Biological complexity ...

**Standards for encoding and exchanging data
must be up to these challenges.**

And it's not just the bits ...

G-P or D (disease)

causes
 contributes to
 is risk factor for
 protects against
 correlates with
 is marker for
 modulates
 involved in
 increases susceptibility to

G-G

regulates
 negatively regulates (inhibits)
 positively regulates (activates)
 directly regulates
 interacts with
 co-localizes with
 co-expressed with

E-P

contributes to (E->P)
 influences (E->P)
 exacerbates (E->P)
 manifest in (P->E)

P/D - P/D

part of

G-E

expressed in
 expressed during
 contains

The relationships too must be captured

part of

Semantics are the ultimate universal converter

The role of cross-species phenotyping

“People are a lot like dogs”

- The dog's retina has area centralis (analogous to the human macula) & fovea-like region, similar to humans; useful to study naturally occurring cone diseases

- Aged cats are natural models of Alzheimer's Disease: they form Abeta oligomers, neurofibrillary tangles, and have neuronal loss

- Naked Mole Rats don't get cancer

- Armadillos are a natural host of *M. leprae*, the mycobacterium that causes leprosy (only one besides humans)

- Tree shrews' glioblastomas are morphologically & genetically similar to humans (& more similar than mouse models)

- Great pond snails are models of inflammation-mediated memory dysfunction, and show evidence of spontaneous neural tissue regeneration after injury

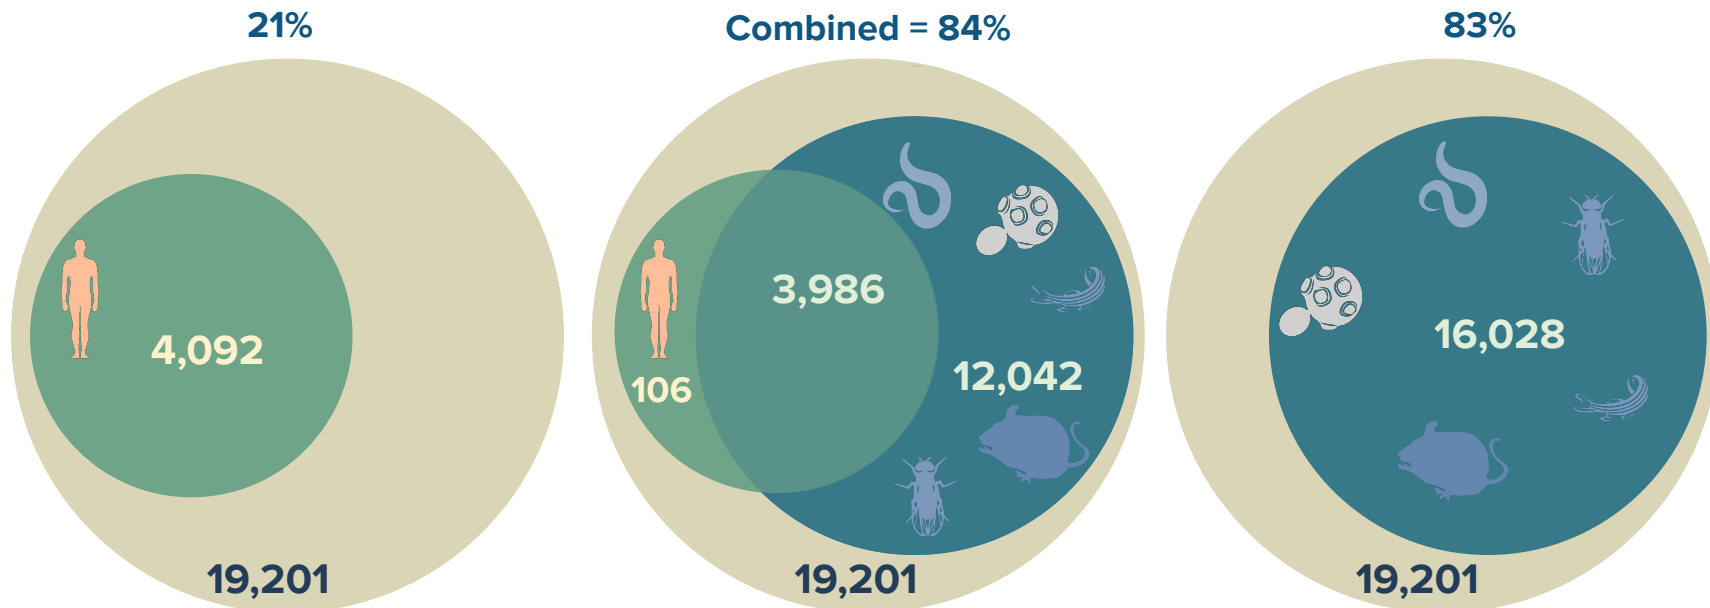

- Silkworms are a model for uric acid metabolism. Decreases in plasma uric acid are correlated with clinical progression of Parkinson's Disease

Other
species
aren't just
relevant;
each has
unique
phenotypes

Model organisms matter to patients

More species = More coverage

Model organisms provide key insight into phenotypic manifestations of human coding genes.

The inclusion of just five species boosts phenotypic coverage of genes by 63%

What is an ontology?

Classification is not a new challenge ...

What is an ontology?

- **Representation of important things in a specific domain**
 - Describes types of entities and relations between them
- **An active, formal computational artifact**
 - A mathematical model based on a subset of first order logic
 - Tools can automatically process ontologies
- **A communication tool**
 - Provides a dictionary and shared understanding
 - Allows data sharing

Domain Ontologies

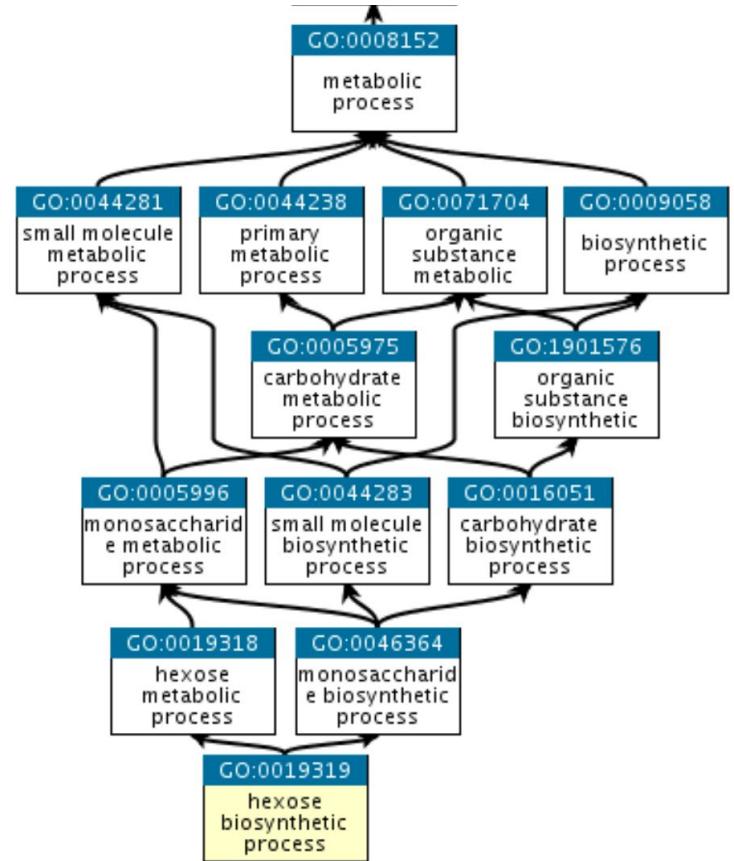

Starting point

Disease = f<G, P, E>

- Molecular function
- Cellular component
- Biological process

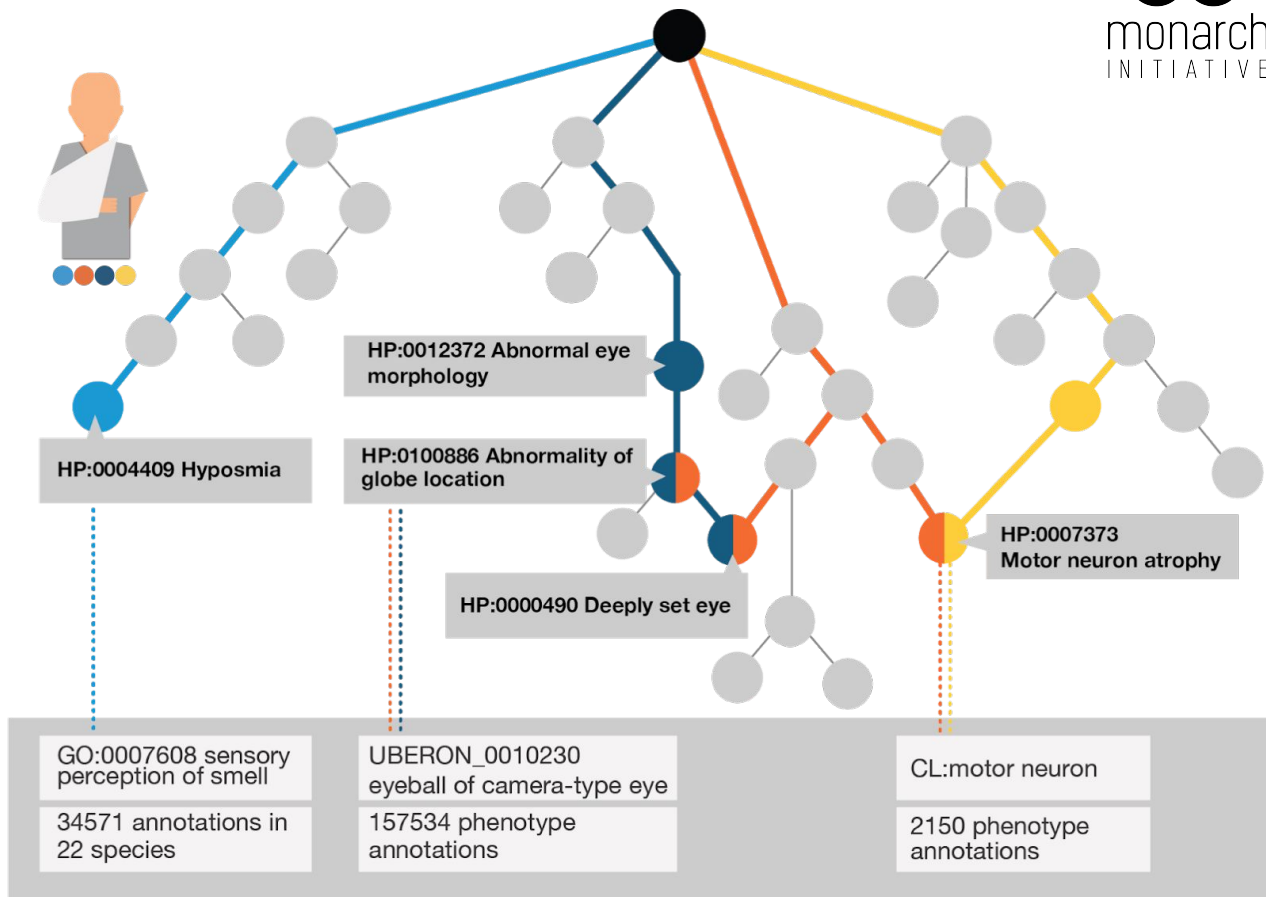

Human Phenotype Ontology (HPO)

- **Phenotyping terminology**

>14,500 terms

- **Widely adopted in rare disease genomic diagnostic tools**

100,000 Genomes Project, SOLVE-RD, NIH-UDP, etc.

Welcome

The **Disease Ontology** has been developed as a standardized ontology for human disease with the purpose of providing the biomedical community with consistent, reusable and sustainable descriptions of human disease terms, phenotype characteristics and related medical vocabulary disease concepts through collaborative efforts of biomedical researchers, coordinated by the University of Maryland School of Medicine, Institute for Genome Sciences.

The Disease Ontology semantically integrates disease and medical vocabularies through extensive cross mapping of DO terms to MeSH, ICD, NCI's thesaurus, SNOMED and OMIM.

To get started please visit the [tutorial page](#).

NCI thesaurus

- Broad coverage of the cancer domain
- >100K concepts

What is the most clinically useful way to define and group diseases?

CANCER
COMPLEX
INFECTIOUS
RARE
MENDELIAN

We needed:

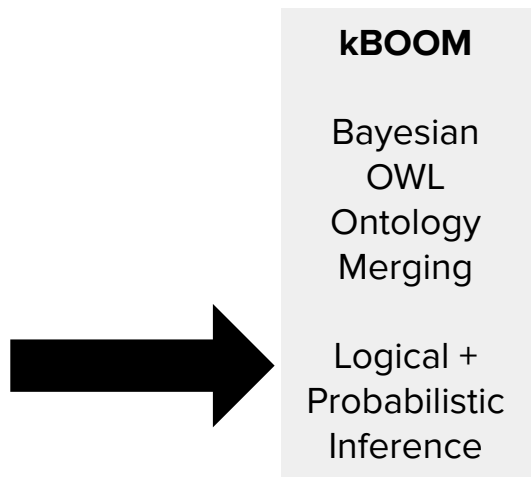

- Disease concepts spanning multiple categories
- A systematic way of relating these concepts

Why not just use mappings?

- Many terminologies / ontologies / lists include mappings
 - These can be used to cross-walk
- Problems:
 - Often mutually inconsistent
 - N^2 sets of mappings!
 - Not 1:1 equivalents

Evidence-based merging of equivalent disease concepts

*iterative curator-assisted
equivalence inference*

curate
feedback

BREAK

Putting it all together

We need computable means to relate form, function, and dysfunction in order to interpret the genome (for diagnostics or otherwise)

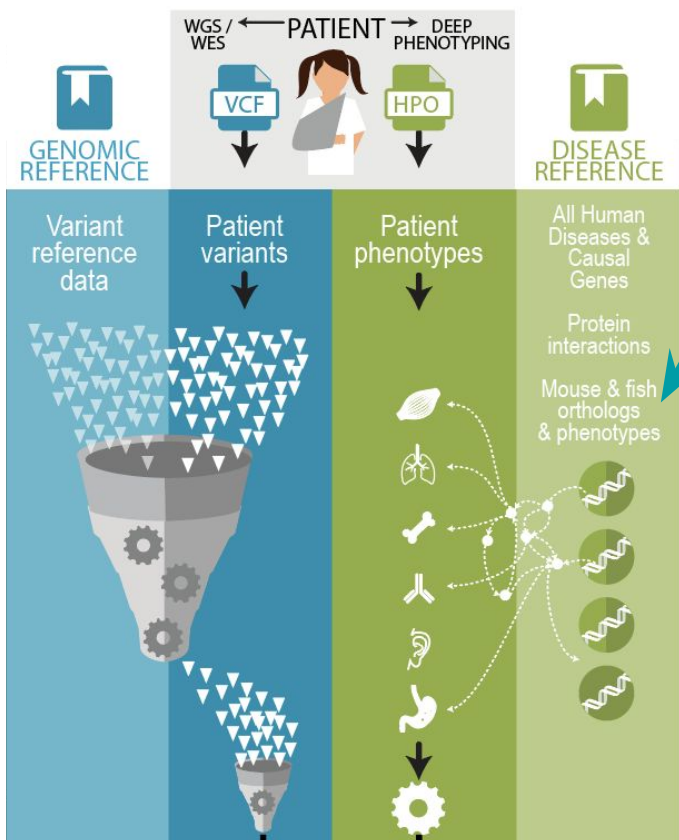

Monarch Knowledge Graph

Genotype-phenotype associations across a variety of species

- Gene to Phenotype Associations: 818,690**
 From approx. 50 species, including mouse, worm, yeast, American mink, Japanese rice fish, various species of livestock, and many species in the Drosophila group
- Causal Gene to Disease Associations: 9,197**
 From human and mouse data
- Non-causal Gene to Disease Associations: 30,220**
 From more than 70 species

Graph Machine Learning on Monarch KG

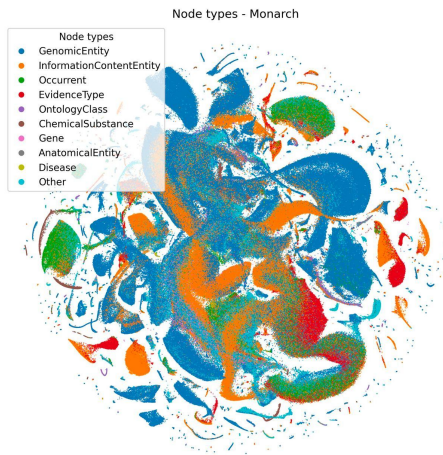

- Several use cases, (e.g., **variant prioritization**,), would benefit from characterizing understudied human proteins
- The Monarch KG contains **rich data** from other a variety of species that can help characterize these proteins
- Graph ML can **effectively capture** the available data
- Deep learning (graph convolutional networks) to characterize understudied proteins by leveraging other species in Monarch KG
- **One application:** feed data from more species into Exomiser (which currently uses human and mouse data from Monarch KG) to allow it to use these species data to prioritize variants

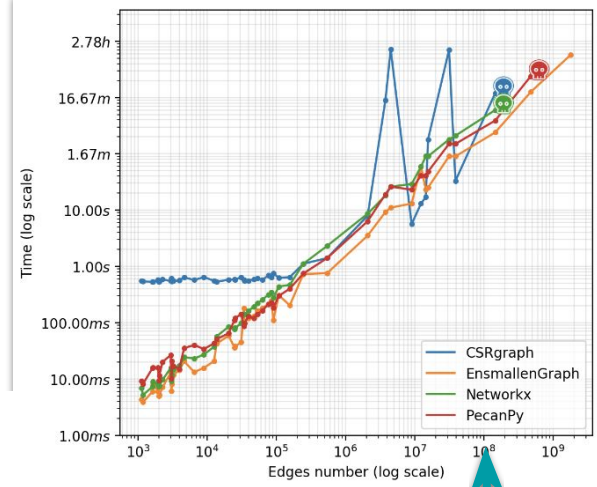

More data means bigger KGs, and slower ML

Enter [EnsmallemGraph](#)/[Embiggen](#):

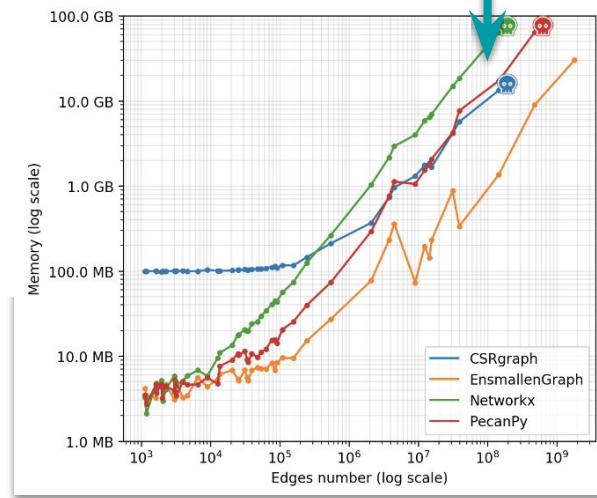

- Monarch KG has $>10^7$ nodes/edges (and getting bigger) - existing software struggles with it
- [EnsmallemGraph](#)/[Embiggen](#): Performant graph machine learning
- Faster loading, lower memory footprint (10x smaller)
- Scales to **billions** of nodes
- Algorithms: graph convolutional networks, node2vec, TransE (and friends), many more
- Novel graph ML algorithms in development
- Other possible graph ML experiments on Monarch KG:
 - learn “vector” for drug \rightarrow disease in latent space, find candidate drugs for untreatable diseases
 - find causal genes for rare/orphan diseases

Embedding of Monarch KG in ~ 3 h (node2vec)

Billions of edges

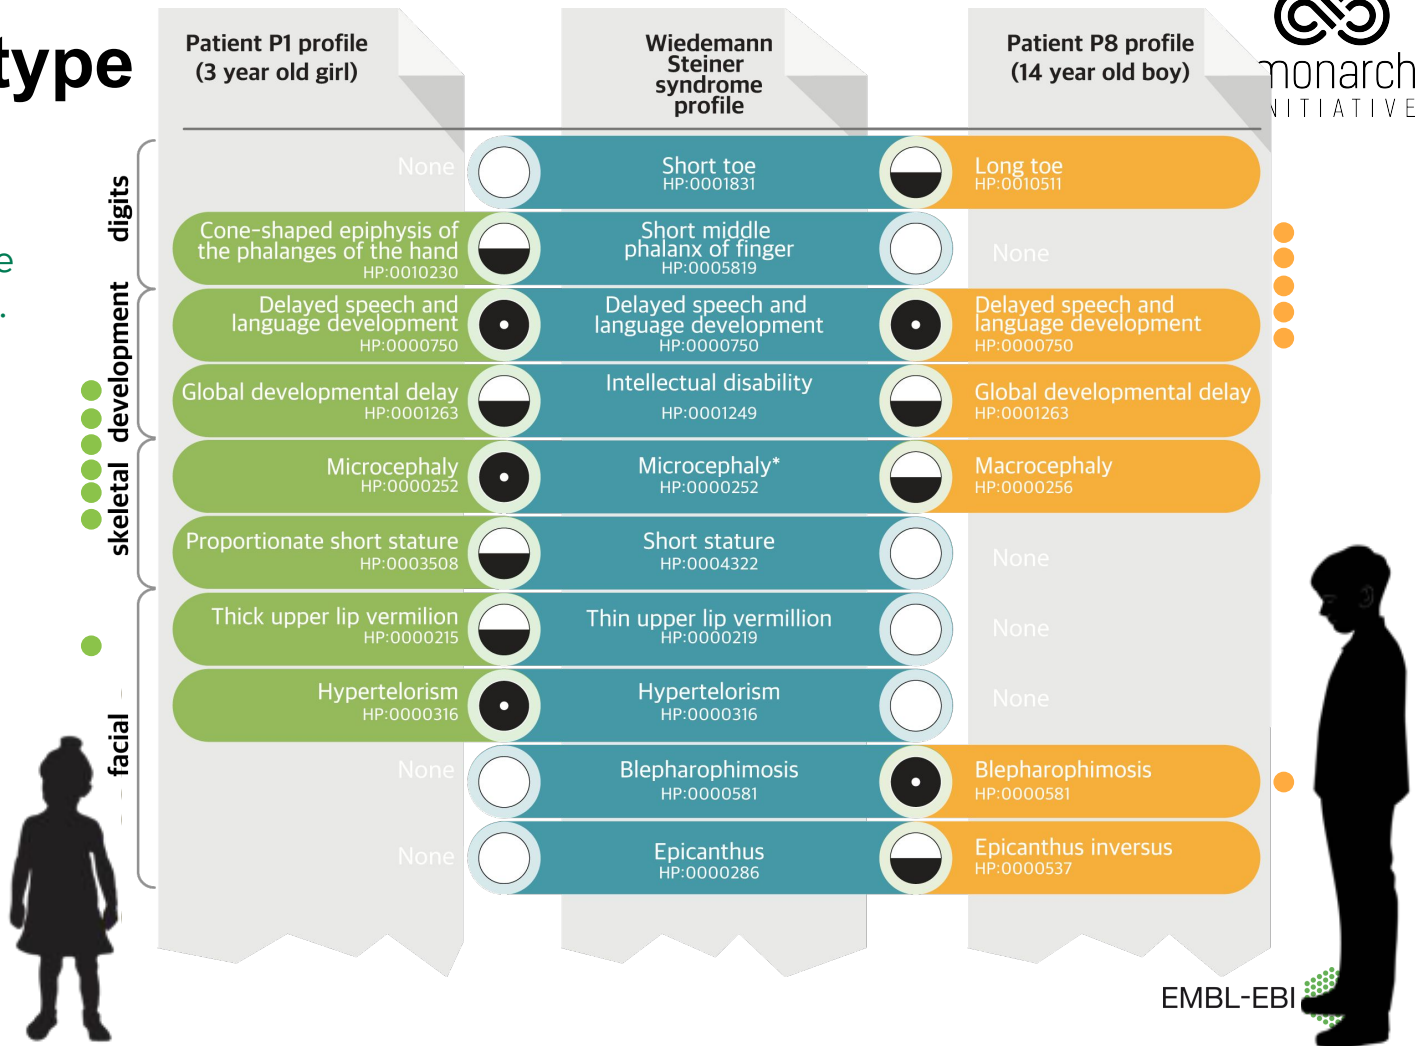

Fuzzy Phenotype Matching

Not same variant, but same disease and gene, KMT2A.

Legend

-  Perfect Match
-  Fuzzy Match

Human Disease:
Hadziselimovic
syndrome

Use Cases

Combining genomic and phenomic data improves variant prioritization for diagnosis

Jessica

- Jessica (age 4) has a rare condition which causes epilepsy, affects her movement and developmental delay. Standard genetics tests negative.
- De novo deletion in *SLC2A1* identified as the cause of her Glut 1 deficiency syndrome
- Exomiser ranked this variant first
- Now being successfully treated with a ketogenic, low-carb diet
- Low risk for future pregnancies

6,414,934
variants in Jessica's

Using phenotype data to inform gene selection for KOMP

7,341 have **no** phenotypes in mouse (MGI). Of these:

- 4,450 **have** phenotypes of interacting proteins in other species
- 4,365 **have** phenotypes of interacting proteins in mice
- 3,748 have **no** phenotypes in human*
- 1,626 **have** phenotypes in other species
- 1,119 have **no** phenotypes in **any** species AND no phenotypes in any interaction partners
- 620 **have** human phenotype or disease ass'n

Number of genes NOT in KOMP/IMPC that satisfy constraints

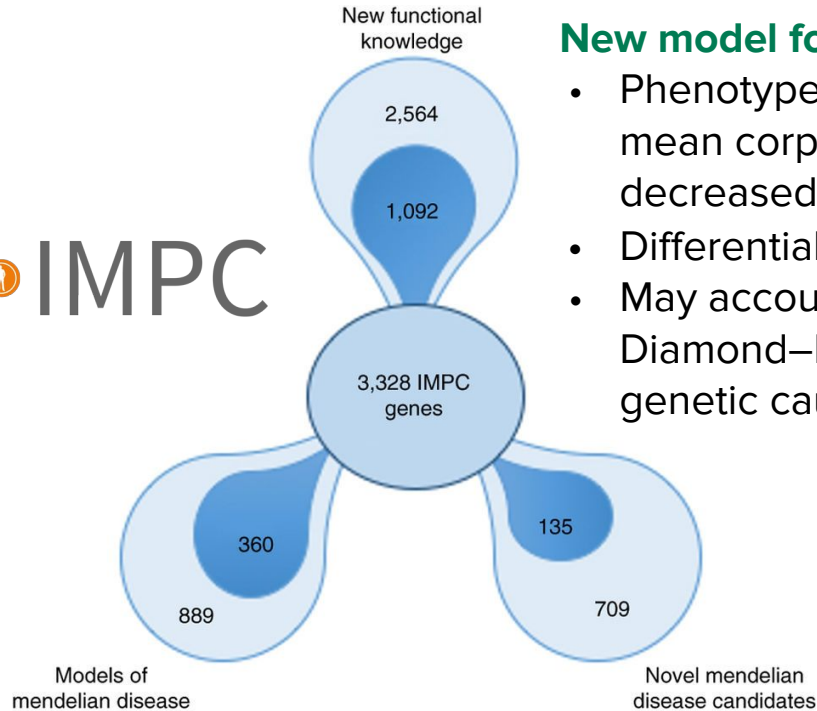

Number of genes	13,432	7,341	4,450	4,365	3,748	1,626	1,119	620	170	8
Mouse (MGI) phenotypes		N	N	N	N	N	N	N	N	N
Ortholog phenotypes (incl human & human gwas)						Y	N		Y	Y
Human ortholog has disease ass'n							N		Y	Y
Human ortholog has pheno ass'n (incl gwas)					N	N	N	Y	Y	N
Human ortholog has gwas ass'n					N	N	N		Y	N
Nonhuman ortho has pheno ass'n							N		Y	Y
Mouse interacting protein has pheno				Y			N		Y	Y
Ortholog interacting protein has pheno		Y					N		Y	Y

Product pipeline

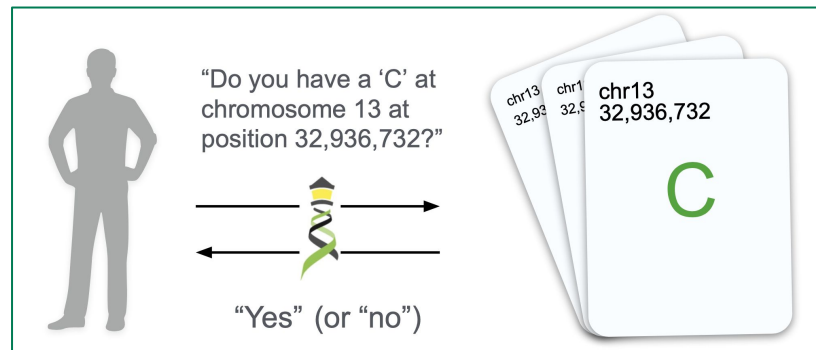

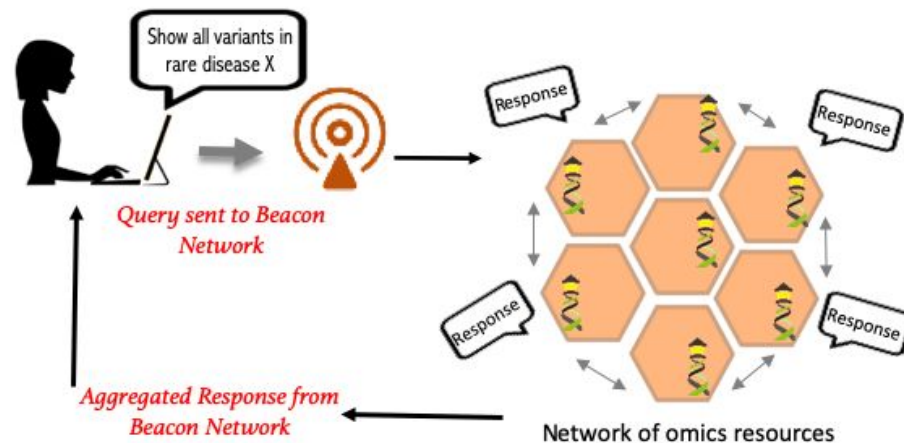

GA4GH Beacon Standard

A. "Beaconize" -omics dataset

B. Exchange of information

GA4GH Beacon Standard

Global Alliance
for Genomics & Health

Collaborate. Innovate. Accelerate.

Have you seen deletions in this region on chromosome 9 in Glioblastomas from a juvenile patient, in a dataset with unrestricted access?

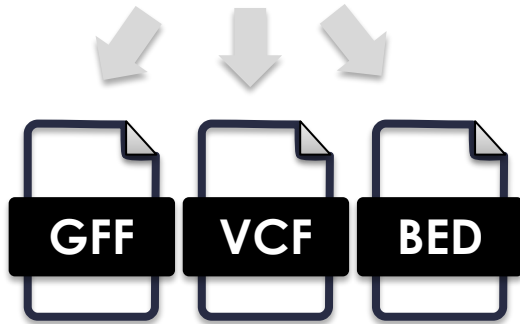

Beacon v2 API

The Beacon API v2 proposal opens the way for the design of a simple but powerful "**genomics API**".

Standard exchange formats exist for sequence/genomes but not for phenotypes

Global Alliance
for Genomics & Health
Collaborate. Innovate. Accelerate.

We need a standard way to share case-level phenotypic information that is not free text, a candidate diagnosis proxy, nor full EHR data exported via PDF

Phenopackets can help us do better

- Craniosynostosis
- Brachydactyly
- Proptosis
- Broad thumb...

Were they  NOT observed?

How are these linked to a patient?
To genomic info?
To samples?
To parents and siblings?

When were they first observed? 

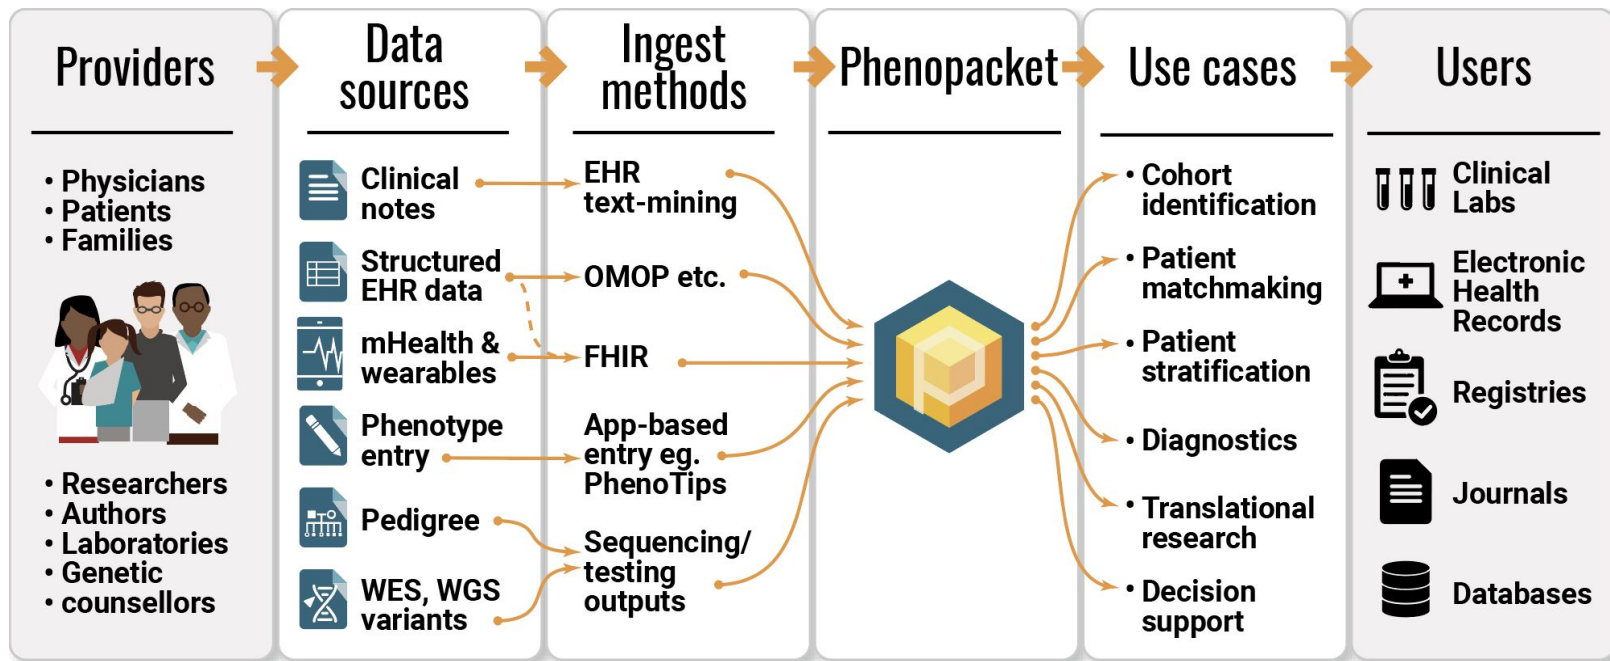

How severe are these? 
Are some more severe than others?

The Phenopacket Ecosystem: Users and use cases

Global Alliance
for Genomics & Health

Global Alliance
for Genomics & Health
Collaborate. Innovate. Accelerate.

A 6-month-old girl conceived by in vitro fertilization (IVF) (own oocytes and anonymous donor sperm) was admitted to the hospital because of **leukocoria** and **strabismus**. Past medical history and physical examination were unremarkable except for **clinodactyly of the right fifth finger**. Indirect ophthalmoscopic examination and examination under anesthesia was performed by ophthalmologists. **Orbital ultrasound** and **magnetic resonance imaging** (MRI) scans showed a **14 × 13 × 11 mm left eye tumor** located in the lower-external retinal side. **Retinal detachment** was also detected. Diagnosis of **retinoblastoma** was made and, based on International Classification for Intraocular Retinoblastoma, a grade E was established.

Gargallo, P., Oltra, S., Balaguer, J. et al.
Retinoblastoma and mosaic 13q deletion: a case

Phenopackets-FHIR Implementation Guide

Global Alliance
for Genomics & Health
Collaborate. Innovate. Accelerate.

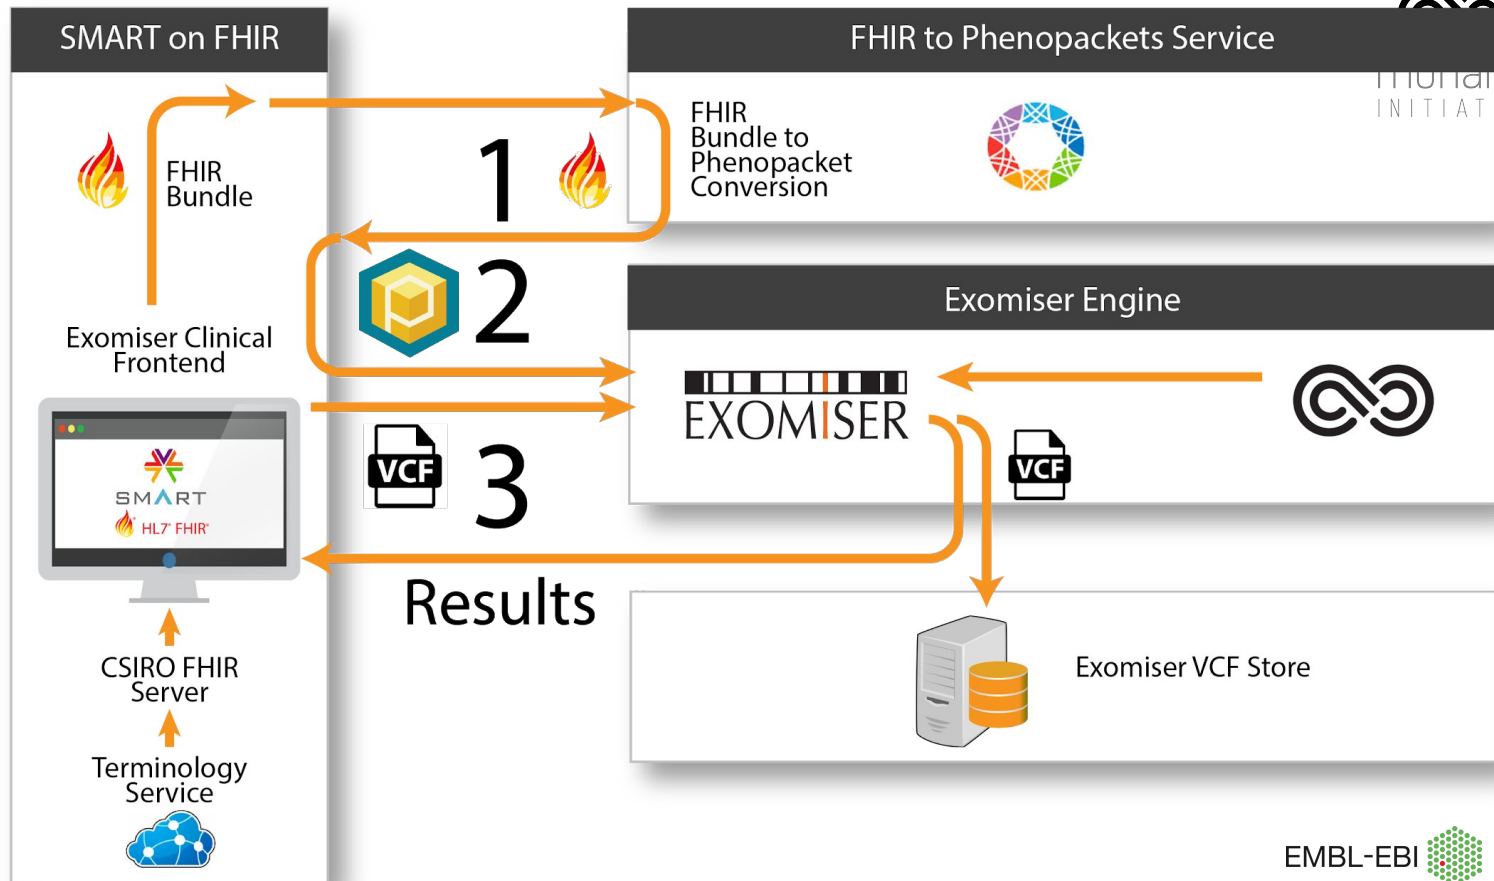

Overall Goal:

Increase availability of high-quality standardized phenotypic information for genomic research and genomic medicine

- Represent the contents of the clinical phenotype profile of a patient, as defined in the Phenopackets schema (including association with pedigree and variant/genome information), in the FHIR structure.
- Allow non-lossy exchange of clinical information between Phenopackets and FHIR structures.
- Include references to existing and/or novel FHIR resources and profiles.

Example System Architecture

Phenopackets-FHIR IG: Objectives

- Leverage what our team has already developed for FHIR IG
- Map Phenopackets schema elements to FHIR Resources
- EHR interoperability
- Evaluation in different infrastructure systems:
 - biobanks, registries, journals

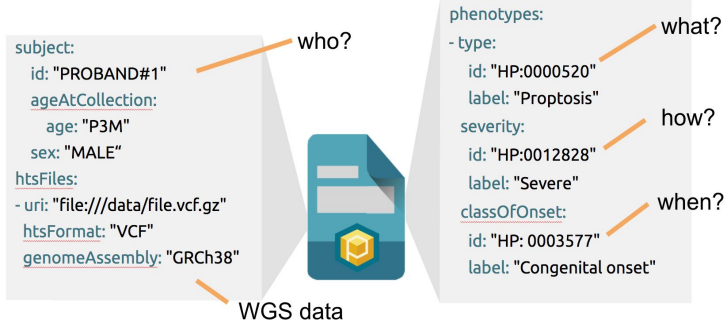

Phenopackets-FHIR IG: Approach

1. Community organization: governance, communications
2. Workflow for collaborative review of current Phenopackets-FHIR mappings
3. Collaborative development of Phenopackets FHIR extensions
4. Pilot Testing
 - a. Engaging candidate pilot test sites: GRIN participants
 - b. Designing and implement testing plan: mappings, testing message round trip
 - c. Pilot use cases: rare diseases, oncology.

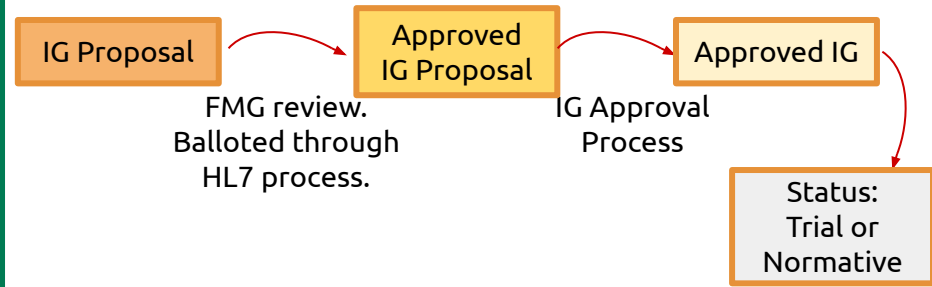

Turning Phenopackets into FHIR is a big endeavour

Ontology Xref Service

OxO Documentation About

Welcome to the EMBL-EBI Ontology Xref Service (OxO).

OxO is a service for finding mappings (or cross-references) between terms from ontologies, vocabularies and coding standards. OxO imports mappings from a variety of sources including the [Ontology Lookup Service](#) and a subset of mappings provided by the [UMLS](#). We're still developing the service so please [get in touch](#) if you have any feedback.

Mapping results

Complete!

Download

Select a term to see more information. The evidence column tells you how many times we have seen this mapping and the distance is how many hops across other mappings you need to go to find this mapping. Distance 1 is a direct mapping, the greater the distance the less likely it is that a mapping holds true. Max distance is set to 2.

Showing 1 to 27 of 27 entries

Search:

Input	Mapped Id	Id source	Evidence	Distance

Query

Use the text box to find possible ontology mappings for free text terms in the ZOOMA repository of curated annotation knowledge. You can add one term (e.g. 'Homo sapiens') per line. If you also have a type for your term (e.g. 'organism'), put this after the term, separated by a tab. If you are new to ZOOMA, take a look at our getting started guide.

[Show me some examples...](#)

Bright nuclei
Agammaglobulinemia 2 phenotype
Reduction in IR-induced 53BP1 foci in HeLa cell
Impaired cell migration with increased protrusive activity phenotype
C57Black/6 strain
nuclei stay close together
Retinal cone dystrophy 3B disease
segregation problems/chromatin bridges/lagging chromosomes/multiple DNA masses
Segawa syndrome autosomal recessive phenotype
BRCA1 gene
Deafness, autosomal dominant 17 phenotype
cooked broccoli compound

Datasources

ZOOMA maps text to ontology terms based on curated mappings from selected datasources (more preferred), and by searching ontologies directly (less preferred). Here, you can select which curated datasources to use, optionally ranked in order of preference. You can also select which ontologies to search directly.

e.g. Marfan Syndrome Multicystic kidney dysplasia SHH

Marfan syndrome MONDO:0007947

Marfan's syndrome, MFS, Marfan syndrome, MARFAN SYNDROME, MFS

Overview

Marfan syndrome is a disorder of the connective tissue. Connective tissue provides strength and flexibility to structures throughout the body such as bones, ligaments, muscles, walls of blood vessels, and heart valves. Marfan syndrome affects most organs and tissues, especially the skeleton, lungs, eyes, heart, and the large blood vessel that distributes blood from the heart to the rest of the body (the aorta). It is caused by mutations in the *FBNI* gene, which provides instructions for making a protein called fibrillin-1. Marfan syndrome is inherited in an autosomal dominant pattern. At least 25% of cases are due to a new (de novo) mutation. Treatment is based on the signs and symptoms in each person.

Key Features

Heritability: Autosomal dominant inheritance

SCIENTIFIC DATA

OPEN Comment: The FAIR Guiding Principles for scientific data management and stewardship

SUBJECT CATEGORIES

- » Research data
- » Publication characteristics

Mark D. Wilkinson *et al.*^a

Received: 10 December 2015
Accepted: 12 February 2016
Published: 15 March 2016

There is an urgent need to improve the infrastructure supporting the reuse of scholarly data. A diverse set of stakeholders—representing academia, industry, funding agencies, and scholarly publishers—have come together to design and jointly endorse a concise and measurable set of principles that we refer to as the FAIR Data Principles. The intent is that these may act as a guideline for those wishing to enhance the reusability of their data holdings. Distinct from peer initiatives that focus on the human scholar, the FAIR Principles put specific emphasis on enhancing the ability of machines to automatically find and use the data, in addition to supporting its reuse by individuals. This Comment is the first formal publication of the FAIR Principles, and includes the rationale behind them, and some exemplar implementations in the community.

Supporting discovery through good data management

Good data management is not a goal in itself, but rather is the key conduit leading to knowledge discovery and innovation, and to subsequent data and knowledge integration and reuse by the community after the data publication process. Unfortunately, the existing digital ecosystem surrounding scholarly data publication prevents us from extracting maximum benefit from our research investments (e.g., ref. 1). Partially in response to this, science funders, publishers and governmental agencies are beginning to require data management and stewardship plans for data generated in publicly funded experiments. Beyond proper collection, annotation, and archival, data stewardship includes the notion of ‘long-term care’ of valuable digital assets, with the goal that they should be discovered and re-used for downstream investigations, either alone, or in combination with newly generated data. The outcomes from good data management and stewardship, therefore, are high quality digital publications that facilitate and simplify this ongoing process of discovery, evaluation, and reuse in downstream studies. What constitutes ‘good data management’ is, however, largely undefined, and is generally left as a decision for the data or repository owner. Therefore, bringing some clarity around the goals and desiderata of good data management and stewardship, and defining simple guideposts to inform those who publish and/or preserve scholarly data, would be of great utility.

This article describes four foundational principles—Findability, Accessibility, Interoperability, and Reusability—that serve to guide data producers and publishers as they navigate around these obstacles, thereby helping to maximize the added-value gained by contemporary, formal scholarly digital publishing. Importantly, it is our intent that the principles apply not only to ‘data’ in the conventional sense, but also to the algorithms, tools, and workflows that led to that data. All scholarly digital research objects—from data to analytical pipelines—benefit from application of these principles, since all components of the research process must be available to ensure transparency, reproducibility, and reusability.

There are numerous and diverse stakeholders who stand to benefit from overcoming these obstacles: researchers wanting to share, get credit, and reuse each other’s data and interpretations; professional data publishers offering their services; software and tool-builders providing data analysis and processing services such as reusable workflows; funding agencies (private and public) increasingly

Correspondence and requests for materials should be addressed to B.M. (email: baren.moss@dtits.nl).
^a A full list of authors and their affiliations appears at the end of the paper.

SCIENTIFIC DATA | 3:160018 | DOI: 10.1038/sdata.2016.18

What does FAIR data mean practically?

Findability

Resource and its metadata are easy to find by both, humans and computer systems. Basic machine readable descriptive metadata allows the discovery of interesting data sets and services.

Accessibility

Resource and metadata are stored for the long term such that they can be easily accessed and downloaded or locally used by humans and ideally also machines using standard communication protocols.

Interoperability

Metadata should be ready to be exchanged, interpreted and combined in a (semi)automated way with other data sets by humans as well as computer systems.

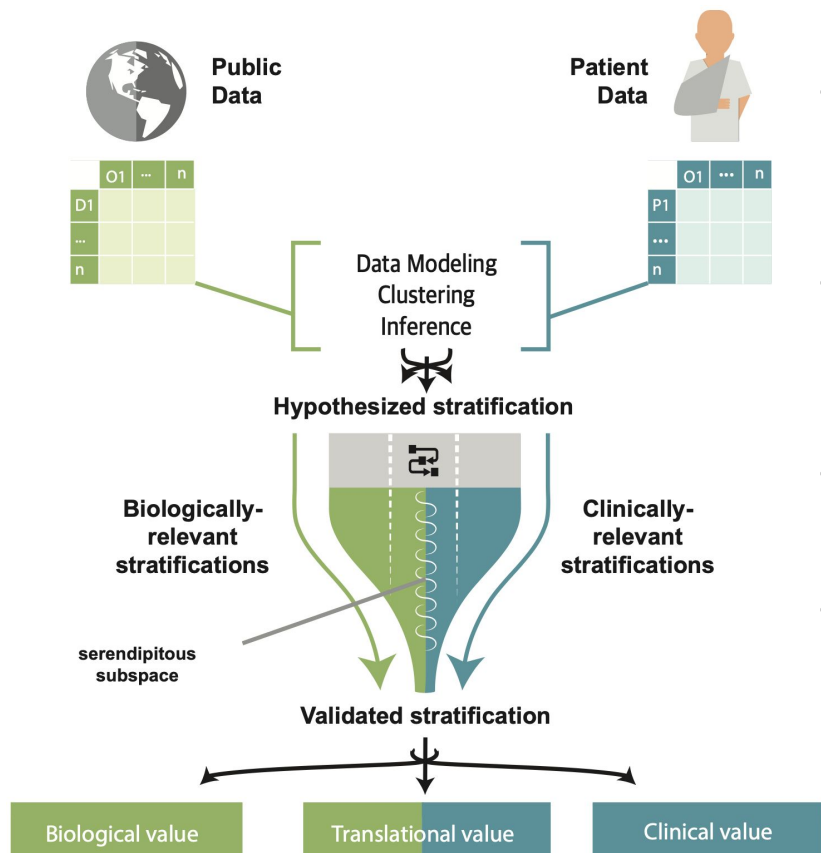

Reusability

Data and metadata are sufficiently well-described to allow data to be reused in future research, allowing for integration with other compatible data sources. Proper citation must be facilitated, and the conditions under which the data can be used should be clear to machines

- Use of appropriate identifiers, versioning and deprecation
- Use and reuse of community-developed and maintained ontologies
- Use of appropriate retrieval mechanisms (preferably REST)

Takeaways

- Semantics can help cross the “chasm of semantic despair” and support more meaningful patient classification
- Realizing standardized and computable phenotypic data akin to genomic data has revolutionized diagnostics and discovery
- Dynamic interplay between public data and clinical/patient-level data
- Combining clinical and basic research data supports new hypotheses, mechanism discovery, and better treatment management
