## 9 Summary

10 EnsembleKalmanProcesses.jl is a Julia-based toolbox that can be used for a broad class of  
11 black-box gradient-free optimization problems. Specifically, the tools enable the optimization,  
12 or calibration, of parameters within a computer model in order to best match user-defined  
13 outputs of the model with available observed data ([Kennedy & O'Hagan, 2001](#)). Some of the  
14 tools can also approximately quantify parametric uncertainty ([Huang, Huang, et al., 2022](#)).  
15 Though the package is written in Julia ([Bezanson et al., 2017](#)), a read-write TOML-file  
16 interface is provided so that the tools can be applied to computer models implemented in any  
17 language. Furthermore, the calibration tools are non-intrusive, relying only on the ability of  
18 users to compute an output of their model given a parameter value.

19 As the package name suggests, the tools are inspired by the well-established class of ensemble  
Kalman methods. Ensemble Kalman filters are currently one of the only practical ways to  
21 assimilate large volumes of observational data into models for operational weather forecasting  
22 ([Evensen, 1994](#); [Houtekamer & Mitchell, 1998, 2001](#)). In the data assimilation setting, a  
23 computational weather model is integrated for a short time over a collection, or ensemble,  
24 of initial conditions, and the ensemble is updated frequently by a variety of atmospheric  
25 observations, allowing the forecasts to keep track of the real system.

26 The workflow is similar for ensemble Kalman processes. Here, a computer code is run (in  
27 parallel) for an ensemble of different values of the parameters that require calibration, producing  
28 an ensemble of outputs. This ensemble of outputs is then compared to observed data, and  
29 the parameters are updated to a new set of values which reduce the output-data misfit. The  
30 process is iterated until a user-defined criterion of convergence is met. Optimality of the update  
31 is guaranteed for linear models and Gaussian uncertainties, but good performance is observed  
32 outside of these settings, see [Schillings & Stuart \(2017\)](#). Optimal values are selected from  
33 statistics of the final ensemble.

## 34 Statement of need

35 The task of estimating parameters of a computer model or simulator such that its outputs  
36 fit with data is ubiquitous in science and engineering, coming under many names such as  
37 calibration, inverse problems, and parameter estimation. In statistics and machine learning,  
38 when closed-form estimators of parameters of a model are unavailable, similar approaches may  
39 need to be employed to fit the model to data. There is a wide variety of algorithms to suit  
40 these applications; however, there are many bottlenecks in the practical application of such  
41 methods to computer codes:

- 42     ▪ Legacy codes: Often code is old, and written in different languages than the packages  
43     implementing the calibration algorithms, requiring elaborate interfaces.
- 44     ▪ Complex codes: Often large complex codes are difficult to change, so application of  
45     intrusive calibration tools to models can be challenging.
- 46     ▪ Derivatives: When derivatives of a model output can be taken with respect to parameters,  
47     they can often improve the rate of convergence. But in many practical cases, these  
48     parameter-to-output maps are not differentiable; they may be chaotic or stochastic. Here  
49     one should not – or cannot – apply gradient-based methods.
- 50     ▪ Lack of parallelism: There is now widespread access to high-performance computing  
51     clusters, cloud computing, and local multi-threading, and such facilities should be  
52     exploited where possible.

53 EnsembleKalmanProcesses.jl aims to provide a flexible and comprehensive solution to address  
54 these challenges:

- 55     1. It is embarrassingly parallel with respect to the ensemble; therefore, all computer model  
56     evaluations within an ensemble can happen simultaneously within an iteration.
- 57     2. It is derivative-free, and so is appropriate for computer codes for which derivatives are  
58     not available. The optimal updates are robust to noise.
- 59     3. It is non-intrusive and so can be applied to black-box computer codes written in any  
60     language or style, or to computer models for which the source code is not available to  
61     the user.
- 62     4. With scalability enhancements, such as the ones provided by the Localizer structure, it  
63     can be applied to high-dimensional problems.

## 64 State of the field

65 Many gradient-based optimizers have been implemented in Julia, collected in Optim.jl (Mo-  
66 gensen & Riseth, 2018) and JuliaSmoothOptimizers.jl, for example. Some gradient-free  
67 optimization tools, better suited for non-deterministic or noisy optimization, are collected  
68 within packages such as BlackBoxOptim.jl and Metaheuristics.jl (Mejía-de-Dios & Mezura-  
69 Montes, 2022). Although these packages feature a number of ensemble-based approaches,  
70 none utilize Kalman-based statistical updates, and instead rely on heuristic algorithms inspired  
71 from biological processes such as natural selection (Genetic Algorithms) or swarming (Particle  
72 Swarm Optimization). A related class of methods to calibrate black-box computer codes are  
73 based on Bayesian inference, such as (Markov Chain) Monte Carlo, implemented in Turing.jl  
74 (Ge et al., 2018), for example. Such methods provide the posterior distribution of parameters,  
75 from which the optimum is taken as the summary statistic. However, they are far more  
76 computationally expensive.

77 EnsembleKalmanProcesses.jl fills the need for computationally inexpensive, gradient-free,  
78 mathematically-grounded, ensemble-based calibration algorithms. Ensemble Kalman processes  
79 are provably optimal in simple settings, and have a large literature of extensions to complex  
80 problems. Although implementations of Kalman filters exist in Julia (EnKF.jl; Kalman.jl;  
81 GaussianFilters.jl), EnsembleKalmanProcesses.jl is the only package to implement  
82 ensemble-based updates for parameter estimation; other packages focus on state estimation  
83 from sequential data.

## 84 Features

85 There are different ensemble Kalman algorithms in the literature, which differ in the way that  
86 the ensemble update is performed. The following ensemble Kalman processes are implemented

87 tools in our package, and we provide published references for detailed descriptions and evidence  
88 of their efficacy:

- 89     ▪ Ensemble Kalman Inversion (EKI, Iglesias et al. (2013)),
- 90     ▪ Ensemble Kalman Sampler (EKS, Garbuno-Inigo, Hoffmann, et al. (2020); Garbuno-Inigo,  
91       Nüsken, et al. (2020)),
- 92     ▪ Unscented Kalman Inversion (UKI, Huang, Schneider, et al. (2022)),
- 93     ▪ Sparse Ensemble Kalman Inversion (SEKI, Schneider, Stuart, et al. (2022)).

94 The package also implements some features to improve robustness and flexibility of the  
95 ensemble algorithms:

- 96     ▪ The `ParameterDistribution` structure allows users to perform calibrations for parameters  
97       with known constraints. It does so by defining transformation maps under-the-hood from  
98       the constrained space to an unconstrained space where the optimization problem can be  
99       suitably defined. Constrained optimization using this framework has been successfully  
100       demonstrated in a variety of settings (Dunbar et al., 2022; Lopez-Gomez et al., 2022;  
101       Schneider, Dunbar, et al., 2022).
- 102     ▪ The `FailureHandler` structure allows calibrations to continue when several ensemble  
103       members fail. Common reasons for failure could be, for instance, simulation blow-up for  
104       certain parameter configurations, user termination of slow computations, data corruption,  
105       or bad nodes in a high-performance computing facility. This methodology is demonstrated  
106       in Lopez-Gomez et al. (2022).
- 107     ▪ The `Localizer` structure allows users to overcome the restriction of the solution of the  
108       calibration to the linear span of the initial ensemble, and to reduce sampling errors  
109       due to the finite size of the ensemble. Various such localization and sampling error  
110       correction methods are implemented in `EnsembleKalmanProcesses.jl` (Lee, 2021; Tong  
111       & Morzfeld, 2022).
- 112     ▪ The TOML-file interface defined in the `TOMLInterface` module allows non-intrusive use  
113       of `EnsembleKalmanProcesses.jl` through TOML files, which are widely used for config-  
114       uration files and easily read in any programming language. Given the computer model  
115       to calibrate and prior distributions on the parameters, `EnsembleKalmanProcesses.jl`  
116       reads these distributions from a file and, after an iteration of the ensemble Kalman  
117       algorithm, writes each member of the updated ensemble to a parameter file. Each  
118       of these parameter files can be then read individually to initiate the ensemble of the  
119       computer model for the next iteration.

## 120 Pedagogical example

121 In this example, the computer code simulates a sine curve

$$f(A, v) = A \sin(t + \varphi) + v, \quad \forall t \in [0, 2\pi],$$

122 with a random phase shift  $\varphi$  applied to every evaluation. We define the observable map

$$G(A, v) = [\max f(A, v) - \min f(A, v), \text{mean} f(A, v)].$$

123 We treat  $\varphi$  as a “nuisance parameter” that we are not interested in estimating, thus the  
124 observable map  $G(A, v)$  is chosen independent of  $\varphi$ . We are given one sample measurement  
125 of  $G$ , polluted by Gaussian noise  $\mathcal{N}(0, \Gamma)$ , and call this  $y$ . Our task is to deduce the most  
126 likely amplitude  $A$  and vertical shift  $v$  of the curve that produced the sample  $y$ .

127 We encode information into prior distributions over the parameters:

```
# A is positive, has likely value 2 with standard deviation 1
# v has likely value 0 with standard deviation 5
prior_A = constrained_gaussian("amplitude", 2, 1, 0, Inf)
prior_v = constrained_gaussian("vert_shift", 0, 5, -Inf, Inf)
prior = combine_distributions([prior_A, prior_v])
```

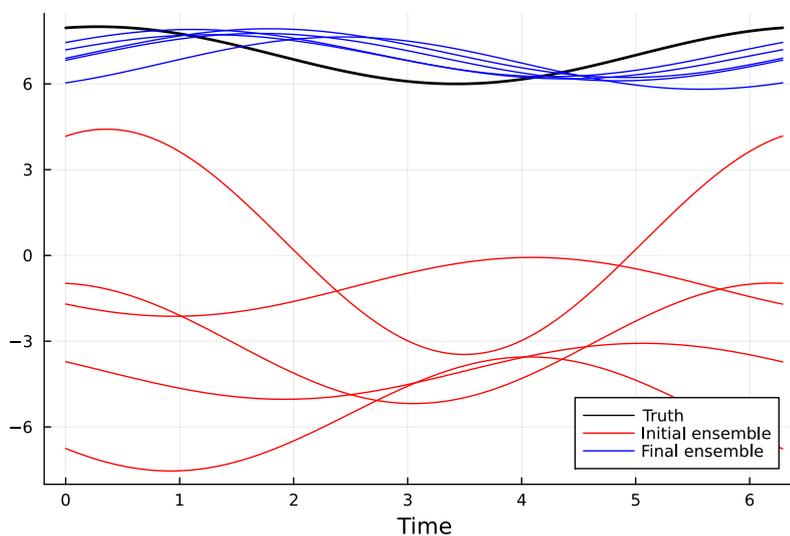

128 To use a basic ensemble method we need to specify the size of the ensemble, which we take to  
 129 be `N_ensemble = 5`. We now initialize the problem, by drawing the initial ensemble from the  
 130 prior and selecting the `Inversion()` tool to perform ensemble Kalman inversion:

```
initial_ensemble = construct_initial_ensemble(prior, N_ensemble)
ensemble_kalman_inversion = EnsembleKalmanProcess(initial_ensemble, y, Γ, Inversion())
```

131 Then we run the algorithm iteratively. In this case, we choose to perform 5 iterations:

```
N_iterations = 5
for i in 1:N_iterations
    # get the latest parameter ensemble
    params_i = get_phi_final(prior, ensemble_kalman_process)
    # run a simulation for each parameter in the ensemble
    G_ens = hcat([G(params_i[:, i]) for i in 1:N_ensemble]...)
    # perform the Kalman update, producing a new ensemble
    update_ensemble!(ensemble_kalman_process, G_ens)
end
```

132 The initial and final ensembles are shown in [Figure 1](#), by evaluating  $f$  at these parameters.  
 133 We observe that the final sinusoid ensemble has greatly reduced the error in amplitude and  
 134 vertical shift, despite the presence of the random phase shifts.

**Figure 1:** Sinusoids produced from the initial and final ensembles, and the sine curve that generated the data (Truth).

135 This final ensemble determines the problem solution; for ensemble Kalman inversion, a best  
 136 estimate of the parameters is taken as the mean of the final ensemble:

```
best_parameter_estimate = get_phi_mean_final(prior, ensemble_kalman_process)
```

137 The Julia code and further explanation of this example is provided in the documentation.

## 138 Research projects using the package

- 162
- EnsembleKalmanProcesses.jl has been used to train physics-based and machine-learning models of atmospheric turbulence and convection, implemented using Flux.jl and TurbulenceConvection.jl (Lopez-Gomez et al., 2022). In this application, the available model outputs are not differentiable with respect to the learnable parameters, so gradient-based optimization was not an option. In addition, the unscented Kalman inversion algorithm was used to approximately quantify parameter uncertainty.
  - EnsembleKalmanProcesses.jl features within Calibrate-Emulate-Sample (CES, Cleary et al. (2021)), a pipeline used to accelerate parameter uncertainty quantification (by a factor of  $10^3$  -  $10^4$  with respect to Monte Carlo methods) by using statistical emulators. EnsembleKalmanProcesses.jl is used to choose training points for these emulators. The training points are naturally concentrated by the ensemble Kalman processes into areas of high posterior probability mass. Within CES, the trained emulators are used to sample this probability distribution, and by design are most accurate where they need to be. CES has been successfully used to quantify parameter uncertainty within the moist convection scheme of a simplified climate model (Dunbar et al., 2021, 2022; Howland et al., 2022), within a droplet collision-coalescence scheme for cloud microphysics (Bieli et al., 2022), and within boundary layer turbulence schemes for ocean modeling (Hillier, 2022).
  - EnsembleKalmanProcesses.jl has been used to learn hyperparameters within a machine learning tool known as Random Features within the Julia package RandomFeatures.jl. Here, the hyperparameters characterize an infinite family of functions, from which a finite sample is drawn to use as a basis in regression problems. The objective for learning the parameters is noisy and non-differentiable due to the random sampling, so ensemble Kalman processes naturally perform well in this setting.

## 163 Acknowledgements

164 We acknowledge contributions from several others who played a role in the evolution of this  
165 package. These include Jake Bolewski, Navid Constantinou, Gregory L. Wagner, Thomas  
166 Jackson, Michael Howland, Melanie Bieli, and Adeline Hillier. The development of this package  
167 was supported by the generosity of Eric and Wendy Schmidt by recommendation of the  
168 Schmidt Futures program, and by the Defense Advanced Research Projects Agency (Agreement  
169 No. HR00112290030).
