Email: Branchiopod@gmail.com

ABSTRACT. — A checklist of the Anostraca (fairy shrimp) is presented with synonyms. More than 700 anostracan taxa are presented, of which 407 are considered valid families, genera and species. Chresonyms are provided for taxa redescribed according to modern standards. Nomenclatural problems are examined and resolved concerning the genus *Chirocephalus* and its junior synonym *Galaziella*. The presentation of the suborders and families follows recent molecular phylogenetic analyses presented elsewhere.

KEY WORDS. — Fairy shrimp, checklist, systematics, nomenclature

INTRODUCTION

In preparation for an examination of anostracan zoogeography, it became apparent that an up to date catalogue of the species was necessary, particularly as pertaining to the distribution of different taxa. This catalogue is patterned in part on the recent catalogues on decapod crustaceans (e.g., Ng et al., 2008; De Grave & Fransen, 2011).

The number of new anostracan species described each year has not decreased substantially since the 1940s and 353 valid species names are recognised here. This represents a 21.4% increase over Belk & Brtek (1995, 1997) (273 species) and a 20.0% increase over Brtek (1997, 2002) (285 species). Endemicity is high, with 28.8% of species known only from the type locality and 56.2% known from ten or less localities.

This catalogue also reflects the many advances in phylogeny made in recent years (e.g., Weekers et al., 2002), as well as classifications based upon modern genus concepts (e.g., Belk, 1995; Brendonck, 1995a, 1995b, 1997; Brendonck & Belk, 1997; Rogers, 2006a). There are 764 taxa presented in this checklist under the order Anostraca, including two suborders, ten valid families, 42 valid genera and subgenera, 353 valid species (including subspecies), and 362 synonyms, homonyms, nomina nuda, nomina dubia, and nomina oblita. Chresonyms are provided for taxon redescriptions that facilitate identification and evolutionary relationships. Spelling errors from the literature are not included.

Fossil anostracans are included. It is important to note that anostracans do not preserve well, being very soft bodied (Tasch, 1969; Schram, 1986), but with very few described or described well (e.g., Schram, 1986; Shen & Huang, 2008;

Harvey et al., 2012). Some fossil taxa (such as *Branchipusites* Goldenberg, 1873 and *Rochdalia* Woodward, 1913) have proved to be insect nymphs (Tasch, 1969).

A brief history of anostracan taxonomy. — Systematic methods in anostracan studies have evolved significantly. The history of the systematic method has taught us that the primary function of the systematist is to expose your predecessor's errors and replace them with your own. The very first definitive record of anostracans comes from an anonymous geographer in the year 982, who reported that the Persian (Iranian) Lake Urmia supported salt worms (Asem, 2008). Possible allusions to anostracans were made in classical Japanese works dating between 712 and 1590 (Harada, 1993). The earliest known anostracan depiction was by Petiver in his “*Gazophylacion Naturae et Artis*” in 1709, of British *Chirocephalus* as “*Squilla lacustris*”. Schlösser (1755) is the next record, reporting an “unknown insect” from salt works in Lymington, England, with an excellent drawing of *Artemia* (Kuenen, 1939). King (1767) reported what would eventually be known as *Chirocephalus* (as “a very remarkable aquatic insect”) from a ditch in Britain stating: “From their being prolific in this state, I suspect it to be their only one, and that they are merely aquatic, and never turn into flies, as many aquatic insect do.” Linnaeus (1746) wondered about that issue as well when he figured a fairy shrimp with the question; “An larva Ephemerae?”

Linnaeus described the first two fairy shrimp species in 1758 under his classification scheme: *Cancer salinus* (=*Artemia salina*) and *Cancer stagnalis* (=*Chirocephalus diaphanus*). Müller (1785) first recognised fairy shrimp (and tadpole shrimp) as a distinct group, which he named the “Entomostraca”. Latreille (1806) defined the Entomostraca,

as containing the orders Phyllopoda (tadpole shrimp) and the order Cephalota (the fairy shrimp). Later, recognising commonalities amongst the fairy shrimp, tadpole shrimp and clam shrimp, Latreille (1817) combined the Phyllopoda and the Cephalota into the order Branchiopoda (which was later raised to subclass by Calman, 1909, and class by Linder, 1945) to encompass these and a few other crustacean groups.

Three of the currently recognised genera (*Branchipus*, *Artemia*, and *Chirocephalus*) had been established by 1840, although six other genera (two synonyms of *Branchipus* and four synonyms of *Artemia*) were reported at that time. Milne-Edwards (1840) established the family Branchipodidae in a taxon he called the 'Legion Branchiopodes' (apparently a synonym of Entomostraca) to accommodate all these genera, and Sars (1867) placed this single family in the suborder Phyllopoda.

Packard (1883) produced the first monograph on branchiopod Crustacea, however the work focused upon the North American fauna and unfortunately caused a great deal of confusion surrounding certain species (see Lynch, 1964; Dexter, 1993). Packard recognised two subfamilies within the Branchipodidae; the Branchipodinae, which contained the currently recognised *Branchinecta*, *Branchipus* (including some *Eubranchipus*), *Artemia*, *Chirocephalus* (including some *Eubranchipus*), and *Streptocephalus*; and the Thamnocephalinae, which contained *Thamnocephalus*.

Simon created the Polyartemiidae in 1886 to encompass the genus *Polyartemia*, and elevated the subfamily Thamnocephalinae to family status. Grochowskii (1896) moved *Artemia* into its own family, the Artemiidae. Eleven additional genera (seven remain valid) had been described by 1909, and Daday published the first monograph addressing all known Anostraca in 1910. Daday described six (two valid) genera, and moved *Branchinecta* and *Streptocephalus* each to their own families. Daday's system recognised five families: Polyartemiidae, Branchinectidae, Chirocephalidae, Branchipodidae, and Streptocephalidae. Daday did not recognise Packard's Thamnocephalidae, and lumped *Thamnocephalus* into a new family, the Chirocephalidae, along with *Chirocephalus*, *Eubranchipus*, *Branchinella*, *Dendrocephalus* plus other genera not currently recognised. Daday's scheme placed *Artemiopsis*, *Artemia*, and *Branchinectella* in the Branchinectidae with *Branchinecta*.

Daday's classification stayed until Linder (1941) revised the Anostraca, and defined the majority of morphological terms currently used in their descriptions. Linder provided the first real definitions and quantifications for anostracan families and genera, as well as a basic framework towards understanding the generic relationships. Linder's choice of the generic and familial level characters gave stability to the higher anostracan classification that had never been there previously: the reason being that his method coincided with biological reality. Linder (1941) first utilised male genitalia to establish higher taxonomic categories of the Anostraca. Since that time male genitalia have been used extensively to define families and genera (Biraben, 1951; Belk, 1991, 1995; Hamer

& Brendonck, 1995; Brendonck, 1995a; Pereira & Ruiz, 1995; Brendonck & Belk, 1997; Rogers, 2002, 2003a, 2003b, 2005, 2006a, 2006b, 2006c). Linder recognised seven anostracan families: Artemiidae, Branchipodidae, Streptocephalidae, Thamnocephalidae, Chirocephalidae, and Polyartemiidae. Linder moved *Branchinectella* and *Artemiopsis* into the Chirocephalidae, based on characters of the genitalia and the thoracopods. Linder also reinstated the Artemiidae and the Thamnocephalidae.

Tasch (1969) combined the anostracans with the fossil Lipostraca under the subclass Sarsostrotraca, named in honour of G. O. Sars. Tasch's grouping was problematic (see discussion in Martin & Davis, 2001), however the assertion that the Anostraca belong in their own subclass is strongly supported by both molecular as well as morphological data (Fryer, 1985, 1987; Wallosek, 1993; Hanner & Fugate, 1997; Negrea, et al., 1999; Spears & Abele, 2000; deWaard et al., 2006). Martin & Davis (2001) resurrected the Sarsostrotraca, to reflect the separate lineage of the anostracans.

Brtek created the families Linderiellidae (1964) (for *Linderiella* and *Dexteria*) and Artemiopsidae (1966) (for *Artemiopsis*) out of the Chirocephalidae. Brtek also raised two subgenera of *Eubranchipus* (*Siphonophanes* and *Drepanosurus*) to genus level. Belk (1995), Brendonck (1995a) and Brendonck & Belk (1997), building on Linder's (1941) work, reemphasized the importance of male genital morphology in anostracan taxonomy and set defensible, quantifiable standards for defining anostracan genera. Belk (1995) demonstrated that *Siphonophanes* and *Drepanosurus* (Simon, 1886) were both junior synonyms of *Eubranchipus* Verrill, 1870, and gave us insight into the geographic origin of the genus. Belk (in Martin & Davis, 2001) following the same reasoning, argued for subsuming the Linderiellidae and Artemiopsidae back into the Chirocephalidae. For the Linderiellidae, this was further supported by molecular data (Weekers et al., 2002), and morphological data (Rogers, 2002a, 2003).

Belk & Brtek (1995, 1997) produced excellent annotated checklists of the world anostracan fauna. However, due to differences of opinion on generic level definitions, Brtek (1997, 2002) published his own checklists (covering all Branchiopoda) to reflect his opinions. Without providing any justification or analyses, and ignoring the corpus of recent literature defining anostracan genera, he added to the confusion surrounding various groups. The English is poor, and many genera and families previously synonymised are resurrected without justification (*Siphonophanes*, *Drepanosurus*, *Nematosurus*, *Branchinellites*; a discussion of Brtek's treatment of *Branchinellites* can be found elsewhere [Rogers, 2006a]). Errors are also present for non-anostracan taxa (e.g., some clam shrimp are presented as having valid names in both *Cyzicus* and *Eocyzicus*).

Brtek & Mura (2000) published keys to the anostracan families and genera. The authors also chose to resurrect the genera *Branchinellites*, *Drepanosurus*, and *Siphonophanes* but again without any morphological or taxonomical analyses

(Rogers, 2003b, 2006a, 2006b). They ignored the critical analyses of Belk (1995) who quantitatively demonstrated that *Drepanosurus* and *Siphonophanes* were junior synonyms of *Eubranchipus*, with the only statement justifying their position being: "...many adjustments have been made... due to the fact that additional characters were considered valid, and helpful in better identification." No methods or materials sections appear and there is no character analysis, no critical analysis of Belk's work, or any citations to defend their position (Rogers, 2003a). Additionally, Brtek & Mura (2000) subdivided the genus *Branchinecta* into "...five distinct groups..." that they claim are supported based on male second antennal morphology. The authors then describe these groups based on geography, with no indication what characters were used to define the groups, nor what species are in those groups (Rogers, 2006c). Furthermore, their keys have rubrics that are mostly long, unclear character combinations, rather than discreet character states.

Naganawa & Orgiljanova (2001) created a subclass they called the 'Protobranchiopoda' to separate the 'Large Branchiopods' (i.e., the Anostraca, Notostraca, Laevicaudata, Spinicaudata, and Cyclosterida) from the Cladocera. However, this move was unwarranted as it obscured the relationships between the Notostraca and the Laevicaudata, the Spinicaudata with the Cyclosterida and the Cladocera, and ignored the strong divergence of the Anostraca from the other extant orders of the class as based upon a vast corpus of morphological and molecular data (for examples: Bowman & Abele, 1982; Wallosek, 1993; Wallosek & Müller, 1998; Fryer, 1985, 1987; Negrea et al., 1999; Spears & Abele, 2000; Martin & Davis, 2001; deWaard et al., 2006).

Molecular analyses of the Anostraca have been conducted in an effort to determine the phylogenetic relationships amongst the families and genera, including: Remigio & Hebert (2000), Spears & Abele (2000) and Weekers et al. (2002). These studies have demonstrated and confirmed the monophyly of the Anostraca. The phylogenetic study of Weekers et al. (2002) analysed the most genera, and has provided us with the clearest picture to date of the relationships between the genera and families. Furthermore, their analyses discovered two suborders within the Anostraca and two cryptic families, moving *Parartemia* to its own family (Parartemiidae), and moving *Tanymastix* and *Tanymastigites* into their own family (Tanymastigidae). In addition, the Polyartemiidae and the Linderiellidae were found to belong within the Chirocephalidae, justifying Belk's (in Martin & Davis, 2001) assertions.

CATALOGUE STRUCTURE

The basic systematic structure for all anostracan taxonomic levels above genus follows Weekers et al. (2002). Supraspecific taxa are presented in bold. Genera and species are presented alphabetically. Subgenera and subspecies are presented with the nominate taxon listed first. Synonyms are presented following an equal sign (=) and are indented. Where an important analysis is presented for a synonymy, a reference

is provided as "fide" the synonymiser. For example: =*Branchipodopsis terpogossiani* Smirnov, 1936 (fide Hartland-Rowe, 1968). Nomina nuda and dubia are listed under separate header for each family. Chresonyms are presented parenthetically after the original author and date, and are referred to as "in the sense of" the redescriber. For example: *Parartemia longicaudata* Linder, 1941 (sensu Timms, 2010).

REMARKS

Brtek's subfamilies and subgenera. — Brtek (1966, 1972, 1997, 2002) created several subfamilies and subgenera, some were eventually elevated to full family or genus status and then further subdivided. Unfortunately, these taxa were never clearly defined, particularly the subfamilies. Difficulties concerning the validity of some of the subgeneric names as well as their composition have been raised elsewhere (Rogers, 2003, 2004), and other names are shown below to be preoccupied. Since these subfamilial and subgeneric concepts need to be properly vetted, they are shown as synonyms in the catalogue below. It is my opinion that subfamilial and subgeneric categories may be useful to elucidate certain relationships, but that they should be used sparingly. It should be remembered that while the species designation is an exclusive concept, the higher taxonomic categories are inclusive concepts.

Chirocephalus and Galaziella. — Naganawa & Orgiljanova (2000) described the genus *Galaziella* based on material from Mongolia, and later Naganawa (2001) placed the genus in a new family, Galaziellidae. Rogers (2003a) discussed the validity of the genus based on the original description, and concluded that the genus was synonymous to *Chirocephalus* in the family Chirocephalidae. Naganawa & Zagas (2003) resurrected and redescribed the genus, along with one new species, moving another species of *Chirocephalus* into *Galaziella*, and created a new subfamily within the Chirocephalidae to accommodate the genus. Rogers (2005) provisionally accepted the genus based on the limited gonopod description, but with reservations. Alonso & Naganawa (2008) described another new species in the genus *Galaziella*, diagnosing the genus with three parameters:

1. Form of the male second antenna distal antennomere. Naganawa & Zagas (2003) and Alonso & Naganawa (2008) state that the proximal projection is posterioventral in *Galaziella* and medial in *Chirocephalus*. However, the form of the second antenna cannot be used to define an anostracan genus (see above). Great variation in second antennal morphology exists within other genera, such as *Branchinella*, *Branchinecta*, *Eubranchipus*, and *Chirocephalus*. The disparate range of morphologies in these genera is much greater than what Naganawa & Zagas (2003) and Alonso & Naganawa (2008) claim separate *Galaziella* and *Chirocephalus*. Furthermore, this character state also occurs in *Chirocephalus shadini* and *C. orchidani*. This projection is entirely absent in *C. josephinae*.

2. Form of the gonopod. Alonso & Naganawa (2008) state that the gonopod morphology is "...a boom-like process with pouch [sic] and a conical toothed cirrus directed outwards, a feature not reported in other anostracans..." As was stated in Rogers (2003) the conical eversible portion of the *Galaziella* gonopod appears to be within the range of variation observed in the genus *Chirocephalus*. The "boom-like" process is present in other *Chirocephalus* species (see Rogers, 2003 for analyses) including *C. carnuntanus*, and *C. shadini*, and in reduced form in *C. brevipalpis*, *C. croaticus*, *Eubranchipus bundyi*, *E. ornatus*, *E. serratus*, *E. vernalis*, and most importantly some (but not all!) forms of *C. diaphanos*.
3. Form of the egg. Alonso & Naganawa (2008) figure the egg and claim that *Galaziella* has "...a unique resting egg morphology, found only in some extinct anostracans..." Contrary to Alonso and Naganwa's assertion, similar egg shell texturing is observed in other species of *Chirocephalus*, most notably *C. skorikowi*, *C. shadini*, and *C. priscus*, as well as to a lesser extent in *C. slovacicus*, *C. chyzeri*, *C. povolnyi*, and *C. marchesonii* (see figures in Mura, 2001). Egg morphology similar to *Galaziella* has been depicted for *Branchinella occidentalis* (Timms et al., 2004) and various *Branchinecta* and *Streptocephalus* species (César, 1989; Hill & Shepard, 1997; Shepard & Hill, 2001). Furthermore, Mura (2001) demonstrated the remarkable plasticity of egg morphology within individual species of *Chirocephalus*.

The genus *Chirocephalus* is obviously in need of revision utilising both morphological and molecular techniques. This is a large genus with many species and with a great deal of morphological variation, and the validity of many species has been called into question (Belk & Brtek, 1995). That being said, I can find neither consistent nor quantitative character states that support the separation of *Galaziella* from *Chirocephalus*. However, any divisions must start from a thorough and proper review of the genus as a whole.

***Chirocephalus graziellae* (Alonso & Naganawa, 2008)**
nomen novum. — This species was described as *Galaziella murae*. It was named in honour of Graziella Mura, who has made vast contributions to the corpus of anostracan knowledge. However, since *Chirocephalus murae* is a preoccupied name, I changed the specific epithet to the Latinised form of her first name.

ACKNOWLEDGEMENTS

I am extremely grateful to Sergey Anosov and Alexey Kotov for helping me find certain Russian literature. As always, I am indebted to my very good friend Brian V. Timms for his excellent reviews and comments. I would also like to extend my gratitude to Alain Thiéry for catching some unfortunate errors.
