26

27 **Abstract**

28 The objective of the study was to describe the etiology, epidemiology, and clinical
29 characteristics of the principal causes of acute infectious diarrhea requiring hospitalization
30 among children under 5 years of age in Rabat, Morocco. A prospective study was conducted
31 from March 2011 to March 2012, designed to describe the main pathogens causing diarrhea
32 in hospitalized children >2 months and less than 5 years of age. Among the 122 children
33 included in the study, Enteroaggregative *E. coli* (EAEC) and rotavirus were the main
34 etiologic causes of diarrhea detected. Twelve (9.8%) children were referred to the intensive
35 care unit, while 2, presenting infection by EAEC and EAEC plus a *Shigella sonnei*
36 respectively, developed a hemolytic uremic syndrome. Additionally, 6 (4.9%) deaths
37 occurred with EAEC being isolated in four of these cases. Diarrheogenic *E. coli* and rotavirus
38 play a significant role as the two main causes of severe diarrhea while other pathogens such
39 as norovirus or parasites seem to have a minimal contribution. Surveillance and prevention
40 programs to facilitate early recognition and improved management of potentially life-
41 threatening diarrhea-episodes are needed.

42

43 **Introduction**

44 Diarrheal disease remains a major contributor to illness and death among children less than
45 five years of age in low and middle-income countries, and is also a relevant cause of
46 morbidity among international travelers to these areas (Liu *et al.*, 2012). Indeed, pediatric
47 diarrheal disease still accounts for >800,000 deaths per year globally (*circa* 11% of the 7.6
48 million estimated annual global child deaths) (Lanata *et al.*, 2013; Liu *et al.*, 2012).
49 Nonetheless, diarrhea-associated mortality is decreasing globally by about 4% yearly;
50 however, the decline in incidence is modest (Levine *et al.*, 2012; Liu *et al.*, 2012;). It is
51 considered that yearly diarrhea accounts for approximately 2.5 billion cases in children less
52 than five years (WHO/UNICEF, 2009), affecting up to 60% of travelers to some low-income
53 areas (Gascón, 2006; Ruiz *et al.*, 2007; WHO/UNICEF, 2009). Additionally, different
54 diarrhea-related severe sequelae have been described, including Guillain-Barré syndrome,
55 hemolytic uremic syndrome (HUS) or reactive arthritis (Fischer Walker *et al.*, 2013). In low
56 and middle income countries, in which children may have several episodes/year, diarrhea
57 may lead to nutritional deficits and subsequent growth stunting and decreased cognitive
58 function (Fischer Walker *et al.*, 2013). Regarding Morocco in 2009, one study of 2009
59 (Oudaïna *et al.*, 2009) showed that stature-ponderal delay was related to the presence of
60 diarrheogenic parasites in at least 1 of each 6 children. These high levels of disease burden
61 can also be translated into economical costs which affect the healthcare systems and also
62 represent a relevant household economic burden, which is of special relevance in developing
63 areas in which access to inexpensive treatments is difficult (Patil *et al.*, 2002; Rheingans *et*
64 *al.*, 2012). These costs are also reflected in social inequities, with a trend towards lower costs
65 related to diarrhea in poorer households, which in some countries may often more frequently
66 affect girls and subsequently result in an increased risk of death (Rheingans *et al.*, 2012).

67 Regarding Morocco, in 2011, 132,000 children less than five years of age were reported to
68 have different degrees of dehydration associated with diarrhea. Of these, circa 23,000
69 (17.5%) were from the Rabat-Salé-Zemmour-Zair region, especially from urban areas (75.5%
70 of the cases). Additionally, at a national level, 7,247 dysentery cases were reported in 2011,
71 of which 320 were from the Rabat-Salé-Zemmour-Zair region, mostly (315 cases, 98.5%)
72 from urban areas (Ministère de la Sante, 2012).

73 A series of pathogens, including bacteria, parasites and viruses, may act as the etiological
74 cause of this illness (Mandomando *et al*, 2007, Vargas *et al*, 2004). Nonetheless, the
75 etiological agents of diarrhea vary greatly depending on the geographical origin. In addition,
76 the clinical relevance of each specific pathogen also differs (Kotloff *et al*, 2013; Lanata *et al*,
77 2013; Pons *et al*, 2014; Prere *et al*, 2006) and, thus, a clear understanding of the prevalent
78 locally-specific etiologies is essential for the design of specific prevention and control
79 measures targeting the main causes.

80 Although some data on the etiological causes of diarrhea in some Northern Africa countries
81 are available (Al-Gallas *et al*, 2007; Hassine-Zaafrane *et al*, 2011; Hassine-Zaafrane *et al*,
82 2013; Sdiri-Loulizi *et al*, 2009; Sdiri-Loulizi *et al*, 2011), little is known about the etiology
83 and epidemiology of diarrhea in Morocco. The latest estimates suggest that diarrhea may be
84 responsible for the death of 36 per 1000 live births annually in Morocco (WHO/UNICEF,
85 2009). However, the few data available regarding the main etiological causes of diarrhea in
86 Morocco are fragmented, and mainly focused on rotavirus, in relation to the introduction of
87 the rotavirus vaccine (Rotarix®) in the year 2010 (Benhafid *et al*, 2012). Data regarding other
88 pathogens are scarce and mostly outdated. The relevance of *Giardia intestinalis* and
89 *Entamoeba histolytica* infections as a cause of diarrhea in this country has also been shown.
90 Thus, a report analyzing 4285 cases of diarrhea showed that these two parasites might
91 altogether account for more than 50% of positive parasite-associated cases (El Guamri *et al*,

92 2009). Local data about the presence of diarrheogenic bacteria in different food products can
93 also be found (Bennani *et al*, 2011), and specific data regarding infections by *Salmonella* spp.
94 have also been published (Ammari *et al*, 2009). However, a comprehensive description of the
95 epidemiology and etiology of diarrhea in Morocco remains to be performed.

96 Thus, the main aim of this study was to describe the etiology, epidemiology, and clinical
97 characteristics of the principal causes of acute infectious diarrhea requiring hospitalization
98 among children less than 5 years of age in a referral pediatric hospital in Rabat, Morocco.

99

100 **Materials and methods**

101 **Site description**

102 This prospective study was conducted in the Gastrointestinal Diseases and Emergency
103 Departments at the *Hôpital d'Enfants de Rabat* (HER) in Rabat (Rabat-Salé-Zemmour-Zair
104 region, Morocco). The HER is the only tertiary pediatric hospital in the Rabat-Salé-
105 Zemmour-Zair region but also attends infants from other Moroccan regions (especially from
106 the north of the country). Thus, in 2011 the HER received 120,771 outpatients visits, with
107 18,471 hospital admissions (Ministère de la Sante, 2012)..

108 In 2011 the population of the country was reportedly of 32,187,000 inhabitants, 2,872,000 of
109 whom were children (8.9%) under the age of 5 years, and 506,000 children (1.6%) were less
110 than 1 year of age (Ministère de la Sante, 2012), The population of the Rabat-Salé-Zemmour-
111 Zair region was 2,695,000 inhabitants, mostly in the urban area of Rabat (2,270,000 persons,
112 84.2%), which included 225,000 children under 5 years of age (Ministère de la Sante, 2012).

113

114 **Study population**

115 The study included children >2 months and less than 5 years of age attending the HER from
116 March 2011 to March 2012, with a primary diagnosis of acute diarrhea, defined as three or
117 more abnormally loose or liquid stools in the previous 24 hours, having begun during the
118 seven days prior to admission to the hospital, with no other known cause of illness, and for
119 whom diarrhea was the principal cause of hospital admission. Diarrhea cases due to chronic
120 ongoing previously diagnosed gastrointestinal diseases were excluded. Likewise, outpatients
121 were not included for not fulfilling the severity inclusion criteria.

122 Children fulfilling the inclusion criteria and whose parents had signed an informed consent
123 underwent standardized procedures. Demographic, socio-economic and clinical data
124 (including evolution during admission and outcome) were routinely collected following a

125 standardized questionnaire and subsequently double entered using a program written in
126 Filemaker Pro 12 (Filemaker inc., Santa Clara, CA, USA). Treatment of the diarrhea episodes
127 and other related diagnoses was done according to national guidelines and decided by
128 hospital clinicians. Antibiotic therapy was reassessed according to culture results and
129 susceptibility patterns.

130 The rotavirus vaccination status was established either by direct revision of vaccination
131 documents or, in the absence of these documents, by asking the parents / guardians.

132 The study protocol was approved by the Ethics Committees of the Hospital Clinic
133 (Barcelona, Spain) and by the Institutional Review Board (Comité d'Éthique de la recherche
134 Biomédicale) of the Faculty of Medicine in Rabat (Morocco).

135

136 **Case Definitions**

137 All case definitions were based on data obtained at admission from standardized study
138 questionnaires. Fever was defined as an axillary temperature of ≥ 37.5 °C, and hyperpyrexia
139 implied a temperature ≥ 39 °C (Guinovart *et al*, 2008). Nutritional status was based on
140 weight-for-age Z scores (WAZ), calculated using the least mean square method and the 2000
141 CDC Growth Reference (Kuczmarski *et al*, 2002). Dehydration status was established
142 according to standard WHO criteria (WHO, 2005). Dehydration was considered moderate
143 when estimated between 5-10% and severe if $>10\%$ (Stoll *et al*, 1982).

144 The minimum community based incidence rates of diarrhea were estimated using the Rabat-
145 Salé-Zemmour-Zair region population as described elsewhere (Kotloff *et al*, 2013).

146

147 **Sample collection:**

148 At enrolment at least 5 ml or 5 gr of stool were collected from each patient by
149 either collection in a waxed cardboard container at the time of defecation or from
150 the diaper if applicable. All samples were processed within a maximum of 12
151 hours after collection. Additionally, 1 to 2 ml of venous whole blood was
152 collected on admission for biomarker evaluations.

153

154 **Biomarker determinations:**

155 Procalcitonine (PCT) and C-reactive protein (CRP) levels were determined using
156 miniVIDAS®, (Biomerieux, Marcy-l'Etoile, France) and Microlab 300, respectively.

157

158 **Bacterial culture**

159 In order to search for the presence of *Shigella* spp., *Salmonella* spp., *Campylobacter* spp.,
160 *Vibrio cholerae*, *Yersinia* spp., *Aeromonas* spp. and diarrheogenic *Escherichia coli*, feces
161 were cultured in different media (McConkey, Campylobacter agar, Blood agar, Salmonella
162 Shigella (SS) agar, Xylose Lysine Deoxycholate (XLD) agar, Cefsulodin-Irgasan-Novobiocin
163 (CIN) agar and Thiosulfate-Citrate-Bile Salts-sucrose (TCBS) agar. Bacterial isolates were
164 identified based on growth in the aforementioned media (e.g.: *Salmonella* spp. and *Shigella*
165 spp. were recovered from McConkey, XLD and SS agar; *E. coli* from Mac Conkey agar;
166 *Campylobacter* spp. from Campylobacter agar; while TCBS was used to detect the presence
167 of *Vibrio* spp., CIN to isolate *Yersinia* spp., and Blood agar to isolate *Aeromonas* spp.) and by
168 colony morphology, conventional biochemical techniques (Murray *et al*, 2007) or by an
169 automated system (Phoenix™ 100, Becton Dickinson, Loveton Circle Sparks, USA).

170

171 **Detection of diarrheogenic *E. coli* strains:**

172 Diarrheogenic strains of *E. coli* (Enteroaggregative *E. coli* - EAEC; Enteropathogenic *E. coli*
173 - EPEC; Enterotoxigenic *E. coli* - ETEC; Diffusely Adherent *E. coli* - DAEC; Enteroinvasive
174 *E. coli* - EIEC; Enterohemorrhagic *E. coli* - EHEC) were detected by RT multiplex PCR using
175 the primers and methodology described by Guion *et al* (2008).

176

177 **Parasite identification:**

178 The fecal material obtained from the patients was concentrated using the Ritchie technique,
179 and then stained following the modified Ziehl Neelsen staining procedure in order to detect
180 *Cryptosporidium* spp. (Bailenger, 1973; Tligui & Agoumi, 2006). The presence of *Giardia*
181 spp. and *Entamoeba histolytica* was determined by microscopy using the Bailenger technique
182 (Bailenger, 1973; Bourée, 1994).

183

184 **Virus detection:**

185 Nucleic acid for viral studies was extracted using a commercial kit (MagMax™ Total nucleic
186 acid Isolation, Applied Biosystems, Foster City, USA). Detection and genotyping of rotavirus
187 was performed following the procedures by Rodriguez *et al.* (2009). Detection of Sapovirus,
188 Norovirus and Astrovirus was done using the primers described by Yan *et al.* (2003) with a
189 multiplex RT-PCR using the standard conditions described in a commercial kit (Super-script
190 III One step RT-PCR; Invitrogen, Genome Biotechnologies, Casablanca, Morocco). The
191 presence of Hepatitis A was established in a monoplex RT-PCR as previously described
192 (Sanchez *et al.* 2002).

193

194 **Results**

195 During the 13 month-long study period, 852 out of the 11,799 children (7.3%) attending the
196 Pediatric Emergency Department of the Hôpital *d'Enfants* in Rabat presented with acute
197 gastro-intestinal symptoms, resulting in a minimum community based incidence rate of
198 diarrhea in the region of Rabat-Salé-Zemmour-Zair of 0.35 episodes/100 child-year. Of these,
199 720 (84.5%) were seen as outpatients and did not require admission, while 132 children
200 fulfilling enrolment criteria and were recruited for the study showing a minimum community
201 based incidence rates of moderate to severe diarrhea in the Rabat-Salé-Zemmour-Zair region
202 of 0.06 episodes/100 child-year. Ten patients were discharged prior to obtaining all the
203 necessary samples, and thus, 122 children were finally included in the analysis (Figure 1).

204 Diarrhea cases were predominantly seen (73/122; 59.8%) during the cold season (January-
205 March). The mean age of the children recruited was 16.5 months (range 2.4 to 54.2), with a
206 predominance of males (53.3%). Diarrhea episodes had a median duration of 4 days (IQR 1-
207 5), and 103 (84.4%) children presented fever and 108 (88.5%) vomiting. Parents of 29 out of
208 the 122 (23.8%) patients referred pre-admission usage of antibiotics, mainly β -lactam (12
209 cases) and cotrimoxazole (12 cases). Malnutrition was common among the study population,
210 with over half of the patients recruited (52.4%) showing some degree of malnutrition
211 (WAZ<-1) and almost 15% of the patients being severely malnourished (WAZ< -3). Other
212 relevant clinical and demographic data are presented in Table 1.

213 A total of 12 (9.8%) children were referred to the intensive care unit (ICU), while 2,
214 presenting EAEC and EAEC plus a *Shigella sonnei* infection, respectively, developed a HUS.
215 Six out of these 12 children (50%) died, representing 4.9% of the total number of children
216 recruited. In four out of these six cases, EAEC infection (one coexisting with an astrovirus)
217 was identified. The final diagnosis obtained by the study clinicians after review of the whole
218 hospitalization file in cases who died corresponded to acute gastroenteritis/diarrhea (4 cases),

219 acute renal failure (one patient with prolonged hospitalization of 14 days) and disseminated
220 intravascular coagulation (DIC, one case). Importantly, neurological abnormalities
221 (convulsions and/or impaired consciousness) were of note during these diarrhea episodes
222 ending in death (table 2).

223 Regarding specific infection biomarkers, 57.0% and 29.0% of the patients with available
224 results (n=100) presented increased levels of PCT or CRP, respectively. The mean PCT value
225 was significantly higher in patients with bacterial infection (18.0) compared to the mean
226 value of patients with viral infection (2.0; $p < 0.001$). However, the mean CRP value was
227 comparable in both bacterial and viral infections, being below the threshold defined as
228 elevated in both cases (0.05 g l^{-1}). Interestingly, patients in whom neither viruses nor bacteria
229 were isolated from stools, showed the highest CRP and PCT levels (Table 3).

230 At least one pathogen was isolated in 89 out of the 122 fecal samples (73.0%). The most
231 frequent etiological agents were diarrheogenic *E. coli* (71 isolates, 58.2%), rotavirus (21,
232 17.2%,) belonging to genotypes G1P8: 16 (76.2%); G3P9: 4 (19.0 %) and G8P9: 1(4.8%);
233 and *Shigella* spp. (8, 6.5%) (Table 4). Co-infections were frequent and present in 25 (20.5%)
234 of the patients, including rotavirus and *E. coli* (EAEC) (7 cases, 28%), and rotavirus and *E.*
235 *coli* (DAEC) (3 cases, 12%) as the most frequent combinations, while three or more
236 pathogens were recovered in another two patients (Table 5).

237 The most frequent diarrheogenic *E. coli*, included EAEC (47 cases; 38.5%), followed by
238 DAEC (15; 12.3%), EPEC (7; 5.7%), ETEC (2; 1.6%), and two (1.6%) isolates presented
239 both the EAEC and DAEC characteristics. Neither EHEC nor EIEC were isolated.

240 Thirty-eight out of the 122 children (31.1%) had received at least one dose of the currently
241 implemented rotavirus vaccine (Rotarix®). Six had received three doses, while 17 had
242 received two doses and 15 reported to have received only one dose of the vaccine. The
243 remaining 84 children recruited were not vaccinated or vaccination data was not documented.

244 Rotaviruses in feces were mainly recovered (14 cases, 66.7 %) from children apparently not
245 vaccinated or for whom data were unavailable. However, rotavirus infections were also
246 detected in children with partial or complete rotavirus vaccination: 2 cases in patients having
247 received 1 dose; 5 further cases in children having received 2 doses; and 1 case in a child
248 reporting three doses (Table 6). Finally, rotavirus infections seemed to show a clear
249 seasonality, being mostly detected during the cold season (Figure 2).

250

251 **Discussion**

252 Diarrhea remains a relevant cause of childhood morbidity and mortality in Morocco, as
253 previously suggested by the scarce reports available from this country or from the Maghreb
254 area (Bourrous *et al.*, 2010; INSPA, 2005). Indeed, while diarrhea-related admissions were
255 relatively uncommon in this hospital (only 122 cases during a 13-month period), mortality
256 associated with this syndrome in Rabat was high (6 deaths, 4.9%), especially when compared
257 to the recent results of a large multicenter study on the global etiology of diarrhea showing a
258 varying range of diarrhea-attributable case fatality rates (from 0.13% in India to 7.5 in
259 Mozambique, with a mean of 2%) (Kotloff *et al.*, 2013). In four out of these six deaths,
260 diarrheogenic *E. coli* (3 EAEC, 1 DAEC) was detected in feces. Despite attributing causality
261 to these microbiological findings, the determination of the precise cause of death in these
262 patients is challenging and may be inappropriate without adequate post-mortem confirmation,
263 and without thorough exclusion of other potential co-morbidities. On the other hand the role
264 of diarrheogenic *E. coli* as a cause of child mortality has been robustly documented and
265 reported elsewhere (Kotloff *et al.*, 2013; Lanata *et al.*, 2013; Nataro *et al.* 1998).

266 Two cases of HUS were detected as severe complications among children admitted with
267 acute diarrhea. HUS is a severe complication which is often associated with the presence of
268 specific pathogens such as EHEC or *Shigella* spp. (Khan *et al.*, 2013; Fischer Walker *et al.*,
269 2012). In our series no EHEC isolate was found, and in both HUS cases an EAEC isolate was
270 detected, one being associated with *Shigella sonnei* co-infection. Although *Shigella*
271 *dysenteriae* type 1 is, by far, the member of the *Shigella* genus most often implicated in the
272 development of HUS (Fischer Walker *et al.*, 2012), a recent report from Bangladesh
273 confirmed the potential of *S. sonnei* as an etiologic trigger for HUS (Khan *et al.*, 2013).
274 Despite the recent outbreak in Germany involving EHEC/EAEC isolates (Aurass *et al.*,
275 2011), to our knowledge, the role of EAEC as a cause of HUS remains undescribed, and thus,

276 no direct association may be extrapolated from current data. Despite data regarding HUS in
277 middle and low-income countries being scarce, this syndrome is the most relevant cause of
278 acute kidney injury among pediatric populations, especially affecting young children (Hofer
279 *et al.*, 2014). Regarding Morocco, HUS has been described as the second cause of acute
280 infantile renal failure (Bourquia *et al.*, 2002) and, similar to other diarrhea complications, this
281 syndrome contributes to long-term diarrhea-related morbidity. Thus, in some cases HUS may
282 lead to the development of different chronic problems such as long-term hypertension,
283 diabetes mellitus or neurological sequelae among other adverse extrarenal outcomes, as well
284 as different degrees of long-term impairment in renal function. Indeed, around 5% of cases
285 develop chronic renal failure requiring dialysis or kidney transplantation (Spinale *et al.*
286 2013), which in low income countries may lead to death due to the lack of adequate
287 treatment.

288 As anticipated, and in accordance with previous studies having shown the potential of PCT as
289 a predictor of bacterial blood infections (Diez-Padrisa *et al.*, 2012), PCT levels were
290 significantly higher amongst bacteria-related diarrhea cases compared to virus-related
291 diarrheal episodes. The higher levels of PCT observed in diarrhea cases in which no specific
292 pathogen was isolated suggest the presence of unidentified bacteria / parasites more than the
293 presence of viruses.

294 A low number of parasitic infections has been described in studies of etiology of diarrhea in
295 the Maghreb area (Al-Gallas *et al.*, 2007). This low prevalence was confirmed in our series, in
296 which only two parasitic infections (*G. intestinalis*, *E. histolytica*) were detected, being lower
297 than that observed in a previous study performed in the same hospital with identical
298 methodologies, in which a total of 10 *Giardia intestinalis* isolates were detected in a series of
299 63 children (15.9%) with stature-ponderal delay (Oudaïna *et al.* 2009). A possible
300 explanation for the difference in positivity between the 2 studies may be that diarrhea

301 associated with parasites does not require hospitalization, and no parasites were detected in
302 the present series. However, it is likely that the use of molecular techniques for parasite
303 detection would result in a higher detection capacity.

304 The vast majority of the cases of diarrhea described in this report were related to bacterial
305 infections, predominantly caused by diarrheogenic *E. coli*, particularly due to the EAEC and
306 DAEC pathotypes, but also by *Shigella* spp., *Salmonella* spp. and *Campylobacter* spp. The
307 role of EAEC as a relevant cause of pediatric diarrhea has been described worldwide (Kotloff
308 *et al*, 2013; Mandomando *et al*, 2007; Ochoa *et al*. 2009; Vargas *et al.*, 2004). Interestingly,
309 the second most frequent diarrheogenic pathotype of *E. coli* isolated was neither EPEC nor
310 ETEC similar to previous studies (Mandomando *et al*, 2007; Vargas *et al.*, 2004), but rather
311 DAEC. Two *E. coli* isolates presenting mixed characteristics (mixed EAEC/DAEC
312 pathotypes) were detected. The presence of diarrheogenic isolates presenting mixed
313 characteristics of two different pathotypes is not a new finding (Aurass *et al.*, 2011; Ruiz *et*
314 *al.*, 2008). Furthermore, the presence of EAEC/DAEC has recently been described in South
315 America (Garcia *et al*, 2011). This fact is of special concern because it might reflect either the
316 intercontinental spread of new mixed pathotypes, or their parallel evolution in geographically
317 distant areas. The public health risk of such mixed pathotypes was clearly established in the
318 recent Germany EHEC/EAEC outbreak which resulted in approximately 4000 infected
319 persons including more than 900 cases of HUS and 59 deaths (Karch *et al.*, 2012).

320 Rotavirus followed by astrovirus accounted for the majority of viral-related diarrheal
321 episodes. Rotavirus infections were essentially recovered during the coldest months, as
322 described elsewhere (Benhafid *et al*. 2013), even in the same geographical area (Hassine-
323 Zaafrane *et al*, 2011). Rotavirus was the most frequent virus involved in the development of
324 cases of diarrhea, and ranking as the specific second cause of diarrhea after EAEC isolates.
325 Three different genotypes were detected: G1P8, G3P9 and G8P8. While G3P9 and G8P8 are

326 not included in the recently introduced rotavirus vaccine in Morocco, G1P8, the most
327 prevalent genotype detected, is adequately covered by this vaccine (Benhafid *et al.* 2013).
328 The G1P8 genotype was detected in 4 children partially or fully vaccinated. This might be
329 explained by the fact that a low incidence of new cases would be expected in children
330 adequately vaccinated.

331 Although the relevant role of rotavirus and the proportion of cases attributable to astrovirus
332 are in agreement with what has been previously described in the north of Africa (Sdiri-
333 Loulizi *et al.*, 2009), the low incidence of norovirus is in clear disagreement with previous
334 data in the Maghreb area (Hassine-Zaafrane *et al.*, 2013). Thus, no clear explanation is
335 available to explain the lack of norovirus as a cause of pediatric diarrhea in our series. On the
336 other hand, sapovirus has been described as a common cause of mild-to-moderate diarrhea,
337 usually not requiring hospitalization, in Tunisian children (Sdiri-Loulizi *et al.*, 2011) which
338 may explain why so few cases of sapovirus were detected among our series of moderate-to-
339 severe patients with diarrhea requiring admission.

340 To the best of our knowledge, this is the first report providing a comprehensive scenario of
341 the etiological causes of severe pediatric diarrhea in Morocco. Despite some limitations such
342 as the inability to detect some recently described emerging pathogens such as *Campylobacter*
343 *concisus* (Nielsen *et al.*, 2013), this study sets the basis for further research regarding
344 pediatric diarrhea in the area, and advocates for the establishment of adequate hospital-based
345 microbiologic surveillance systems. The low-to-moderate burden of diarrhea-related
346 admissions among Moroccan children, as detected in the HER of Rabat poses, however, a
347 major public health problem, particularly due to the unexpectedly high associated case
348 fatality rates. We have demonstrated the relevant role of diarrheogenic *E. coli* and rotavirus
349 as the two main causes of severe diarrhea in this area, with the lower contribution of other
350 pathogens such as norovirus or parasites being of note. These data call for the implementation

351 of better surveillance and prevention programs, as well as improvement in the early

352 recognition and management of potentially life-threatening episodes of diarrhea.

353

Table 5: Common co-infections in patients with acute diarrhea

Coinfection	cases
Rotavirus - <i>E. coli</i> (EAEC)	7
Rotavirus - <i>E. coli</i> (DAEC)	3
<i>E. coli</i> (EAEC)- <i>Shigella</i>	3
<i>E. coli</i> (EAEC)- <i>Campylobacter</i>	3
<i>E. coli</i> (EAEC)- <i>Salmonella</i>	2
Astrovirus - <i>E. coli</i> (EAEC)	2
Rotavirus- <i>E. coli</i> (EPEC)	2
Astrovirus- <i>E. coli</i> (DAEC)	1
Norovirus- <i>E. coli</i> (EAEC)	1
<i>E. coli</i> (DAEC)- <i>Campylobacter</i>	1
Hepatitis A- <i>E. coli</i> (EPEC)	1
Rotavirus- <i>E. coli</i> (EAEC)- <i>Campylobacter</i>	1
Rotavirus- <i>E. coli</i> (DAEC) - <i>Salmonella</i>	1

EAEC: Enteraggregative *E. coli*
DAEC: Diffusely adherent *E. coli*
EPEC: Enteropathogenic *E. coli*
ETEC: Enterotoxigenic *E. coli*

Table 6: Rotavirus genotypes and vaccination status of rotavirus-associated diarrheal episodes

	0 doses	1 dose	2 or 3 doses	Rotarix®
G1P8	12	1	3	*
G3P9	1	0	3	●
G8P9	1	0	0	●

*Serotypes covered by Rotarix® ●Serotypes not covered by Rotarix®
