The Reuse of Software is Central to Research Efficiency & Scientific Exchange

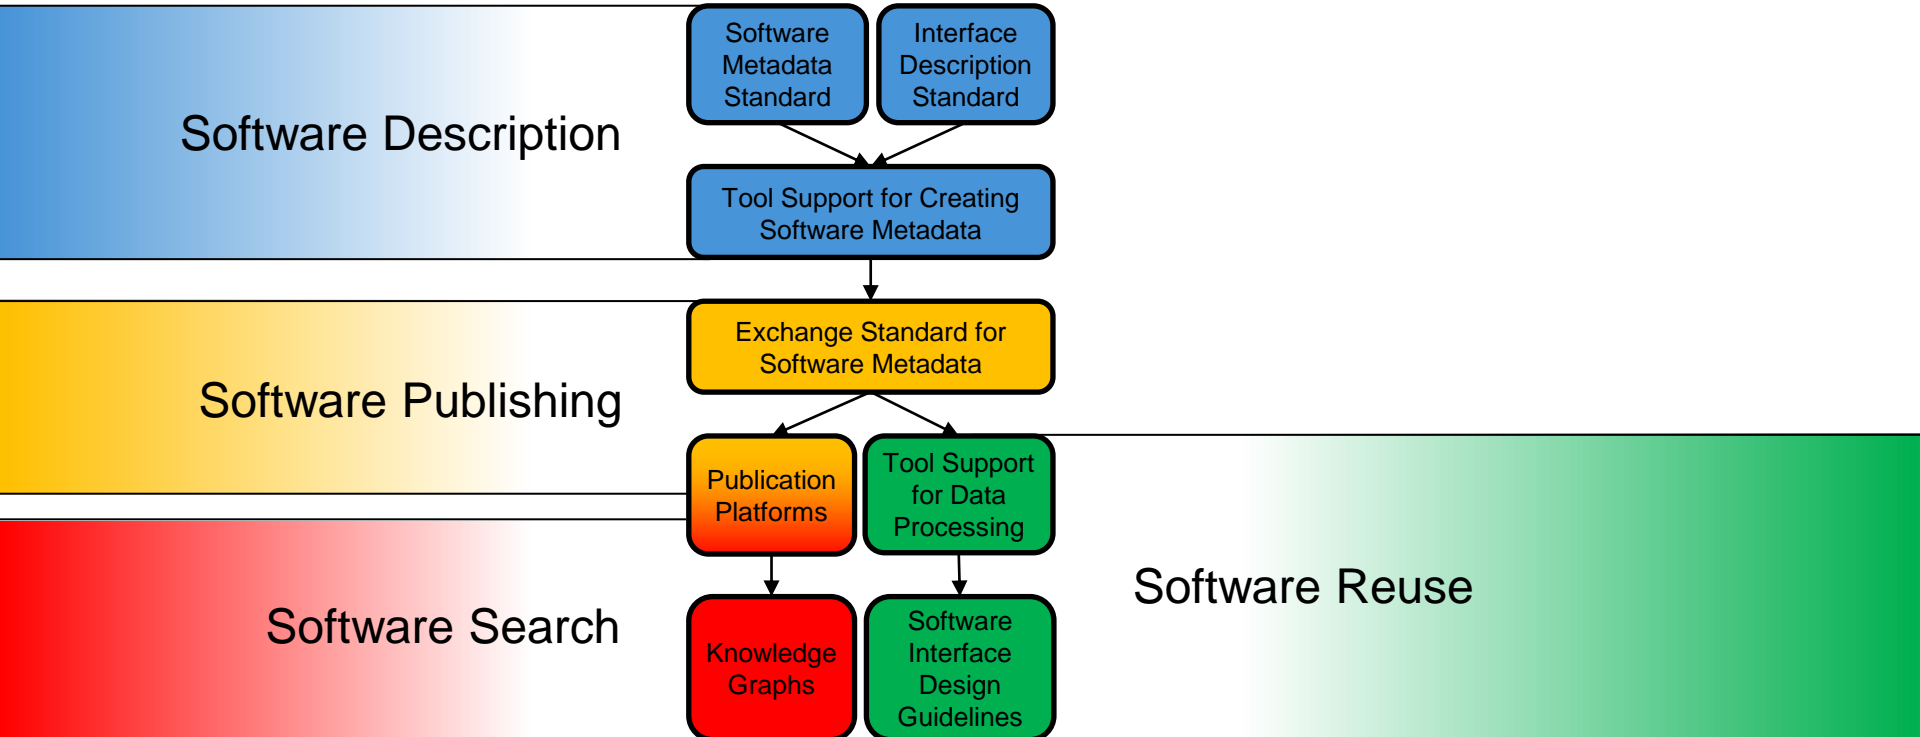

Why is it important?

- It enables the reproduction and validation of results
- It enables the understanding and comparison of methods and approaches
- It reduces redundant software developments that must be individually documented, maintained and further developed
- It increases software quality, since larger developer and user communities translate into more expertise and larger work forces

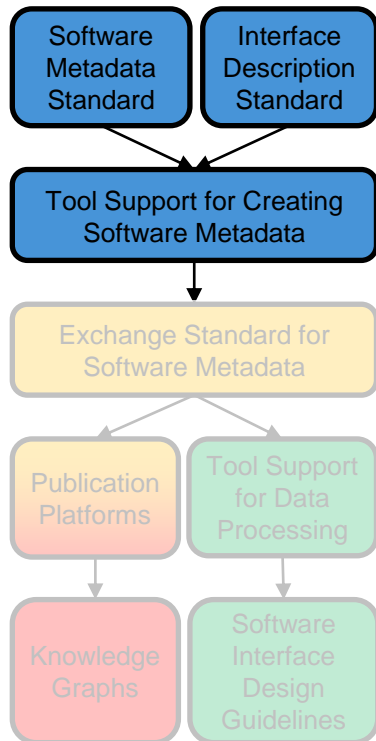

What are current problems?

- Relevant software is hard to find
- Software is published without license, metadata and or insufficient documentation
 - Documentation standards often do not exist or are not adhered to
 - Documentation is only rarely available in a machine-actionable form
- The provision of this information is often associated with a high level of effort

Facilitating Four Areas of the Software Life Cycle

Facilitating Software Description

What metadata do we need?

- **Detailed interface description** in addition to **general software metadata** such as author, license and date created
- Metadata must be semantically enriched to be **machine-actionable** (that is, using ontology terms instead of free text)

Building on existing standards

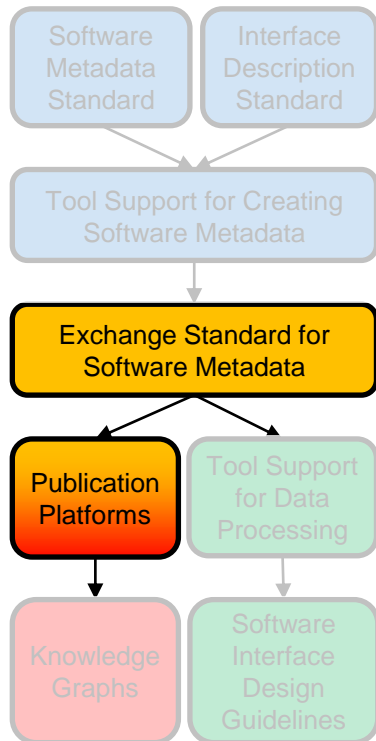

- CodeMeta¹ for general software metadata
- OpenAPI² as interface description standard

The documentation effort must be low!

- **Tool support** for creating metadata
- Metadata annotations are partially **embedded in the source code** supporting code documentation which must be done anyway

¹<https://codemeta.github.io/> ²<https://www.openapis.org/>

Facilitating Software Publishing

Describing software with metadata only once enables many applications.

- Once software is described with metadata, a metadata exchange file is generated
- Upload to many different software publication platforms:
 - a. Documentation publication platforms (e.g., ReadTheDocs¹)
 - b. Software repository platforms for sharing source code (e.g., GitHub²)
 - c. Software publication platforms for package management (e.g., PyPi³)
 - d. Software registry platforms for finding software (e.g., Open Energy Platform⁴)
- Both, using standards and fostering machine-actionability increase the likelihood of widespread dissemination

¹Utilization of the Swagger Editor: <https://editor.swagger.io/>

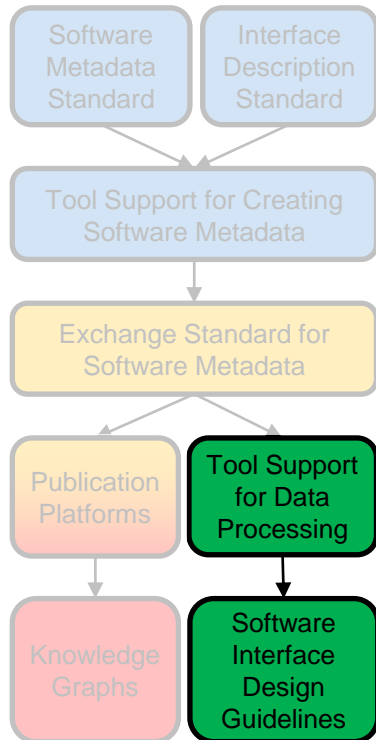

Facilitating Software Search

- Detailed and machine-actionable software metadata improve software search
 - Different research artifacts are linked together via their metadata¹
 - Implementation of semantic search methods that can be used across artifacts (e.g., search for existing data or software which produces the requested data)
- Crawling and generating software metadata from publication platforms for software not adhering to this approach

¹E.g. in the Open Research Knowledge Graph: <https://orkg.org/>

Facilitating Software Reuse

- Focus on innovative downstream applications
 - Automated data validation against software interfaces
 - Automated data conversion for matching software interfaces
 - Automated compilation of software and data to software workflows
- Development of interface design guidelines
