

Computing Cost and Time Contingency for Box Culverts Construction Projects using Integrated Risk Management Technique

Omar Mohamed, Mohamed Nour, Iman Elazizy, Mona A. Hagras

Abstract: Construction and rehabilitation of water control structures in Egypt considered as an important project, as it influences the usage of water resources in Egypt which become limited resources due to water scarcity existed in the last decades. Also these projects helps in the optimization of water resources, Moreover it helps in the growth of agricultural and industrial sector. Project Risk Management (RMP) is considered as a vital and important tool in decision making, thus RMP used as a planning management system to detect risks affecting project deliverables; such as cost and time target. This research shows how to optimize the deliverables for construction of box culverts in Egypt, through a well-defined risk management framework and real case study for a certain project executed in the last decade. Finally, this study shows how to calculate cost and time contingency for these projects through an integrated risk management technique. Finally this study shows hazard risk identification and assessment for these type of projects. The conclusion of this study show that the cost contingency needed to resolve different risk factors arise in the shown case study is to increase the estimated budget with average value 11.50 percent on the total estimated budget, as well as the time contingency is found with average value 16.00 percent to be added over the total original baseline schedule of the construction project.

Keywords: Risk, Risk Management, Cost Contingency, Time Contingency, Construction of Box Culverts in Egypt.

I. INTRODUCTION

Risk is the state of uncertainty, as an event or condition that, if it occurs, has a positive or negative effect on projects deliverables. Managing risk is an integral part of sound management and risk management helps to achieve projects objectives (Omar et al., 2020). Moreover, Business Risk

can be defined as the inherent chances for either profit or loss associated with a particular endeavor which approved that risk occurs due to limited knowledge, and due to projects consequences versus targets (Rashid, 2009). Also, Business risk is the probability that an actual return of an investment will be less than the expected return. The continuing process to identify, analyze, evaluate and monitor risk to alleviate the adverse effect of loss (Saeed, 2018). Projects are exposed to internal risks (financial, design, contractual, construction, personal, involved parties and operational risks) and external risks (economic, social, political, legal, public, logistical and environmental risks). All the risks may influence cost, or time of the project in both negative and positive ways (Choudhry et.al, 2018). Risk concerns the deviation of one or more results, or of one or more future events from expected value. Technically, the main purpose of RMP is solving problems that suffer due to deviation of project deliverables, as to create an alternatives to proper functioning under conditions (Pooworakulchai, 2018).

The Egyptian water resources system is composed to many interacting components and intermingles with social, economic and environmental systems, which are also complex and uncertain. Fresh water resources include River Nile flow, precipitation and groundwater from both renewable and non-renewable aguifers (Gunidy, 2015). There is a large number of hydraulic control structures in the Nile valley and the Nile Delta, which play an important role for controlling, distribution and allocation of water, but these structures suffers different stages of degradation. The main problems in these structures is hydraulic inefficiency resulting from leakage and dysfunctional of gate operating. Also these structures suffer from structural instability resulting from the erosion of their foundations and differential settlement caused by high traffic loads. With the increasing trend of replacing barrages in Egypt, especially those built before the High Dam in 1971, there is a need to reduce their construction costs. Barrages/regulators and box culverts are structures used to control water levels along irrigation canals. The main elements of a these structures consist of a floor, abutments, piers, and a bridge. The cost of these structures depends primarily on its floor and secondarily on its abutments, piers, and bridge.

Computing Cost and Time Contingency for Box Culverts Construction Projects using Integrated Risk Management **Technique**

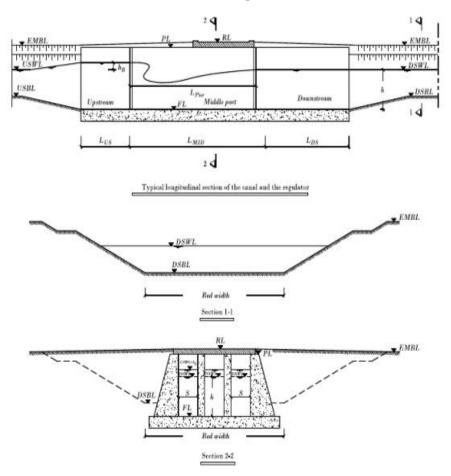

Fig.1 Barrage and canal sections showing the hydraulic parameters (Ashour et al., 2009).

II. PROBLEM STATEMENT AND RESEARCH **SCOPE**

Project participants mostly take their judgment and control their project activates by their intuitions and experience and randomly data handled inside projects, not by performing systematic RMP. This leads to not achieve project deliverables (Zabaal, 2007). The aim of this research is to optimize the deliverables of box culvert construction project through a risk management framework and accurate calculation of cost and time contingency of these projects. This research depends on case study, and to show how to compute cost and time contingency using integrated risk management technique, as data is classified into the following:

- **Background information:** The technical information about box culverts as water structure constructed in Egypt for the last decade.
- -Description of the real projects: As describing full analysis about the risk management process of a certain project, as real project is discussed; showing cost and time analysis for this project, also describing the different risks occurred, finally shows how to measure cost and time contingency needed.

III. METHODLOGY

The main methodology of data formulation and its analysis is meeting with project participants, to provide benchmark for this study. The following flow chart figure (2) shows the study methodology:

Retrieval Number: 100.1/ijeat.E35360611522 DOI: 10.35940/ijeat.E3536.0611522 Journal Website: www.ijeat.org

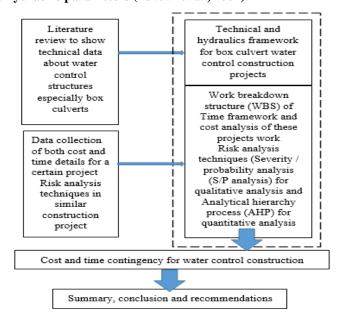

Fig .2. Study methodology flow chart

A.Technical data about construction of box culvert

Culvert is a hydraulic structure which may be fully or partially submerged in water stream. Culverts mostly change the natural flow of water. It can be used to divert, disrupt or completely stop water flow. and Advanced Technology

Exploring Innovation

Published By: Blue Eyes Intelligence Engineering and Sciences Publication (BEIESP)

Moreover culverts can be built on any water stream for a specific function. Culverts are water structures that allows water to flow under a road, rail way road, or similar obstruction from one side to the other side. As may be typically embedded so as to be surrounded by soil (Nanni et al., 2001). And figure (3) shows how box culvert is used in the intersection between water stream (channel) and a highway road.

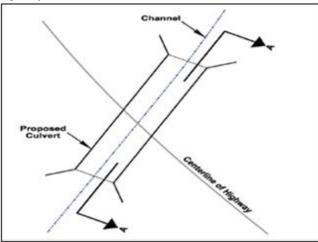

Fig.3. Roadway cross culvert length

Culverts design depends on hydraulic technical data, which should contain the culvert length, loading analysis, and other items that lead to the completed culvert plans and its dimension. Box culverts may be made of reinforced concrete frames as closed system which support vertical or lateral earth pressure to be passive or active and part of load may be vehicles load. Culverts either single or multi-cell based on the hydraulic requirements.

Culverts life time depends on the material that used to resist corrosion, as culverts having high initial cost can have a longer service life and also can have lower total operation and maintains (O&M) cost. The (O&M) cost includes maintenance costs, operational cleaning cost and risks associated with flooding. Moreover, future maintenance requirements can also save money in the long run. Maintenance costs for culverts may result from channel erosion at the inlet of water stream and its outlet, also erosion, deterioration of the culvert invert, sedimentation and embankment repair in case of overtopping.

B. Case study for a box culvert construction project.

Background for the project and discussing cost and time breakdown

The following **Table-1** and **Figure (4)** shows cost and time breakdown allover project life cycle for Box culvert project with number of three vents, each vent width equals three meters and with height of vent is about 2.50m. This box culvert exists in Alexandria city, as canal width equals 12meters, This project executed in 2016 with total project budget 9 100 000 L.E. (9Million 100 Thousand L.E.) with duration about 294days (9.8 Months).

Moreover, this realistic water structure construction project in Egypt began in 5/2016, as the project began in its conceptual and feasibility studies phase and finished in 3/2017 after rediverting water stream to the main stream and accomplish handover of the project.

IV. ANAYLSIS AND DISCUSSION

A.Risk identification and qualitative assessment for a box culvert s project

Risk identification is considered as a critical step in the risk management process, risk identification is an organized, through approach to finding real risks associated with a project. Risk identification determines which risks might affect the project and their characteristics at each project phase. In this study, Participants in risk identification and assessment activities are (6) personnel whom are: Project managers for (Owner reprehensive - Consultant & Contractor) and project site engineers for contractors.

Risk probability assessment investigates the likelihood that each specific risk will occur, risk impact assessment investigates the potential effect on a project objective. Notice that the influence of risk factors (RF) on the matrices are assigned in table -2

Table-2: Numerical qualitative risk analysis matrix for the project cost. Where: "Red Color shows important high risk factors, Yellow Color shows high risk factors, Green Color shows medium risk factors":

		Increase	in budget a	nd duration	
Severity Probability	From 0 to 3% (1)	From 3% to 10% (2)	From 10% to 20% (3)	From 20% to 30% (4)	More than 30%
Rare (1)	1	2	3	4	5
Unlikely (2)	2	4	6	8	10
Possible (3)	3	6	9	12	15
Likely (4)	4	8	12	16	20
Certain (5)	5	10	15	20	25

Table- 2 shows the frequency of each RF occurs as: (Rare) from zero to one time all over the project, (Unlike hood) two times through the project, (Possible) three times through the project, (Likely) four times through the project, (Frequently) five or more through the project. Finally the risk factors are classified into:

- -If the magnitude of risk is from (15 to 25) for Red color, it means that this RF is important high risk factors as those should be avoided or to be controlled by some engineering or administrative control measures, also these risk factors should be subjected to frequent assessment.
- -If the magnitude of risk is from (6 to 12) for Yellow color, it means that the risk is high risk factors, so it has to be monitored but less priority than important high risk factors.
- -If the magnitude of risk is from (1 to 6) for Green color, it means that the risk is medium so to be monitored and controlled by a lower cost engineering and administrative

And the tables below (3) & (4) shows the risk factor identified and assessed through project participants as the risk factors are nine risk factors affecting on both cost and time targets.

Table -3: Risk identification and qualitative assessment concerning cost target of Box culvert water structure project:

	0.4	0.0	0.2	0.4	0.	0.4	
Factors	Q1	Q2	Q3	Q4	Q5	Q6	μ
Unexpected changes in cash flow	10	10	12	8	12	8	10.00
Over-Design for components of the project	8	8	10	6	12	8	8.67
Assigning non-applicable constructability method	10	8	10	6	12	8	9.00
Site accessibility problems	15	15	17	13	15	17	15.33
Geotechnical and soil analysis troubles issues	12	12	14	10	12	14	12.33
Labor productivity lower than required	12	15	17	13	15	17	14.83
Material transportation delay	8	8	10	6	8	10	8.33
Change orders at construction phase	4	20	22	18	20	22	17.67
Bad weather conditions	12	15	17	13	15	17	14.83

Table - 4: Risk identification and qualitative assessment concerning time target of Box culvert water structure project:

Factors	Q1	Q2	Q3	Q4	Q5	Q6	μ
Unexpected changes in cash flow	10	8	10	4	12	8	8.67
Over-Design for components of the project	8	8	8	4	12	8	8.00
Assigning non-applicable constructability method	12	8	12	12	16	8	11.33
Site accessibility problems	15	15	18	20	22	24	19.00

Continue Table -4: Risk identification and qualitative assessment concerning time target of Box culvert water structure project:

Factors	Q1	Q2	Q3	Q4	Q5	Q6	μ
Geotechnical and soil analysis troubles issues	12	12	14	10	10	12	11.67
Labor productivity lower than required	12	15	17	13	20	22	16.50

Published By: Blue Eyes Intelligence Engineering and Sciences Publication (BEIESP) 43 © Copyright: All rights reserved.

Material transportation delay	12	12	14	10	10	12	11.67
Change orders at construction phase	8	20	22	18	20	22	18.33
Bad weather conditions	12	20	22	20	22	24	20.00

Thus the RF "Changes orders at construction phase "is highest influence with perspective to cost target, where this factor depends on number of change orders done in the project and if there is change orders effect on the critical path of the project or not, as handling this point is so important to not have conflicts when the project is executed. Moreover change order has a lot of other terminology; such as change proposal at engineering phase and variation order at construction phase.

"Bad weather condition " RF is highest influence with perspective to time target in this case study, as this factor depend on a well forecasting of the weather through over the project construction and take into consideration where scheduling of the project. Also site accessibility problems risk factor influence both budget and duration of the project, as this factor depends on the location of the site, the route of entrance to the site, type of activities and equipment's used in execution in this site. This factor can be controlled by a well discussion of routes and entrances to the work site, to study the possible accessibility or to make suitable routes for equipment and labors to enter to site.

Geotechnical and soil analysis troubles issues is a medium influence risk factor for both cost and time target , as soil – analysis investigation reports and studies is one of the important studies that must be accomplished in the engineering phase where early duration of project cycle and continual updated , thus to define all the features and criteria of the soil and then design all the footings and sub-structure of the project executed , so any change in the expected feature of this soil would give change in the design of the structure, which may lead to higher cost or delaying in the project duration due to change in recommendation of the soil or change in the statically system of the structure.

And the sensitivity analysis for the means values showing the influences concerning budget and duration of the project is shown in **figure (5):**

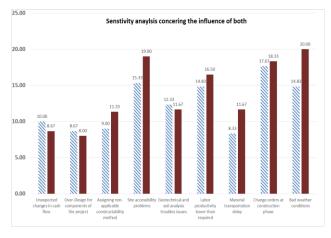

Fig .5. Sensitivity analysis concerning the influence of both cost (in hatched) and time target (in solid) – box culvert construction project

B. Quantitative risk analysis (QRA) by AHP for a box culvert project

The methodology of QRA is using Analytical hierarchy process (AHP) to measure cost and time contingency for the case study shown. AHP developed by Thomas L.Saaty based on pair wise compression as it is consider as a multi-criteria decision-making approach. These comparisons are used to obtain the weights of importance of the decision criteria, and the relative performance measures of the alternatives in terms of each individual decision criterion. The assigned scale in this case study from 1 to 9 is adopted. In that scale, a score of 1 indicates equal importance and a score of 9 indicates that an element is extremely important than the other. Meanwhile, reciprocals to these scores (i.e. 1/2, 1/3...1/9) represent the counter importance relationships for assigning numerical scale values, survey forms are designed.

Moreover, for calculating cost contingency the methodology is formulated by the following steps:

- The First step is calculating the effectiveness (Eff.) for each project phase , to use this Eff. factor in the AHP cycle , table (5) shows the breakdown of the project, as the project is simply classified into main three phases as shown (Conceptual &feasibility studies and Engineering phase Construction phase (I) Construction phase (II) and handover.
- The second step is beginning with the AHP analysis model for the three phases of the project with the mathematical model shown in tables (6), (7), and (8).

And the calculation of cost contingency is adopted by superposition of the three tables shown above, and by the following equation:

Cost contingency in (percent) =
$$0.80 (Sc) + (S.V.)$$
 (1)

As the result shows Summation of Influences affecting cost target (Sc) in tables (7), (8) and (9) equal to (10.57) and also standard deviation (S.V.) is equal (3.45), so equation (1) gives a cost contingency equal (11.91perecnt), as this contingency needed to be add on the original estimated budget of the project.

Moreover, for calculating time contingency the methodology is formulated by the following steps:

- The First step is calculating the effectiveness (Eff.) for each project phase, to use this Eff. factor in the AHP cycle, table (9) shows the time breakdown of the project, as the project is simply classified into main three phases as shown (Conceptual &feasibility studies and Engineering phase Construction phase (I) Construction phase (II) and handover.
- The second step beginning the AHP analysis model for the three phases of the project with the mathematical model in shown in tables (10), (11), and (12).

Table-9: Risk effectiveness in each project phase concerning time target:

Project phases (Box- Culvert water)	Duration (Days)	Eff.
Conceptual and feasibility studies & Engineering phase	132	0.449
Construction phase (I).	84	0.2857
Construction phase (II) & handover	78	0.2653
Total Project duration	294	

Table- 10: Pairwise compression and AHP analysis (concerning time target) for risk factors at Conceptual & feasibility studies and Engineering phase:

And the calculation of cost contingency is adopted by superposition of the three tables shown above, and by the following equation:

Time contingency in (percent) = $0.80 (S_t) + (S.V.)$ **(2)**

As the result shows Summation of Influences affecting time target (St) in tables (10), (11) and (12) is equal to (13.91) and also standard deviation (S.V.) is equal (4.86), so equation (2) gives a time contingency equals (15.99 percent), as this contingency needed to be added on the baseline time schedule of the project.

V. HAZARD IDENTIFICATION AND RISK ASSESSMENT

Hazard identification and risk assessment is an important issue affecting the project success. And should be integrated by the above RMP to achieve project objective. Moreover,

Retrieval Number: 100.1/ijeat.E35360611522 DOI: 10.35940/ijeat.E3536.0611522 Journal Website: www.ijeat.org

there are some definitions concerning management issues as follows:

Hazard: Anything (e.g. condition, situation, practice, behavior) that has the potential to cause harm, including injury, disease, death, environmental, property and equipment damage. A hazard can be a thing or a situation.

Hazard Identification (HAZID): This is the process of examining each work area and work task for the purpose of identifying all the hazards which are "inherent in the job". Work areas include but are not limited to machine workshops, laboratories, office areas, agricultural and horticultural environments, stores and transport, maintenance and grounds, reprographics, and

and Advanced Technology

Exploring Innovation

theatres and teaching spaces.

b leunor lenousement Published By: Blue Eyes Intelligence Engineering © Copyright: All rights reserved.

HAZOP: is to conduct a meeting for complying the proposed design with operation and safe conditions The tables (14) & (15) and (16) show how to identify hazard risks in construction of box culverts as to show HAZID process and risk assessment in table (14), also they show how to control this risk using exiting and additional controls and how to calculate residuals influence value after controlling hazard risk arise in the project as these points shown in tables (15) & (16). Also, table (13) shows hazard risk matrix which adopted in this type of construction project in Egypt.

Table-13: Numerical hazard qualitative risk analysis matrix

Severity		Con	cerning Injury and a	sset loss	
Probability	A	В	С	D	Е
Rare (1)	1	2	3	4	5
Unlikely (2)	2	4	6	8	10
Possible (3)	3	6	9	12	15
Likely (4)	4	8	12	16	20
Certain (5)	5	10	15	20	25

Where:

- A is the hazard severity leads to injury to be resolved by first aid or asset loss is less to 300K Egyptian pound.
- **B** is the hazard severity leads to minor injury or asset loss is less than 400K Egyptian pound.
- C is the hazard severity leads to major injury or asset loss is less than 500K Egyptian pound.
- **D** is the hazard severity leads to single fatality or asset loss less than 600K Egyptian pound.
- E is the hazard severity leads to Multi-fatality or asset loss more than 600K Egyptian pound.

VI. CONCLUSION

This study underline the significance of accomplishing a successful risk management process for box culvert construction project. As these projects are having interrelated activities and specific risk factors. Also these specific risk factors are mostly affecting cost and time targets, thus give obligation of identifying these risk factors and showing their influences on both estimated budget and duration.

And the main conclusion shows in this study is as follows:

- ✓ This study shows how to perform a RMP for box culvert construction project and also how to use data come out from this process to achieve project deliverables.
- ✓ According to the case study shown , the cost contingency needed to resolve different risk factors arise in the shown case study is to increase the estimated budget by 11.50 percent on the total estimated budget of the project , and time contingency 16.00 percent to be added over the total original baseline schedule.
- ✓ This study shows in a tubular from the hazard risk identification (HAZID) framework and its assessment, as to help to perform the project in safe condition without accidents, as health safety and environment (HSE) is an important issue in construction projects.

Computing Cost and Time Contingency for Box Culverts Construction Projects using Integrated Risk Management **Technique**

AUTHORS PROFILE

Eng. Omar Mohamed, studied Civil Engineering at faculty of Engineering / Ain Shams University from 1999 to 2004. And awarded Master of Science (M.Sc.) for Arab Academy for Science and Technology and Maritime (AAST) at April 2016 with thesis entitled (Risk management in construction of gas plants and gas pipelines in Egypt. I began my Ph.D. research work in

Faculty of Engineering / Ain shams University at 2017 and I'm still a Ph.D. student in the topic of (Risk management in the construction of water control structures). I'm still working at in Cairo, Egypt as a civil Engineer. And also I attend a lot of technical conference and sessions as a Technical speaker, and I'm looking forward to attend a conference in Egypt known as EGYPS2020.

Professor Dr. Mohamed Nour El-Din, is a Water Resources scientist with extensive long experience in applying integrated water resources management and development in arid and semi-arid regions, water supply, rural sanitation, water resources planning, monitoring and evaluation of irrigation projects and drainage systems. The main experience is in Egypt, as well as

several assignments in other countries as well through cooperation with consultants and international organizations. The experience is acquired also through his career as a university professor and as a consultant in several water resources and irrigation projects. And mainly the current work is a Professor of hydraulics and irrigation in faculty of Engineering / Ain shams University.

Prof. Dr. Iman Elazizy, is a Vice -president of student affairs at 6th of October University, and Professor of Hydraulics and water resources - Faculty of Engineering., Ain Shams University Cairo, Egypt. The research interest is; Water quality modeling, Water recourses management, natural treatment process, wetland, GIS application in water recourses, Open channel hydraulics.

Environmental Impact Assessment. Works as consultant for Environmental water project for EEAA Egypt.

Dr. Mona A. Hagras, is Associate Professor of Irrigation& Hydraulics Department, Faculty Engineering, Ain Shams University, Cairo, Egypt. She received PhD and MSc from Ain Shams University. She supervised many theses and published many papers in referred national and international journals. She is a reviewer of ASEJ journals. Her area of interest is Water

Resources Management, Hydrology, Hydraulics, and Groundwater modeling.
