#### Abstract

The process to create a corpus suitable for evaluating computer keyboard layouts optimised for typing English and computer program code. After sourcing, sampling and cleaning suitable texts, the texts are processed to extract bigrams, which are then used to create sample input texts of a desired length. These texts have a character distribution, and letter sequence, closely matching either English or computer programs, even though they look random. The resulting texts are excellent for evaluating keyboard layouts. Corpus analysis is included.

Keywords: English text corpus, computer code corpus, English letter frequency, computer program character frequency, bigram frequency, letter follows letter probability, letter precedes letter probability, keyboard layout, keyboard layout evaluation.

## 1. Introduction

When designing or evaluating a computer keyboard layout for a given language, it is necessary to know the character frequency for that language. It is also useful to know the bigram and trigram frequencies. These frequencies are calculated by analysing a suitable corpus of text.

However, the available corpora or indeed analysis, was driven by other needs, typically cryptographic or lexical analysis, which are totally different to the keyboard layout problem. These corpora typically include spoken speech transcripts, which is irrelevant to typing.

Keyboard layouts are usually analysed in one of two ways:

1. By feeding sample texts to an analysis program, or
2. By a program using known bigram pairs

There are problems with both approaches. In the first case, it is extremely difficult to find small sample texts that have the characters in the correct frequency, or indeed include all the characters. This leads to incorrect results.

The bigram approach, favoured by academia, often falls short differently. Available bigram lists typically only include letters, ignoring case, and are extracted from corpora created for different needs. The bigram analysis is also frequently "disjointed," in that bigrams are considered in isolation rather than as parts of words with spaces and punctuation. This approach also leads to incorrect results.

Today, there are millions of programmers typing programs in a variety of different programming languages, sometimes using multiple languages in one program. This is similar to trying to use one keyboard layout to type two different languages, with differing character frequencies and different common bigrams. Creating a layout that is optimal for both use cases is difficult.

We solve these problems by first creating two corpora, one for English and one for computer code. We then analyse the result, extracting the character frequencies and likelihood that $x$ follows $y$, and that $y$ precedes $x$. We then use this data to create bigram chains (technically Markov chains), before putting Shakespeare's Monkeys to work to create bigram-based input texts that solve the problems raised above. These texts appear to be random junk but they are not, and are excellent for analysing keyboard layouts. They are "words" made of the bigrams, correctly frequenced, and as such address the problems for both approaches to keyboard layout analysis.

This exercise was done around September 2020, all files sourced from the Internet are as of that date.

## 2. Existing corpora and results

Two frequently used resources are the analysis by Peter Norvig [1], published around 2012, and the study by Jones and Mewhort [2], published in 2004.

Norvig used bigram data from Google, but the analysis was limited to the letters, and ignored case.

Jones and Mewhort assembled a mixed corpus. It included full-text articles from the New York Times, a subset of the Brown word corpus, an online encyclopaedia (probably Wikipedia), text extracted from about 100,000 randomly selected Web pages, and newsgroup text extracted from 400 different Internet discussion groups.

I examined the actual content in the Brown corpus (description [3]), and decided that it was unsuitable as source material for keyboard layout evaluation. I also took a look at an available newsgroup corpus [4]. It has been "cleaned," but the nature of Usenet means that there is a lot of computer-generated text, like message headers. Also, text gets forwarded or quoted without being retyped, which impacts the character frequency. Even the newsgroup naming scheme leads to excess "." or other letters,

Much of the text is just a mess, here's a sample:

```

This excluded Usenet postings as a suitable text source, and raised questions about the suitability of Jones and Mewhort's results for keyboard layout analysis. Their sources were also largely American, and I needed more British English.

So I decided to create a new corpus, more suited to the task at hand. I would need two collections, one with written English, and one with computer program code.

## 3. Creating the English corpus

I thought it prudent to follow a similar approach to Jones and Mewhort. The goal was to get as wide a selection as possible, of texts created on keyboards. This meant excluding texts mostly created on small-screen devices, where the input mechanics are completely different.

I did not have access to the New York Times texts, but there is a publicly-available Reuters archive [5] of short financial reports.

This required some cleaning. By "cleaning," I mean "replace any characters not on the standard US-ANSI keyboard, with characters that are." For example, typographic quotes get replaced with ASCII quotes. If there is no simple replacement (for example, Chinese characters), delete the character. Some characters were replaced with their non-diacritic version, for example "e" became "e", or its HTML version,"\é", depending on context. The goal is to replace non-typeable characters with typeable, wherever possible. This process was necessary for all files is the corpus, and was done using a program that did regular-expression replacements.

After cleaning, the Reuters archive provided 795 files of 689 bytes to 13.9 kB in size.
For encyclopaedia articles, the obvious solution is Wikipedia. Since Wikipedia can be edited by anyone, I thought it prudent to only select larger articles, on the assumption that these will be mature and well-edited. This assumption is not necessarily true. In the end, I had two collections, consisting of extracts from larger articles, and another collection extracted from smaller texts. These extracts required considerable cleaning. The result was 3757 files of $10-15 \mathrm{kB}$ each.

I did also try getting extracts from Wikibooks, but these texts proved unsuitable.
Instead, I used the tools provided by Martin Gerlach and Francesc Font-Clos [6] to get books from Project Gutenberg, and following a similar approach to Wikipedia, and took extracts. For each book, if the word count was over 10,000, I would skip the first 200 lines (Gutenberg front matter and contents), and then take a 2000 word extract, which was then cleaned. This produced 7433 files of 9 to 39 kB each.

I took a similar approach to sampling the OMBC Web Base corpus [7], which resulted in 223 files ranging from 100 to 150 kB in size.

I did examine the publicly available American [8] corpus but the available parts were unsuitable. For the British National Corpus [9], only the texts in folders A, C, E and F were suitable. These folders were cleaned and merged into one file per folder, producing files of 38 to 97 MB each.

Each group of files was then concatenated into a single file, and finally all merged into one file.

## 4. Creating the computer code corpus

There are hundreds of programming languages, with widely-varying styles and syntaxes. Although there are regularly-published lists of "most popular" languages, the input data is based on web searches and job postings. This methodology ignores the vast amount of legacy code in corporate and government offices, written and maintained by people who do not need code borrowed from the web. So "popular" by these metrics does not mean "most used."

Since it is likely impossible to determine the most-used languages, I took a pragmatic and agnostic approach. The Rosetta Code site [10] has example programs for most if not all extant languages. More popular or mature languages have more examples. So we can use this as a proxy for "most used". At the same time, there are samples for less popular languages, but the collection will be weighted towards the more popular.

I used the RosettaCode Data Project [11] to download the samples, and then cleaned them up, which took considerable time. Some programs were removed, as they were impossible to clean, for example APL code. The thousands of program snippets were then concatenated into one 40.8 MB file.

## 5. Corpora analysis

The resulting files were analysed for letter frequency, and bigrams.
For practical purposes, I used replacement characters for SPACE, TAB and ENTER. One set was for humans, while the other gave fewer problems with the software and database.

| Character | ASCII decimal | Unicode | For Humans | For computers |
| :--- | :--- | :--- | :---: | :---: |
| Space | 32 | $\mathrm{U}+0020$ | $\checkmark$ | $\S$ |
| Tab | 09 | $\mathrm{U}+0009$ | $\rightarrow$ | $\neg$ |
| Enter | 13 | $\mathrm{U}+000 \mathrm{D}$ | $\hookleftarrow$ | $\mathbb{I}$ |

Table 1: Replacement characters used

Depending on context, both sets may appear below.
The components of the final corpus are in Table 2.

| File | Size | Chars | Most frequent 15 chars |
| :---: | :---: | :---: | :---: |
| FinalCorpus.txt | 483,410,236 | 97 / 97 | etaoinsrhldcum |

## 6. Creating chained bigrams (Markov chains) and texts

Using the bigram counts for English or code, we can create bigram chains that Shakespeare's Monkeys can use to create texts of arbitrary length.

The procedure is as follows.

1. Decide on the required number of characters, for example 10,000. Add some excess capacity, say $10 \%$.
2. Read in the bigram counts.
3. Add up the total number of bigrams,
4. Divide the number required, by the total. This gives us a scaling factor.
5. For each bigram, populate a table with (scaling factor $\times$ count) many bigrams. This creates a potentially large table.
6 . When all bigrams are stored, shuffle the table.
6. Build an output text, starting with the first bigram.
7. Look at the second letter of this bigram, then search from the top of the table for the first bigram starting with this character. Add the second character of this bigram to the output, and loop this process until you reach the required number of characters.
8. If you fail to find a match, start again with the current first bigram.

10 . Write out the output text.
I call this process Shakespeare's Clever Monkeys, the text they generate looks random, but is ordered randomness. Essentially, we have taken what is in a large corpus, sliced and diced it, and re-assembled it with the correct character frequency. Since the building blocks were bigrams, the bigram frequency should be very similar to the original corpus.

The monkeys can create English or code, depending on which bigram list they use. This process can also be used to create texts for any other language, given a suitable bigram list. Proof of concept code is included in the archive.

## 7. Samples and analysis

Here is an extract from a sample of random text. Shakespeare's Not-so-clever Monkeys, if you like.

The real question is, what is the character frequency like? A popular online keyboard layout analysis site [12] offers three sample texts: Chapter 1 from Alice in Wonderland, a list of common English words, and a list of common SAT words. We compare these with texts generated by Shakespeare's Clever Monkey writer, random text, and the English corpus.

| File | Size | Chars | Most frequent 15 chars |
| :---: | :---: | :---: | :---: |
| FinalCorpus.txt | 483,410,236 | 97 / 97 | etaoinsrhldcum |
| monkey7.txt | 1,001,337 | 93 / 97 | eetaoinsrhldcum |
| monkey6.txt | 100,920 | 86 / 97 | etaoinsrhldcum |
| monkey5.txt | 60,653 | $83 / 97$ | eetaoinsrhldcum |
| monkey3.txt | 40,502 | 82 / 97 | eetaoinsrhldcum |
| monkey4.txt | 50,291 | 82 / 97 | etaoinsrhldcum |
| monkey2.txt | 30,327 | 80 / 97 | etaoinsrhldcum |
| monkey1.txt | 20,089 | 79 / 97 | etaoinsrhldcum |
| monkey0.txt | 4,908 | 69 / 97 | -etaoinsrhldcum |
| alice-ch1.txt | 11,245 | 63 / 97 | etoahnisrlduwg |
| common-english-words.txt | 6,265 | 32 / 97 | etraonisldchum |
| common-sat-words.txt | 9,027 | 28 / 97 | eeiatnorcsuldpm |
| random10k.txt | 10,000 | 97 / 97 | kK]Rner:*Wipv-? |
| random30k.txt | 30,000 | 97 / 97 | $\mathrm{y}=\mathrm{z}$ ?-(eOu'V8NaL |

| coder0.txt | 10,067 | 96 / 97 | et $\lrcorner$ niraosl)(dc |
| random10k.txt | 10,000 | 97 / 97 | kK]Rner:*Wipv-? |
| random30k.txt | 30,000 | 97 / 97 | $\mathrm{y}=\mathrm{z}$ ?-(eOu'V8NaL |
| random20k.txt | 20,000 | 97 / 97 | \#\}wWcVLvQXN\$"! |

Table 9: Analysis of the generated code against Code.

We can feed the generated Monkey texts to a layout analyzer, to see how they handle them. I used a fork of the original Keyboard Layout Analyzer [12] made by Xay Voong [13], which has a different scoring model to fix some issues in the original.

The layouts chosen for demonstration are either well-known, or good. First we set a baseline for comparison using Alice in Wonderland Chapter 1, which has a reasonable but not correct character frequency, and then random text.

## Best Layout Is:

## TIP Nirvana ANSI

| Rank | Layout | Board | +Effort | Overall Score | Distance | Finger Usage | Same Finger | Same Hand | Words |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| \#1 | Nirvana ANSI | standard | +0\% | 76.45 | 30.03 | 24.08 | 10.64 | 10.02 | 1.68 |

| \#8 | Simplified Dvorak | standard | +26\% | 96.67 | 31.24 | 28.32 | 20.25 | 11.90 | 4.96 |
| \#9 | Colemak | standard | +33\% | 101.63 | 29.10 | 27.14 | 15.52 | 22.44 | 7.42 |
| \#10 | Workman | standard | +36\% | 103.87 | 28.37 | 26.73 | 15.04 | 26.32 | 7.41 |
| \#11 | Norman | standard | +43\% | 109.21 | 28.41 | 26.95 | 20.32 | 26.61 | 6.93 |
| \#12 | QWERTY | standard | +65\% | 126.46 | 40.20 | 24.98 | 18.97 | 30.50 | 11.81 |

The optimal layout score is based on a weighed calculation that factors in the distance your fingers moved (1/3), how often you use particular fingers (1/3), how often you switch fingers ( $1 / 6$ ) and hands ( $1 / 6$ ) while typing, and how easy it is to type whole words ( $1 / 13$ ). Lower scores are better, means less effort will be used during typing.
Figure 1: Layout performance on Alice chapter 1.

The spread between the best and worst layouts is $65 \%$.

## Best Layout Is: <br> CIP Simplified Dvorak

| Rank | Layout | Board | +Effort | Overall Score | Distance | Finger Usage | Same Finger | Same Hand | Words |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| \#1 | Simplified Dvorak | standard | +0\% | 338.88 | 134.97 | 63.10 | 92.45 | 21.41 | 26.95 |
| \#2 | MTGAP | standard | +3\% | 350.17 | 135.46 | 64.11 | 100.02 | 21.57 | 29.02 |
| \#3 | Nirvana ANSI | standard | +4\% | 352.81 | 135.36 | 63.93 | 99.34 | 20.78 | 33.39 |

| \#9 | MTGAP | standard | +12\% | 220.50 | 62.48 | 39.67 | 86.30 | 27.83 | 4.23 |
| \#10 | Workman | standard | +14\% | 223.65 | 62.79 | 39.49 | 83.20 | 30.42 | 7.76 |
| \#11 | Norman | standard | +15\% | 226.68 | 62.38 | 38.15 | 85.66 | 32.54 | 7.95 |
| \#12 | QWERTY | standard | +22\% | 239.56 | 68.94 | 38.38 | 85.60 | 35.08 | 11.56 |

The optimal layout score is based on a weighed calculation that factors in the distance your fingers moved (1/3), how often you use particular fingers (1/3), how often you switch fingers ( $1 / 6$ ) and hands ( $1 / 6$ ) while typing, and how easy it is to type whole words ( $1 / 13$ ). Lower scores are better, means less effort will be used during typing.
Figure 9: Layout performance on Monkey Coder 3

From these tests, it should be clear that as far as the analyzer is concerned, there is no difference between actual English or code, and that generated by Shakespeare's Monkeys. Thus, Shakespeare's Monkeys can be used to produce arbitrary length inputs, for either text or bigram analysis engines.
