## XPS results

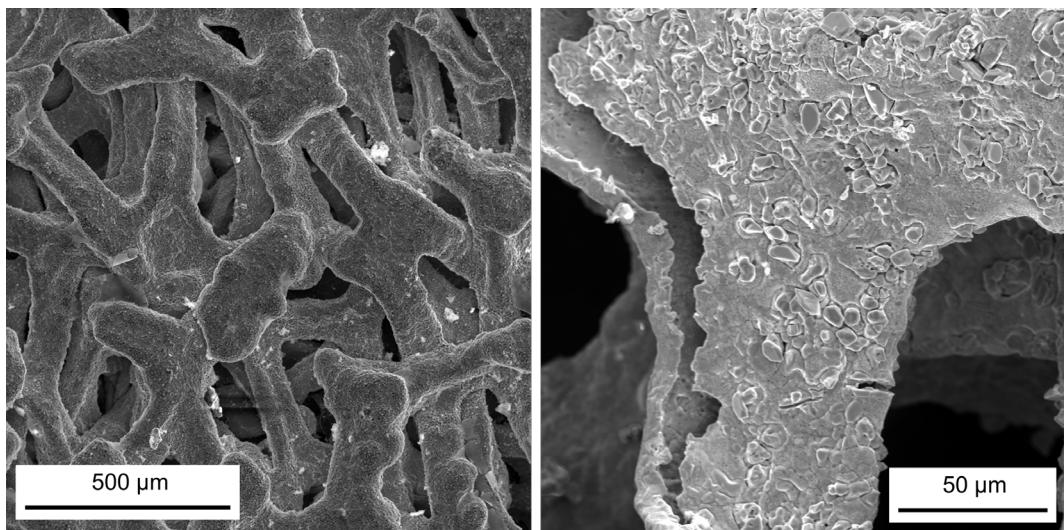

**Figure S1.** High-resolution XPS spectra of the Bi 4f (a), O 1s (b), and Br 3d (c) regions before and after electrolysis.

**Figure S2.** High-resolution XPS spectra of the Ni 2p (a) and B 1s (c) regions before and after electrolysis.

## SEM results

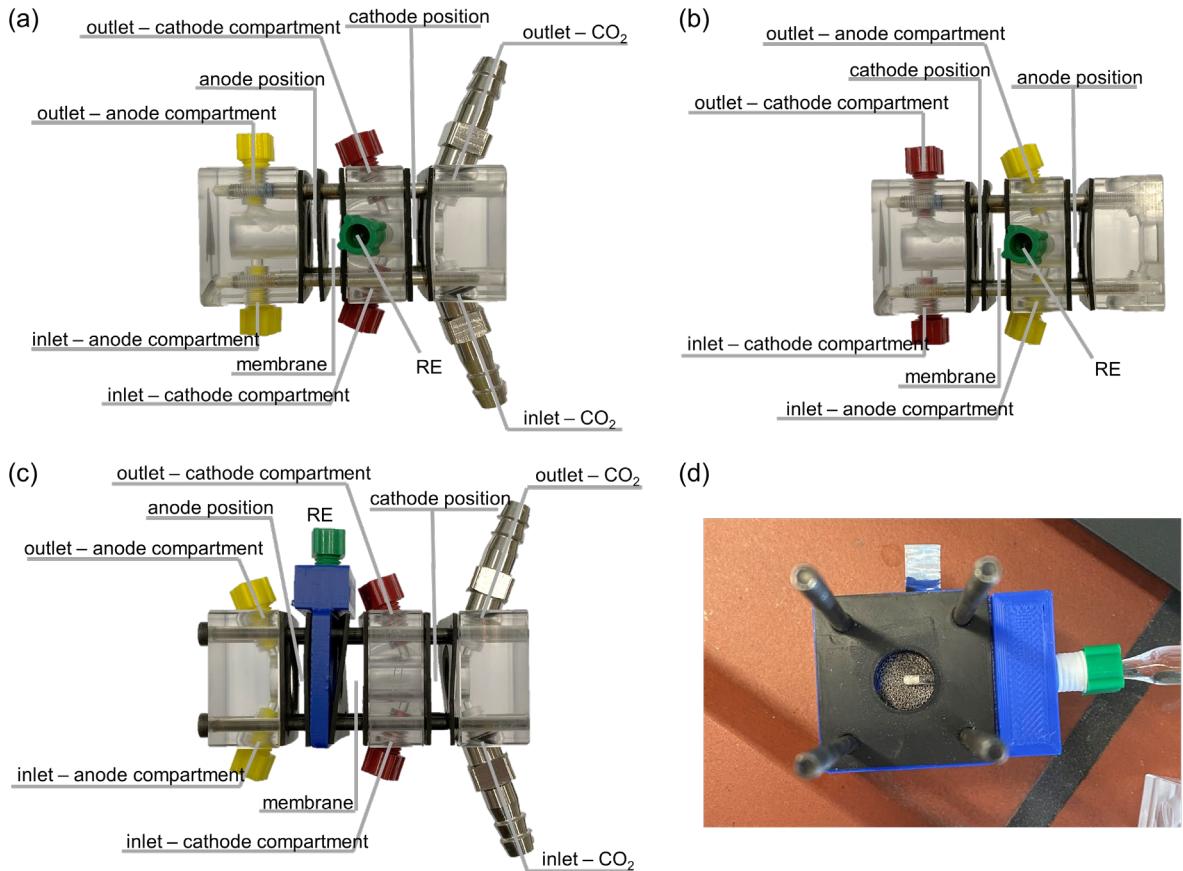

**Figure S3.** SEM micrographs of the  $\text{Ni}_x\text{B}$  anode after electrolysis at different magnifications.

### ICP-MS results

Table S1. ICP-MS results for the  $\text{Ni}_x\text{B}$  electrode before and after electrolysis.

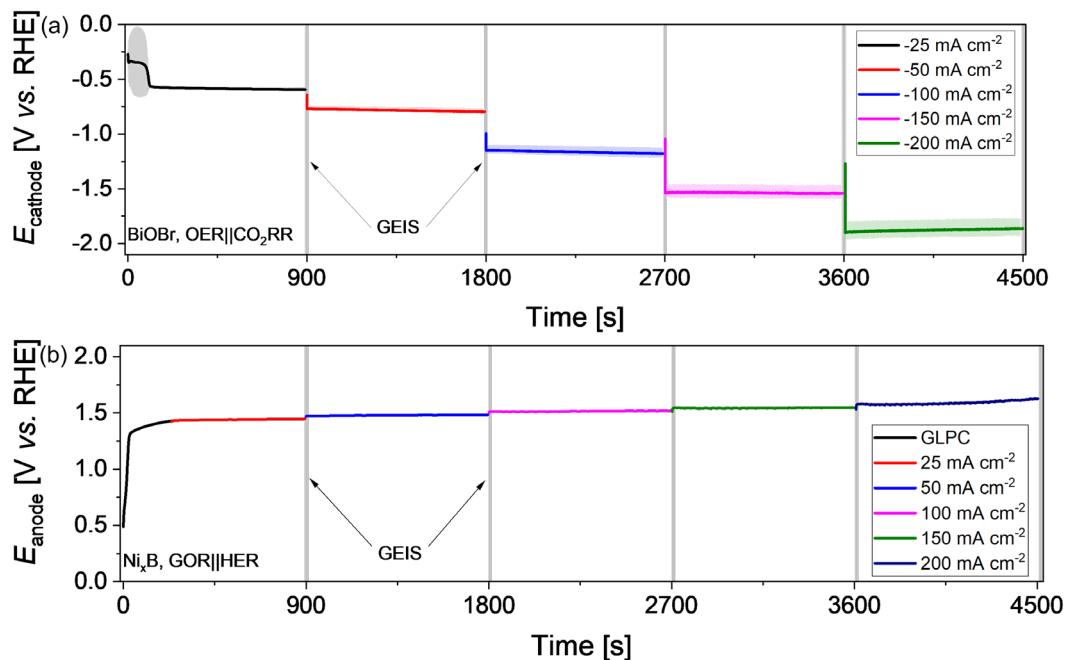

element	$\text{Ni}_x\text{B}$ before		$\text{Ni}_x\text{B}$ after	
	ppb	$\mu\text{mol L}^{-1}$	ppb	$\mu\text{mol L}^{-1}$
$^{60}\text{Ni}$	805360	13722.3	843760	14376.6
$^{11}\text{B}$	50098	4634.4	10780	997.2
total	855458	18356.7	854540	15373.8
Ni content	94.1	74.8	98.7	93.5
B content	5.9	25.2	1.3	6.5
total	100.0	100.0	100.0	100.0

From the ICP-MS results the initial  $\text{Ni}_x\text{B}$  composition was estimated as  $\text{Ni}_3\text{B}$ . After electrolysis, a smaller B content was determined, indicating that B dissolves during the electrolysis.

**Figure S4.** Images of the half-cell reactor for the OER||CO<sub>2</sub>RR experiments (a), the GOR||HER experiments (b), and the paired electrolysis reactor for the GOR||CO<sub>2</sub>RR experiments (c), and RE and Ni<sub>x</sub>B anode (d).

### Half-cell electrolysis

**Figure S5.** Average potentials recorded during half-cell electrolysis average  $E_{\text{cathode}}$  BiOBr (a), and  $E_{\text{anode}}$  Ni<sub>x</sub>B (b). Initially, a galvanostatic linear polarization curve (GLPC) from 0 to 25 mA cm<sup>-2</sup> at 0.1 mA s<sup>-1</sup> was recorded followed by chronopotentiometries at 25, 50, 100, 150 and 200 mA cm<sup>-2</sup> for 14.88 min, and finally a galvanostatic electrochemical impedance spectroscopy from 100 kHz to 2 Hz with the amplitude current at 10 % of the applied current. Light grey lines are shown when GEIS was measured.

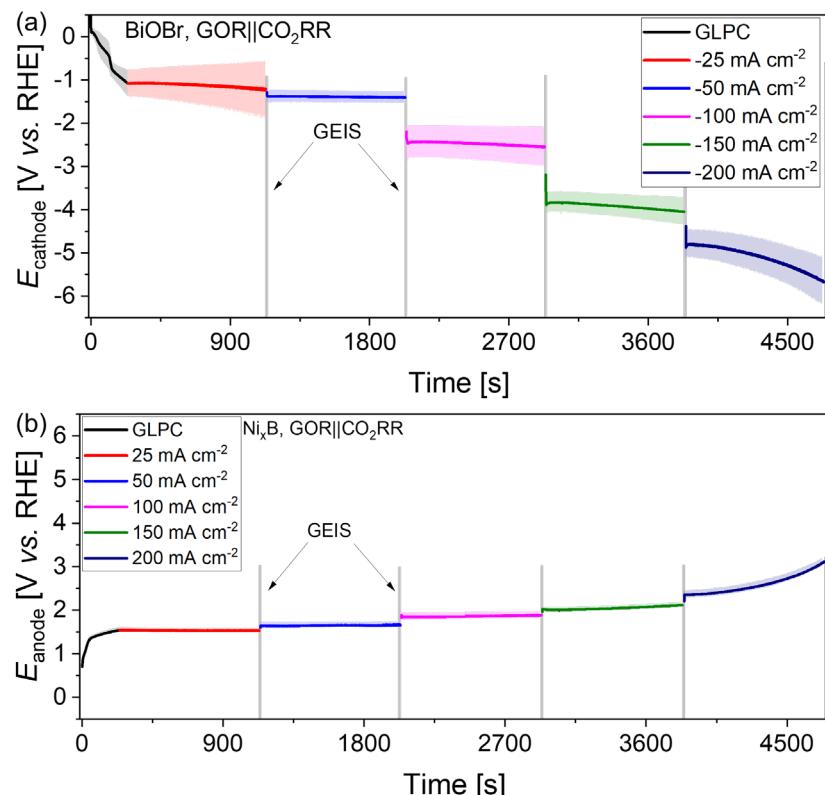

**Table S2.** Half-cell reactor average FE for H<sub>2</sub>, CO, and HCO<sub>3</sub><sup>-</sup>, and  $E_{\text{cathode}}$  determined at different currents for BiOBr.

BiOBr	H <sub>2</sub>		CO		HCO <sub>3</sub> <sup>-</sup>		$E_{\text{cathode}}$	
	$j$ [mA cm <sup>-2</sup> ]	FE [%]	st.dev.	FE [%]	st.dev.	FE [%]	st.dev.	V vs. RHE

## CO<sub>2</sub> reduction half-cell reactions

## Glycerol oxidation half-cell reactions [6]

## Energy-efficiency calculation

To determine the energy-efficiency of the measured systems was calculated using equation S12:

$$\text{Energy-efficiency} = \frac{n_{\text{formate}} \times \Delta H_{\text{formate}}^0}{E_{\text{cell}} \times Q} \quad (\text{S12})$$

$n_{\text{formate}}$  is the total produced mols of formate (anode + cathode) in mol,  $\Delta H_{\text{formate}}^0$  the formate heat of combustion (278.2 kJ mol<sup>-1</sup>) in J mol<sup>-1</sup>,  $E_{\text{cell}}$  the cell voltage ( $E_{\text{cell}} = E_{\text{anode}} - E_{\text{cathode}}$ ) in V, and Q the charge (Q = i \* t) in C. The formate heat of combustion,  $\Delta H_{\text{formate}}^0$  was determined using equation S13:

$$\Delta H_{\text{formate}}^0(298.15 \text{ K}) = \left| \Delta_f H^0(\text{CO}_2) + \frac{1}{2} \Delta_f H^0(\text{H}_2\text{O}) - \Delta_f H^0(\text{HCO}_2^-) - \frac{1}{4} \Delta_f H^0(\text{O}_2) \right| \quad (\text{S13})$$

Where  $\Delta_f H^0(\text{CO}_2) = -393.476 \text{ kJ mol}^{-1}$ ,  $\Delta_f H^0(\text{H}_2\text{O}) = -285.796 \text{ kJ mol}^{-1}$ ,  $\Delta_f H^0(\text{HCO}_2^-) = -466.8 \text{ kJ mol}^{-1}$ , and  $\Delta_f H^0(\text{O}_2) = 0.0 \text{ kJ mol}^{-1}$ . Values from the Active Thermochemical Tables version 1.124.<sup>[7]</sup>

**Table S9.** Results of the energy-efficiency calculations for the paired electrolyte performing GOR||CO<sub>2</sub>RR (a), half-cell performing OER||CO<sub>2</sub>RR (b), and GOR||HER (c). The relative energy-efficiency of the different reactors configurations (d) at different applied current densities.

(d)		Relative energy-efficiency [%]	
$j$ [mA cm <sup>-2</sup> ]	GOR  CO <sub>2</sub> RR vs. OER  CO <sub>2</sub> RR	GOR  CO <sub>2</sub> RR vs. GOR  HER	
25	-5.2	201.7	
50	55.5	233.0	
100	52.8	225.0	
150	43.0	189.0	
200	41.0	202.8	

These calculations show that the used paired electrolyze performing GOR||CO<sub>2</sub>RR is in general more energy-efficient when compared to the OER||CO<sub>2</sub>RR and GOR||HER reactors. Considering the total formate production of each kind of reactor, at 200 mA cm<sup>-2</sup>, the paired electrolyzer is 41 % more energy efficient than the OER||CO<sub>2</sub>RR, and 203 % more energy efficient than the GOR||HER reactor.

### CO<sub>2</sub> balance estimation

The CO<sub>2</sub> balance estimation was calculated with equation S15.

$$\text{CO}_2 \text{ balance} = \text{mol}_{\text{CO}_2} \text{ produced from glycerol oxidation} - \text{mol}_{\text{CO}_2} \text{ consumed from formate production} \quad (\text{S15})$$

During the experiments on the GOR side, two possible products were not analyzed. The first one is O<sub>2</sub> from the competitive OER and the second one is CO<sub>2</sub> from the complete glycerol oxidation. Since these products were not analyzed, it is only possible to determine their production. From the HPLC results there is a substantial missing FE on the anode side, which is assumed to come from the presence of the non-analyzed gaseous products O<sub>2</sub> and CO<sub>2</sub>. For the CO<sub>2</sub> balance estimation, it was considered that the Ni<sub>x</sub>B on Ni foam electrode does not perform any OER, so all the missing FE results from the complete glycerol oxidation. Therefore, at 200 mA cm<sup>-2</sup> the FE for CO<sub>2</sub> at the anode is around 33.9 %. From equation S11, there are 14 electrons involved in the complete oxidation of glycerol to CO<sub>2</sub> and the stoichiometric factor is 3, this results in a maximal production of CO<sub>2</sub> of 1.28 x10<sup>-4</sup> mol (over a 15-minute-long experiment, resulting in 5.12 x10<sup>-4</sup> mol h<sup>-1</sup>) or 1.25 x10<sup>-5</sup> m<sup>3</sup> h<sup>-1</sup> (12.5 mL h<sup>-1</sup>).

On the CO<sub>2</sub>RR side, gaseous CO<sub>2</sub> is fixed into liquid formate. From the HPLC results at 200 mA cm<sup>-2</sup>, there is an average formate production of 8.56 x10<sup>-4</sup> mol (over 15 minutes long experiment, resulting in 3.42 x10<sup>-3</sup> mol h<sup>-1</sup>). This results in a CO<sub>2</sub> consumption of around 8.37 x10<sup>-5</sup> m<sup>3</sup> h<sup>-1</sup> (83.7 mL h<sup>-1</sup>) at the cathode.

The presented paired electrolyzer at 200 mA cm<sup>-2</sup> shows a CO<sub>2</sub> balance of -7.28 x10<sup>-4</sup> mol (over a 15-minute-long experiment, resulting in -2.91 x10<sup>-3</sup> mol h<sup>-1</sup>) or -7.12 x10<sup>-5</sup> m<sup>3</sup> h<sup>-1</sup> (-71.2 mL h<sup>-1</sup>). This estimation demonstrates that the paired electrolyze consumes more CO<sub>2</sub> than it releases in the order of 2.91 x10<sup>-3</sup> mol h<sup>-1</sup>. The values were calculated using the ideal gas law and considering 25 °C and 1 atm as ambient temperature and pressure.

**Table S10.** The estimated CO<sub>2</sub> production at the anode from the glycerol complete oxidation (a), the measured CO<sub>2</sub> consumption at the from the formate production (b), and the estimation of the CO<sub>2</sub> balance (c) at different current densities and with different units.
