Supplementary Data Analysis Methods

Word Frequency analysis

To obtain an overall view of the diseases and pathophysiological processes in which ED has been studied over time, we performed a word frequency analysis on the titles of the 10,000 earliest (spanning 1950–1997) and 10,000 latest (spanning 2018–2020) results in PubMed. To this end, we used the search term “endothelial dysfunction”, sorted by date of publication; at the time of writing of the review, this search term resulted in more than 85,000 reports. The titles of the 10,000 earliest and 10,000 latest hits were separately downloaded from PubMed in CSV format. Both files were separately analyzed with an online word counter (countwordsfree.com). In total, there were 117,900 words in the file with the earliest publications and 142,552 words in the file with the latest publications. We kept the top 500 words with the highest counts and only kept words referring to diseases, tissues, organs, or pathophysiological processes. Words with similar meanings or referring to similar processes were grouped. Next, we compared the earliest with the latest publications and assigned color codes using Excel.

This strategy allows one to analyze overall trends in publications on a specific topic without selection bias. However, the analysis is highly dependent on the intensity of research on a specific disease, is hampered by diseases consisting of two or more separate words (high blood pressure), and does not take into account the relevance of the papers for the topic.

Analysis of gene expression in freshly isolated endothelial cells

An excellent tool to explore the endothelial transcriptome has been developed by Khan and coworkers (1). They developed a database called EndoDB that combines transcriptomic data from 360 datasets. Using this tool, we selected all experiments in which the endothelial transcriptome was determined in freshly isolated endothelial cells—i.e., without in vitro culturing steps and thus resembling the *in vivo* endothelial phenotype. We only selected experiments from EndoDB in which a healthy state was compared to a disease state in vascular endothelial cells—excluding studies studying lymphatic, embryonic, or corneal endothelial cells. This resulted in 24 studies from EndoDB supplemented with two other studies outside EndoDB (2, 3). The identity of these datasets is presented in **Suppl. Table 7** (except for data from (2)). Datasets were downloaded from EndoDB in CSV format, with false discovery rate set at a cutoff of 0.1, providing log fold change values for all genes with significantly differential expression between disease state to health state. Genes coded “NA” or “Gm0000000” were removed from datasets. Genes were considered upregulated if fold change > 1.5 and downregulated if fold change < 0.666. Upregulated genes of all datasets were combined in a single table, and downregulated genes of all datasets were combined in a separate table (**Suppl. Dataset 1**).

We downloaded a list of protein-coding human genes from the HUGO Gene Nomenclature Committee website (<https://www.genenames.org/>). Next, we counted the frequency of significant up- or downregulation of each known protein-coding human gene in the data table (**Suppl. Dataset 1**) and ranked them. Out of 48375 genes, 10908 were upregulated in at least one dataset and 11285 downregulated in at least one dataset; 3006 were upregulated and 3055 were downregulated in at least three datasets. For reference, *NOS2* (coding for inducible NOS or iNOS) was upregulated in four datasets, and *NOS3* (coding for endothelial NOS or eNOS) was downregulated in five datasets.

Gene ontology enrichment analysis was performed using g:Profiler (<https://biit.cs.ut.ee/gprofiler/gost>) on 104 genes upregulated in at least 8/26 datasets and on 98 downregulated in at least 7/25 datasets. Results are summarized in **Suppl. Table 5** and **6**.
