## Revision of *Europiella* Reuter in North America, with the Description of a New Genus (Heteroptera: Miridae: Phylinae)

RANDALL T. SCHUH<sup>1</sup>

### ABSTRACT

The New World species of *Europiella* Reuter are revised. Three species from western North America are described as new. A key and illustrations of the habitus and male genitalia for the 13 recognized Nearctic species are provided. Scanning electron micrographs are given for structural details of four species. Detailed locality and host data are offered for all species. *Europiella albipubescens* Knight, 1968 is transferred to *Knightopiella*, new genus. *Europiella lividella* (Kerzhner, 1979) is returned to *Plagiognathus* Fieber.

### INTRODUCTION

Schuh et al. (1995) created numerous new synonymies and integrated the taxonomy of the Palearctic and Nearctic faunas for the predominantly *Artemisia*-feeding genus *Europiella* Reuter. The present paper treats the Nearctic fauna in detail, presenting diagnoses and descriptions for all species, including three previously undescribed species, a key to species, and detailed locality and host information.

Because some *Europiella* spp. feed on relatively common, widely distributed plant

species, they are frequently present in large numbers in collections. As outlined by Schuh et al. (1995), generic placement, species concepts, and species identifications have a history of inconsistency in this group; the present paper represents a further attempt to resolve difficulties encountered in past taxonomies. A detailed revisionary treatment of the Palearctic fauna, although highly desirable, is not attempted here because I lacked access to a sufficient amount of material. Detailed information is provided for most material examined, including number and sex of specimens; however, because of the long pe-

<sup>1</sup> Curator, Division of Invertebrate Zoology, American Museum of Natural History (schuh@amnh.org).

riod over which specimens were examined for this study, in some instances specimen numbers are indicated only as males or no specimen numbers are given. All measurements are in millimeters; see table 1 for measurements of all species.

### *Europiella* Reuter

Type species: *Agallistes stigmaticus* Uhler.

*Europiella* Reuter 1909: 83 (n. gen., descr.);

Schuh et al., 1995: 379 (n. syn., disc.).

*Poliopterus* Wagner, 1949: 53 (n. subgen. of *Plagiognathus*, descr.). (syn. by Schuh et al., 1995: 379).

**DIAGNOSIS:** Recognized by the relatively small size, length 2.14–3.68; body form varying from elongate and nearly parallel-sided to ovoid. Coloration varying from almost completely pale or weakly greenish to almost entirely black, usually with a few dark markings on femora and at bases of tibial spines. Vestiture of dorsum with reclining simple setae and recumbent, weakly woolly, silvery setae; eyes weakly produced laterally, not closely conforming to anterior margin of pronotum. Some species showing strong sexual dimorphism with males elongate, nearly parallel-sided and females strongly ovoid with hemelytra strongly conforming to shape of body. Pale-colored species similar in appearance, including type of vestiture, to *Knightopiella*, new genus and *Megalopsallus* spp. Distinguished from both of those genera by the structure of the male genitalia, and from *Megalopsallus* by the much smaller pygophore in members of that group.

Male genitalia varying greatly in size, but pygophore always moderately large to large relative to total size of abdomen; right paramere truncate apically, with a more or less well-developed protrusion on either side (figs. 3–5), never lanceolate as in most Phylini; body of vesica with a distinctive curvature and form, and usually with a proximal portion of one strap terminating near midpoint of vesica (see fig. 1, *angulata*, fig. 2, *E. lattini*); vesica always with two apical processes, these sometimes elongate, flattened, and broadened basally (figs. 3–5), and in the form of blades very similar to that found in *Plagiognathus* spp., or much shorter and variously acuminate and/or strongly curving and

spinellike (figs. 3–5); secondary gonopore large and heavily sclerotized, placed to the side of the chitinous bands of the vesica rather than in the same plane (figs. 3–5), as in *Plagiognathus*, and distinctly proximad of attachment of spines.

Often breeding exclusively on *Artemisia* spp., occasionally on other Asteraceae, and rarely on Lamiaceae in Palearctic.

**REDESCRIPTION:** *Male:* Relatively small, elongate to ovoid, total length 2.14–3.68; body in transverse cross-section more or less cylindrical, not flattened. **COLORATION** (figs. 1, 2): Coloration varying from almost completely white or pale greenish to nearly all black. Mesoscutum often orange laterally. Femora usually with some contrasting dark spots; tibial spines usually black with black bases, sometimes pale but with bases always at least darkened if not distinctly black. **SURFACE AND VESTITURE** (figs. 1, 2, 7, 9–11): Dorsum smooth, dull, clothed with reclining simple setae and recumbent, weakly woolly, silvery setae. **STRUCTURE** (figs. 7, 9–11): Head transverse, frons weakly bulging, clypeus generally not visible from above; eyes relatively small, not sexually dimorphic; antennal segment 2 slender, tapering to slightly greater diameter distally, sexual dimorphism very weak; length of labium variable, from just reaching middle coxae to just surpassing posterior margin of hind coxae; claws elongate, gently curving, parempodia always setiform, pulvilli small. **GENITALIA** (figs. 3–5): Genital capsule and genitalia moderately large to large relative to size of abdomen; vesica formed of two chitinous bands, always with two apical process, these sometimes elongate and broadened basally, and in the form of blades, or much shorter and variously acuminate and/or strongly curving and in the form of spines; body of vesica with distinctive curvature and form, with a portion of one strap often terminating near midpoint of vesica (e.g., fig. 1, *E. angulata*, fig. 2, *E. lattini*) and most species with a distinctive, broad, membranous projection extending beyond gonopore straps just distad of gonopore (e.g., fig. 4, *E. pilosula*, fig. 5, *E. stigmosa*); secondary gonopore large and heavily sclerotized, placed laterad of the chitinous bands of the vesica rather than between them, slightly proximad

of attachment of spines; phallotheca of relatively uniform structure, typical of Phylini (figs. 4, 5); left paramere boat-shaped, typical of Phylini (fig. 3); right paramere distinctive for the group, truncate apically, with a more or less well-developed protrusion on either side (figs. 3–5), never lanceolate.

*Female*: Elongate ovoid, usually of more robust appearance than male; total body length 2.14–3.32.

**DISTRIBUTION**: Like many other genera of Phylinae in North America, but with the notable exception of *Plagiognathus* Fieber, endemism and species diversity in *Europiella* are restricted almost entirely to the West. Only *Europiella decolor* Uhler and *E. artemisiae* (Becker) occur in eastern North America, both species also occurring in the Palearctic.

**HOST ASSOCIATIONS**: Unlike most members of the Phylini, *Europiella* spp. are usually found on their hosts when the plants are not in flower. This is true in North America for *Artemisia* and *Chrysothamnus*-associated species, which are collected during the late spring and early summer, whereas the plants flower in the late summer. *Europiella* spp. in the Nearctic, with the exception of *E. lattini*, n. sp., are restricted to members of the Asteraceae, primarily *Artemisia* spp., whereas in the Palearctic some species are also found feeding on the Lamiaceae.

**DISCUSSION**: Because sexual dimorphism is pronounced in some *Europiella* spp., the two sexes are not always recognizable as belonging to the same taxon. Accurate identifications of females will require association with males, in most cases. Indeed, as with many phylines, placing females to genus can be difficult. For this reason the following key is designed to be used for male specimens, although it will work for females of some species. Information on host associations is often helpful in placing species to genus. Because some aspects of coloration are quite variable within species, positive identification may require dissection of the male genitalia.

KEY TO MALES OF NORTH AMERICAN SPECIES OF *EUROPIELLA*

- 1. All antennal segments entirely pale; bases of tibial spines with at most a small, weak,

- dark area; coloration of dorsum entirely pale . . . . . 2
- Antennal segment I usually entirely black, much less commonly only black near extreme base or on one face; tibial spines with conspicuous black bases; coloration of dorsum variable . . . . . 3
- 2. Genitalia as in figure 4 (see discussion of color variation under species account) (British Columbia south to Arizona, east to Kansas) . . . . . *pilosula* (Uhler)
- Genitalia as in figure 5 (northern Arizona) . . . . . *signicornis* Knight
- 3. Dorsum entirely pale; femora pale, sometimes with a few darker blotches . . . . . 4
- Dorsum with at least some dark areas, sometimes dorsum almost entirely dark, occasionally dark areas appearing only as faint infuscations of portions of clavus, corium, or cuneus; coloration of femora variable . . . . . 5
- 4. Long, slender species, total length 3.30–3.61, ratio width pronotum/total length 1:3.65; cuneus elongate, as in figure 2; vesica as in figure 4; extreme southern California . . . . . *morrisoni*, new species
- Body form not so elongate and slender; cuneus more broadly triangular; vesica variable . . . . . 8
- 5. Large species, total length always at least 3.22; vesica as in figure 3; coloration of dorsum almost entirely dark in some populations (fig. 1); widely distributed in western North America *consors* (Uhler)
- Smaller species, total length always less than 3.08 . . . . . 6
- 6. Specimens usually with dorsum entirely white, sometimes with some faint infuscation on pronotum and cuneus . . . . . 7
- Males always with some infuscation on dorsum, especially anterior pronotal lobe and areas between veins on hemelytra, giving a mottled appearance (females more frequently almost entirely pale) (fig. 2); vesica with anterior terminal blade very long and decurved (fig. 5); interior western North America . . . . . *stigmosa* Reuter
- 7. Genital capsule large and deep, in lateral view appearing more or less parallel-sided and very broad posteriorly; vesica as in figure 4 (British Columbia south to Mojave Desert, east to Colorado) . . . . .
- Genital capsule more slender, in lateral view tapering to a much less broad posterior margin (see fig. 11B for example conformation); vesica as in figure 3 (Oregon to Wyoming) . . . . . *carvalhoi* Schuh

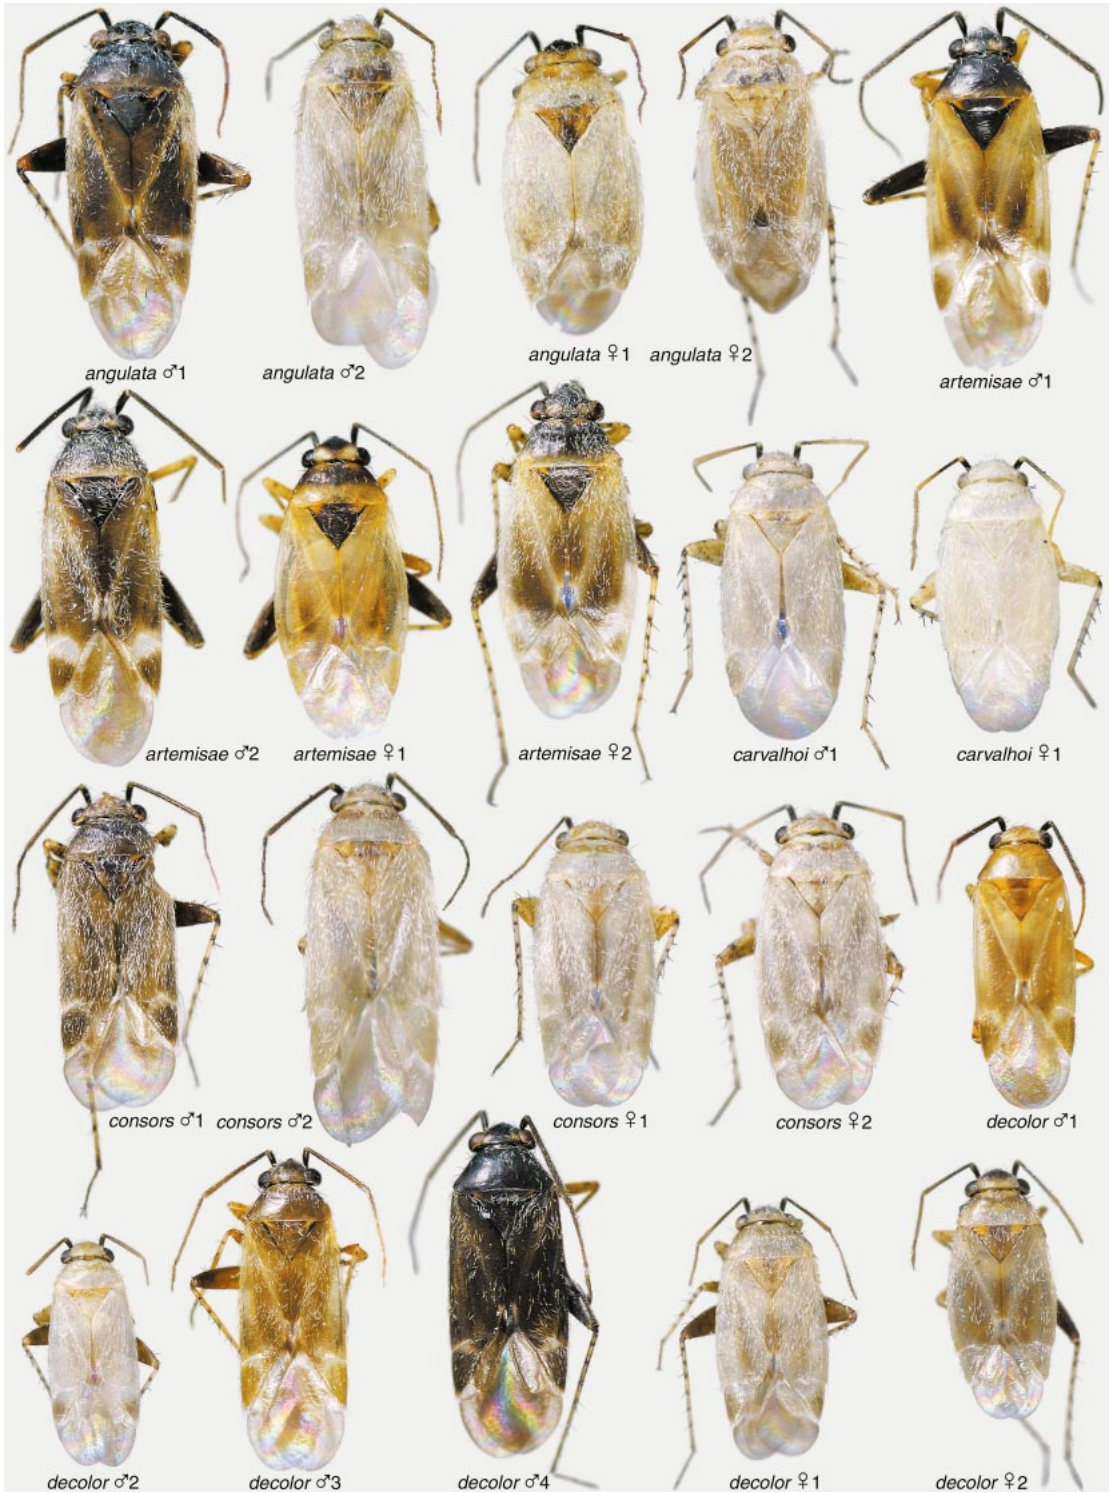

Fig. 1. Habitus views of *Europiella* spp.: *angulata*–*decolor*. See appendix 1 for localities.

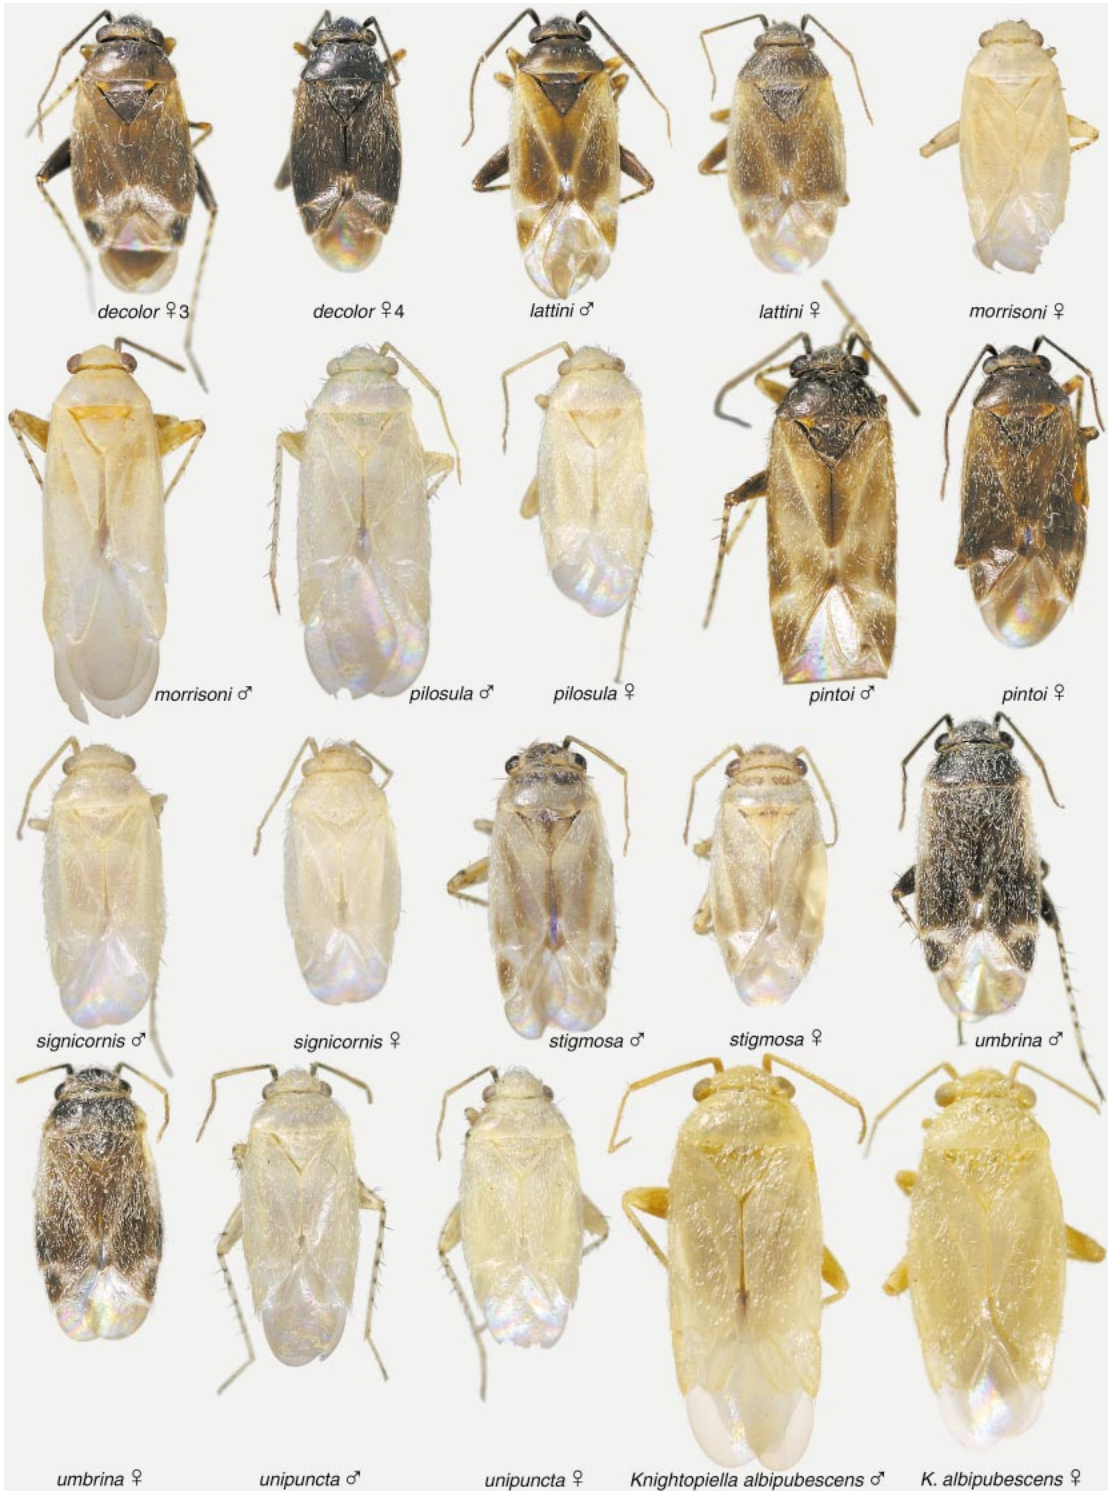

Fig. 2. Habitus views of *Europiella* spp.: *decolor*–*unipuncta*. Habitus of *Knightopiella albipubescens*. See appendix 1 for localities.

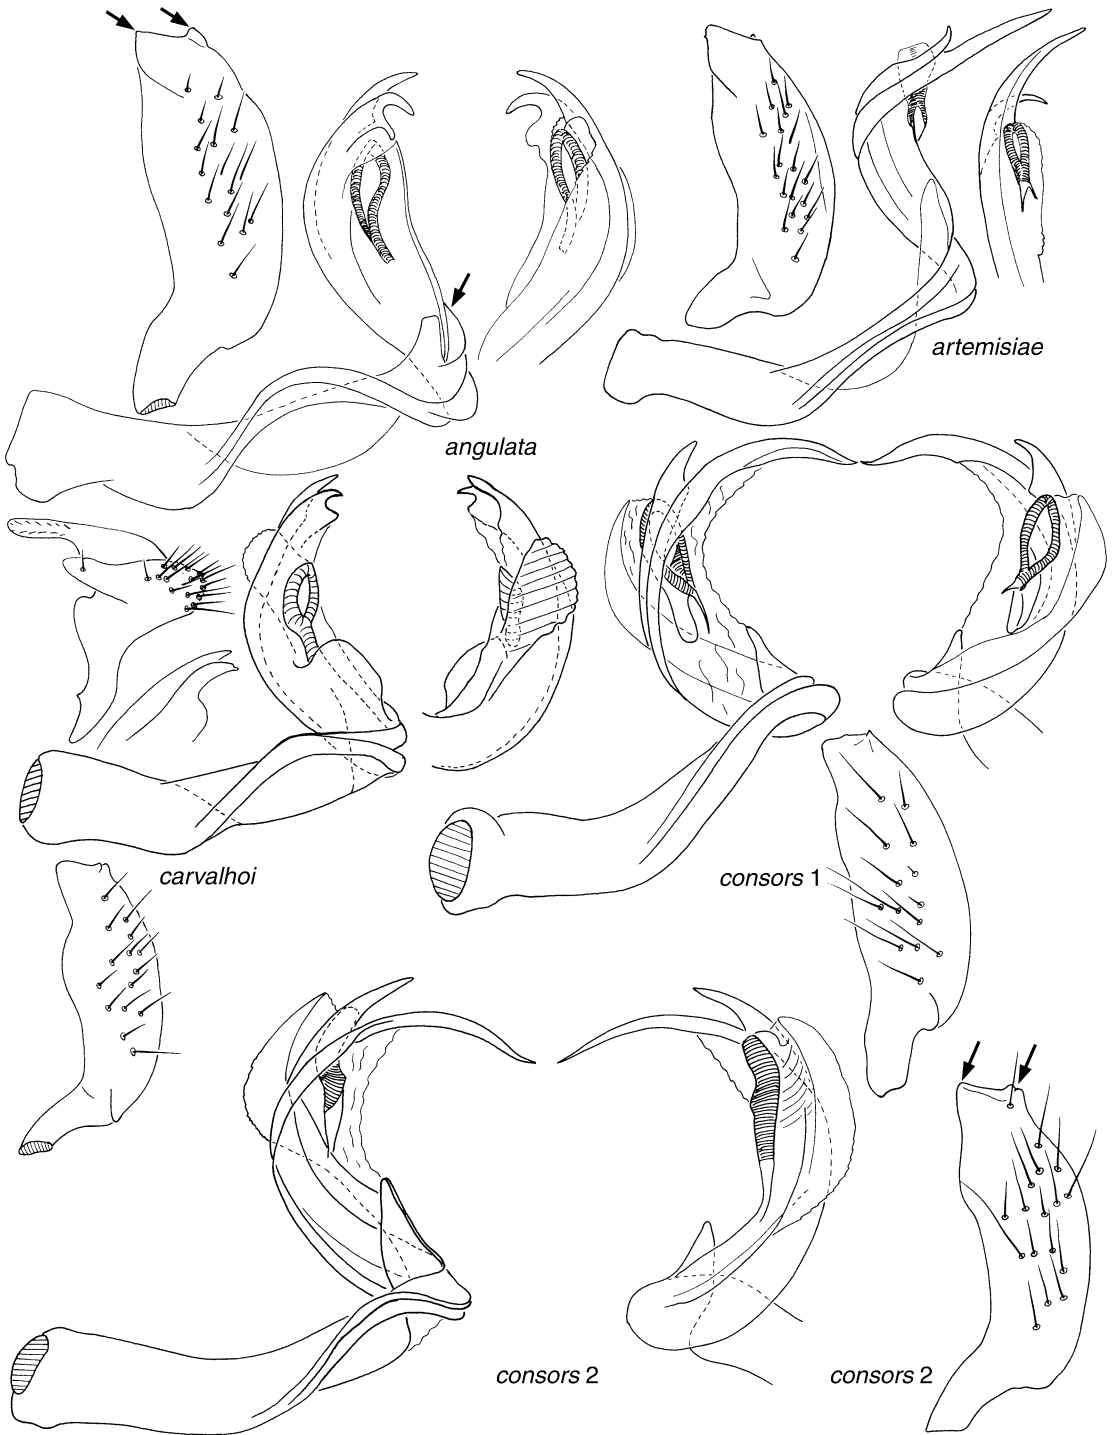

Fig. 3. Male genitalia of *Europiella* spp.: *angulata*–*consors*.

Fig. 4. Male genitalia of *Europiella* spp.: *decolor*–*pintoii*.

Fig. 5. Male genitalia of *Europiella* spp.: *signicornis*–*unipuncta*.

- 8. Relatively large species, total length never less than 3.04 . . . . . 9
- Smaller species, total length never greater than 3.50, usually less than 3.05 . . . . 12
- 9. Length of antennal segment 2 more than one-third greater than width of head (Holarctic) . . . . . *artemisiae* (Becker)
- Length of antennal segment 2 no more than one-fourth greater than width of head . . . . . 10
- 10. Genitalia as in figure 4 (southern California) . . . . . *pintoii*, new species
- Genitalia not as in figure 4 for *pintoii* . . 11
- 11. Genitalia as in figure 3 (western North America) . . . . . *angulata* (Uhler)
- Genitalia as in figure 3 (western North America) . . . . . *consors* (Uhler)
- 12. Antennal segments 1 and 2 entirely black; narrow, elongate to very elongate species, width of pronotum never greater than 0.99, usually less than 0.95 . . . . . 13
- Antennal segment 1 sometimes only partially black, segment 2 always pale on at least distal two-thirds of segment; broader, more ovoid species, width of pronotum always greater than 0.94 . . . . . 14
- 13. Pygophore (and aedeagus) large, diameter of pygophore as measure from side at junction with pregenital abdominal segments about equal to width of head; coloration of dorsum appearing somewhat mottled; size variation limited, total length apex 2.81–3.05; genitalia as in figure 4 (coastal mountains of Pacific Northwest) . . . . . *lattini*, new species
- Pygophore (and aedeagus) smaller, diameter of pygophore as measured from side at junction with pregenital abdominal seg-

- ments distinctly less than width of head; coloration of dorsum varying from nearly uniform brown to completely pale/white; size variation great, total length 2.14–3.50; genitalia as in figure 3 (Holarctic, widely distributed in North America) . . . . . *decolor* (Uhler)
- 14. Dorsum weakly to moderately infusate, appearing mottled, brownish; genitalia as in figure 5 (interior western North America) . . . . . *stigmosa* Reuter
- Dorsum strongly infusate, usually appearing blackish, with some contrasting white areas; genitalia as in figure 5 (Great Basin and California south to northern Baja California) . . . . . *umbrina* Reuter

*Europiella angulata* (Uhler)  
Figures 1, 3, 6, 7

*Maurodactylus angulatus* Uhler, 1895: 53 (n. sp., descr.).  
*Europiella angulata*: Knight, 1968: 41 (n. comb.); Schuh et al., 1995: 386 (n. syn.).  
*Europiella yampae* Knight, 1968: 43 (n. sp.; syn. by Schuh et al., 1995: 386).

DIAGNOSIS: Recognized by the relatively large size, elongate, nearly parallel-sided, broad body form (fig. 6), usually dark general coloration of dorsum, and the vesica with a short, sickle-shaped anterior apical spine and short, weakly curving, posterior spine (fig. 3), a condition shared with *E. carvalhoi*, *E. pilosula*, and *E. unipuncta*. Most similar in size, general appearance, and coloration to *E. consors*, and apparently not sep-

Fig. 6. *Europiella angulata* (Uhler). Male: USA: Colorado: Jefferson Co.: Red Rocks Park near Morrison, 5600 ft.

Fig. 7. Scanning electron micrographs of *Europiella angulata* ( $\delta$ ). **A.** Mesothoracic spiracle and metepisternal scent-efferent system, lateral view. **B.** Pretarsus, lateroventral view. **C.** Setae on hemelytra. **D.** Setae on hemelytra, detail of microstructure.

arable from it with certainty except by dissection of the male genitalia. Sexual dimorphism in this species is pronounced, the females being smaller than the males and conspicuously ovoid rather than parallel-sided (fig. 1).

**REDESCRIPTION:** *Male:* Relatively large, broad-bodied species, total length 3.04–3.53, width across pronotum 0.43–0.51. **COLORATION** (fig. 1): General coloration of dorsum usually largely dark, but sometimes extensively pale; antennal segments 1–4 black; labium with segments 1 and 2 mostly pale, segments 3 and 4 much darker; much of venter dark in dark specimens, largely pale in pale specimens; coxae, trochanters, and femora mostly dark in dark specimens, largely pale in pale specimens, femora when pale with dark spots or blotches; tibiae with pale background coloration, spines black with

black bases. **SURFACE AND VESTITURE** (fig. 7C, D): Surface and vestiture as in generic diagnosis. **STRUCTURE** (fig. 7): Elongate, nearly parallel-sided, corial margin weakly convex. **GENITALIA** (fig. 3): Pygophore moderately large relative to size of abdomen; anterior vesical spine short, sickle-shaped, posterior spine short, weakly curving, spines similar in structure to *E. carvalhoi*, *E. pilosula*, and *E. unipuncta*.

*Female:* Coloration usually light, seldom as dark as in males. Females much shorter than males, ovoid (fig. 1). Total length 2.84–3.32, width pronotum 0.42–0.48.

**HOSTS:** *Artemisia arbustorum*, *A. dracuncululus*, *A. tridentata*. Also recorded from *Chrysothamnus* sp., *Solidago* sp. (Asteraceae).

**DISTRIBUTION:** Widely distributed in the interior of western North America, from Brit-

ish Columbia to Saskatchewan in the north to Arizona and east to west Texas and the foothills of the Rocky Mountains in the south.

**DISCUSSION:** The distribution of *E. angulata* is overlapped almost completely by that of *E. consors*. The great external similarity of these species therefore makes their recognition on the basis of distribution impossible. Consequently, over much of the range of these two taxa dissection of the male genitalia would appear to be necessary to confirm that identifications are accurate.

**SPECIMENS EXAMINED:** Holotype of *angulata*: ♂, Type; Colo., 1691; P. R. Uhler Collection (USNM). Holotype of *Europiella yampae* Knight: ♂, Steamboat Springs, July 12, 1964, COLO., 6700', H. H. Knight (USNM). Additional specimens: CANADA: **Alberta:** Elkwater Park, July 25, 1952, L. A. Konotopetz, 3♂ (CNC). **British Columbia:** Mt. Figures 1, 3

*Capsus artemisiae* Becker, 1864: 487 (n. sp., descr.); Schuh et al., 1995:385 (n. syn., disc., figs.).

*Plagiognathus diversus* Van Duzee, 1917a: 283 (n. sp.). NEW SYNONYMY.

*Plagiognathus solani* Matsumura, 1917: 432 (n. sp.; syn. by Schuh et al., 1995: 386).

*Plagiognathus albipennis* var. *obscura* Sahlberg, 1920: 167 (n. var.; syn. by Schuh et al., 1995: 386).

*Plagiognathus (Poliopterus) gracilis* Wagner, 1956: 74 (n. sp.; syn. by Schuh et al., 1995: 386).

*Psallus artemisicola* Knight, 1964: 149 (n. sp.); Schuh et al., 1995: 384 (n. syn. with *Europiella decolor* [Uhler]). REVISED SYNONYMY.

DIAGNOSIS: Always with strongly infuscate hind femora and dark areas on the hemelytra (fig. 1). Similar in appearance to *E. decolor* and *E. lattini*, but distinguished by its usually larger size and antennal segment 2 in males always greater than width of pronotum; length of antennal segment 2 not diagnostic for females; male genitalia very similar in structure to those of *E. decolor* and *E. lattini*, but pygophore and vesica smaller than those in *E. lattini*, and anterior apical spine longer (compare figs. 3 and 4).

REDESCRIPTION: *Male*: Moderately large, elongate species, total length 3.27–3.58, width pronotum 0.97–1.02. COLORATION (fig. 1): Head, pronotum, and scutellum usually mostly dark; hemelytra usually dark with pale areas at base of corium and base of cuneus; some specimens lighter with posterior margin of pronotum and lateral angles of mesoscutum orange and hemelytra generally yellow-orange except for infuscate posterior half of endocorium and posterior portion of cuneus; all antennal segments black; labium generally pale, segment 4 black; venter of body generally infuscate to nearly black; all trochanters pale; forecoxae almost entirely pale; fore and middle femora only weakly darkened, usually with some orange, hind femora heavily infuscate; all tibiae with black spines with distinct black bases. SURFACE AND VESTITURE: Surface and ves-

titure as in generic diagnosis. STRUCTURE: Elongate, nearly parallel-sided, corial margin only weakly convex; antennal segment about one-third longer than width of head. GENITALIA (fig. 3): Pygophore moderately large relative to size of abdomen; posterior apical spine of vesica short, sharply curving, hook-shaped just surpassing gonopore, anterior spine conspicuously longer and weakly decurved, structure very similar to that of *E. decolor* (fig. 3), also similar to *E. lattini* (fig. 4), but anterior spine much longer and entire vesica smaller than in that species.

*Female*: Coloration similar to male. Body form much more strongly ovoid. Total length 2.94–3.22, width pronotum 0.94–1.10; antennal segment 2 relatively shorter than in males, less than or equal to width of pronotum.

HOSTS: Breeds on various species of *Artemisia*, including both herbaceous and woody taxa. Also recorded from *Chrysothamnus*, *Haplopappus*, and *Solidago* spp. (Asteraceae).

DISTRIBUTION: In the Nearctic ranging from Alaska in the north to Zacatecas, Mexico, in the south. In the Rocky Mountain system ranging south into New Mexico, and at higher latitudes as far east as Minnesota and Wisconsin. Although many localities are what would be called boreal, others—such as those from southern California and Mexico—are not.

DISCUSSION: The status of this holarctic species was discussed by Schuh et al. (1995), who were the first authors to recognize its occurrence in North America.

Van Duzee (1917a) described a species *Plagiognathus diversus* from Santa Cruz County, California. Examination of the holotype and dissection of a male paratype of *P. diversus* from the type locality, as well as examination of a number of other paratypes, indicate that this taxon is a junior synonym of *Europiella artemisiae*, **new synonymy**.

Schuh et al. (1995), without comment, synonymized *Psallus artemisicola* Knight, described from St. Paul, Minnesota, with *Europiella decolor*. I can only conclude that this decision was made in haste, because upon further examination of specimens used by Knight in the preparation of his original description, this nominal taxon is clearly the

same as *E. artemisiae*, not *E. decolor* (Uhler) **revised synonymy.**

**SPECIMENS EXAMINED:** Holotype of *Psallus artemisicola* Knight: ♂, St. Paul, Minn., Sept. 3, 1923, H. H. Knight, *Artemisia ludoviciana*; deposited in the USNM. Holotype of *Plagiognathus diversus* Van Duzee: ♂, Niles Canyon, Cal., W. M. Gifford, Alameda Co., 12-VI-17, Cal., Type *diversus*, Type No. 357; deposited in the CAS. Additional specimens: **CANADA: Alberta:** Head Smashed-in Buffalo Jump Interpretive Park, September 1, 1993, M. D. Schwartz, *Artemisia cana* (Asteraceae), 28♂ (CNC). **British Columbia:** 15.8 km N of S end of Muncho Lake Provincial Park, August 1, 1982, G.G.E. *Europiella carvalhoi* Schuh

Figures 1, 3

*Europiella carvalhoi* Schuh (in Schuh et al.), 1995: 387 (n. sp., descr.).

**DIAGNOSIS:** Recognized by the pale, nearly white coloration of the dorsum in most specimens, the elongate-oval body shape (fig. 1), antennal segment 1 black, segment 2 black on at least proximal one-half but sometimes of lighter coloration distally, and the detailed structure of the vesica spines, the anterior spine short and sickle-shaped, the posterior spine relatively short and weakly curving (fig. 3), a condition shared with *E. angulata*, *E. pilosula*, and *E. unipuncta*. Most similar in body form, coloration, and genitalic structure to *E. unipuncta*, but differing from that species by the smaller pygophore, smaller vesica, and differences in the details of the vesical structure. Separated from *E. pilosula* by the entirely pale antennae in most specimens of that species and from *E. angulata* by that species' larger size and generally darker coloration.

**REDESCRIPTION:** *Male:* Relatively small, elongate-ovoid species, total length 2.64–

3.00, width pronotum 0.85–0.98. **COLORATION** (fig. 1): Dorsum, including membrane pale, white to tan, tinged with green; neck castaneous; thoracic pleura and venter and pregenital abdominal segments weakly infuscate, pygophore somewhat darker; antennal segment 1 black, segment 2 black proximally, progressively lighter distally in most specimens, segments 3 and 4 weakly infuscate; femora pale to weakly infuscate with some dark spots, tibiae pale, narrowly black at femoral articulation, tibial spines black with black bases. **SURFACE AND VESTITURE:** Surface and vestiture as in generic description. **STRUCTURE:** Body elongate ovoid. **GENITALIA** (fig. 3): Pygophore moderately large relative to total size of abdomen; apical vesical spines short, of nearly equal length, anterior spine sickle-shaped.

*Female:* Coloration as in male; body form more strongly ovoid. Total length 2.51–2.86, width pronotum 0.89–0.98.

**HOSTS:** Collected almost exclusively on *Artemisia tridentata*. Also known from a single record on *Chrysothamnus nauseosus*.

**DISTRIBUTION:** Most frequently collected in the northern Great Basin and adjoining areas, ranging from Washington to Wyoming in the North, south into Nevada, Utah, and Colorado.

**DISCUSSION:** The apical spines of the vesica as illustrated by Schuh et al. (1995) were drawn in error. The correct form is shown in figure 3.

**SPECIMENS EXAMINED:** Holotype: ♂, USA: WYOMING: Big Horn Co.: 27 mi W Burgess Jct on Rt 14, 7700 ft., Aug 12, 1986, Schuh Schwartz and Stonedahl; *Artemisia tridentata* Nutt (Asteraceae); deposited in the American Museum of Natural History. Additional specimens: USA: **Colorado:** *Saguache Co.*: 23 mi E of Gunnison on Rt 50, 8100 ft, July 17, 1986, R. T. Schuh, *Artemisia tridentata* (Asteraceae), 10♂, 4♀ (AMNH). **Idaho:** *Ada Co.*: near Kuna, June 21, 1982, T. J. Henry, *Artemisia* sp. (Asteraceae), 3♂, 8♀ (USNM). **Nevada:** *Elko Co.*: 30 mi W of Elko on Rt 80, June 18, 1982, T. J. Henry, *Artemisia* sp. (Asteraceae), 4♂, 5♀ (USNM). *Lander Co.*: 1.5 mi S of Rt 50 on Rt 376, June 28, 1983, R. T. Schuh and M. D. Schwartz, *Artemisia tridentata* (Asteraceae), 1♂, 1♀ (AMNH). 13, 1980, R. T. Schuh and G. M. Stonedahl, 1♂ (AMNH). *Washoe Co.*: 7 mi W of Vya toward Cedarville, 1800 m, July 2, 1979, R. T. Schuh and B. M. Massie, *Artemisia tridentata* (Asteraceae), paratypes: 4♂, 4♀ (AMNH). **Oregon:** *Crook Co.*: 23 mi E of Prineville, June 28, 1988, G. M. Stonedahl, 97♂ (AMNH, USNM). *Jackson Co.*: 1 mi below Mt. Ashland summit, 6500 ft, September 24, 1968, J. D. Lattin, paratypes: 6♂, 7♀ (OSU). Ashland, 6500 ft, September 24, 1968, P. Oman and J. D. Lattin, paratypes: 8♂, 8♀ (OSU). *Umatilla Co.*: 2 mi W of Tollgate, 4600 ft, August 4, 1986, Schuh, Schwartz, and Stonedahl, *Artemisia tridentata* (Asteraceae), paratypes: 22♂, 50♀ (AMNH, USNM). *Wheeler Co.*: 2 mi W of Mitchell on Rt 26, June 22, 1979, M. D. Schwartz, G. M. Stonedahl, R. T. Schuh, *Artemisia tridentata* (Asteraceae), paratypes: 15♂, 20♀ (AMNH). Mitchell, June 22, 1979, R. T. Schuh, *Artemisia tridentata* (Asteraceae), paratypes: 1♂ (AMNH). **Utah:** *Cache Co.*: 0.4 mi off Rt 189 along Franklin Basin Road, 6750 ft, July 17, 2001, T. J. Henry and A. G. Wheeler, Jr., *Artemisia tridentata* (Asteraceae), 3♂ (USNM). Rt 189 (Logan Canyon Road) at milepost 389, 5775 ft, July 17, 2001, T. J. Henry and A. G. Wheeler, Jr., *Artemisia tridentata* (Asteraceae), 3♂, 4♀ (USNM). *Rich Co.*: Logan Canyon, Cache National Forest, 6200 ft, August 9, 1972, L. A. Kelton, 1♂ (CNC). **Washington:** *Benton Co.*: Hanford Reservation A.E.C., Rattlesnake Ridge, June 28, 1978–July 12, 1967, W. W. Cone, *Artemisia tridentata* (Asteraceae), 1♂, 2♀ (WSU). *Douglas Co.*: 7 mi S of Rock Island, Columbia River Orchards, May 28, 1987, R. J. Rathman, *Chrysothamnus nauseosus* (Asteraceae), 1♂ (WSU). **Wyoming:** *Big Horn Co.*: 27 mi W of Burgess Jct on Rt 14, 7700 ft, August 12, 1986, Schuh, Schwartz, and Stonedahl, *Artemisia tridentata* (Asteraceae), paratypes: 3♂, 3♀ (AMNH).

*Europiella consors* (Uhler)

Figures 1, 3, 8, 9

*Maurodactylus consors* Uhler, 1895: 53 (n. sp., descr.); Schuh et al., 1995: 387 (n. syn., disc.). *Europiella fuscicornis* Knight, 1969: 82 (n. sp.; syn. by Schuh et al., 1995: 387). *Europiella basicornis* Knight, 1970: 230 (n. sp.; syn. by Schuh et al., 1995: 387). *Europiella monticola* Knight, 1970: 230 (n. sp., descr.). NEW SYNONYMY. *Europiella yampae*: Kelton, 1980: 341 (misidentification). *Megalopsallus monticola* Schuh et al., 1995: 389 (n. comb.).

**DIAGNOSIS:** Recognized by the relatively large size, elongate, nearly parallel-sided,

broad body form, general coloration of dorsum being either dark or light (figs. 1, 8), and the vesica with a long, flat, decurved, anterior apical spine and shorter posterior spine (fig. 3), a condition shared with *E. umbrina* and *E. stigmosa*. Most similar in size, general appearance, and coloration to *E. angulata*, and apparently not separable from it with certainty except by dissection of male genitalia. Sexual dimorphism pronounced, females being much smaller than males and conspicuously ovoid, in contrast to the nearly monomorphic situation found in *E. stigmosa* and *E. umbrina*.

**REDESCRIPTION:** *Male:* Relatively large, broad-bodied species, total length 3.22–3.68, width pronotum 1.00–1.15. **COLORATION** (figs. 1, 8): General coloration of dorsum either largely dark or mostly pale; antennal segments 1–4 black; labium mostly black in dark specimens, pale basally in pale specimens; much of venter dark in dark specimens, largely pale in pale specimens; coxae, trochanters, and femora mostly dark in dark specimens, largely pale in pale specimens, femora when pale with dark spots or blotches; tibiae with pale background coloration with black spines with black bases. **SURFACE AND VESTITURE** (fig. 9C): Surface and vestiture as in generic diagnosis. **STRUCTURE** (fig. 9): Elongate nearly parallel-sided, corial margin only weakly convex. **GENITALIA** (fig. 3): Pygophore moderately large relative to size of abdomen; vesica with anterior spine long and decurved, posterior spine shorter and nearly erect, similar to condition found in *E. stigmosa* and *E. umbrina*.

*Female:* Coloration usually light, seldom as dark as in males. Females much shorter than males, ovoid. Total length 2.79–3.26, width pronotum 0.98–1.09.

**HOST:** Known from various *Artemisia* spp., although recorded primarily from *A. filifolia* and *A. tridentata*. Also known to breed on *Chrysothamnus* spp. Records from *Cowania* and *Crotalaria* are almost certainly not breeding records.

**DISTRIBUTION:** Ranging from British Columbia to Saskatchewan in the North, south through the western plains to Texas, and west to California.

**DISCUSSION:** Examination of topotypic

Fig. 8. *Europiella consors* (Uhler). Male: USA: Utah: Sevier Co.: 11 mi W of Sevier on Rt 4, 2000 m.

Fig. 9. Scanning electron micrographs of *Europiella consors* (♂). **A.** Mesothoracic spiracle and metepisternal scent-efferent system, lateral view. **B.** Pretarsus, ventral view. **C.** Setae on hemelytra.

paratypes of *E. monticola* Knight suggests that this nominal species is the same as *E. consors*, and I am therefore treating the former as a junior synonym of the latter **new synonymy**. Both specimens examined were

general, and the male genitalia were therefore of no value; nonetheless, judging from the light coloration, which is much more common in *E. consors* than in *E. angulata*, the only other species with which *monticola* could be easily confused, the synonymy with *E. consors* would appear to be reasonably secure. This taxon was placed in *Megalopsalus* in error by Schuh et al. (1995).

**SPECIMENS EXAMINED:** Holotype: ♂, Colo., 1744; P. R. Uhler Collection (USNM). Holotypes of synonyms: *Europiella fuscicornis* Knight: ♂, Hudson, Colo., Aug. 25, 1925, H. H. Knight, *Artem. filifolia* (USNM). *Europiella basicornis* Knight: ♂, Coalville, UTAH, July 13, 1965, H. H. Knight (USNM). Additional specimens: **CANADA: Alberta:** Irvine, June 11, 1952, L. A. Konotopetz, 3♂ (CNC). **British Columbia:** Mt. Kobau, 11 km NW of Osoyoos Summit, 1834 m, August 30, 1993, M. D. Schwartz, *Artemisia tridentata* (Asteraceae), 38♂ (CNC). Wagner, 1949: 53 (n. form; syn. by Schuh et al., 1995: 384).

*Plagiognathus apiatus*: Kelton, 1965: 1142 (n. comb.).

*Europiella nigricornis* Knight, 1968: 40 (n. sp.; syn. by Schuh et al., 1995: 384).

*Plagiognathus (Poliopterus) laeae* Kerzhner, 1978: 46 (n. sp.; syn. by Schuh et al., 1995: 384).

*Europiella yampae*: Kelton, 1980: 341 (diag.) (misidentification).

**DIAGNOSIS:** Variable in size, coloration, and degree of sexual dimorphism (figs. 1, 2); often small, but some populations approaching or exceeding size of *E. artemisiae*; coloration of dorsum ranging from almost uniformly white to almost completely infuscate, specimens from much of western North America often pale, eastern North American specimens always infuscate; antennal seg-

ments 1 and 2, all femora, and entire venter moderately infuscate to black, even in specimens with pale dorsum; sexual dimorphism strong in many western North American populations, males elongate and parallel-sided, females ovoid, such dimorphism much less pronounced in eastern North American populations. Antennae and hind femora always heavily infuscate; apical vesical spines diagnostic. General appearance and structure of male genitalia (fig. 2) most similar to *E. artemisiae* and *E. lattini*, but differing from the former in having a relatively shorter antennal segment 2 in males and a shorter anterior apical vesical spine, and from the latter by having a much smaller pygophore and vesica.

**REDESCRIPTION:** *Male:* Size variable, often small, body form usually elongate, more rarely elongate ovoid, total length 2.14–3.50, width pronotum 0.69–0.96. **COLORATION** (figs. 1, 2): Extremely variable, dorsum ranging from almost entirely white to entirely infuscate, some specimens with dorsum generally dark except base of corium and base of cuneus pale; labium pale to nearly orange, except segment 4 black; all antennal segments black; venter of body generally infuscate to nearly black; all trochanters usually pale; fore and middle femora at most weakly infuscate, hind femora often nearly black; all tibiae of pale background coloration with black spines with black bases. **SURFACE AND VESTITURE** (fig. 10D): Surface and vestiture as in generic diagnosis. **STRUCTURE** (fig. 10): Most populations, especially in western North America elongate, narrow-bodied, nearly parallel-sided, corial margin only weakly convex; eastern North American populations often less conspicuously elongate; antennal segment 2 only slightly longer than the width of the head; pygophore relatively small in comparison to similar appearing *E. lattini*. **GENITALIA** (fig. 3): Pygophore moderately large relative to size of abdomen; posterior apical spine of vesica short, sharply curving, hook-shaped just surpassing gonopore, anterior spine conspicuously longer and weakly decurved, structure very similar to that of *E. artemisiae*, also similar to *E. lattini*, but anterior spine much longer and entire vesica smaller than in that species.

*Female:* Coloration as in male. Body form

much more strongly ovoid. Total length 2.45–2.72, width pronotum 0.81–0.95.

**HOSTS:** Breeds on a variety of herbaceous and woody *Artemisia* spp. Also recorded from other members of the Asteraceae, although probably not breeding. All records from non-Asteraceae are certainly sitting, rather than breeding, records.

**DISTRIBUTION:** Holarctic. In the Nearctic widely distributed in the West from Alaska to northern Mexico, except in wetter coastal regions. Ranging south to about 35 degrees north latitude in eastern North America.

**DISCUSSION:** This species appears to be truly Holarctic. Because of its great variability and the flawed diagnoses of some phyline genera, *E. decolor* was placed in several genera under different names (Schuh et al., 1995). Although the extremes of variation might tempt one to recognize more than one species, examination of several thousand specimens from North America—whose genitalia appear nearly invariable, and whose second antennal segment is always relatively short—has caused me to conclude that a single species is involved, no matter what the extent of variation in sexual dimorphism, size, and coloration. The alternative to recognizing a single species is to recognize many species, most with overlapping temporal, geographic, and host distributions. Studies at the molecular level might help to clarify the underlying nature of variation and thereby further test the single-species theory.

Uhler (1895) described *Agalliastes apiatus* from specimens collected at Fort Collins, Manitou, and Steamboat Springs, Colorado. He indicated that the taxon also occurred in Kansas. As noted by Schuh et al. (1995), the collections of the National Museum of Natural History, Washington, D.C., contain 10 specimens associated with the *A. apiatus* identification. One of these, the data for which are listed below under Specimens Examined, was labelled as a cotype by H. G. Barber. I have designated it as the lectotype. Schuh et al. (1995) treated *E. apiatus* as a junior synonym of *E. decolor*. They stated that the two taxa were “clearly congeneric”, which is true, but the statement should have read “clearly conspecific”.

Without elaboration Schuh et al. (1995) treated *Europiella nigricornis* Knight, 1968

as a junior synonym of *E. decolor*. This action was, in fact, based on comparison of the types of these nominal species and the examination of large numbers of dissected male genitalia of *E. decolor*.

SPECIMENS EXAMINED: Lectotype: ♀, Am. Fork, Ut., 22.6.91, P. R. Uhler Collection USNM). Types of synonyms: *Agalliaestes apiatus* Uhler: lectotype ♂, Colo., 1691, P. R. as *Europiella decolor* by H. H. Knight, 1♀ (CNC).

*Europiella lattini*, new species

Figures 2, 4

**DIAGNOSIS:** Recognized by its relatively small size, strongly infusate hind femora, dark areas on the hemelytra (fig. 2), and very large male genitalia (fig. 4), including pygophore and vesica, of the type found in *E. artemisiae* and *E. decolor*. Distinguished from *E. artemisiae* by its smaller size and shorter second antennal segment relative to the width of the head in males; easily distinguished from *E. artemisiae* and *E. decolor* by the smaller pygophore and vesica and the longer anterior vesical spine in those two species.

**DESCRIPTION:** *Male:* Relatively small species, total length 2.81–3.05, width pronotum 0.91–0.97. **COLORATION** (fig. 2): Head, pronotum, and scutellum generally mostly dark; hemelytra often dark with pale areas at base of corium, base of cuneus, and along costal margin; lateral angles of mesoscutum orange; all antennal segments black; labium generally pale, segment 4 strongly infusate; venter of body generally black; coxae black; trochanters pale; fore- and middle femora generally orange with a few dark spots, never strongly infusate, hind femora much more heavily infusate; tibiae pale with black spines with distinct black bases. **SURFACE AND VESTITURE:** Surface and vestiture as in generic diagnosis. **STRUCTURE:** Moderately elongate, nearly parallel-sided, corial margin only weakly convex. **GENITALIA** (fig. 4): Pygophore very large relative to total size of abdomen; vesica very large, posterior apical spine of vesica short, sharply curving, hook-shaped, just surpassing gonopore, anterior spine only slightly longer and weakly decurved; structure of vesica very similar to that of *E. artemisiae* and *E. decolor*, but anterior spine much shorter and entire vesica much larger than in those species.

*Female:* Coloration similar to that in male. Body form much more strongly ovoid than male. Total length 2.50–2.89, width pronotum 0.89–0.91.

**ETYMOLOGY:** Named in honor of John D. Lattin, who nurtured my interest in the Het-

eroptera and the North American Miridae while I was an undergraduate student at Oregon State University, and whose efforts in the field produced the first specimens of this species examined by me.

**HOSTS:** Recorded from *Achillea* sp. (Asteraceae), *Lupinus latifolius* (Fabaceae), and couch grass (Poaceae). These are certainly not all breeding records. Only further collecting will confirm the actual hosts for this species.

**DISTRIBUTION:** Primarily coastal mountains from Oregon to British Columbia.

**DISCUSSION:** The genital capsule is large relative to the size of the abdomen, and the aedeagus is also relatively large, which, upon careful examination, make this species easily distinguishable from the very similar appearing *E. decolor*.

**SPECIMENS EXAMINED:** Holotype: USA: **Oregon:** *Benton Co.:* Grass Mt., Summit Prairie, Lattin, VIII-14–1980, general sweeping; deposited in the American Museum of Natural History. Paratypes: CANADA: **British Columbia:** 10 mi S of Merritt, July 19, 1959, L. A. Kelton, 1♂, 4♀ (CNC). 24 km E of Cherryville, August 25, 1989, G.G.E. *Europiella morrisoni*, new species

Figures 2, 4

DIAGNOSIS: Recognized by the nearly entirely pale dorsum, the entirely black antennae, and the body in males being long, narrow, and parallel-sided (fig. 1). Sexual dimorphism pronounced, the females being ovoid, with the hemelytra more or less conforming to shape of the abdomen (fig. 1). Most similar in coloration and body form to *E. pilosula*, but differing in having a slightly more elongate body form and black antennae. Apical vesical spines in male short, subequal in length, most similar to those of *carvalhoi* and *pilosula*.

DESCRIPTION: *Male*: Long slender species, total length 3.30–3.61. COLORATION (fig. 2): Head, pronotum, scutellum (except basally sometimes orange), hemelytra, and labium pale. Venter of thorax and abdomen weakly infuscate. Legs generally pale, hind femur with a few black spots apically, all tibiae with strongly contrasting black spots at the bases of black spines. SURFACE AND VESTITURE: Surface and vestiture as in generic description. STRUCTURE: Hemelytra conspicuously elongate, parallel-sided, apex of abdomen reaching only to base of cuneus; cuneus elongate triangular. GENITALIA (fig. 4): Pygophore only moderately large relative to total size of abdomen; apical spines of vesica short, of approximately equal length, anterior spine weakly notched.

*Female*: Coloration as in male; body form ovoid, much shorter than in male. Total length 2.50–2.89, width pronotum 0.93.

ETYMOLOGY: Names for Harold Morrison,

who collected the only known specimens of this species.

HOSTS: *Artemisia* sp. (Asteraceae).

DISTRIBUTION: Imperial Valley of southern California.

DISCUSSION: This species is known only from the type locality and appears never to have been recollected.

SPECIMENS EXAMINED: Holotype: ♂, From Sagebrush beyond Jacumba, San Diego Co., Cal., swept 6:30 A.M., June 11, 1915, Harold Morrison; deposited in the National Museum of Natural History, Washington, D.C. Paratypes: USA: **California**: San Diego Co.: beyond Jacumba, swept 6:30 AM, June 11, 1915, Harold Morrison, *Artemisia* sp. (Asteraceae), 11♂, 3♀ (USNM, AMNH).

*Europiella flavicornis* Knight, 1969: 82 (n. sp.; syn. by Schuh et al., 1995: 388).

*Europiella pallida* Knight, 1969: 83 (n. sp.; syn. by Stonedahl, 1990: 85).

*Europiella albata* Knight, 1969: 85 (n. sp.; syn. by Schuh et al., 1995: 388).

DIAGNOSIS: Recognized by the generally pale coloration of the body and the entirely pale antennae (fig. 2), a combination of attributes otherwise found together only in *E. signicornis*. Separated from *E. signicornis* by the more elongate body form in the males of *E. pilosula* and structure of the vesica, the anterior spine being sickle-shaped in *E. pilosula* (fig. 4) and nearly straight in *E. signicornis* (fig. 5). Body form and coloration also similar to *E. morrisoni*, but that species not so elongate and anterior vesical spine not sickle-shaped.

REDESCRIPTION: *Male*: Moderately elongate, total length 2.63–3.50, width pronotum 0.88–1.07. COLORATION (fig. 2): Dorsum, including membrane, usually pale, white, sometimes weakly to moderately infuscate; all antennal segments pale; labium pale on basal three-fourths, segment 4 black; legs entirely pale, femora with some black spots, tibial spines brown with at most tiny brown

bases; entire venter usually pale, sometimes largely dark in specimens with infuscate dorsum. **SURFACE AND VESTITURE:** Surface and vestiture as in generic diagnosis. **STRUCTURE:** Elongate, hemelytra ranging from nearly parallel-sided to weakly convex. **GENITALIA** (fig. 4): Pygophore only moderately large relative to total size of abdomen; vesica with short apical spines, anterior spine sickle-shaped, posterior spine narrow and weakly decurved.

**Female:** Coloration as in male; body form much more strongly ovoid. Total length 2.42–3.04, width pronotum 0.82–1.02.

**HOSTS:** *Artemisia* spp., recorded chiefly from *A. filifolia* and *A. tridentata*. Records from non-Asteraceae are certainly sitting records.

**DISTRIBUTION:** Interior regions of western North America from British Columbia to southern California, east onto the plains from South Dakota south to Texas.

**DISCUSSION:** The often pale, but somewhat variable, coloration of this rather widespread species would seem to have contributed to the rather large number of junior synonyms.

**SPECIMENS EXAMINED:** Lectotype: ♂, Am. Fork, Ut., 22–6.91 (USNM). Holotypes of synonyms: *Europiella albata* Knight: ♀, Jackson Co., Oklahoma, 11/4, 1939, collected by E. Hixson (USNM). *Europiella flavicornis* Knight: ♂, Sterling, Colo., Aug. 26, 1925, H. H. Knight (USNM). *Europiella pallida* Knight: ♂, St. George, UTAH, June 30, 1965, Harry H. Knight (USNM). *Microphylidea pallens* Knight: ♂, MERCURY, NEVADA, 19M VI-23–1965, H. Knight & J. Merino (USNM). *Europiella pintoii*, new species

Figures 2, 4

DIAGNOSIS: Similar in size and general appearance to *E. artemisiae* and to darker specimens of *E. angulata* and *E. consors*; distinguished from *E. artemisiae* by the shorter second antennal segment in the males, and from all three species by the more shaggy appearance of the vestiture of the dorsum. Also possibly confused with large, dark-colored specimens of *E. decolor*, but *E. decolor* always small and pale in areas where the distributions of the two species overlapping. Male genitalia distinctive, with apical spines flattened and of moderate and nearly equal length (fig. 4). Sexual dimorphism weak in comparison to most other *Europiella* spp., males slightly more elongate than females and with corial margin not so strongly convex.

DESCRIPTION: *Male*: Moderate-sized, relatively broad-bodied species, total length 3.37–3.55, width pronotum 1.05–1.11. COLORATION (fig. 2): Dorsum appearing mottled, head, pronotum, and scutellum gener-

ally dark, dull, base of corium, much of clavus, and base of cuneus pale. Antennae generally dark, although not black. Venter moderately infusate. Femora pale to dirty colored with some darker spots, tibiae pale with distinct, although small, dark spots at bases of spines. SURFACE AND VESTITURE: Surface as in generic description; vestiture of dorsum noticeably shaggy, with numerous elongate, suberect common setae intermixed with weakly woolly, silvery setae. STRUCTURE: Elongate, corial margin weakly convex. GENITALIA (fig. 4): Pygophore moderately large relative to total size of abdomen; apical vesical spines moderately elongate, of nearly equal length, relatively broad.

*Female*: Coloration similar to male; body form stouter, somewhat more strongly ovoid. Total length 2.75–3.00, width pronotum 0.92–1.11.

ETYMOLOGY: Named for John D. Pinto, in recognition of his many contributions to our knowledge of the Miridae of the American Southwest through extensive fieldwork and host documentation.

HOST: *Artemisia californica*, “California sage brush” (Asteraceae).

DISTRIBUTION: Known only from a limited area of southern California.

DISCUSSION: This species has been taken at only four localities in southern California, and along with *E. morrisoni*, is the least well known of all Nearctic *Europiella* spp. This, after extensive springtime collecting on appropriate hosts, by John Pinto, myself, and others.

SPECIMENS EXAMINED: Holotype: ♂, CAL. Riverside Co., Menifee Vly (hills on W end), 33°33'N 117°13'W, 1800' el., IV-10-1979, John D. Pinto, *Artemisia californica* (Asteraceae); deposited in the American Museum of Natural History. Paratypes: USA: **California**: *Riverside Co.*: 2 mi N of Perris, E. I. Schlinger, 1 ♀ (UCD). Quail Valley, Coastal Sage Scrub Community, March 10, 1974, J. D. Pinto, 1 ♀ (UCR). *San Bernardino Co.*: 4 mi E of Mentone, 750 m, May 11, 1978, J. D. Pinto, 5 ♀ (UCR, AMNH). *San Diego Co.*: Mission Dam, March 16, 1929, C. C. Searl (Asteraceae), 2 ♂, 4 ♀ (SDNM, AMNH).

*Europiella signicornis* Knight  
Figures 2, 5

*Europiella signicornis* Knight, 1969: 84 (n. sp., descr., host).

DIAGNOSIS: Recognized by the generally pale body coloration and entirely pale antennae (fig. 2), a combination of attributes otherwise found together only in *E. pilosula*. Sexual dimorphism weak. Separated from *E. pilosula* by the more ovoid body form in the males in the present species and structure of the vesica, with two, short, acuminate spines of unequal length (fig. 5).

REDESCRIPTION: *Male*: Relatively small ovoid species, total length 2.73–2.91, width pronotum. 0.91–0.98. COLORATION (fig. 2): Dorsum, including membrane, white; all antennal segments pale; labium pale on basal three-fourths, segment 4 black; all legs pale, femora with some black spots, tibial spines black with tiny black bases; entire venter pale. SURFACE AND VESTITURE: Surface and vestiture as in generic description. STRUCTURE: Body form elongate ovoid. GENITALIA (fig. 5): Pygophore only moderately large relative to total size of abdomen; vesica with short, acuminate, apical spines, the anterior spine longer than the posterior, the posterior spine barely surpassing distal margin of gonopore.

*Female*: Body form and coloration similar to male. Total length 2.56, width pronotum 0.95.

HOST: Breeds on *Artemisia* sp. (Asteraceae).

DISTRIBUTION: Known only from the south rim of the Grand Canyon.

DISCUSSION: Based on available collections, *E. signicornis* has one of the most restricted distributions of any known *Europiella* sp. There seems to be little question about its status as distinctive, however, as the male genitalia are unlike those found in any other North American *Europiella* sp.

SPECIMENS EXAMINED: Holotype: ♀, *Europiella signicornis* Knight: ♀, Grand Canyon, Alt. 7000, Ariz., July 22, 1925, A. A. Nichol (USNM). Additional specimens: USA: **Arizona**: *Coconino Co.*: Grand Canyon, 7000 ft, June 22, 1925, A. A. Nichol, 4 ♂, 1 ♀ (USNM). Grand Canyon, south Rim, June 27, 1930, R. L. Usinger, *Artemisia* sp. (Asteraceae), 1 ♂ (UCB). Rt 64 just SE of Grand Canyon Natl. Park in Kaibab National Forest, June 26, 1980, K. and R. Schmidt, *Artemisia* sp. (Asteraceae), 19 ♂ (AMNH).

*Europiella stigmosa* Uhler  
Figures 2, 5, 11

*Agalliaestes stigmus* Uhler, 1893: 379 (n. sp., descr.).

Fig. 11. Scanning electron micrographs of *Europiella stigmosa* (♂) **A.** Head and thorax, lateral view. **B.** Lateral view of thorax and abdomen. **C.** Mesothoracic spiracle and metepisternal scent-efferent system, lateral view. **D.** Setae on hemelytra, detail of microstructure. **E.** Pretarsus, frontal view.

**DIAGNOSIS:** Recognized by the relatively small size, elongate oval body shape, mottled coloration of the dorsum (fig. 2), generally pale femora with a relatively large number of dark spots, and the vesica with a long,

flattened, decurved, anterior apical spine and shorter, flattened posterior spine (fig. 5), a condition shared with *E. umbrina* and *E. consors*. Distinguished from *E. umbrina* by its lighter coloration and from *E. consors* by

its much smaller size and more ovate body form in the males; distinguished from both species by the pale antennae in *E. stigmosa*. Sexual dimorphism in *E. stigmosa* (and *E. umbrina*) is weak, the body form in the females being nearly the same as that in the males.

**REDESCRIPTION:** *Male:* Small, relatively broad-bodied species, total length 2.78–3.06, width pronotum 0.96–1.12. **COLORATION** (fig. 2): General coloration somewhat mottled, dorsum generally pale with brown-to-black blotches; antennal segment 1 black, sometimes black only basally, segment 2 at most darkened at extreme base, segments 3 and 4 varying from pale to very dark; labium pale basally, segments 3 and 4 black; much of venter dark; coxae partially pale; trochanters pale; femora pale or weakly darkened and ornamented with numerous dark spots or blotches; tibiae with pale background coloration with black spines with black bases. **SURFACE AND VESTITURE** (fig. 11D): Surface and vestiture as in generic diagnosis. **STRUCTURE** (fig. 11): Elongate ovoid, corial margin moderately convex. **GENITALIA** (fig. 5): Pygophore moderately large relative to total size of abdomen; vesica similar in structure of apical spines to *E. umbrina* and *E. consors*, anterior spine long and decurved, posterior spine shorter and nearly erect.

*Female:* Coloration often paler than in males, with dorsum sometimes almost entire pale. Body form very similar to male. Total length 2.65–2.91, width pronotum 1.02–1.09.

**HOSTS:** Known to breed on *Artemisia californica*, *A. ludoviciana*, and *A. tridentata* (Asteraceae). The record from *Lupinus* is certainly a sitting record.

**DISTRIBUTION:** Widely distributed in western North America, except for wetter coastal areas, ranging from British Columbia south to northern Baja California and east to Nebraska and Oklahoma.

**DISCUSSION:** Schuh et al. (1995) documented the identity of *E. stigmosa*.

**SPECIMENS EXAMINED:** MEXICO: **Baja California Norte:** 3.5 km W of Parque Sierra San Pedro Martir, 1875 m, April 25, 1985, R. T. Schuh and B. M. ### *Europiella umbrina* Reuter

Figures 2, 5

*Europiella umbrina* Reuter, 1909: 85 (n. sp., descr.); Schuh et al. 1995: 389 (n. syn., disc.).  
*Europiella similis* Knight, 1969: 81 (n. sp.; syn. by Schuh et al., 1995: 389).

**DIAGNOSIS:** Recognized by the moderate size, elongate oval body shape, and heavily black coloration of the dorsum except usually for base of cuneus (fig. 2); vesica with a long, decurved, anterior apical spine and shorter posterior spine, a condition shared with *E. stigmosa* and *E. consors*. Distinguished from *E. stigmosa* by its much more extensive black coloration, including the antennae, and from *E. consors* by its much smaller size and more ovate body form in the males. Sexual dimorphism in *E. umbrina* (and *E. stigmosa*) is weak, the body form in the females being nearly the same as that in the males.

**REDESCRIPTION:** *Male:* Moderate-sized, broad-bodied species, total length 2.89–2.96, width pronotum 0.96–1.04. **COLORATION** (fig. 2): General coloration of dorsum black with some white markings, most often at base of cuneus and sometimes at base of corium; antennal segment 1 black, segment 2 entirely black or black on basal one-third with remainder pale, coloration of segments 3 and 4 variable, usually pale; labium mostly black; most of venter black; trochanters pale; femora often heavily darkened but with some pale areas ornamented with dark spots or blotches; tibiae with pale background color-

ation with black spines with black bases. **SURFACE AND VESTITURE:** Surface and vestiture as in generic diagnosis. **STRUCTURE:** Elongate ovoid, corial margin moderately convex. **GENITALIA** (fig. 5): Pygophore moderately large relative to total size of abdomen; vesica similar in structure of apical spines to *E. stigmosa* and *E. consors*, anterior spine long and decurved, posterior spine shorter and weakly decurved.

*Female:* Coloration and structure very similar to that in males. Total length 2.73–2.89, width pronotum 1.02–1.06.

**HOSTS:** Recorded from *Artemisia* spp., including *A. californica*, *A. filifolia*, *A. nova*, and *A. tridentata* (Asteraceae).

**DISTRIBUTION:** Widely distributed in western North America, primarily in the interior.

**DISCUSSION:** Knight (1968: 43) listed *E. umbrina* as a synonym of *E. stigmosa*, a taxonomic decision reflected in the catalog of Henry and Wheeler (1988). Schuh et al. (1995) treated *E. umbrina* as a valid species on the basis of its distinctive male genitalic structure.

**SPECIMENS EXAMINED:** Holotype: ♂, Claremont, Cal., Baker; deposited in the Helsinki Museum. Holotype of *Europiella similis* Knight: ♂, MERCURY, NEVADA, 19 M, VI-23–1965, H. Knight & J. ### *Europiella unipuncta* Knight

Figures 2, 5

*Europiella unipuncta* Knight, 1968: 44 (n. sp., descr., host).

**DIAGNOSIS:** Recognized by the nearly white coloration of the dorsum, the oval body shape, antennal segment 1 black, segment 2 black on at least proximal one-half (fig. 2), the very large pygophore and vesica, and the detailed structure of the vesical spines, the anterior spine short and sickle-shaped, the posterior spine relatively short and weakly curving (fig. 5), a condition shared with *E. angulata*, *E. carvalhoi*, and *E. pilosula*. *Europiella unipuncta* is most similar in general form and coloration to *E. pilosula*, *E. signicornis*, and *E. carvalhoi*, but can be distinguished from the first two by the entirely pale antennae in those species and from the last by the larger pygophore and genitalia in the present species.

**REDESCRIPTION:** *Male:* Moderate-sized, elongate-ovoid species, total length 2.63–3.08, width pronotum 0.85–1.00. **COLORATION** (fig. 2): Dorsum, including membrane pale, white, sometimes partially tinged with green; antennal segment 1 black, segment 2 black at least on proximal half, sometimes entirely black, segments 3 and 4 usually weakly infusate; labium pale on basal three-fourths, segment 4 black; legs pale, femora with some black spots, tibial spines black with black bases; entire venter pale. **SURFACE AND VESTITURE:** Surface and

vestiture as in generic diagnosis. STRUCTURE: Elongate ovoid, corial margin moderately convex. Pygophore very large, occupying well more than half of abdomen. GENITALIA (fig. 5): Pygophore very large relative to total size of abdomen; vesica large, robust, with short apical spines, anterior spine sickle-shaped, posterior spine narrow and weakly decurved.

*Female*: Coloration as in male. Body form more broadly ovoid. Total length 2.49–2.78, width pronotum 0.83–0.99.

HOSTS: Recorded from *Artemisia* spp., including *A. frigida*, *A. ludoviciana*, and most commonly from *A. tridentata* (Asteraceae).

DISTRIBUTION: Distributed in more northerly portions of western North America, ranging from British Columbia to Alberta in the north, south to Colorado, Utah, and Nevada.

SPECIMENS EXAMINED: Holotype: ♂, MERCURY, NEVADA, 12M(W) Aug. 13, 1965, Joe Merino, on *Artemisia tridentata* (USNM). Additional specimens: CANADA: **Alberta**: Elkwater Park, August 13, 1952, L. A. ### *Knightopiella*, new genus

Type species: *Europiella albibubescens* Knight.

DIAGNOSIS: Recognized by the relatively large size, length 3.38–3.64; body very elongate-oval and relatively broad. Coloration weakly greenish, including appendages, with a few diffuse dark markings on femora and

weakly dark bases of tibial spines. Vestiture of dorsum with pale reclining simple setae and recumbent, woolly, silvery, shining setae (figs. 2, 13A–D); head weakly produced and not overlapping anterior margin of pronotum. Sexually dimorphic, females much more strongly ovoid than males and with hemelytra more strongly conforming to shape of body. Most easily confused with pale-colored species on *Europiella* and *Megalopsallus* on the basis of coloration, form of vestiture, and structure of head. Head and vertex both greater in width than in any *Europiella* species. Separated from *Europiella* spp. by its larger size and the form of the male genitalia, *Europiella* spp. always with two apical spines (figs. 2–5), *Knightopiella* with a spinose, cauliflowerlike, membranous apex (fig. 12); separated from *Megalopsallus* spp. also by its larger size and by the much smaller pygophore and more delicate vesica in that group terminating in a single attenuation (see Schuh, 2000).

DESCRIPTION: *Male*: Relatively large, very elongate-oval, relatively broad total length 3.38–3.64, width pronotum 1.05–1.17; dorsal surface of body weakly convex. COLORATION (fig. 2): Coloration pale greenish, including all appendages and ventral body surface; femora with some diffuse, weakly contrasting dark spots; tibial spines dark with weakly dark bases. Mesoscutum often dark mesially; phallosome heavily sclerotized and intensely dark. SURFACE AND VESTITURE (fig. 13A–D): Dorsum smooth, dull, clothed with pale, reclining, simple setae and recumbent, woolly, silvery, shining setae. STRUCTURE (fig. 13): Head transverse, frons bulging, clypeus barely visible from above; eyes bulging, nearly spherical as viewed from above, occupying slightly more than half of height of head in lateral view (fig. 13A), showing only weak sexual dimorphism; antennal segment 2 slender, tapering to slightly greater diameter distally, sexual dimorphism very weak; labium reaching to apex of middle coxae; claws nearly straight over most of length, strongly curving near apex, parempodia setiform, pulvilli relatively large, occupying most of length of claw, basal two-thirds of pulvillus adnate to claw (fig. 13 E, F); abdomen flattened, broad, lateral margins of pregenital segments

Fig. 12. Male genitalia of *Knightopiella albipubescens* and *Plagiognathus lividellus*.

strongly convexly rounded. GENITALIA (fig. 12): Pygophore and genitalia moderately large; vesica formed of two chitinous bands with weakly sclerotized apical ornamentation; secondary gonopore located near apex of vesica, relatively small and only moderately sclerotized; phallosome heavily sclerotized, strongly “hump-backed” on dorsal margin (fig. 13H); left paramere boat-shaped, typical of Phylini; right paramere decurved apically, unlike all species placed in *Europiella* under the diagnosis adopted in the present paper.

*Female*: Elongate ovoid, of more robust appearance than male; total body length 3.31–3.51. Coloration and vestiture as in male.

ETYMOLOGY: A combination of Knight and *Europiella*, in recognition of H. H. Knight,

the author of the type species, and its genus of original placement.

DISCUSSION: Knight (1968: 46) indicated that his new species *Europiella albipubescens* could be “Distinguished from allied species by having only white pubescent hairs and silvery, sericeous pubescence.” Not only is the exact meaning of this statement unclear to me, but it is made in the absence of a clear characterization of the diagnostic characters for *Europiella*. Comparison of the vestiture of *Knightopiella albipubescens* (figs. 2, 13C) with that of *E. stigmosa* and other *Europiella* spp. (figs. 1, 2, 7, 9–11) indicates that the type of vestiture is rather similar in *Europiella* and *Knightopiella* and does not form a strong basis for unequivocally recognizing *K. albipubescens*. The male genitalia, on the other hand, are absolutely distinctive for the

Fig. 13. Scanning electron micrographs of *Knightopiella albipubescens* ( $\delta$ ). **A.** Head, lateral view. **B.** Head, dorsal view. **C.** Setae on hemelytra, detail view. **D.** Mesothoracic spiracle and metepisternal scent-efferent system, lateral view. **E.** Pretarsus, frontal view. **F.** Pretarsus, lateral view. **G.** Hind femura, distal half, dorsal view. **H.** Phallosome, in situ, dorsal view.

taxa and do not ally *K. albipubescens* closely with either *Europiella* or *Megalopsallus*, for both of which Knight included many species under his concept of *Europiella*.

*Knightsiella albipubescens* (Knight),  
new combination  
Figures 2, 12, 13

*Europiella albipubescens* Knight, 1968: 46 (n. sp., host).

*Megalopsallus albipubescens*: Schuh et al., 1995: 389 (n. comb.).

DIAGNOSIS: As for genus.

REDESCRIPTION: As for genus.

Female: As for genus.

HOSTS: *Tetradymia glabrata*, *T. spinosa*, *Chrysothamnus nauseosus* (Asteraceae).

DISTRIBUTION: Widely distributed in the Great Basin. Also known from the Mojave Desert near Rosamond, California.

DISCUSSION: See generic discussion.

SPECIMENS EXAMINED: USA: **California:** *Kern Co.*: 4 mi N of Rosamond, April 23, 1971, Oman, 10♂, 5♀ (OSU). *Mono Co.*: 8 mi W of Nevada state line on Rt 359, 6700 ft, July 2, 1983, R. T. Schuh and M. D. Schwartz, *Tetradymia* sp. (Asteraceae), 15♂, 4♀ (AMNH). **Nevada:** *Elko Co.*: Utah state line on Utah Rt 30, 4760 ft, July 25, 1983, R. T. Schuh and M. D. Schwartz, *Tetradymia* sp. (Asteraceae), 12♂, 20♀ (AMNH). *Nye Co.*: Atomic Test Site, 6.8 mi SE of Mercury Hiway on Orange Blossom Rd (A11), 4000 ft, June 8, 1983, Schuh, Schwartz, Stonedahl, *Tetradymia* sp. (Asteraceae), 10♂, 21♀ (AMNH). Atomic Test Site, Mercury Hwy at Angle Rd. (A3), 3800 ft, June 8, 1983, Schuh, Schwartz, Stonedahl, *Tetradymia* sp. (Asteraceae), 16♂, 23♀ (AMNH). Atomic Test Site, Tweezer Rd at Orange Blossom Rd. (A6), 4750 ft, June 8, 1983, Schuh, Schwartz, Stonedahl, *Tetradymia* sp. (Asteraceae), 6♂, 18♀ (AMNH). Mercury, 16 M, June 11, 1965, H. Knight and J. Merino, *Tetradymia spinosa* (Asteraceae), 16♂, 12♀ (USNM). Mercury, 17 M, June 12, 1965, H. Knight and J. Merino, *Chrysothamnus viscidiflorus* (Asteraceae), 16♂, 15♀ (USNM). Mercury, 401 M, June 11, 1965, H. Knight and J. Merino, *Chrysothamnus nauseosus* (Asteraceae), 19♂, 16♀ (USNM, CNC).

*Plagiognathus lividellus* Kerzhner,  
revised combination  
Figure 12

*Plagiognathus lividellus* Kerzhner, 1979: 51 (n. sp.); Kerzhner, 1988: 854, 855 (key, figs., host).

*Europiella lividella* Schuh, Lindskog, and Kerzhner, 1995: 391 (n. comb.).

DISCUSSION: Schuh et al. (1995) transferred *Plagiognathus lividellus* Kerzhner to *Europiella* on the assumption that it possessed the diagnostic characteristics of that genus. I now judge this action to be in error, because the right paramere does not possess the diagnostic features found in all other species of *Europiella* (compare figs. 2–5 and 12). Although some features of the vesica such as the sawtooth edge of the vesica strap (fig. 12) are not typical of what is found in any species placed in *Plagiognathus* by Schuh (2001), this appears to be the most satisfactory generic placement for the moment.

#### ACKNOWLEDGMENTS

Extensive field assistance was provided by Michael Schwartz and Gary Stonedahl on several collecting expeditions in western North America. John Pinto and his family provided valuable field support and hospitality in southern California. John, Irma, and Dan Polhemus provided hospitality and field support in Colorado. Erica Chiao and Hadee Morgan assisted in recording locality data. Steve Thurston prepared the digital habitus illustrations using a Microptics-USA photomicrographic system equipped with an Infinity Photo-Optical K-2 lense system; he also rendered the habitus illustrations of *E. angulata* and *E. consors* and did the digitization and assembly for the male genitalic illustrations. Michael Schwartz checked the identifications and recorded data for many specimens in the Canadian National Collection of Insects, did many genitalic dissections, and prepared the scanning micrographs of *Knightsiella albipubescens*. Christiane Weirauch assisted with genitalic illustrations. T. J. Henry, J. C. Schaffner, M. D. Schwartz, and C. Weirauch commented on the manuscript. Measurements were taken and tables prepared by Christine Johnson. To all of these individuals, and also to my wife, Brenda Massie, for her assistance and companionship in the field over several seasons, I offer my sincere thanks for their contributions to this project.

Fieldwork for this study was supported by NSF grants DEB-8113481 and BSR-

8516635. This project was partially supported by, and represents a contribution to, the NSF Planetary Biodiversity Inventory grant DEB-0316495 to Randall Schuh and Gerasimos Cassis.

The herbarium staff at the New York Botanical Garden identified the hosts for material collected by my co-workers and me. These authoritative determinations add greatly to confidence in our knowledge concerning host relationships within *Europiella*. Particular thanks go to Jackie Kallunki and Eileen Schofield for their prompt and professional service.

Many individuals and institutions provided material for this study, during the course of which I examined approximately 10,000 specimens. Without their assistance, the diversity of the group would be much less well understood. Institutions, names of curators or other responsible individuals, and institutional abbreviations are presented in the following list:

AMNH	American Museum of Natural History, New York	TAMU	Texas A&M University, College Station, Joseph C. Schaffner and Edward C. Riley
BYU	Monte L. Bean Life Sciences Museum, Brigham Young University, Provo, Utah, Charles Riley Nelson	UAZ	University of Arizona, Tucson, the late Floyd Werner
CAFA	California Department of Food and Agriculture, Sacramento, Alan Hardy	UBC	Spencer Entomological Museum, University of British Columbia, Vancouver, Geoffrey G. E. Scudder
CAS	California Academy of Sciences, San Francisco, Paul Arnaud, Jr., Norman Penny, Keve Ribardo	UCB	University of California, Berkeley, John Chemsak
CNC	Canadian National Collection of Insects, Agriculture Canada, Ottawa, Leonard Kelton and Michael Schwartz	UCD	University of California, Davis, the late Robert Schuster
DAR	David A. Rider Collection	UCR	University of California, Riverside, John D. Pinto and Saul Frommer
