#### Abstract

Structural investigations on a series of six analogous metal(II) isonicotinate tetrahydrates, $\mathrm{M}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ with $\mathrm{M}=\mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}$, $\mathrm{Ni}, \mathrm{Cu}$ and Zn , all crystallizing in $P \overline{1}$ space symmetry, have been carried out. In the crystal structure of each of the six metal complexes of type tetraaquabis(isonicotinato)metal(॥), extensive intermolecular hydrogen bonds involving all possible donor and acceptor sites lead to the formation of a 3D supramolecular network that has been analysed by the graph-set approach. Their comparable lattice parameters and similar PXRD patterns indicate close structural similarity within the series. However, the crystallographic isostructurality of the species evaluated by the method of Kálmán and Fábián suggests that the Cu species presents some differences from the rest. In an overall sense, this behaviour is reflective of the Irving-Williams order of stability of octahedral complexes formed by bivalent metal ions.

Keywords: Meta(II) isonicotinates, $\mathrm{R}_{4}^{4}(12)$ graph-set, isostructurality, Kálmán and Fábián, powder X-ray diffraction, Irving-Williams order.

## Introduction

Chemical compounds having analogous composition and structure are commonly termed as isostructural. In a crystallographic sense, a pair of isostructural compounds is required to belong to the same structure type, i.e. their space groups are identical which ensures nearly identical crystal packing. Kálmán and Fábián have developed an approach based on volumetric measure to estimate the degree of isostructuality between two crystalline compounds from a crystallographic point of view ${ }^{1}$. Two crystal structures may be compared by a parameter called unit cell similarity index given by

$$
\begin{aligned}
& \Pi=\left[(a+b+c) /\left(a^{\prime}+b^{\prime}+c^{\prime}\right)\right]-1 \\
& \quad\left(a+b+c>a^{\prime}+b^{\prime}+c^{\prime}\right)
\end{aligned}
$$

Here $a, b, c$ and $a^{\prime}, b^{\prime}, c^{\prime}$ are the orthogonalized lattice parameters of the structures being compared. If the structural similarity is very high, the $\Pi$ value is expected to be practically equal to zero. Two other parameters viz. mean elongation value $(\in)$ and the asphericity index ( $A$ ), are also used to establish the structural closeness of the species being compared. The $\in$ value describes the difference in cell size, the asphericity index $(A)$ accounts for the shape distor-
tions of the two unit cells. The concept of isostructurality has also been studied in relation to the opposing concept of polymorphism for organic crystalline molecules ${ }^{2}$. Formation of isostructural crystalline species was also reported to have resulted via an exchange of halogen atoms ${ }^{3}$.

Such studies on metal-organic compounds are not common, however. Using this approach, we had earlier evaluated the isostructurality of two species of composition $\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\left(\mathrm{SO}_{4}\right)(4-\mathrm{CNpy})_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ for $\mathrm{M}=\mathrm{Co}$ and Ni which present an inverse bilayer structure due only to supramolecular effects ${ }^{4}$.

Isonicotinic (or 4-pyridine carboxylic) acid (isoH) is a potentially tridentate ligand and, by acting in this fashion, it is known to form polymeric species such as bis(iso)M ${ }^{\text {ll }}$. Coordination of the pyridyl-N as well as the carboxyl ends of 4pyridinecarboxylate anion occurs under non-aqueous/hydrothermal conditions ${ }^{5}$, while in complexes formed in aqueous medium the pyridyl-N atom is only coordinated ${ }^{6}$. The latter situation leaves the uncoordinated carboxyl end as a suitable acceptor in the formation of intermolecular hydrogen bonds. The 1D coordination polymer $[\mathrm{Cl}(\mathrm{isoH}) \mathrm{Cu}(\mathrm{I})]_{n}$, pre-

[^0]pared under hydrothermal conditions at $140^{\circ} \mathrm{C}$, has N -bound isonicotinic acid as the ligand, while - COOH groups from two adjacent chains take part in the formation of a pair O-H...O bonds to add a second dimension to the coordination polymer $^{7}$. Okabe et al. reported ${ }^{8}$ the crystal structure of a compound formulated as $\mathrm{Cu}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$. The $\mathrm{Cu}^{\prime l}$ coordination geometry in this compound was described as being square planar with $\mathrm{N}_{2} \mathrm{O}_{2}$ coordination, with two additional water molecules being present in the crystal lattice as solvent of crystallization.

The crystal structures of several other metal(II) isonicotinates with a chemical composition analogous to $\mathrm{Cu}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, but formulated either as M (iso $)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$, or M (iso). $4 \mathrm{H}_{2} \mathrm{O}$ have been determined by us ${ }^{9,10}$ as well as other authors ${ }^{11-14}$. The thermogravimetric (TG) behaviour of several metal(II) isonicotinate tetrahydrates formed by Mn, $\mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Cu}$ and Zn was also reported ${ }^{15}$ by us earlier. These compounds crystallize in triclinic $P \overline{1}$ space symmetry and comparable unit cell parameters. Herein, we present the detailed analysis of the crystal structure with an emphasis on the supramolecular aspects and also the powder X-ray diffraction behaviour of this series of six compounds, which may also be formulated as $\mathrm{M}(\text { iso })_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$, with $\mathrm{M}=\mathrm{Mn}(1)$, $\mathrm{Fe}(2), \mathrm{Co}(3), \mathrm{Ni}(4), \mathrm{Cu}(5)$ and $\mathrm{Zn}(6)$. Further, the close similarity of their crystal packing behaviour is analysed by evaluating the isostructurality of the crystalline species by following the method of Kálmán and Fábián ${ }^{1}$.

## Experimental

Materials and methods:
All materials used in this work were obtained from commercial sources and used without further purification. 4Cyanopyridine and isonicotinic acid were obtained from Sigma-Aldrich, while the metal salts-nickel(II) acetate, chlorides, nitrates or sulfates were purchased from various ln dian manufacturers/suppliers.

Preparation and crystallization of $M(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}[M=\mathrm{Mn}$ (1), Fe (2), $\mathrm{Co}(3), \mathrm{Ni}(4), \mathrm{Cu}(5), \mathrm{Zn}(6)]:$

The metal(II) isonicotinate tetrahydrates were prepared in very good to excellent yield by following procedures described by us earlier ${ }^{10 a}$. Neutralized isonicotinic acid (4-pyridine carboxylic acid) was reacted with appropriate salts of the above metals and the reaction mixture was stirred for 2 4 h . The microcrystalline products formed were filtered,
washed with water followed by rectified spirit and diethyl ether and dried in air. Yield: $\sim 70 \% ~(M=F e, C o) ; ~ \sim 100 \% ~(M=M n$, $\mathrm{Ni}, \mathrm{Cu}, \mathrm{Zn}$ ). Analytical and other data on the complexes were reported earlier ${ }^{10}$.

## X-Ray crystallographic procedures:

Molecular and crystal structures of 1-6 were determined by using the method of single crystal X-ray diffraction. While the crystals of compounds $1,2,3,5$ and 6 were obtained from undisturbed preparative reaction mixtures kept at room temperature, to obtain compound 4 in crystalline form $\mathrm{Ni}(\mathrm{OAc})_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ was reacted with 4-cyanopyridine under hydrothermal conditions at $210^{\circ} \mathrm{C}$. The chosen crystals of suitable size were mounted on glass fibres for intensity data collection at room temperature using graphite monochromatized Mo-K $\alpha$ radiation ( $0.7107 \AA$ ) on a Bruker SMART CCD Diffractometer ${ }^{16}$. The crystals were found to be stable against thermal/oxidative decomposition and X-radiation induced decay at room temperature. The crystal structures were solved by direct methods (SHELXS) and refined by full-matrix least squares technique (SHELXL) with SHELX-97 ${ }^{17}$ using the WinGX ${ }^{18}$ platform. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms in all the six compounds were located in difference Fourier maps and refined with isotropic atomic displacement parameters. The structural diagrams were drawn using ORTEP-III ${ }^{19}$ for Windows, Diamond ${ }^{20}$ and Mercury ${ }^{21}$. Crystal and structure refinement data for 1-6 are summarized in Table 1.

Powder $X$-ray diffraction data in the $3-60^{\circ} 2 \theta$-range were recorded on a Philips X'Pert PRO instrument using Cu-K $\alpha$ radiation $(1.5418 \AA)$ at a scan rate of $0.5 \mathrm{~s}\left(0.5^{\circ} 2 \theta\right)$ per step at $40 \mathrm{KV} / 30 \mathrm{~mA}$. The calculated diffraction patterns assuming Bragg-Brentano geometry were obtained from results of single crystal structure analyses using PowderCell ${ }^{22}$.

## Results and discussion

The complexes 1, 2, 3, 4, 5, and 6 of the type $M(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ with $\mathrm{M}=\mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Cu}, \mathrm{Zn}$ respectively have been prepared at room temperature following a high yield general route ${ }^{10 \mathrm{a}}$. In this procedure the sodium salt of isonicotinic acid is treated with a suitable $\mathrm{M}^{2+}$ salt in aqueous solution to obtain the desired products as precipitates. The $\mathrm{Ni}^{\mathrm{II}}$ analogue, 4 was originally prepared as a mixture of rod-shaped crystals and powder by reacting nickel acetate tetrahydrate with 4 cyanopyridine under hydrothermal conditions at $210^{\circ} \mathrm{C}^{23}$. Under the high-pressure condition, the

nitrile group of 4-cyanopyridine (py-4-CN) undergoes hydrolysis to form 4-pyridine carboxylic acid, i.e. isonicotinic acid (py-4-COOH) which reacts in situ with the nickel salt to produce 4. Although these complexes may be prepared ${ }^{9 \mathrm{a}}$ from the isolated metal(II) salts and sodium isonicotinate taken in the $1: 2$ ratio, the method was subsequently simplified ${ }^{9 b}$ by making use of a NaOH -neutralized aqueous solution of isonicotinic acid instead of sodium isonicotinate in solid form.

The crystalline compounds are characteristically coloured, air-stable and moisture-insensitive solids that are sparingly soluble in water and common organic solvents. The bright yellow colour of the air stable iron(II) compound, $\mathbf{2}$, resulting from an absorption occurring at 388 nm due to an MLCT transition ${ }^{10 a}$, is quite notable. In addition, this iron(II) complex characterized by its ${ }^{1} A_{1 g}$ ground state instead of the more usual ${ }^{5} T_{2 g}$ ground state is diamagnetic in nature ${ }^{10 \mathrm{a}}$. The $\mu_{\text {eff }}$ values observed (at 298 K ) for the paramagnetic species, 1 ( 5.67 BM ), 3 ( 4.74 BM ), 4 ( 3.15 BM ) and $\mathbf{5}$ ( 1.79 $B M$ ) are in the expected ranges for high-spin $d^{5}-\mathrm{Mn}^{2+}(5.65-$ $6.10 \mathrm{BM})$, high-spin $d^{7}-\mathrm{Co}^{2+}(4.30-5.20 \mathrm{BM}), d^{8}-\mathrm{Ni}^{2+}(2.80-$ $3.50 \mathrm{BM})$ and $d^{9}-\mathrm{Cu}^{2+}(1.70-2.20 \mathrm{BM})$ respectively ${ }^{10 \mathrm{a}}$. Thermal decomposition of the compounds takes place in two welldefined steps in the $50-600^{\circ} \mathrm{C}$ range ${ }^{15}$. While the first step involves dehydration commencing at relatively high initiation temperatures, the second step is due to the decomposition of the isonicotinato ligands to produce metal oxides as the final products.

Crystal structures of $2^{10 \mathrm{~b}}$ and $5^{10 \mathrm{a}}$ were reported earlier from this laboratory. Herein we present a detailed analysis of supramolecular aspects of the crystal structures of 1-6 and the same time, a comparison of the structural parameters of the six analogues formed by the bivalent metal ions. The crystallographic and structure refinement data on all members of this series are presented in Table 1. All six compounds crystallize with triclinic unit cells of analogous distance and angular parameters. In all cases the metal ions lie at a centre of symmetry $(0,0,0)$ in the crystal lattice. Thus, in each case the asymmetric unit consists of one-half the octahedral complex. The thermal ellipsoid plot shown in Fig. 1 is for the manganese compound (1), but similar diagrams may be drawn for the other compounds as well. We compare the geometric parameters for all six structures in Table 2. Identi-

Fig. 1. Thermal ellipsoid plot of $\mathrm{Mn}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(1)$ with anisotropic atoms drawn as $50 \%$ probability ellipsoids. The ' $i$ 'superscripted atoms belong to the centrosymmetrically related half of the molecule.

cal atom naming schemes have been adopted for the structures.

The M-O and M-N bond lengths in these compounds (16) of type $\mathrm{M}(\mathrm{iso})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ are clearly dependent on the metal ions present in them. The observed M-N(1) bond distances in compounds 1-6 follow the order given below, which is also the order of the $\mathrm{M}^{2+}$ ionic radiil ${ }^{24}$.

| $\mathrm{M}^{2+}$ | $\mathrm{Mn}^{2+}$ | $\mathrm{Fe}^{2+}$ | $\mathrm{Co}^{2+}$ | $\mathrm{Ni}^{2+}$ | $\mathrm{Cu}^{2+}$ | $\mathrm{Zn}^{2+}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{M}-\mathrm{N} 1, \AA$ | 2.274 | 2.206 | 2.150 | 2.092 | 2.006 | 2.130 |
| $\mathrm{r}_{\mathrm{M}^{2+}}, \AA$ | 0.97 | 0.92 | 0.89 | 0.83 | 0.87 | 0.88 |

A plot of the observed $\mathrm{M}-\mathrm{N}(1)$ (and also the $\mathrm{M}-\mathrm{O}(2)$ ) distances with respect to the metal ions present in the complexes is shown in Fig. 2. It is interesting to note that the

Fig. 2. The (a) $\mathrm{M}-\mathrm{N}(1)$ and (b) $\mathrm{M}-\mathrm{O}(2)$ bond distances of $\mathrm{M}(\mathrm{iso})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ in 1-6.
observed $\mathrm{M}-\mathrm{N}(1)$ distances are according to the well-known Irving-Williams series $\mathrm{Mn}^{2+}<\mathrm{Fe}^{2+}<\mathrm{Co}^{2+}<\mathrm{Ni}^{2+}<\mathrm{Cu}^{2+}>$ $\left.\mathrm{Zn}^{2+}\right)$. It is also seen that in going from Mn to Zn the $\mathrm{M}-\mathrm{O}(2)$ bond distances follow the same order with the only exception of Cu . This is attributed to the distorted octahedral geometry of six-coordinate copper(II) complex resulting from Jahn-Teller effect which is common in six-coordinate complexes of $\mathrm{Cu}^{2+}$. In the crystal structure of $\mathrm{Cu}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(5)$ two of the M-L bonds [M-O(2)] are over $2.4 \AA$ in length, while the other four $[M-O(1)$ and $M-N(1)]$ are near $2.0 \AA$.

The most remarkable structural feature in the crystal structure of 1 and its analogues is the formation of an exhaustive hydrogen-bonded network involving all possible hydrogen bond acceptors and donors (Fig. 3). The discrete complexes $\left[\mathrm{M}(\mathrm{iso})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]$ are thus strongly linked to one another to give rise to a supramolecular polymer. As shown in Fig. 4, hydrogen bonds between dangling carboxyl groups from the isonicotinato ligand and the water molecules join the molecules into layers that are interconnected through further hydrogen bonds forming a robust 3D architecture. The 0H...O bond lengths and angles listed in Table 3 indicate that their shortness coupled with near-linearity results in strong hydrogen-bonding interactions leading to stability against the loss of coordinated water molecules under ambient conditions as well as low solubility in water and other media.

Fig. 3. Unit cell packing diagram viewed along a in crystal structures of $\mathrm{M}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(1-6)$.

Fig. 4. The 3-D network produced by O-H $\cdots$..O hydrogen bonds present in crystals of $\mathrm{M}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$.

As shown in Fig. 5 , graph set analysis of the crystal structure of $\mathrm{M}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ suggests the presence of three rings formed by $\mathrm{O}-\mathrm{H} \ldots \mathrm{O}$ hydrogen bonds. The 8 -membered ring comprised of two aqua ligands, a carboxylate anion and the metal ion generates a $R_{2}^{2}$ (8) cyclic motif as per notations of Bernstein et al. ${ }^{24}$. A 12-membered twisted ring involving two

Fig. 5. Graph-set description of the hydrogen-bonded network occurring in the crystal structure of $\mathrm{M}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(1-6)$. The inset at the top shows the twisted ring of description $R_{4}^{4}(12)$.
aqua lignds and two carboxylate anions with a description of $R_{4}^{4}(12)$ is also observed as a unique pattern in the crystal structures of 1-6. We are not aware about the occurrence of such rings in other reported crystal structures. This ring unites four $\mathrm{M}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ molecules involving two coordinated water molecules and two - $\mathrm{COO}^{-}$groups from the isonicotinato ligands. An even larger 18-membered $R_{2}^{2}$ (18) ring involving two isonicotinato ligands, two aqua ligands and two metal centres is also found in the crystal structure of the compounds.

Das et al.: Isostructurality of complexes of the type tetraaquabis(isonicotinato)metal(II)

The aromatic rings of the isonicotinato ligands are involved in intermolecular $\pi$ - $\pi$ interactions in the crystal structures of $\mathrm{M}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ (Fig. 6). The centroid-centroid contact between two pyridine ring fragments in compound 1 is found to be $3.894 \AA$. The observed $\pi-\pi$ interaction involving the pyridyl rings in $1-6$ is of offset or slipped stacking type because the aromatic rings are displaced from each other in a parallel manner to give rise to a $\pi-\sigma$ type of attraction between the stacked rings. The displacement value of $\alpha=27^{\circ}$, i.e. the angle ( $\alpha$ ) between the ring-centroid vector and the

Fig. 6. $\pi-\pi$ interactions observed between the pyridyl rings of isonicotinato ligands in compounds 1-6. Symmetry code: $i$, $1-x,-y, 1-z$.
ring normal to one of the pyridine ring planes in 1 is comparable with values observed for other nitrogen containing aromatic ligands ${ }^{26}$. Similar values can be obtained for the other complexes in the series. The centroid-centroid distances for 1-6 are listed in Table 4. The displacement of the pyridyl rings of 5 is greater and hence a higher centroid-centroid separation of $4.248 \AA$ is observed in this compound. Once again, the departure of the Cu species from the expected range of values may be attributed to the structural differences between compound 5 and the other member of the series.

| Table 4. Pyridine ring centroid $\ldots$ centroid distances in 1-6 |  |
| :--- | :---: |
| Compounds | Centroid...Centroid separations (Å) |
| $\mathrm{Mn}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathbf{1}$ | 3.894 |
| $\mathrm{Fe}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathbf{2}$ | 3.880 |
| $\mathrm{Co}(\text { (iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathbf{3}$ | 3.882 |
| $\mathrm{Ni}(\text { (iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathbf{4}$ | 3.878 |
| $\mathrm{Cu}(\text { (iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathbf{5}$ | 4.248 |
| $\mathrm{Zn}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathbf{6}$ | 3.910 |

It is evident from the various structural data that except the Cu complex (5), the other complexes are more similar. In compound $5^{29}$, the coordination sphere is considerably distorted due to Jahn-Teller effect which leads to the familiar $(4,2)$ coordination geometry around the copper(II) centre. The two trans isonicotinato ligands are present at distances $[\mathrm{Cu}(1)-\mathrm{N}(1)=2.006(2) \mathrm{A}]$ comparable to those of the others. On the other hand, while the $\mathrm{Cu}(1)-\mathrm{O}(1)$ distance of 1.986(1) $\AA$ is normal, the $\mathrm{Cu}(1)-\mathrm{O}(2)$ distance of $2.452(2) \AA$ is much longer. The four-fold rotation axis of the approximately $D_{4 h}$ coordination geometry around Cu is along the $\mathrm{O}(2)-\mathrm{Cu}(1)$ $\mathrm{O}(2)^{i}$ direction, which is perpendicular to the plane formed by $\mathrm{O}(1), \mathrm{N}(1), \mathrm{O}(1)^{i}, \mathrm{~N}(1)^{i}$ and $\mathrm{Cu}(1)$.

The Powder X-ray diffraction patterns of compounds 1-6 are shown in Fig. 7. For each species the powder diffraction patterns calculated from the atomic coordinates obtained from

Fig. 7. Comparison of powder XRD patterns observed for compounds 1-6.
single-crystal X -ray diffraction data are closely similar to the observed patterns (Fig. 8). The close similarities between observed and calculated XRD patterns suggest the purity of crystalline bulk samples of the compounds and correctness of the structures described by us. The $d$-spacings and relative intensities found by us for compounds 1-6 are given in Table 5. The indexing of the powder patterns is based on the comparison of the experimental and calculated powder XRD patterns. It is interesting to note that identical reflections with similar relative intensities are observed for all the compounds.

Fig. 8. Experimental and calculated X-ray powder diffraction patterns for compounds (a) 1, (b) 2, (c) 3, (d) 4, (e) 5 and (f) 6.

There is however one odd member (5) in the group because the structure of the copper compound is significantly influenced by Jahn-Teller distortion which renders two of the six Cu -L bonds to become different from the other four. Further, in spite of the identical space symmetry of the six compounds, compound 5 has the longest as well as the shortest hydro-
gen bonds among the six compounds (Table 3). Differences in the molecular and supramolecular structures shown by 5 from the rest of the members in this family are thus believed to be responsible for the differences in $2 \theta$ values and relative intensities of some of the diffraction maxima obtained in the PXRD patterns observed for 5 .

The similar chemical composition, close similarity of lattice parameters, identical space group symmetry and powder XRD patterns of compounds 1-6 suggest the isostructurality among the compounds. In view of this, we have studied the crystal structures by the method of Kalmán and Fábián ${ }^{1}$, whereby two structures can be compared by their unit cell similarity index ( $\Pi$ ), mean elongation value ( $\epsilon$ ), asphericity index $(A)$ and the lattice distortion index $(\in A)$. Since we have six structures to be studied, a total of 15 different sets of calculations have been performed. The calculated parameters obtained for each pair of structures are summarized in Table 6. The nearly zero value of $\Pi$ for each pair of compounds suggests close similarity among the structures. However, on careful examination one can notice relatively higher $A$ values for the pairs of structures containing 5 (the Cu species) as a member viz. $5.72,52.04,7.35,3.23$ and 8.86 for the compound pairs $1 / 5,2 / 5,3 / 5,4 / 5$ and $6 / 5$ respectively. These higher values indicate structural dissimilarities between the two structures under comparison. As discussed above, $\mathrm{Cu}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(5)$ has a more distorted structure compared to the other members in the group. This deviation is therefore supported by the isostructurality parameters determined by us.

## Conclusions

Discrete molecular entities of $\mathrm{M}(\text { iso })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(\mathrm{M}=\mathrm{Mn}$, $\mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Cu}, \mathrm{Zn}$ ) are structurally similar with the Cu species presenting some differences resulting from Jahn-Teller distortion. The complexes are intimately linked to one another via $\mathrm{O}-\mathrm{H} \ldots \mathrm{O}$ hydrogen bonds involving all acceptor (-COO ${ }^{-}$) and donor (water molecules) groups to form robust 3D supramolecular architectures of the species in the crystalline state. The observed $\pi-\pi$ stacking interaction between pyridyl rings is another important structure director for the compounds. The analogous powder XRD patterns of the species indicate the close structural relationship among the six compounds. The isostructurality of the compounds in the series, as evaluated crystallographically via volume-based isostructurality measures, are found to tally with the wellknown Irving-Williams series of coordination chemistry.
