**Predatory publishing in Scopus: evidence on cross-country differences**

Vit Macháček<sup>1,2</sup> · Martin Srholec<sup>1</sup>

**Abstract**  
Predatory publishing represents a major challenge to scholarly communication. This paper maps the infiltration of journals suspected of predatory practices into the citation database Scopus and examines cross-country differences in the propensity of scholars to publish in such journals. Using the names of “potential people”, or probable predatory journals and publishers on Beall’s lists, we derived the ISSNs of 3,296 journals from Ulrichsweb and searched Scopus with them. 324 journals that appear both in Beall’s lists and Scopus with 164 thousand articles published over 2015–2017 were identified. Analysis of data for 172 countries in 4 fields of research indicates that there is a remarkable heterogeneity. In the most affected countries, including Kazakhstan and India, around 17% of articles fall into the predatory category, while some other countries have no predatory articles whatsoever. Countries with large research sectors at the medium level of economic development, especially in Asia and North America, tend to be most susceptible to predatory publishing. Arab, oil-rich and/or east Asian countries also appear to be particularly vulnerable. Policymakers and stakeholders in these and other developing countries need to pay more attention to the quality of research evaluation.

## WORLD VIEW A personal take on events

Jeffrey Beall

### Predatory publishers are corrupting open access

Journals that exploit the author-pays model damage scholarly publishing and promote unethical behaviour by scientists, argues Jeffrey Beall.

promise was doubtful and its validity unlikely to have been vetted.  
Predatory journals are a global threat. They accept articles for publication – along with authors' fees – without performing promised quality checks for issues such as plagiarism or ethical approval. Naive readers are not the only

# Why Most Published Research Findings Are False

John P. A. Ioannidis

## Summary

There is increasing concern that most current published research findings are false. The probability that a research claim is true may depend on study power and bias, the number of other studies on the same question, and, importantly, the ratio of true to no relationships among the relationships probed in each scientific field. In this framework, a research finding is less likely to be true when the studies conducted in a field are smaller; when effect sizes are smaller; when there is a

factors that influence this problem and some corollaries thereof.

## Modeling the Framework for False Positive Findings

Several methodologists have pointed out [9–11] that the high rate of nonreplication (lack of confirmation) of research discoveries is a consequence of the convenient, yet ill-founded strategy of claiming conclusive research findings solely on the basis of a single study assessed by formal statistical significance, typically

is characteristic of the field and can vary a lot depending on whether the field targets highly likely relationships or searches for only one or a few true relationships among thousands and millions of hypotheses that may be postulated. Let us also consider, for computational simplicity, circumscribed fields where either there is only one true relationship (among many that can be hypothesized) or the power is similar to find any of the several existing true relationships. The pre-study probability of a relationship

miracle cures and wild claims.

In my view, we must look at the massive expansion of online publications (most of which are OA journals) as a disruptive technology, resulting in overworked and fatigued reviewers. Quality will suffer — across the board — unless something is done. ■

## **Discussion and conclusions**

This paper has explored various issues relating to the methodology used in bibliometric analyses published in the journal Sustainability in 2019 and 2020, showing that many of the papers published lack the methodological rigour that would normally be required. In

Considering these shortcomings, 181 of the 204 studies analysed (88.7%) have one or more methodological limitations which hinder or prevent their reproducibility. This shows that there is considerable room for improvement in the methodological quality of the bibliometric

## Preserving credibility of open access journals

In their Editorial “Public access is not equal access” (9 September, p. 1361), S. Parikh *et al.* explain how the open access model can compound inequities (*1, 2*) by charging article processing fees that early-career scientists and scientists in underfunded disciplines, teams, or regions (*1*) are unable to afford. They also acknowledge the perverse incentives of a business model based on volume of articles published, which has led to the proliferation of open access journals, many of which are predatory, and risks diluting the scientific literature (*1, 3*). However, they do not address another unintended consequence of open access policies:

notified that another team in a different hospital had submitted and published the same report. In two separate instances, a journal made the mistake of duplicate publication of an article. In general, it seems the main reason underlying these retractions and withdrawals is the rush to quickly publish the COVID-19-related articles, whether by the authors or the journal editors and review teams. The publishing parties must keep in mind that swiftly published but erroneous data is not helpful for the medical community in their ongoing battle with COVID-19. What we actually need (possibly more than any time in history) is reliable information that can withstand continued growth in non-OA publications.

That gold OA is predicted to grow at a much faster rate than green OA further suggests adaptations are being made by scholarly publishers to protect viable scholarly publishing models without ‘losing out’ to the demands and needs of scientists and attentive publics during the COVID-19 pandemic. However, caution is warranted based on findings that most preprints are eventually published as journal articles (Fraser

## The rise and fall of gold OA

At the same time, the gold OA model began to proliferate and, along with this, the focus changed. For many journals, authors became publishers' customers, leaving readers as secondary players in the new OA equation. The fatal flaw of the gold OA model is the built-in conflict of interest: the
