared to simazine and 2,4 D;
- as even the lowest application rates were several times greater than the rates commonly used in agricultural practice, the herbicides tested, when applied at recommended rates, cannot be inhibitory factors in cellulose transformation processes in these soils.

Abstract

This paper presents the results of 10 representative samples of Vertisols collected from different land use of ten locations in Serbia (meadows and arable land). The following basic chemical properties were examined: active soil acidity (pH in H_2O), substitutional acidity (pH in 1M KCl), $CaCO_3$ content, humus content, content of available forms of phosphorus and potassium, content of clay, CEC, content sand and silt. The paper shows the characteristics, origins, behaviour and content of total and available nickel in the soil and nickel in plants *Avena sativa* L. Average value of the total nickel content of the soil samples was above the MAC (50 mg kg^{-1}), and amounts to 54.89 in the soil from the arable land and 56.11 mg kg^{-1} of the soil from a meadow, while the average value of readily available nickel was 2.96 mg kg^{-1} in the soil from the arable land and 2.88 mg kg^{-1} in the meadow land.
The share of available nickel in total nickel was a good indicator of the origin of soil contamination. Since it is determined a percentage of the readily available form in the total nickel (5.45 % in the arable land and 6.04 % from a meadow) is determined, it may be concluded that the Ni content in the soils of Serbia is of natural origin and that there is no danger of input of the elements in the food chain.

Key words: *Vertisol, chemical properties soil, plants, nickel*

Introduction

The contamination of ecosystems may result in phytotoxic and negative effects of heavy metals on the quality of plant products. Heavy metals in the soil are primarily of geochemical i.e. lithospheric origin, and their concentrations in the soil are dependent on their content in the rocks from which the soil parent material has been derived (Ubavić et al., 1995). However, more recently, industrial development and agricultural intensification have led to the use of various substances which contaminate the soil, thus causing an increase in the concentrations of heavy metals in some areas of land due to anthropogenic activities. Recent research has pointed to the increasing presence of heavy metals in agricultural soils (Markoski et al., 2011), which have been additionally threatened by the increasing and improper use of chemicals, waste waters, sewage, sludge and mineral fertilizers. Normal Ni levels range from 2 to 750 mg/kg for soil, and from 0.02 to 5 mg/kg for plant material (Alloway, 1995). In the samples of soil, type Fluvisol, Ni content ranged from 265.70 to 286.05 mg/kg (Jaksić et al., 2013).
The behavior of heavy metals in the soil is governed by a multitude of factors that may affect their mobility and accumulation by plants, the major ones including soil reaction, organic matter content and colloidal clay content (Pelivanoska, 2011). Soil pH has a decisive effect on

Ni mobility and availability in the soil. As soil pH increases from 4.5 to 6.5, the oat kernel Ni content decreases about eight times (Kabati-Pendias, 2011).

Most toxic elements typically react with different organic compounds to form stable complexes with ligands which contain electron-donating oxygen, sulfur or nitrogen atoms. Soil organic matter comprises a large number and variety of functional groups and has high CEC values, resulting in enhanced heavy metal retention ability, mostly through surface complexation, ion exchange, and surface precipitation (Bradl, 2004; Mihaljev et al., 2008).

The toxic effect of elements is based on their irreversible binding to metabolically active groups in amino acids, polypeptides and proteins (Mihaljev et al., 2008). It is generally understood that toxic elements primarily affect the cell membrane, whereas their secondary effects in most cases include damage to the enzymatic systems inside the cell (Milošević and Vitorović, 2008). Heavy metals enter the food chain through plants, and exhibit cumulative properties in the human body by accumulating in some organs or tissues, where they show their harmful effects. Adverse Ni effects range from skin irritation to nervous system damage, in addition to carcinogenic effects.

Cereal crops (oats, barley and triticale) are annual plants considered to be the leading and most important field forage crops for high-quality feed production, used for fresh cut forage or preserved as hay, silage and flour.

The objective of this study was to evaluate factors that affect the behavior and bioavailability of nickel in vertisols of Serbia, to determine total and readily available levels of this heavy metal, and assess its origin and potentially deleterious effects on the environment and plants.

Materials and methods

Samples were taken from Vertisol in the Ap horizon at ten different locations in Serbia: 1) Milutovac, 2) Priština, 3) Trnava, 4) Rekovac, 5) Vranje (Neradovac), 6) Zaječar, 7) Bela Crkva, 8) Blace, 9) Salaš and 10) Kragujevac. Sub-samples were taken from arable land and meadow ecosystems, from a depth of 0 to 20 cm, after which they were air-dried and crushed in a porcelain mortar up to particles of 2 mm in size. The basic physical and chemical properties of soil were determined using standard methods (Soil. Sci. Yug., 1966). Soil pH was determined in a suspension with water and 1M KCl mixture, with the ratio of soil/solution 1:2.5 after a 0.5 - hour equilibration period; the organic content was determined using the humus method by Kotzmann, the available P_2O_5 and K_2O content was determined using the Al method by Egner-Riehm, CEC was determined using the method with 1 M NH_4OAc, pH 7, and particle size distribution was determined by a pipette method (YSSS, 1966) The pseudo-total content of nickel was determined by atomic adsorption spectrophotometry (AAS, model Perkin–Elmer 3300/96, MHS-10) (Ure, 1995), after digested soil concentration. HNO_3 and then treated with 30 % H_2O_2. The content of the available nickel was determined by AAS spectrophotometry, after the extraction with 0.005 M DTPA (Lindsay and Norvell, 1978). In addition a vegetation experiment in pots was performed in Vertisol taken from 10 above mentioned locations. Soil samples, taken from arable land and meadows from a depth of 0-20 cm first air dried, ground and the size of particles of soil samples used in the vegetation experiment was determined. For these tests was taken control variant without fertilization.

The experiment was conducted using “Slavuj” oats (*Avena sativa* L) cultivated with 15 seeds per pot u triplicate; after two weeks the plants were thinned to ten seedlings per pot. The plants were followed 45 days in controlled laboratory conditions. Water was added to obtain optimal humidity. After 45 days the plants were dug up, rinsed with destiled water, and dried at room temperature in a dryer at t=70ºC. The dried plants were ground into a powder.

Content of Ni in oats was determined by AAS method, after digestion with HNO_3-$HClO_4$ with 30% of H_2O_2.

Results and discussion

The analyses have shown that the samples taken from 10 localities in Serbia were considerably differing regarding their physical and chemical properties (Table 1).
The reaction of soil was found to range in a fairly wide interval of pH values from acid to weakly alkaline reaction (from 4.60 to 6.9 in N KCl). The content of humus was considerably varying, ranging from 2.00 to 5.6% (weakly humus to humus soils), being unaffected by land use. In addition, the content of available phosphorous also ranged in a wide interval. Thus, on the vertisol under meadow, the content of available P ranged from 0.8 to 17.8 mg/100g, whereas on those under field, its content ranged from 0.6 to 28 mg/100g. Acording to the content of the available P, the Vertisol in question are low to medium supplied with this element. In contrast to the available phosphorous, the soils were found to be rich in potassium (19.0-59.6 mg/100g). In addition, these soils indicated a high cation exchange capacity and, by mechanical composition, could be defined as medium to heavy clay soils. The above-mentioned average values of the investigated properties proved to be very much the same for the arable land and for the meadow vertisol.

Table 1 *Examined physical-chemical characteristics of Vertisols in Serbia*

Soil characteristic	Arable land			Meadow

Nickel concentrations in the tested soils were highly variable, as the result of the soil parent material (Romić and Romić, 2003). Nickel is essential for plant growth and Fe resorption. However, elevated levels of nickel can disturb life processes, by causing chlorosis, intercostal necrosis and root growth retardation. The average Ni content in plants is 0.1–5.0 mg/kg dry matter. Nickel occurs in the soil as sulfate, copper and silicate minerals at concentrations of 5–500 mg/kg (Kastori et al., 1997). Elevated Ni levels are found in soils formed on serpentine rocks, but may also be due to anthropogenic activities associated with the use of sewage sludge, fertilizers, liquid manure and pesticides, or due to the vicinity of industrial plants, mines and other pollutants (Bogdanović, 2007).
High concentrations of Ni in the environment are toxic to all living organisms. As the soil is the main source of Ni for plants, either as a nutrient or toxicant, the determination of its availability is of high importance. Microelements are uptaken from the soil in small amounts, but at concentrations exceeding optimal levels they can have a harmful effect on plant growth and development. Ni levels in some soil samples were above the maximum permissible

concentration (MPC >50 mg kg^{-1}, Official Gazette of the RS, Issue 23/1994). Total nickel ranged from 21.1 mg kg^{-1} to 145.0 mg kg^{-1} in arable soil samples, and from 14.0 mg kg^{-1} to 139.0 mg kg^{-1} in meadow soil samples, and exceeded the maximum permissible concentration in two locations. The mean value of the pseudo-total concentration of nickel for all arable land and meadow soil samples was 54.89 mg kg^{-1} and 56.11 mg kg^{-1}, respectively, which was somewhat above the maximum permissible concentration (Tab. 2).

Table 2 *Content of total, available nickel, % of readily available out of total nickel, and Ni concentration in Plants in observed Serbian vertisol*

Mode of soil utilisation	Total Ni mg/kg	Available Ni mg/kg	% of readily available out of total Nickel	Ni Concentration in Plants
Arable land	54.89±35.72 21.1-145.0	2.96±2.11 1.14-7.88	5.45±1.70 2.79-8.02	4.92±1.55 3.17-8.33
Meadow	56.11 ± 37.00 14.00 - 139.00	2.88 ± 1.57 0.84 - 5.90	6.04±2.95 2.15-11.97	4.69±1.49 2.67-7.67

In soil samples taken from the arable soils, the coefficients of correlation between total Ni content and main soil properties showed that Ni values largely correlated with phosphorus (r=0.54*), followed by humus (r=0.49*), CEC (r = - 0.43*) and silt (r=-0.50*). Soil organic matter is known to exhibit a large number and variety of functional groups and high CEC values, which results in enhanced heavy metal retention ability, mostly through surface complexation, ion exchange, and surface precipitation. In meadow Vertisol samples, Ni was found to correlate with pH_{H2O} (r=-0.41*), pH_{KCl} (r=-0.42*), clay (r=0.56*) and silt (r=-0.50*) contents, and understandably so, since both soil fractions clay and CEC contribute to the total cation exchange capacity of the soil through their individual capacities (Tab.3). To determine the origin of increased levels of nickel in the soils and to assess the risk of this heavy metal entering the food chain on agricultural soils, the soil content of readily available Ni was measured. Readily available Ni concentrations in soil samples ranged between 1.14 mg kg^{-1} and 7.88 mg kg^{-1} for arable land soil, averaging 2.96 mg kg^{-1}, and between 0.84 mg kg^{-1} and 5.90 mg kg^{-1} for meadow soil, averaging 2.88 mg kg^{-1} (Tab. 2) The very low concentrations of readily available Ni indicate the geochemical i.e. natural origin of total Ni derived from the parent material. The results are consistent with the results of other authors. Dozet et. al (2011) reported that the amount of available DTPA-Ni in fluvisol in the interval 0.337 – 4.826 mg/kg, while in cambisol interval is 2.9 -6.9 mg/kg.

Table 3 *Correlation coefficients between total Ni concentration in the soil and plants and its available content in soil and some chemical and physical properties of soil*

	Available Ni(DTPA)	pH		Humus (%)	Available		CEC	Clay	Silt

NS- No statistically significant differences; *Significant at the 0.05 probability level; ** Significant at the 0.01 probability level

The percent contribution of available nickel to total nickel is a good indicator of soil pollution i.e. if this ratio is low, Ni is generally of natural origin (Romić and Romić, 2003). The mean relative amount of Ni, as determined by extraction with 0.005M DTPA, was 5.45 % in arable land soil samples, and 6.044 % in meadow soil samples, which was indicative of its geochemical origin (Tab.2). These values were consistent with previous results (Elrashidi et al., 1979, Valdares et al., 1983, Antić-Mladenović., 2004). As estimated from the presented data, Ni availability in soil samples collected from both ecosystems was not high.

The average critical concentration of Ni in crops is 20 mg/kg, and the average toxic level is 30 mg/kg dry matter (Kastori et al., 1997). Ni content in the tested plants grown on Vertisol samples was far below these values. The average Ni content in oat shoots from the control group was 4.92 mg/kg (range 3.17-8.33 mg/kg) for arable soil samples, and 4.69 mg/kg (range 2.67-7.67 mg/kg) for meadow soil samples (Tab.2).

The analysis of the correlation coefficients showed that the content of Ni in plants was significantly positively correlated with DTPA-extractable Ni (r=0.53*), pH_{H2O} (r=-0.36*) and pH_{KCl}=-0.43* on arable soil, and with DTPA-extractable Ni (r=0.70**), pH_{H2O} (r= - 0.52*) and pH_{KCl}= -053* on meadow soil, indicating the dependence of Ni mobility and accumulation by plants on soil reaction and available Ni levels. Similar findings were presented by Chhotu and Fulekar (2008) in a study on Ni uptake by alfalfa plants, showing that Ni concentrations in plants increased proportionally to the increase in DTPA-extractable Ni in the soil. Furthermore, comparable results on the dominant effect of soil pH were reported elsewhere (Echevarria et al., 2006).

Conclusion

Total nickel ranged from 21.1 mg kg^{-1} to 145.0 mg kg^{-1} in arable soil samples, and from 14.0 mg kg^{-1} to 139.0 mg kg^{-1} in meadow soil samples, and exceeded the maximum permissible concentration (50 mg/kg, Official Gazette of the RS, 23/1994) in two locations. Nickel mobility and accumulation by oat plants were dominantly affected by soil pH and DTPA-extractable Ni content. Regardless of the mostly geochemical origin of nickel in the tested Vertisols, due to which its forms in the soil exhibit low mobility and, hence, low availability to plants, continuous monitoring of the levels of nickel, as well as of other heavy metals, is required.

Abstract

The influence of long-term application (over 15 years) of different system of fertilization and liming (applied every 5 years) on the state of agrochemical characteristics of soil type pseudogley were investigated. The trial included an untreated control and three ameliorative fertilization treatments: NP_1K (120 kg N ha^{-1}, 80 kg P_2O_5 ha^{-1}, 53 kg K_2O ha^{-1}), NP_2K (120 kg N ha^{-1}, 160 kg P_2O_5 ha^{-1}, 53 kg K_2O ha^{-1}), $NP_1K + CaCO_3$ (120 kg N ha^{-1},80 kg P_2O_5 ha^{-1}, 53 kg K_2O ha^{-1} + 5 tha^{-1} $CaCO_3$), $NP_1K + CaCO_3$ + manure (120 kg N ha^{-1}, 80 kg P_2O_5 ha^{-1}, 53 kg K_2O ha^{-1} + 5 tha^{-1} $CaCO_3$ + 20 t manure ha^{-1}). This investigation carried out at the experimental field of Secondary Agricultural-chemical school "Dr Djordje Radic" in Kraljevo. The results of investigation showed a significant effect of long-term application of fertilizers and liming materials to changes in pH, content of N, P_2O_5, K_2O, Fe, Mn, Zn, Al, and partially indicated the composition of adsorption complex of soil and content of humus in soil. The long term application of NP_1K fertilizer every year in combination with periodical application $NP_1K + CaCO_3$ + manure every five year showed the highest eficient influence on changing the characteristics of pseudogley type of soil. Thus, combined application of $NP_1K + CaCO_3$ + manure reduced soil acidity ($pH_{(KCl)}$ for 1.8 units), the content of mobile Al (from 13 mg 100 g^{-1} to 0.4 mg 100 g^{-1}), and the content of Fe and Mn in several dozen mg kg^{-1}, and increased content of P_2O_5 by about 4.2 mg 100 g^{-1} and K_2O content by about 2.1 mg 100 g^{-1}.

Key words: agrochemical properties, fertilization, liming, soil, pseudogley.

Introduction

Soil acidity is a major yield-limiting factor for crop production worldwide. The land area affected by acidity is estimated at 4 billion hectare, representing approximately 30 % of the total ice-free land area of the world (Sumner and Noble, 2003). The Republic of Serbia also comprises substantial areas of acid soils, accounting for over 60% of total arable land (Stevanovic et al. 1995). According to Fageria and Baligar (2008), soil acidity produces complex interactions of plant growth-limiting factors involving physical, chemical, and biological properties of soil. The pH can affect the soil environment in many ways through influences on sorption potential, cation availability and microbial degradation rates (Sanderman et al., 2008). Calcium, magnesium, and phosphorus deficiencies or unavailability, and aluminium toxicity are considered major chemical constraints that limit plant growth on acid soils.

Liming is the most common and effective practice for reducing soil acidity related problems (Fageria and Baligar, 2001). Liming of acid mineral soils with agricultural limestone or other liming materials is required to reduce levels of toxicity, increase soil pH and increase availability of some nutrients which consequently improve crop yields (Jaskulska et al., 2014). Adequate liming eliminates soil acidity and toxicity of Al, Mn, and H; improves soil structure (aeration); improves availabilities of Ca, P, Mo, and Mg, and N_2-fixation; and reduces the availabilities of Mn, Zn, Cu, and Fe and leaching loss of cations. For several crops, liming results in some chemical changes in the soil such as, increase in pH, effective cation exchange capacity (ECEC), and exchangeable Ca, decrease in toxic elements for example Al^{3+} and Mn^{2+} and changes in the proportion of basic cations in CEC sites (Tang and Rengel, 2003). The objectives of this study is the long-term effects of fertilization and lime application on some agrochemical characteristics of soil type pseudogley.

Material and Methods

This investigation carried out at the experimental field of Secondary Agricultural-chemical school "Dr Djordje Radic" in Kraljevo. The studied soil is extremely acid pseudogley. For the experiment, 2–field crop rotation of wheat-corn was applied. The experiment was established as randomized block system in three replications on the plots of 100 $m^{2.}$. The trial included an untreated control and three ameliorative fertilization treatments: NP_1K (120 kg N ha^{-1}, 80 kg P_2O_5 ha^{-1}, 53 kg K_2O ha^{-1}), NP_2K (120 kg N ha^{-1}, 160 kg P_2O_5 ha^{-1}, 53 kg K_2O ha^{-1}), NP_1K + $CaCO_3$ (120 kg N ha^{-1},80 kg P_2O_5 ha^{-1},53 kg K_2O ha^{-1} + 5 t ha^{-1} $CaCO_3$), NP_1K + $CaCO_3$ + manure (120 kg N ha^{-1}, 80 kg P_2O_5 ha^{-1}, 53 kg K_2O ha^{-1} + 5 t ha^{-1} $CaCO_3$ + 30 t ha^{-1}manure). Fertilizers have used in the form of complex NPK fertilizer (8:24:16, superphosphate (17% P_2O_5) and ammonium nitrate (AN) 34.4% N). For maize the same concentrations of P and K were applied, while N was applied in higher dosage of 150 kg N ha^{-1}. In the experiment a lime fertilizer "Njival Ca" (product of Paracin glass factory) was applied at a rate of 4.0 t ha^{-1}. In wheat total quantity of lime, phosphorus and potassium fertilizers along with 1/3 of nitrogen applied in one plant feeding in early spring. In maize entire quantity of nutrients has been applied after soil preparation. Lime fertilizer has been used periodically every five years (2005, 2010 and 2015). Quantity of the applied well matured manure was 30 t ha^{-1}. Other measures of care that have been carried out during the growing season of winter wheat and maize have been standard. Prior to lime and mineral fertilizers applications, surface-soil samples were taken in a random manner with a soil auger from the top 0–20 cm. They were mixed thoroughly and about 1.0 kg composite sample packed in a polythene bag and analyzed in the laboratory. Soil analyzes have been performed by standard chemical methods, as follows: pH in H_2O and KCl, electrometrically with a glass electrode in a 1:2.5 suspension; content humus by Kotzmann's method; sum of absorbed base cations by Kappen's method; total nitrogen has been determined by the Kjeldahl's method, available phosphorus and potassium by Egner-Riehm's Al method, mobile Al by colorimeter with aluminium acetate buffer, while the content of available forms of heavy metals (Fe, Mn, Zn) have been determined by AAS in 0.1 HCl soil extract.

Results and Discussion

Initial soil characterizations on selected parameters from the study site are presented in Table 1. Agrochemical properties of the treated pseudogley are very unfavorable. The treated soil is highly acid, which in the surface topsoil horizon (0-20 cm) has a relatively low active acidity (pH $_{(H2O)}$ 5.24), while the deepest layers of the soil there was a significant decrease in acidity ($pH_{(H2O)}$ 6.04). Exchangeable acidity (pH in KCl) of this type of soil throughout the profile ranges from 4.48 to 4.80. The examined soil is characterized by very unfavorable composition of the adsorptive complex. The values of adsorption capacity, sum of adsorbed base cations, as well as the degree of saturation adsorptive complex with bases, are very low (Table 1).

Table 1. Agrochemical properties of soil type pseudogley

Depth (cm)	Humus (%)	N (%)	pH H_2O	pH KCl	T	S	T–S	P_2O_5	K_2O
					($cmol^+ kg^{-1}$)			($mg\ 100\ g^{-1}$)	
0–20	2.18	0.14	5.24	4.48	16.71	8.08	8.63	8.0	13.8
20–40	1.84	0.13	5.55	4.58	16.69	9.79	6.90	7.0	13.6
40–60	0.66	0.09	5.46	4.42	26.24	20.02	6.22	1.3	8.5
60–80	0.71	0.07	5.64	4.52	26.29	21.31	4.98	1.0	7.6
80–100	0.63	0.02	6.04	4.80	25.62	22.02	3.60	0.8	4.3

Also it is low (2.18%) humus content in the surface layer (0-20 cm) and significantly decreases with increasing of depth. Reduced humus content in cultivated pseudogley soil profiles, points out the need for a projection of fertilization system and application of pedomeliorative measures, in order to preserve and enrich the adsorptive complex, it is a must to apply ameliorative measure of humification. Analyzed pseudogley profile shows median coverage with total nitrogen in the humus-accumulative horizon. Total nitrogen in the topsoil is represented with an average value of 0.14% and significantly decreases with increasing depth (0.02%). Supply with available phosphorus in this soil type is poor 7.0-8.0 mg 100 g^{-1} of soil, in the soil layer from 0 to 40 cm. When it comes to the content of easily available potassium the treated soil is well supplied, and it belongs to an average supplied soil class (13.8 mg 100 g^{-1}). Long-term application of only NPK fertilizers influenced the increase of acidity of the soil, while the meliorative application of lime and manure in combination with the application of NPK fertilizers significantly reduced the acidity of the soil (Table 2).

Table 2. Changes of pH, humus content, nitrogen and base cations in the treated soil (0-20 cm)

	NP_1K + Ca + manure	7.68	6.83	3.12	0.148	28.2	11.0	10.6	58.4

A – initial state, B – present state

The application of NPK fertilizers in relation to the initial state increased the acidity of the soil from 0.23 (pH in H_2O) to 0.49 pH units (pH in KCl). The periodic meliorative use of lime and manure fertilizers in combination with the application of NPK fertilizers influenced a significant decrease in acidity in relation to control, for: 2.58 in the active and 2.91 pH units, in the case of exchangeable acidity of the soil. In combination with fertilizer NPK variants combined use of lime, manure and mineral NPK fertilizers significantly reduced acidity of the soil (2.37 active and 3.01 pH units exchangeable). In agreement with these results, Foth and Ellis (1997) also pointed out that soil pH change over time due to liming as an increase following application and gradual decrease with time. However, change in soil pH over time in response to lime application depends upon the soil type, lime rate and lime quality (Foth and Ellis, 1997). Lime alone increased soil pH and reduced soil exchangeable acidity when compared to the pre-season and to the control. The increase in soil pH under lime treatment was due to addition of CaO which reacts with water leading to production of OH^- ions which forms $Al(OH)_3$ and H_2O thus raising the soil pH and decreasing exchangeable acidity. On the other hand applied manure through its decomposition releases exchangeable cations to the soil solution, which replace the Al^{3+} and H^+ ions in the soil sorption sites (Crawford et al., 2008). Similar results were reported earlier and by other authors (Jelić et al., 2006; Dugalić et al., 2006; Jelić et al., 2013).

Content of the humus and total nitrogen in the soil varied depending on the long-term application of fertilizers. Long-term application of fertilizers showed a certain influence on the change of the adsorptive soil complex (Table 2). Significant changes in T values were obtained in the periodic combined use of lime, manure and mineral NPK fertilizers. As compared to the initial state and the control it is achieved increasing of adsorption capacity for about 8.0 $cmol^+ kg^{-1}$. Sum of adsorbed basic cation (S) showed minimal changes, with the tendency of slight increase under the influence of long-term application of lime, organic and mineral NPK fertilizer. Degree of soil saturation with adsorbed bases (V%) is slightly reduced if NPK has been used for years, while the combined use of lime, manure and NPK fertilizer increasing the degree of base saturation of about 6%. Realized changes of the soil adsorption complex are result of the positive impact of the applied lime and manure to increase soil pH and humus content. Raising the pH of the soil solution enhances the cation exchange capacity, due to the increase in the activity of the hydroxyl groups in the composition of humic acid, and the increase in negative charge of the amphoteric colloid soils (Dugalić and Gajic, 2012). Using of a mineral NPK, manure and lime application for years has led to significant changes in the content of available phosphorus in the soil (Table 3).

Table 3. Changes in the content of some available forms of macro and micro nutrients and aluminium in the studied soil (0–20 cm)

Years	Variants of Fertilizers	P_2O_5	K_2O	Al	Fe	Mn	Zn
		mg 100 g^{-1} soil			mg kg^{-1} soil		
2002 (A)	Control	7.0	8.5	8.7	227	70	1.7
	NP_1K	8.3	8.5	9.4	280	54	1.0
	NP_2K	9.5	8.3	8.7	273	18	1.5
	NP_1K + Ca	12.9	9.5	1.3	183	23	1.6
	NP_1K + Ca + manure	13.5	10.7	0.1	122	31	1.9
2016 (B)	Control	4.5	7.7	12.3	320	96	0.8
	NP_1K	8.3	7.3	13.1	334	128	1.0
	NP_2K	10.2	6.7	13.0	260	135	1.3
	NP_1K + Ca	13.3	10.4	0.1	110	44	1.5
	NP_1K + Ca + manure	16.8	11.3	0.1	115	35	2.0

A – initial state, B – present state

Applying the complex NPK fertilizers with higher dose of phosphorus, using the combined lime and manure along with the regular application of NPK fertilizer had a significant increase in the content of available phosphorus which are relative to a control baseline ranged from 9.8 to 12.3 mg 100 g^{-1} soil. Also, the application of lime, manure and NPK fertilizers has achieved a significant increase in available phosphorus content in relation to the use of NPK fertilizers. Accumulation of available phosphorus content in soil is the result of long-term application with a phosphate, and lime spreaders which are intensified mobilization process of the element from the reserve area. Similar results have been noticed by other authors (Dugalić et al., 2006; Jelić et al., 2006; Jelić et al., 2013). Changes in the content of available potassium are less in comparison to changes in the content of available phosphorus (Table 3).Variants with K application, in particular, those which are in addition to the regular application of potassium periodically received lime manure as well, are achieved a substantial increase of available potassium according to the control, and the initial state (2.2-3.6 mg 100 g^{-1} soil). Mobility of aluminum in soil is directly dependent on the pH value of the soil. Therefore, the highest content of aluminum was recorded in the control and with the application of the NPK fertilizer in the most acid soil (Table 3). Continuous application of the NPK fertilizer increased the Al content in the soil in relation to the control, as well as the initial state. However, their periodic combined use of the organic, lime and mineral NPK fertilizer has significantly reduced the content of mobile Al in the soil (0.1 mg 100 g^{-1} soil) in relation to the initial state and control. Kheyrodin and Antoun (2012) found that manure increased significantly soil P, Ca and Mg contents in the 15–30 cm depth. Application of 2 t ha^{-1} of lime decreased exchangeable Al, and increased pH, available Ca and Mg in Cameroon (The et al., 2001). Lime and P fertilizers significantly improved soil pH and available P as reported by

Anetor and Akinrinde (2006), who also attributed increased soil pH with lime which in turn reduced P fixation. Ademba et al. (2010) reported significant increase in soil total P, K, Ca, Mg with sole application of 10 t ha^{-1} of manure, 60 kg P_2O_5 ha^{-1} and 250 kg ha^{-1} of lime. The et al. (2001) also reported significant increase of exchangeable Ca after application of manure alone or combined with lime and P fertilizer.

Conclusion

Acid reaction and nutritional imbalances, mainly low levels of plant available phosphorus (P) are often limiting factors of soil fertility in Central Serbia. The soil was strongly acidic, with Al toxicity and low exchangeable Ca^{2+} and poor availability of P. Residual lime and fertilization had also significant effect on some chemical properties of the acidic soils. Farmers can obtain long term economic gain with one-time application of lime and P fertilizer on P deficient acid soil of the region.

AGRO-ECOLOGICAL CONDITIONS OF FRUIT GROWING IN THE PEŠTER (PLATEAU) REGION

Abstract

Pedological and land capability properties of soil in the Pešter plateau region (the Municipality of Tutin, Serbia), indicate that those are predominantly shallow, poorly fertile soils, rated with class 5 and above. By altitude and relief predisposition, agricultural land is extremely mountainous with the average altitude of approx 1000m. Fruit area takes 0.9% of the territory or 340 ha of the area, with plum dominating in the production structure and a tendency of planting raspberry. Analysis of agro-physical and agro-chemical properties of the soil planned for established fruit plantations show that the soils within the same area are significantly different and require different repair measures accordingly. Agro-physical properties indicate the classification of clay to light clay soil, with medium to high interval of cation exchange capacity (T). Degree of soil saturation with adsorbed bases (V%) corresponds to other parameters tested, with the highest values in the Pešter region, in the zone under peat fields from which the peat is utilized for commercial purposes (V 85.14 to 98.57%). Agro-chemical properties of the soil indicate the soil reaction range from acid to slightly acid, non-carbonic at 60-75% of the sampled surface depending on the depth of sampling and culture grown. A high (> 5%) and very high (> 8%) humus content is present in the surface horizon (0-30 cm) in about 75% of the tested surfaces. In most of the sampled localities a very low content of available phosphorus was recorded (<6 mgP_2O_5/100 g of soil) as well as the availability of easily accessible potassium (15-25 mg/100g of soil). For the cultivation of fruit species in these conditions, it is necessary to consider all environmental conditions and then select the type and variety (of the species for cultivation).

Keywords: *Agro-ecological conditions, Pešter plateau, Fruit growing.*

Introduction

Pešter plateau region stretches at an altitude of 900 to 1200 meters and is the highest plateau in the Balkans and one of the largest in Europe. Pešter is well known for its specific microclimate, especially during the winter period. Extreme climatic conditions in certain periods of the year, contributed to the development of extensive livestock production, and the development of fruit production takes place gradually, without any particular impact on the balance of agricultural growth. On the part of the Pester plateau, in the municipality of Tutin, extensive plantations of fruit species are present on a total area of 340 ha, predominant fruit species as plums and apples. Other types of fruit are grown in gardens, sporadically. In recent years, there is a trend of establishing modern plantations of hazelnut and raspberry, and a substantial interest in other types of berries and nuts.

Pedological and land capability properties of soil in the Municipality of Tutin indicate that those are predominantly shallow, poorly fertile soils, rated with class 5 and above. High productive soils account for only 33 km^2 of land, i.e. 4.4%. Due to the high altitude, sub-mountain and mountain conditions, dry areas on one side and waterlogged areas on the other side, as well as a shallow area, it can be said that the agricultural zoning is limited to a small band of up to 800 m above sea level. It is known that proper land management, good agricultural practices (which includes regular soil fertility control and the implementation of the basic principles of fertilization and agrotechnics) can maintain production capacity of land with minimal effects on the environment (Milivojević *et al.,* 2012). The most important preventive measures in the protection of land from degradation are identification of hazards and finding appropriate solutions to overcome them. To this end, a systematic control of fertility i.e. monitoring of soil quality is proposed. (Sekulić *et al.,* 2005). The variability of climate, as well as incomplete agrotechnics due to insufficient application of fertilizers, significantly affect the availability of nutrients in soil, often reducing their accessibility for the plants (Bogdanović, 2009).

The aim of our research is to determine agrophysical and agrochemical characteristics, in agro-ecological conditions of the part of Pester plateau and the possibility of growing different kinds of fruit species.

Material and Methods

The land is sampled in the fall of 2016, in a rural area of the municipality of Tutin in Serbia. The samples were collected on parcels that are not under orchards (meadows, plough fields, stubble field, fallow land, fodder) and parcels under different types of fruit species, of two depths: 0-30 cm, 30-60 cm. Sampled parcels are marked with GPS coordinates with number of samples in village areas, determined on the basis of arable land and agricultural production, Popis poljoprivrede (2012). Agro-mechanical, physical and chemical analyses included examination of: mechanical aggregate composition of soil by sieving and sedimentation of different mechanical fractions JDPZ (1997), determination of the sum of exchangeable adsorbed alkaline cations (S meq $100g^{-1}$) (method Kappen-a), the determination of hydrolytic soil acidity (H meq $100g^{-1}$), cation exchange capacity (T meq $100g^{-1}$), the level of saturation with adsorbed bases (V%). Agro-chemical characteristics of soil are determined by the following methods: pH of the H_2O and 1 MKCl-in (potentiometrically); humus (by the method of Kotzman); total nitrogen (method according to Kjeldahl); readily accessible phosphorus and potassium (AL method, P_2O_5 - colourimetrically, K_2O – light photometrically).

Results and Discussion

The results of mechanical composition of soil in certain village areas in the Municipality of Tutin are shown in Table 1. At the indicated locations (in villages Velje polje, Detane, Raduša, Gluhavica, Crkvine, Melaje and Leskova) there is a tendency of fruit production development.

Table 1. Mechanical composition of soil, Municipality of Tutin

Settlement	Dubina	Sadržaj mehaničkih frakcija (%)						Klasa zemljišta
		2-0,2	0,2-0,02	0,02-0,002	<0,002	>0,02	<0,02	
		mm

Detane	0-30	1.84	63.86	28.00	6.30	65.70	34.30	Sandy loam
	30-60	8.65	42.45	35.10	13.80	51.10	48.90	Loam
Raduša	0-30	3.08	67.72	21.40	7.80	70.80	29.20	Sandy loam

	30-60	0.59	57.61	30.50	11.30	58.20	41.80	Loam
Gluhavica	0-30	2.14	40.56	40.50	16.80	42.70	57.30	Clay loam
	30-60	3.34	31.76	43.79	21.11	35.10	64.90	Clay loam
Melaje	0-30	0.25	35.55	33.00	31.20	35.80	64.20	Light clay
	30-60	2.52	28.38	33.90	35.20	30.90	69.10	Light clay
Leskova	0-30	0.83	52.07	32.10	15.00	52.90	47.10	Clay loam
	30-60	1.18	48.92	31.10	18.80	50.10	49.90	Clay loam
Crkvine	0-30	8.67	40.13	31.00	20.20	48.80	51.20	Clay loam
	30-60	2.13	43.17	30.50	24.20	45.30	54.70	Clay loam

In most of the tested sites, there is a type of clay soil with some differences with respect to the sampling depth. In villages Detane and Velje polje, in the humus Ah horizon (0-30 cm), the fraction share of physical was clay is 33.00-34.30% and 65.70-67.00% is physical sand. In sub humus horizon (30-60 cm) the fraction share of physical clay is increased, with an approximate increase of the powder and clay fraction. Land at the site Raduša is highly humic and by mechanical composition, light to medium loam. In humus (Ah) horizon, they contain 70.80% of physical sand, of which 3.08 % fraction of coarse sand with prevailing powder fraction in relation to the clay fraction. At the site Leskova near the excavation of peat in Gornji Pešter, the land is classified as clay loam with 15.00-18.80% of fraction clay. In villages Gluhavica and Crkvine, in sub humus horizon there comes to an increased content of physical clay with predominant powder fraction with soils of heavier mechanical texture in relation to the former. At the site of Melaje, the highest content of fraction clay (31.20-35.20%) is recorded and with increasing sampling depth, the land in the class of light clays (ISSS classification). According to the American classification, these soils are classified into loamy sand to clay loam. Relatively favourable mechanical composition of the soil for cultivation of different types of fruit species and limited growing conditions indicate that the recommendation for the cultivation of certain fruit species needs to be seen from different angles. The results of research in Table 2 show that the analysed soils have different adsorptive capacity. Analyses show that there is a medium to high cation exchange capacity of the interval (T). Central cation exchange capacity (12-25 meq $100g^{-1}$) at the locality Veljo box Detane, Raduša and Gluhavica, a high capacity in Crkvina and Leskova, while at the site Melaje in humus (Ah) horizon a very high capacity > 40 meq $100g^{-1}$ is present (Kutilek, 1978).

Table 2. Physical and chemical characteristics of soil, Municipality of Tutin

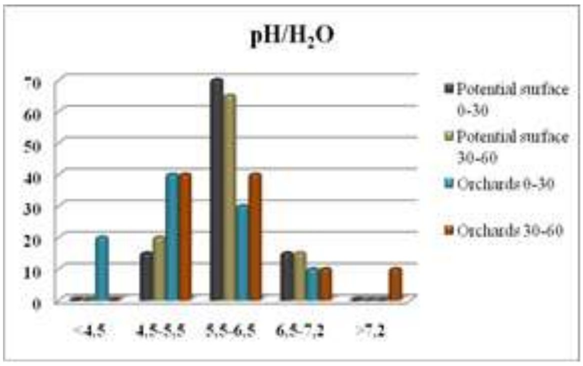
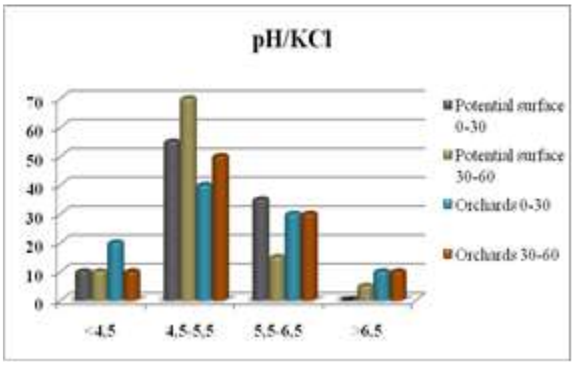
	30-60	26.7	4.21	30.91	86.38

Very high levels of hydrolytic acidity, (15.05 to 16.02 meq $100g^{-1}$) and low degree of base saturation (V 19.69-27.51%) were measured in the village Velje polje. In the areas of village Raduša values of hydrolytic acidity are high and average degree of soil saturation with adsorbed bases 50.00-80.00% (Baize, 1993). In Gluhavica, values of investigated parameters are lower. Hydrolytic acidity in villages Detane and Crkvine is 4.21-6.63 meq $100g^{-1}$ and V 47.09-86.38%. At the sites Melaje and Leskova, the measured values are very low hydrolytic acidity and high to very high degree of soil saturation adsorbed bases (V 80.00-100.00%).
Agrochemical characteristics of soils in the Municipality of Tutin are shown in Graph. 1-7.
In the humus (Ah) horizon (0-30 cm), of the soils that are now no longer used for cultivation of fruits (fields, meadows, stubble field, forage crops), 70.0% of the samples belong to the class of weakly acidic reaction (pH/H_2O 5,5- 6.5), and 15.0% of samples each has an acidic (pH 4.5-5.5) or neutral (pH 6.5-7.2) reaction of soil. With increasing the depth of the sampling, in sub humus horizon (30-60 cm), in 20.0% of the samples soil acidity is increased whereas in 65% of the samples soil reaction is slightly acidic. On 30% of sample areas that have been planted with different types of fruit species, the most common are acidic soils (pH 4.5-5.5), then slightly acidic (pH 5.5-6.5), and in humus (Ah) horizon (0 -30 cm) there are also soils with strong acid reaction at two localities (Graph.1).

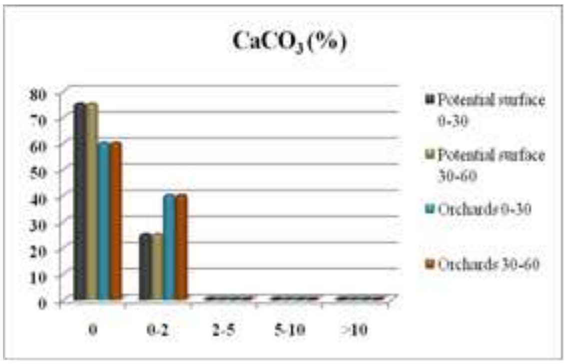


Graph 1. Active acidity of the soil (pH/H_2O)



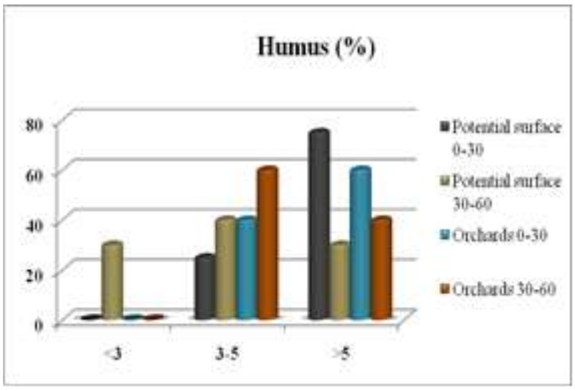
Graph 2. Substitution acidity of the soil(pH/KCl)

Based on the testing results of substitution acidity of soil (Graph. 2), in the humus (Ah) horizon (0-30 cm) of soil which is now not used for the cultivation of fruit trees, 55.0% of the samples has an acidic reaction (pH/KCl 4, 5-5.5) and in the land under orchards 40% of the samples. Weak acid reaction is found in 30-35% of the samples of all tested surface of the first sampling depth. With increasing depth (30-60 cm), an increase of soil acidity happen in the surfaces that are not under orchards to 70.0% and on surfaces under orchards on 50% of the samples in the class of acid reaction. Weakly acidic and weakly alkaline reaction of the sampled soil under orchards is not distinguished by depths of horizons.
Test results (Graph. 3) show that 75% of the samples are carbonate-free (0% CaCO3), and 25% of the samples slightly carbonated ($CaCO_3$ 0-2%) in both sampling depths, on the surfaces that are not under orchards. 60% of the samples on surfaces that are now used for fruit growing are non-carbonated and 40% is slightly carbonated.

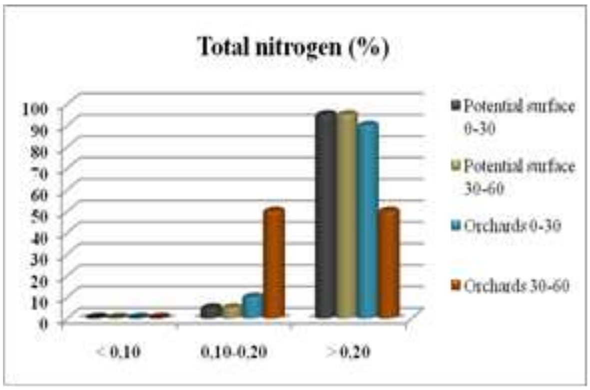


Graph 3. Content of $CaCO_3$ (%)

Based on the testing results of humus content in agricultural soils (Graph. 4), on the surfaces that are not used for fruit cultivation in the humus (Ah) horizon (0-30 cm), 75% of the soil is highly humic and 25% is humic soil. In sub-humic horizon (30-60 cm), there is a reduction of content of humus and the largest percentage of humic (3-5% of humus), 40% of slightly humic (<3% humus) while high humic soils (> 5% humus) are present with 30%. Very high humus content > 8%, is measured in the area of the upper Pester, in the surface horizon of the soil. The surface under various fruit species, depending on the depth of the tested horizon contain from 40-60% of the samples in the class of high humic and highly humic soils.

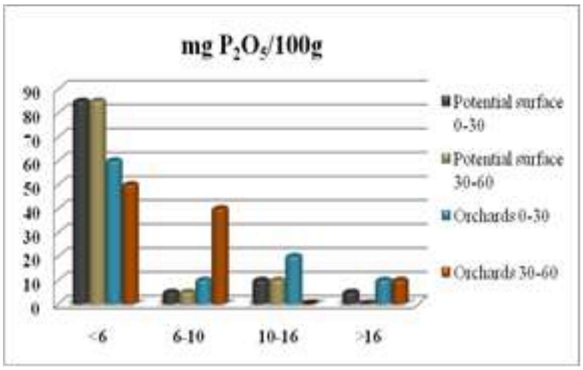


Graph 4. Content of humus (%)

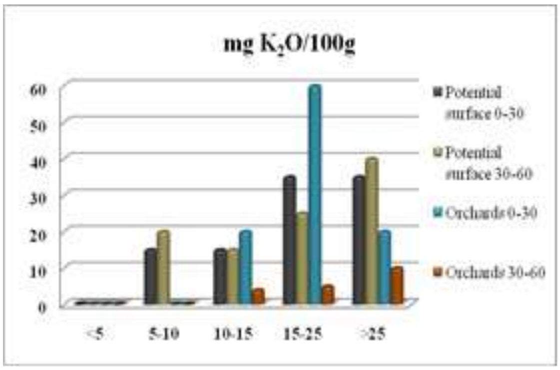


Graph 5. Content of total N (%)

The results of the study shown in Graph. 5 indicate that in the humus (Ah) horizon (0-30 cm) of all tested agricultural areas a high content of total nitrogen in soil (> 0.20%) is found in 90-95% of the samples. Sub humus horizon (30-60 cm) in 95% has a high content of total nitrogen, and in the same soil horizon under orchards, 50% of samples each is with medium and high content of total nitrogen.



Graph 6. Content of easily accessible P_2O_5 (mg $100g^{-1}$ of the soil)



Graph 7. Content of easily accessible K_2O (mg $100g^{-1}$ of the soil)

Soils with reaction pH <6 in 1M KCl in the region of Tutin account for 90%. They have lower content of easily accessible P_2O_5, so that of the samples from potential fruit growing surfaces in both sampling horizon, 75% of them have very low content (<6 mgP_2O_5/100 g soil). Sites of agricultural land under orchards on 50-60% of samples have a very low content of easily accessible phosphorus. The content of easily accessible phosphorus in other threshold value intervals varies in dependence of the sampling depth.

The content of easily accessible potassium (Graph.7), is within the limits of a good supply (K_2O 15-25 mg / 100 g soil). In the humus (Ah) horizon (0-30 cm) of agricultural area which is now not used for fruit cultivation (fields, meadows, stubble, fodder) in 35.0% of the samples show a high content easily accessible potassium, and the same percentage of the samples is in the limits of optimal values, while in the remaining 30% the content is medium to low. Similar results are also obtained with the samples in sub humus horizon (30-60 cm), with minor discrepancies in relation to the volume of overall sample for this Municipality. In the areas under orchards, an optimal content of easily accessible K_2O is found in 50-60% of the tested surface, whereas with a depth horizon increases the medium content of this nutrient. Soil cover represents an important ecological factor for a successful fruit breeding. While evaluating benefits, that is, fertility of a soil in relation to the respective soil and the properties of the soil itself (Sekulić *et al.*, 2005). Even in the best quality soils created under natural conditions, there may be a limiting factor, which reduces yields, in relation to the genetic potential for a particular plant species (Hađžić *et al.,* 1993; 2002). Based on the investigation results, there is a noticeable heterogeneity of soil cover in different regions of the Municipality. Mechanical composition has a great influence on the water-air, thermal, biological and nutritional regime of the soil (Gajić, 2006). Soils of shallow profile, profile, a low content of clay with low capacity of absorption of cations and acid reaction, have limiting possibilities for the cultivation of certain types. The content of clay fractions of 20-30% enables optimum potential soil fertility, given that other suitable agroecological conditions of fruit cultivation must be met.

Generally, most fruit species are best suited to moderately moist, deep loam-like soils. Certain fruit species require moderate lime soil aerated, moderately moist and deep enough, with slightly acidic reaction and well provided with accessible nutrients.

Conclusion

On the majority of tested sites, in the regions with light clay as the class o soil and certain differences with respect to sampling depth, medium to high interval of cation exchange capacity (T), very high values of hydrolytic acidity, (15.05 to 16.02 meq $100g^{-1}$) and a low degree of base saturation (V 19.69-27.51%) are measured in soils of light clay, where an increase of clay fraction is followed by an increase of the adsorptive capability of soil and degree of base saturation.

In agrochemical terms, active soil acidity on 70.0% of the samples is of slightly acidic reaction and based on substitution soil acidity, acidic reaction is predominant. The field of research shows that 75% of the samples is carbonate-free with the same percentage of highly humic soils. The region of Pester peat areas contains > 8% of humus in the upper horizon. The soil characteristic is a very low content of easily accessible phosphorus (<6 mgP_2O_5 100 g^{-1}). The content of potassium is within the limits of good supply.

Limiting factors for fruit cultivation are climatic conditions, which require the selection of fruit species tolerant to the existing environmental conditions and the application of corrective measures of soil in accordance with cultivated species.

Acknowledgements

The research was funded by the Ministry of Agriculture and Environment of the Republic of Serbia through the project "Arrangement of agricultural land in the region of Šumadija and Raška, using agromeliorative measures to develop fruit production" and partly by the Ministry of Education, Science and Technological Development of Republic of Serbia (grant number 31080 TR).

Abstract

For making solid or liquid biofuels, one can use whole plants of annual or perennial species, if they form large biomass per unit area suitable for commercial processing. A large number of plants worldwide in the vegetation season yield large biomass that can be used in different ways as a source of energy. During the two-year research (2014 and 2015), researchers studied morphological and productive characteristics of the Sudan grass variety *Zora* grown on chernozem, namely: leaf mass, stem mass and biomass yield. The results revealed that the biomass was, on average, higher in the second year than in the first. The biomass yield was statistically significantly higher in 2015 (40.47 t/ha) than in 2014 (36.64 t/ha). A statistically significant positive correlation was found between the leaf mass and the stem mass (0.63), while there was a statistically non-significant positive correlation between the leaf mass and the biomass yield (0.47), as well as between the stem mass and the biomass (0.28).

Key words: agro-energy crops, biomass, genotype, morphological characteristics, Sudan grass

Introduction

In order to secure the supply of necessary fuels, most countries are focusing their research towards finding the most efficient way of using renewable energy sources. According to some statistics, approximately 13% of the world's primary energy nowadays is coming from such sources (Janković et al., 2017).

Various forms of renewable energy sources for making electric power (solar, wind power, water power and chemical energy gained through photosynthesis) are significant for many countries from the aspect of environmental protection (Dražić et al. 2016). The same authors point out that there are a large number of plants worldwide, which in the vegetation season produce large biomass that could be used in different ways as a source of energy. Prior to introducing such plants into the production, it is necessary to study their biological characteristics and their relationship with agro-ecological and soil conditions and then use adequate breeding methods to create genotypes with the highest yield.

The economic justification of using fuels from renewable sources lies in cutting off the funding for importing necessary fossil fuels (Josimović et al., 2014). The production of such fuels is affected by the prices for oil and oil derivatives, then "food versus fuel" dilemma (which can increase or reduce the level of poverty), CO2 emissions, sustainable development of biofuel production, increased deforestation, soil erosion, reduction of biodiversity, impact

on the sources of drinking water, as well as by energy efficiency and balance. Not all the biofuels have the same effect on the climate or energy security.
With improvements in the process of extraction from different plant and animal materials and other organic waste, biogas could be produced in large industrial plants but also in small and simple on-farm facilities. For making biogas, one can use fresh biomass from energy crops, manure, secondary products of industrial plant processing, different industrial and farm waste, etc. (Grasi et al., 2004; Glamočlija et al., 2015).
The level of biogas development in Europe differs significantly. Countries like Germany, Austria and Sweden have advanced considerably when it comes to using organic waste for obtaining biogas, while in most eastern European countries large amounts of organic waste and its inadequate disposal pose a huge problem, which has a negative impact on the ecosystem. Lack of awareness of obtaining biogas from these inputs should be changed through educating people and providing a technology suitable for processing these unexploited riches (Janković et al., 2017).
It is important to point out that different fuels have a different impact on climate, securing energy safety and on ecosystems. Thus, one should analyse their long-term impact on the society and the ecosystem and synchronise the production of energy crops with the global demand. The preference should be given to those annual and perennial plants whose productive organs are not used in human diet. Concurrently, these plants prevent soil erosion and yield large biomass for biofuel production, and Sudan grass meets both conditions by producing large above-ground biomass suitable for making gas, liquid and solid forms of biofuels (Pataki, 2011; Ikanović et al., 2013).
Sudan grass is less susceptible to unfavourable environmental conditions and therefore it could be grown in a wide area, thriving in arid areas in Europe (Glamočlija et al., 2011). For making biofuels (biogas or liquid biofuels), harvested biomass has to be chopped to pieces, 2-3 cm in size (Janković et al., 2012).

Materials and Methods

The research was conducted during 2014 and 2015. The field experiment was set up in Stara Pazova on chernozem, in a randomised block system with 5 repetitions. The size of the basic plots was 10 m^2 (5 m x 2 m). The subject-matter of the research was the Sudan grass variety Zora, selected at the Institute of Field and Vegetable Crops in Novi Sad. Sowing was carried out in the last 10 days of April, in both years. The standard practices for growing sorghum were used. The plants were harvested at the beginning of the tasselling stage in the second half of July, after which the yield of the freshly harvested stems was determined. The samples of the freshly harvested biomass were used to analyse morphological characteristics (stem mass, leaf mass). The results were analysed by using the statistical package Statsoft 2012.
As for statistical parameters, the authors used the arithmetic mean, while the significant difference between the mean values was determined with the LSD test.
Meteorological conditions in the both years were favourable for Sudan grass (Tab. 1.). The amount of precipitation was almost the same in the both years (406 mm in 2014 and 408 mm in 2015), while the temperatures were 0.83ºC higher in 2014 than in 2015 (20.83ºC), Figures 1 and 2.

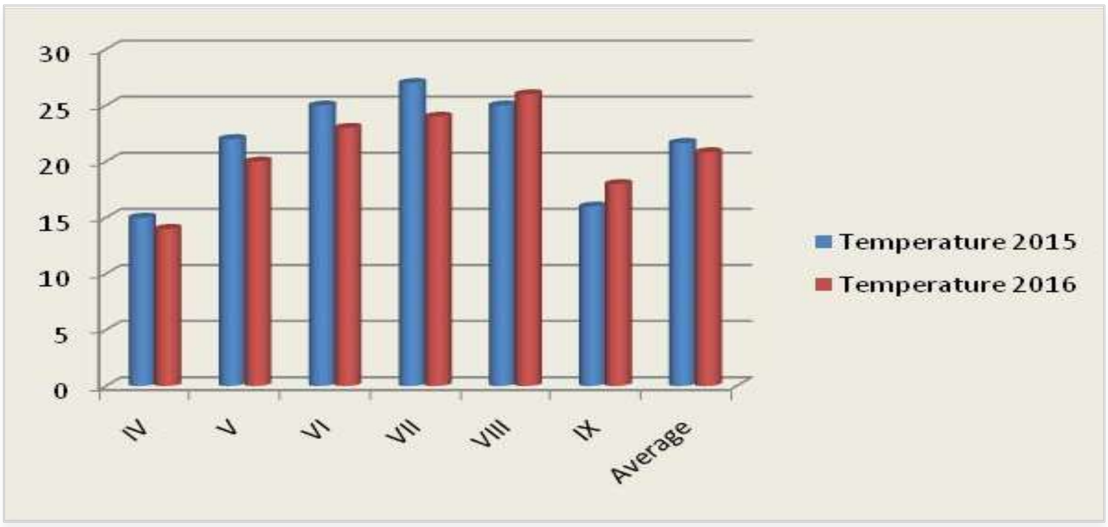

Figure 2. Temperatures during the vegetation season of Sudan grass, ºC

Results and Discussion

From the aspect of environmental protection, Sudan grass could be an alternative "agricultural" crop (on less fertile soil) but also an appreciated energy source in the future, due to its large biomass being a renewable source of energy (Ikanović et al., 2015b). High variability of the *Sorghum* genus enables us to create hybrids for specific use, like hybrids with high concentrations of sugar in the stem, and plants with high concentrations of cellulose are suitable for making bioenergy (renewable energy) (Hovny et al., 2000). Sudan grass is such a plant, and it could be successfully grown in our country. In this research, the year had statistically significant influence on the leaf mass and the biomass yield, Table 1, Figure 3d. In the second year, the mean leaf mass (20.05 g) was statistically significantly higher than in the first year (16.12 g), Table 1, Figure 3a.

Table 1. Descriptive statistics for morphological and production parameters of Sudan grass, variety *Zora*

Effect	Level of Factor	No	Mean	Std. Dev.	Std. Err	-95,00%	+95,00%

Year	2014	5	36.64400	2.204627	0.985939	33.90659	39.38141
Year	2015*	5	40.47000	2.727545	1.219795	37.08331	43.85669

Parameter		Leaf mass	Stem mass	Biomass yield
LSD	0.5	2.8488	11.0794	3.6167
	0.1	4.1448	16.1194	5.2619

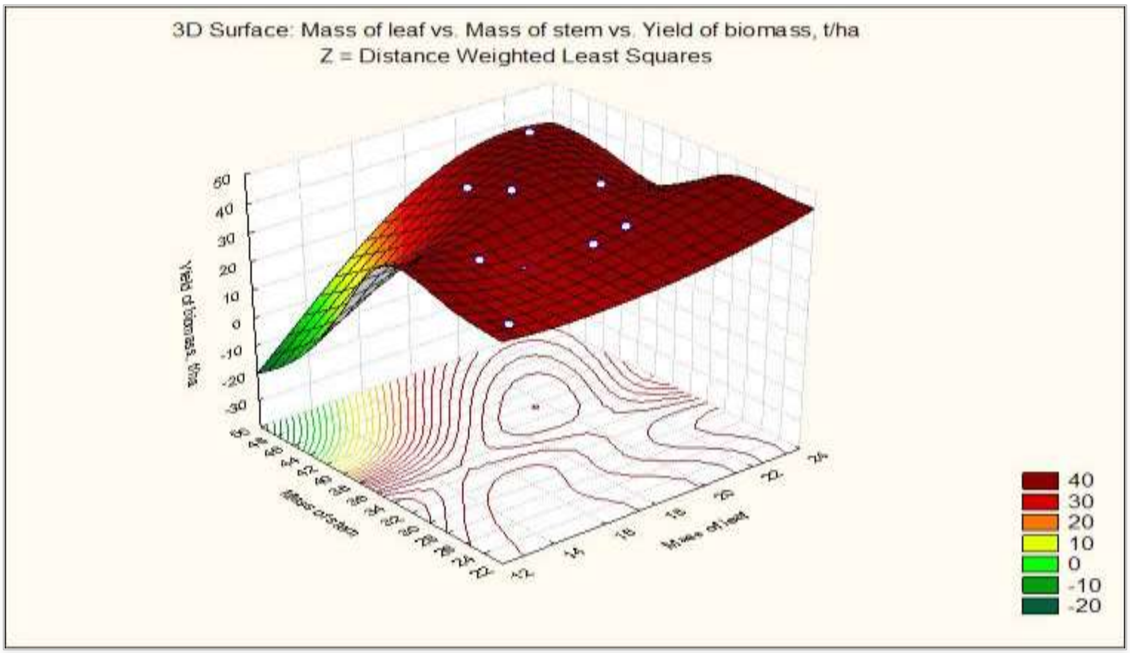

Figure 3. Mean of leaf mass, stem mass and biomass yield

The mean stem mass was higher in the second year (36.08 g) than in the first (32.16 g), but the difference was not significant. The standard error of the mean for the both years was 2.35, Table 1, Figure 3b.
The mean biomass yield was statistically significantly higher in 2015 (40.47 t/ha) than in 2014 (36.64 t/ha), Figure 3c. The standard error of the mean biomass yield was 0.97, Table 1.

Correlation of the studied parameters

Data on the variability of Sudan grass and all other plant species and the way of their use are very important for the development of breeding programmes (Ikanovic et al., 2013, 2015a; Glamočlija et al., 2015, Dražić et al., 2016, Kresovic et al., 2016, Sikora et al., 2016, Marišovà et al., 2016). The correlation analysis revealed the interaction between variables with statistically significant correlations (Table 2).
A statistically significant positive correlation was found between the leaf mass and the stem mass (0.63), while there were some non-significant positive correlations between the leaf mass and the biomass yield (0.47), and the stem mass and the biomass yield (0.28), Table 2.

Table 2. Correlations of the studied parameters

Variable	Leaf mass	Stem mass	Biomass yield
Leaf mass	1.00	0.63*	0.47
Stem mass	0.63*	1.00	0.28
Biomass yield	0.47	0.28	1.00

The variability of the quantitative and quality characteristics of Sudan grass is significant here and can be used as a good starting point for further breading work. The leaf and stem characteristics showed a significant influence on the increase in the biomass yield.
Growing energy crops helps in the development of rural areas (through production of inputs), and industrial production, by increasing the possibilities for employment in the primary plant production and in the biofuel production (Marray et al., 2008; Glamočlija et al., 2015).

Conclusions

- There are a significant number of plants worldwide, which during the vegetation season produce large biomass that can be used as a source of energy. Prior to introducing these plants into the production, it is necessary to study their biological characteristics and their relationship with the agro-ecological and soil conditions, and accordingly, to apply adequate breeding methods in order to create genotypes with the highest yield.
- From the aspect of environmental protection and due to its large biomass production that can be used as a renewable source of energy, Sudan grass could be an alternative “agriculture” crop (on less productive soil) and also an appreciate energy source in the future.
- The mean stem mass was higher in the second year (36.08) than in the first year (32.16). The mean biomass yield was statistically higher in 2005 (40.47 t/ha) than in 2014 (36.64 t/ha).
- There was a statistically significant positive correlation between the leaf mass and the stem mass (0.63), while non-significant positive correlations were found between the leaf mass and the biomass yield (0.47), and the stem mass and the biomass yield. (0.28)

- In the conditions of extensive climate change accompanied by the increase in global temperatures, the production of Sudan grass could provide inputs and be a source of the local biofuel production.

THE ROLE OF FOREST ECOSYSTEMS IN THE RISK MANAGEMENT OF TORRENTIAL FLOODS (THE GRDELICA GORGE IN SERBIA)

Sonja BRAUNOVIĆ*, Mihailo RATKNIĆ, Ljubinko RAKONJAC

Institute of Forestry, KnezaViseslava 3, Belgrade, Serbia
*Corresponding author: sonjabraunovic@yahoo.com

Abstract

The effects of climate, heterogeneous geological composition, topography, aspect and the quality of forest ecosystems accompanied with adverse human activities brought about intensive erosion processes and frequent torrential floods in the Grdelica Gorge in Serbia. Severe erosion processes led to the loss of soil fertility, devastating effects of torrential flows, poverty of the local population and their migration from the mountain villages into the cities of Serbia. In the 1950's and 1960's, small-scale technical works (torrential dams and inlet structures) were carried out in the riverbeds, while most of the erosion control works were focused on afforestation and establishment of the perennial agricultural cover crop on the surface areas with lower slope inclinations. In order to prevent the development of gully erosion and create favorable conditions for the establishment and growth of seedlings, the conventional afforestation practice by means of dense pit planting was replaced with the construction of biotechnical structures (bench terraces, contour ditches, rustic dams on the slopes etc). These new practices significantly decreased the intensity of erosion and the frequency of torrential floods (Z_{mean} = 0.84 in 1955, Z_{mean} = 0.33 in 2016). The paper presents the results of a comparative analysis of the state of forest ecosystems, their share in the total area, population movement, the intensity of erosion and sediment yield in the 1960`s and today (the period before and the period after the biological works were carried out).

Keywords: *forest ecosystems, risk management, biotechnical structures, the Grdelica Gorge, Serbia.*

Introduction

In the 1950's, the devastating torrential flows in the area of the Grdelica Gorge (in the south-east of Serbia) continually endangered human lives, arable land and the Belgrade-Thessaloniki highway and railway. No wonder the first organized works on the torrent channel control in this area began in the late 19th century (written data from 1907). Different methods and structures for the torrent channel control and the protection of soil against erosion were applied, *i.e.* biological and biotechnical works were applied on the catchment slopes and technical works in the riverbeds. In the period from 1955 to 1966, apart from the dense pit planting as a commonly-used afforestation practice, the application of biotechnical works was initiated and erosion control agrotechnics was introduced in the agricultural production of the hilly-mountainous areas (Braunović, 2013). These biotechnical and biological works were carried out with the aim of rehabilitating the barren land, which occupied 25 % of the Gorge surface area. The pattern of land use, accompanied with the study of climate conditions, topography, geological composition, bedrock and distribution of the observed erosion processes, was one of the key factors in the identification and mapping of erosion process. In order to improve the methods of controlling water erosion and torrential floods, it is necessary to examine the effects of the works carried out so far and their impact both on the state of erosion in the basin and on the protection against torrential floods. The analysis of the changes in the intensity of erosion in the period from 1953 to 2016 will reveal the causes of its abatement.

Material and Methods

The 1953 land use pattern was defined on the basis of available documentation (Braunovic, Ratknic, 2012). On the other hand, the current structure of the land use pattern was determined using topographic maps, field mapping and satellite images of the area. Productive areas (forests, degraded forests, meadows and pastures, ploughland, vineyards, orchards, gardens and house yards) and non-productive areas (gullies, rocky grounds, gravel, road network, water courses and settlements) were distinguished and digitized. According to this categorization, there are 2150 homogeneous plots. Sociodemographic characteristics were studied through the analysis of population trends which included 57 settlements (Comparative review of the number of population 1948, 1953, 1961, 1971, 1981, 1991, 2002 and 2011, 2014). We further studied the number and the size of settlements, their population and the population size of the settlements by altitude. The state of erosion was studied in 2 reference periods: in 1953 and in 2016. The 1953 coefficients of erosion (Z) were determined based on the available digitized maps of erosion (The state of soil erosion in the Grdelica Gorge and the Vranje Valley, 1956; The Map of Erosion of Serbia, 1983). The erosion coefficients were calculated by the Erosion Potential Model established by prof. Gavrilović (Gavrilović, S., 1972). The values of Z erosion coefficient were calculated for each homogeneous plot using land survey data (mapping of excessive and intensive erosion processes), data on bedrock, soil, climate and distribution of vegetation. The map was further improved in 2016 with the data obtained from the conducted field research and from satellite images and thematic maps (Ratknić, Braunović, 2016). The total amount of the sediment yield in the catchment was calculated using prof. Gavrilović `s Erosion Potential Model.

Results and Discussion

The comparison of the obtained results with the 1953 data shows that the categories of barren land, forests, meadows and ploughland underwent the most intensive changes (Table 1). Barrens are found on a very small surface area, while the share of ploughland decreased by 26% (due to the abandonment of the ploughland areas above 500 *m* a.s.l.

Table 1. Land use pattern in the Grdelica Gorge (in 1953 and in 2016)

Source: List of torrents of the right and left tributaries of the South Morava River on the Grdelica -Vladičin Han section, 1964; Ratknić and Braunović, 2016

The forests cover of the catchment area increased by 20% and the share of degraded forests decreased by 44% (Figure 1). The right side of the catchment (30234 *ha*) has 15577.7 *ha* covered with forests. The coefficient of stocking is 0.51. The left side of the catchment (12818 *ha*) is covered with forests on 7945.5 *ha*, 71.4 of which is under degraded forests. The coefficient of stocking of this part of the catchment is 0.64. According to the mean erosion coefficient Z_{mean} = 0.84, the Grdelica Gorge area was in 1953 endangered by severe erosion processes. The highest erosion coefficients were determined for the catchments of the Jastrebačka River (Z_{mean} = 1.06), the Palojska River (Z_{mean}= 1.02), the Letoviška River, part of the direct South Morava Basin (Z_{mean} = 0.96) and the Predajene River (Z_{mean} = 0.93). The spatial distribution of the study catchments of the Grdelica Gorge is shown in Figure 2.

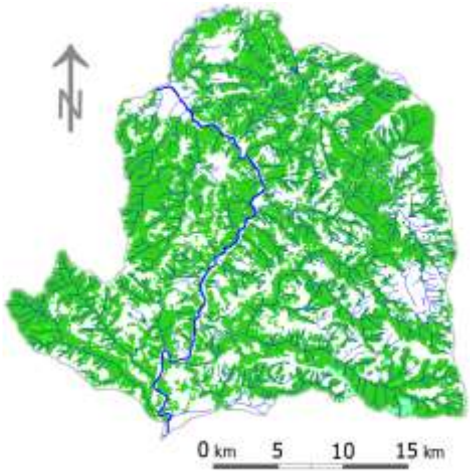

Figure1. Forest cover map

Figure 2. The map of the Grdelica Gorge catchments

Source: Authors

In 2016, a total of 403.06 km^2 or 93.64% of the surface area of the Grdelica Gorge was endangered by erosion processes of different intensities. The mean erosion coefficient was Z_{mean} = 0.34 (weak erosion). The right side of the basin was characterized by higher Z_{mean} values, as was the case in 1953. The processes of severe erosion endangered 0.75% of the total surface area of the gorge.

Table 2. The state of erosion in the Grdelica Gorge catchments in 1953 and in 2016

Catchment	Catchment name	Area (km^2)	Z_{mean}	
			1953	2016
1	Kozarska River	101.00	0.72	0,27
2	Palojska River	6.87	1.02	0,29
3	Predejane River	19.58	0.93	0,26

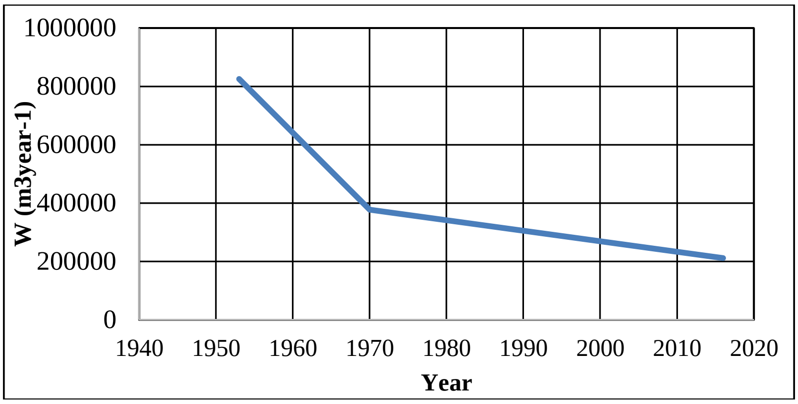
The created erosion maps, the data on the share of different categories of destructiveness, as well as the data on the orographic characteristics (Braunović, 2013) make the basis for the calculation of the sediment yield in the study catchments. The obtained results on the changes in the sediment yield in the study period are shown in Graph 1. The sediment yield was reduced by 3.9 times in the period from 1953 to 2016. This reduction was the result of the following factors: reduction in the intensity and the surface area affected by erosion, effects of the conducted erosion control works, abandonment of the arable land at steeper slope inclinations and higher altitudes, natural regeneration of vegetation, *etc*.



Graph 1. Changes in the sediment yield in the study area 1953-2016. (Source: Authors)

The population analysis was done for 57 cadastral municipalities (Figures 3-5). Tables 3-5 show the data on the population trends, the size of settlements and their altitudinal distribution, and Figure 5 shows population projections for 2021 (Penev, 2007).

Table 3. Population trends (1948-2011 Censuses)

Municipality	Population								Reduction (%)		
	1948	1953	1961	1971	1981	1991	2002	2011	1953-1971	1971-2011	1953-2011
Leskovac	12776	13070	14063	14242	14055	13229	12366	10611	+ 9.0	25.5	18.8

Source: Authors

In the period from 1953 to 2016, the population decreased by 51%, mainly in the settlements above 500 *m* a.s.l., resulting in the abandonment of arable land on steeper slopes, the reduction in the `pressure` on the forested areas and the natural restoration of vegetation. The largest decrease was found in the parts of the municipalities of Crna Trava and Surdulica (Braunović and Ratknić, 2011).

Table 4. Altitudinal distribution of settlements and population

Altitudinal zone	Settlements		Population by census years							
	Number	%	1948	1953	1961	1971	1981	1991	2002	2011
300-500	14	24.6	7974	8381	9458	9225	9331	8795	8281	7118

The intensive processes of depopulation caused the largest changes in the altitude zone over 1000 *m* (35-95% reduction) and in the zone from 700 to 1000 *m* (16.9-75%). The zone from 500 to 700 *m* had a 38% reduction in the period from 1971 to 2011. The population in the altitude zone of 300-500 *m* increased in the period from 1948 to 1981, while it decreased by 24% in the last three Censuses (Table 4). In the study period, the number of settlements with a population below 100 inhabitants increased, while the number of the settlements with the population of 301-500 and 501-1000 decreased (Table 5).

Table 5. The number of settlements and the population numbers in the area of the Grdelica Gorge

Settlement size	1953		2011	
	Number of settlements	Population	Number of settlements	Population
below 100	1	51	25	1012
101-300	17	3667	20	3300
301-500	22	8769	6	2334
501-1000	12	8756	2	1480
> 1000	5	6936	4	6222

On the basis of the Register of conducted erosion control works (Jelić, 1978), we further present the scope of the works that include the establishment of mostly conifer plantations on bench terraces, terraces, contour trenches, wattleworks, and grassing of eroded surfaces (Table 6).

Table 6. Register of the works conducted in the Grdelica Gorge (1947-1977)

Grdelica Gorge	Regulations			Cross structures			Biological works	
	Length (*km*)	Excavation (m^3)	Wall (m^3)	Number of structures	Excavation (m^3)	Wall (m^3)	Afforest. (*ha*)	Grass. (*ha*)
58 torrential catchments	5.96	70405	37389	1087	55472	65087	1041.2	1210.5

Source: Jelić,1978

Conclusions

In order to improve the methods of torrential flood risk management, a comparative analysis was carried out to examine the changes in the land use pattern and sociodemographic factors, as well as the effects of the conducted works on the intensity of erosion. Non-productive areas (barren land) decreased by 22%, ploughland by 26%, and the areas under forests increased by 20%. The research results show that the conducted EC works (the afforestation of barren land with appropriate soil cultivation techniques on slopes, the appropriate selection of species and methods of planting on the catchment slopes) reduced the intensity of erosion processes in the Grdelica Gorge region. Indirect anthropogenic impacts are the result of accelerated depopulation, demographic aging, reduction of livestock and spontaneous large-scale grassing, while the direct ones resulted from the successful erosion control works performed in the period from 1947 to 1977. The use of forest ecosystems in the protection against erosion through biological and biotechnical works is one of the factors of maintaining the stability of the study area.

Abstract

Sweet maize has good prospects in Republika Srpska, a place with good market and natural potentials, favourable geographic position and a significant human potential, which is a factor that affects the success of crop production most. The research investigated two sweet maize hybrids – super-sweet sweet maize and normal sweet maize grown during 2013 and 2014 on brown forest-type soil. The following parameters were investigated: plant height, cob length, cob diameter and cob weight. The results show that the genotype, year and locality had a statistically significant impact on plant height. The investigated parameters – average plant height, cob length, cob diameter, cob weight and kernel yield, for both hybrids and both localities, had higher values in 2013 than in 2014. The average plant height, cob length, cob diameter, cob weight and kernel yield were higher in the locality of Banja Luka than in the locality of Dobrnja. The kernel yield was positively and highly significantly correlated with cob length (r= 0.83), cob diameter (r= 0.87) and cob weight (r= 0.60), and positively correlated with plant height. Stronger networking with other countries' agriculture through joint investments and appearance on the global market could significantly improve the economic stability of the counties in South East Europe in general, since food and energy sources of plant origin are the most demanded commodities on the global market.

Key words: *sweet maize, locality of growing, morphological and productive properties, correlations, yield.*

Introduction

Sweet maize is an annual herbaceous plant from the grass family (*Poaceae*), subfamily *Panicoideae,* genus *Maydeae*. This subspecies of maize is grown for its young cobs used exclusively in human diet, directly as cooked or roasted maize but also in the canned food industry (Aćimović, 2003*;* Sikora *et al.,* 2015). Sweet maize kernels are highly valued foodstuffs for preparing diverse and tasty dishes. Due to its high nutritive value, sweet maize holds first place in grain crop consumption. In our area, this maize subspecies is grown on more and more surfaces, often following the pre-crop and in irrigated fields (Ranđelović, 2008). With the development of the national processing industry, sweet maize from traditional seasonal food becomes food that is consumed all year round.

Maize production is of great importance in our country and worldwide, since food and energy sources of plant origin are the most demanded commodities on the global market (Ikanović *et al.,* 2015). In mercantile production of all types of hybrid maize, for different use, the main task of production technology is to provide necessary number of plants per unit area and their proper pattern in the field *(Popović, 2010*, *Živanović et al., 2012*, *Marić et al., 2013a*, *2013b*).

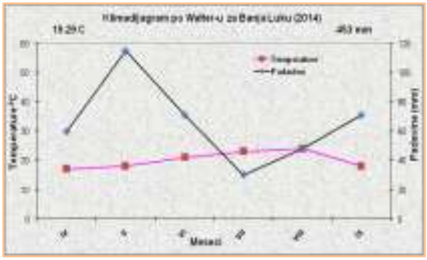
Mercantile sweet maize crops are sown from the beginning of maize sowing in April to stubble sowing at the end of July. In mercantile sweet maize crops, irrigation is a must, starting from the sowing all along to the harvest of cobs with husk (*Sabovljević et al., 1997a, 1997b*). Sweet maize kernels can be preserved longer by freezing or pasteurisation. Due their high nutritive and dietetic value, sweet maize kernels are a highly praised ingredient for different tasty and very nutritious dishes. In Western European countries and the USA sweet maize kernels are quite often used for making different delicacies and therefore they hold first place in grain crop consumption (*Glamočlija et al., 2007*). Daily meals of western European people cannot be imagined without sweet maize. It should be pointed out that nowadays in our country too, sweet maize from a traditionally seasonal product becomes a product that is consumed all year round, due to improvements in kernel processing with the use of pasteurisation or freezing, and having sweet maize in all well-supplied shops (*Glamočlija, 2012*). During processing of kernels, there are also a significant amount of by-products left, plant waste that are used in animal feed, so the whole process of kernel processing and vegetative bio-mass makes one production cycle (*Pandurović et al., 2009*; *Glamočlija et al., 2013*).

Material and Methods

As a material for this research, the researchers used the seed of F_1 generation of the following two combinations of sweet maize seed crops, produced by Syngenta: *GSS 8529 F1* – super-sweet sweet maize with a medium period of vegetation (83 days), high yielding potential, plant height of 280 cm, and resistant to maize dwarf mosaic virus (MDMV). Its advantages are: stable yields, regular and wide cobs of 21 cm length and very good husk coverage. It has a good taste and a nice light yellow colour. *ENTERPRAIS F1* – normal sweet maize with the period of vegetation of 93 days. It is very strong and tall, with pronouncedly large cobs, 22-23 cm long. It is resistant to viral infections. The experiments were carried out in two localities: at an experimental field of the Agricultural Institute of Banja Luka and at the village of Dobrnja on Manjača (near Banja Luka) on brown forest soil. In the first locality, the experiment was carried out in the centre-pivot irrigation system, with the soybean as a preceding crop, whereas the experimental field in Dobrnja had also a highly irrigating system but a preceding crop was a fodder mixture comprising fodder peas and oats. Standard cropping practices for sweet maize were applied. During the vegetation period of sweet corn, the researchers in both localities measured the investigated morphological properties – plant height at the stage of maximum growth, cob length, diameter and weight at the stage of technological maturity, and kernel yield. Agrochemical analyses were conducted at a pedological laboratory of the Agricultural Institute in Banja Luka. The analyses identified the contents of basic parameters of fertility, such as: soil pH – potentiometric analysis; $CaCO_3$ – volumetric analysis according to *Scheibler;* humus – according to *Kotzmann*; total nitrogen – according to *Kotzmann;* easily accessible K_2O – Al method by *Eigner–Reihm*; easily accessible P_2O_5 – Al method by *Eigner–Reihm*.

Soil. Brown forest soil is mostly moderately hard soil, with a pronounced textural differentiation within the profile. The humus-accumulative horizon is characterised by a favourable water-air regime that comes as a result of a good ratio between large, medium and fine pores. Such soil is well-draining and warm. Chemical properties vary depending on exploitation intensity, erosion intensity, chemical properties of the matrix substrate and the level of soil development. Brown forest soil has no carbonates and it is moderately acidic. It has a medium amount of humus (2-5%) (*Glamočlija et al., 2015*). In areas with this type of soil, a limiting factor can be the climate, namely relatively high annual temperatures and little precipitation. The goal of this research was to investigate the importance of the locality of growing on the hybrids.

Meteorological conditions. Meteorological data for 2013 and 2014 were retrieved from the Meteorological Station in Banja Luka. In both production years, temperatures ranged from 19.00^{0}C to 19.29^{0}C, whereas precipitation was 423 mm in 2013 and 443 mm in 2014, respectively (Graph 1 and 2).



Graph 1 and 2. Total precipitation (mm) and average daily temperatures (^{0}C), 2013 – 2014

Maize thrives in good agro-ecological and soil conditions (*Sikora et al., 2015*). When compared to other maize subspecies, sweet maize is least tolerant to adverse agro-ecological and soil conditions. Hence, it should be grown only on fertile soil, and its sowing should start after spring frosts and be conducted in the irrigation regime, if possible (*Ikanović et al., 2007*).

Results and Discussion

The genotype, year and locality had a statistically significant effect on sweet maize plant height. On average, the hybrid *Enterprais* in both localities had higher values for plant height, cob length, cob diameter and kernel yield than the hybrid *GSS 8529;* the latter only had greater cob weight (Table 1). Given that sweet maize is often eaten directly off the cob, cob properties are quite important. Cob shape is very important in the sweet maize processing industry, so breeding is there to create hybrids for different use, i.e. to conform to market requirements (*Pajić et al., 2000*).
The investigated parameters (average plant height cob length, cob diameter, cob weight and kernel yield) for both hybrids and both localities were higher in 2013 than in 2014. The average plant height, cob length, cob diameter, cob weight and kernel yield were higher in the locality of Banja Luka than in Dobrnja (Table 1, Graph 3, 4, 5 and 6).
In the locality of Banja Luka, the hybrid *Enterprais* had higher values for plant height, cob length, cob diameter and cob weight than the hybrid *GSS 8529*, whereas the hybrid *GSS 8529* had higher kernel yield (Table 1). When observed the average values, the hybrid *Enterprais* had higher values for plant height, cob length, cob diameter and kernel yield than the hybrid *GSS 8529*, whereas the latter had greater cob weight (Table 1). The average cob length for both localities and both hybrids was 18.22 cm (Table 1, Graph 4).

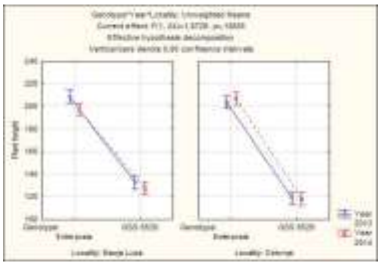
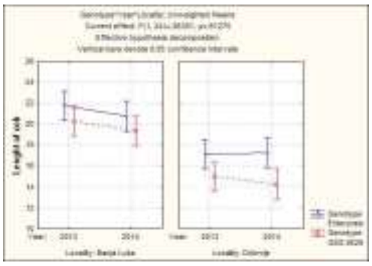
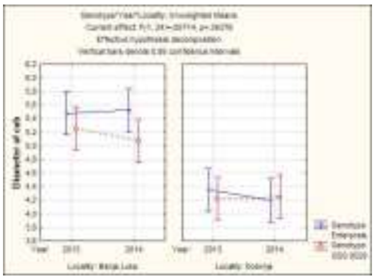


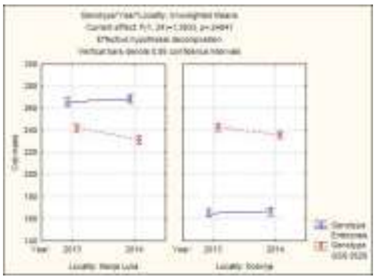


Graph 3. G x Y x L interaction for plant height
Graph 4. G x Y x L interaction for cob length

The average plant height for both localities and both hybrids was 164.13cm (Tab.1, Graph 3). When observed the average values, the hybrid *Enterprais* had higher values for plant height, cob length, cob diameter and kernel yield than the hybrid *GSS 8529*, whereas the latter had greater cob weight (Table 1). The average cob length for both localities and both hybrids was 18.22 cm (Table 1, Graph 4).



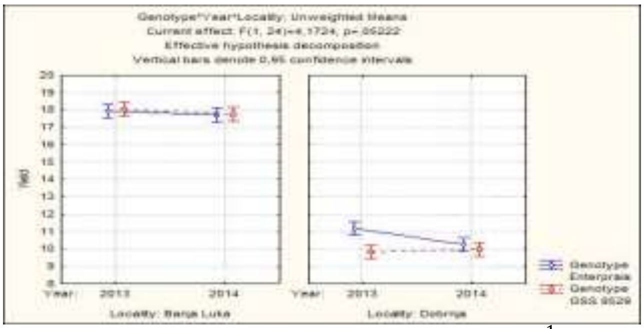
Graph 5. Cob diameter



Graph 6. Cob weight

The average cob diameter for both localities and both hybrids was 4.79 cm (Table 1, Graph 5). The average cob weight for both localities and both hybrids was 227.34 g (Table 1, Graph 6). Apart from yields and pericarp tenderness, each way of use of sweet maize has specific requirements for certain quality (*Pajić et al., 2000*). Taste (sweetness) and cob appearance are most important for fresh consumption of sweet maize. Retaining the sweetness after transportation is also a very important property. The average kernel yield for both localities and both hybrids was 14.07 t ha^{-1} (Table 1, Graph 7). In Dobrnja, the hybrid *Enterprais* had higher values for plant height, cob length, cob diameter and kernel yield than the hybrid *GSS*

8529, whereas greater cob weight was recorded for the hybrid *GSS 8529* (Table 1). Kernel yield in Banja Luka was statistically significantly higher (17.85 t ha^{-1}) than in Dobrnja (10.30 t ha^{-1}), Table 1, Graph. 7.



Graph 7. Average kernel yield, t ha^{-1}

Correlations between the investigated parameters. Kernel yield was positively and highly significantly correlated with cob length (r= 0.83), cob diameter (r= 0.87) and cob weight (r= 0.60), and positively correlated with plant height (Table 2). Cob length was positively and highly significantly correlated with plant height, cob diameter, cob weight and kernel yield (Table 2).

Table 2. Correlation between the investigated parameters

Parameter	**Plant height**	**Cob length**	**Cob diameter**	**Cob weight**	**Kernel yield**
Plant height	1.00	0.42*	0.19 ^{ns}	-0.30 ^{ns}	0.11 ^{ns}
Cob length	0.42*	1.0	0.79**	0.37*	0.83**
Cob diameter	0.19 ^{ns}	0.79**	1.00	0.62**	0.87**
Cob weight	-0.30 ^{ns}	0.37*	0.62**	1.00	0.60**
Kernel yield	0.11 ^{ns}	0.83**	0.87**	0.60**	1.00

$^{ns -}$ non significant, * and ** significant at the 0.5 and 0.1 levels

Cob weight was highly significantly correlated with kernel yield, r= 0.60 (Table 2). Sweet maize kernels have a high energy and nutritive value, containing up to 80% total carbohydrates (NFE), 8-17% total protein, 10-15% oil, 1.5-2% dietary fibre (cellulose) and about 1% mineral salts (*Popović, 2010*, *Glamočlija et al., 2015*). The same authors point out that this group of maize contains twice as less starch (NFE), since the recessive gene slows down its synthesis, retaining monosaccharides and disaccharides to the stage of technological maturity. This type of maize has high protein content, but its kernels contain small amounts of essential amino acids due to the prevailing protein called zein. *Kling and Edmeades* (*1997*), *Pajić and Dumanović* (*1998*), *Jovanović et al.* (*2006*) also point out a high vitamin value of maize, reflected in significant amounts of vitamin V, E and K, as well as in provitamin A in coloured maize. The same authors state there have been a large number of maize hybrids created worldwide for different use – with different lengths of vegetation period, different genes and combinations of genes that increase sugar content in kernels, sugary sweet maize, super-sweet sweet maize – with increased sugar content in kernels.
Almost all the breeding of sweet maize in the world is conducted by private companies, where the breeding material is protected and not available to general public. Sweet maize seed is one of the most profitable commodities.

Conclusions

Sweet maize has good prospects in Republika Srpska, a place with good market and natural potentials, favourable geographic position and a significant human potential, which is a factor that affects the success of crop production most. The genotype, year and locality had a statistically significant impact on plant height. The investigated parameters, such as average plant height, cob, length, cob diameter, cob weight and kernel yield, for both hybrids and both localities had higher values in 2013 than in 2014. The average plant height, cob length, cob diameter, cob weight and kernel yield were higher in Banja Luka than in Dobrnja. The kernel yield was positively and highly significantly correlated with cob length (r=0.83), cob diameter (r= 0.87) and cob weight (r= 0.60), and positively correlated with plant height. Stronger networking with other countries' agriculture through joint investments and appearance on the global market could significantly improve the economic stability of the counties in South East Europe in general, since food and energy sources of plant origin are the most demanded commodities on the global market.

Abstract

The aim of this study was to demonstrate the socio-economic feasibility of protection against flood in the area of the river Sava in Autonomous Province of Vojvodina (Serbia). In this case as a technical solution of protection from external flood water it was proposed construction of new dikes, reconstruction of old dikes and procurement of mobile equipment. The methods that were used for evaluation were: the present value of investment and operating costs, equivalent annual cost, the average economic cost (per 1 ha) of protected areas, average economic cost per protected resident and sensitivity analysis. The study was conducted on the case of the left bank of the Sava River (length 50 km) in order to achieve the optimal level of protection of humans, settlements, agriculture and other material goods in this area. The results of research showed that flood damage to this area could be 3.42 times greater than required investments in the construction of buildings and purchase of related equipment. The largest damage would be on residential buildings and agricultural land. The investments of 3.407 mil. €, in the long term, would protect 23,000 ha of agricultural land, 5,300 hectares of residential and commercial buildings and 135,000 inhabitants.

Keywords: *Embankment, Flooding, Investments, Damage, Operating Cost*

Introduction

For the research of the regulation of the Sava River on the territory of Republic of Serbia and Autonomous Province of Vojvodina (APV) can be approached from different aspects (flood control, agriculture, navigation, hydropower). Most commonly it is the integration of development on the entire basin of the Sava River (EC, 2013). In our study, the regulation of the watercourse Sava was investigated from the aspect of planning of the construction and reconstruction of protective objects (embankments) on the left bank between settlements Progar and Hrtkovci which belong to AP Vojvodina (Gregorović and Potkonjak, 2017). In order to achieve the optimal level of protection of people, material goods, infrastructure, industrial plants, cultural and historical monuments from the relevant large waters of the Sava River, the proposed solutions have been analyzed from several aspects (hydrological, hydraulic, economical and ecological). In this paper, emphasis is placed on the economic aspect of flood protection and economic consequences in case the regulation does not realize. In other countries, the problem of flood control is often investigated and always relevant.(UK, Neththerlands, Denmark).

The methodological approach to the assessment of flood damage, especially on urban areas, has often been studied and improved in case studies done for individual watercourses. The example of a complex study is for the city of Prague (Genovese, 2006). It contains: risk assessment and flood management, as well as the assessment of flood damage in the previous and future periods.

The European flood protection strategy has been implemented, in great number of countries (in Europe), in the Law on Waters. In the Republic of Serbia, flood protection is regulated in the Law on Waters and the Law on Planning and Construction of objects. There is also a methodology for estimating damage from natural disaster, but it is used only after its occurrence.

Material and Methods

The research was carried out from the hydrological, hydrotechnical, economic and ecological aspects. Each aspect required its own methods of research. In this paper, special attention has been aimed to economic aspects. Solving this problem from the hydrotechnical aspect referred to the selection of water management facilities and their dimensioning that will protect the area from floods for 100- years flood protection. Analysis of the water level of the Sava River, hydrotechnical and geodetic surveys and measurements were used in the selection of types of objects and their dimensioning. In the assessment of economic justification, several methods were used: investment, analytical and differential calculations. The investment calculation is adjusted to the specifics of the proposed technical solution of the embankment. Analytical calculation was used to calculate values and costs of agricultural production, as well as to calculate the annual costs of the functioning of the embankment. Differential calculation in this study was used to calculate lost profit in case the proposed objects are not built. Similar methods of research were used in the Netherlands as well.Brauwer and Kind (2005) presented three different case study examples using cost-benefit analysis in the specific area.

Results and Discussion

On the basis of hydrological research in previous period on the part of watercourse of Sava River in the AP Vojvodina, especially on the left bank between the settlements of Progar and Hrtkovci, a plan for protection from large waters and floods (100-years flood protection) is proposed. The defence line is about 50 km in length. The proposed regulation can be realized in 8 sections that are independent of each other. The construction sequence is ranked according to the effects that can be achieved. The water management facilities that are in this case proposed for the protection of coastal land and settlements are embankments that need to protect 236 ha under settlements, 1017 ha of arable land and 6021 inhabitants. The necessary investments for realization of this plan amount 3,407,788.25 EUR , determined on detailed investment calculations (Table 1). Annual operating costs include: maintenance, insurance, labour and overheads. These costs are compared with investments (Table 1). The largest amount of investment and annual operating costs is in section VI.

Benefits that can be expected after the construction of these objects can be classified as direct and indirect. Direct benefits are manifested through reduction of flood damage on agricultural and municipal building land, residential and commercial objects, roads and other infrastructure. Indirect benefits in this case refer to the enabling of favourable conditions for the development of agriculture, the protection of settlements and population, as well as further economic development of the area. For this purpose, statistical data were collected for settlements and agricultural land that are subjected to further processing (Table 2). Analysis of agricultural production was also performed for 6 most common crops in the municipalities of Ruma and Pecinci, to which belong vulnerable settlements (Table 3).

Based on the previous data, it can be concluded that this area belongs to the moderately populated area with medium sized developed transport infrastructure and medium income

land value. It is defended with 100- years flood protection. The profit calculation is based on the following hypothesis:
Profit-benefits from the construction of these objects in this case also present economic damages that are removed with their construction. Determination of economic benefits, that is elimination of damage on agricultural land and residential and commercial objects that would be under the impact of floods, is done by comparing profit after and before construction of these objects (lost profit).

In this case, there is no classic profit calculation. There are only annual operating costs of these objects, and instead of generating income, the construction of objects (embankments and mobile equipment) eliminate the economic damage. The degree of accuracy in calculating damages is quite low, but it can provide the basis for determining social economic efficiency.
Calculation of profit loss is also based on the assumption that different crops (cereals, industrial and fodder plants, vegetables, orchards) may be planted on this endangered area of 617 ha. The calculation of the effects was performed for each crop individually (Table 3).
The obtained costs, profits and production values were used for the calculating potential flood damage for settlements: Kupinovo (Pećinci municipality), Grabovci and Klenak (Ruma municipality). The lower and the upper value of the lost profit depend on the type of crop, (Table 4).

Table 3. Analysis of agricultural production (average values for ten last years)

No.	Crops	Average yield, t/ha		Value of production, €/ha		Costs of production, €/ha		Profit, €/ha

*Source: Census of Agriculture (2012), Belgrade

Estimation of damage from possible floods (with and without objects) implies natural and financial amount of absent agricultural production and damages to residential and commercial objects due to floods compared to actual conditions (without floods).
In this case, it is possible to assume different cases of flood damage in this area, depending on the season of flood occurrence and its probability. The assumption is 100% loss of yield.

Table 4. The potential loss of production value and profit

Settlement	Area, ha	Lost profit, € per year		Lost production value, € per year	
		lower value	upper value	lower value	upper value
Kupinovo (Pećinci)	227	28375	251289	111003	532996
Grabovci (Ruma)	138	21942	343482	73968	529920
Klenak	252	40068	627228	135072	967680
Total	617	90385	1221999	320043	2030596

*Source: Authors data from case study

In the flood damage evaluation, only direct damages are calculated (Table 5). There are also indirect damages that are not insignificant and could amount up to 30% compared to direct damages.
Comparison of damage and total investments (investment for construction + operating costs for a period of 30 years) shows that for the whole project (by 100-year flood protection) flood damage would be 3.42 times higher than the required investment. Observed by sections, the best ratio (damage / investment) is for sections 5, 7 and 1, respectively, while the sections 2, 6 and 8 have unsatisfactory ratio, less than 1. This data can be used to rank the order of construction of individual sections (Table 6).
Unit damages (€ / ha) on agricultural land are calculated for the municipalities of Pećinci (1,200.33 €/ha) and Ruma (1538 €/ha) based on the average value of lost production for 6 most common crops (wheat, corn, sugar beet, sunflower, beans and potatoes). The settlements that will be protected by this embankment belong to these municipalities. These values are shown in Table 5, column 4.
In the case of agricultural land and buildings, only direct damages are counted. There were no valid data for the calculation of indirect damages.

Table 5. Calculation of direct damages for 100 - year flood protection

Conclusions

The results of this multidisciplinary research show the complexity of the problems in resolving flood control on the watercourse of Sava . Beforehand it is needed to make observations and field measurements on the basis of which a technical solution for protection will be proposed. The value of the defended assets also affects the selection of solution.

In this study, a part of the watercourse of Sava was observed, between the settlements Progar and Hrtkovci (about 50 km, the left bank), which is under the jurisdiction of the public water management company "Vojvodina Waters". The proposed technical solution for implementation is that the regulation is carried out by sections (a total of 8 sections), by building embankments and purchasing mobile equipment. Economic and environmental analysis should provide other data that are necessary for making a final decision.

The economic aspects of flood control for the proposed location included: the calculation of the required investments, long term operating costs, damages due to flooding (return period 2, 10 and 100 years), lost production value, value of lost property.

On the basis of these parameters, it can be concluded that the realization of this project in whole (all 8 sections) is economically justified. If observed by parts of 3 sections, the calculated economic indicators are worse.

EFFECT OF INVASIVE SPECIES *IMPATIENS PARVIFLORA* ON SOIL MICROBIAL INDICES IN THE PROTECTED AREAS IN SLOVAKIA

Lenka BOBUĽSKÁ*, Lenka DEMKOVÁ

Abstract

Biological invasions are one of the main threats to natural ecosystems and the impact of invasive plant species on native species, communities, ecosystems and soil biota has been widely recognized over the last decades. Costs of invasive species are estimated to range from millions to billions of euros annually and the success of invasive species has been attributed to their biological and ecological trails. Our study aimed to assess the effect of invasive plant species *Impatiens parviflora* on selected soil microbial indices and physicochemical characteristics. The research was carried out during a vegetation season on 3 protected areas of Norths-Eastern Slovakia in 2015. Soil reaction, soil organic carbon, bulk density, soil porosity and soil moisture were selected to determine soil physicochemical properties. As the microbial indices, that mainly indicate soil microbial activity, we selected soil microbial respiration and soil enzymatic activity (urease, acid and alkaline phosphatases). The results showed that *I. parviflora* prefers acidic and non-compacted soil conditions. The results also suggested that biology of the invasive plants had the high impact on soil ecosystem and soil enzyme activity played an important role in nutrient cycling in the ecosystems, and thus could be considered as biological indicator of soil health and environmental changes.

Keywords: *Impatiens parviflora, Enzymatic activity, Protected areas, Soil characteristics.*

Introduction

Invasive plants dramatically influence biodiversity in non-native areas and often create monocultures where diverse plant communities previously existed (Zhang *et al.,* 2009). Changes in the plant species composition might result in changes in the enzymatic activities of the microbiota. Such changes could be particularly important in plant communities that are heavily invaded by exotic species. Invasion of those species can alter many ecosystem properties, including important soil function and characteristics (Kourtev *et al.,* 2002). Therefore, the documented impacts on soil properties are diverse. In addition, the same species may have different impacts, depending on local conditions (Dassonville *et al.,* 2008). In general, exotic invasive species have higher net primary productivity and higher turnover rates of carbon and nitrogen, but the opposite pattern was also found. These impacts are also mediated by alteration in soil microbial communities (Herr *et al.,* 2009, Kourtev *et al.,* 2002). Moreover, one of the mechanisms of invasive species success is the production and release of allelopathic compounds by invader that are harmful to plant neighbours (Baležentiené and Renčo, 2014).
Characterization of soil state may be mediated by physical and biochemical parameters related to certain soil processes and functions. Monitoring of soil quality and health relies on the use of specific indicators. Mostly biochemical properties are considered to be the best indicators for assessing soil quality, but their use is limited by the lack of available data

(Doran and Zeiss 2000; Miralles *et al.*, 2007). Soil microbial activities, including enzyme activities, are more sensitive compared to physical and chemical properties to changes in soil quality and can be easily quantified. Soil biochemical properties are regarded as relevant indicators of soil quality from an environmental viewpoint and could be useful for monitoring changes in many type of ecosystems (Kizilkaya *et al.*, 2004; Nowak and Schneider, 2017).
The aim of this study is to assess the effect of invasive plant species *I. parviflora* on selected soil physicochemical characteristics and soil microbial indices.

Material and Methods

Site description

The research was carried out during a vegetation season (July 2015) in 3 protected areas of North-Eastern Slovakia - National Nature Reserve (NNR) Šarišský hradný vrch, National Nature Reserve (NNR) Kokošovská dubina and Nature Reserve (NR) Fintické svahy in 2015. One native site, without *I. parviflora*, was also included for comparative purpose (as Control site). This region is known for its high diversity of animal and plant life, and all these forms are highly responsive to environmental changes. Mostly moderate Cambisols are typical in all researched areas in warm, medium wet climatic regions with the cold winter. The soil was sampled in three different microhabitats - meadows (a habitat without tree vegetation), a habitat close to the stumps (as the bottom part of a tree left) and a habitat under dense tree vegetation, in each natural reserve. Soil samples were taken in triplicates from all the microsites to ensure high homogenity of the measured data. Obtained data were tested by mathematical-statistical methods from which analysis of variance and regression analysis were used (the Statgraphics software package).

Soil physicochemical analysis

Air-dried soil samples were used to measure soil pH and organic carbon content. Gravimetric soil moisture was calculated on 10g of fresh subsamples after drying in a 105 °C oven for 24 hours. Soil pH was detected in a 1:3 mixture of soil and 0.01M $CaCl_2$ solution using a digital pH meter. Soil organic carbon (SOC) was determined by the Turin's method. Soil bulk density [$t.m^{-3}$] and porosity [%] were evaluated in a Kopecky physical cylinder with a capacity of 100 cm^3 (Fiala et al. 1999).

Soil respiration and enzyme assays

Soil microbial respiration was (SMR) measured by the CO_2 released from 100g samples of field moist soil in 500 mL hermetically sealed flasks at 25 °C for 14 days. CO_2 was captured by its reaction with NaOH (1 mol L^{-1}) and titrated with HCl (0.5 mol L^{-1}) after the addition of $BaCl_2$ (1 mol L^{-1}). The concentration of the released carbon was estimated in μg C-CO_2 g soil dry^{-1} day^{-1} (Alef and Nannipieri 1995). Enzymatic activity assays were determined using previously selected analysis of field-moist soil samples, which were sieved and properly homogenized. Activity of acid and alkaline phosphatase was determined by Grejtovský (1991) and urease activity by Khaziev (1976).

Results and Discussion

All research sites were located in the forest biotopes that naturally give the ecosystem acidic soil reaction. Lower pH was observed in NR Fintické svahy, as well as organic carbon content. All determined soil physical and chemical average parameters are referred in Table 1.

Soil pH is an important factor of soil health despite of the fact that its value changes under internal and external factors. Jurko (1990) and Chmura (2006) confirmed that *I. parviflora* prefers acidic soil reaction, which was also shown in our study. Chmura (2006) also found out the highest influence of chemical features (organic carbon and nitrogen content) of species *I. parviflora* near the stump habitats. Soil physicochemical characteristics are indicators of soil ability to absorb and maintain soil water. Soil bulk density, porosity, soil moisture, organic matter and soil reaction are considered as ones of the basics soil physical and chemical properties (Fazekašová *et al*., 2011). Soil moisture is considered to be one of the most important factors affecting soil respiration, but our study did not show this significant relation which was also found in the study of Bobuľská et al. (2015). The highest soil moisture was also measured in NR Fintické svahy, especially in the stump habitats. Coombe (1956) states that *I. parviflora* grows on non-compacted and structured soils maintained high humidity, except of flooded localities. Bulk density is closely connected to the total soil porosity. In NR Fintické svahy, the presented research encountered both, the highest porosity and the lowest bulk density in soil. The previous studies also proved that the abundance and biological characteristics of *I. parviflora* also depends on soil physicochemical properties (Bobuľská *et al*., 2016), but our study also confirmed that soil microbial activity is very important factor in characterization of soil state.

Table 1. Soil physicochemical characteristics of three microhabitats in nature reserves

Natural reserves	Microhabitats	pH/CaCl2	Bulk density [t.m-3]	Porosity [%]	Soil moisture [%]	SOC [%]
NNR Šarišský hradný vrch	Meadow	6.7	1.33	49.81	26.2	5.13

Control site		7.2	1.09	49.96	31.5	5.98

Determination of the intensity of microorganisms' respiration is of great importance. It refers not only to the overall biological activity of the soil, but also the speed of mineralization processes. In addition to temperature and humidity, soil respiration isinfluenced by the quality and supply of nutrients in the soil, soil texture, soil aeration, type of ecosystem, and increasingly also by soil managements. In general, invasive species might increase the activity of microbial parameters, as well as the functional diversity of microbial communities with the significant carbohydrate utilization (Zhang *et al*., 2009) that characterize stress of the bacterial communities due to poor nutrient status (Pessi *et al*., 2012). Also in our study, the sites with the invasive species showed higher values of microbial parameters compared to the control sites (*p<0.05). Average values of the selected soil biological (microbial) parameters, such as soil microbial respiration (SMR) and soil enzymatic activities, are given in Table 2. Soil basal respiration was higher under the stamps habitat that was represented by the highest plant individuals with the most number of flowers/fruits as it was mentioned in the previous biological study of *I. parviflora* (Bobuľská *et al*., 2016). Castillo and Joergensen (2001) pointed out that almost all biological properties are significantly influenced by environmental management, of which the soil respiration was the parameter most affected by way of different management and many other factors. Same trend was also observed with the soil urease activity that tends to increase the pH of the environment as it produce ammonia as a basic molecule (Monreal and Bergstrom 2000). There are a number of enzymes in soil, depending on diversity of soil organisms and conditions of organic substances turnover. Several factors may affect directly or indirectly the activities of soil enzymes (Okur *et al*., 2010). Soil reaction differs from the pH optimum for phosphatase activity. Soil phosphatase activity is higher in soils with high humidity and because phosphatases have different optimal pH, therefore are divided into acid and alkaline phosphatases (Speir et al., 2003). Phosphatases are produced not only by the microorganisms, but also by higher plants. In our study, activity of acid phosphatase was higher compared to alkaline phosphatase activity in all localities (**p<0.01), which was closely connected to acidic condition on the research sites. Also the activity of acid phosphatase was significantly higher (*p<0.05) in the microhabitat under tree vegetation. The high activity of this enzyme may originate from roots of such higher plants (Senga *et al*., 2011).

Table 2. Soil microbial characteristics of three microhabitats in nature reserves

Natural reserves	Microhabitats	SMR [µg C-CO_2/g soil]	Urease [mgNH_4^+-N g^{-1} d^{-1}]	Acid Phosphatase [mg P g^{-1} $3h^{-1}$]	Alkaline Phosphatase [mg P g^{-1} $3h^{-1}$]
NNR Šarišský hradný vrch	Meadow	103.55	0.43	377.81	266.23
	Habitat under tree vegetation	127.85	0.55	466.60	305.56
	Stumps habitat	172.05	0.74	394.53	340.09

Control Site		100.88	0.41	237.99	250.65

Conclusion

Soil microbial indices, as well as biochemical are sensitive to not only under the influence management changes, but under the environmental changes. Our findings showed that *I. parviflora*, as invasive plant species, prefers acidic and non-compacted soil conditions. The results also suggested that biology of the invasive plants had the high impact on soil ecosystem and soil enzyme activity played an important role in nutrient cycling in the ecosystems, and thus could be considered as biological indicator of soil health and environmental changes.

THERMOPHILIC BIOMETHANIZATION OF AGRICULTURAL WASTE IN CODIGESTION: EFFECT OF PESTICIDES

Juana FERNÁNDEZ-RODRÍGUEZ*, Beatriz DE DIEGO-DÍAZ, Francisco Javier PEÑAS

Department of Chemistry, University of Navarra (Pamplona) Spain

Abstract

Anaerobic digestion (AD) is becoming one of the most feasible and efficient options for agro-industrial waste management. However, this kind of waste can contain certain substances from the industrial activity, which could potentially inhibit or, at least, modify the biomethanization process. Pesticides are widely used in agricultural activities. Mancozeb is an ethylene dithiocarbamate fungicide with broad spectrum used in crops. It reacts with and inactivates sulfhydryl groups of aminoacids and enzymes of fungal cells, disrupting of respiration, lipid metabolism and production of energy. Tefluthrin is a synthetic pyrethroid insecticide used to control a wide range of soil pests. It causes neurotoxicity and is a sodium channel modulator. This paper assesses the influence of the presence of mancozeb and tefluthrin on thermophilic (55°C) anaerobic co-digestion (carrot, cabbage, green pea, artichoke and fava and broad bean) of synthetic agroindustrial waste. The main results show that the pesticides improve the biomethanization process referred to generation of biogas (123%), consumption of volatile solid –VS- (18%), removal of chemical oxygen demand (5%) and yield of biogas measured like mL biogas/ VS consumed (117%), between other parameters. Anaerobic codigestion on presence of pesticides seems feasible and improved in comparison with the codigestion without these substances.

Keywords: *Agricultural waste, Co-digestion, Thermophilic, Pesticides.*

Introduction

Anaerobic Co-digestion (ACoD) of several organic wastes is a useful configuration in biomethanization, since it allows higher resource recovery and more stable operation than mono-digestion. Additionally, co-digestion has advantages like improving nutrient balance in the digester (Kim *et al.*, 2004), increasing methane production (Zaher *et al.*, 2009) and enhancing system economics (Arnell *et al.*, 2016). In fact AD setups without codigestion are only economically feasible under limited conditions, but scenarios which use codigestion have the potential to contribute to nutrient over-application without nutrient separation technology (Astill *et al.*, 2016). Temperature operation in biomethanization is an important factor to taking account. In this way, three are the main temperature ranges: psychrophilic (to 20ºC, optimal 15ºC), mesophilic (from 20 to 45ºC, optimal 35ºC) and thermophilic (from 45ºC, optimal 55ºC). Thermophilic offers better rates of degradation, speed of growth of microorganisms and hygienization of the final sludge, but also, higher electrical consumption and level of non-biodegradable substrate. In addition, with respect to micro and macroinorganic nutrients, it may not be sufficiently bioavailable to maintain efficient enzymatic processing in thermophilic range.

Codigestion of agricultural waste is a widespread technology to deal with this kind of organic waste (Xing *et al.*, 2014; González-González *et al.*, 2013).To increase the agricultural production, pesticide can be applied to the soil. Most of them are industrial and chemical

products. In this sense, the agricultural waste can contain rests of these chemical products. Two of them are mancozeb and tefluthrin, both are pesticides wide range.
Mancozeb is a fungicide which inactivates and reacts with sulfhydryl (SH) groups of aminoacids and enzymes of fungal cells, disrupting of lipid metabolism, respiration and production of ATP. It is based on a coordination product of zinc ion and manganese ethylene bisdithiocarbamate (until 37.0% weight), being until 7.4% manganese and almost 1% zinc.
Mancozeb shows the capacity of inhibiting the growth and proliferation of a wide range of different fungi such as Alternaria, Botrytis, Cercospora, Colletotrichum, Mycosphaerella, Peronospora, Phythopthora, Rhizoctonia and Septoria.
Other pesticide wide range is Tefluthrin, an insecticide that targets a wide range of myriapods and insects from the orders dermaptera, lepidoptera, diptera and coleoptear, as well as their larvae. Tefluthrin is highly liposoluble, persistent and in vapour stage also has repellent activity. It is disposed directly on the earth along with the seeds to be harvested or prior to the seeding process.
In this paper, the effect of the pesticides presence, Mancozeb and Tefluthrin, on the biomethanization of agricultural waste is studied. Codigestion of several wastes and thermophilic range (55ºC) has been selected.

Material and Methods

The experimental system consisted in sets of batch continuous stirred-tank reactors (total volume of 1L and working volume of 0.6L). In the cap of the digesters two ports allowed biogas collection in a 5L fluorinated ethylene propylene bag (SKC) and sampling (Figure 1). The digesters were stirred magnetically and placed in a thermostatic bath (thermophilic 55ºC). Biogas generation was quantified by bubbling it in a water gas-meter and its content in CH_4 was determined by NaOH displacement after being biogas bubbled in this alkaline solution (Walker *et al.*, 2009).

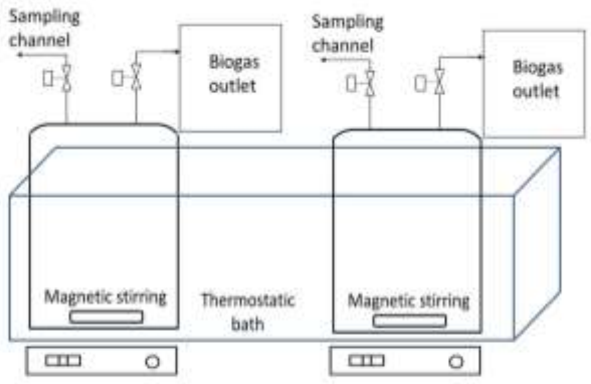

Figure 1: Picture and scheme of the reactors set

Synthetic agricultural waste was prepared in base of a group of vegetables: artichoke, green pea, bean, carrot and cabbage and green bean (Table 1). The reactors were operating in wet range (5-6% Volatile Solids); completed with 0.35L of organic waste; 0.2L of adapted inoculum and 0.05 L of the nutrient solution proposed by Sevillano *et al.* (2011). Pesticides were added to the reactors according to the concentration of field: Mancozeb (ACoD+M) 0.31 g/L and Tefluthrin (ACoD+T) 0.06 g/L. Additionally, a combination of both pesticides (ACoD+M+T) (0.31 g/L + 0.06 g/L) was tested and other system, blank of the experiment, without pesticides (ACoD).
Analytical methods were carried out according to standardized methods (APHA, AWWA, WPCF, 2012). Total solid (TS), volatile solid (VS) total chemical oxygen demand (COD_t) and

were analysed from the reactor. Alkalinity and soluble chemical oxygen demand (COD_s) required centrifugation of samples and later filtering through 0.45 µm and 0.2 µm.

Table 1. Characterization of the substrate and inoculum

Substrate	Scientific name	Percentage in reactor (%)	TS (%)	VS (%)	COD_t (gO_2/L)	COD_s (gO_2/L)	pH	Alkalinity ($mgCaCO_3$/L)
Inoculum	---	33.3	1.10	1.00	7.50	5.50	6.60	900
Nutrients	---	8.3	---	---	---	---	---	---
Artichoke	*Cynara scolymus*	6.7	10.45	9.86	56.43	29.88	7.03	1150
Green Pea	*Pisum sativum*	19.3	24.02	23.21	56.14	25.93	6.98	970
Bean	*Vicia faba*	6.9	17.82	17.13	42.03	22.48	8.21	1200
Carrot	*Daucus carota*	7.3	7.39	6.80	49.37	20.85	6.76	1050
Cabbage	*Brassica oleracea var. gemmifera*	3.8	15.52	14.21	54.98	26.53	8.34	1410
Green bean	*Phaseolus vulgaris*	14.4	13.58	12.74	45.40	23.71	7.52	1320

Results and Discussion

The evolution of the main parameters has been studied. The pH has shown different values according with the anaerobic stage. During the 8-9 first days, it was reduced until 4-4.5 due to the hydrolysis and acidogenesis. NaOH was used to increase the pH in the reactor in order to favour the methanogenic population. From this time to the end of the processes, the value of pH was close to 7-7.5, optimal for methanogenics. Alkalinity is a parameter use to estimate the stability of the process since the concentration of Volatile Fatty Acids (VFA) begins to increase; these are neutralized by the alkalinity to bicarbonate. In all cases, alkalinity has been in values around 20g/L, what is giving information about the high stability of the systems.

VS have decreased in all cases (Figure 2a), being the best results for the conditions in presence of pesticides, 58% reduction approx. in ACoD in front of 70% approx. (Table 2). The production of biogas is shown in the Figure 2b. It was higher (55-220%) in the reactors with pesticides comparing without them (2506 mL). The maximum biogas collected was in ACoD+T, 8206 mL. In all cases, the total biomethanization of the waste in the operational conditions lasted 15-20 days approx.

COD total was decreasing during the biomethanization, but it was not the same with COD soluble. In this case, the values were increasing until more than 200% over the initial value in ACoD+T. It can be supposed that in different conditions after these assays, the production of biogas can be higher, because it still remains organic soluble matter in the reactor.

TOC removal also showed higher values in ACoD+M (38.44%) comparing with ACoD (18.22%)

Relating to the productivity, the reactors with pesticides obtained better results than the system operating only in codigestion (112 mL biogas/gVS consumed). The higher productivity was reached in ACoD+T with 357.6 mL biogas/gVS, followed by ACoD+M with 224.0 mL biogas/gVS (Table 2). The productivities referred to biogas production per COD consumed are similar to the previous one. The minimum productivity was ACoD (95.9 mL biogas/gCOD), being ACoD+M (464.3 mL biogas/gCOD) and ACoD+T (367.5 mL biogas/gCOD) the maximums. The results obtained are not in concordance to those obtained previously. There is not so much studies dealing with the effect of pesticides in biomethanization, but Khalil *et al.*, 1991 concluded that mancozeb caused a pronounced inhibition of methanogenesis from glucose was observed at a concentration of 100 mg/L. Perhaps the industrial formats of pesticides contain micronutrients that aim the biomethanization process.

Biogas/COD_t cons (mL/g)	95.9	464.3	367.5	102.3

Kinetic study of the consumption of VS was developed. The Figure 3 shows the graphical adjust to the VS logarithm. The order of reaction and the velocity constant are similar in all cases (Table 3).

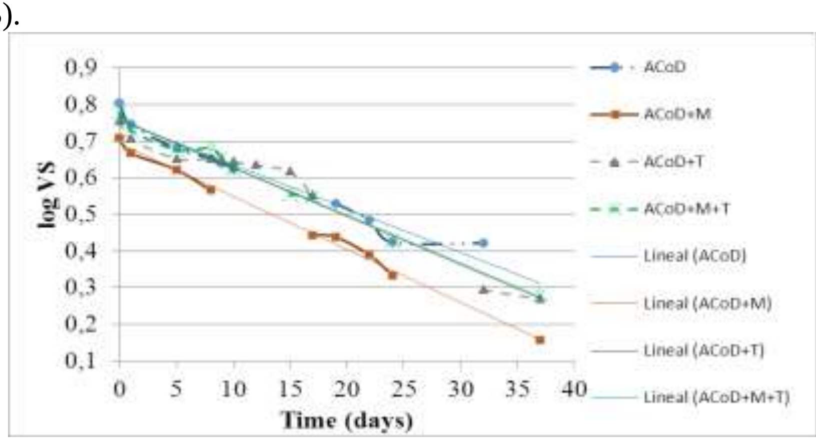

Figure 3. Velocity of the anaerobic reactions in codigestion of agricultural waste in presence of pesticides

Table 3. Kinetic parameters in anaerobic codigestion of agricultural waste in presence of pesticides

	ACoD	ACoD+M	ACoD+T	ACoD+M+T
General equation y= log VS x= time (days)	y = -0.012x + 0.7568	y = -0.0144x + 0.6939	y = -0.0131x + 0.7579	y = -0.0131x + 0.7611
R^2	58.55	71.95	67.33	68.05
Order of reaction (n)	-0.012	-0.0144	-0.0131	-0.0131
Log (k)	0.757	0.694	0.758	0.761
k (d^{-1})	5.712	4.942	5.727	5.769

Conclusions

The main results obtained in this paper indicate that the AD of several agricultural organic (ACoD) wastes can be feasible in thermophilic range. The ACoD in presence of pesticides, mancozeb and tefluthrin, has shown better results than the codigestion without pesticides. The reduction of VS was around 70% average in pesticide presence and 58% without. In this way, the production of the biogas was higher in the system with tefluthrin (8206 mL), followed to mancozeb (4935 mL) comparing with ACoD without pesticides (2506 mL). Additionally, the productivity measured as mL biogas/gVS consumed was of 357.6 and 224.0 with mancozeb and tefluthrin respectively; whereas it was of 112.0 in ACoD. The order and the velocity of the anaerobic reactions seem to be similar in all studied cases.

Abstract

Anaerobic codigestion has shown to be feasible to manage organic waste. Different wastes treated together can be the supplement of nutritional deficiencies for the microorganisms involved. In this study, the presence of macromolecules and trace elements on anaerobic codigestion of agricultural waste has been assessed. An extra nutrients solution containing elements, which play a key role in the anaerobic microbiological metabolism, was used at three different temperature conditions: mesophilic (35°C), intermediate (42°C) and thermophilic (55°C). The main results showed that at 35°C in the presence of nutrients, biogas production reached 6.2L, almost 1.5-fold the production of biogas without them. Additionally, productivity was 359.3mL-CH4 / g-VS, which is 1.9 times higher than that for the process without nutrients. At 42°C up to 55% of VS were eliminated and more than 10.0L-biogas were produced, while biomethanization without extra nutrients solution only reached 7.4L. The anaerobic codigestion at 55°C showed that biogas production also surpassed 10.2L in the presence of nutrients and 146.99mL-CH4 / g-VS were obtained, being these results 1.2-fold those obtained for the process without extra solution. Results for each temperature showed that the nutrients solution could contribute to the biomethanization process of codigestion waste. Furthermore, 35°C was the temperature range at which the impact of nutrients was more remarkable.

Keywords: *nutrients solution, anaerobic digestion, agricultural waste, temperature*

Introduction

Anaerobic codigestion (AcoD) has shown to be an effective approach when optimizing biomethanization of organic waste. The combination of various substrates leads to nutritional augmentation through synergies established between different types of feedstock (Jang *et al.*, 2016). The microbial consortia has, therefore, access to an enriched media with a proper nutritional balance. The main objectives of AcoD should be favoring beneficial interactions, avoiding inhibition and enhancing methane production (Astals, *et al.*, 2013; Mata-Alvarez *et al.*, 2011). AcoD presents several advantages regarding economic, technological and environmental aspects. Among the economic advantages, sharing potential costs between industries and higher biogas production can be found. The latter can be translated in higher economic feasibility of the treatment plant (Macias-Corral *et al.*, 2008). Additionally, an anaerobic process for waste treatme is already environmentally positive. This is because the environmental impact is less than that with aerobic processes as the greenhouse gas emissions are lower.

AD has already shown to be able to stabilize organic waste, among which agricultural residue is worth-mentioning. The activity derived from agriculture generates a great amount of waste that cannot longer be utilized for commercial purposes. Therefore, the codigestion of these substrates that are linked to the same sector can be treated together and both agronomic and energetic valorization can be implemented (Hobbs *et al.*, 2017).

However, AcoD can be further optimized through extra nutrients or elements that can improve the C/N balance or microbial metabolism. Mineral solutions containing trace elements can enhance the digestive process. Among them, nickel, cobalt, iron and molybdenum have shown to have a positive effect on the stabilization of anaerobic waste (Choong *et al.*, 2016).

Also, operative conditions such as temperature can play a key role in the process. Generally, biomethanization is performed at psychrophilic (<20°C), mesophilic (20-45°C) or thermophilic (45-60°C) range and each of them can impact the process. Each range shows its general advantages and disadvantages. Thermophilic range, for instance, contributes to the removal of pathogens and antibiotic resistance genes, and yields higher CH_4 productions. On the other hand, operative costs derived from higher energetic requirements have to be considered in life cycle assessments.

In this study, AcoD at three different temperatures (35°C, 42°C and 55°C) was carried out. Also, the effect of a nutrient solution on biomethanization performance was assessed at the same operative conditions.

Material and Methods

Stirred anaerobic digesters with a total volume of 1 L and a working volume of 0.6 L were used. Batch assays were carried out with codigestion of various vegetables using 0.2 L of adapted inoculum, which was taken from an anaerobic digestion treatment plant of local wastes. Reactors were set-up according to total solids (TS) in order to work at a wet range (4-10% of TS). The synthetic waste used in this study was a combination of 6 vegetables from a commercial product. The characterization of each substrate is described in Table 1.

The reactors that contained the extra nutrients (W/) were filled up with 0.05 L of the solution, while this volume for the reactors without extra nutrients was filled up with water (W/O). The nutrient solution used in this study was taken from Sevillano *et al.* (2011).

The parameters that were monitored are chemical oxygen demand (COD), TS, volatile solids (VS), pH and alkalinity. These were analyzed according to the Standardized Methods (APHA, *et al.*, 2012). Biogas was collected in 5-L Tedlar bags (SKC, USA) and was quantified using a water gasometer through water displacement and its content in methane using a gasometer with an alkaline solution. Results were contrasted with a biogas analyzer (Geotech Biogas-5000, UK). This research was performed at the University of Navarra (Spain) by the Environmental Technology Group.

Green bean	*Phaseolus vulgaris*	13.6	12.7	45.4	23.7	7.5	1320

Results and Discussion

Temperature and nutrient results are summarized in Table 2. Temperature studies for both conditions showed how thermophilic range (T55) yielded the highest biogas productions with up to 8.1 L and 10.1 L for W/O and W/, respectively (Fig. 1c). This is in accordance with the literature, as thermophilic range has shown to yield higher productions than mesophilic conditions (Peces *et al.*, 2013). Also VS removal was the most successful at T55, managing to remove 68.6% and 63.3% of VS for W/O and W/. The latter was 1.31-fold higher than the same condition at mesophilic range (M35) (Fig. 2). Productivities, however, showed better results at an intermediate temperature (I42). This had to do with relatively high biogas and methane generations and a lower solids removal in comparison to the other operative conditions. I42 produced 1049.9 mL-biogas/g-VS and 409.8 mL-CH_4/g-VS for W/O, which is 2.81-times the biogas productivity at T55 and 3.39 that of CH_4. This is because, in spite having a similar biogas and CH_4 generation, the solids removal was considerably higher at T55. On the other hand, M35 granted a more stable process with a less demanding pH control. This can also be seen attending to the CH_4 content. For M35 the total CH_4 production reached 70-72% for both conditions, while for I42 and T55 it only accounted with 27-39% of the total biogas produced. Nutrient studies showed a clear difference between W/O and W/ for every temperature. Biogas productions were always higher for W/, being W/ 1.27-1.37 times higher than W/O. It is also worth-mentioning, that the differences for each temperature were higher at lower temperatures. This can be explained by the effect of temperature on AcoD, as explained before (Fig. 1). Also, total CH_4 was higher for W/, showing T55 once again less differences than the other conditions. This is in accordance with the literature, as various studies have shown how supplementation enhances AD (Choong *et al.*, 2016; Wintsche *et al.* 2016). Regarding productivities, only I42 showed better values for W/O than W/. For W/ at M35 biogas and CH_4 productions per g-VS consumed were 1.88 and 1.93 times higher than those for W/O, respectively. The same scenario can be seen for T55. However, these were only 1.48 and 1.21-fold.

Biogas production begins to arrest at different times for each condition. However, when comparing nutrients effect, it is W/ that generally continues to produce biogas for longer than W/O (Fig. 1).

Additionally, statistical studies on biogas production and VS removal showed that for each temperature, W/O and W/ were significantly different (α<0.05).

Time (≃days)	10	21	16	16	13	15

Conclusions

AcoD on agricultural wastes has shown to be an efficacious process at the three temperatures studied. The condition that yielded higher biogas productions was the thermophilic range, with up to 10.3 L with nutrient solution and almost 8.1 L without them. Also solids removal was highest at this temperature. However, methane content (>70%) was highest at 35°C due to the stability of the process. Nutrient studies showed that the presence of a mineral solution enhances the AcoD at every operative condition assessed in this study. As described elsewhere (Choong *et al.*, 2016), the optimal proportion of trace elements and micronutrients should be studied, especially because the effect of each one is yet to be elucidated.

EVOLUTION OF SOME EDAPHIC PROPERTIES IN AN AGRICULTURAL SOIL AFTER ITS CHANGE OF USE - RAINFED TO IRRIGATED

Antonio SÁNCHEZ NAVARRO, Juan SÁNCHEZ MARTÍNEZ, María José DELGADO INIESTA*

Department of Agricultural Chemistry, Geology and Edaphology, Campus de Espinardo (30100), University of Murcia, Spain

Abstract

This study aims to assess the influence of cropland use change (rainfed to irrigated) on some soil properties. To this effect, three profiles (P1, P2, P3) were sampled and analysed to determine macromorphology and electrical conductivity, as well as total organic carbon, total nitrogen, base cations (Na, K) and assimilable phosphorous and micronutrient (Fe, Mn, Cu, Zn) concentration. The profiles were located in the closest point of three different rainfed patches. Cropland use change occurred in 1998 for P2 and P3. Sampling of profiles took place in 2003 (P1 and P2) and 2015 (P3). Analytical results were submitted to one-way ANOVA, comparing the same horizons of the three profiles. Use change led to organic carbon enrichment (≈6 $g \cdot Kg^{-1}$ in P1; ≈10 $g \cdot Kg^{-1}$ in P3) and browning of the Ap horizons. As a result, the soil evolved from a Cambic Calcisol (P1, P2) to a Fluvic Calcic Kastanozem (P3). The highest concentration of phosphorous was measured in surface layers of P3 (37 $mg \cdot Kg^{-1}$), which might be linked to soil carbon enrichment; in contrast, a slight nitrogen-leaching process was detected in deep horizons (P2, P3), likely caused by nitrogen lixiviation and intense irrigation. EC values were doubled in P2 (2.3 $ds \cdot m^{-1}$), due to salinity of irrigation water, organic amendment and fertirrigation. Lower values of EC were measured in P3 (1.4 $ds \cdot m^{-1}$), as a result of a readjusted management. Potassium concentrations were higher in Ap horizons, especially in P2 (0.5 $g \cdot Kg^{-1}$); sodium concentration evolved similarly to EC; micronutrients accumulated in upper horizons similarly to potassium. Irrigation and fertilisation schedule have proved to be appropriate for the intensive management of the cropland, reducing soil salinisation and increasing soil fertility. Furthermore, crop rotation and addition of organic compost were key points to favour a carbon sequestration process in the soil, promoting a classification change to a more developed soil.

Keywords: *Change of use, salinisation, fertility, carbon sequestration, nitrogen, Spain.*

Introduction

In the last few years, with the agricultural development of the Mediterranean Basin, soil salinisation processes and loss of soil fertility have been enhanced (Al-Jaloud, 1994) due to the indiscriminate use of poor quality water and the excessive addition of manures. The European Commission (2003) issued a report in which it stated that 1-3 millions of hectares of land in Europe hold this concern, mostly in the Mediterranean Basin. Arid and semi-arid regions, such as the southeast of Spain, especially suffer from the effects of high salt contents in the soil (Hernández-Bastida et al., 2004). In Spain, the 18 percent of 3.5 millions of hectares of irrigated crops is seriously affected by or in serious risk of soil salinisation (European Commission, 2002). However, the most intense degradation has been occurring in the last decades, due to the utilisation of inadequate agricultural practices. In an area where periods of severe drought are frequent and cultivations require high contents of water and nutrients, the trend has been to apply fertilisers and manures as well as to utilise poor quality water for irrigation and inadequate tillage (Arnaldos, 2001), which progressively leads to an increase in the number of hectares of soil disabled by the loss of their properties.

The present study is framed in this context, which has been conducted in a land located in the municipality of Puebla de Don Fadrique, in the province of Granada (SE Spain). This area has experienced, in the last few years, a remarkable change in the model of cultivation. In particular, a significant proportion of the cultivation soils has evolved from a rainfed and extensive agriculture to an irrigated agriculture. Concurrently, traditional rainfed crops have been replaced with horticultural crops (broccoli, tomato, celery, potato, etc.), whose management implies moving from an agrosystem which is slightly aggressive to the environment, to another one in which processes such as soil degradation, pollution and overexploitation of aquifers are frequent.

As some authors point out, these processes of soil degradation are manifested throughout the soil profile. Thus, vertical distribution of total organic carbon (TOC) shows a great variability in agricultural soils (Van Oost et al., 2007).

Therefore, this study aims to assess, in short and long term, the influence of cropland use change (rainfed to irrigated) on some soil properties, the suitability of agricultural management techniques and its agroenvironmental influence.

Material and methods

The experimental patch is located in the SE of Spain, with an average yearly precipitation around 473 mm and an average yearly temperature of 12.70 °C, being framed within the supramediterranean bioclimatic stage. The study area has highly seasonal nature, with minimum temperatures of around -10 °C and maximum temperatures of around 40 °C.

Three complete soil profiles were sampled following the FAO Guidelines for Soil Description (1977). Profile 1 (P1), sampled in 1998, corresponds to a rainfed cereal soil. Profiles 2 and 3 (P2 and P3), were sampled in the same location, but in 2003 and 2015, respectively.

During the 1998 and 2015 period, the patch has been used to cultivate vegetables throughout the summer period: broccoli (2 years), tomato (4 years), pepper (1 year), lettuce (7 years) and maize (1 year). Likewise, crop rotations with arable crops such as barley, oat and vetch have been carried out during the autumn and winter seasons. Water supply varied from 6,200 $m^3 \cdot ha^{-1}$ in tomato cultivations to 4,000 $m^3 \cdot ha^{-1}$ in lettuce crops and it was considered as good quality water by Wilcox and Green combined index. The organic amendment consisted in 20,000 $kg \cdot ha^{-1}$ of sheep manure, applied biennially, and supplemented with macro and micronutrients by fertirrigation (N, P_2O_5, $MgSO_4$, K_2SO_4 y HNO_3), whose concentration was adjusted according to crop requirements.

Following the World Reference Base (2006), soil samples were air-dried, sieved with a 2 mm sieve and processed in order to analyse their properties and features. Soil colour was described using a Munsell Colour Chart, whereas TOC, electrical conductivity (EC), assimilable phosphorous, total nitrogen (TN), texture and assimilable metals (Fe, Mn, Cu y Zn) were measured using the Soil Survey Laboratory Methods Manual (USDA, 1996).

A one-way ANOVA and Tuckey's Test were carried out in order to seek significant differences among P1, P2 and P3 horizons.

Results and discussion

P1, P2 y P3 were relatively developed, containing an Ap-Bw-C sequence. The macromorphologial study of the complete profiles revealed changes in the Ap horizon depth. In fact, P2 and P3 have an Ap horizon divided in Ap1 and Ap2, with more than 50 cm deep, whereas the Ap horizon of P1 is around 30 cm deep (Table 1). This might be explained by the subsoiling process at 50-60 cm deep occurring in P2 and P3 for cropland use change. As a consequence, part of the previous Bw was integrated in the upper horizon. Soil texture in P1, P2 and P3 is silty clay loam for Ap and Bw horizon, clay loam for Ck1 and loam for C2, except in P1, which is clay loam. Soil structure is blocky subangular for Ap and Bw in the three profiles. Hence, cropland use change did not affect soil structure. Regarding soil colour, Ap1 horizon darkened remarkably quick due to the addition of manure and crop wastes (Table 1). Furthermore, Bw presents reddish tones, soil structure and a lower carbonate content than the underlying horizons, so it was denoted as a cambic horizon.

Table 1. Macromorphological aspects of interest.

	P2	72-110	10YR 8/4	10YR 6/8	
	P3	92-125	10YR 8/2	2.5YR 6/4	

P1, P2 and P3 had low to moderate TOC contents which diminish in depth (Table 2). Similar results were obtained in the same cropland area by other authors (Pérez-Pujalte et al., 1990). The highest values were obtained in the upper horizons (especially in P2 and P3≈10 $g \cdot kg^{-1}$) while the lowest values were found in the C horizons (< 3 $g \cdot kg^{-1}$). The statistical analysis revealed significant differences in TOC contents among P1, P2 and P3, specifically in Ap1, Ap2 and Ck1 horizons, which have been justified through the application of manure in alternate years.

The results suggest that a carbon sequestration process would have been manifesting in the soil, favoured by the cropland use change (Hontoria et al., 2004). The carbon sequestration process has been extensively studied in mild and humid climate (Heath et al., 2002) and tropical climate (Fearnside, 2000), but is still relatively unknown in soils under the effect of a Mediterranean climate. These soils often contain low levels of TOC that are even decreased due to mineralisation of organic substances, especially when the application of inorganic fertilizers is prioritized and inadequate agricultural labours are carried out (Stevenson & Cole, 1999). Nevertheless, areas with Mediterranean climate have a high potential to fix carbon, and favour the development of interesting ecological functions (FAO, 2004).

TN contents (Table 2), in general, did not vary significantly with the cropland use change. The highest values of TN were found in the upper horizons of P1 and P2 (1.1 $g \cdot kg^{-1}$ y 1.2 $g \cdot kg^{-1}$, respectively). However, N accumulation was detected in C2 and Ck1 horizons of P2 and P3, with a maximum of 0.9 $g \cdot kg^{-1}$ and exceeding the concentrations measured in the surface. This might be explained by a large supply of manure and basal-dressing fertilisers in order to satisfy the demanding nutritional requirements of crops, as well as by an excessive irrigation that led to soil washing and N leaching to deeper horizons (Riley et al., 2001).

C/N ratio was significantly different in Ap1, Ap2 and C2, reaching values from 7 to 9 in Ap and Bw of P1 and P2, whereas the maximum values were found in Ap2 of P3 (C/N=15) (Table 2). In C horizons of P2 and P3, C/N ratio was the lowest found, as a result of the increase of N mentioned in the previous section. In conclusion, P3 contained the best C/N ratio, favoured by the presence of high concentrations of TOC, which highlights the sustainability of the crop management and the organic amendments applied.

EC values varied significantly in all horizons with the cropland use change (Table 2). In P1, EC was lower to 2 $dS \cdot m^{-1}$, while in P2 horizons it was above that value, except in Bw (1.2 $dS \cdot m^{-1}$) and Ap2 (1.6 $dS \cdot m^{-1}$); therefore, the first 5 years of vegetables cultivation has led to increases of EC in P2 which are 2-fold and 4-fold higher for upper and deeper horizons, respectively. These increases could be related to the incorporation of soluble salts such as sulphates, chlorides or nitrates to the soils, coming from the application of organic amendments, fertirrigation (K_2SO_4, $MgSO_4$) or irrigation water (30 $mg \cdot l^{-1}$). EC in P3 showed values between P1 and P2, but in any case reached 2 $dS \cdot m^{-1}$, which is a significant reduction with P2. This fact is explained by adjustments in the composition and quantity of the manure and a process of salt washing caused by a period of intense rains occurring in 2011-2012.

Regarding to base cation concentrations, cropland use change caused a short-term enrichment in Na and K (P2) (Table 3). Both cations were found in similar concentrations, which concurrently changed in time, showing significant differences in Ap, Bw and Ck1 along the study period. The quick increase of K would be related to inputs coming from organic amendments, irrigation and fertirrigation. In P3, Na and K concentrations were reduced, reaching values prior to the cropland use change. This reduction was likely produced by the adjustments of the manure and the process of salt washing as mentioned for EC. In the case of K, the reduction of its concentration could also be linked with a greater demand for crops.

P distribution in P1, P2 and P3 was similar, with the highest concentrations in the upper horizons and increasing over time (Table 2). According to Abdala et al. (2012), this fact is produced because P is adsorbed to soil colloids and increases of TOC enhance that process. Therefore, cropland use change has largely affected assimilable P concentrations, determining its progressive accumulation, fundamentally in Ap1 and Ap2 horizons.

Micronutrient concentrations (Fe, Mn, Cu y Zn) showed similar dynamics, increasing over time until reaching values 3-fold higher (P2) and 8-fold higher (P3) than in P1 (Table 3). On the one hand, these results could be explained by an excessive addition of manure in order to avoid nutritional deficiencies in the cultivations. On the other hand, the calcareous nature of the soil hinders micronutrients solubility, leading to a concentration decrease in deeper horizons. It could be expected that the major part of micronutrients are adsorbed to organic matter (Larchevêque et al., 2006), reason that would justify the fact that the maximum concentrations of micronutrients were measured in the horizons with higher contents of that component. The statistical analysis revealed the presence of significant differences among the profiles, being able to affirm that the cropland use change has contributed to a progressive accumulation of Fe, Cu, Mn and Zn in the soil, especially in the upper horizons.

Table 3. Assimilable elements in P1, P2 and P3 horizons.

P1 and P2 are classified (IUSS Working Group WRB (2014) as Cambic Calcisols (Aric, Fluvic, Loamic) for only presenting a calcic horizon and a cambic horizon. In contrast, P3 includes, apart from the previous horizons, an A mollic horizon; consequently, it is classified as Fluvic Calcic Kastanozem (Aric, Cambic, Loamic). This change in the classification suggests that the crop management has acted as a brake on the degradation of the crops and has produced a positive development of the soil.

Conclusion

In the 17 years of soil monitoring, cropland use change has not produced a significant soil degradation, even some properties have significantly improved, especially at A horizon. In this sense, an enrichment of organic carbon, macro and micronutrients have been observed.
As a consequence of the increase of organic matter, soil colour has darkened, leading to a change in its taxonomy. Moreover, this increase may contribute to the reduction of climatic change through carbon storage. Cropland use change has led to an increase in salt concentration in all horizons, although the initial trend of linear increase has been attenuated, even decreased, when comparing P2 and P3, due to the adjustments of fertirrigation programs. Therefore, the treatments used have proved to be appropriate, even advisable, for the intensive management of the cropland Likewise, evidences of leaching of N and other salts have been detected due to the presence of mottling in the Ck1 horizon of P2 and P3, as well as by the EC values.

Abstract

Mediterranean rainfed agricultural landscapes provide ecosystem services such as water harvesting, agricultural production and erosion mitigation. Assessing the impact of global changes (e.g., land use, climate forcing) on these services can be useful for streamlining agrosystem management. Such assessment can be done by implementing land surface models that simulate the spatiotemporal dynamics of the targeted processes, provided model simulations are constrained with reference data. Model calibration at the catchment scale is challenging within semiarid mediterranean agricultural landscapes, because of gaps between complex hydro-agricultural processes and simplified model descriptions in relation to extreme events, spatial heterogeneities and crack distribution across different land uses on vertisols. The aim of this paper was to explore the capability of the Soil and Water Assessment Tool (SWAT) model to predict the hydrological regime within a small agricultural catchment in the Cap Bon peninsula in Tunisia. The study took place within the Kamech catchment that belongs to the OMERE long-term monitoring system (http://www.obs-omere.org/). Measurements under the common cereals/ legumes/ pasture cropping systems were used to adjust model parameters to the conditions induced by different land use practices under edaphic conditions related to vertisols. Numerous field observations within the catchment were used to evaluate the ability of SWAT to mimic the spatiotemporal dynamics of the hydrologic regime.

Keywords: *Hydrological processes, SWAT, cracks, agricultural catchment, Tunisia*

Introduction

Models that can simulate hydrological budget of agricultural catchments have main implications to support decisions about management strategies related to land use change, climate change, water allocation, and pollution control (Abbaspour *et al.,* 2007). Soil and Water Assessment Tool (SWAT) is a process-based continuous hydrological model (Srinivasan *et al.,* 2010; Arnold *et al.,* 2012; Gassman *et al.,* 2014). It was recommended by Dechmi *et al.,* (2012) as the most suitable model for long-term simulations in catchments dominated by agricultural land uses, since its original design was to assess the impact of land management practices on water, sediments and agricultural residues. It has been successfully applied in numerous studies for evaluating the impact of land management practices on hydrological budget within large scale basins (Eckhardt *et al.,* 2002; Schneider *et al.,* 2007; Srinivasan *et al.,* 2010; Mukundan *et al.,* 2015). It has been used and validated to simulate ecological, hydrological and environmental processes under multiple climates and management conditions throughout the world, and it is extremely useful to link crop yields and basin hydrology over long time periods (Neitsch *et al.,* 2011). However, using SWAT is a delicate task when addressing Mediterranean agricultural catchments typified by semiarid climate and marly soils. Precipitation distribution, land use and subsequent agricultural practices, water requirements combined with varying soil properties induce significant spatiotemporal variations for runoff processes (Mekki *et al.,* 2006). In addition, vertisols or vertic intergrades soils with highly dynamic shrink-swell behaviour generate extreme seasonal variations in soil infiltration rates and make hydrological regime much more complex across several spatial scales from micro to catchment scales (Inoubli *et al.,* 2016). To our knowledge, such challenging conditions have not been investigated up to now with SWAT, and it is necessary to investigate the model capabilities to properly mimic the hydrological regime within Mediterranean agricultural catchments with semiarid climate and marly soils. This is now possible thanks to several time series of measurements collected in the framework of long-term environmental research observatories. The aim of this paper was to describe the work progress, with a focus on the SWAT capabilities to mimic surface water flows in response to land use.

Material and Methods

Study area and data

The experiment took place within the 2.6 km² size Kamech small marly agricultural catchment that belongs to the OMERE long-term monitoring system (http://www.obs-omere.org/). Kamech is located upstream of the Lebna catchment, Cap Bon peninsula, Tunisia. The climate is classified as semiarid Mediterranean. It is typified by rainfalls mostly concentrated in autumn and winter (75% of the total annual rainfall occurs between October and April) and by dry summer periods with high temperature and evaporation rates (Figure 1). The long-term (1996-2016) average annual precipitation is 650 mm, but annual precipitation is highly variable, between 400 to 1000 mm. The mean inter-annual temperature is 14 °C, and the mean annual evapotranspiration is 1200 mm (Zitouna-Chebbi *et al.,* 2014). The rainfall variability is very large, including periods without runoff and periods with extreme rainstorm events. The latter occurred between May and October, with short durations and high rainfall intensity. The hydrological regime is typified by the highly predominance of hortonian overflow process and significant hydrological connectivities. Catchment elevation ranges from 100 to 200 m. The main soil types are vertisols, luvisols, cambisols and regosols. However, the main part of the catchment is underlain by clay texture, and the soils are therefore merged into two main types: vertisols or assimilated (65% of the catchment), and regosols (35%). Soil depth and topsoil conditions are highly variable (Mekki *et al.,* 2006). Vertisols or assimilated correspond to deep soils (>2 m) while the regosols correspond to thin soils (<1 m). About 60% of the catchment area exhibit a strong potential for shrinking and swelling processes with numerous wide and deep open cracks throughout the dry summer period (Inoubli *et al.,* 2016). The catchment is dominated by annual croplands (70 % of the catchment area) mainly located over slopes lower than 15%. Land use includes rainfed cropping systems (cereals, legumes, spices and fallow), and natural pasture vegetation (pastures-annual and pastures-shrubs). The most common crops are winter cereals (wheat, triticale, oat and barley), and legumes (fababean, chickpeas, peas, fenugreek). The catchment landscape is typified by small agricultural fields, and by a large panel of tillage and management operations. SWAT requires land use, soil type and digital elevation model (DEM) data (Neitsch *et al.,* 2011). Each of these data was obtained within the framework of the OMERE observatory and used as input for the model. Precipitation and runoff have been monitored continuously at the level of the catchment outlet since 1994 (http://www.obs-omere.org/). The datasets are detailed in Raclot and Albergel (2006), Mekki *et al.*, (2006), and Albergel *et al*., (2007). Meteorological data have been recorded by the weather station at the catchment outlet since 1994, and they were used in the current study to estimate potential evapotranspiration (PET) as detailed in Zitouna-Chebbi *et al.*, (2014).

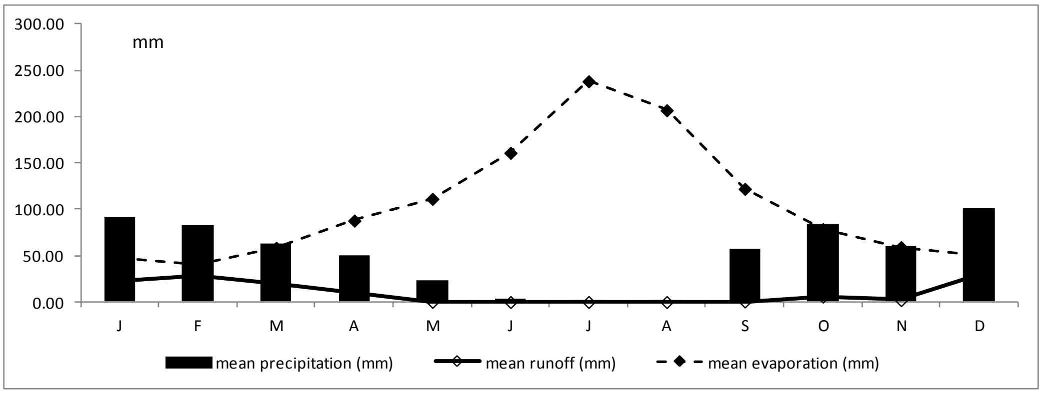

Figure 1: Mean monthly rainfall, runoff and evaporation at the Kamech catchment outlet for the period 2005 to 2012.

Model description, implementation and calibration / validation

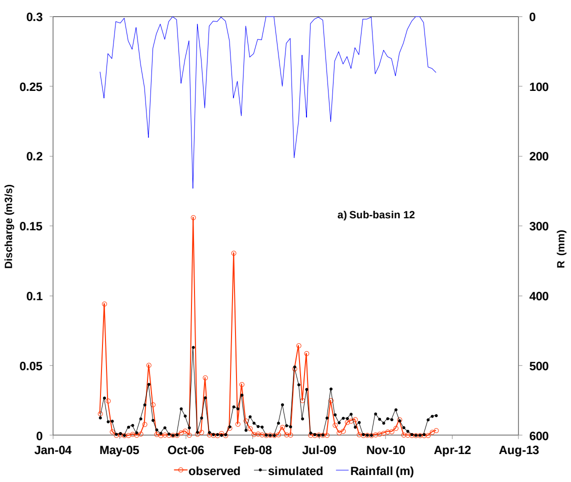
SWAT is a continuous-time, semi-distributed, process-based, river basin scale model (Arnold *et al.*, 2012). It operates at a daily time step, and it requires a large panel of input parameters. Main model inputs are related to hydrography, terrain, land use, soil, weather and management practices (Srinivasan *et al.*, 2010). In this study, ArcSWAT (Version 2012.10.2) for ArcGIS10.2 platform was used. The catchment terrain was characterized using 2 slope classes; 0-15%, >15%. The impacts of land use on water flows were assessed both at the catchment scale and on the Hydrologic Response Units (HRUs) where measurements were available. SWAT model provides, for each sub-basin and for each HRU, the amount of the surface runoff, potential and actual evapotranspiration, percolate and stored water in the soil profile at the end of simulation time step (day, month, year). The soil water balance is conceptualized in SWAT using the following Eq. (1) as described in Neitsch *et al.*, (2011):

$$SW_t = SW_0 + \sum_{i=1}^{t}\left[R_{day} - Q_{surf} - E_a - W_{seep} - Q_{gw}\right] \quad (1)$$

Where SWt is the soil water content [mm], SW0 is the initial soil water content on day 1 [mm], t is the time [days], Rday is the daily precipitation [mm], Qsurf is the amount of surface runoff [mm], Ea is the evapotranspiration [mm], Wseep is the amount of water entering the unsaturated zone [mm], and Qgw is the amount of return flow [mm]. The model defines two phases: the land phase and the water, or routing, phase of the hydrological cycle. For the current study, the model was run from 2004 to 2012 using the SCS curve number method to simulate surface runoff and the Penman-Monteith approach to simulate the evapotranspiration. Simulated flow has been compared to the observed data at the outlet of the catchment. We used SWAT - Calibration and Uncertainty Program (SWAT-CUP) and its Sequential Uncertainty Fitting algorithm (SUFI-2) to achieve calibration (Abbaspour *et al.*, 2015). The selection of the calibrated parameters relied upon sensitivity analysis procedure and upon analyses previously carried out by various authors (Neitsch *et al.* 2011; Arnold *et al.*, 2012; Ha *et al.*, 2017). Sensitivity analysis included saturated hydraulic conductivity (SOL_K), available water capacity of the soil layer (SOL_AWC), and baseflow recession constant (ALPHA_BF). The SCS runoff curve number (CN) also was included because of its influences on the surface-subsurface hydrological processes. The calibration relied on these parameters and modelling performance was evaluated by Nash and Sutcliffe coefficient (NS).

Results and Discussion

Although the SWAT model is still in calibration phase, some analyses are reported here, where simulations rely on a simple classification of HRU based on dominant soil type, land use, slope and a subdivision of the catchment into 30 sub-basins. The years 2004 and 2005 served as a warm-up period for model simulations. The daily discharge values were loaded to SWAT-CUP and compared with the discharge simulated by SWAT. The initial results for uncalibrated model were not very good, with low and unreliable river discharge values. The NS coefficient for daily flow with uncalibrated model ranged between -0.12 and 0.45 depending on sub-basins. Therefore, we calibrated the model at a monthly time scale by using the river discharge measurements at the catchment outlet. As previously reported by former studies, the global sensitivity analysis showed that saturated hydraulic conductivity (SOL_K), available water capacity of the soil layer (SOL_AWC), and baseflow recession constant (ALPHA_BF) are the most sensitive parameters for river discharge calibration. The model was well calibrated dynamically, and the simulations depicted the seasonality trend of infiltration-runoff response with a strong relationship between surface runoff and rainfall, but some peaks were not well simulated. The figure 2 illustrates the results at the catchment outlet and at one sub-basin. Monthly NS was 0.5 for the calibration period on sub-basins, which was considered satisfactory. Similarly, mean simulated and observed flows were in agreement, with a slight under-prediction by the model on average. The simulated monthly stream flow at one sub-basin and at the catchment outlet during the calibration period (2004-2012) closely matched with the observed stream flow (Figure 2). The NS, R^2, and PBIAS values for monthly predictions of stream flow over the calibration period at the catchment outlet were 0.57, 0.54, and -23.3%, respectively, demonstrating an acceptable agreement between simulations and observations, with regards to the uncertainties on hydrograph data.



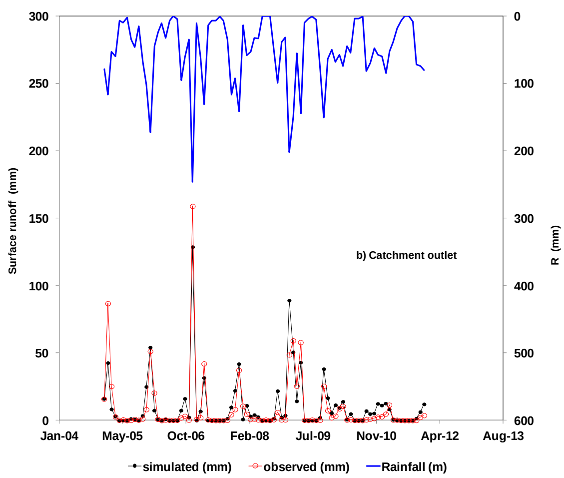


Figure 2. Observed and simulated monthly streamflow after calibration at: a) one sub-basin (12), and b) the catchment outlet.

Most runoff events happened between October and March with variable rates. The surface runoff occurring during September to November had the highest uncertainty. At this stage, it is ascribed to the pedotransfer functions used for parameterizing soil hydraulic properties. These functions were developed at the point scale, and they might tend to underestimate soil hydraulic properties (SOL_AWC and SOL_K) since they did not reflect spatial variability induced by preferential flow paths that affect the behaviour at larger scales. Also, open cracks are widespread across Kamech in autumn and they are likely to induce high variations in soil hydraulic properties that drive runoff at the beginning of the hydrological year. This increase in soil hydraulic conductivity and available soil water content during the calibration process is highly connected with the presence of macropores (cracks) and preferential paths within the soil profile within the Kamech catchment. In addition, the underestimation of runoff flows observed in all the sub-basins and at the catchment outlet, might be primarily explained by the occurring of rainstorm events with a short duration and high rainfall intensity. Therefore, using daily precipitation does not enable to predict accurately these runoff events.

The temporal dynamic of potential evapotranspiration (calculated using Penman-Monteith method) was well captured. However, simulated values were far too low as compared to observed data, and ET under-estimation during summer reached up to 40%. The prediction uncertainty was larger in summer than in winter, which makes prediction unreliable for these months. At the annual timescale, the initial assessment of SWAT simulations for the Kamech catchment showed satisfying results for the hydrological budget. The preliminary results of simulations indicated that the runoff amounts were low (less than 20% of the annual rainfall amount) and that actual evapotranspiration (ETa) was relatively high (more than 40% the annual rainfall amount). The model structure was able to capture the temporal trend of hydrological behavior of some HRU, as well as of annual discharge. The main annual ETa component was related to the cropping growth period. The fraction of ETa was low during wet year, while it corresponded to almost 60% of total rainfall during a dry year.

Conclusions

SWAT was implemented in the Kamech catchment in Tunisia in order to evaluate the model capability to predict the hydrologic response within a small marly agricultural catchment under semiarid climate. Although the SWAT model is still in calibration phase, first analysis results are reported here. Our study showed the significant benefit of long-term measurement dataset for constraining model simulations. Indeed, we noted significant simulation improvements after calibration based on hydrological data time series, and simulations give reasonable estimations of the monthly stream flows at the outlet. However, for a complete complexity overview and an appropriate simulation of the considered processes, a multi-calibration procedure is necessary, where the latter must account for the stream flow, but also for cracking characteristics of soils, for actual evapotranspiration, for sediment concentrations and for crop yield. Research is currently underway to address these issues and for better model calibration at different time and space scales. Future works are also needed to analyze the influence of land use choices on crop water requirements, on soil water availability, and on sediment production at the catchment outlet. The availability of a reliable set of sub-daily data is likely to increase the capability of SWAT to serve a useful tool for optimizing ecosystem services such as water conservation, agricultural production, and soil erosion mitigation.

Acknowledgements

Financial support for this study was provided by the ANR TRANSMED ALMIRA project (grant agreement no. ANR-12-TMED-0003-01). The OMERE observatory (http://www.obs-omere.org), funded by the French institutes INRA and IRD and coordinated by INRGREF Tunis, INAT Tunis, and UMR LISAH Montpellier, is acknowledged for providing the data used in this study. The authors would like to acknowledge all the staff of OMERE who achieves a very demanding work for running, maintaining and operating all equipment and field data collection.

Abstract

After using nitrogen fertilizers to soil a part of the nitrogen in the fertilizer losses with volatilization are important in agriculture. Sometimes the loss of level with volatilization has reach to 50 %. The purpose of this investigation is to determine nitrogen losses as NH_3 volatilization, effect of some factors on the losses and being limited some materials in soil samples. In the experiment, urea from the nitrogen fertilizers were applied to soil samples and these samples were dried in the closed system under constant air flow. In addition to this experiment, the ammonia losses from nitrogenous fertilizer (urea) were studied to limit with mixing some different organic materials (bark talk of pine (BToP), peat, straw, wood shaving) to this samples. The soil samples were selected from 3 areas in the Pazarcık-Kahramanmaraş, Turkey. To limitation of NH_3 losing by BToP was added to the soil at the level of 0, 5, 10, and 20%. As the nitrogen source urea and ammoniawas added to the soil at the level of 0, 250, and 500 kg N/ha. In a closed system it was held air compressed to the soil+BToP+nitrogen solution mixings at 8 hours and 1 bar/minute at atmospheric pressure. Then NH_3 losing was held in the boric acid solution in the closed and air controlled system. The absorbed NH_3 in this system was determined with titrimetric method. According to the results, 50% of minimum limitation was obtained from BToP treatments and 65,57% as maximum limitations of ammonia losses at 300 ppm with wood shaving application. Absorption by peat in this experiment recovered at 11.6% and 20.6% of the volatilized ammonia.

Key words: *Nitrogen fertilizers, Volatilization, Organic material, Soil.*

Introduction

Nitrogen fertilizers present high solubility and are effective for agricultural practices. Some of nitrogen in the nitrogenous fertilizers using to soil has been lost by volatilization and this losing has been reached to high levels (Allison, 1955). Urea is characterized as the granulated solid nitrogenous fertilizer of highest N concentration (45 %). Among the sources of N in the world, it has lower market value and is the most used. Therefore, there is some concern regarding on its use due to the fact that its application on surface promotes N losses by volatilization in the form of N-NH_3. Among the advantages of urea, besides the high N concentration and low cost, one may mention the low expenses with transportation, storage and application, high solubility, low corrosive properties as well as easiness to mix with other sources (Cantarella & Raij, 1986; Melgar et al., 1999; Pereira at al., 2009).

The NH_3 losing from being the urea was obtained relating with pH and other factors. In the high levels of pH urea has changed to ammonium by hydrolyzing and then been ammonium carbonate importantly (Fenn and Kissel, 1975; Sağlam, 1976b; Du Plessis and Kroontje, 1964; Terman and Hunt, 1964). Nitrogen may be from the soil in the form of gases. A considerable loss of NH_3 may occur when NH_4^+ -salts are applied to calcareous soils. Such high pH soils should not to treated with NH_4^+ -salts. The same is also true for the use of urea as a top dressing (Cooke, 1972). When the nitrogen fertilizer was given to the soil NH_3 losing by volatilization has changed according to the fertilizer types and soil conditions. In addition to the matter it has appeared to increasing nitrogen level giving to the soil has been increased to the NH_3 losing. Separately, the soil texture has affected the NH_3 losing (Fenn and Kissel, 1975; Sağlam, 1976a). According to the studies of Sağlam et al. (1997), loss of from urea was obtained between 9.66 and 14.44% at the level of 100 and 150 kg N/da respectively.

According to the Lehr and van Wesemael (1961), urea application leads to the loss of NH_3 by volatilization as it is very rapidly converted to NH_4^+ particularly in alkaline soils. This losing of nitrogen by volatilization is changed according to the $CaCO_3$ content of soil, pH, type of fertilizer, type using of fertilizer, level of fertilizer etc. (Sağlam, 1976a). The calcium carbonate content of soil is important affected factor to losing in the nitrogen fertilizer as ammonia. In general, with increasing to the $CaCO_3$ content of the soil is increase losing of nitrogen as ammonia. According to the researches, it has been obtained correlation between the $CaCO_3$ content of the soil and losing of nitrogen as ammonia (Fenn and Kissel, 1975). It has been known that pH level effects to the NH_3 losing. On the other hand, with increasing to the reaction of soil is increased losing of nitrogen as ammonia (Sağlam, 1976a).

Bark of trees mainly used as power fuel as replacement for natural fuel (oil and gas). Recently, the bark, complex chemical mixture of many organic compounds bearing a large amount of hydroxyl, carboxyl, methoxyl functional groups etc. has also been used as an environmental pollution control product, e.g., erosion controller and slope stabilizer, odor scavenger in sulfate pulp mills and oil pollutant, mulch, and soil conditioner, replacement with phenol in resolve adhesives, etc. (Fengel and Wegener, 1984; Alma and Kelley, 2002).

In this study, for the determination of ammonia losses it was used different organic materials (bark talk of pine: BToP, peat, straw, wood shaving) in laboratory experiment and the losses from nitrogenous fertilizer- urea were determined with these organic materials to limit with mixing to this soil samples.

Materials and Methods

1. The experiment with using of BToP

To limitation of NH_3 losing Bark Talk of Pine (*Pinus brutia* L.) (BToP) was added to the soil at the level of 0, 5, 10, and 20%. As the nitrogen source urea fertilizer (N: 46 %) was added to the soil at the level of 0, 250, and 500 kg N/ha. In a closed system it was held air compressed to the soil+BToP+nitrogen solution mixings at 8 hours and 1 bar/minute at atmospheric pressure. Then NH_3 losing was held in the boric acid solution in the closed and air controlled system. Experimental set-up for absorption of NH_3 comprised two 500-mL conical flasks, in the first conical flask was packed soil+ure samples, and the second conical flask was filled with 50-mL boric acid solution. There was also an air source by compressor in this system for air transport and increasing volatilization of NH_3. The absorbed NH_3 in this system was determined with using 0.002 N HCl as titrimetric method. Physical and chemical analysis of 3 soils and BToP used in the study was given into the Table 1 and Table 2.

Table 1. Physical and chemical analysis of soils used.

Soil	pH	EC	$CaCO_3$	O.M.	Na^+	K^+	Ca^{++}	Mg^{++}	P	Zn	Fe	Texture			
		%			meq.100 g^{-1}				mg.kg^{-1}			Sand	Loam	Clay	Group
1	8,15	0,125	26,32	2,28	0,17	0,71	29,27	12,55	26,02	0,25	5,03	23,96	26,81	49,24	C
2	8,02	0,100	22,07	2,14	0,11	0,79	31,29	5,69	11,56	0,21	7,77	21,60	35,50	46,90	C
3	8,01	0,186	4,84	1,48	0,21	0,77	35,12	12,36	17,20	0,26	5,40	17,65	19,19	63,16	C

The soil samples were selected from 3 areas in the Pazarcık-Kahramanmaraş, Turkey (Elinç, 2000; Güvercin 2001) in this study and were used to determine NH_3 losing by volatilization.

Table 2. Physical and chemical contents (%) of BToP (Fengel and Wegener, 1984).

Bark Talk of Pine	Lignin	Ash	Carbohydrates		Extractives	Constitute of Pine
			Cellulose	Hemicellulose		
BToP	23,7	3,5	35,2	19,0	18,6	10-20

2. The experiment with using of straw and wood shaving

To limitation of NH_3 losing straw and wood shaving were added to the soil at 2 g level of organic materials. The nitrogen source urea (N: 46 %) fertilizer as 100, 200, and 300 ppm doses were mixed to 10 g soil. In a closed system it was held air compressed to the soil+straw or wood shaving+nitrogen solution mixings at 8 hours and 1 bar/minute at atmospheric pressure. Then NH_3 losing was held in the boric acid solution in the closed and controlled air system. For absorption of NH_3 experimental set-up designed with two 500-mL conical flasks, in the first conical flask was packed soil+organic material+nitrogenous solution fertilizer samples, and the second conical flask was filled with 50-mL boric acid solution to absorb NH_3 losses. There was also an air source by compressor in this system as income and outcome for increasing volatilization of NH_3. The absorbed NH_3 in this system was determined with using 0.002 N HCl as titrimetric method. The texture analysis of soils was determined as clay.

3. The experiment with using of peat

An apparatus to measure ammonia losses in soil+peat+nitrogenous fertilizer (urea) samples by volatilization was developed under laboratory-controlled conditions. The apparatus has a sample and an absorption chamber system. The absorption chamber systems were used a controlled capture system which comprised a 500-mL flask container with a lid with an air inlet (8 hours and 1 bar/minute) and outlet on top side. The soil+peat+urea sample was set as 25 g soil+0.4 g peat+urea fertilizer (100 and 200 kg N/ha) and without peat as control to each application. The pure water enriched with these nitrogenous fertilizers and applied to the soil in the controlled system. The pump outlet was connected to the absorption system, forcing the head-space gases to bubble-up through a 2% boric acid solution, so absorbing the volatilized ammonia was determined with using 0.005 N H_2SO_4.

Results and Discussions

1. The losses and of NH_3 (%) with using BToP

The environmental pollution and theirs effecting factors have been studies in recent years. These studies have aimed regulating and reducing this pollution. It follows that ammonia pollution must be managed without excessive contribution to soil, water, or air pollution and be compatible with efficient using nitrogen fertilizers. Comparative ammonia (NH_3) losses were assessed using BToP as a static sorbent in this laboratory study. The loss of NH_3 (%) from urea was given into the Table 3.

Table 3. The losses and of NH_3 (%) from urea and limiting with using BToP .

Soil	Urea treatment, kg N/ha	Losses of NH_3, %				Limitation of losses of $NH_3$with BToP treatment, %		
		Control	BToP treatment, %					
		0	5	10	20	5	10	20
1	250	3,6	3,3	3,2	3,2	8,3	11,1	11,1
	500	6,9	5,6	5,2	5,1	18,8	24,6	26,1
2	250	3,6	3,2	2,9	2,9	11,1	19,4	19,4
	500	4,4	3,9	3,1	3,0	11,4	29,5	31,8
3	250	4,2	4,2	3,5	3,5	0	16,7	16,7
	500	7,2	5,9	5,5	5,5	18,1	23,6	25,0
Min.	250	3,6	3,2	2,9	2,9	0	11,1	11,1
	500	4,4	3,9	3,1	3,1	11,4	23,6	25,5
Max.	250	4,2	4,2	3,5	3,5	11,1	19,4	19,4
	500	7,2	5,9	5,5	5,5	18,8	29,5	31,8

For having high calcareous soils and clay content, at the 1^{st} and 2^{nd} samples maximum limitations were obtained from BToP treatments. But for having low calcareous soils, at the 3^{rd} sample 31.8% of maximum limitation was obtained from BToP treatments. Bark of trees especially in this BToP mainly may be used as a limitation matter to loss of NH_3 by volatilization.

2. The losses and of NH_3 (%) with using straw and wood shaving

Comparative ammonia losses form nitrogenous fertilizers were determined and limited with using straw and wood shaving as sorbent were added to the soil and fertilizer compound. The losses of NH_3 (ppm) from urea and ammonium sulfate fertilizers were given into the Table 4.

Table 4. The losses of NH_3 (ppm) from urea fertilizers with using straw and wood shaving.

Fertilizer	N dose, ppm	The losses of NH_3, ppm	N losses, %	Limitation of N losses, %	
				Straw	Wood shaving
Urea	100	3,50	3,50	2,42 (30,86%)	2,80 (20,00%)
	200	3,50	1,75	1,33 (24,00%)	1,54 (12,00%)
	300	3,50	1,17	0,89 (23,93%)	0,99 (15,39%)

For having soil with high clay content, the losses of ammonia from urea fertilizer were limited to 20.00% as maximum limitations of ammonia losses at 100 ppm with wood shaving application. With application of urea the losses of ammonia were limited 30.86% as maximum limitations of ammonia losses at 100 ppm with straw application. Generally, the losses of ammonia were increased with increasing of urea - nitrogen content. The losses from two fertilizer types were limited with using straw and wood shaving, but cause of two types organic material level was used 2 g in the high level of fertilizer applications to limiting of ammonia losses decreased with high level of nitrogen applications.

3. The losses and of NH_3 (ppm) with using of peat

The volatilized ammonia was determined from the controlled system at the concentration of NH_3-N (Table 5). Absorption by peat in this experiment recovered at 11.6% and 20.6% of the volatilized ammonia.

Table 5. The losses of NH_3 (ppm) from urea with using peat.

Fertilizer	Nitrogen doses, kg/ha	The losses of NH_3, ppm	NH_3 losses with peat, ppm	Limitation of N losses, %
Urea	100	3,08	2,97	11.6
	200	3,36	3,00	20.6

Conclusion

Separately, in this subject it is necessary to many studies will be to limitation of volatilization. A special injection assembly is to apply it into the soil at a depth of 15 to 20 cm to avoid loss of NH_3 by volatilization. In many cases it is not opportune to apply all the nitrogen in one dressing but rather to split the total amount into two or several application. This type of nitrogen treatment is particularly common in intensive cropping systems where crop yields are high and where large amounts of nutrients are applied. Comparative ammonia (NH_3) losses were assessed using BToP, wood, straw, and peat as a static sorbent in this laboratory study. According to the results, to using BToP, straw, wood and peat as a static sorbents were determined 31.8%, 20.0%, 30.9%, and 20.6% of maximum limitation of ammonia losses at using urea fertilizer, respectively. Absorption of ammionia by different organic materials as in this experiment recovered at high levels of the volatilized ammonia.

Abstract

The population growth, migration from rural to urban areas, industrial developments increase the number and amount of waste day after day. Wastes can be reused in different areas like agricultural and industrial areas. This study was carried out to determine the usage chances of some wastes such as sawdust, coconut fiber, hazelnut husk and sewage sludge in *Primula vulgaris* cultivation between January and April, 2017. *Primula vulgaris* plants were cultivated in growing media such as 50 % coconut fiber + 50 % soil (S1), 50 % sewage sludge + 50 % soil (S2), 25 % sewage sludge + 75 % soil (S3), 25 % sawdust + 75 % soil (S4), 50 % sawdust + 50 % soil (S5), 25 % hazelnut husk + 75 % soil (S6) and 50 % hazelnut husk + 50 % soil (S7). The study was designed as a randomized plot design with 3 replications and 6 plants were used in each plot. Leaf number, leaf length, plant diameter, number of flowers, flower diameter, E.C. and pH of drainage water were measured as parameters every four weeks. These parameters were analyzed statistically by analysis of variance, Duncan's multiple comparison test and Pearson correlation with SPSS 23 software. Plant height were best value in S1 (11.22 cm), S4 (10.28 cm), S5 (9.94 cm), S6 (10.50 cm) and S7 (11.56 cm) within 4 weeks and best values in a term of number of flowers were obtained from S1 (12.28), S3 (12.89), S5 (14.61), S6 (14.11) and S7 (13.67).

Keywords: *Primula vulgaris, Wastes, Substrate, Cultivation, Ornamental plants.*

** This study "The use of some wastes in the cultivation of *Primula vulgaris*" was produced from a master thesis titled

Introduction

In recent years with the increasing population growth, some activities performed by human beings have resulted in a noticeable effect on the environment of some of the wastes that have emerged. Taking into consideration the possibility of adaptation to the environment in case of elimination of these wastes, it is a matter which should be considered in terms of the possibility of benefiting and acquiring in the communal public order. The most important consumption component of the ornamental plant sector is the growing media. It is seen that natural soil and peat are used as a filling material most in the ornamental plant cultivation of our country, especially in outdoor ornamental plants. When sustainable agriculture and environment are considered together, the use of natural soil as a filling material for flowerpot is not appropriate. At the same time, the soil cannot provide sufficient plant growth performance since it cannot provide the desired characteristics for the growing media of ornamental plant. On the other hand, although natural peat beds are renewable sources, they are not considered as an eco-friendly method and they even get reactions due to reasons such as the formation of the limited beds taking a long time, destruction of environmental integrity

with excavations and deterioration of the carbon dioxide cycle (Özdemir and Dede, 2014). The soil is considered to be a three-phase system consisting of solid, liquid and gaseous substances. For a good plant growth, a certain balance is required among these three phases (Demirbaş, 2010). For this reason, it is possible to establish a balance between the components of soil by adding supplemental material to the growing media. In an ideal growing media, sufficient ventilation should be provided for the root system of the plant, it should have sufficient water holding capacity, it should be able to protect its structure for a long time and be completely free from weed seeds, diseases and harms. It should not contain any substances that may poison the plants, it should provide support and stability to the plants. It should be easy to provide and cost-effective (Megep, 2008). *Primula vulgaris Primulaceae* family *Primula* forms the genus from. The major species that are important are *P. vulgaris and P.veris*. This plant, whose origin is estimated to be Turkey or Paşaeli, nowadays grows in a wide area from Western Europe to East Turkestan and is cultivated as an ornamental plant. It grows on the foothills of Turkey's Eastern Anatolia and Northeast Anatolia Region and on grass. It is cultivated in a peat or leaf decay with lightly structured soil mixtures in terms of organic substance (Meb, 2012). *Primula vulgaris* is one of the ornamental plants commonly used in landscape fields.
This study was carried out to determine the usage chances of some wastes on cultivation of *Primula vulgaris*.

Material and Methods

This study was carried out between January and April 2017 in a private residential garden located in the center of Çanakkale province. Seedlings with an average plant height of 7.5 cm and a hill diameter of 16.7 cm was used as plant substance. *Primula vulgaris* . Seedlings were provided from a private company that cultivates ornamental plants in Çanakkale. After opening the drainage holes of 40x50x25 cm sized styrofoam flowerpots, 50 % coco peat + 50 % soil (S1), 50 % sewage sludge + 50 % soil (S2), 25 % sewage sludge + 75 % soil (S3), 25 % sawdust + 75 % soil (S4), 50 % sawdust + 50 % soil (S5), 25 % hazelnut husk + 75 % soil (S6) and 50 % hazelnut husk + 50 % soil (S7) mixes were placed in the flowerpots. The flowers of seedlings were plucked before planting, and on January 6th, 2017, the seedlings were sewn with a distance of 12.5 cm. The completely randomized design of the plot was set up in 3 replications according to pattern of the plot and 6 seedlings were placed in each replicate (in the flowerpot). After planting, the seedlings were irrigated until the drainage water came out, and irrigation was carried out according to climatic conditions in later periods. E.C. (MS/cm), pH, number of leaves (number), leaf length (cm), crown diameter (cm), number of flowers (number/plant) and flower diameter (cm) measurements were made every four weeks in the experiment. Variance analysis with SPSS 23 statistical software and Duncan's multiple comparison test ($p < 0.05$) were applied to the obtained data.

Results and Discussion

At the end of the 8th week of cultivation of *Primula vulgaris*, plants with 50 % sewage sludge + 50 % soil (S2) and 25 % sewage sludge + 75 % soil (S3) from growing media were lost due to high E.C. value. At the end of the 4th week, it occurred at E.C. 5.43 mS/cm in S2 media, at 3.60 mS/cm in S3 media and between at 0.53 and 0.67 mS/cm in the other S1, S4, S5, S6 and S7 medias. The pH of the growing media ranged from 7.45 to 8.31. The highest pH was detected in S2 media. 8th and 12th week data were not obtained due to plant deaths in S2 and S3 medias. Akat et all. (2015) stated that in plants of different proportions, *Limonium sinuatum* 'Compindi White', which they cultivated in the mixture of sewage sludge and soil, death did not occur in the plants where the sewage sludge was used directly but some values fell.

According to the variance analysis; it was determined that the growing media did not make any difference on the number of leaves at 4th, 8th, and 12th weeks. The number of leaves was 9.44 to 13.23 units in the 4th week, 9.89 to 11.78 units in the 8th week and 6.72 to 8.72 units at the end of the 12th week (Figure 1). Although there was no statistical difference between growing medias, the lowest values at the end of the 4th week in the multiple comparison test were obtained from the sewage sludge mixtures. The highest values occurred in S1, S4, S5, S6 and S7 medias. A decrease in the number of *Primula vulgaris* leaf was observed at the 8th and 12th weeks.

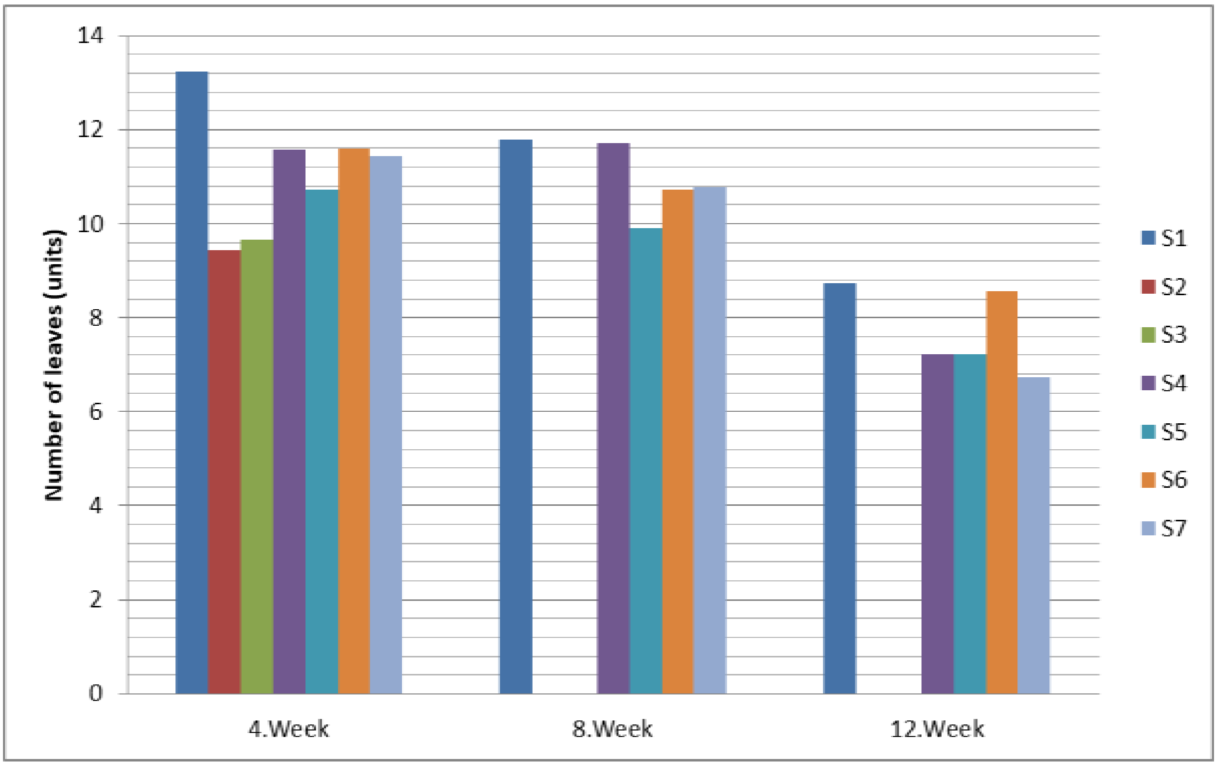

Figure 1. Effect of growing medias on the number of leaves.

The effect of growing medias on leaf length was found to be insignificant. In the first statistical group, the leaf length values of the 4th week were S7 (8.97 cm), S3 (8.69 cm), S6 (8.30 cm) and S1 (7.97 cm) medias according to the multiple comparison test (Figure 2). Leaf length occurred between 8.25-9.97 cm at 8th week and 7.25-10.36 cm at 12th week. Dede et all. (2012) suggests a mixture of 50 % hazelnut husk + 50 % sewage sludge in palm cultivation. Similar results were also obtained in this study.

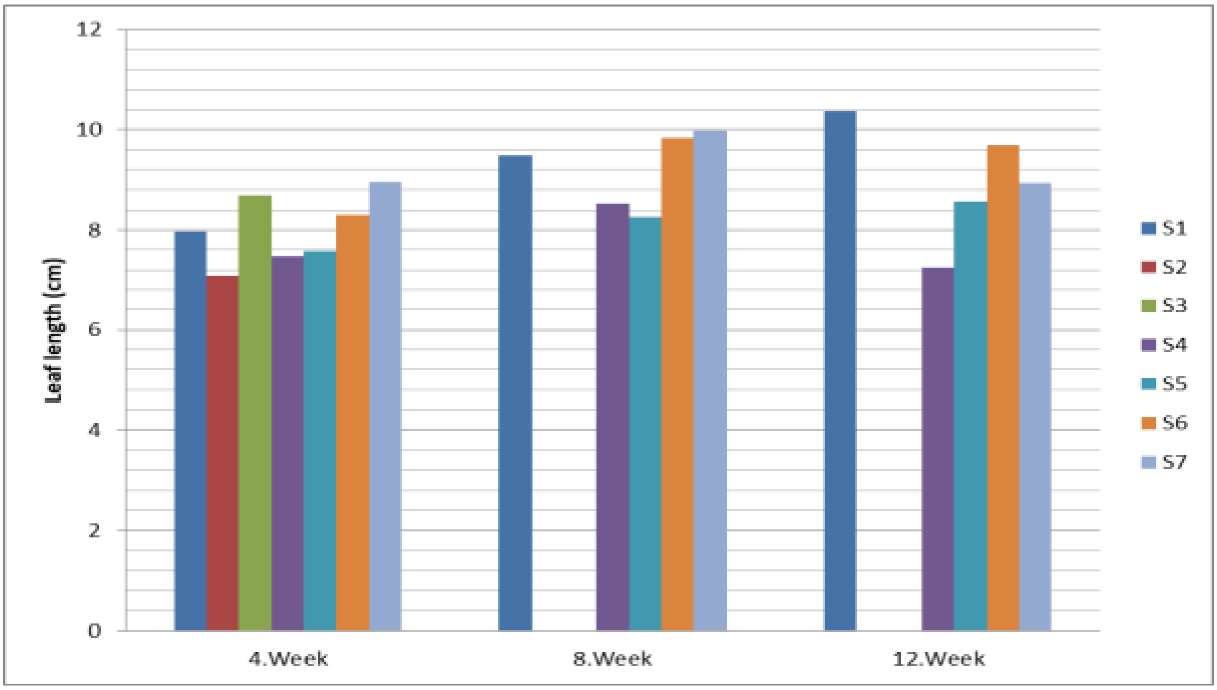

Figure 2. The effect of growing medias on leaf length.

According to the variance analysis, the effect of growing media on crown diameter was found to be insignificant at 4th and 12th week and it was found to be significant with 95% confidence at 8th week. The lowest crown diameter of the 4th week was 15.64 cm and the highest crown diameter was 17.42 cm (Figure 3).

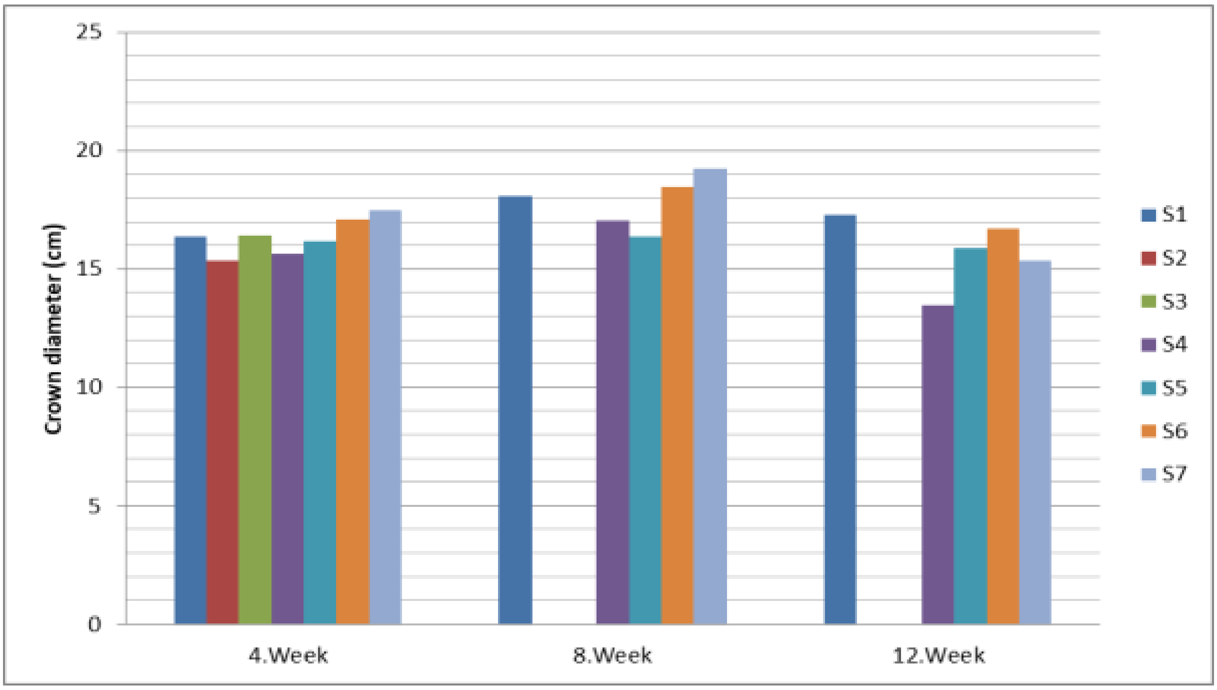

Figure 3. The effect of growing medias on crown diameter.

Three statistical groups were formed at the 8th week in terms of crown diameter. S7, S6 and S1 medias were in the first group, S6, S4 and S1 medias were in the second group.

In the study, the effect of growing medias on the number of flowers was found to be statistically significant at the 4th week ($p < 0.05$) and 12th week ($p < 0.01$), and it was found to be insignificant at the 8th week. The highest number of flowers in the 4th week was obtained from S5, S6, S7, S3 and S1 medias (Figure 4).

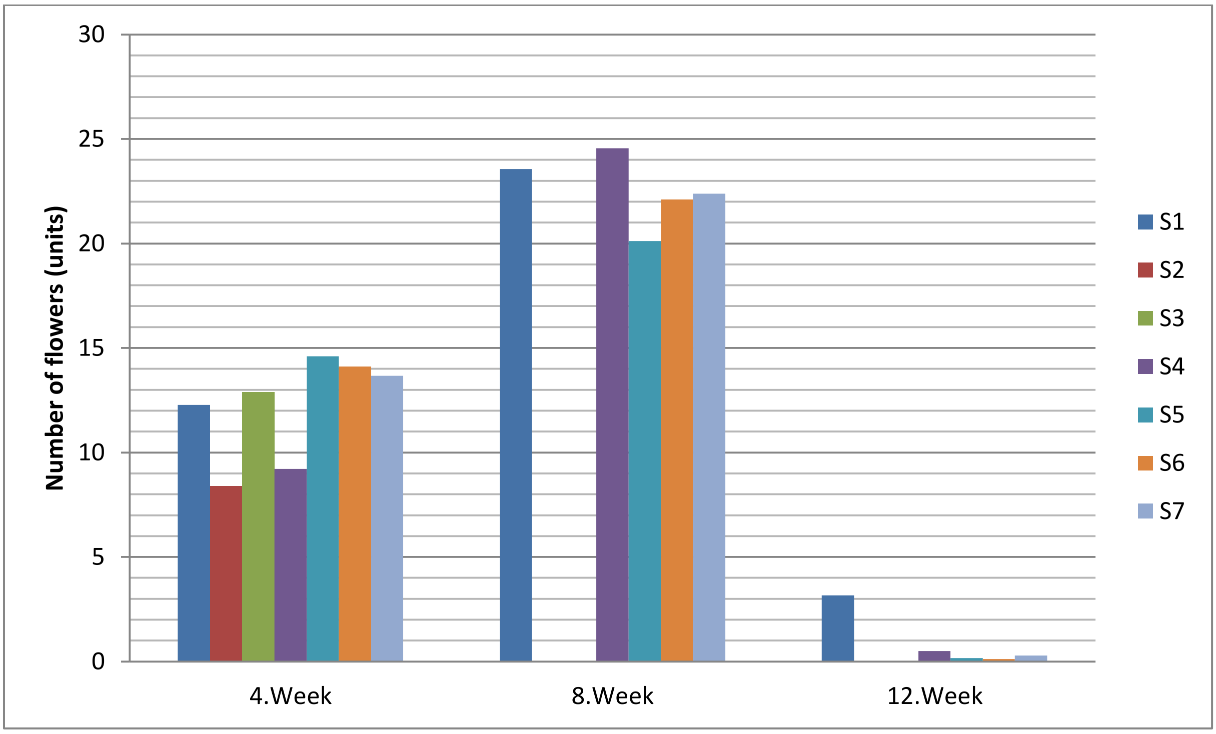

Figure 4. The effect of growing medias on the number of flowers.

The number of flowers in 8th week ranged from 19.94 to 24.56. In the 12th week, a decrease in the number of flowers was observed and the highest value occurred in S1 media. Demirkan et all. (2014); *Clarkia amoena* Ünal et all. (2011); *Freesia* species stated that the sewage sludge, which is mixed in increasing proportions to the soil in, increases the number of flowers. No effect of growing medias on flower diameter was detected. The diameter of the flower was 4.44 to 5.25 cm at the 4th week and 5.22 to 5.44 cm at the 8th week. The highest flower diameter was found in the S1 media.

Conclusions

After cultivation, the results showed that it is possible to grow the *Primula vulgaris* in all the medias except the wastewater sewage sludge. The amount of salt in the media needs to be reduced in order to be able to cultivate in the wastewater sewage sludge media. The use of all the growing medias added to the soil after the composting process has been carried out effectively will be suitable for sustainable cultivation. Carrying out studies on the use of wastes repeatedly in the cultivation of ornamental plants will ensure the widespread use of waste.

Acknowledgment

This study was produced from the master thesis titled "The use of some wastes in the cultivation of *Primula vulgaris*" by Çanakkale Onsekiz Mart University, Graduate School of Natural and Applied Sciences, Landscape Architecture Department. We would like to thank Çanakkale Onsekiz Mart University, Graduate School of Natural and Applied Sciences, Landscape Architecture Department for their contributions.

Abstract

Çukurova which is characterized by the Mediterranean ecosystem is the most important plain in Turkey. About 10% of the agricultural proceeds of Turkey has been produced in the region and 5% from Seyhan and Ceyhan River Basins. This study was carried out in the Lower Seyhan and Ceyhan River Basins located in the Çukurova in southern of the Turkey.
In this paper, the cumulative impact of existing irrigation projects in Seyhan and Ceyhan Basin was evaluated by considering technical, economic, social and training problems. Irrigation efficiencies were computed according to the amount of water diverted into the canals and crop evapotranspiration. Physical state of the irrigation infrastructure was examined. In order to determine judicial attitudes and behaviours of farmers related to irrigation, a survey was conducted with 253 farmers.
The findings obtained and survey results showed that there were many problems related to irrigation efficiency, irrigation management, irrigation infrastructure, training and extension issues. Performance of irrigation practices, especially in the efficiency of water application is still too low, i.e. 41-44% in the catchment level. This is due to inadequate irrigation infrastructure and farmers lacking the management skills to manage their irrigation systems properly. As a result, the immediate improvement of the irrigation infrastructure are needed besides improvement the farmers' irrigation management skills.

Keywords: *irrigation management, irrigation infrastructure, irrigation efficiency, Lower Seyhan Plains, Lower Ceyhan Plains*

Introduction

Soil and water resources are the first among the most important natural wealth of the community. Society of the social and economic aspects of development, said the development of these resources and rational use is of paramount importance. The development and rational use of these resources are great importance.
In 2025, the world population is predicted to increase to 8 billion (UN, 2013) Therefore, food sufficiency and security will be most important problems of the world in future. Feeding the growing population, meeting the raw material needs of the agricultural industry, increasing the share of the national product of the agricultural sector depends on increased production in agricultural areas. Irrigation is one of the most influential factor in increasing agricultural production obtained from unit area. The overall objective of irrigation investments, intended for soil and water resources development, is to increase to the highest level of welfare of the population working in agriculture along with increasing agricultural production. Since agriculture continues to be the main water consumer, improved agricultural water use in irrigated agriculture will have a direct impact on local and regional water demands. Improved agricultural water use results in higher crop yields. In order to achieve this improvement,

some technical advances in two key areas are anticipated: (i) irrigation network water management and (ii) on-farm irrigation management.
Irrigation infrastructure is one of the key factor for governments to increase productivity and economic growth and meet its policy objectives. More specifically, irrigation is crucial for the part it plays in responding to the challenges of climate change, agricultural drought, desertification, food security, sustainability, enhancing economic development, reducing migration and enhancing social inclusion (Barutçu et al., 2013).
As a result, the purpose of this study is to evaluate the cumulative impact of existing irrigation projects in Seyhan and Ceyhan River Basin by considering technical, economic, social and training problems, and to identify local farmers' judicial attitudes and behaviours on irrigation and irrigated agriculture.

Material and Methods

In this study, agricultural irrigation and related problems in Lower Seyhan and Lower Ceyhan Plains were determined and evaluated by the participation of relevant stakeholders and field studies. Net irrigation area of the plains is 261636 hectares (Figure 1). The main material of the study is based on measurement, observation, extended review of secondary data and the original data collected by surveys from the agricultural enterprise owners making production in the Lower Seyhan and Ceyhan plains. Irrigation efficiency was computed according to the amount of water diverted into the canals, crop pattern, crop evapotranspiration and net irrigation area. In order to determine judicial attitudes and behaviours of farmers related to irrigation, a survey was conducted face to face with 253 farmers in 75 villages. Surveyed villages and towns were randomly selected in Seyhan, Yüreğir, İmamoğlu, Ceyhan, Karataş and Yumurtalık districts where production is intensively performed. Besides the information on the participants, different topics on irrigated agriculture, irrigation infrastructure and irrigation organisation were examined.

Figure 1. Lower Seyhan (a) and Lower Ceyhan Plain (b) irrigation scheme

Results and Discussion

Agricultural irrigation and related problems in Lower Seyhan and Lower Ceyhan Plain have been determined and evaluated by the participation of related stakeholders and field studies considering current situation.

In the study area, 96.8% of the irrigated land was designed according to the open canal system. The remaining 3.2% is irrigated by pumped irrigation. When it is evaluated on the basis of conveyance line, pipeline system is used in 9.8% of water transmission lines while open canal system is used in 90.2%. The main irrigation canals are trapezoidal and covered with concrete, and the majority of secondary canals are in oval type.

Planning and designing the irrigation infrastructure according to the open canal system bring with many problems related to agricultural irrigation. More than 50% of the problems identified related to irrigation in the region have been associated directly or indirectly with open irrigation canal transmission lines by relevant stakeholders in face-to-face meetings. Although open canals have high water carrying capacity and smooth easier to use depending topography, water transmission losses in open canals are quite high. These transmission losses include evaporations from canal water surface, leaks at canal connection points, losses resulting from breakage of canals. Inadequate maintenance and repair in canals increase the leakage losses. Some data obtained and calculated for LSP irrigation and LCP irrigation were given below.

Table 1. Irrigation performance values of LSP nd LCP irrigation projects (average of 5 years between 2012-2016)

Land	Irrigation efficiency (%)	Irrigation ratio (%)	Irrigation area (ha)	Irrigated area* (ha)	Crop water requirement (hm^3)	Water consumption (m^3/ha)	Water delivered (hm^3)
LSP	41.1	88	153143	145026	770,4	13272	1876
LCP	44.2	83	107394	96970	463,2	10899	1542

**Incuding aftercrop and non-network irrigation*

Water use efficiency (WUE) in the region was quite low ranging 28.1 to 58.1 for the last 5 years. When other losses and leaks in the transmission and distribution were added, the total irrigation efficiency in the Lower Seyhan Plain (LSP) and Lower Ceyhan Plain (LCP) was determined to be 41.1% and 44.2% respectively in average (Table 1). The increase in irrigation efficiency in recent years in LCP is due to reducing water given to the network because of decrease in water resources and drought. The most important reason for lowering irrigation efficiency is the fact that the water transmission networks are consisting of open canals. Another important reason is that the efficiency of on-farm irrigation systems is too low. Similar to our result Özekici et al. (2007) revealed that canal tail losses were determined 36,6% and 11,5% in two different WUAs. Additionally, total irrigation efficiency is determined as %48 and %53 in LSP (Tekinel et al, 1988). One can understand from the results; it has not been any progress in the irrigation efficiencies for last 30 years.

Irrigation rate in the irrigated areas was 88% in LSP and 83% in LCP for an average of 85% for 2012-2016. The amount of unirrigated area in irrigated farmlands is approximately 30250 ha. As a result of surveys conducted with farmers, the reasons for non-irrigating in irrigated areas were given in Figure 2.

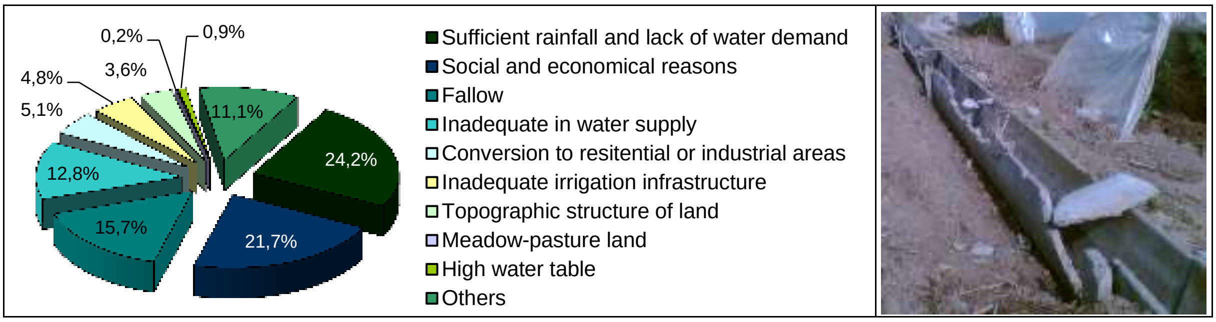

Figure 2. The ratio of unirrigated area and reasons in the area having irrigation infrastructure

One can understand from the figure above, the most important reason (23%) for giving up irrigation is that the producers find the precipitation to be sufficient and they are not in demand of water for irrigation depending on the crop pattern. Especially wheat, barley and so on. Producers have not preferred to irrigate the crops particularly wheat, barley and other crops in the cereal group, depending on the rainfall. The other important reason for not irrigating was social and economic reasons (22%). Especially in the areas where water distribution are made with pumping, the high irrigation water charges economically challenged the producers. Ultimately, producers could prefer to cultivate crops that need less water. The use of variable speed pumps and high-efficient (energy efficient) electric motors in such pumped irrigation areas can reduce pumping energy costs by 10 to 40% depending on flow demand conditions (Barutçu, 2005, Barutçu et al. 2007). Therefore, it is considered important that the technological transformation of such pumping stations as soon as possible in terms of energy efficiency and profitability of production.

Another important reason was the inadequacy of water resources (13%) due to poor irrigation infrastructure and organization. Failure to supply irrigation water at the amount and time requested by the farmer could eventually lead farmer to give up irrigation.

The fact that irrigation infrastructures in the region are old is one of the factors that increase the need for maintenance and repair. According to the data of 2016, the maintenance and repair costs of irrigation network were approximately €6 357 293. In the calculations, maintenance and repair costs per unit area were determined as 24,3 €/ ha. Considering that these facilities have complete their economic lives, the costs mentioned above will continue to increase much more each year. On the other hand, existing underground drainage systems also cannot function due to filling their economic life and does not meet the needs hence it need to be renewed. For this reasons, in the region, it is necessary to project the new irrigation infrastructures as collective pressurized irrigation systems, and to replace the structures that have completed their economic life must be transformed into pressure irrigation system over time.

In the existing irrigation facilities in the region, the water supplied to the land cannot be measured because the existing irrigation infrastructure is not appropriate for measuring water at the field level. Only the water given to the canal can be measured. Inadequacy of farmers' knowledge and skills on irrigation, lack of practice to apply balanced and measured water to crops, and lack of irrigation system tools and equipment affect production. On the other hand, the water used by the farmer is charged on the basis of area and cultivated crop (Barutçu et. al, 2013, Özekici et.al., 2007). Because water fees are not determined on the volume basis, farmers tend to use more water than they need. Beside this, the wrong mentality like "more water, more yield" in the farmers leads them to extreme irrigation. In terms of effective use of irrigation water, it is absolutely necessary that water supplied to the land should be priced according to basis of volume by measuring it. Therefore, the development of the existing irrigation infrastructure is important for conservative water use and the future of the agriculture sector.

The small size of the irrigation area increases the maintenance, repair and investment costs. Optimum area size for a water user association in Turkey is recommended as 7,000 ha. There are total of 34 irrigation associations within the region. The area of only 9 of these is more than the optimum area size. The remaining WUA's have the area below the optimum limit. The average area operated by WUA's is 3209 ha. When unit costs WUA's per hectare were analysed, it was seen that the costs of 12 of the 18 WUA's in LSP and 6 of the 9 WUA's in LCP were higher than the average cost. It was observed that costs of small irrigation associations were high due to the fixed operating costs. The fact that the operating area of the WUE's is very small, increases the maintenance, repair and investment costs in other words the irrigation water prices. WUA's that have small operating areas are needed to reorganise by combining to reach the optimum area size

Although there were water prices differences among the irrigation associations, it was found that irrigation water prices in the pumped irrigation region were minimum 3 times higher than water prices in gravity irrigation areas in 2016. The high irrigation water prices in these areas force producers to switch from irrigated agriculture to rainfed agriculture. This caused some irrigation facilities to not being operated particularly in pumped irrigation areas. For this reason, energy costs should be reduced in irrigation sector.

Increasing the value of agricultural production depends on obtaining more quantities of production and better quality products in agricultural areas. The realization of this situation is possible with the training of the farmer, in other words by agricultural extension. Extension services in the region are carried out by the staff of the Provincial Directorate of the Ministry of Food, Agriculture and Livestock but are not carried out effectively due to the insufficient number of trained personnel. Inefficient and ineffective extension services has adverse effects on water resources, agricultural environment and production quality. Thus, there is a tendency to use excessive water. Hence water losses such as surface runoff, deep seepage could be increased. As a result, irrigation efficiency falls. As a consequence, many problems such as poor preparation of land for irrigation, drainage, high groundwater, salinity may emerging.

In the survey conducted within the study, 83% of respondents stated that they had never been trained on irrigation. Therefore, it could be said that extension services in the region was very lack in irrigation. The Ministry of Food, Agriculture and Livestock, particularly the irrigation cooperatives and associations, have a major duty for extension. These institutions should work together to eliminate the training requirement that the farmer needs for irrigation.

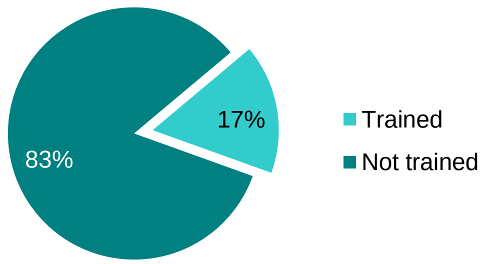

Figure 3. Share of farmers having irrigation training

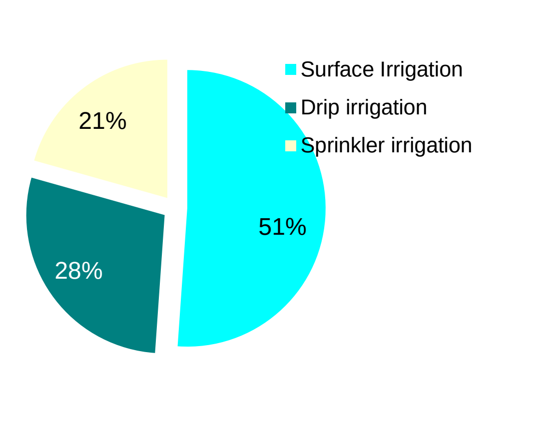
According to survey results, when the on-farm irrigation methods were evaluated, it was seen that the using rate of surface irrigation methods in the region was 51% and the remaining 49% was in pressurized irrigation systems. In pressurized irrigation systems, drip irrigation methods had a bigger share with 28% (Figure 4). The respondents were also asked which irrigation method they would like to prefer for their effective use of water resources. 74% of the respondents preferred drip irrigation system. One can understand from this result that the advantages of drip irrigation systems in many respects have been recognized by farmers.

Among the reason of drip irrigation preferences; better plant nutrition, lack of labour cost, low water consumption, ease of operation and high yield were prioritized. Those who prefer surface irrigation mostly answered that low investment cost due to the existence of canal system and the absence of additional energy costs (Figure 5).



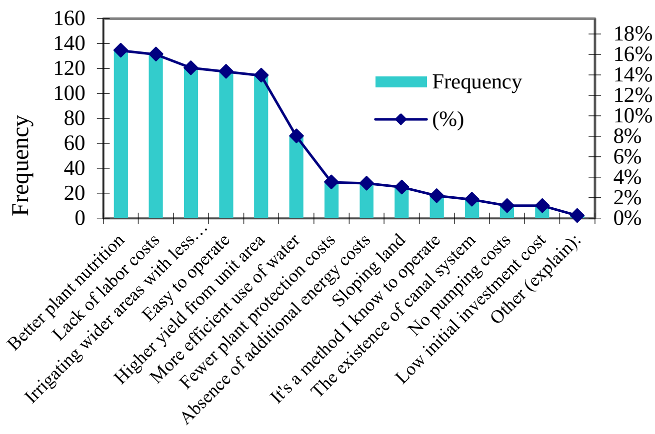


Figure 4. Rate of the irrigation methods Figure 5. Reasons for selection irrigation system

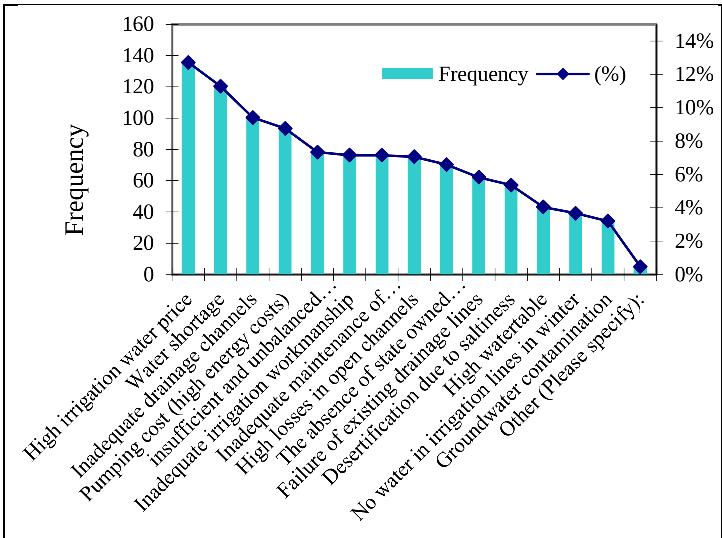
The respondents reported the most important irrigation problems they faced in their production areas as high irrigation water price, water shortage, inadequacy of drainage canals, high energy costs for pumping, inadequate and unbalanced water distribution respectively (Figure 6). The high irrigation water price are due to the high maintenance and repair costs. In addition, when determining irrigation water prices, it can be said that introducing a participative, transparent and standard approach will change the high perception of water rates.



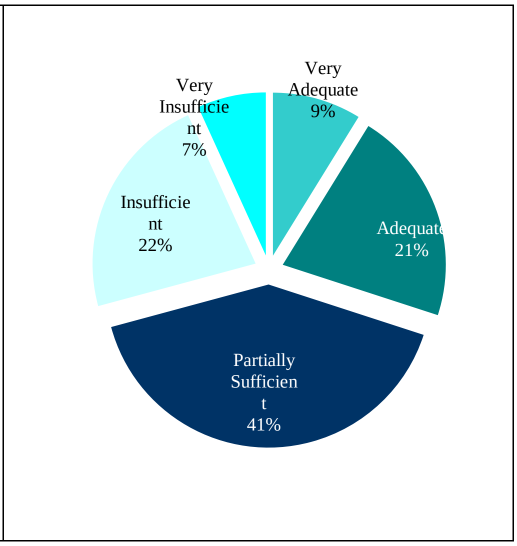


Figure 6. Irrigation problems of respondents Figure 7. Water sufficiency assessment

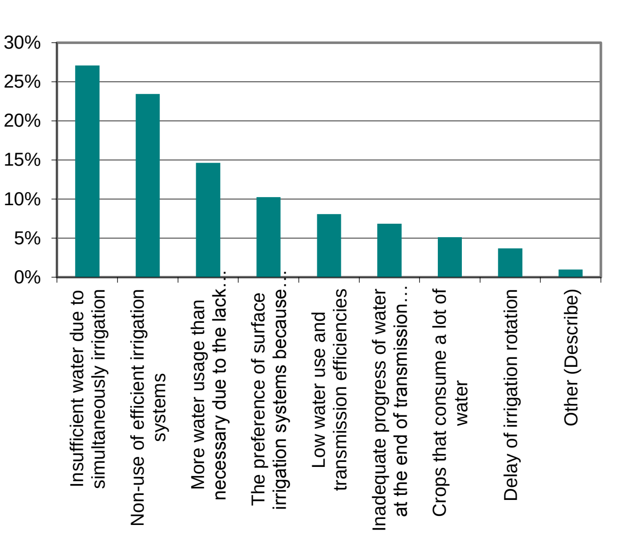
When respondents asked if irrigation water is sufficient during the whole production season, those who think that is inadequate had a share of 29% in total. The share of those who think that irrigation water is very inadequate in this group was 7%. It was noted that this group was consisted mainly of farmers who are farming at the end of irrigation lines so they could not benefit from irrigation water sufficiently. 41% of respondents who think irrigation water “partially sufficient” declared that they did not have serious water problem throughout the irrigation season although they suffered from water shortages in small levels (Figure 7). The perception of irrigation water as inadequate in the region, which has plenty of water resources shows troubles of inefficiency in the transmission and usage of irrigation water and organisational problems in distribution of irrigation water. Moreover, most farmers have no technical knowledge of the amount of water they need for irrigation.



Most of those who suffer from water shortages have declared that the water in the canals was not sufficient due to the simultaneous use of water (Figure 8). This is also the result of the fact that night-time irrigation is not very common in the region. The water level in the canals falls due to the simultaneous irrigation especially during the daytime hours and the farmers at the end of the irrigation lines cannot benefit from irrigation water at desired level. On the other hand, in evaluations on the use of open canals, the biggest problem (30.6%) was reported as the lack of maintenance and repair.

Figure 8. Reasons of water shortage according to respondents

If irrigation water is sufficient for each period, 62% of the respondents think to change their cropping patterns. It has been determined that the respondents who have this idea are more monoculture farmers. This shows that if the water is sufficient, there will be a change in the crop patterns of the region with the tendency towards the competitive products which are economically profitable (Figure 9).

According to the interviewees, the services provided by irrigation related institutions and institutions are not adequate with share of 42% in total. Only 20% of the interviewees think the services are adequate. One can find out from this result that the services provided are not well publicized to the beneficiaries (Figure 10).

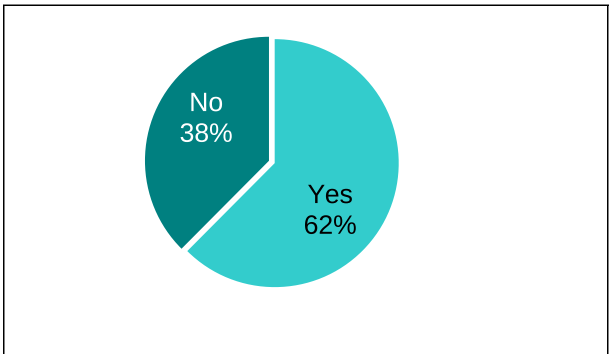


Figure 9. Tendency of changing crop pattern

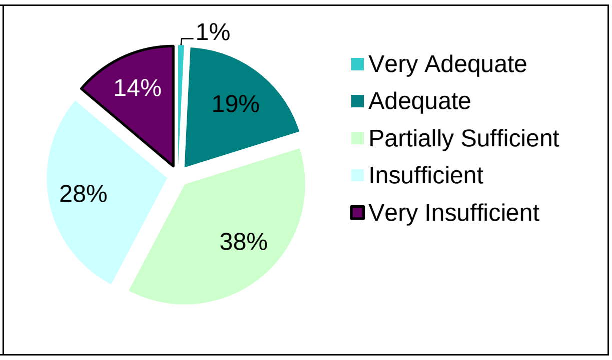

Figure 10.Sufficiency of the services provided

On the other hand, 43% of the interviewees thought consulting agricultural institution related to irrigation in solving irrigation problems. Having only about 5% of those who thought to get technical support from universities shows that the communication between the university and the producers is weak. The private sector has also a significant influence on the producers in solving irrigation problems with a share of 24%.

Conclusions

As a result of the field studies and survey results, it has been determined that there was excessive water use in both plains. Irrigating most of the areas with surface irrigation methods unconsciously causes a lot of problems, especially in poor drainage areas, and also prevents the efficient distribution of the irrigation water which is sufficient for the region.

The average irrigation efficiency in the region is around 41-44%. Although there are many reasons of low irrigation efficiency, an important problem is the type of the on farm irrigation method and the application technique of the method used. Efficiencies of surface irrigation systems is very low in the region. For example Önder et al. (2004) have found irrigation efficiency 48-60% on corn-cultivated fields using surface irrigation. However, it is known that the efficiencies of surface irrigation systems in some developed countries can rise up to 85% depending on the type of the surface irrigation method. Accordingly, it is possible to increase the water use efficiencies to the higher levels by training in the region.

As a result of the field surveys, it has been understood that farmers have had significant problems such as irrigation costs, maintenance and repair of irrigation networks, water distribution, drainage, training and extension. The research findings revealed that local producers did not have sufficient information on irrigated agriculture and that the relevant institutions were not successful at the desired level for irrigation extension and farmer training.

It is predicted that if all the projects in the Seyhan Basin are to be implemented in the future, there will be 20% water shortage in arid years (Selek et al., 2008). For this reason, design of the new investments must be projected as collective pressurized irrigation network besides replacing existing irrigation projects that have completed their economic life with pressurized irrigation system over time. Conversion of Lower Seyhan Plain Irrigation into a pressurized closed irrigation network by taking the irrigation water directly from the Seyhan Dam Lake is an option that should be taken into consideration.

Abstract

Hydraulic conductivity is an essential base for applied research in soil and water management, landscape, and environmental disciplines. Saturated hydraulic conductivity (K_s) is one of the most important soil physical properties, which is considered in planning of irrigation and drainage and predicting other soil hydrological processes. However, it has been frequently reported that measurement of K_s is laborious, time-consuming, and expensive due to its high spatial variability and this has motivated researchers to develop indirect methods such as pedotransfer functions (PTFs) for developing K_s-database in regional and national scales. In this study, we reviewed studies for K_s conducted on Anatolian soils. PTFs were reviewed regarding their type, predictors used, and their performance. The majority of studied PTFs were developed on alluvial, collivial, and alkaline soils in semi-arid and semi-humid climates. Multiple linear regression, continuous and class PTFs, and neural networks have been common PTFs, and soil texture, bulk density, organic matter content, pH, and EC have been common predictors used with these PTFs. Root mean squared error, mean absolute error, and coefficient of determination were the commonly used criteria used in verification and validation of the PTFs. Studies conducted on K_s are inadequate and research is still needed to develop an adequate database for nationwide use.

Keywords: *Hydraulic conductivity, PTF, Resourse management, Turkish soils*

Introduction

Soil saturated hydraulic conductivity (K_s) is a basic characteristic used in modeling of water flow and solute transport in soils. It can measured directly by field or laboratory methods, however, both of are time consuming, labor intensive, and expensive processes. In addition, Merdun et al. (2006) noted that the results of direct measurements may not be accurate due to spatial and temporal variability in soil physical and hydraulic properties. Therefore limited conditions led researchers to develop indirect methods using different techniques.

Mathematical models have been developed to predict saturated hydraulic conductivity from easily measureable basic parameters due to the importance of K_s in hydrologic cycle. There are many studies contain different models and techniques for predict K_s from basic soil properties; empirical (Hazen, 1892; Puckett et al., 1985; Nemes et al., 2005; Parasuraman et al., 2006; Ghanbarian-Alavijeh et al., 2010), quasi-physical (Kozeny, 1927; Carman, 1937; Ahuja et al., 1984;1989; Rawls et al., 1993; Arya et al., 1999; Timlin et al., 1999), physically-based (Katz and Thompson, 1986; Xu and Yu, 2008; Skaggs, 2011; Porter et al., 2013; Hunt et al., 2014; Ghanbarian et al., 2016), and numerical (Zhang et al., 2005; Elliot et al., 2010; Mostaghimi et al., 2013; Ghanbarian and Daigle, 2015; Dal Ferro and Morari, 2015) (Ghanbarian et al., 2016).

According to Pachepsky and Rawls (2004), many models have been developed to quantify K_s but pedotransfer functions preferred for K_s estimation is commonly done using empirical relationships linking K_s to soil basic properties such as textural fraction and organic matter content, etc. PTFs are completely empirical model which predict soil properties from easily measured or available datas. In PTFs, basic soil properties are used as input, hydraulic functions are also obtained as output of model (Bouma, 1989). However, literatures in predict of K_s using PTFs are limited and generally they restricted to assessments at small scales.

There are also many studies about soil saturated hydraulic conductivity and PTFs conducted on Anatolian soils. However, the use of PTFs for K_s in Turkey is very new and the first study was done in 2004 by Tombul et al. Published PTFs for predicting soil saturated hydraulic conductivity are very inadequate. Candemir and Gülser (2012) also noted that there are limited studies related to prediction of saturated hydraulic conductivity of fine-textured, especially alkaline soils.

The aim of this study is encourage to researchers for new researches by giving information about PTF studies conducted on Anatolian soils. We evaluated the performance of ten published PTFs between 2004 and 2016 in predicting the soil saturated hydraulic conductivity for Anatolian soils.

Material and Methods

In totaly, 887 soil samples were used in studies conducted on ten different regions of Anatolia in Turkey between 2004 and 2016. Although the studied regions represent to different climatic and soil characteristics, there is not enough PTF studies for Anatolian soils as seen from the map (Fig.1). A summary of the soil datasets used in this paper were given on Table (1).

Soil samples were taken from different dephts (0-15, 0-20, 15-30, 30-60, and 60-90 cm). Using predictive input datas consisting of soil texture (PSD), bulk density (BD), organic matter content (OM), soil pH, electrical conductivity (EC), field capacity (FC), permenant wilting point (PWP), cation exchange capacity (CEC), volumetric moisture content (VMC), soil moisture content (SMC), sodium absorption ratio (SAR), exchangeable Na percentage (ESP), spesific surface area (SSA), agregatte stability index (ASI), penetration resistance (PR), calcium carbonate ($CaCO_3$), soil color, soil depth, and soil morphological properties such as coefficient of linear extensibility (COLE), structure class (SC), structure type (ST), structure size (SS), pore size (PS), pore quantity (PQ), root size (RS), root quantity (RQ), mottles quantity (MQ), soil plasticity, and stickiness. The studied regions have alluvial, collivial, and alkaline soils and semi-arid and semi-humid climates.

Pedotransfer functions used in this study were developed using various techniques for predict the K_s from other soil parameters; multiple linear regression (Merdun et al., 2006; Öztekin et al., 2007; Candemir and Gülser, 2012; Yakupoğlu et al., 2013; Gülser and Candemir, 2014; Karahan and Erşahin, 2016), artificial neural networks, ANN (Merdun et al., 2006; Haghverdi et al., 2014), support vector machines (Haghverdi et al., 2014), Rosetta (Tombul et al., 2004; Haghverdi et al., 2010), and continuous and class PTFs (Mihalikova et al., 2015).

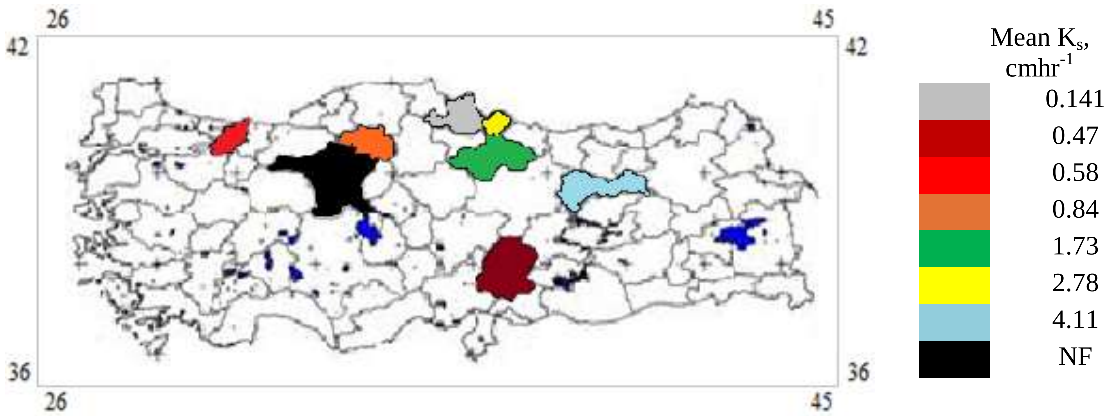

Figure 1. Soil sampling areas of assessed PTFs studies (NF: Not found)

Results and Discussion

In published PTFs, generally multiple-linear regression (MLR), Artificial neural networks (ANN), Support vector machine (SVM), Continuous and Class PTF, and Rosetta used for PTF type and determination coefficient (R^2), root mean square error (RMSE), mean absolute error (MAE), mean error (ME), mean absolute error (MAE), mean bias error (MBE), mean squared error (MSE), mean residual error (MRE), and average relative percent error (ARPE) were used for model performance.

We evaluated performance of models according to R^2 and RMSE model criterias. In these studies, MRL was used for predicting the saturated hydraulic conductivity in 5 of ten papers (Table 2). The highest values of R^2 (0.97 and 0.95) were found in Merdun et al. (2006) and Karahan and Erşahin (2016), respectively. The highest determination coefficient values for estimating K_s were found for medium and clay soil texture classes. ANN was used for predicting the saturated hydraulic conductivity in 2 of ten papers (Table 2). The values of R^2 (0.95 and 0.82) and RMSE (0.020 and 0.047) were found in Merdun et al. (2006) and Haghverdi et al. (2014), respectively. SVM was used for predicting the saturated hydraulic conductivity in 1 of ten papers. The values of R^2 (0.75) and RMSE (0.054) were found in Haghverdi et al. (2014). Rosetta was used in 2 of ten papers. The values of R^2 (NF and 0.75) and RMSE (0.051 and 1.61) were found in Tombul et al. (2014) and Haghverdi et al. (2010) respectively. Class and Continuous PTFs were used for predicting the saturated hydraulic conductivity in 1 of ten papers. The values of R^2 (0.92) and MSE (71.56) were found in Mihalikova et al. (2015) (Table 2).

In K_s modeling studies, soil parametric variables are generally preferred. However, it's well known that a slight change in soil structure has a considerable impact on K_s since K_s is strongly controlled by soil pores and their geometry and their orientations in soils (Karahan and Erşahin, 2016). Their results were highly promising, suggesting that soil morphological properties can be used besides soil parametric variables in K_s modeling studies. Pore size distribution and bulk density, which are the most common parametric variables in PTFs, have been also the most used input data in these evaluated studies. Except from other physical and chemical properties, Merdun (2006) and Karahan and Erşahin (2016) are the first and only studies which used soil morphological properties as input data of model (only PS and SS, SQ, ST, PS, PQ, RS, RQ, MQ, COLE, plasticity, and stickiness, respectively) (Table 1). The success of the models can be attributed to effect of these variables on K_s.

For paper ten, the best model performance occurred with the multiple linear regression (R^2: 0.97 and 0.95). Published PTFs based on MLR gave better prediction than SVM and Rosetta in these papers. Even though the performance of SVM is slightly worse than that of MRL and ANN. There are a number of studies which compared the performance of PTFs types. Merdun et al. (2006), Fereshte (2014) noted that MRL showed better performance than ANN.

PTFs have some limitations which effect the it's performance. Schaap and Leij (1998a) noted that PTF_s were used due to its simplicity and successful results although they have some limitations. Therefore, train (develop) and test (validate) datas should be determined correctly as well as soil sampling for the performance of pedotransfer functions (Schaap and Leij, 1998a). Moreover, the number of soil samples should be sufficient and choosing more input variables to correctly represent the field. However, estimating soil properties were restricted to 2-3 soil input properties in evaluated published papers (Tombul et al. 2004; Merdun et al. 2006; Haghverdi et al. 2010; Candemir and Gülser, 2012;Gülser and Candemir, 2014) whereas more soil properties use as input variables will improve the model result. In addition, it is mentioned that some factors such as vegetation, climate, and geograpy effect soils types and properties and the performance of PTFs studies. Because, recent studies in PTF should be focus on the development of better functions to predict soil hydraulic properties for different geographical areas or soil types and determination of the most important basic soil properties as input (Pachepsky and Rawls, 1999). Cemek et al. (2015) also noted that PTF can not perform very well in predicting soil moisture because every PTF is not suitable for all soil types.

Conclusions

In this study, we evaluated ten papers available in the literature to estimate soil saturated hydraulic conductivity (K_s) using PTFs. The published PTFs are inadequate for prediction and determination of K_s for Anatolian soils. It is not correct to evaluate the success of the PTFs with few samples. Even though the study was carried out on the 10 published papers about saturated hydraulic conductivity of Anatolian soils, this study is important with regard to effect of morphological properties on saturated hydraulic conductivity. Soil morphological properties in addition to physical and chemical properties as input data for predict to K_s can improve the model performance. Therefore, future work must be testing PTF's performance by adding soil morphological properties and these studies should be increased for obtain a nationwide K_s database on Anatolian soils. In addition, the PTFs have some problems in some conditions. Overall, applying same PTF under different conditions regions is not correct and does not give reliable results. Therefore, for saving time and labour, and practical for larger scale applications, studies of PTFs should motivate researchers to work on it further. So that estimate saturated hydraulic conductivity using PTFs can be possible with a large database that consists of various soil samples from all around the Anatolia. Because it have not been done so far.

Abstract

This study was carried out to determine the effect of different salt concentrations on seed germination performance of 85 different Tedera genotypes with 4 replicates at seed Laboratory of Agronomy Department in Ondokuz Mayis University, Samsun, Turkey. In study, five different salt concentrations (0 (Control), 25, 50, 75, 100 mM) were used. For germinations tests the seeds put inside petri dishes and process were performed at a fully controlled climatic chamber with a constant temperature (24°C) and 60% aerial relative humidity. In control test, the seeds achieved full germination level in 11 days but as salt concentration increase, germination period was also increased up to 30 days for 100 mM concentration. Increasing salt concentration affected on negatively germination ratio, seedling and root weights and seedling length. For example, while germination ratio was about 48.77% for control, it was decreased to 11.37% for 100 mM dose. Decreasing rate was 76.69%. The least decrease was observed for fresh seedling rate against to increasing NaCI doses. Decreasing rate were 42.86%, 82.49% and 81.70% for fresh seeding weight, root length and shoot length, respectively at 100 mM dose.

Key words: *Tedera, Salt Tolerance, Germination, Seed*

Introduction

In order to plants grow normally enough moisture must be found in soil. If moisture content of soil would decline in root zone plant water consuming level is decrease. Another factor that is affect water consuming level is salinity. In the soil, when underground water rise to surface and moisture evaporate to atmosphere and salt particles stay on surface in arid and semiarid regions, thus salinity is occur (Kwiatowsky, 1998; Kara, 2002). In these regions, salt particles could not transport to depth levels of soil because of less precipitation and high evaporation in arid and semiarid regions (Saruhan *et al.*, 2008). Regard the salinity, there would be important differences amongst the families, genus and species, furthermore the cultivars in the same species were effected differently from salinity. Though, plants are effected from salinity throughout the whole growing stages, the most susceptible phase is germination period (Khan *et al.*, 2010; Kusvuran *et al.*, 2007; Zamani *et al.*, 2010). Salt affect germination process negatively by increasing osmotic pressure of soil moisture, in addition Na^+ and Cl^- ions cause toxic effect on germinating seeds (Mohammadi, 2009). *Bituminaria bituminosa* is naturally grows in our region. It is an important natural feed source for livestock, because of its adaptation to marginal lands and keeps the greenery throughout the year. Even if depends on the genotypes, *Bituminaria bituminosa* plants have a level tolerance to saltiness. Aim of this study is to determine saltiness tolerance level of *Bituminaria bituminosa* genotypes in seed germination stage.

Material and Methods

This study was carried out in seed Laboratory of OMU Agricultural Faculty with using the seeds of 85 *Bituminaria bituminosa* genotypes collected from Central Black Sea Region of Turkey in 2017. The seeds scarified with sandpaper in order to ease water absorption and germination. Seeds were germinated in five different NaCl solutions as 0 (Control),25,50,75 and 100 mM with 4 replications. 20-seed placed between blotting paper in petri dishes and watered with 10 ml solution for each genotype and each dose. Blotting papers changed every two days and watered again with 10 ml solution. All process was conducted inside a germination chamber fixed at 24˚C and 60% humidity. After process completed germination ratio, seedling weight, root and stem length was determined. Germination process lasted 30 days for 100 mM dose while it was 12 days for control dose, because salinity was slow down germination (Day *et al.,* 2008). Identifying statistical analysis was applied to data as considered average of genotypes by using SPSS 17.0 software program.

Results and Discussion

Regard the germination ratio, seedling weight, root and shoot length, wide range variations were determined amongst the *Bituminaria bituminosa* genotypes (Table 1). Average germination ratio was 48.77% for Control, but this value decreased linearly as salt concentration increase and it declined to 11.37% at 100 mM NaCI dose. In other word, declining rate of germination ratio reached to 76.69% for 100 mM NaCI dose (Table 1; Figure 1). Though *Bituminaria bituminosa* plants have limited tolerance to salinity and mineral compiling, level of tolerance is depends on genotype and environmental conditions (Walker and Bernal, 2007). On the other hand, probably increasing salinity doses would be prevented water absorption and made toxic effects to seeds and decreased germination. In order to start metabolic activity inside the seed, firstly it has to absorb some moisture. Additionally, salt stress prevents synthesis of gibberellin (Bozcuk, 1991) and it causes decrease of ɑ amylase activity (Adda *et al.*, 2014) during germination process. Thus, degradation of carbohydrates is decrease and in the result germination process is slow down.

Fresh seedling weight was decrease as NaCI doses increased. While fresh seedling weight was 0.21 g at Control, it was decreased to 0.12 g at 100 mM NaCI dose (Table 1 and Figure2). When we assumed fresh seedling weight as 100% at Control, it was decrease to 42.86% at 100 mM NaCI dose. But decreasing rate was less compare to the other investigated traits. Despite Na+ and CI are necessary minerals for plants, they cause toxic effect in high levels (Kacar *et al.,* 2009).

Root and shoot lengths are most important parameters to determine the effect of salt stress. Because roots absorb the moisture and shoots transmit water to necessary organs. For this reason, root and shoot lengths show reactions of plants against to salt stress (Bahrani and Hagh Joo, 2012). Consider root length of *Bituminaria bituminosa* genotypes, the value was altered from 0 to 8.30 cm while average root length was 2.17 cm for Control, it decreased to 0.38 cm for 100 mM NaCI dose and declining ratio was 82.49 % (Table 1 and Figure 3). Under stress conditions, plants synthesis abscisic acid, ethylene and brassinosteroids. Those chemicals stimulate root elongation at low doses, but decelerate in higher dose (Julkowska *et al.,* 2014).

Table1. Identifying statistic values of *Bituminaria bituminosa* genotypes in terms of germination ratio, seedling weight, root and shoot length

Traits	Statistics	0 mM NaCI	25 mM NaCI	50 mM NaCI	75 mM NaCI	100 mM NaCI
Germination ratio (%)	Average	48,77	46,99	31,18	26,67	11,37
	Declinng rate (%)	-	3,65	36,07	45,31	76,69

	Maximum	7,57	11,2	4,9	4,5	4,2

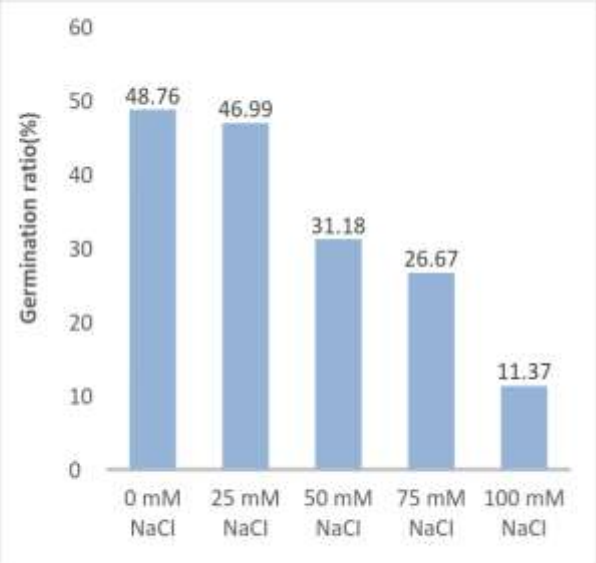

Figure 1. Effect of salt concentrations on germination ratio

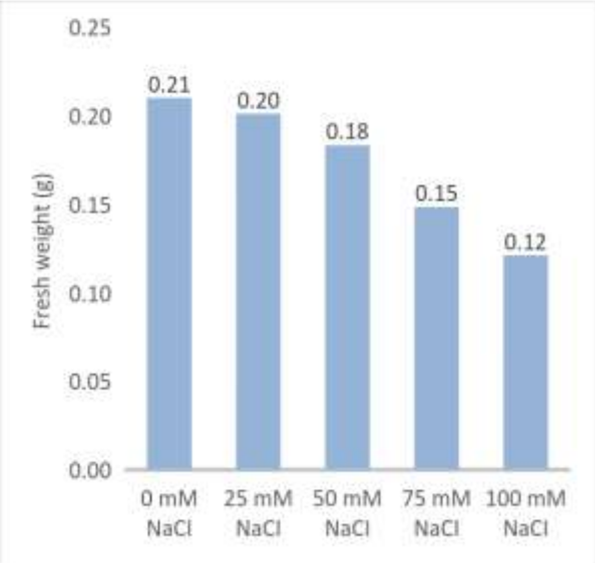

Figure 2. Effect of salt concentrations on fresh seedling weight

Effect of NaCI concentrations on shoot length was similar to effects on root length. Average shoot length was determined as 4.59 cm for Control, but it was decreased to 0.84 cm for 100 mM NaCI dose. In other word, average shoot length was decrease about 81.70% at the highest dose (Table 1 and Figure 4).

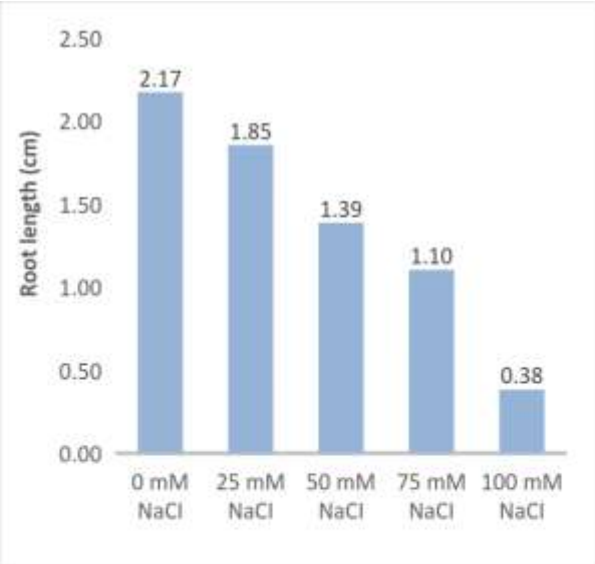

Figure 3. Effect of salt concentrations on root length

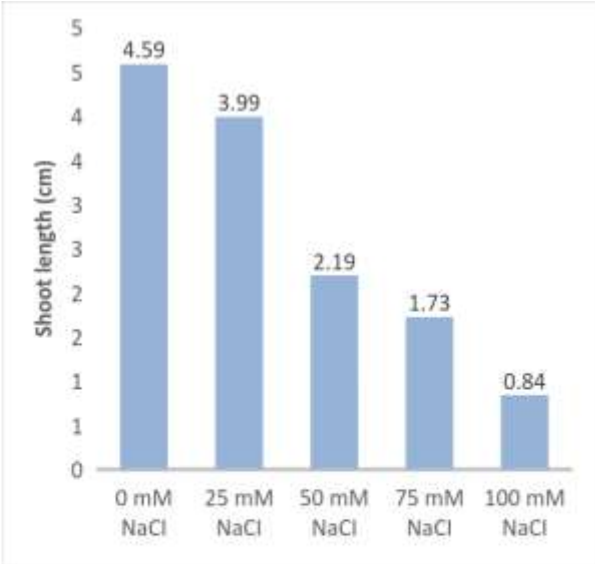

Figure 4. Effect of salt concentrations on shoot length

Conclusion

All of the investigated traits were affected negatively from increasing NaCI concentrations. The least effected characteristic was fresh seedling weight. Compare to Control, decreasing rate of fresh seedling weight for 100 mM NaCI dose was 42.86%. The same value was more than 76% for the other traits. But there were wide range of variation amongst the *Bituminaria bituminosa* genotypes for all investigated characteristics.

THE EFFECTS OF CUTTING FREQUENCY ON BOTANICAL AND QUALITY TRAITS OF A LOWLAND PASTURE

Çaglayan CANDAN, Ilknur AYAN*, Mehmet CAN, Zeki ACAR

Ondokuz Mayis University, Agricultural Faculty, Department of Agronomy, Samsun, Turkey
*Corresponding author: ilknuray@omu.edu.tr

Abstract

This study was conducted to determine the effects of different cutting frequency on forage yield and botanical composition of a lowland natural range in Engiz Village of Ondokuz Mayis County of Samsun Province during 2013 and 2014 spring growing periods. The experiment was established according to randomized block design with four replicates. Total hay yield was ranged from 1460.9 to 2741.9 and from 1009.5 to 3410.5 kg ha^{-1} in 2013 and 2014, respectively. The ratios of grasses, legumes and the other species in botanical composition ranged between 31.24-57.19, 20.77-42.79 and 8.75-47.13%, respectively. Crude protein ratios of hay were determined as 11.62-20.27% for grasses, 17.44-26.32% for legumes and 18.06-24.31% for the other species. While ADF ratios ranged between 28.38-38.27% for grasses, 22.54-34.67% for legumes and 23.48-32.33% for the other species; NDF ratios were determined between 46.61-60.27% for grasses, 35.19-46.68% for legumes and 38.49-52.64% for the other species. While phosphorus content of hay was adequate, potassium, calcium and magnesium was high. K/Ca+Mg and Ca/P ratios ranged between 0.82-2.76 and 1.98-8.60, respectively. In the light of the results obtained from this study, the pasture should be grazed concerning appropriate animal density; otherwise the weeds could increase at the low density grazing conditions. In order to sustain pasture yield, suitable range management program should be prepared and applied.

Keywords: *Cutting frequency; hay yield; botanical composition; mineral contents.*

Introduction

One of the most important problems to be solved in the development of Turkey animal breeding quality is the regular fulfilling of cheap and plentiful roughage needs. In addition to compliance with the animal feed physiology of forage due to its quality and low price, the usage of more expensive and intensive or concentrated feed used in the human diet has been reduced in animal nutrition. The low price of roughage such as hay, green and silo forage increases the profitability of animal breeding firms (Buyukburc, 1999). Considering the dynamic nature of natural pastures in Turkey, to determine the time-dependent changes in the quality and quantity is essential. In addition, regard the balance between livestock feeding and pasture management, to determine the amount of forage, botanical composition and yield of the pasture is really important (Gokkus and Koc, 2001; Holechek *et al*.,1995; Vallentine 1990). The main aim of this study was to determine the time-dependent changes in quality and quantity of hay meadows by considering the dynamic nature of the Black Sea lowland pastures and animal interactions. It was also aimed to determine the yield and botanical composition of the grass consumed by the animals simultaneously.

Material and Methods

This study was conducted at Engiz Village of Ondokuzmayis town of Samsun Province during 2013 and 2014. The soil properties of the experimental area show clay structure when examined in texture. High organic matter content (5.16%), very low nitrogen content, low phosphorus (1.846 ppm), and moderate lime (1.19%) and salt (560.3 µmhos/cm) content was determined. Pasture soil was also slightly alkaline with pH 7.8. The average temperature of Samsun was 13.9^{0}C in long-time period, while in 2013 and 2014 it was measured as 14.7^{0}C and 15.9^{0}C, respectively. For many years, the total annual rainfall of Samsun was 707.0 mm as the average while in 2013 and 2014, this value was determined to be 515.9 and 525.0 mm, respectively. The experiment was established according to randomized block design with four replicates. The applied different cutting frequencies were; each week cutting, cutting biweekly, cutting triweekly, cutting four weeks, cutting five weeks, cutting six weeks, cutting seven weeks and cutting by changing location every week. Only one cage has been placed in every parcel of the study area. In all harvests two 0.21 m^2 areas were cut, after plants were sorted according to family and they were dried at 60^{0}C until constant weight and ground to pass through 1 mm screen. Chemical characters; dry matter, crude protein, ADF, NDF, Ca, Mg, K, P content of samples were determined by using Near Infrared Reflectance Spectroscopy (NIRS, “Foss 6500”) with software package program “IC-0904F”. Statistical analysis was performed with SPSS 17.0 program.

Results and Discussion

The data obtained in 2013 and 2014 showed that there was statistically significant difference between cutting frequencies in terms of grasses, other species and total of hay yields ($p \leq 0.01$), while no statistically significant difference was observed in terms of legume yield. In 2013 the highest grass yield was obtained from cutting every seven week (1134.6 kg ha^{-1}), and the least was obtained with cutting triweekly (497.6 kg ha^{-1}); while in 2014 the highest yield was in plots cutting every week by changing place of cages (Figure 1).

The legume yield in different years was not statistically different. The legume yields were range between 471.2 kg ha^{-1} (cutting biweekly) and 892.7 kg ha^{-1} (cutting by changing location every week) in 2013 and 788.5 kg ha^{-1} (cutting by changing location every week) and 425.4 kg ha^{-1} (each week cutting) in 2014. (Figure 2). The highest yield of other species was obtained with cutting by changing location every week, 830.7 kg ha^{-1} and 1081.4 kg ha^{-1} in 2013 and 2014, respectively. (Figure 3). The highest yield for plants from the other families is taken from cutting which is made by changing the places of the cages every week as 830.7 kg ha^{-1} in 2013 year, is taken from cutting which is made by changing the places of the cages every week as 1081.4 kg ha^{-1} in 2014 year (Figure 3). According to whole hay yield, when we evaluate botanical composition rates for treatments in 2013, it was seen that in treatments number 1,2,6,7 and 8 grasses, in treatments number 3, 4 and 5 legumes have the highest rates. The highest hay yield was obtained from number 8 treatment the spots of the cages and cut (every week) as 3411 kg ha $^{-1}$ in 2014. Operation number 1 follows treatment number 8 which includes reaping every week but fixing the places of cages (2121.6 kg ha^{-1}) and the lowest hay yield was taken from the operation number 4 with 1010 kg / ha^{-1}. According to participation to botanical composition for whole hay yield, in treatments number 3,5,7 and 8 grasses, in treatments number 4 and 6 legumes and in treatments 1 and 2 plants from the other species rank in the front (Figure 4).

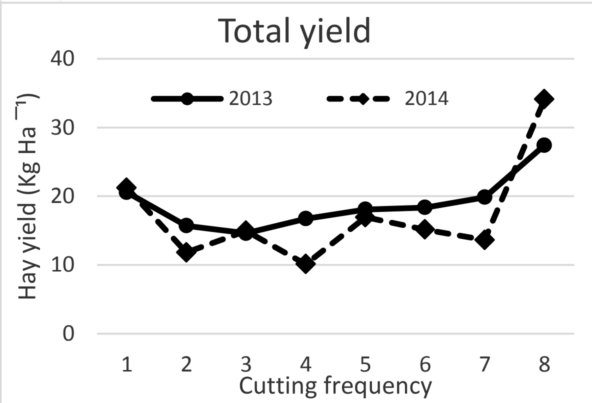

Figure 4. Total hay yield lowland natural range

In Turkey, because of grasslands are rich for grasses (Erkovan *et al*. 2003, Terzioğlu and Yalvaç, 2004, Türker, 2006, Şen and Hatipoğlu, 2010, Nadir *et al* . 2012) it was determined that grasses ratio was over 30% at whole plots. According to applied different reaping frequencies at a base grassland; determinations of the ratios of raw protein, ADF, NDF, Ca, Mg, K, P, K/(Ca+Mg) and Ca/P for grasses, legumes and other species in year 2013-2014 are shown at Table 1. The crude protein ratios determined according to 2013 year reports are changed between 11.62-20.27% for grasses,17.44-26.32% for legumes, 18.06-24.3% for other species; according to 2014 year reports 14.43-20.14% for grasses, 18.84-25.11% for legumes, 16.46-23.23% for other species (Table 1). Ratios of crude protein determined in this study are same as the results of Aydın and Uzun ,2000; Acar et al., 2001 and higher than the results of Çınar ,2001; Türker, 2006; İptaş *et al*., 2007; Tan and Yolcu, 2001; Acar *et al*., 2009. The maturation period of plants and the climate and soil in which they grow also effect the ratio of crude protein. It was detected that in 2013 year the ADF ratios which determined according to different reaping frequencies changed between 28.38-38.27% for grasses, 22.54-34.67% for legumes, 23.48-28.37% for other species, in 2014 year 28.90-33.46% for grasses, 23.82-32.8% for legumes, 25.34-32.33% for other species. Evaluating the quality class of forage regarding to ADF composition, obtained other species were in the very good (%31-35) class. As growing stage of forage plants advance, usually ADF ratio is increase. At trial, it was detected that in 2013 year NDF rates which determined according to different reaping frequencies changed between 46.61-60.25% for grasses, 35.19-46.25% for legumes, 38.49-43.09% for other species; and in 2014 year 49.38-56.07% for grasses, 36.72-46.68% for legumes, 40.63-52.64% for the other species.

At quality classification for NDF ratios it was determined that grasses produce good/average forages, legumes produce good forages, other species produce very good forages in 2013 year and very good/ good forages in 2014 year. As the reaping interim increased, ratios of NDF also increased. The phosphorus content of grasses was detected to be 0.30 – 0.45% in 2013 and 0.38 – 0.42 % in 2014. The phosphorus content of legume in 2013 was 0.33 – 0.43%, and in 2014 it was 0.36 – 0.40%. The phosphorus content of other species were 0.25 – 0.40% in 2013 and 0.26 – 0.38 % in 2014.
The potassium content of grasses was detected to be 2.11 – 3.18% in 2013 and 2.01 – 2.81 % in 2014. The potassium content of legume in 2013 was 2.34 – 2.77%, and in 2014 it was 2.15 – 2.77 %. The potassium content of other species were 2.315– 3.08% in 2013 and 2.27 – 3.03% in 2014. The Ca content of grasses ranged between 72 – 1.17% 0 in 2013 and 0.78 – 1.37 % in 2014. The Ca content of legume ranged between 1.53 – 1.73% in 2013 and 1.54 – 1.81% in 2014. The Ca content of other species were 1.61 – 2.15% in 2013 and 1.74 – 2.11% in 2014. The magnesium content of grasses was 0.21 – 0.28% in 2013, 0.23 – 0.34 % in 2014, the magnesium content of legume was 0.23 – 0.34% in 2013, 0.33 – 0.38% in 2014. The Magnesium content of other species were 0.34 – 0.49% in 2013 and 0.36 – 0.51% in 2014. Mg contents of some species were higher than recommended value (0.2%) by Tajeda *et al.* (1985). The K/Ca + Mg ratio of grasses in 2013 was 1.80 – 2.76, in 2014 1.18 – 2.39, while this ratio for legume was 1.19 – 1.48 in 2013 and 1.04 – 1.35 in 2014. The K/Ca+Mg ratio of other species were 0.82 – 1.56 and 0.87 – 1.42 in 2013 and 2014, respectively. It is recommended that K/(Ca+Mg) ratio of forages should be below 2.20 (Mayland and Grunes 1979, Kidambi *et al.* 1989; Aydın and Uzun, 2008). K/ (Ca+Mg) ratios of all species, except grasses were below 2.20. The Ca/P ratio of grasses ranged between 1.98 – 3.16 in 2013, 2.05 – 3.61 in 2014. The Ca/P ratio of legume ranged between 2.90 and 4.64 in 2013, 4.15 and 4.76 in 2014. The Ca/P ratio of other species ranged between 4.23 – 8.60 in 2013, 4.61 – 7.96 in 2014.

Conclusion

While grazing planning on this type of pasture areas, benefit ratio and botanical composition should be considered together. The frequency of utilization of the pasture could be very important. To determine the degree the degradation of pasture vegetation and take measures accordingly, is so important to start pasture management. Pastures should be grazed at an appropriate frequency. There could be an increase of weeds at light grazing pastures. Ensuring sustainability in pasture an appropriate grazing plan should be done by considering pasture vegetation, climatic conditions, soil structure, type and intensity of grazing animals. In the lights of the results obtained from this biannual study, it was considered both forage yield and nutritious value of forage, grazing the pasture every 3 or 4 week is more favorable than the other treatments.

Abstract

Agriculture has become the most important part of the global economy since the 1950s.While local trade gives the place to complex commercial networks and trade relations, agriculture as well as modern economy in agriculture and the accumulation of capital have become “industrial sector”. Until the early years of 90s, with almost every country being in the first place, the main objective of the developed countries is to increase agricultural yield per unit area and thus ensure maximum profit by decreasing the production cost. The most prominent milestone is called “green revolution” which is scientific developments on plant nutrition products and plant protection pesticides. That the agricultural production increase is much higher than the desired level, revealing waste and demand problems along with the ecological crisis and the developments in demographics bringing up different purposes to the agenda. Awareness is arisen among the consumers with interest of sustainable and healthier agricultural production and food consumption in all over the world. It is essential that all the systems regarding food production and consumption in the future have to be based on ecological and integrated approaches. Besides, minimum environmental impacts and efficient natural resources usage should be considered as criteria in these systems. Different approaches upon dynamic agricultural production system will be evaluated in a holistic way in this study.

Keywords: *Agriculture, ecological crises, consumption.*

Introduction

People, who have made little changes in the biosphere during their lifetime as gatherers and hunters, have begun to take control of nature with the invention of fire. As known so far, the relationship between humanity and nature had started before the start of agriculture. However, after agricultural activities had started, this relationship provided people with intervention power to the nature and it has continued as a structural lifestyle afterwards. G.Child said that, thanks to agriculture, “by making an active partnership with nature instead of living in nature” people have become productive. In the 18th century, F. Engels said that human should not be proud of being superior to nature even it’s for agricultural purposes, and people, who destroy forests to earn more, are responsible for desertification and poverty in these countries. There are also philosophers remarking that nature can always win in this comparison (Fotourechi ve Sahinoz, 2016; Ponting, 2007). In the book "The Vulnerable Planet," he argued that the arrival of the end of great civilizations like the Sumerians is the reason for the superiority of nature and the construction on the capacity that nature can carry (Foster, 2002; Burkett, 2009). The three functions of agriculture which is seen as the basis of civilization are classified as: keeping a human being who is a part of nature in contact with nature, humanitarianism and gentrification of people’s extensive environment, producing foodstuffs and other materials needed for human life

(Schumacher, 2010). With switching to permanent settlement, living areas have been established, agriculture and industry activities have been started and the natural exploitation capacity of people, who are breaking away from nature and slowly drifting away, have increased. Therefore, environmental problems have increased too. There are many factors related to the ecosystem and the continuity of rural life, as well as the increase in production, the creation of surplus value and the reduction of product costs during agricultural activities. These items cannot be explained only by classical agricultural economy principles or cost elements. For example, problems such as hunger or food security in the world, the disappearance of rainforests, genetically modified organisms, or pesticide residues cannot be explained only by economic models. For this reason, in this study, the relations between agriculture and environment were tried to be reinterpreted with different schools of thought.

Material and Method

The materials of this study are the structured secondary data within the scope of research project ‘109O169’ financed by TUBITAK. For this purpose, studies on agricultural economics, ecology, anthropology and social environment have been compiled and this paperwork was created.

Results and Discussion

When natural resources are converted to a “commodity”, and eventually turned into capital accumulation, today's environmental problems have also begun. Especially after the Second World War, agricultural products have become subject to international agreements and international trade network have begun to be directed by multinational companies. While local trade leaving its place to complex commercial networks and associations, agriculture has also begun to become a "sector" with the accumulation of modern economy and capital. Especially in the developed countries, until the beginning of the 1990's, increasing agricultural production and achieving maximum profit with scale economy has become the main purpose. In this process, to increase production and hence income, the policy, which is adopted by developed countries and recommended for other countries, is "green revolution" policies. Together with these policies, the monetary economy in cities has also moved to the villages and the input markets behind the agricultural production and producers have begun to form important consumer masses. When the “green revolutionary politics” produced in contrast with its name begin to show its effect, the increase in agricultural production is much higher than desired, surplus and effective demand problem aroused. Thus, while ecological crises are occurring in areas with particularly fragile ecosystems, "ecological injustice" has begun to become a debated subject too. The "sustainability" antithesis produced to overcome these problems has not been sufficient to resolve structural ecological problems in developing countries. Given the threats to ecology in the agricultural fields, any agricultural activity affects the environment; however, at the same time agricultural production is also exposed to negative externalities from environmental pollution. In this case, we can say that the relations between agriculture and the environment emerge bilaterally. Agriculture is "one of the causes of environmental pollution", especially because of modern production methods. In traditional societies, the natural production was returned to the soil through manuring. However, this balance does not seem possible in the presence of the techniques developed today. The disruption of cycle between living things causes a problem called "metabolic fracture’’. Agriculture can no longer find the natural conditions of its production in its natural ways, instant, readily emerging and ready to use because all these conditions have turned into a separate industry. Today, this discourse is taken even further by Clark and York (2010), accusing "modern agriculture, turning oil into the art of turning food into food". Reducing the transformation and environmental relations in agricultural production systems to the "scale" level is missing in many respects. Establishing standards in the production or production process, establishing and certifying traceable systems may seem refreshing for food security for consumers at a certain level of income, but as long as the soil becomes inefficient, the economic crises deepen and financial problems increase, this method will also be difficult to produce. When "scale size" and "small business problem in agriculture" is considered by focusing on cost reduction and high profits, wrong investment decisions could be given. The separation of agricultural land into small pieces and production is important for producers who do not have sources of income other than land, even if they are not rational. The issue of ownership in agricultural land is still important in many countries.The international conventions, resolutions and practices against the mentioned problems are rooted in the 1972 Stockholm Human and Environmental Conference. Gandhi's statement, "Poverty is the biggest polluter," quoted by Gupta (1993), provoked a wide response in this conference. Thus, the economic, social and environmental dimension of development brought up to the agenda. If a country has employment in the agriculture sector, preferably over 50%, and if the share of agriculture in national income is important, you cannot both impoverish and improve its environment. The 'Boundaries of Growth' declaration published in the Roma Club emphasized the contradiction between economic growth and sustainability, but it was accused by many countries. Nowadays, either to keep the agriculture sector alive and save the natural resources innovative and traditional approaches combined to implement in different part of the world. These approaches could be summarized at below;

a. **Bioregional approach:** What is important now in the agriculture sector is not the more production but the holistic healing that will be provided in the rural area. For this reason, "bioregional" approaches have begun to be adopted. Because, the economics of a bioregion takes its character from nature's laws and conditions. In an economic system defined in this way, it is anticipated that it will have the capacity to plan and share resources in the region it is in, to develop in the safest rate and most ecologically advanced manner. This idea claims that world need instead of more production rural area need holistic improvements or recovery. Because, the economy in a bioregional zone constitute its own characters from the nature law and specific conditions. The defined area allows farmers to plan in an appropriate way and use rationally resources for the future.
b. **Agro-ecological approach:** This approach is essential to built proper Agricultural policies. To motivate the farmers with financial supportive or some tax exemption implementations for preventing biodiversity losses.
c. **Free Nature Friendly System Certificate:** This system is applied in Mexico to sustain the farming in disadvantage arable land. For example, local governments give subsidies to farmers keep forest and land. They also tried to reduce carbon emissions in those plantations and succeed in return.
d. **Climate friendly production system:** Agriculture to total food system emissions is from 7,300 to 12,700 MtCO_2e per year. Of global anthropogenic emissions agriculture is estimated to account for about 60% of N2O and about 50% of CH4 (Warford et.al, 2010). It’s about 14% to 24% of total global emissions (Vermeulen et. al., 2012). The system foreseen adaption and mitigation with sustainability.
e. **Consume local foods:** After organic production system, a new trend is now consuming local foods. This approach is also covering climate smart agriculture approach. Because according to this, organic food is not enough to protect nature. Solution is combining local organic food to reduce carbon emission with reducing transporting long distance.

Conclusion

All over the world, there is a considerable awareness about the current production of agricultural products and food consumption. Future systems for food production and consumption are needed to be based on a holistic and ecological point of view. Also, in the development of food products and in systems to be applied in food, minimum environmental impacts and effective use of natural resources have to be made important criteria. The ecological crisis in the world should be emphasized more according to Zizek (1992). The crisis is not important only because of its actual danger, namely survival of human, but because it questions our perceptions of "nature". Individuals have different reactions to ecological crises. Zizek divides these reactions into three parts. First idea is: “I certainly know that the issue developed by those who are reluctant to take the ecological crisis seriously is so critical but still I don’t believe it, I am not ready to include it to my symbolic universe, so I can continue to pretend that ecological problems will not affect my daily life”. The other reaction may realized obsessive to ecological crises. The person in question thinks that “If I do not do it, it will cause a horrible disorder”. The third type of reaction is “it is a punishment for our exploitation of nature ruthlessly, making the nature a throwaway object and a warehouse where we supply materials”. The outcome of responders in this way is that we need to live as part of nature, adapt ourselves to its rhythm and root in it. Zizek says, with a Lacanian approach, about the ecological crisis, we should learn to accept it without making sense of it. Human being can both heal and destroy the environment that provides his own development. The situation of the environment, affects both a better life and economic development. The idea that ‘individual efforts will always bring the world to a better position’ should not be just a 'positive and optimistic’ idea. To maintain this, the need for collective plans and programs is likely to be greater than ever.

Abstract

This study was carried out with 86 *Bituminaria bituminosa* genotypes collected from Central Black Sea Region of Northern Anatolia in Samsun (Turkey) in 2012. After seed cleaning, germination tests and scarifying the seeds with sandpaper, seeds were sown in small pots. In November of 2012, the seedlings were transplanted to experimental field. Neither fertilizer nor water applied throughout the study and spring (6 times with 10 days interval in April and May) and autumn elongation. Hay yield and harvesting number in the second year of the plants (2014) were observed during the study. According to correlation analysis, increasing altitude that the genotypes were collected from affected other traits, negatively. In other words, as the altitude increased, the genotypes started elongation later in spring and autumn, and hay and seed yields and harvested number were decreased. There were positive linear correlation between hay yield and autumn and spring elongations. Though autumn and spring elongations affected the seed yield of genotypes positively, relationships only between seed yield and mid of May elongation and hay yield were significant ($p \leq 0.05$).

Key words: *Tedera, yield, relationship, elongation.*

Introduction

There are 150 species in *Bituminaria* genus held inside *Fabaceae* family (Hooker and Jackson, 1960). *Bituminaria bituminosa* (*Bitbit*) is a perennial herbaceous species in *Bituminaria* genus. Its origin is Mediterranean environment and distributed to Turkey, Western Syria, Crimea peninsula, Cyprus, Caucasia region, Israel, North part of Africa, Portugal, Spain, Canary Islands and the other parts of Southern Europa (Davis, 1965). *Bitbit* is a herbaceous deep rooted perennial legume that has been used by farmers in the Canary Islands for hundreds of years where it is grazed in situ or is cut and fed green to dairy goats (Méndez, 2000). It is an extreme drought tolerant species, and produce good quality feed throughout the year. *Bitbit* remains green in summer and autumn in Mediterranean-type climates with minimal loss of leaves (Gulumser and Acar, 2012; Finlayson *et al*., 2012). The var. *bituminosa* has a wide adaptation across the Canary Islands (300-1000 mm) and is the only one present in the Mediterranean basin. In the Iberian Peninsula it is found in environments ranging from 250-1000 mm of rainfall and up to 1250-1500 m of altitude (Stenberg *et al*., 2006; Méndez *et al.*, 2006). Natural distribution of Bitbit is in coastal provinces, located such as Samsun, Sinop, Kastamonu, Trabzon, Zonguldak, Antalya, Adana, Mersin, Hatay, Mugla, Izmir, Canakkale, Tekirdag and Yozgat in North, West and South of Anatolia (Kilinc *et al.* 1998; Akcin *et al.* 2010). A strong relation was determined amongst the altitude, hay and seed yield, spring and autumn elongation of *bitbit* genotypes (Acar *et al.*, 2016). The main aim of the study was to obtain more detailed information about relationships amongst yield, harvest number, spring and autumn elongation, original altitudes of genotypes.

Materials and Methods

Seed samples of 86 *Bitbit* genotypes were collected from Central Black Sea Region in 2012. Regarding the altitude, *Bitbit* plants naturally grow from just nearby the sea (3 m) to south-eastern skirts of Mount Dranaz (985 m). After seed cleaning and germination tests, seeds were scarified and sown in small pots. In November of 2012, the seedlings were transplanted to the experimental field with 70 cm*70 cm spaces as 20 plants for each genotype. Measurements were realised on 10 plant samples for all genotypes in 2014. Plant height in spring was measured on April 1 (1.04.2014), April 2 (17.4.2014), April 3 (25.4.2014), May 1 (8.5.2014), May 2 (15.5.2014) and May 3 (22.5.2014). Last harvest was performed at the end of September and plant height data about autumn growing before winter were taken at the beginning of November. In 2014, samples of 86 *Bitbit* genotypes were determined hay yield (g/plant) and seed yield (g/plant). 55 genotypes gave twice harvest but 31 genotypes only once. Linear correlation and some regression analysis were performed amongst the traits with SPSS 17.0 program.

Results and discussion

Linear correlation analysis results amongst the traits can be seen at Table 1. The altitude affected the measured traits negatively. As altitude increased, plant heights in autumn and spring, hay yield, seed yield and harvest number decreased. While effects of altitude on plant height in autumn, April 1,2,3, May 1 and harvest number are significant or highly significant ($p \leq 0.05;0.01$); on seed and hay yield and plant height in May 2 and 3 are nonsignificant. Effect of altitude on plant height decreased by the growing period progress in Spring season.

Table1. Linear correlation values amongst the traits and their significance levels.

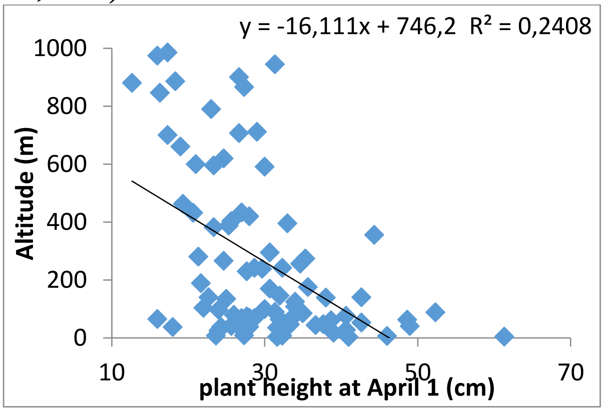
Traits		**Altitude (m)**	**Plant height in autumn (cm)**	**Plant height in spring (cm)**						**Hay yield (g/plant)**	**Seed yield (g/plant)**	**Harvest number**
				April1	April2	April3	May1	May2	May3			
Altitude (m)		1										
Plant height in autumn (cm)		-,224*	1									
Plant height in spring (cm)	April 1	-,491**	,363**	1								
	April 2	-,410**	,376**	,840**	1							
	April 3	-,327**	,440**	,361**	,510**	1						
	May 1	-,237*	,395**	,278**	,457**	,956**	1					
	May 2	-,168	,387**	,263*	,424**	,899**	,947**	1				
	May 3	-,204	,374**	,214*	,354**	,869**	,899**	,915**	1			
Hay yield (g/plant)		-,096	,278*	,262*	,435**	,605**	,649**	,612**	,590**	1		
Seed yield (g/plant)		-,016	,163	,144	,194	,207	,184	,215*	,088	,260*	1	
Harvest number		-,337**	,064	,318**	,320**	,362**	,341**	,298**	,240*	,345**	,122	1

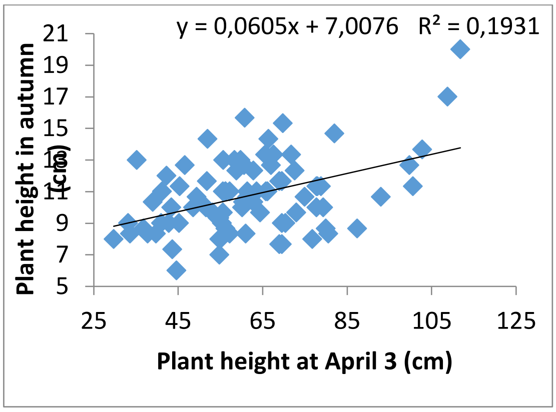
*indicated values at $p \leq 0.05$; **indicated values at $p \leq 0.01$ levels are important.

More hay yield was obtained from the genotypes when elongations in autumn and spring were high. The genotypes with elongation earlier in Spring, had higher hay yield and number of harvest (Table 1).

The genotypes from high altitudes started elongation later than the others (Figure 1). The effect of plant height in autumn on elongation in april 3 was statistically significant (r=-

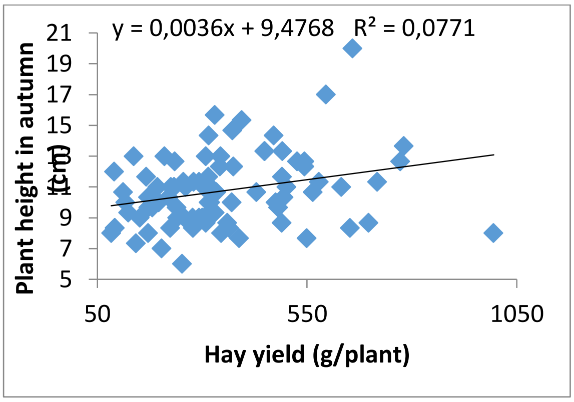
0.440**), there was a strong correlation between plant heights in autumn and april 3 (Table 1 and Figure 2). The plants adapted to high altitudes generally have dormancy characteristics and they stay dormant in autumn, winter and early spring period to survive in harsh conditions (Acar *et al*., 2016; Kilinc and Kutbay, 2004). *Bitbit* genotypes adapted to high altitudes had less elongation in autumn and also started to elongate late in spring (Acar *et al.*,2016).

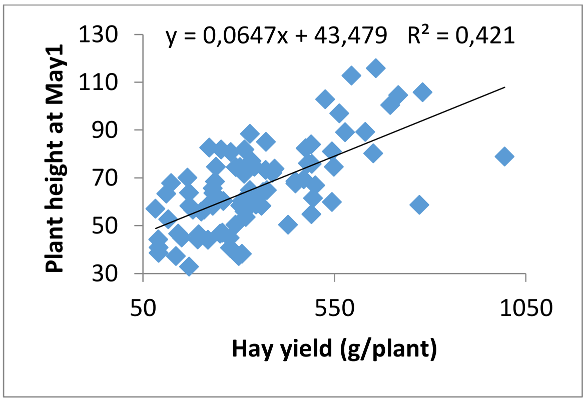




Figures 1. and 2; 1) Relations between altitude and plant height at April 1; 2) Relations between plant height in autumn and at April 3

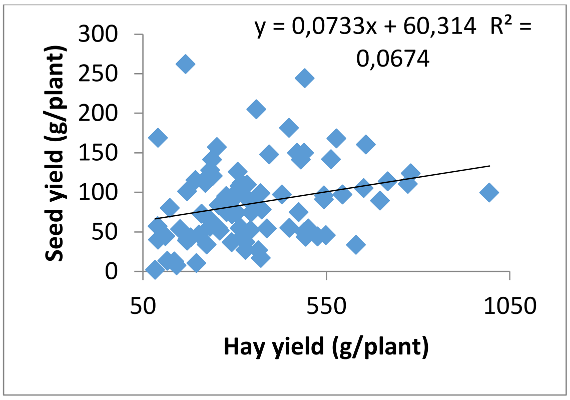
There were statistically significant correlation between hay yield and plant height in autumn (r= 0.278*) and at May 1 (r=0.649**) (Table 1 and Figures 3 and 4). The genotypes taken from low altitudes started elongation early in spring and continue their growth until autumn and they gave more cutting and higher hay yield than the others. Probably those genotypes have better regeneration ability. Furthermore, if a genotype started elongation early it has more time and natural resources for growing. Even if the plants keep growing and greenery in summer period, there are the best environmental conditions in spring, thus earlier genotypes have more advantage compare to the others.

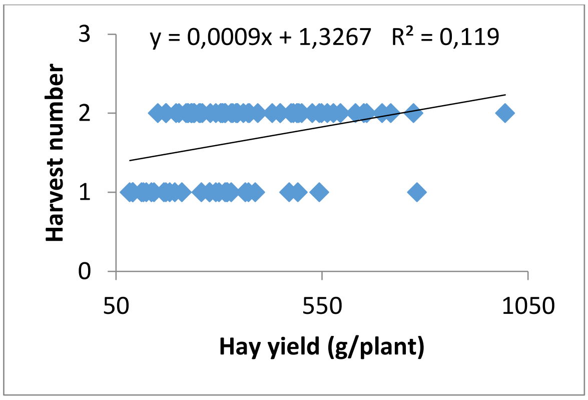




Figures 3. and 4; Relations between plant height in autumn and hay yield; May 1 and hay yield

There was a significant correlation between seed yield and hay yield (r= 0.260*) (Table 1 and Figure 5). The genotypes have more branches and grow vigorously, those gave both more hay and more seed yield. It is not surprised that increasing number of harvest causes increasing hay yield (Figure 6). Despite the decreasing hay yields through to sequencing harvests, the genotypes had higher number of harvest gave higher hay yield.





Figures 5. and 6; Relations between seed yield and hay yield; harvest number and hay yield

The genotypes stayed dormant in winter, they started elongation late and natural consequence of this situation, number of harvest decreased. Some researchers determined clear differences amongst *Bitbit* genotypes in terms of cold tolerance, harvest number and hay yield (Correal, 2012; Real *et al*., 2014; Acar *et al.*, 2016).

Conclusions

There was a strong relation amongst the altitude, *Bitbit* genotypes, and growing characteristics. The genotypes adapted to high altitudes had a slight growth in autumn and they also started elongation later than the others in spring. They survived in cold period owing to dormancy or semi-dormancy. This behaviour of *Bitbit* plants is similar to alfalfa.

Abstract

Cowpea is often used as human and animal nutrition and green manure. This study was conducted in order to determine the effects of different row spacing and sowing-time on hay yields and some properties of forage cowpea cultivar "Ülkem" and a genotype in ecological condition of Amasya-Suluova. Different row spacing (30, 45, 60, 75 cm) and sowing time (1 May and 1 June) were used according to split block design. In this study, plant height, main stem width, branch number, pod weight, leaf ratio and hay yield were determined.

In this study, it was clear that the cultivar Ülkem was superior to the promising genotype; higher yields were obtained in sowing date 1st May; larger row spacing caused decreasing of hay yield. The highest forage yields were determined at 30 cm row spacing (15.87 and 9.78 t/ha) for both sowing date. Crude protein ratios of hay varied from 18.61% to 20.00%. NDF ratios of hay were 33.21% and 32.73% for 1st May and 1st June sown, respectively. Average ADF ratios were 30.09% and % 30.81 for the same sowing dates. P, K, Ca and Mg contents were 0.35% and 0.37%, 1.97% and 2.01%, 1.51% and 1.56%, 0.49% and 0.52% for 1st May and 1st June sown, respectively. In conclusion, in order to obtain high and quality forage yield, Ülkem cultivar should planted with 30 cm row space at the beginning of May in Suluova conditions.

Keywords: *forage cowpea, hay quality, row spacing, hay yield, sowing date,*

Introduction

Cowpea (*Vigna unguiculata* L. Walp) is a substantial food and a valuable part of the conventional cropping systems in the drier region tropics of Asia, Africa and Central America (Mortimore et al., 1997). This precious tropical and subtropical legume is especially important for the semi-arid regions of the tropics for forage, green pods and grains (Adeyanju et al., 2007; Ali et al., 2004). Cowpea is one of the plants among legumes regarding resistance to high temperature and drought. Considering the temperature rise and reduction of water resources due to global climate change, it is emerging as a plant to be worked on. Cowpea is often used as human and animal nutrition and green manure. Green herbage, hay, silage and seeds of cowpea are used for animal nutrition. Cowpea hay is a nutritious balanced fodder for animals (Singh et al., 2003) and has a great function in feeding animals. Having a high nutritive value of green forage cowpea, hay contains 14-21% crude protein, while the seeds have the rate of 18-26% crude protein. It is stated that cowpea is grown alone for forage yield. However, it could be grown mixed with maize, sorghum and millets for silage (Ismail and Hall, 2000; Saricicek et al., 2002; Bilgili, 2009; Basaran et al., 2011; Ayan et al. , 2012). The biggest technical constraint in livestock production in Turkey is forage deficiency especially during summer period when pasture vegetation is dry. So there is a need for new warm-season forages to fill forage gap in this period. In general, solutions to forage shortages during the summer months have included the use of perennial and annual warm-season species for pastures, hay, or silage. The objective of the present study was to investigate forage yield, some quality characters and mineral contents of a cowpea cultivar Ülkem and a genotype in response to four different row spaces and two planting dates.

Material and Methods

The study was carried out in 2013 and was designed as split plots with 4 replicates in Amasya-Suluova (Turkey) ecological conditions. The experiment was designed as sowing dates at main plots, inter row distances at split plots and cultivars at split-split plots. The experimental plots consisted of four rows, each 5 m in length with 50 cm row spacing. Throughout the vegetation period (from May to September) of 2013 total rainfall were 103.1 mm, mean temperature was 19.5 ^{0}C, average value of relative humidity was 62.0 %. Released forage cowpea cultivar "ÜLKEM" and a promising cowpea genotype were examined to figure out the effects of different row spacing (30, 45, 60 and 75 cm) and two sowing dates (1st May and 1st June). In this study, plant height, main stem width, number of branches, leaf ratio and hay yield were determined. Crude protein, acid detergent fiber (ADF), neutral detergent fiber (NDF), K (Potassium), Mg (Magnesium), P (Phosphorus) and Ca (Calcium) contents of samples were determined by using near infrared reflectance spectroscopy (NIRS) 13-15. With software program coded IC-0904FE. The study was completed in irrigated conditions three times. Irrigation process was continued until soil humidity comes to field capacity. All data obtained from this study was analyzed by using SPSS 17.0 program. The differences amongst the mean values were calculated according to DUNCAN test.

Results and Discussion

Average performance of the released forage cowpea cultivar "Ülkem" and genotype regarding forage yield and quality over sowing dates and row spacing are shown in Table 1. Average plant height of the genotypes and the cultivar Ülkem sown on 1st May was 166.18 cm, however it was found 110.10 cm on those which were sown on 1st June. In both sowing times, plant height increased as row spacing increased. The longest average plant height was found 75 cm and 60 cm. Overall, the cultivar Ülkem sown on May 1, and the genotype sown on June 1 had highest plant heights. Average stem diameter sown on May 1 was 12.01 mm and 9.39 mm sown on June1. Increasing row spacing caused increasing stem diameter as well. The stem diameter of Ülkem was lower than the stem diameters of the genotype. The number of branches of the genotypes sown on May 1 and June 1 was 5.67 and 4.39, respectively (Table 1). Even if cowpea is a warm season plant, late spring period is very suitable for vegetative grow. Thus, the sowing date of May 1 is superior to June 1 in terms of plant height, branch number and stem diameter. As increase of row spacing each plant has more opportunity to take water, nutrients and sunlight.

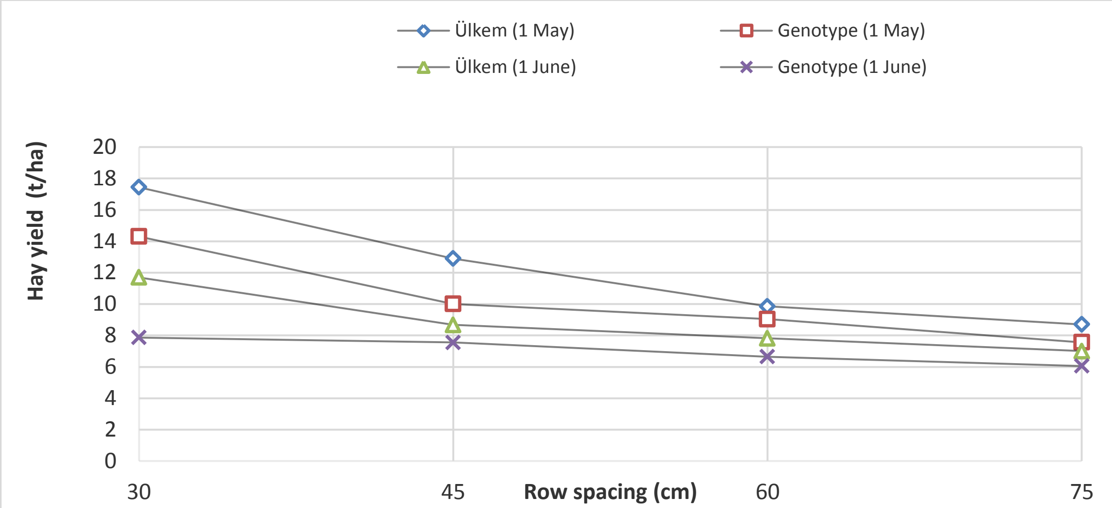

Figure 1. Forage yields of cultivar Ülkem and a genotype grown in different row spacing in sowing dates of 1^{st} May and 1^{st} Jun

Average hay yield was found 11.22 t ha^{-1} in the genotypes sown in May 1 and 7.91 t ha^{-1} in the genotypes sown in June 1. The highest hay yield in both sowing date was determined at 30 cm row spacing. Hay yield also increased in parallel to increase of number of plant per square meter. Rest of the row spacing is statistically located in the same group. More hay yield was obtained from Cultivar Ülkem in all treatments of row spacing (Figure 1). With a longer growing time period owing to early sowing, higher hay yield was obtained from the genotypes sown in May 1. One of the most important factors determining the forage yield of cowpea is appropriate sowing date (Mojaddam and Nouri, 2014). There were no statistical differences in terms of leaf ratio. Average leaf ratio was found 69.15% in the genotypes sown in May 1 and 69.70% in the genotypes sown in June 1. More leaf ratio was measured in Cultivar Ülkem compared to the genotypes.

**There are no differences amongst the means indicated same letter at the same line and same column at 0.05 (P≤0.05) probability level.*

There was no statistical difference between treatments in terms of crude protein content. The crude protein content ranged from 20.22% to 18.61% (Table 2). Cowpea fodder is a rich source of crude protein up to 184 g kg^{-1} (Khan et al., 2010). NDF and ADF rates of May 1 and June 1 sowing dates were 33.21% - 32.73%; 30.09% - 30.81%, respectively. The CP, ADF and NDF contents of the cowpea genotypes studied indicated that they came within the high quality forage group according to standards developed by the Hay Marketing Task Force of American Forage and Grassland Council (Rohweder et al., 1978). Low of stem diameter and high protein content in the second sowing time could cause lower ADF and NDF values. The average Mg content of May 1 and June 1 sowing dates were 0.49% - to 0.52%, while the average Ca contents were determined to be 1.51% - 1.56%. Average P content of May 1 and June 1 were 10.35%, and 0.37%. K contents of genotypes were greater in both sowing dates than the cultivar Ülkem. K content of May 1 and June 1 were 1.97% and 2.01% (Table 2). The mineral matter needs of gestating or lactating beef are 1.8 -4.4 g kg^{-1} for Ca, 0.4 - 1 g kg^{-1} for Mg, 6 – 8 g kg^{-1} for K and 1.8 – 3.9 g kg^{-1} for P (NRC, 1996; Tekeli and Ates, 2005). Tajeda et al. (1985) reported that forage should contain at the level of 2 g kg^{-1} Mg and at least 3 g kg^{-1} Ca for the ruminant. For this respect, P, Mg, Ca and K content of the forage in released forage cowpea cultivar "Ülkem" and genotype were higher than animal needs recommended by the previous studies.

Conclusions

In future farming system, the importance of cowpea, known as resistant to high temperature and drought, is likely to increase due to changing climatic conditions. Cowpea can play an important role to fill forage gap by cutting for hay or by grazing during summer-autumn period when pasture yield is very low. Kiesling and Swartz (1997) reported that lambs grazing on cowpea had greater total gain and carcass weight than lambs grazing on sudangrass, fed corn/soybean meal or corn/whole cottonseed with certain ratios. In this study, 30 cm distance, 1st May sowing date and cultivar Ülkem has emerged as the most suitable for forage production.

Abstract

Pomegranate for which Asia Minor is the gene centre is a tropic and subtropic fruit and one of the oldest cultivated agricultural products. According to 2015 statistics Turkey has 445.750 tons of total pomegranate production. In Turkey, pomegranate is one of the many investigated fruit species in selection studies. The richness of our country on genetic variation of this species provides facility for achievement in breeding studies in a short period of time. Because this fruit is cultivated on many regions of Turkey, it is extremely important to develop varieties proper for many areas. Pomegranate is one of the most important fruit species that are consumed in Turkey. Therefore, some of several superior pomegranate types obtained during the selection studies performed in different areas of our country to date have been registered as cultivar. The some pomegranate varieties located in the registered list of Food, Agriculture and Livestock Ministry are Fellahyemez (01N04), Katırbaşılı (31N07), Ekşilik (01N07), Hicaznar (07N08), İzmir-1264, İzmir-1499, İzmir-1513, Erdemli-Aşınar (33N11), İzmir-23, İzmir-26, Ernar (07N03), Lefan (31N06), Silifke Aşısı (33N16), Ekşi Göknar (33N12) and Mayhoş-IV (07N14). This study aimed to determine the status of pomegranate cultivation and to demonstrate of some pomegranate types selected from different regions to produce better quality and more efficient pomegranates in Turkey.

Keywords: *Pomegranate, Genetic resources, Selection, Production*

Introduction

Pomegranate (*Punica granatum* L.) is a popular fruit of tropical and subtropical regions that is native to the area stretching from Iran to the Himalayas in northern India (Fawole and Opara, 2013; Parvizi *et al*., 2016). A pomegranate is a fruit tree, which in recent years has seen great expansion in several countries, especially those with Mediterranean like climates, where fruit of excellent quality can be obtained. Pomegranates are cultivated in the Mediterranean Basin, Southern Asia and several countries in North and South America (Hernández *et al*., 2014). The main regions for pomegranate cultivation and production are Iran, Afghanistan, India, Mediterranean countries (Morocco, Spain, Turkey, Tunisia and Egypt) and Middle Eastern countries (Melgarejo *et al*., 2009; Gundogdu and Yilmaz, 2013). Pomegranate cultivars are mainly grown in the Aegean, Mediterranean and Southeastern Anatolian regions of Turkey. Nowadays, pomegranate growing is increasing, especially in these regions because of their suitable ecological conditions (Derin and Eti, 2001). According to 2015 statistics Turkey has 445.750 tons of total pomegranate production (TUIK, 2015). Turkey has different pomegranate genotypes and forms because it is one of the origins of the pomegranate. Therefore, various selection and breeding studies have been carried out and a quite number of pomegranate genotypes have been determined in some regions of Turkey. Up to now, many pomegranate varieties in Turkey have been obtained by selection in other regions. Some pomegranate varieties in the registered list of Food, Agriculture and Livestock Ministry are Fellahyemez (01N04), Katırbaşılı (31N07), Ekşilik (01N07), Hicaznar (07N08), İzmir-1264, İzmir-1499, İzmir-1513, Erdemli-Aşınar (33N11), İzmir-23, İzmir-26, Ernar (07N03), Lefan (31N06), Silifke Aşısı (33N16), Ekşi Göknar (33N12) and Mayhoş-IV (07N14) (Golukcu *et al*., 2008). However, Turkey still has many valuable pomegranate genotypes. Objectives of this research are to highlight the pomegranate potential, to examine some of the pomegranate selection studies and to shed light on the future work of pomegranate of Turkey.

Turkey's Pomegranate Production Potential

Turkey's total pomegranate production is given in Table 1. In this table, our country's total pomegranate production of 1995, 2000, 2005, 2010 and 2015 were 53.000, 59.000, 80.000, 208.502 and 445.750 tons, respectively. In addition, in these years, The yield per pomegranate tree were 23, 24, 25, 32 and 33 kg, respectively. As seen in the table, Turkey's pomegranate potantial production have increased.

Table 1. Turkey's total pomegranate production.

Year	Area covered by bulk fruit (ha)	Production (t)	Average yield per tree (kg)	Number of fruitful trees	Total number of trees
1995	4.640	53.000	23	2.304.000	2.799.000
2000	4.675	59.000	24	2.485.000	3.294.000
2005	6.700	80.000	25	3.220.000	4.629.000
2010	20.607	208.502	32	6.431.358	12.110.150
2015	30.751	445.750	33	13.310.323	17.382.612

The regions of pomegranate production more than 1.000 tons were given in Table 2. As seen from the Table 2, Mediterranean, Aegean and Southeast Anatolia regions rank first, second and third with 136.332, 88.497 and 72.550 tons of pomegranate productions respectively. Considering the yield per pomegranate tree of the regions, West Anatolia, Mediterranean and Northeastern Anatolia Regions rank the first, the second and the third with 42, 40 and 37 kg of pomegranate productions respectively (TUIK, 2015).

Table 2. Total pomegranate production of Turkey's Regions (TUIK, 2015).

Regions	Area covered by bulk fruit (ha)	Production (t)	Average yield per tree (kg)	Number of fruitful trees	Total number of trees
Southeast Anatolia	7.255	51.790	22	2.378.768	3.396.251
West Marmara	0.250	2.484	22	114.591	184.792
Aegean	8.850	146.080	32	4.593.047	5.488.731
East Marmara	0.508	7.258	29	246.506	338.387
Eastern Anatolia	0.187	1.932	42	46.090	100.350
Mediterranean	13.633	234.609	40	5.841.431	7.747.966

The provinces with a pomogrenate production more than 5.000 tons is given in Table 2. Antalya, Mersin and Denizli provinces rank first, second and third with 107.237, 61.919 and 45.594 tons of production, respectively (Table 2) (TUIK, 2015). Considering the yield per pomegranate tree of the provinces, Mersin and Karaman, Mardin, and Adana province rank first, second and third with 47 and 47, 46, and 44 kg of pomegranate productions respectively. Şanlıurfa province is the last with a production of 12 kg (TUIK, 2015).

Table 3. Pomegranate production of Turkey's Important Provinces.

Provinces	**Area covered by bulk fruit (ha)**	**Production (t)**	**Average yield per tree (kg)**	**Number of fruitful trees**	**Total number of trees**
Adıyaman	1.243	5.112	19	268.750	732.995
Antalya	5.737	107.237	40	2.675.648	3.334.156
Adana	2.156	39.715	44	899.427	1.180.802
Bilecik	0.318	5.759	37	156.900	209.228
Gaziantep	1.760	19.370	32	613.778	679.590
Denizli	2.677	45.594	32	1.430.527	1.740.672
İzmir	0.702	11.854	27	433.069	572.234

Şanlıurfa	2.140	9.261	12	791.282	1.120.672
Türkiye	30.751	445.750	33	13.310.323	17.382.612

Some Selection Studies on Pomegranate in Turkey

1. Gundogdu (2006) determined the tree and fruit characteristics of important pomegranate genotypes grown in Pervari town of Siirt province. During the observation, the fruit weights of 25 genotypes ranged from 197g to 328 g. These genotypes were classified as sweet based on their acidity content. The twelve genotypes were chosen for fruit juice industry because they met the suitable criteria. Seed yield varied from 56.60 % to 66.40 %. Seed color was either pink or red. Total soluble solid content in fruit juice ranged from 13 % to 25 %. All investigated 25 genotypes were found to advisable for economical production.
2. Muradoglu *et al*. (2006) selected wild pomegranate genotypes grown in Hakkari province of Turkey. During the observation, it was described desirable pomological traits of 46 pomegranate genotypes selected from Çukurca district (Hakkari). These genotypes had a range of 131-337 g for fruit weight, 60.0-81.0 mm for fruit height, 30.8-88.9 mm for fruit width, 11.0-26.1 mm for calyx length and 11.2-18.1 mm for calyx diameter. In addition, the total soluble solid content was between 12.2 % and 17.6 %. The values of pH ranged from 2.6 to 3.8. The acidity was between 1.5 % and 2.9 %. The genotypes had green or yellow colored bottom skins, red or pink colored seeds, soft, semi-hard and hard hardiness seeds. Their seed percentage changed between 49.5 % and 71.5 %. Many genotypes were considered promising.
3. Ak *et al.* (2009) determined some pomological traits of different pomegranate varieties grown in Sanliurfa-Turkey. The cultivated varieties in this study was selected by growers among chance seedlings. In this paper, the traits of some regional pomegranate varieties were

compared. These varieties were Katir Nari, Kus Nari, Millesi, Suruc Tatli Narı, Boncuk, etc. selected in Southeast Anatolia, especially in Sanliurfa province. Other varieties such as Devedisi, Mayhos, Cekirdeksiz, Fellahyemez were selected in other parts of Turkey.

4. Gundogdu *et al*. (2010) determinened some pomological traits of pomegranate grown in Şirvan (Siirt) region. In the study, fruit weights ranged from 161.45 g to 302.35 g; fruit heights ranged from 60.79 mm to 78.67 mm; fruit diameters ranged from 67.27 mm to 86.92 mm; fruit volumes ranged from 177.5 ml to 305.0 ml; fruit juice amounts ranged from 69 ml to 121 ml; fruit densities ranged from 0.84 g cm^{-3} to 1.17 g cm^{-3}; seed weights ranged from 80.00 g to 162.35 g; calyx heights ranged from 16.58 mm to 34.64 mm; calyx half-diameters ranged from 9.32 mm to 14.27 mm; Soluble solid contents (SSC) ranged from 12 brix to 16 brix; pH ranged from 3.63 to 5.87; shape indices ranged from 0.84 to 1.03; and total acidity ranged from 0.47% to 1.08%. Moreover, sub skin color, upper skin color, seed hardness, fruit taste, seed color, upper fruit compartment, sub fruit compartment, compartment number, compartment appearance, easiness in separating arils, fruit pulp weights were also determined.

5. Ercisli *et al*. (2011) determined 19 promising pomegranate genotypes originating from the Coruh Valley in using fluorescent dye AFLP markers and capillary electrophoresis. Four AFLP primer combinations were used, generating a total of 297 fragments, 213 of which were polymorphic (73.0%). Resolving powers of the AFLP primers ranged from 0.700 to 1.018, with a total of 3.440, while polymorphism information contents ranged from 0.707 to 0.837 with an average of 0.764. UPGMA clustering of the genotypes showed two major groups. Most of the fruit characteristics of the genotypes within the same group were variable. Therefore, the results showed that molecular characterization is necessary to get reliable relationships among pomegranate genotypes and AFLP markers can be used effectively in pomegranate.

6. Orhan *et al*. (2013) determined the morphological diversity among pomegranate genetic resources from Coruh Valley located in Northeastern part of Turkey. This valley is accepted one of the 34 hotspots in terms of plant biodiversity in the world. Pomegranate cultivation in this region is one of the main agricultural activities with viticulture. In spite of importance and richness of pomegranate biodiversity from this region, local germplasm of this region has not been investigated yet. For this reason pomegranate (*Punica granatum* L.) population of 10.000 seedling shrubs was examined with regard to morphological fruit properties. In the study, 56 promising pomegranate genotypes were selected from the valley. There was huge morphological variation among genotypes, in terms of particular fruit color, fruit weight, fruit dimensions, aril color and fruit firmness. The genotypes exhibited a range of 147-769 g for fruit weight, 65.19- 107.08 mm for fruit width, 56.84-96.93 mm for fruit length, 2.69-6.05 mm peel thickness and 14.8-49.8 kg/cm2 fruit firmness. The selected promising genotypes were preserved in a collection parcel as perspective parental genotypes for future breeding activities.

7.Okatan *et al*. (2015) described the desirable pomological and chemical traits of seventeen pomegranate genotypes selected from Narlidere district (Bitlis) in between 2010–2011 years. They found considerable variation on fruit weight, aril weight, fruit length and fruit width that important for pomegranate breeding ranged from 99.77 to 515.97 g, 14.16 to 41.92 g, 51.03 to 90.99 mm and 58.99 to 103.11 mm among genotypes, respectively. In this study, It was determined that soluble solid content, titratable acidity, pH and juice yield of genotypes varied between 5.96 to 9.13%, 0.12 to 0.91%, 2.51 to 4.52 and 48.58 to72.07%, respectively.

8. Ikinci and Kilic (2016) determined the some pomological and chemical properties of local pomegranate (*Punica granatum* L.) genotypes for high adaptation to local climate grown in the Siverek (Şanlıurfa) county between the years of 2012-2014. In this study, out of the 26 pomegranate genotypes 15 of them were identified as promising cultivars. Fruit weight ranged from 267.72-650.56 g, fruit lenght ranged from 69-92.72 mm, fruit width ranged from 80.12-109.61 mm, fruit volume ranged from 275.00-731.67 cm^3, fruit juice amount ranged from 81-98 ml; fruit density ranged from 0.868-0.974 $g.cm^{-3}$ and 1000-grain weight ranged from 141.33-361.33 g among the selected pomegranate genotypes. The soluble solid content, pH and titratable acidity of promising genotypes were determined between 12.64-16.68 brix, 2.84-3.31 and 0.55-2.99% of pomegranate, respectively.

In Turkey, a number of research studies have been excuted on pomogrenate. For instance; pomological studies on pomegranate varieties of Aegean region (Dokuzoguz and Mendilcioglu, 1978), selection of Mediterranean region pomegranates grown in Mediterranean region of Turkey (Onur and Kaska, 1985), selection of Mediterranean region pomegranates (Yilmaz et al., 1992), combination breeding of pomegranates (Onur and Tibet, 1995), determination of fruit properties of Pervari (Siirt) pomegranates (Kazankaya et al., 2003), pomological properties of growing pomegranates in Hizan (Yildiz et al., 2003),the pomegranate genetic resources in Turkey (Yilmaz et al., 2011), morphological diversity among pomegranate genetic resources from Northeastern part of Turkey (Orhan et al., 2013).

Conclusion

As stated earlier, a number of research studies have been carried out on pomegranate, regarding both agronomy and selection. As a result, pomegranate production has been increasing day by day in Turkey. In this study, status of pomegranate potential production was determined and some promising pomegranate genotypes for fresh consumption and processing were selected from different regions in Turkey. These promising genotypes also indicate their importance for genetic resources and for breeding purposes in the future.

EVALUATION OF AGRICULTURAL ENVIRONMENT INDICATORS WITHIN THE SCOPE OF AGRICULTURAL SUSTAINABILITY

Tuba BEŞEN[1]*, Emine OLHAN[2]

[1]Batı Akdeniz Agricultural Research Institute, Turkey
[2]Ankara University, Agricultural Faculty, Department of Agricultural Economics, Turkey
*Corresponding author: tubabesen@gmail.com

Abstract

In this work, the concept of sustainability and the indicators of the agricultural environment are explained. In the study, agri-environmental sustainability was assessed by index method in Sinop province Sarıkum Lake basin. The index consisted of ten indicators: ratio of farm operators applied synthetic fertilizer, ratio of farm operators applied pesticide, ratio of farms faced with soil erosion, ratio of protected area, ratio of farm operators who were satisfied with the existence of the protected area, ratio of farm operators making soil analysis, ratio of farm damaged by wild animals, crop diversity, the size of land with the slope more than 20% total land, and number of land parcels. As a result, the level of agri-environment sustainability was found on the unsatisfactory level in Sinop Province, Sarıkum Lake Basin. However, the use of unconscious input in the research area was common, damage to wild animals in the land was high, and amount of protected area was low. Despite the damage of wild animal, satisfaction levels of the farmers' were very high in this area. This result requires a separate sociological investigation. In this basin, supports based on the environment should be extended (support of ÇATAK, organic agriculture, and good agricultural practices), the amount of protected area should be increased to the micro catchment level, population control methods should be developed by conducting a research for wild boar population.

Key words: *Sustainability, agriculture, indicator, index, Sinop.*

Introductıon

Agriculture is the most important sector which provides food for humankind. Increased consumption, global climate change, and increased population make agriculture much more important for humankind than ever. Turkey is located in Mediterranean basin, one of the most affected areas from climate changes according to IPCC reports. For this reason, agricultural studies should be focused on effective natural resources use. In this study, agricultural sustainability, agricultural environment indicators in agricultural sustainability are explained, agri-environment indicators used within the context of EU CAP (Common Agricultural Policy) are mentioned. The agri-environmental sustainability has been revealed with selected area based on agri-environment indicators in Sarıkum Lake Basin, Sinop province, Turkey. The agri-environment index includes ten indicators.

The meaning of sustainability differs from one person to another one. According to Jacobs (1995), sustainability has 386 different definitions (Rigby et all., 2001). The definition of sustainability was introduced by the report first "The Borders of Growth" published by the Club of Rome (Akgül, 2010). Sustainability concept launched in 1972 during the United Nations Human and Environment Conference gained a formal conceptual meaning in the report of Our Common Future in 1987.

The present situation in the world was first announced by Stockholm United Nations Declaration on Human Environment (Anonymous 1972) in 1972, the concept of sustainable development started to be used internationally with the Brundtland Report in 1987 (Anonymous 2016, b). 1992 United Nations Conference on Human and Environment in Rio (Anonymous 1992), 2000 United Nations Millennium Summit on Millennium Declaration (Anonymous 2000) and Millennium Development Goals, 2002 Johannesburg Sustainable Development Summit, The United Nations Conference on Sustainable Development, the Conference on Sustainable Development for the Transformation of the Earth for Humanity and the Planet (Anonymous 2015) emerges as the basis for activities that have evolved in this process and that have made international efforts to ensure that all policies are environmentally sound. These studies, which laid the basis for sustainability at the international level, have shaped policies and practices at a national level.

Sustainability is the main principle of Rio Declaration and Agenda 21, which was established in the United Nations Environment and Development Conference in 1992. According to Agenda 21, the concept of sustainability is multidimensional and includes ecological, social and economic objectives (Anonymous, 2001b). With Agenda 21, the decision to form national sustainability strategies and the sustainability strategies that became a national obligation has been transformed into a strategy that each sector must put forward.

In order to ensure the sustainability of human life and for a progressive development we also need to ensure the sustainability of resources (Harrison 1993). The sustainability of development depends on the sustainability of natural resources (Berkes 1991).

If the increase of human well-being is continuous, the continuity of the environment and natural resources must be ensured. In this context, environmental sustainability is at the forefront and means the sustainability of natural resources. The level of use of resources must not exceed the rate of self-renewal of these resources and also the proportion of released pollutants must not exceed the rate at which natural resources are able to handle with these pollutants (Kaypak 2011).

When assessing sustainability, it is necessary to evaluate the temporal and spatial effects of human activities, as well as the environmental, social, economic and institutional dimensions and their interactions (Anonymous, 2001a). In order to achieve sustainability, social, environmental and economic dimensions need to be balanced (Tschirley 1996).

Three basic components of sustainability, economic, social and environmental factors are taken independently at first. Then, the assessment shows that there is a relation between them. But now Hart (1999)'s approach accepts that environment dimension involves social and economic dimensions (Figure 1).

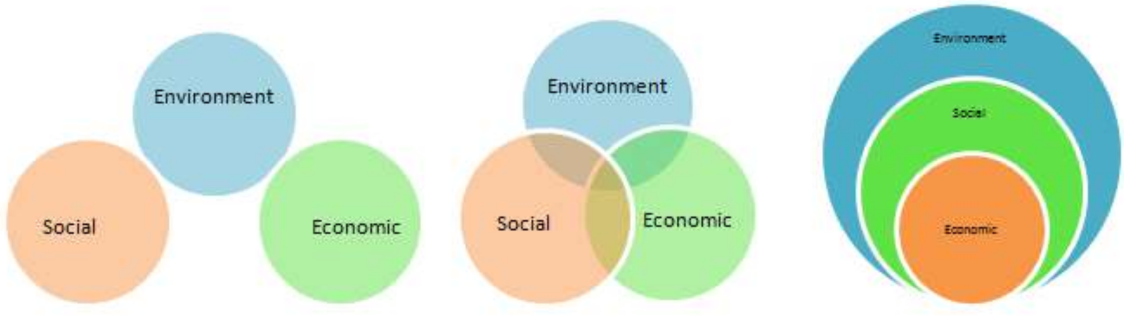

Figure 1 Sustainable development approach

The assessment of sustainability in agriculture is very complex (Gorrie 1999, Andreoli and Tellarini 2000). Many international studies have been carried out on the evaluation of agricultural sustainability by index method. Studies of agricultural sustainability can cover much larger areas such as the region, the country and even the EU from the farm level (Rigby et al., 2001, Vecchione 2010).

The index sizes and indicators, index development methods are different from each other and these studies reveal different approaches in the determination of agricultural sustainability.

Indicators and indices are used to identify and measure sustainability. Operational definitions and indicators in policy decisions is a precondition for the implementation of sustainability (Rennings and Wiggering, 1997). A good indicator should provide many criteria (Tate 2000). Walker (1998) cited the indicator as a set of many features that could be used to quantify a given terrain, watershed or ecosystem conditions (Walker 2002). Meyer (1992) identified the indicators as measurable environmental features that can be observed by field observation, field sampling, remote sensing or by combining existing data (Walker 2002).

The basic functions of environmental indicators are to give clear and simple messages to the public and to non-expert decision makers about what is happening in the environment. The introduction of open messages in this way will enable decision makers to shed light on the most important points in complex environmental issues without getting lost in detail. As complex environmental issues become more understandable, people can expand their understanding of environmental issues while creating a computable format for the creation of environmental policies. It also helps to evaluate economic and environmental issues together (Anonymous 2002). Agri-environmental indicators are useful tools for analyzing the relationship between agriculture and the environment and identifying trends in this evolving interaction (Anonymous 2017a).

In January 2000, the European Commission published the policy document "Indicators for the Integration of Environmental Concerns into the Common Agricultural Policy", which identified a set of agri-environmental indicators to serve the following purposes:

- provide information on the state of the environment in agriculture,
- understand and monitor the linkages between agricultural practices and their effects on the environment,
- provide contextual information, particularly concerning the diversity of the EU's agro-ecosystems,
- assess the extent to which agricultural and rural development policies promote environment-friendly farming activities and sustainable agriculture,
- inform the global assessment process of agricultural sustainability (Anonymous 2017a).

The Commission is currently working on the development and improvement of the agri-environmental indicators. A streamlined set of 28 indicators is under development, close to cooperation with the Member States (Anonymous 2017a).

Bockstaller et al. (2008) describe what different agro-environmental indicators produced in previous years were and how they worked in the development of these indicators. They have examined the applications of different indicator groups in terms of nitrogen loss and pesticide risk. It has been stated that the indicators related to farmer activities may be based on one or more variables, indicating that the indicators can also be transformed into more complex simulation models in the operational area evaluating pollutant emissions. Niemeijer (2002) studied in three approaches to the development of environmental indicators in policy-based and theory-based approaches to policy development. Moore et al. (2014) used information gathered from local, especially in their studies of agricultural sustainability in small-scale agricultural enterprises.

Materials and Methods

The research area is located in the Central Black Sea Region, in the north of Sinop province (Turkey) and in the coordinates of 654000-664000 D and 4642000-4654000 K (36 Zone, UTM, WGS-84 m). Basin includes Sarıkum, Başaran, Gümüşsuyu, Tekke, Yeniçam, Selbeyi and İncepınar villages (Anonymous 2017b).

The material of the study is gathered both from original data which have been collected through the questionnaire form from farmers randomly selected in the province of Sinop, Sarıkum Lake Basin and from the available literature review.

The methods that used in this study were collected in two sub-headings. One is used for data collection method, another one consists of the analysis of collected data. The questionnaires consist of 100 questions under 3 separate headings

In selected sample size, the proportional approach that best represents the main mass is used (Miran 2002, Miran 2003, Sahin and Miran 2007, Cankurt and Miran 2010). The main mass is 413. A sample size of 40% was determined with a 10% error margin in the 90% confidence interval. P = 0.2. The total number of farmers in Erfelek and Merkez districts is 2060.

$$n = \frac{Np(1-p)}{(N-1)\sigma^2_{\hat{p}_x} + p(1-p)}$$

n: Sample size
N: Number of farmers
p: proportion of farmers in the basin
$\sigma^2_{p_x}$: Variance

The sample size was calculated 40 as the proportional sampling Formula was used 90% confidence interval and 10% error margin. Index method used to calculate agri-environment sustainability (Anonymous 2002, Demiryürek et all. 2013, Ceyhan 2010, Vecchione 2010). The aggregation of two or more indicators to form an index comprises four-part process are a selection of variables, data transformation, the weighting of index and valuation of the index (Anonymous 2002, Ceyhan 2010). Transformation methods include normalization, standardization, and distance to policy target analysis of data (Anonymous 2002, Ceyhan 2010). In index valuation, maximum and minimum values are determined from existing real figures rather than a theoretical maximum or theoretical minimum. So, maximum and minimum values were assigned for all indicators and used in equation 1 and 2 (Ceyhan 2010).

$$Indeks = 1 - \frac{[\text{Maximum value}]-[\text{X}]}{[Maximum\ value - Minimum\ value]} \quad Indeks = 1 - \frac{[\text{X}]-[\text{Maximum value}]}{[Minimum\ value - Maximum\ value]}$$

Ten indicators used: ratio of farm operators applied synthetic fertilizer (%), ratio of farm operators applied pesticide (%), ratio of farms faced with soil erosion (%), ratio of protected area (%),ratio of farm operators who are satisfied with the existence of the protected area, ratio of farm operators make soil analysis (%), ratio of farm wild animal damaged (%), crop diversity, the size of land that their slope is more than 20%/total land (%), number of land parcels. Indicators used in this study were field-specific indicators, and implementation in another area may not be correct (Waney et all. 2014). Each indicator weighted equally. From this, each indicator multiplied by ten out of 100. Agri-environment sustainability index was calculated by summing the indicators.

Results and Discussion

Research results showed that sample farms conducted their activities on 64.61 da of farmland, in which only 2.5% of that irrigated consisted of 5 different plots, on average. Farm households compromised 4 people on average. Farm operators averaged 57 years old and their education levels were moderate. The average annual agricultural income per business is 27.257 TL. Agricultural income per decare is 422 TL. Meadow pasture and feed crops constitute 51.17% of farm land.
Agri-environmental sustainability is defined by ten indicators. Environmental sustainability level in the basin is unsatisfactory.

Table 1 Agri-environment sustainability index

Indicators	Value	Index value
Fragmantation farm index	0.44	4.4
Crop diversity.	0.38	3.8
The ratio of farms faced with soil erosion (%).	0.29	7.1
The ratio of farm operators applied a pesticide (%).	0.44	5.6
The ratio of farm operators applied synthetic fertilizer (%).	0.68	3.2
The ratio of farm operators makes soil analysis (%).	0.22	2.2
The ratio of the protected area (%).	0.12	1.2
Ratio of farm operators who are satisfied with the existence of the protected area (%)	0.94	9.4
Ratio of farm wild animal damaged (%)	0.94	0.6
The size of land that their slope is more than 20%/total land (%)	0.19	8.1
Agri-environmental sustainability		45.6

As it can be understood from the indicators, the rate of chemical fertilizer usage is high despite the fact that the number of farmers who make soil analysis in the basin is not much. The ratio of farm operators applied synthetic fertilizer is 68%, the index value is 3.2. The ratio of farm operators make soil analysis is 22%. The addition of fertilizer that does not need soil affects soil structure as well as crop production in the negative direction. This indicator is also an indication of the level of environmental consciousness of the farmers (Kızlaslan and Kızılaslan 2005). However, the levels of pesticide use are high in the basin. Usage of pesticide affects the entire habitat negatively, especially soil and water resources (Olhan 1997, Algan and Bilen 2005, Dişbudak 2008). The ratio of farm operators applied pesticide 44%, the index value is 5.6. The unconscious use of chemical fertilizers and pesticides in these farms located around the protected area may cause much greater environmental problems. As in the world, environmentally friendly agricultural activities are supported in Turkey too. ÇATAK (Environmentally Based Agricultural Land Protection) supports, good agricultural practices and organic farming supports are that kinds of support. ÇATAK scheme aims to protect the quality of soil and water, to provide sustainability of natural resources, to prevent erosion and to reduce adverse effects of agricultural practices on the environment. These three supports should be wide spread in villages located in protected areas and/or in buffer zones of protected areas. In this way, the use of chemical fertilizers and the use of pesticides can be reduced or controlled. Sustainable use of soil and water resources will also be ensured. The high variety of crops in the farms has an environmental positive effect and supports the conservation of bio diversity. Crop diversity index is 3.8. The high level of fragmentation has a positive effect on sustainability at the environmental dimension. Because small-scale businesses produce biodiversity, landscape, environmental protection and local products (Vecchione 2010). The number of parcels on farms ranges from 1 to 12. Fragmentation farm index value 4.4. The high rate of slope is a high risk of erosion in the research area. Erosion, one of the most important problems of agricultural land, affects agricultural sustainability negatively (Doğan 2011). The ratio of farms faced with soil erosion is 29%, index value 7,1. In 19% of the study area, the slope is over 20, while in 81% the slope is below 20%. The index value of slope indicator is 8,1. The low rate of slope in most of these basins is a factor that reduces the risk of erosion. It is advisable to use terracing or soil-covering plants in sloping terrain. The need to protect the Sarıkum Lake Basin due to its rich biological diversity and the fact that it is one of the world's bird migration routes, hosts five different ecosystems. In addition, these properties in the Sarıkum Lake basin make it more inevitable that the existing environmental balance is more fragile and affects all ecosystems hosted by a false application in the field. For this reason, the presence of protected areas within the Sarıkum Lake Basin has a positive impact on environmental sustainability (Demirayak 2002). The ratio of protected area 12%, index value was 1.2. The low amount of protected area in this basin has a negative impact on environmental sustainability. The border of the protected area should be enhanced micro basin level (the border of the research area). The ratio of farm operators who are satisfied with the existence of the protected area quite high (94%), the index value is 9.4. The fact that there is a positive view towards protected areas is a reflection of the importance given to environmental values. This indicator also indicates that the Sarıkum Lake basin will be successful in supporting environmental conditions as one of the landmarks that can be covered by Natura 2000 in terms of its environmental characteristics. The number of wild animals in this basin was also high, with a high level of biological diversity. The wild boar population in the basin was quite high. The wild boar damage was present in 94% of the farms. Index value is 0.6. This shows that wild animals and human conflict are high. The high level of the wild boar populations in the basin suggests that there is also a type of imbalance between species. Populations need to be provided at a certain level to ensure a balance between species and to reduce human animal conflict.

Conclusions

As a result, the level of agri-environment sustainability was found to be on the unsatisfactory level in Sinop Province, Sarıkum Lake Basin. However, the use of unconscious input in the research area was common, damage to wild animals in the farm was high, and amount of protected area was low. Despite the high wild animal damage, farmers' level of satisfaction from the protected area was very high. This result requires a separate sociological investigation. In this basin, support based on the environment should be extended (support of ÇATAK, organic agriculture, and good agricultural practices), the amount of protected area should be increased to the micro catchment level, population control methods should be developed by conducting a research for wild boar population.

Abstract

The research for pesticide toxicity on non-target mammals has been the subject of many studies. Neonicotinoids, including acetamiprid are among the most widely used insecticides worldwide since 1991on several agricultural crops. The main aim of this work is to study the short-term toxicity of acetamiprid on mice liver structure which is the major site of metabolism including detoxification. Eighteen adult male albino mice were divided into three groups, group 1 was kept as control, Which is administered orally with distilled water whereas groups 2 and 3 was administered with acetamiprid. The insecticide was given at two dose levels (1/20 LD50 and 1/30 LD50) through oral route for 15 days. The mice receive water and food every day at will. The liver sections were observed with optical microscope. At the end of treatment, the mice are sacrificed, and the liver is removed for study by light microscopy. Body weight gain showed a non-significant increase in all mice. However, microscopic observation showed significant alterations in the hepatic parenchyma. The histopathological effects included disorganization of the hepatic architecture in some areas, frequent sinusoids dilatation, congestion in the central vein, thickening of portal vein's endothelial membrane, swelling and vacuolization of local hepatocytes in addition to nuclear hypertrophy. These results are in favor of an inflammatory process at the tissue level. According to the results, we conclude that even low doses of acetamiprid can be toxic to adult male mice at the tissue level.

Key words: *Acetamiprid; Liver; Male mice; Histopathology; Toxicity.*

Introduction

With the introduction of the neonicotinoids, an important economic advantage was obtained in the improvement of the agro-alimentary productivity (Maienfisch et *al.,* 2001). Acetamiprid, neonicotinoid insecticide, is an extensively used for crop protection worldwide from the last decade due to its low soil persistence and high insecticidal activity at very low application rate (Pisa et *al*., 2015). The selective toxicity of acetamiprid to insects and not to mammals reported to be due to differences in the structure and binding affinity at the nicotinic acetylcholine receptor (Tomizawa and Casida, 2003). Acetamiprid exposure leads to block a type of neuronal pathway which causes the accumulation of acetylcholine which leads to paralysis and eventually death of the insect pests (Iwasa, 2004). In the mammals, several work announced signs of toxicity of acetamiprid with concentrations lower than the lethal amount (Mondal et *al.,* 2014). These signs comprise morpho-functional deteriorations on the level of certain vital organs such as the liver, the kidneys, the lungs and the brain (Keshta et *al*., 2016) associated with disturbances of biochemical parameters (Shakthi Devan et *al*., 2015). Therefore, the present study was carried out to investigate the effect of two different doses of acetamiprid on histology of liver in male albino mice.

Material and Methods

Male albino mice a rodent species, was selected as experimental animal and were obtained from from the national institute of the agricultural research, Algeria. Mice were kept in cages for at least 7 days prior to dosing for acclimatization to the laboratory conditions in a wire topped polypropylene cage with paddy husk bedding. The animals were maintained for a period of acclimatization under controlled conditions of temperature (22 ± 2°C) and humidity (65 ± 10%) with 12h light and dark cycle. The control and treated animals were given food in pellet form and water *ad libitum*. The Faculty Institutional Animal Ethics Committee approved this experimental protocol.

The mice were randomly selected, marked by tail painting to permit individual identification. After acclimatization animals were divided into three groups consisting of 6 mice each. Group 1 served as control, groups 2 and 3 were treated with acetamiprid doses at the rate of 1/20 LD50 and 1/30 LD50. The doses were administered by oral gavage for 15 days. All groups of mice were weighed and sacrificed. The tissues of liver were removed and immediately fixed in 10% formaldehyde. After the routine procedure, the fixed tissues were embedded in paraffin and 5 µm thick tissue sections were stained with routine haemotoxylin and eosin in order to examine under light microscopy. All data were expressed as mean ± standard error. The statistical significance of the mean differences between control and treated groups was analyzed by ANOVA, with Tukey HSD post hoc test for multiple comparisons. Statistical calculations were performed with the SPSS 11.5 computer program (SPSS Inc. Chicago, Illions, USA). The values of ($P<0.05$) were taken as the cut-off value to consider differences statistically significant.

Results and Discussion

According to the results, it appears that treatment with both doses of acetamiprid does not affect growth in mice (fig.1) and does not produce any signs of toxicity and mortality during 15 days exposure.

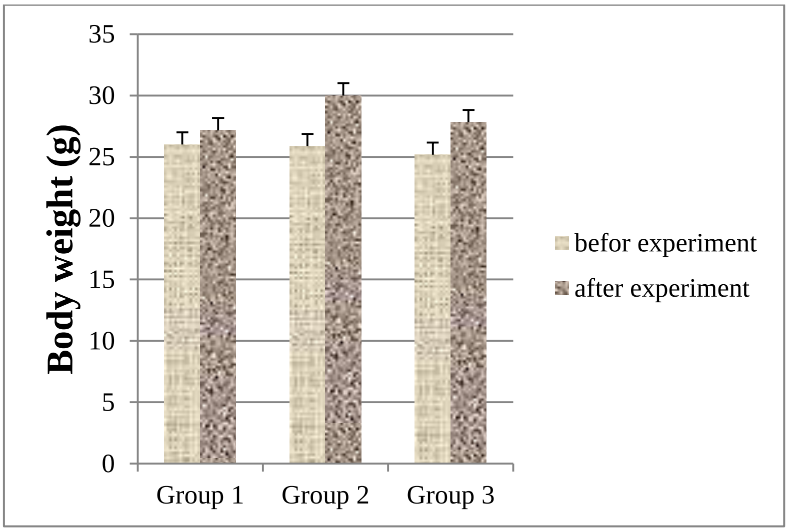

Fig. 1 Effect of acetamiprid treatment on mice body weight (g). Group 1 was kept as control, which is administered orally with distilled water whereas groups 2 and 3 was administered with acetamiprid at the rate of 1/20 LD50 and 1/30 LD50 respectively.

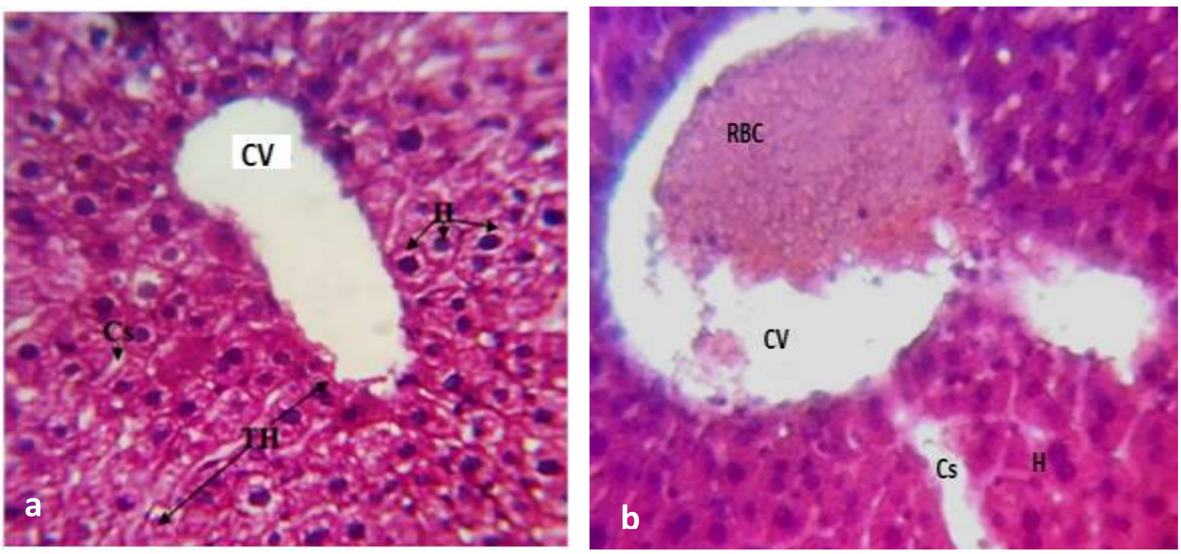
Liver is a target organ for detoxification and is prone to various disorders as a consequence of exposure to environmental pollutants. Histopathological alterations in tissue may be used as a

rapid method to evaluate the toxic effects of chemicals in different tissues and organs (Hinton and Lauren, 1990; Bernet *et al*., 1999). Histopathological examination of liver specimens taken from control group showed normal histological structure of the central vein and surrounding hepatocytes in the parenchyma (Fig.2a). Compared with those of control, liver sections of mice treated with 1/20 LD50 and 1/30 LD50 of acetamiprid for 15 days showed heavily congested central vein and blood sinusoids, mononuclear cell infiltration, hypertrophied hepatocytes and cytoplasm vacuolization. The major histopathological changes in liver following an exposure to acetamiprid were showed in Figure 2 b-f. These results are in agreement with study conducted by Mondal *et a*l. (2014) who reporting no significant changes in liver parenchyma of rats received 25 mg/kg, 100 and 200 mg/kg of acetamiprid.
Our study confirms that lead by Rasgele *et al*. (2015) who noted vacuolar degeneration and sinusoidal dilatation in the liver parenchyma of mice treated with different doses of Acetmiprid. There are a few studies on the histological effects of acetamiprid on different tissues and organs in the different organisms. It has been reported that acetamiprid damaged seminiferous tubules and Leydig cells of mice (Zhang *et al*., 2011); renal corpuscles and tubules in kidney of mice (Zhang *et al*., 2012). However, previous studies also demonstrated that neonicotinoid insecticides such as imidacloprid and thiamethoxam have caused impairment of the histopathological parameters in different organisms. It was reported in rats that imidacloprid induced heavily congested central vein and blood sinusoids and leukocyte infiltration in liver (Mohany *et al*., 2011 and condensation of nuclear material in neurons, degenerative changes in glial cells, congestion in blood vessels and vesicular bodies in different brain regions (Kishandar *et al*., 2013). It is observed in layer chickens a degeneration, coagulative necrosis and hemorrhages in liver and hemorrhages, vacuolar degeneration of tubular epithelial cells as well as focal coagulative necrosis in kidney (Kammon *et al*., 2010). It was also indicated that thiamethoxam caused histopathological changes in liver of rats (Shalaby *et al*., 2010) and mice (Al-Sharqi *et al*., 2012). All the study suggested that toxic responses occur relatively more frequently in the liver, mainly because the liver is a predominant organ for the metabolism, and is also the first major organ to be exposed to ingested toxins, due to its portal blood supply (Popp and Cattley, 1999).



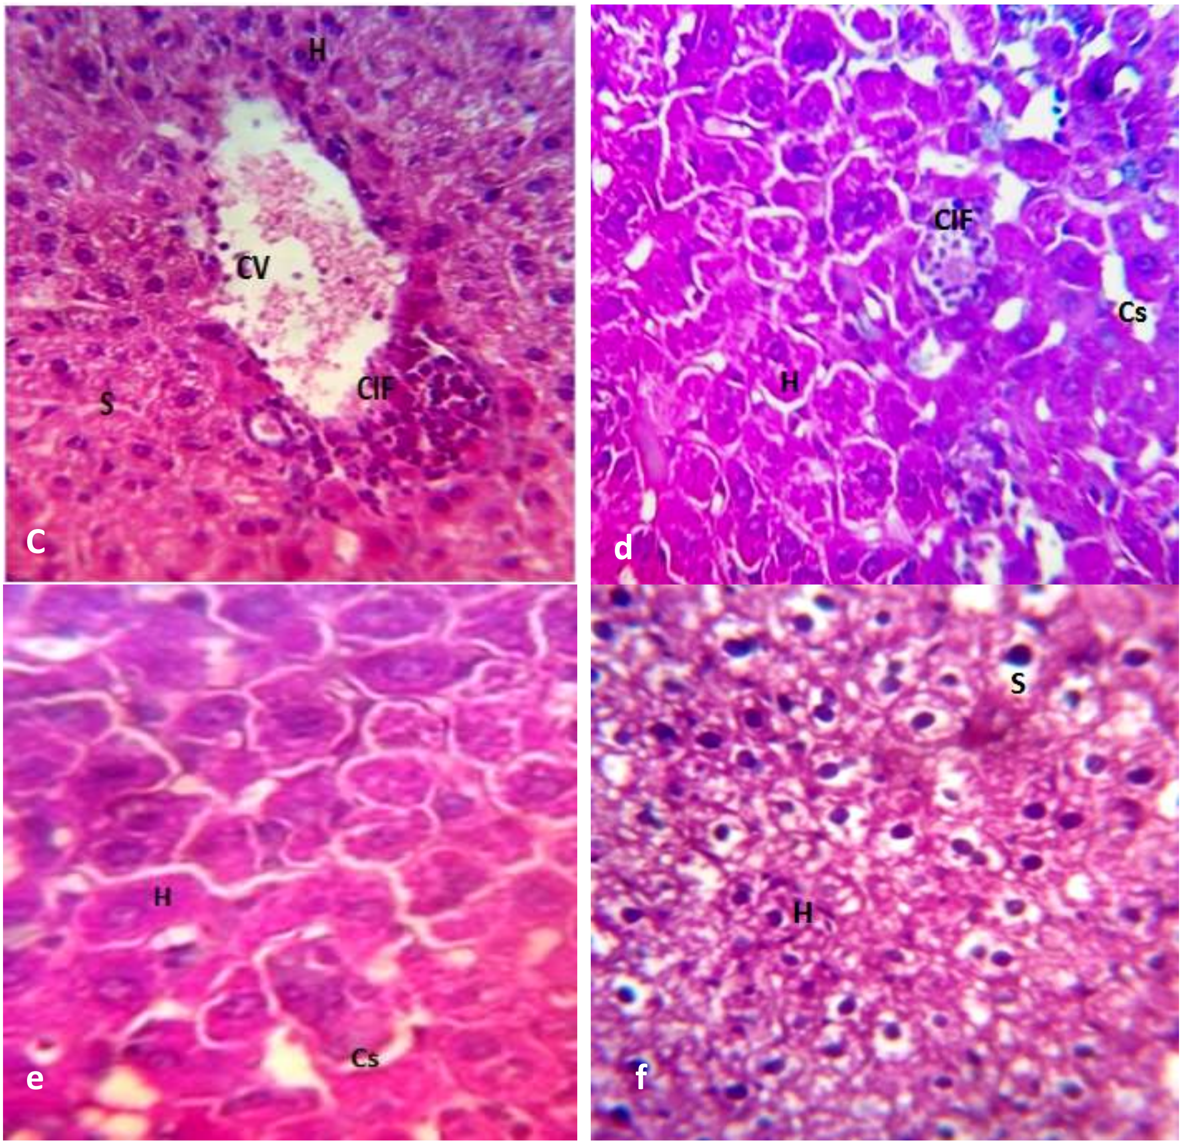


Fig. 2 The photomicrograph of mice liver sections (x400). (a), control group showing normal histological structure of hepatocytes (H) ; (b-f), the liver treated with acetamiprid showing dilation of sinusoids (Cs) with congestion and accumulation of red blood cell (RBC) in vein central (b), cell infiltration (CIF) (c,d), hypertrophic hepatocytes (e) and cytoplasm vacuolization (S) (f).

Conclusion

According to the histopathological findings in this study, exposure to 1/20 LD50 and 1/30 LD50 acetamiprid led to toxicological effects on the liver tissue of mice. These results showed that tissue alterations caused by chemicals in liver may result in functional problems and may lead to cell in animals. However, to gain better insight into the damaging potential of acetamiprid, further studies at molecular level should be conducted.

SCIENCE AND TECHNOLOGY INNOVATION FOR SUSTAINABLE DEVELOPMENT

Atef HAMDY*, Noureddin DRIOUECH, Adel ALY

International Centre for Advanced Mediterranean Agronomic Studies of Bari (CIHEAM-Bari), Valenzano (Bari), Italy

*Corresponding author: hamdy@iamb.it

Abstract

Nowadays, technically and politically, there is a growing international consensus about science and technology (S&T) being a key for achieving global sustainable development. It is well recognized worldwide that international science and technology cooperation initiatives could play an important role in steering developing economies towards sustainable development. However, most of the information we have clearly indicate that very few countries, if any, have the capacity knowledge platforms and resources to do this alone. Initiatives are needed to integrate certain elements, including science and technology and knowledge transfer, in the long run, and to build effective knowledge networks involving the local community and variety of stakeholders, including business stakeholders. To put such initiatives in action, however, requires more effective partnerships, and cooperation between regions, between countries, between institutions and between people. This cooperation should be both North-South and South-South oriented and between governments, academia, and business in both developed industrialized countries and developing ones. Furthermore, such cooperation should be fundamentally directed towards fostering capacity building in science and technology, facilitating effective diffusion of scientific knowledge and technology transfer and towards developing knowledge infrastructure and networks. Those approaches are indeed the driving force that helps in providing a platform appropriate for most countries to learn and find innovative ways of taking ownership of their sustainable development areas, especially ecological problems related to land degradation, climate change and fresh water shortage. In this way, those country would find options and innovative modalities to tackle the challenges of producing more with less water.

Key words: *Agriculture, knowledge transfer, S&T, cooperation, sustainable development*

Introduction

As we enter the twenty-first century the pace of technological advances continues to accelerate, with great potential to improve the lives and livelihoods of people in developing and developed countries, and with profound implications for the global economy **UNESCO (2007).**

Technically and politically it is fully agreed that the road to the promising future, all, we are looking for can be found through science and technology. Being far away from science and technology and or both being neglected from our daily practices are the main factors seriously and negatively affecting any environmental performance improvement ,while even more importantly the raising of the resource efficiency and profitability (**OECDA, 2015**). Indeed there is nothing new in what was mentioned above, hence, on the globe it is well recognized the important means the emerging new innovation technologies are providing to deal with the challenges we are facing .Today despite of the political momentum generated started since the **Rio Earth Summit of 1992** and the follow up and adoption of series of multilateral environmental conventions of key issues the degradation of the global environment goes on. Ecological problems such as lost of biodiversity, land degradation, ozone layer depletion, climate change, fresh water shortages and marine and coastal areas deterioration are more and more frequent. This is the actual situation that demonstrates clearly that if we continue to devour our ecological capital in this way, the bio-capacity of our planet to meet our needs will be seriously jeopardized. Here comes the important role science, technology and innovation could provide being the key elements to be used in order to achieve the sustainable developing goals (SDGs). Indeed, (STI) have the potential to increase the efficiency, effectiveness and impact of our efforts to meet the ambitious of the 2030 agenda for sustainable development and create benefits for society, the economy, and the environment (**OECDB, 2015; ECOSOC, 2013; UN, 2015)**. Now there is consensus that STI is critical to any strategy to improve quality of life and the socio economic and environmental situation of any country as shown in **Box 1**.

ISSUES to the WHAT's and the HOW's of Science and Technology

The What's, those are the today challenges. The what's could be addressing the following issues:

- What technology do we want to encourage and develop?
- What are the technologies that can bring true benefits to society?
- What technologies can be readily transferred to regions where they can be best used?
- What beneficial technologies can be developed locally?
- What technologies show the most promise for the future?
- What types of research do we want to fund?
- What science should be exploring so that they can be applied to provide beneficial technologies?

Answering the above mentioned What's issues will result in an appropriate identification types of technologies emphasizing on those that restore or improve the environment and draw upon natural resources without significant long-term depletion of resources.

THE HOW'S: the further step which is relatively difficult is addressing the how's is uses the representing stand desire policy key elements including:

- How best to establish the right technologies for sustainable development and how to overcome barriers to their implementation?
- How to develop institutions and decision making so as to promote implementation, greater openness and participation by different sectors and a better balance sometimes conflicting aspects?
- How to improve the measurement of sustainability through the integration of economic, social and environmental aspects.
- How best to enhance international cooperation between industrialized developed countries and developing ones?
- How can technologies be transferred around the world and perfected locally to overcome the surrounding barriers?

The above fore mentioned What's and How's will be mostly discussed in this paper.

BOX (1) Sciences and Technology Innovation (STI): Major Impacts

Economically: STI are the main drivers of productivity increase in all sectors, from manufacturing to agriculture and basis of economic growth. Environmentally: STI provide the answer of managing resources and reducing pollution, addressing climate change and preserving bio diversity. Socially STI: help reduce disease and safe guard our health and well being while maintaining the general quality of life.

Science and Technology Innovation (STI): The Policy

The overlap in STI policy occurs due to the existing gaps in policy articulation and design, insufficient capacity to conduct policy evaluation and monitoring, and a lack of coordination between policy making, governmental interventions and business environment. The Policy should give answers to the following issues: (i) How does innovation policy fit into the broader context of industrial development strategies? (ii) What are the most critical areas of coordination? (iii) What lessons can be drawn from countries experiences in promoting policy coordination and how to be applied to other countries?

The main elements of an optimal science policy inclusive of technology and innovation are the followings (**Box 2**)

Box (2): **Optimal Science Policy: Main Elements**

- The linkage between innovation and research
- New initiatives undertaken in view of emergence of blue economy at international, regional national and local levels
- Coherence at the levels of policy-conceptualization and design, and policy implementation and coordination
- Monitoring and evaluation mechanisms
- Innovation practices and research policies across different countries and regions both developed and developing.

STI National Strategies

Those strategies serve several functions in government policy making: First, articulate the governments' vision regarding the contribution of STI to their countries social and economic development. Second, thy set priorities for public investment in STI and identify the focus on government reforms. Third, the development of these strategies can engage stakeholders ranging from the research community, funding agencies business, and civil society to regional and local governments in policy making implementation.

STI: Focusing Issues

There are several issues where STI POLICY should be focusing on among them:

- Prioritize critical areas like agriculture, climate variability and change, communication, energy, food security, environment and water management.

- Promote inter disciplinary research
- Foster use of innovation from both strategic and non-strategic sectors of research
- Invest into young innovators through education training and monitoring.
- Search strategic alliance and partnerships with other nations both in policy and implementation spaces
- Discuss ethical, social, and economic dimensions of emerging technologies.

STI And How Best To Be Effectively Implemented

Despite consensus on the transformation potential of STI there remains a lack of clarity on how best to effectively implement it for inclusive and sustainable development. To address this gap we must develop a common understanding of an effective conceptual framework that will enable STI to be economically and socially inclusive. The critical components of this framework are effective institutions digital infrastructure, appropriate legal and regulatory frameworks and incentives for investment, and a work force to the future. Equally it is critically needed to first chart the practical steps required for balanced and integrated development. In this regard some of the core elements of an effective innovation system for inclusive and sustainable development are as follows: first, to harness the potential of STI for inclusive and sustainable development through engaging all actors in the innovation system to ensure plans incorporate the economic social and environmental dimensions of sustainable development. However this will not happen automatically. Harnessing STI for inclusive and sustainable development will require committed deliberate actions for integrated government approach. Second, effective institutions as they are the foundation of effective STI creation, development and implementation. Indeed institutions define the rules and principles and establish the infrastructure pattern for interactions. Third, committing to and incentivizing investment in STI. This is critical element as for innovators often lack funding at crucial stages will result in preventing basic research as well as early-stage startup (**ECOSOC, 2004; WCS, 1999; Juma and Lee, 2005).**

International CIT Cooperation

In many cases developing countries are simply not technologically capable of using innovative cleaner technology and moving towards the sustainable development in harmony with the nature. Here, it is to be stressed that unless the new technologies are adequately diffuse and applied at the global level, their optimal effectiveness will never be attained. The today's challenge is how to enable the developing countries to properly utilize these technologies through international cooperation although the priorities and needs of the developing countries are not those of the developed ones. Here, comes the important role cold have the international science and technology cooperation between developed industrialized countries and the developing ones. Such cooperation can have several means such as conducting programmes to combat environmental problems, the coordination of collaborative R&D programmes, facilitating technology transfer and through providing the developing countries with the technical and financial assistance they are in real need to. Globally as a blue print it is totally accepted that sustainable development can be effectively achieved only close collaboration among countries Here the question to be raised what are the developing countries major duties, and what are the tasks of developed countries in strengthening international science and technology co-operation ?

Developing Countries Major Duties

Governments of developing countries can play an important role in improving education, R&D and technology policies to enable their countries to more effectively reap the benefits of international cooperation. They could also play a crucial role in the identification of the country specific barriers, needs and steps towards the introduction of environmentally sound technologies. **Hamdy and Trisorio Liuzzi (2004)** reported that in order to solve environmental problems of developing countries, firstly, they must increase their own efforts through implementing strategic structural adjustment programmes and striving for scientific and technological progress. Secondly, they should strengthen international cooperation especially between developed and developing countries and their ability in the research and development of new technologies to be applied and used appropriately in the developing countries in order to enable those countries to solve successfully their environmental problems. In this regard, current international SIT cooperation programmes need to be assessed from the perspective of the needs of the developing countries, and good practices should be identified and diffused.

Developed Countries: Major Tasks

The developed countries can assist the developing countries in vital areas like improving the institutional capacity building and human resources development in the field of environmental technologies (**UN, 2000**). Scientific and technological Capacity building, including personnel training, cooperative research and supply of basic scientific research instruments and apparatus should be actively supported. Those items represent the crucial elements required for effective favorable environmental conditions. Successful long-term partnerships in technology cooperation necessarily require continuing systematic training and capacity building at all levels over an extended period of time . It is necessary to improve conditions and processes on information access to and transfer of technology including state-of-the-art technology and related know-how in particular to developing countries.

Information and communication techniques are a key role in science and technology development (**Soutr & Maclean, 2012**). Access to and capacity to use relevant ICT need to be improved and the appropriate infrastructure to be developed in most developing countries. Further the developed countries can have an effective role in improving and the dissemination of the knowhow by building the knowledge networks those linking business, universities ,research institutions and the local community to build up local, national regional innovation systems. In addition one of the tasks of developed countries is the set up of policies, frameworks conducive to increasing demand for cleaner technologies as well as enhancing the flows of technologies arising from their publicly funded R&D programmes. As crucial task the developed countries should bear their historical responsibilities and play a key role in environmental protection, increase their financial contribution to provide new and additional funding for the developing countries.

International S&T Cooperation: Major Barriers

In both developed and developing countries there are existing barriers hindering the contribution the international science and technology cooperation can make to the diffusion and stimulating environment innovative technology (**Metz *et al.*, 2000, Chase, 1997**). Developing countries often face difficulties in accessing appropriate scientific knowledge and technical skills. Their own knowledge base needs to be strengthened and the qualified human resources that are needed to develop and implement environmental technologies must be updated and increased (**Hamdy, 2003**).

Many of the countries particularly those that urgently need to build STI capabilities are facing tremendous constraints in mobilizing financial resources. These financial commitments are currently lacking even within sectors such as climate change or energy access, where financing innovation capacity needs to become a priority of sustainable development. The international community will have to step in to fill this gap.

The migration of the highly skilled human resources in science and technology is a major constraint towards sustainable development. The brain drain of university trained researchers and engineers exert a serious negative impact in building up effective research and innovation capacities and systems in many countries of the developing World. The challenge is how this trend can be diversified to brain circulation or brain return, which should be able to check the one way drain brain from the developing countries.

Another barrier which is notably lowering the cooperation level between developed countries and developing ones that for the latter the inadequacy of the research and development infrastructure and other framework conditions such as effective research network and suitable funding mechanisms to develop and utilize cleaner technologies. Generally for a greater number of developing countries, there is a lack of mature engineering technology for ecological protection, reconstruction and reasonable utilization (**Hamdy and Sardo, 2002**).

Indeed for several development countries, although small scale experiments on non- harmful production technologies have been undertaken yet they are in short supply as there are a number of technical problems need to be addressed before full-scale practical engineering application can be developed. The experience gained from the realized projects is in sufficient.

Information is a major obstacle towards sustainable development. The issue of access of information has been addressed in the future we want **UNESCO, 2012** and the public right-to know is fundamental in engaging all relevant stakeholders in sustainable development. Sharing and exchange of information across the three pillars of sustainable development can result in synergies and bring increased benefits for a wide spectrum of users from policy makers to the business community to citizens. Mobile learning and the use of mobile devices for communicating data and information for sustainable development has enormous potential offering new avenues for collaboration and open approaches to innovation and providing real opportunities for this innovation to be truly inclusive.

Sustainable Development: The Technological Challenge

According to the UN System Task Team (2011), technological learning and innovation capacity are cross-cutting issues for inclusive development. Meeting the increasingly environmental challenges, requires access to a range of appropriate technologies.. Much of the required technology is already available in the public domain but accessing and linking them to the required knowledge and skills within countries is neither automatic nor costless. It calls for investments in dynamic capabilities, particularly those that shape the ability of national stakeholders to uptake and absorb technologies and make improvements in line with local circumstances. In such a case, the international community as such has a collective responsibility in connecting local technological needs to international technological opportunities which represent a particular challenge for many developing countries. In least developing countries (LDCS) sustainable development implies a well functions STI ecosystems including, interlay, political stability and well functioning institutions ,an educated work force, sound research and education infrastructure and linkages between public and private innovation actors ,enterprises committed to research and development as well as balanced intellectual property rights (IPRS) framework.

Research And Knowledge Production And Innovation

In many developing countries there is still a great need for improving of research innovation activities The dynamic of research and innovation is not a simple response to national policies and national frontiers. rather it is a dynamic that is based upon the social actors that are directly or indirectly involved in the development of scientific activities, individual researchers ,research groups, research institutions ,universities ,high educational institutions, research communities, enterprises, and public polices enacted by governments and inter-governmental programmes. Things are different for innovation than research, since not all innovations are research based. However, it is important to emphasize that for research, as for innovation, the growth of activities follows a cumulative path. This path dependency is particularly important because new research and innovation activities will always depend upon former investments and former experiences. And, this is true both for research-driven activities as well as for innovation and technology generally. All technologies are constructed on prior experiences and this progressive technological learning builds paths made up of accumulated practices.

Technology Diffusion And Transfer Between Developed And Developing Countries

Technology diffusion is essential in realizing sustainable development goals. However the technology may not be widespread use because of its price, the lack of information on the part of firms or other market failures. Technology transfer and capacity building to adapt, absorb and diffuse technologies, and finally, reach higher level of capability for technological innovation are two sides of the same process. The world community has reached the conclusion that ,developing countries are facing sever constraints in their efforts to advance in the transfer of environmentally sound technology EST transfer and cooperation since they lack adequate financial resources and have limited human institutional capacities. In order to support the transfer of ESTs on terms that will promote their use and rapid diffusion, priorities should be given to the following key areas:

i) dissemination of and access to information on ESTs;
ii) institutional development and capacity building;
iii) financial arrangements, technology cooperation and partnerships.

There is a wide gap in the views between the north and south regarding the technology transfer and its development. The north emphasizes the key role of the private sector as a principal conduit through which technology is developed transferred and disseminated. On the other hand south stresses the need to promote and finance for answers. There is no unique solution or single mechanism which could solve the transfer of environmentally sound technologies and corresponding know-how on favorable terms. Enhancing the transfer of ESTs has stimulated a great deal of debate and discussions. However the topic is still searching for answers. There is no unique solution or single mechanism which could solve all the problems related to ESTs transfer between developed and developing countries. Some framing guidelines are missing, those are needed for setting up effective and efficient action programmes to facilitate ESTs transfer, It should be kept clear in mind that technology transfer between developed and developing countries is not a one-way flow of resources. It works best when it builds upon sustained partnerships or cooperative arrangements in which all partners can realize their interests and share responsibilities and benefits over the entire technology transfer process. For developing countries, it is essential to ensure that the technological solutions fit the conditions, needs and capacities of the potential user, and are consistent with community requirements for sustaining economic growth (**Abu Zeid and Hamdy, 2010**).

Indigenous and local knowledge(s) and science(s) for sustainable development

The adoption of the 2030 Agenda by the UN General Assembly on 25 September 2015 open up a unique chance to align indigenous and local knowledge with national strategies and marginalization planning for sustainable development, climate change, conservation agendas, and tackling persistent poverty and marginalization of indigenous people and local communities.

Scientific Advisory Board Of the UN-Secretary General (**UNSGSAB) 2015**; The UN-System Wide Action Plan **(SWAP) 2015**; **AGENDA (AAAA), 2015; UN, 2015**; and The Power of Culture for Development **UNESCO (2012)**, all recognized that traditional knowledge, innovation, and practices of indigenous people and local communities can support social well-being and sustainable livelihoods. These organizations in their meetings on sustainable development and the 2030 new global agenda to take the world on a sustainable pathway reaffirmed and fully agreed that recognition, protection and promotion of indigenous and local knowledge strengthens economic, environmental, social, and cultural resilience within societies and forms knowledge base for addressing critical sustainability problems of the 21 century. In addition they highlighted the synergies between implementing the out-comes of the world conference on indigenous people and the 2030 development AGENDA.

Concluding remarks and recommendations

- Partnerships amongst science and technology communities and indigenous peoples and local communities together with major groups and other stakeholders should be fostered to enhance the implementation of the 2030 sustainable development agenda.

- The widespread and successful EST's transfer to developing countries is in great need to capacity building programmes for managing technological change. Many developing countries continue to lack the level of national scientific capacity including critical mass of well trained scientists, technicians and engineers those are required to generate scientific inventions ;and produce technological innovation ; and to adapt and absorb technologies; In this context ;there is great need for developing and supporting intensive interaction between institutions of education and training and of research development on the one hand and local industries on the other.

- Technology needs assessment (TNA) can be useful tool for environmental technology assessment. TNA can enable the government or the constituencies to identify a portfolio of technology transfer projects and capacity building activities that need to be undertaken to facilitate and possibly accelerate; the development; adaptation and diffusion of EST's in the various developing sectors, Further; it offers opportunities for the collaborations of donners in financing and implementing capacity building projects and in coordinating follow-up activities at the national level.

- Information and communication technologist is at the forefront of technological advances in environmental protection as well as it is also means of spread best practices. Indeed the use of ICT for environmental protection; exchange of experience; information access and technology transfer is becoming an important factor in efforts towards sustainable development. Globally; information technology is no longer restricted to developed industrialized countries either in innovation or application; however in several developing countries still lack the technologies soft ware and hard ware to make adequate use of the rapid development modes of information and communications.

- For the transfer of EST studies have indicated that the problem is not just a lack of financing per se and that the issue more on market development than existence of funds. Considering that this argument is true; particularly within developing countries perhaps there will be no lack of financing. However for most cases the opposite is true and that mobilizing of investment funds have proved to be the major constraint system are all critically important for understanding and addressing complex challenges and opportunities for people and planet .

- Diverse knowledge systems, encompassing the physical and natural science, social science and humanities as well as indigenous and local knowledge are all critically important for understanding and addressing complex challenges and opportunities for people and planet. In as much as biological diversity underpins the resilience of ecosystems ,like wise cultural diversity underpins sustainable development.

ROLE OF TREES IN AGRICUTURAL LANDSCAPE

Ewa ZARAŚ-JANUSZKIEWICZ, Barbara ŻARSKA, Tatiana SWOCZYNA

Department of Environmental Protection, Faculty of Horticulute, Biotechnology and Landscape Architecture, Warsaw University of Life Sciences - SGGW, Poland
*Corresponding author: ewa_zaras-januszkiewicz@sggw.pl

Abstract

Trees and shrubs as the buffer strips play an important role in the landscape, and can be supplemented, if necessary by different landscape structures. For landscape with inadequate or improperly disposed of woody vegetation should be introduced plantings row, belts or clumps. Because the way their location can and should be adapted to the needs of agriculture. The aim of the work was to define the role of trees in shaping the agricultural landscape. The field of research and observation were the fields surrounding the southern boundaries of Warsaw – The Wilanowskie Fields. Observations were made throughout the year. The structure and species composition of the trees were analyzed. On the basis of the observations and the map of potential vegetation, it was proposed to supplement the tree structure to one of the distinctive tree types.

Keywords: *Trees, bounds, buffer strip, landslides*

Introduction

Afforestation, meaning concentrations of trees and shrubs, is an important instrument of protecting and forming agricultural environments, but manners of their introduction should be fitted for requirements of fields. An advantageous influence of afforestation on landscape, distribution from the viewpoint of functions, kind, form, manner of confounding were presented in this paper. It presents most important functions of afforestation in agricultural landscape, first of all, replenishing water in the environment, limiting the erosion of soil and enrichment of landscape.

The trees are primarily farmers' allies in the struggle for better yields. The farm produces a large functional whole with a possibly closed loop of matter. Looking at the countryside, it is necessary to evaluate in it elements such as the size and distribution of fields and the environment: crows, clumps or bushes and trees, watercourses and reservoirs, sequences of arable land and grassland and high woody vegetation, named meadfield trees. Good farming can not do without trees. They are particularly important in the non-forested area, poorly planted with poorly spaced forests, and in areas with light soils, with insufficient rainfall and limited groundwater and soil resources. Trees are an essential element of the landscape, stabilizing the conditions of agricultural production, as:

- they protect the fields from harmful winds on average 15-26%, maximum 50-70%,
- they contribute to the storage of water - they reduce the water loss caused by soil evaporation by an average of 25%, affect the soaking of the soil in the summer and in the winter of its freezing,
- they raise the humidity of the air in the ground layer, ie they increase the condensation of water vapor in the plants, on their surface and in the soil, also due to the greater amount of precipitation,
- limit wind erosion,

- limiting the water erosion, ie the surface runoff of water to the underground advantage which is particularly important in the rippled area,
- they reduce the daily air temperature fluctuations in this occurrence of spring frosts, raise the soil temperature to a depth of 20 cm on average by 0.2°C,
- they are a habitat for the life of many organisms, including useful ones, which help to combat crop pests (biodiversity).

Landslides, strips or clumps should be planted to the landscape with insufficient or inadequately placed vegetation. Since the way they are located can and should be adapted to the needs of agriculture, it should be regarded as the most important tree formation, especially in lowland woodlands.

Material and Methods

The method chosen was:

- study of literature and basic materials concerning the role of trees in the shaping of the agricultural landscape and the role of trees in their functioning,
- field studies based on the implementation of dendrological species of general character - species and localization within the group structure, using the Braun-Blanquet method, general dendrological inventory was carried out with the definition of species composition, horizontal and vertical structure, phytosociological analysis; based on a map of potential and real vegetation, plant selection was made.

Parallel research has been carried out on literature related to the history of trees and shrubs in buffer strips at the borders of Polish research, their role in contemporary agriculture and field research related to the inventory of selected areas, the definition of species and the spatial structure. The study was carried out to formulate indications for the creation of field crops to improve landscaping and to create models that take into account landscaping guidelines.

Fields of field research were selected in the administrative boundaries of Warsaw – the Wilanowskie Fields.

The information collected was the first to implement the typology of trees and spatial structure. Then assigned tree groups were observed to a predetermined type. In the final phase, the spatial and species structure of the examined and observed group was supplemented according to the model developed for the specific tree type and selected species of trees and shrubs according to the habitat and potential vegetation map.

Results and Discussion

Today, agricultural areas in Poland account for about 60%, and trees and shrubs are the most important environmental elements in such a landscape. They along with herbaceous vegetation form a network of exceptionally valuable microbes, which is particularly important in lowland areas, where forest stands are a substitute for forest (Budzyński, 1996).

In the open landscape - non-forested, special attention is given to small clusters of trees, small groves, reeds. The most important in the shaping of the natural balance are not the single trees, but those that form whole systems that connect to the forest surfaces (Bałazy and Ryszkowski, 2001).

In the structure of open and agricultural landscaping, field crops are always elements that fulfill many different functions. Their role to protect sediments and usable land from the destructive or cumbersome effects of climate factors has been appreciated for hundreds of years. The best example of this is the protected network of lines and streaks of trees lines and hedges in the Atlantic belt of Wenstern European countries (Meiggs, 1989). In central Europe

plantings are usually used single or multi-tiered trees and shrubs established to protect crops, settlements, roads, wind, noise, dust (Jakubowski, 1994).
Already in the Baroque, roadside were planned. Avenue plantings stretched straight through the mountains and valleys, fulfilling a unique spatial function as a green belt separating the open landscape. Today, most of these belts have been removed by the widening of roads, withstood usually only those they are growing along local roads (Obmiński, 1975).
In Poland, Gen. Dezydery Chłapowski (1788-1879) was the pioneer. Napoleonic officer, General attending the November uprising, farmer worker who educated shelterbelts England. Chłapowski in the 20's the nineteenth century on the area of 10.000 ha introduced the band of buffer strips. These purposeful plantings of field plants were geared towards improving climatic conditions and reducing wind erosion. Today, this area, with tree-huts established is unique in the country and is located within the Agroecological Landscape Park, founded in 1992 (Ryszkowski and Bałazy, 1998).

Forms, types and structure of trees buffer strips

The trees we distinguish depending on their location, the mutual arrangement of trees and bushes, and the shape and size of the area occupied. We can distinguish the following forms of trees:
single - formerly known as unit, loosely located in the open landscape single trees and shrubs (eg field pear), occupy little space;
rows - trees and bushes linearly arranged, planted in a single row, most commonly found in roadside and floodplains. They may be one or two sides;

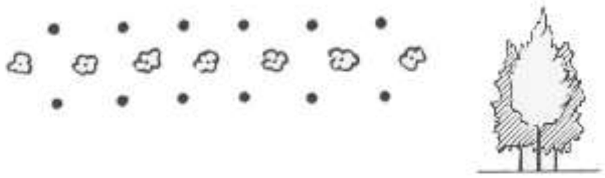

Figure 1. Rows (Hejmanowski, 1964, Meggis 1989).

belts - at least a 2-row width of trees not more 20 m (along rivers, near industrial plants);
group - cluster of trees and shrubs of any shape, with an area of no more than 0.02 hectares, in the group there are several of the same species (frequent on pasture) should be created in the land of agricultural land. The form is also a field fighter. Especially valuable as a living environment for many animals (birds, small mammals, insects);

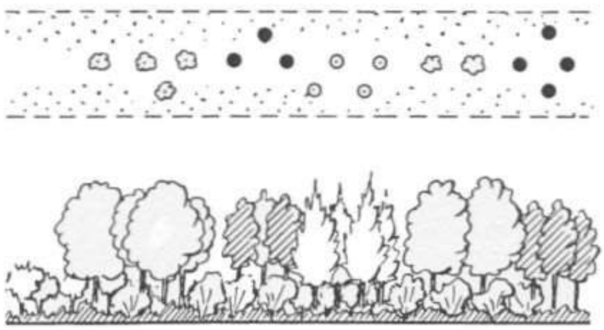

Figure 2. Group trees (Hejmanowski, 1964, Meggis 1989).

clump - trees where they are mixed together within one clump of any shape, the same species of trees, has the same biocenotic properties as grouped trees;

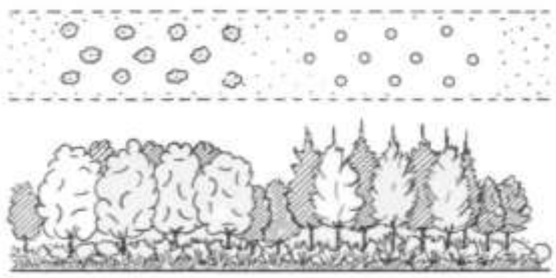

Figure 3. Clump trees (Hejmanowski, 1964, Meggis 1989).

surface - trees above 0.10 ha. Their optimum size is 2 ha. They are planted in fields of different species of trees and bushes, but due to the way they are managed they do not form a forest. They are a kind of refuge to provide shelter and food for many species of birds, mammals, insects (Hejmanowski, 1964).

Structure of buffer strips

The structure of the tree plantings can be called by specifying the relative position relative to each other trees and shrubs in the vertical and horizontal directions. Branches can also be divided in terms of structure differentiation. We distinguish vertical and horizontal structure (Karg, Karlik, 1993):
• the vertical structure depends on the vegetation of the tree forming the tree,
• one-storey - the crowns of trees are situated at a similar level, there are no high altitude differences between them,
• two-storey - the trees form two non-overlapping crown layers,
• multi-storey - most often found in fertile habitats. There is a layer of trees, bushes acting as an undergrowth (their height can not exceed 5 m) and a fleece, which includes herbaceous plants and pods up to a height of 0.5 m (Obmiński, 1978).
Crowns of high, medium and low trees penetrate. In such trees, the aboveground space is better utilized (Karg, Kundziewicz, 1992).
Storeyed building of shelterbelts conforms them to the teams natural variety and brings valuable artistic elements to the landscape and contributes to better development in the same biocenosis plantings, as well as neighboring areas (Hejmanowski, 1964).

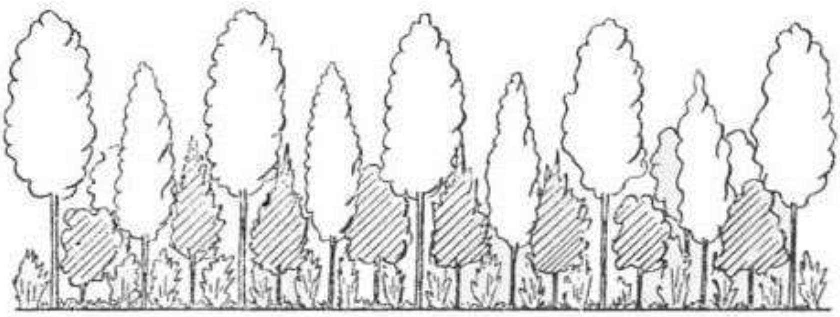

Figure 4. Buffer strip with multi-storey structure (Hejmanowski, 1964, Meggis 1989).

Horizontal structure - we can characterize it by the notion of space and distance.

Scantlings - refers to the group tree plantings, and the belt surface, can be regular with equal distances (eg. square, rectangular), or irregular; It should be dense, similar to that used for afforestation. Trees with a dense grove better fulfill the biocenotic and landscape functions.
Distance - also known as the interval between components; It concerns single-row trees and hedges can be eg 0.8 m (Hejmanowski, 1964)

Buffer strips trees complexes

Buffer strips trees complexes are well-functioning in terms of biocenosis in the environment, improving plastic values in the open landscape. The tree plant is characterized by one-storey construction, short-crowned trees, suitable species selection, which depends on the habitat and character of such a team. The species system should contain 90% of the primary species and 10% of the species. Shrubs in such bands serve as a lining, also serve as a border. Such teams can be created for all types of trees (Hejmanowski, 1964).

Hedges

Shrubs and trees planted strangely to form hedges. Plants grow at low intervals and usually do not reach their maximum height. Hedge hedges should be compact hedges their branches grow up. In the hedges forming the field plants, their spatial structure is important, which should be adequate to the existing environmental conditions. Types of hedges:

- low hedges: not exceeding 2 m high, they are often low shrubs,
- high hedges: *Sambucus nigra*, *Cornus sanguinea*, *Corylus avellava, Rhamnus cathartica* (Kremer, 1997),
- trees hedges: *Fraxinus excelsior, Alnus glutinosa, Carpinus betulus* (Kremer, 1997).

Trees grow mostly in striped form surrounded by shrubs (Kremer, 1997).
Hedges emphasize terrain, are the determinant of space when it is divided. Hedges can have different functions: curtain walls, wind, snow (Jackowska, 2000).
The species composition of the tree is also divided by the number of species they form:

- single species - a tree that forms one species of tree or shrub irrespective of the floor and the number of varieties,
- multispecies - planting consisting of two or more species of trees, shrubs or trees and shrubs.

Buffer strips shaping

In Poland in the nineteenth century, General Dezydery Chłapowski was the first to see the possibilities of shaping agricultural landscapes with the aid of field plants. He drew attention to their effect on wind erosion; he recommended planting protective plants from north and west, but alternating at a distance. He found that the foliage influenced the shaping of the local microclimate. They reduce the evaporation of water from the soil, and increase the humidity (Jackowska, 2000).
The problem of shaping of tree beds in the landscape should be treated comprehensively already at the stage of design and execution. Depending on the purpose we want to achieve, the trees have the required functions (Zajaczkowski, 2005).
Consider all environmental conditions. Forests are often not suitable for forestation. Rare species are also hardly ever used, but for biocenotic reasons, it is worthwhile to use them in small groups.
When creating whole tree-planting groups, it is important to keep in mind the possibility of using ornamental values of particular tree and shrub species. This is a task for landscape

architects, because artistic sense is important here. One can only give general guidelines that should guide the design of such trees:

- do not create monotonous and monotonous single-
- even multi-species trees, but with a large construction on a large surface will look monotonous,
- compositions will be mixed with doped trees and shrubs that can enhance decorative and biocenotic qualities,
- too many species with contrasting leaf colors or crowns, can create a droopy effect,
- too many alien species should be avoided,
- objects (roads, canals) running through forest areas should not be planted (the forest wall is sufficiently bordered);
- should not cut trees and bushes, they should maintain their natural habitat (Hejmanowski, 1964).

Selection of species of trees and shrubs

The selection of trees should be adapted to the soil and climatic conditions of the habitat, and also for the purpose of the given tree. The tree that creates a natural combination of species is not only more resistant to external environmental conditions, but also more aesthetic and viable. Whereas selection does not necessarily have to be limited to plants from one substitute community, vegetation does not have to have the same species composition as the naturally occurring or semi-natural phytocenoses (Wysocki, Sikorski, 2000). Buffer strips should have such a species composition that their properties can fulfill specific functions. It must be taken into account that trees and shrubs will not be provided with care as they are planted in the city. Therefore vitality and resilience to adverse environmental conditions are important. Such characteristics are predominantly native species (Zajączkowski, 2005). When making selections also from plants of foreign origin, you need to know exactly what their requirements are, in their case no origin is taken into account, but the possibility to perform specific functions in the project of our plantation (Wysocki, Sikorski, 2000).
Native species planted in a suitable habitat are characterized by optimal growth, high health and well tolerated by unfavorable conditions. The pattern, therefore, should be planted spontaneously. The bushes that make the species physiologically consistent with the habitat are more resistant to external factors, are more vigorous and aesthetical, thus increasing the stability and resistance of all phytocenoses to unfavorable factors. Habitat requirements mainly concern fertility and humidity (Wysocki and Sikorski, 2002).
The selection should be based on native species that are better suited to our conditions, both habitat and climate. Introducing alien species to naturalistic plantings is quite risky. Selection of species for existing plants depends on ecological conditions and aims to improve their stability, climate and decorative features. Selection made on the phytosociological basis requires knowledge of the habitat.
I defined the habitat based on the map of potential vegetation. Its use in shaping the selection is necessary. Potential vegetation is an abstract state to which the vegetation in the area is tending. In phytosociological terms, it is simply an expression of habitat conditions. Knowing from the map the potential vegetation can roughly be defined, so the characteristics of the habitat. Habitats where, if not the final community, there are substitute communities within the circle of substitute communities. Their type depends on the external impact to which the subject is subject, eg cattle grazing, mowing, stripping (Wysocki, Sikorski, 2002).
Today's potential natural vegetation in the Wilanowskie Fields a hail subcontinental linden - oak - hornbeam (*Tilio - Carpinetum*) var. typical for central Poland (Wysocki, Sikorski, 2000, Matuszkiewicz, 2006).

Within the Wilanowskie Fields prevail phytocenoses shrubby, meadow, grassland and ruderal belong to the circle of communities foster hornbeam forests (*Tilio - Carpinetum*) and alluvial ash - alder (*Circaeo - Alnetum*) as a result of specific water conditions in podnuża slope (exudates), in depressions off-road, near ditches. Habitat is there a more moist, ground water comes up to almost the same surface.
State is a target species selected supplement composition woodlots (increase in species diversity), so that:

- improve their stability (also by increasing the area of the trees),
- structure,
- climatic function,
- decorative values.

The middlefield buffer strips are a bit like a forest border bordering the open field. There are two distinctly different environments here. Where the forest ends and a meadow or arable field begins, plants and animals from the forest and the agro-ecosystem meet. The mixed communities of trees and bushes can be considered as a very narrow and stretched form of forest consisting almost exclusively of the edge. There are many phenomena typical of the contact between the two environments. Trees are specific, they do not belong to forest communities or shrubs. They are a mosaic composition of fragments of forest vegetation, scrub and peat. So the choice should take that into account.
Species, trees and bushes, selected for bushes, and bushes from the *Pruno spinosae - Crataegetum*, are the clans of the *Rhamno - Prunetea* Rivas Goday et Carb. 1961, from the forest shrub community and the association Berberidio Br.-Bl. (1947) 1950.

General characteristics of the buffer strips present in the Wilanowskie Fields

Basing on Wysocki, Sikorski (2000) and Matuszkiewicz (2006) the buffer strips in the Wilanow Fields are relatively young planted. The dominant species are poplar species: Populus tremula, Populus alba, Willow ivy (*Salix caprea*). In the eastern part of the plots, many meadows that are not mown are overgrown with groves composed almost entirely of the birch (*Betula pendula*).
Clumpet-like foliage is made up of species such as various species of poplars and willows, *Pyrus pyraster, Crateagus monogyna*, and common woodpecker (*Padus avium*), *Tilia cordata, Quercus robur*, ash (*Fraxinus excesior*), black alder (*Alnus glutinosa*), are characteristic species of the gras.
The shallow bushes mainly produce species such as willow, poplar and black alder (*Alnus glutinosa*). In the southern part of the planted stripes mainly consists of white willow (*Salix alba*) with a mixture of ash (*Fraxinus excesior*). The rows of trees are poplar (*Populus nigra*), small-leaved lime (*Tilia cordata*). Many individual trees form monstrous multi-stage hawks (*Crateagus monogyna*) and *Quercus robur* L.

The buffer strips subdivision

As a result of inventory during field work, the following tree sharing was made:

- hedges - trees in the form of small clumps and tight draws,
- trees - multi-row tree growing between the fields,
- row crops - single row trees on the road,
- watering - shrubs occurring at watercourses: canals and drainage ditches, where water is maintained all year round, trees that have an indirect belt or clump character,
- single middle fields trees.

Characteristics of the existing state on one example

Tree lying in the north of the Wilanow Fields, a small tree consisting of a picturesque white willow. It grows at a small ditch, but not filled with water even in the spring.
Tree species: *Salix alba*.
The shrub layer represents the species: *Crataegus monogyna* (single-hawed horn) and *Sambucus nigra* (without black).
Climatic function: The tree is in the north-south direction and functions properly.
Habitat: fertile and with increased humidity at the ditch.

3. *Sambucus nigra*

Species sellection:
1.*Salix alba*
4. *Salix caprea*
5. *Salix viminalis*

Figure 9. The status of the proposed selection.

Conclusions

Lastly, it is important to add that there are different types of foliage between fields:
1. Single - single trees (solitaire), eg field pears or shrubs,
2 Rows - linearly arranged trees and shrubs, eg along roads,
3. Pulleys - a 20 m wide strip of breadth, eg along rivers or around plants,
4. Group - clusters of trees and shrubs of < 0.02 ha, eg pasture,
5. Clump - clusters of trees and bushes with an area of 0.02-0.1 ha, eg,
6. Surface - trees with an area of > 0.1 hectares, which due to the way of management do not constitute a forest, such as woodland wasteland.

Assuming and cultivating the foliage, one should know that:
• The tree index should be about 10 trees per hectare;
• Well-planted along watercourses and in the field;
• Plants should be planted firmly so that they do not bounce off the wind but absorb it (the most effective are 2 or 3-storey woods, forming the wall from the ground to the tree top);
• It is best if the trees are made up of species that are not intermediate hosts of pests and diseases of plants (eg beetle, cherry, buckthorn); Birch, ash, maple, lime, willow, poplar, as well as bushes such as black, hazel, crumb, plum or many others.

Shaping a buffer strip the instructions below must be realized:
1. Avoid creating single-layer trees, giving the impression of a template and monotony.
2. Trees, even multi-species, but with a template structure, on large spaces, especially on roads, are also monotonous.
3. The variety of wood-based can be contributed by the doped species as so-called. Interfering elements: their role may be double because they may be biocenotic species.
4. Avid species of contrasting colors and shapes should be avoided.
5. It would be advisable to avoid the use of too much exotic and exotic species in the woods; They can be reduced to barnyards and, if necessary, special plantations.
6. Objects such as roads, railways, rivers, canals, running through forest areas, should not be planted, since adjacent forest walls are aesthetically sufficient border.
7. The trees and shrubs in the trees should have a specific natural habit; Making them artificial shapes by crown molding or often, unfortunately propagated clipping hedges to give them forms of geometric bodies should not occur in the landscape.

Abstract

Mercury does not undergo the biodegradation, so it persists in the environment for a long period of time. It is easily soluble in soils and is able to migrate deep into the profile. Mercury and its organic compounds are included in various specimens such as plant protection products, fungicides and phosphorous fertilizers (0,01-1,2 mg $Hg \cdot kg^{-1}$) and nitrogenous fertilizers (0,01-1,2 mg $Hg \cdot kg^{-1}$). The aim of these studies was the assessment of the mercury content in soils with intensive agricultural impact. The research was carried on soil samplers originated from plough land after using nitrogenous fertilizers and manure. Soil samples were obtained from four corners and from the middle of 10 x 10 research area and, then, a mixed sample was created. Samples were obtained from two depths -0-20 cm and 20-40 cm. In samples obtained with that technique the texture was marked using the laser method, organic carbon content using the carbon analizer and nitrogen, pH by the potentiometric method in the KCl solution with 1 $mol \cdot dm^{-3}$ concentration and H_2O, $CaCO_3$ using Scheibler's method, mercury using AMA 254 analizer, statistic analysis Statistica 12.0. On the basis of the texture analysis examined soils were ranked among sandy loam. Content of fraction ø < 0.002 mm was ranged between 3.93-5.19%. They were distinguished by C org. content within range 1.79- 7.2 $g \cdot kg^{-1}$ and pH_{KCl} within range 6.02-7.72. Mercury contents were within range17.72 to 30.55 $\mu g \cdot kg^{-1}$. Mercury contents were balanced in examined soils. In spite of the established mercury with fertilizers, the concentration growth was not declared in the examined soils.

Keywords: *agricultural soil, mercury, nitrogen fertilizers*

Introduction

Toxic elements such as mercury are natural components of earth's crust. Modernly it may be stated, that the amount of mercury in soils is 2-3 times higher than in pre-industrial era (Monteiro, 1995). World annual emission of this metal is in range from 4400 to 7500 tons (Wojnar, 2006). The average content of mercury in atmosphere is in range from 1,2$ng \cdot m^{-3}$ to 4,0$ng \cdot m^{-3}$ (Szynkowska 2003). The average content of mercury in European soils is estimated at the level of 0.02-0.15 mg·kg-1 (Freedman, 1989; Mihaljevič, 1999). The content of this element in surface horizon of soils located in undeveloped areas in Europe is 0,037 mg·kg-1 (Salminen, 2005). Plants absorb mercury directly from the soil as well as from the air. Absorbed amounts mostly depends on the form of occurrence of this element, but also on the species of absorbing plant (Malczyk and Dąbkowska-Naskręt, 2001). The use of mineral and organic fertilizers provides delivery of essential nutrients to the soils. It also causes delivery of usually toxic and undesirable heavy metals and trace elements to soils. The content of mercury in phosphoric fertilizers ranges from 0,01 to 1,2 $mg \cdot kg^{-1}$, while in nitric fertilizers ranges from 0,3 to 3,0 $mg \cdot kg^{-1}$. Usually responsible for the amount of this element

in nitric fertilizers is ammonium sulfate (VI). In Poland phosphoric fertilizers originates mostly from phosphorites and apatites. Mercury also occurs in agriculture as a supplement to seed mortars and plant protection products. The main factors contaminating agroecosystems are: industrial waste, insecticides, herbicides, mineral fertilizers originated from contaminated deposits (Filipek, 2003; Kopeć and Gondek, 2009).
The aim of the study was to estimate the content of mercury in soils, after the application of organic and mineral and fertilizer plant protection products.

Materials and methods

Research material was collected from soils from agricultural soils from the village of Kościerzyn Wielki (Poland) with the following geographical coordinates 53° 12′ 39″ N, 17° 15′ 34″ E . The material was collected in October 2016 during 2 days of outdoor work. Soil samples were obtained from four corners and from the middle of 10 x 10 research area and, then, a mixed sample was created. Soil samples were collected at 11 points. Samples were obtained from two depths -0-20 cm and 20- 40 cm (Fig.1).

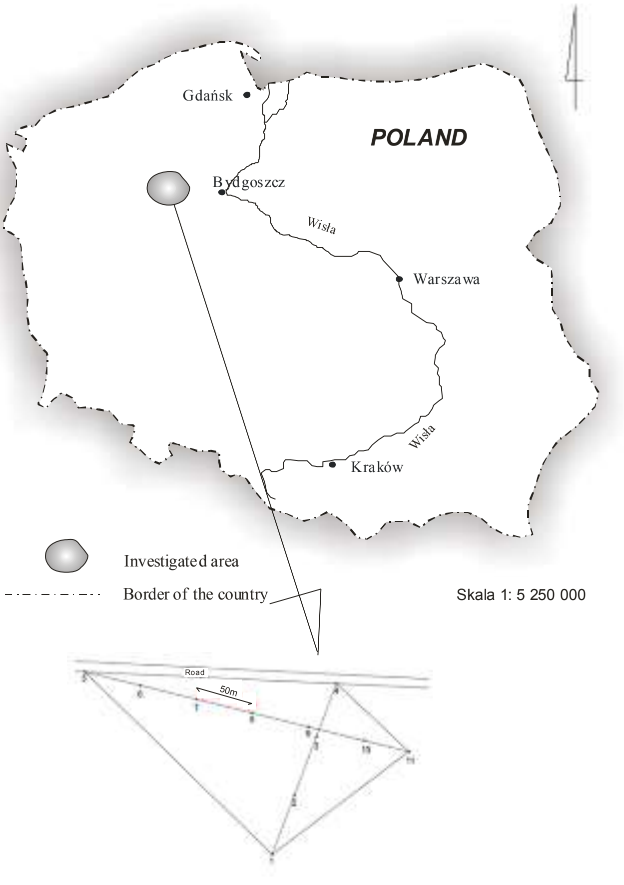

Fig. 1 Location of research points

In the air-dried soil samples, crushed and passed through a 2-mm sieve, the following analysis was conducted: pH using a glass electrode in a 1:5 (by volume) suspension of soil indeionized water (pH in H_2O) and again in 1 M potassium chloride solution (pH in KCl) (ISO 10390: 2005), total organic carbon content (TOC) using the carbon analizer and nitrogen, carbonate content in calcimeter according to the volumetric Scheibler's method, soil texture by laser diffraction method using a Mastersizer 2000E (ISO11277:2009) and mercury using AMA 254 analizer. Statistical analysis of the results was calculated in the Statistica 12.0 for Windows Pl software. All analyses were conducted in three replicates and the validation of the results was based on the certified materials (reference soil sample TILL-3 and SO-4 (Canada Centre for Mineral and Energy Technology). The following organic and mineral fertilizers were used on researched soils: ammonium nitrate, urea, bovine manure.

Results and discussion

The analysis of texture allowed classification of the investigated soils into sandy loam (USDA 2016). The percentage of sand (ø 2.0-0.05 mm) ranged from 55.37 to 62.18 %, silt (ø 0.05-0.002 mm) from 33.52 to 42.93 % and clay (ø< <0.002 mm) from 3.96 to 5.19 % (Table 1).

Table 1. Percentage of fraction in diameter [mm]

No	Depth [cm]	Texture [%]

The granulometric composition affects the transformation of Hg in soils, which is related to the ammount of clay material [Boszke et al., 2004]. The content of total organic carbon (TOC) ranged from 1.79 to 7.2 g kg^{-1} in surface samples and from 0.76 to 6.05 $g \cdot kg^{-1}$ in subsurface samples. In the analysed samples pH_{H2O} ranged from 6.46 to 7.73, while pH_{KCl}

from 6.02 to 7.62 in surface samples and pH_{H2O} ranged from 6.57 to 7.8, while pH_{KCl} from pH 6.01-7.72 in subsurface samples. These are worths typical for soils i the researched area. (Wiśniewski and Wojtasik 2014). The content of CaCO3 ranged from <1% to 9.3% (Table 2).

Table 2. Selected physicochemical properties and total content of Hg of soils

No	Depth [cm]	TOC [$g \cdot kg^{-1}$]	pH		$CaCO_3$ [%]	Hg [$\mu g \cdot kg^{-1}$]
			H_2O	KCl		
1.	0-20	6.95	7.53	7.46	<1%	29.68

	20-40	4.46	6.72	6.39	<1%	27.71

The total content of mercury in analysed soils was ranged from 17.72 to 30.55 $\mu g \cdot kg^{-1}$. In surface samples content of total Hg ranged from 17.74 to 29.69 $\mu g \cdot kg^{-1}$ and from 17.72 to 30.55 $\mu g \cdot kg^{-1}$ in subsurface samples (Table 2). The highest values were determined in surface horizons. were significantly enriched in organic matter. It is commonly known that the crucial parameter in mercury transformation in the environment is the content of organic matter (Dmytriw et al. 1995; Henderson et al. 1998).

Statistical analysis of the obtained results confirms this dependence. The simple correlation analysis allowed to state a significant positive correlation between the content of mercury and the content of C-org. (Table 3).

Table 3. Corelation

Corelation	Clay fraction	pH H_2O	pH KCl	TOC $g \cdot kg^{-1}$
Mercury	- 0.48203	0.051389	0.126466	0.659096

According to Polish Minister of the Environment Regulation (1.08.2016).concerning soil quality standards and earth quality standards the analyzed soils were classified as not contaminated with mercury. Currently in Poland on the basis of the Regulation of the Minister of Agriculture and Rural Development (2008), the amount of contaminating components in organic and mineral fertilizers and in plant growth aids cannot be higher than 2 mg Hg.

Determination of natural mercury content in soils is difficult to estimate due to the presence of anthropogenic contaminants. Concentration its form and transformations depends on many factors such as the quantity and quality of soil colloids. surface area. pH. sorption capacity. redox conditions or microbial activity. The main properties that lead to transformation of this element in soils are affinity to sulfur compounds, organic matter and volatile properties of elemental form (Yin et al., 1996). Distribution of mercury was mainly the result of antropopression. Alkaline conditions and low organic matter content in studied soils favoured the retention of Hg species by soil. Furthermore, low organic matter content decreases the formation of soluble organic complexes (Lafont et al. 2013).

Mercury contents were balanced in examined soils. In spite of the established mercury with fertilizers, the concentration growth was not declared in the examined soils.

Conclusion

The total content of mercury in the investigated arable soils ranged from 17,72 to 30,55 μg·kg-1. In the surface horizon the content of this element ranged from 17,74 to 29,69 μg·kg-1, and in subsurface horizon from 17,72 to 30,55 μg·kg-1. These values are normal for the occurrence of this element in soil, which does not eliminate this soil from the agricultural use. It needs to be stated that the use of plant protection products and mineral and organic fertilizers does not influence the content of mercury in soils from the investigated area.

Abstract

The soil salinity which affects the plants is the soil water salinity i.e. the EC of soil water absorbed by soil particles which remains within the soil components against the gravity forces, not the EC of soil water extract which is the excess water added to the soil to fill the gaps in the soil volume. In this study the soil water was extracted from the soil after the irrigation practices by using suction probes which were situated at 20, 40, 60 and 80 cm depth of soil columns and the salinities were measured by EC meter (YSI3200), and analyzed Cl- by using ion chromatography (Dionex 1600) system. On the other hand, the EC of soil water was simulated by using HYDRUS-1D mathematical model for the same depths of soil and for the same irrigation times.

Experiments were conducted in 40 cm diameter and 115 cm depth soil columns using with 5 irrigation water salinities (0.25-control, 1.5 and 3.0 dS m^{-1} with $NaCl+CaC_2$ and with $NaCl+CaSO_4$ salts), and two leaching fractions (15% and 35%) with initially saline silty-clay ($EC_{e1/2}$=1.9 dS m^{-1}) soil.

The results were evaluated using MAE, RMSE, RE, and R^2. Results showed that the HYDRUS-1D simulations were significantly close to the measured salinity and Cl^- values and thus HYDRUS-1D simulations can be used successfully for determining the soil salinity and Cl^- changes due to the irrigation water salinity and leaching fractions in sandy-loam soils.

Introductıon

Irrigated agriculture is by far the greatest user of water on earth. The limits to the availability of land, and especially of water, necessitate the careful use of these resources, particularly the efficient use of water in irrigation.

In arid and semi-arid climate throughout the world, in irrigated areas, salinization is the most widespread problem, due to the presence of various ions in irrigation water. Salinization generally occurs when salts accumulate in the soil profile at a hazardous level, depending on the relationship between irrigation applied, precipitation, evapotranspiration, and leaching fraction. When the concentration of salts exceeds a level harmful for crops, yields decrease. It is inevitably that some salts accumulate in the root zone since all waters used for irrigation contain soluble ions. The higher the content of salts in irrigation water, the faster the process of soil salinization. Evaporation and transpiration are the predominant mechanisms causing the accumulation of salts in irrigated soils. Both evaporation and transpiration processes remove water from the soil, while leaving salts behind and increasing their concentrations in the remaining soil water. Therefore, the higher the evaporation and/or transpiration rates, the faster the soil salinization (Corwin et al., 2007; Gonçalves et al., 2006).

Salinity restrains root water uptake of plants by increasing the osmotic pressure in soil water. Thus making it more difficult for plants to extract water from the soil. Some components of salinity may cause specific-ion toxicity and imbalance the nutritional stability of plants. In addition, the salt composition of soil water influences the composition of cations in the exchange complex of soil particles, which may significantly influence soil permeability and tilth (Yurtseven and Sönmez, 1992; Corwin et al., 2007).

Soils not only contain a mixture of salts, but the distribution of these salts is not uniform spatially, nor constant with a soil depth and/or time (Hoffman and van Genuchten, 1983). Excessive salts accumulated in soil profiles of irrigated lands can be leached out by adding more water than required to meet the evapotranspiration needs of the crops. The ratio of additional irrigation water, with respect to evaporation and transpiration, is usually expressed as a leaching fraction (*LF*) or a leaching requirement (*LR*), which are identical mathematical expressions, but with different meanings (USSL Staff, 1954; Rhoades, 1974).

Many methods are available to determine the impact of irrigation water quality and existing farm irrigation management in soil salinity. The most precise assessment of salinity is taking soil samples and carrying out laboratory analyses of salinity and its components using several types of laboratory instruments and methods. However, classical methods of evaluating soil salinity are time demanding, expensive, and require a lot of effort, yet cannot completely cover the spatial and temporal variability at the field scale (Rasouli et al., 2012).

Mathematical models that can consider various soil, climate, and crop factors have been suggested as useful tools for evaluating the optimum management strategies for saline conditions (Ramos et al., 2011; Rasouli et al., 2012). A variety of analytical and numerical models have been developed during the past several decades to predict water and solute transfer processes between the soil surface and groundwater table. The HYDRUS-1D software package (Šimůnek et al. 2008) is one of such models simulating water movement and solute transport in the soil. The objective of this study is to use HYDRUS-1D to analyze salinity changes and solute transport in soil columns irrigated with waters of different quality at different leaching rates and to assess its applicability for practical applications.

Material And Methods

The experiment was held in Ankara University Agricultural Faculty Campus, between June 9th and September 16th with sunflower. Lysimeters were set up with corruge PVC tubes of 40 cm diameter and 115 cm height. The soil, was provided from the top 20-60 cm profile of the surrounding cultivated area and sieved and put into lysimeters in equal amounts according to their bulk density. The soil used was sandy-loam and its bulk density is 1.35 g cm^{-3}, its pH is 8.03, its ECp (at 1:2 saturation) is 1.92 dS m^{-1}, its field capacity is 25.1%, and its wilting point is 15.2%. The sunflower used was “Meriç” which is an original variety from Turkey.

A total of 45 lysimeters with 5 salinity levels and 3 irrigation amounts as treatments with 3 replications were used. Experiments were conducted as a factorial experiment in fully randomized design. Irrigation water salinity levels were S_1=top water (0.25 dS m^{-1}), S_2=1.5 dS m^{-1} $NaCl+CaCl_2$, S_3=3 dS m^{-1} $NaCl+CaCl_2$, S_4=1.5 dS m^{-1} $NaCl+CaSO_4.2H_2O$ and S_5=3 dS m^{-1} $NaCl+CaSO_4.2H_2O$. Irrigation water was applied with a limited irrigation (75% of required amount) and with leaching fractions of 115% (L_{15}) and 135% (L_{35}). Drainage water was collected from the cups which were previously put at the bottom of lyzimeters.

The experiment was completed with 8 irrigations during growing season with the usage of 40% of available soil water. EC measurements were taken with ECmeter (YSI-3200) according to USSL (1954). The anion analysis were taken via ion chromatography (DIONEX IC-1600) apparatus according to Anonymous (1993).

To collect the soil solution samples, 4 suction probes were put into the lyzimeters at the depths of 20, 40, 60, and 80 cm, with leaching treatments of L_{15} and L_{35}, and the samples were taken during irrigation. The results were than compared with those obtained by running HYDRUS-1D simulation model.

The HYDRUS-1D program numerically solves the Richards equation for variably-saturated water flow and the convection-dispersion equation for heat and solute transport. The program may be used to analyze water and solute movement in unsaturated or fully saturated porous media.

This study used the UnsatChem module (Šimůnek and Suarez, 1994) of the HYDRUS-1D software package (Šimůnek et al., 2008), simulating the major ion chemistry/transport and carbon dioxide transport.

In addition to a visual check, field measured values were compared with the results of the HYDRUS-1D simulations using the mean absolute error (*MAE*), the root mean square error (*RMSE*), and the relative error (*RE*) which are defined as follows;

$$MAE = \frac{1}{N}\sum_{i=1}^{N}\left|O_i - P_i\right| \tag{3}$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}\left|O_i - P_i\right|}{N-1}} \tag{4}$$

$$RE = \frac{RMSE}{Obs_{avg}} \tag{5}$$

where O_i and P_i are observed and model-predicted values in units of a particular variable, N is the number of observations, and Obs_{avg} is the mean observed value. In general, $RMSE \geq MAE$. The degree at which the *RMSE* value exceeds *MAE* is usually a good indicator of the presence and extent of outliers, or the variance of the differences between the modeled and observed values (Legates and McCabe, 1999; Kobayashi and Salam, 2000). *RE* was used to evaluate the quality of the *RMSE* value. The simulation is considered to be excellent when a relative error is less than 10%, good if it is greater than 10% and less than 20%, fair if it is greater than 20% and less than 30%, and poor if it is greater than 30% (Loague and Green, 1991).

Results And Discussion

In this study the soil salinity (EC) and Cl^- results were taken into consideration and compared with the HYDRUS-1D simulation values due to EC being the main parameter to explain total soil salinity and Cl^- being the most movable, i.e., leachable ion in the soil. Statistical parameters enabling us to evaluate the HYDRUS-1D modelling results for EC and Cl^- are given in Table 1, according to the treatments.

Generally, RMSE values were greater than MAE values. Conversely RE values were variable. The RE values are for 20 cm depth between 0.07-0.22, for 40 cm depth between 0.83-1.06, for 60 cm depth between 0.99-1.36 and for 80 cm depth between 0.03-0.49. The small values show that the measured and simulated values are consistent (Yurtseven et al 2013).

The graphics of measured and simulated EC and Cl^- values for 1st, 3rd, 5th, and 7th irrigation applications are shown in figures 1, 2, 3, 4, and 5. In all graphics, the measured and simulated values of EC and Cl, showed to be in sync, i.e., there was a good compatibility. In other words, HYDRUS-1D simulated the EC and Cl values very closely to that of the measured values.

Measured and simulated values compared with the R^2 (coefficient of determination) statistic as well. This R^2 statistics for EC and Cl^- are given in Table 2. Generally, the R^2 were considerably high, the average value for EC was 0.826, and the average value for Cl^- was 0.952.

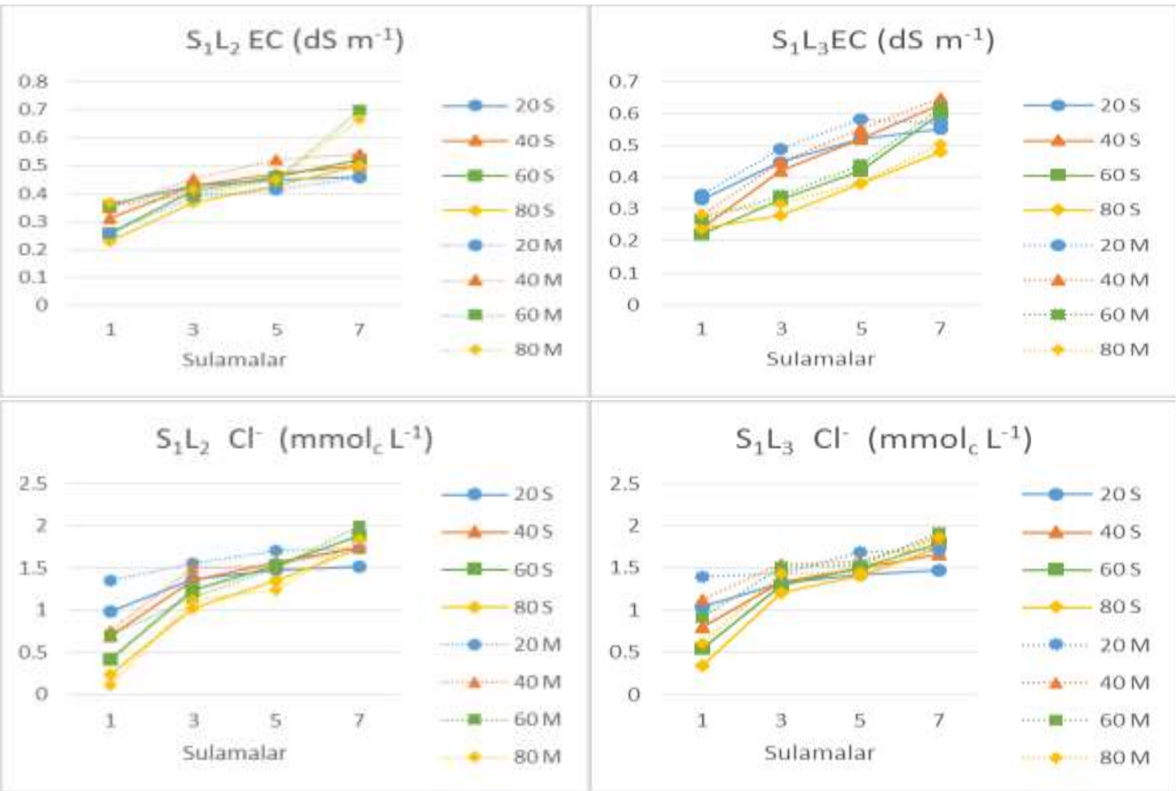

Figure 1. Measured and simulated EC, and Cl^- graphics during 1st, 3rd, 5th, and 7th irrigations for S_1 treatment

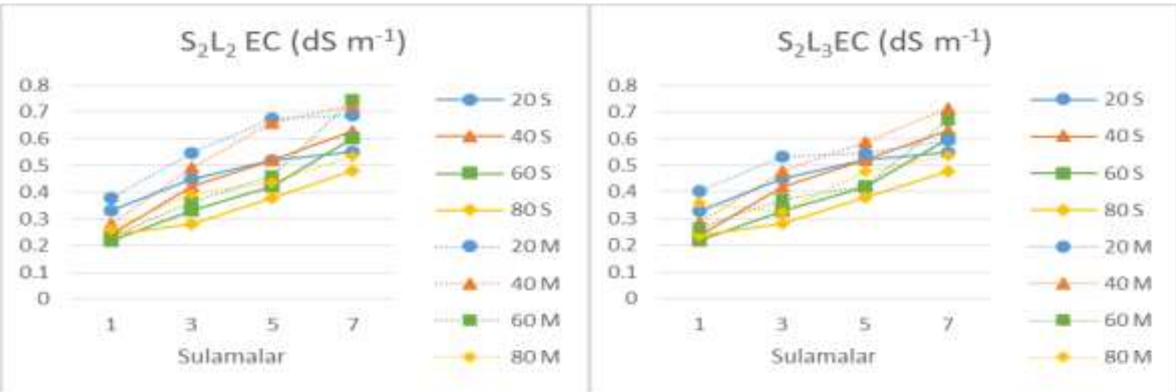

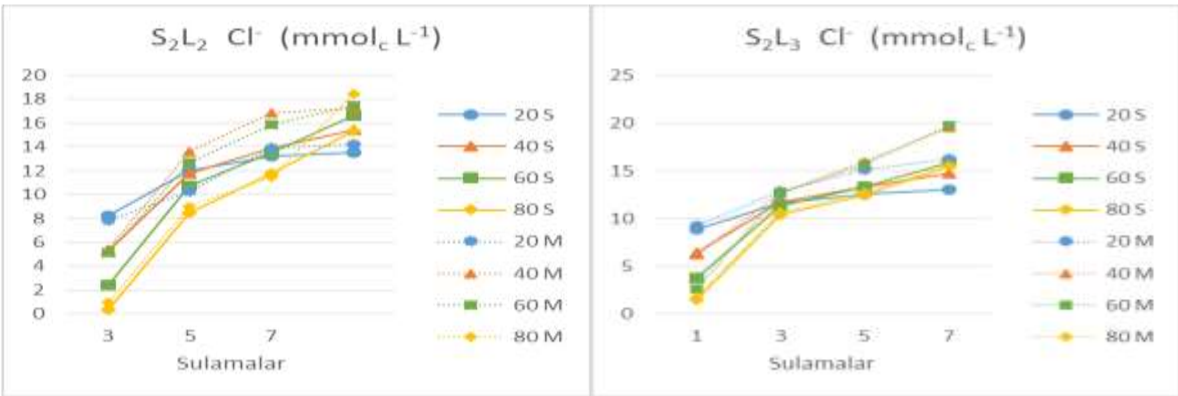

Figure 2. Measured and simulated EC, and Cl^- graphics during 1st, 3rd, 5th, and 7th irrigations for S_2 treatment

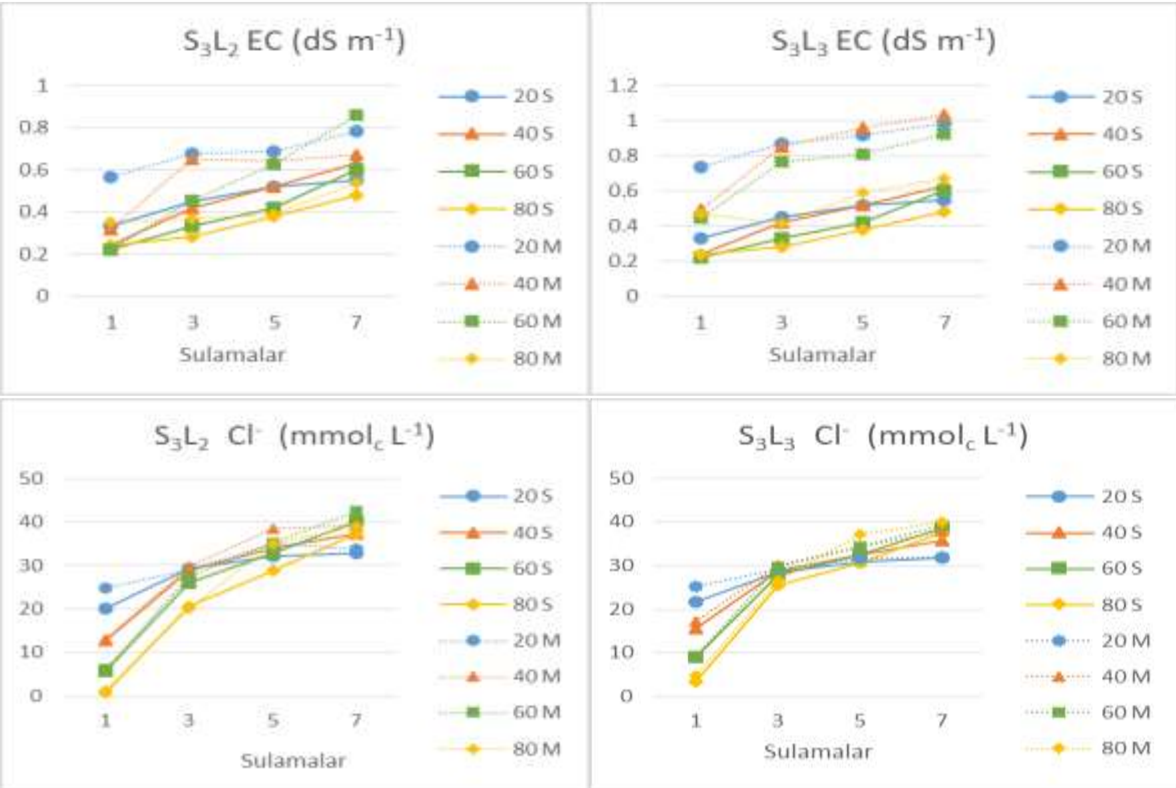

Figure 3. Measured and simulated EC, and Cl^- graphics during 1st, 3rd, 5th, and 7th irrigations for S_3 treatment

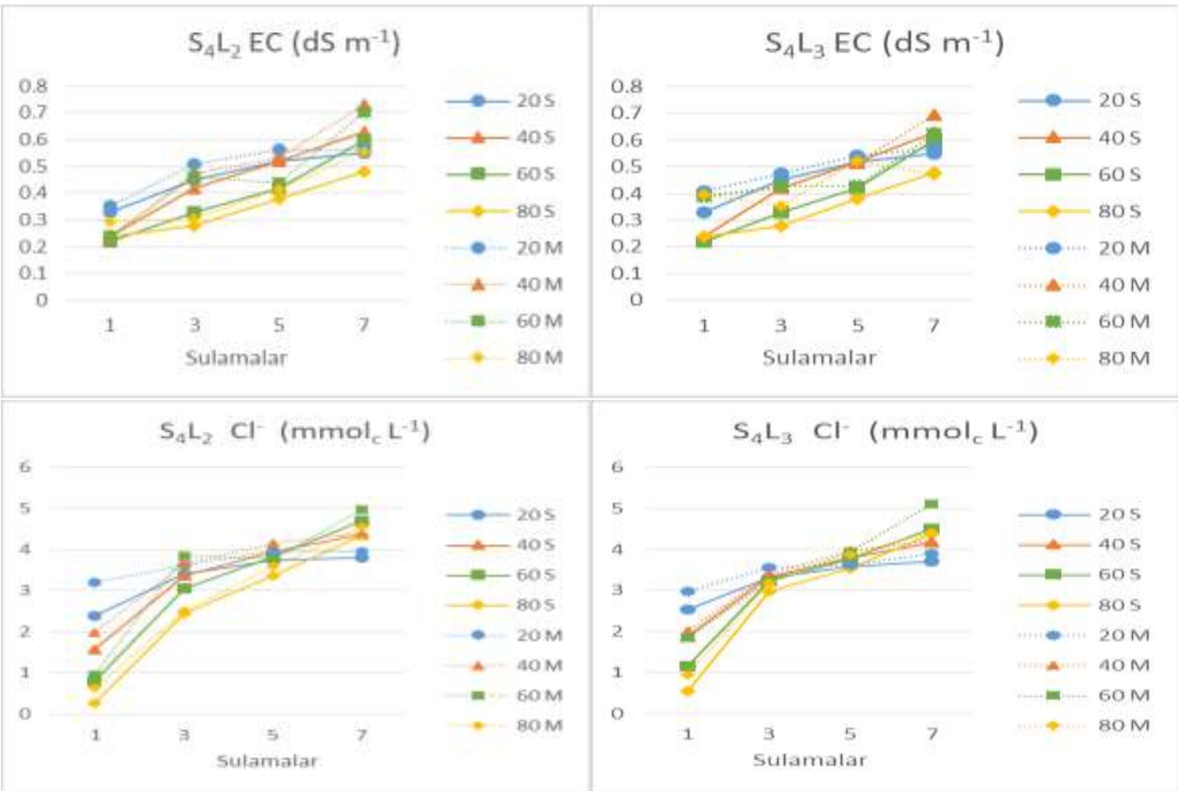

Figure 4. Measured and simulated EC, and Cl^- graphics during 1st, 3rd, 5th, and 7th irrigations for S_4 treatment

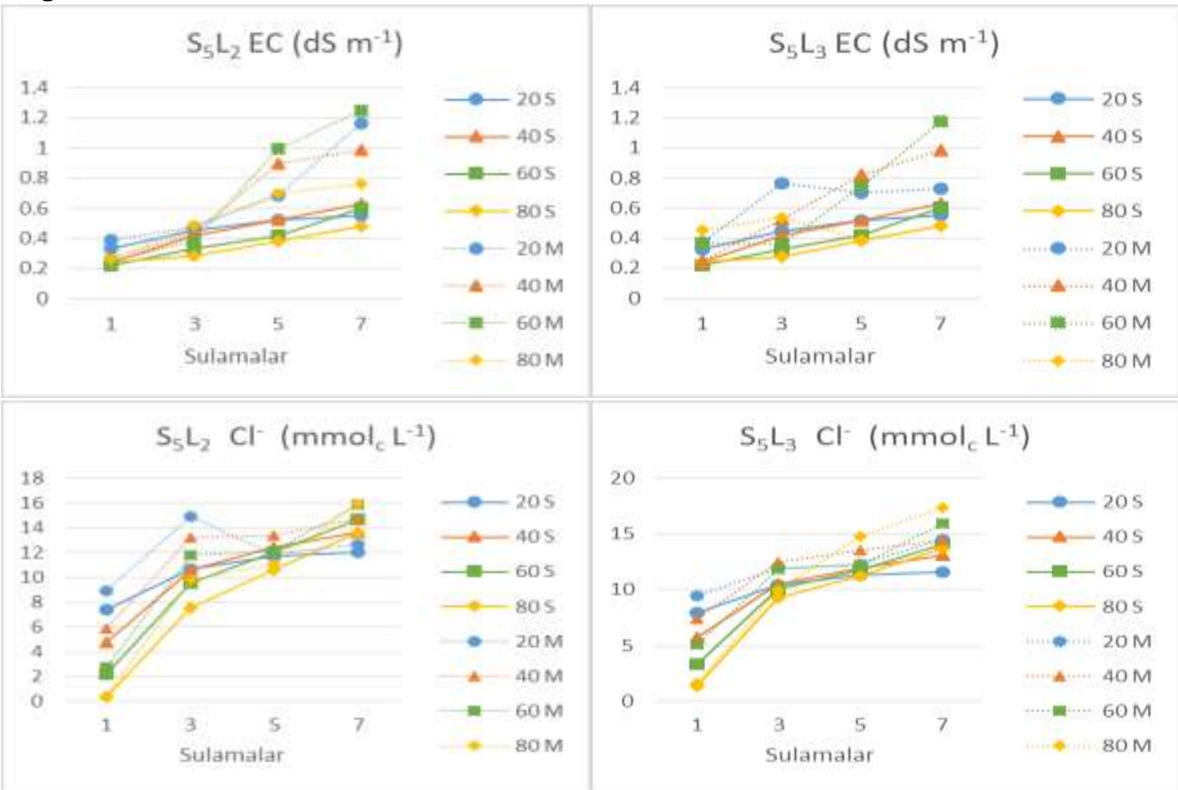

Figure 5. Measured and simulated EC, and Cl^- graphics during 1st, 3rd, 5th, and 7th irrigations for S_5 treatment

The correlation between the measured and simulated EC and Cl^- values were drawn in Figure 6, and the coefficients of determination (R^2) for S_2L_3 treatment is shown as an example.

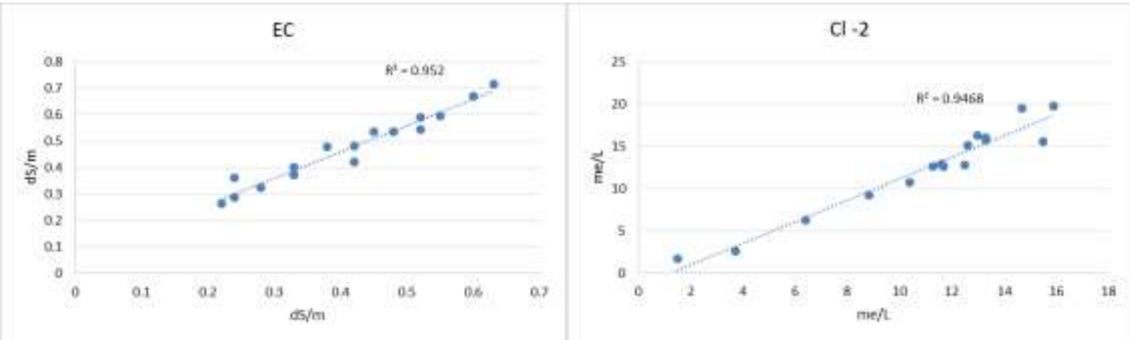

Figure 6. Correlation between the measured and simulated EC and Cl^- values and calculated coefficients of determination for S_2L_3 treatment

Conclusion

In this study, we evaluated the measured and simulated EC and Cl^- values with HYDRUS-1D using the statistics such as MAE, RMSE, RE, and coefficient of determination (R^2).
It can be seen that, HYDRUS-1D simulation model simulated these two parameters and the coefficient of determination at a level of high accuracy. The results showed that HYDRUS-1D was able to successfully simulate soil water salinity and movement of salts (ions, Cl^-) in the soil profile. The model describes better scenarios with lower values of salt concentrations (EC). Similar results were obtained for individual ion concentrations. The same results were reported by other researchers (e.g., Gonçalves et al., 2006; Ramos et al., 2011; Yurtseven et al., 2013).

Abstract

SAR value is one of the most significant parameters in evaluating soil sodicity. In this study, we analyzed the content of SAR components Na^+, Ca^{+2} and Mg^{+2} in the soil solutions obtained by using suction probes, during irrigation practices, situated in 20, 40, 60 and 80 cm of soil depths, in relation with irrigation water salinity and leaching fractions in soil columns. Experiments were conducted in 40 cm diameter and 115 cm depth soil columns using with 5 irrigation water salinities (0.25-control, 1.5 and 3.0 dS m^{-1} with $NaCl+CaC_2$ and with $NaCl+CaSO_4$ salts), and two leaching fractions (15% and 35%) with initially saline sandy-loam ($ECsp_{1/2}$=1.92 dS m^{-1}) soil. The Na^+, Ca^{+2}, and Mg^{+2} concentrations of soil solutions were compared with the same ion concentrations simulated by using HYDRUS-1D mathematical model with the correlation coefficients.
The correlation coefficients (R^2) were between 0.870-0.994 for Na^+, 0.917-0.984 for Ca^{+2}, and 0.337-0.965 for Mg^{+2} at 15% of leaching fraction level and were between 0.246-0.986 for Na^+, 0.915-0.980 for Ca^{+2}, and 0.835-0.956 for Mg^{+2} at 35% of leaching fraction level, respectively. The major part of the correlation coefficients were high enough to evaluate a good relation between the measured and simulated concentrations of these ions.

Introduction

Water scarcity and high salinity are major limiting factors for agroproductivity in many arid and semi-arid zones. The future of irrigated agriculture is threatened by increasing water scarcity and the ancient problems of water-logging, salinization, and degraded soil and water quality (Skaggs et al, 2006).
Water quality criteria for irrigation must consider both the direct impact on crop yield and the indirect impact related to effects on soil chemical and physical properties. It is well recognized that the salinity of a irrigation water and the sodium adsorption ratio (SAR), have an interactive effect on soil physical properties. Elevated values of SAR result in decreased hydraulic conductivity, decreased aggregate stability, clay dispersion, swelling of expandable clays, surface crusting and reduced tilth (Suarez et al 2006).
Salinity restrains root water uptake of plants by increasing the osmotic pressure in soil water. Thus making it more difficult for plants to extract water from the soil. Some components of salinity may cause specific-ion toxicity and imbalance the nutritional stability of plants. In addition, the salt composition of soil water influences the composition of cations in the

exchange complex of soil particles, which may significantly influence soil permeability and tilth (Yurtseven and Sönmez, 1992; Corwin et al., 2007).

Soils not only contain a mixture of salts, but the distribution of these salts is not uniform spatially, nor constant with a soil depth and/or time (Hoffman and van Genuchten, 1983). Excessive salts accumulated in soil profiles of irrigated lands can be leached out by adding more water than required to meet the evapotranspiration needs of the crops. The ratio of additional irrigation water, with respect to evaporation and transpiration, is usually expressed as a leaching fraction (LF) or a leaching requirement (LR), which are identical mathematical expressions, but with different meanings (USSL Staff, 1954; Rhoades, 1974).

Many methods are available to determine the impact of irrigation water quality and existing farm irrigation management in soil salinity. The most precise assessment of salinity is taking soil samples and carrying out laboratory analyses of salinity and its components using several types of laboratory instruments and methods. However, classical methods of evaluating soil salinity are time demanding, expensive, and require a lot of effort, yet cannot completely cover the spatial and temporal variability at the field scale (Rasouli et al., 2012).

Mathematical models that can consider various soil, climate, and crop factors have been suggested as useful tools for evaluating the optimum management strategies for saline conditions (Ramos et al., 2011; Rasouli et al., 2012). A variety of analytical and numerical models have been developed during the past several decades to predict water and solute transfer processes between the soil surface and groundwater table. The HYDRUS-1D software package (Šimůnek et al. 2008) is one of such models simulating water movement and solute transport in the soil. The objective of this study is to use HYDRUS-1D to analyze SAR and its components changes and solute transport in soil columns irrigated with waters of different quality at different leaching rates and to assess its applicability for practical applications.

Material and Methods

The experiment was held in Ankara University Agricultural Faculty Campus (Turkey), between June 9th and September 16th with sunflower. Lysimeters were set up with corruge PVC tubes of 40 cm diameter and 115 cm height. The soil, was provided from the top 20-60 cm profile of the surrounding cultivated area and sieved and put into lysimeters in equal amounts according to their bulk density. The soil used was sandy-loam and its bulk density is 1.35 g cm^{-3}, its pH is 8.03, its ECp (at 1:2 saturation) is 1.92 dS m^{-1}, its field capacity is 25.1%, and its wilting point is 15.2%. The sunflower used was “Meriç” which is an original variety from Turkey.

A total of 45 lysimeters with 5 salinity levels and 3 irrigation amounts as treatments with 3 replications were used. Experiments were conducted as a factorial experiment in fully randomized design. Irrigation water salinity levels were S_1=top water (0.25 dS m^{-1}), S_2=1.5 dS m^{-1} NaCl+$CaCl_2$, S_3=3 dS m^{-1} NaCl+$CaCl_2$, S_4=1.5 dS m^{-1} NaCl+$CaSO_4.2H_2O$ and S_5=3 dS m^{-1} NaCl+$CaSO_4.2H_2O$. Irrigation water was applied with a limited irrigation (75% of required amount) and with leaching fractions of 115% (L_{15}) and 135% (L_{35}). Drainage water was collected from the cups which were previously put at the bottom of lyzimeters.

The experiment was completed with 8 irrigations during growing season with the usage of 40% of available soil water. EC measurements were taken with ECmeter (YSI-3200) according to USSL (1954). The anion analysis were taken via ion chromatography (DIONEX IC-1600) apparatus according to Anonymous (1993).

To collect the soil solution samples, 4 suction probes were put into the lyzimeters at the depths of 20, 40, 60, and 80 cm, with leaching treatments of L_{15} and L_{35}, and the samples were taken during irrigation. The results were than compared with those obtained by running HYDRUS-1D simulation model.

The HYDRUS-1D program numerically solves the Richards equation for variably-saturated water flow and the convection-dispersion equation for heat and solute transport. The program may be used to analyze water and solute movement in unsaturated or fully saturated porous media.
This study used the UnsatChem module (Šimůnek and Suarez, 1994) of the HYDRUS-1D software package (Šimůnek et al., 2008), simulating the major ion chemistry/transport and carbon dioxide transport.
In addition to a visual check, field measured values were compared with the results of the HYDRUS-1D simulations using the mean absolute error (*MAE*), the root mean square error (*RMSE*), and the relative error (*RE*) which are defined as follows:

$$MAE = \frac{1}{N}\sum_{i=1}^{N}\left|O_i - P_i\right| \tag{1}$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N}\left|O_i - P_i\right|}{N-1}} \tag{2}$$

$$RE = \frac{RMSE}{Obs_{avg}} \tag{3}$$

where O_i and P_i are observed and model-predicted values in units of a particular variable, N is the number of observations, and Obs_{avg} is the mean observed value. In general, $RMSE \geq MAE$. The degree at which the *RMSE* value exceeds *MAE* is usually a good indicator of the presence and extent of outliers, or the variance of the differences between the modeled and observed values (Legates and McCabe, 1999; Kobayashi and Salam, 2000). *RE* was used to evaluate the quality of the *RMSE* value. The simulation is considered to be excellent when a relative error is less than 10%, good if it is greater than 10% and less than 20%, fair if it is greater than 20% and less than 30%, and poor if it is greater than 30% (Loague and Green, 1991).

Results and Discussion

In this study, the calculated SAR and the soil's analyzed components Na^{+}, Ca^{+2}, and Mg^{+2} results were taken into consideration and compared with the simulated HYDRUS-1D values, since soil sodicity hazard is mostly explained by the SAR calculation. Statistical parameters in order to evaluate the HYDRUS-1D modelling results for SAR and its components are given in Table 1, according to the treatments.
In general, the MAE and RMSE values increased, and RE values decreased with increasing soil depth. The soil salt and ion concentrations, in general, increase with depth, and it is almost the same for our experiments. As it was mentioned early RMSE values greater than MAE values in every treatment. The RMSE values for all treatments and for different soil depths varied for SAR between 3.37-9.54. The MAE values for all treatments and for different soil depths varied for SAR between 2.24-8.23. Furthermore The RE values for all treatments and for different soil depths varied for SAR between 1.13-1.37. As Loague and Green stated when a relative error is less than 10%; the simulation is good.

The graphics of measured and simulated SAR and its components for 1st, 3rd, 5th, and 7th irrigation applications are shown in figures 1, 2, and 3 for the easily soluble salt treatments, i.e., S1, S2 and S3. In all graphics, the measured and simulated values of Na, Ca, and Mg showed to be in sync, i.e., there was a good compatibility. But, the SAR showed a relatively poor compatibility. In other words, HYDRUS-1D simulated the analyzed data Na, Ca, and Mg values very closely to that of the measured values but calculated SAR didn't. Measured and simulated values were compared with the R^2 (coefficient of determination) statistic as well. This R^2 statistics for SAR and its components are given in Table 2. The R^2 graphics are shown in figüre 4, 5, and 6, for S1, S2, and S3 treatments respectively.

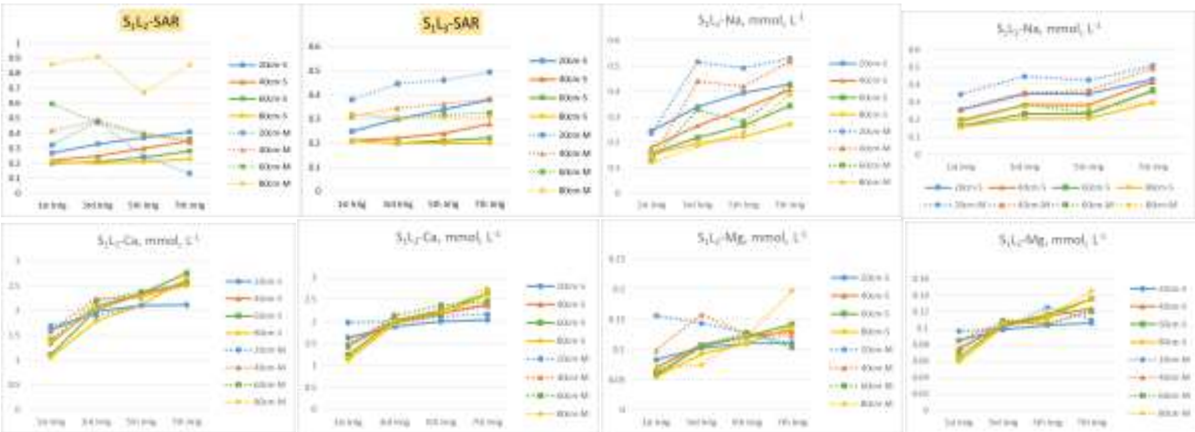

Fig. 1. Measured and simulated SAR, and its components graphics during 1st, 3rd, 5th, and 7th irrigations for S_1 treatment

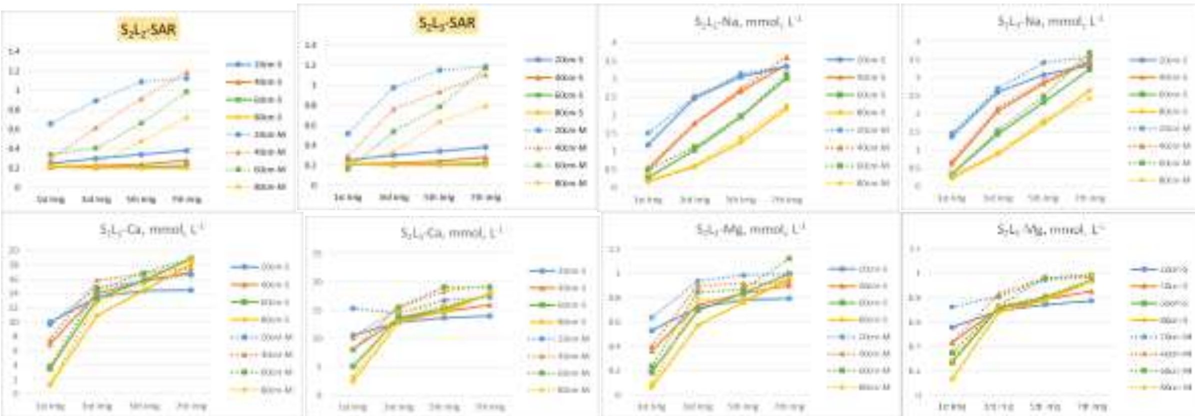

Fig. 2. Measured and simulated SAR, and its components graphics during 1st, 3rd, 5th, and 7th irrigations for S_2 treatment

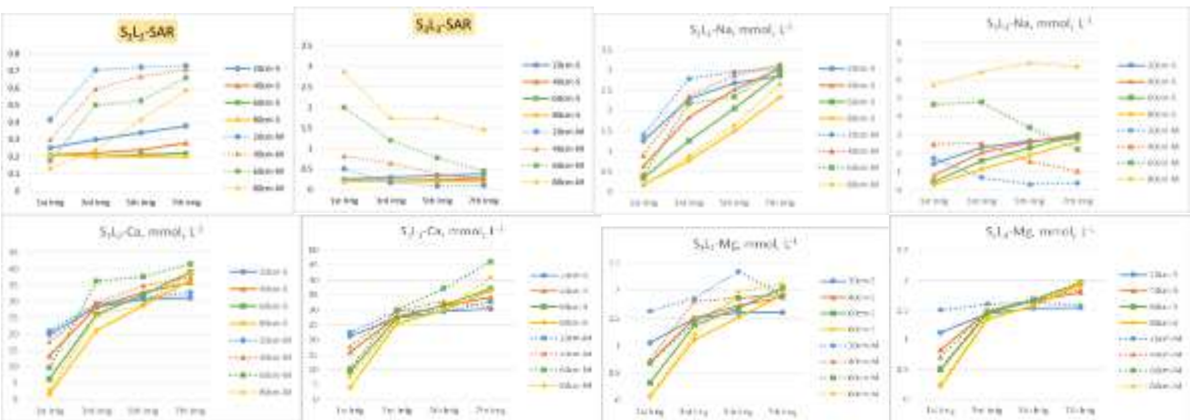

Fig. 3. Measured and simulated SAR, and its components graphics during 1st, 3rd, 5th, and 7th irrigations for S_3 treatment

Average R^2 values for Na, Ca, and Mg are 0.87, 0.95, and 0.86 respectively. These R^2 values are high enough to able to say the measured and simulated values are compatible. The results were compatible with those reported by other researchers (Gonçalves et al., 2006; Ramos et al., 2011; Yurtseven et al., 2013).

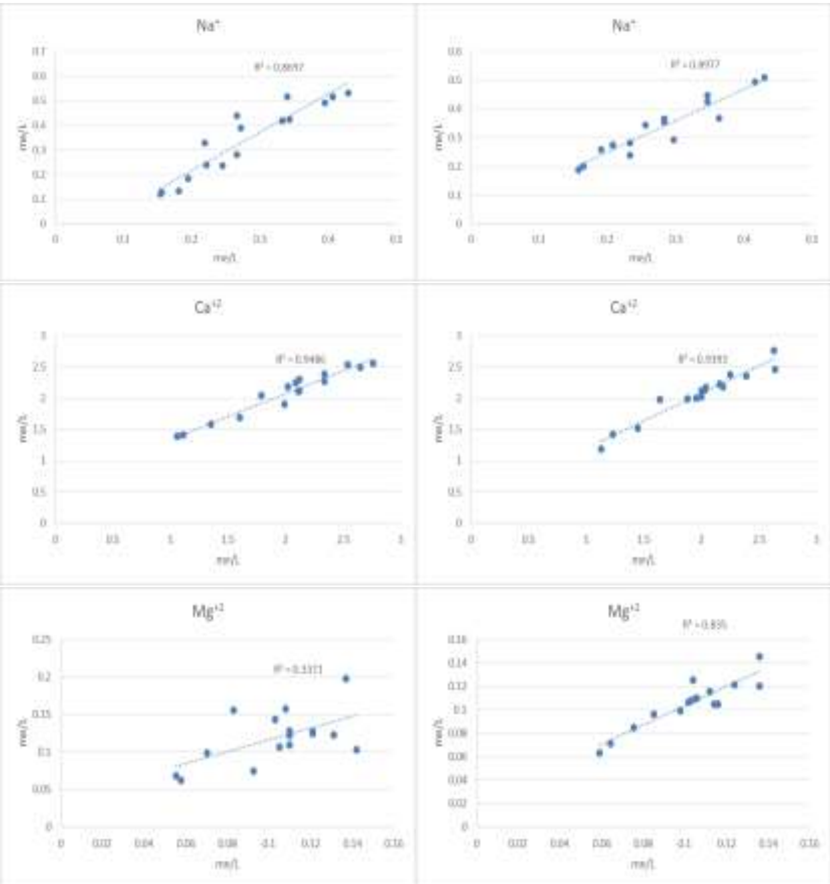

Fig. 4. The SAR components Na, Ca, and Mg R^2 values for S_1 treatment

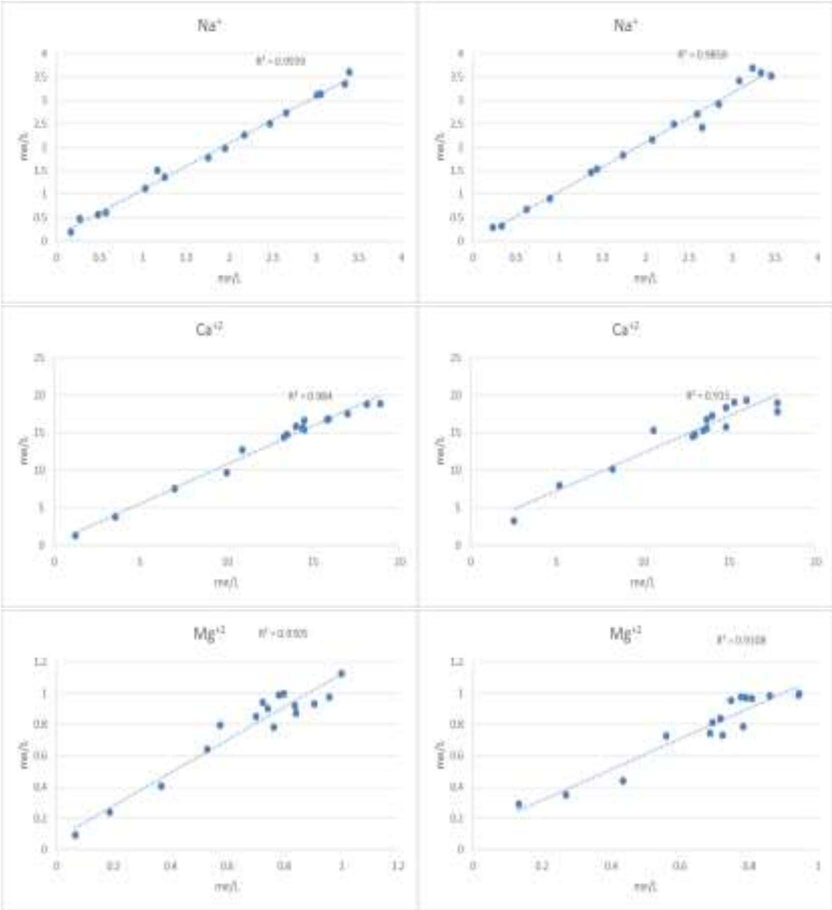

Fig. 5. The SAR components Na, Ca, and Mg R^2 values for S_2 treatment

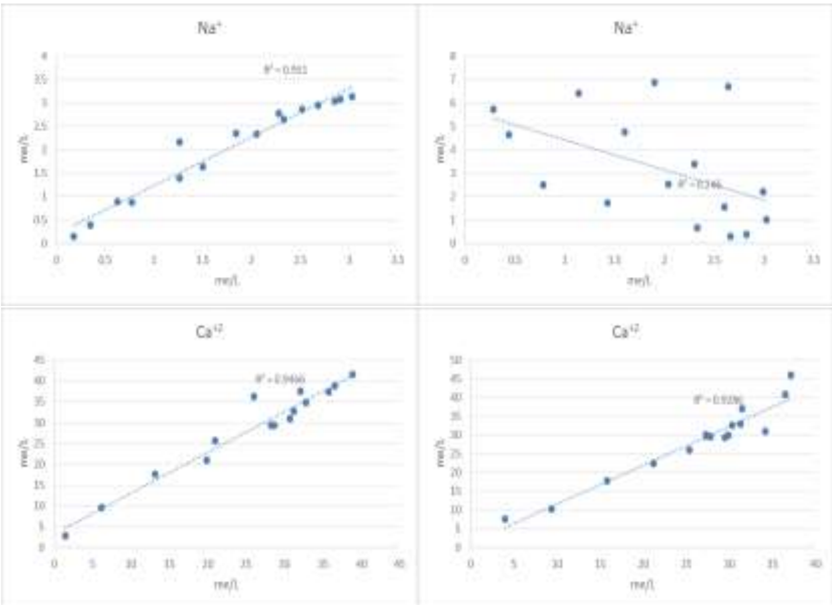

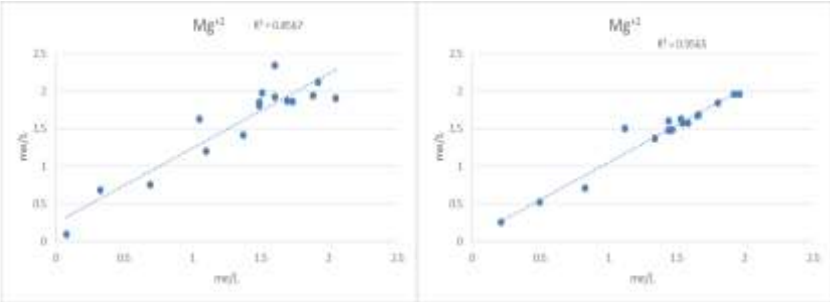

Fig. 6. The SAR components Na, Ca, and Mg R^2 values for S_3 treatment

Conclusions

In this study, we evaluated the SAR and its components Na, Ca, and Mg by means of measuring and simulating values using HYDRUS-1D and statistical analysis such as MAE, RMSE, RE, and coefficient of determination (R^2).

It can be said that, HYDRUS-1D mathematical simulation model simulated the SAR components Na, Ca, and Mg parameters with a high accuracy. But it didn't simulate the calculated SAR values in high accuracy.

The results showed that HYDRUS-1D was able to successfully simulate soil water SAR components of Na, Ca, and Mg in the soil profile.

THE ECONOMIC IMPACT OF CLIMATE CHANGE ON AGRICULTURAL WATER DEMAND IN FRANCE

Pierre-Alain JAYET*, Delphine BARBERIS, Pierre HUMBLOT

UMR INRA-Agro Paris Tech "Economie Publique", Grignon, France

Abstract

Present resource pressures and climate change should strongly impact water's availability and, correlatively, the economic situation of farming systems in terms of irrigation demand. The prospective approach that we develop focuses on the link between climate, crop yield and water, in order to assist public decision-making. The objective is to estimate future water demand in France, in a context of farm gross margin maximization. The method is based on the coupling of the AROPAj agricultural supply model with the STICS crop model. Simulations were performed for three climate projections (SRES-AR4 A1B, A2 and B1) from 2010 to 2100. Due to high inter-annual variability of precipitation and existence of substitutions between agricultural productions, irrigation results don't vary regularly from one "climatic" year to the next. Nevertheless, the results suggest a significant increase in water demand for the three projections in case of prices unchanged. The regional study revealed wide disparities. The most irrigated regions such as Aquitaine, Poitou-Charentes or Pays de la Loire would be characterized by the largest increase in demand for irrigation from the 2011-2020 decade to the 2091-2100 decade. We account of pressure on the resource by simulating changing water price scenarios. As expected, rising costs would contribute to a decline in demand, highly differentiated by region. The most affected regions would correspond to the most irrigated ones in absolute and relative terms.

Keywords: *water demand, water prices, climate change, bio-economic supply model.*

Introduction

With 3 billion cubic meters extracted in 2009, agriculture is a significant water-intensive sector of activity in France (Eau France, 2012). Given present resource pressures and the potential harmful effects of climate change (CC), a decline in water availability and, as a consequence, a change in current agricultural systems, are to be feared in the years to come. In France, existence of disparate irrigation practices from one region to another, intensive in the South and less widespread in the North, complicates territorial decision-making.
In order to ensure an optimal resource management, the objective of this work is to estimate future irrigation demand, and analyse the influence of regulatory policies. We adopt a bio-economic approach, widely used in the literature to simulate the behavior of farmers by incorporating agronomic information (Cortignani and Severini 2009; Kampas et al. 2012, Graveline et al. 2014). A prospective analysis centered on the link between climate, yields and water demand, is developed. An agro-economic model, called AROPAj, is used and coupled with STICS, a plant growth simulation tool. Various information such as gross margin and irrigation inputs is obtained at the country's scale on the basis of climatic projections provided by the ARPEGE-CLIMAT model (from 2010 to 2100) related to scenarios proposed by the IPCC (A2, A1b and B1). Thereafter, rising water costs simulations are proposed to symbolize the medium-term importance of pressure on resource in a context

of CC. Although the process is developed at the European level, France was chosen as a case study because of its representation in terms of agricultural production, soil and climatic diversity.
The P. Humblot's approach (2016) has been extended in order to obtain high resolution maps aiming at illustrate the existence of disparate irrigation practices from one region to another. The inter-annual and inter-regional variability of irrigation demand under CC scenarios is evaluated following the extension of simulation times over a period from 2010 to 2100 instead of 2050.
The next section provides the method, including the AROPAj optimization problem, the yield function elaboration, the spatial downscaling procedure and the different scenarios elaborated. Then, the results of the impact of CC on irrigation demand and the effect of water prices changes are described. Finally, the last part delivers concluding remarks and future research perspectives.

Material and Methods

In order to simulate agriculture response to economic and climate changes, we integrate agronomic information to the AROPAj[9] supply model using STICS, a plant growth simulation tool (Godard et al. 2008; Leclère et al. 2013; Humblot et al. 2016) (refer to **Figure 1**). AROPAj is a linear programming model based on the design of agricultural systems representative of the wide diversity of European productions. The main assumption is the maximisation of agricultural holder's profits under different constraints. The economic agent considered for computation is the farm group. An automatic classification is used to aggregate systems with similar technical and economic characteristics. The data used for the clustering procedure was extracted from the European Farm Accounting Data Network (FADN) of 2009. This typology respects the privacy rules specific to the FADN.

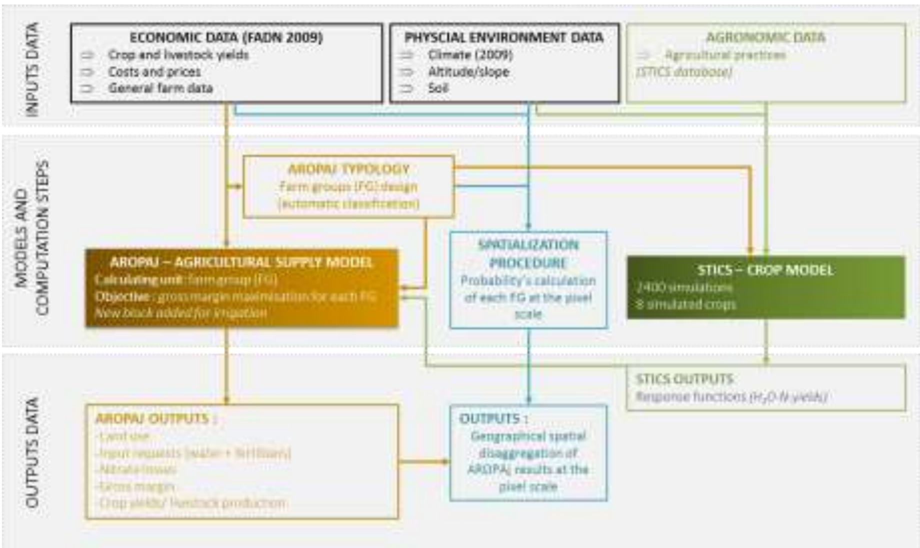

Figure 7: General method and AROPAj-STICS models coupling
(In yellow - AROPAj module, in green - STICS module, in blue - spatialization module)

STICS is a dynamic, generic and robust model for simulating the soil-atmosphere-crop system in any region. It operates at a daily time step, over one or two calendar years depending on the type of plant considered (Brisson et al. 2003). Data on climate, soil type

[9] Jayet, P.-A. (n.d.). The European agro-economic AROPAj model. https://www6.versailles-grignon.inra.fr/economie_publique/Publications

and management practices are required as inputs (refer to **Figure 1**). To compensate the lack of information at the farm group scale, a large number of simulations were carried out under different conditions. Various soil types, sowing dates, previous crops and varieties were tested. A total of 2400 combinations were simulated for each farm group and each of the 8 most marketed production in Europe (wheat, maize, barley, rapeseed, sunflower, beet, potato, soya). STICS estimates agricultural and environmental variables such as yields, quantity requested of fertilizers and water applied. These outputs contribute to the conception of H_2O-N-yield relation calibrated on data "observed" in 2009 via an economic criterion. The method presented in this study is extracted from the work of Humblot et al. (2017). The equation chosen can be expressed as follow:

$$Y = Y_{max} \times (1 - e^{-\sigma(W+W0)}) \times (1 - e^{-\tau(N+N0)})$$

W : water input (m^3)	$W0$: rain and initial soil water (m^3)	σ : slope parameter relative to water (m^{-3})
N : nitrogen input (T)	$N0$: organic and initial soil nitrogen (T)	τ : slope parameter relative to nitrogen (T^{-1})
Y : yield (T)	$Ymax$: agronomic potential (T)	Y, $Ymax$, W, N : quantities obtained per hectar

Response function use helps overcome the lack of information on nitrogen or water costs, respectively called cn and cw in our method. Instead of assuming a precise value for each component, a reasonable range for cw and cn is used in accordance with all available information obtained from expert opinion and the literature (Graveline et al. 2014). For water prices, it depends on regions considered. In this way, cn and cw fluctuate around an average value of 1,89 €/kg and 0,2€/m3 respectively.

Due to FADN's personal data protection policy, the geographical localization of an individual farm is not provided. Nevertheless, we are able to mobilize physical data and spatial econometric methods to give a probabilistic localization of AROPAj farm group at the pixel scale (refer to **Figure 1**). The spatial disaggregation approach is explained in Chakir (2009) and Cantelaube (2012). This procedure has been extended to integrate the irrigated land proportion. In order to create high-resolution maps, AROPAj outputs are weighted by the probabilities obtained in the previous step. Information on the resources' consumption, yields, gross margin and nitrate losses are calculated at different scales (countries, regions, farms, and/or watersheds).

A first modelling step is based on the evaluation of the CC effect on irrigation water demand in the future, without taking into account any resource management policy. Yield functions are produced based on the ARPEGE-CLIMAT model's climatic projections from 2010 to 2100. Three evolution scenarios, derived from the IPCC SRES, are studied in this paper. They correspond to different levels of radiative forcing (W/m^2): extreme (A2), medium (B1) and intermediate (A1b) compared to the current constant tendency. In our approach, farmers are maximizing their gross margin, according to yields evolution under future climatic conditions, by optimizing cultivated land allocation and quantities of inputs. Sowing date, varietal choices and previous crop selection remain unchanged. AROPAj results are obtained on an annual time step and calculated per decade from 2011-2020 to 2091-2100. In the following analysis, additional scenarios for increasing access to water costs, cw, are simulated to illustrate the medium-term importance of pressure on resource in a context of CC. A multiplication coefficient was applied uniformly to all water prices data. For different climatic evolution from 2010 to 2100 (A2, B1 and A1b), the selected range was +0% to +100% around the initial price with a step of 25%.

Results and Discussion

First, simulations were performed for three climate projections (SRES A1B, A2 and B1) from 2010 to 2100, without intervention of any policy. **Figure 2** illustrates the effect of CC on total required irrigation quantities to maximize agricultural gross margin. Each point represents one modelling for a particular year. Using a 10-year moving averages computation, different dotted trend curves are obtained. The three scenarios are characterized by a potential global demand increase: +70 % for A1b versus +23% for B1 between 2010 and 2100. Under constraints of available water supply, we should expect a relative decline in yields or the emergence of other cropping if this proves to be more beneficial for farmers. For the most extreme scenario A2, it is difficult to obtain a clear trend compared to other climate projections. We can assume that this irregular trajectory is strongly dependent on the inter-annual variability of the rainfall pattern (dates and quantities). Through these results, we demonstrate the importance of using data on various future climate years as opposed to an average climate. Nevertheless, it appears that irrigation water request could be higher for A2. According to the trend curves, water demands would exceed 3700.10^6 m3 by the year 2050 for A2, unlike A1b (2065) and B1 (2075).

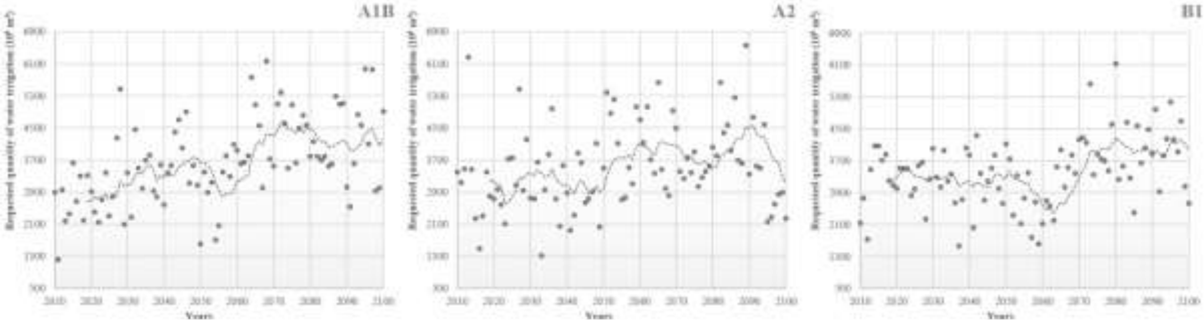

Figure 8: Evolution of water demand for three climate projections (A1B, A2 et B1) from 2010 to 2100. The trend curves in dotted lines symbolize the moving averages calculated over 10 years

Figure 3 represents the type of maps obtained from the spatial downscaling procedure. In this example, we study the water demand evolution for the intermediate climate scenario A1b. Averages for three decades were calculated: 2011-2010, 2051-2061 and 2091-2100. Values range from 25 to 200 m3/ha/year. Classes are created by identifying breakpoints in the data's distribution. A colour change of certain regions, from light to dark shade, symbolizes a potential increase in irrigation demand by 2100. The agricultural systems response to CC appears irregular according to regions. The southwest and western areas of the country (in particular regions Provence-Alpes-Côte-d'Azur, Aquitaine, Centre, Poitou-Charente and Pays de la Loire) would be irrigated a lot in the coming years. It is interesting to note that there is a good correspondence between the 2011-2020 AROPAj outputs and the data recorded in 2012 by the French Observation and Statistics Department.

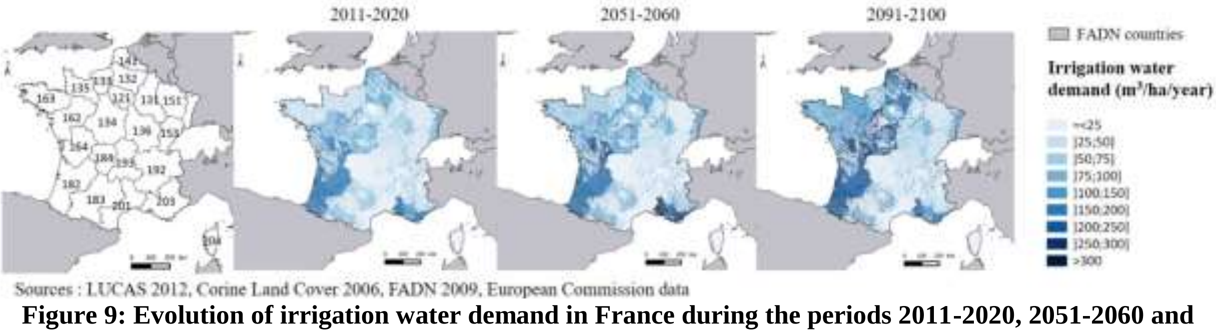

Figure 9: Evolution of irrigation water demand in France during the periods 2011-2020, 2051-2060 and 2091-2100 (averages per decades) for A1b

Region legend: 121 - Île-de-France; 131 - Champagne-Ardenne; 132 - Picardie; 133 - Haute-Normandie; 134 - Centre; 135 – Basse Normandie; 136 - Bourgogne; 141 - Nord-Pas-de-Calais; 151 - Lorraine; 152 - Alsace; 153 - Franche-Comté; 162 - Pays de la Loire; 163 - Bretagne; 164 - Poitou-Charentes; 182 - Aquitaine; 183 - Midi-Pyrénées; 184 - Limousin; 192 - Rhône-Alpes; 193 - Auvergne; 201 - Languedoc-Roussillon; 203 - Provence-Alpes-Côte d'Azur

Through this study, we have demonstrated the capacity of the model to capture regional diversity of climate and agricultural systems. Therefore, irrigation results are very heterogeneous both spatially (between regions) and temporally (between climatic years).

In a second step, we introduce regulation policies and we analyse the effect of a possible change in constraints concerning resource access in France on agricultural systems. The procedure remains the same. The only difference concerns the water prices values, ranging from + 0% to + 100% around the initial cost (+0%/+25%/+50%/+75%/+100%), for different climatic evolutions during the period 2010-2100 (A2, B1 and A1b).

Figure 4 illustrates evolution of the variable "irrigation" for A2, B1 and A1b, from 2011-2020 to 2091-2100, under different constraints of access to the resource. Increasing water prices from 0% to 100% leads to a gradual decrease in demand for each decade and each climate projection. The relation seems to be linear. For instance, multiplying the price by two would divide demand by three for A1b, during 2051-2060 period.

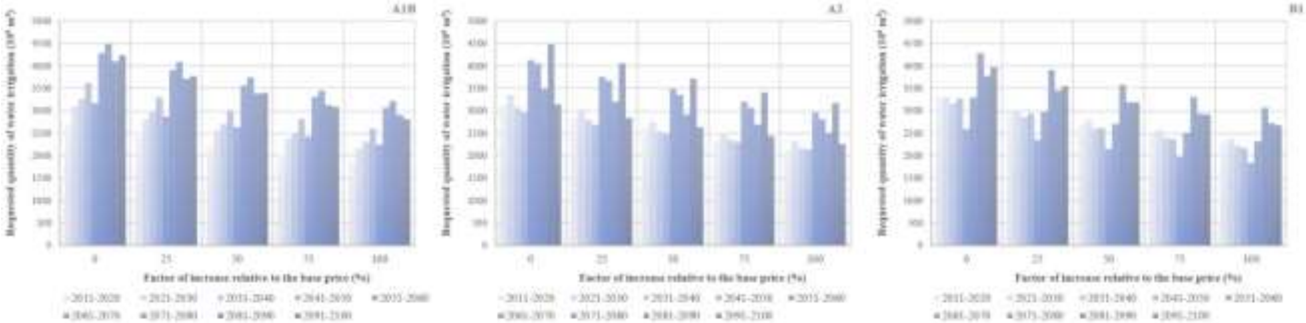

Figure 4: Impact of changes in water price on irrigation demand (averages per decade) in France for three climate projections (A1B, A2 et B1).

Relative values of irrigation quantity requested are estimated compared to the baseline scenario in **table 1**. A colour gradient from light yellow to dark red indicates a significant drop in demand from 0 to 100% relative to the outputs obtained in the baseline scenario. We note, in all cases, a decrease differentiated according to the region considered. Some of them would be less sensitive than others such as Bretagne (163) and Limousin (184). Some low-irrigated areas will see their water consumption fall by more than 40% due to the doubling of prices for the decades 2051-2060 and 2091-2100 (121 – Ile de France; 135 – Basse Normandie; 153- Franche-Comté). Nevertheless, even if this variation seems to be significant, these results should be compared with outputs obtained for the other highly irrigated regions more impacted (134 - Centre; 162 - Pays de la Loire; 164 - Poitou-Charentes; 182 - Aquitaine; 183 - Midi-Pyrénées, same regions as in figure 4). These effects are different depending on the period considered (see decades 2011-2020 and 2091-2100 for Poitou-Charente region).

Table 4: Impact of changes in water prices on irrigation demand for A1b by region during the periods 2011-2020, 2051-2060 and 2091-2100.

Due to the high demand for future irrigation water (refer to **figure 3**), limiting water withdrawals by imposing taxes could have an impact on the productivity of the agricultural sector. Policy maker will have to consider different options to cope with these effects.

Conclusions

Given the present agricultural withdrawals and the potentially harmful consequences of CC on the resource's availability, the development of appropriate modelling tools is essential for integrated water management. For this purpose, we developed a prospective approach based on AROPAj-STICS association and focused on the link between climate, crop yields and water inputs. Simulations were performed for three climate projections (SRES A1b, A2 and B1) from 2010 to 2100. The objective is to estimate the requested irrigation quantities in a context of gross margin maximization, independently of a water supply limit. Our results suggest an increase in water demand from 2010 to 2100 particularly marked for the most extreme scenarios A2 and A1b. Nevertheless, irrigation trajectory is irregular due to the inter-annual variability of the rainfall pattern. The realization of cartographic representations at the France scale illustrates the great capacity of the method to grasp the regional diversity of farming systems. This spatial analysis highlights the existence of disparate irrigation practices at the regional level, mainly concentrated in the western and southeastern parts of France. Most irrigated regions such as Aquitaine, Poitou-Charentes or Pays de la Loire would be characterized by the largest increase in demand from the 2011-2020 decade to the 2091-2100 decade. In this paper, scenarios of rising water prices are simulated to illustrate the medium-term importance of pressure on resource in a context of CC. As expected, rising costs would contribute to a decline in demand, highly differentiated by region. The most affected would correspond to the most irrigated in absolute and relative terms. An interesting perspective of this study would be to evaluate the effect of different levers of agriculture practices adaptation such as changes in sowing dates and varietal choices in a CC context. It is also envisaged to extend this approach to all European countries for several RCP scenarios proposed by the IPCC-AR5.

Abstract

Biodiversity is globally recognized as a foundation stone of healthy ecosystems, and biodiversity conservation is increasingly becoming one of the important aims of environmental management. In spite of this fact, human-driven land-use changes, especially during the last century, have already caused decline in biodiversity. In this regard, the intensification and expansion of modern agricultural practices in many countries has led to the biological simplification of the farmed environment and has declined farmland biodiversity during the last century. Since attitudes and intentions towards viability of specific conservation practices strongly impact human decisions on adoption of these practices and change, this study aimed to investigate farmers' attitude and intension towards biodiversity conservation. A survey was conducted by questionnaire in Fars province, southwest of Iran, and data was collected from 274 farmers, who were selected using stratified random sampling. The results of the study showed that age, education and knowledge have significant effects on attitude towards biodiversity conservation. Also, attitude towards biodiversity conservation, skill to use strategies for biodiversity conservation and perception of the impacts of agricultural practice on biodiversity had significant and direct effects on the farmers' intention towards biodiversity conservation. The findings of this study could be used by planners and policy-makers to improve farm biodiversity in different parts of the world.

Keywords: *Agriculture, Attitude, Biodiversity, Farmers' intention, Iran.*

Introduction

Agricultural landscapes host wild biodiversity of many types, with neutral or even positive effects on ecosystem, agricultural production and livelihoods (Scherr and McNeely, 2008). While agriculture is a dominant land use worldwide with approximately 40% of the land's surface used for production of food and fiber, it has been become one of the main drivers reducing wild flora and fauna species in the world since the start of the 20th century (Park, 2015). The expansion and intensification of agriculture activities such as increasing availability of modern hybrid species, extensive usage of pesticides and fertilizers, rapid land use changes and forest clearance for agricultural use and for harvesting timber and wood fuels have generated fundamental changes in plant species composition, vegetation structure, soil chemistry, and consequently the flora and fauna depending on these ecosystem fundamentals (Scherr and McNeely, 2008; Greiner, 2015; Coromaldi et al., 2015). These changes in farming practices and management styles have caused biological simplification of the farmed environment during the last century (Greiner, 2015; Park, 2015; Deng et al., 2016).

In Iran there is about 16.5 million hectares of farm land which currently are being utilized for agricultural production (Statistical Centre of Iran, 2014). Although, many parts of Iran are dry, the complex and varied climates, topography and geological formations have led to a varied and unique biological diversity in this country. Iran's biodiversity contains some of the world's important genetic resources, being the home of the original stocks of plant and animal species of great commercial value (The Fifth National Report to the Convention on Biological Diversity, 2015). In spite of this fact, the level of biodiversity in Iran has faced many different threats, especially in the last decades. Many valuable species have become extinct due to human ambitions; the level of forest coverage has significantly decreased; and more than 70% of protected areas and over 50% of wildlife sanctuaries will need a long time to restore due to excessive exploitation of vegetation (The Forth National Report to the Convention on Biological Diversity, 2010). Threats such as population growth, competition over the exploitation of water resources besides other destructive human activities such as land use changes, especially in the agricultural sector still threat biodiversity in Iran (Cheetah-CHECCO institute, 2016).

While biodiversity conservation on the agricultural landscapes is necessary for the ecological stability and productivity in natural ecosystems, it depends on a set of factors, such as soil condition, water availability, climate, and management aspects, intensity of farming methods, and scale of use (Henle et al., 2008). Farmers as the main farm managers can administrate biodiversity at many scales. Farmers interact with different components of biodiversity at several spatial scales: from local fields and their surroundings; to the layout of agro-ecosystems at the farm level; and across the landscape at larger scales (Jackson et al., 2010). Therefore, management decisions which they apply to their farmlands could potentially affect biodiversity in agricultural landscapes (Guillem et al., 2015).

While farmers are the key players both in agriculture and biodiversity conservation on the farmlands, many studies (Herzon and Mikk, 2007; Ahnström et al., 2008) have shown that farmers behavior and the way that they manage their farms and participate in environmental support schemes depends on their attitudes and intentions towards the environment. Therefore, this research aims to explore farmers' attitude and intention towards biodiversity conservation on the farmlands in Fars province, southwest of Iran.

Material and Methods

This study was conducted in Fars province, southwest of Iran. The target population of the study was all farmers who lived and worked in this area. The sample size (n=274) was determined based on the formula suggested by Scheaffer et al. (1979). A multistage stratified random sampling technique was used to select the study sample. Data for this cross-sectional survey study were collected using a questionnaire and face-to face interviews. Face validity of the scale applied for the study was confirmed by a panel of experts. To examine the reliability of the questionnaire, a pilot study was conducted on 30 farmers in a region outside of the study area. Cronbach's alpha for the items of Likert-type scales were 0.61-0.80.

Results and Discussion

Profile of the participants

Participants were aged from 25 to 70 and their average age was about 47 years (SD=12.37). The mean education level of farmers was 5.53 years of schooling (SD=5.18). The average land ownership was 5.50 hectares (SD=4.23) which indicated that most farmers were smallholders.

Farmers ‘attitude and intention towards biodiversity conservation

The model for independent variables and intention towards biodiversity conservation (Fig. 1) was used as a cause and effect chain to work out a path analysis. The path coefficients showed that the direct effects of some variables on the others were not significant. So, in the final model (Fig. 1), these paths were deleted for a better understanding of the relations between independent variables with attitude and intention towards biodiversity conservation.

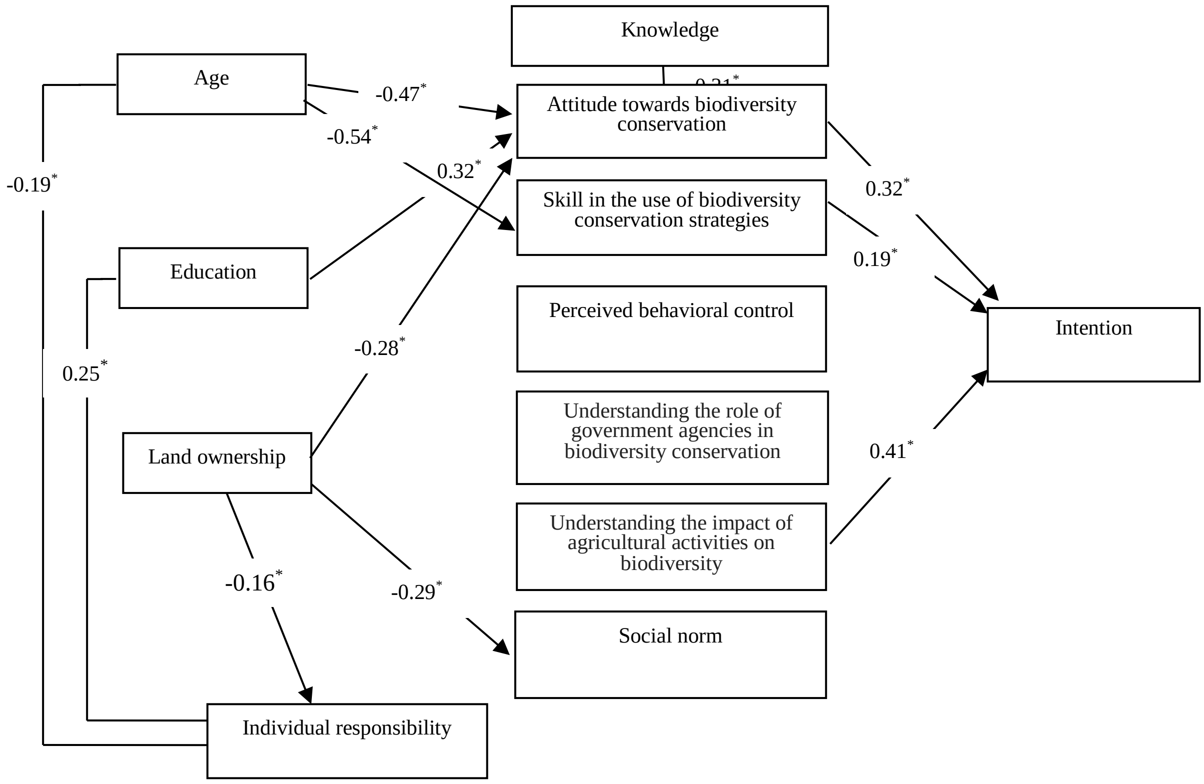

Figure 1. Path diagram of variables influencing attitude and intention towards biodiversity conservation. The path coefficients are linear and standardized (ß). The significance of test is: $*0.05 \geq p > 0.01$ and $**0.01 \geq p > 0.001$.

Fig. 1 shows that age (-0.47) and land ownership (-0.28) have significant negative effects on farmers’ attitude at the 0.05 level. The negative impact of age on attitude is consistence with the findings of the study by Abebaw and Virchow (2006). It is likely to be due to the fact that older people have beliefs that are institutionalized within them, and that the change in these beliefs is more difficult and time consuming. The negative impact of land ownership on the attitude is probably due to the fact that large landowners, unlike smallholder farmers, often live in urban areas and do not belong to the village. Therefore, they are seeking their own commercial interests, rather than considering biodiversity conservation in rural areas. According to Fig. 1, education and knowledge are the two other variables that have a significant effect on attitude at the 0.05 level. The positive effect of education (0.32) and knowledge (0.31) on attitude suggests that people with higher knowledge and higher education level are more aware of the value of biodiversity and thus have a more positive attitude toward maintaining this natural capital.

As shown in Fig. 1, the variable understanding the impact of agricultural activities on biodiversity has the most significant positive and significant effect (β=0.41; P= 0.05) on farmers' intention to maintain biodiversity in the farm and outside the farm. This finding shows farmers who believe conventional agriculture is currently unsustainable and produces low quality products have higher positive attitude towards biodiversity conservation. This finding is consistent with the findings of Alelign et al. (2011). After understanding the impact of agricultural activities on biodiversity, the variables of attitudes toward biodiversity conservation and skills in using biodiversity conservation strategies, respectively, have the most positive and significant effects on farmers' intention to preserve biodiversity. The direct effect of the attitude ($\beta=0.32$, $P=0.05$) is congruent with the findings of the study by Abebaw and Virchow (2006) and Kibert (2000).

Conclusions

In this study we revisited factors affecting attitude and intention towards biodiversity among farmers in Fars Province, Iran. Findings showed that age, land ownership, education and knowledge have significant effects on farmers' attitude towards biodiversity conservation. Also, attitude towards biodiversity conservation, skill to use strategies for biodiversity conservation and perception of the impacts of agricultural practice on biodiversity had significant and direct effects on the farmers' intention towards biodiversity conservation. As the findings of this study indicated various factors, directly or indirectly, interact with each other on the attitude and intention towards biodiversity conservation. Given the importance of the issue, a larger national-level study on farmers can provide more significant evidence of the role of knowledge, attitudes and other variables on biodiversity conservation, and thus provide the framework for accurate planning to improve and to preserve this huge national capital in the country.

Abstract

This study was conducted to determine different mixture ratios of some cool season grasses with factorial design at randomized blocks with 6 replicates in ecological conditions of Samsun, Northern Turkey in 2016. In this research, *Lolium perenne (Lp), Poa pratensis (Pp), Festuca arundinacea (Fa), Festuca rubra rubra (Frr), Festuca ovina (Fo), Agrostis tenuis (At)* species and different mixture ratios of these species were used as material. The nursery trial was planned as 4 different mixtures, i) 45%Lp+40%Frr+15%Pp, ii) 30%Lp+35% Frr+15%Fo+10%Pp+10%At, iii) 45%Fa+40%Frr+15%Pp, iv) 30%Fa+15%Fo+35%Frr+ 10%Pp+ 10%At; 2 solely treatments (Lp and Fa); 4 seeding rates (30,40,50,60 g^{-1} m^2). While time values to emergence were 43-53 days for Lp and its mixtures, these values were changed between 53-64 days for Fa mixtures. All the plots were moved 5 times and green herbage yield was altered from 13.1 to 934.0 g^{-1} m^2 according to the plots**.** The highest green herbage yield was obtained from 45% Fa + 45% Frr + 15% Pp mixture and 40 $g^{-1}m^2$ sowing rate plots. The least weed ratios were observed in the mixture of Fa. Additionally, as seeding ratios increased, weed ratio was decreased.

Key words: *Cool season grasses seeding ratio, weed ratio.*

Introduction

Green area requirement of people increases day by day for some reasons like as rapid population increase, unplanned and dense settlement, industrialization, decrease of green vegetation cover both in urban and country. But, a green area that is a lateral component of natural environment is very important for physical and psychological health of human (Gül and Avcioglu, 1999). The most important part of outdoor is turfgrass covered areas. These areas are used commonly for improve architectural, scenery and aesthetic quality. Additionally, turfgrass is an indispensable part of recreational areas and it creates a peaceful and relaxing atmosphere for humanity (Avcioglu *et al.,* 1998; Acikgöz, 1994). In order to fulfil their functions, during establishment process most suitable grasses should be chosen in addition to nursing (Avcioğlu and Soya, 1996). Heat and drought are the most important factors limited growing of grasses during summer period (Jiang and Huang, 2001). Before choose the grasses, we have to know their usage aim, ecological conditions, sustainability and view of them (Harivandi *et al.*, 1984). An ideal turfgrass area should be homogeny and look like a carpet. To obtain this result, we should determine suitable grass species and cultivars and mixture rates (Avcioglu, 1995: Avcioglu and Soya, 1996; Oral and Acikgoz, 2002). Aim of this study is to determine the performance of some cool season grasses at different mixture rates in Samsun ecological conditions.

Material and Methods

This study was carried in Çarsamba County of Samsun province in 2016. The experiment was planned as factorial design at randomized blocks with six different mixtures and sowing rates. In this research, *Lolium perenne* (Lp), *Poa pratensis* (Pp), *Festuca arundinacea* (Fa), *Festuca rubra rubra* (Frr), *Festuca ovina* (Fo), *Agrostis tenuis* (At) species and different mixture ratios of these species were used as material. The nursery trial was planned as 4 different mixtures, i) 45%Lp+40%Frr+15%Pp, ii) 30%Lp+35% Frr+15%Fo+10%Pp+10%At, iii) 45%Fa+40%Frr+15%Pp, iv) 30%Fa+15%Fo+35%Frr+ 10%Pp+ 10%At; 2 solely treatments (Lp and Fa); 4 seeding rates (30,40,50,60 g^{-1} m^2). Average temperature and total precipitation were 15.7˚C and 916.1 mm respectively at experiment site in 2016. Soil of experiment site is clay-loam, slightly alkaline (pH=7.67), lime is medium (7.33%), saltless (EC dsm^{-1}0.186), organic matter is low (1.71%), phosphorus is high (62.57 kg/da^{-1}) and potassium is enough (43.69 kg/da^{-1}). Consider the soil analysis, 5 kg N and 6 kg P_2O_5 was applied at sowing time. Later, regard the growing performance of plants 10 g N m^{-2} was given every month. Area was irrigated with sprinkler after every cut, if necessary. The experiment was established at November 11, 2015. The cuts were made when the plants reach to 15-20 cm height. Five cuts were made in the first year. The cutting dates were April 30, June 2, June19, July 30 and October 22, 2016. In spite of irrigation, there were no enough growing during August and September, because of cool season grasses. Resultant data were subjected to statistical analysis with SPSS 17.0 software. Differences in means were tested with Duncan's multiple range tests.

Results and Discussion

Time values to emergence and green herbage yield of *Lp, Pp, Fa, Frr, Fo, At* species and different mixture ratios of these species are provided in Table 1. When consider time the emergence differences amongst the mixtures and sowing rates were highly significant. The earliest 50% emergence was observed at *Lp* plots and its mixtures. Time to emergence was 37 days at 40, 50 and 60 g seed m^{-2} with perennial ryegrass while it was 41 days for 30 g seed m^2 plots. The latest time to emergence was determined at solely *Fa* plots (64 days). Time to emergence was altered between 43-64 days for the other plots (Table 1). Genetics and soil temperature are the most important factors that affect time to emergence. In general, the earliest time to emergence can be obtained from perennial ryegrass compare to whole cool season grasses (Acikgoz, 1994; Avcioglu, 1997).

In terms of green herbage yield, significant differences were observed in fourth cut, but there was no difference in the other cuts. The highest green herbage yield was obtained from treatment 6 (45% Fa+45%Frr+15%Pp and 40 g m^{-2} sowing rate) as 934 g m^{-2}. Treatment 6 was followed by treatment 15 with 893 g m^{-2} herbage yield. Solely perennial ryegrass sowing 30 g m^{-2} sowing rate supplied the lowest herbage yield. Herbage yield of the other treatments were ranged between these values and most of them has been included in the same statistical group. As mean of the treatments, the highest green herbage yields were obtained from the first and third cuts, while the lowest was from the fifth cut (Table1 and Figure 1).

Table1. Time to emergence and green herbage yield values of some cool season turfgrass mixtures.

In general there was less weed in mixtures with *Fa* and as the sowing rate increase, weed ratio was decreased. The lowest weed number was observed in third cut. Because, at the third cutting time cool season weeds were disappear and warm season weeds did not start to grow yet. The highest weed number was determined in the first cut. Turfgrass seedlings were very young at this time and probably could not compete with weeds (Figure 2).

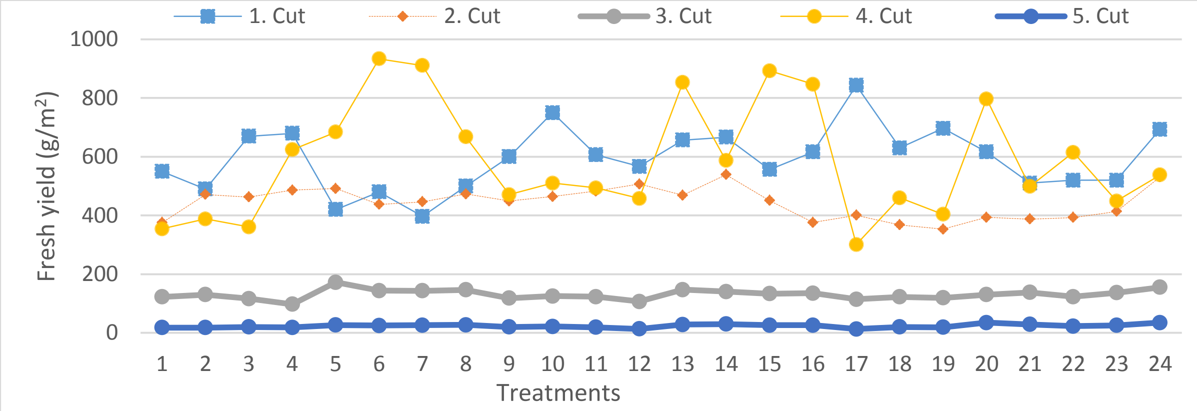

Figure1. Green herbage yield of some cool season turfgrass mixtures ($g^{-1}m^{-2}$)

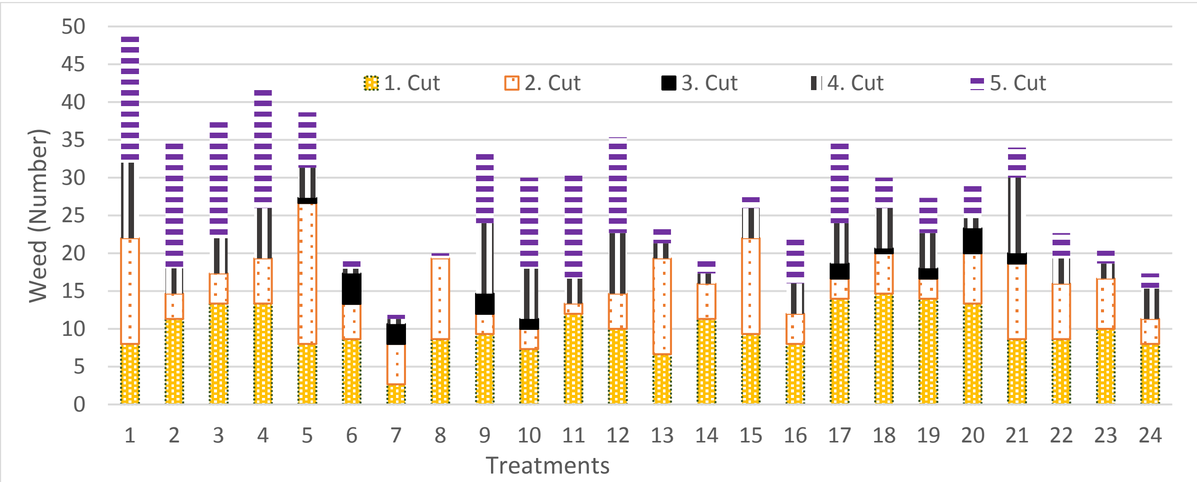

Figure2. Weed numbers in some cool season turfgrass mixtures.

Conclusions

In this research that was conducted to determine the performance of some cool season turfgrass mixtures with different sowing rates, 5 cuts were made in 2016. The earliest time to emergence was observed in solely perennial ryegrass plots and its mixtures. It was determined that as sowing rate increase, weed number was decreased. Weeds had less chance to grow with in the mixtures consist of *Fa*, compare to the other treatments.

Abstract

Turkey has ecological and extended vineyard areas for agricultural production. Many varieties and types of grapevines have been cultivated in our country. Aegean region is one of the important regions with intensive vineyard cultivation. Generally, without irrigation vineyard cultivation/production is done in Aegean region which has different ecological conditions for grapewine cultivation. Wild irrigation methods are more commonly used for irrigation. Effect of irrigation on yield is more important in relation to drought in winter and summer seasons regarding quality and also quantitative production. According to the researches, amount of irrigation water ranges between 110 mm and 120 mm for one application of irrigation which average amount in Aegean region. Deficit humidity in the root depth of grapevine is completed artificially by means of irrigation and usable humidity capture for more suitable level in the soil. Soil processing after irrigation effect on the yield has been positive. In this study, effects of capacity of soil humidity and soil processing on the grapewine yield and applied irrigation methods were explained for grapewine cultivation in Aegean region, Turkey.

Keywords: *Capacity of humidity, Evapotranspiration, Grapewine, Irrigation method, Irrigation period, Soil process.*

Introduction

Adequate soil water availability, according to the phenological stage of the vines, must be maintained over the growing season in order to obtain good quality grapes (Jackson and Lombard, 1993; Deloire *et al.*, 2004). Deficit irrigation strategies have been successfully adopted as management tools to ensure an adequate balance between vine vegetative and reproductive development while preserving yield and water resources and improving fruit composition (Dry *et al.*, 2001; Intrigliolo and Castel, 2008). However, irrigation must be applied (amount and time) in accordance with the climate and soil characteristics of the region and the type of wine to be produced to avoid potential negative impacts on vine vigour, berry composition and wine quality. Several reserchers showed that irrigation effects on the yield of grapewine depend on climatic conditions and soil process in wineyards (Avalos *et al.,* 2016). Stoimenov et.al. (2012) explained irrigation and irrigation depth for soil and plant water regime relation to grapewine plantations. The goal of this research is to show soil processing on the grapewine yield and applied irrigation methods for grapewine cultivation in Aegean region, Turkey.

Material and Methods

Grape is among the oldest cultivated fruits on the earth. It dates back to 5000 B.C. Being the gene center of grapewine, Turkey is located on the most favorable viticultural belt of the world. Aegean, Marmara, Mediterranean and Southeast Anatolian regions of Turkey are the territories where grape is cultivated (Fig.1).

Fig.1. Grapewine plantations in Salihli of Aegean region, Turkey.

Results and Discussion

Most important principles for water requirements are to:
*Know the symptoms on the vine of water stress
*Know the physiological stages when a lack of water will affect the size and quality of the crop
*Know the depth and size of the root system
*Know the soil in order to know what the storage capacity of the soil is for water
*Know how much water to apply

What kind of water in the soil?
*Gravitational water Free drainage after irrigation/rainfall
*Drainage water
*Available water (between field capacity FC and permanent wilting point PWP)

Symptoms of water shortages (Teubes, 2017)
*Irrespective of the previous critical physiological stages; vine will show physical symptoms of water shortages
*Important to recognize the symptoms to know when the vine requires irrigation
*Growing tip pulls back
*Tendril orientation sags
*Leaf orientation away from sun
*Leaf petioles start to sag
*Yellow leaves in cluster zone
*Berries shrink

How long must I irrigate?

*Length of time of flood irrigation depends on Strength of water current from canal
*Length of furrow (Fig.2)
*Width of furrow (Fig.2)
*Rooting depth (depth of water penetration)
*Infiltration time to required depth
*Water losses through evaporation, drainage, etc.

If the above information is not available it will be very difficult to determine the correct time of an irrigation. Practical answer is to apply irrigation and to make a profile pit to determine the depth of wetting after 2 days (Teubes, 2017).

Fig.2. Furrow irrigation in the grapewine plantations

When to irrigate?

If the precipitation regime is irregular and insufficient, then irrigation is a must in vineyards. In areas where vine is cultivated in Turkey, precipitation is seen in winter or spring. Therefore, the water piling up in the soil meets the water needs of the plant until around mid-June. And after the harvest, vineyards must be irrigated in accordance with need (Fig.3).

Although the amount of irrigated water for maximum efficiency depends on the type of grape, rootstock and soil type, the amount of precipitation received by the plant during the vegetation phase, the yearly distribution of precipitation, the irrigation system and cultural practices. it is stated that the average value is around 150-200 mm.

Fig.3. Drip irrigation in the grapewine plantations

Soil Processing

The roots of grapewine plant go deep. This is why this plant is suitable for soft-textured soil. Since vineyards grow ideally in dry areas or in areas with small ammount of precipitation, it is desired that the vineyard soil be deep and of high water retention capacity. Grapewine can grow even in poor soil conditions as long as the soil structure allows the roots to grow.

On locations with high water retention capacity, drainage precautions are taken. The grapewine plant depends on the conditions of wellness under the soil for growing its roots deep down. In loamy sandy soils, the roots go very very deep. Vineyard soil must be plowed at least 40 cm deep (Fig.4)

In viniculture plowing helps with the struggle against weeds, the airing out and warming up of the soil, the facilitation of the receptability of the nutrients within the soil and the prevention of losses, the increasing of soil's water retention capacity, the prevention of water loss as a result of breaking the duff layer caused by irrigation or precipitation and the mixing of fertilizers with soil.

Fig.4. Soil processing in the grapewine plantations

Conclusion

For good quality and efficiency, irrigation according to need is a must. Irrigation increases efficiency by 0-40%. In Turkey, irrigation is applied especially in the seedless vineyards located in the Lake District and the Eagean Region. In vineyards with dry or semi-dry climate conditions, irrigation must be applied. Types of irrigation are furrow, overhead sprinkler systems, micro jets and drip systems. Grapevines have good resistance to salinity. Water for irrigation containing saline salts and/or elements which has direct and indirect effects on the plant.

The main reason of plowing 20-25-cm-deep in autumn is to allow the precipitation water received throughout the winter to be absorbed well by the soil, thus increasing the water retention capacity of the soil. The reason of plowing more shallowly (10-15-cm-deep) in spring and summer is weed-control and letting the soil breathe, thus preventing water loss.

Abstract

Water is an important natural resource in arid areas. The rainfall is usually lost from the surface like runoff and evaporation in these regions. Gathered rainwater is used for agricultural production in arid region. Water harvesting is an old tradition in many countries in the world and water harvesting techniques are used for thousand years. It was developed in order to obtain drinking and domestic water for people. Water harvesting systems in semi-arid areas feed from precipitation and it supplies enough water for human life. Water harvesting is the best way to increase the amount of water per unit of cultivated area. It is reduce impact of drought and surface flow. Water harvesting systems help to reduce environmental damage, increase of plant vegetation and prevent to soil and water erosion. Some strong runoff which is caused erosion therefore these must be stored in the soil profile by water harvesting practices. Sloping land is available for water and soil erosion in semi-arid climate. This study explained that on the importance of rainwater harvesting on soil moisture and conservation. Rainwater is one of the natural resources when collecting water in the soil for agricultural cultivation.Water harvesting techniques help to local farmers and also to take advantage in terms of alternative irrigation for pistachio orchards in dry agricultural areas in Souteastern Anatolia Region in Turkey.

Keywords: *Dry areas, Soil conservation, Water conservation, Water harvesting.*

Introduction

Precipitation is generally insufficient to supply basic needs for crop production in semi-arid areas. Usually rain water lost with evaporations and runoff, leaving commonly dry seasons during the rearing period. Total annual rainfall enough to sustainable farm needs in agricultural land, this is often distributed very unevenly so that long dry periods are interspersed with periods of intense rainfall. In many cases, a crop is unable to use a high proportion of this water, as much of its lost through runoff or leaching. This may cause soil erosion and loss of soil nutrients. Even in places with relatively abundant water resources, it is not sufficient to meet the water demand of crop growth all the year round. With increasing acreage of crop growing, unreasonable crop planting structure, high irrigation quota, and low water use efficiency, the shortage of water resources is becoming increasingly serious (Shen *et. al.*, 2013). Transfer of irrigation management responsibilities from government agencies to farmers has been made as an important policy in many countries (Mishra *et. al*., 2013). As a result, farmers' participation in irrigation management has taken the center stage and the irrigators who were considered as beneficiaries are now considered partners in planning, development, operation and maintenance of irrigation systems (Parthasarathy, 2000). Water harvesting techniques defined in this study aim to maximise the available water through water harvesting and conservation. Water harvesting techniques gather water from an area termed the ‘catchment area’ and channel it to the cropping area or wherever it is required. Conservation techniques, conserve water within the biomass and the soil by reducing run-off and keeping the water where it falls, as much as possible. In deciding which techniques to use to make more efficient use of the available water, it is important to consider how crops receive or lose water.

Crops receive water through rainfall, irrigation and stored soil water. Rain-water loses through run off, evaporation and drainage. Soil stores water from rainfall providing a reserve that is available to the crop? How much water is available depends on the soil type and the rooting system of the crop. Sandy soils hold much less water than clay or silt soils, so crops will require watering more often. Run off is where water is not absorbed by the soil but runs across the surface away from where the crop can use it. Structures such as contour schemes, terracing, pits and bunds can reduce run-off. Run off is more likely to occur on silt or clay soils where the surface has been subjected to intense rainfall then baked in the sun to form a crust or cap. Adding mulch to break up the intensity of rainfall, or adding manure, compost or incorporating green manure residues will reduce the tendency of the soil to form a crust (FAO, 1991).

Water that evaporates directly from bare soil is wasteful as it is not being used for productive plant growth. It is desirable to maintain full ground cover for as much of the time as practically possible. Applying mulch to the soil will also reduce evaporation considerably. Use of drip irrigation and irrigating in the evening will also reduce the amount of water lost through evaporation. When water drains out of the soil, not only is it wasted but essential mobile nutrients such as nitrogen are also washed out. This is more of a problem on light sandy soils. Adding organic matter in the form of compost, manures or plant residues will eventually increase the amount of water a soil can retain, but this will only have an effect if it is added over a longer period of years.

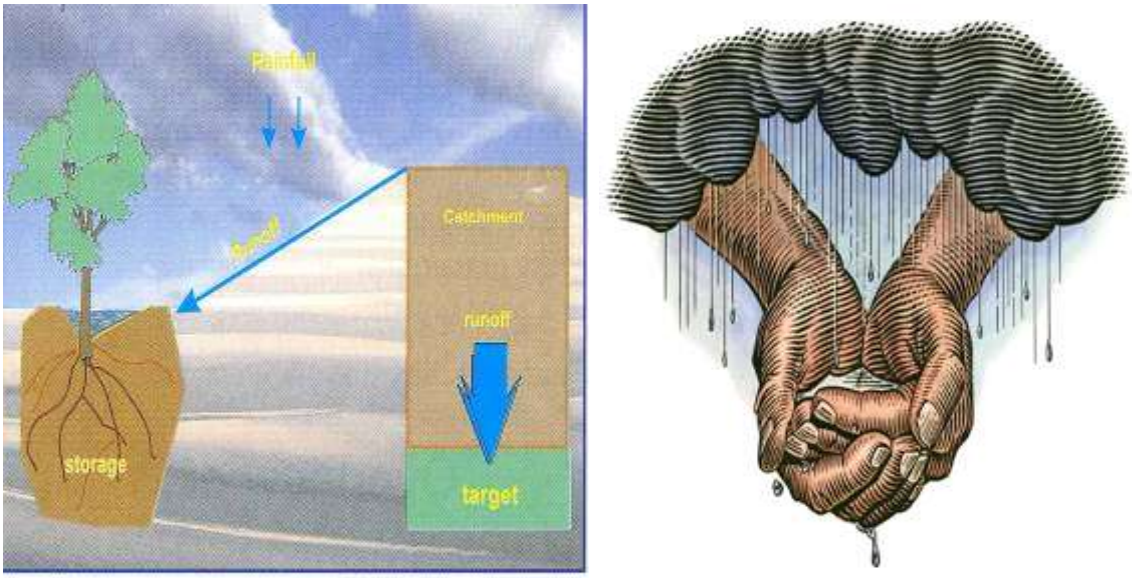
In this study will be investigated the importance of water harvesting practices for the arid cities of Turkey.

Materials and Methods

Some water harvesting techniques cause soil and water erosion in dry areas. They are used successfully in the dry countries, also in south-east of Turkey. Most of the agriculture products like wheat, barley, pistachio and olive are grown using rainwater (non-irrigation), in South-east of Turkey. This region has an arid climate with total 250-450 mm rainfall in the winter season Because of that water harvesting practices are necessary for increase catchment of rainfall per unit area in this region.. These methods that can be used in these arid areas will be described.

Results and discussion

In arid and semi-arid areas over accumulation or runoff of rainwater falling through inadequate storage is called water harvesting. Components of rainwater harvesting are catchment area, storage and target area (Fig. 1 a, b).



(a) (b)

Fig.1. Water Harvesting Components (Oweis, 2001)

Contour Tillage Water Harvesting

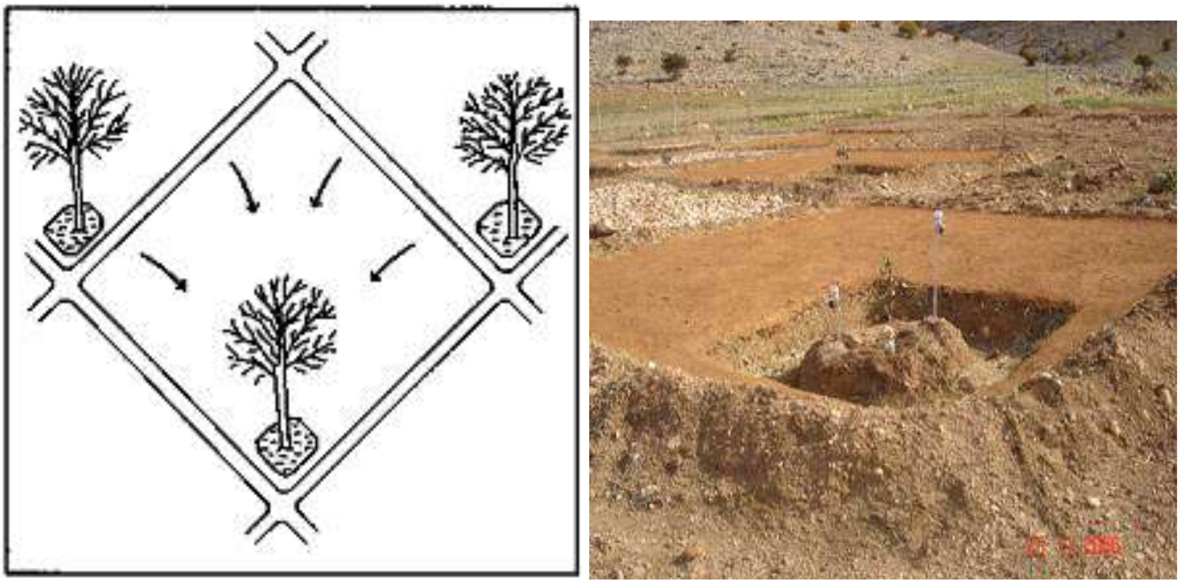
Water harvesting techniques are based along contours including: contour plugging; contour ridges; stone lines; grass strips and terraces (Fig. 2 a, b). Ideally, any plugging on a slope should be carried out along the contours rather than up and down as this reduces run off and soil erosion and increases moisture retention. Contour ridges are one of the most important techniques for supporting the regeneration and new plantations of forages, grasses and hardy trees on gentle to steep slopes in the steppe (Rocheleau, 1988).

(a) (b)

Fig.2 (a,b) Water Harvesting Contour Tillage

Negarim Technique

Small runoff basins consist of small diamond shaped structures surrounded by low earth bunds. They are directional to have the maximum land slope parallel to the long diagonal of the diamond. Runoff flows to the lowest corner, where the plants is placed (Fig. 3 a, b).



(a) (b)

Fig. 3 (a,b). Water Harvesting Negarim Micro-catchment Technique

Semi-circular and Trapezoidal Bunds

Semi-circular bunds are usually shape of a semi-circle, a crescent or a trapezoid facing directly upslope. They are created at a spacing that allows sufficient catchment to provide the required runoff water, which accumulates in front of the bunds, where plants are grown. Runoff is stopped and stored here in the plant root zone. These bunds are used mainly for the rehabilitation of rangeland or fodder production (Fig. 4 a, b). They provide soil and water erosion control.

(a) (b)

Fig. 4 (a, b). Water Harvesting Technique for Erosion Control

Contour - Bench Terraces

Water and soil conservation and water harvesting techniques to combine the very steep are built on slopes. Agricultural terraces slow down the flow of water and to control erosion are constructed to be straight and stone walls supported. Mostly they are plants used to form of trees and shrubs (Fig. 5). The historic contour-bench terraces supporting coffee and gat trees in the mountains of Yemen (Oweis 1994 & 2001).

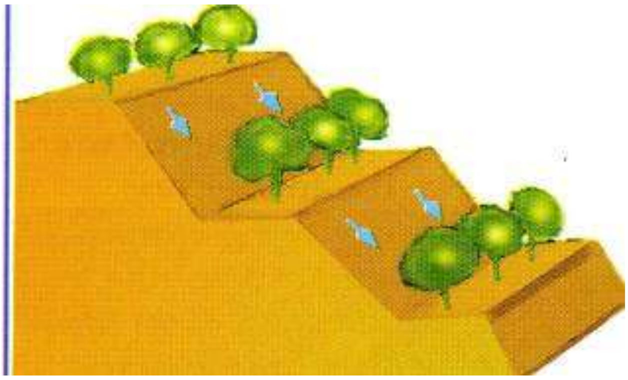


Fig. 5. Contour- bench Terrace for Conserving Erosion

Wadi-bed Cultivation

Stonewalls, if properly constructed across the wadi bed, can help to store and distribute runoff water evenly and to build up soil behind them (Fig. 6). Low-pitched valley floors sediment, valley base precipitates and around good agricultural fields arise (Oweis 1994 & 2001).

Fig. 6. Wadi-bed Cultivation Water Harvesting System for Erosion Control

Water Harvesting Paraffin Application

This application generally used to increase of runoff efficiency to collect rainwater in dry areas. At the same time this application provides to soil and water erosion control in sloping lands (Fig. 7).

Fig. 7. Paraffin Application for Collecting Rain Water

Negarim Micro- catchment Straw Mulch Application

Water harvesting techniques should be followed by some some applications. Plastic, stone, gravel and straw mulching are a few of them. These water harvesting mulching applications collect rain water, as well as conserve soil sediment loss (Fig. 8). This is the best erosion control known for micro-catchment surface covered with plastic sheet (Fig. 9) (Kuzucu 2013).

Fig. 8. Straw Mulch Application for Rainwater Harvesting and Erosion Control

Fig. 9. Plastic Mulch Application to Collect Rainwater and Erosion Control

Conclusion

In semi-arid areas precipitation amount is low and most of the harvested rainwater that gathers at the surface is lost due to evaporation. One of the most important problems is erosion in slopes and arid areas. Water harvesting practices are very importnat in these areas. Water harvesting is the most important goal of the agricultural production in a sustainable and environmentally friendly water supply system to reveal. Water harvesting, soil erosion control, as well as in rural and arid areas provide enough water for drinking and agricultural production. Therefore, quantifying agricultural irrigation water demand in the agricultural region, are of importance to help improve the water towards sustainable use. Water harvesting provides the best way to take advantage of rainwater for agricultural activities.

Abstract

With the aim to evaluate economic impact of feeding factors in milk production, one year study was done (January – December 2015) involving 12 Holstein dairy farms (284 cows) in Kosovo. During the study period the structure of the diet and the amount of feed and the amount of milk produced were measured monthly based. The cost of in-farm produced feed, or the prices of purchased feed and the price of milk were used to do the calculations. Results showed that 74% of the feed is produced in the farm and includes roughages while all concentrates (either ingredients or mixtures) are purchased. Economic analysis showed that prices of feed produced within a farm were lower (30 €/ton for silages and 30 €/ton for hay) compared with feeds bought from local markets (80€/ton for hay and 280€/ton for concentrate mixture). Average cost of the ration was 2.33 €/cow/day, while average milk income was only 4.9 €/d. Total average sold milk price with all subsidies given by the state was 0.34 €/kg. Average production cost for milk was 0.29 €/kg with net profit of 0.05 €/kg of milk. Individual feed groups contributed as follows: silages with 0.04 €/kg, dry roughages with 0.02 €/kg, and concentrates with 0.10 €/kg, while all other factors make 0.13 €/kg of milk price. About 62.5 % of milk produced within these farms was categorized in Extra Class, farmers were additionally rewarded by the state with 0.06 €/kg.
The main finding of this study is that feed makes the largest expense in all analysed farms and in average makes 55% of the milk production cost or 68% of all farm costs.

Key words: *milk cost, feed cost, farm income.*

Introduction

Dairy sector in Kosovo is an important sector of sustainable development of the country economy. However, it is still faced with many difficulties, where small farm size (as a consequence of last War) and loss of cattle is of important contributors (Nushi and Selimi, 2009). As estimated by MAFRD (2015a) average farm size is between 1-5 heads, representing 94.2% of all farms. Dairy cows make 55.6% of the cattle population, and though only 5.8% of the farms bred more than five cows, they are main milk suppliers for processing industry (Zeqiri et al., 2015). With existing numbers, locally produced milk covers about 84% of domestic consumption (MAFRD, 2015a). According to Belegu et al., 2010, sustainable development of dairy sector requires not only increased number of animals per farm, but also increase of their economic efficiency Although cow milk makes 97.8% of all milk produced, with low yields ranging from 2000–5000 kg/cow/lactation (MAFRD, 2015a) which is too far from genetic potential. As reported by Bytyqi et al., (2014), average income from milk is 144.78 €/cow/month. Same authors reported that income over feed cost is 78.04

€/month since average feed costs is 66.74 €/month. After inclusion of all other expenses, net income falls to 67.44 €/month per cow.
Holstein dairy cows which are known for their high production potential are the most present type in Kosovo. However they are still not being exploited at desired extent, since many factors of influence in their performance are not duly respected.
The objective of this paper was to evaluate the economic importance of feeding factors in farm incomes, especially related to milk production.

Material and methods

Economic impact of feeding factors in milk production was measured through one year study (January – December 2015). The study was done in two regions of Kosovo and included 12 Holstein dairy farms breeding 284 cows in total. More than 10 milking cows per farm and contractual agreements with the milk collection centres were the criteria for including of farms in this study. Each month of the study period the structure of the diet, the amount of feed used and the amount of milk produced were measured. All costs and incomes were also recorded during entire study period. The cost of all feeds either produced in the farm or prices of feed ingredients purchased and the price of milk paid were used to do the calculations.
The structure of the ration was estimated by measurement of all ration ingredients used. Production feed parameters were estimated based on energy and protein content of feeds and the amount of these nutrients supplied to animals. This is done by exact weighing of daily feed amount offered and feed rest. Milk production at farm level was measured by farmer in daily basis. The amount produced was then converted to monthly and total production per cow. A 305 day milk production was calculated by division of the amount per year by the factor 1.1967 (365/305). Average milk price payed to farmer was calculated per month. Basically the milk price was dependent on milk fat unit (as a criterion of milk collection centres) but some farmers got additional 0.04-0.06 €/per litre if milk was within standards set by Administrative Instruction nr. 04/2015 (MAFRD, 2015b). Based on the same regulation, farmers were also subsidized based on the area they have cultivated with maize and the number of dairy cows they have. Total farm income was therefore the amount of income from milk, sold calves and heifers, manure plus subsidies. This is a one year investigation and it is based on information generated from the costs farmers made to produce (declared by farmers but not always fully documented) and all forms of incomes (exactly proven by milk collection centres and the government payments). Statistical analysis of results included descriptive analysis using Analysis Tool pack MS Office Excel 2007.

Results and discussion

Feed production and land use

Feed is known to be a main determinant factor of performance in livestock production and represents the main part of costs in milk production (Singh and Narang 1993). The surface of the land, available mechanisation and farmer's knowledge about fodder production generally affects overall production costs. Providing adequate feed to animals both in quantity and quality is essential to maximize production for dairy farms.
Results on the structure of land (own or rented) are presented in table 1. As shown in the table, farmers owned very small land area and therefore were forced to rent land. They pay rent for land between 200 500€/ha.

Table 1. Average area of land used for fodder production owned or rented (with rent price) by dairy farms.

N=12	Total land area ha/farm	Area owned, /ha	Area rented, ha	Rent price €/ha
$\bar{X}$	11.7	3.5	8.3	318.8
Min	6.5	2.0	4.0	200.0
Max	30.5	6.0	27.0	500.0

According to last agricultural census (KAS, 2015), Kosovo has 512,000 hectares of land considered as agricultural, of which a very large part is utilized land (413,635 ha). Most of the utilized land consists of arable land (180,381 ha) and meadows and pastures (224,411 ha) which is also a good potential for fodder production. But, still the capacity to produce sufficient and cheap (low cost) feed is limited due to varying agronomic and climatic conditions.

The structure of the ration and feed costs

Prices of purchased feeds were variable and dependent on the production costs (table 2) the yields, prices of fertilizers, costs of machines hired for soil cultivation, prices of irrigation etc. Since there is no official market for feeds, these prices are collected based on interviews in local markets and from information given by farmers included in study. In average 74% of the feed was produced within a farm. Results show that all concentrated feeds (ingredients or compound feed) were purchased. However, some farmers grinded and mixed them to produce own compound feeds. This resulted in savings of about 30 €/ton feed. To balance fibre content of the ration, some farmers used to use wheat straw which was also purchased by all farms. In general, production of feed by farm resulted in differences from 20-60€/ton in feed prices. Of roughages, maize silage generally considered the main feed (Chase et al., 2009) in extensive dairy compounds is produced by all farms.

Table 2. The costs and the structure of feed produced or purchased

Type of feed	Production price, €/kg	Purchase price, €/kg	Difference in price €/kg	The source of feed, %	
				Produced	Purchased
Meadow hay	0.03	0.08	0.05	32	68
Alfalfa hay	0.04	0.10	0.06	86	14
Wheat straw	-	0.04	0.03	0	100
Corn Silage	0.03	0.05	0.02	100	0
Haylage	0.05	0.07	0.02	37	63
Compound feed*	0.25	0.28	0.03	0	100

* Compound feed made in farm was produced from purchased ingredients

Nutritional status and dry matter source

An analysis of the structure of dry matter, groups of feed in relation with milk production in two milk production scenarios is presented in table 3. It is observed that total DM intake was not changed with the increase of milk yield from to over 4500 kilograms per lactation. However more efficient use of energy and proteins is seen. Decrease in energy (8.6 to 7.8 MJ ENL/kg of milk) and protein consumption (124.7 to 119.7 g/kg of milk) is observed in farms with more than 4500 litres of milk per lactation (table 3). This finding is comparable with findings of Emiri, (1999) who also reported that protein consumption per unit of milk produced also reflects the level of fibres and indigestible proteins in the ration. Analysis of DM, energy and protein consumption (table 3) in two milk production levels obtained in this study show that in general, consumption of these nutrients is considered to be high for both levels of milk production. The reason for this is that calculations are done on the basis of the feed given to animal without exact calculation of feed rests which may account 10-15 % (Emiri, 1999). Another interesting result is that the increase of milk yield is associated with consumption of less dry roughages and more concentrated feeds which are used to overcome nutrient deficiencies and lower availability of roughages.

Table 3. Average of DM, NEL and protein consumption for two levels of milk production obtained during the studied period*.

Number of farms	Milk production, kg/day	Dry Matter Intake, kg/day	NEL, MJ /kg milk	Protein, g/kg milk	Silage (corn and grass) %	Dry roughages, %	Concentrated feeds, %
N=5	Milk yield, under 3500 kg/cow						
$\bar{X}$	11.4	17.47	8.6	128.7	52.3	22.4	25.3

*Duration of studied period from January to December 2015.

Analysis of farm incomes

Economic analysis of the contribution of the ration and the feed groups in milk price is presented in table 4. Results show that an average sale price of milk was 0.34€/kg while production cost of one litre of milk was 0.29€. The main contributor of this cost is definitely feed (51.7-65% of the price). The highest portion of this cost is from concentrated feed followed by silages and dry roughages (62.5; 25 and 12.5%, respectively). Income over feed cost ranged from -0.03€/kg to + 0.04€/kg. There is established subsidy direct payment programme in Kosovo since 2014 and farmers who succeeded to reach certain milk quality standards (Extra, First and Second Class) will benefit (0.06; 0.04 and 0.02 €/kg of milk for respective quality class). In this respect, the majority (62.5%) of milk produced in farms involved in this study belonged in Extra Class, 7.69% in first and 29.8% in second class. This type of income represented very important part of the milk income and averaged 0.05 €/kg.

Table 4. Economic analysis of the effects of feed groups in milk production in dairy farms.

Number dairy farms (N=12)	Cost of the ration, €/day	Portion of the feed group, €/kg			The structure of the total milk cost, €/kg		Net income, €/kg milk	
		Silage	Dry roughages	Concentrated feeds	Feed	Other	Without subsidies	With subsidies
$\bar{X}$	2.33	0.04	0.02	0.10	0.16	0.13	0.00	0.05
Min	1.94	0.03	0.01	0.09	0.15	0.10	-0.03	0.00
Max	2.61	0.07	0.03	0.12	0.19	0.17	0.04	0.06

From the costs structure analysis which represents the average of all farms (Figure 1), it can be seen that feed took the main portion with 68% of all costs. Depreciation rate, work force, veterinary expenses and other costs make 32 % of the costs. Under other costs expenses for fuel in feeding operations and manure removal within a farm, electricity, water, cleaning and sanitizing as well as maintenance costs for mechanization were included.

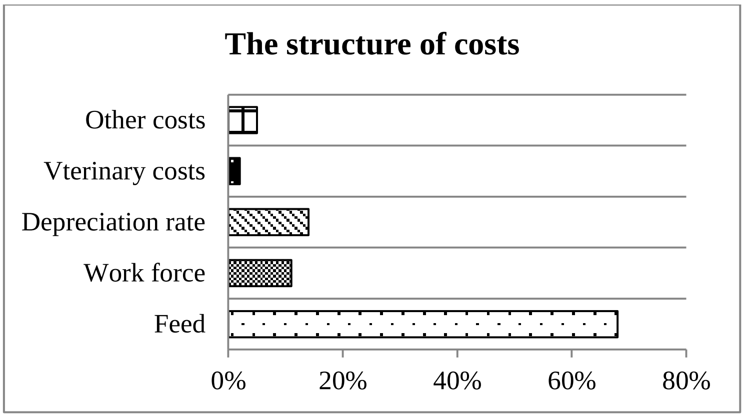

Figure 1. Average contribution of each cost group

Through figures 2, 3 and 4, an analysis of the structure of incomes is given. Analysis of the structure of production incomes (figure 2) unexpectedly show that without subsidies, milk production makes the lowest farm income (only 8%), even lower than manure. Subsidies per hectare of maize (150 €/ha), per cow (70€/head) and per level and quality of produced milk (0.05€/kg) have substantially contributed in total farm income (figure 3). With the average of 64%, subsidies are the main farm income (table 5), with some farms where subsidies are the sole income.

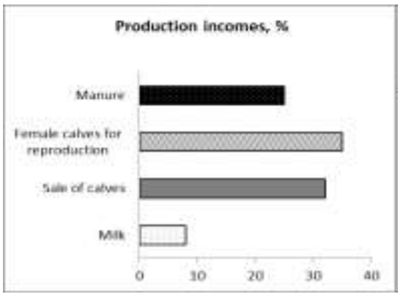

Figure 2.The structure of production farm incomes

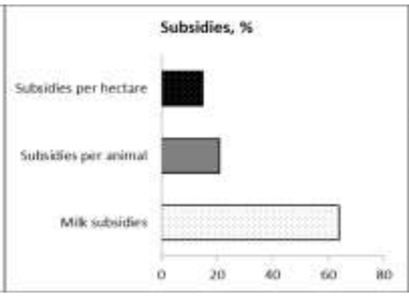

Figure 3. The structure of subsidies

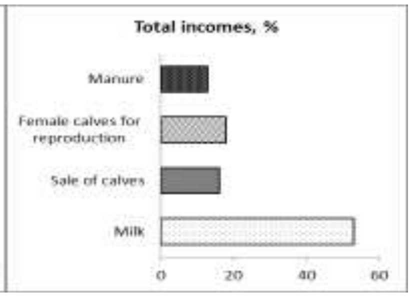

Figure 4. The structure of all incomes

Table 5. Contribution of production and subsidies in dairy farm income in € or in %

Number of dairy farms	Incomes €/year		Incomes, %	
N=12	Production	Subsidies	Production	Subsidies
$\bar{X}$	4876	7930	35.99	64.01
MIN	81.40	2967.24	0.77	49.31
MAX	17867.62	18837.12	50.69	99.23

However subsidies have positively affected dairy farm business enabling them to either produce feed at lower cost ore purchase required amounts of concentrates. This improved nutritional status of animals and their overall performance. Farms involved in this study bred between 11-47 dairy cows and used from 6.5-30.5 ha (table 1). This difference resulted in different management practices and effectiveness of the use of resources. The largest farm (47 cows and 30.5 ha of land) produced more in-farm feed and more milk (16.54 kg/day/cow) at lower costs of milk (0.27€/kg) as compared with smaller farms.

Conclusions

Feed is the main expense in all analysed farms and in average makes 55% of the milk production cost or 68% of all farm costs. Of feed groups, concentrates contribute with 34.48% followed by silages and dry roughages with 13.79 and 6.9% respectively.
Results of present study reveal that only one third of farm incomes are generated from animal production (milk, calves and heifers) with the lowest contribution of milk. Economic analysis of this study show that subsidies are main form of income and only 42% of farms managed to have profitable business without them. This profit ranged from 0.01 to 0.04 €/kg of milk. The other 58% of farms were either at subsistent state (no profit- no losses) or the cost of milk produced was higher than sale price for 0.03€, which would generate losses and endanger the sustainability of farm business.
After several farm visits during entire investigation we found that feeding and other management practices are not in full accordance with requirements of animals so the low milk yield and overall cow performance is a logical consequence. Though the amount of subsidies given is considered low by farmers it is more or less comparable with the region, but we think that this is not the best form to overcome low performance and bad farming practices for a longer period.
The only sustainable tool to ensure competitiveness of milk production of Kosovo dairy farmers is to put more efforts and knowledge in order to more efficiently utilise the genetic potential of the animal.

Abstract

The rations of monogastrics, especially poultry, are mainly made up of soybean meal and maize, raw materials totally imported by Algeria. Their substitution by local raw materials or their co-products would be able to reduce the cost of production of animal products.
It is within this framework that this study proposes to determine the effects of the incorporation of dehydrated citrus pulps at a fixed rate (5%) and dehydrated local barley grains partially substituting for corn, in the diet on the performance of growth of broiler chickens. A total of 200 one day old F15 broiler chickens was randomly divided into 4 equal groups according to the substitution rate of maize with brewers' grains (0%, 20%, 25% and 30%) for 48 days. No mortality was observed in any groups. The weight to 10 days were significantly greater for lots 20%(+19%) and 30% (+11%), while for the weight to 20 days, only the lot 20% has a weight significantly greater with 578g. In the growth phase, the weight of the control and the 30% batch are similar. In the finishing phase, the control batches, 25 and 30% have similar weights (2600g). The Consumption Index and intake quantities change proportionally to substitution rates, while costs are inversely proportional. The prices of the kilograms of live weight and eviscerated carcass of lots 20 and 25% are promising with less than 8 and 12 DZA respectively. The incorporation of 5% citrus pulp and 30% dehydrated barley grains, in substitution for maize, alters consumption and intake rates but produces significant economic results for their uses in chicken dietary formulas.

Keywords: *Weight growth, Brewery dreches, consumption index, Corn, Citrus pulp.*

Introduction

The rations of the monogastrics, particularly those of the poultry, are mainly composed of cakes of soya and maize, raw materials totally imported by Algeria. Their substitution by local raw materials or their co-products would be able to reduce the cost of livestock production (Arbouche, 2012; Boudouma and Berchiche, 2010). The use of co-products from the processing of citrus and brewery based on local barley varieties in the dietary formulas of broiler chicken will have the advantage of reducing corn imports and upgrading local products.
In Algeria, the raw materials that can be used in brewing are barley from local varieties (*Tichedrett* and *Saida*) whose average chemical composition is different from that of their European counterparts (Arbouche et al., 2008: Arbouche, 2012) And co-products of citrus processing whose cultural aspects do not involve any source of pesticides or phytosanitary products.
The introduction of the latter into the poultry feed has been the subject of several studies which demonstrate a restriction of its incorporation (5%) for broiler chickens (Arbouche

2015 ; Lanza 1982 ; Oluremi et *al.*, 2007 ; ElBoushy et *al.*, 2000). This rate of incorporation is capable of lowering the cost price of the kilogram of food produced, since maize is imported almost entirely. The combination of these two by-products could have an associative effect in the improvement of the weight productivity of broiler chickens.
The aim of our study is to determine the optimal incorporation rate of barley brewers into broiler feed with a constant rate (5%) of barley brewers.

Materials and methods

Animals, diets and experimental protocol

Our experimentation took place at the level of the cooperative poultry of the wilaya of EL TARF in Algeria, during the months of March and April 2014. This period was characterized by an average temperature of 18 ° C and an average humidity level of 82%.
Two hundred one-day chicks; Of Hubbard F15 strain, weighing on average 40 ± 2.8 g, were divided into four homogeneous parquet floors with a surface area of 5 m2 each and consisting of 50 subjects in a closed building with static ventilation. The litter consisted of sawdust. The barley brewer's brewery came from the beer-making unit in the wilaya of Annaba and the citrus pulp from the juice and canning unit of SIJICO (*Ramdane Djamel* wilaya of *SKIKDA*). The drying was carried out by exposure to the open air and the sun in order to avoid the disadvantages reported by Fritzch and Abadjieff (1977). The chemical composition of brewery grains and citrus pulp was determined by the AOAC method (1990) with a repeatability of 3 (Table 1 and 2).

Table 1. Chemical composition of dehydrated

The analyzes included organic matter, total nitrogenous matter, crude fiber, fat and mineral matter. The crude energy was determined by adiabatic calorimetry. Four iso-energetic rations were designed, containing 0% (control food), 20, 25, and 30% brewery dairy and 5% dried citrus pulp in substitution for maize during the various stages of rearing (Table 3).

During the first ten days, continuous lighting was maintained in the chicken coop and then reduced to 18 hours of daytime for 6 pm nocturnal. A temperature between 36 and 38 ° C was maintained during the first ten days thanks to gas brooders. Water and food were distributed ad libitum. Chickens were vaccinated against Newcastle disease and infectious bronchitis on the fifth and twenty-fourth day of rearing and against Gumboro disease at 123 and 128 days of age; An anticoccidial was administered by buccal voice at 15 and 28 days for 3 consecutive days.

The animals were individually weighed at 10 and 20 days of age during the start-up phase, at 33 days and at 48 days of age during the finishing phase. During the entire breeding phase, the food was distributed at will and the refusal weighed daily. The mortality rate was collected daily on the whole experiment.

Statistical analysis

The descriptive statistics and the variance analysis of the univariate general linear model were carried out with the SPSS software (version 18, 2008) for the analysis of the live weight (LW), the daily weight gain (ADG), the Food intake and consumption index (CI). The general linear model was used to test the effects of factors on variables, the post hoc test by applying the SNK test (Student-Newman-Keules) and Duncan, to estimate the significance or homogeneity between the different sub Sets (comparison test between averages). The differences were considered significant with a risk of error of 5%.

Results and discussion

Over the whole of the experimental period, the mortality rate remained zero whatever the diet considered. 10-day weights are significantly higher for lots 20 and 30%, while for 20-day weights, only the 20% lot dominates with a weight of 578.2 g (Table 4). In the growth phase, the weight of the control and the 30% batch are similar. In the finishing phase, the batches, control, 25 and 30% have identical weights.

The average daily gains (ADG) are in the start-up phase, identical for the batches, control, 20 and 30% from 0 to 10 days, whereas for the period from 11 to 20 days, the control batches, 20 and 25% are similar. During the entire start-up phase, the $ADG_{1\text{-}20d}$ is more expressive for the batch 20% (26.9 g), identical for batches 25 and 30% while remaining below the ADG of the control batch. The ADG of the growth phase remains similar for the control batches, 25 and 30%, the 20% batch being the least expressive. For the finishing phase, the ADG of lots 25 and 30% are similar and more important.

During the entire breeding period, the $ADG_{1\text{-}48d}$ is similar for the control, 25 and 30% (53.5g on average).

Table 4: Evolution of weight growth during the start-up, growth and finishing phases in broiler chickens as a function of the percentage of substitution of maize by brewed grains

	% of substitution				ESM	P
	0	20	25	30

$ADG_{1\text{-}48}$ (g/d/subject)	$53{,}3^{a}$	$50{,}2^{b}$	$53{,}5^{a}$	$53{,}7^{a}$	0,872	0,001

ADG: Average Daily Gain (The indices indicate the period in days on which this parameter was calculated). The presence of different letters on the same row and column indicates a significant difference between diets and strains [P <0.05].

During all periods of breeding, ingested and indices of consumption are significantly different between the batches (Table 5). Live weights and weights of eviscerated carcasses are similar for the control batches, 20 and 30% with an average of 2800 and 2000 g respectively (Table 6). The by-products have significantly different weights between batches.

Table 5: Evolution of food intake and consumption index during start-up (1 to 20 days), growth (21 to 33 days) and finishing (34 to 48 days) as a function of the percentage substitution of maize by brewers' grains.

	% of substitution				ESM	P
	0	20	25	30		
Food insecurity (g)						
To 1 to 10 days	162[a]	167[b]	156[c]	161[a]	5,43	0,01
To 11 to20 days	766[a]	797[b]	780[c]	788[d]	1,87	0,02
To 21 to 33 days	1850[a]	1899[b]	2038[c]	2510[d]	3,85	0,01
To 34 to 48 days	3497[b]	3943[c]	3967[c]	4916[a]	2,51	0,02
To 1 to 48 days	6275[a]	6806[b]	6941[b]	8375[c]	4,48

To 1 to 10 days	1,12[a]	0,96[b]	1,37[c]	0,94[b]	0,08	0,01
To 11 to 20 days	1,39[a]	1,38[a]	1,53[b]	1,50[b]	1,63	0,001
To 21 to 33 days	1,25[a]	1,35[b]	1,41[c]	1,72[d]	0,85	0,001
To 34 to 48 days	1,34[a]	1,60[b]	1,52[c]	1,88[d]	1,46	0,001
To 1 to 48 days	2,41[a]	2,77[b]	2,66[c]	3,19[d]	1,59	

The results are expressed as a function of mean ± standard error to mean (SEM). The presence of different letters on the same row and column indicates a significant difference between diets and strains [P <0.05].

Table 6: Evolution of liveweight, weight of carcasses and by-products of slaughter of broiler chicken according to the percentage of substitution of the maize by the dregs of brewery.

	% of substitution				ESM	P
	0	20	25	30		
Live weight (g)	2793[a]	2815[b]	2729[c]	2813[b]	2,95	0,02
Eviscerated carcass (g)	1993[b]	2024[a]	1997[b]	2019[a]	2,41	0,01
Paws (g)	105[a]	106[a]	99[b]	109[c]	4,93	0,02
Heads (g)	70[a]	81[b]	67[c]	72[a]	0,97	0,01
Feathers (g)	112[a]	99[b]	78[c]	92[ab]	0,67	0,01
Liver (g)	65[a]	46[b]	41[c]	47[ab]	0,18	0,001
Gizzard (g)	64[a]	64[a]	59[b]	62[ab]	0, 75	0,001

The presence of different letters on the same row and column indicates a significant difference between diets and strains [P <0.05].

Interestingly, the fixed incorporation of citrus pulps (5%) and brewery grains as a partial replacement of maize induced a delay in weight growth in the broiler chicken only in the 10% lot between 0 and 10 days, whereas Arbouche et *al*. (2014) reported a marked decrease in starting weights on the same strain for substitution rates of 30 and 40%. At 20 days, the 20% lot is the most expressive (578.2 g / d / subject) compared to the control batch, the same finding was made by Arbouche et *al.* (2014) for identical substitution and on the same strain. In the growth phase, the control lot and the 30% lot have similar weights (1468 gen mean) whereas Arbouche et *al*. (2014), Metayer et *al* .(2009), Branckaert (1967) and Branckaert and Vallerand (1970). Different weights. For the finishing phase, the control batches, 25% and 30% have significantly different weights, while Morrison (1956), Borgioli (1962), Simmons (1965) and Ademosson (1973) find different weights.

For consumption indices and intake quantities, they increase in proportion to the substitution rate, contrary to Metayer et *al* (2009), who note a decrease in these parameters from a substitution rate of 5%. Skiba et *al* (2009) note a degradation of the chicken consumption index for an incorporation rate of 15% of grains and 20% for Bouvarel et *al* (2009). The weights of the eviscerated carcasses are similar for all lots with an average weight of 2010 g.

In conclusion, the incorporation of 5% citrus pulps and 30% dehydrated barley grains, in substitution for corn, gives good results in food formulas for broiler chicken.

Abstract

Atriplex halimus L. (Chenopodiaceae), has a large role in the feeding of livestock as a halophyte plant in the arid and semi-arid zones of the Mediterranean regions. Its adaptation to pedoclimatic conditions gives it ecological and economic importance. This species is used as a forage plant, particularly during the summer drought period, and is highly valued by camelids, sheep and goats, particularly during the lean season. The variation of the nutritive value through the different phenological stages reveals maximum values of UF (0,81/kg of DM of UFL and 0,79/kg of DM in UFV) and in PDI (165g/kg of DM in PDIN), at the flowering stage and mature grains respectively. The sodium level is minimal at the vegetative stage (2,06% of DM) and maximum at the mature grain stage (4,36% of DM). The Ca and P contents are related to the halomorphic character of the soil. The alkaline pH of the soil inhibits the assimilation of phosphorus. Since the Ca/P ratios are balanced for all the phenological stages. In order to be able to reconciling the nutritive values of the Atriplex halimus and its absorbency in Na, it should be exploited in zero grazing, in the mature grain stage. This will make it possible to provide livestock farmers with packaged fodder that will avoid the practice of transhumance (Achaba).

Keywords : *Atriplex, Food, chemical composition, phenology, halophyte plant*.

Introduction

Atriplex halimus L. (Chenopodiaceae), halophyte plant has a great ecological and economic importance in the Mediterranean regions due to its adaptation to the pedoclimatic conditions of the arid and semi-arid zones and its role in the feeding of livestock (McKell 1989 ; Le Houérou 2000 ; Martinez *et al.* 2003 et Haddioui et Baaziz, 2001). This species is used as a forage plant, especially during the summer drought period (Le Houerou 1992, Valderrábano *et al*. 1996 ; Bajji *et al.* 2002 ; Abbad *et al*. 2004a). Kinet *et al*. (1998), have shown that this species is a highly valued fodder for camelids, sheep and goats, particularly during the lean season.

Forage and biomass production studies have shown the value of Atriplex halimus in Mediterranean semi-arid regions (Ben Ahmed *et al*. 1996 ; Kinet *et al*. 1998).

Under an annual rainfall of 200 to 400 mm, the Atriplex. Halimus can produce 2,000 to 4,000 kg of dry matter per year per hectare ((Le Houerou 1992, Ben Ahmed *et al*. 1996). The ecological performance of this species and its adaptation to the soil salinity conditions make this species an important part of the pastoral value of the rangelands. In addition, Atriplex halimus is a species used both for erosion and desertification control and for the valorization of marginal and degraded soils (Wills *et al.*1990).

However, the acceleration of the destruction of the best rangelands to the benefit of cereal crops and fruit trees has led to a progressive narrowing of these rangelands. The eradication of many timber trees and abusive overgrazing, following the abandonment of certain pastoral traditions (rotation of the trails, maintenance of a suitable load per hectare, etc.), have brought about profound changes in potential and physiognomy routes. The combined effects of these factors has resulted in a decrease in the production of the average biomass, the scarcity of the best populations of pastoral species and the proliferation of species with little palatability (Aidoud et Aidoud, 1991).

Although many actions considered to be priorities (natural seeding trials, search for modalities of herd management, creation of forage reserves and extension of fodder crops) have been undertaken, their efficiency remains limited, however, due to the complexity of socio-economic constraints Specific to each region, as well as the lack of strategies integrating the different components of the environment (humans, animals, plants, physical or edaphic factors, etc.).

While there is unanimous support for the need to conserve and develop local plant genetic resources, the main question to be answered is the definition of the different methods of conservation and valorisation.

Materials and methods

Presentation of the study area

The El-Outaya region is a halomorphic soil depression composed of clay and silt. It is surrounded by mountains ranging from El-Kantara, at the beginning of the city of Biskra. This course, consisting mainly of Atriplex and Salsola, is located 18 km from the town of Wilaya. The climatic characteristics are: annual rainfall of about 124 mm with a maximum rainfall of 13.1 mm in January and a minimum of 1.7 mm in July. The autumn period (September to November) is the rainiest with 15.2mm. The annual average temperature is 21.9 ° C; the warmest month is August (33 ° C) and the coldest January (11.5 ° C). Emberger's climatogram classifies this region in a Saharan winter. An area of one hectare has been protected for five years, for the purposes of experimentation.

Samples

They were carried out throughout the year. The samples for the chemical analysis and the determination of the weight by weight were carried out on the basis of the appearance of the various phenological reference stages of the species.

Analyzes and calculations

Dry matter, crude fiber, total nitrogen and mineral content were carried out on 06 samples according of AOAC (1990). The in vitro digestibility of the organic matter was determined by the method of Aufrère (1982). We used the formulas of Demarquilly and Andrieu (1988) and Sauvant et al. (2004), for methods of calculating nutritional value.

Results and discussion

Chemical composition and digestibility

The rate of dry matter according to the phenological stages reached its maximum at the mature grain stage (32.6%) (Table 1), which is closely related to the climatic conditions.

The percentage of mineral matter varies according to the development and needs of the plant in minerals. The maximum level is at the mature grain stage (28.0% DM) and that of the minimal (23.8% DM) at the vegetative stage.
The rate of crude cellulose changes with the development of the plant to reach a maximum content of 18.3% of MS at the stage mature grain.
The Atriplex halimus is well provided with total nitrogenous matter, particularly at the flowering stage where the content is maximum (28,2 % of DM). This is in line with the findings of El Shatnawi and Mohawesh (2000), which report the raw protein richness. The latter is an important source of nitrogen for livestock.
The digestibility of the organic matter is below 50% for all the phenological stages, with a maximum of 0.75 at the fruiting stage.

Table 1. Chemical composition of Atriplex halimus according to the reference phenological stages

Components	Vegetative	buds	Flowering	Fruit	Grain mature
Dry matter	25.9±0,4	18.3±0,3	24.2±0,1	28.8±2,1	32.6±6,6
Mineral matter (% of DM)	23.8±0,2	24.0±0,1	25.9±0,3	26.1±1,2	28.0±1,9
Fat (% of DM)	2.2±0,9	2.5±0,1	3.40±0,09	2.8±0,2	2.1±0,2
Crude fiber (% of DM)	11.7±0,09	12.4.6±0,2	16.0±0,7	16.1±2,2	18.3±3,7
Nitrogenous material (% of DM)	18.5.0±0,1	16.1±0,08	28.2±0,4	27.9±1,4	24.3±4,5
DMO	0.64	0.70	0.71	0.75	0.65

DOM : Digestibility of organic matter .

Energetic values

Values MFU and Meat FUF (table 2) are maximal at the flowering stage (0,81 and 0,79/kg of DM, respectively). Essafi et *al.* (2007), have found values fluctuating between 0,71 and 0,75/kg of DM in MFU. Nefzaoui and Chermiti (1989), have advanced values in MFU Between 0,60 and 0,80/kg of DM. On the other hand Le houerou (1971), mentioned results that fall between 0,50 and 0,60FU.

Table 2. Forage values (UFL and meatFU / Kg of DM) of the Atriplex halimus according to the reference phenological stages

Components	Vegetative	buds	Flowering	Fruit	Grain mature
UFL	0,60	0,72	**0,81**	0,78	0,68
UFV	0,58	0,69	**0,79**	0,77	0,66

FUL : Fodder unit for lactation ; meat FU : Fodder unit for meat

Protein values

PDI (table 3) have maximum values at the mature grain stage with a predominance of PDIN (165.32g / kg DM). Kessler (1990), Reported that high levels of protein and mineral salts permit the use of Atriplex halimus as a forage reserve in summer and fall to address the deficiency in forage that occurs prior to the spring growth of herbaceous forage species.

Table 3. Protein values in g / kg DM of Atriplex halimus according to the reference phenological stages

Components	Vegetative	buds	Flowering	Fruit	Grain mature
DPIN	94,22	118,62	163,41	128,71	**165,32**
DPIE	81,63	93,94	116,68	100,02	**118,07**
DPIA	32,86	28,59	**50,08**	49,55	43,15

DPIN *: Digestible protein in the intestine allowed for nitrogen*
DPIE : Digestible protein in the intestine allowed for energy
DPAI: Digestible protein in the intestine allowed for alimentary

Contents of macro elements (Ca; P and Na)

The Ca level is higher at the setting stage with 2.71% DM. El hamrouni and Sarson (1974), Reported a maximum level of 1.98% DM for cultured Atriplex. The absorption of this element is closely related to the nature of the soil. For Na, the maximum level was 4.38% DM in the mature grain stage, lower than that observed by these same authors (7.4% DM). For Phosphorus, its assimilation is less (1.06% DM), due to the interaction with Ca.
For feeding ruminants, the Ca / P ratio is balanced for all the phenological stages.

Table 4. Ca, P and Na (% DM) content of the Atriplex halimus according to the reference phenological stages

Components	Vegetative	buds	Flowering	Fruit	Grain mature
Ca	1,68	1,62	2,41	**2,71**	1,82
P	0,43	**1,06**	0,84	0,60	0,52
Na	2,06	3,21	2,93	3,64	**4,38**

Ca : Calcium ; P : Phosphore ; Na : Sodium

Conclusion

The energy values are maximal at the flowering stage and the protein values are at the mature grain stage. In order to be able to reconcile the nutritive values of the Atriplex halimus and its absorbency in Na, it should be exploited in zero grazing, in the mature grain stage. This will make it possible to provide livestock farmers with packaged fodder that will avoid the practice of transhumance (Achaba).

Abstract

Our work aims to determine the chemical composition, digestibility and forage production capacity of floodplains, in order to determine their quantitative and qualitative potentialities. These data will allow the determination of the optimal time grazing or mowing, related to the nutritional value and dry matter yields per hectare. These data will allow the determination of the optimal date of grazing or mowing, related to the nutritional value and dry matter yields per hectare. Two stations were set up, one at the edge of Lake Tonga and one in the marsh Mekhada. There is a better floristic diversity and a harmonious distribution of grass species (Poaceae) and legumes (Fabaceae), ensuring a good balance of the basic ration (energy / protein) in Lake Tonga. The dry matter (DM) and green (GM) levels were maximal at the heading stage for the two stations with 35.77 t of GM and 26.27 t of DM for Lake Tonga and 1.84 t of GM and 0, 95 t of DM for the marsh. Crude fiber content is less important in the vicinity of Lake Tonga than in the Mekhada marsh with a difference of about 3 percentage points. The level of nitrogenous matter is higher in Lake Tonga (between 21 and 26%). In vitro digestibility remains substantially the same for the same phenological stage and feed values take larger values at the edge of the lake Tonga (0.92 to 1.03 / kg DM). Protein values in Lake Tonga are higher than in the Mekhada Marsh. The floodplains around Lake Tonga offer satisfactory forage potential but remain poor in the Mekhada marsh.

Keywords: *biodiversity, biomass, lake Tonga, Mekhada marsh, phenological stage*

Introduction

In flooded areas, major natural vegetation areas are available for rearing and form the basis of animal production, as is the case of the water meadows of the Far East of the country, characterized by a number of very heavy rain (up to 1100 mm of rainfall a year) and clayey nature of its soils. With 40,000 hectares of grasslands, the region of El Tarf covers over 53% of the agricultural area (DSA 2013). Besides their interest in animal feed, grasslands have many environmental advantages and a significant genetic diversity of the present species (Huyghe and al 2010). It has a plant resource in quantity and quality data (nature of the species, digestibility) at the right time, but the demands on these levels vary considerably in the manner of holding and the periods of the year. It is in this level that the natural reserves require a great care for the role that cannot be replaced for any development and the conservation of the biodiversity (Ramade 2002). The botanic composition of the meadow on a given site at a given time is dependent on complex interactions between environmental factors (climate, soil, topography) and management factors (mowing, grazing, organic or mineral fertilization mode) present or past (Louault et al 2002), causes of abundance and dominance variation among plant species, which can affect the recruitment of new species or

the disappearance of old species if they are not adapted to the new conditions (Loiseau et al 1998).
Our work aims to determine the chemical composition, digestibility and forage production capacity of floodplains, in order to determine their quantitative and qualitative potentialities. These data will allow the determination of the optimal time grazing or mowing, related to the nutritional value and dry matter yields per hectare.

Materials and methods

Study area

Located at the extreme North East of Algeria, the wilaya of El -Tarf with an area of 2908 km² consists of 40 000ha grassland located around lakes including the Lake tanga and the Marshes of Mekhada which occupies the central part of the plain of Mafragh, over an area of 8 900 ha.

Sampling and samples

Two stations were set up at the edge of Lake Tonga and in the Mekhada marsh on the principle of Rol (1980). The method used is that developed by (Braun-blanquet et al 1952). Its basic concept of minimum area of **(**Gounot1961**)** and the concept of association of (Guinochet1973**)**. The samples for analysis and the determination of the weight mass were made on the basis of phenological periods of the main grass species (Demarquilly 1981), because the phenological periods of grasses are more stable over temperature (Durand 1969).

Chemical composition and in vitro digestibility

They are based on the methods laid down by(AOAC 1990). They relate to the determination of the dry matter (DM), mineral matter (MM), crude fiber (CF) and total crude protein (TCP). Cellulose digestibility of organic matter (CellDOM) of the samples was determined by the method of (Tilley and Terry 1963) and improved by (Van Soest and Robertson 1985). The calculation methods Nutrition Facts are based on the formulas by (Demarquilly and Andrieu 1988).

Statistical Analyses

The chemical composition and in vitro digestibility of the OM were analyzed using analysis of variance (**ANOVA**) followed by the linear analysis procedure of the Statistical Analysis System.

Results and discussion

Phytosociological records

Table 2: Abundance and dominance (1 to 5) or presence (+ or ++) of the main plant species surveyed in station 1 (lake Tonta) and station 2 (marsh Mekhada)

family	latin name	Station 1	Station 2

"	*Phleum pratense L*	+	
"	*Poa trivialis L*	+	
Polygonaceae	*Rumex sp*		++
Primulaceae	*Anagallis foemina Mill*	+	
"	*Anagallis monelli*		+
Rubiaceae	*Asperula laevigata L*	+	

In station 1, we note the dominance of Lolium perenne L (English ryegrass) and station 2, that of Avena fatua L. (wild oats).
At Lake Tonga, there is a better floristic diversity and a harmonious distribution of grasses species (Poaceae) and legumes (Fabaceae), ensuring a good balance of the basic ration (energy / protein). The number of species is smaller (between 12 and 26) than in the El Feden grasslands in the same region (48 species) (Arbouche et al 2009).

Total production of plant materials

Whatever the phenological stage, flood meadows near Lake Tonga yields of green and dry matter higher than the marsh Mekhada. There is a change of the green matter greater than that of the dry matter (DM) (table 1). The dry and green material rates are highest at heading stage for both stations with 35.77Tde green matter (VM) and DM 26.27T for Lake Tonga and VM and DM 0.95T 1.84T respectively for marshes. Arbouche et al (2009), find a production of maximum dry matter at heading period 2.8 T of DM / Ha at the meadows of El Feden in the same region but at an altitude of 560m. Similarly to Arbouche et al (2008) on a herbaceous stratum under cork oak, yields of the order of 5.43 t of GM / ha are obtained for a yield of 1.26 t / ha of DM. At the level of the Belezma (Aures), Arbouche (1995), at the level of the lawns found a production of 1.76 t DM / ha at heading stage and 2.38 t DM / ha at the fructification stage for prairies with as dominant species Dactylis glomerata (orchard grass).

Table 1: Production of green and dry matter (t / ha) according to stations and phenological stages

		Vegetative	Montaison	Heading
Lac Tonga	Green matter	30,9	31,43	35,44
	Dry matter	11,66	24,41	26,27
Marais	Green matter	1,24	1,58	1,84
	Dry matter	0,42	0,67	0,95

Nutritional value

Chemical composition and digestibility

The results of the chemical composition and in vitro digestibility are traced in Table 2.We notice a rate of dry mastter more important at the level of Tonga Lake , whatever the phenological period. Arbouche et al 2008 and (2009), found lower rates (about 20%) for the same phenological periods. The crude fiber rate is less important to First Lake Tonga as Mekhada marshes around 3 points. The rate of nitrogenous matter is more important at the Lake Tonga (between 21 and 26%), highlighting the richness of this station legumes. In the low and medium altitudes grasslands in the region of El Tarf, Arbouche and Arbouche (2007) found less significant rates (of the order of 10 to 15%). In vitro digestibility remains substantially the same for the same phenological stage; It tends to decrease with the maturity of plant species. The contents of crude fiber and nitrogenous matter are of great importance since during the growing cycle, the digestibility of a plant is positively related to its nitrogen content and negatively to its crude fiber content (Andrieu and Weiss 1981).

Table 2 Chemical composition in% DM digestibility and based on phenological stages and stations

	Vegetative		Montaison		Heading		SEM	W
	T	M	T	M	T	M		
Dry matter	55.5^{a}	45.3^{b}	68.9^{c}	58.8^{a}	78.2^{d}	72.8^{d}	12.19	0.002
Mineral matter	7.7^{a}	10.4^{b}	7.0^{c}	10.4^{b}	6.8^{c}	9.4^{d}	4.53	0.005
Fat	1.2^{a}	2.2^{b}	1.4^{c}	1.8^{d}	0.87^{e}	0.78	1.18	0.0001
crude fiber	15.7^{a}	19.7^{b}	19.9^{b}	22.9^{c}	21.4^{d}	23.9^{e}	6.25	0.0004
nitrogenous material	26.3^{a}	20.3^{b}	22.6^{c}	15.5^{d}	21.5^{bc}	14.2^{e}	2.65	0.003
In vitro digestibility of organic matter	0.72^{a}	0.71^{a}	0.65^{b}	0.67^{b}	0.60^{c}	0.58^{c}	1.18	0.0005

T : lacke Tonga ; M : march of Mekhada
On the same line, the values with the same sign are comparable to the threshold of 5%

forage values

They take the most important values at the shores of Lake Tonga (0.92 à 1.03/kg of DM) whatever their purpose (milk or meat) (Table 4). Contributions in UF are most important in the vegetative period.

Arbouche and Arbouche (2007) on medium altitude grasslands at the same area, are fluctuating between values from 0.73 to 0.65 / kg DM of UFL and 0.64 to 0.61 / kg DM of UFV. For cork oak pastures, Arbouche et al (2008) have advanced UFL values of 0.86 / kg DM and UFV values of 0.59 to 0.60 / kg DM for the heading stage. For grasslands enclaved at medium altitude, Arbouche et al (2009) found results fluctuating between 0.86 and 0.95 / kg DM for UFL and 0.76 to 0.85 / kg DM for UFV for the same phenological stages.

Table 4: Forage values (/ kg DM) according to stations and phenological stages

		Vegetative	Montaison	Heading
Tonga lake	UFL	1.03	0.94	0.98
	UFV	1.01	0.92	0.94
Marsh	UFL	0.57	0.54	0.51
	UFV	0.55	0.52	0.49

UFL : Feeding unit for lactation; UFV : Fodding unit for meat

Proteins values

The protein values at the lake Tonga are more important than the marsh Mekhada (table 4) This is due to the stronger presence of legumes in Lake Tonga. Note that contributions in PDIE are equivalent at both sites. The vegetative period, intakes of PDI are the most important.

Lawn enclosed 560 m altitude, Arbouche et Arbouche (2007), found that the PDI are less important values including ear and ear emergence stage sheathed (respectively 66.8 g / kg DM and 60.2 g / kg DM). The DPIF values are equally weak at the enclosed pasture and under cork oak (Arbouche et al 2008 et 2009).

Table 4 Protein values (g / kg DM) in the stations and phenological stages

		vegetative	upstream	heading
Lake TONGA	DPIF	101	92	90
	PDIN	143	99	91
	PDIE	40	32	31
MARSH	DPIF	12.5	12	12
	PDIN	39.5	37	38
	PDIE	42	29,5	32

DPIF: Digestible protein in the intestine foodborne*;*
PDIE : digestible protein in the intestine permitted for energy*;*
PDIN : protein digestible in the intestine permitted for nitrogen

Conclusion

The floodplains around Lake Tonga and marshes of the Mekhada offer forage potentialities that are good for the first site but poor for the second. The areas of the marsh are important, it is necessary to improve yields by introducing new forage native species and conducting farming techniques to increase productivity weight.

Abstract

The region of El Fedden located at the border to Tunisia mountainous areas is forestry-pastoral. The tree species are mainly zeen oak and cork oak. The herbaceous layer present in permanent grassland remains the main source of food in the area existing ruminants. The study of these fields after five years of exclosure; allowed us to determine the yields of green matter, dry and nutritional value through the different phenological periods. The optimum period of operation is the heading period the most representative grass. At this period, the fields at this area develop green matter production 14T / Ha to a dry matter value 2,8T / Ha. At the period of optimal exploitation (heading), the crude protein rate is 13.6%. The evolution of crude fiber rate varies by phenological period of the plant and it is maximum fruit set period with 38.3%. The digestibility of organic matter is the most important period in pasture (0.74%). The protein content is more important at the stage pasture (66.47; 95.03; 20.54 from respectively for PIDA; PDIE and PDIN). The grasslands of El Fedden (municipality of bougous), located north of the Algerian level is at an altitude of 560m, offer opportunities in dry matter production and nutritional value that can be improved. The floristic diversity is a predominantly grass.

Keywords: *food value, pasture, production, Algeria*

Introduction

Plant formations, corresponding to different types of shrubs or herbaceous associations, play an important role in the diet of cattle especially in the dry period. Their operations are carried out through various types of transhumance shorter or longer and often interspersed with many steps conditioned by the appearance of the first grass growth.

This type of pasture that uses the forest management (Sarson and Salmon, 1977) must consider the socio-economic context of rural populations. It must be accompanied by silvicultural treatments to stabilize a forest grazing activity whose aim is to produce these landlocked pasture grass as main production intended generally to be grazed on site.

As such, the meadows at the forest of the municipality of bougous through conton of El Fedden, constitute a ground of privileged pathway, providing a herbaceous diet, where the animal can convert vegetation adapted to this milk box, and especially meat (Derkaoui 1977). However, the practice of breeding and extensive anarchic way in the forest, can only lead to overgrazing, posing the problem of regeneration and sustainability of the forest (El Hamrouni and Sarson 1975).

Materials and methods

Presentation of the study area

The region of El Fedden a forest ecosystem is located in the town of bougous north-eastern Algeria. Relief perspective, this is a woody mountainous together 80% of zeen oak (*Quercus canariensis*) and cork (*Quercus suber*) a with a density of 600 trees / ha on average (Arbouche et al 2008). The average area is 12 hectares, of between 5 and 43 hectares. The remaining rangelands is located under cork oak (Arbouche et al 2008).

Samplings

They were performed according to the method of Braun-Blanquet et al (1952). The choice of plant was performed according to the principle of minimum area.

The area being grazed on a surface of one hectare was exclosure for five years at the most representative site area grazed. A station 10 x 10 m was carried out.

Sampling and phytosociological surveys

They were performed throughout the year. The samples for chemical analysis and determination of the weight mass were made based on the occurrence of phenological periods of the case main dominant grass (Demarquilly et Jarrige 1981) and the fact that the phenological periods of grasses are the most stable compared to the sum of cumulative temperatures (Durand 1969).

The phenological periods are selected according with Andrieu et al (1988).

Temperatures

A maxi-mini thermometer was placed in the station according to the standards recommended by Durand (1969). The temperatures were recorded twice a week at the same hour, Friday and Monday from February.

Analyzes and calculations

The contents of dry matter, crude fiber, crude protein materials and inorganic materials were determined according to the methods of AOAC (1990). The calculation methods Nutrition Facts are based on the formulas of Demarquilly et Andrieu (1988). Statistical analyzes were performed using Statistica program 6.0.

Results and discussion

Temperatures

At the station, the respective values of maximum and minimum temperatures range from 18.2 to 35.6 ° C and ° C from 3 to 9.7, respectively. The average maximum temperature value for this region, a 32-year period is of 19.1 ° C.

Duration and temperature sum for the arrival of phenological periods

The period from 1 February of the onset of phenological periods at the station shows the predominance of *Bromus mollis* is to rank among early species (Table 1).

Table 1. Duration in days for the advent of phenological stages.

Species	Pasture	Ear bowden	Heading	Flowering	Nouaison
Bromus mollis	71	77	85	106	113

Sum of temperatures

The appearance of the first phenological period (pasture) at the station is 153 ° C (Table 2). The flowering periods and fruit set are made at 266 ° C and 293 ° C respectively.
At high altitude grasslands (1800m) located in the mountains of Belezma (Aures), the species *Bromus madritensis* totals from vegetation 51.6 ° C, stadiums heading, flowering are reached respectively sums of temperatures of 70 ° C and 103 ° C (Arbouche 1995).

Table 2. Sum of the weekly average temperatures (> 0 ° C) required for the various phenological stages from 1 February (° C)

Species	Pasture	Ear bowden	Heading	Flowering	Nouaison
Bromus mollis	153	173	193	266	293

Phytosociological survey

Altitude : 560m.
Exposition : multiple.
Slope : 0%.
Area : 100m^2.
Global recovery: 1
Strate : herbacée.
Soil : heavy.

Species	Abundance / dominance
Asphodelus microcarpus	4-4
Bromus mollis	3-3
Phalaris bulbosa	2-1
Trifolium rupens	2-1
Bellis sylvestris	1-2
Medicago merecxe	1-1

Total production of plant materials

The green matter (GM) is evolving exponentially grazing period to heading period (10T (tones) of GM / Ha (hectares) and 14T of GM / ha respectively) and regresses to the period fruit set (7T of GM / Ha). Dry matter production is maximum at heading period (2.8 T of DM / Ha). Grazing period is the least expressive value (2.1 T of DM / Ha).
De Montard (1991), estimated at the level of French worked grasslands, dry matter production averages 8 T of DM / Ha. Arbouche (1995), at the lawns of Belezma (Aures) is a production of 1.76 T of DM / Ha at heading period and 2.38 T of DM/ Ha fruiting period for grasslands with the dominant species *Dactylus glomerata*.

Production of plant material according to the botanical families

At the station, the peak of maximum production of green material is to be given to grass with a contribution of 86.5% and made up 12.7%. The maximum contribution pulses appear at the period spike sheathed (2T of GM / ha) with 14.8%. At the heading period, the production of dry matter (2.8 T) is best represented by grasses (2.5T of DM). At stage spur grazing and under gain, dry matter contribution is dominated by compounds with 1.1T / Ha.

Nutritional value

Chemical composition and digestibility

The solids content of the fruit-set period is higher (34.6 %) (Table 6).

Table 6: Chemical composition per % of DM of fields according to the different phonological periods

Components	Pasture	Ear bowden	Heading	Flowering	Nouaison
Dry matter	21.6±0,4[a]	20.3±0,3[a]	19.8±0,1[a]	28.8±2,1[b]	34.6±6,6[c]
Miniral matter	9.6±0,2[a]	11.0±0,1[a]	10.6±0,3[a]	6.6±1,2[b]	6.0±1,9[b]

Crude fiber	21.7±0,09[a]	24.6±0,2[b]	26.0±0,7[c]	28.1±2,2[d]	38.3±6,7[e]
Nitrogenous material	15.0±0,1[a]	15.1±0,08[a]	13.6±0,4[b]	8.3±1,4[c]	10.3±4,5[d]
Digestibility of organic matter	0.74	0.72	0.71	0.63	0.55

On the same line, the values with the same sign are comparable to the threshold of 5%

In period pasture, sheathed ear and ear emergence, the dry matter content is significantly the same. At these same periods, Andrieu et al (1988), refers to the level grasslands half mountain, DM rate of 16.2% in period pasture, 20.4% in the heading period and 21.7% at flowering period. The percentage of inorganic material is dominant in the ear period gain with 11.0%. At the station, the fat content is lower than in European grasslands (1.5%) (Andrieu et al 1988) except grazing period (3.2%). The fat content at this period is related to the chlorophyll pigments content of plants. The percentage of crude fiber rate varies by phenological period of the plant, which is related to weather conditions. It is maximum fruit set period with 38.3%. On the grasslands of medium altitudes, Andrieu et al (1988) suggests a rate of 33.5% at flowering period. At the period of optimal exploitation (heading), the crude protein rate is 13.6%. A smaller rate (11.1%) is reported by Andrieu et al (1988) on medium altitude meadows in the same phenological period. The digestibility of organic matter is the most important period in pasture (0.74%).

Energy values

They are the highest period spike sheathed (0.95 UFL (Fodder unit for milk) / kg DM and 0.85 UFV (Fodder unit for meat) / kg DM). Arbouche and Arbouche (2007) on medium altitude grasslands at the same area, are fluctuating between values from 0.73 to 0.65 UFL / kg DM and 0.64 to 0.61 UFV / kg DM.

Protein values

At the station, PDI (Digestible intestinal proteins) files are the maximum cob period sheathed with 63.82 ; 95.50 et 20.65 and minimum at flowering period with 36.70 ; 71.08 et 11.34G/kg of DM for the PDIN, PDIE et PDIA respectively. They remain low compared to the results found by Arbouche et Arbouche (2007) (168.5 to 88.96g/kg de DM) period and those of grazing Andrieu et al (1988) (108 à 39g/kg of DM).

Conclusion

The grasslands of El Fedden (municipality of bougous), located north of the Algerian level is at an altitude of 560m, offer opportunities in dry matter production and nutritional value that can be improved. The floristic diversity is a predominantly grass.

Abstract

Understanding responses of dairy cows to the effect of hot climate is essential to select more resilient animals. Our study investigated the relationship between hair cortisol level, hair and coat characteristics and fertility of 28 Fleckvieh and 67 Montbéliarde cows during hot and cold season in a commercial farm. Cows were maintained indoors with summer grazing. The following characteristics of hair and coat have been measured : hair cortisol level (C), Hair Weight (W), hair length (L); number of hairs per unit area (N), total hair diameter (HD), hair medullar diameter (MD) and percentage of white coat color (C%). Fertility parameters were estimated: interval from calving to first service (ICS), insemination per conception (IPC), and interval from calving to conception (IC). Statistical analysis was carried using Pearson correlation and Spearman's correlation rank when variables were not normally distributed with the SPSS package program, version 21. In Montbéliarde breed, hair total diameter was negatively correlated with IPC ($r = -0.338$, $p=0.01$) in winter indicating that Montbéliarde cows, with large total hair diameter, required reduced number of IPC to be pregnant, while in summer hair coat traits were not correlated with all fertility parameters. Positive correlations were observed between cows' hair coat characteristics and fertility parameters during Summer. In Montbéliarde breed, hair coat traits were not correlated with all fertility parameters. In Fleckvieh cows, coat color was significantly correlated with ICS and IC ($r=0.674$, $p=0.02$; $r=0.596$, $p=0.04$, respectively) during Summer. No association between hair cortisol level and fertility was observed. Proportion of white color in Fleckvieh cows significantly affected fertility. These results indicate that reproductive efficiency parameters are related to coat characteristics; this association was more expressed in Fluckvieh than in Montbéliarde breed. Also, possibility exists to select more adapted animals to warm climate regions.

Keywords: *Fertility; hair coat; cortisol; hot season; cows; Algeria*

Introduction

Heat stress can reduce fertility in cattle (Ealy et al.,1993; Ryan et al., 1992) . The mechanism by which heat stress causes embryonic mortality is multifactorial, as heat stress can alter several aspects of reproductive physiology, including blood flow to the reproductive tract (Roman-Ponce et al., 1977), ovarian steroid concentrations similarly, increased culture temperatures can compromise fertilization rate .To better clarify the physiological adaptations of dairy cows in the semiarid climate, it seemed interesting to follow the reproduction of cows and changes in the activity of the adrenal glucocorticoid versus the axis during a reproductive cycle Hypophyso gonadic. Body surface traits of cattle are of great importance as for the relationships between the animals and their ambience. In semi arid regions animals must be able to dissipate the heat excess through the skin and from the respiratory surfaces, at the same time they must avoid thermal energy incoming from the environment. The protective properties depend on the morphological characteristics of the skin (color) and of the hair coat (thickness, number of hairs per unit area, diameter of the hairs, length of the hairs),which allow to exchange heat with the environment (DaSilva, 2000). Therefore, genetic progress towards a hair coat, appropriate for hot and humid environments, could be a strategy to enhance reproductive function of cows in Algeria. The present study the relationship between characteristics of hair coat, hair cortisol level and reproduction of Fleckvieh and Montbéliarde during tow season

Materials and methods

This work was conducted from August 2012 to August 2013 on 95 dairy cows comprising two breeds, 28 Fleckvieh and 67 Montbéliarde cows reared in a commercial dairy farm. Cows were separated into two groups according to month of mating: cows mated in 'cool' season, and cows mated in 'hot' season. The farmer preferred natural service by sires for detection of oestrus. Individual records included cow identification number, parity, dates of natural inseminations and calving dates for all cows. Three fertility parameters were estimated: interval from calving to first service (ICS), interval form calving to conception (IC) and number of services per conception (IPC). Measurements of percentage of white coat color (C%) were carried out and hair sampling as well. To obtain the percentage of white color relative to the whole body surface area, pictures were taken using a digital camera. Then the pictures were transferred to special software (IPWin32) to estimate, at the same magnification, both sides of each animal, except the tail, head, legs, and belly regions, according to the method of Becerril and Wilcox (1992). Hair samples were taken from the center of the thorax of each animal about 20 cm below dorsal line by means of an electrician's pliers adapted in such a way that all the hairs in an 1 cm^2 area could be plucked out (DaSilva et al., 1988; Silva, 2000a). Hair samples were stored in plastic envelopes and measurements [Hair Weight (W), hair length (L); number of hairs per unit area (N), hair total diameter (HD), diameter of hair medulla (MD)] were done later in the laboratory. The average hair length (mm) of each sample was calculated from the 20 longest hairs of the sample by using a thin metal ruler, according to the method of Udo (1978) ; number of hairs (hairs/cm^2) was obtained by direct counting of all hairs present in the sample ; an ocular micrometer scale of microscope (Leica DM1000) was used to measure hair total diameters and medullar hair diameters (µm) of the same hairs used for length measurement, to about 10 µm of the hair root. Samples were taken from the scapula (shoulder) in August and February respectively for summer and winter seasons. On the scalp, hair growth rate is between 0.2 mm/day and 1.12 mm/day, or 6 to 33.5 mm/ month (Harkey, 1993).In order to avoid the effect of calving stress on level of cortisol only animals that calved more than one month before hair sampling were included in the study. Hair samples were stored in dry conditions at room temperature in the dark, until analysis. To prepare the hair samples, 250 mg hair samples were weighted and washed twice in 9 ml polypropylene tubes containing 5 ml methanol, as proposed by Davenport et al. (2006), and then the samples were gently mixed on a rotator at room temperature for 3 min per wash. The hair was then allowed to dry for approximately 5 days (Paulsen et al, 2001), then weighed and minced into 3-4 mm pieces with fine scissors. To extract cortisol, 50 mg of hair were placed in a glass vial with 3 ml of methanol for 18h at 37° C. Samples were then centrifuged (15 min/1000 rpm) in a centrifuge (Hettich EBA 20) as suggested by Comin et al (2013), and the supernatant collected and transferred to a glass test tube. The supernatant (0.6 ml) was taken from the top, and aliquot was dried using a dry bath SBH200D / 3 Stuart at 37 ° C (Davenport et al., 2006; Bennett and Hayssen., 2010) and reconstituted with 0.3 ml of phosphate buffer. The samples were analyzed for cortisol using a commercially available Enzyme-linked immunosorbent assay (ELISA) (Human), in duplicates. The average inter- and intra-assay CV was 4.65% and 9.86%, respectively. The mean and standard deviation were calculated and the test for normality (Kolmogorov-Smirnov) was performed for all parameters. Correlation was used to estimate the relationship between characteristics of hair coat, cortisol concentration and reproduction parameters using Pearson correlation, and Spearman's correlation rank when variables were not normally distributed. All statistical analyses were performed using the SPSS package program, version 21.

Results and discussion

Changes in hair coat characteristics and cortisol concentration are summarized in Table 1. In summer, Fleckvieh cows showed low density coat (393.76hairs/cm^2); longer hairs (16.50 mm) ;large hair and medulla hair diameter (88.47; 57.47µm respectively) and colored coat (32.58%).However, Montbeliarde cows present White coat (42.45%),with short hairs (15.83mm) and Many hairs (414.97 hairs/cm^2) little hair and medulla hair diameter (83.81; 49,49 µm respectively). The cortisol concentration of the hair of both breeds is comparable during this season (table 1). According to the table2, the phenotype of the cows (montbeliarde and Fleckvieh) of the winter season is characterized by a decrease compared to the warm season, the density of the hairs and the cortisol concentration with a higher concentration in Fleckvieh (16.10±2.96 *ng / ml).* Bertipaglia et al. (2005) reported Holstein coats having average low thickness (2.64 mm), low density (1050 hairs/cm^2), with short (12.81 mm), thick hairs (62.98 µ m); these findings were interpreted as indicating successful adaptation to the hot conditions in the State of São Paulo, Brazil.

Table 3 depicts correlations between hair coat traits in summer and winter seasons of Montbéliarde and Fleckvieh breeds and reproduction efficiency parameters. For Montbéliarde breed, HD was negatively correlated with IPC (r = - 0.338, p=0,01) in winter indicating that Montbéliarde cows, with large total hair diameter, required reduced number of IPC to be pregnant, while in summer hair coat traits were not correlated with all fertility parameters. For Fleckvieh cows, coat color was significantly correlated with ICS and IC (r=0.674, p=0,02 ; r=0.596, p=0,04 respectively) during summer, while negative association was observed only between C% and IPC(r = 0.858, p=0,01) in winter. These results indicate that reproductive efficiency parameters are related to coat characteristics. Coat cover affects temperature regulation and fertility of temperate climate breeds when transposed to warm climate regions (Turner, 1964). Our results also showed that this association was more expressed for Fluckvieh than for Montbéliarde breed. Fleckvieh cows with light colored coat had significant lower fertility, particularly during hot and dry season. Becerril and al, (1993) observed negative, but no significant regression coefficient, for Holstein cows reared under sub tropical climate, while King et al. (1988) observed, during winter months, that white Holstein cows required fewer services per conception and had fewer open days than black cows. Differences in environmental conditions and management were probably the causes of the differences reported.

Table 3. Correlation between hair coat characteristics and reproduction parameters in summer and winter

***IPC:** insemination per conception**; ICS:** interval from calving to first service**; IC:** interval from calving to conception.*

Conclusion

The study of the relationship between hair cortisol level, hair and coat characteristics and fertility of Montbéliardes and fleckvieh in semi- arid area shows that cows with thicker hairs during cold season was associated to improved number of mating per conception for Montbéliarde breed, suggesting that the difference was probably generated by the ability of cows to be more adapted to cold season, although the correlation coefficient was moderate. Fleckvieh cows with light colored coat had significant lower fertility, particularly during hot and dry season. Our results suggest the possibility to incorporate certain characteristics of the hair in the selection animals to facilitate their adaptation to this type of environment.

Abstract

This article addresses the issue of the valorisation and incorporation of agroindustrial by-products into animal feed. The objective of this study was to determine the effects of incorporation of the complex, apricot kernel cake and date rebus in substitution for imported maize and imported soybean meal, on the fattening performance of rabbits, local "white population". A total of 288 rabbits of both sexes, aged 35 days, were divided into 4 equal lots at a rate of 72 individuals per batch and in packs of 06 rabbits per cage, depending on the rate of maize substitution by date scrap and of soybean meal by the apricot kernel cake (0 %, 10 %, 20 % and 30 %). The change in weight from 35 to 77 days is not significantly different between diets. The average daily gain $_{(35\text{-}77\ d)}$ showed a significant difference for the 20 and 30% diets (+ 6 %), an increase in meat proteins in particular for the 10% (+ 8.8 %) and 30% (+ 5.6 %) batchs and a marked reduction in the lipid content of the 20% (-19 %) batch. The financial gain being 17.3 € on the quintal of food produced. Incorporation of rebus of dates and apricot kernel cake at a rate of 30 % in substitution for maize and soybean meal, is promising and its increase could define its optimum threshold in the diet of the local strain "white population".

Key words : *Rebus of dates, apricot kernel meal, rabbits, local strain, fattening.*

Introduction

The rabbit species in East Algeria is mostly represented by the local strain known as the "white population". In farming cycles, food expenditures account for 60-70% of production costs (Nworgu et al., 1999), including those of rabbits (60%) (Guermah et al., 2016). The use of unconventional food is one of the alternatives to reduce production costs [Lounaouci-Ouyed et al., 2012]. Economically, it would make available to the most deprived layers, cheap animal proteins. Feed rations for fattening rabbits are mainly made up of soybean meal and maize, raw materials imported by Algeria. Their reduction in the food intake can be done through the dates scrap for maize and apricot kernel meal for soybean meal. The by-products of the date palm are low protein (5.2% total nitrogenous matter), which are concentrated in the nuclei (Chehma et al.,2002). Their chemical composition is variable and depends on the region, the nature of the cultivar (*Degletnor*, *Mechdeglat*, *Litima*)(Bousdira, 2006) And the proportion of cores in the mixture [Genin and al., 2004]. They represent on average 25% of the annual production of dates (M.A. 2007). The use of apricot kernel meal as a protein source in domestic animal feed has been studied only on broiler chickens (Arbouche et al., 2012) and on fattening sheep (Arbouche et al., 2014) and therefore remains very scarce. However, several studies have examined the levels of hydrocyanic acid in apricot kernels (Arbouche, 2012). This rate depends on the varieties of cultivated apricots (sweet almonds or bitter almonds) (Arbouche et al., 2007) and the percentage of each variety in the aggregate quota treated by the agro-food industries. The increase in apricot areas in Algeria, thanks to the successive national agricultural development plans (NADP), especially at the Hodna level, resulted in an accumulation of by-products generated by agro-industry as the young orchards, which occupy an average of 31 000 ha (M. A, 2007), Planted with a density of 300 trees per hectare.

Material and methods

Animals, food diets and experimental protocol

The trial took place during the period from 12/03/2015 to 23/05/2015 at the level of a hutch of a professional breeder located in the commune Rasfa of the wilaya of Setif in the North East Algerian. The 80 m² building is equipped with thermal insulation in polystyrene panels. Fans and a pad-cooling humidifier ensure good ambient conditions.

Two hundred and eighty-eight rabbits (288) of both sexes, weaned at the age of 35 days, from the local strain "white population", were randomly distributed into 4 lots at 72 subjects per diet. The rabbits of each lot were housed in collective metal cages at the rate of 6 rabbits / cages. The date scrap comes from the date processing and processing unit located in Tolga wilaya of Biskra and consists of a significant proportion of cores (45%) and pulps de date (55%). The whole was dried in the sun then crushed. The kernels of apricots (mixture of sweet almonds and amamers) come from the apricot processing unit located in N'gaous wilaya de Batna. They were husked and the shell and almond were separated manually. The almond previously dried in the sun was processed to obtain the cake by a hydraulic press according to the principle recommended by Ferradji et al., [2001] and detoxified by a 1% sodium bicarbonate solution (Arbouche et *al.*,2007). The chemical composition of dates and almond cake was determined using AOAC methods [1990] with triple repetition. The analyzes were carried out on dry matter, total nitrogenous matter, crude fiber, fat, mineral matter and hydrocyanic acid, and gross energy was determined adiabatic calorimetry.

Four rations were formulated, containing 0% (control food), 10, 20, 30% almond spider substitutes for soybean meal and date rejects in substitution for maize during the fattening phase (Table 1). Granular foods were distributed ad libitum daily at 9 am and 4 pm.

The animals were weighed individually at 35; 49; 63 and 77 days at an interval of 15 days. The food consumption of each cage was checked weekly at a fixed time throughout the experiment.

Statistical analysis

The different results were treated using the Microsoft Excel spreadsheet. The statistical analysis and the comparison of the mean values between the various food treatments (control and those based on apricot kernel meal and date rejects) were carried out by the ANOVA at A factor using the Statistical Package for Social Science software (SPSS version 21) and then completed by the SNK test (Student-Newman-Keules) and Duncan, when the ANOVA test showed a significant difference in the risk of 5% error ($p < 0.05$).

Results and discussion

Incorporation of the apricot kernel complex and date scraps into food rations did not result in a significant change in the weight of the local strain (Table 2), although it was to be a function of the evolution of the sulfur-containing amino acids of As suggested by Colin [1978] who proposed a maximum threshold of 0.63%, Cheeke [1971] a minimum threshold of 0.45% and Berchiche and Lebas [1994] for the imported strain a rate of 0.62%. Although the levels of cellulose and lignin produced by the apricot kernel meal and the date scraps in the rations are clearly increasing, the $ADG_{63\text{-}77d}$ of experimental diets are better valued by the local strain, but according to Gidenne and Perez [1993], fiber digestibility may increase or decrease between weaning and slaughter age and is a function of the fiber source [De Blas and Carabano 1996] and the nature of the parietal constituents [Gidenne 2003]. Mean daily intake and consumption indices are affected by the incorporation rates of apricot kernel meal and date discards in the diets throughout the rearing phase (35^{th} to 77^{th} days). These regressions are due to the polysaccharides contained in the date rejects (1996) and to the interactions of the fibers of dates and almond cake as De Blas and Carabano (1996) point out, on various agroindustrial sub-products used in the aquaculture feed. The substitution of maize and soybean meal has no influence on the yield at slaughter (Pcf / Pva) of the local strain (64,50%), and remains in the range advanced by Bouguerra [2012] (64.25 to 69.87%), and is lower than that of the New Zealand strain imported (between 58 and 60%) (Berchiche and Lebas 1994). The other slaughter parameters and carcass characteristics are not influenced by the by-products incorporation rates (Table 3). Incorporation of 30% date rejects increases the fattenability of the local strain by reference to the peri-renal weights of Moulla (2006) (20.06%) and Bouguerra [2012] (18.64%), for the same strain.

The results of the pH of the meat remain different from those of other authors (Blasco and Piles 1990, Parigi Bini et al., 1992) and are not influenced by the genetic type as reported by Lambertini et al., [1996]. They evolve proportionally with the rates of incorporation of by-products of dates and apricot kernel for the strains of rabbit and remain high (6,60) because the measurement of an hour post mortem did not Allowed the triggering of the different glycolytic activities in the muscles as reported by Lambertini et al., [1996], which only intervene after 24 h post mortem. This high pH causes the maladjustment at the refrigeration because the proteolytic microorganisms develop bad odors there [Gill and Newton 1981].
Because of its rusticity, the local strain enhances the protein sources of the diets by better protein synthesis, and remains in the standards advanced by Ouhayoun [1992] (20 to 23%).
The lipid contents of the meat of the strains are inversely proportional to the rates of incorporation of the dates scraps and the apricot kernel meal and are higher for the New Zealand strain. According to Dalle Zotte [2002], they depend on age, sex, genotype, diet and type of rearing. They remain in the interval by Salvini et al, [1998] (0.6-14.4%).
The production costs of the two by-products were calculated according to the fixed or variable loads. The apricot kernel meal is obtained after treatment of the apricot kernels in several stages: drying, dehulling, sorting, oil extraction and detoxification. The two raw materials obtained are: meal and almond oil. Taking into account all the expenses and the sale of the oils, the price of the kilogram of almond cake produced is DZD (Algerian dinar) 00.
The date scrap is generated by the processing and packaging units, these by-products are sold at the rate of 10DZD per kilogram. Taking into account the four dietary formulas used in our study; Control diet with 0% substitution (standard diet), experimental diets with 10%, 20% and 30% soybean turnover by apricot kernel meal and maize by date scrap and prices, the financial opportunity of the by-products integration is fairly consistent with - 9% on the price of the quintal of food produced for an incorporation rate of 30%.

Conclusion

The complex dated / apricot kernel complex can be considered a source rich in total nitrogen (47%) and fiber (32%) and can be used as an alternative to the maize / soybean meal complex Substitution rates of up to 30%, without adverse effects on growth rate, dietary intake or slaughter yield. It improves the feed conversion rate for both strains of rabbit, as well as the chemical composition of the meat especially of the local strain and lowers the cost price of the quintal of food produced. It would be interesting to increase the substitution rates in order to determine the optimum thresholds.

Abstract

An experiment was conducted to investigate the effect of a medicinal herb plantain (*Plantago lanceolata* L.) supplementation on growth performance, carcass characteristics in sheep. For this experiment 12 indigenous Garole sheep (*Ovis aries*) of one year of age around 9±0.7 kg of live weight (LW) were divided into two groups and each group having randomly selected six sheep using Randomized Block Design. One group was supplied roadside grass, wheat bran, molasses based total mixed ration (TMR) pellet (ME=2240 kcal/kg dry matter, CP=14.21%) which was considered as control diet (TMRP-diet). In another group, the TMRP-diet was supplemented with 5% plantain (*Plantago lanceolata* L.) herb that was termed as TMRPPL-diet. In both the dietary treatments the energy and protein were offered at 1.5 times of the maintenance level for a period of 90 days. The LW was recorded at the onset of, and then every week interval throughout, the experimental period. The LW gain, and total digestible nutrients were higher ($P < 0.05$), and the feed conversion ratio was significantly lower ($P < 0.05$) in TMRPPL-diet compared to TMRP-diet. Plasma glucose and triglycerides concentration, and caul fat and pelvic fat were significantly lower ($P < 0.05$) in sheep fed TMRPPL-diet compared to the sheep fed TMRP-diet. It could be concluded that supplementation of plantain herb might be used as additive in Garole sheep diet for better growth performance and lean meat production.

Key words: *Plantain, sheep, TMR pellet, plasma metabolites, meat characteristics.*

Introduction

The livestock sector globally is highly dynamic. In developing countries, it is evolving in response to rapidly increasing demand for livestock products. In developed countries, demand for livestock products is stagnating, while many production systems are increasing their efficiency and environmental sustainability. Consumption of sheep meat increases from 75000 MT (1990) to 140000 MT (2002) with an annual growth rate of 5.8% which is greater than beef (2%) and poultry (3.4%) (FAO, 2005). In Bangladesh, around 8% of total protein for human consumption comes from livestock. Commercial livestock farming requires huge amount of land for fodder production but intensive stall feeding can overcome this condition and in this situation total mixed ration (TMR) pellet prepared using rice straw, grass, wheat bran, mustard oil cake, molasses would be one of the best solution for boosting up livestock productivity in our country. Different agro industrial by products could be used in pellet preparation and dry grass and straw could be used in pelleting which are normally rejected by sheep when that is offered in loose condition. Antibiotic growth promoter enhances the productivity of livestock but it is reported that the use of antibiotics and synthetic growth promoters create a hazardous long-term effect in the human body. Since January 2006, the European Union (EU) has taken steps towards phasing out the authorization of antimicrobial growth promoters after that scientists started their research to explore new alternative for the antibiotic growth promoter (Castanon 2007). Now-a- days people are more conscious about their health and most of the people prefer low cholesterol content food. A growing awareness among consumers to consume antioxidant-rich foods has provided opportunities for the livestock industry to focus on production of antioxidant-rich milk and meat or functional foods. In this situation plantain (*Plantago lanceolata L.*) would be one of the best solution to produce animal products of low cholesterol content and safe food for human. Because plantain is one of the perennial herbs contain bioactive components (Al-Mamun *et al*. 2008), anti-bacterial property (Ishiguro *et al.,* 1982), enzyme inhibitory activity, and anti-oxidative activity (Al-Mamun *et al*. 2007a). Plantain also had positive influence on plasma nutrient metabolism in ruminants (Sano *et al*. 2002; Al-Mamun *et al*. 2007b). The plantain showed resistance to exogenous insulin in sheep (Al-Mamun *et al*. 2017). Therefore, it was expected that due to the antioxidant potential, the supplementation of plantain to TMR pellet would enhance the meat quality through reducing body fat, and plasma lipids, and might improve growth performance of sheep.

Materials and methods

This study was ethically approved by the Bangladesh Agricultural University Research System (Approval no. A 39.069.2016-2017). The experiment was conducted at the Department of Animal Nutrition, Bangladesh Agricultural University, Bangladesh during August-December, 2016. Twelve local Garole sheep (*Ovis aries L*), aged around one year and weighing around 9±0.7 kg was used to conduct the experiment. The animals were divided into two groups having randomly selected six sheep in each group. One group was supplied roadside grass, wheat bran, molasses based total mixed ration (TMR) pellet (ME=2240 kcal/kg dry matter, CP=14.21%) which was considered as control diet (TMRP-diet). In another group the TMRP-diet was supplemented with 5% plantain (*Plantago lanceolata* L.) herb that was termed as TMRPPL-diet. The feeding trial was performed for a period of 90 days. Urine and feces samples were collected last 7 days of experimental period. Blood samples (5 ml each) were collected on day 89 of the feeding trial in a heparinized tube and kept in an ice box until centrifugation. On day 90, the animals were slaughtered and meat samples were collected. Weight of caul fat and pelvic fat were also recorded. The hot carcass weight was measured after complete dressing and evisceration. Proximate components of feed feces and meat sample, and nitrogen content of urine was analyzed by Khzeldhal method (AOAC, 1995). Concentration of plasma glucose was enzymatically determined by the method of Huggett and Nixon (1957). Cholesterol was determined by Cholesterol oxidase method or CHOD/POD method (Allain *et al.*, 1974). Triglycerides were estimated using commercial available reagent kit (Atlass Co. Ltd) according to Buccolo and David (1973). Phosphotungstic and magnesium ions specifically precipitate LDL. After centrifugation the cholesterol content of the HDL in supernatant was determined using crescent diagnostics cholesterol test kit (Cat No. CS 603) using the equation developed by Friedewald *et al.* (1972).

Results and discussion

Live weight gain and Feed Conversion Ratio

Total live weight gain, daily live weight gain was significantly higher (P < 0.05) in TMRPPL-diet group and FCR was lower in TMRPPL-diet group than TMRP-diet group which indicates the efficient utilization of feed in TMRPPL-diet group. Rumball (1997) also reported higher growth rates of calves and lambs by supplementing plantain herbs that agreed with the current finding. Kemp *et al.* (2010), also reported that plantain fed with mixed pasture had better live weight gain in sheep and cattle. Higher body weight gain might be due to the improved metabolism of Fulkerson *et al*. (2008) stated that improvement of lamb’s growth rate from grazing plantain might be due to increased metabolizable protein supply and another scientist Al-Mamun *et al*. (2008) reported that plantain helped to increase whole body protein synthesis in Sheep.

Carcass characteristics and fat deposition

There was no significant difference ($P < 0.05$) in carcass characteristics between TMRPPL-diet group and TMRP-diet group other than caul fat and pelvic fat. Caul fat and pelvic fat have significant difference between the two groups and caul fat and pelvic fat was lower in TMRPPL-diet group than TMRP-diet group. There was also significant difference ($P < 0.05$) in dressing percentage and dressing percentage was higher in TMRPPL-diet group.

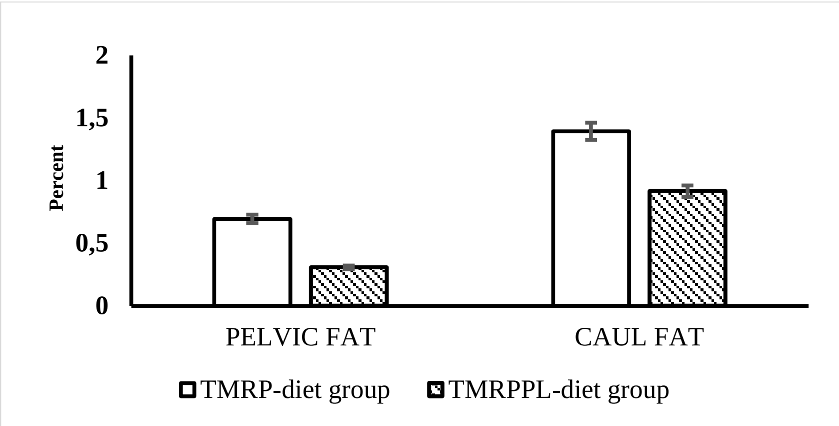

Figure 1: Graphical presentation shows the effect of plantain (*Plantago lanceolata L.*) supplementation on caul fat and pelvic fat depostion in sheep.TMRP-diet, total mixed ration pellet; TMRPPL-diet, total mixed ration pellet plus 5% plantain (*Plantago lanceolata L.*) herb.

Plasma metabolites

Supplementation of plantain reduced serum glucose and triglyceride concentration in treatment group. Total cholesterol, HDL-cholesterol and LDL- cholesterol had no significant difference between the treatment groups, but numerically lower in TMRPPL-diet group. Yoshida *et al*., (2013) reported that supplementation of plantain reduced serum free-fatty acid and glucose levels which also supports the present findings.

Table 1: Effect of plantain on plasma metabolites of sheep

Parameters	TMRP-diet	TMRPPL-diet	SEM	p-value
Plasma Glucose (mmol/dL)	5.26	4.43	0.21	0.002
Triglycerides (mg/dL)	69.94	55.80	3.23	0.001
Total Cholesterol (mg/dL)	85.06	75.62	2.15	0.100
HDL-Cholesterol (mg/dL)	51.04	48.12	1.01	0.558
LDL-Cholesterol (mg/dL)	20.04	16.34	0.98	0.154

SEM=Standard error of means, TMRP-diet, total mixed ration pellet; TMRPPL-diet, total mixed ration pellet plus 5% plantain (*Plantago lanceolata*) herb.

Mutton quality and sensory properties

Proximate components of mutton had no significant difference except ether extract. Zhou *et al.*, (1991) stated that plantain acts as a strong superoxide anion scavenger and antioxidant. Antioxidant prevents auto oxidation in the body for which fat is reduced. Launert (1984) was also showed that plantain contains tannins thus they might affect carcass composition. No significant difference was found between two dietary treatment group in term of meat quality like cooking loss, dripped loss but higher rib eye was found in TMRPPL-diet group. There was significant difference in flavor, juiciness, tenderness and overall acceptability between the two dietary groups and overall acceptability was higher in TMRPPL-diet group than TMRP-diet group, which might be due to the presence of antioxidant potential of plantain (Al-Mamun *et al.*, 2007a). According to Aberle *et al.*, (2001) after slaughtering oxidation deteriorate the color and flavor of meat, but if antioxidant rich feed is supplied sufficiently, it will helpful for preserving the quality of meat. For this reason, the meat of TMRPPL-diet group has good color, flavor and juiciness than TMRP-diet group.

Table 2. Effect of plantain supplementation on proximate composition and quality of sheep meat

Parameters	TMRP-diet	TMRPPL-diet	SEM	P-value
Moisture (%)	72.68	72.5	0.41	0.857
Crude protein (%)	21.4	21.9	0.39	0.588
Crude fiber (%)	0.71	0.72	0.03	0.872
Ether extract (%)	4.3	4.01	0.07	0.023
Ash (%)	1.15	0.99	0.06	0.217
Nitrogen free extract (%)	72.42	72.38	0.38	0.959
Cooking loss (%)	30.51	32.69	0.77	0.18
Dripped loss (%)	4.15	4.26	0.07	0.549
Rib eye area (%)	5.05	6.15	0.27	0.012

SEM=Standard error of means; TMRP-diet, total mixed ration pellet; TMRPPL-diet, total mixed ration pellet plus 5% plantain (*Plantago lanceolata*) herb.

Conclusion

Under present experimental condition, it could be concluded that supplementation of plantain (*Plantago lanceolata* L.) to TMR pellet might be practiced to produce lean meat, and to improve production performance of Bangladeshi Garole sheep.

Abstract

In the histological analysis of the ovaries of Dubska pramenka during the gravidity weeks 3, 7, and 16, we tried to establish the intensity of folliculogenesis and highlight their importance in the course of gravidity. Considering that there has been little research on the ovaries of Dubska pramenka during gravidity, and that their unquestionable role in neuroendocrine system has a significant influence on the outcome of gravidity, we analysed the germ-germinal epithelium during different periods of gravidity, and we focused special attention to the representation of various follicular development stages in the cortex of gravid ovaries and blood supply of the medulla. The analyses showed that histology of the ovaries of Dubska pramenka varied considerably, especially in terms of the height of the cells constituting the germ-germinal epithelium, the presence of different forms of the follicles that exist at different stages of gravidity, while the blood supply of the medulla and the presence of connective tissue elements also varied, especially the morph of the connective tissues and their density.

Key words: *Dubska pramenka, gravidity, ovaries*

Introduction

Considering that sheep are seasonally polyestrous animals, i.e. with more investments in the production cycle, oestrus can occur at any time throughout a year, hence they can be impregnated regardless of the period of the year. However, Dubska pramenka in a free-nomadic breeding in Bosnia and Herzegovina, mountain Vlasic, regardless of being polyestrous, mates mainly in autumn, and lambing occurs during early spring months. Autumn period, which is characterised by shorter days and longer nights, is favourable to the activity of the pituitary gland. Hence, decreased daylight stimulates more pituitary activity, and the hypothalamus produces releasing hormones that stimulate the pituitary gland through the portal blood flow and nerve tissues to secrete more gonadotropin that will further stimulate the gonads to instigate folliculogenesis and onset of oestrus, *Nett (1987*). As we focused our research on the ovaries at different stages of gravidity, we observed the size of the germinal epithelium, the occurrence of different stages of follicular development and the presence of yellow bodies. It is a known fact that following the ovulation of a mature Graaf follicle and under the influence of LH hormone, granulosa cells in the wall of a ruptured follicle proliferate and transform into lutein cells that fill the cavity of the follicle in the next 5 (five) days. The yellow body is being created and it starts to secrete progesterone – the keeper of gravidity. However, after ovulation the ovary still continues with folliculogenesis even during gravidity, because the histological analyses of the ovaries in gravid ewes indicate the presence of almost all forms of follicular development. Although, independently of estrogen secreted by the mature De Graaf follicle, hormone inhibin, which selectively inhibits the FSH hormone of the pituitary gland, also contributes to the maturation of the follicles. By limiting the secretion of the pituitary FSH hormone, inhibin should prevent the further follicular development and limit the degree of ovulation.

Materials and methods

The research material was collected on the mountain Vlasic during autumn and winter months. The research animals, total of 6 ewes, were euthanized due to various etiology (bone fractures, indigestion, wild animal attacks...). The degree of gravidity was established based on a controlled pairing and breeder's evidence, and based on the development of a foetus following the post-mortem examination. The research animals were in the gravidity weeks three, seven and sixteen.All histological examination have been conducted at the Veterinary Faculty University of Sarajevo, Departement of Histology and embriology.In this research we used comon histological method of making histological slides for light microscopy analysis.. The ovaries and their surrounding tissue were placed in plastic bottles with screw caps, in 10% formalin until the time of transport to the laboratory and the making of histological preparations, i.e. until the moment of their moulding in paraffin blocks. Moulding in paraffin blocks was done in a way that the samples of the ovaries were placed in 70% alcohol for two days, then in 96% alcohol for one day and in the end, in 100% alcohol for one day. From this procedure, the samples were transferred to a solution of 100 % alcohol and toluol for two hours and then to toluol for four hours. The prepared samples were left in paraffin I for five hours and in paraffin II for twelve hours, and the moulding procedure in paraffin blocks was completed. The paraffin blocks with moulded samples of the ovaries were cut by digital microtome in several serial incisions of 0.5 to 1.5 micron depth. The incisions were placed on glass slides, stained with haematoxylin eosin and azan, covered with cover glass, and glued with Canada balsam. Histological examinations were done using light microscope under magnification of 100, 200 and 400 times. Microscopic examination included the entire preparations of the ovaries, in order to get a complete picture of the organs examined during the research period. The hormonal measures we did not analysis because of *post mortem* changes on the blood. The assay results were presented using descriptive interpretation of the histological preparations, taking into account that comparative description of the histological preparations is representative of our research.

Results and discussion

To provide an answer to this important question, which is what causes interruption of the ovulation during seasonal anoestrus in sheep, i.e. during gravidity, taking care that folliculogenesis occurs continually throughout the year, requires a complete understanding of the hormonal picture and mechanisms continually involved in the control of the ovary activity, *Karsch et al. (1983*). Ovaries in cows, sheep and goats are of oval shape, with a size of a smaller or larger plum. Depending on the stage of the oestrus cycle, there are several antral follicles, follicle(s) preceding the ovulation, hemorrhagic bodies and yellow bodies on the ovaries. In cows, there is usually one preovulatory follicle, or one hemorrhagic, i.e. yellow body, because a cow is monovulatory animal species. In sheep and goats, there can be more of these ovarian structures, depending on the number of ovulations in specific oestrus.

Yellow body in cows, sheep and goats is yellow-brownish, *Stančić et al.(2014).*Ovaries in mammals, and in sheep are pair organs, with germ or germinal epithelium on their surface. Germinal epithelium is particularly active during foetal period, and it can be active during sexual activity to create follicular cells as well as oogonia, *Katica et al. (2010)*. *Mutevelić et al. (2003)*, emphasize that the height of the germinal epithelium may vary depending on the type of animal; it can vary in the same animal as well, which will depend on the stage of the sexual cycle, way of keeping, diet, climate conditions. Histological assays of the germ epithelium in the course of gravidity week 3 established that it was made of a continual series of high prismatic, densely compressed cells (Image 1. Epithelium of the sheep in the gravidity week 3; haematoxylin eosin; x 400).

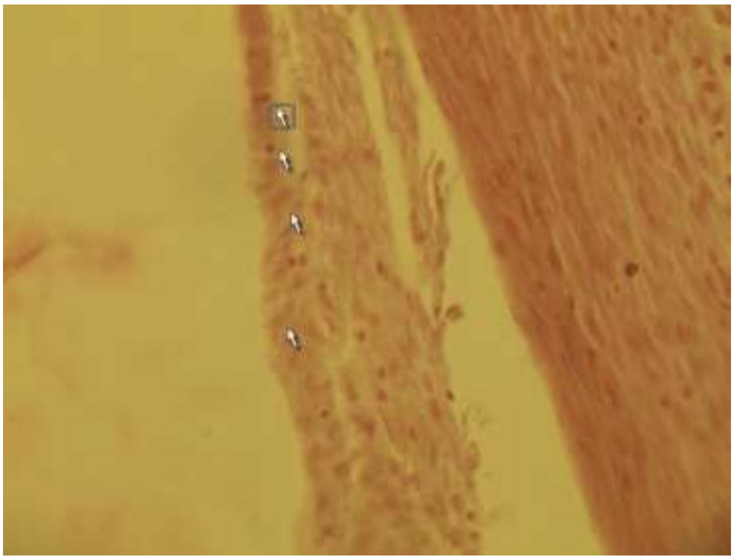

Image 1. Epithelium of the sheep in the gravidity week 3; HxE x 400

Under the germinal epithelium, we observed a dense network of parallel collagen tissues and clearly visible primordial follicles with egg cells in the centre, and one layer of laminated follicular cells. These follicles were arranged almost in a regular line under Tunica albuginea (Image 2. The crust of the ovary of the sheep in the gravidity week 3; haematoxylin eosin; x200).

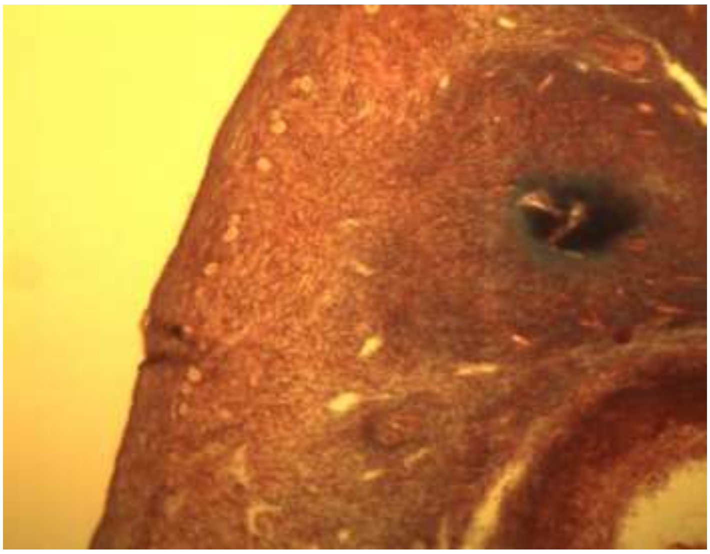

Image 2. The crust of the ovary of the sheep in the gravidity week 3; HxE x 200

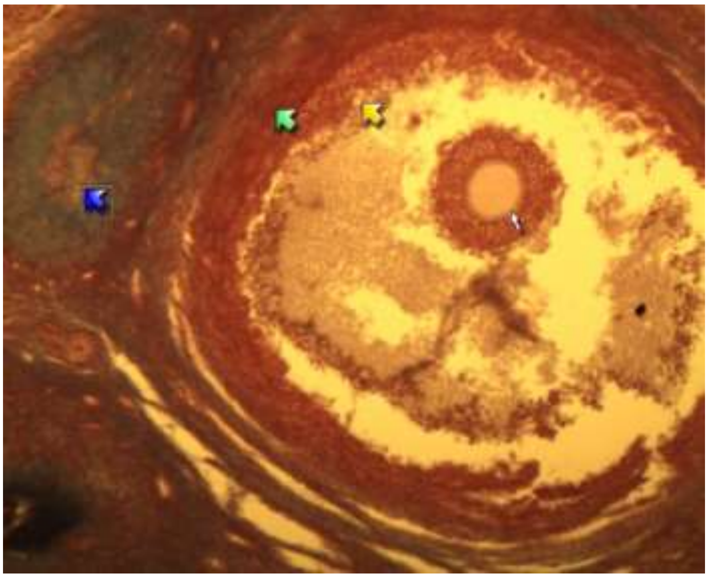

Image 3. Arrows indicate a mature De Graaf follicle, atretic follicle in the gravidity week 3; Azan x 200

The crust of the ovary in the gravidity week 3 is rich in mature, tertiary follicles surrounded by connective tissue. We observe a looseness of stroma and collagen tissues, preparing the follicle for ovulation under the influence of hormone relaxin produced by the follicle cells, and a large number of atretic follicles that are being formed or have already been formed (Image 3. Arrows indicate a mature De Graaf follicle, atretic follicle in the gravidity week 3; azan x200). The tertiary follicles clearly show *Theca folliculi*, which subsequently differentiate in two layers - internal *Theca folliculi interna* and external *Theca folliculi externa*. Yellow body, which will secrete steroid hormone progesterone during gravidity, is formed of the internal layer made of polygonal cells, *Mohammadpour (2007).*

On the histological preparations in the gravidity week 3, we also observed several yellow bodies of different size, with theca lutein cells located peripherally, darkly coloured, with flat nuclei and granulosa lutein cells located centrally, quite large, lighter and with clearly noticeable ball-like nuclei (Image 4. Yellow body in the gravidity week 3; haematoxylin eosin; x 200).

Microscopic examinations of the crust of the ovary in the gravidity week 3 did not show any large number of primary and secondary follicles. The core of the ovary in the gravidity week 3 was rich in blood vessels, with quite thick walls, irregular lumen, with the presence of connective tissue elements (Image 5. The core of the ovary in the gravidity week 3; azan x 200).

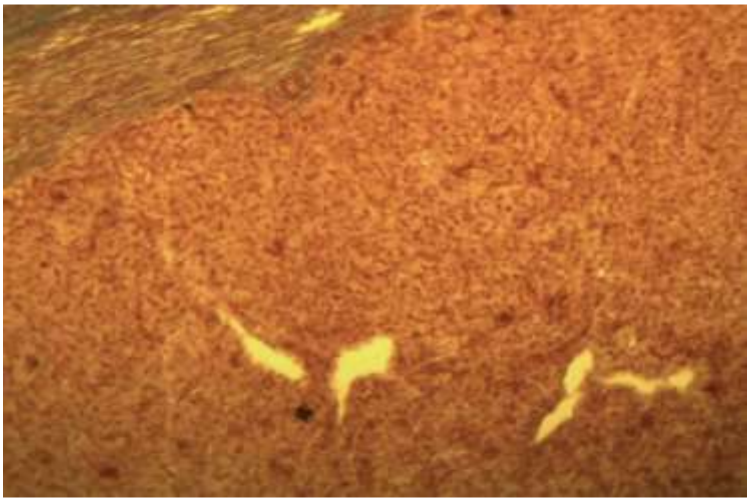

Image 4. Yellow body in the gravidity week 3; HxE x 200

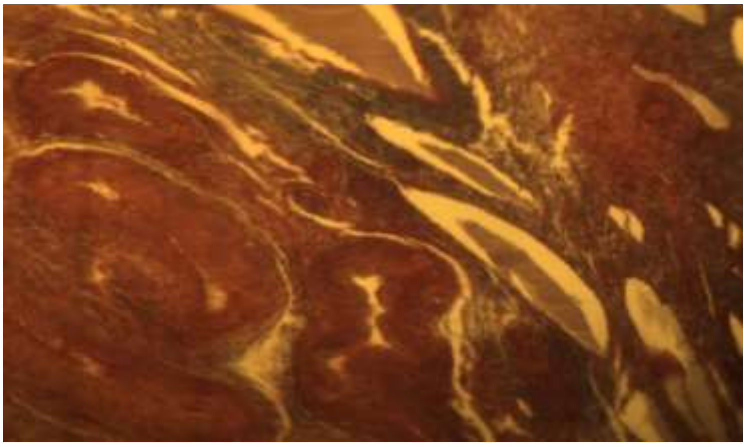

Image 5. The core of the ovary in the gravidity week 3; Azan x 200

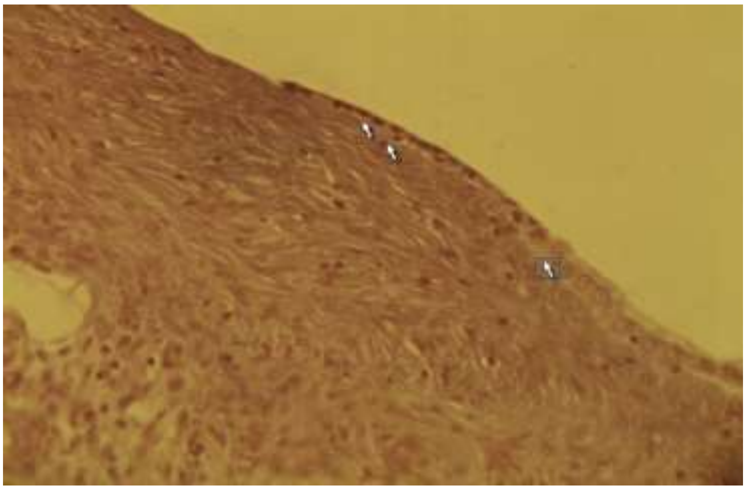

Image 6. Epithelium in the gravidity week 7; HxE x 400

The germinal epithelium in the gravidity week 7 varied in the height of the cells, from low to high prismatic cells, with clear oval nuclei, lightly coloured (Image 6. Epithelium in the gravidity week 7; haematoxylin eosin; x 400). At that particular time of gravidity, tunica albuginea is built of shorter, densely compressed collagen and elastic tissues laid parallel.

Gravidity week 7 is characterised by the presence of a larger number of secondary follicles, which are either at the stage of being formed or at the stage of transition (Image 7. The crust of the ovary with visible secondary follicles in the gravidity week 7; haematoxylin eosin x 200), **(**granulosa cells moving apart) and formation of the follicular antrum, i.e. the beginning of the formation of tertiary follicles (Image 8. The crust of the ovary in the gravidity week 7; haematoxylin eosin x 200). Such follicles were the most numerous in week 7. The presence of primordial and primary follicles is scarce. The core is permeated with connective tissues and rich in intersections of blood vessels with thinner irregular walls.

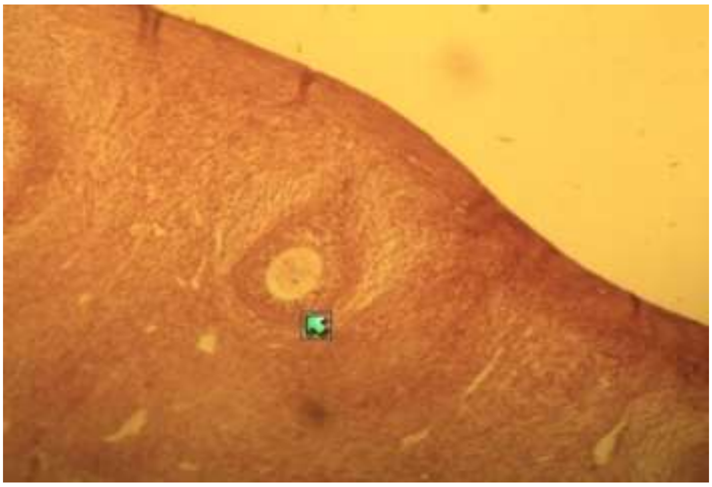

Image 7. The crust of the ovary with visible secondary follicle in the gravidity week 7; HxE x 200

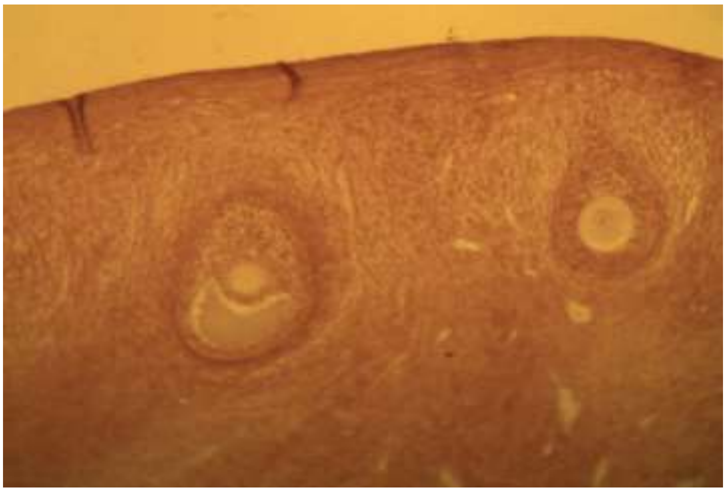

Image 8. The crust of the ovary in the gravidity week 7; HxE x 200

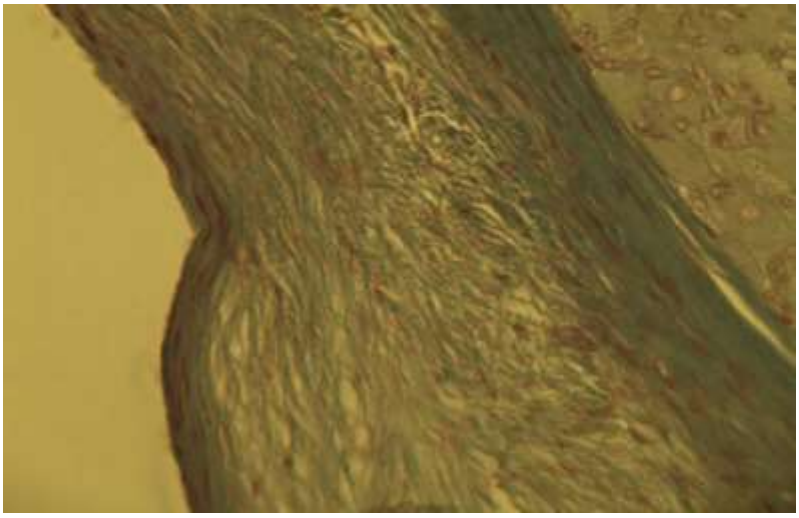

Image 9. Epithelium of the ovary of the sheep in the gravidity week 16; Azan x 400

Already in the gravidity week 16, the germinal epithelium makes a series of laminated cells leaning one on another. Underneath, there are noticeable elastic and collagen tissues aiming in one direction, with *prominent density* (Image 9. Epithelium of the ovary of the sheep in the gravidity week 16; azan x 400). The crust of the ovary is rich in primordial follicles of smaller dimensions, with an egg cell and a layer of laminated follicular cells (Image 10. Primordial follicles in the crust of the gravid sheep in the week 16; haematoxylin eosin x400). It is striking at this degree of gravidity that there are visible just ovulated tertiary follicles of quite large dimensions, and that there are yellow bodies at the stage of being formed (Image 12. Ovulated De Graaf follicle of the ovary of the sheep in the gravidity week 16; haematoxylin eosin x 200). It is interesting to highlight that during this research period we did not observe any significant presence of any other forms of follicular development, primary or secondary follicles.

The ovaries in week 16 are characterised by the presence of a larger number of yellow bodies, of various dimensions, however, one is dominant; it has a distinct histological structure and is moved to the very edge of the germ epithelium (Image 13. Yellow body of the ovary of the sheep in the gravidity week 16; azan x 400). Following the ovulation, granulosa cells of mature follicles proliferate and hypertrophy and transform into granulosa lutein cells. Similar also occurs with the cells of theca interna, *Z. Kozarić,(1997)*. Yellow-brownish lutein accumulates in granulosa cells *Stančić, (2014*) and corpus luteum is being created. Lutein cells are round and polygonal, with a noticeable nucleus; during gravidity they secrete progesterone *Keeton, W.T.,J.L.Gould,(1986)*. Peripherally, there are theca lutein cells, which are smaller, darkly coloured and with flat nuclei.

Medulla is well supplied with blood elements; there are numerous blood and lymph vessels and there is also an extremely rich in connective tissue, so called Zona vasculosa, where there are also hilus cells, homologous Leyding cells in males' testicles, *Eurel et al. (2006).*

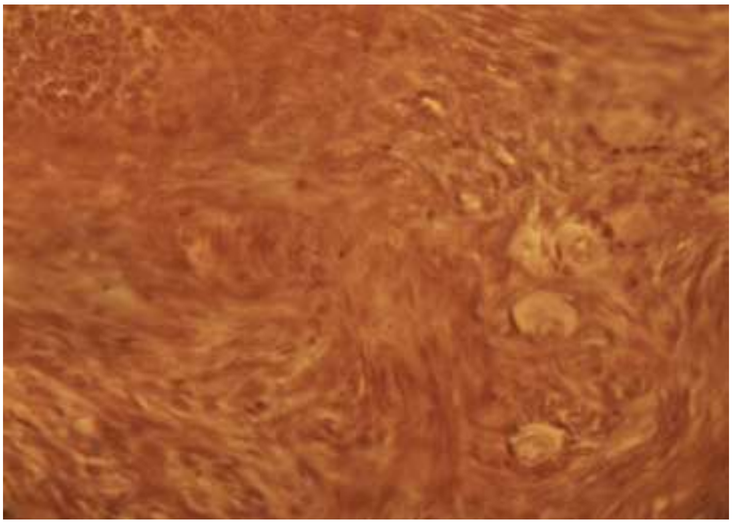

Image 10. Primordial follicles in the crust of the gravid sheep in the week 16; HxE x 400

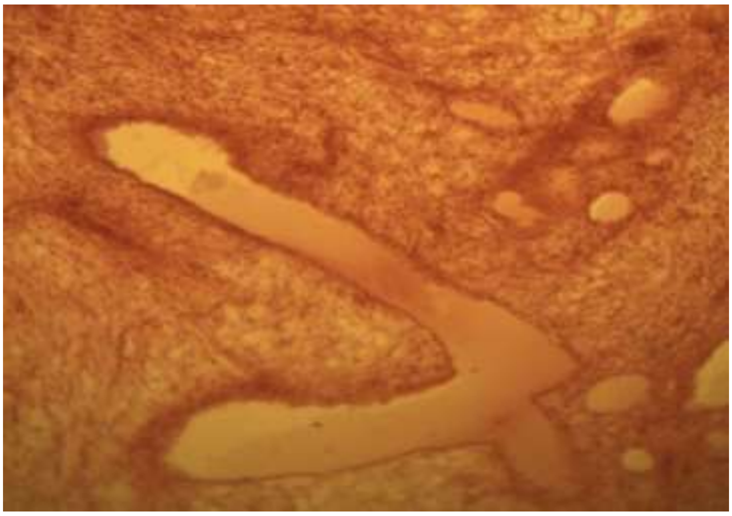

Image 11. The core of the ovary of gravid sheep in the week 16; HxE x 200

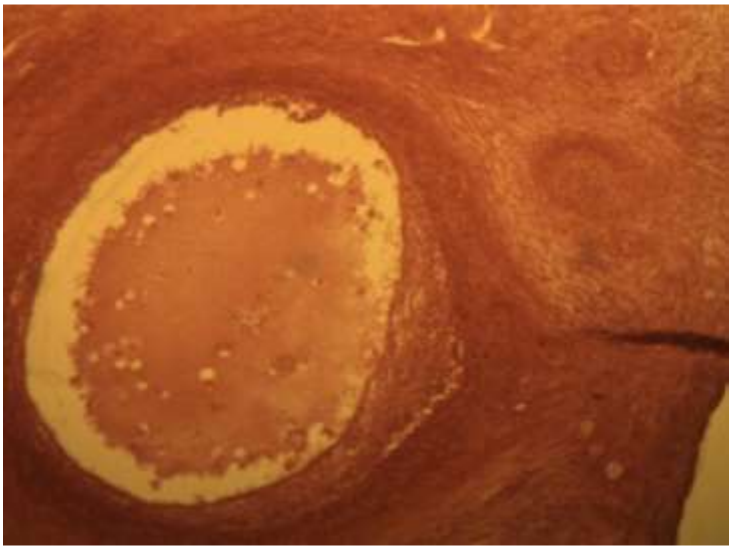

Image 12. Ovulated De Graaf follicle of the sheep in the gravidity week 16; HxE x 200

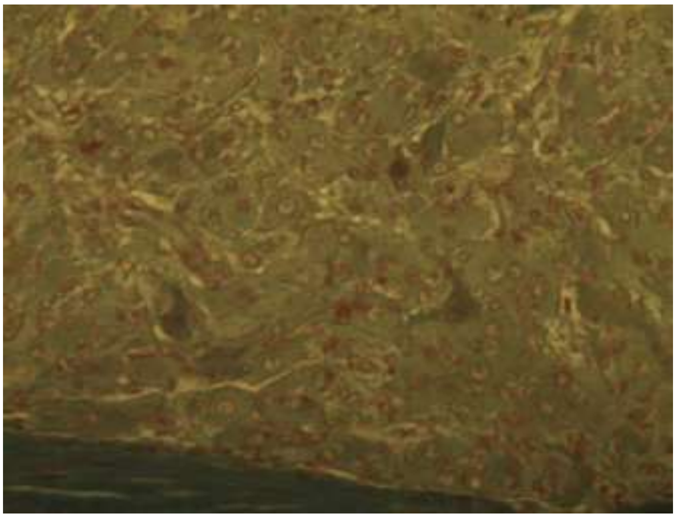

Image 13. A yellow body of the ovary in gravid sheep in the week 16; Azan x 400

Conclusions

Folliculogenesis in sheep occurs in the reproductive chain throughout the year, but the intensity and dynamics of the follicular development vary according to the periods of the year and physiological condition. The height of the germ germinal epithelium varies, from laminated to highly prismatic. All forms of follicular development are present in the gravidity weeks 3, 7 and 16; in week 3 - less primary and secondary follicles; in week 7 - larger number of secondary follicles, and in week 16 - ovulated tertiary follicles and formed yellow bodies. The core of the ovary is rich in initiated blood vessels, of thicker Tunica media.
