Insights into first-principles characterization of the monoclinic VO₂(B) polymorph *via* DFT + U calculation: electronic, magnetic and optical properties

Elaheh Mohebbi,^a Eleonora Pavoni,^{ID}^a Davide Mencarelli,^b Pierluigi Stipa,^a Luca Pierantoni^b and Emiliano Laudadio^{ID} *^a

We have studied the structural, electronic, magnetic, and optical properties of the VO₂(B) polymorph using first-principles calculations based on density functional theory (DFT). This polymorph was found to display four optimized structures namely VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} using the generalized gradient approximation (GGA) PBE exchange-correlation functional by including/excluding van der Waals interaction. Our derivation provides a theoretical justification for adding an on-site Coulomb *U* value in the conventional DFT calculations to allow a direct comparison of the two methods. We predicted a zero bandgap of the VO₂(B) structure based on GGA/PBE. However, by GGA/PBE + *U*, we found accurate bandgap values of 0.76, 0.66, and 0.70 eV for VO₂(B)_{PP}, VO₂(B)_{LP}, and VO₂(B)_{PPD}, respectively. The results obtained from DFT + *U* were accompanied by a structural transition from the metallic to semiconductor property. Here, we verified the non-magnetic characteristic of the monoclinic VO₂(B) phase with some available experimental and theoretical data. However, the debate on the magnetic property of this polymorph remains unresolved. Imaginary and real parts of the dielectric function, as computed with the GGA/PBE functional and the GGA/PBE + *U* functional, were also reported. The first absorption peaks of all considered geometries in the imaginary part of the dielectric constants indicated that the VO₂(B) structure could perfectly absorb infrared light. The computed static dielectric constants with positive values, as derived from the optical properties, confirmed the conductivity of this material. Among the four proposed geometries of VO₂(B) in this study, the outcomes obtained by VO₂(B)_{PPD} reveal good results owing to the excellent consistency of its bandgap, magnetic and optical properties with other experimental and theoretical observations. The theoretical framework in our study will provide useful insight for future practical applications of the VO₂(B) polymorph in electronics and optoelectronics.

Introduction

Transition metal oxides^{1–3} have been widely studied during the last decades because of their unique physical properties that are exploitable in the areas of dielectrics,^{4,5} thermoelectricity,^{6–8} catalysis,^{9–11} microelectronics,^{12,13} and thin-film transistors.^{14–18} Vanadium oxides are of particular interest due to these materials provide outstanding advantages in many optoelectronic devices, such as smart windows,^{19–21} sensors,^{22–24} and resistive memories.^{25–29} They have received considerable attention since they are studied as a metal–insulator transition (MIT) material.^{30–34} The MIT can be induced by increasing the temperature/

pressure, which causes changes to the structural, electronic, electrical, and optical properties of the materials.^{35–42}

According to experimental and theoretical studies, different structures of vanadium oxides have been found at high and low-temperature phases. So far, VO₂,^{43–46} V₂O₅,^{47,48} V₂O₃,^{49–51} V₃O₅,⁵² V₄O₇,⁵³ and V₆O₁₃ (ref. 54 and 55) are the most interesting compounds with well known structural properties for the MIT. Vanadium dioxides (VO₂) are very well known materials with several polymorphs, including tetragonal (R),⁵⁶ monoclinic (M),⁵⁷ triclinic (T),⁵⁸ tetragonal (A),⁵⁹ monoclinic (B),⁶⁰ parantroseite⁶¹ and the new body centered-cubic (bcc) structure.⁶² At a high temperature, a metallic phase (VO₂(R)) with a rutile structure can be achieved, while cooling to below 340 K, the R phase changes into an insulating monoclinic structure M phase.^{63–65} Because the phase transition from the rutile VO₂(R) and the monoclinic VO₂(M) is associated with a huge change in resistivity, it has attracted considerable attention for electronic and optical applications.^{43,66–69}

VO₂(B) has been explored as a promising cathode material in Li ion batteries, mainly because of its prominent advantages of high discharge capacity of 323 mA h g⁻¹ and low cost.^{70–73} Moreover, the VO₂(M) and VO₂(R) phases can be prepared by the irreversible transformation of VO₂(B) as a precursor.^{74,75}

Advanced theoretical and experimental techniques have been implemented to study the VO₂(B) polymorph. While an experimental bandgap of 0.6–0.7 eV (ref. 76–78) was found for VO₂ near the semiconductor–metal transition, an X-ray photoelectron spectroscopy study revealed a metallic observation of this material at room temperature.⁶⁴ In agreement with the experimental results, the first-principles calculations confirmed both metallic and insulating features of VO₂(B).^{64,74,79,80} In the study conducted by Lee *et al.*,⁸⁰ XAS, optical spectroscopy, and DFT calculations were applied to assess the bandgap in the VO₂(B), VO₂(M), and VO₂(A) structures. This study revealed that by comparing the electronic structures of the A, B, and M phases, conventional DFT calculations estimated signatures of a metallic behavior for the A, B, and M phases. Meanwhile, hybrid functional calculations indicated bandgaps of 0.6 eV and 0.5 eV for the M and A phases, respectively, and a very narrow bandgap of 25 meV for the B phase. Zhang *et al.*⁷⁴ investigated the phase transition process from VO₂(B) to VO₂(A) based on X-ray absorption spectroscopy (XAS) analysis and DFT calculations. They reported on the metastability of VO₂(B) in comparison with the VO₂(A) and VO₂(R) phases. The calculation of the formation energy in a different phase of VO₂ showed that the VO₂(B) structure has less geometrical stability with –6.66 eV formation energy compared to –6.93 and –7.18 eV for VO₂(R) and VO₂(M), respectively. This study proposed that the different electronic structure completely depended on the different stabilities of the VO₂ phases. In a recent study carried out by Popuri *et al.*,⁸¹ the electron transport properties of the VO₂(B) structure at low (25–200 K), intermediate (200–320 K), and high temperatures (320–350 K) were investigated using spark plasma sintering. They found different electronic and magnetic properties at different thermal phases. At the low and intermediate temperature phases, nonmagnetic ordering was associated with the insulating characteristic of the structure. At a high temperature, metallic behavior and antiferromagnetic property were observed. In another study, Lourembam *et al.*⁸² used terahertz time-domain spectroscopy (THz-TDS) to investigate the temperature-dependent complex optical conductivity of the VO₂(B) structure. They observed that VO₂(B) transformed from an insulating system to a conducting system at 240 K. Furthermore, there was a broad intermediate state with the transition onset being much closer to room temperature, allowing this polymorph to be more suitable for optoelectronic devices near room temperature. In an extensive experimental and theoretical research recently conducted by Wan *et al.*,⁸³ they indicated that pure VO₂(B) has weak absorption in infrared light, with excellent agreement between theory and experiment.

So far, some experimental results have been determined for the geometrical data and MIT for this compound.^{82–88} The electronic properties have been investigated with some experimental and theoretical methodologies; however, the data are still limited and variable.^{64,74,79,83,89} Furthermore, magnetic and

optical features are potentially important properties that have not yet been systematically studied for this polymorph with first-principles calculations, and no detailed values have been reported yet. Since a systematic investigation of the efficacy of advanced theoretical methods for computing the chemical and physical properties of VO₂(B) is missing, our study seeks to fill this gap in the literature. Our present work is focused on the complete theoretical description of the electronic, magnetic, and optical properties of the VO₂(B) polymorph using GGA/PBE and GA/PBE + U functionals. Recent studies have shown how the combined use of these methods makes it possible to calculate different material properties.⁹⁰ The main objectives of this work are as follows: (i) investigation of the structural parameters of VO₂(B) by employing different theoretical approaches. The geometry optimization of this polymorph will be assessed by different methodologies in order to find the most accurate results of the material characterization in agreement with the experimental outcomes. (ii) Calculation of the electronic band structure and magnetic properties, (iii) and analysis of the optical properties of the proposed different geometries of VO₂(B).

Computational methods

We carried out the atomistic calculations using the Quantum ESPRESSO (QE)⁹¹ and QuantumATK (QATK)⁹² packages. The DFT approach was implemented in the Kohn–Sham (KS) formulation^{93,94} within the framework of the linear combination of atomic orbitals (LCAO) and plane-wave (PW) basis set approaches, combined with the pseudopotential (PPs) method. PseudoDojo⁹⁵ and Projector Augmented Wave (PAW) PPs⁹⁶ were used for the LCAO and PW calculations, respectively, with the aim to describe the interaction between ion cores and valence electrons. DFT-LCAO and DFT-PW calculations were performed within the GGA framework adopting the PBE exchange–correlation (XC) functional.⁹⁷ Valence orbitals were expanded in a PW basis set with a kinetic energy cut-off of 70 Ry. Brillouin-zone (BZ)⁹⁸ integrations were limited to the gamma point mesh, and a smearing parameter of 0.0001 Ry was considered for the electron population function.⁹⁹ The van der Waals corrections were included by the Grimme's DFT-D3 method,¹⁰⁰ and the structure was relaxed with the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.¹⁰¹ We implemented both PBE and PBE + U^{102,103} in post-processing calculations in order to make an exhaustive comparison between the different geometries. Since previous studies have shown that the outcomes substantially depended on the magnitude of U , we tested different Hubbard U values for the vanadium d orbital (U^d) and oxygen p orbital (U^p). In this study, we have set $U^d = 5.20$ eV and $U^p = 0.95$ eV, wherein they have more similarity to the results reported by Huffman *et al.*¹⁰⁴ ($U^d = 5.00$ eV and $U^p = 0.00$ eV). However, our chosen Hubbard values show more agreement between the theoretical and experimental bandgaps, as we will discuss later.

To calculate the electronic band structure and Projected DOS (PDOS), since the KS equation is a nonlinear differential formula, we first converged the charge density with the self-

consistent field (SCF) calculations to compute the DOS on a uniform k -mesh (we used the $6 \times 6 \times 6$ k -points). Then, we ran the non-self-consistent (NSCF) calculation with a twice high k -mesh with respect to the SCF calculations ($12 \times 12 \times 12$ Monkhorst-Pack mesh) in order to construct the Hamiltonian for the charge density by using the tetrahedron method. PDOS was also considered to account for the magnetic ordering of the compound. Optical calculations were analyzed based on the random phase approximation (RPA).^{105,106} The optical properties of the VO₂(B) structure in this study are discussed by the two components of the dielectric function ($\epsilon(\omega) = \epsilon_1(\omega) + i\epsilon_2(\omega)$) related to different polarizations in the electric field. The imaginary part of the dielectric coefficient can be obtained from the direct interband transitions through Fermi's golden rule as:¹⁰⁷⁻¹⁰⁹

$$\epsilon_2(\omega) = \frac{4\pi^2}{\Omega\omega^2} \sum_{i \in \text{VB}, j \in \text{CB}} \sum_k W_k |\rho_{ij}|^2 \delta(\epsilon_{kj} - \epsilon_{ki} - \hbar\omega) \quad (1)$$

where VB, CB, ω , Ω , W_k , and ρ_{ij} denote the valence band, conduction band, photon frequency, volume of the unit cell, weight of the k -point, and elements of the dipole transition matrix, respectively. Moreover, the real part of the dielectric constant can be obtained using the Kramers-Kronig relation in eqn (2):

$$\epsilon_1(\omega) = 1 + \frac{1}{\pi} P \int_0^\infty d\bar{\omega} \frac{\bar{\omega} \epsilon_2(\bar{\omega})}{\bar{\omega}^2 - \omega^2} \quad (2)$$

where P is the principal value. The real part of the dielectric constants determines the polarization of a material subjected to an external electric field (in this case, the light beam). In addition, the imaginary part shows the amount of light absorption.¹¹⁰

The electron energy loss spectrum, $L(\omega)$, can also be described using the dielectric constants by:^{111,112}

$$L(\omega) = \frac{\epsilon_2(\omega)}{\epsilon_2^2(\omega) - \epsilon_1^2(\omega)} \quad (3)$$

The energy loss function determines the loss of energy while traversing through the material. Molecular graphics were generated using the XCRYSDEN graphical package.¹¹³

Results and discussion

Analysis of the polymeric structure

VO₂(B) with the space group $C2/m$ was simulated in periodic boundary conditions (PBC) along with three Cartesian coordinates. As shown in Fig. 1, the base-centered monoclinic unit cell has dimensions of $11.85 \times 3.74 \times 6.49 \text{ \AA}^3$. This included 12 atoms in the primitive unit cell (4 vanadium and 8 oxygen) and 24 atoms in the conventional unit cell (8 vanadium and 16 oxygen atoms) (see Fig. 1(b)). This unit cell dimension is in good agreement with the previous experimental patterns^{64,81,85} and theoretical studies.^{74,79,83} As shown in Fig. 1(a) and (b), the VO₂(B) structure can be considered as two identical atom layers including 3D frameworks of VO₆ octahedra. These octahedra packings of VO₆ are only linked by oxygen atoms in the corners.

The second layer is shifted with respect to the first one by $1/2, 1/2, 0$. This polymorph is distorted because of the out-of-center vanadium atoms, resulting in the presence of short/long V-V and two different types of octahedra.

The lattice energy minimized for VO₂(B) was obtained by employing geometry optimizations of the atomic positions and altering the size and angle of the unit cell, systematically. After the optimization of the lattices, we evaluated the structural parameters and bond lengths on different types of vanadium atoms in the 3D structure. As shown in Fig. 1(b), there are 4 types of V-V bonds in the VO₂(B) structure. From the experimental bond lengths (see Table 1), they are as follows: (i) the shortest V₁-V₂ bond in the center of the xy plane with a bond length of 2.89 Å, (ii) V₂-V₃ vanadium atoms in the xy plane with a length of 3.24 Å, (iii) long V₃-V₄ vanadium bonds with an average distance of 3.33 Å, and (iv) medium bond length of V₁-V₄ characterized by 3.06 Å.

Table 1 indicates that the VO₂(B) compound exhibits different ranges of the V-V bond distance with the four optimized geometries obtained from the PW and LCAO approaches by including/excluding the dispersion corrections (DFT-D3) in the GGA/PBE calculations. For the convenience of discussion, the experimental and theoretical V-V bond lengths and their differences are listed in Table 1. In comparison to the experimental results in ref. 81, the VO₂(B) optimized structure obtained from the PW approach and PBE XC functional without including the dispersion corrections (PW(PBE)) (the material named VO₂(B)_{PP}) exhibited V₁ and V₃ atoms that were greatly displaced away from the central vanadium atom V₂ with V₁-V₂ = 3.33 Å and V₂-V₃ = 3.79 Å. Moreover, V₄ became closer to V₃ and V₁ with distances of 3.18 Å and 2.94 Å, respectively. In the case of PW(PBE-D3) (VO₂(B)_{PPD}) including the van der Waals interactions, the V₁-V₂ and V₂-V₃ bond distances were shortened to 2.98 Å and 3.34 Å in more agreement with the experimental values of 2.89 Å and 3.24 Å, respectively. However, the V₃-V₄ bond distance reached the length of 3.45 Å, which is far from the experimental distance of 3.33 Å. In the VO₂(B)_{LP} structure obtained from the LCAO(PBE) method, the V₃-V₄ and V₁-V₄ bond distances were elongated from 3.18 Å and 2.94 Å in VO₂(B)_{PP} to 3.45 Å and 3.05 Å in VO₂(B)_{LP}, respectively, while the V₂-V₃ bond distance decreased from 3.79 Å in VO₂(B)_{PP} to 3.27 Å in this geometry. In this case, V₁ and V₂ significantly became closer together by 2.81 Å, which is less than the experimental value of 2.89 Å. Finally, the optimized structure of VO₂(B)_{LPD} obtained from LCAO(PBE-D3) including the dispersion corrections exhibited the greatest similarity to the results obtained from VO₂(B)_{PPD} with distances V₁-V₂ = 3.02 Å, V₂-V₃ = 3.32 Å, V₃-V₄ = 3.55 Å, and V₁-V₄ = 3.17 Å.

From the structural parameters computed by the two different PW and LCAO approaches presented in Table 1, we can understand the trend with regards to the treatment of the chosen basis set and XC functional. By using the PW basis set and the PAW XC functional, the approximation tends to overestimate V₁-V₂ and underestimate V₃-V₄. Conversely, the LCAO basis set associated with the PseudoDojo XC functional leads to an underestimate of V₁-V₂ and overestimate of V₃-V₄. However, including the van der Waals interactions moderated the system

Fig. 1 Schematic representations of (a) the 3D frameworks of VO_6 octahedra in $\text{VO}_2(\text{B})$ (b) $2\text{D } 2 \times 2$ supercell of the $\text{VO}_2(\text{B})$ polymorph, solid red line represents the unit cell of the structure. Color code in the model: V blue and O red.

in both approximations. From these results, it is important to note that the basis set approximation can have a significant effect on the computed structures. Calculations on the bulk of similar materials have demonstrated that the LCAO approximation tends to give results that agree less with experimental results compared to the PW. In addition, it is worth noting that van der Waals interactions have a remarkable role in reducing the $\text{V}_1\text{-V}_2$ and $\text{V}_2\text{-V}_3$ interlayer distances when we consider our system by the PW basis set (Table 1). Meanwhile, it has the opposite effect when the LCAO basis set is used by enhancing the corresponding bond lengths of $\text{V}_1\text{-V}_2$ and $\text{V}_2\text{-V}_3$. As we shall discuss later, since the shortest $\text{V}_1\text{-V}_2$ bond distance plays a critical role in the electronic structure of the $\text{VO}_2(\text{B})$ polymorphs, the PW(DFT-D3) method gives us more accurate

results related to the different physical properties of the $\text{VO}_2(\text{B})$ nanostructure.

In the next step, we calculated the post-processing computations of the electronic, magnetic, and optical properties of four different geometries of the $\text{VO}_2(\text{B})$ polymorph in order to discover which geometry indicates better accordance to experimental and theoretical studies for this material.

Electronic and magnetic properties

We studied the electronic properties of the $\text{VO}_2(\text{B})$ polymorph by computing the electronic band structure and the corresponding PDOS curves for total, V-3d, and O-2p for $\text{VO}_2(\text{B})_{\text{PP}}$, $\text{VO}_2(\text{B})_{\text{LP}}$, $\text{VO}_2(\text{B})_{\text{PPD}}$, and $\text{VO}_2(\text{B})_{\text{LPD}}$ geometries based on the

Table 1 Theoretically determined bond lengths of $\text{VO}_2(\text{B})$ optimized structures from the PW and LCAO with and without including the dispersion corrections calculations

Structural parameters (Å)	PW (PBE)	LCAO (PBE)	PW (PBE-D3)	LCAO (PBE-D3)	Experiment ^{B1}
$\text{V}_1\text{-V}_2$	3.33	2.81	2.98	3.02	2.89
$\text{V}_2\text{-V}_3$	3.79	3.27	3.34	3.32	3.24
$\text{V}_3\text{-V}_4$	3.18	3.45	3.50	3.55	3.33
$\text{V}_1\text{-V}_4$	2.94	3.05	3.18	3.17	3.06

PBE and PBE + U approximations. The band structure was analyzed along the high symmetry G–M–G–X–Y–I–L–G directions in the first BZ. The results calculated by GGA/PBE revealed the zero bandgap for all four geometries of the VO₂(B) polymorph. Since conventional XC functionals such as PBE often underestimate the bandgap in semiconductors,¹¹⁴ we also employed the DFT + U method to provide a more accurate prediction of the V d–d orbital correlations and bandgap. So far, the DFT + U method was successful in the prediction of the bandgap for different polymorphs of vanadium oxides. Furthermore, the outcomes agreed relatively well with experimental results.^{83,115–118} Fig. 2 and 3 describe the band structure and DOS predicted by the PBE + U functional, respectively. From these results, we found that the Hubbard method described the electronic bandgap in VO₂(B) well when the U correction effect is considered in DFT. The corresponding bandgap of the VO₂(B) geometries based on GGA/PBE + U became much larger, *i.e.*, 0.76 eV, 0.66 eV, and 0.70 eV for VO₂(B)_{PP} (a), VO₂(B)_{LP} (b), and VO₂(B)_{PPD} (c), respectively, leading to the semiconductor character of this material. An inspection of Fig. 3 indicates that with the main contribution of total DOS belonged to the V-3d orbital accompanied by less contribution from the O-2p state. As reported in Fig. 2 and 3 (d), excluding/including the U correction

in the PBE calculation showed the same zero bandgap for the VO₂(B)_{LPD} geometry. VO₂(B)_{LPD} might have a very narrow bandgap. Hence, DFT calculations could not accurately describe the electronic ground states of this structure. Our results from PBE and PBE + U approximations indicate good consistency with the previous experimental and theoretical studies. Our estimated bandgap values by GGA/PBE + U approximation for the optimized structure VO₂(B)_{PP}, VO₂(B)_{LP} and VO₂(B)_{PPD} were fitted with the experimental value of 0.6–0.7 eV,^{76–78} comparable with 0.65 eV computed by the HSE method,⁷⁴ and the values predicted by DFT + U ($U^d = 4.00$ eV) with 0.60 eV⁸³ and 0.78 eV ($U^d = 3.25$ eV).⁷⁹ Moreover, the outcomes predicted by Lee *et al.*⁸⁰ revealed the narrow bandgap semiconductor (<25 meV) for the VO₂(B) structure using the PBE0 hybrid functional.

Next, we examined the magnetism ordering of VO₂(B) geometries by consideration of the SCF output files and *Lowdin* charge^{119,120} analysis from PDOS calculations.

The magnetism has been reported as two values of the total magnetization and absolute magnetization. While the total magnetization indicates the same value of 4.00 μ_B for all four geometries of the VO₂(B) polymorph, the absolute magnetization (Table 2) shows different values of magnetism. As expected, Table 2 reveals that with the Hubbard approximation, the

Fig. 2 Band structure of VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} structures predicted by the GGA/PBE + U functional. Fermi energy aligned in the dash line.

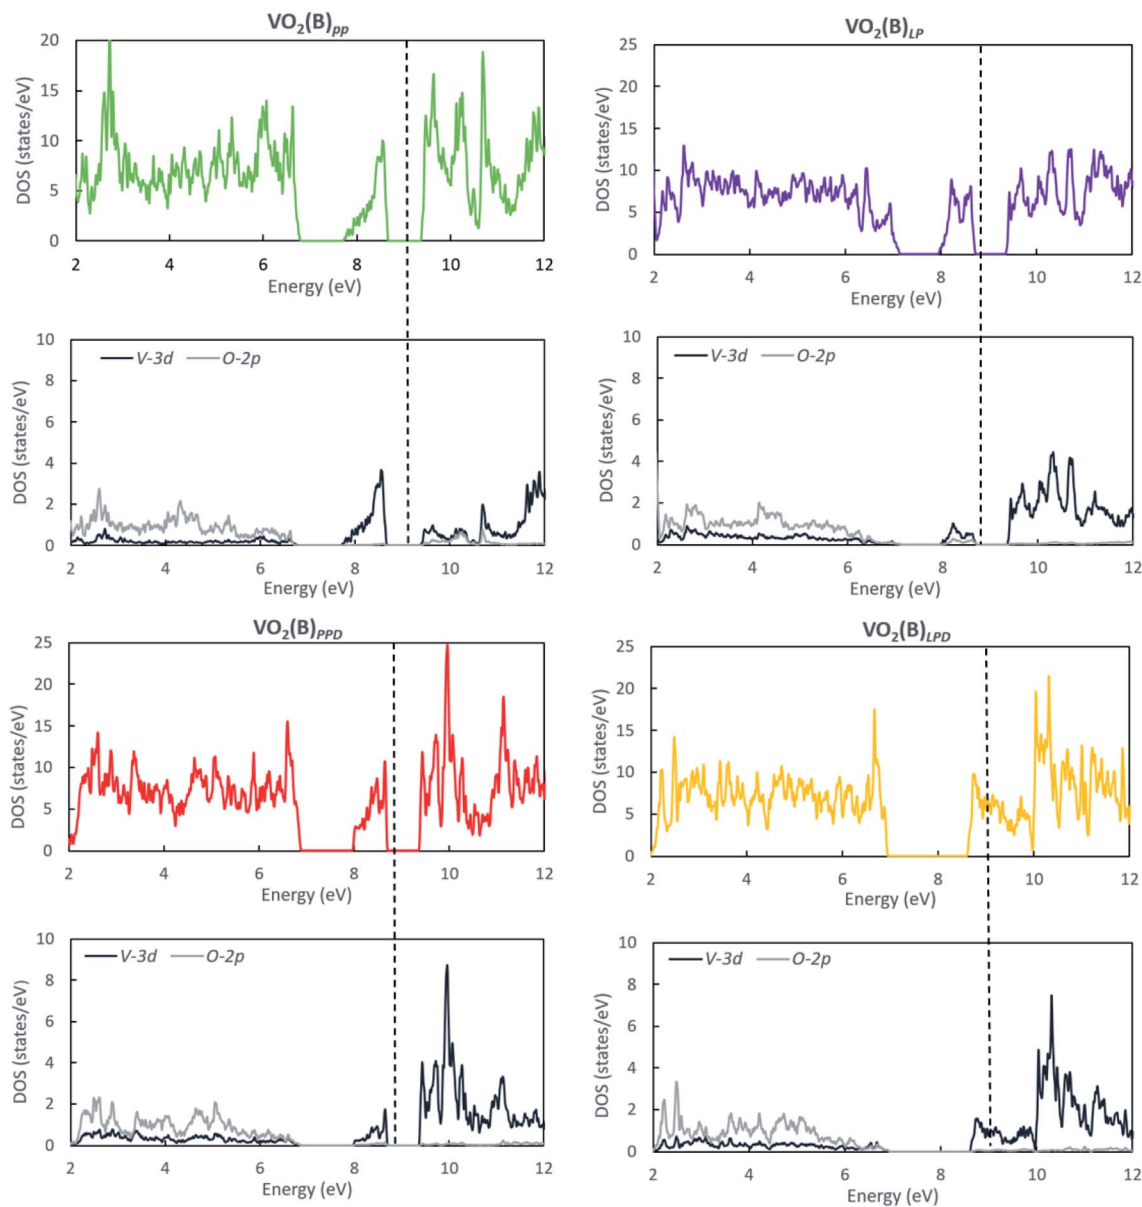

Fig. 3 Total and partial DOS curves for the total, V-3d, and O-2p of $\text{VO}_2(\text{B})_{\text{PP}}$, $\text{VO}_2(\text{B})_{\text{LP}}$, $\text{VO}_2(\text{B})_{\text{PPD}}$, and $\text{VO}_2(\text{B})_{\text{LPD}}$ structures predicted by the GGA/PBE + U functional. Fermi energy aligned in the dash line.

absolute magnetization resulted in higher values than that observed using the conventional DFT, while $\text{VO}_2(\text{B})_{\text{PP}}$ and $\text{VO}_2(\text{B})_{\text{LPD}}$ showed higher and lower magnetization, respectively.

To elucidate the amount of magnetism contribution of vanadium and oxygen orbitals in the unit cell, we collected the

Table 2 Absolute magnetization (in μ_{B}) of $\text{VO}_2(\text{B})_{\text{PP}}$, $\text{VO}_2(\text{B})_{\text{LP}}$, $\text{VO}_2(\text{B})_{\text{PPD}}$, and $\text{VO}_2(\text{B})_{\text{LPD}}$, predicted by GGA/PBE and GGA/PBE + U

Method	$\text{VO}_2(\text{B})_{\text{PP}}$	$\text{VO}_2(\text{B})_{\text{LP}}$	$\text{VO}_2(\text{B})_{\text{PPD}}$	$\text{VO}_2(\text{B})_{\text{LPD}}$
GGA/PBE	4.21	4.94	5.10	5.07
GGA/PBE + U	6.01	5.81	5.77	5.55

Lowdin charges and the magnetic moment (MM) of the V-3d and O-2p orbitals (s and p orbitals for vanadium atoms and s orbitals for oxygen atoms can be neglected because these orbitals have negligible MM contributions). Table 3 indicates the total MM per unit cell (MM/cell) for different geometries of the $\text{VO}_2(\text{B})$ polymorph predicted by GGA/PBE and GGA/PBE + U approximations. With both approaches, the main contribution of the total MM is related to the vanadium 3d orbitals. Inspecting Table 3 reveals that $\text{VO}_2(\text{B})_{\text{PP}}$ has increased its total MM by $1 \mu_{\text{B}}$ for V-3d and $0.77 \mu_{\text{B}}$ for O-2p orbitals when we included U correction value, while these values have slightly reduced for other geometries by V-3d = $0.47 \mu_{\text{B}}$ and O-2p = $0.51 \mu_{\text{B}}$ for $\text{VO}_2(\text{B})_{\text{LP}}$, V-3d = $0.38 \mu_{\text{B}}$ and O-2p = $0.38 \mu_{\text{B}}$ for $\text{VO}_2(\text{B})_{\text{PPD}}$, and V-3d = $0.23 \mu_{\text{B}}$ and O-2p = $0.15 \mu_{\text{B}}$ for $\text{VO}_2(\text{B})_{\text{LPD}}$.

Table 3 Total MM/cell (in μ_B) for the V-3d and O-2p orbitals of VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} predicted by GGA/PBE and GGA/PBE + U

Method	VO ₂ (B) _{PP}	VO ₂ (B) _{LP}	VO ₂ (B) _{PPD}	VO ₂ (B) _{LPD}
V-3d (GGA/PBE)	3.9582	4.3588	4.4502	4.4928
O-2p (GGA/PBE)	0.2904	0.4796	0.5428	1.0296
V-3d (GGA/PBE + U)	4.9598	4.8310	4.8298	4.7266
O-2p (GGA/PBE + U)	1.0654	0.9998	0.9286	1.1864

According to the data in Tables 2 and 3, the highest/lowest difference in the total MM/cell between DFT and DFT + U are related to the VO₂(B)_{PP}/VO₂(B)_{LPD}, with the corresponding bandgap of 0.76/0.00 eV. In contrast, the two other VO₂(B)_{LP} and VO₂(B)_{PPD} geometries with similar MM have very close bandgaps of 0.66 and 0.70 eV, respectively. The zero bandgap of VO₂(B)_{LPD} can be attributed to fewer electrons occupying the O-2p orbitals with including the Coulomb repulsive parameter. Therefore, it can be concluded that the metallic state of this geometry is composed of dispersive bands of Vanadium 3d electrons.

Since the vanadium 3d orbitals contribute the most to the magnetism of the VO₂(B) polymorph, we considered the detail of the total MM/cell of the V-3d orbitals. In the transition metal oxides, the d level is fivefold degenerate. The degeneracy of the d level is split into the lower energy t_{2g} level and higher energy e_g level by the crystal field splitting in an octahedral field. In this system, the vanadium atom is octahedrally coordinated by oxygen. In the earlier study by Zhang *et al.*,⁷⁴ the semi-conducting band structure diagram of VO₂(B) was precisely explained. It is worth noting that V-V localized pairing interactions influenced the π band and consequently the 3d_{xz}, 3d_{yz} and 3d_{xy} orbitals in t_{2g} level. Meanwhile, the 3d_{z²} and 3d_{x²-y²} orbitals (both in the e_g level) that are involved in the σ band, are mainly affected by the indirect V-O-V metal-ligand interactions. Table 4 reveals that the electrons predominantly occupy the π band. In contrast, very few electrons occupy the σ band. Based on the outcomes collected in Table 4, it can be observed that the 3d_{xz} and 3d_{yz} orbitals have the prevailing contribution in the MM/cell, 3d_{xy} has some contribution to a lesser extent, while the 3d_{z²} and 3d_{x²-y²} orbitals have negligible contributions. Among the four geometries, VO₂(B)_{LP} produces quite a different effect. The charge accumulation in the 3d_{xy} orbital is more than that for the 3d_{xz} and 3d_{yz} orbitals (MM = 1.8746 μ_B for 3d_{xy} in comparison to MM = 1.2118 μ_B and MM = 1.2444 μ_B for the 3d_{xz} and 3d_{yz} orbitals, respectively, with PBE + U

approximation). In this case, the accumulation of the charge in the 3d_{xy} orbitals are greater than those of other geometries. This can be interpreted from the existence of the very short distance V₁-V₂ = 1.81 Å (Table 1) in this structure. By comparison, in the other three considered geometries, this bond distance is about 3 Å. Taking into account that the GGA + U method adds a Hubbard-type term to the density functional that increases the electron localization in the correlated orbitals, it is generally believed to provide better results.

According to the experiments carried out by Popuri *et al.*,⁸¹ macroscopic magnetic measurement results showed that the interactions for the vanadium ions were antiferromagnetic during the high temperature phase. A very weak ferromagnetic property of the VO₂(B) polymorph can be observed at low temperature. As proposed in this study, the Curie constant (the contribution percentage of the half-spin ($S_{1/2}$)) in the vanadium cation is varied in different phases. The obtained curie constant at the low-temperature phase of the VO₂(B) structure was 12% for $S_{1/2}$ in the V-3d cation (spin singlets). This contribution increased to 50% and 100% at the intermediate temperature and high temperature phases (free spins), respectively. Furthermore, experimental X-band EPR spectra in this work revealed a broad resonance line related to the weak interaction of the V-V pairs in the low temperature phase. In contrast, this line became significantly narrower in the intermediate temperature and high temperature phases because of the unlocalized interactions. Similar observations were made by Oka *et al.*,⁸⁵ with the paramagnetic vanadium ions in the high temperature phase and the formation of nonmagnetic V-V pairs in the low temperature phase. In agreement with the outcomes obtained for these studies, our calculations based on GGA/PBE and GGA/PBE + U confirmed the total contribution of 12.5–15.5% for V-3d (as see in Table 3, the MM/cell for V-3d altering between ~3.95–4.95 μ_B), instead of 32 μ_B for eight vanadium atoms in the unit cell. These outcomes suggested the presence of less free spins in the VO₂(B) polymorph, resulting in weak interactions of the vanadium atoms and very poor magnetic (not-magnetic) property of this material. However, the magnetic description of the VO₂(B) structure has been controversial. Conflicting experimental reports of ferromagnetism,^{121,122} nonmagnetic/antiferromagnetic,⁸⁵ paramagnetic/antiferromagnetic,⁸¹ and paramagnetic¹²³ properties suggest that this material probably has a negligible magnetic susceptibility. We therefore designate it as non-magnetic, as previously reported.^{79,81,85,123}

Table 4 Total MM/cell in μ_B for the V-3d orbitals of VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD}, computed by GGA/PBE and GGA/PBE + U

Optical properties

Once the electronic structure calculations confirmed the semi-conducting character of the VO₂(B) polymorph, we probed their optical properties for possible optoelectronics applications. The imaginary ($\epsilon_2(\omega)$) and real parts ($\epsilon_1(\omega)$) of the dielectric function, as well as the energy loss function for the VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} structures are presented in Fig. 4–6 as functions of photon energy. We considered the parallel (in-plane) and perpendicular (out-of-plane) polarization directions within RPA + PBE and RPA + PBE + U. According to Fig. 4 and 5, the first main peak of $\epsilon_2(\omega)$ shows a weak absorption in the infrared range (1.24 meV to 1.7 eV) for the VO₂(B)_{PP} structure along the in-plane/out-of-plane polarizations. However, the situation changes remarkably for the VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} geometries, in which they indicate that the adsorption peaks in the infrared light are only along the out-of-plane polarizations. Based on the GGA/PBE calculations (Fig. 4), in the case of the in-plane polarization, only VO₂(B)_{PP} reveals a broad intense peak in the energy range of 0.47 eV, while all considered structures show peaks at 0.46, 1.06, 0.83 and 0.86 for the VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} geometries, respectively, along the out-of-plane polarization direction. These peaks correspond to the transitions from $\pi \rightarrow \pi^*$. The next highly intense peaks in all geometries are related to the $\pi \rightarrow \sigma^*$ transitions. We obtained the optical bandgap of 0.63, 0.56, and 0.60 eV for VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD}, respectively, along the out-of-plane polarization direction. This is comparable (slightly smaller) to the bulk value of ~ 0.6 eV.⁷⁷

For the real part of the dielectric function related to the static dielectric function, it was found that the $\epsilon_1(\omega)$ part for VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} geometries shows the positive values of 38.53, 4.60, 5.08 and 5.06 along the in-plane polarization, and 65.99, 19.50, 20.46 and 18.43 for the out-of-plane polarization directions, respectively.

From the predicted data based on the DFT + U calculations, as shown in Fig. 5, the adsorption peaks of $\epsilon_2(\omega)$ along the in-plane polarization show similar results to the PBE calculations. However, the peaks existing in the optical spectrum of the out-of-plane direction exhibit a blue shift in the light energy range of 1.43 eV for VO₂(B)_{LP} and an intense peak at 3.10 eV. By applying the U correction in the PBE calculations, the light polarization becomes more intense in VO₂(B)_{PP}, whereas the other three geometries exhibit the opposite behavior by decreasing the peak intensity. Moreover, our theoretical calculations indicate that the optical bandgaps of the VO₂(B)_{PPD} and VO₂(B)_{LPD} geometries slightly increase by ~ 0.95 eV. Meanwhile, the optical bandgap of VO₂(B)_{LP} is situated at higher energies at 1.20 eV. A strange behavior is represented by the zero optical bandgap of VO₂(B)_{PP} at low photon energy. This distinct difference might occur because VO₂(B)_{PP} contains a longer V₁–V₂ = 3.33 Å (more weakly bonded) than the three other configurations with shorter V₁–V₂ bond distances of 2.81, 2.98 and 3.02 Å for VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} (Table 1), respectively. The amounts of static dielectric constants were calculated to be 39.32, 4.33, 4.86 and 4.83 along the in-plane direction, and 49.91, 14.55, 10.84 and 10.87 along the out-of-

Fig. 4 Imaginary and real parts of the dielectric function of VO₂(B)_{PP} (green), VO₂(B)_{LP} (purple), VO₂(B)_{PPD} (red), and VO₂(B)_{LPD} (orange) structures along the in-plane (a and c) and out-of-plane (b and d) polarizations, as predicted by RPA + PBE.

Fig. 5 Imaginary and real parts of the dielectric function of VO₂(B)_{PP} (green), VO₂(B)_{LP} (purple), VO₂(B)_{PPD} (red), and VO₂(B)_{LPD} (orange) structures along the in-plane (a and c) and out-of-plane (b and d) polarizations, as predicted by RPA + PBE + U.

Fig. 6 Energy loss function spectra of VO₂(B)_{PP} (green), VO₂(B)_{LP} (purple), VO₂(B)_{PPD} (red), and VO₂(B)_{LPD} (orange) structures along the in-plane and out-of-plane polarizations, as predicted by RPA + PBE (a and b) and RPA + PBE + U (c and d).

plane polarization direction, with a drop in comparison to the PBE functional. The static optical spectra with the positive value of both in-plane/out-of-plane dielectric constants are further proof of the VO₂(B) conductivity. Lourembam *et al.*⁸² and Lee *et al.*⁸⁰ experimentally confirmed the non-zero frequency of the real part of the optical conductivity of this polymorph.

As reported in the literature, the different experimental values of the static dielectric constant of VO₂ have been observed. Yang *et al.*¹²⁴ investigated the temperature dependence of the dielectric constant and carrier conduction in VO₂ thin films. They outlined that the dielectric constant of VO₂ can be increased from ~36 at room temperature to a value exceeding 6×10^4 at 100 °C. In another study, Hood *et al.*¹²⁵ measured the dielectric constant of the VO₂ structure across the phase transformation at 68 °C. In this work, the real part of the dielectric constant increased from less than 1000 to higher than 90 000 by elongating the film thickness. Furthermore, the outcomes obtained by Mansingh *et al.*¹²⁶ showed the approximated value of 100 for the static dielectric constant of VO₂ single crystals in the frequency range of 30 to 10⁵ Hz, and in the temperature range 77 to 250 K. From the theoretical side, Wan *et al.*⁸³ used both experiment and first-principles PBE + U calculations to investigate the optical property of the VO₂(B) structure. They observed the weak adsorption of this polymorph in the infrared light along the in-plane/out-of-plane polarization directions. According to the data presented in the literature for the other 2D oxides, VO₂(B) possesses an excellent dielectric constant along the in-plane and out-of-plane directions. Its dielectric constant is higher than that for Al₂O₃ with a value of 8–10 and SiO₂ with 3.9,¹²⁷ and is comparable with that for HfO₂ with a dielectric constant of 20–25.¹²⁸ Our calculations indicate that VO₂(B) can be a good replacement for SiO₂ with a higher dielectric constant for application in field effect transistors (FETs) and capacitors of dynamic random-access memories. Meanwhile, the stronger infrared absorption of the VO₂(B) polymorph is favorable for achieving the maximum sensitivity for the applications in uncooled infrared bolometer.^{129,130}

The theoretical energy loss function computed by GGA/PBE and GGA/PBE + U is presented in Fig. 6(a)–(d). The energy-loss spectrum is important for describing the energy loss of electrons passing through the materials. While the spectrum calculated by GGA/PBE indicated broad peaks for the in-plane polarization in the energy range of 14–20 eV, GGA/PBE + U indicated in the high intensity peaks along the in-plane and out-of-plane polarization directions. The results reveal that the maximum energy loss peak value predicted by GGA/PBE for VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD} and VO₂(B)_{LPD} reaches 19.26, 15.99, 16.09 and 16.09 eV along the in-plane polarization direction, and 14.45, 16.96, 15.96 and 15.96 eV for the out-of-plane polarization direction, respectively. The corresponding values predicted by the PBE + U functional are 19.06, 16.32, 16.62 and 15.55 eV along the in-plane polarization direction, and 14.45, 15.92, 16.02 and 16.02 eV along the out-of-plane polarization direction.

According to the theoretical study by Wan *et al.*,⁸³ they found an electronic bandgap of 0.60 eV for the VO₂(B) polymorph. However, the zero optical bandgap was observed in the $\epsilon_2(\omega)$ optical graph. This disagreement also occurred in our

calculations, in which the VO₂(B)_{PP} structure showed an 0.76 eV electronic bandgap and zero optical bandgap. Conversely, VO₂(-B)_{PPD} indicated a zero bandgap in the band structure calculations and a semiconductor optical property. On the other hand, VO₂(B)_{LP} was not able to support the correct optical bandgap when the *U* value was included in the PBE calculations. In conclusion, the subtle interplay between the electronic, magnetic, and optical properties leads to the VO₂(B)_{PPD} configuration describing the semiconductor electronic and optical bandgap well, and shows excellent agreement between experimental and theoretical observations. Therefore, on the basis of the DFT calculations with the PW approach and PBE-D3 method, this configuration strongly suggests a VO₂(B) polymorph.

Conclusions

We have successfully reproduced the experimental electronic, magnetic and optical properties of the VO₂(B) polymorph *via* DFT calculations. In this study, we optimized the geometry of the VO₂(B) polymorph on the basis of the PW and LCAO approaches using the GGA/PBE functional and with exclusion/inclusion of the dispersion corrections. The analysis of the structural parameters showed the existence of four different geometries of VO₂(B), namely VO₂(B)_{PP}, VO₂(B)_{LP}, VO₂(B)_{PPD}, and VO₂(B)_{LPD} obtained from different methods. In order to check for the reliability of the computational methods, particularly for the selected energy functional (PBE + U) with the Coulomb correlation effect, we calculated the electronic and optical bandgaps and magnetic state of the VO₂(B) configurations for comparison with experiments. The electronic band structure and DOS revealed a zero bandgap for all considered geometries by using the conventional GGA/PBE approximation. However, applying a Hubbard *U* value of 5.20 eV for the V-3d orbitals significantly opened the bandgap up to 0.76, 0.66 eV and 0.70 eV for VO₂(B)_{PP}, VO₂(B)_{LP} and VO₂(B)_{PPD}, respectively. From these numerical calculations, we indicated that the DFT + U method can be used to change the gap size and induce a metal–semiconductor transition. PDOS solution was used in our potential energy scan and the magnetic properties were assessed. The PBE and PBE + U predicted the nonmagnetic state of the ground-state VO₂(B) phase, which is consistent with the magnetic moment observed in experiments. Moreover, the optical properties including the imaginary and real parts of the dielectric function for the in-plane and out-of-plane polarizations for the VO₂(B) geometries were evaluated. The first absorption peaks revealed that all considered geometries can perfectly absorb infrared light along the out-of-plane polarization. Notably, PBE and PBE + U confirmed its VO₂(B) semiconducting feature with the static dielectric constants having positive values. The DFT-based verification of the nonmagnetic feature as well as the electronic and optical measurements of VO₂(B)_{PPD}, provide the important future research lines to physical characterization of other VO₂ polymorphs.
