# What are the host galaxies of unobscured QSOs?

Modestly luminous unobscured AGN have SFRs that are consistent with their hosts lying mostly in **normal, star-forming galaxies.**

**Rosario+ (2013c)**

# IRAC power-law selection: Incomplete, but reliable(?)

**Donley+ (2012)**

This simple selection picks out sources to  $z \sim 3$  dominated by AGN light in the mid-IR, but it is quite free of star-bursting galaxies.

# New and powerful ancillary datasets

Chandra COSMOS Legacy X-ray catalog

**Civano+ (2016), Marchesi+ (2016)**

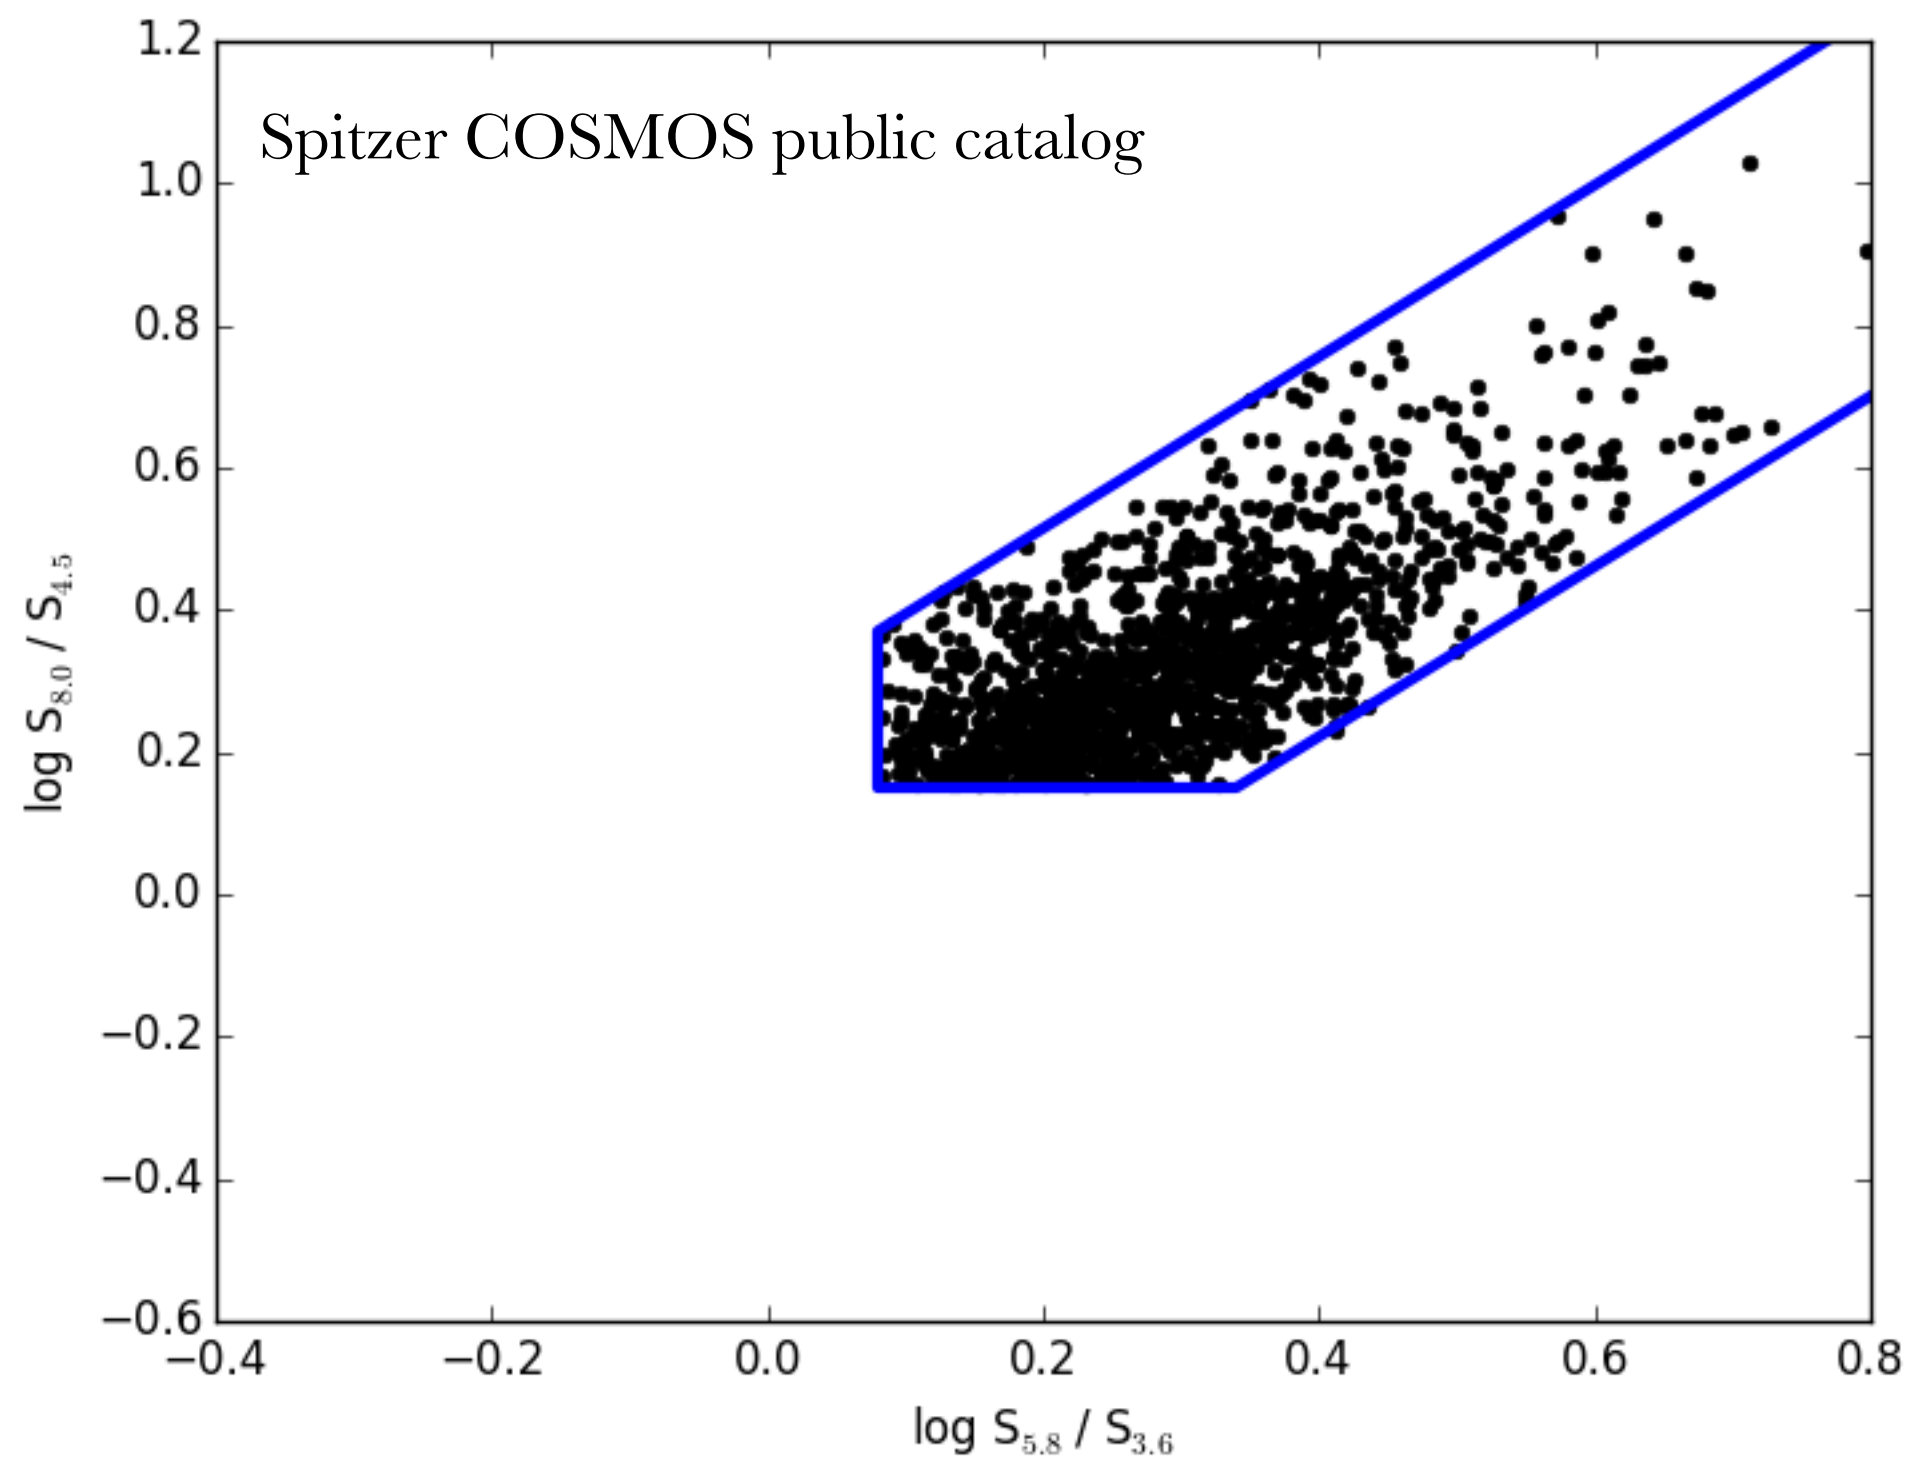

COSMOS2015 NIR-selected MW catalog

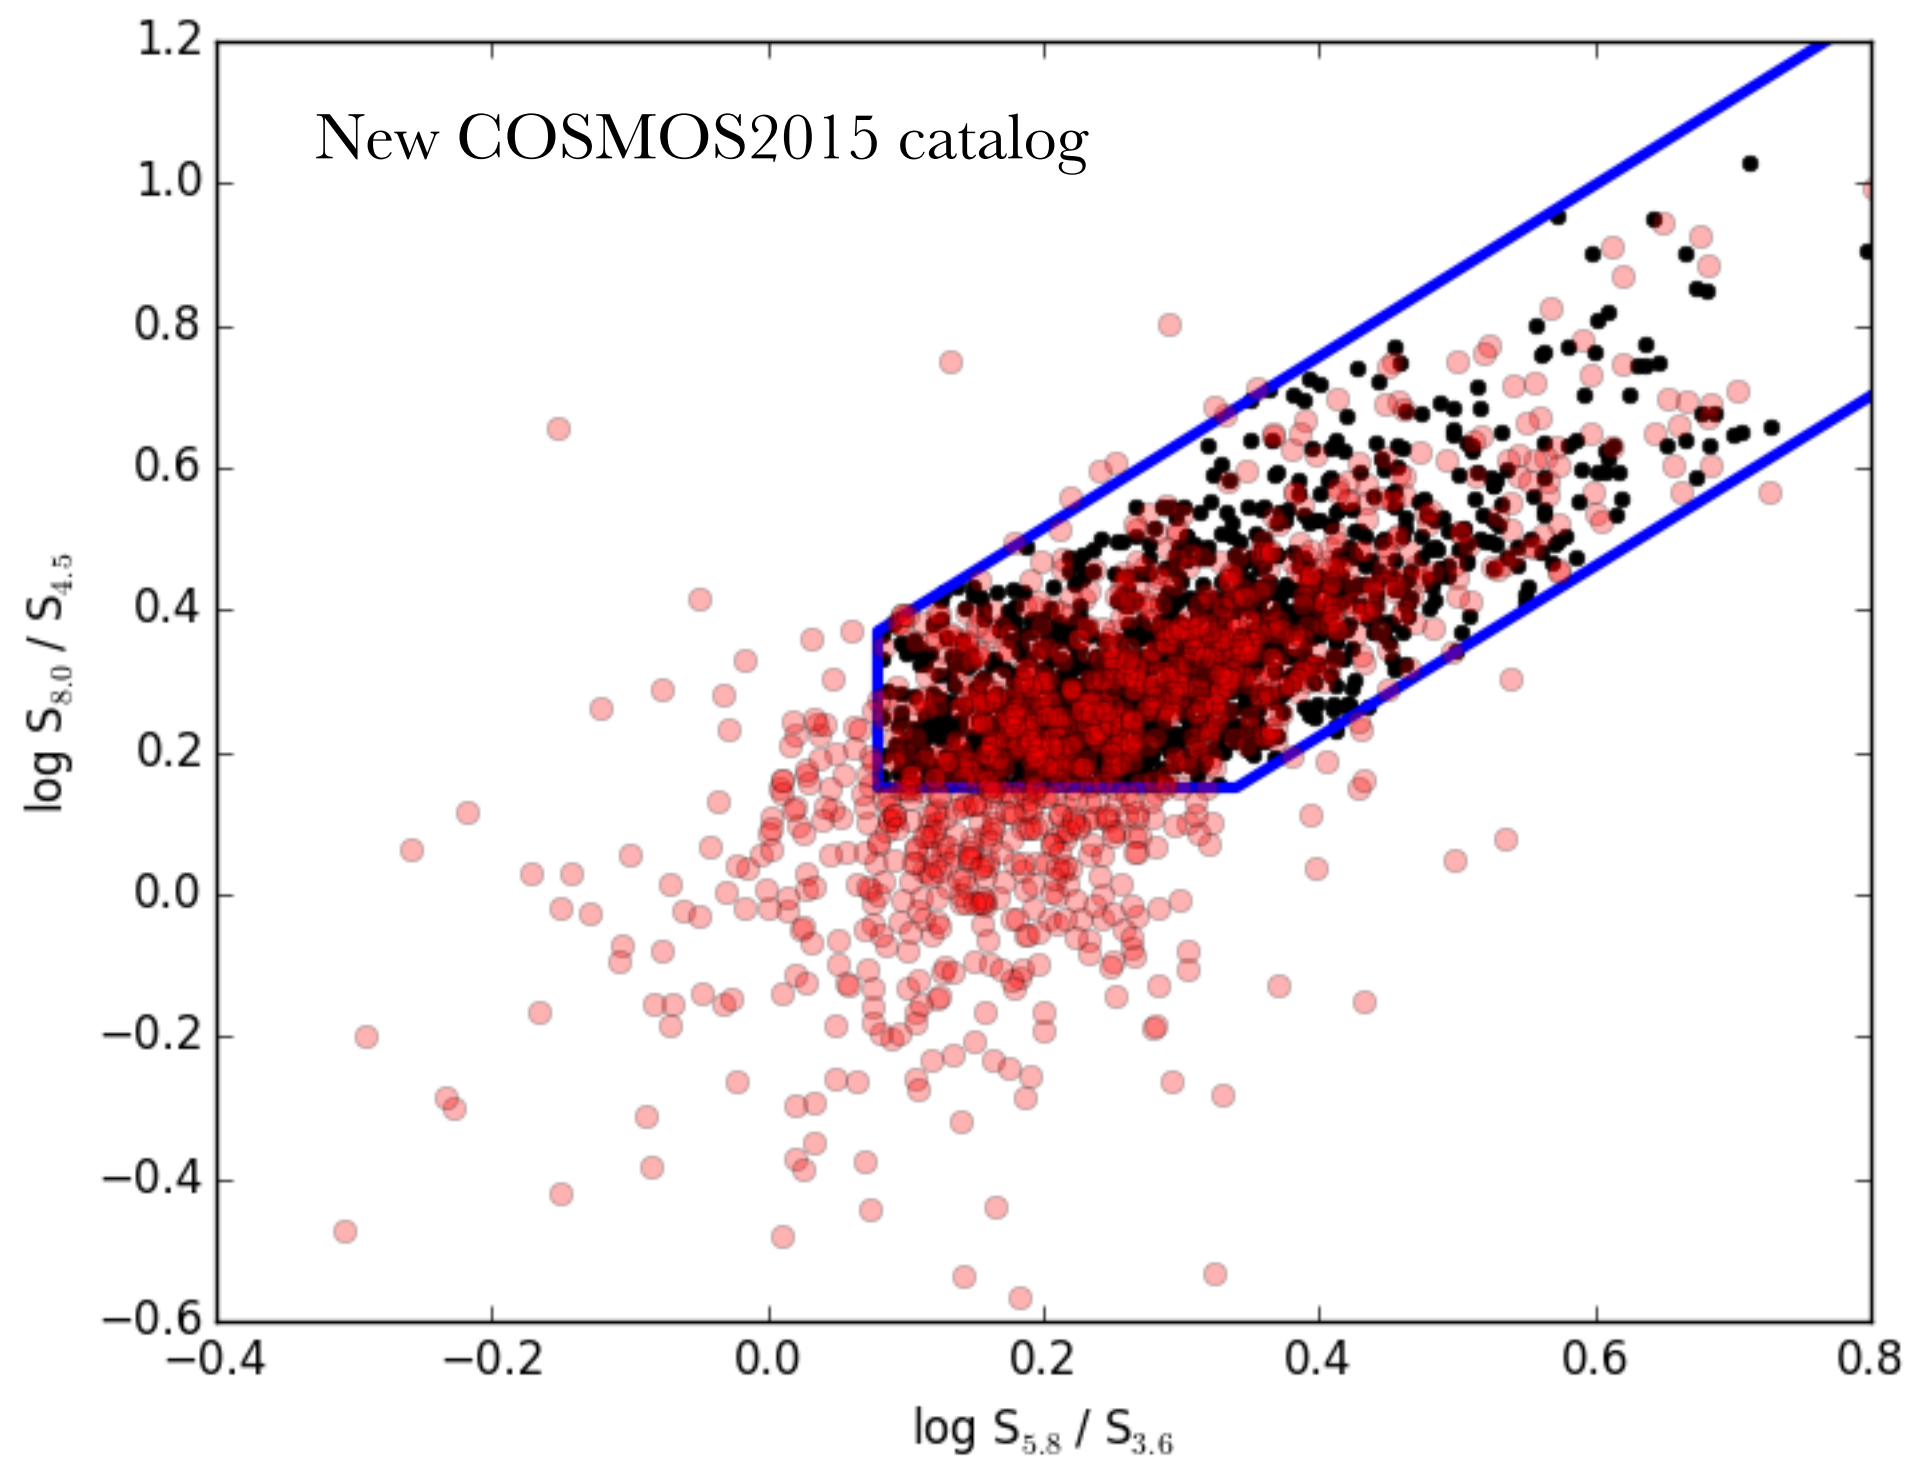

**Laigle+ (2016)**

# New photometric redshifts optimised for AGN

Following methodology of Salvato+ (2009), Salvato+ (2011)

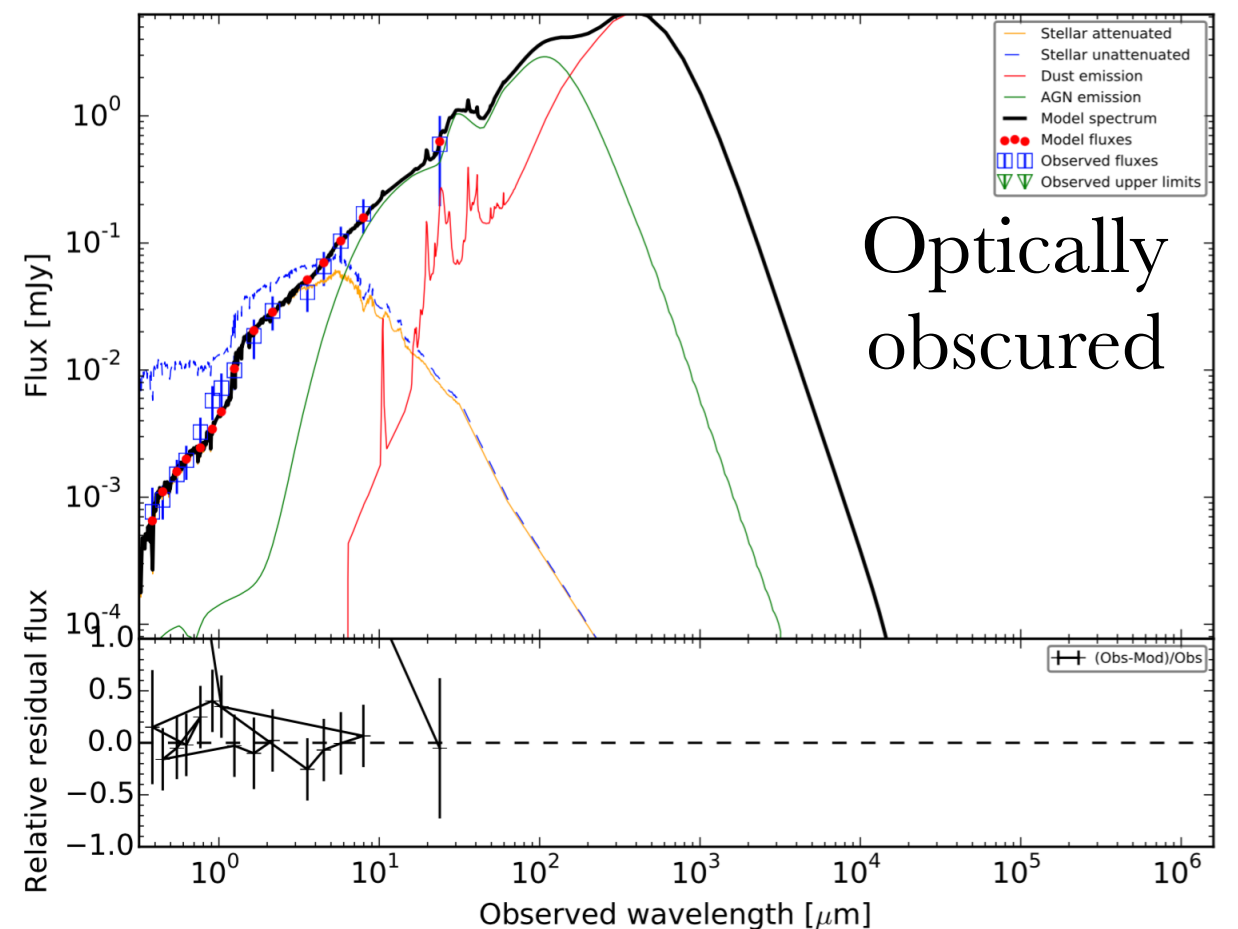

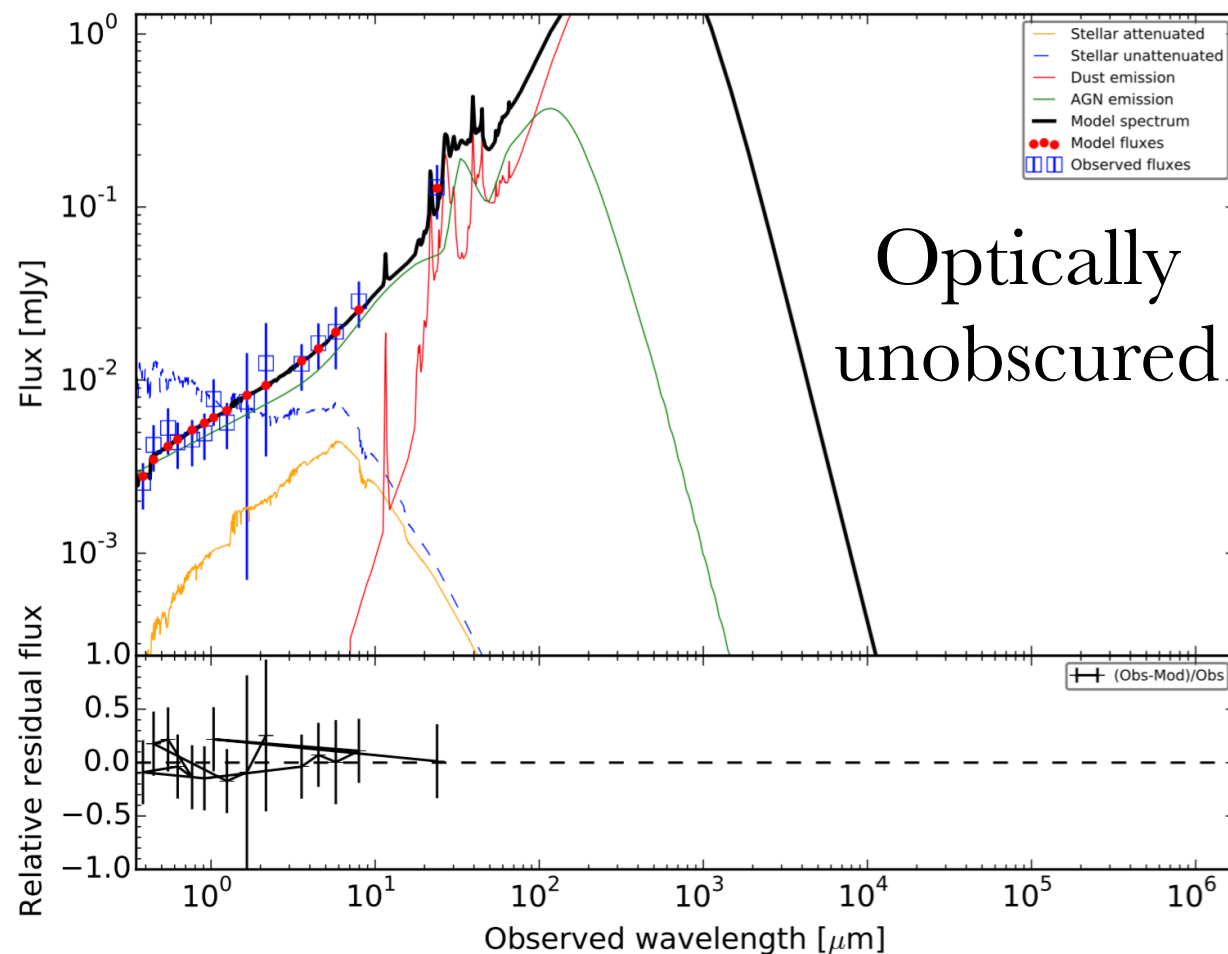

Coloured by best-fit template used for photo-z.

Blue (galaxies), low-mid green (QSO2 hybrids), late green to red (QSO1 hybrids).

# Multi-component SED fits with CIGALE

Following methodology of Ciesla+ (2015) with specialised improvements

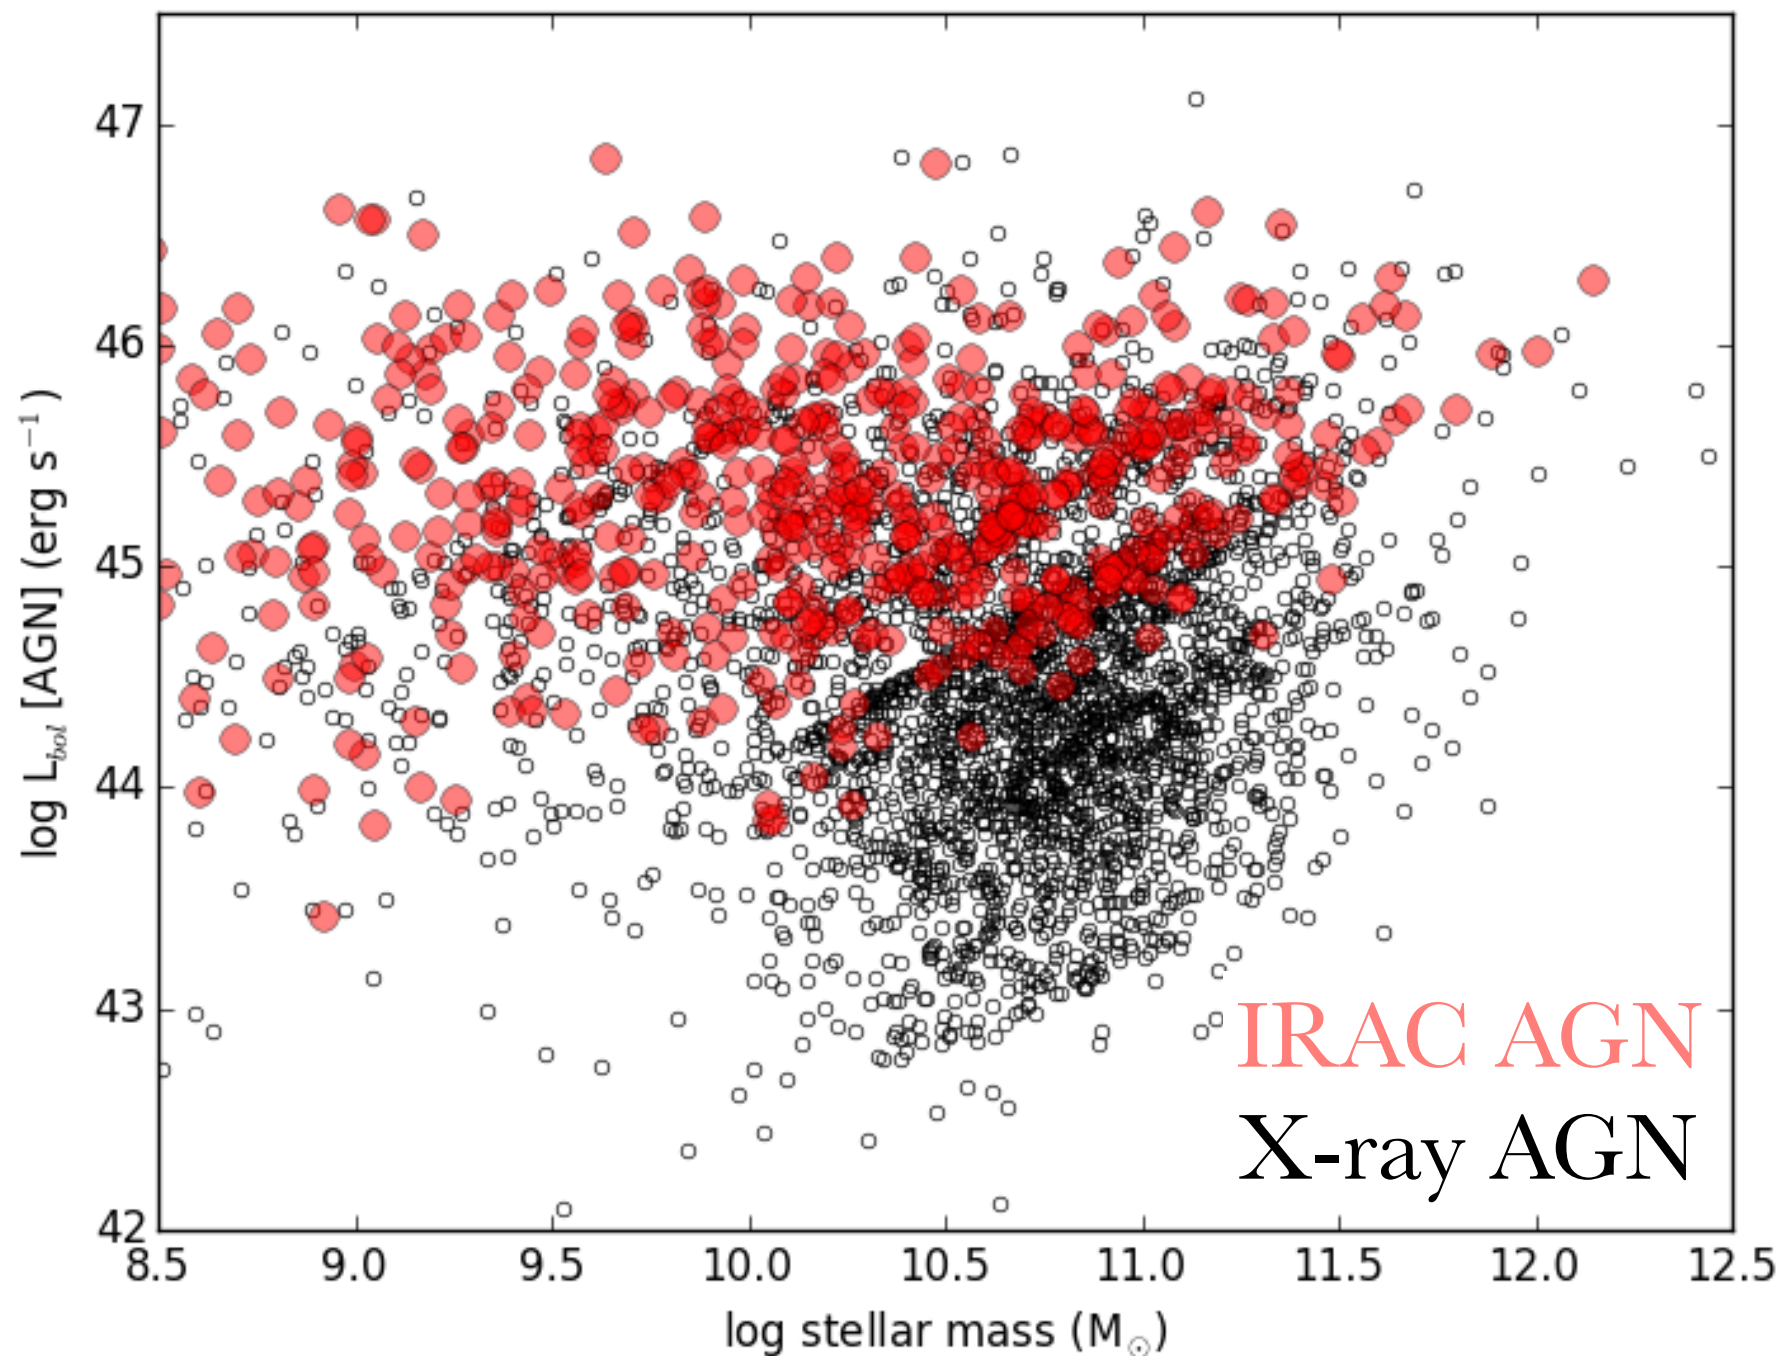

Host stellar masses, bolometric AGN luminosities and the decomposition of AGN- and SF-heated dust in the FIR.

Also for X-ray selected AGN from the Chandra Legacy program.

# IRAC AGN hosts are lighter than X-ray AGN hosts

# Biases!

Test before concluding evolution.

# Herschel constraints on the SFRs

About 25% of COSMOS IRAC-selected AGN are detected in  
at least two  
Herschel photometric bands.

For the rest, we stack in all 5 bands to get mean fluxes (with  
bootstrap errors).

The mean stacked fluxes are fit using CIGALE to get stacked  
FIR luminosities.

# Current conclusions

IRAC-based selection tends to pick out luminous, low mass AGN hosts.

This leads to important biases which must be taken into account when studying these, and possibly other MIR-selected AGN samples. Especially regarding host properties, clustering, and their evolution.

To first order, X-ray detected and undetected IRAC AGN have very similar FIR-based SFRs with redshift.

Trends with stellar mass (the Main Sequence) are forthcoming.
