In the second experiment, the recipient disk and part of the cable were wrapped with white paper, so that both papers became scarlet after the flow of electricity. Only a part of the wrapping paper was covered with a thin layer of gold, while a part of the conductor was covered with the lime.[2094] The lime coverage of metal leaflets in the hydrogen atmosphere was as good as in the oxygen atmosphere during Heidmann's repetitions of the experiments of Kraškovič's Parisian model Charles.[2095]

Kraškovič bought the Art of Medicine of Johannes Hirn. Kraškovič also acquired the indispensable Chemistry[2096] and Pharmacy, compiled by father and son Jacquin. Joseph Franz Baron Jacquin (* 1766; † 1839) and his father Nikolaus Joseph Baron Jacquin (* 1727; † 1817) were, of course, the nephew and brother of Ingenhousz's wife. In 1797 Joseph Franz Jacquin inherited the botanical department after the dead of his father Nikolaus Joseph Baron Jacquin (1727-1817) passed away. He introduced Lavoisier's Chemistry to the Viennese University.

Kraškovič did not miss even two copies of the book on the obstetrics of his Luxembourg predecessor in the position of district physician Joannis Baptiste Lalangue, which was considered

[2096] Kraškovič used the *Lehrbuch der allgemeinen und medicinische Chymie* of the younger Jacquin printed in 1810, or perhaps somewhat older *Anfangsgründe der medicinisch-practischen Chymie: zum Gebrauche seiner Vorlesungen* of his father.

as the first Croatian written professional medicine.[2097]

The famous Avicenna and both Jacquins were not the only important writers of several different books in Kraškovič's collection. Kraškovič also acquired several works of the professor of pathology in Vilnius Joseph Franko (1771-1842) and the father of modern pathology Giambattista Morgagni (1682-1771). Kraškovič read Giambattista Morgagni's letter on anatomy.

Kraškovič examined the works on fevers and practical experiences of the first director of the Viennese General Hospital, Joseph Baron Quarin (1733-1814) who served as the physician of Maria Theresia after van Swieten and Ingenhousz. Kraškovič cultivated his love for experiments by reading some older work of Antony Vallisnieri (1661-1730), a student of Marcello Malpighi. Kraškovič was also interested in the healing effect of mineral waters, so he read about them in the works of the freemasonic father of the German seaside resorted medical baths Samuel Gottlieb Vogel (1750-1837), and in the Viennese medical dissertation of the Bratislava physician Heinrich Johann Nepomuk von Crantz's (1722 Roodt-sur-Eisch in Luxenburg-1799 Judenburg) student József Ferenz Staehling (* 1743) which was defended an entire generation prior to Kraškovič's doctorate.[2098] Ceanz used to be the student of van Swieten and belonged to the contingent of Luxemburg physicians imported together with Kraškovič's predecessor in Varaždin, J. Battista Lalangue.

Kraškovič used Metzburg's physics-mathematical textbook. Baron Georg Ignaz Metzburg began with Newton's experiments and published his textbook in many reprints. It is therefore difficult to find out today which edition was used by Kraškovič; Kraškovič's library was subsequently sold at auction, while his legacy list of books does not have years of their printouts. Although Kraškovič did not mention him among his literature on aviation in 1810, his principal writer on gases was precisely the Viennese professor Metzburg[2099] in the book, which was also read by Franciscan Ivo Bonelli as a professor in Innsbruck, who at that time was not far from Tyrolean border of the Illyrian Provinces with its center in Ljubljana. Bonelli wrote his name in most of the then books dedicated to vacuum techniques in the Ljubljana Franciscan collection. The Ljubljana Franciscans obtained three different editions of Metzburg's lectures, each of them in seven works; barely smaller was the popularity of this reading among their neighbors, since two Metzburg collections were procured by the barons Erberg, while they were not missing even in the Ljubljana Lyceum.[2100]

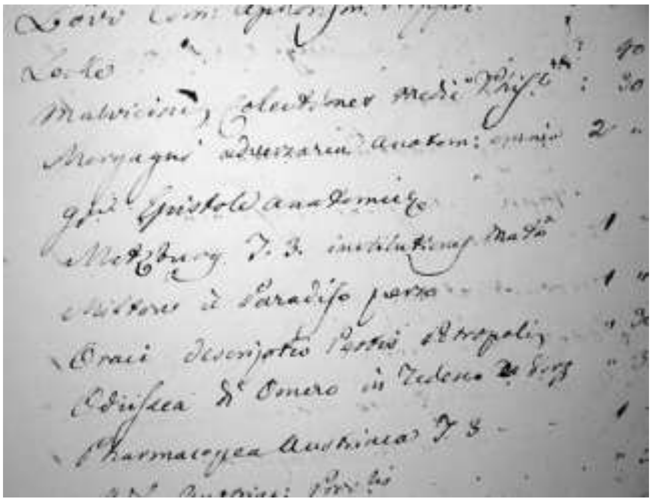

Figure 16-19: Metzburg's textbook for the exploration of vacuum and gases, listed in Kraškovič's legacy in the fourth place, counting from the bottom (HR DADU, Se. E, Fasc. VI, No. 45).

Metzburg, like Kraškovič himself, used his knowledge of vacuum techniques for balloons, although he did not fly himself because of his advanced age. Graz printmaker and meteorite explorer Alois Beckh-Widmanstätten (Aloys Joseph Franz Xaver Beckh Edler von Widmanstetten, * 1754, Graz; † 1849, Vienna), in front of some 800 spectators, launched a balloon 200 m above Vienna in later Kraškovič's home 4th district Wieden from the garden of the court secretary of the mints and mining (Hofsekretär des Münz- und Bergwesens) Anton Wenzel von Damm; the former Jesuit Ignaz Metzburg acted as

a censor of the balloon undertaking on 14 January 1784 and in the spring of 1784 after several months of indoor experiments commenced at the end of the year 1783.[2101] Metzburg dedicated to gases the first fifty-seven pages of the fifth part of his mathematical lessons. He described in detail the vacuum balloon of Francesco Lana Terzi as the predecessor of Kraškovič's modern models Montgolfier and Jean François Pilatre de Rozier (1756; † 15 June 1785). The head of the Paris museum Pilatre de Rozier happily made a myth from the flight of his younger fellow Montgolfier, watched by the king himself. The ruler initially wanted to bring the prisoners under the balloon, but Rozier successfully applied himself for this honor, which, unfortunately, was very costly. He was overconfident about the possibility of flying under a hybrid hydrogen & warmed air balloon, which was shaken by the electrostatic discharge of the metal structure. The news of Rozier's accident was reported immediately in a comprehensive article published in the Ljubljana newspaper.[2102]

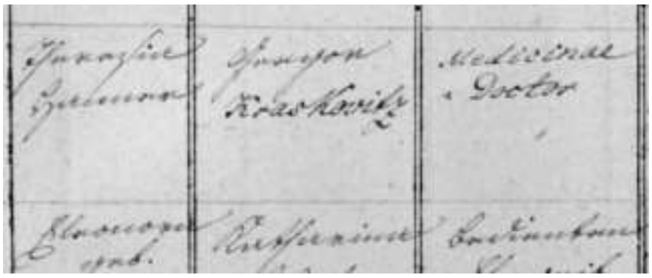

Figure 16-20: The godfather Kraškovič's signature upon the baptism of his own son Gregor Hanner at St. Stephan Platz no. 523 in Vienna on 20. 8. 1807 (Baptismal book of St. Stefan Viennese parish 1804-1807, reference code 01-104)

Jean Pierre François Blanchard (* 1753; † 1809) made more careful use of Rozier's ideas.[2103] During his flight above Vienna Blanchard also "infected" Kraškovič. Metzburg accurately described and illustrated the valves of his various vacuum pumps,[2104] which Kraškovič had arranged a decade later to prepare for the regulation of their pressure with hydrogen filled balloons. Just the highly developed technique of the valves and the vacuum pumps enabled the safe lifting and lowering of the balloons, and sometimes even those achievements were not enough due to freezing at unexpectedly low temperatures and pressures at the high altitudes.

In his mathematical theses, Metzburg first started with algebra, then followed by geometry, angles, triangles and the trigonometric postulates of Hipparchus of Nicaea focusing the surfaces of the triangles. In the last thesis, the student had to draw a circle through the three points.[2105] Of course, in the textbook Metzburg could not easily include Bošković's ideas from general physics, especially not into the books on applied mathematics. In the first edition of the three-grade Lyceums' textbook, the former Jesuit Metzburg published three books with logarithms in the end, but he did not mention Bošković. In his closing volume he dealt with applied mathematics, especially geodesy, which was the parade horse of Bošković and other Jesuits. In the second edition, a half a decade later, Metzburg added four books on mechanics, aero- and hydrodynamics with vacuum techniques, optics and astronomy. Despite the brief general introduction, he did not mention Bošković, although, for example, he noted the experiments with the free fall of Riccioli, Grimaldi and Galileo.[2106]

Bošković had a basic role in the books of Metzburg's much younger colleague Jurij Vega, who taught at the neighboring artillery school. Vega published his lectures in parallel with the second edition of Metzburg's textbook. As an experienced surveyor, Metzburg had offered much more beautiful images from his field, and Vega, as a navigational engineer and artillerist, overtook Metzburg in the areas of hydrodynamics and ballistics. In the second edition, Metzburg published seven sections in three books, and also wrote a book on optics and mechanics, which Vega avoided. Perhaps Vega planned such a purpose as at least optical devices would also be useful for his military measurements. His principal Colloredo was persuading Vega to publish books, and perhaps he also had in mind a summary of the then vacuum techniques. Of course, Metzburg and Vega did not deal with heat, magnetism, or electricity as separate chapters in their books, since these areas had a completely different tradition in special physics outside the applicable mathematics of Aristotle's scheme.

On 15 June 1787, Vega, along with other important scientists, watched the eclipse of the Sun from the Viennese Observatory. The court astronomer Hell was accompanied by the adjutant Triesnecker, who later allowed Kraškovič to fly from the premises of the Viennese Astronomical Observatory. There was also Gusmann, a professor of physics and mechanics with his students,[2107] the professor of mathematics Baron Metzburg, Jurij Vega from the bombarding school as well as a geometer and geographer Wussin. The great eclipse was also observed in Vienna by Hell's helper employed in 1753, Anton Pilgram. The observation reports were published in the newspaper after five days, while detailed measurements were discussed later in Hell's ephemeris.[2108] Hell used Newton's 158 cm long mirror telescope with a fifty-fold magnification. On the tube of the telescope he attached the micrometer with the thread. The beginning of the eclipse was observed at 5h 24 min and 1 s. At 6h 11 min and 36 s the eclipse was in its darkest mood. The eclipse was finally over on 6h 57 min and 28 s.

In the same building Triesnecker also observed with Dollond's[2109] telescope. He noticed the beginning of the eclipse 8 seconds after Hell, and its end probably 7 seconds, but surely at least 3 seconds before Hell. Metzburg watched along with them through another Dollond's telescope. He noticed the first signs of eclipse 12 seconds before Triesnecker, and the end of the eclipse 7 seconds after Triesnecker.

As a young magister of the philosophy the Jesuit Metzburg collaborated with Liesganig and Güssmann on measuring and mapping of Galicia.[2110] On April 30, 1801 Zach in his letter to

Schedius, as well as Joseph Johann Littrow and later many others severely criticized the mistakes that the (former) Jesuits made in their measurements.[2111] Astronomer Zach was a black beast for those ex-Jesuits; among his "main friends" he counted Liesganig, Metzburg and Güssmann; both the first ones were from the devil, he claimed. Zach thus did not exactly like some Vega's colleagues who observed the solar eclipse in 1787; considering Vega himself, Zach repeatedly named Vega as his friend in his letter to Schedius.[2112] Zach dated the letter at Seeberg near Gotha on 23. 5. 1798 and Schedius received the letter in Pest on June 2nd, 1798.[2113]

After the suppression of the Jesuit society, Metzburg became a full-time professor of mathematics at the University of Vienna in 1774, instead of Joseph Walcher, who used to write on balloons-related vacuum techniques in 1754. On 20 October 1778, Metzburg's book was declared an official textbook.[2114] As dean, he sought to modernize the Viennese Faculty of Philosophy. Two years after his appointment as a court councilor, together with his mentor, Celovec (Klagenfurt) vicar Sigmund Hohenwart (* 1745, Celje; † 1825, Linz), he examined various Hungarian-Slovakian mines in 1798. The former Ljubljana student Hohenwart equipped one of the best physics laboratories in Klagenfurt full of vacuum devices. Later as a Bishop in Linz, he organized balloon flights that inspired Kraškovič. As a true intellectual, Kraškovič certainly did not only read scientific literature. He had in his library the Lost Paradise of John Milton, probably in Italian translation[2115] or maybe even in the English original. He also obtained the works of the ancient Roman poet Horace, Odyssey and the book by English empiricist John Locke. Kraškovič laughed at Jean-Baptiste Willart de Grécouro's (1684-1743) jokes, and he gladly bought four British magazines Tatler for rich people designed by Sir Richard Steele (1672 Dublin-1729 Wales) or his later imitators, which may have served to amuse Kraškovič's patients at the waiting rooms.

The most estimated Kraškovič's book was worth 10 forints. That was the monumental work of Galen of Pergamon. All other books were evaluated to 5 forints or less, but this was primarily an antiquarian valuation of old books needed for an auction.

The books tell us a lot about the studies of a learned man. They are also very important

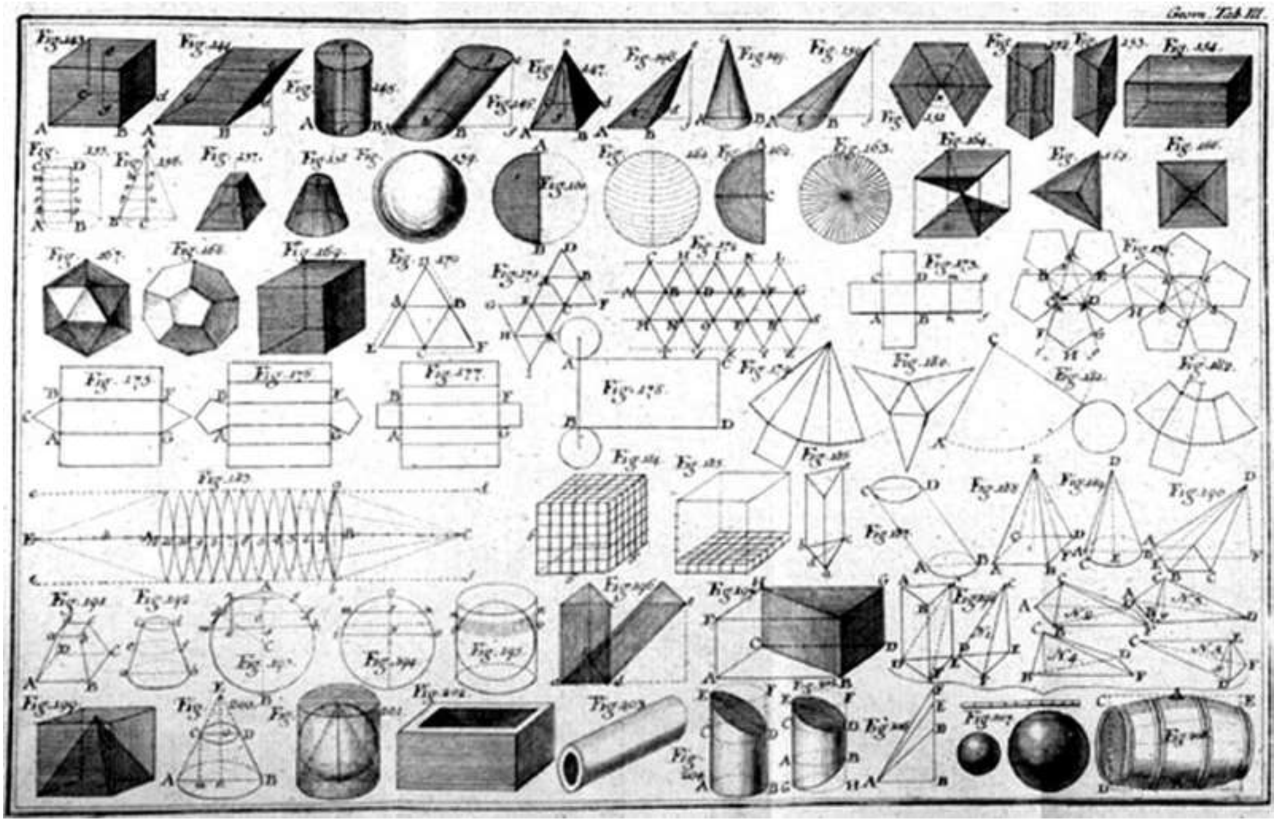

Figure 16-24: Images from the Metzburg's Manual of Vacuum Techniques from 1775, which was used by Kraškovič

illustration of Kraškovič's work in Dubrovnik. Matija Gregor Kraškovič was a famous doctor, chemist and aeronaut balloonist. Although born outside Croatia, he left an indelible mark on Croatian technical, scientific and healthcareactivities in Varaždin, Kotor, Dalmatia, and especially in Dubrovnik and Mljet. Several of his works had a strong echo even beyond the boundaries of the Habsburg Monarchy, and at the end of his life he was celebrated by analyzing the causes of detonation on the island of Mljet. He explored it with a full heart, but unfortunately, he did not experience the time when the detonations had completely stopped. Kraškovič's knowledge was something special for the then Kotor, Dubrovnik and Dalmatia. He learned from the best Jesuit mathematician-naturalists of Bošković's tradition, who still lectured in Ljubljana at the time of Kraškovič's philosophical studies. Kraškovič's medical studies can be linked with the Bohemian Jesuit academic ancestors of his mentor Prochaska. On the other hand, Prochaska, as a doctor, was studying with the students of the famous Herman Boerhaave, in the atmosphere of Dutch experiments with treatment of electricity, which had a deep effect on Kraškovič's work, and reflected the research of Kraškovič's scientific idol Alessandro Volta.

On the other hand, Kraškovič's relation to his son shows that he was a man of deep feelings. Thus, we can observe the characteristics of scientists and physicians even through the knowledge of his human virtues, which is especially important in modern times, when the private life of scientists is often forgotten.

16.2.9 Conclusion

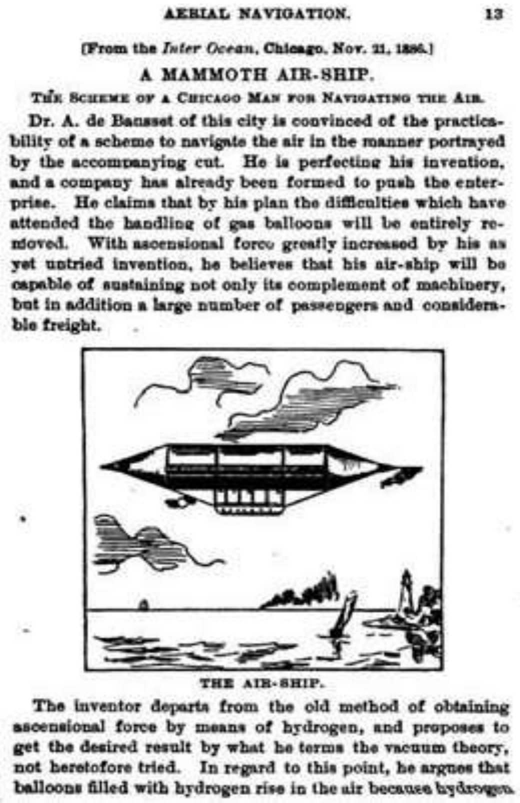
Gregor Kraškovič was the first successful Slovenian aeronaut. Until recently numerous Carniolan neighbors wanted to own him, while his memory was fading among Slovenes.

Despite of Kraškovič's merits, the future of vacuum balloons is still uncertain. In 1843, two decades after the death of Kraškovič, almost two hundred years after Lana launched his ideas, the Frenchman Edmond Marey Monge decided to test Lana's boat. The student of Parisian Polytechnic Edmond Marey Monge was a son of the eldest daughter of the famous popular Napoleonic mathematician Gaspard Monge (1746-1818). On

August 2, 1844, Edmond Marey Monge (Louis Eduard Marey-Monge, 1807 Nuits-Saint-Georges in Eastern France-1868 Paris) tried Lana's boat under a single vacuum balloon with a slight help from the Secretary of the Aragon Academy; he spent over 25,000 francs for his beloved science; he needed to perform a lot of experiments. According to Lana's instructions, he used 0.1 mm thick sheet metal brass plate. The balloons were sealed off with two thin films of lacquered paper and he exhausted air. The device did not rise because the external air pressure compressed the ball during pumping. Lana not only neglected the influence of external pressure on the vacuum balloon; his budget was also insufficient. In addition to money, he lacked modern hardwoods and lightweight materials.

In 1854/55, the professor bishop Vittorio Angius (* 1797, Calgiari; † 1862, Turin), seriously discussed the Lana’s design equipped with new, then known types of metals including aluminium. Unfortunately, Lana's ship is still awaiting a successful flight despite numerous experiments by Arthur de Bausset (* 1828, France; † 1905, New York) in Chicago between 1886 and 1900. The US Congress supported him until their enthusiasm was compromised by the advocates of brother Wright, the railway engineer Octave Chanute (* 1832; † 1910) and professor of physics Albert Francis Zahm (* 1862; † 1954). The heavier than air aircrafts replaced balloons after heavy duels.

Figure 16-25: Cover page of the Arthur de Bausset’s Aerial Navigation book of 1887 (Bausset, 1887)



AERIAL NAVIGATION. 13

[From the *Inter Ocean*, Chicago, Nov. 21, 1886.]

A MAMMOTH AIR-SHIP.

THE SCHEME OF A CHICAGO MAN FOR NAVIGATING THE AIR.

Dr. A. de Bausset of this city is convinced of the practicability of a scheme to navigate the air in the manner portrayed by the accompanying cut. He is perfecting his invention, and a company has already been formed to push the enterprise. He claims that by his plan the difficulties which have attended the handling of gas balloons will be entirely removed. With ascensional force greatly increased by his as yet untried invention, he believes that his air-ship will be capable of sustaining not only its complement of machinery, but in addition a large number of passengers and considerable freight.

THE AIR-SHIP.

The inventor departs from the old method of obtaining ascensional force by means of hydrogen, and proposes to get the desired result by what he terms the vacuum theory, not heretofore tried. In regard to this point, he argues that balloons filled with hydrogen rise in the air because hydrogen.

Figure 16-26: Vacuumed vessel according to Arthur de Bausset's book issued in 1887 (Bausset, 1887, 13)

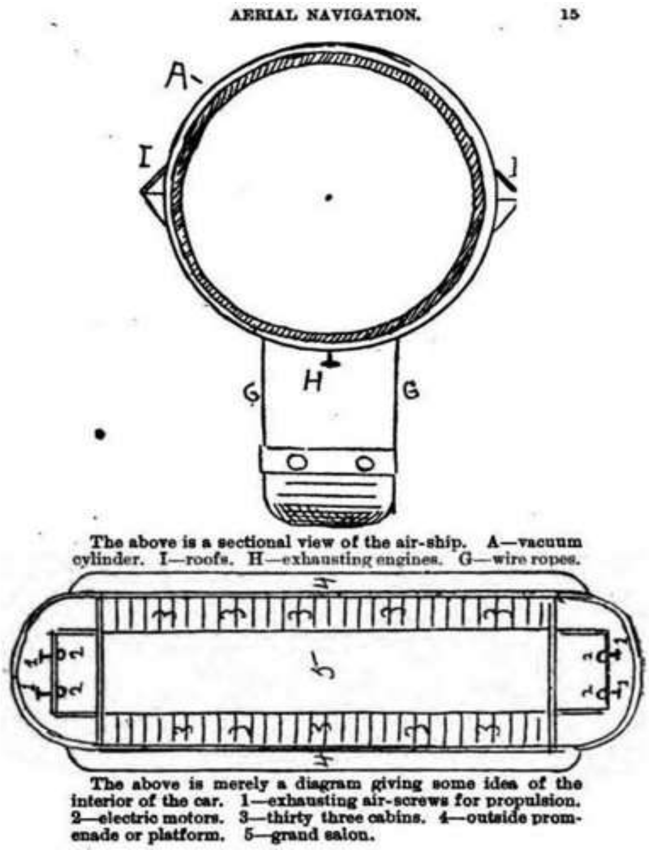


Figure 16-27: Arthur de Bausset's vacuumed vessel from 1887 (Bausset, 1887, 14)

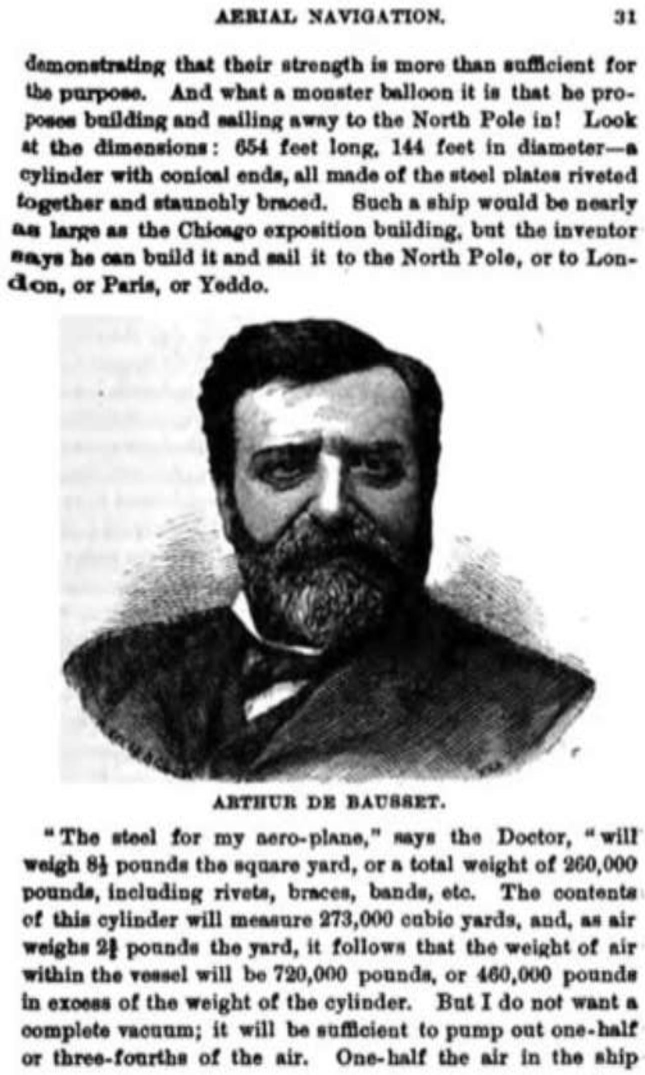
Lana’s vacuum balloons are not useful even today. The mass of the steel shell far exceeds the buoyancy, insofar as the shell is at the same time the only framework. The installation of support releases the requirement for wall thickness, but unfortunately the internal frame increases the mass of the system. Even five times specifically lighter polymers with steel-like mechanical properties are too heavy frame for small vacuum balloons. The volume of the round balloon increases with the third exponent of the radius of the balloon; the mass of the frame and the force on it increase only with the second exponent of the radius. The vacuum balloon would rise at a sufficiently large radius and a sufficiently thick skeleton, when the thickness of the framework can be increased in proportion to the radius. Unfortunately, the size of such devices still exceeds the capacity of the modern industry. For a round vacuum balloon of 24 m radius with a 1 mm thick framework made of rolled steel of 8 kg / dm^3, the buoyancy force is equal to the weight. For a balance of 1 cm wide frame we need a round balloon with a radius of 240 m, which is slightly less than the volume of the largest Zeppelin so far built and operated. In 1910, Codelli conceived an airship in Ljubljana. It was 1 km long, with a diameter of 100 m. Its volume of 1.25 million m^3 would be eleven times smaller than a balloon with a radius of 240 m. The lift would exceed the weight of a steel frame, barely 0.9 mm thick, if a vacuum was to be used in Codelli's ship. The vacuum balloon with a 16 kg / dm^3 polymeric framework could fly by its radius of 4.8 m, with a volume close to half a million liters and weighing less than half of a ton; but the external pressure could damage 1 mm thick frame. Unfortunately, just the pumping out of a balloon with a radius over 50 m and a 1 cm thick polymeric frame might enable the bargain price of passengers’ travel tickets.

The useful time of ordinary balloons depends on helium leakage or on heat loss in warmed air balloons. For larger vacuum balloons, the possibility of leakage is higher and pumping more expensive. The helium and hydrogen balloons do not require a solid framework, as the internal pressure can be equal to the external pressure. The upsurge of a vacuum balloon is only a fifteen point higher than that of the same spacious hydrogen balloon, which does not justify the use of an expensive and heavy frame. A vacuum balloon would only be economical if a strong balloon framework was needed at the same time for safety or if the vacuum was used for experiments. Problems with external pressure are decreasing in higher areas of the atmosphere where the vacuum balloon would be more durable than competitors full of gas. Those lighter than air rivals were driven away from the airspace a century ago. Could the progress of vacuum technique, new materials and thin films bring a new turnaround?



AERIAL NAVIGATION. 31

demonstrating that their strength is more than sufficient for the purpose. And what a monster balloon it is that he proposes building and sailing away to the North Pole in! Look at the dimensions: 654 feet long, 144 feet in diameter—a cylinder with conical ends, all made of the steel plates riveted together and staunchly braced. Such a ship would be nearly as large as the Chicago exposition building, but the inventor says he can build it and sail it to the North Pole, or to London, or Paris, or Yeddo.

ARTHUR DE BAUSSET.

"The steel for my aero-plane," says the Doctor, "will weigh 8½ pounds the square yard, or a total weight of 260,000 pounds, including rivets, braces, bands, etc. The contents of this cylinder will measure 273,000 cubic yards, and, as air weighs 2⅝ pounds the yard, it follows that the weight of air within the vessel will be 720,000 pounds, or 460,000 pounds in excess of the weight of the cylinder. But I do not want a complete vacuum; it will be sufficient to pump out one-half or three-fourths of the air. One-half the air in the ship

Figure 16-28: Portrait of Arthur de Bausset (Bausset, 1887, 31)

Tell me what you read, and I tell you who you are. The first Slovenian balloonist is by no means an exception. As an examined scholar, he did not limit his library to purely natural sciences; He also bought the works of John Locke, who refused Descartes' doubts about the existence of a vacuum. In the white world, Kraškovič became multilingual and did not use Slovene language even as much as did A. Hallerstein, who at least took the Slovenian songbook with him on his sailings to far-away

Beijing. Kraškovič's homeland was merely his profession: he tried to follow the latest findings in the fields of vacuum techniques, chemistry and medicine, which included his basic scientific and technical activity.

Gregor Kraškovič was one of the best Mid-European physicists of his era, especially famous for his medical measurements during his aeronautic flight. He supposedly flied sixty-five times which was certainly a record for a physician of his times and one of the best results of all aeronauts. His smallpox vaccination in Varaždin was an example of pioneering work. There is no doubt about his Slovenian origin after this publication. During his work in Hungary, Gregor Kraškovič began the operative research of medical protection of workers and tried to include handicapped persons to useful work in Varaždin area while he accomplished his most extraordinary flights in Hungary. The list of his published works and reports on his deeds speak for themselves about his eminence.

Kraškovič did not fly his balloons in Kotor or Dubrovnik. Was he too old or there was not enough material support from the local magnates? Blanchard and his widow certainly performed their ballooning until their very death in their fifties and forties, therefore Kraškovič was free to do the same. Certainly, the donations of local magnates could be much better in Hungary than in south Dalmatian Kotor and Dubrovnik. Kraškovič probably even avoided to risk his life in ballooning after he became a caretaker of his son Gregor Hanner whose last name had some resemblances with Kraškovič’s co-pilot Ivan Nepomuk Menner (Maenner, Manner, Männer).

17 Ether in Vacuum

17.1 Ether as a Vacuum: Cauchy's Gorizia Vacuum Theory - Introduction

Kraškovič was a practical vacuum researcher; soon after he passed away the Slovenians of Friuli borrowed the most eminent vacuum theoretician of those times. It's time to present that researcher in Slovenian soil, as he will perform a great role to our excursion in the past. Of course, he was a leading mathematician and physicist Cauchy, the greatest scientist ever living among Slovenes. He worked in Gorizia from 21 October 1836 until the middle of October 1838,[2116] which means that he was there full of two years before the beginning of the modern vacuum firms like Heraeus and Leybold. Since Cauchy published his works for nearly half a century, more than 4% of Cauchy's discoveries belong to his Gorizian period; this is by no means a bit. In doing so, we are silently assuming that Gorizia was at least partially Slovenian at that time. Of course, something like this will not be easy to prove, since only a quarter of Gorizia folks boasted Slovenian speech as their communicative public language during those years. The statistics is sadly silent on languages the Gorizia folks used to talk at home. Even today, of course, everyone speaks well there in Slovenian own way, even though most of folks in Gorizia might be ashamed of it. God knows if Cauchy did not learn some Slovene words among the Gorizia folks; he did not have any problems with the languages, since he already learned the Italian language for his lectures in Turin.

Cauchy was born to the family of successful Parisian citizens on the eve of the French Revolution; Cauchy's father Louis-François Cauchy (* 1760; † 28 December 1848) suddenly lost his work and bread in the middle of revolutionaries. The sad experience angered Augustine-Louis Cauchy much more than his father or brother: until the end of his day, he scolded all the revolutions and revolutionaries as far the most conservative among all Parisian mathematicians. His early fears at the dawn of the French Revolution, developed Cauchy's prominent anti-revolutionary stances.

His father moved the family from difficult hardest times which terrified his family in a safer suburban city of Arcueil, where he met Bertholet, Laplace, and especially Lagrange. Cauchy was sick half-hungry boy and preferred to sit behind his book as he disliked running around with his peers. Lagrange immediately recognized his next greatness and pointed it out to his father, Louis-François Cauchy. Lagrange advised a solid elementary education of his son. Only then he should allow him to read mathematical books. Lagrange knew what he was talking about: the successful mathematical and physical research must be based on a solid foundation and vision.

Figure 17-1: Academician Cauchy smiles kindly to his fate from the French stamp issued to commemorate the anniversary of his birth. Other important scientists and inventors of his time are: Benjamin Franklin (* 1706; † 1790), Karl Linnaeus (* 1707; † 1778), Ruđer Bošković (* 1711; † 1787), Žiga Zois (* 1747; † 1819) , Johann Carl Friedrich Gauss (* 1777; † 1855), Charles Babbage (* 1792; † 1871), Janez Puhar (* 1814; † 1864), Werner von Siemens (* 1816; † 1892), Sebastian Kneip (* 1821; † 1897), Louis Pasteur (1822; † 1895), Ferdinand von Mueler (* 1825; † 1896), Marcelin Berthelot (*1827; † 1907), Heinrich von Stephan (* 1831; † 1897), Alfred Nobel (* 1833; † 1896), Jožef Stefan (* 1835; † 1893), Robert Koch (* 1843; † 1910), zoologist Spiridon Brusina (* 1845; † 1908), geologist Gjuro Pilar (* 1846; † 1893), Janez Puch (Puh, * 1862; † 1914), Nikola Tesla (* 1856; † 1943), Rudolf Diesel (* 1858; † 1913).

[2116] Belhoste, 1991, 178.

In 1804, Cauchy began to study mathematics according to Lagrange's advice. Next year, he enrolled in Polytechnic and took second place at exams after Biot. With Biot, they remained friends even later, although Biot and Brewster were the last advocates of Newtonian theory of light particles that no longer pleased Cauchy's peers.

Cauchy attended lectures of Lacroix, de Prony, Hachette, and most of all to Ampère's analysis, which with its optics and the theory of vacuum later influenced Cauchy research in Gorizia. After graduating from the Polytechnic, Cauchy studied the engineering at École des Ponts et Chaussés. Like many other important French scientists of this unusual era of intolerant revolutionaries, Cauchy was also primary educated as an engineer. After Napoleon's second and final fall, Cauchy realized his dream: in 1816 he became an academician. Of course, the Bourbon king Louis XVIII († 16 September 1824), the older brother of Karl X, had to put away the famous geometer and Napoleon's supporter G. Monge to get a place for Cauchy; but you should not properly examine the teeth of the donated horse. Cauchy accepted the position, although he angered many students; Monge enjoyed a great deal of love as the founder of the Polytechnic. Besides the seventy-year-old revolutionary Monge, his three years younger fellow Lazare Carnot, the godfather of revolutionary victories, was also excluded from the Academy. The similarity with modern Slovenian events is, of course, completely inadvertent.

In 1817 Biot went to Scotland; Cauchy assumed his position at the Collège de France. Cauchy was not in good relations with Poncelet and other researchers, as he supported the Jesuits against Parisian academicians. At that time, the Parisian Jesuits even had some first-class mathematicians, among them Cauchy's friend Moigno, who, however, left the Society because of the debts incurred despite of his and Cauchy's long-standing support of the invention of the Marseille based Achille Jouffroy's engine. Cauchy praised Jouffroy's invention in his reports to the Parisian Academy on 2 November 1840, 12 June 1843 and 3 August 1846.[2117] Cauchy was interested in public transport problems already during his travels across Europe. On October 19, 1832, he suggested his improvements to Parisian academics. During that same year, the first train with a vacuum-based steam engine was launched in France. A similar Viennese train reached Trieste only in the year of Cauchy's death.[2118]

Achille's father Marquis Claude da Jouffroy d'Abbans (* 1751; † 1832) already described steamers in 1775 and tested them on the Doubs River on the Swiss-French border in 1776 and on the Saône River in 1780 before the successful experiments of American engineer Robert Fulton (* 1765; † 1815) in Lyon and at the river Seine. Immediately after returning from Gorizia to Paris, Cauchy, certainly ardent because of a long-lasting multi-day trip in a carriage and slow boat, praised the use of the vacuum in Achille's steam-powered steam propulsion machine. Achille assembled a spinning wheel on the tail of a ship with blades resembling double swans' swords and provided better combustion in the vacuum space of the steam engine during his test drive on which he also invited Cauchy.[2119]

Unfortunately, Achille did not make money with his steamers, in the same way as his father had been unsuccessful before. His invention was successfully sold only by Fulton. At the time of Moigno's departure from the Jesuit society, Achille therefore preferred his steam engine locomotives on just opened French railways. Cauchy sharply protested during the first railway accidents, which were due to the congestion of vacuum steam engines in cases where just two locomotives tried to pull and push too many wagons.[2120] Achille placed a third rail elevated by a quarter meter between the two broad-gauge rails. There steam engine of a locomotive with a giant wheel propelled the composition.

The novelty seemed to Cauchy to be more stable drive especially during braking when the Achille vacuum system took care of the loss of steam. Of course, marketing was also the great problematic Achilles' heel while his newly achieved invention, despite Cauchy's support, soon flashed into oblivion.

After the July Revolution of 1830, Cauchy did not want to swear loyalty to the new king Louis Philip

"Egalité." To the utmost loyalty to his principles, he suddenly found himself in a political vacuum. He left his family and his profitable Parisian services and went with the King Karl (Charles) X to exile. He owed to that Parisian ruler some sort of feudal infidelity, while his father and his two brothers were by no means exposed to such an extent; despite of their disapproval, they repeatedly bowed adhered to the authorities who changed very often in Paris of those days.

Of course, **François-Napoléon-Marie Moigno** (* April 15, 1804 Guémené (Morbihan) in Brittany; SJ 2 9. 1822-Oct 1843; † 14. 7. 1884 Saint-Denis (Seine)) was baptized by the name of the Emperor Napoleon himself, which was somewhat unusual for the Jesuits. Moigno studied theology in Montrouge and successfully devoted himself to mathematics and physics. After the July Revolution of 1830, he escaped to Brieg (Brigg) in Switzerland, certainly with the help of his friend Cauchy, who hid many Jesuits in his home to prevent further violence. Endowed with an extraordinary memory, Moigno has even learned Hebrew and Arabic languages in Switzerland. In September 1833, he took over Cauchy's Torino Chair after Cauchy recommended him on 24 September 1833 together with another Jesuit La Chéze (Chaise) who took over Cauchy's editorship of *Résumés Analytiques* in Torino.[2121] Moigno, unlike Cauchy, soon returned to his homeland, and in 1836 he became a professor of mathematics at the famous college of Saint Genoffe at Roue des Postes in the Latin Quarter of Paris. There he taught at the École Normale Écclésiastique for the education of Jesuit professors of mathematics and physics with the help of Cauchy.[2122] Moigno became famous as a scholar, preacher, and writer. In 1839, he first began using the camera obscura, lighting projections and other then audiovisual devices in his lectures. Even before he left the Jesuits, he published the first part of the Differential and Integral Calculus according to Cauchy's procedures. He then traveled throughout Europe and corresponded to the Parisian L'Epoque magazine. He was a chaplain in the Lyceum of Louis the Great from 1848 to 1851. In 1850 he became editor of the journal Presse, the next year editor of journal Pays, and in 1852 he founded the famous scientific magazine Cosmos. In 1862 he founded Le Mondes and joined the priests in St-Germain des Prés. In 1873 he became one of the Canons in Saint-Denis. He translated many scientific works of Italian and English writers into French language, while he edited Actualités Scietifiques. In 1849, he published a book on electric telegraph in Paris, which was in many respects a Jesuit invention. In 1869, in Paris, after the Cauchy Gorizian research, he published a book on the polarization of light and the optical activity of sugar solutions. In 1873, he published a book on molecular optics in Paris, based on Cauchy's modern optics of thin layers.

From 26 November 1830 to March 1831, Cauchy was deprived of all three of his chairs because of his absence. He remained only a Parisian academic. At first, he wanted to travel a little abroad to consolidate his health; he hoped for the rapid end of the revolution and with it the end of July Monarchy. In September 1830 he was shortly in Switzerland where he unsuccessfully tried to establish a Swiss academy with the help of the Jesuits in October 1830. In August 1831, Cauchy went to Turin, and the following year began to teach theoretical physics at the request of King of Sardinia Carl Albert himself who also did not like the new French king. Cauchy got a chair of the famous Amedeo Avogadro, the pioneer of modern molecular theory of gases. Avogadro took over the chair again after Cauchy's Moigno's departure in November 1834. In 1833, Cauchy lectured on the physics of molecules in Turin. His lecture was later published by his Torino co-worker and successor Moigno. On June 22, 1833, the main tutor of Charles V, the Baron Maxence de Damas of Toeplice invited Cauchy. In September 1833, Cauchy went to Prague to King Charles X and by October 1838 he taught mathematical and natural sciences to the royal pretender Henrique Count Chambord, Duke of Bordeaux (* 29 September 1820; † 24 August 1883 Viennese Neustadt), who was later buried next to his grandfather Charles (Karl) X in Kostanjevica above Nova Gorica. In 1834 in Prague, Bolzano invited Cauchy to discuss the definition of continuity, infinity, and empty vacuum space; Cauchy presented his discussion of the squaring of functions, which he wrote specifically for Bolzano in French language. Bolzano was then and again a few years after his meeting with Cauchy the President of the Czech

[2121] Belhoste, 1991, 178, 328.
[2122] Belhoste, 1991, 177.

Science Society in Prague, formerly led by Tobias Gruber. In 1816 and 1817 Bolzano enabled the independent development of the analysis with his modern definition of the continuity in the intermediate value theorem, which was compiled under the indirect influence of Bošković's theory of vacuum. When the new Emperor Ferdinand planned his coronation in Prague, the exiled Bourbon court suddenly ran out of space in Hradčany. In March 1836 and finally on 8 October 1836 the French court moved away from Prague and finally settled in Gorizia after a short stop in Linz and Kirchberg's Castle; there the climate seemed more favorable than in Ljubljana. Unfortunately, after a few weeks Karl X in Gorizia succumbed to the insidious cholera, which only killed him among all of his escorts. As the king of France, he came to Slovenian lands and sadly passed away soon after his arrival; he already had more than eighty years of age, and that was his third exile. By the contract, his court first settled in the Palace of Michael Coronini-Cronberg on Grafenberg with a magnificent garden. After the death of the king they moved to the palace of Counts Strassoldo. In November 1837, Cauchy was noted in the list of hundreds of people in the Bourbon service. Occasionally they lived in the Gorizia hotel Pri Treh Kronah (Tre Corone).[2123] Now, Cauchy had his wife and daughters with him, while in his free time he filled up the notebook with new theories and dreamed of a future glory. The Gorizia Sun mainly influenced Cauchy's research of vacuum, optics and ether for the transmission of waves of light.

17.2 Cauchy's Gorizia Vacuum

Among Cauchy's Graz and Prague associates was the physicist Hessler, who subsequently also helped Karl Robida, later professor of Jožef Stefan. In 1845, Robida began to teach mathematics on a Klagenfurt Lyceum. During the summer holidays in 1847 he went to Vienna Polytechnic to Professor Hessler. He designed complicated vacuum experiments there; Hessler kindly taught him about their interpretation.[2124] Robida needed such an experience, since he had already taken over the lectures of physics on a Klagenfurt Lyceum after Matija Ahacel who passed away in autumn of 1845. A decade earlier, Hessler worked closely with Cauchy just before Cauchy's resettlement in Gorizia, when they were briefly together in Prague; Hessler made experiments to verify Cauchy's theories of ether and vacuum.

Dr. Ferdinand Hessler (* 23. 2. 1803 Regensburg; † 13. 10. 1865 Vienna) studied in Prague and Vienna. From 1826 to 1830 he worked at the University and Polytechnic in Graz called Technische Hochschule in Graz which was developed from Joanneum of Archduke Janez in 1811. There the first professor of popular astronomy was former Ljubljana professor Philip Neumann. From 1830 to 1835 Hessler taught mathematics and physics at the Karl-Franz University in Graz founded in 1827. From 1836 to 1838, at the time of Cauchy's service in Gorizia, Hessler was a professor of physics and applied mathematics at the University of Prague. In 1843 he achieved a chair as a professor of physics in the Viennese Polytechnic. Hessler was regular member of the Royal Czech Society of sciences in Prague and of the Natural Science Society of Halle and a correspondent member of the Viennese Academy. Thus, the naturalized "Gorizian" Cauchy was in close contact with both major Viennese physicists of the German genus, Hessler and Ettingshausen, who decisively influenced the development of many Slovenian scientists. Among them were Robida, Stefan and Franc Močnik. Soon after Hessler's departure Močnik began to prepare exams for his PhD degree at the University of Graz.

On 4 April 1836, Cauchy in his letter to his former student and trustee Libri reported his research on amplification of light after its total reflection. On May 20, 1835, these predictions of his calculations were shown to Graz Professor Hessler, who confirmed them with simple and easily repeatable experiments. He bend over the black paper into rectangular triangles and placed them under the glass prism and under two smaller three-sided prisms. Then, with a needle, he penetrated the hole through the paper, which covered one of the side panels. Cauchy and Hessler noticed a picture of a candle that passed through a prism with very high intensity if the incident beam was parallel to the output surface. Cauchy did not escalate the intensity of the output beam while decreasing the angle between the incident beam and the incident surface. He was convinced that this was the first

[2123] Bader, 1994, 59, 61-62, 106, 290, 358.
[2124] Scheitz, 1878, 54.

discovery of a readily repeatable experiment where the interfering light added to light produces a darkness, just like the Jesuit Grimaldi taught two centuries earlier. In this new Cauchy's experiment, the totally reflected beam is better transmitted through the substance by increasing the intensity of light, which was a new argument against the emission theory of light and against Newtonian light particles. According to Cauchy's equations, the intensity of light is proportional to the square of the highest velocity of ether molecules.

On 11 April 1836, Cauchy published his letter mailed to Ampère. Cuachy discussed the propagation and reflection of light in opaque bodies near the surfaces by the equitation of Young, Poisson, Fresnel and Brewster. Cauchy explored mostly the thin surface layers of metals that became the main business of the heirs of Leybold and Heraeus a century later.
Hessler experimentally proved Cauchy's assumptions about the orthogonal direction of polarization with respect to the incident plane and the intensity of light after passing through the prisms. Hessler tabulated it as a "scattering relation" in his textbook about physics.[2125] So, Hessler and Cauchy based modern thin-film optics as an important part of the vacuum technique of Leybold, Heraeus and, of course, also of Slovenian companies.

17.3 Cauchy's Thin Layer Optics of Stefan's Teacher Robida

On 18 May 1836, Cauchy investigated the elliptical polarization of light in metals; he linked his ideas with Brewster's experiments.[2126] Cauchy's findings have become the basis of modern optics of thin metal layers. Cauchy's research had a strong influence even on Robida's optics from 1860, 1861 and 1862, which Robida began to publish seven years after he taught mathematics and physics to J. Stefan in his Matura year of the Klagenfurt Grammar School. Robida's optics was, in many ways, a continuation of Cauchy's optics, as Robida calculated his velocity of light for the supposed longitudinal component of a wave.[2127]

According to Robida, the transversal part of the wave is weaker than the longitudinal and is soon damped because it cannot pass through a vacuum. Robida did not write the relationship between the two types of waves, although in 1829 and 1831 in Paris Simeon Dénis Poisson (* 1781; † 1840) published that the molecules' amplitudes in the direction of propagation of wave are four times greater than the amplitude perpendicular to it. In 1848 the measurements of Wilhelm Wertheim (* 1815; † 1861) suggested up to three times greater ratio depending on the type of substance.[2128] The Viennese Jew Wertheim became an examiner of candidates in the Parisian Polytechnic in 1855.

The idea of two types of waves was used by many researchers in various branches of physics. In 1817 Young introduced transversal waves of light only as companions of longitudinal waves. A similar description was adopted by both Robida and Šubic. Everybody thought that the longitudinal components of light cannot be seen with the human eyes. Nevertheless, longitudinal waves could not be easily eliminated even after the prevailing transversal theory in the 19th century. Longitudinal waves of light that the eye does not perceive were described by Augustin Fresnel (* 1788; † 1827) and André-Marie Ampère (* 1775; † 1836) on 30 August 1816, by Herman Helmholtz (* 1821; † 1894), Konrad Wilhelm Röntgen (* 1845; † 1923) and others.[2129] Šubic used a different model to describe electric waves;[2130] with it, the secondary transverse component can be detected as the Joule's heat, which warms up the conductor.

Robida later changed his opinion that the ocular retina can detect only the transverse part of the waves of light. The longitudinal part of the oscillation also affects the retina of Robida's eye. The change may have been related to the original incompatibility of Robida's theory with his contemporary mainstream optics.[2131] That is why he has also given to his longitudinal impulse a role in spreading of disorder which manifests itself as light. He assumed that the wave propagates in the form of a truncated cone. The axis of the cone determines the longitudinal component, and the radius of the larger base of the cone determines the

transversal component of the wave.[2132] Robida developed his equation describing the changing of the refractive index with the density of the substance by the Parisian professors Dominique François Jean Arago (* 1786; † 1853) and Jean-Baptiste Biot (* 1774; † 1862),[2133] but not according to Cauchy.

In his last chapters Robida described polarization, which was discovered by French Étienne Louis Malus (* 1775; † 1812) as the main theory of particles of light at the beginning of the century. First, he described the structure of the Iceland spar's birefringence, which Erasmus Bartholin (* 1625; † 1698) had already tried to clarify with his experiments two hundred years earlier. Robida determined the distance between the molecules in various directions. He calculated the regular and extraordinary beam pulses according to the theorem on the preservation of the quantity of fluid.[2134] He specifically considered four directions of the incident beam relative to the axes of crystal.

In his Chapter 21, Robida described polarization with reflection and a simple refraction. The transverse fluctuation of the reflected rays is also polarized, as the only allowed oscillations are perpendicular to the plane of the reflection. The Kiel professor Christian Heinrich Pfaff (* 1773; † 1852) measured his polarization ascending by the greater angle of incidence. Scotsman David Brewster showed that the greatest possible angle between the refracted and the reflected beam is equal to 90^o upon the total polarization.[2135]

Robida also described polarization in the Birefringent Iceland spar crystal, where the light fluctuates in two rectangular directions.[2136] With the refractive index Robida has tried to explain the properties of the molecules of matter and vacuum. He considered that the speed of light does not depend on the wavelength, but only on the intensity of the disturbance that triggers the oscillation, that is, the amplitude of the oscillations of the molecules.

In the 17th century, the double refraction (birefringence) and the corresponding polarization was initially attributed only to the Iceland spar. In 1811, Malus described these two characteristics of the light for other substances, and even for all phenomena where the light beam pulse separated to its components after refraction. Robida described the double refraction with the interaction of the luminous impulse and the attractive force between the molecules.

Although Robida investigated the light and especially the polarization with Cauchy's theory of vacuum and atoms, Robida mentioned Cauchy's connection between the velocity and the wavelength of the waves studied in Cauchy's Mémoire sur la dispersion de la lumière (1830) and the corresponding Hessler's table from Hessler's textbook only in Robida's history of physics,[2137] but not in subsequent Robida's papers about optics.

17.4 The Vacuum in Cauchy's Optics

Cauchy began to research the dispersion as early as 1835 and 1836 in Prague. The sunny Gorizia areas had then a beneficial influence on his thinking about light, ether and vacuum. As early as January 1836, Cauchy's distribution of light in an isotropic ether was compared with Fraunhofer's measurements of refractive indexes. In the last few weeks before his arrival in Gorizia, Cauchy began researching the dispersion of light while he was studying the properties of a vacuum full of molecules of ether. In a satisfactory way he adjusted the famous Bošković's force, which was until those times the main subject of the study of Gorizia and Ljubljana physicists. In ~~the~~ Cauchy's model, at higher distances, the ether molecules were attracted by the force of gravity that diminishes with the inverse value of the square of the distance. At smaller distances, Bošković's assumptions about repelling of molecules were taken into consideration, which were inversely proportional to the fourth exponent of distance. Cauchy's ether is necessarily very dense system of molecules; ts density is greatest in a vacuum without dispersion and smaller in bodies with a dispersion. He published a general equation of motion in a uniaxial system of molecules and

[2137] Robida, 1854, 28; Hessler, 1852, XXXII-XLV.

studied propagation of waves in an isotropic and uniaxial system.[2138]

In Gorizia, Cauchy conceived new reflections on optics based on Jamin's studies of reflection and Fraunhofer's researches of dispersion. On December 15, 1837 Cauchy wrote to the Jesuit Moigno in Paris about an orthogonal polarization; he was forced to change his opinion and accept Fresnel's assumption of the vibrations of molecules perpendicular to the plane of polarization. In this Gorizia paper, under the title Lois de propagation de la lumière dans le vide et dans les milieux qui ne dispersent pas les couleurs, Cauchy discussed the spread of light in a vacuum and in metals; this is one of the rare papers which was also preserved in Cauchy's manuscripts.[2139] Thus, Cauchy devoted himself to the research of the properties of the vacuum in Gorizia. At the same time, he examined among them Gorizia folks the behaviour of light on the surface of metals and of other opaque materials. A few days before his departure to Gorizia, on 3. 10. 1836, he wrote to Libri in Paris in a great anger due to Arago's criticism, published on August 10, 1836. Arago rejected Cauchy's presumption of null dispersion in a vacuum; Cauchy's political views also annoyed the liberal Arago. Of course, Cauchy returned the insult to Arago, and he ensured his readers that physicists did not discover phenomena which Arago's predicted, that therefore would not bring novelties to science. Cauchy did not like Arago, primarily because after the initial support of Fresnel optics Arago later deflected the theory of transversal waves and even used the emission system of Newtonian optics.[2140] Thus, together with Parisian academic papers, the news about the Parisian academic quarrels reached Cauchy in Prague and later to Gorizia only with a one-month delay. With Cauchy, Gorizia became the center of physical and mathematical research worldwide for two full years.

In 1838 at the Parisian Academy, Cauchy published two papers about the similarities between plane waves and waves that cause polarization and double refraction of the light. Immediately after returning from Gorizia to Paris, on October 29, 1838, Cauchy reported about the vibrations of the ether-vacuum in the homogenous environment or in a system of two medias where the light is spreading in parallel with the axis or perpendicular to them. On 28 October 1839, he reported on pressures and tensions in the dual system of molecules of two different substances with mutual attraction and reflection based on Mariotte's Law about the relative pressure of gas and on Ampère's ideas about heat and light. Cauchy imagined his molecules as polygons consisting of three or more atoms, preferably as octahedrons with six atoms linked to Avogadro's and Ampère's new two-atomic gas molecules. In the vacuum atoms of the same elements rejected each other and occupy the opposite sites in the polygonal molecule. Of course, given the lack of results of measurements, atoms of the same species could even be attracted to one another. Cauchy explained the modification of the molecular components and variations observed by Mitcherlich when he was changing the angles of the crystal expanded due to heat. The form of molecules is thus not permanent, as the crystal is a system of material points almost in Bošković's sense. Due to the large enthalpy of vaporization and enthalpy of fusion, Cauchy assumed that the heat of solid bodies depends only on the vibrations of molecules around the center of gravity while in individual gases, individual molecules can rotate themselves.[2141] He thus announced his new kind of reflections on the degrees of freedom that became the basis of the later Boltzmann's statistical mechanics and Stefan's extended use of the hydrodynamic equations.

On November 29, 1838, Cauchy described the spread of surface (plain) waves in a system of molecules with the attraction and reflection at very small distances while the polarization and double refraction were also in charge. He developed a very simple process, from which immediately followed the formula for surface waves. A similar equation was derived by Cauchy's Viennese colleague the physicist Ettingshausen for polarization in transparent bodies based on Cauchy's Gorizian paper published in Paris on 29 October 1837.[2142] The sunny Gorizia has always repeatedly godfathered the interesting predictions of optics and the theory of vacuum. Ettingshausen has explained bright and dark lines in the spectrum of the Sun and other sources of light by the wave

theory of light, while he reported to Cauchy about his results. A few years later, Cauchy published a similar theory of ether and vacuum at the Parisian Academy on 22 April 1839.[2143]

The later Stefan's teacher Baron **Andreas von Ettingshausen** (* 1796; † 1878) collaborated with the "temporary" Gorizian Cauchy. Ettingshausen arrived in Vienna with his father who served as an officer in Habsburgian army. He studied philosophy, law and artillery at Bombardierschule, where Vega lectured few years before Ettingshausen's matriculation. Vega was followed by professor Ramutha,[2144] the later professor of mathematics in Novo Mesto. In 1817, Ettingshausen became an associate professor of mathematics at the University of Innsbruck. From 1821 to 1835, Ettingshausen was a professor of higher mathematics at the University of Vienna; then he replaced his chair of mathematics for the chair of physics, applied mathematics and mechanics while in 1826 he was already the leading Viennese researcher of atoms and vacuum. In Vienna, Ettingshausen and Baumgartner began to publish a highly regarded physics-mathematical magazine as the first of its kind in Vienna. On 4 March 1840, Ettingshausen was the first in the world to take a photo through a microscope by Daguerre's process. In 1852 he became a professor of engineering sciences at the Viennese Polytechnic Institute. In 1853 he reorganized the new Doppler's Institute of Physics at the University of Vienna with high vacuum experiments, although he beforehand dismissed Doppler with Petzval's help. Ettingshausen founded the Viennese Academy of Sciences and served there as general secretary from 1847 to 1850. In 1862 he was the rector of the University of Vienna. Unfortunately, he soon began to suffer from illness, and he had to choose Stefan as his successor at the Institute of physics.)

Immediately after leaving Gorizia on 10 December 1838, Cauchy, imagined the oscillation of molecules around the equilibrium position that he described as parallel ellipse.[2145] He completed Descartes' law of refraction for the case of opaque substances and described the motion of the beam in a vacuum.[2146] When traveling through the universe, the earth was carrying with it a considerable mass of ether and caused aberration.[2147]

Figure 17-2: Cauchy's collaborator the Viennese physicist and vacuumist Andreas von Ettingshausen (* 25. 11. 1796 Heidelberg; † 25. 5. 1878 Vienna).

Cauchy persisted in Gorizia until the royal pretender come to his age and Cauchy subsequently gained the baron title according to his ambitions. After returning to Paris, it took quite a while until he regained his previous academic chairs and honors. He was supported by Biot and Arago, but he was opposed by Poisson. Immediately upon returning to Paris, on 22 April 1839, Cauchy refused Poisson's criticism that Cauchy's equations describe well the passage of light from the air to water, but rather clumsy the pathways from air to glass.[2148]

Laplace once prophesied the great future of the little fish Poisson, while Lagrange did the same to his domestic friend Cauchy. Unfortunately, no one announced Poisson and Cauchy's grievous disputes.

On 17 June 1839, the Irishman James MacCullagh (* 24. 10. 1809 Landahaussy; † 24. 10. 1847 Dublin) intervened in those Parisian quarrels; in a

letter to Arago, he demanded his own priority in discovering some Cauchy's equations for calculating the intensity, changing of the phase, and polarization of light reflected from metals. Both Cauchy and MacCullagh particularly considered Brewster's experiments, although Brewster rejected the wave theory of light. MacCullagh liked to clash in many circumstances in disputes for his pioneering championship; it seemed that he always entered the battlefield of a certain promising scientific problem for the thickness of a hair too late. MacCullagh collaborated with his fellow Hamilton in his optical research, and in 1840, in Turin, in his friend Babbage's apartment, MacCullagh met Cauchy's former student Luigi Federico Menabrea (4 September 1809 – 24 May 1896) later count and 1st marquess of Valdora as Italian general, statesman and PM. MacCullagh also met Cauchy's opponent from the Turin university the astronomer Jean Plana (Giovanni Antonio Amedeo, 1781-1864). Babbage visited Carniola to get some Proteus on that occasion, but MacCullagh was probably not with him there.

Figure 17-3: Cauchy's villa in the suburbs of Paris, where he died two decades after returning from Gorizia.

Cauchy proved that MacCullagh used a different equation for the index of refraction of metals and their thin surface layers. Immediately after leaving Gorizia, on 28 April 1839, Cauchy published a study of the six equations of motion and the infinitely small movements of two molecular systems that penetrate each other. He described an isolated ether-like vacuum in the environment with a velocity of longitudinal waves equal to zero as he had been doing nine years earlier. In the second version of his theory, he was so much committed to his mathematics that he unlimitedly believed in the future measurement of longitudinal waves by changing the density of the ether, possibly in connection with heat, as Cauchy noted in his letter mailed to Ampère on February 19, 1836. That Cauchy's hope was close to Robida's, Helmholtz, Hertz and Röntgen's later thoughts. It seems that they were wrong, anyway.

Christiaan Huygens was among the first to conceive ether as a gas of light. Cauchy's earth dragged ether behind itself on its way around the Sun. Unfortunately, this made it difficult to understand the aberration which James Bradley measured in 1728. Due to the immeasurability of never detected longitudinal waves in the ether-vacuum, Cauchy assumed the negative compressibility of the ether-vacuum. Unfortunately, George Green (1793–1841 Nottingham) proved the instability of such an ether. Longitudinal waves cannot spread through a vacuum, as there is nothing that could be thinned or thickened in a void.

Like Robida, Cauchy considered the heat as vibrational movement, which can spread in a vacuum, that is, in an isolated ether. According to Ampère, the equation which describes the transfer of heat is of second order in time and of fourth order in terms of coordinates, like Cauchy's vibrations by varying the density of the ether which measured the degree of vacuum. Fourier's general equation designed for his describing of the heat allowed the total polarization. That's the way how astronomer Herschel could have conceived a light that travels without waves of heat in the vacuum of the interstellar space or through other completely transparent and isotropic bodies.

The problem of mathematical predictions of the undetectable longitudinal waves already appeared from Cauchy's description of deformation in a crystal calculated by tensors in 1822. On January 27, 1823, Cauchy investigated the movement of two liquids put one above the other, where only one of them was compressible. At the contact junction points of both liquids he used a wave equation from his wave theory, for which he received the award of the Parisian Academy of Sciences in 1815.

On 17 November 1823, Cauchy reported to the Parisian Academy of the influence of the attractive force of molecules on the motion of waves. The viscosity of liquids causes the attraction of molecules at small distances in the same way as in Bošković's theory of atoms and vacuum. In 1827, Cauchy spoke to the Parisian academicians about Navier's equations of motion, which he generalized for anisotropic solid matter in the following year, independently of simultaneous Poisson's similar works. On 4 May 1829, Cauchy summarized his research on the equilibrium and movement of fluids. On 21 July 1829, in a letter to Libri, he described a torsion of elastic bars, which Savart had just confirmed by his experiments.[2149]

Cauchy's diminution of the velocity of longitudinal waves towards zero or its escalation towards infinity was, of course, an urgent desperate search for a principle from which the equation of motion could be derived. This succeeded only in MacCullagh's work. MacCullagh imagined a solid substance with a flexible energy which only depends on the rotation. Although he wrote the idea already in his run-up with Cauchy in 1839, it was only published after MacCullagh's suicide nine years later. Of course, the idea was far too wild that it could be accepted by most of serious mainstream scientists.
Stokes described the ether as a plastic solid substance, which becomes flexible by rapid motion. Cauchy has imagined his molecules of ether as much smaller than their mutual distance; the speed of Cauchy's light depended solely on the composition of the bodies. In the confusion caused by insufficient experiments, Cauchy subsequently published two different theories of crystal optics, three different models of reflections, and three different theories of elasticity, ether and vacuum in the years 1830, 1836, and 1839. All his ideas gave at least approximately exact equations. They opposed each other because of their inaccurate boundary conditions and the unrealistic values of constants involved. Later, he abandoned the assumption of the same density of the ether in vacuum and in bodies with idea of the pressure of molecules proportional to the third exponent of the density of ether. Those were just arrows launched in the fog full of darkness. Only Fresnel's laws of reflection were measured accurately; Cauchy had to guess as much accurately as possible without serious measurements of the orientation of the plane of oscillation with respect to the plane of polarization, the density and elasticity of the ether-vacuum. Thus, the foundations of a modern vacuum theory were developed on relatively damp shaky foundations under the hot Gorizia sun.

Cauchy initially assumed a parallel plane of oscillation, and later, a perpendicular plane of oscillation and a plane of polarization. At the same time, he developed three variants of boundary conditions for the rays of light passing from one environment to another. Of course, he had the very right point once and again, since he was such a kind of important person who always has the right solution at hand and is always confident in himself; especially when disturbed with his own errors. Cauchy's idea of longitudinal heat wave in the ether from 1837 and 1842 was brutally rejected by Biot in Journal des Savants; so, Cauchy even abandoned the printing of his work and did not announce any of his researches in optics until the revolutionary year of 1848.[2150]

17.5 Conclusion

Cauchy was a king, one of three French kings who settled in sunny Gorizia of those times: the formally exiled king, his royal son and the king of mathematicians. Even Galois admitted that Cauchy was the only one of that era, who knew how mathematics should be done despite of the fact that Galois was an evident Cauchy's political opponent and Cauchy treated Galois's manuscript very unjustly. Cauchy's conservative politics influenced his mathematics just like Galois' revolutionary unsteady life shaped his ideas. The genial Irish friends MacCullagh and Hamilton killed themselves or drank too much, which was again the fatal influence on their genial mathematics. Cauchy staid cool and deeply conservative upstart focused on his title of baron.

The long-term stay in sunny Gorizia for two years particularly stimulated Cauchy's interest in optics and vacuum. Already in Prague, Cauchy wrote a lot about ether in space; he used primarily the ideas

[2149] Belhoste, 1991, 297, 302, 324-325.

[2150] Cauchy, 1884, 1/4: 333, 343, 431, 493, 495; Rosenberger, 1890, 311, 314; Mladjenović, 1985, 145-146; Belhoste, 1991, 200.

of his teacher Ampère. He continued with his reflections under a clear Gorizia sky and then published them well after his return from Gorizia.[2151]

With Cauchy's work in Gorizia, the Slovene lands surpassed most of the Central European space of discussions about vacuum. Parallel with Cauchy's work, the first successful Central European vacuum companies Leybold and Heraeus based their success on vacuum, ether and optics of thin metal layers. The theory and practice, the academic and profitable applied thinking about the vacuum have thus evolved in parallel and yet each as a separate one; from Boyle's and Guericke's times, the theoretical and experimental research of vacuum never again joined in the same networks as they were no longer developed by the same people. Almost nobody could be the successful experimentalist and a great mathematician at the same time as Plücker was, not to speak about the technological applications. The theory and experiment have become the subject of two different professional occupations of physicists; the theorists of vacuum were increasingly separated from researchers of vacuum technology. Cauchy's concept of vacuum as ether challenged Crookes' ether full of forth aggregate state filaments later nicknamed as plasma. Finally, Cauchy's concept of vacuum and ether suffered a severe blow with Einstein's theory designed without an ether.

18 Industrial Uses of Vacuum Technologies: Modern Electronics

18.1 Cathode Ray Tubes's Electronics among Slovenes

Nicolò Vlacovich was of Slavic origin according to his surname. He was born in Vis or in the fishing village of Portira (Postira) on the northern coast of the island of Brač in 1832 - at the place where the Croatian poet Vladimir Nazor was born a century later. Vlacovich was a Slavic mountains' leaf from the islands. During his studies at the University of Vienna he worked in collaborated with his few years younger colleague later professor Jožef Stefan at the Ettingshausen's Institute of Physics. While studying at the University of Vienna, Vlacovich researched at the Ettingshausen's Institute of Physics, where, five years after Vlacovich's departure to Koper, Jožef Stefan became Ettingshausen's co-director and later successor.

J. Pöschl's successor Albert Ettingshausen, Andreas Ettingshausen's grandson, proudly recalled Tesla's former schooling in their institution at the rector's speech in Graz Polytechnics later in 1893.

Stefan was one of the students (Zögling) at the Viennese Physical Institute, where he showed "extraordinary talent". On August 5, 1858, he was confirmed as a teacher of mathematics and physics. In 1860, he lectured on the Higher Real school of 1st Viennese department called Innere Stadt at Bauernmarkt, while at the same time he was assistant professor of higher physics at the University of Vienna. Vlacovich was also a researcher at the Physics Institute until he was confirmed as a teacher of mathematics and physics a month and a half after his younger colleague Stefan on 25 September 1858. As the substitute (suplent) teacher lecturing from 5 October 1858 until the end of the school year 1862/63, he taught physics at a higher gymnasium in Koper,[2152] where he was also a curator of the cabinet of physics.

In the first years in Koper and Trieste, professor Vlacovich developed a rich scientific activity. He particularly enjoyed ~~by~~ experiments with electricity, since the Trieste port was developed into an important center of physics and mathematics. Among the most important achievements in researching high-frequency discharges on today's Slovenian soil is Vlacovich's discussion on the duration of the electric spark, published in Koper in 1863. He continued his experiments published in previous year in Italy and Vienna.

In 1863/64 Vlacovich gained a place in the urban higher real school of the Civic Scuola Reale Superiore Autonoma in Trieste, which later developed into the modern Oberdan Lyceum. Vlacovich was director of the high school in Trieste from 1863 until his death in 1890. Bartolomeo Biasoletto[2153] taught physics in Trieste before Vlacovich. For more than two decades, Vlacovich directed the development of the Trieste education, since he was still professor of physics and director in the school year 1884/85. The Real school in Trieste was initially lower, and then it was complemented by a higher sixth grade. In 1865/66, Vlacovich also lectured in physics five hours per week in the second year after Schabus's textbook published in 1859. In 1871/72, he taught physics only in the sixth grade.

Already upon his arrival in Trieste in 1863/64, Vlacovich was a member of the Society of Natural Sciences in Augusta in Sicilian Syracuse and a member of the Agricultural Society in Gorizia. In the first years in Trieste, Vlacovich developed a rich scientific activity, and his experiments with electricity were especially awesome.

In addition to Vlacovich, the report of the Real school in Trieste was supplemented by other physical contributions. In 1875, G. Derase described procedures for determining the refractive index in solids, liquids and gases. In 1871, M. Lovrich, a supplied teacher of geometry, investigated strings vibration, clustered between

[2152] OSTA, 1, 26. 1. 1863, 9; Vaniček, 1860; Dassenbacher, 1868-1869.

[2153] Twenty-year-old native of Istria Biasoletto graduated from pharmacy school in Vienna in the year 1814 and in the year 1823 he received his doctorate from natural science in Padua. In the year 1828 he established the first botanical garden in Trieste, and in the year 1838 he visited Istria, Montenegro and Dalmatia; his vision of the inhabitants of those areas was published in his book three years later.

Cauchy left Gorizia when **Nicolò Vlacovich** was only a kid in nearby Adriatic island somewhat south. Nicolò Vlacovich learned his physics in the institute of Cauchy's collaborator von Ettingshausen; Cauchy's deep conservatism was melted there a little bit. Nikola Vlahović (Nicolò Vlacovich) from the island of Brač or Vis studied at Ettingshausen's Viennese Physical Institute, where he met three years younger Stefan. On 5 October 1858, he was installed at the Higher Gymnasium in Koper, where he taught physics until the end of the school year 1862/63. During this time, he published his first experimental research on discharges in the most important Italian and Hapsburgian physics journals. He was then a physicist for more than two decades, and later a director at the Scuola Reale Superiore in Trieste. At least in 1863/64 he was a correspondent member of the Society of Natural Sciences in Augusta and the Agricultural Society in Gorizia. He published all his papers in the Italian language. Nicolò's older brother was a Paduan professor of anatomy Giampaolo Vlacovich (23. 10. 1825 Vis (Lissa)-11. 1. 1899 Padua). Nicolò and Giampaolo Vlacovich were both members of the *Società Italiana di scienze naturali* in Vicenza where they published about microscopy and about the zinc in Robert Wilhelm Bunsen's pile in 1868. Nicolò Vlacovich was also a member of *Società agraria di Trieste*.[2154] Nicolò was active lecturer of the Minerva society with themes of natural sciences like 'On the fluorescence (Delle fluorescenza)', 'On the manufacture of the ice (Sulla fabbricazione del ghiaccio)', 'On the electric clocks (Sugli orologi elettrici)', etc. The other Nicolò Vidacovich also collaborated in the leadership Minerva society as a close friend and German language translator of James Joyce. Nicolò Vidacovich (Vida-Covi, 1875 Trieste-1934) also served as director of Minerva Society of Trieste in 1872 and 1905-1909. Società di Minerva published the journal *Archeografo Triestino*. Nicolò Vlacovich died in 1890.[2155] Nicolò Vlacovich's best student in Koper was Antonio Pizzarello (1846 Koper-1933) until Vlacovich left Koper for Trieste in autumn 1863. The Grammar school of Koper acquired textbooks of Vlacovich and his student Pizzarello, both published in 1880. Antonio Pizzarello graduated with Matura in Koper Grammar school under the presidency of Trieste state grammar school director Venceslao Giuseppe Menzel in August 1864. Among his classmates was the archaeologist Geminiano Pellegrini (* 1845 Koper) who also became a professor in Italy. Their professor of mathematics and physics in final class was Vlacovich's replacement from the Higher real school of Split (supplente, Scuola Reale Superiore di Spalato) Antonio Lorenzo Gossetti (Gosselti, Zadar-1895 Trieste), author of paper about the conservation of forces (Cenni intorno alla conservazione della forza, *Programma del Ginnasio comunale superiore di Trieste pubblicato alla fine dell'anno scolastico 1870-1871*) in Trieste in 1871, the doctor of mathematics, civil engineer and architect and later director in Trieste named in 1883. The other Antonio Pizzarello (* 1869 Koper) graduated with Matura in Koper Grammar school and became the counsellor of finances in Sarajevo of recently dominated Habsburg Bosnia. A. Pizzarello senior fought in Garibaldi's Risorgimento units in Mentana on November 3, 1867, and married Koper native Nicolina Gambini. Their son Ugo von Pizzarello (1877 Macerata-1955) studied physics-mathematics and became the highly decorated general of alpine units. Nicolina Gambini was the aunt of Pio Riego Gambini (1893-1915) the leader of the Istrian Mazzini's fans and the founder of Fascio Giovanile Istriano in 1913. Antonio Pizzarello (* 1846 Koper) graduated in Paduan University in 1868 and became a professor of 2nd class in 1872. The Habsburgians exiled Antonio Pizzarello (* 1846 Koper) after a political process in 1879, when he was already a professor of Lyceum of Macerata in Italy where he researched kinetic properties of atoms in gases. Antonio Pizzarello and Marangoni unsuccessfully tried to get a chair of physics in the university of Modena under the commission of Pietro Blaserna, Antonio Roiti, Andrea Naccari, Emilio Villari and Adolfo Bartoli in 1888. Antonio Pizzarello got a golden prize for his physics instrument in Torino Exposition (Esposizione) Nazionale in April-October 1898. Marconi already exhibited there his radio, but Tesla did not. Antonio Pizzarello's instrument was a clever modification of Torricellian, Helmholtz Giuseppe Martinotti of Urbino University (1888) and the Florentine Carlo

Giuseppe Matteo Marangoni's (1840 Pavia–1925 Firenze) vacuum experiments. The essential part of Pizzarello's device were two strong pipes placed in communication by a thick rubber tube filled with mercury. The barrels were fixed to sliding supports along a large vertical rule, which was divided into centimeters and had a graduation clearly visible at a distance. The supports can be fixed on the side wooden rods by means of pressure screws. Pizzarello's apparatus allows to show the law of Boyle and Mariotte, to determine the coefficient of expansion and tension of the gases. It can also be used as the eudiometer, piezometer, pressure gauge, vacuum pump, or gas thermometer for Pizzarello's studies of the thermodynamic properties of saturated gases and vapors. in 1927 Pizzarello became a corresponding member of 2nd Class of Istituto marchigiano di scienze lettere arti of Ancona founded in 1925.

two weights. In addition, in 1872 (J. Streissler), 1878, 1879, 1881, 1884, 1885, and 1887 (E. Lindenthal) published papers on geometry, curves of the second order and other mathematical problems in the reports of the Real school in Trieste. Hofman wrote papers about ancient astronomy for the report of the gymnasium in Trieste in 1865, 1870, 1871, and 1873; the city thus developed into an important center of physics and mathematics.

Among the most important achievements on now Slovenian soil is Vlacovich's discussion on the duration of the electric spark, published in Koper in 1863. He continued the experiments he published in the previous year in Nuovo Cimento and in the Viennese academic magazine Wien.Ber. According to the example of Berlin's Professor of Mathematical Physics, Peter Theophil Riess, he proved[2156] that the spark is only apparently triggered in a moment; in fact, it contains a series of successive discharges, during which counter-currents are gradually eliminated. He measured the relationship between bound and free charge and produced high voltage with Riess generator in the Koper cabinet. Vlacovich's Klagenfurt colleague Robida also supported Riess's achievements from 1838, although the Viennese researchers were suspicious because of Riess's provocative assumptions that only the magnetism of a natural magnet lasts, while all other substances are expected to be discharged over time.[2157]

Vlacovich's research was inspired by the measurements of the light rays of the spark of Ruggiero Fabbri (Ruggero Fabri, * 1830 Ravenna; † aft. 1882 Ravenna) from the Roman university, published in the notoriously famous magazine Il Nuovo Cimento in 1855 ad 1858. Vlacovich used Riccardo Felici's supposed independence of the duration of the electrical spark from the circuit in which sparking occurs, published in the 15th volume of the same newspaper.[2158] Felici published his work simultaneously with Vlacovich and initially did not know the findings of his competitor Vlacovich. The sparking time is supposed to determine only the distance that the spark skips;[2159] according to Felici, the properties of the circuit should only affect the luminosity of the spark during discharges. Today we know that the luminosity of discharges depends on the tension that causes it, and therefore Vlacovich's doubts seem to be justified.

Vlacovich's critical attention was mostly focused on Carlo Matteucci (1811 Forli–1868 Livorno)[2160] and Felici's achievements in Pisa. Matteucci studied physics and mathematics in Bologna until his promotion in 1828/29. During his specializations at the Paris Polytechnic School, he became acquainted with academician Arago. In 1831 he returned to his native Forlì and Bologna, full of liberal views, nothing that his respective authorities loved: he had to escape to Florence in 1834. They offered him a position in pharmacy, but he preferred to live among the merry Parisians, and after the publication of his paper in Parisian academical journal, Humboldt and Arago helped him to achieve a chair in Pisa (1840). In 1835, independently of Faraday, he laid down the laws of electrolysis, in 1841 he was rewarded by the Parisian Academy for physiological experiments, and three years later he also received the Copley medal in London. The spring of nations did not leave him in the short term: in 1847 he started politics, and after the unification of Italy, he unified the programs of various universities in the

Italian Kingdom as Minister of Education (1862). Despite of new challenges, he studied the polarization of dielectrics in 1847, and between 1853 and 1854 he researched the distribution of electricity in insulators besides magnetic and diamagnetic phenomena, which mostly interested Vlacovich. In 1859, he explained the effect of the northern light on telegraphic conductors.
The source of electricity in the fish torpedo was illustrated by the first physical model of the nerve as the basis of the subsequent achievements of Emil Du Bois-Reymond, who began to research under the direct Matteucci's influence. Riccardo Felici (* 1819 Pisa; † 1902 S. Alessio in Lucca) matriculated in Parma to finish his studies in Parisian Polytechnic and in Pisa, where he became Matteucci's assistant in 1846; in the revolutionary year of 1848, as a lieutenant, he fought in the university battalion, and in 1862 he took over the chair of just-named Minister Matteucci. Felici was one of the founders, initially the sole owner and, in the years before his death, the editor of the magazine Il Nuovo Cimento, where he also published Vlacovich's achievements; Felici became one of the directors of the Scuola Normale Superiore and a member of the national academy dei Lincei, which has been known since Galileo's days. Basically, he devoted himself to the theory of electrical induction and the mathematical form of Faraday's induction law (1851-1859), which the self-taught Faraday initially preferred to express in words. Felici investigated in parallel with Franz Ernst Neumann and Vlacovich; Felici's findings turned Hermann Helmholtz into a more general theory of potential. Vlacovich, of course, went a long way beyond the scope of the then experiments, claiming that the spark at the discharge consists of a quick sequence of shocks. Unlike Felici, he claimed the first shock to be the strongest among all of them. Despite the small total time, the spacing between individual shocks should still be much longer than the time that an electrical disorder needs to travel through the circuit with which we are sparking. The speed of electromagnetic disturbances was measured for the first time by the Englishman Charles Wheatstone in 1834 and 1835,[2161] while important measurements were also made by Lower Carniolan (Dolenjec) Ignac Klemenčič in 1884 in Graz. During the time of Vlacovich's research, The Scotsman James Clerk Maxwell published the first discussions on a similar matter of electromagnetic waves and light. The resistance of the circuit does not have any influence on the length of the spark[2162] in contrast to Wheatstone's findings. Vlacovich tried to obtain accurate data on the absolute surplus of electricity during sparking.[2163] Vlacovich used the ideas about polarization of the vibrating molecules of the Geneva professor of physics August Arthur de la Rive for a polite criticism of the mathematics of Matteucci's book from 1852[2164] in accordance with the atomistic beliefs of Ettingshausen's School of Vlacovich's student years. Vlacovich was not far from the London views of John Frederick Daniell (1790-1845 London) or the induction ideas of Faraday himself, who, together with Wheatstone, researched the sequence of sparking in fire[2165] and studied Georg Christoph Lichtenberg's figures.[2166]

To compile with the Matteucci's research of discharges by the negative electrode, Vlacovich used a textbook of the Parisian Polytechnic professor Jamin.[2167] He thoughtfully studied the breakthrough of the electrical spark through the molecules of card[2168] used for a tarot game or he even preferred a coastal popular briscola cards; Matteucci's measurements also dealt with discharges in a vacuum.[2169] Vlacovich promised further experiments to complement the achievements of the "famous" Matteucci:[2170] he completed them in the following year in Koper reports with experiments on semiconductor cotton and conductive water.[2171] According to Riess's measurements of frictional electricity published in 1853 and 1867, he proved that the duration of the spark is inversely proportional to the warming[2172] and the distance, and proportional to the resistance.[2173] Vlacovich's course of discharge remains interesting nowadays, as we do not yet have the prevailing theory to describe the events of atmospheric discharges during lightnings and thunder.

2173 Vlacovich, 1863, 10-11.

On 16 September 1868the Veronese chemist Teodoro Triulzi as the secretary on second meeting of third extraordinary session (Seconda Seduta of terza riunione straordinaria) of *Società Italiana di scienze naturali* in Vicenza reported that Nicolò Vlacovich communicated his discovery. Vlacovich observed that a glass stick, slightly rubbed with a foxtail, gives negative electricity, while it shows signs of positive electricity if the scrubbing is prolonged sufficiently. Vlacovich also observed that a glass stick, rubbed until it began to show signs of positive electricity, and then abandoned to a natural discharging, indicated ever smaller quantities of this electricity, then passed through a point where electricity was negligible, and next gave the signs of its negative electricity. Finally, Vlacovich, guided by some theoretical considerations, made another experience. In a Bunsen's zinc-carbon pile or in another pile, Vlacovich covered with a substance suitable for defending the zinc itself from the action of the acid the surface of zinc, which is not directed towards coal, copper, etc. Vlacovich obtained the same deflection of Gaugain's compass that he observed with all the surface covered. In the first case the consumption of zinc was about half smaller than in the second. Vlacovich announced his right to make further experiments confirming this fact, which he believed to be important for the practical applications of electricity.[2174]

During his other experiment in Trieste Vlacovich added a negative electricity to a glass rod with scratching, and with stronger rubbing made it positive. With Bunsen's battery, he rejected a magnetic needle in Gaugain's compass obtained from Paris.[2175] He then proceeded to compile electric batteries for the then fashionable lamps,[2176] which he later published as an echo to the prize awarded by the Venetian scientific institute to Paduan professor of technical physics Andrea Naccari (1841 Padua-1924 Torino) in 1872/72. First, according to Naccari, he summarized the development of research until Galvani's discovery;[2177] Vlacovich particularly praised Georges Leclanché's cell and de la Rive's experiments with peroxides at the Parisian exhibition in 1867.[2178] The French railway engineer Leclanché developed his cell in Brussels during his self-imposed exile from Second Empire just few years earlier in 1866. Vlacovich was interested in the role of ammonium chloride as an electrolyte between carbon and zinc electrodes in Leclanché's cell,[2179] to which various researchers attributed surprisingly equal voltages.[2180] Vlacovich himself used Leclanché cell for regulating the movement of clocks for nine months;[2181] the battery with chromic acid initially gave high voltage, but it quickly weakened.[2182]

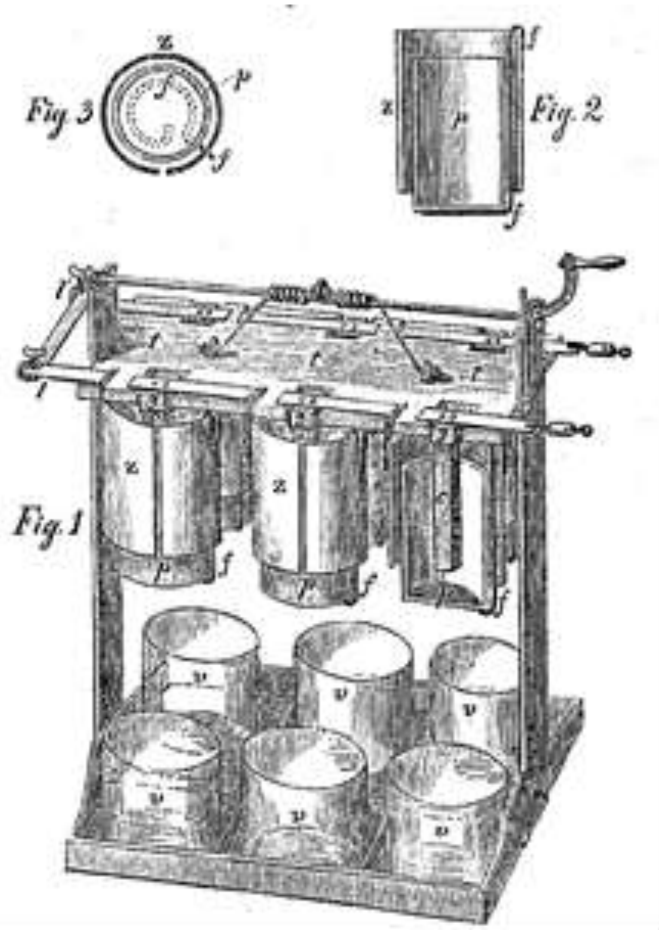

Figure 18-1: The sketch of a battery with zinc plates used in Vlacovich's experiments (Vlacovich, 1875, 144).

Naccari received his doctorate from mathematics in Padua in 1862. Then he lectured on experimental physics in Turin between 1878-1916; together with the relative of his fiancée, another Paduan professor of technical physics Manfredo

Bellati (1848 Feltre in Belluno-1832 Feltre), they used chromic acid, but Vlacovich found out Naccari's discrepancy because he was not in conformity with Voltaic theories of electrolysis. Therefore, Vlacovich undertook independent experiments with Bunsen's[2183] battery and three batteries of the professor of analytical chemistry of Parisian École centrale des Arts et Manufactures Félix Leblanc (1813 Firenze-1886 Paris).[2184] Naccari improved Ohm and Poggendorff's procedure, supplemented by Du Bois Reymond; he measured the voltage of Daniell, Siemens, Grove, Smee and Bunsen's batteries with pure nitric acid[2185] to find suitable sources of voltage for the proper uses in telegraphy, just like Leclanché did for railways. Smee's battery was popular in Koper even later, as Carlo Sbuelz (Karol Žbuelz, * 1844 Solkan-Gorizia) bought it for the cabinet of physics in 1876 and in 1892 with twelve elements.[2186] The telegraphic batteries should avoid transmitting vapors: therefore, the French telegraphers used Leclanché's invention, processed towards later portable "dry cell",[2187] finally modified and patented by the physician Carl Gassner in Mainz in 1885/86. Naccari and after him Vlacovich were particularly interested in electric lamps powered with the batteries of the priest Nicholas Joseph Callan (1799 Darver between Drogheda and Dundalk north of Dublin-1864 Maynooth east of Dublin) and Bunsen;[2188] Vlacovich personally sketched his experimental devices with zinc and carbon electrodes soaked in sulfuric acid.[2189] As a diligent student of Ettingshausen who was already ill in that time, Vlacovich presented the hydrogen atom as a part of the acid molecule in the electrolyte.[2190] Although the littoral (Primorska) oil lamps had not yet been replaced by electric lights, Vlacovich has already studied the dynamos of the Parisian Belgian Gramme from 1869/70, which he observed at the Viennese International Exhibition in 1873 and published a report about the show.[2191] Vlacovich was also interested in the use of electricity in medicine and galvanoplasty;[2192] the latter was presented by Prof. H. Mitteis of Ljubljana at a lecture in front of the Society of Carniolan Provincial Museum on March 5, 1856 under the title Use of galvanometry; light, thermal and electrical effects of electroplating and on 18. 3. 1856 under the title History of galvanoplasty.[2193]

Vlacovich attributed the decisive importance to the affinities of gas and the electric force - therefore, according to Bologna University professor Emilie Villari, Vlacovich preferred to use palladium than Grove's platinum in the battery, as Vlacovich discovered an increased activity of hydrogen needed for production of palladium oxide on a positive electrode. In contact with palladium, hydrogen is more prone to oxidation than in contact with platinum: Vlacovich searched for the correct chemical formulas of palladium compounds with hydrogen and promised to continue his investigation of hydrogen compounds with potassium or sodium.[2194]

18.2 Vacuum Pumps among Slovenes after the Spring of Nations of 1848

18.2.1 Geissler, Crookes, X-ray and Braun's Cathode Ray Tubes for Slovenians

The Slovenian aeronaut Kraškovič (Kaskovich) flew in the era when steam engines with vacuum techniques also began to develop in Slovenian towns. The steam engine was a kind of introduction to the triumph of vacuum technologies that followed Geissler's invention of the cathode-ray tube and Vlacovich's research of discharges already oriented towards the Italian milieu. In addition to Ljubljana, the cathode ray tubes were also purchased early by Vlacovich and the other Koper professors, among them a costly rubber balloon with a copper tap, usually designed for exploring gases and a Ruhmkorff inductor, discharged through the cathode ray tube of Heinrich Geissler. It was purchased Koper in 1870 for a price of 3 fl. In the years 1897 and 1907 they acquired the new (Braun's) cathode ray tube in an adapted collection. In 1905 they received a radiotelegraphic Marconian apparatus, and in 1907 and 1908 X-ray machine along with Crookes and Hittorf cathode ray tube for experiments with just discovered rays or particles.[2195] Under the auspice of Boltzmann's brother-in-law Šantel Gorizia high school equipment was comparable to nearby Koper.

In 1876, the Ljubljana cathedral priest, canon, and speleologist Anton Urbas was interested in Geissler tubes, galvanic electric engraving, electric light and artificial fire.[2196] The only true Carniolan breakthrough was achieved by Anton Codelli, the baron of Ljubljana, who already used the term electron for a cathode ray,[2197] although he also repeatedly wrote about the cathode ray deflection in his typewritten application for US Patent application.[2198] He explicitly described a transmitter with a long Geissler tube placed on the same surface with a diffused reflector made of glass.[2199] The Ljubljana vacuum was therefore born at least on Kodeljevo, if we ignore the school experiments of Codelli's predecessors. It is not possible to prove convincingly that the first Slovenian vacuum researcher, Prince Janez Vajkard Auersperg, brought a vacuum pump to Ljubljana, although he significantly contributed to the first pumping experiments. As expected, Slovenes became acquainted with the first vacuum pumps more through technology than by any theoretical scientific concepts. During the advent of the French Revolution, the first books on steam engines started to appear among Slovenes; right then, professor Gabriel Gruber on Mura river tested the early steamer and together with his brother commented on the freezing of the steam at the valve of pump used for of the extractions of waters from mine in the Slovakian Banská Štiavnica. Early vacuum experiments did not have a real echo in Ljubljana, although among the city inhabitants was a vacuum research pioneer, the prince Janez Vajkard Auersperg. Even the first industrial-oriented vacuum pumps can be found in the schools of the Slovene national territory following the efforts of individual educators like Stefan's teacher Robida in Klagenfurt. Barely ~~a~~ Geissler's invention and the obvious advantages of cathode ray tube in electrical engineering have enabled the massive contact of Slovenes with the technology of vacuum pumps, which lasts even today when Slovenians are among the top experts for them.

18.2.2 *The First Photographs of the Supersonic Missiles of the Son of the Landowner in Gorjanci Region for the Recording of Modern Plasma Turbulences in the Magnetron*

18.2.2.1 Introduction

Both metal sputtering and high-speed flash photography of ultrasonic missiles were closely connected with Slovenes through Stefan's and Salcher's homeroom gymnasium professor Robida, and Mach's father the landowner in Veliki Slatnik between 1858 and 1879. The merger of both achievements with the modern ultra-speed recording of plasma turbulences by sputtering with the magnetron developed for radars during the Second World War, may once again witness an important Slovenian participation. It builds on the shoulders of the Ljubljana physical core, as it began to develop in the Jesuitical classrooms three centuries ago.

18.2.2.2 Machs among the Butterflies from Veliki Slatnik

130 years ago, in January 1886, a renowned Prague physicist, Ernst Mach, wrote to his ten years younger professor of physics from the department of the Maritime College of Rijeka, the Carinthia native Peter Salcher. Until then they did not know each other, but Ernst urgently needed Peter's help. What was the problem that marked so profoundly their and ours everyday life? Why did pacifist Mach need access to the Rijeka factory of two decades previously invented torpedoes that even Napoleon rejected at his time as unethical along with submarines of the American Robert Fulton
At the first International Electricity Exhibition in Paris in October 1881, Mach looked for new experimental challenges. He listened extensively to the lecturer Louis Henry Friderik Melsens (1814 Leuven-1886), a permanent adviser to the Belgian military School. Dumas' Parisian student Melsens spoke about the tearing of tissues and in widening the sphere of injury of gunshot wounds of people and horses, especially about the acute victims of the French, who injured their enemies with the fastest supersonic missiles of that time. As early as 1872, immediately after the Prussian-French war, Melsens assumed that the destruction of the wounded tissue was caused by the compressed air that the projectile pushes ahead. Of course, Melsens was based solely on observations of wounds of poor victims without any photographic review of events that had not yet been available to him at that time. Ernst was a different man, since he already learned all about the photographic procedures from his teacher, the officer's son, Andreas Baron Ettingshausen, who studied in his time at the Bombardier Viennese School with the disciple of prematurely killed Jurij baron Vega, the captain Ignac Lindner. Ettingshausen used the process of L. Daguerre (1787-1851) and first photographed through the microscope in 1840, while Ettingshausen's assistant was his son-in-law crystallographer Josef Grailich. Mach enthusiastically picked up the photography as the new experimental aid. So, he took a photographing as his enthusiastic work, especially during his holidays with his parents and three younger sisters in Veliki Slatnik under Gorjanci, 5 km south of Novo mesto. After their mother's death, Ernst Mach's youngest sister Wilhelmina, was somehow attached to the nice domestic servant, which Janez Trdina cleverly arranged in his story Zakleti oreh (Cursed Nut). The otherwise liberal Ernst Mach proved to be a hard member of his privileged social class as he sent his own sister Wilhelmina into an Austrian monastery for good. During his Lower Carniolan (Dolenjska) vacation, Ernst often designed his experiments, which he then showed to the world. He was strongly advised by his father, the imaginative Slatnik landowner Johan Nepomuk Mach (1805-1879), who studied at Charles University in Prague in his time and taught his teenaged son Ernst at home. In 1840, Johann became the owner of the large estate of Untersiebenbrunn in Marchfelde in Lower Austria between Vienna and Bratislava, so that Ernst grew up in the countryside. At the time of Ernst's birth in Brno, Johann Mach was the educator of the children of Baron Breton and Josephine, born Lanhaus,[2200] and later he tutored the children of Kunigunde and Franz Seraph Stadium Count Warthausen (1806-8. 6. 1856) the later interior and school minister in the years 1848-1849. E. Mach's grandfather was Joseph Mach. Ernst's mother, Josepha Lanhaus's father, Wenzl Lanhaus, designed the roads. Ernst himself studied for three years and graduated with his Matura in the Piarists' college developed from the former Moravian non-Jesuitical grammar school in Kremsier (Kroměříž). E. Mach's teacher of science was Franz Xavier Wessely (Veselý, 1819, Rajnocovice-1904, Kroměříž), who lectured in Kroměříž between 1854 and 1881 and described in detail the local plants[2201] while Mach's older Viennese classmate, Gregor Mendel of Vienna, established his genetic laws in the Augustinian monastery not far away in Brno.

Despite all their skills, the father and the son Mach under Gorjanci could not solve the experimental puzzles of Melsens' ballistics, since the photography of the wave head of the projectile in the air was by no means successful. Ernst carried out numerous experiments in Slatnik and Prague, but he did not see anything promising on his expensive photographs, which was already supplemented by the inventions of Janez Puhar in Ernst's teenage years in Bled. Ernst suspected that his missiles were too slow and did not reach the supersonic speed. He suspected that the high speed with the breakthrough of the sonic barrier is responsible for the terrible wounds of fast French missiles, and not just the compressed air from the

[2200] Carus, 1911, 22.
[2201] Carus, 1911, 24.

Melsens' assumptions. Ernst and his father repeatedly overwhelmed the situation, since his father was well acquainted with his year and a half older Prague teacher between 1835 and 1847, Christian Doppler. In 1842 Doppler presented the famous Doppler effect to the Prague-based scientific society once lead by T. Gruber and Bernard Bolzano, of course known under its academic name barely later. Ernst, after his father's narrative, accepted the inventive Doppler for his idol, even though Doppler died too fast before Mach's studies in Vienna, where Doppler was replaced by Ettingshausen. Of course, Ernst did not disturb himself, and in his first independent work, according to Ettingshausen's advice in 1859/60, he proved the exactness of Doppler's theory of changed frequency of the sound and light of moving missiles, which was opposed by the Viennese university professor of mathematics, an expert in optics, somewhat special Hungarian Josef Petzval. In 1873 Ernst published a book on Doppler optical-acoustical experiments, which he honestly dedicated to his idol for many inspirations.

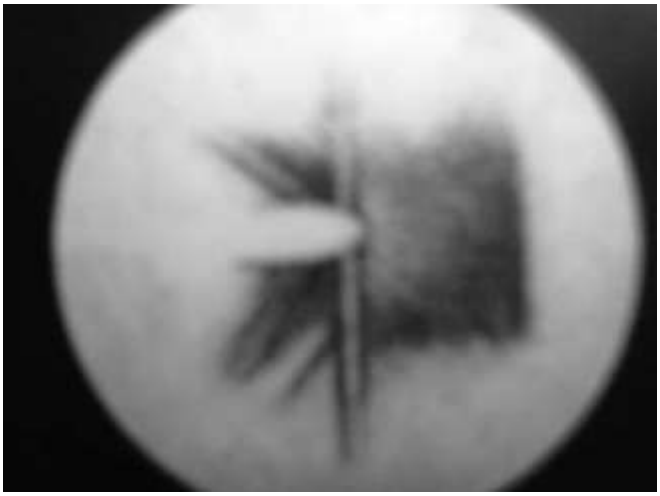

Figure 18-9: The last of the six photographs published by Mach and Salcher under the title Photographische Fixierung der Projectile und der Luft in the newsletter of the Viennese Academy in 1887.

To both father and son Mach it was soon apparent that their research of supersonic ballistics would led them nowhere without the participation of leading Hapsburg military circles, which only had access to sufficiently fast missiles, while their findings were often kept confidential. Mach needed connections with senior officers, and the choice of course naturally dropped to the nearest among them. In 1853 75 km south of Mach's farm in Rijeka (Fiume) they started work in the later Torpedofabrik, and in 1854 they founded the Imperial Royal Military Maritime Academy. Rijeka was traditionally connected with Carniola and even formally its part in the times of Ernst's grandfather, but now Rijeka has progressed urgently as the main port of the Hungarian half of the monarchy, subordinated directly to Budapest. The prematurely died dr. Albrecht Wenzel von Tegetthoff (1841 Graz-July 22, 1871) was the youngest brother of the supreme commander of the Habsburg Navy vice-admiral victorious by Vis Wilhelm von Tegetthoff (1827 Maribor - 7. 4. 1871). Albrecht taught mathematics and hydrography at the Rijeka Military Maritime Academy. The son of retired major Franz Charles Gabriel (1790-1858), Albrecht, studied at the Theresian Academy and at the Viennese Faculty of Philosophy. Immediately after his doctorate he published a computing manual when he was twenty-four years old. Ernst's younger friend Giulio Peterin (Julije, Julius, * 1846) graduated from the Grammar School in 1854/55 and, after completing his studies, lectured at the Rijeka Military Maritime Academy from 1861 to 1893 or even 1897. He published at the journals of Viennese Academy, just like Ernst Mach himself. Thus, the clever Mach used a common friend from Rijeka Peterin for an intermediate, so that he could send a letter addressed to the professor of physics at the military-naval academy Peter Salcher. Mach asked Salcher to set up experiments suitable for photographing supersonic missiles in the new Rijeka torpedo factory.

Peter's intervention was crucial for the very beginning of work if Ernst wanted to verify the presumption of ballistic impact wave head in front of the supersonic missile of Melsens who recently passed away. Ernst had an idea, and Peter added his owns with the opportunity to experiment within the military facilities included. Ernst and Peter did not personally know about each other much: Ernst stopped teaching at the University of Graz just before his decade younger Peter matriculated there in the year 1868/69. At the Viennese Electric Exhibition under the scientific and technical leadership of Jožef Stefan, Peter and Ernst indeed exhibited their inventions in the adjacent pavilions, but they did not even meet much in person at the time. Now it was time for great collaborations. Although he did not emphasize this in his first letter on 25. 1. 1886, Ernst certainly knew that his experimental ideas could only be carried out in a fabric of torpedoes bought by Englishman Whitehead (1823-1905) in 1875 before his son-in-law renamed it to Torpedofabrik Whitehead & Comp. In 1878, representatives of governments of eighteen countries, including the pedantic Japanese, signed contracts with the factory, and in 1881 they had already exported torpedoes from Rijeka worldwide. In 1889, the original caliber of 356 mm was increased to 381 mm, 450 mm and 533 mm, thus exceeding the half-meter limit; and in 1892 a branch in Weymouth near Boston in the United States was established to avoid US import taxes. Ernst's father, from the nice castle under Gorjanci, keep himself well informed with the progress of the factory in nearby Rijeka, so he advised his son to connect with the Rijeka military experts. Unfortunately, Johann, died as a widower in Veliki Slatnik at the end of 1879, and thus did not see his son's supersonic ballistic successes. In Veliki Slatnik, among other things, he cultivated giant Japanese butterflies Antheraea jamamao, which are still flying around Slovenia and nearby, but for now still deep under the supersonic speed.

18.2.2.3 Robida's Student Salcher at the Torpedo Factory in Rijeka

Peter Salcher may have disagreed with some of Ernst's positivistic or even atheistic ideas that lifted a lot of dust in those days and even led Lenin to write a book against Mach and his Russian advocates. The more so, then, Peter respected Ernst's reputation as an older physicist, experienced in ingenious experiments. So, Peter did not have to be asked twice. He linked with the older co-owner of the torpedo factory John Whitehead (1854, Trieste - 1902, Rijeka). Together with Ernst, Peter published the findings of photographed supersonic ballistic experiments at the Viennese Academic journal from 1887 to 1890. In the final paper they highlighted the advantages of illumination of the photographed wave-head with Geissler's Cathode ray tube, whose "light had a very good photographic effect".[2202] They were assisted by the excellent photographers and chemists. Whiteheads were very interested in the results, as thermodynamic phenomena accompanying the high pressure leakage of the air explained numerous problems of torpedo propagation, ranging from freezing due to Joule-Thomson expansion all the way to turbulences.

In Prague, Ernst used a pistol whose missiles did not break the sonic barrier and, therefore, the expected supersonic photographs, of course, were not successful. Salcher preferred to use 8 mm to 11 mm gun calibres to shoot off supersonic bullets with their speeds up to 530 m / s. The missiles were illuminated by the electric spark of the Leyden jar, while other local photographers helped in the shooting. They were firing their bullets at the military-naval academy, but not necessarily in the main building where shooting combat ammunitions was certainly not common. On 24 April 1886, Salcher sent Mach his first six successful photographs, barely three months after Mach's initial proposal. One of the first team designed for physical research succeeded, closely related to military needs at that time. Mach visited Salcher in Rijeka and attended an experimental launch of a torpedo during the Easter holidays between 22 March and 18 April 1887. In the autumn of 1887, Salcher continued the experiments in nearby Pula.

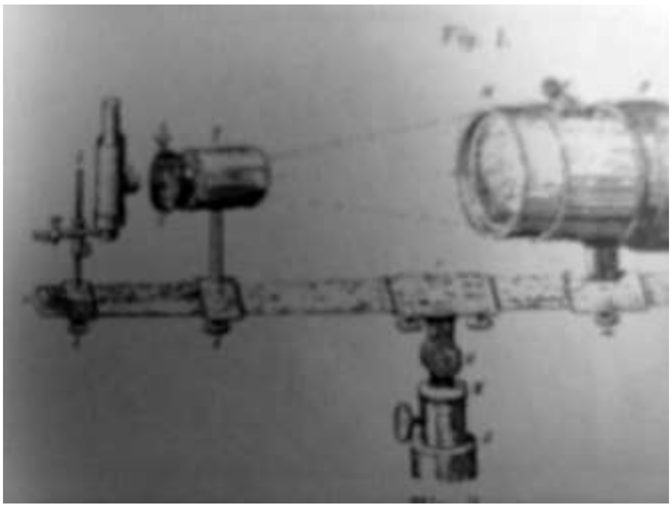

Figure 18-10:Töpler optical bench "Schieleren" from 1864, which inspired the successes of his pupil Salcher and Mach

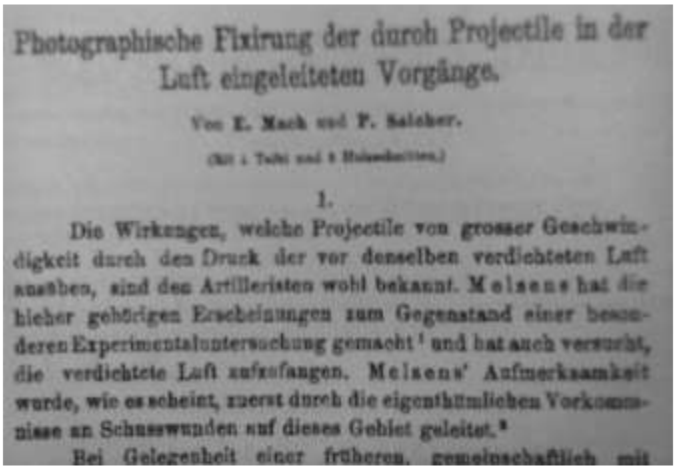
Salcher shot a 90 mm bullet at a speed of 448 m / s in Pula, while Ernst Mach and his elder son, the Viennese medical student Ludwig, took photographs at the Krupp plant in Meppen by Hanover with 40 mm missiles at 670 m / s. Of course, the Mach unit was established only later, but it would do no harm if it was named after the equally deserving Salcher.

[2202] Mach, Salcher, 1890, 1306.



Photographische Fixirung der durch Projectile in der Luft eingeleiteten Vorgänge.

Von E. Mach und P. Salcher.

1.

Die Wirkungen, welche Projectile von grosser Geschwindigkeit durch den Druck der vor denselben verdichteten Luft ausüben, sind den Artilleristen wohl bekannt. Melsens hat die hieher gehörigen Erscheinungen zum Gegenstand einer besonderen Experimentaluntersuchung gemacht[1] und hat auch versucht, die verdichtete Luft aufzufangen. Melsens' Aufmerksamkeit wurde, wie es scheint, zuerst durch die eigenthümlichen Vorkommnisse an Schusswunden auf dieses Gebiet geleitet.[2]

Bei Gelegenheit einer früheren, gemeinschaftlich mit

Figure 18-11: The cover page of Mach's and Salcher's pioneering article of supersonic photographs, which Mach communicated in the Viennese Academicians for publication in Wien. Berichte in 1887 in Volume 95/2 on page 764

Mach found that Melsens's ideas were not perfect, because the compressed air, pushed by the missile did not cause the unbearable wounds, nor did the air in front of the missile imagined by Aristotle in his time; the speed and shape of the bullet were the main factors. Also, Mach was finally able to explain why a bullet shot was heard twice on the battlefield; the first of the sounds originated from the breakthrough of the sonic barrier, which has since started to play its important decisive role in the physics of rapid movements. Mach became famous, even trendy; his and Salcher's photographs of supersonic missiles were also published by popular newspapers. Of course, Mach's old opponent Jožef Stefan was even more powerful, and he easily set Boltzmann and his other supporters of kinetic theory to fill all the important professorial positions in the Habsburg Monarchy, just as the advocates of Bošković's point centers of forces as the unique ancestors of the Stefan's atomists had done in the previous century. Mach's doubts about the existence of atoms were soon limited to his rare political supporters, which did not affect his successful experiments in couple with Salcher. In the early 1888's, Salcher reversed the idea of experiment and left the projectile steady while he directed on the projectile his jet of compressed air at 250 atmospheres at the Rijeka factory, where they produced the first torpedoes in 1866 and two years later in 1868 installed the torpedo ship named the Gemse, the first of its kind in the world. On April 4, 1888, at the Viennese Academy, Mach reported on the successful photographs obtained by the reversed Salcher's experiment.[2203] The experiments and correspondence between Peter and Ernst lasted until 1892, and a new chapter in ballistic science was written with them on the route between Prague, Veliki Slatnik, Rijeka and Vienna. The paths of both collaborators then split up: Salcher was already a naval officer of 8th rank in 1902, highly respected on the court. In 1894 immediately after his exceptionally successful promotion in Göttingen, Mach's younger son afforded one of the very modern suicides[2204] that effected even the most prominent heir Rudolf Habsburg in 1889; four years after his son's tragedy, the saddened father Ernst was hit by the stroke, which disabled his right arm. Therefore, he had to abandon his Viennese philosophically oriented chair, which pleased Mach so much and caused his great disputes with Leninists and Mach's successor Ludwig Boltzmann, along with his half-Slovenian wife Jetti. Until his very end, Mach's work helped the Slovenes, among others, a professor of philosophy, mathematics, classical and living languages from Novo Mesto in the period between 1897 and 1921 Mihael Markič (M. Posavski, 1864 Kranj - 1839 Ljubljana). Mihael's adaptation of Boolean algebra, published in 1899, 1900, and 1914 in German reports of the Novo Mesto (New City) grammar school, was recommended by Ernst's oldest unmarried sister Marie (* 1844; † 1929), a rather successful writer of novels about Veliki Slatnik after her educational work with the Montenegrin royal family. In 1912 and in a revised edition in the following year she published memories of her mother with Ernst's foreword.[2205] Despite of Mach's support, the Ljubljana professor France Veber (1890 Gornja Radgona-1975 Ljubljana) strongly criticized Markič and the mathematical logic in general in 1920.

Ernst's supersonic dream of Gorjanci was realized. The sound barrier (sonic wall) was intentionally broken for the first time. Half a century after Mach's death, the first supersonic aircraft Concorde flew with passengers on March 2, 1969, but after 26/11/2003 all twenty Concord aircraft were "retired". Similarly, it happened to Soviet Tupolev TU-1544 supersonic aircrafts, which were slightly faster by speeding up to 2.35 Mach, but they flied only from 1975 to 1978. Mach would certainly be sorry.

18.2.2.4 Ultraquick Photos to Improve the Thin Layer Sputtering

Mach ultraquick photography soon came to life out of strict ballistic use. Today, its of special importance for the study of plasma and its turbulences, which have a significant effect on the application of nanometric sputtered thin films. According to Grove's and Robida's sputtering of metals, Arthur Williams Wright announced the successful sputtering of many layers of platinum, gold, aluminium, zinc, iron and many other metals in the American Journal of Science in 1877. He also described their stability in the atmosphere as a condition for usability. Robida repeated Grove's sputtering experiment only five years after Grove in 1857. A decade later Robida became a homeroom (classmaster), professor of mathematics and physics of Peter Salcher. Robida's chief associate Simon Šubic was Salcher's professor of complete field of theoretical physics in the first year of Salcher's Graz studies, as Šubic lectured on physics in Graz from 19th March 1865 until 11 March 1867. In Graz, Ernst Mach taught mathematics in 1864. Šubic published a lot about photography for scientific purposes, including his popular articles in the Slovene language, while Robida already showed Salcher in Klagenfurt his decades old photograph taken with a microscope, probably obtained by Ettingshausen's newly invented method designed in 1840. Naturally, Salcher comprehensively complemented Robida's knowledge with his Graz-based study of experimental physics during the construction of the largest physical institute in the Habsburg Monarchy of his professor August Toepler of Graz. Toepler's so-called schlieren photographic method, based on differences in air density, has become the foundation of Salcher's photos of supersonic missiles in Rijeka following Mach's instructions. Toepler did not participate in Rijeka experiments. Toepler was the bestman at Boltzmann's wedding with half Slovene maid Jetti. Jetti used to be the first Habsburgian female student of physics, while she ingeniously complained to her future fiancée Boltzmann about the supposed Toepler's antipathy. The physicist Toepler may have been somewhat reluctant about new experimenting in Rijeka after he was just upgrading his physical Institute in Graz in 1874. In the middle of his success he felt from the upper floor to the ground floor and severely damaged his body at Christmas in 1875.[2206]

Mach and Salcher did not use ultrasonic photography to record sputtering, but they made a great contribution to both fields. Initially after the invention of cathode ray tubes, metal sputtering seemed more like an unpleasant cathode ray tube failure, but not as an industry-friendly contribution to science of materials. Mach's admirer Einstein closely approached the development of magnetron, which is today one of the most promising devices for plasma sputtering of thin films, and at the same time a promising area for exploring plasma turbulences with ultra-fast bombardment. Einstein was Zurich university associate professor between 1909 and 1911. His heir to his position of university associate professor at Zurich University, his one-year younger fellow Heinrich Greinacher (31. 5. 1880-1974), developed a cavity magnetron as a new opportunity to measure or calculate the mass of electrons in Zurich in 1912, immediately after his arrival at a Zurich university. Einstein was then between 1912 and 1914 his neighbor as a professor at the Zurich ETH. In 1914, Einstein did not want to take over double professorships at Zurich University and ETH as Greinacher's co-worker, after both got doctorates or habilitated at the University of Zurich in 1905 and 1907 respectively. Einstein's neighbor in Zurich was also his onetime classmate, the researcher of specific heat Friedrich Adler, while Lenin wrote a devastating critique of Mach and Adler in nearby

[2206] Jungnickel & McCormmach, 1986, 67; Stiller, 1989, 53.

Zurich libraries.[2207] The poor Lenin's victims certainly did not know exactly what's going on until Adler shot a hungry Hapsburg Prime Minister in a prestigious hotel restaurant seven years later on the afternoon of October 21, 1916. A year later Lenin got his fatal Russian power.

The promising beginnings of the magnetron were then taken over by the scholars on the other side of the Atlantic who were more favorable for moneymaking. The American Albert Hull (1880-1966) made his magnetron for General Electrics, Schenectady, New York, to circumvent the Western Electrics patent of triode. Hull controlled the magnetic field flow instead of the grid. Initially Hull did not intend to apply the highest frequencies of electromagnetic waves to his magnetron which was left to Prague University student Czech Avgust Žáček (1886-1961) and the Jena PhD student Erich Habann (1892-1968). They used the frequencies up to the gigahertz in 1924. The invention flourished during the development of radar in the Second World War, especially for the sake of the war for England, where John Randall (1905-1984) and Harry Boot (1917-1983)~~,~~ assisted by James Sayers (1912-1983) from the University of Birmingham developed the cavity magnetron in 1940. Secretly hidden from the Germans, the high security study was directed by the descendant of steam engine inventor James Watt, Robert Alexander Watson-Watt (1892-1873). He was a funny leader. When he was later as a famous man stopped by Canadian police officers for speeding, he exclaimed outrageously: "If I knew what you would do with my radar, I would never invent it!" It did not help and he was forced to pay a fee.

The industrial use of millions of cavity magnetrons then went on for many years in favor of microwave ovens until their fast-food households were criticized. A promising technique, however, found urgent new applications when competitors superseded it even in radars. While the cavity magnetron has an internal pressure of less than 0.01 Pa, the plasma sputtering magnetron has a working pressure of the order of 1 Pa. In the plasma magnetron, plasma is of key importance, since positive ions from plasma accelerate towards the negative cathode and thus disperse it. The similarity between the devices is in their crossing of the electric and magnetic fields in the greater part of the space, which causes the electrons to move along specific trajectories; they rotate around magneticlines of forces and move simultaneously in a direction perpendicular to the electric and magnetic fields. Such an electron motion is used in cavity magnetrons to produce microwaves, while in plasma sputtering magnetron it is needed for the most frequent electron-gas collisions, that is, for the generation of as thick as possible plasma. The promising application of nanometric thin films in the magnetron for sputtering was first used in the 1970s in the simultaneous inventions of many planar magnetron researchers, where secondary electrons in the sputtering process and increasing the energy of the electrons on the surface and beside it~~,~~ provide the energy necessary to maintain the discharge in the magnetron, which is alternately used as a cathode and anode at medium frequencies, high energies, but not at high densities of energy on wide surfaces.

Figure 18-13: Magnetron plasma shot with a fast camera (exposure time 10 ns, author of the image: dr Matjaž Panjan)

Unbalanced magnetron as the first step to the use of plasma for the growth of thin films with magnetron was first used by Brian Window and Nicholas Savvides (Nick Savides) at the Commonwealth Scientific and Industrial Research Organisation (CSIRO) at Sidney in 1986. The self-ignition with ions of the target itself was observed for the first time in 1977. The East German André Anders of Berkeley and others independently noticed the location of ionization in zones and self-organization in turbulences in 2012. Ionized parts

[2207] Adler, Mach, 2001, 45.

contribute to the transfer of charge along the magnetic field forces with turbulent flow.[2208] The naked eye sees the ionization process, distributed homogeneously. With the help of Mach-Salcher's device descendants called high speed CCD (ICCD) cameras, we distinguish several bright areas moving along the pattern. Such ionizing areas are called "spokes" in analogy with similar phenomena in plasma. They are maintained by electrons in complex electric and magnetic fields. Fast photography, of course, much faster than Mach-Salcher's, is a fundamental tool for determining the nature of these turbulences resembling older Mach-Salcher's turbulence of the impact wave of a projectile. High-energy pulse magnetron sputtering (HiPIMS) as a highly ionized technology already has good references from thin-layer manufacturers since it is compatible with existing PVD devices and offers very hard coatings and optical thin films. HiPIMS successfully supersedes the technologically identical High Power Pulsed Magnetron Sputtering (HPPMS) by increasing the ionization of the diffused target atoms with hundreds of times greater power densities compared to conventional methods.[2209] Anders' collaborator the Carniolan Matjaž Panjan (* 1980) belongs to the most promising researcher of magnetron plasmas.

18.2.2.5 Conclusion

The picture captures the present moment for future generations. Fast or ultrafast photography capture even what a relatively cumbersome human eye cannot ever perceive. Therefore, it makes visible the things which are completely invisible to human eyes, like a microscope, a telescope, or the detectors of ultraviolet and infrared lights did in their times. The invisible might be too small, too quick or in wrong wavelength, but the tool could convert it for us. During Mach and Salcher's time, the flashing photography revealed the turbulence with supersonic bullet-proof missiles, which both Mach, father and son, discussed under Gorjanci. Tomorrow, for sure, will reveal turbulent plasma currents for more efficient sputtering with magnetrons.

18.3 Hočevar's Vacuum Techniques

18.3.1 Introduction

Ettingshausen and Robida's students Mach and Salcher developed the artistic ultrafast photography into scientific tool. The plasma figured as joint product of several field of research including Crooke's cathode ray tube fourth aggregation state and compressed ultrafast photography (CUP). As always, the careful mixing of different fields of scientific (and artistic) research brings unexpectedly useful results as vacuum technology has already intertwined with the testing of electrical devices at Guericke's beginnings; so, Otto Guericke indeed invented the basic device for both areas. The most important London manufacturers of vacuum pumps, Hauksbee and Ramsden, had upgraded Guericke's electrostatic friction to a modern device with plates;[2210] in the Leiden Musschenbroek vacuum pump factory or in a university laboratory across the street, Musschenbroek Leyden jar was developed as the first electric capacitor. The intertwining of vacuum and electrical research continued in the 19th century with the experiments of the Ljubljana professors Hummel and Bela Krajina native Hočevar. The research of vacuum and electromagnetism finally joined in Geisler's cathode ray vacuum tubes into a uniform field of research that is still flowering.

18.3.2 Hočevar in Ljubljana

Hočevar was the son of a district commissioner and a court adjunct in Metlika; according to his surname, he may have belonged to a Kočevje based family. With him, centuries after Klemen Kukec, Metlika produced another great mathematician and physicist. Between 1864 and 1871 he attended a gymnasium in Ljubljana in the class of a with popular mathematician Nejedli;[2211] of course, he could afford a much closer Novo Mesto Franciscan Gymnasium with first-class physicist Bernard Vovk, who raised Ignac Klemenčič, but Hočevar's father had enough money to give his son the best instruction.

Josip Nejedli of Prague was not only a mathematician, but also one of the most important philosophers in Ljubljana. He came to Ljubljana as forty-one years old accredited researcher and pedagogue. He has taught mathematics at a gymnasium in Ljubljana for twenty-three years. In his first years in Ljubljana, he worked with physicist and director Mitteis. Soon after Nejedli, the mathematician and physicist dr. Jakob Rumpf from Graz arrived in Ljubljana. So, mathematical sciences were extremely well covered. Together with them, the supplied teacher Zindler has taught for a while at the Ljubljana grammar school. He published a discussion on arithmetic and number theory later in the Grammar School Senj in 1870. He described a new theorem on the connection of periodic decimal fractions with ordinary fractions. Later, Nejedli's closest collaborator at the Ljubljana Gymnasium was Matej Vodušek, who published interesting mathematically well-supported research of theoretical astronomy in gymnasium reports and books. Vodušek was a professor of classical languages; before him the professor of classical languages Karl Grünwald has successfully dealt with astronomy in Ljubljana, but more with observation than with theory.

In the Ljubljana Gymnasium Reports, Nejedli published numerous discussions on algebraic analysis. In 1863 he dealt with Euler's procedure for solving indeterminate equations of the first order. In 1865, Nejedli supplemented Močnik's treatment of Cauchy's methods with a discussion of Budan-Horner's algorithms for solving numerical equations of higher orders. Ferdinand François Désiré Budan de Boislaurent (1761 Haiti-1840 Paris) and William George Horner (1786 Bristol-1837) published their results half of a century earlier.

In 1868 Nejedli expressed algebraic partial fraction expansion of a rational function as a sum of a polynomial and one or several fractions with a simpler denominator (Zerlegung in Partialbrüche). In 1870, he wrote about multiple and arbitrary values of a definite integral (mehrfachen und willkürlich Werte einiger bestimmter Integrale), and in 1874 he discussed the square equation.

In 1882, he published his last discussion of the theory of perception, which of course made him more profoundly involved in philosophical sciences. A similar philosophical work about natural historical materialism was published by his associate new supplied professor of physics, mathematics and natural history with PhD obtained in Strasbourg Heinrich M. Gartenauer in the Ljubljana gymnasium report in 1878. It was commented by the famous Wallentin in Viennese referenced anthology of comments on Habsburgian school reports. The connection between mathematics and philosophy has a long tradition in Ljubljana. The best Nejedli student in Ljubljana was Franc Hočevar.[2212]

As a young gymnasium student, Hočevar attended physics lectures of Heinrich Mitteis until 1866. Then, a famous meteorologist Mihael Wurner returned to the classical gymnasium in Ljubljana to teach in 1868/69-1887/88 and became Hočevar's professor of physics in Hočevar's final high school years. Wurner studied natural science and mathematics in Vienna at the same time as Jožef Stefan between 1853-1856; there he became interested in new vacuum techniques in the study of molecules and meteorology, which he also transferred to the student Hočevar. Finally, Wurner's mind deteriorated because of his sixteen years younger fiancée Ana Pogačnik or because his naughty students, or both.

Figure 18-18: Hočevar's portrait (* 1853; † 1919).

[2212] Razpet, 2009, 136.

18.3.3 Study in Vienna

Following the (educational) example of his teacher Wurner, Hočevar studied at the University of Vienna at Stefan and Boltzmann's class. Boltzmann was named Moth's successor as a full-time professor of mathematics at the University of Vienna on August 30, 1873, as opposed to his competitor for the Viennese chair Anton Winkler from Prague. Boltzmann retained the Viennese chair until 1876. In the spring semester of 1874, he taught three hours a week on differential equations and two hours a week on mechanical theory of heat; in the latter case, the study of heat transfer through a vacuum paved the way for the only physics law named after the Slovenian, Boltzmann's teacher Stefan. In the autumn semester 1874/75, Boltzmann lectured five hours a week on the differential and integral calculus, while in the next semester he taught three hours per week the number theory and two hours per week higher analysis. He continued his lectures on the integral and differential calculus in the next semester, adding to them the exercises in the mathematical seminar. Boltzmann confirmed the dissertation which Hočevar had prepared at the Viennese Technical College in Anton Winkler's class.[2213] It was one of the few mathematical dissertations under the umbrella of the physicists Boltzmann.[2214]

After his doctorate at Boltzmann's class in 1875/76,[2215] Hočevar became Winkler's assistant at the Viennese Technical College. Shortly after Hočevar, the other Lower Carniolan (Dolenjec) Ignac Klemenčič from Trebnje received a PhD at Boltzmann with a study of the behavior of glass after the relief of burdens of force on glass in 1879.[2216] At that time Boltzmann was once again a professor in Graz.

Under the influence of Boltzmann and Stefan, Hočevar insisted in the publication of his physical papers with vacuum experiments in the early 1880s, especially after moving from the position of a Viennese assistant to the work of a gymnasium professor in Innsbruck. In Innsbruck, he had an enviable cabinet of physics available, where he designed several high-profile experiments with the Wheatstone's bridge, Holtz's electrophorus and Geissler's vacuum tubes. He wrote mathematical-physical discussions about the gamma function, Varignon's theorem and Hamiltonian, and after 1882, except some pedagogically oriented thoughts, he devoted himself to pure mathematics. He began his research of vacuum techniques and electricity upon the opening of the International Exhibition in Vienna in 1873 and completed it a decade later during an even more important third International Electric Exhibition in Vienna in 1883, which was technically and scientifically led by Jožef Stefan.

18.3.4 In Tyrol and Moravia

From 1879 to 1891, Hočevar was professor at the gymnasium in Innsbruck, where he was habilitated as a private assistant at the university in 1883. His acquaintances helped a lot.[2217] The support of the professor of physics Pfaundler enabled Hočevar's high-profile publications at the Viennese Academy. A decade later, the Innsbruck University Chair of Physics of Pfaundler's successor, Ernst Lecher, was taken over by Hočevar's Lower Carniola neighbor Ignac Klemenčič in 1895. In 1882, Lecher inspected Kirchhoff's and later Stefan's radiation laws in Innsbruck and in Stefan's Viennese institute. Thus, Innsbruck of Hočevar's and Klemenčič's days was in fact one of the most important centers for the use of new vacuum technologies based on a long tradition, since the instruction in Innsbruck, both at the middle and at the university level, was successfully led by the Jesuits who acquired the physics vacuum cabinet devices in the middle of the 18th century. Among the Jesuitical students in Innsbruck was even a future Habsburg emperor Leopold I. Klemenčič later departed to Innsbruck just like Hočevar, since there was initially no bread for either of them in Graz. The academic chairs in Graz were particularly politically important at that time because of the emerging contradictions between the Germans and the Slovenes, so, that the determined Slovenian could not easily get a job at the University of Graz. In 1891, Hočevar became an associate professor of mathematics at the German Technical College in Brno. In 1894, he was promoted to full professor. Already the following year in 1895, he was called to the Graz Technical High School, where he taught

[2213] Höflechner, 1994, 1: 38, 46.
[2214] Boltzmann, 1994, 1: 46; Dick, Kerber, 1993, 35.
[2215] Razpet, 2009, 136.
[2216] Razpet, 2009, 137.
[2217] Razpet, 2009, 137.

mathematics until his death.[2218] He received the chair even though the former professor of physics and headmaster of Ljubljana Grammar School now Secretary-General of all universities state counsellor Johann knight Kleeman (Kleemann, 1808 Černovice (Tschernowitz) in Bohemia probably in Brno-City District–1885 Vienna) had explained to Boltzmann and a Viennese PM Fran Šuklje several years earlier that Klemenčič would not get the position of Boltzmann's successor on the Chair of Physics at the University of Graz as a knowledgeable Slovenian; such a nomination had great political weight in the uneven balance between German and Slovenian nationalists in the city. Instead of Klemenčič, Pfaundler achieved the position in Graz in 1890/91. Pfaundler was very close to Hočevar, as Pfaundler presented his physics discussions at the Viennese Academy. Soon Pfaundler was followed by Hočevar, although not at the university, but on Technical school. Hočevar has been the Dean of the Faculty of Mechanical Engineering in Technics school for many years; just before his death, he received the official honorary title of the imperial court councilor of the empire, which was in fact a great honor in those once noble times. In other circumstances, that high honor would open the way to Hočevar's noble title, which lost its meaning and became publicly forbidden in Austria after the WW1.

In 1881, Hočevar published in the Reports of the Innsbruck Gymnasium a discussion on combinatorics and on the theory of divisibility of integers. From 1876 to 1907, at the Viennese Academy, he published many papers about the Differential and Integral Calculus, which he learned from Boltzmann. He wrote three more discussions on algebra, and one on the each of related fields of theory of numbers, combinatorics, series, and analytic geometry of space.

He published a lot in Monatschefte für Mathematik und Physik, much like Plemelj did later. He was thinking about a whole range of areas spread from high school mathematics to mechanics and electrical engineering, but above all about differential calculus, algebra, number theory, numerical analysis, analytical geometry of space, infinite series and products.[2219] He mainly excelled with writing textbooks; from 1886 on, he covered all areas of mathematics for with different types and levels of secondary schools. David Segen prepared Hočevar's textbooks for Croats, while the professor of mathematics and physics at the First Grammar School Sarajevo Tomislav Bosutić did the same for the Bosnians. Both were used after the First World War. Due to difficulties in introducing Slovene language in Habsburg secondary schools the authorities did not publish any Slovene translations of Hočevar's textbooks before 1910, while later the competitive textbook of Močnik prevailed.

Figure 18-19 : A sketch of Gervais' Montpellier tools and Hummel's devices for improving the quality of beer and wine in Franciscans' library of Ljubljana, written on the skin of thirsty Ljubljana lovers of Styrian wines (Gervais, Hummel, 1821, 13, 19-20, picture at the end of the book). From 8. 4. 1822 to 1830 Hummel held ten years privilege for his invention of maintaining alcohol spirits in H_2CO_3 acid, while the fabricant Vinzenz Huber of Germignana got similar privilege on 24. 6. 1822-1829. The co-owner of Diana Baths (Mitinhabers des Dianabades) in Leopoldstadt of Vienna the painter of miniature portrait, the first efficient Viennese architect, lithographer who escaped from the French revolutionary terror Karl Ludwig Hummel de Bourdon (1769 Besançon in France, † 23. April 1840 Leopoldstadt 9 (2, Obere Donaustraße 81, today Numbers 93-95) received another privileged patent granted for five years for his apparatus designed to destem and crush the grapes in the same time (Weintrauben zu glechen

[2218] Razpet, 2009, 137.
[2219] Razpet, 2009, 139.

zeit abzubeeren und zu zerquetschen) on 25. 8. 1822-1827. From 30. 9. 1824 to 1833 he held a patent for his machine joiner of timbers (Tischlerhölzer). Carl Hummel set up a device for the improved fermentation of wine and beer and he was granted the imperial privilege in 1821.[2220] In the distillation boiling plant, he used gaskets and receivers typical of the then vacuum and overpressure processes, and in December he made experiments with beer.[2221] He used the successes of the French inventor Miss Elizabeth Gervais at the Montpellier College of Science at the end of October 1819. A little more than a year after the invention of a lovely Frenchman Gervais' twenty inches high apparatus, Anton Albert baron Masten has already approved the use of her achievement at the Styrian agricultural society in Graz on 28 March 1821. Of course, all Ljubljana lovers of noble drops with Franciscans included immediately obtained a well-informed and useful booklet reprinted in Ljubljana. The first Diana Bathes bad on the Vienna Danube Canal was built between 1808 and 1810 by French-born master builder Charles de Moreau and the Viennese painter Carl Hummel on a plot bought in 1804 and opened on 1 July 1810. The bathhouse in Parisian style offered tubes with heated water from the Danube Canal. After a renovation they offered 68 bath cabins around a garden courtyard for 78 baths, which were filled with heated water in 1830. In 1841-1843 they built the first covered swimming pool on the continent with a steel structure.

Hočevar wanted to introduce the teaching of derivatives and integrals correctly treated for secondary school physics problems according to the ideas of Felix Klein. In his paper entitled Is it good to introduce elements of an infinitesimal calculus in high school or not? Hočevar first studied mathematics teaching at Habsburgian universities, high technical and secondary schools, including the education of professors at teachers preparatory. He proved that the derivative and the integral must be introduced into the function theory; he suggested cutting some of the content of curricula to enable the new ones.[2222]

Ninety years and one day after Hočevar's death, his compatriots in Metlika provided a memorial plaque in cooperation with DMFA, Metlika and the Bela krajina Museum Society. They followed the initiative of a Metlika elementary and middle school teacher of mathematics Jože Vraničar, on June 20, 2009.[2223]

18.3.5 *Hočevar on Holtz's Influence Machine and Geissler's Vacuum Cathode Ray Tube*

Basic of the influential machine (electrostatic generator) was designed by A. Hallerstein's Jesuits in Beijing in their vacuumistic and electrical experiments. The European version of the influential machine was first published by A. Volta in 1775, and thus earned him high school chair in Como as he used to be a Jesuitical fan and highly motivated lecturer. In the middle of the Lago Maggiore swamps, Volta isolated the methane gas by vacuum procedures. In 1792 he admired the vacuum experiments of Lavoisier and Laplace in Paris. By the way, he gained an external membership in the Parisian Academy and the Royal Society of London.[2224] During the Illyrian Provinces, Volta's discoveries quickly became established in Ljubljana, since Kersnik's Electrophorus had already been classified among electrical and vacuum devices of his cabinet of physics in 1811.

Another Karl Hummel became Kersnik's collaborator-mathematician on the Ljubljana Lyceum and a full professor in 1837. In 1833, just before he arrived at Ljubljana, he published a paper about a simple electrophorus as a collector of electric charge by friction[2225] in Baumgartner's and Ettingshausen's first journal for mathematical-physical sciences in the Habsburg monarchy. To obtain static electricity, he used cat's fur, and, above all, he was interested in the natural electricity of molecules released by friction in a vacuum.[2226] He named the Leyden jar after Kleist and translated its electricity using the valves developed in vacuum technology. The bottle was insulated with resin and filled with Pfaff's mixture including Venetian turpentine;[2227] Dr. Pfaff

[2227] Hummel, 1833, 221, 222.

defended Volta's electrolysis theory, and in 1801 he became a full professor of medicine, chemistry and physics in Kiel.[2228] Hummel summarized the operation of the electric battery according to Gehler's textbook,[2229] the research of Georg Christoph Lichtenberg and Lichtenberg's friend Johann Christian Polycarp Erxleben who prematurely died; later Hummel used it in Kersnik's cabinet in Ljubljana. He was interested in the highest possible charge of the Voltaic electrophorus charge, which he measured with the Voltaic electroscope by the golden leaf. He searched for the geometric shape of the electrophorus, which would have the greatest effect. On 3. 2. 1842 in Ljubljana Franciscan Church of St. Mary's Assumption, the member of Carniola Agricultural Society Hummel married Franziska Marquise Gozani (Maria Agnes Elisabeth Gozana (Gozzani) de St. Georges, * 1824). The godfathers of Hummel's fiancé were the father of Fidelis Terpinc (* 1799; † 1875), the wealthy merchant Blaž Terpinc (Terpinz, 1759 Bled-1836 Kranj) and Bartolome's wife Elisabeth Paulitsch. Blaž was a granduncle and guardian of the mother of the first Slovenian female poet Josipina Urbančič Turnograjska. Hummel's bride-marquise Franziska Gozani was the daughter of the Commissioner for Roads (Strassenbaukomisär) the marquis Johann Nepomuk (* 1782; † 18. 6. 1836) of the Torino-native family and his wife Eve (Eveline, * 1792; † 25. 3. 1872) born Trockenbrot. Their children were also Carolina Leopoldine Elisabeth Franziska (* 2. 3. 1815), Johanna Nep. Katharina Elisabeth Franziska (baptized on August 24, 1818), Ferdinand (Bartholomäus Felix Konrad baptized on 1. 11. 1819) and Guido Josef Fidelizs Vinzenz (* 5. 4. 1831), who was the only one baptized in the cathedral of Ljubljana, while the others were baptized in Kranj.[2230] Franciscans of Ljubljana buried both Hummel's father-in-law and mother-in-law. Hummel's bestmen were the court lawyer Dr. Leopold Baumgartner, and the physician Johan Nepomuk Birtzen.

Hummel's brother in-law Ferdinand and his children were the officers and owners of the Volčji potok manor from 1846 to 1882. By so many wealthy connections Hummel left the job in Ljubljana as the new professor of the University of Graz in 1850. He became there the first professor of physics of renewed University and retained his chair until his retirement on 31 May 1867. After he left Ljubljana in 1850, Hummel lectured on physics at the University of Graz as the predecessor of Boltzmann and Töpler; the latter also developed electrophorus and vacuum pumps. After Hummel's death, his devastating mathematical critique of life insurances was published in Munich.

The Gorizian physicist and Boltzmann brother-in-law Šantel learned Töpler's experimental physics in Graz including Töpler's award wining vacuum pump awarded. However, Töpler got only 1000 marks as half the prize money, because Geissler at the same time invented a potentially even better pump. In their competition for the invention of the influential spinning wheel, Töpler's rival the Berliner W. Holtz provided more sparks with his device, although it was sensitive to moisture and demanded an initial charge. Holtz experimented with his influence machine in Berlin; later in 1869 he lectured on physics in Halle and then he was employed as full professor in Greifswald in 1884.[2231] He used a dual electrophorus, which Lichtenberg compiled shortly after Volta's invention. Holtz also used an amplifier (doubler) of the electric power designed by Erasmus Darwin's friend a pastor from Bentley, Abraham Bennett FRS (1749-1799). The Italian turned Englishmen Volta's correspondent Tiberius Cavallo first placed the electrophorus' plates perpendicular to one another in the form of amplifier, while the Englishman Nicholson's increased the efficiency of plates by the silver coating; Žiga Zois read Nicholson's book on Breg in Ljubljana, where he often hosted the professor of physics Kersnik. Volta's younger colleague, the physicist Giuseppe Belli, made a rotating electrophorus in 1831 and published his discovery in Venice. In 1865 and 1867, the professor in Estonian Dorpat (Tartu) later transferred to Graz August Töpler proposed his improvements. In 1869, Poggendorff developed Holtz's ideas into the compiled the ancestor of the modern dynamo of Zénobe Théophile Gramme.[2232] Töpler used his spindle to trigger a meter of long electric sparks at a world exhibition in Paris.

Unfortunately, the device was broken along the path.[2233]

Holtz investigated the shape of his spark in the discharge,[2234] and instead of the conductor, he used the recently invented Geissler's cathode ray vacuum tube for his discharges as early as in 1854/55. The interior of his cathode ray tube was steadily illuminated by a weak bluish light, similarly as if the electrodes were closer to each other. In the case of a large charge or when it focused small surface, his cathode ray vacuum tube provided enough light to show that the discharge was easily visible even by the daylight.

Über einige Versuche mit einer Holtz'schen Influenzmaschine.

Von Dr. Franz Hočevar,

Die besondere Einrichtung der mir (im physikalischen Cabinet des Innsbrucker Staatsgymnasiums) zur Verfügung stehenden Influenzmaschine ermöglichte mir einige Beobachtungen, welche in theoretischer Beziehung bemerkenswerth erscheinen. Der Apparat, dessen rotirende Scheibe einen Durchmesser von 48 Ctm. Länge besitzt, ist im Jahre 1869 von Herrn C. Winter geliefert worden und weicht in der Construction von der einfachen Holtz'schen Influenzmaschine erster Art in zwei Punkten ab. Vor Allem ist die feststehende Scheibe durch zwei getrennte und symmetrische Scheibentheile ersetzt, von denen jeder eine Papierbelegung trägt. Die beiden Theile stossen in der verticalen Kante *ab* (Figur 1) zusammen, lassen sich in den beiden Holzrahmen *cd*, *ef* nach den entsprechenden Seiten hin verschieben und auch ohne Mühe entfernen. Ferner besitzt die Influenzmaschine ausser den beiden an den Enden eines Scheibendurchmessers angebrachten Conductoren (Saugkämmen) k_1, k_2 noch einen dritten Conductor k_3, welcher sich um eine verticale Axe in *g* (Figur 2) drehen, aber auch vollständig herausheben lässt

Figure 18-20: Hočevar's sketch of Holtz's electrophorus (Hočevar, 1881, 710).

Holtz was also interested in the physiological effects, so, he replaced the vacuum cathode ray tube with the human body without being aware of the potential dangers of warming measured by the thermometer on air of Peter Theophil Riess. Then he replaced the vacuum cathode ray tube with phosphorus, which was even hotter. He examined the chemical effects of the discharge and magnetic measurements with Emil Stöhrer's spiral device invented in 1844.[2235] According to the ideas of the Berliner professor of physics at Gewerbeakademie (later Technische Universität Berlin) and at Preußische Kriegsakademie dr. K. A. Paalzow, Holtz made a smaller electrophorus.[2236] The editor of Holtz's discussion, Poggendorff, of course, remembered that he himself had already described a similar device in a monthly academic report, but Poggendorf's Ann.Phys magazine also briefly summarized Töpler's type of experiment.[2237]

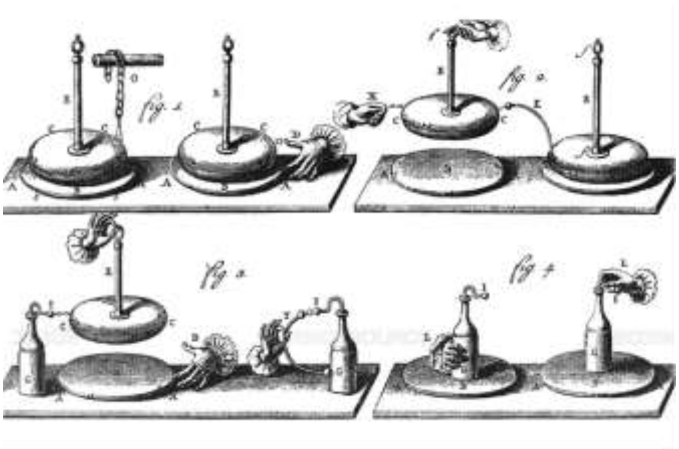

Figure 18-21: Volta's electrophorus (Ganot, 1886, 691).

A decade and a half after Holtz on 31 March 1881, the Innsbruck professor Hočevar completed Holtz's research. Because Hočevar was not an academician, he submitted his work to the Viennese Academy through his sponsor, professor L. Pfaunder from the University of Innsbruck. Of course, Pfaunder was willing to help, as Hočevar had imaginatively described experiments with Holtz's influential machine or an electrophorus, which supplemented the works of Hummel and Holtz; that was the only Hočevar's experimental physics paper in addition to his discussions of mechanics and Wheatstone's bridge.[2238] Hočevar's mentor Pfaundler was a renowned knight of the 3rd grade Iron Crown, a bearer of the Golden Cross with a crown for merit and a member of many academies and societies. He published his own Compendium der Experimentalphysik, where he described, inter alia, A. Šantel's invention of a mercury vacuum pump designed with mercury to

pump air from the vessel in 1883. At the Graz physics institute, Pfaundler immediately photographed X-rays photos soon after Röntgen's discovery.[2239] On 21 January 1896, at a session of the Viennese Academy, he presented X-ray photographs of the needle in the palm for the needs of surgery with illuminations of 15 to 20 minutes[2240]. In any case, Pfaundler informed Hočevar about the latest vacuum techniques. Above all, his influential connection enabled Hočevar's access to the best lecturing posts in Habsburgian monarchy which was rather unusual for a kid from the remote Metlika near recently disbanded Croatian military Krajina.

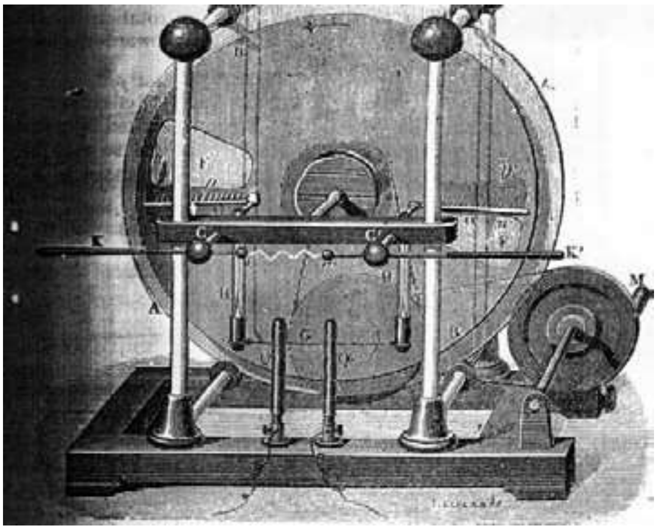

Figure 18-22: Sketch of the operation of Holtz’s electrophorus (Ganot, 1886, 69, Holtz, 1865, 192/193 (Figure 2-5, Tab 1))

Hočevar used Holtz’s influencer (electrophorus) with unequal discs of 60 cm diameter at the distance of 3 mm.[2241] In those days, he was a gymnasium professor in Innsbruck, and he used the device in his school lab. Holtz’s device was used up until recently in high schools,[2242] as its obtained voltages are greater than ordinary electrostatic spinning wheels or batteries of Grove as the discoverer of sputtering according to the measurements of Rudolph Kohlrausch and Stefan’s Viennese classmate Francesco Rossetti (1833 Trento–1885 Padova) who excelled as Naccari’s doctoral advisor. The electrical current from Holtz’s device is almost proportional to its speed of rotation. The problem was occasional wetting, which hampered the sparking of Holtz’s device, but the Parisian expert of the German genus Ruhmkorff pulled it off with a few drops of petroleum. Ferdinand Philippe Edouard Carré (1824 Moislains in Somme–1900) successfully completed Holtz’s friction device and improved its results without any further problems with moisture.[2243]

According to Holtz's suggestion, Hočevar put Geissler's cathode ray tube between the plates of Holtz's influential machine and thus observed discharges in a vacuum. Hočevar's description of Holtz’s electrophorus with the vacuum Geisler’s cathode ray tube received a lot of attention; in the leading Berliner physics magazine, it was valued by Otto Lummer, a rosy young man, who later became famous with his verification of Stefan's law by measuring the radiation of an electrically heated hollow platinum cylinder in a vacuum in Berlin between 1896-1899.

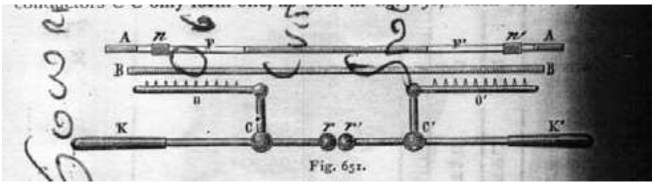

Figure 18-23: A drawing of the operation of the Holtz’s electrophorus (Ganot, 1886, 698).

Vlacovich acquired electric power in Koper and Trieste with the generator of the electrician (Georg) Karl Winter,[2244] who first compiled his plates as an improvement of Adolph Poppe’s (1847) and Holtz’s inventions with his smaller design in Vienna on 26. 2. 1847 and 1869. Baron Moriz von Ebner-Eschenbach (1815 Vienna–1898 Vienna) as professor of physics and chemistry at a Viennese engineering academy (militärischen Ingenieur-Akademie) bought Winter’s bigger design for his academy as presented on 16. 4. 1847.[2245] Winter’s bigger design was on sale by A.

Die Wheatstone'sche Brücke.

Von Dr. Franz Hočevar in Innsbruck.

Um die Formel, auf welcher die Anwendung der Wheatstone'schen Brücke beruht, abzuleiten, bedarf es bekanntlich ziemlich langwieriger Rechnungen, sowie auch der Kenntnis der beiden Kirchhoff'schen Sätze über Stromverzweigungen. Diese Sätze selbst lassen sich, wenn sie nicht bloß als Erfahrungssätze hingestellt werden sollen, nur mit Hilfe der Potentialtheorie begründen.*) Mit Rücksicht auf alle diese Umstände begnügt man sich wohl in den meisten physikalischen Lehrbüchern für Mittelschulen und ebenso auch beim praktischen Unterrichte an denselben mit der Besprechung jener Widerstandsbestimmung, welche passend als „die Methode der unmittelbaren Substitution" bezeichnet wird. Es ist jedoch leicht ersichtlich, dass man wegen der oft ziemlich raschen Abnahme der Stromstärke, der geringen Empfindlichkeit der Tangenten- und selbst der Sinusbussole etc. nach jener Methode nur sehr ungenaue Resultate erhalten kann.

Um nun die elegante und ungleich genauere Methode von Wheatstone mit möglichst geringem Zeitaufwand vorzunehmen, kann man den folgenden, höchst einfachen Weg einschlagen.

Ein Stromleiter sei zwischen A und B (Figur 1) in die beiden Zweige ACB und ADB getheilt, und diese selbst seien durch die Brücke CD mit einander verbunden. Die Widerstände in den Leitern AC, CB, AD, DB wollen wir in derselben Reihenfolge mit w_1, w_2, w_3, w_4 bezeichnen. Durch passende Veränderung eines dieser Widerstände, z. B. von w_4, kann man es stets erreichen, dass durch die Brücke kein Strom mehr

*) Gilt wohl strenge nur für den Maschensatz und nicht für den Satz bezüglich der Knotenstellen. D. Red.

the Hočevar's days was crowned by Van de Graaff's generator in 1931; between 1953 and 1957, Van de Graaff's generator was assembled at the Jožef Stefan Institute in Ljubljana. Winter provided the largest generator of its kind as the final development of plate frictional electrical machines. His glass plate has a composite axle of glass and brass. It is supported on the brass side by two glass pillars, and on the glass side by a stout wooden one. In this way, strength of construction is combined with efficient insulation. The plate is rubbed by two cushions in a mahogany frame supported on a glass stand. The most noteworthy construction feature is the two large "inductor" rings coated in gold foil and insulated on glass supports on either side of the machine. One of these acts as the "negative" conductor when connected to the cushions. The other is the prime or "positive" conductor, the glass plate rotating between its ring-shaped collectors. At the front is a brass sphere on an insulated support which could be replaced. At the back Winter put two discharging conductors, one on a cleared glass support, the other on a green glass support. At the prime-conductor side is a very large Leyden jar, protected in an eight-sided glass and wood case. Two long wooden rods, terminating in hooks and coated in gold foil, are suspended from the rings that were probably used to connect the various parts of the machine together. The machine has been heavily restored in the Florentine Lorraine collections. Karl Winter devised this generator type as essential descendant of Jean Baptiste Le Roy's "long spark" machine of 1772. The capacity of this design was augmented by Winter's "inductor" rings, which contained one or more coils of thick iron wire.

18.3.6 Hočevar about Wheatstone Bridge

Vlacovich and Klemenčič among the first Slovenian physicists measured the speed of electromagnetic interferences in a vacuum or in a substance. The first useful measurement of the speed of electricity was carried out by the Englishman Wheatstone in 1834 and 1835. The other important measurements were achieved by the Lower Carniolan (Dolenjec) Klemenčič in 1884 in Graz shortly after Maxwell's discussions on the uniform nature of electromagnetic and light waves in a vacuum. Wheatstone did not mention Vlacovich or Klemenčič, although he published even in French language with his enviable knowledge of Italian and German languages, which was extremely rare among the British electro-technicians of the Faraday's Circle.

In his lectures, Faraday showed his own and Wheatstone's experiments, as Wheatstone's shyness complicated his public appearances, although, of course, he taught his Baker lessons. Once Wheatstone was so afraid of public that he escaped just before his own prearranged lecture; he left a full hall of curious visitors with long noses. Together with Babbage, he condemned scientists who would take part in spiritistic sessions. Nevertheless, in 1880, when Faraday lectured at the Royal Institution, he sat next to a spirit-loving vacuumist Crookes, while the bearded Charles Darwin was placed behind Crookes.[2246] Wheatstone and his brother were selling vacuum and other physical devices in London.[2247] In King's College, he directed individual students to experimental studies. He tutored some students. He lectured bit, if anything, immensely shy about his small posture. He fluctuated between science and business while by his youthful scientific work he primarily improved vacuum measuring techniques.

By Chladni's designs, Wheatstone obtained figures by strewing sand for the display of knots of waves. In London, Geissler's Bonn co-worker vacuum researcher Plücker examined Wheatstone's device in 1848 and the Jesuit Roman astronomer Pietro Angelo Secchi (1818-1878) did the same next year. At first, Wheatstone measured the speed of sound, and then started to measure the speed of light and electricity. He considered the possibility of two electric fluids and reported his results to the Royal Society on July 14, 1834. The photography pioneer, Assyriologist, and a member of Parliament W.H. Fox Talbot wrote about Wheatstone's achievements for Philosophical Magazine. Of course, Wheatstone at Londoner King's College did not have enough room for decisive measurements of any speed of electricity; so, he used the old Parisian Charles-Augustin de Coulomb's mirror design, which was successfully completed by Foucault in Paris again fifteen years after Wheatstone. The ideas of multiplying resolution of human eye switched from Paris to London and back borrowed from the millennia older design of recently enslaved easterners.[2248]

Hočevar began his discussion on the Wheatstone Bridge immediately after his experiments with Geissler vacuum cathode ray tube put between the plates of Holtz's electrophorus. Even though Hočevar was already at that time in a relatively remote Innsbruck, the atmosphere of anticipation for the announced Viennese Electric Exhibition under the leadership of Hočevar's Professor Stefan of 1883 was already felt. After Stefan's exhibition, Hočevar redirected his scientific talent into mathematics.

18.3.7 Conclusion

In his early vacuum experiments Hočevar upgraded the previous knowledge of electrophorus and early vacuum tubes under the beneficial influence of his Viennese professors Stefan and Boltzmann. Although he later devoted himself mainly to mathematics, Hočevar initially proved an enviable physical talent by his imaginative use of Geissler's vacuum tubes. Hočevar's simultaneous orientation to experimental vacuum technique and pure mathematics was not so unusual as today might seem at first glance, since Geissler's co-worker, Bonn professor Plücker or Fox Talbot, also proceeded in the similar nicest way.

18.4 Tesla's Vacuum Researches

18.4.1 Introduction

Southeast of F. Hočevar's Metlika, the conglomerate of cultures and religions used to produce even more complex minds. Nikola Tesla, a descendant of Dalmatians removed to Croatian Lika, shows the fertility of this religious and ethnically mixed and painfully traumatized Military Krajina. He graduated at the higher school in Rakovac, in the class of Šubic's friend, the physicist Martin Sekulić, who also has his cradle in the stony Lika. Right at the time of Tesla's Matura exams, Poljanska dolina by Škofja Loka native Šubic published his Telegraphy, and before it a series of articles in the journal Rad (Work) of the Yugoslav Academy of Sciences and Arts in Zagreb, whose member Šubic was together with Sekulić.

During his two years of study (1877-1878) at the polytechnics in Graz with physicist Pöschl and

[2246] Bowers, 2001, 191, 213.
[2247] Bowers, 2001, 69.
[2248] Bowers, 2001, 43, 57, 59, 61, 68.

mathematician Allé, Tesla met the university professors of physics, Šubic and Lower Carniolan (Dolenjec) Klemenčič. Tesla admired Klemenčič's very interesting measurements of speed of electromagnetic waves which Klemenčič designed as a student between 1871/72 and 1875/76 and as a demonstrator at Boltzmann's lab in 1877/78. At the beginning of Tesla's studies, Boltzmann returned to Graz University; he was the most distinguished Central European expert for the new Maxwellian theories. Among the most famous inhabitants of Graz, a mathematician and school supervisor Franc knight Močnik has retired in 1871; Tesla could not pass without Močnik's influence as a schoolboy or even when he tried his luck a lower real school lecturer of religion in his native Gospić. During his studies, Tesla read the work of William Crookes on radiation in the cathode ray tube and on the supposed 4th aggregate state of matter. Tesla visited the elderly Crookes in London three decades later and talked with him mainly about William's inflammatory research of spiritism.

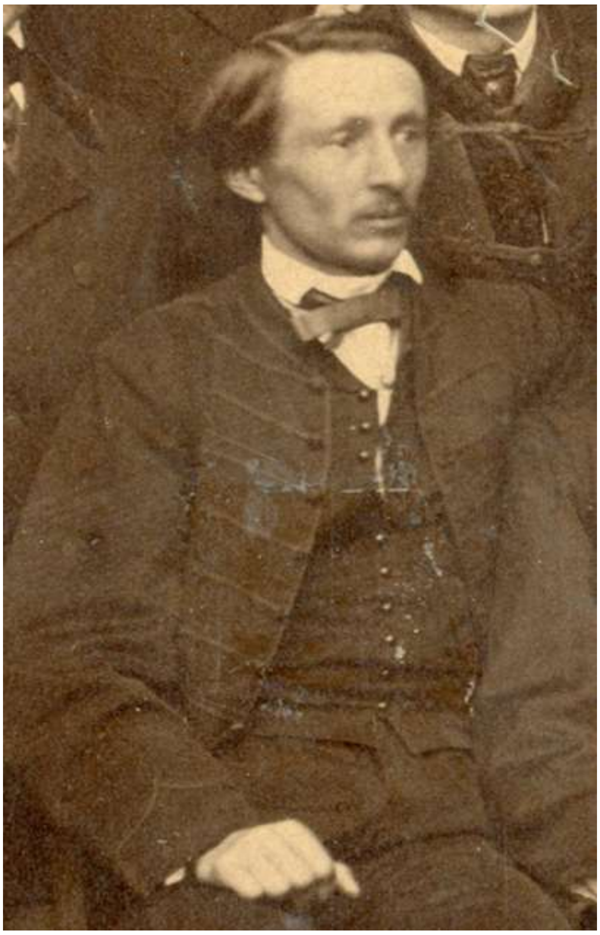

Figure 18-26: A portrait of Tesla's high school professor and fellow of JAZU Martin Sekulić (* 1833; † 1905)

In 1878/1879, Tesla went into hiding in Maribor. He supposedly worked at the technical office of an industrial engineer with 60 guldens of monthly salary, while there were also allowances for successful work. Thus, he became machine engineer and only later beyond the sea – he transformed into an electrical engineer. It can be that young Nikola, even in his Maribor time, was playing hazardous games excessively, gambling for luck or just for his other juvenile irrationalities. That is why he never shouted about that period of his life from the rooftops. Perhaps he found his youthful love among the Styrian folks, who provided his romantic memories to the end of his days. Shortly after Tesla's departure, Maribor as the first in this part of Europe, equipped its public road lighting with light bulbs in 1883.[2249] On 24 May 1892, Tesla personally gave advice to the mayor of Zagreb[2250] and his assistants on the public electrical lighting of lamps in Zagreb, and he certainly had a good overview of the situation in neighboring Maribor. Despite the interest and prosperity of Maribor's electrical engineers at the time, Tesla could not keep up with Slovenians. Of course, Slovenians can only regret it.

In Maribor, Tesla saved enough to study in Prague, but he did not seriously work on it. Much later he became an Honorary Doctor in Zagreb; similarly, Edison without any official schools came to honorary doctorates. Edison excellently mastered the writing of journalists, but his method was, at least in the beginning, only trial-and-correction of errors, while Tesla put more emphasis on his own thought experiments and loved media even more.

In 1882 in Parisian Edison Company CCE (Compagnie Continentale Edison) Tesla collaborated with Edison's friend Charles Batchelor (Batchellor). Five years earlier, Edison ordered Batchelor to use a conventional air pump for evacuation of the cathode ray tube equipped with a plug of carbon. Due to poor vacuum, the carbon burned there almost as fast as in the air;[2251] however, under Batchelor's patronage, Tesla for the first time became acquainted with serious modern vacuum experiments.

[2249] Information of Andrej Simon Luneznik, pro-dean for students' affairs Pedagogic faculty of Maribor university.
[2250] Dadić, 2004, 12.
[2251] Edison, 1994, XXXVI, 540-547.

At the beginning of 1883, the CCE sent Tesla to Strasbourg. In the following year a hopeful young man, following the recommendation of Parisian friends and Batchelor sailed to Edison's dreams of New York. So, he went into the New World. In the land of once "wild" Native Americans, he worked for Edison's favor until the spring of 1885. He then set up his own Tesla's street lighting company only a year after the introduction of lighting in Maribor. The following year he completed his own imaginative lighting system with arcs; about it, Slovenian ancestors only read a decade after the invention in their native language: "If we link two metal plates that stand opposite each other with Tesla's currents, then there are very strong electric forces among them. Geissler's tubes, which we bring into such a space, immediately flash off. This behavior of Geissler's tubes enabled Tesla's hope that it would be possible for him to introduce new, all enveloping electrical lighting. In the space that we would like to enlighten in this way, we would insert two opposite walls of a large metal plate and tie them with Tesla's currents. Then, at each end of this space, a Geissler tube would illuminate, which would be freely wirelessly transmitted and put in any place. Sadly, we are still far from this ideal lighting."[2252] A dozen decades later the distance is still here ... For how long?

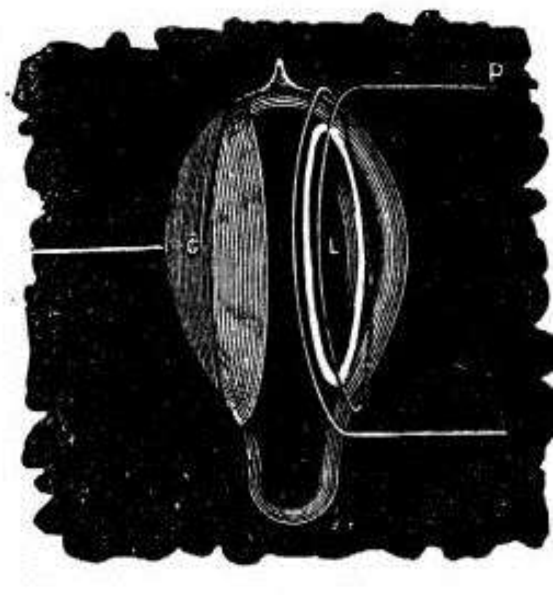

Figure 18-27: Tesla's glass ball of a regular bulb surrounded by one or two turns of the conducting thick copper wire P and the luminous circle L excited by discharge

18.4.2 Tesla's Electrons and X-rays in Crookes's Vacuum

Tesla was, of course, the "predecessor" of many discoveries attributed to others: X-rays, lasers, Marconian radio, electron microscope, induced radioactivity, accelerator of charged particles ... Let's look at the educational story about his "discovery" of the electron in a controversy with a valid declared discoverer, J.J. Thomson.

The former W. Thomson's collaborator on submarine telegraphing Thomas Commerford Martin (1856 London–1924) used to be Tesla's friend but turned enemy after criticizing Tesla's

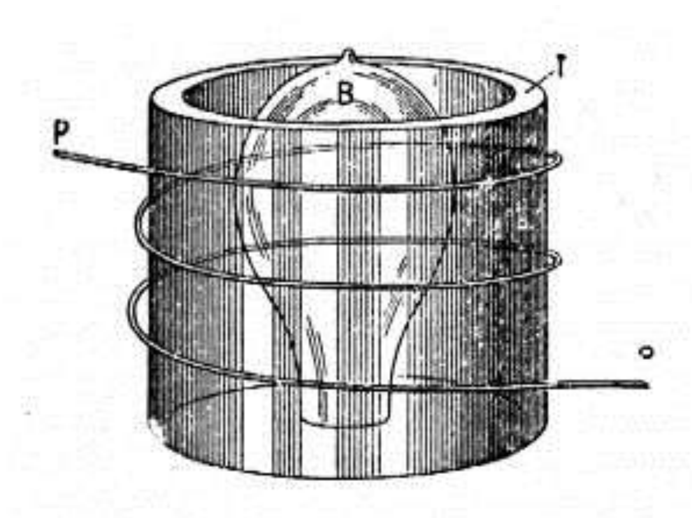

Figure 18-28: Tesla glass tube T around vacuumed bulb B to increase the specific inductive capacity of the medium between the primary and secondary for augmented inductive effect

warlike devil automata on November 24, 1898. On June 10, 1891 Martin[2253] as the editor of New Yorker *Electrical Engineer* published a summary of J.J. Thomson's description of the electrical arc discharge in a vacuum in front of the Physical Society of London printed in *The Electrician* of London. Two weeks later, Martin published similar thoughts of American professor Elihu Thomson.[2254] The next week, Tesla added his own pot to the same magazine. At that time, in his New York Laboratory, Tesla investigated the creation of an electromotive force and light emitting in the vacuum cathode ray tube, preferably without electrodes, using a strong induction in a powerful electromagnetic field. Tesla shared his ideas with

[2253] Jovanović, 1998, 11.
[2254] Horvat, 1988, 265, 271; Paar, 2004, 38-39.

Alfred G. Braun of the Western Union Telegraph Company. On one side Tesla extended his tube to form a plain vacuum lamp, inserted copper or even gold plated into it and watched the circle of light between the copper and the glass frame. The visual effects were much greater when the copper was closer to the glass, and the the glass appeared to be heated by particles bombarding in a rectangular direction. In experiments with alternating low-frequency currents, the phenomena were attributed to electrostatic effects, while J.J. Thomson's division of electricity in a static and dynamic parts did not make sense at all in this line of circumstances. Thomson even convincingly told Tesla that he did not even read the writings of *The Electrician* about his own speech before the Physical Society of London.

Figure 18-29: Tesla with a field-sensing light in a New York lab during his polemic controversies with J.J. Thomson and Röntgen (Museum of Nikola Tesla, Belgrade).

Of course, Tesla, was a good son of recently disturbed brotherly Yugoslavian nation. So, he didn't remain silent. He replied as soon as Thomson's London defense was noted in Martin's New York newspaper. Tesla completed his paper with a prophetic claim that "the observed phenomenon is a consequence of the movement of small charged particles that collide with the gas molecule at a high speed." Thomson, of course, did not agree with Tesla at the time, but in less than six years he did, because he suddenly announced his own - discovery of the electron. Whoever knows, he knows. The poor Tesla once again stayed with a long nose. In 1894, Tesla and his assistant the Century Magazine photographer Dickenson V. Alley noticed the blackening of the photographic plates after the discharges of Crookes' cathode ray tube. At the beginning of next year, Tesla's New York Laboratory was burnt to the ground, perhaps with little help or even with some merits of his competitors; nevertheless, immediately after Röntgen's discovery, Tesla continued experiments with reflections and other properties of new rays. On August 1, 1896, and again on August 29, 1896, Tesla's X-rays reflected as tiny small particles to break the charge from atoms.

In his dispute with Thomson and Röntgen, Tesla remained torso; he preferred to undertake research on high frequency discharges in diluted gases, where he had virtually no competitors. From May

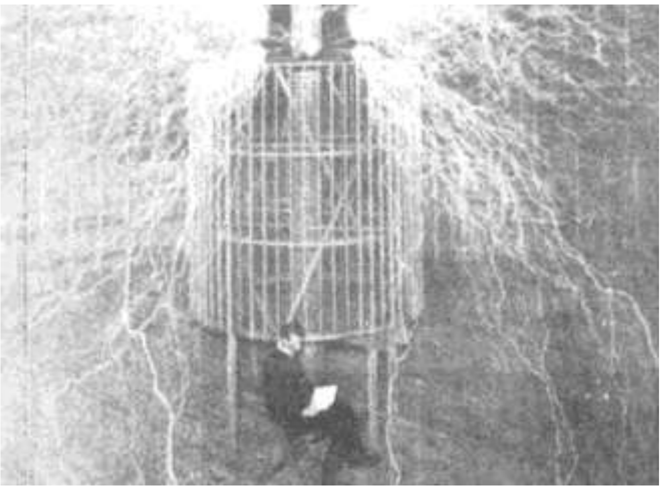

Figure 18-30: Undisturbed Tesla in the middle of his lightnings at his laboratory in Colorado.

1899 to February 1900 in Colorado Springs Tesla tested wireless high-power transmission, his second magnificent invention of the engine in the rotating magnetic field of alternating multiphase current. He thought of the earth and the upper layers of the atmosphere as a plate of a huge capacitor with the lower layers of air as an insulator. It resembled a later model of Earth as the electrode of a vacuum tube collecting particles of the northern light (Aurora Borealis). It seems that in his thoughts Tesla attributed to Earth too high electrical conductivity; he liked to put much on his feelings, but they still let him down and astray there. He chose Colorado because the lightnings are as common there as possible, except for the famous summer tornadoes on the Oklahoma plains. Tesla investigated at 120 mm Hg to 150 mm Hg (1/6 to 1/5 kbar) at voltages between two and four million V. In the meantime, on 4 July 1899, he continued to explore the properties of the Lenard and Röntgen’s rays.[2255]

In Colorado, where summer is often so hot that rain evaporates before it falls on the ground, Tesla mainly planned to transfer high-voltage electricity over long distances. According to Irishman George Francis FitzGerald, most researchers thought that the diffraction of waves along the rounded Earth's surface would allow electricity to cross the Atlantic. Tesla defended his similar assumption in the patent filed on June 24, 1899, and even after a year in the popular The Century Magazine in June 1900.[2256]

18.4.3 High Voltage Discharges of Tesla's Slovenian Jesuitical Precursors

Among the predecessors of the Tesla’s exploration were numerous Slovenians, among them Jurij Vega and his teachers. In August 1775, Vega completed his studies of philosophy in Ljubljana together with Carniolan Fidelio Poglajen. The mathematical and physical part of their exam was led by professor Jožef Jakob Maffei from Gorizia and Gregor Schöttl. Their examination papers were printed in Latin, and they were bound together with the German translation of Mako's book. Maffei has already met the Hungarian Mako during their joint service at the Theresianum, and the Latin version of Mako's book was also published in Maffei's native Gorizia. So, we can think that Maffei was the one who decisively contributed to the choice of the book in which Vega and his classmates bound their examination theses.

They cleverly devoted their publication to Franciscus Antonio de Raab (1755 Ritter von Raab zu Ravenheim, 1722 Klagenfurt-1783 Vienna);[2257] in March 1871. The Empress entrusted Raab with construction work on the waters, and after the ban of the Jesuit order in 1773, she appointed him as a court counsellor. Raab was deeply involved with the regulation of the Mura river; therefore such choice of dedication could not have been more fortunate. Soon after the exam Vega and his classmate Poglajen were employed precisely at Gruber's works on the Mura river.

The selection of the book for the binding of Maffei's exam questions was influenced by close links with the translator, Maffei and Mako's Viennese student Joseph Friedrich baron Retzer (1754 Krems an der Donau-1824 Vienna). On 24. 5. 1782, Retzer entered the new freemasonic lodge. That same year he became a master while his influence almost surpassed the heads of the lodge Born and Sonnenfels. Retzer belonged even to the highest circle of the Order of Illuminati, which was founded on 1 May 1776 by the former Jesuitical student Adam Weishaupt, the professor of law in Ingolstadt in Bavaria. Along with Tobias Gruber Retzer was one of the main contributors to Born's Viennese Freemasonry Bulletin. He published few researches about electricity. He often met with Vega in the lodge, but he did not attend his reception at the Freemasonic lodge. In 1800, Retzer became a baron,[2258] coincidentally with his two-month-older fellow Vega.

Figure 18-31 The cover of Retzer’s translation of Mako’s book in the first edition of 1772

The translation of Mako’s book was first published together with the original in Vienna in 1772. The numbering of the pages of main text followed the introduction pages numbered in Roman fashion. Mako did not enclose images other than a sketch of the storm in front of the cover, under which he published the verse from Ovid's Metamorphoses.

2257 Maffei, Tschokl, Schöttl, 1775, 1.
2258 Message of dr. Matevž Košir, 3. 11. 2003.

In the introduction, Mako described the investigations of electrical sparks. In the first part, he reported on the nature of the thunder,[2259] and in the other, he discussed the lightning.[2260] He approached Franklin's theory of the surplus with positive and the deficit with negative electricity.[2261] Benjamin Franklin was an influential freemason and at the same time a good friend of Jesuit Bošković when he intertwined those two companies that apparently were not always in quarrels.

Vega and Maffei were certainly proud when they saw how Mako even quoted Valvasor's book Glory (Die Ehre, Slava)[2262] with a description of two waterfalls in Cerknica Lake. When there was flashing and lightning from the sky, the good old Valvasor heard the donation, as if there were simultaneously banging around the various timpani or kettledrums. The Cerknica fountains seemed to him to be like the caves. In one, he noticed the light, and from the other, a fog accumulated along the storm. Valvasor did not doubt that the phenomenon was caused by electricity, although today it would have been hard to believe him. Bošković's friend, the maker of the first lightning rods in Turin, the Piarist Giacomo Battista Beccaria, reported on similar water vortices as whirlpools in Modena.[2263] Certainly, that description of the inquiries of their compatriot Valvasor finally convinced Maffei, Vega and his classmates to bind their theses of their final exam with the Mako's Book.

In the last twenty pages of the first part, Mako summed up the thunderstorms across Europe. In 1761, the lightning struck at his Viennese home college. From the copper roof it slid down without damaging the wooden casing; then it hit the bell loudly. From there, through the conductor between a solid casing and a roof, it entered the chapel of St. Xavier and finally struck in a silver-plated and gold-plated statue of the Mother of God. In 1770, the lighting hit a small tower of the same college; it traveled through the copper roof, descended through the iron door, and penetrated the rooms.[2264] In 1770 the lightning again dangerously burst, this time in the door of the Viennese Jesuit College.[2265] Mako also described the lightning in Venice on May 26, 1752 and on June 18, 1764,[2266] the storm in Timisoara on February 1, 1772,[2267] and the recent lightning that hit a gilded ball in Berlin on July 20, 1772.[2268] The events in Timisoara were certainly reported by then navigation director of Timisoara areas the Jesuit Tobias Gruber.

Figure 18-32: The ships by the seashore painted before the front cover of the translation of Mako's book, bind to the examination theses of the professors Maffei, Schöttl and Tschokl, defended by Vega and his schoolmates in August 1775. The same ships were published in 1772

The former Jesuit of Ljubljana, Biwald, set up the first lightning rods in Styria. Of course, Carniolans did not lag much behind their neighbors; in the continuation of Maffei's mathematical part of the exam the Ljubljana professor G. Schöttl, in his last 38th physical thesis, dealt with the iron lightning rod put on the stick.[2269]

The Ljubljana Rector Anton Ambschell described the lightning in the monastery church of St. Martin: "... in 1782, the lightning struck three

miles south of Ljubljana in Carniola, crossing the tower of the Church of the Nuns (...) from where it passed through the monastery to the ground". The event triggered a general interest. That is why Ambschell placed the lightning rod from the wire on the tower of a high building near his Ljubljana apartment and thus became the pioneer of modern Carniolan defense against the lightning. In lightning rods, the then obscure observers often saw the novelty of a dubious reputation. Thus, in 1783, the future revolutionary, the lawyer Maximilian Robespierre, defended the French nobleman in the Arras court. The nobleman disturbed by the neighbors and even the mayor himself by setting the lightning rod. The good-natured Robespierre was then a promising man; his fateful friendship with the guillotine developed only a decade later.

In the second part of the book, Mako accepted Franklin's look at the nature of the lightning and the numerous weather phenomena.[2270] He described Bianchini's letter (16 December 1758) about lightning experiments at the Devin castle "near the borders of Carniola."[2271] Even a century later, the professor of physics at the Grammar school of Ljubljana and its later director Mitteis was interested in Bianchini's research; in the high school report he described the dispute between Nollet and Franklin, which, however, did not seem to be very satisfactory to his Viennese criticists. Grailich, the predecessor of Jožef Stefan, who criticized Robida a bit earlier, refuted Mitteis in Viennese journal for the review of papers printed in annual publications of high schools and textbooks. In the Slovene national territory, they began to be interested in arc discharges at an early age. The cabinet of physics was not intended for students only. A gymnasium professor of physics between 1853 and 1866, the gymnasium director and for some time director of Real school the Bohemian German Mitteis, also tested his interesting acquisitions in front of the selected company of educated fellow citizens at lectures at the Society of the Carniolan Museum in Ljubljana. The Regional Museum also hosted interesting features. Thus, physicist Thomas Schrey, Mitteis's deputy, supplemented Mitteis's lecture on the development of a stereoscope, showing the latest methods for measuring the magnitude of the electrical spark-on December 10, 1856.

[2270] Mako, 1775, 85.
[2271] Mako, 1775, 93-95.

Mako summed up Bianchini's[2272] experiment of 1750 when he stuck into the ground a bolt upright halberd and connected it with a chain. He noticed the illumination known as the "fire of St. Helene" or of St. Erasmus. Bianchini found that the electrical matter from the atmosphere entered the halberd. The experiment lasted only for a quarter of an hour, and then the scared researchers hid themselves under the roof of the Devin castle an hour before the storm. The dry head is still more valuable than a promising scientific discovery. The guardian of Castle was Maffei's godfather Josef Thurn-Hoffer and Valsassina (Hofer, 1681-1775) until 1774 when the Devin along with the castles of Sagredo and Vipulziano took over his younger brother, the count Janez Krstnik Thurn-Hoffer and Valsassina (1699-1783). Thus, Maffei knew Bianchini's work, which in 1754 described the source and the stream of the subterranean river Timavo in the letter to Gorizia guy, Gvido Kobencl.

Mako knew that the sound did not move the airborne particles over longer distances. Therefore, he correctly assumed that the ringing could not effectively persecute clouds that threaten us by the lightning.[2273] Similar views were also put forward by Carinthia native Joseph Herbert, a professor of physics in Vienna, and a co-worker of the Ljubljana rector Ambschell.

In 1778, Mako discussed relatively new electrical experiments, such as the papers published in Hanover in 1761;[2274] but he described only a few of his own discoveries. He did not mention Bošković, since Bošković did not publish much about electricity. Mako was one of Bošković's most important advocates, especially regarding the problems of vacuum and infinitely small quantities that the Jesuits learned to solve only with Bošković's physics. Since the Jesuits of Ljubljana were also in favor of Bošković's ideas, G. Schöttl devoted two among his examination questions to Bošković's "famous curve of forces";[2275] the selection of Mako's book for the binding of the examination theses was also well expected on Bošković's side.

18.4.4 Tesla's Contemporaries Explore Arc Discharges in Slovenia

18.4.4.1 Vlacovich

Nicolò Vlacovich's[2276] spark was apparently triggered suddenly; in fact, it had a series of successive discharges, as Tesla already knew.

Vlacovich's experiments on the duration of the electric spark independent of the circuit in which spark arose, determined only by the skipped distance,[2277] was induced by new thinking. During Vlacovich's research, Maxwell published the first discussions about the similarity of light and electromagnetic waves, which no longer restricted them to the area of the conductor and enabled Tesla's subsequent success.

Figure 18-33: The first page of the unpackaged list of the Koper cabinet of physics with devices that started to acquire years 1850. Vlacovich used devices 5-11 to investigate sparks (Vlacovich, Nicolò and others, 1850-1871 (1885), Inventoryio del Gabinetto di Fisica, IR Ginnasio Superiore di Capodistria, Koper Urban Archive, Box 10/3).

Vlacovich, of course, intervened far beyond the potential experiments with the claim that the arc discharges consist of a fast sequence of shocks; Tesla later accepted the idea. Vlacovich supposed that the first discharge is the strongest among them all. Despite the smallness of the entire time of sparking, the spacing between the individual strokes is still much longer than the time that an electrical disorder needs to travel through the circuit with which we make the spark. Vlacovich did not measure this speed, which was first convincingly determined by Wheatstone in 1834 and 1835, followed by Klemenčič in 1884 in Graz. Vlacovich's[2278] resistance to the circuit does not affect the sparking length; the problem of arc discharging is still interesting today because, despite Tesla's efforts, we do not yet have the prevailing theory of atmospheric discharges during lightning and thunder.

18.4.4.2 Robida and Šubic

In his research, Stefan's professor Robida participated in the first measurements of the sputtered of metals and the propagation of electromagnets waves; but the approach of the younger Vlacovich was more modern. Robida initially did not undertake more difficult experiments without suitable pumps and seals; Nevertheless, three decades before Hertz, Robida published his measurements of electromagnetic waves.[2279] The first among the Slovenes, Robida sputtered a pointed platinum electrode into a "white round stain from a giant number of platinum grains that took on plates at the higher temperature..."[2280] François Napoleon Marie Moigno recommended Ruhmkorff's inductor in collaboration with Cauchy who worked in "Slovenian" Gorizia during Robida's era. According to Robida's view, Moigno should overlook the warming of the positive electrode and the flow of the particles towards the negative electrode. Robida's friend Poljane native Simon Šubic has purchased several Geissler's tubes among electromagnetic instruments for his collection of cabinet of physics in Pest, two decades before Tesla was employed by a neighboring telephone company. Both Šubic and Tesla considered Crookes' findings from 1869. However, Šubic did not accurately describe the proportionality of the length of the dark "Crookes" area along the cathode with the average free path of molecules in gas.

In 1875, Šubic published the first Slovenian booklet on telegraphy, and Tesla, of course, was among its first readers. Until those days, the telegraph has been operating for almost three decades in Habsburg countries including their Slovene parts. In 1846 Bain's telegraph dominated, and later he was forced out by Morse's invention; like Tesla's alternating current for some of the key usages replaced Edison's DC current.

Up to its 17th page Šubic's Telegraphy addressed the development and theories of electricity as it suited the telegraphists. He then proceeded to the individual versions of the telegraph and related fashion models.

18.4.4.3 Codelli

Although Idrija and Ljubljana professor Nardin patented a lot in the direction of Tesla's ideas, the Ljubljana baron Anton Codelli is the only Slovenian inventor at least to some extent comparable to Tesla. Alongside Tesla's 170 patents, Codelli also applied for many patents, although he did not have enough experience in the US. Codelli was almost two decades younger than Tesla during the rapid development of electrical engineering, when the new inventions were inflaming each other. Codelli studied cathode ray tubes primarily as a device for establishing his model of spiral television image broadcasting on the US market; he devoted less attention to Tesla's coils.

Since they were moving in the same electrotechnical environment, Tesla and Codelli had many common friends and acquaintances. Tesla corresponded with Adolf Slaby[2281] in 1901 and 1903. As a professor of electrical engineering at the Technical College in Charlottenburg, Slaby had used German translation of Tesla's work as the basis for high-frequency techniques. He also taught George Count Arco. Arco soon corresponded with Tesla himself.[2282] At the same time, the count Arco became a friend and major Codelli's associator within the Berliner Telefunken. Thus, the networks of Codelli were at least indirectly associated with Tesla whom he resembled by his inventive approach. Of course, Codelli was the son of a rich man, but he wasted most his property of Kodeljevo in Ljubljana on the altar of science. A decade after

[2281] Jovanović, 1998, 13, figure 20.
[2282] Pertot, 1962, 103.

Tesla, Codelli also died relatively poorly enough in a faraway country.

Figure 18-34: Yugoslav and American stamps with Tesla portrait from a private collection of writer

18.4.4.4 Conclusions

Tesla worked all year long among the noble people of Maribor. That's not all that binds him to Slovenian ancestors. Many of his studies were related to scientists of Slovenian genus. Of course, Slovenians do not want to assimilate Tesla for the time being, as Americans, Serbs or Croats do successively every now and again. In the future, who knows?

18.5 Tesla's Early Contacts with Vacuum Techniques

18.5.1 Introduction

Geissler's glow discharge tubes filled with dilute gases were calling for new inventions, and basically, they were engaged in whereabouts of the Prague student of E. Mach's days, Nikola Tesla (1856; † 1943) as a temporary resident of Maribor. Tesla took the first steps in vacuum technique and electrical engineering during his studies at the higher real school in Rakovac near Karlovac with Martin Sekulić (* 29 September 1833, Sankt Michael, today Lovinac in Lika; † 14 April 1905, Zagreb), between 1870/71 and 1873. How did Martin gain Tesla's respect?

18.5.2 Tesla Teacher Sekulić and his Colleagues in Hungary

Martin Sekulić was born in Lovinac in the southern hinterland of Velebit, which today has 90% of the Croatian population; Sekulić family moved from the areas of Senj to Lovinac where they now confess the Catholic faith. The inhabitants of Lovinac had resisted the Habsburg authorities a century before Sekulić's birth in the wider rebellion in Lika; of course, they lost. To punish them the Habsburgian revenge-seekers changed the name of Lovinac to Sankt Michael because of the local Church of St. Mihovil, built in 1704. The penalty was in charge between 1751 and 1861.

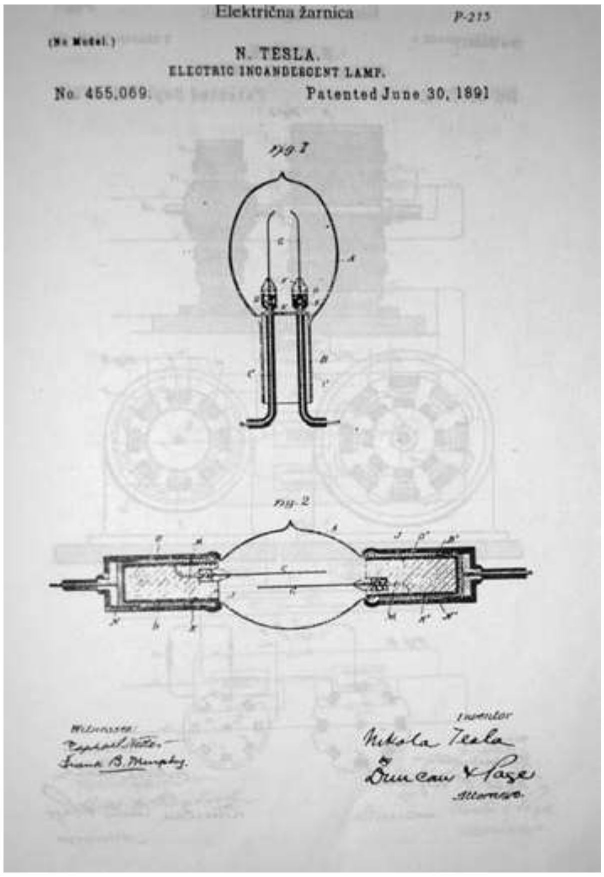

Figure 18-35: Tesla's invention of a vacuum bulb, patented in the USA on June 30, 1891

Tesla's secondary school teacher, Martin Sekulić, began his education in the Military Krajina, after which he was recruited in 1849, in 1852 he joined the Artillery Academy in Olomouc (k. k. Artillerie-Akademie zu Olmütz). He was promoted in 1856 to lieutenant of the 2nd order of light (field) artillery, but he left the service in 1858 without adhering to officer ranks. Later, he completed pedagogical studies of mathematics and physics by acquiring the right to teach at high schools on 20 July 1861. Unfortunately, the Austrian State Archive (Österreichisches Staatsarchiv) does not have information about Sekulić's promotion, as it has, among others, the data of Simon Šubic or Jožef Stefan's studies. Sekulić did not study at the Royal University of Pest, today's Eötvös Lorand University (ELTE) in 1858/59, according to an archive book that mentions students from 1852 to 1871. The University Archives has poor documentation for the period 1852-1859. Reports were kept by the National Archives of Hungary but were badly damaged during the 1956 revolution when data for the 19th century were burned.[2283]

Otto Balthasar Petzval (* July 7, 1809, Spišská Belá (Zipser Bela); 28 August 1873, Budapest), brother of the Viennese professor Stefan Josef, studied mathematics and from 1851 to 1857 served as the professor of dynamo studies at Kaiser-Josef-Polytechnikum in Pest, and after 1858 he was a teacher of higher mathematics at the University of Pest (later ELTE). Sekulić was not far away assistant of geometric drawing on the Real school in Pest in 1859/60 and 1860/61 until he became professor on July 20, 1861, and in 1861/62 he was assigned to teach in Rakovac. Josef and Otto Petzval studied at the Royal Academy in Košice between 1822-1825 and 1825-1828 in the class of Buda astronomer the Slovakian Piarist Matej Daniel Kmet (Kmetch, * 1783, Brezno; † 1825, Košice).[2284] Afterwards, Petzval brothers studied at the Institutum Geometricum in Buda, where the dean and rector of the university was a Slovak Adam Tomcsányi (* 1755; † 1831), and after 1839 the famous physicist Štefan A. Jedlík lectured there as a later colleague of Otto Petzval at the Institutum Geometricum of the modern University in Budapest. The professor of Mathematics at the Institutum Geometricum was the Croatian Josef Wolfstein, who taught mathematics at the Academy in Košice between 1803 and 1818.

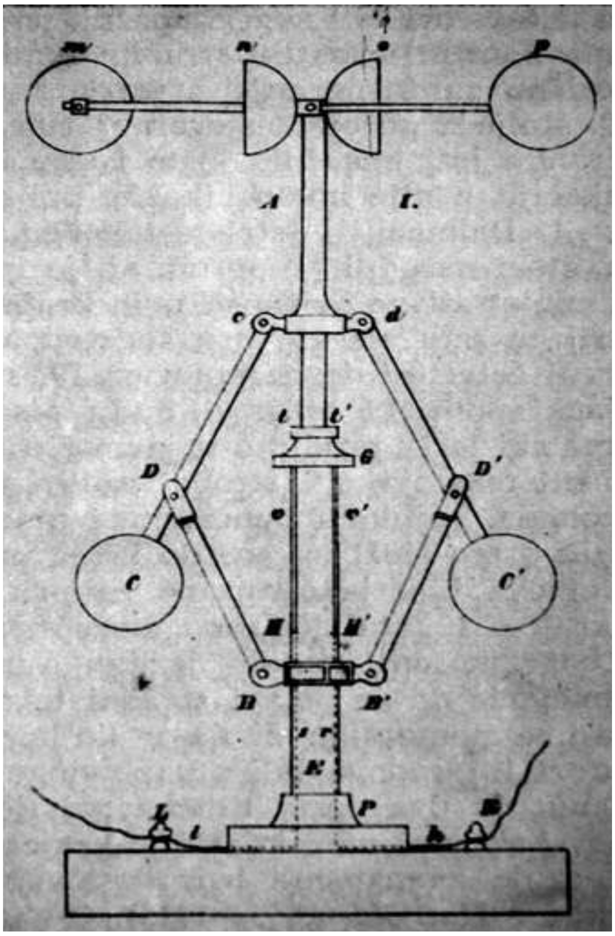

Figure 18-36: The invention for measuring speed of wind for safer driving of trains, which are supposed to stop or slow down while facing the threats of excessive lateral winds. The novelty was described by Tesla's secondary school professor Sekulić at Rad JAZU in 1874 who named it a "Bora-Tool (Burnjak)". The device was probably designed and made several months earlier, after a severe wind caused a local railway accident. "Burnjak" was thus created during Tesla schooling in Sekulić's class in Rakovac, to where Tesla traveled through Slunj in Kordun after his home vacations in Gospić with horse-drawn carriage by the hitchhiking of those days so-called "kirijanje".[2285]

2285 Sekulić, 1874 Burnjak, 27: 225; note of Miran Perhavec from Maribor.

Ányos István Jedlik (Štefan Anián Jedlík, Stephanus Anianus Jedlik, * 11. 1. 1800; † 13. 12. 1895) was an inventor, an engineer and physicist of a Slovakian genus; as a writer of numerous books, he is recognized as an inventor of dynamo and an electric motor in Hungary and Slovakia. After entering the Benedictine order in 1817, he studied at their schools. He taught Benedictines until 1839, then lectured at the Department of Physics and Mechanics at the University of Budapest (Institutum Geometricum) for four decades; Josef Petzval graduated there in 1828. Jedlik became the dean of the faculty in 1848 and rector of the university in 1863. In 1858 he became a correspondent member of the Hungarian Academy of Sciences, and in 1873 he was promoted to extraordinary membership. After retirement, he continued his work in complete isolation in Győr. Pezval and Jedlik greatly influenced Sekulić as a colleagues, teachers, and role models. The university of Technology and economy Budapest (Budapesti Műszaki és Gazdaságtudományi Egyetem, BME) was founded in 1782 as Institutum Geometricum Hydrotechnicum, a unit of the Royal University in Buda. It acquired status of the university in 1871. In 1949, it was reorganized as the Technical University of Budapest, incorporating the former Technical University of Civil and Transport Engineering, founded in 1952. In 2000 it got the present name under the administration of the State Treasury Department.[2286]

After the Second World War, documents for matriculation and dissertations at Charles University in Prague disappeared for Sekulić's period.[2287] Sekulič did not study in Graz or in Vienna, as Bruno Besser explored in Graz. Higher studies in Zagreb were not possible for him because after the ban of the Jesuits only the Royal Academy of Sciences in Zagreb operated from 1777 to 1850 while the University of Zagreb was in charge barely after 1874; so, he did not decide to study in Zagreb. Sekulić is likely to have completed 6 or 8 years of secondary education in the territory of modern Croatia, when the only highest education institution from 1850 to 1874 was the law faculty (Regia academia iuris) in Zagreb. Already before the end of his studies, Sekulić was employed as one of two assistants at the real School in Pest in the school year 1859/60. He helped professor Dionis Pospischil's teaching. He assisted the professor Dionysus Pospischil in the first grade of the lower curriculum in geometric design classes (Geometrisches Zeichnen), which Tesla did not like later the real school in Rakovac. Pospischil came to the Städtische Ober-Realschule in Pest in 1855/56 from the service of assistant of that same geometrical drawings at k. k. Schottenfelder Oberrealschule in the 7th Viennese district.[2288] Until the merger took place in 1873, the Danube separated Pest in the east bank form Buda on the west bank.

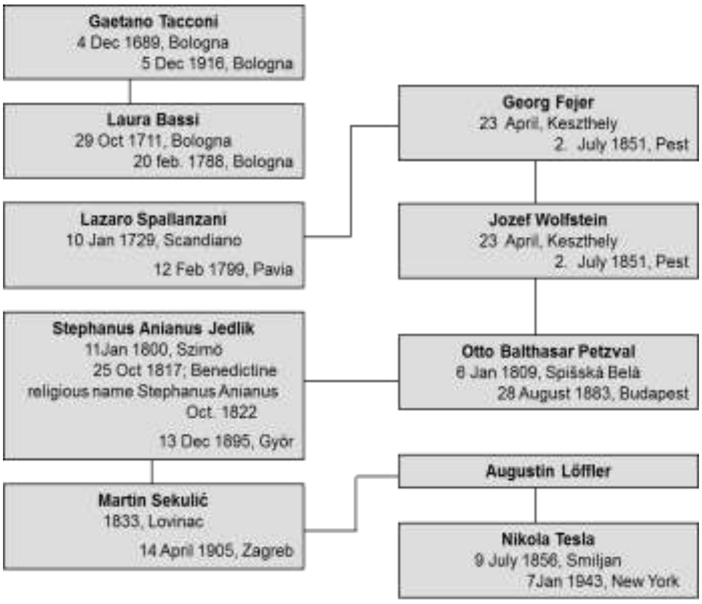

Figure 18-37: Tesla's academic ancestors by his Rakovac studies as teachers of physics (left) and mathematics

In addition to the state (Städtische) real school, the public (Öffentliche) Oberrealschule also operated in Pest. Sekulić's best friend and associate in Pest was a little older Simon Šubic (Schubitz, Subić, Subič, * 28th of October 1830, in Brodeh number 13 in Poljanska dolina near Škofja Loka (Brod bei Lack); † 27. July 1903, Graz). Šubic remained a bachelor male, while Sekulić was already married in Hungary to enable the birth of his son Rudolf (* 1860, Pest; † 10. 10. 1917), later Lieutenant Colonel of the 42nd Zagreb Infantry Division. Soon after Tesla's graduation, Martin again

[2288] www.uni-klu.ac.at/elechner/schulmuseum/schulchroniken/gppest_1_1855.PDF, Retrieved on 17. 1. 2012 married in 1877 and got a new son followed by two daughters. Šubic quickly and successfully completed his studies of mathematics and physics at the Faculty of Philosophy of the University of Vienna between 1852 and 1856. Unfortunately, there was no suitable service for him in Vienna or in his native Carniola.

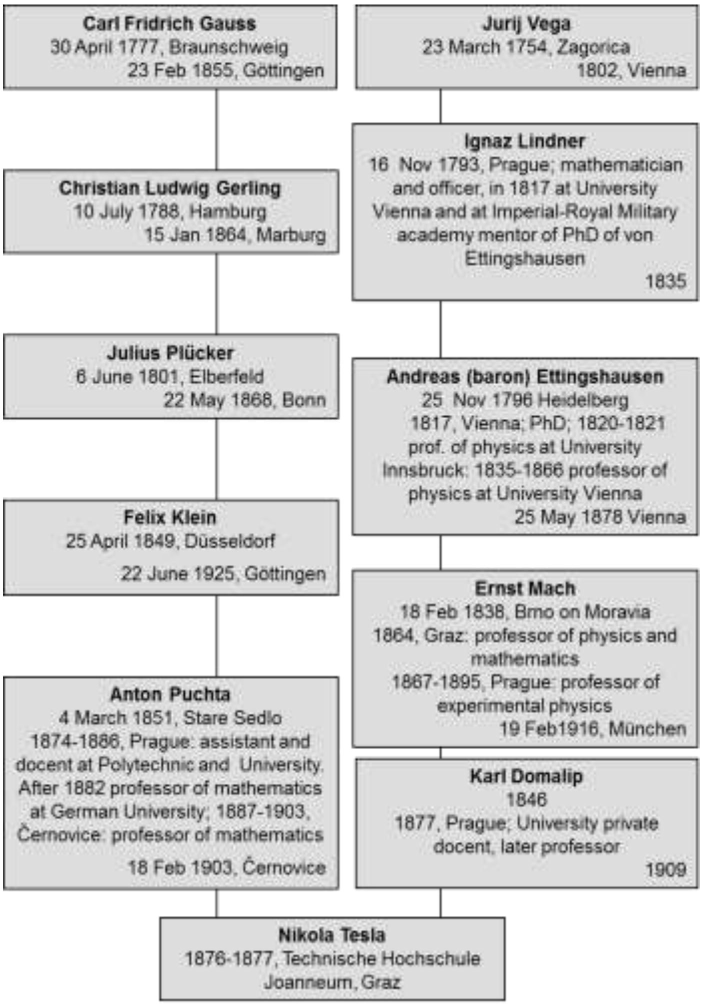

Figure 18-38: Tesla's academic ancestors by his Prague studies as teachers of physics and mathematics. Under their physics education we noted their lecturing services in connection with the famous vacuum researchers Plücker and Vega

Šubic went to Hungary, where on 1 October 1856 he became a trainee at the State Catholic Gymnasium in Buda.[2289] He started teaching on October 26, 1856, and he soon earned a complimentary certificate. On 18 September 1857, he was transferred to a higher real school in Pest with order number 15.783.[2290] He taught as a professor of physics from 31 October 1857 until the summer of 1861. At the same time, he was employed by the newly established state gymnasium in Pest in 1858/59, where he received two praise certificates for "demanding work" and "basic pedagogical-scientific qualities".[2291] During his service in Pest, Šubic mainly dealt with mechanics. In 1860, he compiled his first physical discussion in the reports of the Real school in Pest. He wrote about the operation of Friedrich Fessel's rotating machine, which was also briefly reported by Sekulić.[2292] From a more geometric point of view, the substitute (suplent) teacher at the Ljubljana high school Luka Lavtar (* 1846; † 1915) added his comments in 1872/73.[2293]

In 1855/56, for the state real school of Pest they acquired the aerometer of French chemist and pharmacist Antoine Baumé (* 1728; † 1804), a barometer, a vacuum pump, a Heron's sphere rotating due to a propulsion of sputtering steam, a suction nozzle and thermometers. For the study of electromagnetism, they bought an electrical power machine, a Volta's battery, a magnet, and a magnetic needle.[2294] In 1856/57, a gas compressor pump, an additional Heron's sphere and a vacuum pump with two pistons for the voiding of Magdeburg hemispheres were purchased at the state real school in Pest at the same time. In electromagnetic surveys, they have since been given a tourmaline in the clamp for the piezoelectricity long before Pierre Curie and his older brother Jacques described the effect in 1880. They also acquired the Viennese spindle of Karl Winter for friction charge designed in 1847[2295] and a lightning producing board, especially important for Sekulić's and later Tesla's research. The equipment was also updated with the electroscope

[2289] Vaniček, 1860 Schematismus, p. 139 a date 25. 9. 1856 was noted as a date of Šubic's appointment in Buda, although he as a supplied professor replaced the ill professor of physics only on 4. 10. 1856 (www.uni-klu.ac.at/elechner/schulmuseum/schulchroniken/gofen1856.PDF)

and two resin plates to display figures named after Georg Christoph Lichtenberg (* 1742; † 1799), which was used by Sekulić a decade later.

Šubic also obtained an electrometer in a bottle of London's pharmacist Timothy Lane (* 1743; † 1807) for measuring the charge of the Leyden jar, invented in the late 1760s to prevent excessive electrifying of the patients during treatments.[2296] Tesla later impressed the audience with the spreading of electricity through his body, knowing the skin effect phenomenon that Maxwell predicted in 1873; in 1887 Jožef Stefan supplemented it in the discussion of variable electric currents in thick conductors, with which the effect became decisive for production of vacuum tubes filled with gases. Of course, Šubic also afforded a Leyden jar, an induction machine, two batteries of the Benedictine dean of the University of Pest, Ányos István Jedlik (* 1800; † 1895) with carbon electrodes, an electro-galvanic amplifier - a 400-coin transformer, a twelve-square-inch capacitor and Morse's telegraph,[2297] invented quarter of a century earlier. In 1857/58, according to Šubic's order, a device for displaying the aerostatic paradox was purchased on the state-owned real school in Pest needed for the exploration of gases and vacuum. The electromagnetic research was supported by much more demanding purchases, among which excelled: a horseshoe magnet, a compass with dioptra (dioptre, dioptre, διόπτρα) as an early form of theodolite for measurements of angles, the electric egg shaped as cathode ray tube for multiple discharges with a vacuum pump, with which Sekulić impressed his class with Tesla included a decade later, an electromagnet with Ampère's framework and the apparatus showing influence of terrestrial magnetism on a mobile frame crossed by an electric current discovered by Auguste Arthur de la Rive (* 1801; † 1873) in Geneva in 1820/21.

Especially convenient became a single-pole engine without commutator in the shape of a wheel of Peter Barlow (* 1776; † 1862) with a U-shaped magnet. In 1822 it was designed at the Royal Military Academy in Woolwich a year after the first Faraday's performance. The engine used a single coil to rotate around the fixed axis at low voltages and low torque due to the absence of commutator of Hippolyte Pixi. In 1832 Pixi designed it according to Ampère's ideas to become a kind of ancestor of the later Tesla's electric motor on alternating current patented in 1887/88. Šubic did not forget either two square-shaped magnets and four pounds of conductors insulated with wool. He bought also the ancestor of the turbine of János András Segner (Johann Andreas Zegner, * 1704, Bratislava; † 1777) from 1750, together with connecting pipes.[2298] In 1858/59, the chemistry cabinet was advanced with a purchased gas meter (gasometer), while Šubic brought only physics clock and a tangential compass galvanometer, first described by Claude Servais Mathias Pouillet (* 1791; † 1868) in the Sorbonne in 1837. Therefore, Šubic, with Sekulić's help, has considered numerous textbooks about physics: Pisek's textbook published also with Slovene translations of terminology, Ganot in German translation and the work of a student associate of Justus Liebig and Robert Bunsen, Heinrich Buff (* 1805; † 1878). Šubic commissioned the latest summary of the current achievements of electrical engineering from the professor of physics at the Faculty of Medicine in Paris, Dr. Jules Gavarrett (Louis Denis, * 1809; † 1890) in the translation of Rudolf Arendt (* 1828; † 1902), and three volumes of *Lehrbuch der Ingenieur - und Maschinen Mechanik* of Ludwig Julius Weisbach (* 1806; † 1871) from the Mining and Metallurgical Academy in Freiburg.[2299]

In 1859/60, Šubic with Sekulić's help commissioned an up-to-date collection of electrotechnical innovations: a galvanic flow for rotating movable bodies as a unique electric motor, several Geissler's electrical glow discharges in the tube of diluted gases invented in Bonn two years earlier, an electric gun designed by the Volta's eudiometer, a tubular machine frame for the discharges, the transmission of a galvanic pulse, Charles Wheatstone's (* 1802; † 1875) bridge, a large Smee's battery, several collodium-balloons (collodion) in the form of thin light hollow nitrocellulose layers to observe an electric attraction according to the invention of Louise-Nicolas Ménard of 1846, a galvanoplastic device, a large Schwarz's engine, an electromotor with double coils and magnets beside the commutator designed by Charles Grafton Page (* 1812; † 1868) in the late 1830s. The professor Niccolò Vlahović

(Vlacovich) acquired Page's invention for his gymnasium in Koper before the year 1864.[2300]

Šubic also acquired Gottlieb's device probably designed by professor of chemistry at Tesla's Graz school Johann Gottlieb (1815 Brno-1875 Graz), a vacuum magnetically-deflective recipient of the "galvanic light" (cathode rays or electron by the modern terminology), a device with coils to show the induction law of electric current, the famous Coulomb's torsion scales, four magnetic inductors, coils with twelve rod magnets and an electromagnetic device. For experiments with gases he also afforded Saussure's hygrometer, a psychrometer, a sensor and a preparation for Torricelli's vacuum. He also bought a blood pressure gauge of Charles Nicolas Alexandre Haldat du Lys designed in 1830s, and a centrifuge (Schwungmaschine, Rotazionsmaschine, Fessel),[2301] which was compiled in 1852/53 by former high school professor Friedrich Fessel (* 1821; † 1860) and a pioneering vacuum technician Julius Plücker in Bonn. Three years later, Šubic also acquired it for his cabinet of physics in the Rossau district of Vienna. At the gymnasium in Ljubljana they received the same device only in 1866/67 after paying 4.15 forints of ordinary value, while in the gymnasium in Klagenfurt they got it after Robida's retirement in 1874/75.

In his reports of the real school in Pest, Šubic relied on Lehrbuch der reinen Mechanik of the Sorbonne professor of pure mathematics, Jean Marie Constant Duhanel (* 1797; † 1872) in the German translation of Wilhelm Wagner in Braunschweig published in 1853 and 1858.[2302] In the school year 1861/62, Šubic acquired Duhanel's textbook for the library in the Rossau district of Vienna. In his doctoral dissertation in 1861 Šubic did not investigate the operation of Fessel's centrifuge, although he included it next year in an expanded version of the dissertation published in school reports. In 1859/60 in Pest Šubic acquired Foucault's pendulum, which they acquired at the gymnasium in Ljubljana four years earlier.

Šubic acquired in Pest the vacuum tubes of Heinrich Geissler (* 1814; † 1879) three years before the gymnasium in Ljubljana. He and Sekulić were enabled to researchthe vacuum technique, which later decisively influenced the young Tesla, not only during schooling in Rakovac, but also in the work for the telephone company Ferenc Puskás (* 1848; † 1884) and his brother Tivadar (* 1844; † 1893), founded in Pest on 1. 5. 1881. The noble brother Puskás studied at the elite Theresianum; Tivadar also matriculated at the Polytechnic of Vienna.[2303] None of the brothers Puskás had attended Sekulić's or Šubic's lessons on the real school in Pest in front of their domestic house. The Hungarian university was founded only in 1872.[2304]

The comparison between two three-year periods reveals about twice as much new tools with Šubic in charge. He has acquired many more devices for measuring sound, light, and electricity in accordance with Sekulić's and later Tesla's field of research. During his service in Pest, the curator of the Cabinet of physics Šubic befriended Sekulić; therefore, the acquisition of instruments reflects their scientific aspirations, which then directed Tesla's path.

Šubic acquired the following heat-sensing devices at the Cabinet of physics of the Pest Real School: Thermometers with different scales, thermocouple, thermophone for producing tones by infrared radiation as described by B. Higgins' singing flames in which flame heat induced air motion along tubes or jars to produce sound in 1777-1802, a sphere with a ring of different material to demonstrate a thermal expansion of the substance and cryophorus in which the water was rapidly freezing by evaporation due to the Joule-Thomson (1852) phenomenon (Throttling) by the propagation of most gases into the vacuum. Four decades earlier in 1802 William Hyde Wollaston described the events for water vapor,[2305] based on previous findings by Tobias Gruber, the brother of professors from Ljubljana.[2306] Šubic has received relatively few new devices for teaching about thermal phenomena. To study the mechanics of solids, gases and meteorology, he bought about as many devices as his predecessors in the real school in Pest, although he also devoted his research work

to these fields of knowledge. Even later, on the real school in the Rossau district of Vienna, Šubic did not acquire more tools for teachings about heat in comparison with other curators of high school physics labs. The lack of interest in the experimental study of thermal phenomena hampered later Šubic's ideas and, moreover, Sekulić's or even by Tesla's theories.After the fall of Bach's absolutism in 1859, the Hungarian conditions radically changed, and with them the circumstances in Croatia within the then kingdom of Hungary. In 1860, Hungarian speech was accepted as an official language, while foreign-speaking officials had to leave Hungary;[2307] the same happened to “foreign” professors in Croatia. Together with other "propagators of German civilization" Simon Šubic and Martin Sekulić were expelled from Pest. Šubic went to Vienna, where he helped to establish a lower real school (Kommunal-Realschule) in the Viennese Ninth District of Rossau, together with other deported Hungarian professors. There, Šubic was confirmed as a full-time professor in the autumn of 1861.[2308]

During Šubic's three-year service in 1861/62-1863/64, Rossau real school had only three lower grades. After Šubic's resettlement in Graz, in the year 1864/65 the Rossau real school got the 4th and the next year the 5th grade. At the time of the foundation of 1861/62, the real school in the Rossau district of Vienna had nine professors; five of them came from the Pest areas. The director of the Pest school and the director of the Rossau real school of Vienna the clairvoyant Rudolf Steiner’s benefactor Eduard Walser, gave lectures on Geometry and Construction (Baukunst), the professor of Mathematics, Dionis Pospischil (Dionyz Pospíšil) taught geometry; Stefan Stern was a professor of German language, a member of several scientific and pedagogical societies doctor Gustav Ludwig Mayr (* 12th of October 1830, Vienna; † 14th July 1908, Vienna) taught chemistry and natural science. Between 1854 and 1855, Mayr worked at the Cologne Department of the Allgemeinen Krankenhause in Vienna, and between 1856 and 1861 he taught natural science in the Pest, and between 1863 and 1892, he lectured at the Rossau Higher Real school in Vienna. He published many researches of insects in hemipterological frames based on research by Professor J. Sapetz from Rakovac.[2309]

18.5.3 *Sekulić and other Tesla’s Teachers in Rakovac*

Tesla started his schooling at a three-grades lower trivial school in his native Smiljan. In 1869/70 a lower grade teacher Nikolaus Kreković, and the teacher Mathias Sekulić[2310] taught there; Mathias was probably a relative of Martin Sekulić. Between 1867/68 and 1869/70, Tesla attended a lower real school in Gospić for three years. At the higher (main) elementary school in Gospić, lecturers Anton Knežević, teachers Stephan Ratković and Franz Dubravčić and lower teachers Paul Orešković and Elias Janić taught in 1869/70.[2311] In 1869/70 at the brand new building of the lower three-grade real school in Gospić a freshmen Tesla was taught by later director Ivan Balaško, Joseph Vitasek (Wittassek), meteorologist Johann Jamnički (Jamnicky, † 1881) and Joseph Bukvić.

At least since 1866 Tesla's father taught religious instruction on the Gospić Real school, also to his son and Mojo Medić. As the teacher he was officially set up only later. From the foundation in 1860 to 1871, the professor of grammar, Josip Velko (Welko, * 1825; † 1896), governed the Gospić Real school.[2312]

Martin Sekulić, along with Šubic, left Pest in the summer of 1861; the fall of Bach's absolutism has closed their Hungarian gate, while at the same time Sekulić was permitted to enter the Croatian education at the big door. It was more difficult to introduce Šubic, because Slovene lessons were not as quickly established as Croatian. From 1861/62 Sekulić served on a real school in Rakovac in Military (Vojna) Krajina, which is today in the southern part of Karlovac, outside the fortress on the left bank of Korana. On 28 January 1863, the Emperor increased the lower level real school in Rakovac established in 1851/52 into the high real school. In Tesla's time in Karlovac, there was also a gymnasium, which was led by the Franciscans until 1865, just like in Novo mesto. In the era of Tesla, from 1 November 1871 until 1876, the Slovenian historian Ivan Steklasa (* 1846; † 1921) lectured at the grammar school (gymnasium) of Karlovac, followed by the ill Valentin Mandelc (* 1837; † 1872). In 1882/83, the Real school and the gymnasium were merged into the Royal High real gymnasium of Karlovac to save costs; the economizing was already on the stage.

The Ministry of Foreign Affairs appointed nine lecturers of the higher school in Rakovac on 23 August 1863, among them a teacher of mathematics and physics Sekulić as a librarian, professor of engineering, Croatian language and arithmetic. At the beginning of Tesla's schooling, Sekulić became a curator of the cabinet of physics responsible for assembling electric devices[2313] and a supervisor of the school meteorological station; he retained that task after the merger of the school with the gymnasium in Karlovac, which in 1882/83 followed the demilitarization (1871) and the abolition of the Military Krajina on 15 July 1881. During the construction of the new building of the Rakovac Real school in 1863, a botanical garden was arranged. By the buildings Sekulić set up his tools for meteorological measurements. In 1870, the general of engineering corps Anton Mollinary (Molinari baron Monte Pastello, 1820 Titel in Bačka-1904 Soave by Como in Lombardy) as the newly appointed general commander of the Croatian-Slavonic Krajina donated the Milano-made aerometer for measuring the velocities of winds. It costed 300 francs in gold as he really wanted to excel himself at his new duties. Its inventor was Ferdinand Brusotti (1837-1899 Pavia), who perfected electrostatic devices and received a golden medal for his inventing at an exhibition in Alexandria in 1870. Brusotti designed a new type of moisture meter. Sekulić arranged his own design of clock for it. An astronomical observatory was installed on the roof of the Rakovac real school building, but for one reason or another Tesla was never particularly interested in his own astronomical observations although Tesla supported the highly disputed observations of canals on Mars of Schiaparelli.

In the second half of 1863/64 Sekulić was the temporary director of the newly established higher school. The philanthropic mathematician and physicist Ferdinand Peche (* 1820 Pisek in southern Bohemia; † 1898 Innsbruck) was employed in 1849. Peche was among the first trained Czech mathematicians who came to Croatia to teach. Between 1864-1868, Peche was the director of the real school in Rakovac after Sekulić's short intermezzo. Peche received his Ph. D. in philosophy at the University of Prague and specialized at the University of Vienna as well as at the Polytechnic in Vienna. In 1850, he published on the Integration of elliptic functions in a (impossible) closed form and General solution of the 3rd degree equations with avoidance of imaginary forms in the irreducible case in 1851. In 1851, he passed the teaching examination for mathematics and physics in Vienna and became a high school professor. In 1851, Peche was the substitute teacher in Silesian Český Těšín (Cieszyn) on modern Polish-Bohemian border. In 1854 he got the chair of physics at the Joanneum in Graz and habilitated in the same year at the local University for rational mechanics. In 1856 he worked for the Trade Ministerium as a telegraph official of 2nd class in Serbia, which was mostly then Habsburg Vojvodina. In 1857-1864 he was telegraph officer of the first class in Vienna. In

2312 babel.hathitrust.org/cgi/pt?id=mdp.39015062383578;seq=877;view=1up;num=873, www.novosti.rs/dodatni_sadrzaj/clanci.119.html:280070-Nikola-nece-mantiju, www.cro-eu.com/forum/index.php?topic=35.0, Retrieved 19. 1. 2013.
2313 Šešić, 1996, 57; Muljević, 1973, 331.

1864 as director of the secondary school in Rakovac, Peche led his students to independent designs in the field of actuarial science. In that actuarial field Peche published on Life insurance as a convenient means of providing subsistence to youth, organizing schools and promoting trade in 1867 before Tesla's arrival to Rakovac. In 1868-1889 Peche worked with a wide-ranging lecture program as ordinary Professor of mathematical physics at the University of Innsbruck. He left to the Innsbruck community his house and park for the construction of a poorhouse. Peche could be the best available mathematician for Tesla's early formation, but Peche left Rakovac too early. The use of physics textbook of Majer, lectures and rector-ship of Ferdinand Peche, Löffler and Uhlíř testify about the greatest influence of Bohemian mathematical-physics sciences on Rakovac Real School. Even broader, that was a period of expansion of the Bohemian mathematical-technical knowledge in all Croatia and in Ljubljana with Nejedli, H. Mitteis and J. Finger.
At the time of Tesla's education, former professor of economics and natural sciences Sigismund Šoštarić von Letovanićki (Šišman) was the director of the Royal higher real school in Rakovac between 1868 and 1875.[2314]

In 1869/70, besides Sekulić, the Doctor of philosophy Christian Lechleitner lectured in the Real school in Rakovac. After 28 September 1858, Moriz Antolić (Мориц Антолић, Mavro, Moritz, Mavricij, Vid, * 1835 Rakovac; † 1870) taught mathematics and physics in Rakovac. From 26 August 1864, the German Franz Sehr (* 1834 Frankstadt in Moravia) lectured on the German language, geography and history. Since 23. 8. 1863 the history and geography were also taught by Christian Nieper (* 1819 Braunschweig). Since 7. 2. 1862, mathematics and geometric designs were taught by Franz Kreminger (* 1835/6 Pančevo). From 26. 9. 1865, Chemistry and physics was taught by Emanuel Kregez (Kregetz, * 1829 Rakovník (Rakonitz, Rakonic) in the central Bohemia). Since August 21, 1864. Joseph Vitanović (* 1843 Tenja in eastern Slavonia southeast of Osijek) taught Croatian Language. The freehand drawing lectures in Rakovac were entrusted to Carl Pallasmann (* 1840 Schlotten in Bohemia)[2315] after he arrived from Villach in Carinthia on 18 February 1866. Tesla disliked the teachings of freehand drawings. Adolph Waldau was also in Rakovac while the professor of the natural sciences, mathematics and physics was Johann Max Hinterwaldner (* 1844 Schwaz in Tyrol; † 1912) who replaced Joseph Sapetz (* Všechovic in Moravia). Joseph Sapetz was employed on September 26, 1865 and retained his chair of the professor of chemistry and natural science in 1868.[2316] Löffler was not Tesla's favourite, probably because of his physical exercises taught with wooden rifles and the trouble he gave Tesla in first semester of math. On August 23, 1863 Catholic catechist Joseph Jagunić (* 1831 Plešivica in Croatia; † 1891) was employed and from 23 August 1863 the Orthodox priest Nikolaus Živković (* 1839 Meminska in Vojna Krajina) taught.[2317] In 1871, Sekulić, Antolić, Sehr, Kreminger, Kregez, Löffler, Alois Möstl, Joseph Palm, Jagunić and Živković lectured at Real school in Rakovac.[2318] In 1872, the professors were the same, but without the deceased Antolić and Sehr,[2319] since Sehr preferred to become a professor at the Marine Lower Real School in Pula.[2320] Among the twelve professors, Sekulić lectured on mechanical engineering and arithmetic in 1871/72.[2321]

At the end of Tesla's studies in high school of Rakovac, the seventh grade of the Rakovac real school was added in 1871, and in 1871/72 the

[2321] Muljević, 1973, 332; *Siebente Jahresberichte der k. k. Ober-Realschule zu Rakovac in der k. k. Kroatisch-Slavonischen Militär-Grenze* 1871/1782.

Matura exam was performed for the first time. After Matura, Tesla and other students did not have to pass the matriculation entrance exams for higher level technical schools anymore. At the end of his schooling, Tesla was praised for his knowledge of history certainly narrated by his mother at home, but Tesla was warned of his defective mathematics by the professor Löffler. Tesla soon corrected it, as a problem was plainly due to Tesla's recent illness. In any case, Löffler was much less mentioned in Tesla's memories as compared to Sekulić, perhaps also for Löffler's military-oriented gym exercises with the funny rods used instead of rifles. Tesla clearly disliked that kind of stuff.[2322]

On 24 July 1873, a school supervisor in the Krajina, a founding member of the JAZU the Zoologist Živko Vukasović (* 1829; † 1874) and a principal, under the leadership of the school's supervisor led the Matura exam of Tesla and his seven schoolmates. The exam results were signed by the following professors: Sekulić, Löffler, Živković, history and geography professor dr. Petar Tomić (* 1839 Zabok in Zagorje; † 1918), G. Fridrih, Jagunić, the historian Mijo Brašnić (* 1849; † 1868) who praised Tesla, and the meteorologist Johann Jamnicky.[2323]

Jamnicky's reports on Sekulić's meteorological measurements were later supplemented by Marko Mikšić (* 1847). Tomić was awarded with his doctorate at the University of Graz the next year, but as a premature retiree, he retreated to the Russians' headquarters for some time due to political upheaval. Tomić and another historian Brašnić were not in the military service, unlike the other Tesla's Matura examiners. The maturity exam of Tesla and his classmates of different faiths was signed by the catechists of both Christian churches. Tesla received Matura grades for his behaviour, the knowledges of religion, Croatian language, German language, geography with history, mathematics, plane geometry, natural history, physics, chemistry and freehand drawings.[2324]

Sekulić published a lot of his original works outside the school; this must have influenced his admirable student Tesla, who was, of course, of a different religion as the son of an Orthodox priest. The Catholic Sekulić worked in the administration of Pokupski Falcon (Sokol) founded in Karlovac on 5 July 1885.[2325] Sekulić was its president in 1888. Sokol was a nationalistic liberal Slavic gymnastic organization which copied Czech examples. After his retirement, Sekulić even joined the high politics in 1895;[2326] his hatchet fell in honey during the fifth consecutive elections in Perušić north of Gospić on 19. 5. 1897. Of the sixty registered voters, thirty-eight voted for Sekulić. All Sekulić's fans were in government services, which is why they had to vote for retired professor Martin Sekulić who was the candidate of the Hungarian-fans "People's Party". Sekulić's fans of Hungarians, nicknamed Madjarons of the Croatian-Hungarian Party alias *Horvatsko-vugerska stranka*,did not gain great popularity among the Croatian nationalists, but Sekulić probably joined them because of his previous job and because of his connections in Budapest. Sekulić represented the Croats at the congress of Slavic pedagogues in Prague[2327] and Vienna.[2328] Sekulić was re-elected as a Member of the National Assembly of the Kingdom of Croatia, Slavonia and Dalmatia (*Zemaljskom saboru kraljevina Hrvatske, Slavonije i Dalmacije*) on 9 November 1901. Of sixty-two authorized voters altogether fifty-five voted, among them thirty-six for Sekulić, who remained at a representative Member post until his last days. His competitor was Mark Došen, a trader from Gospić. Došen was a member of the Croatian nationalistic Party of Rights (Stranka Prava) which relied on Croatian historical monarchic rights and is still influential in modern Croatian Politics. In 1861, it was established by Nikola Tesla's generation older alter ego Ante Starčević (1823-1896) who was born in Veliki Žitnik near Gospić just across the hill from Tesla's Smiljan on the north to develop into the father of Croatian nationalism in no way friendly to Serbs of Jews although his mother was born in orthodox religion. After the spring of nation of 1848, Ante Starčević entered the democratic Habsburg politics which soon proved to be just another way to spread the endless religious based hatred across Balkans. Tesla was among the rare

Military Krajina natives who was able to escape that endless chain of nationalistic hatreds, but he was eventually unable to prevent the same competitive hatred among his fans who will never agree on questions of Tesla's nationality. But, their funny confrontations in media are still slightly better than their recent mutual bombing. The bloodthirsty quarrels for Tesla's supposed intimate national feelings are funny just until armies are not involved, which could happen any day.

Tesla's imagination was attracted by Sekulić's clockwise rotating sphere-balloon nicknamed egg wrapped with a tin-foil (staniol) paper and connected to an electrostatic machine.[2329] The experiment illustrated the spread of waves through a vacuum. Sekulić informally hired an enthusiastic Tesla for his assistant in experimenting[2330] with the inductor of the Parisian German Heinrich Daniel Ruhmkorff (* 1803; † 1877) for stimulating the light emission of metallic powder in vacuum tubes.[2331] With an inductor, Sekulić studied spectral differences at several accessible levels of air exhaustion. Tesla especially enjoyed Sekulić's experiments with the rotating sphere-balloon object shaped like an egg in the electromagnetic field which gave to Tesla the idea of his later remote control of Wireless Distance Navigation nicknamed Teleautomatics. Sekulić hired Tesla also because Tesla used to live in the school building of Gospić, where Tesla occasionally had his secret chances to visit the smal-school lab even outside the proscribed classes. On 28 February 1863, the later Tesla Graz Professor Pöschl presented to the Styrian Natural Science Society the newly acquired Ruhmkorff's Inductor constructed in Paris in 1851. Pöschl performed the experiments in Geissler's tubes of various fillers, which showed multiple colours stimulated by the ultraviolet and phosphorescent phenomena.[2332]

In the year 1880/81 in Rakovac lab, Sekulić had 277 physical devices and teaching aids. The generous military administration allowed higher salaries with special prizes for lecturers and more expensive equipment than elsewhere in the Habsburg monarchy.[2333]

Tesla wanted to invent his novelties in a stimulating environment. He carefully chose his teaching profession while he realistically counted on the available piece of bread during the demilitarization of his domestic Military Krajina which caused the impoverishment of the centuries-old local men who were accustomed primarily to warfare. Therefore, Tesla decided to study for a teacher of chemistry in Graz, although Tesla later narrated that he studied to become an inventor. The inventor was not an occupation domestic in Tesla's Military Krajina, which proves that Tesla's claim was false as he might have heard some news about professional inventing only later in Graz, Budapest, France, and most of all in the USA.

Sekulić's explanation of the cause of electricity has long been held by Tesla.[2334] Tesla was a respectable pupil, at least in high school, just as Jurij Vega praised his Ljubljana professor Jožef Maffei, even in the glow of Vega's own glory. On the contrary, Carl Friedrich Gauss, as a young man, realized the limitations of his teacher Abraham Gotthelf Kästner, like it happened to Tesla on the Polytechnic in Graz or a little later to Albert Einstein in Zurich.

On 24 November 1874, Sekulić was ranked among the correspondent members of the mathematical-natural class of JAZU in Zagreb, just like Šubic six years before him.[2335] Tesla was chosen as an honorary member of the JAZU in 1896. Tesla was awarded honorary doctorate at the University of Zagreb, which Sekulić certainly liked. Regular members of JAZU were also the inspector Franz Maixner from Zagreb, Michael Kišpatić, and Andreas Mohorovičić. The correspondent members of JAZU were Simon Šubic, the pioneer of Slavic studies Louis Léger (1843–1923) from Paris, Sekulić as retired professor in Zagreb and Mathias Murko as private docent in Vienna in 1900.[2336] Tesla certainly loved to be listed next to the famous chemist Mendeleev among the honorary member of the JAZU after Tesla failed his studies of chemistry in Graz. A lot of professors from Russia, Ukraine, Prague, Vienna and Beograd were among members, but none from Hungary which indicated anti-Hungarian stance of Zagreb academic circles of those times. In Rad

journal of JAZU, Sekulić published eight scientific papers between 1872-1882; in one he quoted his friend Šubic in 1874.[2337] There were six regular and just as many correspondent members in the class of mathematics and natural sciences of JAZU. At the founding of the Academy JAZU in May 1866, Ljubljana veterinarian-editor Janez Bleiweis was elected among the regular members. In the same class, Josip Torbar (* 1824; † 1900) was a regular member of JAZU in Tesla's time as a professor of physics at a higher real school in Zagreb. He was the editor of the RAD (Work) journal of the Academy of Sciences, and he was president of the JAZU from 1890 until his death. Šubić's friend, the Slovenian zoologist Fran Erjavec, was elected as a correspondent member of the mathematical-natural science class on 23 November 1875. Thus, among the twelve regular and correspondent members of the mathematical-naturalistic class of JAZU, as many as three Carniolan natives were elected in the second half of the 1870s. In 1883, the Viennese professor Fran knight Miklošič was one of three members of honour of JAZU. Zagreb professor Matija Valjavec (Kračmánov, 1831 Srednja Bela by Preddvor-1897 Zagreb) was the only Slovenian among twenty ordinary members of JAZU in 1883 after his election in 1880 while Šubic and Erjavec were the only Slovenes among twenty-three corresponding members including Sekulić in 1883.[2338] Ljubljana did not have its own Academy, but the Zagreb guys at least initially wanted to print their works in Slovene language. Šubic worked closely with the Croatian scientific circles, and especially with his friend Sekulić; one after another, they published the first original physical discussions in Rad. Šubic interrupted his participation in Rad when they no longer wanted to print papers in the Slovene language in 1877.

Tesla attended the lectures about physics, mathematics and gymnastics of Augustin Löffler who was nicknamed Ante by his Croatian friends. The historian Mijo Brašnić taught in Rakovac only between 1872-1874. As a beginner, Brašnić started to teach mathematics in 1872. Brašnić helped the publication of Löffler's New Science of Geometry in the Rakovac school reports.[2339] Löffler also led the gym for the Firefighter Society;[2340] he summarized his system by the Czech model. He first published and spoke in Croatian language about gymnastics.[2341] He might have been the son of Johann Siegfried Löffler who was since 1822 the first forest director (Wald Director) of the Karlovac Forest Management.[2342]

Augustin Löffler was a member of Bohemian mathematical society (*Jednota českých matematiků v Praze*) and later went to Bohemia, so he was probably a Czech by nationality. The mathematics of Bohemia was also promoted in the mathematics and natural sciences section of the *Královská česká společnost nauk* (The Royal Czech Scientific Society) founded in 1770, and in the similar section of the *Česká akademie císaře Františka Josefa pro vědy, slovesnost a umění* (The Czech Academy of Franz Josef for Science, Literature and Arts, founded in 1890. *Jednota českých matematiků v Praze* was proposed by the Prague student, the future Ljubljana professor Josef Finger (1841–1925) and his classmates in 1861 and established next year in 1862 under the German and Czech name *Verein fur freie Vortrage aus der Mathematik und Physik* (*Spolek pro volné přednášky z mathematiky a fysiky,* The Association for Free Lectures of Mathematics and Physics. In 1862, the secretary of association Finger lectured for the new association *Jednota českých matematiků* under the title Ueber die allgemeinen Kennzeichen der Theilbarkeit der Zahlen. Dr. Antonín Grünwald joined them soon as president and gave a paper Über die Bewegung eines festen materiellen Systems um irgend eine Rotationsaxe unter dem Einfluss der Schwere und des Erdmagnetismus und Anwendung auf Declinations- und Inclinationsnadel in 1862/63. In 1863/64, Anton Wassmuth (1844-1927) joined the association *Jednota českých matematiků*. J. Dvořák joined in 1864/65, and J. Mach in 1866/67. The

professor Dr. Viktor Pierre also helped a lot, while Alois Vaniček, K. Domalíp and V. Dvořák signed a petition for the *Jednota českých matematiků* in 1866. In 1863 the professor J. Kulik donated a large part of his mathematical library to the Society *Jednota českých matematiků* and after his death, the Society received the second part of Kulik's library from his heirs. In 1868, Prague Professor Ernst Mach offered to the Society *Jednota českých matematiků* his lecture room and cabinet for experimentation. In 1868/69 Anton Láska joined the association *Jednota českých matematiků*. In 1869 k.k. police headquarters confirmed the new statutes of the association, which had 69 members and got the new name as the Union of Czech Mathematicians (Jednota českých mathematiků) with the toponym of Prague omitted. On August 5 and 6, 1870 the Unity of Czech Mathematicians organized the first congress of Czech mathematicians and physicists in Prague. On February 11, 1872, *Jednota českých matematiků* founded the *Journal for Cultivation of Mathematics and Physics*.[2343]

Besides Sekulić, Tesla had many other useful role models among the professors of Rakovac real school. For examples, there was a talented Moriz Antolić. He was a son of the head of the normal school in Rakovac, Imbra Antolić (Имбра Антолић, Mirko, * 1801 Nevinac; † 1854) who finished the surveying school in Bjelovar in Slavonia.[2344] In 1864, Moriz published ten pages of reflections on diamagnetism in the Rakovac real school reports.[2345] The phenomenon has been known for almost a century, but it was identified only by Faraday as the universal characteristic of all substances in 1845, while the matter shows a more pronounced phenomenon in predominantly ferromagnetic and paramagnetic environments. Tesla was very interested in magnetic phenomena and discussed magnetic effects of iron in June 1900.

The professor of natural sciences, of mathematics, and of physics Johann Max Hinterwaldner (* 1844; † 1912) wrote about animals from the Karlovac areas in the reports of the Rakovac real school in 1869/70, 1876/77, 1879/80 and 1880/81. He was initially a substitute teacher (suplent) at the gymnasium in Innsbruck. From 1868 to 1870, he lectured in Rakovac, and then returned to Innsbruck again.

In 1875 Tesla's professor Löffler left Rakovac for Teacher's preparatory school of Budejovice (Budweis, České Budějovice), and he taught in Teacher's preparatory school in Prague later. Mollinary donated 433 florins for building the botanic garden in the Gymnastic-place where Löffler made his famous "gombalište" following the Czech gymnastic model. Mollinary also helped the newly founded bank of Rakovac school. In the second semester of 1871/72 the domestic field-marshal lieutenant von Križ and Brigade-colonel von Hayek visited Tesla's school and spoke to Tesla and his fellow students. The colonel of the Slunj Frontier-Regiment on the south von Gieorgievics (Đorđević), the members of Karlovac firework brigade, and other distinguished guests visited the final gymnastic show on the end of the schoolyear. Tesla's professor of mathematics-physics A. Löffler led the show. In 1871/72, from thirteen students of final 7th class in Rakovac, eleven were designed for military regiments in Croatia or Military Frontier including a noble fellow Levin Šloser knight Klekovski from Križ in Croatia. Two were designed to comparatively far away Banat Regiment according to their domiciles. The exceptions were two of them who were considered[2346] ill like Tesla was pretending to be sick next year, by the arrangement of his father's relatives on high military posts. Tesla could have met Löffler again during his attempted studies in Prague in 1879/80. In 1874/75 in Rakovac,

Löffler's replacement was the supplier of ordinary professor of 5th class the mathematician Ivan Štrkljević (J. Strkljević, Јохан Штркљевић, † 4. 5. 1896 Vinkovci) who left for Zemun in 1878 and died as the professor of High Grammar School in Vinkovci. In 1877 in Rakovac, Štrkljević published on Stefan's mechanical theory of heat. He discussed the kinetic theory of collisions as a source of heat in transformation of mechanical work, which was not completely in accordance with Simon Šubic and his friend Sekulić's views.[2347] Perhaps Strkljević chose his field of research because he had such a meaningful surname as Strk or trk means something like collision in Croatian and Slovenian languages?

Other mathematician in 1875/76 in Rakovac was Wilhelm Marášek who published on the Solar Astronomy in Jahresberichte in that year.[2348] It seems that Sekulić was Tesla's favourite teacher, but Tesla eventually paid homage to his professor of physics without mentioning his name. So, Löffler also could be the one, although most people picked up Sekulić. Tesla probably disliked the freehand drawings of Möstl who went to High Real School of Gorizia on November 7, 1872.[2349] Tesla also hated the young Gjuro Fridrich's freehand drawings, and Löffler's Gym. Tesla never mentioned Kreminger, Jamnicki, or Löffler. Nikola Tesla's freehand drawings were so awful that his father Milutin Tesla had a lot of headaches every summer when he was forced to persuade his own teaching colleague the professor of freehand drawings to let Nikola Tesla to pass into the next class.

18.5.4 Tesla's Rakovac Classmates

Tesla was not the only genius of his generation in his native Military Border area. Among the students of the Rakovac real school there were already many more talented boys before Tesla. On June 27, 1867, the pupil of the 5th grade of Rakovac real school Franjo Plentaj excelled. His paper on mathematical roots was read for the Viennese Academy, which immediately began to send its journals to the proud Rakovac real school.[2350] Franjo Plentaj's work was a great step for a small peripheral student few years before Tesla enrolled in the same school. Plentaj (* 1850-1851 probably in Polish Galicia; † November 24, 1901) published his research on extraction of roots with Viennese academy even before he finished his studies in then six-grades higher real school in Rakovac in 1868. As majority of Military Krajina technical talents except Tesla or Ferdinand Kovačević, Franjo Plentaj was unable to pursuit his initial scientific-technical calls because the Military Krajina authorities expected to employ Franjo Plentaj's talents into the more administrative or pedagogical frames. In 1880-1892 Franjo von Plentaj was head of district Bijeljina and in 1885 he arranged the building of monumental new Orthodox church in Brodac with the help of local magnates after Muslim devastations, therefore his memorial plate was put beneath the church door. In 1882, Franjo Plentaj received a Franz Joseph's ordain. He died as counsellor of government and head of Sarajevo district (Bezirk Vorstadt) before Tesla's former roommate Kosta Kulišić was employed in Sarajevo. Franjo Plentaj's probable son was a popular physician of Sarajevo provincial hospital of 4th gynaecologic-obstetrics department in 1900 Dr. Dragan Plentaj who served in Bosnian city Livno later in 1902[2351] In 1869/70 eighteen students enrolled in Tesla's 4th class. All of them were Croatians, and there were seven guys of orthodox faith among them. In those times the Croatian was not yet a synonym for a Catholic, as also the Orthodox people were noted as Croatians if they were born in Military Krajina or in other Croatian places[2352]. In those times the authorities did not yet specify Orthodox folks as Serbians. Serbian could mean some connection with Serbian state which was not always friendly to Habsburgs. The authorities rather designated the students geographically, therefore as the guys born inside the territory of Croatia including Military Krajina.

Almost all Tesla's classmates were very successful in his Matura class of 1872/73. On Matura written exam in early July and on oral exam performed later, on July 23, 1873, Tesla's best awarded classmates were Tesla's closest friend Mojsije Medić (Mojo, 1855 Ličko Dobroselo east of Gospić-1939 Zemun), and Nikola Prica. Later Prica taught in Military Frontier Real Schools of Petrinja, Zemun (1881/82), and after September 8, 1882 he was appointed as full teacher of geography, Natural History and chemistry and the curator of chemical cabinet in Rakovac. He was the School-Referent of the Greek-Orthodox bishopric of Karlovac in 1901[2353]

Nikola Prica (Priča, * 1853 Korenica; † 1903 Karlovac) was born near the village Prečani which was a native place of Tito's last wife Jovanka. Prica came to Rakovac after teaching at other military secondary schools in Petrinja and Zemun, and he even translated the Czech Zoology just like the Slovenians did in the same era. In Rakovac, Prica immediately published on Clausius' theory of relations among the densities of gases and the mases of their molecules[2354] which was in accordance with views of Prica's teacher and now retired colleague Sekulić who supported Clausius' careful avoiding of the hypothesis of ether. Prica described the initial division of chemistry from physics and did not mention deuterium but still relied on old Dalton's theory of atoms. Prica praised Cannizzaro's (1858) way of finding the mass of atoms and disliked the use of Faraday's electrolysis for that purpose.[2355] Prica narrated the relationship between the density of gases and the weight of their molecules based on the findings of the then available vacuum techniques in the real school reports of 1883.[2356] Prica's kinetic theory was certainly more in the contemporary mainstream while Tesla never abandoned ether.

Prica used Henri Victor Regnault's measurements, but also the work of Jean Baptiste André Dumas (1800-1884) and the Belgian analytical chemist Jean Servais Stas (1813-1891) who co-discovered the weight of carbon. Prica noted E. Ludvig, H. Sainte Claire Deville and his collaborator Louis Joseph Troost (1825 Paris-1911), Biot, Arago, the organic chemist August André Thomas Cahours (1813 Paris-1891), August Friedrich Horstmann (1842, Mannheim-1929 Heidelberg), Liebig's collaborator the Scottish politician Lyon 1st Baron Playfair (1818-1898), the English chemist James Alfred Wanklyn (1834-1906), B. Bineau as Dumas' collaborator Amand Beinau, German discoverer of isomorphism Eilhard Mitscherlich (1794-1863), Gladstone, Hermann Kopp, A. Kekulé, and Pebal's Graz calculations and experiments. Prica explained the dissociation of gases with the Mechanical theory of heat for molecules in gas but also for atoms in molecules whose velocities grow with temperatures[2357].

The other Tesla's classmate Mojo Medić finished the Viennese Polytechnic studies of Natural History and chemistry as Tesla tried to do in Graz. Medić returned as supplied teacher of natural history and physics in German or Serbo-Croatian languages to his native Gospić Lower real school in 1878/79 according to the decision of Graz commission. Tesla worked together with Mojo Medić in Gospić, but only as the replacement of his deceased father as the religion teacher. Medić made a speech on funeral of Tesla's father who used to be Medić and Tesla's religion teacher. Tesla was not on his father's deathbed but might have attended his father's funeral in Divoselo Orthodox cemetery south of Gospić.

According to Prica's publications and Medić's public polemics about the scientific use of Serbian language, they were the early supporters of kinetical theory of atoms and fans of Serbian Piedmont Garibaldi's role in Balkans, at least Medić's published his ideas in that direction. Five student of Tesla's graduating class studied physics-chemistry in Graz or Viennese Polytechnic, and all become professors in Military Border except Tesla, who was unique in failing to finish his studies. Prica, Medić, Kordić and Bielić certainly ashamed Tesla when they returned home with diplomas while Tesla in the same year returned with police

guardians from Maribor as a kind of criminal. The humiliated Nikola Tesla tried to find the solution in gambling until his mother offered him all family possession to gamble it away. Other three Tesla's classmates became the post officers, one became military officer, one economist, and the destiny of other two or three is unknown. With about the half of Rakovac Tesla's classmate students making successful inventors-professors carrier in physics-chemistry, Tesla's class was certainly the best of them all. The mathematicians-physicists Sekulić and Löffler, the chemists Emanuel Kregez and Ivan Jamnicki, as well as their final principal teacher the professor of descriptive geometry Franz Kreminger certainly enjoyed teaching there in Tesla's class. Jamnicki was the only one who taught Tesla in Gospić and continued to do so in Rakovac.

On July 23, 1873 Tesla's classmates who passed successfully the Matura Exam were Julius Bartaković as the later officer with 6th class military stipend of 100 florins (fl), and Ivan Bielić (Jovan) as the professor of chemistry, geometry and geometrical drawing and curator of chemistry lab of Real School in Rakovac later after 1881. Tesla's classmates who passed successfully the Matura Exam were also Isak Kordić (Iso, * Kosinj 25 km north of Gospić) with 6th class military fellowship of 100 fl who studied at Viennese Polytechnic to became a supplied professor of mathematics and physics in Real School Rakovac from 1878 until his death on April 22, 1880. Jovan Ljuština became the postal official after his studies in Rakovac with 6th class military fellowship of 100 fl, while Dragutin Šir later also became official of Post. Tesla was noted on 7th place in Matura exams. Tesla's classmates which were not mentioned on Matura exam in 1873 were Eugen Vuletić with 6th class military fellowship of 100 florins (fl) and additional 150 fl, and Georg Bach who received 6th class military fellowship of 300 fl, as well as Gjuro Amšel as later postal official and Julius König who became the economist. In 1873 seven or eight students with Tesla included passed the Matura final exam. We know the names of 12 of all 13 students of Tesla's final 7th class in Rakovac in 1872/73, just one of them is still missing. We'll dig him out on the next occasion.
After Tesla left, in 1873/74 in August 1874, Rakovac Matura exam proof with award was given to Nikola Božanić, the later professor of Grammar School in Gospić in 1883. In 1873, Nikola Božanić received military stipend of 100 fl. The later official Daniel Krga received military stipend of 100 fl, Ivan Modrušan became the maritime engineer, and Adolf Seifert worked as the officer later. The Matura without award was won by Ljubomir Dobrić (later officer), Ivan Glamočlija (theologian in 1883), Luka Momčilović (official), Milutin Pokrajac (official), and Bogdan Sekirica who became a technician but died before 1882. Bogdan Sekirica received the military stipend of 100 fl, and the Real School paid for his flat during his studies in Rakovac high school. In 1872 thirteen students enrolled in Tesla's 7th class. On the end of Tesla's 7th class seventeen students were noted, among them sixteen Croatians and a foreigner. Nine of them were Catholics (Prica, Šir, König, Bach), eight orthodox (Medić, Kordić, Tesla), but nobody was Jewish. The absence of any Jews in Tesla's class was striking, because six Jews matriculated in 1st class in Tesla's final year 1872/73.

18.5.5 Tesla's Theory of Capillarity

Šubic's friend August Toepler (Töpler, * 1836; † 1912) was the professor of experimental physics and director of the new institute at the University of Graz from August 1868 to July 21, 1876. On 10 April 1875, Toepler lectured in front of the Styrian Science Society about capillarity. Tesla was not in the audience, but he certainly heard a lot about the event.

In 1756 Johann Gottlob Leidenfrost (* 1715; † 1794) designed strongly illuminated droplets with the illuminated limestone of Scottish engineer Thomas Drummond (Drumond, * 1797; † 1840); the image was projected on the screen with a system of mirrors and lenses to the great satisfaction of visitors. The curved surface of water or mercury was indicated by means of a specially adapted device of Louis Jules Dubosq (* 1817; † 1886). Toepler also used a limestone of a new type for a good illumination of his experiments in the lecture room with the help of Oxyhydrogen (Knallgas).[2358]

Just when Tesla arrived in Graz, Toepler finished the new university physics institute in Graz. In 1875, Toepler was severely injured by accidental

[2358] *Jahresberichte Rakovac* 1880, pp. 92-95; *Jahresberichte Rakovac* 1882, pp. 26; Toepler, 1875, L–LI.

fall from the second floor to a bottom.[2359] Shortly afterwards, he went to Polytechnic in Dresden, and Boltzmann replaced Toepler in Graz.

In any case, Toepler's lecture resounded in Graz, although Tesla probably arrived too late to hear him. On January 18, 1876, Tesla, after several months of study in Graz, decided to follow Toepler's example. In front of the society of Serbs in Graz, Tesla lectured like Toepler before him under the title "About capillary tubes". Another member of the society Gjuro Dimić (Ђура Б. Димић) lectured on modern theories of the [2360]creation and development of the Earth,[2361] certainly in Darwinist spirit. In 1898 and 1903, Dimić translated the sacred texts of Athos Holy Mountain (Ἅγιον Ὄρος). Tesla associated with Dimić, Jovan Grbičić, Graz University student of philosophy romantic writer later professor of Karlovci Grammar School Paja Marković-Adamov (Pavle, Паја Адамов Марковић, 1855 Novi Karlovci in Srem-1907), Joca Šević, Milan D. Nikolajević who authored *Uput za čitanje karata i planova. Krokiranje i izvidjanje sa krokiranjem. Sa zasebnim atlasom slika* published in Beograd by Davidović in 1912, and Kulišić. As the group of Graz students, including Tesla's classmates, they helped to establish the Society Srbadija to counterbalance German students' organisations on 19 December 1875. Tesla's lecture was put in the eighth place of the program in Almanac published in Novi Sad in 1884. Novi Sad was a centre of the Serbian minority in the Habsburg Monarchy in those times in 1884. On 10. 4. 1897 N. Tesla of New York donated 100 florins to the Srbadija organization.[2362]

Similarly, Mihajlo Pupin received his doctorate from the same subject of capillarity in Berlin in 1889. A quarter century after Tesla, Albert Einstein began his physics research path with capillarity in 1901. In 1906 the same phenomenon was researched by Niels Bohr, who was then also just the beginner.

Tesla's first step in the physics of kinetic theory, vacuum and capillarity was based on the lectures of his professor Sekulić. In the third quarter of the 19th century, two papers on kinetic theory were printed in high school reports of Croatian areas, while Sekulić published on kinetic theory in Rad journal of JAZU in 1874. In 1876 in Rad and in the reports of 1877 the Bohemian A. Laska published yet another discussion with similar content. Ivan Benigar's discussion on kinetic theory, published during his studies in Vienna, can be considered as a Slovenian although he later taught in Croatia; the Croatians, of course, jokingly called him "Janez.". The kinetic theory and capillarity were in the air and Tesla caught that wind. The mainstream physics was a natural way of the initialization of the young Tesla even if he began to follow his own ways soon enough.

Among the Austrian researches we also included the born Austrian Ferdinand Redtenbacher (* 1809; † 1863), who, after studying and working for three years at the University of Vienna, moved to Switzerland first in 1834 and then to Karlsruhe in 1841 in 1841. His influence on Habsburgian places remained significant through his second cousins: the Viennese chemist Josef Redtenbacher (* 1810; † 1870) and the Prague physician and zoologist Ludwig Redtenbacher (* 1814; † 1876). Emil Herrmann (* 1840, Dognecea in Hungary in present-day Romania; † 1925) worked both in the Habsburg monarchy and in Germany. He studied the technique in Vienna (1856-1858), in Pest and in Banská Štiavnica (Schemnitz) in Slovakia between 1859 and 1863. Between 1863 and 1867 he worked in Austria and later in Banská Štiavnica.

Several researchers of kinetic theory, among them Šubic, Wenzel Svoboda as colleague of doctor of philosophy priest Gregor Tuschar, professor,[2363]Czechs Franjo Mathon and Antun Laska, Joseph Polák, Karl Klekler and Julius Puluj (* 1845; † 1918) worked or studied on both sides of the border of Leitha river during the period from 1855 to 1875. included secondary school reports from the Hungarian half of the monarchy if researchers native in the Austrian half of monarchy published there including Prlekija native Josip Križan in the Varaždin grammar school, Klekler on the Higher Real school in Pančevo,[2364] Mathon and Puluj in Rijeka, Wenzel Svoboda in Bratislava, and Polák at the Catholic Gymnasium of the Piarists in the city of Kecskemét, southeast of Budapest. Austrian research includes posts directly subordinate to Vienna in the Military Krajina (Pančevo, Varaždin, Rakovac), but not the published works of Hungarian researchers, such as the findings of Kálmán Szily von Nagy-Sziget (1838; † 1924) in Pogg. Ann. and Phil. Mag. In addition, we did not include Andreas baron Ettingshausen (* 1796; † 1878), physiologist Carl Friedrich Wilchelm Luddwig and Joseph Wilhelm Grailich (1829; † 1859). All three of them were important organizers of the research of kinetic theory in Vienna, and especially excelled as Stefan's teachers; among their publications there are no major research on kinetic theory, although they were very close to them.[2365]

Between 1856 and 1875, thirty-two Habsburgian (Austrian) researchers published 48 works in support of kinetic theory and the same amount against it. However, three more researchers have accepted the novelty nicknamed kinetic theory. Of course, in the following years of Tesla's studies in Graz and Prague, Stefan's co-workers dominated. Apart from the Mach's chair in Prague, they occupied all the most important positions in the monarchy. Between 1850 and 1875, nine Austrian secondary schoolteachers supported kinetic theory, with only four against it. The secondary school teachers thus predominantly supported the novelty, since they were mostly raised in that kinetic spirit

[2365] Ludwig, 1856; Ettingshausen, 1857.

during their Viennese schooling with Andreas Ettingshausen and his successor, Jožef Stefan.

It cannot be argued that support for kinetic theory would depend on the distance between Vienna and the place in which the individual writer investigated. In the era of Tesla's schooling in Sekulić's class in Rakovac, opposition to kinetic theory and Boltzmann's statistical mechanics was still possible. Soon afterwards, it was no longer fashionable except for E. Mach's networks; the new theory became part of unambiguous basic lessons at universities, and attention of Tesla and other upcoming researchers re-orientated to vacuum technology as the foundation of modern electrical engineering two centuries after its humble beginnings. During Tesla's studies at the secondary school in Rakovac, papers about electromagnetism already prevalent among the discussions in high school reports in Germany and t the Habsburg Monarchy.[2366]

Tesla passed the exam in statistics (political arithmetic) at Graz in Rogner's class and, of course, he knew Boltzmann's statistical theory of entropy. Like Boltzmann or Einstein, due to classical teaching at Sekulić's class, Tesla could never really agree with the statistical notion of invisible movements in a vacuum, as presented by quantum mechanics after Tesla's meeting with Abraham in Tesla's 40th year. Šubic and Sekulić[2367] preferred to replace Redtenbacher's Dynamides with Clausius's kinetic conception of an atom, where ether was unimportant.

Redtenbacher's Dynamide played a similar role in central Europe as did Bošković's altering force in the British islands where it was fertilized by Maxwell's repulsive force decreasing with the fifth exponent of distance.

On 27 June 1871 Šubic gave up Redtenbacher's theory in favor of Clausius's kinetic conception of heat, which did not offer any special model of atom.[2368] Šubic's friend Sekulić endorsed a similar opinion,[2369] but Sekulić (July 9, 1873) contradicted Šubic by sharp critique of the very concept of ether half of a month before Tesla's Matura (24 July 1873) while referring to Šubic's earlier text from 1862.[2370] Šubic did not explain his opinion on Redtenbacher's Dynamides, but the existence of the ether was advocated by Šubic in his textbooks and even in some scientific works.[2371] Contrary to dynamics, Šubic's acceptance of atomistic theory is also witnessed by his description of the capillary force with molecular forces that transform the droplet into the oval shape of the molecule[2372] and are indeed the forces of cohesion.[2373]

18.5.6 Ether

In 1874, the sharp critic of the use of the ether in vacuum physics was Sekulić, but above all, of course, Ernst Mach disliked such things which nobody could touch. Jožef Stefan's beliefs in physics differed deeply from the assumptions of Simon Šubic, Sekulić or Tesla. In February 1883, Tesla was in Strasbourg. The opening of the 3rd International Electrical Exhibition in Vienna under Stefan's technical guidance was on August 11, 1883. Tesla could not miss that. But Tesla was just a telephone expert. So, Tesla may not personally know two decades older Stefan unless he met Stefan a little before Stefan's death when Tesla visited Vienna in April 1892[2374] to attend his mother's deathbed during her last hours. Stefan and most of Andreas Ettingshausen's other pupils including Boltzmann, were the fans of ether consisting of constantly moving molecules resembling the (larger) molecules of ordinary matter.

Simon Šubic has rejected this model of ether already during his service in Pest.[2375] In his early discussions Šubic opposed the physical theories of matter without weight, among which the ether dominated.[2376] In the textbook for higher grades, Šubic used the ether hypothesis only for the spreading of light in the first edition of the foreword dated in "the summer of 1860".[2377] In later editions of his textbook[2378] and in his papers,

[2378] Šubic at his second edition in 1867 on p. 17, in third edition in the year 1874 on p. 26.

Šubic accepted the hypothesis of the ether, although ether did not play any very important role in his theoretical models. Šubic obviously changed his opinion on the ether between 1864-1867. Karl Robida supported Šubic's initial doubts about the ether, when he commented on the Šubic's book of 1862. Robida said that he was looking forward to "rejection" (Verwerfung) of the matter of various ethers[2379] that Šubic would publish in future. None of them even went as far as Sekulić, who even called ether a "fictitious means... by which naturalists jump out of the frying pan into the fire... an imagination tool of avoiding problems."[2380] At least partly, Sekulić referred to Šubic himself.[2381]

Šubic was reluctant to deny the existence of an electrical immobile media-substance. Šubic otherwise resolutely rejected the imponderable matter in his optics and thermodynamics.[2382] However, this does not necessarily mean that Šubic was emancipated from ether as the first 'in Šubic's papers' as Tesla's teacher Sekulić claimed.[2383]

Sekulić did not see a significant difference between the ether that emerged from Fresnel's wave theory (of light) compared to the other weightless substances from the 18th century and the early decades of the 19th century, such as caloric. Šubic initially rejected the description of the ether as a substance without weight.[2384] It seemed to him that we were returning with such an ether to already abandoned but secretly surviving forms of theory. However, Šubic later acknowledged the existence of a weightless ether for the transfer of a light wave[2385] as well as for the transfer of a thermal wave[2386] in a vacuum. With this he denied Sekulić's claims.[2387] Between the submission of Sekulić's papers on July 9, 1873 and the submission of Šubić's paper on 26 March 1874 for the press in the same newspaper Rad only half of a year passed. The contradictory statements of the two authors testify that in this time, shortly after Tesla's graduation, they were no longer in close personal or written scientific contacts, although Sekulić named his former colleague from Pest Šubic as a friend.[2388]

Sekulić relied to the assumption[2389] that Šubic (1862) was not favorable to the ether, especially not in the theory of heat; there may have been the least need for ether in the theory of heat because heat was not primarily related to radiation. This duality of the treatment of the same phenomenon in various circumstances later enabled Planck (1900) to partially quantify the electromagnetic field, which, before Einstein's intervention in 1905, focused only the radiation, not the absorption. Such double criteria were the roots of modern dualism of quantum mechanics, which links the properties of particles and waves in matter.

The development of the concepts of ether was and still is extremely complex. In his papers in 1874 Sekulić tried to ignore ether completely. The main researchers of Boltzmann's ideas did not come to serious doubts about the necessity of ether before Einstein. Perhaps the doubt of atomism and ether among scholars waited for the turn of the century. Because of his illness Boltzmann has almost ignored much of his contemporary development of physics in the last decade of his life. He did not mention Planck (1900) and Einstein (1905) in his Viennese lectures, and thus closed himself behind the fascicles of classical physics, which he himself most helped to change!

Tesla was close to that nice Boltzmann's opinion, because Tesla did not accept Sekulić's judgements in 1891 when Tesla claimed that the ether-related thing can be called electricity, although theyθ are not the same.

Tesla had electric charge for the state of tension of the ether, much like the Liverpool radio pioneer Oliver Lodge. One year after Tesla on 14 August 1894 during his Oxford lecture, Lodge transmitted radio waves as evidence of their communication possibilities. So, Tesla opposed Einstein's deletion of the ether from the theory of relativity. Tesla did not agree that ether was just a superfluous unnecessary medium.[2390]

Tesla and Kelvin knew, respected and cited each other as they were both fans of Bošković.

Therefore, Tesla's vison of the dynamic ether was related to Kelvin's ether in motion which than could behave as a solid transmitting the transversal electromagnetic waves while the same ether behaves like highly exhausted fluid gas resembling vacuum needed for the frictionless movements of cosmic bodies. Tesla's molecules rotated their ether like the Dynamides of director of the Polytechnic in Karlsruhe the initiator of scientific mechanical engineering Ferdinand Redtenbacher (* 1809 Steyr in Upper Austria; † 1863 Karlsruhe). Ferdinand Redtenbacher published the theory of smallest ultimate material elementary nuclei with envelopes from the ether in 1852 and 1857 in the times of Tesla's birth.[2391] Redtenbacher's theory was based on Regnault's Parisian experiments and on the model of vibrations in solids. Ferdinand Redtenbacher gained a great initial support in Habsburg monarchy thanks to the key position of Ferdinand Redtenbacher's younger second cousin the chemist Josef Redtenbacher (1810 Kirchdorf by Krems-1870) in the Viennese academy and Josef's brother the director of Viennese natural history museum correspondent member of the Viennese Academy Ludwig Redtenbacher (1814 Kirchdorf-1876 Vienna). Josef Redtenbacher used to be F. Mohs and Liebig's student.

Tesla proposed few great thought experiments about gravity, just like Einstein. Tesla stated in June 1900: "To make the disk rotate by the force of gravity we have only to invent a screen against this force. By such a screen we could prevent this force from acting on one half of the disk, and the rotation of the latter would follow. At least, we cannot deny such a possibility until we know exactly the nature of the force of gravity." Tesla indeed repeated the old model of Newton's friend Nicolas Fatio de Duillier (1690) and Bošković's friend Georges-Louis Le Sage (1748). Even Einstein's relativity did not give the final answers to Tesla's puzzle five years later, nor in continuing Einstein's efforts, until both guys passed away.

Tesla's dynamic gravity replaced Einstein's curved space with the equivalent forces. Non-Euclidian geometry of Einstein's general relativity was beyond Tesla's mathematical education, while the classic concepts of forces were clearly Tesla's favourites. To make himself more popular and to compete with Einstein's laws, thermodynamic laws or quantum mechanical laws, Tesla declared his own law without any energy in matter except the energy attracted from the outer media.[2392]

18.5.7 Northern Light and Fluorescence

The examination of spark and lightning enabled Sekulić's studies of fluorescence in Tesla's student years. Stokes assumed that the force between the molecules is in a simple relationship with their distances from the equilibrium position. It depends on the composition of the ether and the distance

[2391] Tesla 1956 (1891) L-15-17; Redtenbacher, *Principien der Mechanik*, Mannheim 1852; *Das Dynamiden-System*, Mannheim 1857.

[2392] Tesla 1937; Pandur 2018.

between the molecules of the substance, while the vibration amplitude is infinitely small in comparison with the size of the molecules. The period of oscillation of the molecules is different from period of oscillation of the particles of the ether, and the frequency of fluorescence is reduced by decreasing the amplitude.[2393] In 1853, Anders Jonas Ångström did similar experiments independently of Stokes, but he came to the opposite conclusion. According to him, the atoms of the ether should even oscillate quicker and fluorescent light would therefore have a higher frequency than absorbed.[2394] Josip Torbar (* 1824; † 1900), professor of physics and natural history at a Higher Real school in Zagreb, supported Olmsted's theory of the cosmic genesis of the northern light in his paper North Dawn (*Sjeverna zora*). Torbar rejected the theory of August de la Rive about electricity as the causative agent of the northern light (Aurora Borealis). The following year Tesla's professor Sekulić published a discussion on the electric nature of the northern light: Polar Dawn as the effect of the Earth's Electricity (*Polarna zora kao učinak zemaljske munjine*).[2395] Sekulić opposed Torbar, and he even compiled his own machine for the simulation of northern light (Aurora Borealis) in laboratory and the spectral analysis of its light,[2396] which was certainly used by Sekulić's informal assistant Tesla. Tesla later repeatedly magnified that idea with his lightning sparks in Colorado Springs. Sekulić relied on very early assumptions about the electrical nature of weather phenomena, including the report of the red rain of Edmund Halley from 1731 and the ideas of Benjamin Franklin.[2397] Sekulić made immediate use of Kirchhoff's books which he bought with the help of the librarian in Rakovac Kreminger in 1872/73 after the Aurora Borealis was seen in his areas on October 14th and 15th, 1870. Such events are extremely rare on Mid-European geographic longitudes. Therefore, everybody took his or her opportunity to examine and explain them because many curious funny Central-European folks preferred to see Aurora Borealis as a kind of miracle. Sekulić backed the Geneva professor Auguste Arthur de la Rive's (1801-1873) theory, which soon lost its popularity. De la Rive tried to prove with spectral analysis the similarity of Aurora Borealis, lightning, and ordinary discharge which stimulated Sekulić to do the same in 1872. Sekulić observed the ultraviolet part of Solar spectrum after he studied Tyndall's book *Heat* which Kreminger also bought in Rakovac in 1871/72.[2398] Sekulić's Aurora Borealis research with Tesla's as his informal assistant was admired by the reader of Sekulić' paper William Garrow Lettsom (1805-14/12/1887).[2399] The expert of astrophysics, crystallography, electrical engineering, geology and spectroscopy William Garrow Lettsom took a personal interest in Sekulić's exploration of the northern light (Aurora Borealis) and (ultra)violet light of the Sun. Lettsom became famous in 1858 when he joined the Manchester magnate Robert Philips Greg and published his well-documented high-profile history of English geology. Lettsom was a diplomat in Europe and South America until 1869; then he retired. He was a member of the Royal Astronomical Society in London since 1849. During Tesla's studies at Sekulić's class in the mid-1870s, Lettsom mainly studied minerals with their optical properties and a comet visible in 1882.

Lettsom's intervention was described as the discovery of ultraviolet rays in the Solar spectrum by JAZU secretary Josip Torbar at the celebratory JAZU session.[2400] On 15 August 1873, the most important German physical journal supported Sekulić's theory of interference which was translated from the Croatian language. [2401] On 15/8/1873 the translation of Sekulić's theory of interference[2402] pleased Kirchhoff's student Friedrich Wilhelm Feussner (* 1843; † 1928) who came across the similar discovery previously but preferred to support Sekulić without disputing his priority.[2403] Feussner ensured that he already noticed Sekulić's interference; but he was not running for a priority, but mostly supplemented Sekulić's observations. Feussner advocated the wave–theory of light. Feussner later taught kinetic theory of gases in Marburg University from 1887

until 1901/1902.[2404] Feissner tried to upgrade Sekulić's theory even with the citations of Bošković's student Karl Benvenuti (1716-1789).[2405] The international echoes of Sekulić's research soon gained attention of his superiors in Zagreb, as well as the admiration of Tesla and his classmates.

Figure 18-40: Portrait of Tesla High School Professor Martin Sekulić with His Own Signature

Robida opposed the entropy law of R. Clausius, while Šubic devoted his most relevant publications to criticism of Boltzmann's H-theorem in 1872 against the framework of emerging statistical mechanics. Next to them, Sekulić entered the shabby soil of the theory with the claim that the electromotive force or the energy of the Voltaic battery is proportional to the produced heat. Sekulić tried to prove that the energy of the chemical reaction is proportional to the produced heat, perhaps as the example of the Energy Conservation Law adopted in Sekulić's boyish years by R. Mayer and Helmholtz. Sekulić thus supported the theory of his friend Peter Jørgen Julius Thomsen (1826-1909) from the University of Copenhagen published in 1854 and assisted a decade later with the theory of Marcellin Berthelot (1827-1907). Sekulić's conclusion was in accordance with the opinion of Sekulić's friend Thomsen. However, the Energy Conservation Law was already out of the mainstream focus of those days which was predominantly directed to the 2nd law of thermodynamics in Sekulić's era. Thus, Sekulić's assumptions did not coincide with the results of the measurements of the former director of the Munich Polytechnic Wilhelm von Beetz (1822-1886). Sekulić also opposed J. Stefan's student the director of former Loschmid's Viennese Physics-Chemical Institute Franz Serafin Exner (1849-1929),[2406] and Sekulić even contradicted Hermann Helmholtz's ideas developed in Berlin in 1882. Helmholtz explained that affinity is not related to the heat of the chemical reaction, but with the maximal possible work of the reversible reaction.

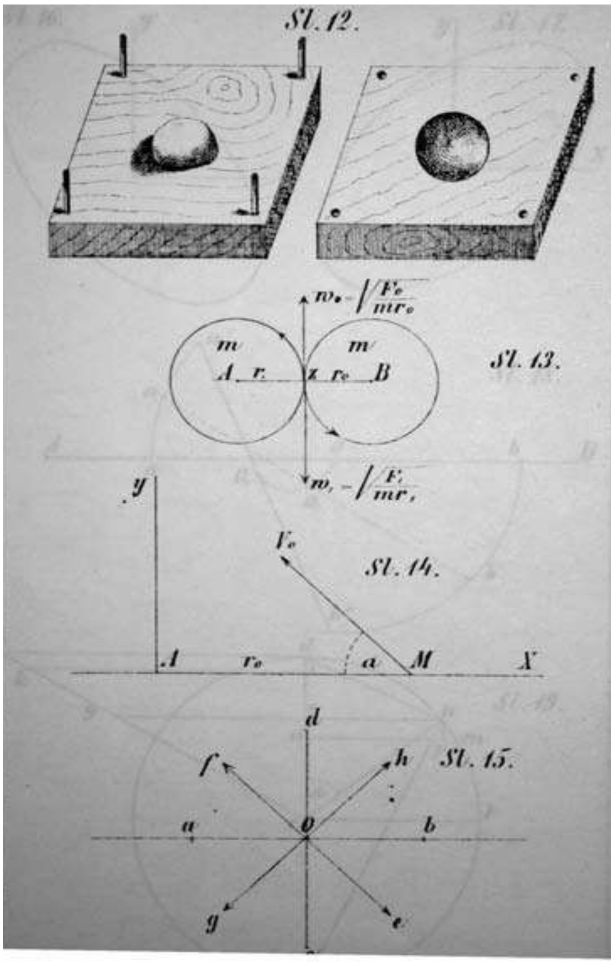

Figure 18-41: Third Group of Sekulić Illustrations of Molecules (Sekulić, 1874).

Sekulić's claim was the generalization of Thomsen-Berthelot's principle, which Thomsen set in 1854, and Marcellin Bertelot supplemented in 1864 with thermal theory of affinity. Such a discovery was too great achievement for secondary school

[2404] Feussner, 1873, 561.
[2405] Feussner, 1877, 323.
[2406] Sekulić, 1881, 171–172; Šešić, 1996, 72.

professor Sekulić; although he published his ideas in Zagreb, he presented just his summaries in Vienna and Leipzig.[2407] Immediately after Sekulić's announcement in Zagreb, Hermann Helmholtz in Berlin in 1882 used the entropy law to prove that affinity was not given by the heat evolved in a chemical reaction but rather by the maximum work produced when the reaction was carried out reversibly. However, while kinetic and mechanical energy can be converted into heat in every case, only in restricted cases can heat be converted into kinetic and mechanical energy. Hence, the equations describing chemical processes involving heat could not always be reversed, therefore the affinity does not determine the heat of the chemical reaction, but the maximum work in a reversibly derived reaction. Of course, the disappointed defeated Sekulić abandoned his scientific pursuits and became so much louder in politics. Helmholtz was certainly not his match.

That was the final blow to the just retired Sekulić whose paper Helmholtz's backer Jožef Stefan read in front of Viennese academy on June 21, 1878. As a secretary, Stefan prevented the publication of Sekulić's ideas in Viennese academical networks as did Wiedemann in *Annalen der Physik* in Leipzig. Wiedemann just became the new editor of *Annalen der Physik* as a replacement of the deceased Poggendorff's (1796-1877). In his paper, Sekulić cleverly stated that Poggendorff supported ssimilar theory, but Poggendorff died too soon to use those novelties. Tesla and his classmates initially certainly shared Sekulić's views as Sekulić's students because Sekulić's international fame was very challenging in Rakovac. In the same way, Stefan shared the wave theory approach of his high school teacher Robida but abandoned it soon after Stefan became the Viennese student. When Sekulić published his total critique of reality of ether in article printed in Zagreb Academic journal Rad in 1874, Tesla was certainly immediately informed during his illness in Gospić. It was probably unclear to local Croatian non-experts that Sekulić was challenging the mainstream physics (and chemistry), but it became obvious on June 21, 1878, when the uncrowned chief of Habsburg physics Jožef Stefan refused to back Sekulić. It is hard to guess which side did Löffler pick up in that quarrel because he published only on mathematics and gymnastics. In that time Tesla had a bad luck with his lenders and took a shelter in Maribor, but such Stefan-Sekulić's scandal was loud enough to catch his ears because even later Tesla was interested in Sekulić's whereabouts in Tesla's letters to Tesla's domestic friend Mojo Medić. In that Tesla's Maribor times it was probably a high time for Tesla to choose sides and he eventually backed the ether and Sekulić's opponents. On 20h May 1891 (sic!) Tesla stated for *American Society of Electrical Engineers* in New York Columbia University where Mihajlo Pupin lectured that the ether is connected to matter and may be called electricity although both are not completely identical. Tesla's electrical charges were a state of strength of ether like in the contemporary visions of Oliver Joseph Lodge (1851-1940). Tesla even stated that „light can be nothing else than a sound wave in the ether; and the shorter the waves the more penetrative they will be." The wave of sound is certainly a longitudinal wave. Indeed, Tesla "forgot" to mention the fact of transversal waves of light in the times when even Helmholtz believed in the longitudinal component of electromagnetic waves.

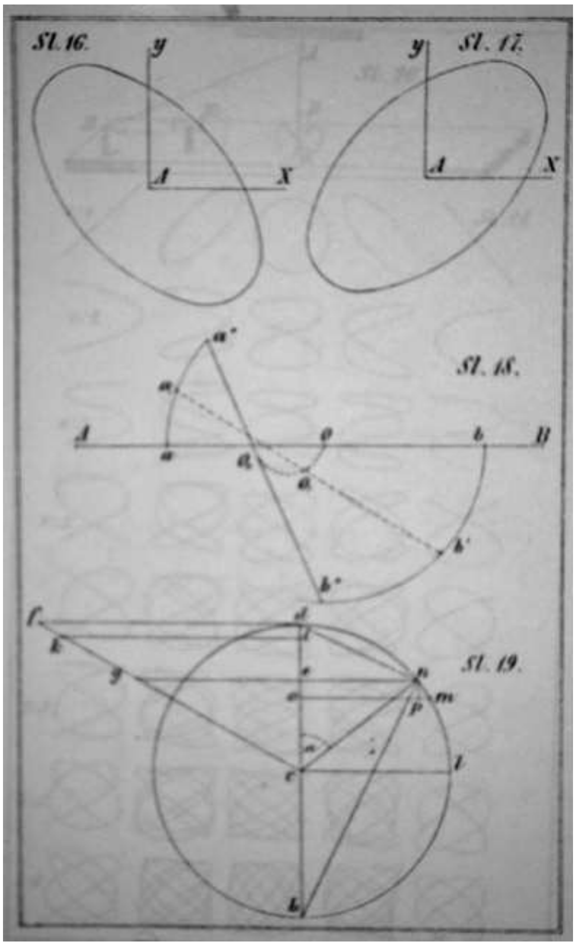

Figure 18-42: The fourth group of Sekulić illustrations of molecules (Sekulić, 1874)

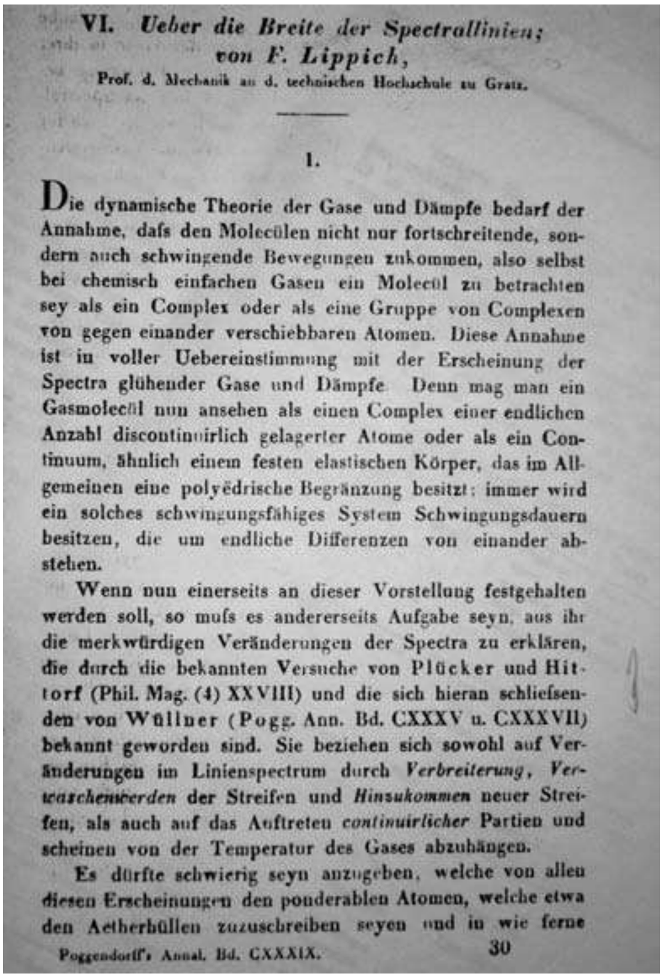
[2407] Sekulić, 1881, 190; Sekulić, 1878 Anzeiger, 129.

During that time, Tesla was already quite anchored in electrical engineering, and Sekulić again met Tesla a decade later in Zagreb. Sekulić was certainly extremely proud of Tesla's class, as half of Tesla's classmates studied chemistry-physics in Vienna or Graz, but only Tesla did not finish his studies. Tesla's ideas required the American business moneymaking confirmations under Niagara Falls before they were accepted in his native domestic European environment.



VI. *Ueber die Breite der Spectrallinien;*
von F. Lippich,
Prof. d. Mechanik an d. technischen Hochschule zu Gratz.

1.

Die dynamische Theorie der Gase und Dämpfe bedarf der Annahme, dafs den Molecülen nicht nur fortschreitende, sondern auch schwingende Bewegungen zukommen, also selbst bei chemisch einfachen Gasen ein Molecül zu betrachten sey als ein Complex oder als eine Gruppe von Complexen von gegen einander verschiebbaren Atomen. Diese Annahme ist in voller Uebereinstimmung mit der Erscheinung der Spectra glühender Gase und Dämpfe. Denn mag man ein Gasmolecül nun ansehen als einen Complex einer endlichen Anzahl discontinuirlich gelagerter Atome oder als ein Continuum, ähnlich einem festen elastischen Körper, das im Allgemeinen eine polyëdrische Begränzung besitzt; immer wird ein solches schwingungsfähiges System Schwingungsdauern besitzen, die um endliche Differenzen von einander abstehen.

Wenn nun einerseits an dieser Vorstellung festgehalten werden soll, so mufs es andererseits Aufgabe seyn, aus ihr die merkwürdigen Veränderungen der Spectra zu erklären, die durch die bekannten Versuche von Plücker und Hittorf (Phil. Mag. (4) XXVIII) und die sich hieran schliefsenden von Wüllner (Pogg. Ann. Bd. CXXXV u. CXXXVII) bekannt geworden sind. Sie beziehen sich sowohl auf Veränderungen im Linienspectrum durch *Verbreiterung*, *Verwaschenwerden* der Streifen und *Hinzukommen* neuer Streifen, als auch auf das Auftreten *continuirlicher* Partien und scheinen von der Temperatur des Gases abzuhängen.

Es dürfte schwierig seyn anzugeben, welche von allen diesen Erscheinungen den ponderablen Atomen, welche etwa den Aetherhüllen zuzuschreiben seyen und in wie ferne

Poggendorff's Annal. Bd. CXXXIX. 30

Figure 18-43: The beginning of Lippich's Graz discussion of cathode ray tubes in a leading physics journal with an explanation of the results of Plücker and Hittorf experiments in Bonn (Lippich, 1870).

18.5.8 Tesla in Graz

Sekulić and other professors in Rakovac were so enthusiastic about Tesla that Tesla did not want to continue family traditions in a military or priestly skirt, but he also wanted to become a teacher himself. In the autumn of 1875, he enrolled in the pedagogical or chemistry-technological field of the Polytechnic (Technische Hochschule am Joanneum zu Graz). In the previous year Graz Polytechnic its curricula and students' opportunities into four faculties: building, mechanical mechanics, chemistry, technology and forestry.

Ferdinand Lippich[2408] studied in Prague as a guest of his aunt Tereza. He was the professor of the graphical statics, theoretical and applied mechanics in Graz Polytechnic between the years 1865-1874. Just before Tesla's matriculation he became the ordinary professor of mathematical physics at the University of Prague. In Graz he was the rector from 1 October 1870 to 30 August 1871, and the Dean of the Mechanical School (Engineering Faculty) from 1 October 1869 to 30 September 1870. Initially, like his friend Ernst Mach during his Viennese youth, he defended the winning branch of the kinetic theory, referring to experiments with cathode ray tubes of Julius Plücker and his student Johann Wilhelm Hittorf. By his precise vacuum experiments, Lippich determined the influence of the motion of gas molecules on the width of the spectral lines.

Figure 18-44: Vacuum researcher of the Slovenian genus Ferdinand Lippich, the son of a doctor from Ljubljana and the grandsons of Upper Carniolan folks (Gorenjci) from Kropa. There flows the stream of Kroparica to the mouth of the Lipnica stream, which may have lent the name to the Lipič (Lippich) family of Carniola.

2408 http://www.landesmuseum.at/pdf_frei_remote/Lotos_62_0013-0018.pdf consulted on February 2, 2013.

With Clausius-König's kinetic theory Lippich researched the spectra of oxygen in Geissler's tube at the same time when Tesla's professor Sekulić published similar spectral analysis. Lippich continued with that topics in Prague, criticized the electrodynamics of Franz Neumann (1877), and experiment of Leipzig professor of astrophysics Johann Karl Friedrich Zöllner performed in 1874.[2409] Zöllner visited Crookes immediately after discovering a radiometer with more spiritual inclinations, just like later Tesla. Lippich retired in 1910 and Albert Einstein took over Lippich's Prague chair. The thrifty Einstein and his bride from the Military Krajina did not want to buy new mattresses, even though the old ones full of funny insects were most probably fatal for their marriage.

Figure 18-45: Tesla's Graz Professor of Mathematics, Moritz Allé (* 1837; † 1913)

Lippich's obituary was accomplished by the main Prague supporter of Einstein's theory of relativity Anton Lampe (* 1868, Pest; † 1938)[2410] who got his PhD with Boltzmann in 1893. The research of kinetics theory and atmospheric electricity of Ferdinand Lippich and his nephew Paul Czermak became very fruitful in Tesla's hands.

Tesla studied with all his forces in his first year of the Polytechnic in Graz, and to a considerable extent also as a sophomore. He did not pass any examsduring his third year until January 1878. His principal professors at the Polytechnic School were Jakob Pöschl for theoretical and experimental physics, and Moritz Allé (* 1837, Brno; † 1913) for higher mathematics.[2411] Johann Rogner taught the differential and integral calculus, mathematics I, about the volume of solids of revolution, and applied arithmetic. On 23 January 1937, in his thanking for the honorary doctorate of the Technical and Montanist High School in Graz, Tesla in his telegram remembered the rector Allé with gratefulness, as well as the friendly lessons of Rogner and even[2412] Pöschl maybe with his fingers crossed.

On the first year of his Graz Machine engineering Studies[2413] in 1875/76, Tesla also excelled in Maly's exam of organic and inorganic chemistry. Tesla passed his exam in Graber's class in zoology. Tesla was also successful on the exam in the class of S. Šubic's enemy full professor of botanic appointed in 1869 Hubert Leitgib of general botanic with demonstrations, and in Josef Bart's class of popular mechanical engineering. Tesla also excelled with his knowledge of French language at Plisnier's class. Of course, this was twice too much for and average student in Graz. Thus, the chemist Heinrich Schwarz (Karl Leonhard, * 1824; † 1890) was worried. Heinrich Schwarz was the dean of the chemistry-technical faculty from October 1, 1874 to 30, September 9, 1876, and next served as the rector from October 1, 1876 to 30 September 1877. Heinrich Schwarz wrote to Tesla's father to describe Nikola as a star in experimental, theoretical and linguistic terms.[2414] At the same time, Schwarz warned Tesla's father against Tesla's excessive efforts which could ruin Tesla's health. That's why the father Milutin received Nikola with coldness when Nikola arrived in Gospić for holidays. The humiliated Nikola understood his father's behavior only few years later after his father passed away

The most important Tesla's Graz connection with Slovenian science was **Ferdinand Lippich** (Lipič, * 1838 Padua; † 1913), the son of Ljubljana physician Fran Viljem Lipič (Lippich, * June 13, 1799 Spišská Nová Ves (Igló) west of Košice in Slovakia; † December 12, 1845 Vienna). It's a pity that Lippich left Graz for Prague University just before Tesla matriculated in Graz, but they certainly met later during Tesla's studies in the University of Prague. Ferdinand's grandfather physician Jožef (* February 5, 1761 Ljubljana) descended from Venetian family of Boka Kotorska which settled in Kropa in Upper Carniola. Ferdinand's father began his studies of medicine in his 18th year in Pest which was a part of later Budapest. He was promoted in Vienna on May 26, 1823.[2415] In the same year he became the second physician of the Ljubljana city, in 1832 he was the provisory district physician, and next year he became the deputy head of hospital. He invited to Ljubljana his sister Tereza (* 1800). In Venice Tereza married the psychiatrist in Graz and later in Prague dr. Franc Koestl (Köstel, * 1811 Cerklje in Upper Carniola; † 1882 Graz). She became a talented student of painter Matej Langus. Fran Viljem Lipič (Lippich) had problems with Ljubljana monks who were homeopaths as opposed to the authorities and therefore Lipič accepted the chair of internal medicine in Padua in 1834. In 1841 he left for Viennese University as the predecessor of Jožef Škoda (* 1805; † 1881), the mentor of Jožef Stefan. In 1826 Fran Viljem married the Styrian orphan Alojzija Kajetana Kahr (* 1805 Ilz). They had a dozen children but just five of them grew up, among them Wilhelmine (* 1831 Ljubljana; † 1885 Prague) and Friedrik (* 1832 Ljubljana). Wilhelmine married her father's assistant the psychiatrist Josef Czermak (* 1825/26; † 1872). After his PhD with Boltzmann focussed on Maxwell's kinetic theory of gases, their younger son Paul Czermak (* December 27, 1857 Brno; † 1912 Innsbruck)[2416] taught in Graz University and replaced the Lower Carniolan Ignac Klemenčič (* 1853; † 1901) in the University of Innsbruck in 1901. Paul Czermak and Klemenčič's research of the interference of electrical waves in air influenced Tesla's inventions.

when Nikola found Heinrich Schwarz's letter in the attic of the flat of his parents in Gospić school. Tesla did not listen to Schwarz's lectures, but he did the exams in the class of his successor in the position of Dean of the Faculty of Chemistry and Technology (1876-1878), the beginner of physiological chemistry Richard Maly (1839; † 1891).

Figure 18-46: After Tesla was expelled from the Polytechnic, the former Graz rector chemist Heinrich Schwarz gave a lecture on the Philosophy of Technology on December 20th, 1879 in front of the Styrian Natural Science Society.2417 Tesla's Graz rector in 1876/77, the president of Styrian society and professor of technical chemistry Heinrich Schwarz (1824 Eisleben in Prussia-1890 Eberswalde in Prussia), discussed the philosophy of technics which always interested Tesla very much. Schwarz's speech was summarized on page LXV. Tesla did not hear the speech as he was already exiled to Gospić earlier in that year. Heinrich Schwarz taught in Graz from 1865 until his death and published a lot of popular works like Die Chemie und Industrie unserer Zeit, oder die wichtigsten chemischen Fabrikationszweige nach dem Standpunkte der heutigen Wissenschaft: in populären Vorträgen in Wroclaw in 1857-1858.

[2417] Schwarz, 1879, LXV

In his second year in Graz, Tesla first wanted to be brilliant again, but his experience at home with his worried father convinced him that he should take it easy. Therefore, Tesla performed excellent exams only in Allé's mathematics III, in Stark's technical mechanics and in Pöschl's technical physics. Tesla announced his studies of Stark's analytical mechanics too but did not show up at the exam;[2418] this could have caused later anger of the ignorant rector Stark. At the same time, Tesla successfully passed the exam of Rogner's composition of numbers and selected chapters from political arithmetic, which was then popular useful title for statistics. Tesla also intended to learn Pöschl's fundamentals of wave theory, Karl Pelz's Theory of conic sections and the lectures of Johann Rumpf on mineralogy.[2419] Unfortunately, Tesla did not come to those exams. Karl Pelz published on similar advanced topics in his book Die Axenbestimmung der Kegelflächen zweiten Grades in Vienna in 1874. In 1876, Pelz published in program on the Real School of the Habsburg Silesian Duchy of Teschen (Cieszyn, Těšín). From 1878 to 1880, Pelz was the assistant professor in Graz and taught until 1896, while his mathematical books were published also in Prague in 1893 and 1895. Pelz polemized with the painter Karl Wilhelm Pohlke (1810 Berlin-1876 Berlin) who established an important geometric theorem for the axonometric projections. Johan Rumpf taught from 1875 to 1911. From 1st October 1886 until 30th September 1887 he was the rector in Graz. Tesla's ideas of crystals as the kinds of living matter were certainly based on Rumpf's lectures and Rumpf's book *Über den Krystallbau des Apophylits* published in Vienna in 1880.

In his third academic year 1877/78 in Graz, Tesla again planned many mathematical or engineering exams, as well as French and English language exams, but Tesla did not appear on any test of his knowledge. Karl Pelz's continuation of conic sections was among those lectures, as well as different useful aspects of general and applied mathematics with determinants or analytical mechanics. and general and special (Spezielle) Theoretische Maschinenlehre. The mathematical lectures should have been especially useful for Tesla and his later misunderstanding of Einstein's theories. The gambling and fine Styrian wine looked like much nicer to the extravagant Tesla of those days even if there were not much Styrian girls involved.

Jakob Pöschl (* 1828; † 1907 Graz) of Tyrolean family was known among students for his unchanged evergreen suit that he wore for two decades; a similar reputation dogged his peer from the University of Graz, Simon Šubic. Between 1865 and 1867 Pöschl was the first dean of the Graz Mechanical School (Maschinenbauschule), the dean of general lectures in 1870/71, and the rector of all Technical Hochschule in Graz in 1871/72. During Tesla's studies in Graz Jakob Pöschl served as the dean of Tesla's Faculty of Chemistry and Technical Sciences between 1878 and 1888 with some intervals in-between. Pöschl became an Imperial Adviser. With his one generation younger love Magdalena born Nömayer (* 1849) Pöschl had two sons: the professor of Chemistry and rector of the High School of Commerce in Mannheim Victor Pöschl (* 1884; † 1948) and the University of Karlsruhe professor Theodor Michael Friedrich Pöschl (* 1882; † 1955). Jacob's grandson was the classic philologist Viktor Pöschl (* 1910; † 1997).[2420] Jakob Pöschl was an ordinary highly respected guy of his class which provided absolutely no reason for his quarrels with Tesla. Except for the fact that Tesla in his early twenties was an impossibly difficult student as he claimed to be cleverer than his professors who were nearly of the age of Tesla's father. There are just few professors who could understand that heavy challenge of having a real genius in their class, and Jakob Pöschl did not happen to be one of those rare exceptions. Einstein had no better luck with his Zürich professors Heinrich Friedrich Weber and Jean Pernet.

At the University of Graz, Tesla probably met a friend of his high school professor Sekulić, the associate professor of meteorology and thermodynamics Simon Šubic. Perhaps he even knew Klemenčič who tried to replace the retired Pöschl in vain in 1888. Klemenčič's students' measurements of the speed of electromagnetic waves between 1871/72 and 1875/76, which he continued as Boltzmann's demonstrator in 1877/78, must have been extremely interesting for Tesla. At

the beginning of Tesla's studies, Ludwig Boltzmann returned to Graz as one of Europe's leading experts in the new Maxwell's theory of electromagnetism which enabled Tesla's inventions. Among the most famous inhabitants of Graz, in the era of Tesla's studies was a mathematician and chief school inspector Franc knight Močnik who retired in 1871. Tesla was surely aware of Močnik's influence as a schoolboy in Lika, but not more than a lecturer at a lower real school in Gospić after his expulsion from Maribor. The Graz student Tesla read the works of William Crookes about radiation in a vacuum cathode ray tube and the alleged fourth aggregate state of matter. Three decades later, Tesla visited old Crookes in London, where they talked more about William's influential reverberating research of spiritism than about vacuum techniques.

On 28 February 1870, Pöschl lectured on a "flying flame" at the Styrian Natural Science Society. The phenomenon was described by the chemist Bryan Higgins (*1737/41 Collooney in Sigo in Ireland; † 1818/1821) as a "chemical harmonic" in 1777 after Higgins studied in Leyden with Pieter Musschenbroek's heirs and before Higgins visited Russia. Among Higgins's students in his School of Practical Chemistry in London was Higgins' later antagonist the chief promoter of electrostatics Joseph Priestley in 1770s. Faraday observed the stratification of the flame projected by sunlight as a shadow on white paper. In 1818 Faraday published his first physics discussion "about the flying flame" of various gases in the tube and encouraged many further researchers. In 1845, Faraday as a greatest Tesla's model began to explore the "magnetic properties of gases", and his discoveries were supplemented by the pioneer of cathode ray tubes Plücker.

Diamagnetism of the flame was discovered by a Genova university professor of physics, a provincial of Piarists Michele Alberto Bancalari who was born in 1805 in Chiavari by Genova. He reported on his discovery to a physics group of the 4th assembly of Italian naturalists in the debate on the universality of magnetism in Venice on September 21, 1847. Three months later, Zantedeschi added his own research as a professor of physics and mathematics at Lyceum of St. Catherine in Venice and a member of the Institute there. Diamagnetism of the flame had roots in Kepler's theory of the magnetic Sun that attracts the planets, but Poggendorff as the editor of the German translation of Zantedeschi's paper disliked that connection. Zantedeschi sent a copy of his discussion to Arago in Paris and to Faraday to London, knowing about Faraday's research of diamagnetism. In December 1847, Faraday published his experiments with Richard Taylor, the editor of Phil. Mag. Faraday found that heated air and flames are more diamagnetic than the cooled air and are therefore separated from it during their flow to the pole of the magnet. Bancalari's discovery convinced Faraday about the temperature dependence of diamagnetism, which he noticed only in gases, but not in solid matter and liquids. Faraday made numerous comparisons between the diamagnetism of various gases and its dependency on the temperature. After recovering from illness, Faraday continued the research of diamagnetism of gases at normal temperatures with atmospheric measurements three years later.

Figure 18-47: Portrait of Tesla's Professor Pöschl. His suit is probably the same as always

The flame had also attracted the attention of young Karl Ferdinand Braun, who continued Hittorf's (1869) research of increased conductivity of flame in one direction in Geissler's electronics cathode ray tube at the University of Marburg between December 1877 and 1878. Braun was Kundt's assistant professor in Strasbourg university between 1880-1883 when Tesla and Puluj frequently visited there. Braun was probably not Tesla's best friend but figured more as a competitor.

Figure 18-48: Pöschl's discussion of the "flying flame" in the collection of the Styrian Science Society, whose secretary Pöschl was at that time[2421]

In 1878/79 just after Tesla escaped from Graz, Pöschl's Graz lectures of technical physics were collected by Pöschl's student Tesla's younger classmate, later assistant electrician engineer Josef Schaschl (Šašel, Šašl, * 15. 2 1860 Slovenji Plajberk (Windisch Bleiberg, Svinčnica); † 1908/9).[2422] Josef Schaschl (Šašel) was a descendant from the famous gunsmith family in the areas of Borovlje (Ferlach) south of Klagenfurt, but not in Ferlach, Kappel by Drau River (Kapla) or Glainach (Glina) where the relatives of J. Stefan's mother used to produce guns. His relative was the ethnologist Josip Šašel (Wieser, 1883, Windisch-Bleiberg-1961 Municipality of Prevalje). Josef Schaschl's other relative gunsmith-painter Jakob Šašel (Schaschel, 1832 Kappel (Kapla pri Borovljah)-1902 Karlovac) worked as the famous gunsmith in Karlovac after 1857. Tesla knew him very well and in Karlovac Tesla frequently met his son the writer-priest Jakob Šašel (13th April 1862 Karlovac-1911 Mahićno suburb village of Karlovac). Josef Schaschl himself later published first-class work about the electrical engineering, coatings of metals using galvanic current and most of all on the high-pressure two-cylinder steam engine of Tesla's "friend" Westinghouse in the monthly magazine of the Hydrographic Institute in Pula.[2423] The marine electrical engineer J. Schaschl made the devices convenient for ships without the use of electric motors, so he did not mention his former classmate Tesla. In July 1888, George Westinghouse (* 1846; † 1914) approved and then applied Tesla's American patents for induction motor and transformers. J. Schaschl (Šašel) was not a member of the Styrian Natural Science Society, despite the leadership of his superior Pöschl in Styrian Natural Science Society.

Schaschl (Šašel) also never habilitated or taught in Technical Hochschule of Graz. After Pöschl's retirement, Schaschl (Šašel) worked as an assistant in electrical engineering in Pula in 1889. On October 27, 1890 he became an engineer of the second grade in marine office of Technical office in e) department of electrotechnics of Military-Marine together with Wladimir Čermák, while Ernst Codelli served as Marine-Commissary adjunct of 1st class and a member of Marine-Control-Office in 1893-1896 and dr. Joseph Potočnik was the physician of Marine Staff headquarters. On 1 November 1894 Josef Schaschl (Šašel) became a first-class engineer in marine office of Technical office in e) department of electrotechnics of Military-Marine where he served under his Jewish boss Moses Burstyn (1841 Lvov-1908) who invented dry cell as the Senior engineer of 2nd class promoted into 1st class on 1. 5. 1896.[2424] Josef Schaschl (Šašel) became a senior engineer on November 1, 1906, but he was listed no more in Marine in December 1907. Among Josef Schaschl's (Šašel) collaborators in Pula was the physician general Jožef Potočnik (Josef, 1841 Zgornji Razbor near Slovenji Gradec-1894 Pula), the father of the famous Herman Potočnik Noordung. Jožef Potočnik worked in Pula military bases. He fought at Vis under Tegetthoff's command and became general; he was the father of the inventor of the geostationary satellite the engineering captain Herman Potočnik - Noordung (1892 Pula - 1929). While Potočnik's family name was noted in Slovenian transcription in Marine official listing, Schaschl (Šašel) preferred to use the German transcription as Schaschl, which echoes the national consciousness of both guys. In autumn 1887, Peter Salcher continued his experiments in Pula. The naval officer Karl Josef baron Codelli (1846-1878 Pula) served in Pula. After his graduation, between 1894 to 1897, his son, a navy officer inventor of the television Anton baron Codelli (1875-1954) also served in Pula as See-Aspirant ranged in 1. 10. 1894 among See-Cadets of 1st and 2nd class as Josef Schaschl's

(Šašel) younger colleague electrician.[2425] In any case, we can think that the Habsburg command of military Navy in Pula has become obsessed with new technical ideas, including Slovenian ones.

Table 18-5: Pöschl's lectures on the use of electricity included many Tesla's favorite areas

Electrotechnical Telegraphy
Electrical Watches
Electromagnetic Machines
Galvanoplastic
Production of Conductors for Lightning Rods
Electric lightning ignition techniques for underwater mining

Table 18-6: Pöschl's lectures about thermodynamics

The science of fuels
Dynamics of gases in pipes
The theory of tunnels and chimneys
Stoves and furnaces, gas production
Dynamics of heat, radiation and transmission
Boilers and steam generators
Drying and evaporation equipment
The heating and ventilation of the houses

In 1879, according to Josef Schaschl's (Šašel) notes, Pöschl lectured on the "Use of electricity" and "Use of thermodynamics", but he did not have enough time for the announced "use of Optics". He could have presented his studies of light in lectures on Theory of Waves, which Tesla did not attendas a sophomore.

On 25 January 1868, in front of the Styrian Science Society, Pöschl demonstrated experiments on an underwater telegraph cable over 2,000 miles long between Ireland and Newfoundland. New Yorker Cyrus Field project succeeded on September 1, 1866 with the help of William Thomson, later Lord Kelvin. They used lower voltages than in the previous failed trials.

At the end of 1875 or perhaps hardly in January or February 1877, among other things, Pöschl in Tesla's class tested brand new dynamo. He used DC of 400 A, 25 V by design of Zenobe Gramme and his entrepreneur Hippolyte Fontaine (* 1833 Dijon; † 1910 Hyères on Mediterranean coast). The item was invented in 1873 in the Edison's Parisian Laboratory, and sent the same year to illuminate the Viennese World Exposition. During his classroom lesson Pöschl sharply rejected Tesla's novelty about the adaptation of the Gramme's invention for alternating current.[2426] Pöschl was an expert and Tesla was just a kid! At the same time, on 11 November 1875, Pöschl introduced Gramme's invention to the Styrian Natural Science Society.

Gramme's electric motor was tested as the power supply for lighting of the Heilman factory in Mühlhausen in eastern Franconia on a three-state border with France and Switzerland.[2427] The textile manufacturer Johann Heilmann (* 1771; † 1834) developed their family company. He was followed by his older son Josua Heilmann (* 1796; † 1848) with the invention of machine embroidery. The invention brought the money to Josua's son Johann Jacques Heilmann (* 1822; † 1859), and especially to his grandson Jean-Jacques Heilmann (* 1853, Mülhausen; † 1922), the French inventor of modern electric locomotive and steam-electric car.

Pöschl's apparently first-class international connections enabled his forecasting the transition of steam engines to electric motors. He immediately began to calculate the savings in terms of coal consumption of the steam engine compared to the expensive maintenance of zinc-carbon galvanic battery with acids or stearin

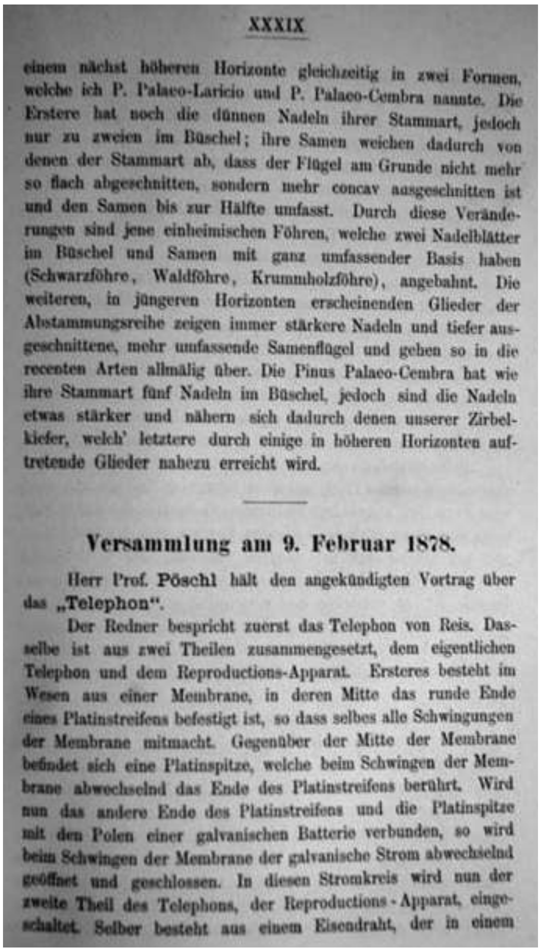
candles. He anticipated the conversion into alternating current with brushes, which Tesla sharply disliked due to unwanted losses by sparkling.

Pöschl announced the distribution of electricity through telegraph cables, which soon no longer helped. In favor of Tesla's later Niagara project, Pöschl announced power plants because he was aware of the daily losses of 3,000 horsepower by the lifting locks via intermediate agricultural consumers in Port-à-l'Anglais near Paris, built in 1864 and repaired in 1869. The lifting would be much cheaper with an electric motor, powered trough the conductors of current nearer to Paris.[2428] Of course, Pöschl knew that Aristide Bergès (* 1833; † 1904) set up the first hydro power plant in Lancey, 15 km northeast of Grenoble, for the paper mill operation on September 28, 1869.

Figure 18-49: Pöschl on the Belgian Gramme's electromotor, whom by the way he introduced as Frenchman.[2429]

In his lectures on Electromagnetic Machines, Pöschl certainly also showed Geissler's or even Crookes' vacuum tubes. Tesla knew a lot about them already from Sekulić's lectures in Rakovac.
After Pöschl's retirement he left the Styrian Science Society. In 1888 he was replaced by the former Toepler's and Boltzmann's assistant Andreas' grandson Albert von Ettingshausen. Obviously, the candidate Klemenčič was not so pleasing, since his Slovenan nationalism was not welcomed at the leading academic positions in nationally divided Styrian Graz. With Ettingshausen in Graz, a new wind has blown up.

A dozen years after Tesla's studies Karl Pichelmayer (* 1868; † 1914) become a mechanical engineer and subsequently Ettingshausen's electrical engineering assistant.[2430] Of course, this could also happen to Tesla, although Europe would be even less hospitable to Tesla's precious gigantic towers than the USA.



XXXIX

einem nächst höheren Horizonte gleichzeitig in zwei Formen, welche ich P. Palaeo-Laricio und P. Palaeo-Cembra nannte. Die Erstere hat noch die dünnen Nadeln ihrer Stammart, jedoch nur zu zweien im Büschel; ihre Samen weichen dadurch von denen der Stammart ab, dass der Flügel am Grunde nicht mehr so flach abgeschnitten, sondern mehr concav ausgeschnitten ist und den Samen bis zur Hälfte umfasst. Durch diese Veränderungen sind jene einheimischen Föhren, welche zwei Nadelblätter im Büschel und Samen mit ganz umfassender Basis haben (Schwarzföhre, Waldföhre, Krummholzföhre), angebahnt. Die weiteren, in jüngeren Horizonten erscheinenden Glieder der Abstammungsreihe zeigen immer stärkere Nadeln und tiefer ausgeschnittene, mehr umfassende Samenflügel und gehen so in die recenten Arten allmälig über. Die Pinus Palaeo-Cembra hat wie ihre Stammart fünf Nadeln im Büschel, jedoch sind die Nadeln etwas stärker und nähern sich dadurch denen unserer Zirbelkiefer, welch' letztere durch einige in höheren Horizonten auftretende Glieder nahezu erreicht wird.

Versammlung am 9. Februar 1878.

Herr Prof. **Pöschl** hält den angekündigten Vortrag über das **„Telephon"**.

Der Redner bespricht zuerst das Telephon von Reis. Dasselbe ist aus zwei Theilen zusammengesetzt, dem eigentlichen Telephon und dem Reproductions-Apparat. Ersteres besteht im Wesen aus einer Membrane, in deren Mitte das runde Ende eines Platinstreifens befestigt ist, so dass selbes alle Schwingungen der Membrane mitmacht. Gegenüber der Mitte der Membrane befindet sich eine Platinspitze, welche beim Schwingen der Membrane abwechselnd das Ende des Platinstreifens berührt. Wird nun das andere Ende des Platinstreifens und die Platinspitze mit den Polen einer galvanischen Batterie verbunden, so wird beim Schwingen der Membrane der galvanische Strom abwechselnd geöffnet und geschlossen. In diesen Stromkreis wird nun der zweite Theil des Telephons, der Reproductions-Apparat, eingeschaltet. Selber besteht aus einem Eisendraht, der in einem

Figure 18-50: Tesla's professor Pöschl on phones at the end of Tesla's studies on February 9, 1879; the first part of the lecture in front of the Styrian Science Society.[2431]

Ettingshausen soon assumed a new modern lecturing on Electro-technique, and in the inaugural rector's speech at the Polytechnics Graz, he remembered Tesla's former schooling in Graz in 1893. On November 11, 1894, Ettingshausen, with the general approval of the Styrian Natural Science Society, showed Tesla's image of the high voltage alternating current,[2432] which proved again that Tesla has fully established himself in his Graz Alma Mater, unfortunately a decade too late. The

retired Professor Pöschl did not publish much about sciences anymore in those times.

Despite Pöschl who had somewhat strange relations with Tesla, Tesla liked two other important teachers of mathematics in Graz. Pöschl did not publish much, except in the Proceedings of the Styrian Natural Science Society, while Moritz Allé published with the Viennese Academy and by the Prague Mathematical Society. Moritz Allé began his studies in Vienna and got his Ph.D. from the University of Kiel in 1860. Allé got his first jobs in astronomical observatories: in 1856-1859 in Vienna, in 1859-1862 in Krakow, and in 1862/63 in Prague. He got the chair of mathematics in Graz Polytechnic in 1867 and became rector in 1875/76, just in the time when Tesla matriculated. After Tesla left Graz, Allé became the professor of mathematics under the rector Ernst Mach in recently split German part of the University of Prague in 1882, but in 1896 he left for Viennese Polytechnic.

Other Tesla's mathematical teacher was Johann Baptist Rogner (* 1823; † 1886) who graduated at the Viennese Polytechnic in 1845. He was hired as the assistant lecturer of mathematics there and later taught in Graz High Real School. In 1851 he became the very first assistant professor (docent) of higher mathematics in Graz Polytechnic and he got the chair of elementary mathematics in 1866. In 1874 Rogner was employed as the professor of higher mathematics just before Tesla matriculated. He was also the director of proof-examinations of professors at Graz High Real Schools and Merchants-Commercial Schools. In 1869 Rogner discussed the new inventions of calculator in front of Styrian Naturalists Society whose member he was.[2433] He criticized the calculator on tooth wheels of the factory owner Peter Hlubek from Villingen in the Land of Baden. A similar invention received US patent no. 30264 on 2 October 1860. In 1875 it was probably the same P. Hlubek who patented a piston pump in Vienna.[2434] Rogner also wrote Kepler's biography.[2435] Kepler was certainly the most important scientist who ever worked in Graz and Tesla inherited many Keplerian mystic visions. Did Rogner tell Tesla that Protestant Kepler planned to take Zrinski's shelter from hostile Graz based Catholics in Tesla's own Military Border in modern Croatia but eventually reached just Petanjci in now Slovenian Prekmurje on September 28, 1598?

From 1866 to 1870, Tesla's professor Josef Bartl (* 1850, Friesach north of Klagenfurt; † 1925, Graz) studied at the Polytechnic in Graz, and in 1875 he began teaching as an adjunct there. He habilitated in 1878 when Tesla had already left Graz. Between 1886 and 1890, Bartl lectured at the Polytechnic in Brno, and then returned to Graz and published Die Berechnung der Zentrifugal-Regulatoren in Leipzig with A. Felix in 1900. Ten years later, Bartl published *Zur Theorie der Zentrifugalpumpen*.

Figure 18-51: Tesla's Graz Mechanical Engineering Professor Josef Bartl

18.5.9 Tesla in Maribor

In early 1876 in Graz Tesla lived in high first floor (*Hochparterre*) in Attemsgasse No. 8 of Graz Geidorf district. The street was called after the counts of Attems who possessed their huge manors in Lower Styria and in Habsburg Littoral. In 1875/76 Tesla's roomie was the second-year student of jurisprudence, history and geography the Bosnian Kosta Kulišić who later became the

professor at Serbian Maritime School in Srbina of east Herceg-Novi (1 October 1881-1 April 1883), at Grammar School Kotor, at Dubrovnik, at Split in 1900, and at Sarajevo but not at first Gymnasium where Zoch used to be a director and where Gavrilo Princip studied in 1910-1912. Because of money troubles Tesla later moved to Hans-Sach Gasse, Jahngasse 5, and Heinrichstrasse 11 in Graz. Two of his student flats still exist, but other two were replaced with new buildings.[2436] Tesla excellently studied his first year in Graz and was good enough in his second year, but he made no examinations in his third year until January 1878 which caused his move to Maribor. Tesla never abandoned his later famous way of using official clothes and his Graz tailor was Jožef Murko from Maribor. After the advice of the law student, later military priest Milan Panajotović († before 1936), Tesla borrowed money from Jožef Murko. Kosta Kulišić also borrowed from Murko and paid him extremely high interests of over 9%. Tesla had no better luck and soon went broke. Once he joked that Murko should pass Tesla's mathematical exam to get Tesla's stipend of 210 florins. In 1868 Habsburg's laws against usurers like Murko were abolished. In 1871, Jožef Murko worked as a tailor (*Schneidermeister, Kleidermacher*) in Bischofplatz No. 2 in Graz, but he moved to Bürgergasse No. 18 in inner city of Graz downtown where he lived in the years 1877-1886. Josef Murko was not buried after a funeral ceremony in Graz-Dom church which served his domestic areas of Bürgergasse, nor in Graz-Mariahilf church nearby. Additionally, starting in 1882 his Graz relative Jakob Murko (7. 7. 1851 Ptuj-16. 2. 1916 Graz Schlossberg (City Hill) no. 36) was tailoring in Maifredygasse No. 10 in Graz. On 8. 11. 1880 in Graz Jakob Murko married Maria Meichenič widow Malleg.[2437]

Tesla's empty pockets forced him to leave Graz; he did not have enough money to continue his studies, while at the same time he tried to avoid military obligations. Tesla had to abandon the city of Graz where his indebtedness to Murko troubled him. His incomes were too scarce to pay Murko off and to continue his studies. At the same time, Tesla tried to avoid military service which he and his father disliked. The Army threatened him because Tesla received the stipend of Military Border according to the order issued on September 22, 1876. The stipend was eventually achieved with a little help of the husband of Tesla's aunt Stanka the colonel Dane Branković whose guest was Tesla during his studies in Rakovac. The Military Border authorities agreed to support three years of Tesla's studies in yearly amounts of 420 forints payable in two rates on the end of each semester. Tesla had to provide the proofs of the exams accomplished each time before he could get the fellowship money. The main problem was the part of the agreement which demanded at least eight years of Tesla's service for the military after he finishes studies.[2438] As a child of Military Border folks, Tesla was a part of military unit as soon as he was born despite of the fact that Habsburg authorities were abolishing the Military Border system as an old-fashioned relict in Tesla's times. The lost military jobs soon forced majority of Military Border people to leave their native country with Tesla and Mihajlo Pupin somewhat included. But Tesla had his vision and didn't care much for any military appointment. To avoid the uniform or military border professorships, Tesla twice unsuccessfully asked *Matica Srpska* officials for their stipend. On October 14, 1876 as a student who finished the first year of Chemistry-Technological Faculty, Tesla applied for the first time, and he did it again in November 1878.[2439] He was not successful in the first place because he already had a stipend while he was a priest's son and not some poor fellow. On the second occasion Tesla was probably already in Maribor but he pretended that he recovered from illness with a wish to continue the studies in Graz. The *Matica Srpska* officials eventually did not believe him, while nobody suspected that the young extravagant Tesla could be a genius. It is probable that Tesla spent

scholarships on gambling and had nothing left to pay for school fees for the third year of the Polytechnic.

Tesla certainly learned about Maribor from his Graz classmates. Tesla got his data from his several months younger classmate, the son of the Maribor regimental doctor, Ferdinand Wittenbauer (18 February 1857; † 1922, Graz). Early orphaned Wittenbauer had an uncle major who enabled his brilliant studies at the Graz Real School, which he completed in 1872. He studied for five years for a degree in the engineering department of the Graz Polytechnic which he received in 1879. In 1883/84 he visited Helmholtz and Kirchhoff, and in 1886 he took over Stark's Chair of Pure and Technical Mechanics and the Theory of Mechanical Engineering at the Polytechnic of Graz. There he became the beginner of the graphic methods of kinematical geometry and the rector of the Polytechnic in 1911/12. At the same time, he excelled as a lyricist and successful dramatist of student life. He described conflicts between nationality colored student organizations from a relatively sharp German nationalist position.[2440] In 1901 he published a survey of turbines and pumps with elements of vacuum techniques.

In a letter dated 12 March 1878, the rector of the Polytechnic, Stark, informed the military authorities in Zagreb that Nikola Tesla was excluded from the list of students. On 31 March 1878, Zagrebians answered and asked the rector, until which day the Tesla scholarship was paid. Does Tesla really lie sick in the hospital, as Tesla's father claimed? On 15 April 1878 the Rector approved the payment of Tesla's scholarship until January 1878; but he did not believe that Tesla could be in the hospital or even anywhere near Graz. On 4 May 1878, the military authorities in Zagreb ordered the rector to stop paying Tesla's scholarship and inform Tesla about that decision.[2441]

In the spring or at the latest at the end of 1878, Tesla left Graz. He was denied the grants because he did not pass any examinations in 1877/78; he no longer had a scholarship, and his father also stopped sending his support. He could not, in any case, pay back debts to Murko. Tesla was depressed, and some acquaintances were afraid that he succumbed to suicide in the Mura River. Tesla's relative, Graz student of law Gjuro Banjanin had to search for Tesla; but it would be easier to find a needle in a haystack. Not later than November 1878 Tesla turned his legs to the south secretly; with the new railroad, he landed in the hourly rising second largest Styrian town of his days - Maribor.[2442]

Maribor schools of Tesla's times were attractive for Tesla although he probably didn't compete for a teaching job in Maribor because he did not finish his studies. The Maribor High Real School professors and students' libraries collected nearly 10000 books including most important electro-technical and vacuum technique journals until 1914. The presents of Essl, Jonasch, and Ferlinz were formidable. The Library of the Maribor Real school of Tesla's days offered the descriptive geometry of Jules-Antoine-René de la Gournerie (* 1814; † 1883) published for the first time by Parisian Mallet-Bachelier in 1850-1864. They acquired the *Zeitschrift für mathematischen und naturwissenschaftlichen Unterricht*: *ein Organ für Methodik, Bildungsgehalt und Organisation der exakten Unterrichtsfächer an Gymnasien, Realschulen, Lehrerseminarien und gehobenen Bürgerschulen* (1869-, Berlin/Leipzig: B.G. Teubner), *Zeitschrift für analytische Chemie* (1864-1889, Wiesbaden: C.W. Kreidel, edited by C. Remigius Fresenius (* 1818; † 1897)), *Chemisches Centralblatt* (1856-1969. Berlin: Deutsche chemische Gesellschaft), *Naturwissenschaftliche Wochenschrift: allgemeinverständliche Wochenschrift für sämtliche Gebiete der Naturwissenschaften* (1887-. *Deutsche Gesellschaft für Volkstümliche Naturkunde in Berlin*, Berlin: F. Dümmler & Jena: Fischer), *Zeitschrift für den physikalischen und chemischen Unterricht* (1887/88-1943. Berlin: J. Springer, edited by Friedrich Wilhelm Paul Poske. They offered to the local scholars the works of Ernst Mach; Bernhard Schwalbe; H. Matthée; K. Metzner; Otto Ohmann), *Österreichische Chemische Zeitung* and for Tesla especially important reports on Viennese Stefan's exhibition in *Zeitschrift für Elektrotechnik* (1883. *Organ des Elektrotechnischen Vereines in Wien*. Wien: Spielhagen u. Schurich) and *Internationale*

Elektronische Zeitschrift und Bericht über die elektrische Ausstellung in Wien (1883. Wien: A. Hartleben's Verlag. In those items J. Stefan published a lot of contributions. Maribor school also had *Internationale Zeitschrift für die elektrische Ausstellung. Wochenschrift für die Gesamtinteressen der internationalen elektrotechnischen Ausstellung, Internationale elektrotechnische Zeitschrift und Bericht über die elektrische Ausstellung in Wien*, edited by J. Krämer and Ernst Lecher. They acquired the works about the use of electricity, the production of electrical light, and about telegraphs. For students in Maribor, they kept Edmund Hoppe's (* 1854) *Geschichte der Elektrizität* published in Leipzig by J.A. Barth in 1884.

Similarly, there was well-staffed Gymnasium Library of Maribor which was more focused on humanistic. There they acquired the authors like Laplace, Lagrange, Jurij Vega, Crelle, or Duhamel. Certainly, all School Libraries restricted their offer to the readers connected with schools.

As the passionate reader and patriot Tesla may have joined the *(National) Slovanska čitalnica* (Slavic Reading-room) of Maribor established in 1861. There they offered the journals reading room and library in pub *Pivnica pri moki* of the lady Marija Schraml. On January 9, 1879 the elected board members of *Slovanska Čitalnica* were Kalčič, Holobar, Škoflek, Dominikuš, Ambroš (Valentin Ambrusch as professor of Maribor Grammar School in 1879), Srnec (Sernec), Brelih, and Ulrih.[2443] In 1881 *Slovanska Čitalnica* had eighty-four members carefully chosen among the local well-to-do. Later they read there the journals *Serbski dnevnik* (*Srbski dnevnik. List za politiku, prosvetu, privredu, radinost i trgovinu* owned by baron Feodor Nikolić (* 1836; † 1903) and edited by Aleksandar Stojačković in 1888), *Hrvatska vila* (Sušak/Zagreb, 1882-1885) or *Slovan* (Ljubljana 1884-1887). The editor of journal *Zora* was Janko Pajk (* 1847; † 1899), who was the owner of Maribor *Narodna Tiskarna* where he also printed the liberal daily *Slovenski Narod* which began with the three issues per week in 1868 and continued up to the war years of 1943. Tesla was probably interested in Josip Križan's papers or in M.J. Kokalj's article about telephone which discussed Bell's patent and recent experiments on the line Graz-Maribor-Klagenfurt published in *Zora*.[2444]

Tesla could have used the commercial lending library of Maribor printers Edvard Janschitz (* 1882) and his son-in-law Leopold Kralik with 5000 volumes available. The Reading and educational society *Theater- und Casino-Verein* was also appealing despite of its German spirit. Already in Tesla's times the lending library of Railway Society offered 1500 books, but eventually just to its employers for a monthly fee. The Madame Dirnböck from Graz, whom Tesla could have already met in Graz, opened Maribor branch of her lending library in 1869. After Tesla's depart the libraries of bookseller Max Isslin (Islin) and the branch library of Graz bookseller Josef Kienreich prospered in Maribor. In one way or another Tesla probably followed the quarrels focussed on the monument of bishop Martin Slomšek with Slovenian inscription in Maribor Cathedral erected on June 24, 1878.[2445] It was the greatest event of the era and Tesla certainly supported the Slavic feelings of Slomšek and his fans.

The modern science was held in the high esteem in Maribor High schools. After his undergraduate measurements of diffusion of gases in J. Stefan's Viennese lab, the Maribor professor Vrečko published mostly on mathematics including Jurij Vega's biography. For his unofficial assistant he picked up his High School student Karl Heider (* April 28, 1856; † 1935) who was just several weeks Tesla's senior and later became the famous zoologist. Just before Tesla's arrival Heider and his classmates in their homes enthusiastically constructed their own galvanic batteries in late November 1872.[2446]
Vrečko's colleague was Boltzmann's brother-in-law and collaborator Šantel who began his pedagogic career in 1869 in Maribor Gymnasium where he taught the future schoolmaster of Maribor Teacher's preparatory college Henrich

Schreiner (* 1850 Ljutomer; † 1920 Maribor). In Maribor Šantel additionally studied mathematics, physics, and pedagogy for his Graz University exams scheduled for March 28, 1870.[2447] In 1870 Šantel began to teach in Celje and on 23. 10. 1870 Šantel replaced his former teacher Essl in Maribor Gymnasium[2448] after Essl got the directorship of Maribor Real School. Although Tesla never approved the entropy of 2nd law of Šantel's brother-in-law Boltzmann, Tesla was interested in Šantel's pre-Freud approach to the secrets of dreams in Šantel's *Poskus razkladbe nekaterih pomenljivih prikazni spanja in sanj*, as well as in Šantel's electric reflux of liquids, the use of solar energy for mechanical work and a new way of transmitting sound, which we know as Bell's phone since 1876.[2449]

Two Maribor professors in the time of Tesla's Maribor funny days published comparatively profound papers on optics and electricity: Jettmar wrote on genesis of waves after reflection and refraction on the plane surfaces, and later as Viennese professor published in top mathematical journals. In 1877 Nagy's replacement on the post of the president of Maribor Philharmonic Society. Spiller was thinking about the influences of new data of galvanic electricity on the theory of chemistry, and dozen years later Spiller analysed Maribor water sources like Baltasar (Knapitsch, Knappitsch) Knapič did in Ljubljana. Spiller's secretary and later vice-president of Maribor Philharmonic Society Britto published on congruity and mechanics. In their own ways, they combined the music of Philharmonic Society with physics[2450].

Luka Lavtar published on kinetic theory during his stay in Ljubljana, but in Maribor he mostly discussed pedagogical puzzles. Luka Lavtar was a decade older than Tesla and among the rare Maribor natives who could understand Tesla's ideas during Tesla's stay in Maribor. The Jew Hirschler disliked Slovenians and arrived in Maribor immediately after Tesla's depart. A dozen of years later in Marburg School Program Hirschler published the list of experimental methods for measuring the data about molecules within the kinetic theory. In 1891, Hirschler's paper *Methoden zur Bestimmung von Näherungswerten der Molecülgröße* certainly had much clearer physical background compared with the earlier Lavtar work and Hirschler also criticized some of the old ideas of Jožef Stefan's Klagenfurt teacher Karl Robida. The Slovenians disliked Hirschler and he was replaced by Karl Zahlbrucker, the older brother of the head of botanic part of Viennese Natural History Museum Aleksander Zahlbrucker (* 1860; † May 8, 1938). In his great school laboratory of Maribor Karl Zahlbrucker showed to his students the experiments with Tesla's rays[2451] with the little *help of dr.* Adolf Pečovnik (* May 25, 1883 Sv. Lenart). Pečovnik got his PhD after his studies of mathematics, physics and philosophy in the University of Vienna soon after Boltzmann's suicide on November 23, 1906.[2452] Later, Adolf Pečovnik became the school inspector of former Maribor area, and after second semester of 1939/40 he was a headmaster of Bežigrad High School (Gymnasium) in Ljubljana.

Knobloch came to Maribor from the Maritime Lower Real School of Pula. He became the president of Maribor German Gymnastic Society (1876-1886), and published a lot on geometry and on history of Maribor High Real School (1896, 1900) as Maribor High Real School schoolmaster between the years 1895-1907.

Before his appointment on the newly established High Real School of Maribor, the Mineralogist-chemist Anton Franz Reibenschuh was assistant in Polytechnic in Graz. In 1875 he became the professor on High Real School of Graz and researched in Chemistry Laboratory of Tesla's professor Richard Maly[2453] until he was appointed director of High Real School in Graz before the year 1896. In 1868 he published the research of cave Pekel near Žalec (Sachsenfeld) of Lower

Table 18-7: Comparatively successful physicists and mathematicians who taught in Maribor of Tesla's times

Name	Era	Maribor institution
Andrej Vrečko (Wretschko, * 1846)	1871-1873	Gymnasium **p**
Anton Šantel	1969/70, 23. 10. 1870-31. 5. 1872 **m**	Gymnasium **m**
Josef Essl (* 1830 Berneck (Pernek); † 19/4/1874 Maribor)	14/11/1856-1870 Gymnasium **m**, 20/10/1870-1874 director of Real School	Real School **m**[2454]
Anton Franz Reibenschuh[2455]	20/10/1870/71-	Real School **p**
Josef Jonasch[2456]	20/10/1870-1879- came from the Orthodox High Real School of Černivci	Real School **m**, geometrical drawing, handwriting, German language, librarian
Josef Nawratil[2457]	1871- Gymnasium **m,** geography, Natural Sciences; 1874 head of Real School	Real School **m**
Robert Spiller(† abt. 1913 Maribor)	1876-1897-	Real School **p**
Gaston knight Britto[2458]	11/9/1874-31/5/1900	Real School **m, p**
Gustav Knobloch[2459]	11/9/1874-1907	Real School **m**, descriptive geometry
Josef Frank[2460]	1878-1895	Real School **p**, headmaster and boss head of professor's library
Luka Lavtar	1875-1915	Teachers' preparation College **m**
Alfonz Müllner (1840 Velikovec-1918 Vienna)	-1879-	Teachers' preparation College, Natural Historian, later custodian of Museum in Ljubljana
Heinrich knight Jettmar (* 1849 Lvov)	1879-1883	Gymnasium **p**
Franz Horak (Horák)	-1879-1882-	Gymnasium **p**
Jakob Hirschler (* 1852 Bratislava)[2461]	1880-1897	Gymnasium **p, m**
Karl Zahlbrucker (* 1858 Bratislava; † 7/11/1931 Maribor)	1897-	Gymnasium **p, m**

Styria and compared it to Postojnska Jama.[2462] On January 20, 1877, when Tesla was still in Graz, Reibenschuh experimented in Graz in front of the Styrian Naturalists Society to explain the theory of flame according to ideas of Edward Frankland (* 1825; † 1899), several years after Pöschl discussed the similar singing flame in front of the same Styrian Naturalists Society. Reibenschuh described Davy's safety lamp, and Karl Knapp's experiments with gases published in *Chemisches Centralblatt* in 1870 on page 386. Knapp' experiments were advanced by the Privatdocent of chemistry of Polytechnicum in Darmstadt Karl Heumann (* 1850 Darmstadt; † 1894 Zürich) under the title Zur Theorie leuchtender Flammen in several journals including the most important ones[2463].

18.5.10 Maribor Telephones

Besides good school laboratories and teaching stuff Maribor was able to show to the newcomer Tesla quite a developing technology. After his Prague studies Tesla in Budapest worked for a local telephone company of Ferenc Puskás (* 1848; † 1884) and his brother Tivadar Puskás (* 1844; † 1893) established in Pest part of Budapest on May 1, 1881. Among others Tesla installed the first telephone for company Ganz & co. *(*Ganz *vállalatok)* which later supported Tesla's AC motors.[2464] Did Tesla work on telephones also in Maribor in 1878/79 while the electric communications began spreading to Slovenian lands? In 1847 Maribor got a greater telegraph station for state and military purposes while the public use of Maribor telegraph was possible after the year 1850. On December 10, 1877 they tried the first telephonic debate between the main stations in Graz, Klagenfurt and Maribor[2465] through the existing telegraph connections. Whatever was said on one side was heard on the other, and in Maribor they were able to hear the talking between Graz and Klagenfurt.[2466]

On 6. 12. 1877 the professors of Real School of Ljubljana used their recently acquired telephone for a successful experiment in the office of the Carniolan Land Hauptmann Bohuslav Ritter von Widmann (1836 Olomouc-1911) with reports immediately published in *Laibacher Zeitung*.

On January 14, 1882 Ljubljana clockmaker and electro-mechanic Josip Geba (* 1854) began Ljubljana telephony. Josip and Anton Geba (* 1860; † after 1901) were the sons of Marija (* 1818) and the co-owner of city barracks Franz Geba (Fran, * 1823; † after 1881). Josip used Siemens' system with a trumpet to get a telephonic connection through the telegraphic cable between the fireman's watch on the tower of Ljubljana Castle and the rooms of Ljubljana Fireman's Society designed to speed up the response time. On 14. 1. 1882, the Narodna Čitalnica member Geba installed the first firemen telephone line in Ljubljana. In Ljubljana High Real School, Josip Geba presented his instruments including Hughes'[2467] microphone. In 1881, Albert Samassa (1808-1883) and his son Albert Samassa (1833-1917) used Geba's system to connect their office in villa on the southern slopes of Castle Hill above Karlovška Street with their foundry casting bells and cannons further south on Dolenjska Street of Ljubljana by 140 m long telephone line.[2468] Geba used two Siemens' telephones: Dr. Bötther's (Karl Böttcher) and Bell's designs. In 1893 Karl Böttcher reported on his designs at Chicago fair where he met Tesla. Geba also used two converters: one of Emil Berliner (* 1851; † 1929) from Bell's enterprise in Boston and Siemens'

[2467] On April 27, 1867 Pöschl reported on Writing telegraph of David Edward Hughes (* 1831 London; † 1900) to the Styrian Naturalists Society. In between he wrote and tried several telegraphs (Jakob Pöschl, Über den neuesten Typendruck-Telegrafen von Hughes, Mitt.nat.Ver.Steier., 5 (1868), 31, p. XXXI; Simon Šubic, Telegrafija, zgodovina njena in današnji stan, Letopis slovenske matice (1875), pp. 31-35).

[2468] Žarko Lazarević, Začetki uvajanja telefonije v Ljubljani, Kronika (Ljubljana), 35 (1987), 1-2, p. 97; Slovenski Narod, (1882), 16, January 20; Slovenski narod, 14 (1881), 223, September 1; Laibacher Zeitung, (1881), September 22, and (1882), March 16; Laibacher Wochenblatt, (1882), February 28; Primož Kuret, Mahler in Laibach, Ljubljana 1881-1882, Wien 2001.

apparatus. On first floor of Židovska steza No. 3 (earlier City no 307) of Ljubljana downtown Geba opened the clockmaker enterprise in 1877 and become a member of Ljubljana Sokol society tightly connected with Prague liberal Sokol and the Sokol of Tesla's teachers in Rakovac. The treasurer Geba and deputy chief Srečko Nolli attended the meeting on 20the anniversary of Sokol in Prague on 18. 6. 1882 as well as in 1884. The South Sokol was established in Ljubljana in 1863 and re-established as the Gymnastic society Sokol in Ljubljana in 1868 with their own monthly. In 1882-1892 Geba also used the enterprise in Slonova (Elephant's) Street No. 11 in Lukman's house of Ljubljana to sell his clocks and electromagnetic telegraphs until Franc Čuden († 1912) took it over.[2469] In 1887 he designed telegraph and lighting lightning rods for Dežman's Land museum Rudolfinum in Ljubljana while for Rijeka theatre he did the same in 1884. His son Dr. Josef Geba (* 21 February 1882) finished grammar school in Ljubljana on 4-12 July 1901 as a classmate of his friend Pavel Grošelj, studied philosophy in Graz as a member of Styrian Natural Science Society in 1908 to became director of library of the Viennese patent office (Österreichisches Patentamt Wien).

However, the experts of Geba's level were not yet frequent among Maribor's Tesla employers in Tesla's time. In 1892 the longest European telephone connection Vienna-Graz-Maribor-Celje-Ljubljana-Trieste was established along the south railway tracks and began its operation on October 1, 1892. The connection was a direct one which meant that all cities nearby did not get their telephones, in fact no place between Graz and Trieste was linked. That line was a pride of Habsburg state with its 505 km of total distance covered.[2470]

Already during his studies in Pöschl's class in Graz Tesla was acquainted with the telephone of Alexander Graham Bell, and on the end of Tesla's Graz studies description of telephone of the self-taught Philipp Reis presented in a lecture before the Physical Society of Frankfurt on 26 October 1861.As Tesla, Philipp Reis believed that the electricity could be propagated wirelessly through space like light, without an artificial conductor. Reis performed some experiments for his paper "On the Radiation of Electricity" in 1859, but the professor Poggendorff refused to publish it in *Ann.Phys*. which enabled the USA inventors to claim their priorities. Pöschl continued his presentation with induction telephone of Graham Bell which Pöschl illustrated with the nice illuminating experiments. Pöschl concluded his paper with experimental use of two pairs of telephones.[2471] He certainly accomplished similar experiments in Tesla's class soon after Carniolan Simon Šubic of Graz University seriously questioned the future of telephones in 1875 just before Bell's ground-breaking patent.[2472]

In 1875 before Bell's patent, Simon Šubic doubted the future of the novelty: "The phone cannot do more than repeating the orders of sounds or rhythm and cannot telegraph neither singing nor music."

18.5.11 Lower Styrian Members of Naturalists Society

The erudite Maribor guys of Tesla's days were closely connected with the Styrian Natural Science Society Naturwissenschaftlicher Verein für Steiermark., founded on 4. 4. 1862 in Graz;[2473] S. Šubic used to be its member; then he stepped out because of hostilities of his colleague the chemist Leopold von Pebal (* 1826; † 1887). In 1871, the Society had 509 regular and 20 correspondent members. Among the correspondent members were Karl Dežman from 1870 until his death and the physicist Johann Prettner (1812; † 1875). Prettner was the director of the Klagenfurt factory and at the same time a researcher of the Carinthian climate which he described in the reports of the Society.[2474]

Between the years 1867-1870 Šubic was an ordinary member of Styrian Naturalists Society

established in Graz on April 4, 1862,[2475] but later he left the Society to save some money and because of his quarrels with his university colleague the chemist Leopold von Pebal (* 1826; † 1887). In 1871 the Styrian Naturalists Society had 509 ordinary members, and twenty corresponding members. Among the corresponding members were Karl Dežman between the year 1870 and his death, and the physicist Johann Prettner (* 1812; † 1875) who was the director of factory in Klagenfurt and researcher of meteorology in Carinthia which he described in Society's Journal.[2476]

After 1872 the ordinary member of Society was the Slovenian popular scientific writer Vinko Borštner, the professor of physics in Klagenfurt and later Plemelj's teacher in Ljubljana. Among the ordinary members were Šubic's colleagues from the physics chair of the University of Graz: Toepler joined the Society in 1869, Boltzmann was a member after 1871 with a pause in the years 1874-1876. Albert von Ettingshausen (* 1850; † 1932), a nephew of famous Viennese professor Andreas von Ettingshausen, became a member of the Society's board in 1877.

On May 27, 1871 Toepler became vice president of the Society, and he served on that post together with Pöschl in 1874. In 1880, after he left Graz, Toepler became the honorary member of the Society while his successor Boltzmann became the vice-president. In the beginning, Pöschl was the secretary of Society. In 1875 Pöschl became a member of board of Society, but he left the Society after he retired.

Only the ordinary members supported the work of Society with annual donations of 2 florins. The Society met with scientific lectures and experiments every month with a pause during summer holidays. The Society published a yearly report entitled *Mittheilungen der naturwissenschaftlichen Vereines* which was printed with a year of delay after 1874. A report included scientific papers, abstract of talks given on meetings, list of members, and list of journals accomplished by exchange with other similar Societies. After 1871 they got Rad JAZU of Zagreb among others, but they did not receive the reports of Carniolan Museum Society.

Most scientific papers published in reports of Society discussed biology. Until 1875 they published two papers on physics by Graz University professors Boltzmann and astrophysicist Karl Friesach (* 1821; † 1891), one astronomical, eight meteorological, and nine mathematical papers.[2477]

Each of early Society's reports was concluded with local meteorological data similar as the Reports of Carniolan Museum Society. Tesla's professor Pöschl and Graz engineer Marek gathered meteorological observations from all over Styria and published the results of eleven and later of ten measuring points for Styrian Naturalistic Society in 1865 and 1867. Their Lower Styrian reporters were the professor Josef Essl of Maribor after June 1, 1863, and Anton Emil Reithammer from Ptuj. Ivan Kastelic reported about the weather in Lisca (Leisberg) Hill by Celje and in Celje with a help of Konrad Pasch. They used the barometrical data of the teacher of technique Eulogius Dirmhirn (* 1823 Schärding; † 1887). In Lisca and in Ptuj they did not use the barometer or psychrometer. The former Benedictine Dirmhirn studied technique in Vienna and after the Spring of Nations he became the official of Celje telegraph station. In 1854 he passed the technical examinations which enabled him to teach and finally to work as a schoolmaster of the new Provincial Civic School in Celje between the years 1870-1884.[2478]

The physician trained for treating patients at pools and spa facilities the palaeontologist dr. Emanuel Bunzel (* 1828 Prague) became the Viennese physician in 1881. He and H.W. Kern reported on weather circumstances in Rimske Toplice spa by Laško after July 1864. In 1866 Bunzel published a book about the guests of Rimske Toplice spa and on May 30, 1871 he became famous with the research of the parts of dinosaurs' skull in the coal mine near Wiener (Viennese) Neustadt.

Kastelic, Essl, and Reithammer also independently reported to the Society about their local meteorological data on December 27, 1862, July 25, 1863, and February 27, 1864. It was a part of

their reports for the Viennese Central Office[2479] which also gathered the reports of Karl Dežman and later of his sister Serafina's on Ljubljana data. On December 10, 1865 Reithammer presented to the Society a paper on ozone, and he described the Ball Lightnings near Franciscans' Monastery of Ptuj which disturbed him on September 6, 1866.[2480]

In 1865 Marek and Pöschl added the measurements of Jožef Rathberger of Laško and concluded their report with the comparison of meteorological data in the years 1863-1865, as well as notices on earthquakes, and about the hail which damaged vineyards of Slovenska Bistrica on July 12, 1865.[2481]

Verzeichniss der Beobachtungs-Stationen

im Jahre 1865.

Name	Länge von Ferro	Breite	Seehöhe in Wr.-Fuss	Beobachtungsstunden Mrg.	Mitt.	Ab.	Beobachter

Markt Tüffer	—	—	—	—	—	—	Jos. Rathberger.

Anmerkungen.

1. Aus Steinberg bei Alt-Aussee wurden seit September 1865 keine Beobachtungen mitgetheilt.
2. In Aussee wurde der Regenmesser nur in den Monaten Mai bis incl. November in Anwendung gebracht.
3. Im Stifte Admont mussten die Beobachtungen in Folge des verheerenden Brandes Ende April 1865 abgebrochen werden; dieselben wurden jedoch mit 1. Jänner 1866 wieder aufgenommen.
4. In Pettau begannen die Beobachtungen mit dem Barometer und Psychrometer am 1. Februar 1865.
5. Auf dem Leisberg bei Cilli wurden die Beobachtungen vom Mai bis incl. October 1865 von Herrn Joh. Castelliz sen. angestellt. In den übrigen Monaten beobachtete derselbe gemeinschaftlich mit Herrn Conrad Pasch in der Station Cilli, gleichwie im verflossenen Jahre.

The student Tesla was probably not admitted to the sessions of Styrian Naturalistic Society, but he certainly heard a lot about them in his classrooms and in debates with his professors and classmates. Albert von Ettingshausen later became a fan of Tesla, and Albert von Ettingshausen's lectures in front of Styrian Naturalistic Society natural society on induction were certainly Tesla's favourite. Even before Tesla matriculated in Graz, Tesla knew a lot about the motor of Charles Grafton Page (* 1812; † 1868 Washington D.C.) designed in late 1830s and up to 1851. Simon Šubic and Tesla's teacher Sekulić acquired Page's motor already for their lab in Hungary, while the professor Niccolò Vlahović got Page's motor for the lab of Grammar School of Koper before 1864.[2483]

Dušan Mrkić (Dan Mrkich, * 1939; † 2005 Canada) was Rakovac High Real School alumni and lived in former Tesla's provisional home in Karlovac house of Tesla's uncle for a year before he followed Tesla's footsteps through Europe including Maribor. By Dan Mrkić's and Tesla's friend Kulišić's report Tesla worked as technical designer for Maribor master Druško, the draftsman with a Tool and Die machine shop. Tesla lived illegally in Tegetthofstrasse before the policemen arrested him down there. Mrkić's Maribor informer was Momčilo Radić who knew about Kulišić's report.[2484]

Tesla disliked drawing during his student years in Rakovac but later he obviously changed his mind when he settled down in Maribor in winter 1878/1879. Tesla needed money, so drawing was as good as any other job. For his supposed work in technical office of the industrial engineer Druško, Tesla allegedly earned 60 forints per month and additional salaries for successful work with which he at least doubled his former Graz student incomes. The principal actor of Maribor theatre had lower income in those times[2485] which could mean that Tesla tried to better his real position in the eyes of his friend Kosta Kulišić because Tesla wished to hide his own humiliating whereabouts. It seems that the young Nikola liked to gamble and drink in Maribor which was the reason why he

never fully explained that period of his life. Who was master Druško whom Tesla praised to his former rummy Kosta? He could have been Druškovič, Drušković or Druscovich because all those three forms of family name are still available in the state of Slovenia although they aren't frequent.

Table 18-8: Important lectures and discussions of professors of physics at Polytechnics and at the University of Graz were published in full or summarized in the reports of the Styrian Natural Science Society; among the listed ones, only Mach was not a member of the Society.

Author	**Date and page of the publication in the Reports**	**Thematics**	**Lecture or published Paper**
Mach	28. 10. 1865, 1867: XXXII–XXXIV	Plateau'sexperiments with difficultly soluble liquids (schwerlösen Flüssigkeiten) and the nature of the molecular forces	P
Mach	23. 2. 1867 1868: XXXI	Helmholtz' Vibrational Microscope	P
Schwarz	23. 2. 1867, 1868: XXXI	Johnson & Mathey's London melting of Platinum established by Percival Norton Johnson (1792–1866) and a stockbroker George Matthey (1786-1853 Rosemount in Sussex) in 1851	P
Toepler	29. 1. 1870	Induced Electrics and Siemens' Dynamo from 1870	P
Toepler	1872, 64–116	Physical interpretation of representation by power series	R
Ettingshausen	1873	Phosphorescence and fluorescence	P
Toepler	1873	Aurora Borealis	P
Boltzmann	1873, 25–36	About Maxwell's Theory of Electricity	R
Toepler	10. 4. 1875 XLIX–LI	Capillarity	P
Ettingshausen	1877/1878, 46–51	Magnetic phenomena in Graz in 1877	R
Ettingshausen	12. 5. 1877/1878, 46–51	Electrodynamic-electromagnetic rotation, Page's motor	P
Boltzmann	17. 11. 1877/1878, LI–LII	Current state of mechanical theory of heat, experiments of Stefan and Loschmidt	P
Boltzmann	28. 12. 1878, XVII, LXIX–LXX	Physical theory of pitch and color with the use of Fourier's analysis	P
Ettingshausen	1878	Electric induction	R

Name	**Volumes and pages of notes in the Reports**	**Places and jobs**
Karl Dežman	1870, XLVI, associate member	Ljubljana, curator
Ivan Prettnar	1870, XLVI, associate member	Celovec (Klagenfurt), manufacturer

Jožef D. Bancalari	1882, III	Maribor, pharmacist, director of the town savings bank, cyclist, mayor in 1867-1870, member of Schlarafia Marpurgia[2486]
Jožef Birnbacher	1882, III	Maribor, financial councilor
Vincent Borštner	1873; 1882, III	Celovec (Klagenfurt), Grammar school professor
dr. Emanuel Bunzel (Bunzl)	1870, XLVIII	Rimske Toplice, spa physician
Friedrich Byloff	1875, 1882, IV, 1885	c. Engineer, son of a Celje city engineer who planned a bridge over Savinja, 1824-1826
Barthilomäus knight Careneri	1882, IV	Castle Wildhaus above Selnica ob Dravi, huge landowner, Member of the National Assembly
Anton Elschnig (Elšnik)	1870, XLIX	Maribor, professor of the higher real school, Zoologist Botanist
Edvard Ferlinz (* 1817; † 1874)	1863, 12; 1870, XLIX	Maribor, Bookshop
Karl Fontaine von Felsenbrunn	1865, 3	Ljubljana, senior financial adviser, colonel, writer of the Carinthian tax manual in 1866
Karl von Formacher	1882, V	Slovenska Bistrica, landowner
Grammar school	1870, L	Celje
Karl Hauser	1870, LI, 1882, VI	Maribor, head procurator
Jožef Heinisch	1882, VI	***Oberhaag***/Osek, Headmaster
Jožef Huber	1870, LI	Celje, priest, gymnasium professor of mathematics and physics 1860- 1874, made inventory of coal available in the vicinity [2487]
Heinrich Kalmann	1882, VII	Maribor, leader of the wine-growing school (Sadjarsko-vinarska) school; established in 1872
Ivan Kastelic	1870, XLVIII	Celje, court associate (judicial adjunct)
Ignac Klemenčič	1882, VIII	Graz, docent
Klöpfer	1882, VIII	Eibiswald/Ivnik, practicing physician
Jožef Koczbek	1870, LII	Radgona, doctor of physics
Magister farmacije Wenzel König (Venčeslav, * 1836; † 1901)	1882, VIII	Maribor, pharmacist, provided a guide for the pilot of aircrafts at the Parisian exhibition in 1877, member of Schlarafia Marpurgia [2488]
Franc Krause	1870, LII	Ptuj, railway physician
Ferdinand Lippich	1870, LIII	Graz, professor of Polytechnics
Jožef Kupferschmied	1882, VIII	Celje, pharmacist
Aleksander Mell (* 1850 Prague; † 1931 Vienna)	1882, IX	Maribor, professor of teachers' preparatory and writer, studied natural sciences in Graz, since 1886 he led the Vienna Institute for the Blind
Franc Močnik	1870, LIV	Graz school counsellor
Dr. Karl Julius Potpeschnigg	1870, LV	Feldbach/Vrbna, District Commissioner, in 1882 in Graz
Julius Pfrimer	1882, XI	wine merchant, cashier of the Philharmonic Society and German politician[2489]
Dr. Florian Puschtrauser	1882, XI	Hrastnik, department physician
Matej Reiser	1895, 1896	Maribor mayor
Anton Emil Reithammer	1870, LV	Ptuj, pharmacist

Emanuel Riedl	1882, XII	Celje, senior Mining Commissioner
Rudolf Sadnik	1882, XII	Ptuj, sanitary assistant
Karl Schaumburg	1870, LVI	Ljubljana, construction councilor
Dr. Max Jožef Schüler	1870, LVI	Rohitsch/Rogatec, Imperial councilor, director
Konrad Seidl (* 1830; † 1879)	1870, LVI	Maribor, Member of the Viennese parliament for the Maribor district in the years 1870-1873
Dr. Janko Sernec (* 1834; † 1909)	1882, XIII	Maribor, the founder of the Slovene Reading Room, lawyer
Simon Šubic	1870, LVIII	Graz, university professor
Sigmund Vaczulik	1870, LVIII	Windisch Landsberg / Podčetrtek, pharmacist
Gundaker Count Wurmbrand	1882, XV	Ankenstein / Borl Castle, Captain, chamberlain member of the National Assembly in winter of 1878/1879; state minister in 1893-1895

Anton Druskowitsch of Maribor was probably not a right guy as he was a manufacturer in Livada No. 11 on left bank of Drava River outside the city of Maribor of those days. The shoemaker Josef Družkovič in Koroška Street No. 12 in those days 3rd Maribor quart on left bank of Drava was more promising candidate because several years after Tesla's departure he was noted among other Maribor manufacturers in 1884,[2490] but Josef Družkovič was not officially registered during Tesla's Maribor months which sounds nice because the illegally employed worker Tesla most likely worked for the firm which was by itself also not legally registered yet.

Forty years earlier Josef Družkovič's house in Koroška Street No. 12 belonged to the painter Vincenz Lubiz but several shoemakers worked in the neighbourhood in Koroška Street No. 7 house possessed by his relative shoemaker Lubiz. In Koroška Street No. 1 there was a nice new house of shoemaker Klementschitsch (Klemenčič). Somewhat further there were several good situated owners: the district surgeon Josef Förderek owned the house in Koroška Street No. 25 and producer of flower-liquors Jakob Felber owned Koroška Street No. 35 and No. 36 which was extremely elegant with eight windows on the front. The house in Koroška Street No. 12 hosted the city fireman after 1892, but the numbers of houses eventually slightly changed from Puff to Curk's times so that Puff's house of miller Senekowitsch (Senekovič) or his widow Jožefa in Koroška Street No. 20 became Koroška No. 13 and later Vojašniška Square No. 7.[2491]

Josef Družkovič was later noted as owner of house in Tržaška Street No. 65 in Maribor in the times when Koroška Street No. 12 was already the fire station. Certainly, a very promising guy as Tesla's onetime boss. What else could we say about Josef Družkovič (Druškovič), especially about the size of his manufacture and the number of employees with Tesla illegally included?

18.5.12 Maribor Opportunities

Tesla certainly had many opportunities in quickly developing Lower Styria after the abolition of guilds in 1859. Kager's metallic enterprise and foundry began to operate in 1737 and a century later it used motor supply in a modern works in 1889.[2492] The girdler and silversmith Kager was one of the predecessors of Maribor foundry. In 1868 Denzl's (Dencl) established bell-foundry which produced Maribor industrial tradition[2493] as did Heriček's pottery. Heriček introduced gas motors. After they proved to be too expensive, he introduced Sinković's oil motors in early 20th century. Milko Sinković was probably from Split. Sinković also produced electromotors before First World War because the use of electrical energy increased after Frohm's Smithy developed into an

industrial foundry in the late 19th century. By using the new railway, the manufacturers did not settle in singular production but established branches producing unrelated subjects. Therefore, Frohm besides foundry also managed oil factory, distillation, vinegar works, liquors, and vine-shop.

Johann Pengg's bell-foundry inherited Dencl's (Johann Denzl) and later Bühl's bell-foundry and smelting-plant on Meljska Street near the harbour of Drava River. After 1902 in the same neighbourhood fabric of machines and iron-foundry on motored power of Anton Bendl from Graz worked until Karl Ježek (1851 Blansko-1919) and his brother Richard Ježek **(**1860 Blansko-1948) from Blansko in Moravia bought it (1908-1910) as one of the rare strong Slavic-owned enterprises in predominantly German businesses of Maribor.

Figure 18-53: Tesla's expulsion from Maribor under the numbers 2160 and 2675[2494]

Tesla was not the only one who found the industrial future of Maribor appealing, although Tesla might have been the poorest of those inventive guys. Franz Swaty was few months Tesla's younger technological chemist. He was raised in a family of construction engineers from of Lower Austria, Vienna and Mainz. Swaty and Tesla had similar education although Tesla did not finish his chemical technology studies in Graz.[2495]

During Tesla's Maribor challenges, the hones, grinding wheels and tools factory Swaty was established by the technical chemist Franz Swaty (* 1855) and his father construction engineer of the same name Franz Swaty (* 1826) in Vienna in 1879. At least two decades earlier, the Swaty's firm was already registered in Vienna because Franz Swaty (* 1826) and his father were both the Viennese city magistrate construction engineers and in that capacity holders of the Viennese registered business just with the right of the engineer authorized and sworn by the Habsburg state authorities in their domestic flat in Vienna. They used that opportunity for different engineering tasks in the area, but they switched into the hones and grinding business only after Franz Swaty (* 1855) finished his studies of the applicative technical chemistry with fresh modern ideas which immediately proved to sell very well after their prizes won at the fairs all around Central Europe including Maribor.

[2496] Ibidem, ledger1879 (splošna registratura), notes on the cover of ledger.

Swaty's enterprise was among the oldest European producers of hones as the grinding tools. Initially, the production was based on Swaty's own patented procedure for production of hones, grinding tools and wheels in mineral bond. Franz Swaty and his son of the same name Franz Swaty (* 1826), whose own son was just few months older than Tesla, worked in Vienna as the construction engineer of the Viennese city magistrate builder department. After his father passed away, Franz Swaty (* 1855) indicated his father as the inventor which could mean that the initial patent of grinding was the work of Franz Swaty (* 1826) also because it was not quite far from constructions. Certainly, their grinding tools were patented as the work of chemical technology and Franz Swaty (* 1855) had a note on his Maribor tombstone verifying that he was an expert for chemical technology with no construction noted as his previous business. Franz Swaty (* 1855) therefore partly abandoned the construction tradition of this ancestors for the then modern applicative chemistry which recently excelled with Liebig's chemical agricultural fertilizations which Tesla highly praised after it penetrated in many other branches of technical needs including the grinding. Franz Swaty's (* 1826) son the technical chemist Franz (Francis) Swaty took over the Maribor factory of aluminium grindstones and hones for the sharping of razors and additionally advertised Swaty's honing-oil for the protection of hones before and after grinding or shaving. Franz Swaty (* 1855) proudly stated that he is the only heir of his deceased father's factory in Maribor. That proves that Franz Swaty (1826-1888) established the Maribor enterprise designed for the successful production of hones based on the invention of Franz Swaty (* 1826) and not his son Franz Swaty (* 1855), probably because Franz Swaty (* 1855) was underaged up to 1882 according to Habsburg laws used in those times.

Before 1890, Franz Swaty left his native Vienna and moved to Maribor. He resettled at the latest after he was orphaned. Franz Swaty (* 1855) married Franziska Maria Wenedikter (Fanny, * 1863), who was probably the descendant of the former owner of the manor Kozjak nad Pesnico in Zgornja Kungota in the hills above Maribor on the north.

Besides mighty Swaty, Tesla had other opportunities in Maribor. The "Kovina-Metal"

Figure 18-55: Craft of Tesla's master Druško. He was probably a city shoemaker at Leitnerhofgasse no. 234 Josef Druschkovitsh (Družkovich, Druškovič), noted under the serial number 1125 on 17. 7. 1873 with no. 6504 in the craft register of the city of Maribor (SI_PAM / 0005, K 531 - Craft registers managed as based in craft legislation 1859-1907: register for free and handicraft crafts 1866-1883). Druschkovits's manufacture first worked illegally with Tesla illegally included. It was officially registered only after Tesla's expulsion.

enterprise in Tezno was also successful. In Maribor, they had a large glass factory, and in 1884 there were already thirteen engineers: superintendent Mauras Franzc, widow of the engineer Schnabel (Schnabl) named Theresa, Carl Arthlet, Byloff, J. Eger, F. Hallmann, Anton Heimann, Adelbert Markhl (Markl), Franz Nowak, J. Prodnigg (Prodnik), C. Rakoneli, Josef Swoboda, architect of the Maribor theater railway district engineer Adam Wiesinger.[2497] Adam Wiesinger was in Maribor already before 1859. His construction of Maribor theatre began in 1848, paid by the large group of founders of the Maribor theatre. The plans were created by the railway engineers Adam Wiesinger and Gustav Lahn, while Janez Nusshold took over the building work for 50,000 golden coins (*goldinars)*. The stage equipment was supplied by the Maribor carpenter, hewer and mechanical engineer Anton Halleger. In front of the main façade of the new theatre building, on the location where a casino had been envisaged, there was access to the theatre café in an older building situated south-west of the theatre. The café and theatre were connected by a covered wooden walkway. In 1863 the building of café was

[2497] Cverava, 2006, 40; Jurik, 1884.

demolished and in 1864 a casino was built on the initiative of the "Reading (Casino) and Social Society" in front of the main façade with today's address Slomškov trg No. 17. The Graz architect Johann Schöbl planed the works, whilst the building work was led by the Maribor town builder Josef Lobenwein and the building engineer Hugo Skale. Before Tesla's arrival between 1866 and 1870 the theatre building was renovated for the first time.

The son of Maribor magistrate secretary Aleksander Nagy (1834 Ptuj-1909 Maribor) came to Maribor only in 1881, therefore after Tesla's deportation. Nagy finished the Technical Hochschule. Slowly, the considerably perspective networks of engineers developed in Maribor although they remained in the shadow of Graz communities until the ancient land of Styria was split in Austrian and Yugoslavian part in 1918. That's why Puh, who used to be the very best self-taught inventor of all Styrian guys, preferred to concentrate his businesses in Graz.

In Tesla's times the engineer W. Fischer donated New-Year forint for poor fellows as did the author of Maribor telegraph-textbooks Johann Kral or the machine-operators Hartl and Franz Mayer.[2498] In 1879, Johann Kral was a head of Bureau of Maribor Telegraph Station (k.k. Telegraphen-Aemter) in Maribor in Tesla's time.[2499] Tesla certainly had a lot to learn from J. Kral, although the telegraph technology was finished to the extent which did not offer many chances for new discoveries of the young inventor like Tesla. In 1881 Johann Kral was still in Maribor, but in 1882 he was not listed anywhere in office in Habsburg monarchy. In 1883-1885, the holder of the great papal ordain Johann Kral headed the postal-telegraphic direction Ústí nad Labem (Aussig) situated in a mountainous district at the confluence of the Bílina and Laba (Elbe) rivers as a major industrial centre, river port, and important railway junction. In 1887-1889, J. Kral had the same duty in nearby České Budějovice (Budweis), in 1888-1889 also as the controller of post of the Viennese Post & Telegraph direction in the times when Richard Lischke was still not noted as important enough Maribor telegraph official in the official listings. In 1901-1902 Johann Král was High Post Administrator (Ober-Post-Verwalter) of k.k. Aerarial-Post- und Post- und Telegraphenämter in Viennese First Brezirk Post- und Telegraphenämt no. 7 on Schottenring no. 16 and Börsegasse no 8. In 1904, he served no more. In 1902-1903, Johann August Kral as Ober-Post-Verwalter and Amts-Vorstand lived in VII/2 Bezirk Neubau of Vienna in Kirchengasse no. 40. He was still there already as retired official in 1904. In 1905, Johann Kral lived no more and his supposed daughter the unmarried milliner (Modistin) Antonie Kral took over his flat in VII/2 Bezirk of Vienna in Kirchengasse no. 40. Johann Kral was not buried in any of the three churches of the 7th Viennese Bezirk in 1904 or 1905. His supposed son and publisher Ernest Kral used to be an adjunct of k.k. State Roads (Bahnen) and lived in the Viennese II/8 Bezirk in Borharienstrasse no. 144.[2500]
The expansion of Maribor industry in no way stooped with Swaty, Richard Lischke, and Kral's successes. In 1869, Maribor gas station was established and next year the modern gas lighters were used. Shortly after Tesla left Maribor, as the first in that part of Europe Karl Scherbaum used thirty-six incandescent lamps to lighten the city of Maribor in April 1883 several weeks before the Viennese Internationale Elektrische Ausstellung. In the same year, his Maribor steam engine mill used the first Wieghorst's Hamburg furnaces[2501] in Habsburg Austria and Scherbaum developed his branches in Maribor, in Fram, and in Bistrica. His mill in Bistrica had its own electric plant with turbines before the end of century. Gustav Scherbaum later joined the funny society *Schlarafia Marpurgia.*[2502] Several days after Scherbaum the locksmith-master Jožef Martini used electrical lamps in his showrooms on Vetrinjska Street in Maribor and prepared the similar ones for the merchant Jožef Martinz in Gosposka Street. There were some opportunities for Tesla in Maribor, but even the USA magnates

were unable to back Tesla's Wardenclyffe Tower which was even further from Maribor possibilities.

18.5.13 Puch's Bicycles

Puh (Puch) was five years Tesla's younger and with no doubt one of the ablest industrialists in Styria of Tesla's times. Puh was more of Edison's sort because he never seriously thought about any academic positions or studies as he was able to advance without them.

In 1889 Puh's brother-in-law Franc Neger (* 1859; † 1944) from Bischofegg near Ivnik (Eibiswald) established a factory of bicycles and sewing machines in Maribor, but Janez Puh (Johann Puch, * 1862; † 1914) himself in spite of his locksmith schooling in Rotman near his native Juršinci-Oblaček (1874-February 21, 1877), and in Radgona (1877/78) preferred to run his bicycle factory in Graz in 1889 and 1899, although he liked to visit his lower-Styrian relatives.[2503] In 1886 in Celje *Cillier Radfahrer Verein* was established and its competitor more Slovenian *Klub biciklistov* became a part of Celje *Sokol* Society. In 1898, the predominantly Slovenian railway workers founded *Delavski kolesarski klub* in Maribor.

In Tesla's times many flats were offered in »Houses of Southern Railway Colony workshops« near the train station of Studenci on the right bank of Drava River which developed into a prosperous suburb of Maribor. The Southern Railway Colony workshops were the biggest Maribor enterprise situated in Graz suburb where they hired over 1000 workers already upon their beginning in 1863, but Tesla or Druškovič were not among them.[2504] Maribor had quickly expanding workers' suburbs which gave ideal opportunities to the semi-professional gamblers like Tesla. In September 1868 some modern revolutionary elements developed after the establishment of Educational Society under the leadership of Franz Wiesthaler (* 1825; † 1890) who became the editor of *Marburg Zeitung* next year and again between the years 1882-1887. He kept his liberal ideas of the Spring of Nations from the year 1848 alive and afloat, and he certainly did not support the United Slovenia movements which threatened to transform his Lower-Styrian Germans into minority.[2505]

18.5.14 Humiliating Arrest and Exile

Tesla could have worked for the small enterprises as were Dencl or Kager's, but Southern Railway workshops were also attractive near Tesla's favourite pub in Graz suburb[2506] with their forty new workers' buildings housing 724 flats built in 1863 and 1868 on the right bank of Drava outside the Maribor Down Town. That was the biggest urbane complex in the Habsburg countries! The workers used their own kindergarten, school, store, and two pools.[2507]
Tesla was deported as a vagabond: he probably slept illegally in Maribor Graz suburb in one of 724 flats available there. As a declared vagabond Tesla certainly did not have a regular job and gained some extra money with gambling cards and billiard until one of his angry loosing companions denounced Tesla to the city authorities, if Murko or Tesla's father did not do that ugly job themselves. Maribor of those days and especially its Graz suburb was quickly filled with comparatively educated workers from the north which provided excellent opportunities for a versed gambler of blackjack or even tarock which was played among Bohemians, Austrians, and Slovenians but probably did not become that popular in Karlovac or Lika.

After Graz debacle Tesla spent his free hours playing cards and chess in Maribor pub By the Southern Railway (Pri Južni železnici, Zur Suedbahn, Zur Süd-bahn) as the pub was called during Habsburgian Monarchy. Only after the year 1919 the pub was called National pub (Narodna gostilna, vulgo *Veseli km*et, *Pri Veselem Kmetu*, By Happy farmer). According to Kulišić the pub was also called »Tegetof« by its street name borrowed from Maribor-Born admiral Wilhelm

von Tegetthoff. The pub Zur Süd-bahn (Veseli Kmet) had another domestic name "Vlahović" on the corner of modern Partizanska street no. 26 and Mlinska Street across the coffeehouse Jadran, later Jeklotehna. In 1985 the pub was destroyed to provide more room for the new bus station[2508] which Tesla would never approve. The pub Zur Süd-bahn (Veseli kmet) was a little building near the bigger Vlahovič's house with a store and pharmacy in the corner of Meljska and Partizanska Street no. 36. The other pub called Prlek was on Meljska Street the first building on the left side after you passed the railway bridge.

Kulišić used to be Tesla's rummy in Graz from January to June 1876. In January 1879 Kulišić accidentally found Tesla in Zur Süd-bahn (Veseli kmet) pub while Kulišić was waiting for his return train from Maribor. In Maribor Kulišić tried in vain to get a job of lecturer of geography and Italian language in Merchants School of the Schoolmaster Peter Resch († after 1918), who posted the invitation in *Tagespost*. Resch tried to equip Maribor High Schools classrooms with gas lighters,[2509] and later as the director of Public Merchant School in Bolzano and important author of law books agitated against duels in 1903.[2510] Resch paid Kulišić's travel expenses and next morning accompanied him to the railway station. Because they were too early, both Resch and Kulišić, or Kulišić alone, went to the nearby pub Zur Süd-bahn (Veseli kmet) and met Tesla who was playing piquet cards with two other guys there. Peter Resch was later the director of Simon Šubic's former Trade School (Handelschule) in Graz and Fachexaminator (Job-Examiner) of k.k. Prüfungs-commission of two-class Trade schools in Vienna in 1910. In the same year, Konstantin (Kosta) Kulišić was a professor in k.k. higher Grammar school of Ragusa (Dubrovnik) with Serbian-Croatian teaching language in 1910. In 1913 and on the end of WWI in 1918, Peter Resch was still Fachexaminator (Job-Examiner) of k.k. Prüfungs-commission of two-class Trade schools in Vienna, but he was already retired.[2511]

In early March 1879 after prolonged search for lost Nikola, Tesla's father Milutin Tesla (1819 Raduč-1879 Gospić) arrived in Maribor to convince his son to return home and continue his studies in Prague in autumn of 1879. Tesla refused although Milutin eventually even learned about Nikola's fame in Nikola's Maribor workplace.[2512] The father Milutin or somebody else soon afterwards denounced Tesla to the city authorities. The coincidence of just few days which passed between the dialogue of Milutin and Nikola Tesla and Nikola's arrest strongly suggests that Milutin asked the authorities of Maribor to bring his still underaged son back to his school-home of Gospić. Milutin probably informed the Maribor guys where they could find his poor son Nikola.

Figure 18-56: Tesla gambling inn Zur Süd-bahn (Veseli kmet, Happy farmer) in Maribor

The police broke into Tegetthofstrasse of unknown number where the would-be inventor Nikola Tesla was living illegally. The poor fellow wasn't registered at that address where he was living.[2513]

In those times the mayor of Maribor was a nephew of the former mayor notary-lawyer decorated by the imperial Franz Josef's medal Otmar Reiser (Othmar, 1792 Villingen in Schwarzwald-1868

Maribor), the member of Styrian Naturalistic Society the notary Matej Reiser (Matevž, * 1830 Weilersbach in Baden; † 1895). Matej Reiser served as a mayor of Maribor between the years 1870-1882.[2514] He lived long enough to learn about Tesla's fame, but it is doubtful if Matej Reiser ever realised that the famous Tesla was just the same poor kid whom Matej Reiser expelled from Maribor with such a great aggressive haste. Matej Reiser's substitute mayor was a lawyer dr. Ferdinand Duchach (Duhač, † 1887), who later replaced the liberal notary Reiser on the post of mayor in Maribor. Duhač's replacement was an engineer Aleksander Nagy, who at least by education was nearer to Tesla's networks. During Tesla's time of troubles, the examiner of Maribor City bills was the district governor (Bezirk Hauptmann) of Maribor the German Julius Seeder who was also the citizen of honour of the manor (Orts Gemeinde) Hitzendorf west of Graz.[2515]

In 1869 Maribor City Administration had twenty-nine employers together with the head of office, eight officials, sergeant major and eleven policemen with the manager of prison among them. In 1875 the Municipal Administration (Magistrate) was managed by mayor, his substitute, four city counsellors voted among the municipal advisers, the office head, eighteen officials and lower officials, lithographer, servant, and servant's help. In 1900 Maribor already had fifty-five policemen.[2516]

After the year 1850 Maribor City Administration (Magistrate) also worked as the local political district. The officer of Maribor city authorities Oldrich Taube (Ulrih Golob, Glušec by the narration of the writer Praštalo) after the police accusation signed the order for Tesla's deportation on March 8, 1879. In 1879, the local police commander (Abtheilung-Commandanten) in Maribor was the lieutenant Adolph Smole and Taube was not employed anywhere near[2517], which indicates that the writer Praštalo might have been wrong. The Maribor police guards accompanied Tesla to his hometown Gospić as it was usual to exile the illegal immigrants to their domestic places and Tesla was still underaged according to Habsburg laws. Tesla was probably under arrest on the later International Women's day celebrated after 1909 and the day after. Tesla's rummy behind the bars was Anton Klaus born south of Ljubljana or in Škofja Loka before the Maribor policeman handed him over to Ljubljana officials. Tesla and Anton Klaus were punished for similar crimes as vagabonds and afterwards deported to Gospić and Ljubljana. In 1884, the authorities started to build Maribor men's prison only after Tesla's forced depart in 1879. In those years there was nobody with family name Klaus in Ljubljana except for the Viennese born architect Karl Klaus (* January 27, 1889), but somewhat later we find numerous persons named Klavs or Klaus as workers or housewives born in the neighbourhoods of Bela Cerkev, Ribnica, Velike Lašče, or Turjak.[2518] In 1879, the right bank of Drava River part of Maribor district attorney (Bezirk Richter) was Alojzij Čeh (Alois Tschech), but immediately after Tesla's debacle he became land law-court counsellor in Ljubljana.[2519]

Maribor was a quickly expanding city full of outlaws in the era when Tesla tried his luck there. In Tesla's times in 1878, the Maribor city security police arrested 1740 lawbreakers which was 181 more than in 1877. Among them they exiled 131 persons, 555 persons were transported with force to their hometown as Tesla was exiled *mit Schub in die Heimat befördert*, in Tesla's case *mit Schub nach Gospić befördert*. 243 guys were punished in their hometowns and were not added to the total of 1740 Maribor penalties, 767 were discharged with rebuke after few hours of police arrest, and 287 of arrested guys were handed over to the law court. The main city emigration station 'welcomed' 1165 exiled persons from other similar authorities and all those unhappy folks were promptly transported ahead.[2520] Tesla was no exception of that crazy routine which prevented the tired Tesla's jailers from anything about Tesla's talents.

In 1879 the authorities of Maribor took over 1335 persons and transported them ahead which was 170 more than the previous year.[2521] In Tesla's times

the elected vice-mayor was Stampfl, and four Maribor city counsellors were Johann Girstmayr, Marco, Ludwig Bitterl von Tessenberg, and dr. Josef Schmiderer (Schmiederer) who was president of Philharmonic Society, deputy of state parliament, and deputy of land parliament. The financials maters were entrusted to the big landowner Kokoschinegg from Čebelarska (Beekeeper's) Street No. 18 and soap-manufacturer Franz Bindlechner (* 1820; † 1897) from Gosposka Street No. 13 who was the members of Maribor Loan Bank Board, the laic official (key-keeper) of Cathedral, and unsuccessful candidate for former Duhač's Viennese PM post in the list of government's national Clerical Party in 1880.[2522] The members of control commission for gas-lighting were Wiesinger, the president innkeeper Johann Girstmayr (Girstmajer) from Graz Street of today Vetrinjska Street No. 12, Dr. Lorber, the librarian of Manufacturers' Society established on January 16, 1882 Karl Flucher (Fluch), and Franz Bindlechner.[2523] Just before Tesla's exile the adjunct of Maribor district law-court dr. Alois Banmann got the similar job in the Styrian city Mureck (Cmurek).[2524] Because of so frequent expulsions from the city of Maribor, the officials did not have time to examine Tesla's talents at all. There were many other events in the city of Maribor to be aware of and Tesla's case seemingly interested no one as no prophet predicted how important Tesla will became. The Maribor folks were more interested in the suit of Fala near Ruše landowner baron Max (Maximilian Ignac) Rast considering his supposed offence in the local Ptuj press,[2525] and most of all the lost suit of the Schoolmaster of Teachers' preparatory College (k.k. Lehrer-Bildungs-Anstalt) and inspector of Maribor city schools dr. Anton Elschnigg (Elschnig, Elšnik, Director of K.K. Lehrer-Bildungs-Anstalt in Maribor) against the Schoolmaster of Girls' School (Director of Bildungskurs für Arbeitslehrerinnen) Alojz Habianitsch (Habjanič) dealing with the physical assault during the defence against attack with a chair in Habjanič's own office. The lawsuit of Maribor District-Court of the left bank of Drava River took place in Wednesday March 5, 1879 between 3 p.m. and half past 6 p.m. Habjanič's lawyer was a member of the disciplinary committee and counsel (Ausschusses und Disciplinar-Rathes) dr. Julius Kosjek of Graz while Elšnik did not hire any lawyer at all. The rooms were so crowded that they had to lock the door. The law-court adjunct of Maribor right bank of Drava River Karl Nadamlenzki led the trial and the law-court adjunct of Maribor's right bank of Drava River Slovenian politician dr. Franc Voušek (Vouschek) represented the state public prosecutor. The witnesses were the city school counsellor mayor M. Reiser, the city counsellor Marco dr. Schmiderer, the Schoolmaster Frank Stampfl of probable Gottscheer descent, Arthur Mally, the teacher of gymnastics master of exercises Rudolf Markl (Markel) who was also librarian of German Turnverein, the School-servant Stracher, the retailer Leth, and the schoolmistress of Habjanič's Girl's-School Maßenauer (Matzenauer) whose relative served in Klagenfurt (Celovec) and in peripheral Carinthia in 1879. On Saturday January 25, 1879 in 3 p.m. the school inspector of Maribor Elšnik entered Habjanič's office in the time when school provided just French language lessons. Elšnik acted in his function of school inspector and demanded the school diary to check about his daughter as a schoolmistress of Girl's-School who supplied her colleague Janžekovič. Habjanič have accused miss Elšnik of taking holidays because of her illness but in the meanwhile, she supposedly had fun with skating without her collaborator-boss teacher Matzenauer. Elšnik's friends stated that they could prove the opposite. The schoolmaster Habjanič supposedly scolded his fellow schoolmaster Elšnik as a liar, hypocrite, and smacked his face, which forced Elšnik to hand up a chair. Habjanič denied and admitted just a loud quarrel. The teacher Matzenauer and her girl-students heard the noise and rushed to witness the fight, but according to other sources they didn't observe the event because they escaped out of the building in fear. On the next day the land school inspector (Director of K.K. steiermärkischer Prüfungs-Commission für allgemeine Volks- und Bürgerschulen in Graz) dr. Johann Alexander Roschek (Rožek) from Graz ascertained the striped wound on Elšnik's face. The future author of Maribor-Streets description, the local physician's son, head physician of the Maribor hospital's medical department Dr. Arthur Mally (1843-1919) treated Elšnik's wound on February 3, 1789. The mayor suspended Elšnik from the post of school inspector despite of the fact that the Viennese

government and not the mayor hired Elšnik. The mayor knew that he acted beyond his authorities as he did few months earlier with his ban on Slovenian talk during the erection of the bishop Slomšek's monument in the Cathedral. Therefore, the mayor explained that he tried to stop further fighting between Elšnik and Habjanič. The law-court refused Elšnik's accusation therefore he had to pay 10 florins to the local School-Fund. The public applauded Habjanič's release as his behaviour was described as self-defence. The happy Habjanič was released with an acclamation from the audience: "Bravo". Both fighters were eventually dismissed from Maribor as Georg Kaas got Habjanič post in 1880 while Elšnik's post remained vacant in 1880. In 1881, Georg Kaas retained Elšnik's post and Habjanič post passed to Joseph Riedler. In 1875-1880, Elšnik and Georg Kaas's employee was the professor of mathematics Luka Lavtar, who kept his job without any additional fights.[2526]

Habjanič was the schoolmaster of Girl's-School already in 1869,[2527] while the mountaineer and zoologist Anton Elšnik (* 1827 Sv. Jurij (St. Georg) in Slovenske Gorice) was professor of Trieste Gymnasium between the years 1861-1865, and professor in High Real School in Salzburg in 1869 before he became the professor of Maribor High Real School in 1870 and later the Schoolmaster of Teacher's preparatory College in Maribor.[2528] In 1839/40 in his 3rd grammatical class of Maribor Gymnasium Elšnik was the best student with first premium while the later admiral Tegetthoff (* December 23, 1827) was praised as one of his nearly equals in knowledge (his proxime). Elšnik and his wife Antonie Braun also had a younger son Anton Elschnig (* August 22, 1863 Lipnica (Leibnitz) in Styria; † 1939) who promoted in Graz and became the leading ophthalmologist. With such scandal at hand, nobody in Maribor was interested in Nikola Tesla's whereabouts which soon proved to be much more important than those little sweet boxing between schoolmasters.

Figure 18-57: On February 16, 1879 in Tesla's Maribor neighbourhood in Tegetthoffstrasse No. 21, Veltée's Panopticon performed their final local show with the moving projections of exotic animals, advertised on the right corner of a page.[2529]

The scandalous schoolmasters' trial could be considered as another victory of mayor's German party against the Slavic elements in Maribor, and three days later the same antagonism during the much shorter and unattractive trial caused Tesla's exile. As in the earlier case of Pontius Pilate in Near East, the later history proved judges and contemporary lawsuits as unimportant and just their victims Christ and Tesla's fame never faded away. The times were especially hard after German candidates Seidl and J. Seeder lost their Maribor polls on September 12, 1878.[2530] The Schoolmaster of Celje Gymnasium Svoboda punished thirty-eight students because they sang Slavic songs in the pub and even tried to sing the Russian Hymn which they probably did not know very well at all even if some Russian travellers passed through Maribor from time to time. Five of those naughty

drunken brave students were exiled because of high-treason and they lost their stipends and the other thirty-three were imprisoned. The editor of Slovene Maribor journal Dr. Lavoslav Gregoréc (* 1839; † 1924) doubted if the punishment will be similar for any singing of Prussian songs.[2531] Formally, the Russians and the Prussians who just united Bismarck's Germany were equally hostile to

Keine Kerze mehr!

Petroleum-Sparkerze in Kerzenform, womit man um ⅓ Kreuzer Petroleum das größte Lokal 10 Stunden brillant beleuchten kann. 1 Stück aus Metall 30 kr., aus Porzellan 40 kr.

Elektrische Zündmaschine in der Größe eines kleinen Telegrafen-Apparates, höchst elegant ausgestattet, aus Ebenholz mit Bronze verziert, eine Zierde für den elegantesten Salon. Mit einem Finger die Batterie berührt und es entzündet sich das dabeistehende Lämpchen, wo man im Nu Licht hat und ist selbes, da jede Gefahr ausgeschlossen ist, der leichten Handhabung und der staunenden Billigkeit halber für Reich und Arm bestens zu empfehlen, besonders für Raucher, Krankenzimmer etc. Preis per Apparat fl. 4.50.

Licht in der Westentasche.

Eine auf der Ausstellung in Paris 1878 prämiirte Erfindung, welche es Jedermann ermöglicht die größten Entfernungen auf freiem Felde tageshell zu beleuchten. Diese Laterne kostet lackirt fl. 1.50, feiner aus Nickel mit Feuerzeug und Sprungwerk fl. 3 bis fl. 4. (198

Das Zündhölzchen hat sich überlebt!

Elektrische Selbstzünder-Feuerzeuge, womit man im größten Sturm Feuer machen kann. Der ganze Apparat ist in der Größe einer Fliege und kostet 1 Stück 10 kr. feiner mit Uhrwerk aus echtem Nickel, nie abzunützen, 1 Stück fl. 1.50 bis fl. 2.50.

Salon-Feuerwerk, geruch- und gefahrlos, 1 Karton, enthält 12erlei verschiedene effektvolle Zimmerfeuerwerke, Jedes anders, sammt Belehrung. Der ganze Karton 95 kr.

Elektrische Sonne, ganz neu, gibt ein elektrisches Tageslicht, das höchste was bis jetzt in Beleuchtung erfunden wurde. Die stärksten 50 Gasflammen werden verdunkelt, wenn dieses Licht angezündet wird; sehr empfehlenswerth für Kränzchen, Bälle, besonders beim Cotillon-Tanz zu verwenden und kostet 1 Stück fl. 3.50, größere fl. 5 bis fl. 8.50.

Der Hausfreund. Ein sehr verwendbares Instrument für jede Haushaltung, erfüllt 14 verschiedene Zwecke, als: Hammer, Zange, Hebel etc. per Stück 75 kr., so auch die neuesten **Pipen-Korke,** auf jede Flasche zu verwenden. Um die Flasche zu entleeren braucht man nur den Hahn zu öffnen. 1 Stück 45 kr.

Knall-Bonbons in größter Auswahl, enthaltend Narrenkappen, komische Anzüge, Thierköpfe etc. etc. zu den billigsten Preisen von 5 kr. angefangen bis 60 kr.

Bouquet-Fächer, ganz neu; selbes stellt ein prachtvolles Bouquet vor, mit den feinsten und schönsten Blumen ausgestattet, die beinahe von den echten nicht zu unter-

Figure 18-58: Advertising for electric lighters, lamps and similar vacuum devices awarded at the Paris World Exhibition in 1878, just one day before Tesla's arrest (Marburger Zeitung, March 7, 1879, page 4).

Habsburg's pride, but in fact the German nationalists were getting brasher and stronger in Viennese networks. In Tesla's Maribor days of preparation for the celebration of Imperial silver marriage anniversary the national feelings of Maribor native folks were especially delicate.

Tesla was exiled soon after carnival in the very beginning of the fasting. In those times on February 16, 1879 in Tesla's Maribor neighbourhood in Tegetthoffstrasse No. 21, Veltée's Panopticon with the moving projections of exotic animals performed.[2532] Louis Veltée's ancestors were from Lyon of the inventor-brothers Lumière. Together with his children and grandchild Louis Veltée used to be a pioneer of Viennese cinema. Louis Veltée's daughter was the later famous film director Luise Fleck (Luise Kolm, Luise Kolm-Fleck, Louise Veltée, 1 August 1873–15 March 1950). Louis Veltée's son Claudius Veltée later also became known as a film director. On August 26, 1896 in Viennese downtown Louis Veltée opened the wax-figures museum with a steady fixed Panopticon.

In Maribor Casino the family tombola was performed in Tesla's time.[2533] The editor Wiesthaler informed his readers of the leading local German newspaper in Maribor on the Habsburg occupation of Bosnia, on the preparations of silver-jubilee of marriage of Imperial couple celebrated on April 24, 1879 on the political fights of Viennese powerful parties between the Prince Auersperg, Taaffe, and Count Hohenwart,[2534] and on the organization of monument-erection of Maribor native admiral Tegetthoff which was attended by the Emperor himself in 1883 before the Viennese Internationale Elektrische Ausstellung. Certainly, the monument of admiral Tegetthoff had much less problems than the monument of the bishop Slomšek. Wiesthaler reported on Emil du Bois-Reymond's (* 1818; † 1896) speech in Bremen about the age of Earth,[2535] of the streets of San Francisco as the first ones illuminated with electricity worldwide linked with the lighting up of the reading-room of British Museum of London.[2536] Wiesthaler advertised Maribor photographer Henrich Krappek, electrical

lighter, lamp and similar equipment rewarded in Parisian World Fair in 1878.[2537] The funny destiny decided that the Viennese lecturer professor G. Egestreß came to talk and experiment with Edison's phonograph in the Chemistry lecture-room of Maribor High Real School with an entrée-fee of 30 kr on March 21, 1879 in 6 p.m.[2538] just after Tesla's exile. Tesla would have liked to join the fans, but he had no such luck.

18.5.15 Gospić Again

It's a pity that the *Pokrajinski arhiv* Maribor today keeps just the notes of documents considering Tesla's deportation under the numbers 2160 »p«,[2539] number 2675 »H«, and 7019 for Tesla, and number 2659 for Klaus. There is no trace for the documents themselves in Maribor, nor in Styrian Lands Archive in Graz. Those small notes of policemen were probably not considered to be worth of keeping. Whatever were the peculiarities, Nikola's father Milutin who was never very healthy went ill that winter after he returned to Gospić from his search. Milutin died without Nikola near his deathbed on April 17/30, 1879.[2540] Mojo Medić eventually gave the funeral speech. Milutin and Nikola had their dispute in Maribor, Milutin decided to use his paternal authority and they probably never resolved their quarrel. Nikola's mother was different and politer, but Nikola already suffered from the early death of his elder talented brother during their horse sledding winter adventure on a hill above their Smiljan house and Orthodox church, and now Nikola had another unresolvable trouble on his back. He probably gambled and drank a little bit more in Gospić, but finally matured under the carrying eyes of his sad clever mother.

How did it feel to be humiliated by one's own father before causing your father's death like a kind of Oedipus'patricide? After his shameful deportation Tesla taught the Orthodox religion in the Lower Real School of Gospić for a while as the substitute for his deceased father. Nikola Tesla would rather teach some technical stuff, but he had no academic diploma and Mojo Medić got the job.

After the confirmation of the Graz Commission in 1878/1879, the post of the substitute teacher for natural sciences and physics in the German or Serbo-Croatian language was established at the lower real school in Gospić. Tesla's Orthodox classmate the zoology expert Mojo Medić got the job after he completed his studies of natural sciences and chemistry at the Viennese Polytechnics College. In the autumn of 1879 after a year of teaching together with his old classmate Nikola Tesla, Mojo left Gospić. The dropout student Tesla was not officially set up in Gospić because he had no academic degree, but instead substituted for the religion courses after his father's death in April 1879. On June 1, 1892 Medić met Tesla again during Tesla's brief visit to Belgrade, and Medić became headmaster of Real school in Ruma city in 1921. Medić corresponded with Tesla between the two wars, like Tesla's Graz classmate Anton Zorić.[2541]
Nikola Tesla and Mojo Medić were the students in the same Gospić school nine years earlier. The school has Tesla's memorial plate and his statue inside, but the next-door Orthodox church was destroyed with no trace left except the memories of the elderly locals. The teaching was Tesla's goal during his Graz studies but now he dreamed more and more about inventing as no military had any power over Nikola Tesla anymore. Tesla tried his luck again in Prague University but after Maribor and other debacles Tesla did not want to learn from others because he felt as their superior. He soon even became reluctant to work for others: and he was certainly right. Despite of relative progress of Maribor know-how in Tesla's time he was unable to stay in Maribor. Considering his later career, we could only regret that Tesla did not make his

alternative current hydroelectric power plant on Drava river near Maribor instead of Niagara.

18.5.16 Tesla in Prague

Gospić was too small for the humiliated Tesla as his neighbour classmates returned with their advanced schools'diplomas much earlier while Tesla returned with policemen detention. Tesla's uncles as higher military officers enabled his studies in Prague where Mach was the leading erudite, but electrotechnics was not Mach's primary goal. There was no German provocation in Prague like Tesla experienced it in Graz, but Tesla preferred billiard anyway. Budapest, Strasbourg and Paris were next steps and Tesla finally left to USA for good. To enable his better salary in Edison's firm the uncle sent to Tesla the copy of Tesla's high school diploma of Rakovac overseas.

Der Minister für Cultus und Unterricht hat das **Öffentlichkeitsrecht** ertheilt: der Privat-Mädchen-Volksschule der Natalie **Kalmann** in Wien.
(Ministerial-Erlass vom 17. Juli 1879 [illegible])

Figure 18-59: The setting of Mojo Medić as a physicist in Gospić in 1878/79. The dropped-out student Tesla was not noted (Verordnungsblatt für den Dienstbereich des k.k. Ministeriums für Kultus und Unterricht. Jahrgang 1880. Wien: Staatsdruckerei, 336).

In Maribor, Tesla may have saved some money for studying in Prague, which he did not undertake more seriously; of course, Tesla got a lot of money from his mother, and much more from his uncle Dane Branković and from his other two uncles. The additions came through Tesla's salaries in

Gospić school, and more from the playing billiards in Zlata Praha (Golden Prague), with which Tesla later boasted during his US interviews.

The teaching was Tesla's goal during his Graz's studies, but he was increasingly dreaming of inventing. He probably fulfilled his promise or at least his father's wish when he tried to finish his studies at the Polytechnic in Prague in the spring semester began in January 1880. In Maribor, he may have saved something for studying in Prague, which he did not undertake even seriously. Of course, his mother brought a lot of money, and much more Dane Branković together with the other two neighbors. The additions came in the middle classes in Gospić, and more and more playing the billiards in golden Prague, with which Tesla later boasted during US interviews.

In 1881, they started introducing the electric public lighting and the first telephone connections in Prague, which certainly'terested Tesla. Nevertheless, the gambler Tesla in Prague never paid a school fee or passed exams. Tesla also enrolled two mathematical lectures in German language and a philosophical Stumpf's lecture on David Hume. The professor Karl Domalip (Domalíp, * 1846; † 1909) announced his lectures of experimental physics in Czech language before the Prague University split into the German and Czech parts in 1882. The similar split happened in the Prague Polytechnic as early as 1869. In 1867/68, Domalip was a student of the first year at Ernest Mach's class immediately after Mach came from Graz to Prague; Domalip's classmate was the later professor of Zagreb university Vincenz (Čeněk) Dvořak. In 1877, Domalip became a private assistant with Mach's support, and later Domalip was also the first assistant to Adalbert Karl Waltenhofen (* 1828; † 1914) at the Prague German Technical University. In the autumn semester of 1879/80, the private assistant Domalip did not only lecture on experimental physics (Electricitatslehre) and exercises (Ubungen in der Experimentalphysik), but also by Mach's influence taught the history of electricity under the German title Electricitatlehre and ihrer historischen Entwicklung. Unfortunately, Tesla did not enrol in that course.

During Tesla's "studies" in Prague, Mach was there a rector for his first time, but Tesla did not enroll his daily lessons of the Experimentalphysics class. Tesla also did not register on Mach's one-hour public lectures Theoretische Erganzungen zur Experimentalphysik. On February 17, 1880 Tesla may have listened to a popular lecture by Mach in a physical lecture room at Lotus Union under the title Über die Theorie des Radiometers und ein an die Radiometeranordnung anknüpfender Versuch, which Tesla certainly upgraded later in his subsequent vacuum experiments with Crookes radiometer. Domalip started teaching electrical engineering as a professor barely after graduating from the university in 1884/85, and in 1893 he took over the newly established Chair of Electrical Engineering at Prague Czech Technical University (*Česká škola technická*, School of strojního a elektrotechnického inženýrství). In January 1896, Domalip set up his first experiments with newly discovered X-rays, which Tesla also dealt with some controversy involved. Domalip published mostly in the domestic Prague Magazine for mathematics and physics. Domalip authored several books and a textbook for electrical engineering. He used the valuable help of František Koláček (* 1851; † 1913). František Koláček published altogether a dozen articles in *Časopis pro pěstování mathematiky a fysiky* of Prague based *Jednota českých matematiků*. Among them Tesla praised the most an interesting Koláček's Czech article written in Brno on electrometers. [2542] Koláček relied on W. Thomson's nomenclature while Koláček described Daniel, Maxwell's and other devices which Tesla used in Budapest in that time. Koláček developed his own electromagnetic theory of light based on the foundation of mechanics and published it in *Ann.Phys*.

In 1886, when Tesla already left for USA, K. *Domalíp published the Czech article which* could *be extremely interesting for Tesla under the title* O *elektrických strojích influenčních [On the electrical infuence machines]. Časopis pro pěstování mathematiky a fysiky, vol. 15, issue 4, pp. 157-170*. That was the only *Domalíp*'s ~~s~~ publication edited by Prague Jednota českých matematiků. In 1867/69, K. *Domalíp gave a paper on the session of* Jednota českých matematiků *under the title* O elektřině (June 26, 1869), Č. Dvořák lectured by the title O mechanické theorii tepla (July 10, 1869), while Jos. Hervert gave the speeches: 1. O úkolu fysiky, o poměru fysiky k fysiologii a psychologii a o methodě fysiky (26th November 1869). 2. The Importance of Insulators in Electric Theory (O významu isolatorů v theorii elektřiny on 11th *February* 1868). 3. *On the elliptical orbits* (O eliptické dráze oběžnic, 24th April 1869). 4. The Mechanics of Solid Bodies (O mechanice pevných těles, 26th June 69). 5. The Mechanics of Liquid and Gaseous Bodies (O mechanice tekutých a plynných těles, 10th July 1869). In Prague, Tesla became acquainted with the work of his year and the half younger Viennese colleague later professor of Electrotechnics and rector of the Viennese Polytechnic (Technische Hochschule) Johann Sahulka (Sakulka, * 1857 Deutsch-Wagram; † 1927 Vienna).[2543]

Heinrich Jakob Karl Durege (Durège, * 1821; † 1893) arrived in Prague in 1864 from Zürich; first to the Polytechnic Institute and then to the University in 1869. In the autumn semester 1879/80, Durège taught Differential and integral calculus, curves in space, curved surfaces and mathematical exercises. In the spring semester of 1880, he switched to the second stage of the Differential and Integral calculus, while at the

[2542] O elektrometrech. Časopis pro pěstování mathematiky a fysiky, vol. 11 (1882), issue 4, pp. 251-265; Jungnickel & McCormach, 1986, 2: 97, 104, 106, 315.

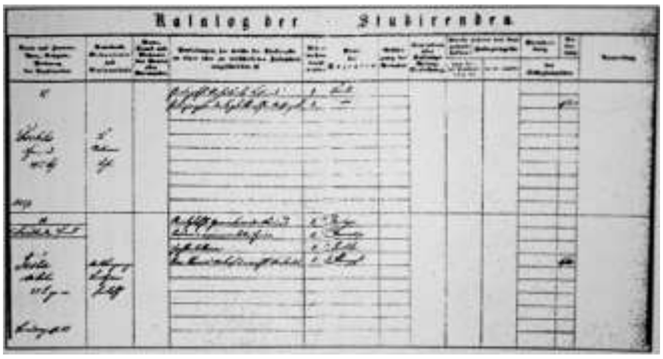
same time he lectured on the Analytical Geometry of the Space, which should be attended by Tesla two hours a week. Before Tesla’s arrival, Durège published *Elemente der Theorie der Functionen einer Complexen veränderlichen Grösse. Mit besonderer berücksichtigung "Der schöpfungen Riemann´s"*. Leipzig: B. G. Teubner, 1864. Durège’s book was noted in *Časopis pro pěstování mathematiky a fysiky* of Prague based *Jednota českých matematiků*, but Durège did not publish his articles there, probably because of his German language preferences. Puchta also didn’t publish in that Slavic language journal.



Katalog der Studirenden

Figure 18-60: List of Prague lectures that Tesla wished to attend as a 38th student in a row, residing Ve Smečkách (Smechlgasse) number 13 (Archives of the University of Prague, Main Book of Philosophers in the spring semester of 1880; Mayer, 1996, VI / 68)

The private lecturer F. Klein’s student Anton Puchta (* 1851 Staré Sedlo in Bohemia; † 1903 Černovice (Чернівці)) lectured on elliptic functions in the autumn semester of 1879/80, then on the theory of numbers and functions of one complex variable; first of them Tesla intended to listen for two hours a week. In 1887, Puchta was offered a chair in the Ukrainian Bukovina Czernowitz (Tserniwzi, Černivci, Černovice, Чернівці). In exceptional cases, they have honored an associate professor from another university with a chair. Puchta developed procedures for calculating curved areas and kept his Ukrainian chair until he passed away. His successor was Robert Sterneck (* 1871; † 1928); Sterneck was replaced by the Bled native Josip Plemelj (* 1873; † 1967), who started his Viennese studies with Boltzmann, Gegenbauer and Escherich.
Carl Stumpf (* 1848; † 1936) was a German philosopher and psychologist under the influence of Franz Brentan and Hermann Lotz. He directed the phenomenology of the 20th century, including his influences on Edmund Husserl. Stumpf works were read by Max Wertheimer, Wolfgang Köhler and Kurt Koffka. Between 1879-1884, Stumpf lectured at the Prague University, while it was divided between German and the Czech parts. Between 1883-1884 Stumpf was the Dean of the Prague German Faculty of Philosophy. He designed the physiology of tones, comparative studies of music and ethnomusicology. When the Prague engineer claimed that he invented a device for changing photos of acoustical waves into sounds, Stumpf looked at the demonstration and angrily put together a devastating critique of that strange ancestor of Edison's invention. God knows if the similar events attracted Tesla to the lectures of Stumpf, who later taught philosophy at the universities of Gottingen, Würzburg, Munich and Halle until he was honored with a prestigious Berliner chair.

Figure 18-61: Tesla's Prague Professor of Mathematics Heinrich Durege

18.5.17 Tesla Celebrated in his Native Central Europe

The Montenegro and Prague Slavic networks might be the first to recognize the rising star of Tesla, while the Prussians and the important Habsburg places followed only after Tesla’s clear success in Chicago Fair and by Niagara Falls. Graz, Vienna, Budapest and German part of

Prague networks began to praise Tesla almost simultaneously in 1893/94, although the greatest star of electrical cathode ray tube discharges Ivan Pavlovich Pului (Johan Puluj, Іва́н Па́влович Пулю́й, 1845 Hrymailiv in Galicia in Ukraine–1918 Prague) remained silent about Tesla and published mostly on local big industrial electromagnetic complexes.

In 1869 Puluj graduated with honors from the Faculty of Theology at the University of Vienna and later participated in the very first translation of the Bible into Ukrainian language from original languages and from Russian as a help of Шевче́нко's (Shevchenko) friend Panteleimon Oleksandrovych Kulish (Panteleymon Kuliš, Пантелеймон Куліш, 1819-1897). Their work was entitled Svjate pis'mo Novogo Zavitu (Сьвяте Письмо Старого і Нового Завіту: Мовою русько-українською) in 1871, 1880, and 1887. It was the latest translation rising star of Bible to one of major European languages which caused Arnold Toynbee's revelation when he and his fellow historians recognized that such a numerous nation as Ukrainian existed so long unnoticed in Europe.

Tesla's Strasbourg friend Puluj was J. Stefan and Viktor von Lang's Viennese student, and Klekler's assistant at the Naval Academy in Rijeka in 1874. He used the scholarship of Habsburg ministry of education to broaden his experimental skills as August Kundt's Strasbourg Ph.D. student in 1875-1876 while Kundt organized the Physical Institute in new university of the recently conquered Strasbourg in 1872-1888. In Strasbourg University, Puluj became interested in the phenomena generated by an electric current in a vacuum. In 1878, Puluj's lamp was awarded the Silver Medal at the Exposition universelle de Paris and Puluj was praised again at the International Electrotechnical Exhibition in Paris in 1881. Wächter and Puluj showed their inventions including cathode ray tubes at the Viennese exhibition under Stefan's scientific leadership in 1883. Having mastered the craft of the glass blower, Puluj blew glass tubes for his own experiments, and for the needs of fellow physicists. Among Kundt's students were also Roentgen, Franz S. Exner, Karl Ferdinand Braun, Emil Gabriel Warburg (1846-1931) and the Russian P.N. Lebedev (1866-1912) to form a kind of international experimental networks. In 1882, Puluj was a Viennese university private docent for physics like J. Finger was for mechanics.[2545] In that capacity Puluj frequently visited Kundt's lab for experiments on inner friction in extremely rarefied cathode ray tubes with their results jointly published.[2546] On those occasions Nikola Tesla befriended Puluj as Tesla visited the professor A. Kundt's lab where Tesla learned Puluj's art of producing cathode ray tubes. After conducting a series of studies with gas-discharge tubes, Puluj and Nikola Tesla were the closest to the solution of the nature of radiation generated by cathode rays before J.J. Thomson. In February 1888 in Prague, Puluj might have been slightly more supportive for the controversial fourth aggregate state and the explanations of radiometer of Tesla's friend Crookes than Puluj's Prague predecessor Gintl in 1880. Gustave Glaser (Gustave Glaser de Cew) translated Puluj's opinions from *Chemiker Zeitung* for Edison's Journal *Science*. Puluj noted the electrode particles as the real elements of an electric currents and sputtered the mirrors of all metals except aluminium. Puluj's extreme fine matter called ether fills all space and pierces all bodes, surrounds the molecule, as the atmosphere surrounds our globe. When the quantity of ether is greater than the normal quantity, the molecules are positive electric, otherwise they are negative. Crookes observed the phosphorescence during the restoration of ether's equilibrium and not because of the heated glass. Puluj's unitarian hypothesis maintained that electric current is nothing else but a current of ether. The number of scientists who follows the dualistic hypothesis of electricity is by far greater, but unitarian view deserved attention especially when B. Franklin, the Jesuit Angelo Secchi in 1863 and Edlund in 1871 approved it. In 1880, Puluj borrowed J. Stefan's Viennese inductor of Ruhmkorff for Puluj's experiments which mostly supported Hittorf's results.[2547] Still, Puluj as most of German writing guys, supported the electromagnetic waves of ether against the particles of Crookes and J.J. Thomson.

After he returned from Strasbourg to Vienna, Puluj continued to study the discharge phenomena. In 1880-1882 he described in detail the visible cathode rays. For some time, the device~~,~~ known as

[2545] *Hof- und Staat…*, Wien 1882, p. 121.
[2546] in*Ann*. Phys. 1878 vol. 155 and in *Wien.Ber*. 1878 vol. 78; Puluj, Ueber die Abhängigkeit der Reibung der Gase von der Temperatur. *Ann. Phys.* 1877 237/6: 296-310.
[2547] Puluj, 1880, 58-59; Puluj, 1880, 870, 883, 922; Puluj, 1889,. 317.

the "Puluj's lamp" was a mass-produced glow discharge cathode ray tube. In 1888/89 Puluj was the rector of German Technical Hochschule in Prague and gave to Roentgen Puluj's cathode rays tubes upon Roentgen's visit in Puluj's Prague laboratory in 1895. Immediately after Roentgen's discovery, Tesla and Puluj published their own X-ray photographs. Puluj's photos were so clear that they enabled the revelations of pathological changes in patients' bodies.

The support of Puluj could be decisive for Tesla as both guys were raised in their strict Orthodox religion, joined their nationalist student organisations, and had similar experimental-business interests in then biggest AC industrial projects. In the years 1899-1900 Puluj served as the rector, and in 1902, Puluj was the dean of the Electrical Department. In 1903 the dean Puluj as the first in Europe established the chair for physic and electrotechnics in Prague Technical Hochschule in accordance with Siemens' pursuits in Germany. The fact that Puluj taught in German and not in Czech Technical Hochschule could mean that Puluj loved his Habsburg citizenship higher than any Pan-Slavism just like J. Stefan which might have prevented greater Puluj's support of the Slavic Tesla. However, Puluj never abandoned his Ukrainian nationalism which was certainly not approved by Poles or Russians. Puluj was a member of Shevchenko Scientific Society (Науко́ве товари́ство імені Шевче́нка) named after the tortured Ukrainian poet Тара́с Григо́рович Шевче́нко (Taras Hryhorovych Shevchenko, 1814-1861). It was founded in Lvov (Lviv) in 1873 as a literary society devoted to the promotion of literature in Ukrainian language which was prohibited in Russia. In 1893, due to the change in its statute, the Shevchenko Scientific Society was transformed into a real scholarly multidisciplinary academy of sciences with its periodical the *Zapysky NTSh* (Notes of the Shevchenko Scientific Society). It still focused on the Ukrainian Studies. Throughout most of its history it had three sections: historical-philosophical, philological, and mathematical-medical-natural scientific. It greatly expanded its activities, contributing to both the humanities and the physical sciences, law and medicine, but most specifically once again it concentrated on Ukrainian studies to publish several hundred volumes of scholarly research and notices by 1914. Puluj activities for benevolence of his Ukrainians might have been a model for Tesla.

Tesla was a king for a while! But, there's no Sun without the spots. Some antagonists of Tesla's student days never acknowledged their errors, but their younger descendants grew up with Tesla's glory and promoted Tesla's merits. The author of Tesla's abolishment decree from Polytechnic in Graz Franz Xaver Stark von Rungberg (* 1840 Prague; † 1914) belonged to the first group. He studied in his native Prague Polytechnic between the years 1858-1862. In 1869/70 he was constructor of machines as he was attached to the chair of construction mechanics of the professor Gustav Johann Leopold Schmidt (* 1826; † 1883). In 1841-1846, Schmidt studied at the Viennese Technische Hochschule with additional lectures from Viennese university. From 1856 to 1858 Schmidt visited F. Redtenbacher in Karlsruhe to learn how to criticize kinetic theory together with Ernst Mach. Mach became Stark's lifelong model. Stark also worked in commission for locomotive drivers and fireman until he was promoted to the job in Miners Academy of Leoben. Stark had held the chair of mechanics, engineering and construction mechanics, soon also for graphic static in Graz Polytechnic between the years 1872-1886. He was the dean of Engineering (Mechanical) School from 1st October 1874 until 30th September 1876, and the rector of Polytechnic (*Technische Hochschule*) in Graz between October 1, 1877 and September 30, 1878. So, Stark expelled Tesla from Graz studies. Before he learned about the huge mistake he made against Tesla, Stark moved to the German Prague Polytechnic (German *Technische Hochschule*) in 1886. Due to the excess of his office work during Tesla's Graz studies Stark only published his work presented in front of the Graz Polytechnic Club on a new material strength test and the paper Die sociale und staatliche Stellung des Technikers. Referat gehalten in der Wochenversammlung des Polytechnischen Clubs in Graz am 10. Marz, 1877. Tesla was able to see both Stark's performances. In Prague, Stark was the editor and redactor of Polytechnic (*Technische Hochschule*) journal *Technische Blatter: Vierteljahrschrift des deutschen polytechnischen Vereines in Böhmen*. Their *polytechnischen Vereines in Böhmen* was established as Architekten- und Ingenieur-Vereins in Prague in March 1869, but soon it split on

German and Czech parts as did their schools in Prague.[2548]

As a replacement of E. Czuber, Stark edited volumes 23–40 of *Technische Blatter* in 1891–1908. In 1891 in first volume under his redaction Stark published Beitrag zur Berechnung des continuierlichen Trägers on pages 23: 107-112 of *Technische Blatter*. In 1895, Stark published his paper Die Energie und Energetik based on ideas of W. Ostwald on pages 27: 159-173 after Stark's speech in front of Prague Polytechnic Society (Vereins) on 27. 12. 1895. Next appeared Stark's paper Maßsysteme und Grundbegriffe in *Technische Blätter* in Prague on pages 26: 167-189 with F. Redetenbacher and E. Mach's mass of a body as the quantity of inertia of the body. Both were the leading authorities for Stark on page 26: 181 in 1894. Stark endorsed the negation of matter, as matter must be a conglomerate of the different energy forms according to W. Ostwald's Lübeck paper against materialism of Boltzmann, Karl Marx, the blind Eugen Dühring's (1833-1921) antagonist F. Engels and similar fellows. Ostwald's energism was very popular for a while as a refutation of the revolutionary and other kinds of materialism, which on its turn defeated the idealistic philosophy of romanticism after the spring of nation of 1848. On 20. 9. 1895, Ostwald entitled his paper as Overcoming scientific materialism (Die Überwindung des wissenschaftlichen Materialismus) which speaks for itself and explains why Engels and Lenin were so upset with that kind of ideas; Ostwald was an active pacifist like Tesla, but communism was far from his agenda. Dühring's anti-Semitic positivistic biography of Robert Mayer entitled *Robert Mayer, der Galilei des neunzehnten Jahrhunderts: eine Einfuehrung in seine Leistungen und Schicksale* of 1889, and F. Redtenbacher's living force (Lebendiger Kraft) were Stark's chief trumps, both extremely far from Engels' materialism of *Anti-Dühring* of 1877 or later Lenin's *Materialism and Empirio-criticism* (*Материализм и эмпириокритицизм*) against Mach and Alexander Aleksandrovich Bogdanov (Алекса́ндр Алекса́ндрович Богда́нов Малiно́ўскi, 1873-1928) issued in 1909. Stark relied on kinetic energy formula:

$$E = (1/2) \cdot m \cdot v^2 = A$$

where E was Energy and A was work on page 170, just like Tesla did in June 1900 and Einstein more sophisticatedly finally in his general theory of relativity later. Stark even tried to develop his idea "Matter is Energy" from Maxwell's book Matter and motion on Stark's next to last page 172. Stark praised Ostwald as well as Mach and forgot to notice that Ostwald was defeated in Georg Helm's (1851 Dresden -1923 Dresden) arrangement of Ostwald-Boltzmann duel in Lübeck which Stark wrongly described as Ostwald's victory. The duel was in Lübeck during the Congress of German Scientists in September 1895. Years after, Arnold Sommerfeld (1868-1951) described what happened: 'Helm was the champion of energism; then came Ostwald and, afterwards, the philosophical theories of Mach (who was not present at the event). In the opposite corner was Boltzmann, supported by Felix Klein (1849-1925). The skirmish between Boltzmann and Ostwald looked pretty much like a duel between a hefty bull and a trembling bullfighter. Yet on that occasion the bull defeated the man and his agility. Boltzmann's arguments convinced everybody. All young mathematicians like myself were on Boltzmann's side'. After his defeat in the confrontation, Ostwald was very upset as he bitterly wrote to his wife about 'tight antagonism' when he 'faced such an openly hostile group of people'. The harsh contention between Ostwald and Boltzmann, who nevertheless remained friends, was continued through series of papers. Only in 1909 after Perrin's experiments with atoms did Ostwald eventually acknowledge to Sommerfeld that he had been wrong, but Mach never really accepted Stefan-Boltzmann's atoms. Tesla did not acknowledge Boltzmann's victory and Tesla's early 1900 Problem of Increasing Human Energy was still a kind of simplified Ostwald's energism designed for broader American public all over again. Stark and his student victim Tesla were therefore extremely close in their philosophical views. Albert Einstein and his family tried in vain to obtain Ostwald's support for Albert Einstein as a young upstart who hided Ostwald's energism in his own general theory of relativity after Friedrich Wilhelm Ostwald (1853 Riga-1832 Leipzig) retired in 1906 to escape from his ungrateful students and to abandon his concepts of antiatomic energism. As Tesla's ether, Tesla's energism was also near mainstream before Fin de Siècle, but not after it.

[2548] F. Steiner, Geschichtlichen… *Technische Blatter* 1894 25: 225.

Einstein taught in German University of Prague next door to Stark's school for seventeen months after April 1911. He was full of jokes about bugs in his own bed and about that half of lunatics which do not discuss quantum mechanics under Einstein widow facing the mental hospital. Einstein socialized with the Prague Jewish community of philosophical-literary debating circle in the salon of the fan of Nietzsche and Richard Wagner the Jewish Bertha Fanta (née Sohr, 1865-1918), or in the pharmacy "Zum Einhorn (U jednorožce)", both in Staroměstské náměstí. There Einstein frequented the Jewish folks and musical-literary society like the Jewish writers Max Brod (1884-1968) and Franz Kafka, the philosopher-Zionist Hugo Bergmann and the physicist Philipp Frank (1884 Vienna–1966 Cambridge Massachusetts), who later replaced Einstein in Prague. Stark probably did not care much for Einstein's Prague popularity as Stark retired in 1912 and the invalided E. Mach already left for the flat of Ernst Mach's son in Munich. In 1897, Stark glorified Mach's Mechanic and its development in its 3rd reprint issued in 1897 on pages 29: 183-188. Stark added some notes on Redenbacher's *Die Principen* of 1859 on page 39: 186 and on H. Hertz's last genial work Principles of Mechanic published without the concept of force in 1894. Stark probably never mentioned Tesla in public except when he expelled Tesla from Graz school. Sancta Simplicitas.

After Emanuel Fait (1854 Beroun (Verona, Beraun) 20 km southwest of Prague-1929 Prague), next Tesla's Central-European biographer became Tesla's former Hungarian-French boss AC currents' backer Etienne de Fodor (Étienne, István, 1856 Bratislava-1929 Budapest). Emil Müller published a recension of Etienne de Fodor's recent book.[2549] On 30. 11. 1894 the first Tesla's fan in Prague and Kaliningrad the Sudeten German Emil Müller (22. 4. 1861 Landskron (Lanškroun)-1. 9. 1927 Vienna) spoke in hall of physics of German Technical Hochschule on Neuer Ansichten über Elektricität. Müller relied on Faraday-Maxwell's theory backed by Hertz's experiments for electrostatic induction, dialectic polarisation and the substance of ether.[2550] Emil Müller studied at the University and in the Technical Hochschule in Vienna and graduated with a teaching degree in 1885. In 1885/86 he completed his probationary year at the Schottenfeld Realschule, then he was Assistant for Performing Geometry at the Technical Hochschule in Vienna for four years and then until 1892 suppler at the Technological Trade Museum in Vienna. In 1892 he got a position as a senior teacher at the newly built construction school in Königsberg (Kaliningrad) where he received his doctorate in 1898 with the dissertation entitled the geometry of oriented spheres of Graßmann's methods. He habilitated in 1899. In 1902 he was appointed to the Viennese University of Technology as a chair for Performing Geometry, where he worked until his death. He was the founder of the Viennese School of Performing Geometry. He has adapted the introductory lectures for Civil Engineering, Surveying and Architecture students to the latest technical requirements by completely redesigned teaching program of Performing Geometry. His textbooks were widely used. He was a founding member of the Viennese Mathematical Society and for many years its chairman. In 1906 he became a corresponding member of the Austrian Academy of Sciences, in 1912/13 a Rector of the Viennese University of Technology, in 1916 a Hofrat and full member of the Austrian Academy of Sciences. Emil Müller authored *Lehrbuch der Darstellenden Geometrie für techn. Hochschulen* 1-2, Leipzig/Berlin in 1908-1923 and *Vorlesungen über Darstellende Geometrie 1-3, bearbeitet von E. Kruppa*, Leipzig/Wien in 1913-1929.

Emil Müller was clearly a great backer for the famous Tesla. In 1895 on page 27: 91 of *Technische Blatter: Vierteljahrschrift des deutschen polytechnischen Vereines in Böhmen* the engineer Emil Müller reviewed the work of Tesla and his collaborator the director of electric central station in Athens Etienne de Fodor entitled *Experimente mit Strömen Hoher Wechselzahl und Frequenz: Zusammengestellt von Etienne de Fodor; Revidirt und mit Anmerkungen Versehen von Nikolas Tesla; mit 94 Abbildungen*, Wien: A. Hartleben, 1894. Next, E. Müller published a recension of W. Weiler's Dynamomaschine. E. Müller wrote a recension of book of Edmund Reitlinger's (1830 Pest-1882) Viennese collaborator in magnetized cathode ray tubes research Alfred Ritter von Urbanitzky (* 1852) entitled *Die Elektrizität im Dienste der*

2549 *Die elektrische Schweissung und Löthung* of Wien/Pest/Leipzig: A. Hartleben, 1892; Emil Müller, 1892, *Technische Blatter*, 24: 151.

2550 F. Steiner, Geschichtlichen… *Technische Blatter* 1894 25: 231-232.

Menschheit: eine Darstellung der magnetischen und elektrischen Naturkräfte und ihrer praktischen Anwendungen: nach dem gegenwärtigen Standpunkte der Wissenschaft, Wien: A. Hartleben, 1895 on pages 27: 92-93.

István Fodor's family lived under tight financial conditions in Bratislava, so he only finished the lower secondary school, which was still more than Edison absolved. Along with his daily work, Fodor studied technics and learned languages. His goals and thoughts were directed by Edison's inventions. In 1880 he traveled to Paris to learn the necessary practical knowledge about lamps with Zénobe Gramme (1826-1901) and the freemasonic Russian inventor of lamps for electrical lighting Pavel Nikolayevich Yablochkov (Jabločkov, Jablochkoff, Павел Николаевич Яблочков, 1847-1894). Through Tivadar Puskás, who represented Edison's European interests in electrical lighting in Paris, Edison used Tesla's and Fodor's abilities for Société Electrique Edison. Edison introduced the incandescent lighting system designed for the cities at the International Electrotechnical Exhibition in Paris in 1881. Puskás and Fodor worked together to prepare the exhibition which was opened on August 1, 1881 while Tesla was involved in less glorious telephone installation works in Budapest. The 125-horsepower Edison's Dynamo was commissioned as the famous Jupiter, while the joker Puskás rather nicknamed it into the Circus Elephant. The famous architect of Parisian Opera Charles Garnier (1825-1898) was also in charge of the committee researching impacts of Garnier's masterpieces on gas illumination. The inventiveness of electricians went hand in hand to amuse the mob. The simultaneous competitive testing of several lighting systems took place in the Opera House itself including Edison's system of "foyer du public", a huge design 54 meters long, 13 meters wide, 18 meters tall. The dynamos were placed in the woods on the corner of the Opera House. On October 18, 1881, the experiment proved the unsuitability of the arc lamps and brought Edison's full victory as the first major European success of lighting with incandescent lamps.

The success accelerated the orders while Tesla had his AC motor vision in Budapest park in February 1882. The main building at Strasbourg Train Station was illuminated by Fodor and finally also with Tesla's knowhow. Tesla was sent to Strasbourg to resolve the troubles with the local lighting plant in February 1883. Tesla supposedly demonstrated his AC motor to the former Strasbourg French mayor the professor of medicine Émile Küss' (Kuss, 1815 Strasbourg-1. 3. 1871 Bordeaux) employee Bauzin and Bauzin's fellows few months later. Tesla narrated that Bauzin was a former mayor of the city who served his best wine to Tesla after he hided it from the German invasion of 1870/71. No guy with similar Christian or family name was in that position in Strasbourg, in Alsace, nor in whole France. Otherwise, Bauzin's family is frequent in the Alsace and the red wine Saint-Estèphe from Médoc region in Bordeaux which Bauzin hided from the thirsty German soldiers for Tesla is famous worldwide. Otherwise, like usual in Tesla's stories, Tesla just mixed some facts to make them sound better for his audience as Tesla was not aware that the future fans of web might have checked his narrations. Otherwise, Tesla's problems with German pedantic Alsace administration might have been true. The German mayor pastor Otto Back (1834-1917) used to be the Germanizing freak of Strasbourg in 1873–1880, and 1887–1906 as a supporter of Kundt's local institute of physics. Tesla was not a great fan of Germans, but he certainly loved Kundt's lab.[2551]

Fodor set up a warehouse in Hamburg and established a branch in Antwerp. At the same time, Fodor directed the installation work in Belgium and the Netherlands until he was recalled to France where Fodor directed Tesla's installation and commissioning of a factory in Ivry-sur-Seine suburb of Paris. In 1882, in St. Petersburg, in addition to several industrial facilities, Fodor illuminated a luxury yacht and part of the royal palace. After Tesla left for USA, Fodor worked in Hungary in 1885, at a sugar factory in Sládkovičovo (Diosek, Diószeg) of southwestern Slovakia, in Tirol, Grenoble, then even in North Africa. Fodor's experiences were summarized in his first book on the incandescent light *Das Glühlicht* published in Vienna in 1885. In Athens, Fodor directed the construction of the city's electric power station, where for the first time, at the suggestion of Fodor, they applied a triple wiring system led by Fodor which began operating in 1889. István Fodor wrote the first European Electrical Welding Manual, which was published as "Electrical Welding and Soldering" in 1892. In

[2551] Bokšan, 1932. *Nikola Tesla,* 312; Tesla, *Moji Pronalasci,* Zagreb: Školska knjiga, 1981, 48.

1893 he arranged the lighting of the Corinthian Canal. He also tried to incorporate Ganz & co. (*Ganz vállalatok*) of András Mechwart de Belecska (Andreas, 1834 Schweinfurt-1907 Budapest) who took over the firm after the Calvinist Ábrahám Ganz's (Abraham, 1814 Unter-Embrach in Switzerland-1867 Pest) suicide. To include the powerful Ganz & co., István Fodor promoted Tesla's AC ideas for design and construction but eventually failed because of Edison's lifelong aversion against Tesla's alternating currents. So, the unconvinced Fodor was forced to return to the usual Edison's system. The Greek King rewarded Fodor with the Knight Cross-medal of the Saviour Order. After short work in Turkey, Fodor became Director of Budapest General Electricity Co. in 1894. Fodor used DC electrification for the illumination of the Andrássy Avenue in Budapest at Köröndt. Fodor's more than two decades purposeful activity developed a model DC system of BÁV Rt, (Budapesti Általános Villamossági Rt., Budapest General Electricity Co.). In 1909, BÁV Rt. built streetlights with 38 light arches at their own expense at the Rákóczi út between the Museum Boulevard and the Erzsébet Boulevard of Budapest. After their work gained public satisfaction, the public lighting was built in the City Park, Teréz körút (Boulevard), Erzsébet körút (Boulevard), József körút, Ferenc körút (Boulevard), Andrássy út (Avenue), and Lajos Kossuth street in Budapest in 1911. Fodor's DC power supply was operational until 1962. Fodor authored many electrical engineering, general technical and economics books and studies. He lectured in Germany and in Vienna including the somewhat ecological "The smokeless city and industry" in 1907. In 1911, Fodor personally welcomed his model Edison in Budapest and then in Bratislava. Edison originally planned just to see Vienna, but Fodor convinced him that it would be worthwhile to see Hungary for a few days. Edison was glad while Edison and Fodor cooperation proved that the inventor could be successful businessman if only he was able to please his Maecenas with occasional humility, which Tesla ultimately failed to practice. Tesla was just to clever to worship his usually foolish wealthy would-bee investors. In 1894, Fodor was able to be nice for both Edison and Tesla while Fodor with Tesla's help added one of the first Tesla's biographies to Fodor's book focused on AC and impedance phenomena of electrical resonance. Tesla personally revised and amended Fodor's book and Emil Müller published its glorifying review.

In that way, the German parts of Tesla's former Prague headquarters and Tesla's Budapest networks praised Tesla with Fodor's efforts soon after Tesla's successes in Chicago & Niagara. Boltzmann's best Graz assistant and nephew of his teacher Albert von Ettingshausen (1850-1932) did the same after Albert highly praised Boltzmann immediately after Albert left the university of Graz to replace the retired J. Pöschl in former Tesla's Graz Technical High School in 1890.[2552] In 1893 in his inauguration rector speech in Graz Technical High School Albert von Ettingshausen proudly remembered Tesla's student years there and forgot to mention Tesla's troubles in Graz. On 11. 11. 1894 just after he publication of Fodor's book, Albert von Ettingshausen lectured for Styrian Society to gain a huge applause with Tesla's pictures of high frequency alternative currents. The title of Albert von Ettingshausen's paper was Über hochgespannte Wechselströme as it became usual for the presentation of Tesla's ideas. The classroom proved to be too small for the huge audience. Albert's assistant was Karl Pichelmayer (1868-1914). Before Albert von Ettingshausen, Ignaz Klemenčič, Leopold Pfaundler, Fr. Streintz and other spoke.[2553] Pöschl was not a member of *Naturwissenschaftlicher Verein für Steiermark* anymore, but he was still in Graz and he might attend the presentation just for fun to see the picture of his old fan Tesla? Tesla got his glory in his Graz and Prague *Alma Mater*, and soon after Albert von Ettingshausen's death also Graz honorary Ph.D. Ettingshausen glorified Tesla in his speech "Vortragende auch das Bild des Nikola Tesla vor" as "ein geborener Österreicher ist und seine Studien an der Grazer Technischen Hochschule gemacht hat". On 11. 11. 1894 Albert von Ettingshausen lectured in front of *Naturwissenschaftlicher Verein für Steiermark.* There he presented the picture of Nikola Tesla presented in front of the audience of his former Graz teachers, and there was a small lie as Tesla "is a born Austrian and has made his studies at the Graz technical college" because it sounded like Tesla graduated in Graz. Similarly, at the same time, the guys from Prague tried to say that Tesla

[2552] Stiller, Wolfgang. *Ludwig Boltzmann*. Frankfurt: Harri Deutsch, 1989, 22, 24.
[2553] Ettingshausen, 1895, *Mitt. Naturwissenschaftlicher Verein für Steiermark* 31: LI.

graduated in Prague. During Tesla's real studies there, in Prague they were never so kind.

In 1898, the great pioneering researcher of cathode ray tube the Ukrainian Puluj reported on electric waves and wireless telegraphy in his paper published in *Wochenversammlung* on 2. 2. 1898. Puluj noted Faraday and Maxwell but listed only the new research of Righi and Marconi with Morse's device without mentioning Tesla on pages 30: 37-38. On page 30: 197, Stark reported on flying machines. In 1899 they reported on Anton Daul's Mid-European description of Perpetuum mobile in the journal Technic (Technikers) of New York on page 31: 59. In 1901 on pages 33: 67-71, and 84 they reported on Wilhelm Kress' (1836 Saint Petersburg-1913 Vienna) aircrafts which Boltzmann also supported. In 1902 they reported on vacuum cleaner.[2554]

In 1903, J. Puluj of German Technische Hochschule in Prague discussed diagrams of generators of alternating electric currents designed by Heyland, Kapp and Heubach without noting Tesla on pages 35: 93-113. In 1904, J. Puluj described the local firm Ignatz Spiro (1817-1894) & Sohne Český Krumlov (Krumau) without mentioning Tesla but with the use of G. Ferraris' voltmeter on pages 36: 18-40. In 1907 Stark published his paper Über Probleme der Knickfestigkeit with figures on pages 39: 1-28. In review of the book about wireless, Edison was noted but Tesla was ignored on page 39: 197. In 1908 in his last edited volume Stark already published a comparison between direct current (DC) and alternating current (AC) although without mentioning Tesla's name on page 40: 74. Under Stark's editorship, most contributors wrote on mechanical engineering or even on modern aircrafts heavier than air, but except J. Puluj who reported on electrotechnics in nearly every volume, that modern Tesla's field was almost neglected.

During Tesla's Graz studies Stark had a lot of administrative work and published just his speeches in Polytechnic Club in Graz on March 11, 1876 (*Über einige neuere Festigkeitversuche* in 1877 and *Die sociale und staatliche Stellung des Technikers. Referat gehalten in der Wochenversammlung des Polytechnischen Clubs in Graz am 10. Marz, 1877.* In 1877, both works were printed in Graz in *Selbstverlag des Polytechnischen Clubs*, the first one on thirty-four pages with three tables together with two other technical papers, and the other on seventy pages. After graduation Stark worked in railway wagon fabric in Prague, and hardness of solid matter became his primary field. Tesla may have attended his lectures in Polytechnic Club or at least heard some rumours about them, but Stark probably never understood Tesla's talents.

The Slovenian fans of Tesla soon appeared. The German-Slovenian Maribor authorities certainly made a huge error, but the Slovenians tried to repair it decades later. Between 11th and 20th October 1960 in Parisian 11th General Conference on Weights and Measures (*Conférence générale des poids et mesures*), the electro-engineer France Avčin (1910 Ljubljana-1984 Ljubljana) successfully proposed Tesla's name for the unit of the strength of a magnetic field.

Avčin excelled at fourth session of that meeting of the general conference of weights and measures held at the foreign affairs office at avenue Kléber no 19 in Paris on Tuesday, October 18, 1960, at 3 pm headed by Émile Georges Barrillon (1879 Mézières in Ardennes-1967 Montreuil-sous-bois), the president of the Academy of Sciences of the Institut de France. By point 15 they discussed the International System of Units. That famous event in fact earned Tesla more fame than the Nobel Prize a dozen and a half dozen years after his death. The Austrian Josef Stulla-Götz (1901 Vienna-after 1972) led the event. He received his doctorate in physics and mathematics from the University of Vienna in 1924. He excelled by important measurements of radioactivity and temperatures. As a physicist and expert in metrology, Josef Stulla-Götz became chairman of the Austrian Federal Office for Calibration and Surveying. In the absence of professor Bourdoun (Burdun, Григорий Дмитриевич Бурдун) as the Chairman of the Committee of System of Units, his deputy Stulla-Götz introduced the report on the International System of Units. Burdun defended his doctoral dissertation in 1952. From 1954 to 1962 he was a deputy chairman of his boss Andrej Erofeevič Vjatkin (Андрей Ерофеевич Вяткин,

[2554] on page 34: 104 (Anton Daul, *Das perpetuum mobile: eine Beschreibung der interessantesten, wenn auch vergeblichen, aber doch immer sinnreichen und belehrenden Versuche, eine Vorrichtung oder Maschine herzustellen, welche sich beständig, ohne äussere Anregung, von selbst in Bewegung erhalten soll*. Wien/Pest/Leipzig: A. Hartleben, 1900).

1903-1970) at the Committee of Standards, Measures and Measuring Instruments of the Council of Ministers of the USSR (Commité des Normes, des Mesures et Instruments de Mesure, Leninski prospect (Ленинский проспект and partly the проспект of Academician Sakharov) 9 b in Moscow (Москва) V 49, Государственный комитет СССР по стандартам (комитет стандартов, мер и измерительных приборов при Совете министров СССР), later Государственный комитет РФ по стандартизации и метрологии (Госстандарт), now Rosstandart). Stulla-Götz noted a century and half after Vega began to introduce metric system in his neighborhood: "One of the tasks of Convention of measures is to perfect the metric system and to promote its expansion. This task includes, as it was deemed necessary, the establishment of a practical system of units for international relations, which could be adopted in all member States of our Convention. Already in 1913, on occasion of the Fifth General Conference, the son of a Swiss horologist pioneer in plasma cosmology Nobel laureate of 1920 Charles Édouard Guillaume (1861 Fleurier in Switzerland-1938 Sèvres in France) as a head of International Bureau of Weights and Measures paid great attention to the MKS system completed by an electrical unit. In 1948, the Ninth General Conference endorsed a request from the International Union of Pure and Applied Physics by repeating that question. They instructed the International Committee to open an inquiry into the opinion of the scientific, technical and educational circles from all countries to make recommendations for the foundation of practical system of units. In 1951, the Tenth General Conference established the basic units of this system, which are well known: meter, kilogram, second, ampere, Kelvin and candela. The International Committee then formed within itself a Committee for the System of Units, composed of seven members of the Committee and the Director of the Bureau Burdun. The Commission deeply regrets that an illness prevented Burdun from submitting the report on the work of this Commission himself and from summing up the very comprehensive presentation he had prepared as annex on six pages of problems concerning the establishment of the International System of Units. The results of Commission's deliberations and the decisions taken by the International Committee have been compiled in the draft resolution submitted on page 87. Finally, I would like to mention that the International Committee for Metrology legally declared to adhere to the resolution of the International Committee of Weights and Measures on the establishment of the International System of Unities. The Committee for Legal Metrology recommends to the Member States of its organization the adoption of this System in their legislation of units of measurement."

The co-editor of Niels Bohr's latest works professor of theoretical physics at Copenhagen Polytechnic Henning Højgaard Jensen (1918 Emb of Blistrup Parish on Mors-2001) proposed that in the list of recommended derived units, the magnetic induction unit should be expressed in Weber per square meter (Wb/m^2) and that the name "tesla" must be deleted. Indeed, it is fair to limit the use of special names for units. There is no question of abandoning the well-known names of units such as farad, henry, etc., but this is not the same case for tesla.

The Armenian professor Valentin Osipovich Arutyunov (Aroutunov, Arutyunov, О́сипович Арутю́нов, 1908 the capital of Turkmenistan (Turkmenistan) Askhabad (Ašhabád, Aşgabat)-1976 Leningrad) as director of the Institute of Metrology of DI Mendeleyev in Leningrad in 1956-1975 disagreed with this proposal. He noted on the contrary the tendency to give an individual rather short name to each unit; this is how his country recently proposed the name of " lenz" for the unit of magnetized field strength (ampere per meter), certainly by the Russian expert of Jacobi's electroplating Emil Lenz (1804 Tartu-1865 Rome). The name of Tesla, approved by the International Electrotechnical Commission and adopted the same year by the International Committee, is already used in teaching at Soviet Union.

The professor of theoretical physics of the University of Amsterdam Jan de Boer (1911 Haarlem–2010 Doorn), however, supported the thesis of Hojgaard Jensen; he considered that the introduction of special names for derived units can only detriment the clarity of the International System.

Former Naccari's assistant now professor at Polytechnic University of Turin Eligio Perucca (1890 Potenza-1965 Rome) intervened in the same direction.

President of the Physikalisch-Technische Bundesanstalt in Braunschweig Gotthold Richard Vieweg (* 1896 Topfseifersdorf; † 1972 Kälberbronn) also thought that the use of new names should be restricted; he felt, however, that the name of Tesla was already sufficiently used to be retained. Apparently, it sounded strange because the unit tesla was about to replace the ten thousand times smaller now obsolete CGS unit named after German mathematician-physicist Carl Friedrich Gauss in 1936. Vieweg was certainly a German, but his residence in Braunschweig might be so close to East Germany and his native Saxon Topfseifersdorf was a part of East Germany that he kind a secretly changed sides.

Avčin intervened in favor of the maintenance of tesla which is already included in the laws of some countries. If the removal of tesla is requested, he would then propose to delete the newton too.

Director of Service Belge de la Métrologie Maurice-Jacques Jacob said that his country could not agree to paragraph 10 of the proposed resolution, unless their less imperative character was specified. The decisions of the General Conference have the force of law in Belgium and this would oblige the Belgian Government to prepare a new law.

The director of Parisian observatory André-Louis Danjon (1890 Caen-1967 Paris) considers that the General Conference cannot follow the directives of a Government.

The director International Bureau of Weights and Measures Charles Volet (1895 Vevey in Switzerland-1992) observed in this connection that there is obviously no international police force to ensure the implementation of the resolutions of the Conference; these resolutions have the value of recommendations for each of the member states.

Jensen vainly assured that the unit of magnetic induction could be expressed in Weber per square meter (Wb/m^2). He considered that the name "tesla" should therefore be deleted, since it measures 10,000 Gauss units in now obsolete CGS system adopted in 1936. This was incorrect because Wb measures magnetic flux as a function of space geometry and is therefore useless for magnetic field measurements. Jansen was supported by Astin who got his PhD from New York University as a student of WA Lewis in 1929. Allen Varley Astin (1904 Salt Lake City in Utah-1984 Bethesda northwest of Washington, Maryland) was director of the National Bureau of Standardization in Washington from 1951 to 1969. During World War II, Astin developed a contact fuse that detonates an explosive device automatically when the distance to the target becomes less than a predetermined value. His invention was embedded in bombs donated to the Japanese in 1945. Astin was an advocate of the incomplete introduction of metric weights in the United States, but he disliked those quarrels because he mostly expected entertainment in Paris in 1960, as the American scientific tourist in Europe usually does. Despite Tesla's American citizenship that Tesla was so proud of, Astin was therefore drawn to the opposing Jensen Cold War pole in a dispute which became aggravated a couple of weeks later by the futile US disembarkation in Cuban Bay of Pigs in April 1961. Astin said that this discussion complicated the task of the Conference; that is why he will abstain in the vote on this resolution, while he approves paragraph 3.

Stulla-Götz said that the decisions of the General Conference morally committed the Member States; for example, the symbol of the prefix deca (da), although embarrassing for Austria, will nevertheless be accepted by his country. He therefore asked the Conference to adopt the resolution which had been proposed.

De Boer again intervenes against the unit tesla and regrets the tendency of electrical engineers to introduce many special names for units. Physicists are of the opposite opinion and, when opinions are divided on the advisability of adding a name to a unit, it is better to obey the experts.
Anutunov disagreed with Perucca who has argued that education is better without too many unit names. He admits that it is wise to study these questions with slow caution and to postpone some proposals, but such a position is not currently justified for tesla.

After one last intervention of Avčin in favor of tesla, the maintenance of Tesla’s name for the magnetic induction unit was approved by 11 votes for, 6 against and 12 abstentions.

De Boer considered it unfortunate to use for a unit a name which has collected such a small number of votes. The deputy president of Hungarian National Office of Measures Peter Honti (1907-1981) remarked that the acquired simple majority is sufficiently enough; he proposed, with Arutunov, that the Conference take a decision on the whole of the resolution presented.

Before vote, Perucca and Inspector General of Agricultural and Industrial Products in Lisbon F.A. de Alcantara Carreira drew attention to the name of the unit of mass, the kilogram, whose symbol (kg) is not suitable for a basic unit; how can one indeed think to add to the symbol kg the prefixes of multiples and submultiples (as it already contain a prefix kilo)? They regret that this issue has not been taken into consideration.

Avčin was the only Yugoslavian delegate eligible to vote in than polarized east-west politics where Arutunov stated that the Soviets will use Tesla's unit in any case and Avčin cleverly noted that the unit of Newton should be abandoned if the unit of Tesla would not be accepted in their same packet of novelties. Nobody was prepared to challenge Newton! After those discussions, the resolution of the International Committee on the International System of Units was adopted as whole by repeated 18 votes in favor, 1 against and 2 abstentions in Resolution 12 on page 87. In that way, the Slovenian Avčin at least partly reimbursed the damage done to Tesla in Slovenian Maribor.

Avčin wrote a foreword for Milan Pertot's (1884 Trst-1967 Ljubljana) biography of Nikola Tesla in 1962, while Avčin collaborated with his students and colleagues Venčeslav Koželj (1901-1968), Albert Čebulj (1918 Glarus in Switzerland-1995), and Božidar Magajna (11. 12. 1912 Ljubljana-2012) who studied electrotechnics in Ljubljana in 1937-1941. They published their papers delivered on occasion of quarter of century of Tesla's death in 1968. Two years later, their works were printed as another biography of Tesla for Ljubljana based Elektrotehniška zveza Slovenije in 1970.

On 2. 5. 1935 Avčin graduated in electrical engineering at Ljubljana university in the class of chess grandmaster Milan Vidmar (1885 Ljubljana-1962 Ljubljana). On 29. 5. 1936 *Glas Naroda* in Ljubljana anonymously published about Tesla's approaching 80th birthday with several typographic and other errors about years involved. In August 10–28, 1936, Vidmar won 9th place among 15 masters at then strongest chess tournament in Nottingham University after he excelled with his fair play during his match against then world champion the Cuban José Raúl Capablanca y Graupera (1888-1942) in London on August 16th on the end of tournament which lasted from 31st of July to the 19th of August 1922. In London, Capablanca won his first place and Vidmar was third after the Russian turned Nazi Frenchman future world champion Alexander Alekhine (Алекса́ндр Алекса́ндрович Але́хин, 1892-1946), but Vidmar could have won in he would not have been so fair to the delayer Capablanca.

After his disappointing Nottingham scores Vidmar embarked his ship named Bremen for the USA. Soon after Tesla's 80th birthday, on 5th September 1936 Vidmar and the engineer of tunnels and bridges Vitomir M. Joksić from Beograd visited Tesla in New York before Vidmar's attendance of the World Energy Congress (Power Conference) in Washington D.C. on September 7-12, 1936 and concurrently therewith second congress of International commission on large dams of the World power conference. Vidmar subsequently published a lot about Tesla whereabouts including Vidmar's speech at on Academic club of electrotechnics in Ljubljana where Vidmar reported about his visit in Tesla's headquarters. In that year 1936 Tesla received his honorary Ph.D. of the technical university of Prague where he once studied, while the honorary Ph.D. of the technical university of Graz where he also studied followed in 1937. In 1936, Tesla got the Yugoslavian Order of the White Eagle of I Class. On 11. 2. 1937, Vidmar described his talks with Tesla. Vidmar compared Tesla to much wealthier Pupin whom Vidmar visited in 1927 and declared that Tesla's lab worth three quarters of million loaned dollars was destroyed with dynamite which Tesla never forgave although his Wardenclyffe Tower lab was bombed two decades earlier as a disastrous nonsense. The poor Tesla worked just for the welfare of all humanity and believed that he had a solution for the wireless distribution of energies which Vidmar did not comment in any further details or opinions. Few months later, the taxicab hit Tesla during his regular pigeons' related walks after midnight in the fall of 1936.[2555]

[2555] Vidmar, Obisk pri Nikoli Tesli, *Slovenski dom* 11. 2. 1937, no. 33: 3; Bokšan, *Nikola Tesla* 1946; Nagler, Vienna.

Vidmar graduated in Vienna in the class of Tesla's friend Johann Sahulka. Vidmar advanced his chess and transformers' knowhow with his Ganz factory boss Ottó Titusz Bláthy as his personal assistant in Budapest in 1912-1913, three decades after Tesla began his research in that same Budapest. In 1894, Ganz factory guys with Ottó Titusz Bláthy and Kálmán Kandó included understood that Nikola Tesla's induction engine could be used for railway traction, so they began to investigate the problems of three-phase electric system for tractions. Bláthy modified the one-phase generator and transformer into a three-phase one and improved the phase-converter electric locomotive devised in 1923. Vidmar was born five years after Tesla's humiliations in Maribor which made him unable to help, but Vidmar and his students were the decisive Tesla's helpers later.

Since 1902, Vidmar has been studying mechanical engineering and since 1904 he has been an electrical engineer at the Viennese Technical Faculty. He graduated in 1907 and received his doctorate in 1910/11. He passed his first rigorous exam in 1905 and graduated by his second rigorous exam as a mechanical engineer in July 1907. In the meantime, Vidmar passed a partial exam from the basics of electrical engineering, while much more was not possible because the electrotechnical department in Vienna had not yet fully functioned. Vidmar was a frequent guest in Grand Viennese Chess Club where the great magnate Albert Salomon Anselm baron Rothschild (1844-1911) regularly played. In February 1909, as a recently married engineer in Weiz northeast of Graz, Vidmar submitted a dissertation in the field of mechanical engineering *Die Theorie der Kreiselpumpen* (centrifugal pumps). In the Foreword, Vidmar mentioned the publisher dr. prof. Fritz Emde (1873 Uszyce in Śląsk (Silesia)-1951 Stuttgart), editor of the *Sammlung Vieweg* collection of Braunschweig: F. Vieweg & Sohn from Stuttgart and Vidmar's colleague-classmate Josip Boncelj (1884 Železniki-1971 Zagreb). In 1938, Fritz Emde replaced Wilhelm Dietrich as professor of Theoretische Elektrotechnik and Director of Elektrotechnischen Instituts an die Technische Hochschule Stuttgart.[2556]

In the summer of 1910, Vidmar had a rigorous defense and he was promoted in Vienna at the Technical High School on 16 July 1910. In electrical engineering, in which he later became famous, he was self-taught. In 1910, his mentors in the discipline of centrifugal pumps were not electrical engineers, while the mechanical engineers included:

The physicist and electrical technician Adalbert Carl Ritter von Waltenhofen zu Eglofsheimb (* May 14, 1828 castle Admontbichl west of Graz in Styria, † 5 February 1914 Vienna) was the first professor and later the director of the Institute of Electrical Engineering at the Viennese University of Technology from 1883 to 1899, nominated during Stefan's Viennese Internationale Elektrische Ausstellung of 1883.

An Austrian electrical engineer Johann Sahulka was the son of the railway expert and studied physics and mathematics at the University of Vienna. In 1881 he passed his master's exam and completed his Ph.D. in 1882. Then he taught at Währinger Realschule from 1884 to 1888 and in Theresianum in 1888/1889. His habilitation at the Technical University of Vienna took place in 1892. He was there as the designer of the Electrotechnical Institute. From 1894 to 1898, Sahulka was employed by the Austrian Standard Legal Commission. In 1899 he became a technical councilor at the Patent Office. From 1903 he was a full professor of electrical engineering at the Technical University. 1909/10 and 1910/11 he was a dean, and a rector in 1913/14.

In 1915, Sahulka received the title of the court counsellor (Hofrat). In 1907 Sahulka advised Milan Vidmar to keep his hands away from electrical engineering and at the same time gave Vidmar a positive grade at the exam to praise him at the five-member commission at the docent examination led by Karl Hochenegg in Vienna on 14 October 1918. In 1899, Hochenegg became a

[2556] Vidmar, Milan, 1964. *Spomini (Memories)*. Maribor: Obzorja, 1: 31, 292.

professor of electrical engineering. In 1903 he worked for the Ministry of Construction and Operations of Electrical Devices and Communications at the Technical University of Vienna also as Rector in 1906-1907. He was an engineer of the General staff of the Habsburg Army[2557].

Max Reithofferplatz (* October 27, 1864 in Vienna, † 10 March 1945) was an Austrian university professor of electrical engineering at the Viennese Technical University (TU) and the inventor. After completing his studies in physics, mathematics and philosophy at the University of Vienna, he received his doctorate in 1889 and obtained his teaching qualifications in subjects of mathematics and physics in 1890. Since 1891, Reithoffer was scientific assistant of Adalbert von Waltenhofen, and he received habilitation in electrical engineering in 1898. In 1903 at the opening of the new building of the electrotechnical institute, he was appointed as associate professor. In 1908 he became a professor of electrical engineering and he gained the rank of a counsellor in 1922.

Karl Pichelmayer (* 6 August 1868 Bern village of municipality Bruck an der Mur; † 23 January 1914 Vienna) studied mechanical engineering at the Technical University of Graz. As an assistant to Albert von Ettingshausen, he was engaged in electrical engineering and he became the leading producer of electrical machines for Siemens and Halske in subdistrict Leopoldau in Vienna after 1891. In 1900, he received the gold medal for designing at the World Exposition in Paris. In 1905/06 he was a professor of the construction and design of electrical machines and appliances at the Technical University of Vienna.

In addition to his industrial work August Kann (February 19, 1871 Vienna-September 11, 1937) worked at the Institute of Electrical Engineering at the Viennese University of Technology as a demonstrator between 1903 and 1906. In 1905 he was promoted to the PhD engineer of technology. In 1924 he was appointed as a full professor of electrical engineering at the Viennese University of Technology. In the academic year 1934/35 he was a rector of the university.

Rudolf Saliger (* February 1, 1873, Spachendorf at Freudenthal in Silesia now Leskovec nad Moravicí (Špachov) in Czechian Moravia; † 31 January 1958 Vienna) taught at the Technical University of Vienna in 1910-1933. In 1924/25, he was also a rector of department of science there.

Franz Aigner received his doctorate in medicine and philosophy in 1907. Then he became an assistant to G. Jager, an associate professor in 1925, and full professor in 1930. He excelled especially in the development of radio.

Gustav Jäger (April 6, 1865 Krásná by Aš (Schönbach by Asch) in Bohemia-January 21, 1938 Vienna) studied physics at the University of Vienna with his fellow Bohemian Joseph Loschmidt, Victor Lang and Jožef Stefan to get his Ph.D. in 1888. From 1891 he was a lecturer at the Institute of Theoretical Physics and assistant to Stefan and after his death to Ludwig Boltzmann. From 1897 he was an associate professor of theoretical physics in Vienna. In 1905 he became a full professor at the Technical University of Vienna, where he was the rector in 1915/16. Since 1918, he was a member of the board of the Institute of Theoretical Physics at the University of Vienna and the Management Board of the 2nd Physics Institute of the University since 1920. He retired in 1934.

After his doctorate, Vidmar worked in industry first in Graz and then in Budapest as assistant to the chess player Ottó Titusz Bláthy who was a leading Hungarian electrical engineer. In 1882, Blathy completed his studies in Vienna, but as an electrical engineer he formed himself in the class of Károly Zipernowsky (1853 Vienna - 1942 Budapest).

Blathy was the co-inventor of the transformer and other AC technologies. With Zipenowsky, Blathy completed his studies in Budapest. During his Technical University years, he gave many lectures on the electronics. In 1878 Zipernowsky graduated from the Hungarian Palatine Joseph Technical University in Budapest and became a professor at the university in 1893. In 1878, the Ganz factory's managing director András Mechwart entrusted him with organizing their electricity department. Mechwart (December 6th, 1834 Schweinfurt-June 14th, 1907 Budapest) studied at the Augsburg Polytechnic with a fellowship granted by his

[2557] Vidmar, 1964, *Memories* 1: 212.

hometown and obtained his diploma in engineering in 1855. In 1859, he joined Ábrahám Ganz iron foundry in Buda.

In 1925, Vidmar lectured on the theoretical basics of electrical engineering at the Technical Faculty in Ljubljana. On the chair of theory of electrical machines Vidmar was replaced by V. Bedjanič, who independently taught in 1945. M. Papler later became Vidmar's assistant lecturer focused on the transmission of electricity.[2558]

18.5.18 Tesla and Bošković

We all know the popular photograph showing the reader Tesla in Faraday cage, with a lot of lightning all over the place. However, it was only recently discovered that he reads - Bošković's Theory of the Philosophy of Nature.[2559] In any case, Tesla was especially impressed by Bošković, as he himself defended Bošković's physics with one single force.

After the publication of R. Clausius's virial theorem in 1870 the existence of both opposing forces in the molecule was already quite unambiguous, although, for example, Lavtar (1873) and Sekulić (1874) still tried to explain the repulsions only by the attraction. In 1865, Robida probably also backed uniqueness of Newtonian attraction in his defense of Šubic against Krönig's criticism. August Karl Krönig chose Šubic as an example of a theory opposite to his own. He read only the introduction and the first chapter of Šubic's book, because his persistent pain in eyes has prevented him from reading for almost three years.[2560] On 24 February 1864, Krönig wrote a critique a year and a half after the publication of Šubic's book in the summer of 1862. Šubic seemed to him like Lavtar (1873) or Sekulić (1874), who tried to derive all physical phenomena from the effects of a single gravity force.

Lavtar's idea was like Ampère's theory of electric current vortex in molecules resembling Bošković, although Lavtar did not specifically emphasize this. Ampère's wave theory of heat from 1835-1836 was upgraded by the discoverer of the sputtering of metals William Robert Grove (* 1811; † 1896) in 1842/43. It was accepted by the Viennese university professor of physics and the president of the academy Andreas Baumgartner (* 1793; † 1865), followed by Robida and Sekulić. Tesla's professor Sekulić also added electromagnetism[2561] to his wave theories at the same time as Maxwell, which stimulated Tesla's love for the transfer of waves through a vacuum: the path through the invisible brought the light forth.

Figure 18-62: Tesla reads Bošković's Theory in New York in front of his laboratory full of sparks of a high-frequency transformer.

The couple (the twin forces, dual, the twins) were the fundamental principle on which Tesla's professor Sekulić built his physics of atoms and molecules[2562] and outlined his vision of the vacuum of his recent graduate Tesla.
Sekulić considered that all influences on the body can be described by the force of the resultant in the translation or by a pair of forces (couple) in rotation.

18.5.19 Tesla and Pupin

Tesla and his two-years senior Mihajlo Pupin (* 1854; † 1935) arrived in the USA from their homeland from the same Orthodox environment of

the Military Border during the Military Krajina painful fateful abolition. Tesla's Military Krajina has Croatian=Catholic majority, while in Pupin's Vojvodina part of Military Krajina the Orthodox religious practices were prevailing. Tesla had full support in his Slavic inspired higher real school in Rakovac, while Pupin got much more problems with German professors at the higher real school in Pančevo, where he was defended by the physicist Simon Kos who grew up in Blejski Kot, and the Orthodox Priest Basil Živković, a relative of Tesla's catechetic Nikolaus Živković. Pupin's professor of geometric rendering and mechanics Karl Klekler (* 1842 Wiener Neustadt; † after 1901) was employed on 30 December 1865. According to his publications like *Die Methoden Der Darstellenden Geometrie* in 1877, Klekler was similarly remarkably educated as Tesla's professor Sekulić; this is not particularly surprising given that professors in the Military Krajina were better paid and better equipped. Similar as Sekulić, Klekler also wrote about kinetic theory but with much more support. On the other hand, Klekler, as a German and Habsburg fan, did not like Pupin's Serbian nationalism, while Tesla did not have these problems in Rakovac. Klekler published numerous geometric books. He lectured at the Higher School in Pančevo between 1869-1872; then he was a professor of mathematics at the Naval Academy in Rijeka until 1878. In 1874 he first taught the basics of mathematics, with the assistance of the Ukrainian vacuum researcher Puluj. Tesla's friend Puluj later became the rector of the Prague Polytechnic and the dean of the electrotechnical faculty.

In 1877 in Rijeka Klekler lectured on higher mathematics, while Peter Salcher taught mechanics with physics. For Ernst Mach designs, Salcher photographed waves of the supersonic speed missiles in the Adriatic Sea by Rijeka. Klekler continued his schooling career by the end of the century as director of the higher real school in Linz and then in the 7th district of Vienna. Pupin later remembered his professors the Slovene Kos and Živković, but disliked Klekler. Similarly, Tesla denied or at last forgot the merits of his professor Löffler from Rakovac real school.

In the meantime, Tesla felt some ethnic intolerance in Graz; with Pupin, they preferred studying at the Technical High School in the Slavic-friendly Prague even if they were not successful there. When just the pieces of bread remained, they, once again one after another, legendary with a few cents in their pockets, sailed to the promised land called America. Pupin was more successful on the academic side and even on the long run with his moneymaking. Of course, the modern popularity of Tesla is inappropriately larger than Pupin's, although they had both a few notable inventions. Pupin arranged a pension from the Yugoslav king for Pupin's two years younger Tesla, but in professional and business terms, Pupin and Tesla were often in quarrels. They were probably just too much similar Orthodox guys with their great egos, and even the huge America was not broad enough for both. Just like in the old Serbian proverb: two hens could not be in the same chickenyard.

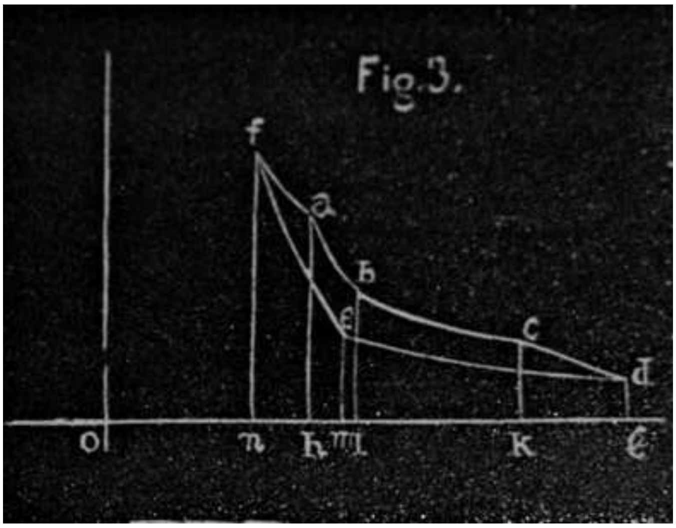

Figure 18-63: Klekler's sketch of the Carnot-Clapeyron's circular process by which he did not sufficiently impress his fifteen years old pupil Pupin (Klekler, 1869, 13).

They both loved Yugoslavia, but their approach was different. Pupin helped Tesla's few weeks younger coeval Thomas Woodrow Wilson (1856-1924) to define Yugoslavian borders after WWI also for Simon Kos' Blejski Kot included, while Tesla was in knockdown in those times after his bankruptcy of 1916. Pupin even helped Tesla to get a pension of Yugoslav king, but none of those enabled a mutual love between Pupin and Tesla who were far too equal to respect each other. After 1934, the annual pension of $ 7500 of the Yugoslav king received by the Yugoslav general consul in Chicago up to 1929 and in New York in 1929-1936 Radoje Janković (1879 Čačak-1943) helped a lot, but Westinghouse electric & manufacturing company paying Tesla's New

Yorker hotel bills and monthly $ 125 as Tesla's informal consultancy was even more welcome after 1934. Finally, Radoje Janković's wife Natalija Kalmić married in 1918 in Samara fulfilled the wish of Pupin's daughter Vida and arranged a half of hour deathbed meeting of reconciliation between freemason Pupin and Tesla in March 1935.

18.5.20 Importance of Maribor Affairs for Tesla's Success

After Maribor and other challenges, Tesla dropped out of his studies; he was no longer teachable, at least not in official school systems, and in fact he knew more than others. Tesla's path was not unusual at all, as it is common whenever any challenging newly advanced technologies overrun the classroom lectures on their own topics. The students soon discover that they know more than their professors in their narrowly focused fields and – dropout. Tesla's electrotechnical challenges repeat today with web technologies of dropout students like Americans Bill Gates (* 1955), Mark Zuckerberg (* 1984), Matt Mullenweg (* 1984), the Syrian-American Steve Jobs (1955-2011), Iranian-American Arash Ferdowsi (* 1985) or the Swede Daniel Ek (* 1983).

Undoubtedly, Tesla was not self-taught, since he studied the most advanced vacuum techniques and electrical engineering in Graz. On the other hand, the vision of Sekulić's rotating sphere with Bošković's uniform force grabbed Tesla's view of the world, which he never allowed to change.

Later, on May 24, 1892, Tesla personally gave advice to the mayor of Zagreb and his colleagues about public electric lighting with light bulbs in Zagreb.[2563] The later mayor of Zagreb Franjo Hanaman (* 1878; † 1941) was at that time a student of a real gymnasium in Zemun until graduation in 1895, and eight years later he began to invent incandescent lamps under Tesla's influence in Vienna. During his visit to Zagreb, Tesla almost certainly studied the situation in neighboring Maribor. Despite the interest and progress of the then electro-technic of Maribor in Tesla's time, he was unable to stay there. Of course, we can only regret it, but it is probably too late.

[2563] Dadić, 2004, 12.

In 1904, Tesla gained his honorable Ph.D. in Vienna,[2564] later also in Zagreb, Graz and in many other places. Even more witty, Edison got his honorary doctorates without any schools. Edison better mastered the writing of journalists, but his engineering method was, at least initially, only an experiment and a repeated correction of its error, while Tesla bet on his thought experiments. After July 1904, the friendly John Pierpont Morgan (* 1837; † 1913) suspended support for Tesla's life-long project Wardenclyffe Tower which lasted in 1901-1917, as it seemed that the inventor intended to export US electric power to the whole lot of world for free. Tesla then began to intertwine the legend around his own personality and achievements, although he was relatively modest before the tragedy. As the stream of Tesla's electrotechnical novelties dried up, his reputation is upgrading up to this day.[2565]

Another American Morgan (namely Avigdor M. Vic Morgan) later stopped his initial supporting of Codelli's cathode ray tube television patents in the United States. A coincidence of fatal South Slavic connections with Welsh Morgan family?

18.5.21 Nikola Tesla for Healthy Eating and Free Energy

Nikola Tesla spoke a lot and wrote again and again about proper healthy diet and the experiments to accommodate the hungry part of the world's population. To reach that goal, Nikola Tesla wanted to provide the world with free energy by awakening planetary resonances, later named after German physicist Winfried Otto Schumann (1888 Tubingen-1974 Munich). Nikola Tesla would then empty them to another energy-needy place. In Tesla's mind mistreated in Maribor, an unusual physical intuition has grown up, which enabled him to perceive the resonances of the Earth's atmosphere between the conductive surface and the lower layer of the ionosphere during the Tesla's sparking and flashing of Colorado Springs, which Schumann more accurately calculated after Tesla's death in 1952.

[2564] Mrkić, 2004, 45.
[2565] Pištalo, 2009, 348.

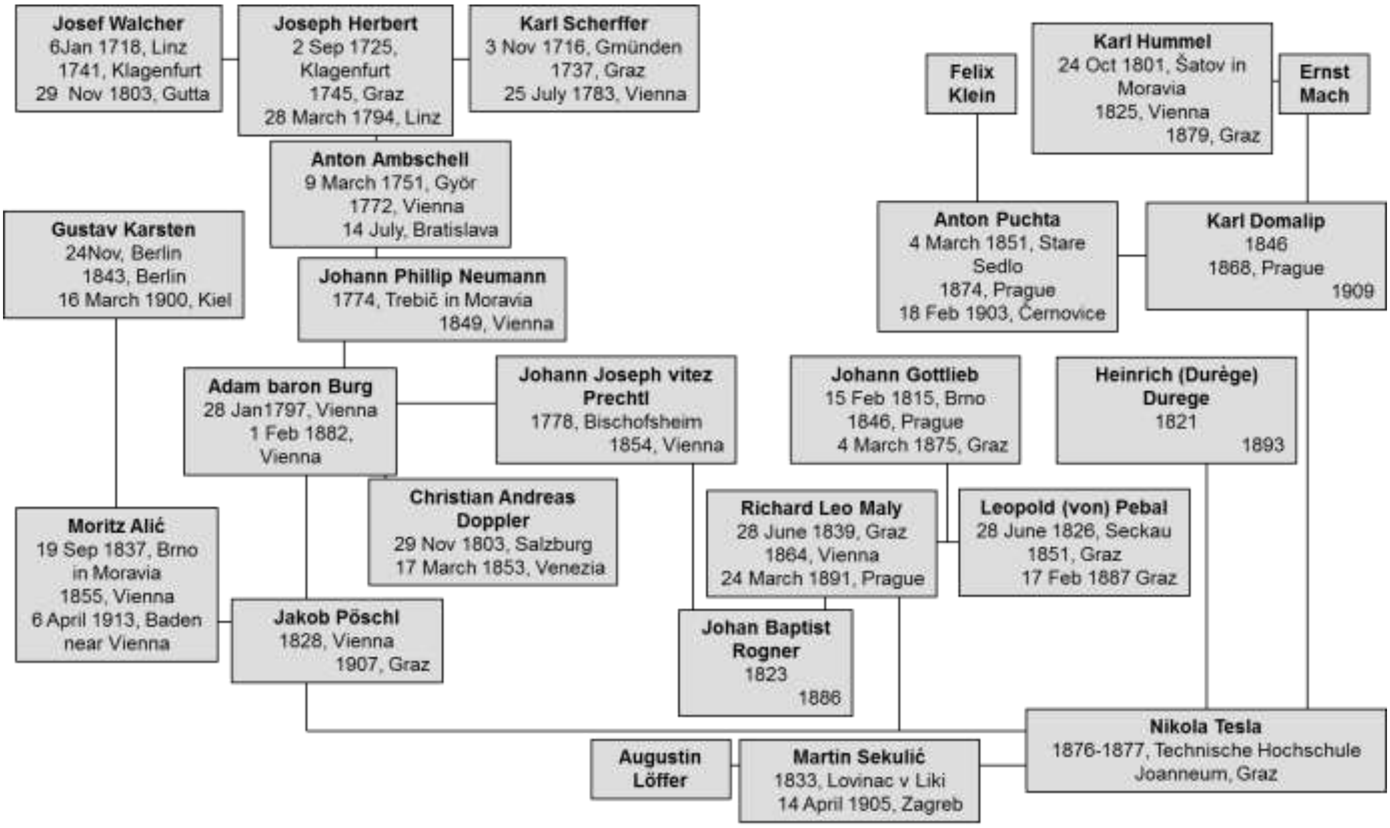

Figure 18-64: Tesla's academic ancestors down from the collaborator of Bošković, whose book he calmly reads under the sparkling in Faraday cage. The picture shows Tesla's academic ancestors among professors of mathematical and physical subjects with data about their studies. They include the researchers of vacuum noted in this book including Mach, Neumann, Ambschell, Gruber, Robida and Stefan.

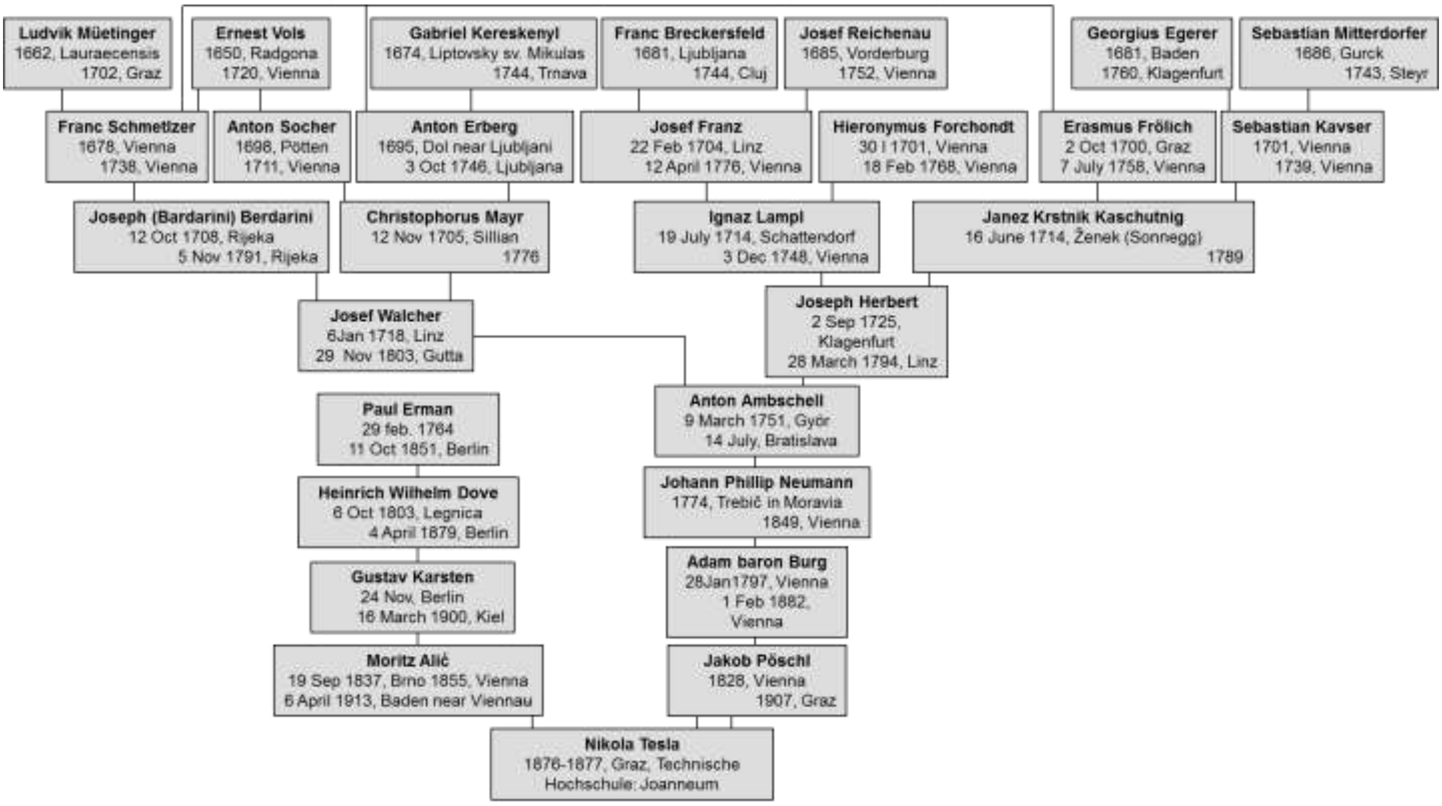

Figure 18-65: Tesla's academic ancestors according to his studies in Graz with specially marked Slovenians

Among Tesla's many undoubtedly interesting and numerous domains of crazy ideas, it is difficult to choose the most imaginative, just as it is difficult to choose the best record of many other guys. Tesla's unique surplus is almost certainly a planetary resonator, a tower in Wardenclyffe near the New York City metropolis. Tesla's extraordinary deep intuition had realized there: during the measurements of the flash frequencies in Colorado Springs not far from Buffalo Bill's grave, Tesla recognized the basic frequency of the earth electromagnetic oscillator, which was later calculated by Winfried Otto Schumann more precisely with better mathematical approaches after Schumann spent a long time in Krupp's town of Berndorf not far from the metropolis of Vienna. God knows, if Schumann was not there to meet a Slovenian literati Ivan Cankar who was not exactly the adversary of Krupp's cannons. Tesla was also not particularly enthusiastic about them; perhaps Schumann anticipated a promising discovery already in Berndorf? Tesla understood the operation of the earth's oscillator. In a megalomaniac wish, Tesla wanted to stimulate the resonator in planetary dimensions and draw energy from it for anywhere on the surface of the planet. It's really a genuine idea with which Tesla overcame himself. Because Tesla told G. Westinghouse and J.P. Morgan about insubstantial assurances that he would not be able to put counters on his tower and reimburse the customers' consumed electricity with their paid bills, those magnates stopped their support. More likely, Tesla increased his original budget to an impossible height, just as Gabriel Gruber did with a canal in Ljubljana or the advocates of the Texas Superconductive Super Collider did in USA. In the same way in 1993, the opponents of the Republican Lonely Texas Stars helped their European rivals who discovered the predicted "God particle" of Scottish Englishman Peter Higgs at CERN's Great Hadron's Collider a decade after the abandoned Texas project. If the Russians or any others on the opposite side of the Great Blue Water called Atlantic really could erect Tesla's Tower, that would probably mean that Donald Trump, with his Zasavje bride, made it too late for America to make Great Again, Slovenian aircraft carrier up or down.

So, we do not know for sure whether Tesla's idea is quite possible, but its undoubtedly worth a try as it is so brilliant. It is not worth looking for an all-encompassing predecessor of later inventions and discoveries in Tesla, for even the story of Tesla's X-ray does not hold water. It was mainly the question of names: many experimented with invisible rays, but only the Nobel prize-winning Roentgen picked up the cream after hitting his nail on the head by pulling the right strings of the scientific networks. In 1897 before New York academy of science, Tesla in his paper *The Streams of Lenard and Roentgen and Novel Apparatus for Production* in fact claimed that Philipp Lenard was Roentgen's equal, but after Lenard's racist stances against Einstein Tesla could have changed his mind. Race is the child of racism not the father.[2566] Tesla distinguished between Lenard's rays later called electrons after J. J. Thomson measurements of that same year 1897, and Roentgen's rays soon nicknamed X-rays. Tesla suggested that all of them were not transversal as most of the researchers though because Tesla hoped that some longitudinal waves are also involved. The basic difference among that bunch of new rays and waves discovered in Fin de Siècle were their behaviours in magnetic field which curved just the orbits of charged particles, although Tesla also erroneously claimed that he deflected the Roentgen's rays with a magnet which made them similar if not equal to Lenard's rays.

In April 22 and August 12, 1896 issues of the *Electrical Review* Tesla was more precise and narrated that only Lenard's rays could be deflected in a magnetic field. In his cathode ray tube, Tesla used the electrodes of platinum and of his bellowed aluminium. M. Pupin also spoke about the induction coils for the generation of Roentgen's rays before Tesla did, but Pupin's address received much less attention than Tesla's which only raised the competition between both Orthodox guys in front of the *New York academy of science* on 5th and 6th April 1897.[2567]

[2566] Leland I. Andreson (ed.) 1992, *Lecture before New York academy of science: The Streams of Lenard and Roentgen and Novel Apparatus for Production* 6. 4. 1897, Colorado: Twenty First Century Books; Tesla on the Hurtful Actions of Lenard and Roentgen, *Electrical Review* (N. Y.), May 5, 1897; Tesla on the Source of Roentgen Rays and the Practical Construction and Safe Operation of Lenard Tubes, *Electrical Review* (N. Y.), May/August 11, 1897; Ta-Nehisi Coates (* 1975 Baltimore). 2015. *Between the World and Me*. New York: Spiegel & Grau, 7.

[2567] Leland I. Andreson (ed.) 1992, *Lecture before New York academy of science: The Streams of Lenard and Roentgen and Novel Apparatus for Production* 6. 4. 1897, Colorado: Twenty First Century Books, 20, 22-23, 99, 100, 114, 115.

Before his Wardenclyffe tower tragic collapse, Tesla used to be a winner in those duels with his competitors. He loved to enter the courtrooms accompanied with his lawyers, tall and self-confident so long as his Wardenclyffe tower staid erected. Besides foreigners like Marconi and Ferraris, Tesla also had to compete with his USA rivals like Elihu Thomson (1853-1937). Elihu Thomson and Edison considered Roentgen's rays as a danger while Tesla even praised the ozone produced by the Roentgen's rays as a benefit for his and his assistants' health and coughing. On the other hand. Lenard's rays could be harmful for the human skin. So, Tesla made few advices for the physicians who used the cathode ray tubes.[2568]

Westinghouse later repaid at least the Slovenes and Croatians for his trickery at the expense of Tesla: Westinghouse company generously established the combined Slovenian-Croatian nuclear energy power plant in Krško by Sava River. The local nuclear energy power plants began for the Slovenians somewhat earlier in Podgorica – which was not the Montenegro Podgorica but Podgorica near Ljubljana, in the then municipality of Bežigrad, which is today's Dol by Sava river municipality. Westinghouse's Slovenian-Croatian nuclear energy power plant in Krško by Sava River in fact gives the electricity to Tesla's native Lika.

Tesla's vision announced as food for everybody flowered until Tesla's "friend" George Westinghouse changed his mind during the construction of a tower in Wardenclyffe on Long Island. George Westinghouse and Morgan were worried about the location of charging meters for their consumers. When tearful Tesla confessed the obvious truth that the counters of his resonances could not be easily charged or glued, the project - and cash inflows - was at its dead end. Another point against Tesla's project was Marconi's disloyal competition and Tesla's hasty proposal for replacing just-introduced alternating-current networks' wires with wireless. Tesla won the battle of currents against Edison and now he wanted to win another battle against his own child called alternative currents' transfer by the wires. It was all too soon for a change, but Tesla was simply not a guy to wait like Gauss did in his time with his non-Euclidean geometry. The surprised businessmen even complained: "Why didn't Tesla introduce the wireless energy transfer in the first places, but he allowed us to spend all that huge money on wires which now Tesla do not need any more?"

On the other hand, Tesla was extremely proud of his slogans of a healthy life, and he liked thejournalists to advertise Tesla's cooking recipes, based primarily on the moderation in nutrition, where Tesla flirted with vegetarianism through the wisdom of the deceased mother of Tesla. Certainly, Georgina nicknamed Đuka Tesla cooked meat as all other mothers do in predominantly shepherds' society of Lika, but she was a wise person anyway.

Tesla initiated something like third major quarrel among the researchers of electricity. The initial dispute between B. Franklin and Nollet's electrotechnics of the shape of lightning conductors barely ceased when Volta's and Galvani's adherents shifted a new one focussed on the source of electrical power. Tesla's dispute with Edison was, above all, a repetition of old problems in which profitability intertwined with knowledge.

18.6 Vacuum of the President's Uncle

The brother of Melania's father-in-law was a central figure in FBI examinations of Nikola Tesla's high voltage designs left as Tesla's heritage. John Trump was the leader of Van de Graaff's high voltage physics which used the different techniques to reach the same goals as Tesla's Coil, eventually without the Tesla's central ideas of wireless distribution of energy. The brother of Melania's father-in-law publicly announced his disappointment with Tesla's Death Rays as a special case of Tesla's wireless distribution of energy. The brother of Melania's father-in-law stated that Tesla made no progress in last decade and a half, that is after early 1928 when the brother of Melania's father-in-law John Trump was undergraduate student in Polytechnic Institute of Brooklyn not far from Tesla's hotel. Did John spoke the truth, or he used Tesla's achievements for his own business like so many others?

[2568] Leland I. Andreson (ed.) 1992, *Lecture before New York academy of science: The Streams of Lenard and Roentgen and Novel Apparatus for Production* 6. 4. 1897, Colorado: Twenty First Century Books, 26-27, 84, 107.

During the atomic race in the 1930s, the researchers knew that the lightning was carrying the energies up to 15 MeV, which was much more than they could produce in laboratories to accelerate the particles. Tesla's Colorado Springs might have been the unique exception. That's why Arno A. Brasch (* 1910 Berlin; † 1963 New York City), Nernst PhD student father of Soviet atomic bombs Fritz Lange (* 1899 Berlin; † 1987 Berlin) and Kurt Urban (1904–1928) made experiments on Mount Generoso in Switzerland 145 km north of Volta's native Como. Between the two rocks they placed a metal mesh on which a positive charge was collected. With a particularly strong bombarding, a spark, 5 m long, corresponding to 10 MeV energy could be obtained. However, during the experiment at ungenerous Generoso mountain, Urban suffered a fatal shock, as did Richman almost two centuries earlier. During the years 1919 and 1932, accelerators were built using high-voltage generators, which directly speeded up the charged particles in a fixed electric field. The development of such devices was crowned by the electrostatic Van de Graaff generator in 1931 and the cascade generators of Cockcroft and Walton a year later.

Robert Van de Graaff (1901-1967) from Alabama improved the electrophorus electrostatic generator. He used the idea of a transformer to increase voltage, and thus followed the old Guericke's ideas from 1671. The electrostatic charge generator with a conveyor belt was first described by Righi's rearranging of an older W. Thomson idea of a generator using charged droplets of water in 1872 and 1890. K. T. Compton from the Physics Department of the University of Princeton backed the idea of his colleague Van de Graaff. Thus, in 1929, the first model was created. In two years, Van de Graaff reached a 1.5 MV voltage and reported enthusiastically to the American Physical Society. In 1932, Van de Graaff moved to MIT, where he began working with stronger generators with Compton's support. At the same time, Merle A. Tuve, Amundsen's North pole expedition aviation assistant Odd Dahl (1898 Drammen in Norway–1994 Norway) and Lawrence Hafstad built the first usable Van de Graaff electrostatic accelerator at Carnegie Institution in Washington (Figure 18-67).[2569] Among the first, they surpassed the magic 1 MeV of energy needed to penetrate the nucleus of the atom.

[2569] Livingston, Blewett, 1962, 31–33.

In 1933, Van de Graaff in MIT assembled a "Grosse Bertha" device from two parts weighting 16 tons, altogether 32-ton. The accelerator was named after the German cannon of the First World War. A carefully dented aluminium sphere of diameter 5 meters and a thickness of 6 mm was placed on top of an insulated cylinder with a diameter of 7.5 m and a height of 2 m. In the hollow cylinder, a movable silk belt pulley was transferred from the silk to transfer the charge from the high voltage rectifier. The spark could be discharged at a voltage of 7 MV. Later, Westinghouse's electric company, on the same principles, set up a huge pear-shaped device for breaking atoms in the suburbs of Pittsburgh.

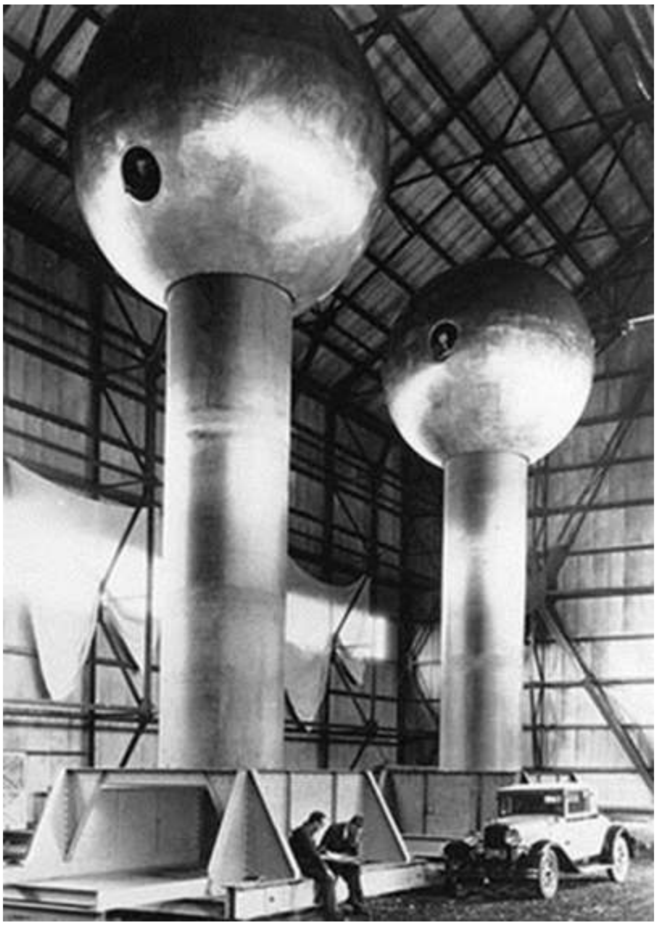

Figure 18-66: 12 m high Van de Graaff generator at MIT, today at the Boston Museum of Science.

After graduation at Polytechnic Institute of Brooklyn in 1929, John Trump got his M.S. in physics with Tesla's antagonist Mihajlo Pupin in Columbia University of New York in 1931. Afterwards, John Trump left his native New York to join the professor Robert J. Van de Graaff in MIT where he defended his Ph.D. entitled Vacuum electrostatic engineering acknowledging Van's experimental work, visionary starting vacuum electrostatic engineering, research technique, ideas, and inspiration in late 1933. John George Trump received his doctorate in electrical engineering from MIT in the decisive year when Hitler took over the power in 1933. Tesla constructed his own Van de Graaff in 1934. The former Tesla-related Westinghouse company developed the similar device in a suburb of Pittsburgh for civil nuclear research in 1937, and seventeen years later Edvard Cilenšek in Ljubljana designed his own Van de Graaff in Ljubljana institute later named IJS, modelled on Trump-Graaff's company products. They were developed after the WWII by Trump's collaborator in Royal Air Force Radar Development Denis M. Robinson (1907-1994) serving as cofounder of High Voltage Engineering Corporation (MA) in 1946, chief operational officer (1946-1970) and chairman of the board together with Trump after 1970. Trump was a technical director of their corporation from 1970 to 1980, and senior consultant afterwards.

Robinson received his doctorate in electrical engineering at the University of London in 1929 before joining MIT for two years. He worked under the supervisions of the Dean of the Department of Engineering at MIT, appointed in 1932, later chairman of the National Defense Research Committee and the initiator of the Manhattan project the Freemason Vannevar Bush (March 11, 1890 Everett-June 28, 1974 Belmont). At MIT, Robinson collaborated with Van de Graaff and Trump. Robinson then proceeded to work for the industry until Charles Percy baron Snow redirected him to scientific work in 1939; two decades later, Snow conceived his famous idea of an insurmountable gulf between technical and humanistic culture. Robinson, along with Trump, developed a radar in a project led by James Watt's descendant Wattson-Watt. Thus, Robinson and Trump came together for three consecutive times in their joint work in several areas of vacuum technique. In July 1945, in the highly popular The Atlantic Monthly magazine, V. Bush published a noteworthy record As We May Think, which was as influential as Emerson's message to the American scholars in 1837. Bush promised the development of knowledge, and not only power in the future. He discussed the achievements of George Mendel, Leibniz and Babbage in the pioneering development of computers. Finally, he focused on the development of photography and computers; with a newly coined term memex, he marked the storage of books and other knowledge resources in memory.

With the support of Natick Laboratory and the Army Quartermaster Corps Trump and his associates developed the methods for the preservation of food by high voltage radiations while experimenting on bactericidal and viricidal effects. Until 1950 almost all radiation therapy relied on the X-rays produced by collisions of high-voltage electron beam with the Rutherford's gold leaves in vacuum, but Trump, Van de Graaff and Robert W. Cloud in their paper promoted the uses of different matter-penetrating directed high voltage-electrons in 1940.[2570]

John Trump worked as Van's research associate in 1933, assistant professor in 1936 full professor from 1952 to 1973, and professor emeritus from 1973 to 1980. John developed the insulation of super-high voltages in vacuum and compressed gases for nuclear physics, the biological applications of high voltage megavolt radiations for medicinal cancer treatment, the food preservation by electron beam, and the 2 Megavolt ecological treatment of dirt in sewage or sludge in 1976. Trump's group with grants from Godfrey M. Hyams (1859–1927) foundation built the air-insulated megavolt generator for Huntington Memorial Hospital for deep tumour treatments in 1937 which was not in its best during the wet days. In 1938 Trump used the same grants to design 1.25 megavolt generator insulated with compressed gas for George Robert White Hospital of the Massachusetts General Hospital, and 1.75 megavolt generator for the American Oncological Hospital of Philadelphia which was used for Manhattan Bombing Project.

After Tesla's death in New Yorker Hotel on January 7, 1943, the FBI seized his heritage with documents and hired the son of German emigrant MIT professor of engineering high voltage electric engineer John George Trump (1907-1985) of OSRD to investigate Tesla's heritage and find out how deadly were those rays. The president of MIT Karl Taylor Compton (1887-1954) hired Trump for

[2570] Trump, J.G., Cloud, R.W. Physical characteristics of supervoltage roentgen rays**.** *Am. J. Roentgenol.* 1940, 44: 615; Trump JG, van de Graaff RJ, Cloud RW. Cathode rays for *radiation therapy*. *Am J Roentgenol Radium Ther Nucl Med (The American Journal of Roentgenology Radium Therapy and Nuclear Medicine)* 1940, 43*:* 728–734.

the checking of Tesla's heritage. In May 1941 the newly established OSRD was headed by Vannevar Bush while John George Trump was supposed to investigate Tesla's heritage and find out how deadly were those Tesla's rays. In those times Trump worked on radar as secretary of Microwave Committee of British branch of MIT Radiation Lab. In 1944 because Brits proved to knew more about radar, Trump became the director of the laboratory while working directly with the General Eisenhower Military Command. At the liberation of Paris Trump rode in with Eisenhower.[2571]

Trump examined Tesla's scientific papers. The review was performed at warehouse of Manhattan Storage and Warehouse Company. Apart from Trump, there were present Willis George from the Maritime Intelligence Office, a naval officer chief yeoman warehouse manager of United States Navy Reserve Edward R. Palmer, and his assistant chief yeoman John J. Corbett. Trump later stated that no large amount of Tesla's stuff had been inspected, which was stored in the basement of the New Yorker hotel full ten years before his death, or any other Tesla writings other than those he had when he died. It should be noted that Tesla's scientific reputation was in decline while many challenged his inventions, robotization and alternating current. In addition, Trump was a very busy man while the FBI barely managed to find enough people for their many investigations into possible sabotage. "As a result of the examinations," wrote dr. Trump, "It is my considered opinion that among his papers and in his property dr. Tesla has no such scientific notes, description of unpublished methods, unpatented devices or ready-made devices that might have some more relevance for this land or could pose a risk when they fall into enemy hands. So, I do not see any technical or military reasons why his property should still be kept confiscated."

He added: "For our needs, however, a bunch of different kinds of materials has been prepared… It covers typical and almost all the ideas he has dealt with over the past years." Trump got Tesla's papers numbered and briefly described in the attachment of this letter.

In conclusion, Trump wrote: "It should not hurt the reputation of distinguished engineers and scientists, whose concrete contributions to electrical engineering were made at the beginning of this century, if I report that his thoughts and endeavors over the last fifteen years were primarily speculative, philosophical, and a bit promotional nature - often involved in the production of wireless energy transfer - but without involving new, healthy and viable methods for achieving such results."

It seems that the documents (for which Trump wrote numberings and abbreviations with descriptions) were copied by photostatic images (the former way of copying to a photopaper with light) or microfilmed by a naval officer, while the original documents were kept in the warehouse and subsequently transferred to Yugoslavia. No detected threating foreign assets were subject to the provisions of the Law on Trade with the Enemy. That's why Tesla's papers, personal documents, drawings and more were handed over to disposing of his nephew Kosanović who governed his legacy in February 1943.

In addition to the report, Trump listed the following short descriptions of Tesla's papers:

a) Art of Telegeodynamics, or Art of Producing Terrestrial Motions at Distance (in connection with earlier Tesla's tower) —This document, in the form of a letter dated June 12, 1940, to the Westinghouse Electric & Manufacturing Co., proposes a method for the transmission of large amounts of power over vast distances by means of mechanical vibrations of the earth's crust. The source of power is a mechanical or electromechanical device bolted to some rocky protuberance and imparting power at a resonance frequency of the earth's crust. The proposed scheme appears to be completely visionary and unworkable. Westinghouse's reply indicates their polite rejection…

b) "New Art of Projecting Concentrated Non-Dispersive Energy through Natural Media—This undated document by Tesla describes an electrostatic method of producing very high voltages and capable of very great power. This generator is used to accelerate charged particles, presumably electrons. Such a beam of high-energy electrons passing through air is the 'concentrated nondispersive' means by which energy is transmitted through natural media. As a component

[2571] Smullin, Louis. 1989. John George Trump (ed. National Academy of Engineering). *Memorial Tributes: National Academy of Engineering*, 3: 333-335.

of this apparatus there is described an open-ended vacuum tube within which the electrons are first accelerated.

“The proposed scheme bears some relation to present means for producing high-energy cathode rays by the cooperative use of a high-voltage electrostatic generator and an evacuated electron acceleration tube. It is well known, however, that such devices, while of scientific and medical interest, are incapable of the transmission of large amounts of power in nondispersed beams over long distances. Tesla’s disclosures in this memorandum would not enable the construction of workable combinations of generator and tube even of limited power, though the general elements of such a combination are succinctly described (Trump was certainly not a fan o Tesla’s tower).

c) “A Method of Producing Powerful Radiations—an undated memorandum in Tesla’s handwriting describing ‘a new process of generating powerful rays or radiations.’ This memorandum reviews the works of Lenard and Crookes, describes Tesla’s work on the production of high voltages, and finally in the last paragraph gives the only description of the invention contained in the memorandum. As Tesla briefly stated, his new simplified process of generating powerful rays consists in creating through the medium of a high-speed jet of suitable fluid a vacuous space around a terminal of a circuit and supplying the same with currents of the required tension and volume.’”

Long after he examined Tesla’s, Trump reported in a letter to a friend about his inspection at the Governor Clinton hotel. He examined the device stored in his basement vault, probably the same box remembered by the messenger boy in Tesla’s room who was not allowed to touch it.

A quote from M. Cheney:[2572] "Tesla warned the hotel management that this device is actually a secret weapon," wrote Dr. Trump “and could explode if opened by an unauthorized person. That is why immediately, as soon as the basement opened and showed where the box was located, the manager and the entire staff rushed out the room quickly. Federal agents, who came accompanied by dr. J. Trump, also retreated to the bottom of the cellar, allegedly to facilitate access to the box. The box was wrapped in hard brown paper and the entire length knitted with ribbons. Trump got the sole distinction of opening the parcel.

Figure 18-67: New Yorker Trump (Right) and the director of MIT Radiation Lab Lee DuBridge (1901-1994) from Indiana, enjoying Paris in their military vehicle

Later, J. Trump remembered how he hesitated himself, thinking that it was really a wonderful time and wondering why he was not out there anymore. He put the package on the table and, checking his own bravery, began careful unbounding of box with his pocketknife. He removed the wrapper. Inside there was just another nicely decorated wooden box, lined with a zipper on the lid. He had to accumulate all the remaining strength and courage to finally release the zipper and lift the lid… He bravely raised the hinged lid…

Inside, there was a ten-year old device for measuring Wheatstone bridge resistance, which they used in every little better electro-laboratory before the turn of the century! It was, therefore, a very common and standard measuring instrument... ohmmeter."

Why did Tesla put the staff and management of that hotel in anxiety and horror with such an innocent object for many years? Perhaps he used that old Serbian trick to manage that his hotel bills were paid for~~t~~ him as he was believing that the hotels he lived in were honoured by his presences; because they had him as a guest they should simply write off his bills. So, he found himself insulted by the fact that the hotel Governor Clinton insisted to settle his unpaid bill of $ 400.[2573]

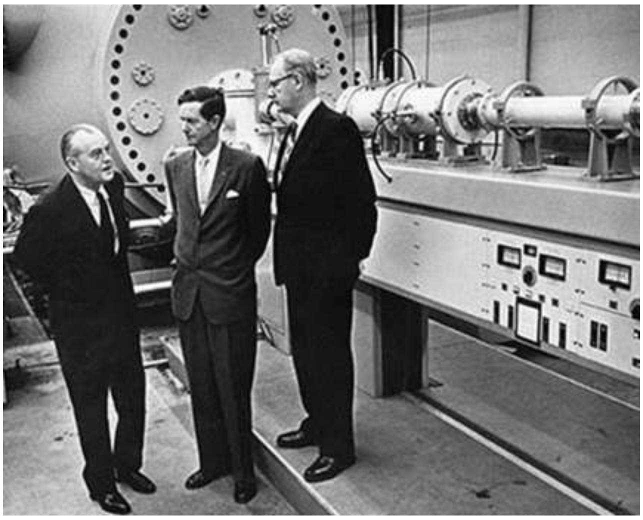

Figure 18-68: Trump on the right, Graaff on the left and Robinson in between

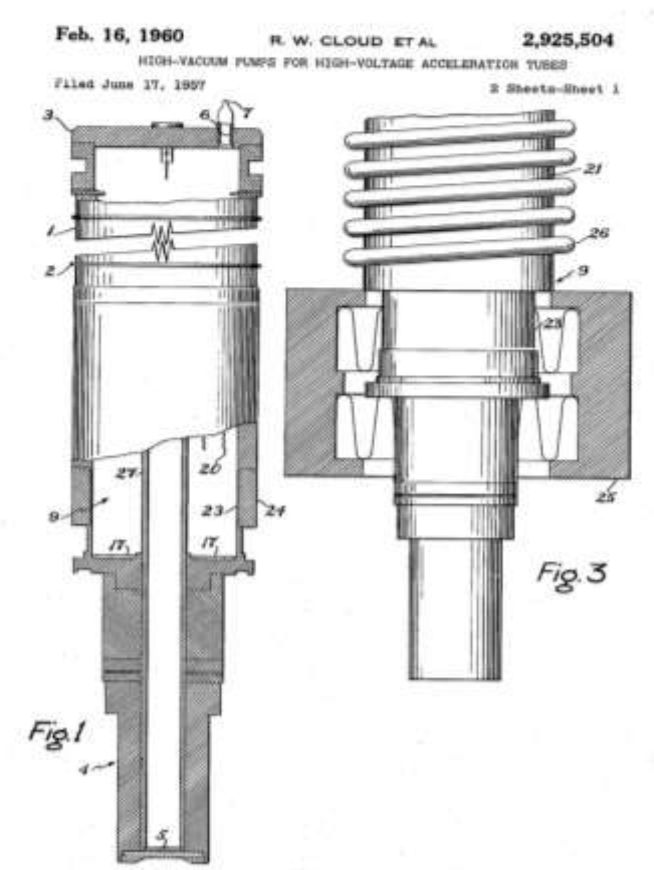

Figure 18-69: The first sketch of Trump and Cloud's patent application for a vacuum pump with serial number 666150 of 17 June 1957.

John George Trump was strict reviewer of Tesla's engineering legacy in January 1943, but he might have learned from Tesla's heritage the items he did not officially present in his FBI report. After the war John George Trump joined Van de Graaff in producing their joint high voltage electrostatic generators of the types like Tesla's Wardenclyffe tower except that Van de Graaff used the largescale triboelectric effect known for two centuries, while Tesla's coil used recently acknowledged transformer based on resonances. It was designed only in 1891. While Van de Graaff's high voltage electrostatic generators are still widely used, Tesla was the only serious user of his own coil which is now almost solely needed just for detection of leaks of high vacuum systems or for fun and entertainments. Tesla's coil is presently primarily an interesting toy like cathode ray tube was in the first decade after its invention in Bonn in mid-19th century. But cathode ray tube got its industrial use of Ferdinand Braun before the turn of century called Fin de Siècle, while Tesla's coil is waiting for its industrial use already twice as long.

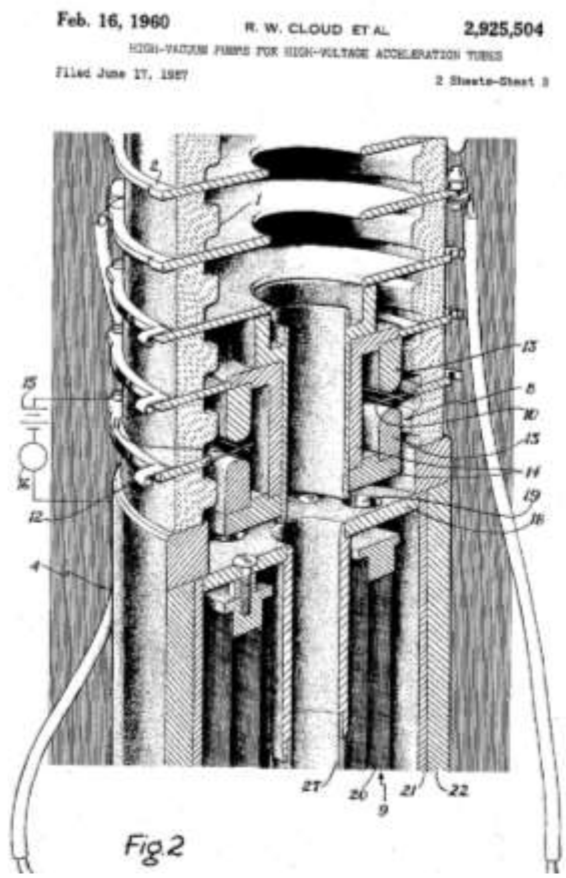

Figure 18-70: The second sketch of Trump and Cloud's patent application for a vacuum pump with serial number 666150 of 17 June 1957.

After three days of examinations John George Trump's results were discouraging with officially nothing military useful which he could find in

technology - works of the EDZ section from 2012 to 2016, Zagreb 2017, pp. 14-15.

Tesla's papers of the last fifteen years. John George Trump noted some old instrument in Tesla's closet. Tesla's heritage was then passed to

Figure 18-71: John Trump

Tesla's nephew, the top Serbian pro-communist politician Sava Kosanović (1894-1956) who happened to be Tito's minister for informatics in March 1945 and the Yugoslavian ambassador in Washington and Mexico in 1946-1949. Sava Kosanović transferred those papers to Beograd for the future museum of Nikola Tesla. Other Tesla's nephew then in USA, the son of Tesla's oldest sister Angelina, was the USA inventor Nikola Trbojevich (Trbojević, May 21, 1886 Petrovoselo in Lika-December 2, 1973 Los Angeles). Donald Trump happened to be John George Trump's nephew,[2574] similarly as Lika-born Kosanović was Nikola Tesla's nephew. Both nephews of both electrical engineers developed into high profile politicians, although Kosanović's positions were more leftist than Trump ever imagined he could be. Tesla and Trumps were different: Tesla had new great ideas, and the money was not his primary goal, while Trumps had money and the new fashionable ideas were not their primary goal. John George Trump was certainly a smart engineer and without all FBI cards on the table it is not quite clear if Tesla slogan could be used for John George Trump in the form of: "I'm not sorry because they steal my ideas, but I'm sorry because they have none of their own (Nije mi žao što mi kradu moje ideje, nego mi je žao što nemaju svojih)."

19 Household Domestic Uses of Vacuum Technologies: Food Processing & Vacuum Cleaners

19.1 Vacuum Technology for Cooking and for the Preparations of Food

19.1.1 Introduction

Tesla recommended a healthy diet based on moderation. Of course, New Year's Eve or at least Easter holidays are coming in again when people like to have something good on the table. How can former and modern vacuum technologies help us?

The vacuum helps a modern man to preserve food, but recently we also learned how to cook in a vacuum. The storage of foods is becoming ever more indispensable for the everyday life of the contemporary people who want non-native delicacies. Although many storage procedures were invented already in Guericke and Boyle's times, the vacuum packing of foodstuffs is gaining momentum even with the offer of convenient home appliances. All those pursuits gained prosperity from the miniaturization of spaceship equipment, where lightweight flimsy vacuum preparations save quite a bit.

19.1.2 Guericke's Grapes

The vacuum pack with a dried up food was already on agenda of the inventor of the vacuum pump the Protestant Otto Guericke, after he served as an engineer in Swedish and then in the Saxon army during the Thirty years war.[2575] Despite of his undeniable Protestant disapproval, he co-operated with his Catholic emperor Ferdinand III after the war. Between 1645 and 1648 the mayor Guericke represented the benefits of his city of Magdeburg at the Osnabrück conference, where the quarreling parties finally agreed to finish their Thirty-year war. There he met with the Count Janez Vajkard Auersperg, who attended the conference in the imperial Embassy. They saw each other again during Guericke's visit to the Viennese court.[2576] The clever Guericke has been eager to report on his vacuum experiments in those days.

Guericke attended the National Assembly in Regensburg as a politician full of scientific honesty. He showed experiments with air pressure and told the emperor and princes about new, barely discovered phenomena. The imaginative mayor was the first to weigh the air, which would still be considered today as a joke. He balanced his instrument with a vacuum container on one side and weights on the other. After he pumped out the air from the container, he discovered that some weight should be removed on the opposite side to regain the balance.[2577]

Guericke told the Emperor Ferdinand III, King Ferdinand IV, the king's tutor Auersperg and other princes about his experiments in an empty space, and by the way he mentioned that we could run out of air if we blow into a vacuumed vessel. He knew that many dangerous things could happen to us, since the external pressure does not only squeeze out all the air from the human or animal body into a vacuumed vessel, but also damages the body with the guts included; because of pressure, we can even die. The prince Auersperg still did not believe him. He was not prepared to abandon Aristotle's teachings from his students' bench, where the vacuum seemed to oppose the common sense. Even the recently deceased Descartes did not recognize any vacuum. Auersperg wanted to make sure of what was happening in a vacuum vessel.

At that time, the Auersperg prince had thirty-nine years and was almost more powerful than the aging emperor. The prince's doubts questioned all other Guericke experiments. It was a query of personal prestige: will Guericke convince the prince of the validity of his considerations? The engineer Guericke was not particularly at home in peripatetic logic, and he did not like discussions about the nature of the vacuum which suited his rival Boyle across the English Channel. As a

trained engineer, Guericke observed an especially useful industrial tool in an empty space.

Guericke avoided a scholastic dispute with the prince Auersperg and left the decision to his carefully designed experiments.[2578] To the Carniolan prince and other surprised magnates he showed how the vacuum "pulls" water up the tube, extinguished the candle and damped the ticking of the recently invented clock. To the lovers of grapes and its processed forms, which at that time were not lacking and are not missed even today, Guericke served a very welcoming news: "Finally, it should be mentioned here: when we place the grapes in such a glass container, we empty it and then store it in cold place for half a year, the grapes' appearance will not change, even though it will lose all the juice." He rushed to explain the storage performance in the empty space: "From here, it follows that the juice in the empty space is evaporated, while otherwise it would return backwards and remain in the interior due to the pressure of the ambient air."[2579]

The vacuum entered the Central European society and its cuisine in a particularly magnificent way, under the critical eye of the Carniolan Auersperg prince, who certainly did not refuse the well-coated table. In 1666, his brother, the Provincial Governor General Volf Engelbert,[2580] ordered to hunt down 2256 quails, 120 forest partridges and 26 field partridges for guests in his Ljubljana palace. He arranged the largest feast when the Emperor Leopold I visited his palace in 1660. The prince Janez Vajkard once captured more than three thousand quails in three weeks of hunting with falcons. He hunted in the Kočevje forests around Lužine around numerous fruit trees. In 1774 he shot eight bears in one day. The last of those bears, however, made a lot of troubles after the bear wounded twelve locals who helped with the hunt. When the bear threw himself on the thirteenth, whose surname happened to be Bear (Medved), the prince finally shot the real bear with its small initials.[2581] At that time the surname bear was very common at Kočevje and Kostel, while the meat of the bear or sheep has always been loved by the hungry local folks with different surnames.

One of the later editions of Scappi's cookbook was in the Auersperg Library of Ljubljana, which enabled Volf's planning his fests. Bartolomeo Scappi (1500-1577) was the cooking master of Pope Pius V, where he certainly did not miss well-stocked tables. He was a match to Walther Hermann Ryff (Rivius, † 1548), who published a small German pharmacy with a description of home remedies, especially cooking in Strasbourg in 1540 and 1542; the work was bought by the convinced lovers of a well-stocked table among the Škofja Loka Capuchins, Hohenwart from Kolovec and other Carniolans. That book with its full-colored sketches of plants[2582] was frequently reprinted in Strasbourg during the whole century under the pseudonym Quintus Appollinaris; one of the last editions was on sale in Mayr's store in Ljubljana in 1678. Many local gourmets were the grateful customers. The Library of Upper Castle belonging to Diocese of Ljubljana kept the medicine of Paracelsus fan Leonard Fioravanti (1518-1588) bind to a manuscript full of chemical and cooking recipes, even in the Slovene language, with the use of "bello (white) wheat flour".[2583] The learned and world-minded Cistercians in Stična want to sweeten themselves with the delicacies by the culinary and pharmacy recipes of Eleonora Maria Rosalia duchesse Crummau (1647-1704) married to the mighty genus of Liechtenstein. The hungry priests bought the first edition of her book supplemented with a cookbook. In 1710, the reprint followed in Vienna, where, of course, good foods were never missed despite the motto "When you go to Vienna, leave your belly out" because of the expensive Viennese pubs. Once upon a time that Stična book, later became NUK's copy. That copy of Mrs. Crummau's book on 516 pages with an alphabetical register has no marginalities of its hungry users. Its prescriptions follow the instructions for using salt and healings.[2584] The baron Erberg purchased the same book. In any case, the good natured Carniolans always accepted many cooking novelties with open arms, if not already with fat bellies, which made them especially perceptible for the modern preparation

of foods by vacuum techniques, that is, by using empty.

19.1.3 Boyle's Vacuum Pump and Wine

While Guericke and Auersperg prince designed their pioneering vacuum-supported culinary art on the continent, they were even surpassed by the wealthy Robert Boyle, whose books were conveniently used by Prince Auersperg's friend Janez Vajkard Valvasor. Boyle devoted his third vacuum booklet to early experiments with Machina Boyliana. After Boyle's relocation to Oxford, he published his first experiments together with Robert Hooke in 1660. In the replies to the complainants, he developed the famous Boyle Law.

Boyle referred to Mersenne's Parisian exploration of compressibility and to the measurements of Florentine academics. He invited the most important Brits to witness his vacuum experiments to add an additional weight, as they used to say in those times. He described the freezingof steam by lowering the temperature when pressing it under the weight of a mercury column. In his criticism of Thomas Hobbes, he cited his older experiments in a mercury barometer.[2585] Boyle rejected Hobbes by Guericke and Torricelli's experiments. According to Boyle's introduction for the reader's preface and in the preface (1680), "Hydrostatic paradoxes" were the continuation of Boyle's "Tractatus de Aëre" (1672), which was sold by bookstore of Janez Mayr in Ljubljana, and after Boyle's death it was translated into English language. Boyle compared the pressure in the liquid with Torricelli's vacuum test over a tube full of mercury. In his introduction for the reader, Boyle scorned Hobbes' rejection of the vacuum, since Boyle also disliked him as a monarchist politician. Boyle devoted his final conclusive chapter to the storage of foods in a vacuum, which particularly impressed Valvasor.

In June 1670, Boyle stored a half liter of pint of good French wine in a vacuum. In July 1671, in front of a cheerful, lightly intoxicated friends gathered around his table, he noticed that the stored wine did not lose his purity and color. We use his novelty today, when we drink half of our bottle of wine, pump out the air above the leftovers and re-seal it again, so that we can drink it unchanged whenever we feel thirsty again. Valvasor and his teenaged sons in Bogenšperk did not drink a lot of wine despite the worry of Valvasor's first wife; however, Boyle's idea of storing wine has deeply touched Valvasor's soul developed above the Sava riverbanks vineyards.

During Boyle's wine vacuum experiment, Valvasor was in France and Germany,[2586] and in the meantime, he also sailed to England. Did he taste Boyle's wine? It might have been nearly as much popular as Papin's digester used for royal cooking for the merry Charles II several years later.

Valvasor bought six Boyle's prints, including the Genevan collection of Boyle's works (1680) in thirteen volumes containing twenty-five major books. Valvasor's enthusiasm for Boyle can be expected as three Boyle's works were offered by the new Ljubljana bookkeeper Mayr in 1678. Valvasor was fourteen years younger than Boyle. Valvasor was in Paris and in England[2587] during Boyle's final resettlement from Oxford to London in April 1668; he was well acquainted with Boyle's vacuum experiments.

Valvasor bought Boyle "Hydrostatic paradoxes" (1670) with three nice groups images showing capillary in the vessel, the pressing liquids and the consequences of the difference in pressure. Boyle's experiments were repeated by Valvasor at Bogenšperk to check the operation of the alleged siphons under Lake Cerknica, which Valvasor's friend Halley then demonstrated before the London Royal Society in honor of Valvasor's election among new fellows in 1687. Valvasor, as the first Carniolan member of that famous society, witnesses the extremely high quality of Carniolan Baroque science and technology, as well as the rapid expansion of English achievements among Carniolans.

19.1.4 Thermos

Guericke's and Boyle's novelties remained for a long time only a curiosity, although the cheap vacuum pumps were soon massively produced in the Netherlands and England. There was no serious industrial use for them before the invention of the

[2585] Boyle, 1680 *Tractatus.*

[2587] Mayr, 1678 *Catalogus*, 51–52; Reisp, 1987, 7.

cathode-ray tube and especially Edison's bulbs. Soon after that, a competition for the liquefaction of “permanent” gases were on the agenda which ended just before the First World War. As often happens with similar seemingly narrow focused scholarly competitions, several allegedly by-products emerged. Among them, in the Royal Institution founded by Rumford, James Dewar (1842-1923) invented the thermos flask for short-term protection of deeply cooled gases. It soon became useful in households.

Many German users of vacuumed vessels did not even know Dewar's successes; on the other hand, the English glassworks were not skillful enough. Thus, prior to 1898, Dewar had ordered the production of his vacuum containers in Germany.[2588] Much more penetrating used to be the Berliner glassworks Fa. R. Burger & Co of Albert Paul Aschenbrenner († 1912) and his juvenile friend Reinhold Burger (1866-1954), while in 1901 Burger patented the X-ray cathode ray tube in collaboration with Wilhelm Conrad Roentgen (1845-1923).

Shortly thereafter in 1903, Burger patented a device named several months later thermos with his Berlin company R. Burger & Co. in Germany. In 1906 Burger was granted his patent in France, as well as in the United Kingdom and the United States; after those successes, the thermoses soon became available first in German shops, then elsewhere.[2589] Initially, he created a thermos for safe short-term storage of liquefied oxygen needed for low-temperature experiments designed by Carl von Linde (1842-1934), a Zurich student of the founder of modern thermodynamic theory Rudolf Clausius.

In 1904 new uses of thermoses were introduced by Burger's compatriot the glassblower Muller from Coburn when he used a silver-plated vacuum insulated thermos to provide quickly a warm milk for his child without any additional cooking. Robert E Perry took thermos to the North Pole in 1909, and Ernest Henry Shackelton had it on the South Pole, while the brothers Wright and count Zeppelin launched thermoses into the atmosphere. The idea of Dewar (1874) and Adolf Ferdinand Weinhold’s (1841-1917) design from 1881 became part of the everyday household needs. The clever Burger then sold his patents to Thermos-Aktiengesellschaft in Berlin in 1909, founded in 1904 as the ancestor of the later Thermos GmbH, where they began to produce serials of thermoses for the market immediately after the World War in 1920. Burger simultaneously sold his rights to New York's Thermos Bottle Company, the sister company of Thermos-Aktiengesellschaft; companies had similar branches in Canada and the United Kingdom. The unprepared Dewar did not patent his discovery; when he remembered that he wanted to earn something, he lost his lawsuit against Thermos L. L. C. (Thermos-Aktiengesellschaft). Dewar tried to sue them to get money for his invention, but he was too late; so, the witty Germans were too clever for him. God knows whether he did not remember his famous ancestor at the Royal Institution Michael Faraday, who never patented his inventions of artifacts to avoid similar conundrums. The deeply religious Faraday felt deeply that big money belonged to businessmen, and poor fame to smart lovers of sciences.

19.1.5 Packing

The thermos flask was often not convenient enough and especially not fit for any long-term food storage; it was clear that the vacuum can extract oxygen from the food and thus eliminate most of the harmful bacteria. Half a century before the writer of these lines was born there, the freshness of the coffee in a vacuum sealed bag was preserved in San Francisco[2590] as a first-class addition to the preparation of coffee. Already in 1812 gourmet Rumford prohibited the spoiling of taste of coffee with fermentation. The first vacuum coffee siphon was patented by the Berlin-based company Loeff in 1830, as Jean Richard recognized with his French patent in 1838. In 1960s the coffee bags took over the market from much slower vacuum coffee makers with their siphons which are again becoming popular in the US nowadays. There was a fast-food era, but it is over today, and folks need to relax.

In 1936, for the first time, frozen foods were delivered in vacuum rubber bags for the soldiers of the famous line of Andreas Maginot (1877-1932) in eastern France, while the polyvinyl displaced

[2588] Mayr, 1678 *Catalogus*, 51–52; Reisp, *1987*, 7.
[2589] Soulen, 1996, 35.
[2590] http://chrisgrande.com/2010/07/24/the-history-of-hills-brothers-coffee-and-the-vacuum-seal-mystery/

other convenient packaging in the 1950s. The modern vacuum packaging was launched by Doctor engineer Karl Busch (* 1929 Lörrach) with the help of his Turkish wife Ayhan (* 1934). In 1963 they founded Dr.-Ing. K. Busch GmbH in Schopfheim in southwest Germany. Karl built a convenient household vacuum pump in the basement of their house; after his verification he sent the device to the market. Half a century later his company gives bread to three and a half thousand workers.

19.1.6 Lyophilisation (Freeze-drying)

The removal of oxygen is not the only opportunity for vacuum to extend the durability of foods; in a vacuum, we can accelerate sublimation of ice from frozen foods. When the Vacuum evaporation process is applied to food and the water is evaporated and removed, the food can be stored for long periods of time without spoiling in a process invented by Henri Nestlé in 1866 for his Nestlé Chocolate fame, although the Inca and Shakers were already using a vacuum pan earlier to inspire Gail Borden's New York Condensed Milk Company in Texas in 1853 and in 1864. In 1897, the Frenchman Jacques-Arséne d'Arsonval (1851-1940) boasted that he used the Dewar flask for biological research on 11 February 1888. In any case, he successfully participated in the liquefaction of various gases, and in 1906, together with his assistant Frédéric Bordas (1860-1936), he initiated the process of lyophilization in the Parisian Collaboration Biophysical Laboratory; a vacuum drying process was discovered by removing sublimated ice from frozen temperature-sensitive biological and inorganic substances. Of course, sublimation has been known in Europe for centuries, but for a long time they have not been using it for drying; they did this only in the Andes in the diluted air at altitudes well above most European mountains. Those native Americans freezed overnight and daily sunbathed potatoes (Papa) to sublimate their moisture thousand years ago to get Chuño useful for many years. The conquistadors, the Spanish Jesuit José de Acosta (* 1540; † 1600) in 1590, or son of the Inca nobleman Garcilaso de la Vega (* 1539; † 1616) in 1609,[2591] of course, described the Native American achievements, which the Europeans could not use; therefore, they later reinvented already sophisticated Latin American ideas, just like they redesigned amalgamation in mining. Not surprising: even though the immoral Europeans military defeated the Native Americans, the Europeans were so filled by greediness that they never learned anything. The Native Americans developed an unparalleled better skilled cultivation of soil which made most modern European foods a Native American heritage. Of course, it is a pity that aggressive conquerors have maimed local civilizations, looking for gold, which was indeed hidden in the superior knowledge of crops developed by the indigenous people. So, we just had to reinvent the technologies that have always been everyday fun of the American native Indians, just because of the abandonment and unbridled grappling of our ancestors in their path of the grabbing of lands of others.

The modern lyophilization is a slow drying process where three times more energy is consumed than in ordinary drying. In the first drying phase (primary drying) we remove frozen water by sublimation in vacuum, in the second (secondary drying) we achieve the same by desorption. Thus, we remove water without breaking down the basic structure and composition of our food. The lyophilized foods are stable for a long time at room temperature, and the addition of water restores them to the original condition before final ingestion.

In the food industry with lyophilization developed between the WW1 and especially supplemented during World War II; we produced the dried mushrooms, spices, beverages, macaroni, cheese, steaks, fruits, leafy vegetables, vegetables, meat, fish with other seafood, poultry, dairy products and other plant or animal raw nourishments. The lyophilization process concentrates fruit juices, produce milk powder, instant coffee and tea; dry soups, children's or dietary foods are also manufactured.

19.1.7 Cooking in a Vacuum

Today, the food storage is not the only culinary use of vacuum; cooking in a vacuum in a way opposes higher pressure cooking of Boyle's assistant Denis Papin, who enthusiastically cooked chicken to the impressed King Charles II soon after Papin’s invention in 1669. It is not just a matter of contrast between low and high pressures, but also the

[2591] Vega (Inka), 2009, 335.

opposition between slow and fast cooking, where the slowness may have a future as quickly as possible due to modern controversy.

The theory and the first loose experiments of prolonged cooking in water below the boiling point succeeded in Benjamin Thompson Count Rumford's kitchen in Munich in 1799, although he still used air for his translation of heat, after he had thoughtfully doubted the temperature of the boiling water as the best for cooking of all thousands types of foods. He often corresponded with the Slovenian expert Jurij Vega. In his essays, Rumford published a popular paper about fireplaces and chimneys, which also interested his American colleague, namesake and political opponent, Benjamin Franklin; Rumford's ideas were also frequently reported in the Ljubljana weekly Wöchentliches Kundschaftsblatt des Herzogthum Krain.[2592]

Rumford was not only happy to describe the cuisine of his era, but also designed one of the first cooking experiments at low temperatures. As a Bavarian war minister, he tested a potato-drying machine by placing a leg of a lamb in the hope that it could be cooked at a temperature considerably below the boiling point of water in the Munich Public Kitchen of the House of Industry. If the water in Munich boils down at temperatures by 10.5 degrees Fahrenheit lower than in London, he was convinced that it would also be possible to cook in London at this lower temperature. Of course, Mont Everest with a water boiling at temperatures by 30°C lower than at the seaside was only climbed for the first time half of a century later, and Rumford did not know much about Tibetan-Nepal cooking habits in the elevated Himalayan regions. In addition, the difference between the London and Munich boiling water was greatly overestimated in Rumford's narrations, since the differences of the altitudes lowered the boiling only by 2°C, and the additional influence of moisture could not be so great. Regardless, for the clever Rumford the boiling in the kitchen seemed like a huge loss, as the cooking in the boiling water is just as efficient as the cooking just below the boiling point, of course, without a significant non-economic fuel consumption used for the unnecessary boiling. Angry, and hungry because his experiment did not produce his expected dinner after three hours of cooking, he left a half-raw roast in his oven, where the surprised chefs found it well cooked in the next morning. The count of course honestly ate well in those years, when he slowly danced away from his widowhood into not very brilliant marriage with the widow of the famous French chemist Lavoisier. It is not certain that Rumford cooked for his new lady by that new slow system, but their domestic quarrels peaked with their kitchen utensils without cooking purposes flying in both directions with to amuse Parisian spectators. Maybe one of the reasons was that Rumford criticized the theory of caloric of the first husband of his wife, the beheaded Lavoisier? Rumford still liked Paris and remained there until his end, while the French chefs endorsed his cooking innovations almost a century and a half later.

The process of Rumford was developed in the industrial way of cooking in the vacuum packing of stored delicacies half a century ago. Why should the vacuum package be open at all, if you can drop it into the pot as an insulation – that was certainly the way how the inventor was thinking about those problems. It's funny fact that most of the cooking is done by females, but still, the leading cooks including Rumford and his heirs were and still are – males. In 1974, the reinvention of Rumford's idea was attributed to Georges Pralus (* 1940; † 2014) at the Troisgros restaurant owned by Pierre and Michel Troisgros in the French city of Roanne. The clever Georges told his boss that Rumford's low-temperature, vacuum-cooked lamb, duck or foie gras retain their original look, fat, and better composition. The new method of cooking sous-vide at temperatures below the Pralus' temperatures was soon developed by a little younger Bruno Goussault (* 26 January 1942) by testing various foods during his teaching of leading chefs after 1970. After he gained his fame in France, he became a scientist at the Cuisine Solutions food company in Alexandria in Virginia. He found suitable cooking times and temperatures in vacuum sealed bags filled with various foods which we still enjoy today. Modern addicts of sous-vide cooking use air-tight plastic containers and cook sometimes for three days, but usually just a few times longer than regular cooks. We cook the meat sealed within the vacuum pack at 55-60°C while we prepare our vegetables at temperatures 80-85 ° C.

[2592] *Kundschaftsblatt*, 2/40: p. 629–638; 2/41: p. 645–653; 2/42: p. 661–670; 2/16: 247–249 (20. 4. 1776); 2/17: 263–267 27. 4. 1776); 2/16: p. 251–252.

19.1.8 Futures of Cooking Sous-vide

The cooking sous-vide saves energy and preserves the original appearance of the food, which promises a prosperous future. Nothing inside the void called a vacuum thus interferes with the very core of cooking art. The void initially featured just as a food storage device, while the vacuum-insulated thermos has long been a traveling aid in everyday lives. The future of vacuum packaging looks promising, because it is a nature-adapted storage process without the introduction of additives, which even deserve the admiration of picky nature protectionist. The cost of production limits the widespread use of lyophilization,[2593] but the lyophilized foods are much lighter and less spacious: therefore, very suitable for a traveler. Here we witness another in a series of improvements developed for the needs of astronauts in their spacecraft that penetrated in everyday use.

The loadings from the hollow to the empty have always been the vanity fairs, but barely the vacuum enabled them to materialize and to "become flesh". Empty food cannot be eaten, but you can use vacuum to please your stomach better... Good appetite!

19.2 Vacuum Cleaners

Mechanical solution to floor cleaning might began in England in 1599 or in China even earlier. Before vacuum cleaners, rugs were cleaned by hanging them over a wall or line and hitting them repeatedly with a carpet beater to pound out as much dirt as possible. On June 8, 1869, Chicago inventor Ives McGaffey patented a "sweeping machine." While this was the first patent for a device that cleaned rugs, it was not a motorized vacuum cleaner yet. McGaffey called his machine - a wood and canvas contraption - the Whirlwind. Today it is known as the first hand-pumped vacuum cleaner in the United States.

John Thurman invented a gasoline-powered vacuum cleaner in 1899 and some historians consider it the first motorized vacuum cleaner. Thurman's machine was patented on October 3, 1899 (patent #634,042). Soon after, he started a horse-drawn vacuum system with door to door service in St Louis. His vacuuming services were priced at $4 per visit in 1903.

The British engineer Hubert Cecil Booth patented a motorized vacuum cleaner on August 30, 1901. Booth's machine took the form of a large, horse-drawn, petrol-driven unit, which was parked outside the building to be cleaned with long hoses being kept through the windows. Booth first demonstrated his vacuuming device in a restaurant that same year and showed how well it can suck dirt.

More inventors would later introduce variations of the same cleaning-by-suction type contraptions. For example, Corinne Dufour invented a device that sucked dust into a wet sponge and David Kenney designed a huge machine that was installed in a cellar and connected to a network of pipes leading to each room of a house. Of course, these early versions of vacuum cleaners were bulky, noisy, smelly, and commercially unsuccessful. The first vacuum-cleaning device to be portable and successful at the domestic market was built in 1905 by Walter Griffiths, a manufacturer in Birmingham in England.

In 1907, a janitor in a Canton Ohio department store James M. Spangler (1848 Pennsylvania-1915 Chicago) deduced that the carpet sweeper he was using was the source of his chronic coughing. So, Spangler mounted an old ceiling fan motor onto a carpet sweeper and cut a hole in the back of the sweeper to attach fan blades which would blow dirt out of the rear of the cleaner into an attached dirt pillow case bag. With pillow as a dust collector, Spangler invented a new portable electric vacuum cleaner. He then improved his basic model, the first to use both a cloth filter bag and cleaning attachments. He received a patent in 1908.

Spangler soon formed the Electric Suction Sweeper Company. One of his first buyers was his cousin, whose husband William Hoover became the founder and president of the Hoover Company, a vacuum cleaner manufacturer. James Spangler eventually sold his patent rights to William Hoover and continued to design for the company while Hoover financed additional improvements to Spangler's vacuum cleaner. The finished Hoover's design resembled a bagpipe attached to a cake box,

2593 http://www.zepter.si/MainMenu/Products/HomeArt/Vacsy/Product-Range.aspx but it worked. The company produced the first commercial bag-on-a-stick upright vacuum cleaner. While initial sales were sluggish, they were given a kick by Hoover's innovative 10-day, free home trial. Eventually, there was a Hoover vacuum cleaner in nearly every home. By 1919, Hoover cleaners were widely manufactured completed with the "beater bar" to establish the famous slogan: "It beats as it sweeps as it cleans".

The Air-way Sanitizor Corporation, established in Toledo, Ohio in 1920, introduced a new product called the "filter fiber" disposable bag, the first disposable paper dust bag for vacuum cleaners, the filter bag. Air-Way also created the first 2-motor upright vacuum as well as the first "power nozzle" vacuum cleaner. Air-Way was the first to use a seal on the dirt bag and first to use a HEPA filter on a vacuum cleaner, according to the company's web site.

James Dyson (* 1947 Cromer Norfolk) invented the G-force Vacuum cleaner in 1983. It was the first bagless dual cyclone machine. After failing to sell his invention to manufacturers, Dyson created his own company and began marketing the Dual Cyclone bagless vacuum cleaner, which works on the principle of cyclonic separation. It quickly became the fastest-selling vacuum cleaner ever made in the UK. He was knighted in the 2007 and elected a Fellow of the Royal Society in 2015 as a proof of usefulness of his fellow English William Shakespeare’s Much Ado About Nothing.

20 Ether Full of Plasma: Total Vacuum: When there is Nothing Left & Forth Aggregate State

20.1 Radiometer and Pursues for the Total Vacuums

Radiometer has been the most interesting physical device for several years, which has spurred a lively discussion. However, it later almost drowned in oblivion of childish toys, as it turned out that it was not measuring the radiation pressure at all, even if it could provide some clues. Despite of those explanationsprepared a decade after Crookes' invention, the misleading term radiometer is still in use, just like the rising sun contradicts Copernicans.

20.2 Introduction: a Complete Vacuum

Many researchers have tried to achieve a perfect vacuum in which there would be no molecules. The effort was like cooling to absolute temperature zero at the end of the 19th and early 20th centuries. Both research plans ended in a similar funny way with incomplete success. In that case of temperatures we even established the "third", Nernst's Law of Thermodynamics of the unreachable absolute temperature zero, which became a kind of limit like Einstein's velocity of light, while the upper limits of temperature, density or time remained unclear and subject to occasional changes just like the businessmen's wealth which seemingly has no upper limit but could go bankrupt. Similarly, the oil and other resources of Earth were openly limited in 1960s.

However, the competition to achieve a complete or at least nearly total vacuum did not get as much international attention as the simultaneous competition between vacuum-related researchers for condensing so-called "permanent" gases. It did not have a predetermined goal, as it has already been shown in the early days of research that billions of molecules are flying well even inside the best of the vacuums. Although Galileo himself did not experiment inside vacuums, the thought experiment with falling in perfect vacuum was one of the foundations of his description of accelerated motion.

The total vacuum was later the center of the Crookes' research program. Despite Crookes' failure, the idea of the extreme limits of the vacuum was never completely abandoned. Thus, in the era of stagnation in bettering vacuum between 1920 and 1950, many researchers thought that with their 10^{-8} mbar they had reached an extreme vacuum which the hot-cathode ionizer can still measure so that progress will be no longer possible.[2594] Or, at last, we will be unable to prove better vacuum with the measurements currently available even if the interstellar space might have approximately 1^{-15} Pa (1 fPa).

The radiometer is often seen in shops, especially in goldsmiths. It is a "light mill" illuminated in a low-pressure container. It is driven by a temperature difference and associated vacuum on the vanes. However, in the mid-1870s, most researchers thought that the mill flaps were rotating under the pressure of light rays. That's why Crookes gave a name to the radiometer, which is still used today, although it does not indeed measure "radiations". The interesting history of the device is intertwined with the exploration of the vacuum.

Crookes' radiometer was already familiar before him. Mairan described his light mill as "a horizontal wheel of iron with a diameter of about 7.5 cm on an iron axis with an oblique vane on each side. The wheel and the axe put together are lighter than 1.95 g."

Under the rays of sunlight in the lens's focal point, the wheel did not rotate properly. Mairan described the air flows near the device. He intended to test it in a vacuum, but he postponed the plan due to difficult implementation.

In 1751, the Cartesian French Oratorian priest Bertier showed Parisian academics Réaumur, Nollet and others an experiment in which the needle was sealed in a vessel by the flame. Jean-Jacques Rousseau's friend the physician Bertier was elected FRS in 1769. For a similar experiment, the geologist Michell used a torsion scale,[2595] with

[2594] Redhead, 1999, 144.
[2595] Rosenberger, 1890, 681, 679.

which Cavendish later measured the gravitational constant.

In the beginning of 1766, Franklin advised his English friend Priestley to handle similar experiments with the windmills. Franklin felt that the windmill, without any obvious cause, could chose this or the opposite direction of rotation. Priestley experimented for almost a year in various circumstances. He first used halves of the playing cards for his vanes; thirteen of them were planted in a cork and fixed with a needle on a glass stand connected to a point conductor few inches away from the recently invented Leyden jar. At discharges, the fan flap always turned in the same direction, often so quickly that it was not possible to distinguish the vanes. Later, he replaced the cards with lighter strong white paper. He made dozens of windmills with diameters of 3 inches and lengths of 2.5 inches. Following Canton's advices Priestley wetted the paper vanes to increase their electrical conductivity. In other experiments, the crevices with metallic glitter or thin pieces of brass are of the same shape. He also used an automatic rotating spindle for the wind turbine. He replaced his paper by lighter gold sheets, even in windscreens with horizontal axes, which were still spinning at the distance of 30 cm from the source of electricity. He placed a candle near the wind turbine, which flowed up the air. Therefore, he thought that the flap was driven by the gust of wind, although, for example, Canton considered it to be an electric deflection.

John Smeaton from Leeds was a civil engineer and first user of a "hydraulic lime" for underwater construction. He paved the way for the discovery of modern cement in 1756. He made a two-way air pump. Priestley used the device during his work at future prime minister William Petty 2nd earl of Shelburne's (1737 Dublin-1805) great lab in Calne in 1774-1780. The Italian Tiberius Cavallo used Smeaton's pumps for his measurement of specific weight of gases.

In Wilson's discussion, Priestley read that the fan in the vacuum does not rotate. He repeated Wilson's experiment with the same result. When he dropped the air into the vacuum container, the windmills revolved.

Differently from Crookes one hundred years later, Priestley did not bleed the windshield vanes and did not put it in a vacuum to often, although he liked experimenting in a void. In the following years, he used primarily a pump for pressures down to 1 mbar.[2596]

William Crookes' father was a rich tailor. Therefore, after studying and serving at the Royal College of Chemistry in 1854, William could devote himself entirely to research. In 1863 he became FRS. In 1885, he moved to Oxford, where he persistently investigated the most pressing issues of physics until his last days. After 1900, he also started researching radioactivity. In 1897, the queen Victoria honored him with the title of the knight. Crookes was a president of the London Ghost club in 1907-1912 before he served as president of the RS between 1913 and 1915. The experimental sciences and paranormal research worked in close connection among the Brits before WW1.

William Crookes (* 1832; † 1919)

In his report in 1792, the Bentley parish priest Abraham Bennett failed to turn the needle under influence of the flame. His negative result has been used by various researchers for a long time against

[2596] Priestley, History 1966, 2: 187–190; Priestley, *Autobiography* 1966, 21, 29, 31–33, 39, 42, 52, 109.

corpuscular theory of light including Thomas Young in London and Stewart at the Kew Observatory in 1866.[2597]

The author of the transversal wave theory of light, Fresnel, built a two-tank metallic mill in an emptied container with a pressure of 1 or 2 mbar in the Parisian Polytechnic in 1825. The mill spun when it was illuminated by sunlight. Like Crookes half a century later, Fresnel also considered that the phenomenon was caused by the convection of warmed air or evaporation from surfaces, as the phenomenon hardly changed at twenty times greater pressures.[2598] In the same year he placed two panels suspended on a silk thread in a vacuum container. The plates mutually repelled each other when lighted by sunlight reflected by the collecting lens. A similar phenomenon was observed by Alexandre Claude Martin Lebaillif in Paris in 1829 and later by Jacques Frédéric Saigey (1797 Montbéliard-1871 Paris).[2599] However, Fresnel soon died, so his discovery was forgotten until Crookes mentioned his research.

Pouillet and Desperetz, a professor of physics at Sorbonne in 1849, explained such experiments with heat and warmed air. Desperetz also examined the thermal effects on the motions of the needle of galvanometer.[2600] In the same year he compiled a furnace heated by the combined action of the Sun, electricity and the torch.

20.2.1 Crookes's Discovery

Crookes liked Kirchhoff and Bunsen's spectroscope, which enabled their discovery of cesium and ruthenium in Heidelberg in 1860 and 1861. The new elements were named by their characteristic blue-gray or dark-red spectrum. Crookes followed their example, discovered thallium and named it after the green leaves in 1861. He was, of course, only a tailor's son, but he was therefore not inclined to lag somewhere behind the more appealing Latin titles of German university professors. Crookes believed the assumptions of the London practical physician W. Prout that the atomic masses of all the elements are always the multiples of the mass of the hydrogen atom, published anonymously in London in 1815. Therefore, Crookes tried to measure accurately the atomic mass of the thallium. However, Crookes measured a value of 203,642, slightly lower than the modern value 204,383, but, clearly contrary to Prout's assumptions.

Crookes' assistant was an extremely skillful glassblower the young Charles Henry Gimingham (1853-1890). In Crookes's research, he played an important decisive role, like that of Geissler at Plücker's lab in Bonn, while Gimingham was also a kind of member of Crookes' household. After his marriage, Gimingham needed more money and left Crookes to join Swan's United company, later joint Swan & Edison company in Newcastle where he worked together with his brother E.A Gimingham and Maxwell's student J. A. Fleming.

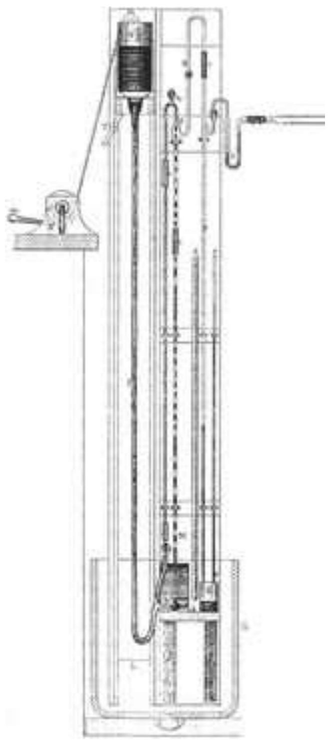

Figure 20-1: Crookes and Gimingham's pumping system with a single Sprengel pump during their initial exploration of a radiometric phenomenon.[2601]

To determine the atomic weight as accurately as possible, Crookes and Gimingham measured in a vacuum. They found that the heating of the device

[2597] Bennet, 1792, 81; Young, Phil.Trans. 1802, 92: 46; Stewart, 1866, 161, 352.

[2599] Fresnel. 1825, Bull. de la Soc. Philomath., 84; Rosenberger, 1890, 679.
[2600] Rosenberger, 1890, 213, 679–680.
[2601] Redhead, 1999, 143.

reduced the measured mass. More detailed research has shown that the mass decreases if the source of heat is below it because the measured object moves upwards.[2602] Therefore, in the 1870s, they experimentally exhausted the container to a "perfect" vacuum, in which the flows of the remaining molecules would not interfere with weighing. They added Andrews' chemical pumping methods to Sprengel's pump.[2603] They developed pumping system with a single Sprengel's pump in 1872. By the following summer, they already produced a vacuum through which the Ruhmkorff inductor could not be discharged (Figure 20-1).[2604]

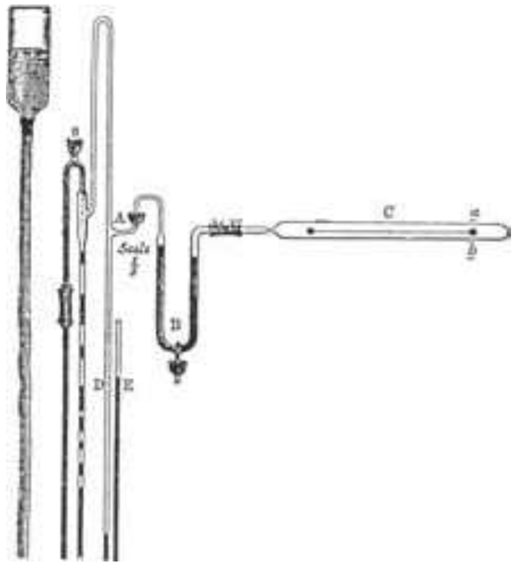

Figure 20-2: Crookes's first device for measuring radiometric force designed in 1874[2605]

To investigate the force that disturbed the measurement of atomic weight in a vacuum, they compiled a device for measuring "repulsion by radiation". That became the title of their series of six papers which they communicated to the RS between the years 1874 and 1878. First, they used a balanced rod in a vacuum vessel, which was heated on one side by the flow of hot water. The meter was later improved so that they measured the simple movement of the lever with the elderberry spheres at the ends in the smaller vacuum vessel. When the elderberry balls were heated from the bottom, they rose. If the container was emptied even more, the effect decreased and at 9 mbar, when "the last trail of the air was removed from the container ..., the elderberry balls remained stationary." When the pressure was lowered, the elderberry sphere rose again if they were warmed from below.

Crookes thought that the relationship between heat and gravity was finally determined: "Although the force that I talk about is certainly not the usual weight, the attraction comes from chemical action. It connects the largest and most mysterious natural force, remote operation, with better known substances. The energy of the Solar radiation can finally turn out to be "constantly working according to certain laws" that Newton had for the cause of gravity" (Figure 29-2).[2606]

Figure 20-3: Photograph of James Clerk Maxwell (* 1831; † 1879)

Crookes hoped that his discovery could solve the problem of tails of comets. The Comet C/1874 H1 of Jérôme Eugène Coggia was the one of those that aroused admiration in Europe in those summer weeks of 1874. Astronomers have been searching for the repulsive force of the Sun for a long time, perhaps even the luminous pressure that forces the gaseous part of the comet away from the core. The phenomenal comet has certainly prepared scientific circles for the forthcoming debates on the radiometer. Due to frequent conversations about the comet at James Clerk Maxwell's house in

[2606] Woodruff, 1966, 190, 191.

Cambridge, his home-grown terrier Toby ran in a circle at each mention of the tail of a comet and chased his own tail to amuse the gathered scientists.

In 1874, Crookes introduced his mill to the RS, where it was then put on display. All visitors felt that the mechanical energy of the light was directly involved. Maxwell initially joined the general opinion (Figure 20-3).

Englishman **Osbourne Reynolds** of Belfast studied in Cambridge. Between 1868 and 1905 he was a professor of engineering at the University of Manchester. He continued his radiometric research with fluid dynamics. In 1883, he announced that the laminar flows turn into a turbulent flow, when the number that we now call by his name grows over the critical value. He also developed a theory of lubricants, measured the mechanical equivalent of heat and designed many turbines.

Osborne Reynolds (* 1842; † 1912)

This phenomenon interested Maxwell because of the kinetic theory he published in 1867, as well as due his electromagnetic theory with which he similarly predicted at much lower pressures:
».. . From here, the average force by which sunlight is pressing against the square meter area equal to 0.00000041 kilogrammeters.[2607] This pressure is created only on the illuminated side of the body, so the body will be pushed in the direction of motion of the solar rays.[2608] The focused electrical light would probably push even more, and it is not impossible that the rays of such light that would fall on a metallic plate in a vacuum would produce a noticeable mechanical effect."

Maxwell accepted to values Crookes paper for the publication in Phil. Trans. At that time, he agreed that Crookes measures the pressure of radiation, the collisions of waves onto a solid surface. Crookes then improved the vacuum in his container with the use of charcoal as getter according to Dewar's advice.

20.2.2 Crookes's Antagonists

Reynolds among the first contradicted Crookes' claims with the assumption that Crookes measured the reflectance phenomenon due to the temperature gradient. A year earlier, Reynolds published a study of condensation of a mixture of steam and air on cold bases in a steam engine. Therefore, he claimed that the radiometric phenomenon also depends on the evaporation of the air molecules on the vanes of mill. Similarly, he wrote that the tail of comets is due to electric force or because of a "negative shadow". He wished to explain Crookes' (1874) experimental results with the repulsion of the elderberry balls from the flame of the candle with the higher temperature of the ball on the heated side. Faster molecules on the hot side are more likely to push the ball and therefore to move it. However, in 1875 Dewar and Tait proved that faster molecules collided quicker with their neighbors. Thus, the pressure should be compensated everywhere despite of temperature differences.[2609] Although the early Reynolds' theory of the radiometric phenomenon was later discarded, it nevertheless directed subsequent explanations to the problem of gas-to-surface interaction.

In the winter of 1873/74, that is, before Crookes's first publication, Schuster returned from observing the solar eclipse in the expedition of Norman Lockyer in Thailand. He immediately examined Crookes' mill, exhibited at the RS. Schuster was an unpaid assistant at the University of Manchester.

[2607] $4.1 \cdot 10^{-7}$ Pa.

[2608] Maxwell, 1873, 793; Brush, Everitt, 1969, 109; Rosenberger, 1890, 683.

[2609] Dewar, Tait, 1875, 217–218; Woodruff, 1966, 193.

There he described to Reynolds and others his decisive experiment measuring whether the radiometer vessel was rotating in the opposite direction of rotation of the vane of the mill. Schuster apparently reversed the experimental focus on whole vessel instead of its vanes, just like Salcher or Torricelli did in their times. Such a rotation of radiometer would mean that the displacement of the vanes was not brought into the container from the outside. The rotation of the vanes was in this case dependent on an internal mechanism, presumably related to the remaining gas in the exhausted vessel. But Schuster did not want to carry out the experiment alone, "because it would appear that he is intervening in the work of others". Schuster, like Crookes, was involved in the spectral analysis of light at the beginning of his research pursuits. Unfortunately, Schuster and Crookes advocated the opposite interpretation of the radiometric phenomenon. In 1875, Schuster returned from Germany to Reynolds's labs at the University of Manchester, where they hung the radiometer housing on two silk threads. The scientific spectacle was awaiting the outcome of their experiment. J. Thomson recalled half a century later "relief when he heard that the device was rotating in the opposite direction from the flap."[2610] In February 1876, Schuster affirmed Reynolds's assumptions that the remaining gas directly rotates a radiometer.

Gimingham carried out a similar experiment. He put the radiometer in the water, prevented the movement of the flap with the external magnet, and noticed the rotation of the casing in the direction opposite to the course of spinning of free flaps without magnets involved.[2611] In April 1875, Crookes measured that the light press more the black than a white or silvered surface of the radiometer flap. The results like those were repeated by other researchers. Because the light rays were reflected from the silvered side, the pressure on them should be twice as high. Therefore, in June 1875 Maxwell also gave up the idea of a radiometer measuring the direct impact of incident rays on the substance. He found that the blackened surface is not pushed more by the source of light because it radiated more, but because it is hotter.[2612] Maxwell referred to the experiments of Kundt and Warburg (1875). With slower cooling of the thermometer in vacuum, they confirmed that the internal friction did not depend on the pressure of ideal gas, which Maxwell described for the first time in a letter to Stokes on May 30, 1859.[2613]

Figure 20-4: Crookes' radiometer[2614]

Clausius's kinetic theory with the mean free path of molecules did not promise a complete description of the radiometric phenomenon. In the mill, the average free pathway of the molecule may be greater than the distance between the solid surfaces of the flaps of the mill at which the molecule collides. Therefore, there is no equilibrium due to collisions between molecules; irregularly heated flaps can cause large temperature differences in the surrounding gas. However, at that time no one was able to calculate the resultant forces due to the temperature gradient without doubtful additional assumptions.

Crookes compiled a "light mill" in the later most famous form with four vanes in a glass container and named it a "radiometer" (Figures 20-4 and 20-5). The weight of horizontally rotatable, on each opposite side blackened vane should not exceed

[2610] Thomson, 1936, 373–374; Woodruff, 1966, 194; Brush, Everitt, 1969, 111; Feffer, 1989, 35–36.

[2614] Ganot, 1886, 400.

0.13 g. The blackened side moved towards the light source at ordinary pressure. When the air was pumped out of the container, the rotational speed of the flap was lowered, and the flap finally stopped. After further pressure reduction, the mill began to turn again, but this time in the opposite direction. The initial presumption was that the radiometer's vanes are spinning faster with the best possible vacuum around them. Crookes had to abandon those ideas due to experimental results in mid-June 1876. It was calculated that at each cm^2 of the flap the pressure was equivalent to the mass of 0,01 mg.[2615] In modern units, this pressure is 10^{-4} Pa, almost 250 times more than predicted by Maxwell in 1873.

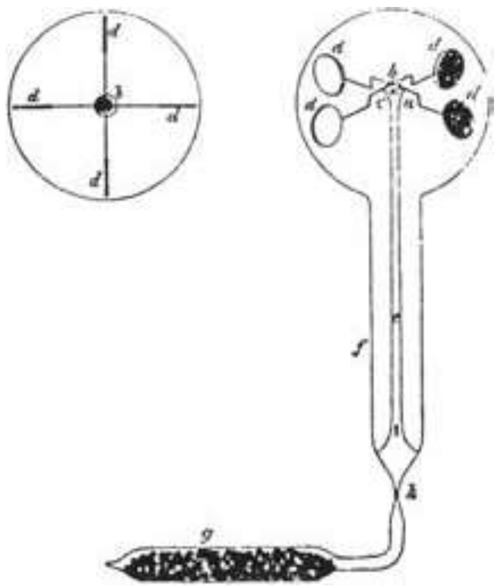

Figure 20-5: Crookes' sketch of radiometer at his discussion On Repulsion Resulting from Radiation published in 1876[2616]

In mid-April 1876, Gimingham used three pipes to drop his mercury instead of one. He reached 0.004 mbar measured with McLeod manometer, which he began to use in the middle of summer 1876 (Figure 20-6). All the researchers agreed that the exact measurement of pressure inside the radiometer would determine what spins the vanes in it. That is why Crookes and Gimingham complemented their measurements of pressure by observing the electrical phenomena and the speed of rotation of the radiometer.[2617]

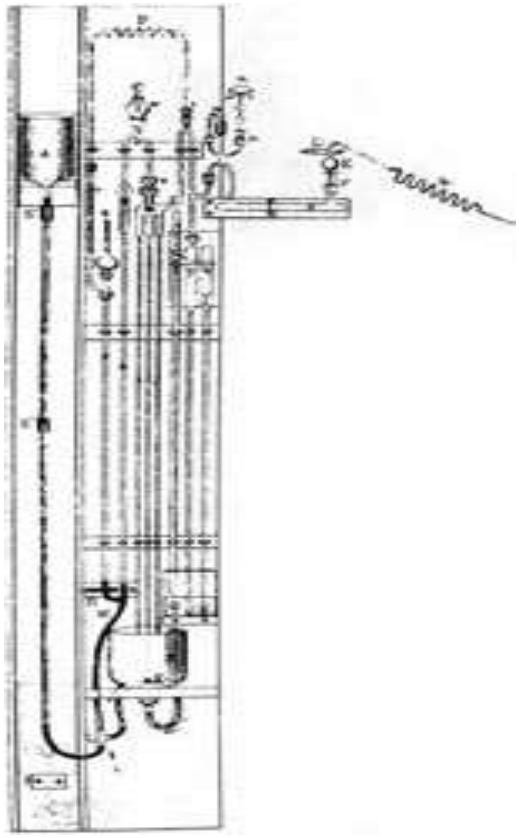

Figure 20-6: Gimingham's improvement of the Sprengel's pump, as used with Crookes at least from mid-April 1876.[2618]

Meanwhile, interest in the radiometric phenomenon has expanded into the highest levels of English society. On May 15, 1876, Maxwell wrote to his maternal uncle Robert Cay (1807-1888) how he describes Guericke's Magdeburg experiments and Crookes vacuum research to Queen Victoria herself. In doing so he wistfully remarked that "... her Majesty however let us off very easily and did not make much ado about nothing, as she had much heavy work cut out for her all the rest of the day."[2619]

In the autumn of 1876, Crookes came to the idea of the fourth aggregate state of the substance during the study of the difference between the illumination of convex and concave flaps in the radiometer.[2620] Two years later, he published experiments with a radiometer that had vanes made of golden leaves blackened on a one side. When the illuminated mill turned in the opposite direction, otherwise that usually, with the side facing forward, he has noticed that one leaf was wrinkled. Crookes took advantage of that random

discovery by covering the top half of the radiometer and illuminating only the lower half, where the flaps were rotated with the blackened side towards the source of illumination (Figure 20-7).

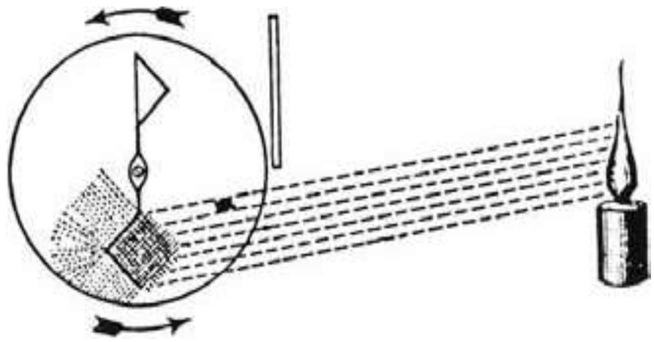

Figure 20-7: Crookes radiometer with field lines of molecular pressure.[2621]

20.3 Maxwell and Reynolds' Theory of Radiometer

Immediately after the exchange of views on the radiometer begun, it turned out that the pressure of the light does not, however, cause the mill to rotate. Maxwell knew that the radiometer was a serious physical problem, although it was possible to do simple experiments with it. That is why he was careful in his judgments, especially in his reviews of the Crookes, Reynolds and Schuster's papers for the RS. At the beginning of 1877, Maxwell persuaded Schuster to move from Manchester to his Cavendish Laboratories. In May 1877 Schuster brought four radiometers to the Cavendish laboratory. He surely inspired Maxwell, who at the same time provided the definition and explanation of the radiometric phenomenon. Maxwell finished the work the next spring, but he added the notes to the paper already gravelly ill a year later. He devoted most of his space to calculating the force due to temperature differences in the interior of the gas, where the pressure is proportional to the second derivative of the temperature with respect to volume. He rejected early theories of FitzGerald and Stoney who believed that a constant temperature gradient should suffice for the difference in pressure. According to Maxwell, a small mill in gas as a source of heat is enough to change the temperature gradient and thus to the pressure that spins the mill.

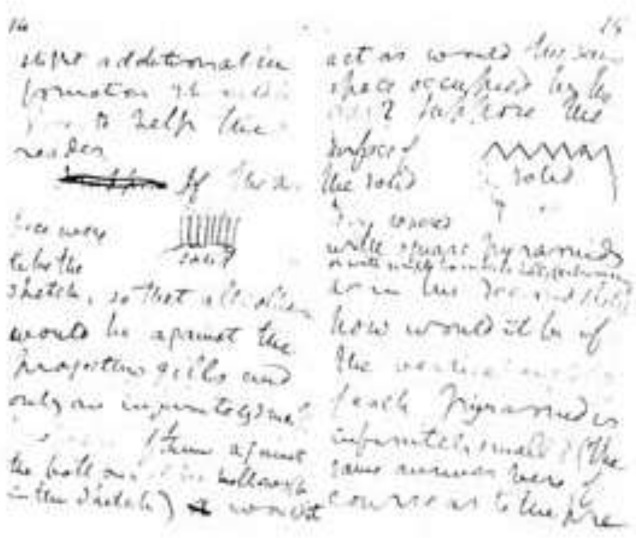

Figure 20-8: Manuscript W. Thomson (later Lord Kelvin) estimation Maxwell's discussion on 15. 6. 1878.[2622]

W. Thomson reviewed Maxwell's paper prior to publication by RS on June 15, 1878. Maxwell further explained the problem in his letter to W. Thomson three months earlier. Maxwell knew, of course, that his friend W. Thomson was a reviewer of his discussion, even though the RS Secretary Stokes sent him just a typed transcript of the review (Figure 20-8).

Crookes' sixth and final paper in his discussion group "On repulsion by radiation" was sent to Maxwell for review only two weeks earlier than Thomson's report on Maxwell's own paper was received. Maxwell supported the publication of Crookes' work on October 23, 1878. Three months later Maxwell received Reynolds's general theory of gas flow in the radiometer with the discovery of "thermal transpiration". Thus, Reynolds named the gas flow through a perforated plate due to the temperature difference between the sides of the panel, which was one of the main discoveries of the quarrels about the radiometer. He found that the radiometric phenomenon depends on the ratio between the size of the flap of the mill and the average free path of the molecule in the gas. The phenomenon disappears at very large flaps or in cases of very small mean free paths. However, to validate the theory, one should diminish the openings so much that the measurement would no longer be possible. Therefore, Reynolds preferred to fix the radiometer flaps in Gimingham's manner, so that the air would move through the

[2621] Woodruff, 1996, 196.

[2622] Brush, Everitt, 1969, 116.

radiometer in the opposite direction. The experiment with small flaps would thus be replaced by an experiment with small spaces designed for the flow of gas; that is, with perforated vanes.

In his assessment of Reynolds' paper, Maxwell supported his experiments, but not his theories. For this reason, the frightened Reynolds slightly corrected his claims, as it was not god to quarrel with the famous guy like Maxwell. In May 1879, Maxwell supplemented his own paper by considering the surface phenomena in gas, about which he was reading in Reynolds's yet unpublished paper. He rated his method as better. Reynolds did not accept Maxwell's ideas, but criticized them in a letter to RS Secretary Stokes. Several hours after Maxwell's death on November 5, 1879, Stokes telegraphed Reynolds to modify his criticism or to allow his comment. The latter possibility prevailed. Thus, Stokes read before RS Reynolds's criticism and Stokes's opinion, in which he said, among other things, that the late Maxwell partly conceived his theory on the advice of W. Thomson. Reynolds, of course, deeply resented the leading members of the RS with the criticism of Maxwell who just passed away. Thomson made a special effort, and after a detailed study of literature, he even questioned Reynolds's priority in the discovery of "thermal transpiration," since the phenomenon was already discussed before him by the German W. Feddersen, assumedly Berend Wilhelm Feddersen (1832-1918 Leipzig), according to the predictions of Carl Gottfried Neumann (1832–1925) from the University of Leipzig, son of the famous crystallographer FE Neumann. Everybody was angry because of Reynolds's insulting the demigod Maxwell, who just passed away without any faults deserving mention.

20.4 From Radiometer to Cathode Ray Tube Electronics - "Electric" Radiometer

Just as Crookes' chemical problem led to the study of a vacuum, which was initially merely a research tool, his ten years-younger friend Dewar went from a chemical problem to the design of thermos and then to the liquefaction of "permanent" gases. With Maxwell's death, Crookes lost the main supporter of his theory of radiometer. In the mid-1880s, Crookes finally accepted the impossibility of a total vacuum and, after a long resistance, confirmed the remaining gas as the cause of the radiometer's motion. The latest Crookes' discussion of "radiation reflections" was, according to Maxwell's reviewing, read before the RS on 21 November 1878. The first discussion on "the light of the molecular pressure lines and the rails of molecules" was read only two weeks later. Thus, Crookes skipped from the radiometer to the cathode-ray tube, from the radiometric forces to the cathode rays, from a perfect vacuum to the phenomena of the "fourth aggregate state of matter in incomplete vacuum".[2623] The "light" mill was placed in a cathode-ray tube and became an "electric radiometer". It seemed to him that the dark area around the cathode is similar if not the same as the invisible layer of gas flow in the radiometer, where the pressure of the molecules is increased. As a devoted researcher of now obsolete radiometer, Crookes planted his radiometric visions whenever he could, as the humans usually do:

"For a long time, I am under the impression of the idea that the dark layer around (electrode of cathode ray tube) is somehow connected to the layer (of overpressure) of the molecules that causes motion in the radiometer."[2624]

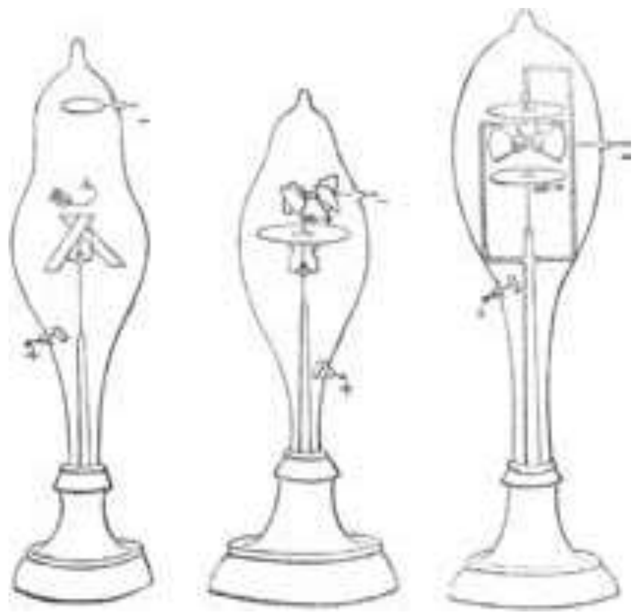

Figure 20-9: Puluj's "electric" radiometers with phosphorescent flaps[2625]

[2623] DeKosky, 1984, 84, 95, 97.
[2624] Woodruff, 1966, 196–197.
[2625] Puluj, 1889, 292.

First, Crookes tried to measure the "layer of molecules' pressure" with the small mills placed around the main mill. However, small mills soon became electrified and thus hampered the measurement. He therefore compiled an "electric radiometer" containing a cathode in a form of a mill with aluminium flaps blackened on one side. The dark area of the discharge stretched longer on the blackened sides of the flap than on the side which was not blackened. When the dark layer reached the wall of the vessel, the mill began to rotate with theblackened side facing forward, like in a regular radiometer. Crookes assumed that the molecules were moving away from the negative electrode therefore rotate his mill. Hittorf considered in Münster that the rotation caused an annealing of the heated glass of the vessel. Puluj from the Viennese Physics Institute, who began investigating the radiometric phenomenon at Kundt's lab in Strasbourg in 1875, rejected them both, Crookes as well as Hittorf. If Hittorf's assumption was to apply, we could rotate the radiometer by heating its glass housing touched with our hand. Puluj attributed the rotation to the three opposing causes: radiation from the electrode, thermal movement due to the heating of aluminium vanes and the thermal radiation of the glass wall of the cathode ray tube. The individual causes prevail at different pressures and therefore, dilution of air changes direction of rotation of the flap. At pressures of 0.03 mbar, radiation was described according to Stefan's law. In subsequent experiments, Puluj coated his flaps with fluorescent substances, including the green CaS. During his experiments, Puluj later developed various fluorescent lamps (Figure 20-9).[2626] Otto Lehmann–also began to examine a radiometer during his studies in Kundt's labs in Strasbourg. Lehmann argued that the mill directly changes the energy of light into mechanical work, but only a small part of the energy of light causes temperature differences.

The professor of astrophysics in Leipzig, Zöllner, opposed Crookes' interpretation of the radiometer, although he supported Crookes' spiritism in the 1870s. In 1880 he collaborated with Weber in the development of the theory of electricity and gravity, a few years after Schuster. Zöllner's opinion was close to Reynolds and Schuster's. Zöllner claimed that the absorbed gas stream does not drive vanes of the radiometer, which were rotated directly by the evaporations from the solid vane of the mill. In interpreting, he considered the theory of the oscillation of the ether against the electrical theory of rotation of the radiometer. Similar ideas were announced at the same time by Boltzmann's PhD student the English supporter of Le Sage's ether named Preston. One year earlier he criticized the assumption of Crookes and Stoney and argued that the average free path of the molecules in the radiometer is smaller compared to the distance between the flaps.[2627]

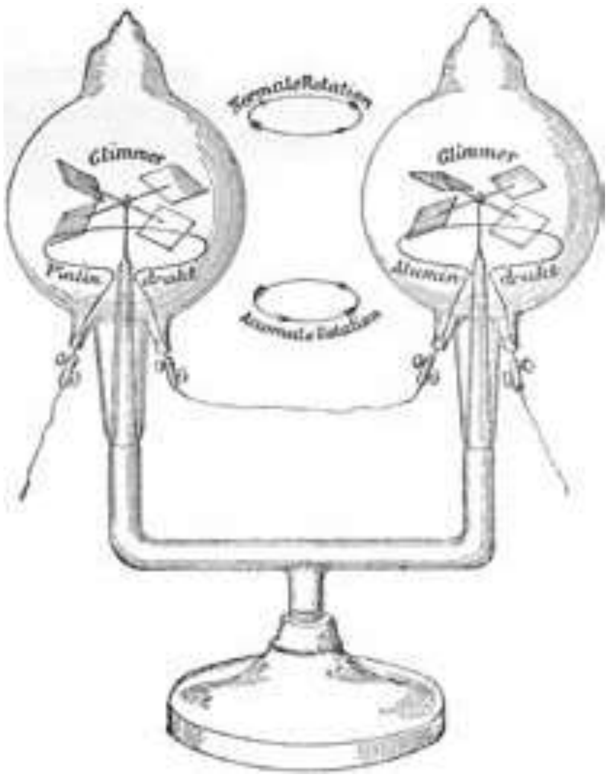

Figure 20-10: Zöllner's double radiometer from 1877[2628]

The Germans already made radiometers before Crookes, but they did not give them so much attention. Geissler from Bonn presented Zöllner's radiometer at the German Association of Naturalists and Physicians (49. Versammlung Deutscher Naturforscher und Ärzte) meeting in Hamburg on 8-24 September 1876, and later Geissler himself successfully used it.[2629]

Crookes assembled a double radiometer with counterclockwise blackened flaps on the same axis, which later gained their great popularity. He

[2626] Puluj, 1889, 278–279, 288–289, 284, 290, 293–294).

[2627] Jungnickel, McCormmach, 1986, 2: 237; Rosenberger, 1890, 582, 683–684.

[2629] Poggendorff, 1875, 489; Puluj, 1889, 274.

measured the rotation due to heating or cooling, and the pressure which balanced them.[2630] Zöllner has compiled a different dual radiometer with short-mounted platinum and aluminium plates rotating around its own axis. At normal pressure, it turned "normally" in the direction of the warmed air flow (Figure 20-10). At a pressure of about 122 mbar, the direction of rotation turned around as if the aluminium and platinum plates were now starting to absorb the surrounding gas. With reduced, then still non-measurable pressures, the direction of rotation was reversed again. At full sunlight, the rotation did not turn even at pressures deep below 122 mbar.[2631]

A live controversy between radiometer researchers continued for several years in the papers of Stoney, E. Pringsheim, Reynolds, Sutherland, and others. Stoney explained the function of the radiometer with a kinetic theory, which was later corrected by Maxwell.[2632] However, in the following forty years there were no new important radiometric studies, as opposed to the vivid quarrels in the mid-1870s. The development has stalled more due to the prevailing opinion that the phenomenon is too complicated to be dealt with, and not as the result of a definitive satisfactory clarification. E. Pringsheim of Breslau (today's Wrocław), together with Lummer in Berlin, preferred to undertake research of the radiation of the black body, which was more promising. The radiometer's theory was primarily developed by the findings of Knudsen, who first successfully used the quantitative measurement of the radiometric force to determine the pressure.[2633] It turned out that the impact of a higher speed of molecules is compensated by a smaller free path just above the mill flap. In the thin area above the edge of the flap, however, the effect of faster molecules prevails.

The new Prague professor Einstein provided two comments on Knudsen's kinetic theory at the 1st Solvay Congress. Thirteen years later, in Berlin, Einstein supplemented Knudsen's calculations of forces applied to the flaps of radiometer for the case where the average free path of the molecules is smaller than, or equal to the size of the flaps in the mill.

20.5 Radiometer, Pressure of Light and Stefan's Law

The pressure of light was discussed already in the 17th century. W. Thomson estimated its size in 1852. Prior to Maxwell, the opinion prevailed that the successful measurement of the pressure of light would confirm corpuscular or longitudinal wave theory, rather than the transversal one. At first, the radiometer seemed to measure the luminous pressure in favor of fans of Newtonian corpuscles. Bartoli of the Institute of Technology in Florence cited the development of a radiometer and assumed that the pressure of light is the result of a thermal radiation which opposes entropy law. His ideas were supported by Eddy who served as the professor of Mathematics and Astronomy between 1874 and 1890, and then President of the University of Cincinnati. Graz professor Boltzmann wrote a review of Eddy's work for Ann. Phys. In doing so, the editor E. Wiedemann drew Boltzmann’s attention to Bartoli's work, which Boltzmann and Boltzmann's former teacher, Stefan, probably did not even know. As the leading defender of second law of thermodynamics Boltzmann rejected Bartoli's opposition to the entropy law, and he used his description of the pressure of light to derive Stefan's law. The first measurements of the pressure of light only succeeded in the labs of professor Lebedev in Moscow in 1899, and he reported on his success at the International Congress in Paris in August of the following year, as the part of Parisian Exposition Universelle. Three years later, the pressure of light was measured by Gordon Ferrie Hull (1870 Garnet in Canada-1956) and Ernest Fox Nichols (1869 Leavenworth in Kansas-1924) in the Wilder lab of Darthmouth College in US, and more precisely by the German Gerlach and co-workers at the University of Frankfurt in 1923.

20.6 Radiometers in Slovenia

20.6.1 Šantel's Experiments in Gorizia

The grammar school professor, Anton Šantel, described the device for converting the solar heat in mechanical energy as the "solar engine". According to Šantel, the idea was "published in several professional journals in 1874". Šantel used three solid glass tubes with an inner diameter of 1 mm and a length of 4 cm. He fixed them on the rotating cylinder so that he arranged the angles of 60 between them. He filled them up to half with ether and then he exhausted them, sealed and additionally fastened tubes with a wrapper made of muslin fabric. According to Šantel's opinion, "there remained no air except for the vapors of ether" in the glassy tubes. The device was covered with a black layer and he exposed its lower half to the sunlight. Due to temperature differences, the remaining ether in the lower part evaporated more, so that the tubes rotated. Such "solar engine" could propel the clock for several months, as it spun 3-4 times per minute. It rotated faster in cold than in a warm environment. At the end, Šantel estimated the pressure that propelled the vanes.[2634]

20.6.2 Radiometers in Cabinets for Physics in Slovenian Areas

Radiometers were very popular since firm Leybold The radiometers were very popular since firm Leybold from Cologne put them on sale; Leybold later became a leading vacuum technology manufacturer. At the end of the 19th century, radiometers were acquired at numerous secondary schools at the Slovene ethnic territory. Already in 1880, the collaborator of Eugen Netoliczka (1829-1889) former Krakow professor Adalbert Wachlowski described a radiometer in gymnasium reports in Chernovtsy in today's Ukraine, which were read throughout the monarchy. The radiometers were purchased in cabinets of physics, but due to their fragility, only few were preserved until today, among them in Kočevje grammar school. The Ljubljana grammar school students learned about the functioning of the radiometer in their textbook about physics in a special chapter on the spread of heat by radiation.[2635]

Radiometer remained interesting for the demonstration in grammar school physics in the next century. Docent Inwinkl, curator of the cabinet of physics of the gymnasium in Koper, decided to buy ~~a~~ Crookes' radiometer in the school year 1906/1907.[2636] The radiometers were sold to schools between the two world wars. Five German marks was a price of the ordinary Crookes' radiometer, while a more complicated version with two opposite black flaps on the same vertical axis was valued 12 marks.

20.7 Conclusion

Crookes and Gimingham improved both the pump and the pressure gauge during their efforts focused on absolute vacuum. On the one hand, they were interested in radiometric, viscous and electrical phenomena related to the theory of matter, and on the other hand, they tried to measure the pressure with these phenomena. With chemical methods they reached a pressure of 5.10^{-5} mbar, and with the use of seven mercury drop pipes, they've got even $2.6.10^{-5}$ mbar in 1884. That remained the record for a decade.[2637]

The radiometer was the first-class discovery in the 1870s. Later, it turned out that it is not rotating due to radiation pressure, but due to temperature differences. Nevertheless, it remains an interesting physical instrument today.

IV. Arias: Vacuum for Advanced Industries, Sciences & Entertainments

21 Maintaining the Vacuums: Insulations

21.1 Thermos Flask: the Discovery and Development of Vacuum Insulation

In 1873 Dewar described his vacuum insulation. Twenty years later, the storage of liquid air in Dewar's flasks became the first-class event in science. Today, we use the Dewar's flask renamed to thermos even in the household. First, let us look at the study of the heat transfer through gases and vacuum, and then we'll follow Dewar's path to discovery.

The first experiments with translation of a vacuum were carried out by Guericke around 1654,[2638] followed by Boyle and Hooke in 1658. Guericke learned that clocks and musical instruments cannot be heard through a vacuum, while light goes through it. Less convincing were the early experiments with the transfer of heat and electricity.

21.1.1 Exploration of Heat Transfer through a Vacuum in England of the 19th Century

In 1785, Morgan announced that vacuum does not translate electricity. Therefore, in 1822, Davy felt that he had a total vacuum available. In February 1838, more careful Faraday did not specify precise measurements in terms of translation of electricity in a vacuum.[2639]

In 1819, the The Scotsman Leslie separated three ways of heat transfer: radiation, mixing and translation. Before Stefan's experiments, it was not possible to measure heat transfer in gases efficiently, especially not in the vacuum. Therefore, the conductivity of the vacuum was adjusted for thermal phenomena depending on whether they considered heat for a phenomenon like sound or for something resembling light.

Rumford had the sound for phenomenon having the same characteristics as the emitted heat.[2640] The connection between acoustics and heat was preserved in textbooks until the second half of the 19th century because acoustics was coupled with optics in the treatment of waves. The heat and light were connected after the discovery of the "invisible thermometric spectrum" today named infrared, published by Herschel on 24. 4. 1800. According to Maxwell's (1873) theory of electromagnetic waves, "extracted-radiated heat" has a longer wavelength than visible light.

21.1.2 Heat Transfer through Gases in Europe of 19th Century: Stefan's Diathermometer

Qualitative findings on thermal conductivity of hydrogen were first published by Magnus at the Academy in Berlin in 1860 and 1861. However, he still could not measure the thermal conductivity before the habilitation thesis of Friedrich Narr (* 1844 Würzburg; † 1893), defended in Munich in 1870. The first useful results were published by Stefan[2641] using his diathermometer measurements. The diathermometer was like a thermocouple of copper or brass sheet, in which the inner vessel is an air thermometer, while the gas in the narrow gap between the containers is a gauge (Figure 21-1). Stefan used a wall of glass, iron or zinc; sometimes one wall made of zinc, the other one made from iron. The diameter of the cylindrical container was 6-7 cm, in other experiments 32 cm. The distance between the containers was from 2.3 to 5.1 mm. In the last (eighth) Stefan's experiment, the pressure of the intermediate air was reduced to 0.56 bar to prove Maxwell's prediction that the thermal conductivity of air is independent of the pressure.

[2638] Guericke, 1986, 45–48.
[2639] Faraday, 1952, 513–514.
[2640] Heilbron, 1993, 121.
[2641] Stefan, 1872, 323–363; Rosenberger, 1890, 672.

In 1875, Winkelmann from Aachen proved the validity of Maxwell's theory down to a pressure of 1 mm Hg. He measured with brass diathermometer of Stefan, in which the distance between the walls is reduced from 1.5 to 2 mm. He recommended observing in a completely glassy container and proved that the vacuum does not translate heat. The results like those were published simultaneously by Kundt and Warburg for diluted gases put between the double walls of the vessel.[2642]

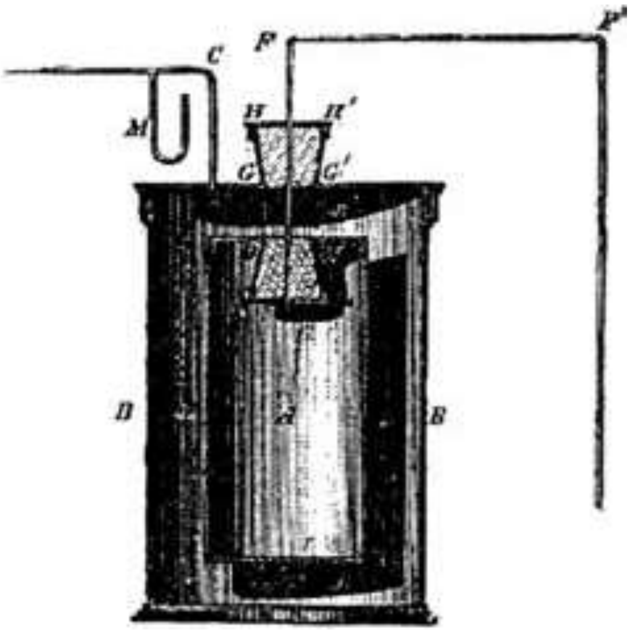

Figure 21-1: Stefan's diathermometer[2643]

Stefan and his assistant Plank continued with the measurements of thermal conductivity between June 1875 and July 1876 while their work was supported by Boltzmann. On February 2, 1872, in a letter to Stefan from Helmholtz's Laboratory in Berlin, Boltzmann described his "curious expectation" of Stefan's first publication of thermometer measurements. According to Stefan's order, he reaffirmed the correctness of Maxwell's (1867) calculations in contrast to other Clausius' (1862) results. However, soon after Stefan's announcement in 1872, Boltzmann discovered and corrected a calculation error in Maxwell's theory and pointed out that there was no matching of the new results with Stefan's measurements.[2644]

Diathermometer was the first usable device for measuring the thermal conductivity of diluted gases. Stefan designed that tool in the first half of the 1870s, and at the same time, Dewar developed a similar device as the ancestor of a modern thermos. While Stefan measured the properties of gas placed in a thin gap between two concentric cylindric vessels, Dewar investigated the substance in the inner vessel. Stefan did not describe his vacuum pump (air extraction device) in 1872; he advised the smoothing and covering of the surface of the vessel to reduce radiation, as Dewar did in his lecture in front of RI during the days of Stefan's death in January 1893.

21.2 Dewar's Invention of Thermos Flask

Dewar was interested in insulations in his early ages when he proposed the use of newspapers to insulate the shoes from the wet Londoner ambient. In the early 1870s Dewar, a lecturer at the Royal Veterinary College in Edinburgh, measured the specific heat of "hydrogenium", the alleged "alloy" of hydrogen and palladium (Figure 21-2).[2645] In a high-temperature calorimeter, he examined the assumption of Graham and Faraday (1852) about the metallic properties of hydrogen, which was opposed by Dewar's former professor Olding in 1861, while it was advocated by Reitlinger in Vienna.

Figure 21-2: James Dewar (* 1842; † 1923)

The designers of calorimeters used double walls to reduce heat transfer already before Dewar. Dewar has exhausted the space between the walls to further diminish the environmental impact. In September 1872 he published a note on the specific

[2642] Winkelmann, 1875, 502, 504, 506, 514; Kundt, 1875, 363–365.
[2643] Winkelmann, 1875.
[2644] Höflechner, 1994, 2: 12, 17; Boltzmann, 1909, 368; Plank, 1876, 215.

[2645] Soulen, 1996, 33.

heat of hydrogen and reported on his measurements with a "specially constructed calorimeter". The following year he published the results of measurements of the physical constants and properties of hydrogen that rejected Graham's assumption of "hydrogenium" by indicating that it was hydrogen absorbed in palladium. Dewar used a calorimeter (A) with a capacity of 0.1 liters placed in the middle of a thick "fully exhausted" brass envelopes. He put the device in a large closed cylindrical container made of tin (E), which was covered by water from the city supply. Unlike Stefan, Dewar did not measure the properties of the gas between the containers, but the substance in the inner vessel. Dewar published a sketch and description of his flask in 1873, and Stefan did the same only two years later (Figure 21-3).

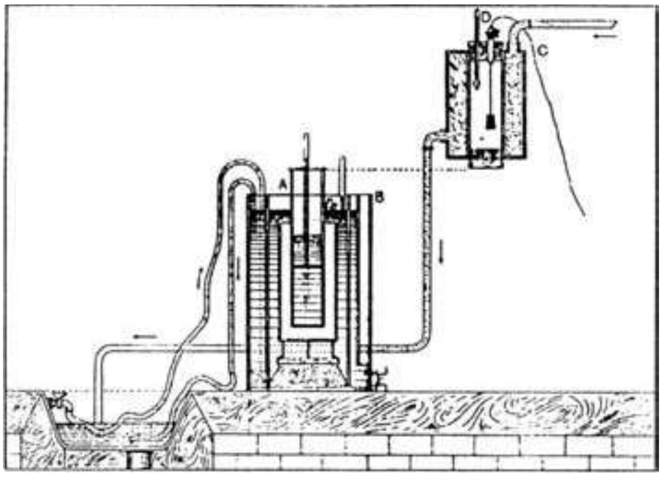

Figure 21-3: The first thermos flask from 1873[2646]

According to its form Dewar's flask did not differ much from the contemporaneous Stefan' invention. The thickness of the space between the containers was 4 to 5 mm in Dewar's design in 1898, which is approximately the same as Stefan used in 1872 and smaller than in Winkelmann's tool in 1875 (Figure 21-4).[2647]

Stefan did not use a diathermometer for the vacuum insulation. He did not lead the fundamental research of the vacuum in Vienna, which he left to Reitlinger and later to Puluj in von Lang's laboratory. Natterer's liquefactions of gases were not continued by researchers of Stefan's school, since the leading Habsburgian researchers of condensation of gases Olszewski and Wroblewski from the Habsburgian University of Krakow studied in Heidelberg, Kiev and Berlin.

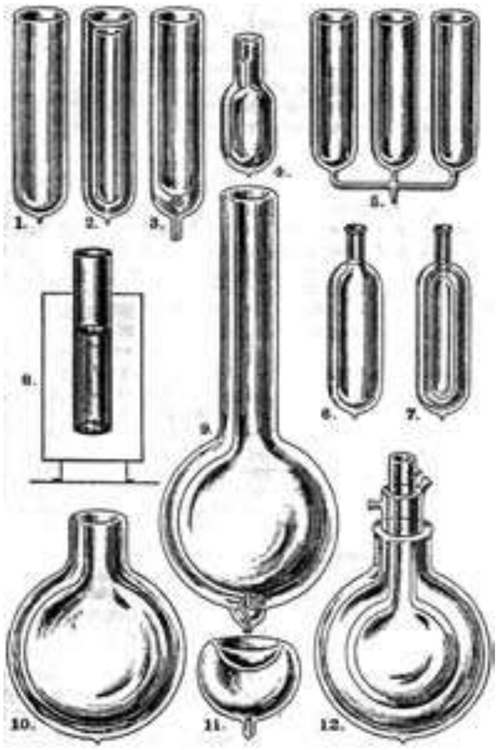

Figure 21-4: Dewar's collection of thermos flasks[2648]

21.3 Dewar in the Liquefaction Competition

At the beginning of the 1890s Dewar replaced the walls from brass with glass to better observe the events in his flasks. The use of metallic walls has been hampered by its higher thermal conductivity, difficulties in polishing the reflecting surface, leaks and gases absorbed in metals and in charcoal. Later, in 1906, he studied liquid air and oxygen at high pressures, which only metallic thermoses withstood.[2649]

In December 1877, Cailletet liquefied oxygen and nitrogen.[2650] He put calcium chloride between the walls of the cryostat to dry out water vapor which would otherwise condense on the walls of the inner vessel. Despite of their subsequent claims, e.g. on their joint receiving of the Davy medal at Prize Royal Society in London on 30 November 1878, Cailletet and Pictet failed to efficiently produce

[2646] Dewar, 1927, 66.
[2647] Reitlinger, 1861, 17; Dewar, 1927, 694, 782, 63, 66, 653.
[2648] Dewar, 1927, 127.
[2649] Soulen, 1996, 34; Dewar, 1927, 1258–1259, 743, 951.
[2650] They liquified gases with Joule-Thomson's expansion which Tobias Gruber also researched.

enough liquefied oxygen and nitrogen for scientific research because they worked without effective vacuum insulation.

On 27 May 1886, Dewar demonstrated to the President of the RS Stokes and others an experiment designed to solidify oxygen (Figure 21-5). On July 16, 1886, a sketch of Dewar's device was published. In the same year, he projected his device to the screen with the aid of an electric lamp

Figure 21-5: Dewar’s tool for solidifying of oxygen manufactured in 1886[2651]

and a lens in front of the audience in the RS. The condensation and solidification were carried out in separate vessels insulated by vacuum. Crookes radiometer and, basically, Bottomley’s experiments, testified to the greatest importance of the role of gas particles in the passage of heat. These studies were more directly influenced by Dewar's experiments at RI at the end of 1892 than Stefan's research. On 20 January 1893, during a lecture in front of RI, Dewar’s vacuum vessel was exhausted with a mercury air pump to a pressure of 10 mm Hg. The vessel was heated to 200°C and then the air was forced out with mercury vapors. After cooling, mercury vapors on the walls of the vessel were hardened into a mirror that prevented radiation. Thus, he did not need to silver plate his walls. The prepared vacuum vessel was filled with liquid ethylene, oxygen or air alternately. He measured the volume of gas that has passed through the tube to another container where it was liquefied. The volume of such distilled liquid was in proportion to the heat supplied to the vacuum vessel, which was kept at constant temperature by water. Since the surface of the liquid dropped during the distillation, it was measured only until a quarter of the initial volume was evaporated. Dewar first showed the liquid oxygen that was "calm as water" in the vacuum vessel. Then he released the air between the double walls so that liquid oxygen began to boil. Vacuum insulation reduced the heat transfer by five times.

Table 21-1: Dewar’s evaporation rate measurements

Substance	Evaporation rate (cm^3/min)
liquid oxygen in a sphere surrounded by vacuum	170
liquid oxygen in a sphere surrounded by air	840
liquid ethylene in a sphere surrounded by vacuum	56
liquid ethylene in a sphere surrounded by air	250

Dewar made thermoses of various shapes in which the ice was not collected on the surface of the outer container, even if the vacuum insulation was only 1/2 inch thick. Liquid oxygen or air evaporated only from the surface and no bubbles appeared. Dewar showed a vacuum vessel with silvered walls that reduced the heat transfer "for more than half. In such containers, liquid oxygen or liquid air can be stored for a long time, so that economy and ease of handling are greatly improved". In 1896, he calculated that vacuum insulation with silver plated inner walls reduce the heat transfer by thirty times, while the dry-air insulation reduces the heat

[2651] Dewar, 1927, 277.

transfer by only by 35%. Nevertheless, the American Charles Eastman Tripler, the Swede Ostergren and Swiss Burger in New York in the winter of 1896/97, developed the principle of self-insulation instead of Dewar’s flask. For their insulation they used gas which lost all its moisture during freezing of the air.

21.4 Heat Transfer through Vacuum Insulation at Liquid Air Temperatures

In 1893, Dewar released the preparation results of his evaporation rate measurements from a liquid oxygen vacuum vessel boiling at -180 ° C.

Table 21-2: Dewar measures the rate of evaporation of liquid oxygen.

Temperature of a Liquid Oxygen(°C)	Evaporation rate (cm^3/min)
–115	60
–78	120
+6	300
+65	600

The evaporation rate was proportional to the evaporation energy flow. Dewar described the results obtained as "radiation (together with the remaining heat transfer by convection), which increases approximately with the third exponent of absolute temperature. There will be many further experiments before the law of radiation at low temperatures can be precisely defined."[2652] Dewar’s claim was not in accordance with Stefan's law which indicated that the communication between both teams was not the best as Stefan published most of his results in Viennese academic journals.

In 1898, Dewar continued his research of the heat transfer at the temperatures of the liquid air. He measured the time needed to distill equal amounts of liquid air from the three interconnected vessels, insofar as the same shapes and sizes have been used. The insulation of two flasks was filled with different powders, while he left the third insulation of the flask empty for comparison. He found that the additions of charcoal at low temperatures in the air increase the thermal conductivity, while in the vacuum they reduce the thermal conductivity. The results of the measurements were also influenced by the silvering of the walls of the flask. The experiments were not precise enough to distinguish between three types of heat transfers. He showed, however, that "we can use liquid air to study many important problems of heat transfer". Dewar has ranked low-temperature radiation among the most important fields of his research of the properties of a low-temperature substance besides the storage and handling of liquid gases in vacuum vessels. Already in 1872 and 1873 he tried to determine the temperature of the Sun; he certainly knew the first useful Stefan’s calculation of solar temperature published in 1879. In the first five years after that publication of the year 1879, Stefan's law was supported mainly by physicists who published in German language, while the Brits joined them much later. Dewar used Dulong and Petit's radiation studies in 1873, and he supported their finding that vacuum obstructs convection. In 1874 and 1875, Dewar published together with Tait from the University of Edinburgh. In 1884 Tait had not yet mentioned Stefan's radiation law and preferred defending the outdated Dulong-Petit's law. Dewar used Stefan's law to compare it with his measurements only in the years 1920 and 1921.[2653]

21.5 Disputes about the Priority in the Discovery of Thermos

In 1893, Dewar presented his audience in RI In 1893, Dewar presented to his audience in RI almost a finished invention of his flask, where the basic problem was only the pumping out of a sufficiently good vacuum. Only the discovery of superinsulation was "missing" as it was the only important improvement of the vacuum vessel, which Dewar did not discover himself.[2654]

In 1904, Dewar declared the vacuum as the best insulator of electricity. He thoroughly rejected doubts about his priority, which appeared after the description of his container in the German press in 1894 and 1896. In 1897, Frenchman d'Arsonval announced that he described Dewar’s flask for his biological research already on 11. 2. 1888. The German Weinhold tried to make himself a pioneer

[2654] Soulen, 1996, 34.

after he promoted some hypnotic Mesmerism on collaboration with Zöllner in 1879-1880. On 15 September 1898, he claimed to describe the same flask in his high school textbook as early as 1881. No one before Dewar used a thermos for the preservation of liquid oxygen, and Dewar's paper was much older than the others in 1873.

On December 12, 1896, Dewar reported in the newspaper Times on German Linde, who patented his device for liquefaction of air in Germany on June 5, 1895. He did not mention the simultaneous independent work of William Hampson (1854-1926 London) patented in England on May 23, 1895. Dewar criticized the professor Tilden of the Royal College of Science, who attributed the invention of Dewar's vacuum flask to Cailletet, like E. Solvay did in his lecture at the Parisian Academy in 1895.[2655]

After several months of experiments, Dewar built a larger tool in which he could condense 20 cubic centimeters of hydrogen in five minutes on May 10, 1898. Hampson protested with a letter published in Nature magazine. At the end of 1894, he supposedly described his device to Dewar's assistant serving in December 1881-1908, Robert Nicol Lennox (* 1861 Killin on Loch Tay in Perthshire in Scotland), which Dewar used without even quoting Hampson. Prior to 4 August 1898, Nature published four Hampson's letters and Dewar's answers to them. Faraday and Dewar did not patent their discoveries, which was not very strange in Londoner academic circles. On the other hand, Kelvin patented many of his discoveries designed in the University of Glasgow, and Dewar collaborated with him on several occasions. Together they worked in the commission, which discussed, inter alia, the determination of the temperature of the Sun in 1873. Thirty years later Dewar wrote to Kelvin about his experiments on radioactivity on August 26, 1903. After World War I, Dewar abandoned the study of low temperatures and devoted himself to the research of capillary surface tension of soap bubbles. Dewar remained an active researcher even when he was eighty years old, with only Crookes still around among his peers.[2656]

21.6 Thermos Flask in Germany and the USA until the Middle of 20th Century

Before WW1 the otherwise unknown glassblower Muller from Coburn used Dewar's silver-plated vacuum milk container to be able to give his child a warm milk in the morning. Muller's and his baby whereabouts were never described in details, but after their successes the thermos flask quickly came into commercial use, first in Germany, then elsewhere.[2657] The German users of vacuum flasks did not even know they had the invention of Dewar in their hands. The English glassworks were not skillful enough, so, Dewar had to order the production of containers in Germany before 1898.[2658]

In 1898, the German chemist Walter Matthias Hempel (1851-1916 Dresden) announced that the coating of fluff was a better thermal insulator than a vacuum. Similarly, the role of wool fibers in the prevention of air movement was already determined by Stefan and after him by Boltzmann in his discourse on the erection of Stefan's commemorative plaque at the University of Vienna on 8 December 1895. In 1904, Siegfried Valentiner of Halle and A. Bestelmeyer of Göttingen measured internal friction, density and the ratio of specific heat of nitrogen at the temperatures of the liquid air at the Röntgen Physics Institute in Munich. The vacuum insulated vessel which they used was named after Dewar and Weinhold in their discussion. Just before World War I, Dewar explored the cooling of boiling water in his flask, which he had already named "thermos".[2659]

In the years before the Second World War, German companies produced Dewar's flasks with the capacities over 1 liter. They offered cylindrical and round containers with silver plated, coated or ordinary glass walls, also equipped with a support for transport. In the vacuum insulation of metal thermoses, they put charcoal getters. The thermos flasks were used primarily for the transport of liquid air.

21.7 Contemporary Followers of Dewar's Work

Dewar's low temperature research was also described very early in the Slovene popular science journal: "On 19th of December 1896, Dewar explained to the 'Chemical Society' how he condensed air in the emptied round container with strong pressure and heavy frost. He obtained half a liter of frozen air and kept it for an entire half hour in this state. From the beginning, the solid matter is somehow an uneven transparent brawn, a mixture of hard nitrogen and liquified oxygen."[2660]

Dewar's idea was soon used on flat glass structures, which provide excellent transparent vacuum thermal insulation. In 1913, the engineer Alfred Zöller (Zoeller) from Charlottenburg in Berlin patented a hollow glass pane of various shapes, including corrugated glass plates containing separate discharged volumes.[2661] Two years later Zöller patented his electric bulb in Germany and also in the USA after application tiled November 10, 1916.

Zöller's vacuum flat insulation is being developed at the Department of Surface Technology and Optoelectronics of the IJS (until 2003 ITPO) to replace low-cost, but ecologically controversial organic foams. Their uses in insulating houses provide greatest results although the vacuum insulation needs to be occasionally repumped.

22 Maintaining the Vacuums: Bulbs and Stefan's Radiations

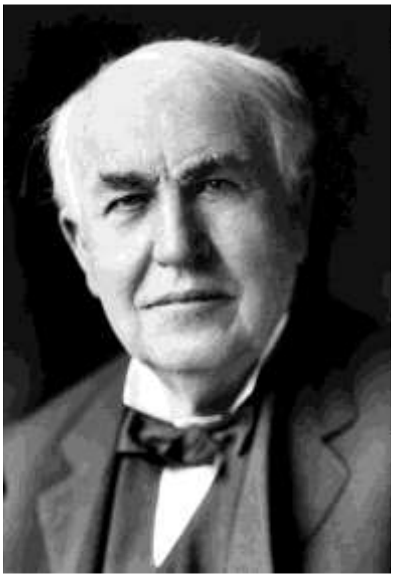
With his uses of a light bulb in Edison's Laboratory in Menlo Park, Edison additionally achieved his fame in sciences, backed by his own journal of the same name. W. Thomson described his success with the words: "... no one else is Edison."[2662] Of course, Edison's work was only a crown of work of numerous researchers during many years.

22.1 The First Light Bulbs

In November 1802, Petrov built a battery with 2100 Cu-Zn elements and a voltage of about 1700 V in St. Petersburg to produce the first stable arc discharge with charcoal. However, next year, his discovery was described only in Russian language. Davy independently came to similar discoveries. In 1802 he noticed that charcoal between the electrodes quickly burns and cannot be glowed in the air like platinum. In 1808 before RI, with a large battery with 2000 pairs Cu-Zn he showed the operation of the arcs and bulbs, which was not developed for practical use. Later in 1853, his former student, Faraday, demonstrated the arc discharge at the Christmas lectures in front of the RI.[2663]

Until the 1860s no cheap sources of electricity were developed. Nevertheless, bulbs have been patented in many countries, but most inventors preferred arcs. The basic problem was finding a material that did not burn too quickly and there was a puzzle in regulating a fixed distance between the electrodes in the arc. In 1838, in Brussels, Jean-Baptiste-Ambroise-Marcellin Jobard (17 May 1792 Baissey in France– 27 October 1861 Brussels) described a carbon bulb in a vacuum, which was later compiled by his student the engineer Charles de Changy (* 1817 Saint-Avertin in France). Next year Jobard became a pioneer of photography in Brussels. As a child of his times, Jobard was involved in spiritism. However, he had to discontinue the research when the Parisian Academy refused his support, although Jobard became the director of Musée royal de l'industrie in Brussels in 1841. In the same year of 1841, the Irish politician Frederick de Moleyns patented Jobard's idea as the production of electricity and its application for illumination and motion. The patent did not bring much luck to Moleyns as he was imprisoned for forgery.

The young self-taught genius **Thomas Alva Edison** created his reputation in the US with the rapid transmission of telegraphic and newspaper information during the secessionist war. He exploited the economic boom after the war and with the support of the New Yorker magnates and the press, set up the first industrial research laboratory in Menlo Park, New Jersey, 40 km southwest of New York in the winter of 1875-1876. Among other things, he continued to research telegraphy, supplemented Bell's phone and set up a phonograph later renamed to gramophone. Above all, he created the light bulb industry, which he triumphally victoriously resettled him to New York as the leading inventor and businessman after five years of continuing research at Menlo Park. Tesla tried to do the same in Colorado Springs but did not master enough funding to stay there long enough.



Thomas Alva Edison (* 1847; † 1931)

In 1840, Grove burned platinum in air and other gases, even for use in mines. Both types of lamp, filled by platinum or carbon, were patented by American Starr, who traveled throughout England and France with his business associates the local Cincinnati daguerreotypist John Milton Sanders and latter USA Union Army colonel Edward

[2662] Friedel, Israel, Finn, 1986, 198.
[2663] Petrov, 1803; Bowers, 1998, 64, 67.

Augustin King to propagate his discoveries of incandescent lamp and generator patented in USA in 1844. His incandescent light bulb in a vacuum over the mercury column blackened too quickly despite of renewable carbon strip, but his description in the book Repertory of patent inventions influenced Swan's research. In the revolutionary year of 1848, the German emigrant Heinrich Goebel (Henry Göbel, * 1818 Springe of Lower Saxony in Germany; † 1893 New York) left for the United States where he used a galvanic battery to glow a platinum wire in a vacuum above the mercury barometer in the year 1858. By lighting the window of his watch shop in New York, he attracted customers; for his novelty he received 15 patents in 1882s, and he also studied the electric arc lightings. In 1882 he patented improvement of the Geissler's system of vacuum pumps and he solved a puzzle of connecting carbon-filaments and metal-wires in a light bulb. Starr and Goebel's merits were used against Edison's bulb patents, but Edison proved to be too strong for those challenges at the courts and in media. Unfortunately, Goebel's invention was soon forgotten until he became a Nazi legend promoted as the inventor of an electric bulb in 1938.[2664] The Nazi minister of propaganda Joseph Goebbels probably loved Goebel because of their similar family names.

In 1872, Lodigin described a carbon-filament vacuum bulb between brass electrodes. The following year, the streets of Petersburg were lightened. He put in some other fillers in his bulb, replacing them after they burned for about half an hour. In November 1874 he received the Lomonosov Prize of the Academy of Sciences, but next year, due to financial difficulties, he continued his research abroad. In January and February 1876, three Lodigin's lamps illuminated the Petersburg stores, and dozens were bought by the Parisian Workshop of pioneering photographer Jules DuBoscq (1817-1886). In the summer of 1873, Edison purchased DuBoscq's electric arc lightings lamps for his laboratory in Newark,[2665] but did not express much interests for his Russian competitors. In September 1874, the Petersburg bankers and electricians established the society «Товарищество электрического освещения Лодыгин и К°» to sell and patent Lodigin's invention of electric lightings on initiative of Petersburg banker Степан Александрович Козлов (Kosloff). Козлов's former collaborator now a Warsaw resident Станислав Викентьевич Кон (Kon, Konn, † 1876) soon joined them and demonstrated the abilities of Lodigin's bulbs in Germany and France until his premature death. The descendant of generations of highest Russian navy officers, the head of electricity department of Admiralty (начальник электрической части Адмиралтейства) lieutenant Bouliguine (Николай Павлович Булыгин, * 1847 Petersburg; † 1912 Crimea) joined them with his official capacities and inventions. But all of them were no match for Edison.

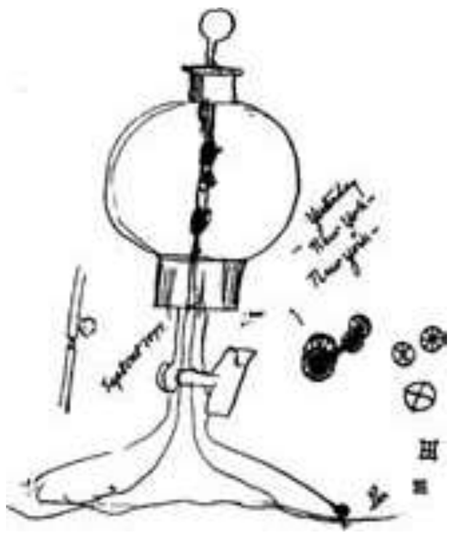


Figure 22-1: Edison's light bulb in September 1877, as he memorized and painted it a year later[2666]

22.1.1 Edison's Bulbs

Since the autumn of 1874, Edison ordered Crookes' Chemical News for his laboratory, so they also monitored the progress of vacuum technology.[2667] At the end of January and early February 1877 Edison began his research of bulbs and continued to explore electric arc lightings and bulbs between September 1877 and January 1878 (Figure 22-1). In the lab, he had a Gassiot's cathode ray tube since 1875. In the middle of September 1877 Edison ordered Charles Batchelor to insert a piece of charcoal into it. Since it was

[2665] Edison, 1991, 45.
[2666] Edison, 1994, 546.
[2667] Israel, 1998, 93, 102.

difficult to get small enough pieces of charcoal, they used preloaded paper, which was also usedfor their parallel surveys of the phone. When the cathode ray tube was sealed again, it was exhausted by a conventional air pump purchased in March 1875. The resulting vacuum was poor, so that the charred charcoal was burning almost as fast as in the air. That's why they prefer the glowing silicon and boron. The lamps were connected in series and at the same times in parallel, which later led to a successful lighting system.[2668]

Henry Draper provided the first photography of the solar spectrum. His father, J. W. Draper, studied at the University of London, then emigrated to the United States and became famous for his research of the luminescence in New York. In 1878, Edison was heavily exhausted after intensive research of telegraphy. For this reason, he accepted the invitation of leading American scientists the physicist Barker and astronomer Draper. They asked him to provide them with a tasimeter[2669] to observe the total solar eclipse in western United States. The journey took place from July 13, 1878 to August 26, 1878. They spotted the British Wallace's laboratory in Ansonia, Connecticut. William Wallace, together with Moses Gerrish Farmer (1820-1893), designed the dynamo that he had been producing since 1875. During Edison's visit, Wallace dealt with the construction of a powerful electric generator "Telemachon" and a system of arc-shaped lighting with carbon plates.[2670]

Just a few days after returning to Menlo Park, Edison knew that he could provide a major improvement in electrical lighting. He also intended to use his experience in distributing telegraph pulses to provide the powered electrical lighting for individual users. The current electric lamps were only useful for strong public lights, while for the individual users, gas lighting was still dominant. Edison planned to adapt gas lighting edifices to his new electrical light bulbs[2671] by changing the fuel while keeping the same old designs like the first automobiles resembling carriages pulled by horses or the modern web books. Following the ambitious statements for the New York Tribune on September 28, 1878, Edison's reputation attracted the magnates from Wall Street to the creation of the Edison Electric Light Company (EELC) on October 17, 1878.[2672]

The self-taught Edison was well-known in scientific circles, but he refused to hire academically trained scientists for a long time. Only under the pressure of J. Pierpont Morgan and other EELC directors he was required to recruit American physicist Francis Robbins Upton (1852 Peabody-1921 Orange New Jersey) in November 1878. Upton finished Bowdoin College in Maine, graduated from Princeton with the very first Ph.D. promoted there, and then advanced his specialization in John Hopkins University and in Helmholtz's labs in Berlin. As a mathematical-technical consultant, Upton, collected literature and patents about the electrical lamps for Edison during his first year, until he devoted himself to experiments and later to managing the production of light bulbs.[2673] Upton mathematicised Edison's ideas as Maxwell mathematicised Faraday's insights in the same time.

Draper also supported Edison in the American Association for the Advancement of Science (AAAS) and in the more elite NAS along with Rowland. When he later took over the AAAS presidency in 1883, Rowland changed his mind in defense of the academic exclusivity. Edison was just not one of his own. In a famous call for pure science, in contrast to most American (Barker) and British (W. Thomson, Crookes) researchers, Rowland said that Edison's research of an electric bulb is not science, just like the new cooking recipes are not chemistry.

Barker met Edison in 1874 at an exhibition at Franklin Institute. On 3. 11. 1874 he invited him in writing to present his inventions to the NAS. As Assistant Editor of Am. J. Phys. and the Chairman of AAAS he addressed Edison and Upton to prepare their own papers for the AAAS meeting in Saint Louis in 1878 and in Saratoga Springs in 1879.

Until 1884, when he focused primarily on marketing, Edison first founded the Telegraph Journal, and then the Science magazine on 3. 6. 1880. For one and a half years he financially supported the Science magazine. The Science devoted two pages and a half to electricity research, and specifically reported on the work of Edison's Laboratory. Thus, in the first volume, Upton's report on the pilot railway at Menlo Park was published. After Edison, the support of Science magazine was taken over by the inventor of the phone, Alexander Graham Bell.[2674] In the 1880s, Edison supported electrical engineering courses in schools with thousands of dollars.

22.1.2 Vacuum Bulbs

During their first months of exploration of lamps in Menlo Park, Edison and his boys primarily searched for suitable radiant materials. Instead of tungsten, charcoal and iridium which Farmer praised in New York on October 7, 1878, they selected platinum. Moses Gerrish Farmer never profited much from his discoveries because of his spiritualist religious reasons resembling Crookes, but Edison did not have such limits. Platinum was expensive, and the electrical current had to be regulated through it by means of relatively complicated return loops, to prevent its heating above 1769°C. The platinum hardly oxidized, and Edison initially avoided the use of a vacuum around his platinum filaments, of course not because of Aristotle's fear of empty.

Edison's laboratory boys used a microscope to study the bubbles and leaks on the materials, which was a novelty in industrial research. By weighing they found that platinum became lighter after heating. Edison assumed that gases in the pores of platinum leave metal and cause damage after heating (Figure 22-2). On February 2, 1879 Upton led the experiment and assumed that hydrogen was mainly adsorbed in platinum. The undesired gases were evaporated by preheating the platinum in vacuo and re-pumping before the bulb was sealed. Therefore, in January 1879, they began to explore in a high vacuum, which they could no longer avoid. Unlike his predecessors, Edison used better technology, especially Sprengel's mercury pump.[2675]

On January 1, 1879, Edison telegraphed in vain to his friend Barker at the University of Philadelphia and the first president of Stevens Institute of technology in Hoboken in Jew Jersey Henry Morton (1836 New York –1902 New York).

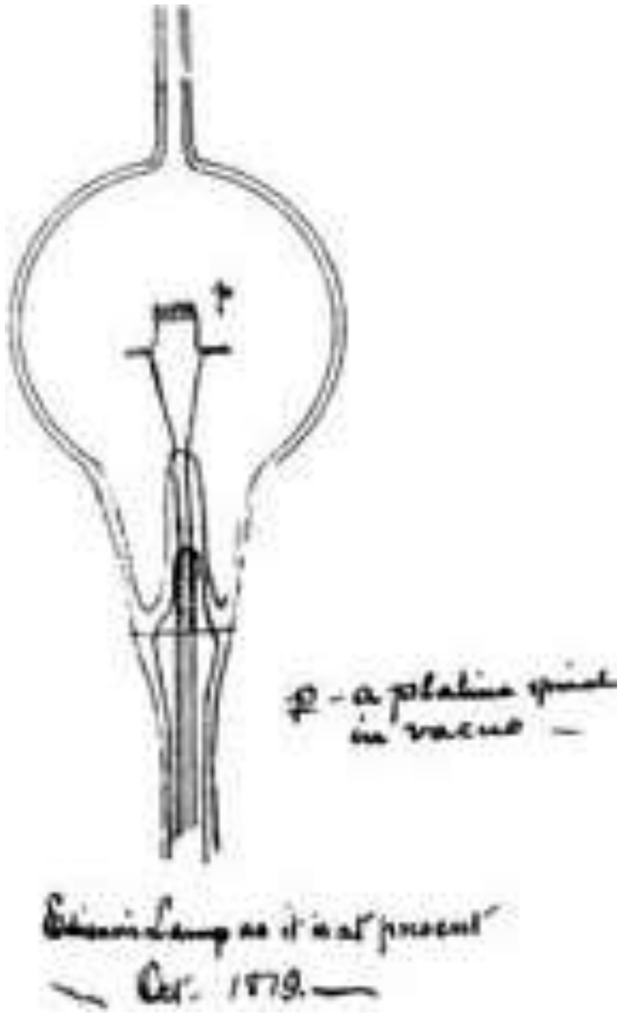

Figure 22-2: A platinum-filamented lamp that did not work well in October 1879.[2676]

Edison asked them to send him Sprengel's pump. Therefore, Edison initially pumped with a mechanical pump, in which the vapor pressure of the seal oil used was even surpassed the residual pressure of vapours of mercury.[2677] Edison's highly capable mechanic Krüsi was unfortunately unable to compile Sprengel’s pumps. On 26 March 1879, Edison received a Geissler’s pump by Albert Reinmann and Williams Baetz from New Yorker glassblowing firm Reinmann & Baetz, and at the same time, Edison got another one from former Upton’s professor Cyrus Fogg Brackett (1833 Parsonfield, Maine-1915) of Princeton, but that one was corrupted although Brackett was famous

2677 Edison, 1991, 375; Hablanian, 1984, 19.

for his manufacturing skills. The master glassblower William Baetz of Albert Reinmann & Baetz firm from New York also helped and arrived several times in a few months to help installing his device in Menlo Park. But he did not want to work with Edison, who, in 1878, hired Boehm, a glassblower formerly working at Geissler's manufacture in Bonn.

Johann Heinrich Krüsi was born in Heiden, Appenzell in Switzerland. He worked as a mechanic in Zurich and Paris. In 1870 he worked on Singer's sewing machines in New Jersey and moved to Edison's firm in 1871 or 1872. His name was cordially Americanized to John Krusi (Cruz). In 1882 he was responsible for production at Edison's first central station in New York.[2678]

In 1878 in the Annales de Chemie et de Physique William de la Rue and Hugo W. Muller published a paper about the combination of the Geissler pump with Sprengel's pump and described McLeod's vacuum measuring instrument. Geissler's pump was faster, while Sprengel's pump gave a better vacuum. In mid-August 1879 Boehm's pumps reached a tenth of Pa and were probably the best in the world. In a little more than a year Boehm produced for Edison more than a fifth of the total exceeding five hundred pumps for the Menlo Park bulb factory (Figure 2-3). The Sprengel-Geissler pump design of Edison's laboratory was used until 1896. Unfortunately, Boehm and Tesla were among the few arrivals who could not adapt to the atmosphere at Menlo Park and Boehm left Edison in October 1879.[2679] Boehm worked for Edison's competitor Maxim, returned to Europe and came back to the USA to establish his own firm. On 12 April 1880 the chemist Dr. Otto A. Moses made for Edison a vacuum pump with a closed bottom and apertures on the side to reduce the mercury pressure to the bottom. Without warming, it could get a good vacuum in five hours, which was very time-consuming part of pumping bulbs process.[2680]

[2678] Edison, 1991, 633–634.
[2679] Israel, 1998, 180–181, 193.
[2680] Friedel, Israel, Finn, 1986, 61, 62, 159, 163, 251; Hablanian, 1984, 19.

Edison published experiments in a vacuum under his own name, which was one of the reasons for the later Upton's anger. A spiral filament of platinum of 0.005 inch of diameter and a mass of 266 mg lost 8 mg after an hour and half of glowing in hydrogen fires, while the second spiral filament of platinum of 343 g lost 42 mg after 9 hours of flaming. After 20 minutes, a thin layer of mirror on the glass walls was noticed. After 5 hours, the platinum spiral was no longer visible through the accumulated thin layer on the walls.

Figure 22-3: Production of vacuum lamps in Menlo Park in 1880[2681]

When the spiral thread was covered with MgO after the magnesium acetate was burned, MgO was accumulated instead of platinum on the surrounding glass. Thus, Edison was convinced that the sputtering phenomenon was caused by gas resulting from the platinum of the spiral. The loading of the metal on the walls of the vessel could not be prevented even with a vacuum of 2 mm Hg. Only Sprengel's pump helped, when half of centimeter long spark from the induction coil was no longer able to pass through a 1 mm wide vacuum.

When the 0.02 mm thick platinum wire was glowing in the Bunsen's burner, it melted somewhere and got a "zigzag" shape. At four times thicker conductor, this did not happen because the

[2681] Friedel, Israel, Finn, 1986, 131.

higher radiation of the surface did not allow such high temperatures. After heating, Edison observed many cracks on the conductor under the microscope. After 20 minutes, the cracks could also be observed with the naked eye, and after a few hours the conductor was broken. The phenomenon was noticed by J. W. Draper and the French chemist Tessie de Motay, who burnt platinum in hydrogen vapour.
When Edison realized the cause of the breakdown of the conductor, he protected it by pre-annealing in a vacuum. He got a very homogeneous and solid platinum without gas bubbles and a high melting point. He produced several platinum spirals with a radiant surface of 3/16 square inches which were glowing with 4 candles at the melting point. Then the air was pumped to 2 mm Hg. The spiral of the conductor was slowly heated by electrical current to the red glow and cooled at intervals of 15 minutes to remove gases from the pores and replace–them with metal. After 100 minutes, the spiral was illuminated by four candles, which would normally melt up the platinum. It gave even 30 candles at very slow warming. Under the microscope, there were no cracks on the smooth silver-white spirals, which thinned down during the process and it was very difficult to melt it. From a surface of 1/32 square inch, resembling a grain of buckwheat, he received a lightness of 8 candles, eight times more than without pre-heating in a vacuum. With less than a horsepower, he could supply 16 such lamps with a luminosity of 128 candles.

Edison tested different metals. After its treatments by that described procedure, the iron became as solid and elastic as the glass, and it lighted better than ordinary platinum, while the aluminium has only melted in a white glow, etc.[2682]

22.1.3 Parallel Discoveries during the Edison's Research of the Bulb: Lamp Survey

In mid-December 1878, Upton discovered that when the bulb resistance is as high as 200-300 Ω, no additional energy is required, since it depends only on the glowing surface. Therefore, the extremly light glowing filaments were used in the light bulb, which were extended by curling the spiral. The invention was patented in England in February 1879.

In 1879, Edison began using a vacuum to extract gold from very pure ores.[2683] It was a kind of modernized amalgamation using physics instead of chemistry.

Even after success with his bulb, Edison continued his experiments in a vacuum. In 1884 he declared and on 18 September 1894 he obtained a patent for coating with evaporation in vacuum by straight heating with a direct current, which he called "electro vacuum deposition". Nevertheless, the discovery of thin layer in a vacuum by resistant heating of platinum conductors is often ascribed to Nahrwold's three-year later work in which Edison was not mentioned. Nor did Kundt mention Edison when he used that discovery to determine the refractive index of thin metal layers in the following year in 1888.[2684] Edison was just not a part of academically trained community and academicians tried to ignore him as the outsider. Edison certainly disliked such treatment which sounded like the invalidations of his patented rights.

By the end of July 1885, Edison applied for three patents for the adsorption of mercury and water from a vacuum with special tubes filled with different getters. In addition to assistant John Otto, another woman Mina born Miller (1865 Akron in Ohio-1947) worked on that experiment. She proved to be so good that the widowed Edison married her on February 24, 1886. In December 1889, the colleague William Kennedy Laurie Dickson demonstrated to Edison the moving images he illuminated with the bright light of the Geissler's cathode ray tube.

Edison used the sputtering with high voltage alternating current, which he most likely accidentally discovered at higher pressures when he explored the carbon lamp. In 1900 he declared his discovery and received the patent for the "Phonograph plates overlay procedure" on 18. 11. 1902. Edison's National Phonograph Company used Edison's patent to sputter thin films of gold on

[2682] Edison, 1879, 152–154.

[2683] Israel, 1998, 341–342.
[2684] Waits, 1997, 18.

phonographic cylinders made of wax between 1901 and 1921.[2685]

The sealing of the lamp was particularly difficult with conductors made of lead. Swan and other researchers did not demonstrate their achievements in this field, so the problem was probably solved solely by Edison's group. Initially they had sealed with wood in Menlo Park, and they began using gypsum from Paris in 1881.[2686]

22.1.4 Carbon Filament Bulbs

Better vacuum re-opened the option of replacing platinum with cheaper charcoal. In October 1879, in Menlo Park, parallel to the research of the bulb, they also dealt with the production of telephone transmitters for the British market. In this way, a lot of charcoal of drum in the phone was available and it was also tested in the bulb. On October 21, 1879, a light bulb with charcoaled cotton thread was lit, which according to the legend was burning for 40 hours, although laboratory notes testify only 30.5 hours. On 4 November 1879, a patent application was filed, which only had to wait for 84 days. In a written request, Edison wrote: "I discovered that even the cotton thread, appropriately greased and placed in a sealed glass container, exhausted to a millionth part of atmosphere, gives a resistance of 100 to 500 Ω of to current and is completely stable at very high temperatures."[2687]

Simon Newcomb was born in Wallace, New Scotland. In 1884, he became a professor of mathematics and astronomy at the John Hopkins University in Baltimore. The University of Leiden awarded him the Honorary Doctorate. Together with the later Nobel Prize winner Michelson from the Maritime Academy, Newcomb was then in the middle of preparations for measuring the speed of light with an interferometer. Edison had such a reputation among American scientists at the time he invited Michelson to place his interferometer in Menlo Park. Michelson cordially refused the invitation.

On 6. 12. 1879, Edison's group used charcoal in the form of a horseshoe. In mid-January, Newcomb as the head of the Nautical Almanac Office at the Naval Observatory in Washington informed Edison that the luminous intensity of the bulb could be greatly increased by using a more homogeneous and more solid form of carbon than greased paper. Edison followed the advice and explored a lot of different of substances. He sent an expedition to India, China, Central and South America with American entrepreneurship onboard. "He started with countless experiments and searched for the right material for the carbon filament and he really found it after thousands and thousands of failed searches in Japanese bamboo whose burnt fibers proved useful."[2688] The story might not be completely true because Edison also wanted to impress his investors and customers, as well as his competitors.

Morton criticized his New Jersey neighbor Edison's bulbs in the Sci. Am. In the United States, European criticism of Edison's arguments also echoed. There, Faraday's RI graduate student William Henry Preece (1834 Bryn Helen, Caernarvon, Wales-1913) and Hippolyte Fontaine even mocked Edison's "distribution of electric current" or power, which was impracticable.[2689] Preece also criticized Heaviside and Maxwell's electromagnetic theories while he backed Marconi's radio. Hippolyte Fontaine was equally important as he helped to organize the Parisian International Exposition of Electricity with first international congress of electricians in 1881.

Henry Augustus Rowland from Honesdale, Pennsylvania, studied at the Polytechnic Institute in Troy, New York until 1870. In 1872, he became an associate professor there, and two years later he became a full professor. After completing his studies at Maxwell's class and four months at Helmholtz's lab in Berlin, he returned to his own laboratory at John Hopkins University in Baltimore in 1875, where he became a full-time professor of physics in 1881 and remained in that position until his death. In 1883 he became president of AAAS, in 1889 FRS, and in 1893 he was a member of AR. He was an unsurpassable producer of diffraction gratings.

George F. Barker from Charlestown, Massachusetts, became assistant to B. Silliman the elder in 1858. Between 1859 and 1861, he taught at the Harvard Medical School in Boston. Since then, he taught natural science at Wheaton College, Illinois in 1861, and the following year he lectured on Chemistry at the Medical Academy in Albany, New York. In 1863, he received his doctorate in medicine. In 1864 he went to Pittsburgh, Pennsylvania, where he became a demonstrator in 1866, and the following year he was a professor of chemistry and toxicology in New Haven, Connecticut. From 1873 he was a professor of physics at the University of Philadelphia. In 1872 and 1879 he was President of AAAS. He was also the assistant editor of Am. J. Phys. and he took care of promoting Edison's discoveries among scientists. Eight years after Rowland, Einstein’s future teacher Heinrich Friedrich Weber (1843-1912) professor of applied physics at ETH in Zurich, published a procedure for measuring all the properties of Naccari’s protegee Alessandro Cruto (1847-1908 Torino) and Edison's bulbs filled by carbon or platinum except for their longevity. Helmholtz presented Weber’s experiments based on J. Stefan’s formula under the title Untersuchungen über die Strahlung fester Körper to Prussian academy on July 26, 1888. Einstein’s uncle and father certainly read it as they were in that same bulb business.

Cyrus F. Bracket and Charles A. Young from Princeton published in Am. J. Sci. a commendable estimate of Edison's lamps after an independent research commissioned by Edison. In April 1880. in the same magazine, one hundred pages in front of them Edison's friends Barker and Rowland published another favorable assessment of the efficiency of the Edison lamp,[2690] measured as the ratio between the consumed part of the generator and the obtained luminosity. Rowland and Barker did not have any usable dynamometer, and the brightness of lamps could not be easily measured at long distances. They could also measure its resistance and current through a single bulb, but also did not have the necessary devices for such a measurement. Therefore, they placed the bulb under the water in the middle of a calorimeter so that the water around it could be mixed. The criterium was the heat emission per minute. The temperature was measured precisely up to a tenth of a degree Celsius with Baudin's thermometer, while a calorimeter made of a very thin copper held about 1.25 kg of water. The measurement was accurate to 3% because they did not consider radiation. With a calorimeter temperature close to the air temperature and low heating, they reduced the error to 1%.

Two bulbs of almost identical power were used. They measured only one, while the other was stored in the calorimeter and they replaced each other for the next measurement. They compared the brightness with a regular Bunsen burner, which lit one candle at the distance of 10 inches.

The measured bulbs with straight lines of greased paper were shining much more in the rectangular direction. Therefore, they also measured in the direction parallel to the surface and used average results. The bulbs had a mass of about 35 g. For the horsepower used they obtained 1000 to 1500 candles, which was promising if they could produce enough cheap and long-lasting light bulbs.

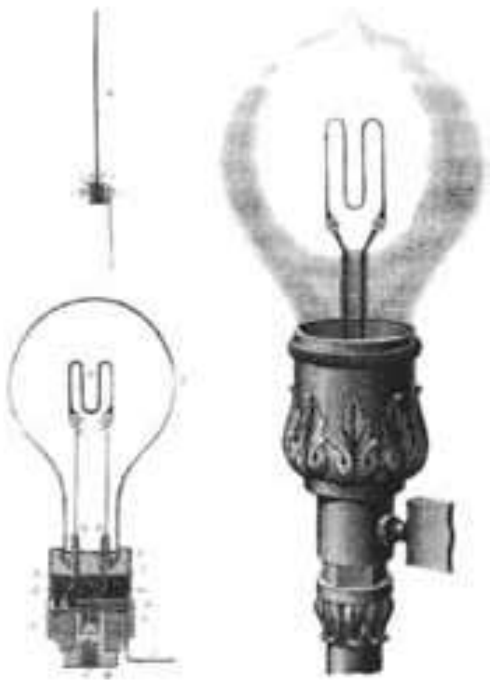

Figure 22-4: Maxim's light bulb at the Viennese Exposition of 1883 where J. Stefan lead the reviews of inventions.[2691]

African American Lewis H. Latimer also worked for Maxim with a decent salary. He designed the improvements of lighting. Nevertheless, he later moved to Edison’s firm, but despite the successes

[2690] Israel, 1998, 465; Friedel, Israel, Finn, 1986, 138–139.

[2691] Urbanitzky, 1885, 404.

of the Bell's parallel phone, he suffered from racism. In the late 1880s, Brush's company set up electric arc street lighting at Broadway, New York, and Maxim started selling bulbs like Edison (Figure 20-4). Barker praised Maxim's invention in the press, shown at the NAS meeting in late 1880 in New York. Perhaps he did a favor to Maxim for the resentment because Edison ignored his request to equip the famous Draper Laboratory with his own lamps.[2692]

Charles Francis Brush of Euclid, Ohio, received a diploma of mechanical engineer in 1869 at the University of Michigan, and then he studied at the Western Reserve University in 1880. In 1878, he invented his own version of the electric arc lightings. He founded the company "The Brush Electric Co & The Linde Air Products Co." In 1878 that company was the first in the US to produce a useful dynamo that was part of the lighting system.

In January 1881 in Menlo Park, for example, they decided to manufacture bulbs under Upton's supervision a quarter of a mile away from the laboratory. The factory employed over 150 people. On 19 April 1881, the group of New York City Councilors secured the privilege of the Edison's Company bulbs, which was the beginning of their worldwide success. Upton's place of Edison's mathematical-technical assistant was taken over by Charles Lorenzo Clarke (1853 Portland Maine-1941 Portland Maine) who became the first president of board of directors of Edison Company for Isolated Lighting in 1882.[2693] For the most appropriate voltage Edison chose 110 V,[2694] which remained the standard in the US and disturbs a lot of Europeans who bring the European-made notebook or shaver during their visit to USA (without an adapter).

After serving at the CCE, from where he was sent to Strasbourg in early 1883, Tesla went to Edison to New York next year with the recommendation of Paris friends and Batchelor. He worked there until the spring of 1885, and then he founded Tesla's street lighting company. The following year he completed his own lighting system with arcs, which was soon described in the Slovene language: "If we link two metal plates that stand opposite each other, with Tesla's currents, then there are very strong electric forces in the entire space between them. Geissler tubes, which we bring into such a space, immediately flash off. This behavior of Geissler's tubes gave birth in Tesla's hope that it might be possible to introduce a new, all other covering electric lighting. In the space that we would like to enlighten in this way, we would be inserted into two opposite walls of a large metal plate and tie them with Tesla's currents. Then, at each end of this space, a Geissler tube would illuminate, which would be freely, without wire, transmitted and placed in any place. Sadly, we are still far from this ideal lighting."[2695]

Hiram P. Maxim from Maine initially worked as an engineer developing the scientific devices, and he studied the bulbs after 1877. He was one of the founders and chief engineer of the United States Electric Lighting Company, which initially produced electric arc lightings, then platinum bulbs filled with the air, and since 1878 the graphite vacuum bulbs. He invented a thermostatically regulated short circuit in the case of excessive heating of the lamp and a "flashing" process of heating charcoal in a hydrocarbon vapor where extra charcoal was applied. The characteristic form of the letter "M" was written on the filament element after his surname. After 1883, he shifted production to rifles and aviation navigation.[2696]

After 1886 with his basic bulb patents expired, Edison quickly began to withdraw from the production of light bulbs so that he could use his time for other inventions. In 1893, the Edison and Swan patents expired and with them the monopoly position of their company.

The price of light bulbs fell rapidly by more than three times, and new manufacturers began to take on the market. Among them, Hirst was the most important. He prepared himself at the end of the Edison Patent monopoly by visiting bulb factories

in Germany, Austria, and the United States. In Vienna, he met C. J. Robertson, who previously worked for Lane-Fox. They were set up by Robertson Electric Lamps Limited, which was owned by GEC (General Electric Company) by half, while others were distributed by individuals. They bought Hammersmith factory that had worked for Brush before, and soon became the most important manufacturers of light bulbs in Britain. In the beginning of 1892, Edison Electric Company merged with Thomson-Huston in General Electric Company. Edison was greatly affected by the fact that his name had been withdrawn from the company's name and, most probably, he therefore started his research metallurgy, to surpass his success in the bulbs.[2697] The main competitor of GE was Westinghouse, who founded a research laboratory in the United States in 1916 and soon added a light bulb on the agendas. In the Soviet Union, they established the first laboratory for the discharge research in 1918 in Nizhny Novgorod. The following year they started producing the electronic valves.

Hugo Hirst (Hirsch) was born in Altenstadt, Bavaria, in the family of owners of a successful distillation company. In 1880, he moved to London and changed his surname to Hirst, and later became Lord of Witton. He worked for Power Storage Company for several years and then joined General Electric Apparatus Company of another Bavarian emigrant Gustav Binswanger (1855-1910 Hampstead in London), who hanged his surname to Bynge later. In 1889, Hirst was granted British citizenship, and the company was renamed General Electric Company Limited (GEC). In 1919, he set up a research center, one of the first focused on bulbs in the UK. It was officially opened by J. J. Thomson and Lord Robert Cecil in February 1923. Six physicists, two chemists, two engineers, and one metalworker out of a total of 29 workers, worked at the laboratory, including the later famous Paterson.[2698]

22.1.5 Tungsten Lamps

The charcoal bulb lighted nly by three watts, therefore they searched for substances with a higher melting point. Edison tested the glowing material from charcoal particles mixed with rare earth oxides patented in March 1897.[2699] Nernst's experiments with MgO only later turned out to be the predecessor of a fluorescent lamp. Siemens rejected it, but AEG bought its patent for £ 50,000 to avoid threatening competition. The tungsten with the highest melting point among metals was promising, but in the 19th century they did not know any of its alloys, which could be hammered.

The Viennese native **Karl Auer baron Wiesbach** was the son of a simple clerk who excelled through his education to become the director of imperial printing office. Karl Auer studied chemistry in Reitlinger's class in Viennese Polytechnic and in Heidelberg where he assisted Bunsen. He accidentally discovered that some salts gave a bright light after heating in a gas burner. Ten years later, he successfully researched lanthanides. In 1892, at the assembly of aeroengineers and hydro-engineers in Kiel, he showed a new possibility of street lighting with a Bunsen burner which glowed a cloth of cotton fabric, soaked in thorium nitrate, doped with cerium and then burned. In 1901 he became baron von Welsbach after the manor, which he bought near the Treibach chemical factory north of Klagenfurt in Carinthia.[2700]

The problem was solved by the Croatian Hanaman from Denovec in the county of Županja, who studied chemistry in Vienna and Berlin. In 1900, he became an assistant to Augusto Vierthaler's (1838 Vienna-1901 Trieste), the Triestino student of Professor Georg Vortmann (Giorgio 1854 Treste-1932 Barcola (Barkovlje)) at the Chemical-Analytical Institute of the Viennese Technical College. The similar post was provided for Dr. Alexander Friedrich Just (Just Sándor Frigyes, 1874 Bremen-1937 Budapest), who also worked for Eugene II Schneider's (1868 Le Creusot 1942 Paris) firm Schneider-Creusot (Schneider & Cie, Schneider et Consorts) on the improvements of carbon filament lamp. Hanaman helped Alexander Just, but Hanaman determined that only metal filaments with the highest melting point can be considered for the light bulb in 1902. From a mixture of chlorine and WO_3, $WOCl_4$ was obtained, evaporated ,and reduced with hydrogen

[2700] Bowers, 1998, 127.

to pure tungsten. The new bulbs patented in Germany in April 1903 were much more economical than carbon filaments, but they were fragile, and they could not get 100 V and 16 candles. They later produced tungsten, pressed in a hydraulic press. The resulting lamps were lit up over 400 hours with the power of 1 W. The professor of electrical engineering at the Viennese Technical College Carl Hohenegg (1860 Vienna-1942 Vienna) published the photometric measurements of their device.

Hirst's negotiations with Siemens & Halske were not successful, so they signed a contract and worked at Egyesült Villamossági es Izól-lámpa R. T. in Ujpest.[2701] Hirst immediately sent his technician to the negotiations in Budapest, but he himself visited Hanaman and Just to introduce their process to Britain. In the meantime, he heard of Welsbach's success with an osram bulb, and in the United Kingdom he founded Osram Lamp Works with a Hammersmith factory and equivalent shares of Hirst, Welsbach, Just and Hanaman. Production began in 1909 and soon showed the advantages of tungsten compared to the osram,[2702] which is the alloy of osmium and tungsten. Hanaman later became the first professor of inorganic chemical technology and metallurgy at the Technical College, later the Technical Faculty in Zagreb. As Mayor of Zagreb, he worked for the city's electric lighting.

After five years of experiments, Auer-Gesellschaft first began manufacturing a lamp with a metal element in 1906. A 0.09 mm thick Osram wire with a length of 28 cm gave one candle at power of one and a half watt, more than twice the amount of carbon lamp. However, even the tiniest of them had only a small resistance. Thus, only 16 to 44 V could be used and had to be connected in series to a 110 V line, which was of course embarrassing.

Charles Proteus Steinmetz was born in the German Jewish family in Breslau (today's Wroclaw). He was a socialist and, due to political problems, he went to Switzerland and then changed his original name Karl in the US.

In January 1905, Siemens & Halske began selling the equally effective tantalum bulb developed by Bolton. Before World War I, tantalum light bulbs were very well placed on the market, as they sold 50 million of them even in 1914, when the bulbs with tungsten filament developed by GE began to push them out form the market. In 1906, Auer-Gesellschaft began to sell Osram bulbs where they replaced the osmium with tungsten, that has a higher melting point and therefore only needs a little over 1 W for a candle. The tungsten powder was mixed with charcoal to the conglomerate from which the wires were drawn and finally the charcoal was removed. In 1919, AEG, Siemens & Halske and Auer's AG combined the production of light bulbs in Osram GmbH KG in Berlin.[2703]

In GE's laboratories, they were also aware of the shortcomings of carbon lamps when the director electrochemist W. Whitney and consultant mathematician Steinmetz took over the development after their studies in Germany. In 1904, the General Electric Metalized (GEM) bulb was marketed, and Whitney improved the incandescent lamp with pre-heating of carbon between 1905 and 1908.

In 1909, at GE in Cleveland, Ohio, Coolidge patented the production of tungsten that could be pulled into thin wires, which did not hang down. The tungsten was usually doped with sodium silicate or aluminium at the level of 100 to 150 ppm. The tungsten powder was heavily heated and compressed into the shape of a stick, which, however, was still fragile after cooling. At 1000°C, it was pierced with diamond tips until it became flexible and it could be stretched first in warmed and then in colder state into wires with high toughness.

Coolidge developed powder metallurgy in a completely controlled manner and quickly laid the foundations of the tungsten lamp industry. In the 1970s with the transmission electron microscope (TEM) they found that material doping creates a series of empty spaces (pores) with a radius of 5 to 100 nm. Pores are placed along the sample during treatment; they are thermally stable and permanent. With mass spectroscopy it has been shown that the pore contains potassium which is not soluble in

[2701] Fox, Guagnini, 1999, 270; Bowers, 1998, 121; Dadić, 1982, 302–303.
[2702] Bowers, 1998, 147–149.
[2703] Siemens, 1957, 1: 284, 286, 288, 290, 2: 32; Dadić, 1982, 302; Fox, Guagnini, 1999, 270; Bowers, 1998, 150; Rosenberg, 1915, 318.

tungsten. After heating, they create high pressure vapors, which cause the pores to rise to a uniform size. In the halogen and study bulbs, at the highest temperatures near the melting point of the tungsten (3410°C) the pores move and tend to aggregate, which is in accordance with the notion of free energy. Some come to the surface where their break release potassium vapor; this can develop a hot stain that destroys the bulb.[2704]

The American **Coolidge** from Hudson, Massachusetts, graduated from MIT in 1896, then moved to the Physics Institute led by G. H. Wiedemann at the University of Leipzig in 1898. He studied electrical waves in conductors and received his doctorate in Leipzig in 1899 with the author of the basic electronic theory of metals Drude. In 1901, Coolidge became a full-time professor at MIT, in 1908 he became assistant director, and in 1932 he was director of the research laboratory GE in New York. In 1913 he became famous together with his assistantLangmuir. They used tungsten for anode in the "Coolidge X-ray tube" with a heated cathode in GE.[2705]

In the GE laboratory, they were initially engaged in the development of a mercury lamp. Later, GE's director, Whitney, improved the charcoal fiber properties in the melting furnace and provided the promising market for his company for several years. Nevertheless, in the following years, the competition forced GE to buy patents from Siemens. Therefore, since 1906, they have failed to test the metal fibers in the bulb until Coolidge override the competitors by using tungsten. GE regained the market again.

In 1913 Langmuir examined the basic characteristics of the bulbs and cooled the filament. He found that the radius of the bulb does not have a major influence at all. He investigated the bulbs filled with nitrogen and then switched to argon atmosphere in his bulbs. Thus, at the end of the 1990s, GE had already managed 96% of the bulbs market in the United States.[2706]

On 7 December 1915, Edison patented the production of a tungsten electrode by pressing tungsten powder in an oxygen-free vacuum container. He evaporated tungsten by "discharges between electrodes". The resulting thin leaves of tungsten or tantalum were cut into strips, twisted into rollers around a soft metal or wax and bent into the horseshoe shapes for bulbs. A similar product was also obtained by direct coating of the melting core of wax with tungsten.[2707] In the first decades of the 20th century, Edison's bulb with tungsten reached a form that we are still using today without major changes.

22.1.6 *Bulb in England, France, and Italy*

Due to the multiple scams the English Parliament voted in 1881 a sharp law called the Lighting Act. It supposedly protected people from excessive promises of electric lighting companies. Later, the law greatly damaged the development of domestic lamp production and raised doubts about the powerful propaganda of Edison's lamps in the US.

Figure 22-5: Swan light bulb at the Viennese exhibition in 1883[2708]

At Exposition Universelle in Paris in 1878, they admired mainly Jablockov's electric arc lightings, and three years later Swan's lamps, Edison, Lane-Fox and Maxim's products excelled at the International Electrical Exhibition from August to

Swan was initially a chemist and pharmacist in his native Sunderland. After the deaths of the owners of his company *Hudson and Osbaldiston* he joined the manufacturing chemical business of his brother-in-law John Mawson in Newcastle-Upon-Tyne, where they developed electric lighting and photography after 1844. In 1845 Swan was impressed with the perspectives of a bulb during William Edwards Staite's lectures on arc lamp, platinum-iridium lamp and Grove's experiments at his home areas of Sunderland and Newcastle, just as happened to Faraday a little earlier in London. After 1846 Staite collaborated with William Petrie who studied in Cape Town and Frankfurt. Staite patented his clockwork or spring system which provided fresh carbon for his bulb on November 12th, 1846. Swan began to test his own bulbs in 1848, but due to poor vacuum he failed to succeed. In 1867, Mawson died in the explosion of nitroglycerine used for his photographing and his widow Elizabeth took over his share. When he became acquainted with the Sprengel pump in Crookes' discourse of 1875, Swan finally designed a workable lightbulb. Swan's associate, the banking officer Charles Henry Stearn (1844 Jamaica-1919), improved it in Birkehead with an added mechanism for lifting silver and preliminary mechanical pumping. On July 12, 1879 in Sci. Am. Swan published a paper on the carbon lamp, which Edison re-examined several months later. After his doctorate, Swan became president of the Literary-Philosophical Society in Newcastle-upon-Tyne. He invented bromine paper, which is still used today in black and white photography.[2709]

November 1881. Edison made some mistakes while preparing lamps for the exhibition, but his people in Paris wrote newspaper articles in his favor. In fact, his light bulbs were slightly more effective than the others. In 1881, at the exhibition in Paris, the Parisian academicians Henri Édouard Tresca (1814 Dunkirk-1885 Paris) and the secretary of the department of experiments at the exhibition Jules François Joubert (1834 Tours-1910 Paris) performed one of the first measurements of the energy conversion efficiency of thirteen devices using direct current, mostly focused on the bulbs and electric arcs. Two years later their work was at the Viennese exhibition under the leadership of Stefan.[2710]

Immediately after the Parisian exhibition, Edison founded three companies in Paris in 1882; their descendant Compagnie Continentale Edison was still active in the next century. Unfortunately, the gravest financial crisis in Paris has ruined the initial capital and successes of Edison's factories around the city. In 1884, they founded Società Italiana Edison, initially to illuminate the wealthy downtown center of Milan.[2711] The Parisian International Electrical Exhibition was followed by similar exhibitions in London and Munich in 1882, in Vienna in 1883 and in Philadelphia 1884.

22.1.7 The Bulb in Germany and the Netherlands

On June 5, 1873, Siemens and Halske's company received an English patent for the automatic regulation of electric arc with charcoal, powered by DC or alternating current. In April 1877, W. Siemens published a paper on electric lighting of the Frenchman Serin who constructed the lighthouse of Havre with electromagnetic machine of Floris Nollet in 1852. By 1880, Siemens developed a metal filament lamp, like that of Edison. On July 21, 1877, Alexander, the nephew and assistant to William Siemens in London, visited the laboratory at Menlo Park. Nevertheless, they later did not take part in the development of the bulb, as Edison tried to disable Siemens's patent of dynamo with Rowland's support in the US, as Siemens's ideas resembled Edison's own dynamo.[2712]

After the crisis that was caused by the collapse of the stock exchange in Vienna on December 27, 1881, Siemens lectured before the German Electrical Association on the advantages of electric lighting compared to the gaslighting in relation to the danger of fire. Among the inventors of the incandescent light bulb Siemens listed de Changy from Paris, Jobard, Swan and finally Edison. Siemens & Halske used compressed carbon and

graphite surfaces, where the heating depends on the thickness of the glowing rod (Figure 20-6).[2713]

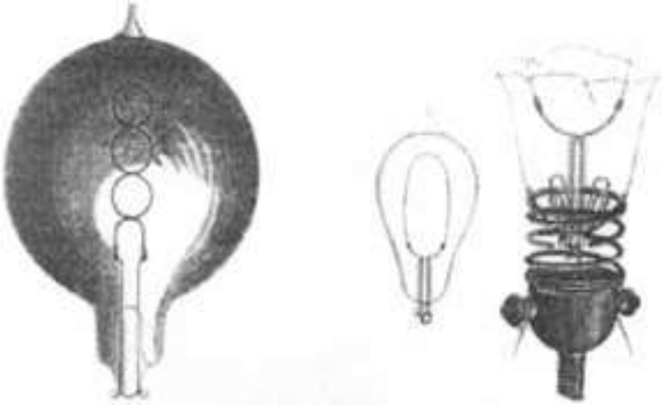

Figure 22-6: Siemens & Halske's light bulb at the Viennese exhibition in 1883[2714]

Many emigrants who returned from the United
Many emigrants who returned from the United States after several years working at Edison’s Menlo Park helped to set up the new electrical industry in Germany. Among them was Sigmund Bergmann (*1851 Tennstedt; † 1927 Berlin), an inventor of an improved selenium photoelement in the year 1931. Francis Jehl (1860 New York-1941 Florida) joined Edison at Menlo Park a few days before Upton and later he updated the Edison system in Habsburgian monarchy, France and Romania. Another Edison assistant, John Krüsi, stayed in the US and supervised machine work in Schenectady, where GE developed later.[2715]

The greatest successes in using Edison's patents in Germany was achieved by engineer Emil Rathenau, born in 1839 in Berlin. He studied in Hannover and Zurich and then specialized in England. He became interested in the light bulb at the first Parisian electrical exhibition in 1881. In the spring of 1882, he was already very successful at the international electric exhibition in Munich. Unlike his competitors, he did not challenge Edison's European patents, but began to work under Edison's license, thus exploiting Edison’s experience. On 13 March 1883, he signed a contract with Siemens & Halske, so he could raise the necessary capital to set up the Deutsche Edisongesellschaft für angewandte Elektricität with a capital of 5 million mark on 19 April 1883 and began to supply very small electrical installations, as the company Siemens & Halske did before him. In 1897, Rathenau's company was renamed Allgemeine Elektrizität Gesellschaft (AEG), which was independent of the Paris Compagnie Continental Edison.[2716]

In 1891, Friderik Philips founded the company NV Philips' Gloeilampenfabrieken in Eindhoven in the Netherlands with his son, engineer Gerard Philips. Their initial capital was 150,000 guilders. Although there were already four other bulb factories in the Netherlands, they soon produced 500 light bulbs per day. His younger son, Anton Philips, who worked on the London Stock Exchange a few years earlier, preferred to join the company as a successful seller. After a favorable contract with Russia, the annual sales exceeded one million light bulbs in 1898. The following year Friderik retired and his sons became equal owners of the company. In 1903, in Berlin, the manufacturers of light bulbs from Germany, Austria-Hungary and the Netherlands, together with Philips, signed the foundation of the Verkaufstelle Vereingter Glülampenfabriken (VVG), the first international cartel for carbon filament lamps.

Gerard Philips graduated in mechanical engineering at the University of Delft. During his work in the Glasgow shipyard he became acquainted with electric lighting. W. Thomson enabled his position at the university there after he had already begun to illuminate his house in Glasgow with light bulbs in 1882. Before he returned to the Netherlands, G. Philips worked briefly in London's British Company and for the Berlin AEG.[2717]

In November 1911, Anton Philips returned from inquiring trip focused on Coolidge's light bulbs in the US. He brought with him trained workers and in December he started producing tungsten lamps. So, he was able to end his old sintering[2718] procedure in July 1912 and arrange with German companies on the right to produce tungsten filled lamps. In 1912, Philips had about 6 million guilders of capital. It was not until the First World War that Philips got rid of the German influence and Philips began to produce all parts of the bulb

independently. Philips built factories in Belgium, Spain, Switzerland and Poland; and he even gained a share in Sweden.

In Eindhoven, Gerard Philips had been continuously studying in his own laboratory, although he formally established it only later. In his laboratory in Eindhoven, Heinrich Hertz's nephew, GL Hertz, has been researching since 1920 to receive his Nobel Prize in Physics in 1925. During the war, Philips began producing amplifiers and televisions. Philips family gained their influence in science and penetrated with the systematic training of their technical assistants and by installing well-equipped laboratories. In the production of light bulbs, Philips became the third most powerful in the world after GE and Osram, while GE controlled 96% of the US market in 1928.[2719]

22.1.8 Bulb in Habsburgian Monarchy

The company Siemens & Halske already established a branch in Vienna in 1858, which was primarily concerned with railways. Due to unsuccessful business, the branch was abolished in 1864 after Halske's efforts. In 1879, W. Siemens opened a technical office in Vienna with a small factory that, in addition to railway signaling devices, soon started small and large lighting installations, production of dynamos and arcs. In 1896, the Viennese subsidiary of Siemens & Halske, at its own expense, set up a small provisional power plant in Ljubljana. For advertising, they illuminated the premises of the Narodni Dom which was officially opened in October.[2720]

The Englishman **George Lane-Fox** failed with his first two light bulbs in 1878 filled with a platinum alloy and iridium or asbestos impregnated with charcoal. In 1880 he began to use French grass (French whisk, bass broom), which he processed in hydrocarbon steam and then carbonized. His patents were later bought by Anglo-American Brush Electric Light Company.

In 1873 Edison did not participate in an international exhibition in Vienna, although a member of the US Commission urged him to present his inventions at least in the report.[2721] At the first international electrical exhibition in Paris in the spring of 1881, the electric arc lightings were still competing with light bulbs. Edison and Maxim from the United States and Swan and Lane-Fox from the United Kingdom[2722] were among the outstanding lamp manufacturers. In 1882 Edison hired Austrian electrical engineer Dr. Hermann Claudius from the Austrian telegraph for arranging, mapping and converting main and replaceable resistors in the lower Manhattan area along the Brooklyn Bridge. Claudius collected data on complaints about gas lighting disadvantages that promoted sales of Edison's light bulbs.[2723] In 1889, Claudius published in his domestic Viennese Zeitschrift für Elektrotechnik a paper About the calculation of heat in electric waveguiding for practitioners (Ueber die Berechnung der Wärme in Elektrisch-Lichtleitungen für Praktiker).

Moses G. Farmer of Massachusetts began to test platinum lamps in 1858, and he examined the graphite rods between the carbon blocks in a nitrogen atmosphere after 1877. In July 1878, together with Barker and John William Draper's son Henry Draper, Moses G. Farmer visited Menlo Park.[2724]

William E. Sawyer, a telegraphist and journalist from Washington, DC, began collaborating with a wealthy lawyer, Albin Man, in 1878. Independently of Maxim, they developed the stopper lamps and a "flashing" process. In collaboration with Westinghouse they were selling their patents to most of the light bulb companies in the US, but not to Edison, who was their main competitors in the US.[2725]

After the Parisian exhibition in 1881, Edison illuminated opera in Paris, Berlin and Milan thus enabling a resounding start to sell his products in

Europe. In 1882 Edison's boys lighted up the theater in Brno.[2726] That same year, Edison's company participated in the electrical engineering exhibition at the crystal palace in London, and from 11 August 1883 at the 3rd International Electrical Exhibition in Vienna, whose technical-scientific manager was Stefan. The exhibition was attended by the electrical engineering company Geba from white Ljubljana. Several electrical technicians from Slovenian countries were members of the Electrotechnical Society on March 5, 1883.

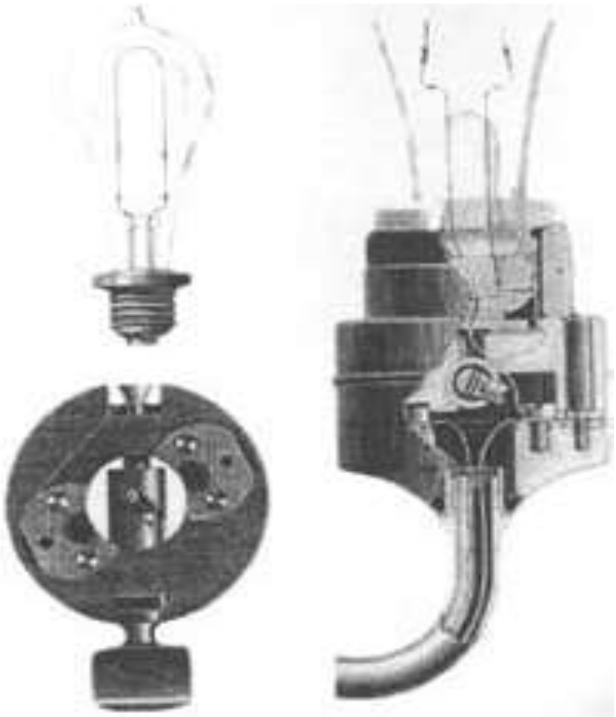

Figure 22-7: Edison's lamp at the Vienna exhibition in 1883[2727]

The exhibition in Viennese Rotunda on 33,000 square meters with 400,000 candles of electric lighting was until then the largest in the world.[2728] A total of five types of electric bulbs were exhibited. Edison's bulb contained a glowing bamboo with a diameter of 1 mm and a length of 12 cm in the form of an inverted letter "U" (Figure 22-7). The hardest part of the production was the inserting and sealing of both conductors from platinum into the liquid mass of the glass. Both ends of the conductor were separated by plaster. The electrical current from the Edison machine was supplied by the Pardon Armington's (1836 Pawtucket-1901 Massachusetts) steam engine. With the Edison's lamps of CCE and SEE (Société Électrique Edison) under the guidance of Viennese firm Brückner, Ross & Consorten they illuminated the "Hall of Arts" and the interior of the premises at the Viennese Exhibition.

In Swan's bulb, the platinum carriers of charcoal were isolated from each other on the lower part of the glass pillar. They were used at the exhibition to illuminate the Imperial Pavilion, theater and interior spaces. Swan's products were represented in Budapest by United Electric Lighting Company (UELC) from London, and in Vienna by the firm of Bernhard Béla Egger (* 1831 Buda; † 1910 Vienna) and the Zionist Johann Kremenezky (Kremenetzky, Josef Josefowitsch Leibensohn, * 1848 Odessa; † 1934 Vienna) & Co.

The Maxim's lamp had a glowing section in the form of a rounded letter "M" worn by two platinum conductors, sealed in the glass. The glass pear was in a metal bowl, sealed with plaster. The bulb of the volcanic or other insulator was wound around the metal core. The air was pumped out with a mercury pump and the vapors of oil were exhausted to 40 mm Hg.

Lane-Fox's lamps contained glowing charcoal in the form of a horseshoe. At 66 V and 0.673 A, they gave 8.7 candles. They illuminated a part of the "Art Theater", the interior spaces, the garden and the pavilion of the British Commission in Vienna. Brush's machine supplied their electricity.

Siemens & Halske's company exhibited a bulb with charcoal filament shaped as horseshoe pressed in a tube-shaped covering made of copper, which was extended into the glass through a platinum conductor.[2729]

The Prague Professor Puluj exhibited a portable lamp in a box of wood and ebonite in the size of 20 × 25 cm, powered by the electrical current of six Bunsen elements. The bulb on the front of the box was wrapped with a strong protective glass and behind it he put a small metal mirror. A lamp weighting 7 kg provided 6 to 7 normal candles during 6 to 7 hours. For the ministry of war interested in mines and diving, Reitlinger's successor at Viennese polytechnics Friedrich Wächter presented lamps weighting only 300 g.

J. Stefan took a special active part in the 3rd Section of the Scientific Commission, which investigated dynamo machines and electric lamps. On 18 September 1883 they were convoked for the first time to elect for Stefan's deputy theprofessor Erasmus Kittler (1852 Nurnberg-1929 Darmstadt) from Munich recently resettled to the first chair of electro-technique in Darmstadt. The head of the subsection responsible for machines became the major Obermayer as former Stefan student and later biographer, and the professor Ernst Voit (1838 Speyer-1921 Munich) from Munich became a secretary and head of the sub-department for photometry.[2730]

On 18 October 1883, Stefan gave a lecture on the goals and results of the work of the scientific and technical commission. Just four years after Edison's invention Stefan presented the facts of Edison's vacuum lamp to the Viennese mayor Eduard Uhl (1813-1892) with his municipal representatives. Even the patron of the exhibition the Habsburgian Crown Prince Rudolf was present just after the birth of his only legitimate daughter Elisabeth on 2 September 1883. Rudolf sadly passed away five years later. Stefan explored the vacuum lamp as an example of his theory of radiation. At the same time, he inherited the useful ideas of his teacher Ettingshausen and emphasized the advantages of the bulb against other sources of light. Wächter and Puluj, the members of Stefan's Viennese physics institute, also showed their vacuum bulbs at the Viennese exhibition under Stefan's leadership. Puluj had already taken over the chair in Prague, but he kept in contact with Viennese vacuum researchers. Stefan has valuated the capacity of bulbs for several years after the Viennese exhibition. He knew that the very experiments with radiation in vacuum bulbs will help recognition of his theory of radiation; modern experiments fully justified his hopes. He described the course of measurements of resistance and current, which were especially common in approvals of designed lightening. The parallel photometric measurements enabled Stefan to provide a transparent table of the dependence of the light power on the energy consumed. A light emitting diode diagram showed that higher voltage reduces thermal radiation and thus increases the economy of the bulb. At the end of the lecture he described the advantages of an electric bulb before lighting gas or candles.[2731] Unmarried Stefan often worked late into the night; of course, he knew very well the importance of a good light bulb.

In Stefan's lab, the efficiency of the lamp was measured using the version of the Siemens electrodynamometer, called "ergometer". Stefan's commission issued a total of 177 certificates in German language, among them 22 for bulbs. The last one was signed by Stefan in the middle of 1885. On 3 November 1883 the exhibition was closed in Vienna. Senekovič described it to the people of Ljubljana, who was by far the most appropriate fir that job. He was the professor of Physics between 1874 and 1884, director of the 1st Ljubljana Gymnasium (and libraries) until his retirement in July 1907, the president of the Carniolan Museum society in Ljubljana and the author of textbooks about physics in 1883 and 1892. He reported: "... I am pleased to mention that the best recognized among the light bulbs were constructed by the Austrians, namely the Slavs ... While the arc lamp sends light produced between its charcoal to all sides, the light is generated in the light bulbs as the electric current glows the carbon thread in the space without air... Edison takes a thin bamboo fibers and chars them up. Such a charcoal thread is then fixed in a small, pear-like container with its ends at platinum wire, welded in glass; and from the vessel he removes air as much as he can ... (At the exhibition) the females were most interested in the use of electric lights for lighting homes..."[2732]

In the report of the scientific commission, which Stefan edited more than two years after the end of the exhibition, Obermayer published dubious measurements by which bulbs using an alternating current consumed more energy than those using direct current for the same amount of light. That was a clear Edison's victory just eight years before Tesla temporary defeated his DC in their war of currents. Because the measurements were not accurate enough, Stefan intended to repeat them, but did not publish the results.[2733]

Stefan's and Edison research did not coincide solely with the bulb. The Tasimeter, which Edison invented just before his light bulb, was designed to measure the heat of the stars and the Solar corona.

It was used to observe the total eclipse of 1878, and the following year they published his description with photographs. At the same time, Stefan published his radiation law and for the first time accurately determined the temperature of the Sun using the measurements of JW Draper, the father of Edison's friend.

22.1.9 Electric Bulb in Slovenia

The first electric bulbs in Slovenia began to be used in high school physics laboratories, since the Slovenians had no domestic universities at that time. Among the curators of cabinet of physics in the territory of present-day Slovenia, Vlahović published the most researches of electrical light. At the Gymnasium in Koper, he studied the duration and shape of the electric spark, consisting of several spatially separated parts.[2734]

The size of the spacing between the spark parts depends on the properties of the circuit that produces it. He compared his calculations with the simultaneous published experiments of the Italian R. Felici and determined the matching. In 1859 in *Nuovo Cimento* Felici excelled with his direct proof of Wilhelm Eduard Weber's theorem.[2735]

Vlahović used universal discharger of William Henley who died by his own hand in 1779.[2736] Vlahović acquired it in Koper in 1857 under no. 50, but it was not listed among the 54 physics instruments in 1863. Among the 22 electrical and magnetics devices he used in his discussions were: a tube for observation of sparks, a Leyden jar, a Volta’s battery and 12 strong Bunsen’s batteries. He listed the appliance for the electric light in a vacuum and arc-lamp.[2737] Vlahović's charcoal vacuum lamp was first described by Jobard in 1838 in Belgium, and it was successfully sold by Edison only after 1879 (Figure 22-8).

In 1863, the cabinet of physics of the Gymnasium in Koper had 126 florins of annual grants, while the physics cabinet of the Ljubljana gymnasium had received 200 florins by 1858/59, and then 210 florins y the end of the 1860s. It is therefore understandable that the curator of the cabinet of physics Mitteis had a much greater possibility of purchasing physical devices. Robida had half smaller grants than Mitteis. Robida did not acquire bulbs in his cabinet of physics in Klagenfurt, which he ran between 1847 and 1874. Several bulbs are found in the cabinet of physics of the Gymnasium in Novo mesto, which was led by Franciscan Bernard Vovk (* 1824 Brezovica in parish Ovsiše; † 1911 Brežice) between 1854 and 1884. Table 22-1 lists the lamps recorded in gymnasium reports and in annual inventories in Ljubljana, Koper, Klagenfurt and Novo Mesto. Unfortunately, most of these physical devices are no longer useful today. Many facilities from the Ljubljana gymnasium are waiting for researchers at the Slovenian School Museum, while Vlahović's lamps are still found today in the well-preserved physical room of the Italian Gymnasium in Koper.

Figure 22-8: Vacuum bulbs in the Vlahović (Vlahovich) inventory list at the Grammar School in Koper in 1858/59 no. 103, 1859/60, No.112[2738]

The census shows how they gradually replaced gas lamps and spirit (alcohol) burners with electric light bulbs in the cabinets of physics of lands inhabited by Slovenes. In 1857, the city council of Ljubljana lent to a gymnasium cabinet of physics a battery with ten elements of Zn-Fe and a regulator for production of electric light.[2739] According to

Table 22-1: Sources of light according to gymnasium reports in Ljubljana (L), Koper (K) and Novo mesto (N)

Source of light (prices according to Ljubljana inventory from 1866)	Year of purchase (place, inventory number)
gas lamp made of black lacquered metal, product of Freyberger	1809–1845 (L, 357)
Davy's safety lamp (Koper miniature version is preserved)	before 1855 (N, 90), before 1857 (K, 45)
lamp from glass, designed with the siphon	1858 (K, 74)
lamp named after Berzelius	1853 (L), 1855 (N, 47), prior to 1857 (K, 21), 1864 (K, 164)
device with carbon peak for producing electric light	1854 (L, 30)
demonstration device for the glow of galvanic electricity	1856 (L)
Three pairs of peaks made of charcoal	1859 (K, 100)
an electric light source with stings made of charcoal, in vacuum	1859 (K, 103)
Tube for electrical sparks	1859 (K, 105)
an electric light source in vacuum	1860 (K, 112)
induction coil with circular breaker in a vacuum	1860 (K, 114)
arc lamp (in Koper, an electromagnetic regulator of the electric arc is preserved)	prior to 1863 (K)
spirit lamp in glass (63 kr)	prior to 1866 (L, 22)
devices used to produce the electric light with a driving force (gear) and a reflector	1868 (L)

the inventory list on August 15, 1876, two kerosene lamps were suspended under the ceiling at the Gymnasium in Koper. In 1886, two electric lamps were purchased for the Koper Cabinet of physics and the authorities announced that "others will be installed". Unfortunately, the manufacturer of these lamps was not listed. At the time of Inwinkl's term as curator, in 1908, the physics cabinet of the Gymnasium in Koper was equipped with an independent electrical installation which gave a voltage of 1 to 250 V and a current of 0.1 to 30 A.[2740]

Thus, the educated Slovenians already knew the characteristics of electric bulbs when these started to come into public use. Outside high school laboratories electricity was used for lighting for the first time in Slovenia in 1880. In April 1883, they lighted up the mill of Karl Scherbaum (1818-1901) in Maribor. The next year, twelve electric arc lightings in the Postojna Cave lit up, while the first public power plant with in Slovenian areas started operating in Škofja Loka. In 1894, the cloth manufacturer Alojzij Krenner (1841 Škofja Loka-1895 Škofja Loka) offered part of his generated electricity of the steam power plant to the purchase to the municipality for the needs of public lighting Škofja Loka. The municipality paid 360 gold denarius a year to Krenner, and under a contract signed on May 8, 1894, he pledged to illuminate the streets of the city for 30 years "every day from the beginning of the darkness to two after midnight and from quarter to six in the morning to a white day with 40 electric bulbs of 16 normal candles" by the Siemens & Halske's system.

Similarly, two years previously, Trbovlje coal mine company installed a steam generator at the engine room of the mine in Kočevje, which, beside the current for its own lighting, also supplied electricity to the city for electric arc lightings of several streets. During the construction of the water supply, the Kočevje natives found that water pumping machines could produce electricity. That is why they supplemented the plans of the regional engineer professor at the Czech Polytechnic in Prague J. V. Jan Vladimír Hráský (Hrasky, 1857–1939 Prague). On 10 October 1896, they obtained a building permit for the construction of a 45-horsepower plant. From 20 March 1896, the little-known building company Carl Greinitz Neffen from Graz built a machine room, an electric power station, a plumbing plant and an administrative

[2740] Journal of Grammar school (Izvestja Gimnazije) in Koper, 1886, 1908.

building for 176 days. The electrical equipment for the engine room was supplied by the Franz Pichler's factory from Weiz, and the well-known Brno enterprise Brand & Lhuillier delivered boilers and two steam engines connected with piston pumps for pumping water. Thus, the steam engines simultaneously propelled both the water pump and the two dynamo machines. They produced a direct current with a voltage of 2 × 150 V, which was very high for those times. A smaller dynamo was installed for the reserve, and a switchboard and a balancing accumulator battery with 200 elements and a capacity of 56-80 Ah.

On 19. 11. 1896, in Kočevje, 4 km of electric lighting lines were opened with 700 light bulbs of 16 candles and power lines with a cross-sections of 8 mm^2. Thus, Kočevje became the first fully electrified city in Slovenian lands.

Since 1889, the Commission of Ljubljana for the Study of the Hydroelectric Power Plant has been studying possibilities for the construction of a hydroelectric power plant or a thermoelectric power plant. Although the commission advocated an alternating current thermal power station, the City Council, following a proposal by a Viennese expert, decided to take a DC. Edison therefore prevailed over Tesla. In 1897, the thermal power plant was located at an inappropriate place in Fužine near Ljubljana, as there was no running water or a railway in the vicinity. The thermal power plant had two steam engines of 200 KM and two dynamos of 140 kW for 300 V. From the plant, a cable was transported to the main road, where the power supply was supplied from the storage station between 24 P.M. and 5 in the morning, when the power plant stopped, until the for full-day operation was needed due to the tram after 1901.

On 1. 1. 1898, half a year after the earthquake, Ljubljana got new thermoelectricity power plant on Slomškova street number 18 with two steam engines of the firm Erste Brünner Maschinenfabrik and DC dynamo of Siemens & Halske. Suddenly, the first 794 light bulbs and 48 electric arc lightings blazed on the streets of Ljubljana. 149 users had 6358 bulbs, 89 arc lighters, 12 engines and 3 appliances with a total of 290 kWh. Until 1905, electric light bulbs in Ljubljana prevailed over the older gas lighting, which remained in some areas with Auer's "bulbs" until 1946.

22.1.10 The Bulbs in the Works of Stefan's Contemporaries and Students

With Edison's success, the research of a bulb in the USA has outperformed development in Europe. Nevertheless, an interesting view of the European achievements and the merits of Slovenian Stefan is offered. Stefan's research path surprisingly interwoven with the discovery of the dozen years younger inventor Edison. Stefan's colleagues and students soon described the Edison lamp in the Slovene language, the first among them Stefan's antagonist Simon Šubic of Graz university: "Edison's electric lamp is like a hollow pear of glass, which is attached by the tail to electric ties. From its inside the air is extracted as much as possible. In its cavity deprived of air it had a thin vault of bamboo charcoal, which is elastic and hard as steel, so that it doesn't burn down while crossed by the strong electric currents. It just warms up and heats without burning so long as it has no air in its interior space. However, since the space cannot be emptied completely, and because it cannot be clogged so well that over a time there will be no air in it, it will burn some of this charcoal with time at the remaining air so that this light bulb does not shine further than some eight hundred to thousand hours.

Then, on the average each half a year, the old lamp should be replaced with a new one ... Before Edison and Swan came up with their handy electrical lamps, and before Siemens introduced its differential lamp, the people had great hope for Jabločkov's candle for some time, but it was impossible to eliminate its unpleasant characteristic. Jabločkov's electric candle consists of two carbon standing nails; the space between the nails is filled with plaster: at the upper end it is covered by a thin graphite plate. When the current of electricity flows through charcoal nails, it goes also through the graphite plate which is heated to light and shine. With time, the ends and even the whole candle are burned down. The greatest obstacle to everyday use is that all electrical candles, which are drawn into that electrical bond, are extinguished if only one or those candles goes out to begin with."[2741]

[2741] Šubic, 1882, 483, 484–485.

[2742] Bowers, 1998, 71.

Henrich Schreiner learned physics at Maribor's Gymnasium by Anton Šantel and studied natural history, mathematics and physics in the class of J. Stefan in Vienna in 1877. He was a professor and director at the gymnasium in Gorizia between 1884-1891. The professor of Physics and Deputy Director in Bolzano Henrich Schreiner (* 1850 Ljutomer; † 1920 Maribor) described Edison's lamp ten years after the discovery: "A platinum wire was burning, if a galvanic electrical current through it is extends, if it is sufficiently thin and the current is strong enough. It produced so much light that it can be used for a glowing electric light. However, the experience teaches that heat and the light of the wire, which is glowing in the direction of the overflowing current, grows stronger as the translation of electricity gets worse. More often they do not use platinum wires for a glowing electric light, but some other substance that poorly translate electricity. Above all, it is required that a substance that readily produces an electric light does not dissolve prematurely in high heat. After numerous attempts, they found that the most fitting body for a glowing electric light is a thin filament of charcoal. We produce those threads by charring thin vegetable fibers or human hair. This method of carbon sequestration was invented by the American Edison. As a result, the lamps which use a glowing electric light are called Edison's incandescent bulbs."[2743] Certainly, any involvement of female hair was never Tesla's favourite.

Chief of the Ljubljana Waterworks and Power Plant Stefan's student between 1875 and 1881 Ivan Šubic, described Edison's lamp in the first Slovene book dedicated to electrical engineering: "We want to describe now the light bulb produced by the modern factories. As we already know, each bulb consists of a glassy, airless balloon in which the charcoal burns. The electrical current is introduced through the glass balloon to the carbon seal using two platinum wires that are immersed in glass. The light bulb therefore has three main parts: glowing carbon, conducting wire and the balloon or pear..."[2744]

In Table 22-2 we have an overview of the development of the electric bulb and its echoes in Slovenian areas.

Pavel Nikolaevich Jablockov from Serdobsk in Saratov gubernia (Сердобск, Саратовской губернии) graduated from Nikolaev Engineering School (Николаевская инженерная академия) in 1866 and, three years later, from the Technical galvanic Institute of Petrograd (Техническое гальваническое заведение в Кронштадте). As a telegraph engineer, he headed the installation between Moscow and Kursk. In 1875, he resigned his job and went to the United States to attend the exhibition in Philadelphia next year. But he only came to Paris, where he worked with Bréguet, who developed telegraphy and electric watches for the French Navy and the railways. At that time, Paris was the center of the development of electricity, as the Belgian Gramme designed the first useful generator in 1870, which was used primarily for lighting. In 1876, Jablockov created the "electric candle" named after him as the first useful electric lamp. As the first one he used an AC power capacitor and made new versions of transformers, batteries and other electrical devices.[2745]

22.1.11 The Arrival & Future of the Light: Lifestyle of the Bulb

Edison's work created the legend. On October 21, 1929, the former Edison worker Ford invited Edison to repeat his experiment with a bulb in the renovated Menlo Park upon its fiftieth anniversary. Despite the replacement of the charcoal element with tungsten and a whole series of small improvements, the bulb is, besides the cathode ray tube, one of the most distinctive unchanged elements in electrical engineering. In the 21st century, however, the question is whether the cathode-ray tube with a luminous fluorescent coatings could force the bulbs out of the market, while liquid crystals screens of televisions and PC work without a cathode-ray tube.

22.2 Stefan's Kinship

J. Stefan certainly prayed one of the leading roles in introductions of incandescent light bulbs and much more. Stefan's unmarried mother was of poor humble origin and Stefan finished his High School in Klagenfurt being more often worried

2743 Schreiner, 1889, 177.
2744 Šubic, 1897, 130.
2745 Bowers, 1998, 65.

than happy. The top physicist Karel Robida used to be high school professor and form master of Jožef Stefan. Robida was born at the Ljubljana suburb and taught at Klagenfurt. He had hard awful times before he got the necessary education required for the professor of physics at Klagenfurt. He was proud of his Slovene origin and passed the same feelings to his students. Just after the March revolution he published the very first Slovenian textbook of physics. He hoped to make an official textbook out of it, but the politics suddenly changed, and he failed because physics was not taught in Slovenian language at secondary schools anywhere. Despite of that Robida's Slovenian physics was widely read even among the Slovenian peasants. Robida's scientific works are worth of serious study. His research began with the original theory of electricity and magnetism. In practically no time Stefan's senior collaborator Grailich published considerably sharp critique of Robida's claims. Just five years after the discovery in England, Robida published his experiments with cathode sputtering, one of the main tools of modern vacuum nanotechnology. Robida's atomic theory was innovative, but never had much of a real influence. Subsequently broader audience read Robida's quarrels with Krönig and Clausius about the fundaments of the new kinetic theory. Robida had some useful objections, but he was a little bit old fashioned and his criticism tried to stop new development of statistical dynamics that soon proved to be very successful. Therefore, despite of the good physics involved, Robida's line of thought had no future for the time being. Robida also discussed the early version of reversibility paradox. His mathematical treatment of atmosphere was very useful and could be compared with the achievements of Laplace and other researchers. Robida's physics was among the best of his time in Habsburg monarchy, and we hope that the neglect of his achievements was just contemporary. Robida should get the due recognition for his great scientific and pedagogic work for the 150th anniversary of his death on October 4, 2027.

Robida's very best students were the famous physicists J. Stefan and Peter Salcher. Stefan did not particularly like somewhat old fashioned Robida's theories, but he certainly learned a lot in Robida's classroom.

Robida was also interested in the history of physics and wrote a useful article about it as Stefan's class teacher. Robida's work was very popular among his contemporary high school students. Robida taught physics and mathematics in Klagenfurt for twenty-seven years and published several articles about atoms which were widely discussed all around Europe. He focused mathematical lecturing and early Stefan's works followed his path. A very good form master Robida's lectures during Stefan's final high school classes paved Stefan's path to fame.

The life and years of study of Slovene teacher Robida enabled his physical papers, the first book about physics in Slovene language and many mathematical, theological, scientific and practical works, mostly in Slovene language. Robida's mathematical pedagogical work influenced the similar Stefan's early publications.

Robida was the author of first book about physics in Slovene language, Stefan's teacher, and forerunner of the reversibility paradox. As most geniuses like Gauss, Stefan soon refused to respect Robida's merit. The physics and its political society's environment went through rapid changes with the spring of nations of 1848. The generation gap between Robida and Stefan proved to be too deep for the mutual understandings of their concepts in physics.

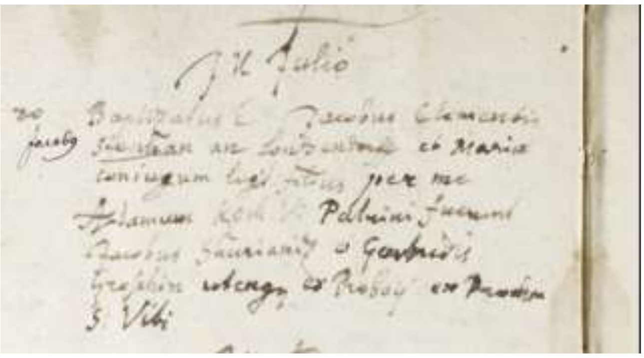

Figure 22-9: Clemens Stephan and his wife Maria as the paternal grandparents of J. Stefan's grandfather Joannes Stephan noted upon the baptism of their son Jacobus in 1687 (Baptism book of Carinthia St. Lancova-Lanzendorf in Škocjan pri Podjuni (Sankt Kanzian am Klopeiner See in Jauntal) page 34v. Godparents were Jacobus Škrjanc (Shurianiz) and Gertrudis Graschin et cogn (and her husband) ex Proboij ex parochia St. Viti (Proboy of parish St. Veit im Jauntal/Št. Vid in Podjuna).

The history of the research of radiation in the Physical institute of Vienna during Stefan's time made its great echo in works of other contemporaries. For the first time in the historiography our relation is established between Stefan radiation law and the simultaneous Edison's and other researches of vacuum incandescent lamp displayed on Stefan's electrotechnical Viennese exhibition in 1883. Few weeks later, Boltzmann's verification of Stefan's law followed Boltzmann's critique of Bartoli's opinion about the radiation in radiometer in vacuum. Therefore, direct connections of Stefan's law and vacuum research of his time is obvious. Stefan was a real godfather of his student Boltzmann even if it meant criticizing Stefan's compatriot Simon Šubic. Quarrels among physicists Stefan, Šubic, and Robida show that the cosmopolite enemy of travels Stefan preferred to promote the supporters of his kinetic statistic atomic ideas over his fellow Slovenian national feeling although Boltzmann's half Slovenian bride might carry some weight anyway.

The vacuum related research at the Institute of Physics of Jožef Stefan was great, probably it filled the early vacuum emptiness absence of Stefan's illegitimate father. The newly discovered archival material about professional and private life of Jožef Stefan and his relatives is used to prove the idea of DNA relations of the successes of talented guys on the ruins of the evil-destinies of his or her less fortunate relatives.

22.2.1 Introduction

Stefan-Boltzmann's story of success in physics Stefan-Boltzmann's story of success in physics ended in suicide. Their archenemy Mach earned fame despite of his son's suicide and Mach's posthumous success in philosophy made his positivism fashionable. We'll try to find out who was the real winner between their antagonist groups. If there ever was any possibility to win such an eternal fight at all between the invisible ultimately small particles and their positivistic criticism.

On the 10th and 18th of December 1879, Jožef Stefan published his famous radiation law for the first time for the Viennese Academy. It is still the single important physical law named after the Slovenian guy. Five years later, Boltzmann confirmed Stefan's law with criticism of Bartoli's radiation analysis in a vacuum radiometer. Therefore, it is right to mark those important innovations with some recent discoveries about the connections of Stefan's radiation studies with the then vacuum surveys at the physics which prepared itself for funny quantum jumps.[2746]

[2746] Many guys wrote about Stefan. Albert von Obermayer, Boltzmann and Eduard Suess' 1893: *Josef Stefan* had reminiscence aspects as Stefan's colleagues. Their follower was G. Jäger with his *Vortrag über Stefan in dessen Geburtsort…*, 1935. The Slovenian local Stefan's fans were Ivan Šubic, Lavo Čermelj, Janez Strnad, Sandi Sitar, and Josef Boncelj's 1958: Jožef Stefan und seine Tätigkeit auf dem Gebiet der Elektrotechnik. In: Sonderdruck der Zeitschrift *„Elektrotechnik und Maschinenbau*", 75th year, volume 24, pp. 666-674. Južnič added 2002. It seems that J. Stefan is on his victorious way to the recognition of his merits worldwide, a little late but from the bottom of many harts. J. Stefan was a mastermind behind the victories of kinetic atomism and statistical mechanic although he as the devoted Catholic was unable to fight Mach's opposition in philosophical grounds like Boltzmann did, and Stefan indeed died prematurely to put his name on quantum mechanics' flags.

22.2.2 Genial Stefan as the Illegitimate Kid

The talent is not enough. You need to give yourself a wind, and J. Stefan's illegitimate birth was a kind of tornado for his ambitions. If he was deprivileged by birth in all aspects, why not pose as cleverer than his classmates? The folks in Geiger's farmhouse loved the smart polite kid J. Stefan, but the opinion of all-prevailing church was decisive: he was a product of forbidden sin, whatever it might be. Period. Full stop. The kid J. Stefan was freak although he did not know that while it was not his fault at all. D'Alembert, B. Hacquet or Riccardo Felici's fathers were also not married to their mothers, but they at least claimed a great (noble) paternal descent which poor Jožef (Josef) was denied. The illegitimate descent was also far more focused by the other kids' ridicule in agricultural Klagenfurt suburb of Josef than in much more cosmopolite Paris or Parma. During the Vormarch Habsburg monarchy the illegitimate descent was even much more stigmatic than being a recent Jewish convert and stimulated the talents of illegitimates, if they had some abilities to spare.

Bericht des General-Secretärs. 257

Wunsch, einen eigenen Herd zu besitzen. Im Jahre 1891 verehelichte er sich zu Friesach in Kärnthen mit Frau Marie Neumann, Witwe des Staatsbahn-Inspectors Adolf Neumann, und diese Ehe ist ihm eine Quelle späten und kurzen, aber, wie aus der Veränderung seines ganzen Wesens sich ergab, überaus tiefen und innigen Familienglückes geworden. Seine Kindheit war so kalt und leer gewesen, dass er, wie er selbst gestand, niemals einen Christbaum gesehen hatte, ausser durch fremde Fensterscheiben hindurch. Im December des vergangenen Jahres war er von dem Gedanken beschäftigt, den Enkeln seiner Frau einen grossen Christbaum zu schaffen. Das war ihm neu und machte den berühmten Physiker glücklich. Noch am 15. December v. J. überreichte Stefan der Akademie eine Abhandlung „über das Gleichgewicht der Elektricität auf einer Scheibe und einem Ellipsoide". Am dritten Tage darauf, am 18. December, bei dem Besuche eines Freundes, wurde er in fremdem Hause von einem Schlagunfalle niedergestreckt. Die ersehnten Weihnachten brachte er in Bewusstlosigkeit zu und am 7. Januar entschlief er für immer.

Unser wirkliches Mitglied Dr. Anton Winckler wurde am 3. August 1821 zu Riegel bei Freiburg im Breisgau geboren; sein Vater war der dortige Adlerwirth. Unter beengten Verhältnissen absolvirte der junge Winckler seine Studien; er legte 1844 mit Auszeichnung die Staatsprüfung als Ingenieur in Karlsruhe ab und wendete sich von da an zuerst dem Studium der Astronomie, dann der reinen Mathematik zu. Seine Lehrer waren Nikolai in Mannheim, dann Dirichlet und Encke in Berlin. Im Jahre 1847 erhielt er eine Stelle als supplirender Lehrer an der polytechnischen Schule in Karlsruhe; 1851 erschien seine erste Schrift: „Nouvelle démonstration d'un théorème de Legendre" in Liouville's

Almanach. 1893. 17

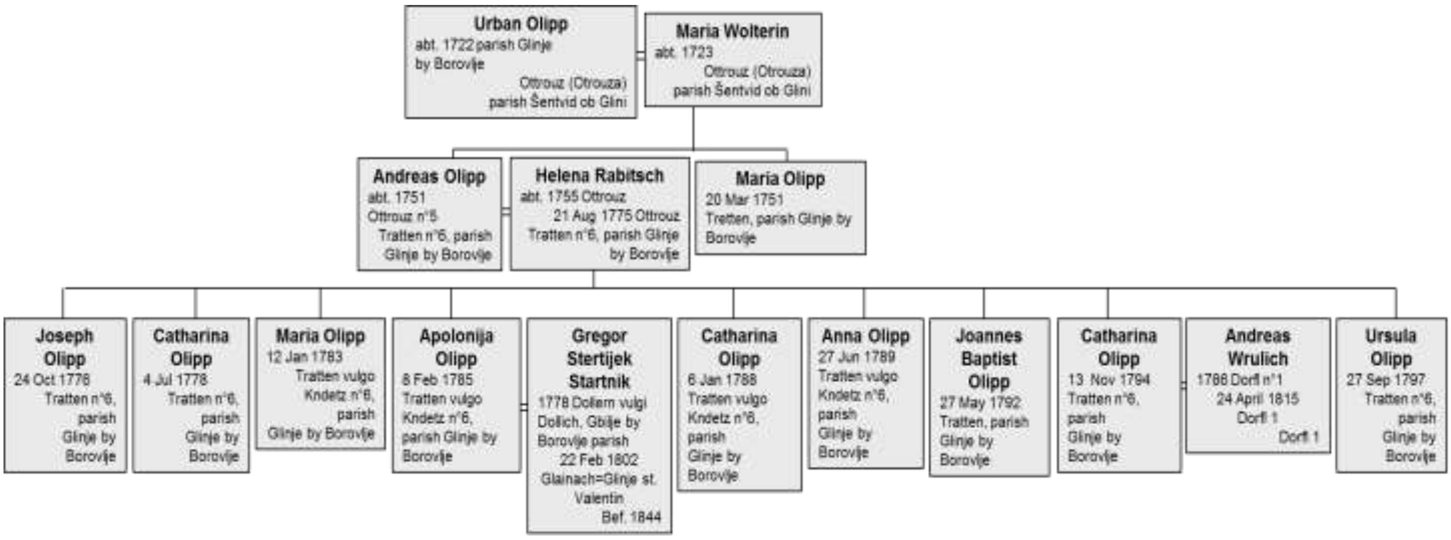

Figure 22-15: Stefan's ancestors on Olipp's branch

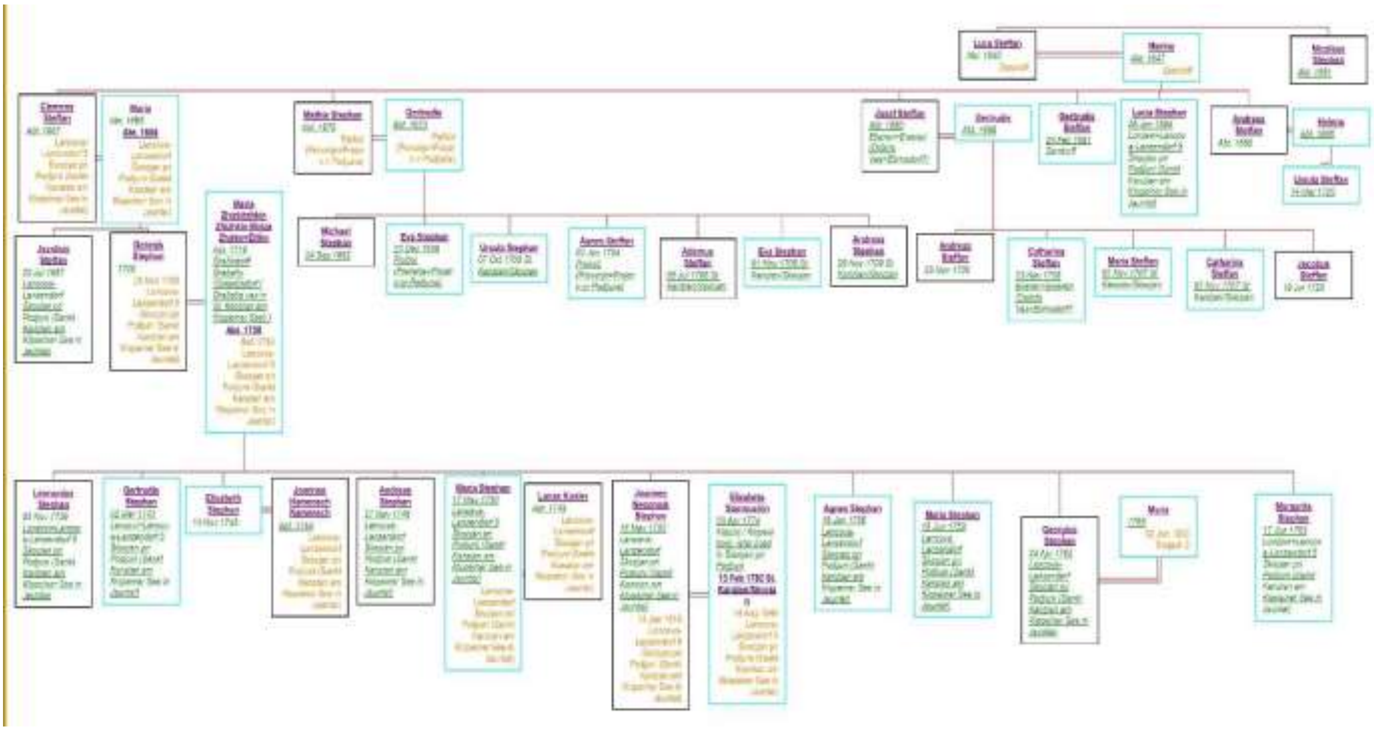

Figure 22-16: Stefan's ancestors on his father's branch

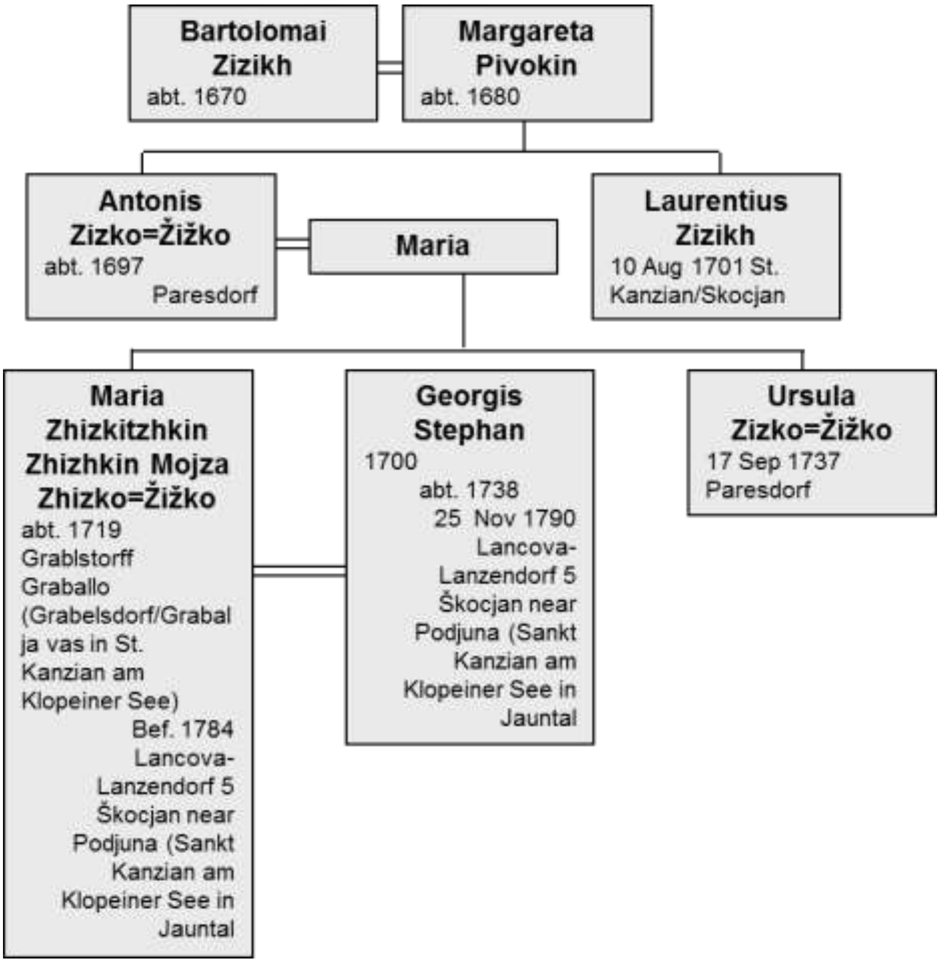

Figure 22-17: Stefan's ancestors on Zizikh's (Žižek) branch, just like the philosopher Slavoj Žižek

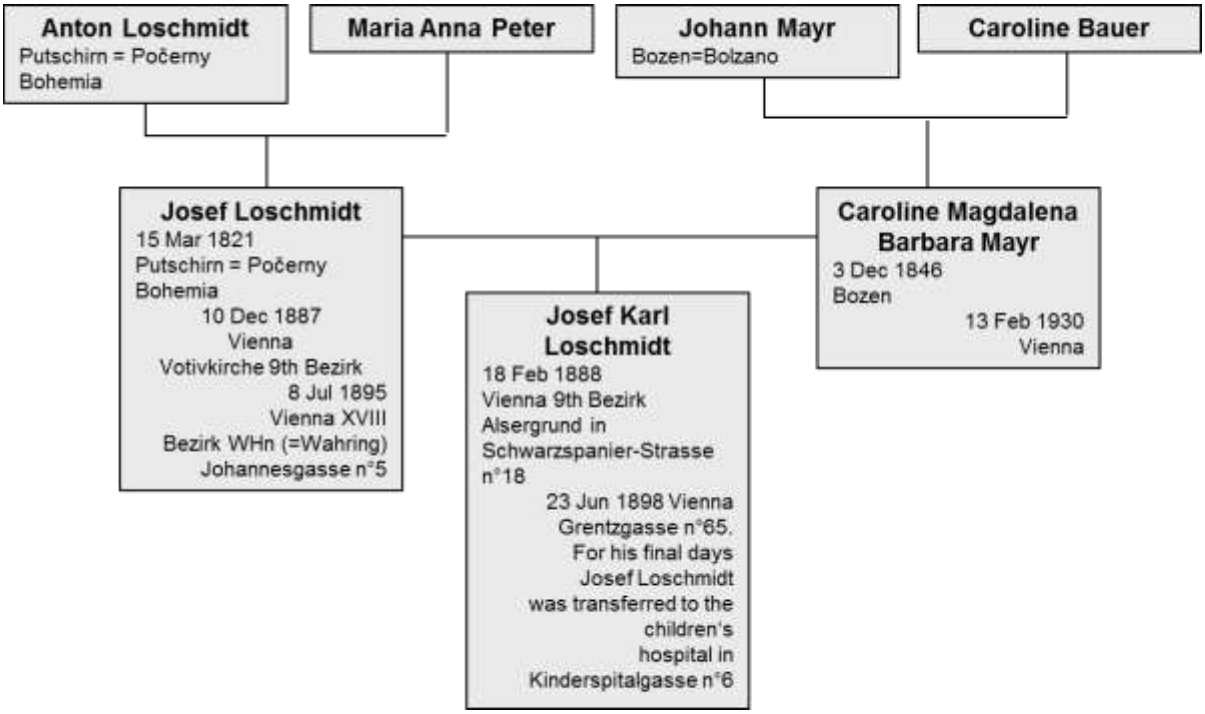

Figure 22-18: Loschmidt's family tree.

For many centuries Stefan's ancestors on his father's branch had managed a prosperous farm in Lancova no. 5 in the parish of Škocjan in Podjuna (Stefanhube in Lanzendorf Haus Nr. 5, St. Kazian, Sankt Kanzian am Klopeiner See, That is a part of a region of Velikovec (*Bezirk Völkermarkt*) where the Slovenian Carinthia native Gregor Slugovc-Sternad in ranch Gorničar) still run a family inherited farm with 24 ha of woods, 60 ha of farming soil, 25 caws, 10 pigs and his touristic capacities. There was not a lot of tourists in Stefan's time when the agricultural machines were rare and inadequate, while otherwise just nothing profoundly changed.

Figure 22-19: Funeral of J. Stefan's great grandfather Georg Stephan on 25 November 1790.

Figure 22-20: Baptism of J. Stefan's maternal grandmother Apolonia Olipp in 1785.

Jožef Stefan's mother Maria was the fifth of eight kids of country craftsmen who became a proletarian in the process of industrialization of early 19th century. She had to serve as farming helping hand in wealthy guys' farms around Klagenfurt to earn her daily bread. Jožef Stefan's father was next to the youngest of seven children, so he had to learn some craft in the suburb of nearby Klagenfurt. Čermelj's data of illegitimate birth of Jožef Stefan's father are false.[2747] Čermelj probably made his error because J. Stefan's grandfather Joannes Nepomuk Stephan (1753-1810 Lancova-Lanzendorf 5 Škocjan pri Podjuni (Sankt Kanzian am Klopeiner See in Jauntal)) died so early as he was for more than two decades older than his wife, J. Stefan's grandmother Elizabet

[2747] Čermelj, 1976, 10.

Starmushin (1774-1846 Lancova-Lanzendorf 5 Škocjan pri Podjuni (Sankt Kanzian am Klopeiner See in Jauntal)). J. Stefan remembered his randmother well and visited her in Lancova-Lanzendorf farm at No 5 Škocjan pri Podjuni (Sankt Kanzian am Klopeiner See in Jauntal), but even J. Stefan's mother never saw his grandfather
Jožef Stefan's father had no chance to inherit his native farm with all those elder brothers around. He had to learn some craft and milling was good as any other. When he met his almost a decade younger neighbour Marija Startinik (Stertizek) from Dollinch no. 9 of parish Glinje by Borovlje, she worked as a maidservant in the house-farm of Josip Geiger vulgo Franzl in St. Ruprecht or ore exactly in nearby hut nicknamed Franzlkeusche (Franzl's shack (kajža)). Josip Geiger could be probably connected with the modern Gasthof Geiger in Bad Sankt Leonhard im Lavanttal. Marija Startinik was from the prosperous manufacturers' family which preferred the traditional carpenter business around Borovlje (Ferlach) for many generations. Her mother's ancestors were all in traditional gunsmith trade which was and still is very successful business around Borovlje (Ferlach). Jožef Stefan was born in St. Peter in district (Bezirk) Ebenthal suburb of Klagenfurt in Ebentalerstrasse no. 19 on 24. 3. 1835 at 8 p.m. Josip Geiger was the owner of that family house St. Peter no. 19 while he also owned no. 11. A kid Jožef (Josef) was born in lateral building of St. Peter no. 19 where his mother lived as a maidservant. The house belonged to the Klagenfurt suburb mayordom of St. Rupert.[2748]

Next day on 25. 3. 1835 at 3:30 P.M. the newborn kid was baptized in the Klagenfurt church of St. Lorenz east of the Klagenfurt downtown.[2749] In index, his baptism was first noted as Startinick Josef ill(egal), but later repaired into Stefan Josef after he was legitimized in 1840s. Many others did not have that luck.[2750]

Josef's midwife was Theresia Staskier from Volk: Vorstadt Klagenfurt no. 10 Wohnstat. His godfather was Joseph Hebernigg (Habernigg) vulgo Gartner. He was a settler (Kauschler, Gartenkeuschler) from St. Peter Ortschaft nearby. He was married to Maria Rabasser who performed his godparent duties for him. She was probably related to J. Startinik-Stefan's great grandmother Helena Rabitsch from Ottrouz. Josef Startinik-Stefan's godmother was Ana Startinik (Anna Startinigg), the younger sister of his mother. J. Stefan's godparents were not some wealthy guys who could indicate that J. Stefan-Startinik's father might be a rich man.

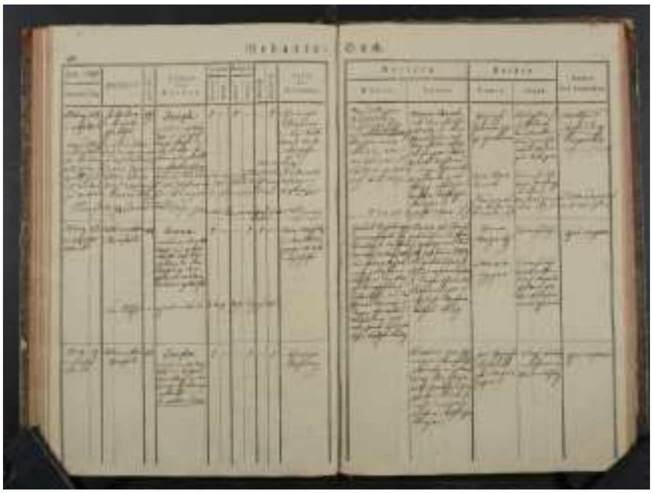

Figure 22-21: Baptism of J. Stefan in 1835.

J. Stefan-Startinik's father was noted as flour-trader (flour-merchant, Mehlhandler), a legitimate son of a farmer (Bauer) born in neighboring parish of St. Kanzian (Sankt Kanzian). On 16 August 1843, Josef Startinik-Stefan nearly got his eight years younger first cousin from his godmother Ana. As unmarried single seamstress (Ledige Nahterin) Anna gave birth to the dead boy. She was noted at Klagenfurt-St. Lorenzen church baptisms as: "von Ebenthal gebürtig, Tochter der Gregor Startinigg Zimmerman & Appolonia in Ebenthal gebürtig". Hebamme (midwife) was Anna Arschitz, but she had no luck. The priest Simon Heber (Hebamn) performed the baptism of poor kid who lived just for few minutes (Morth-Getauft, page 63, Klagenfurt-St. Lorenzen baptism book Geburtsbuch VI). Ana (Anna) lived in Volk. Vorstadt (Folk's Suburb) no. 46 in the suburb of Klagenfurt not far from her sister Maria and Maria's little son Jožef Stefan. None of both sisters got any other children at least they did not have them baptized at Klagenfurt-St. Lorenzen church. Both sisters had problems. Maria was from parish Gleinach while Ana was from Ebenthal to where their parents moved after Maria's birth, certainly in

[2748] Čermelj, 1976, 9.
[2749] Klagenfurt-St. Lorenzen K20_005-1 (book of births) V page 54.
[2750] St-Lorenzen/K20_005-Alph. Index zu den Geburtsbüchern, Kopie K20_037-1. His mother was noted as: "Maria Startinik Dienstenege, gebürtig in der Pharr Gleinach Bez: Hollenberg des Gregor Startinik Tichlers (carpenter)…"

1815 or 1816. Maria worked as maid-hand on a farm, while Anna was a seamstress in the sewing trade. Their younger brother Simon was born in 1820, but again in the different place in baron Rosenberg's castle Rossenegg no. 2 of parish Ebenthal which tells about the frequent resettlements of their father carpenter Gregor Startinegg from one job to another while fathering at least eight children to his productive wife Apolonia. Gregor and Apolonia's first children were born in Ferlach (Borovlje) no. 44, 42 or 43, the next one in Dollinch no. 9 of Glinje by Borovlje. Anna appeared in Gradnitz no. 17 of parish Ebenthal, Simon was born in Rossenegg no. 2, parish Ebenthal and the last child came to this world again back in Ferlach no. 56 domestically called Umniggin. Their father's most prosperous job might have been carpenter and settler (Zimmerman und Inwohner) position in Rossebegger (Rossenegg no. 2, Kedusche, today pub Rosenegg) castle built by baron Rosenberg in Fieberbrunn in Tirol 30 km northwest of Stadt Zell am See of Salzburg areas. Their son Simon had his funny godparents there: Simon Rinkisch vulgo (domestically nicknamed) Rossenegger from the castle and Anna Stephun vulgo Lamglind. The family Stephun might have been remotely related to the family Stefan (Stephan). In 1760s the silverer Johann Michael bought the resold Rossenegg to develop the brewery and a restaurant in the castle. In 1769 the castle was sold again to a mining trust from Salzburg which housed their stewards in the castle. In 1820 when Simon Startinek was born there, the castle Rossenegg was in possession of its last private owner, namely Franz von Lürzer. Lürzer gave Gregor Startinigg some temporary carpenter's job there. In 1842, the castle became the Habsburg k.k. Oberforstamt in Rosenberg as a centre of local forestry.

Gregor Startinigg had something like that travelling carpenter business put into his cradle as he was fifth of six children but the only one whose baptism was for one reason or another not noted in his parents' house Dollinch no. 10 nicknamed (vulgo) Zimmerman in parish Glainach=Glinje. Certainly, he never went far except for Fieberbrunn in Tirol 200 km northwest from Klagenfurt. Otherwise he worked mostly around the central Carinthia in suburbs of Klagenfurt, Ebenthal, Gleinach and Ferlach (Borovec) full of firearms production which needed a carpenter hand for the wooden parts of the guns. Jožef Stefan's experimental skills was a heritage of many carpenters, metal workers as wire pullers at the city silver nail manufacture of Ferlach[2751], and gunsmiths among his ancestors, especially those from Ferlach (Borovec).

Figure 22-22: Baptism of J. Stefan's uncle Simon Startinek in 1820.

Figure 22-23: Baptism of J. Stefan in index of baptisms where he was noted under his unmarried mother's family name.

Maria Startinigg inherited some of her father's travelling business soul. Maria's alleged lover Alex (Aleš) Stefan worked at the "Großnigbauer" of Franz Puntschart as a miller's assistant in the neighbouring settlement in Limersach (Limmersach, Limarče) not far from Geiger's house. Franz Georg Puntschart (1816–1872) also operated a mill as well as another mill on the Glan river and collected paintings of his factories. The Puntschart family even owned the white-lead factory in Ebental by Klagenfurt. Franz Puntschart who died in 1890 opened subsidiary company in St. Veith in 1858. His business was granted several awards for the quality of his product until it was closed in 1890. The industrial revolution with accumulation of the capital, changing of landscape with factories, and wondering poor proletariat was

[2751] page 74 of F05_022-1 Ferlach Sterbebuch IV on 21. 8. 1848 noted J. Stefan's grandfather's first cousin Joseph Startinik (1771-1848 Ferlach no 42) who worked as the puller of wires at the city silver nail manufacture (Dracht Zieher an der B.(Burgerliche) Silber Nagel-schen Gewerkschaft.

in full advance in J. Stefan's juvenile years. The carpenter business of his countryside ancestors was in disadvantage compared to the city carpenters because just town carpenters were able to keep their guilds during the era of Vormarch.

Maria's younger sister Anna Startinick also worked for Franz Puntschart in the nearby town of "Limersach (Limmersach, Limarče)" as a servant girl at the Großnighof according to Westritschnig's data published in 2012. Therefore, she abandoned her earlier sewing craft for a servant job resembling the one her elder sister Maria had. The owner of the Großnighof and the mill on the Glan river was the big farmer and miller Franz Puntschart. Therefore, Anna Startinick used to work for the same boss as did her sister's lover Aleš (Alex) Stefan which enabled Anna to play the role of a kind of in between messengers of the illiterate but devoted sweethearts. Puntschart was a great boss and his family was too mighty to use Glainach (Glinje) church for their weddings and baptisms. Puntschart was a great businessman worldwide while the Geiger family was prominent only locally although Geiger was also well-to-do guy. The gap between the folks who had enough capital to use the opportunities of the early industrial revolution and the other who did not widened very quickly. J. Stefan's ancestors were on the wrong side of moneymaking luck.

Figure 22-24: Baptism of J. Stefan's aunt and godmother Anna Startinik in 1817.

J. Stefan's father could have confessed to the priest that he fathered a child at the first place as it is hard to recognize any deep difference between the inks in notes of J. Stefan's father and J. Stefan's mother in J. Stefan's certification of baptism. But in the index of baptisms the kid J. Stefan was noted as illegitimate child with his mother's surname, so the father was certainly added somewhat later, maybe only after the legitimization of a kid. The priest usually left the blank rubric for fathers always in hope for legitimizations, but they didn't always get the willing men straightaway. Some funny priests even kept their separate books for the baptisms of the illegitimate kids as a threat for their illiterate believers and their secret prohibited love stories. J. Stefan's father traded with flour[2752] and sold his stuff as traveling merchant without a fixed home position before he prospered enough to marry J. Stefan's mother and enable J. Stefan's chances of advanced studies.

Figure 22-25: Sad funeral of J. Stefan's youngest aunt, the six years old Katharina Startinik in 1829.

Figure 22-26: Marriage of the house owner and boss of J. Stefan's mother named Josip Geiger in 1838.

When Jožef Stefan was a little over three years old, there was a huge fest in his boss' house. Josef Geiger and Maria Strutz's son Josip Geiger married Maria Schnitzler (* 1817) at St. Peter no. 19 on 30. 7. 1838. The groom was „the owner of technical plate separator or constructor at Grafenstein as a son of still living Ferlach owner Joseph Geiger of Peterheb No. 19 Besitzer der Scheider nach Hause zu Grafenstein (Grabštajn 12 km east of Klagenfurt) sub Haus No. 11 des nachlebenden Joseph Geiger Besitzer in Ferlach

[2752] Čermelj 1976 10.

verliebte unter allen Peterheb No. 19." One of the marriage witnesses was illiterate Matias Jäger.[2753]

22.2.3 Marry or not to Marry, That is the Question on the Eve of Spring of Nations Revolutions in 1848

The fathering of illegitimate children was a kind of habit in the family of J. Stefan's father which probably provided some obstacle for the marriage of juvenile Stefan later. The youngest of J. Stefan's uncles, Aleš's younger brother Mihael Stephan (* 29 September 1802 Lancova no 5 Škocjan pri Podjuni = Lanzendorf Sankt Kanzian am Klopeiner See in Jauntal) also fathered an illegitimate kid named Simon Jarz (*3 April 1842) in Sankt Kanzian (Škocijan) no. 8 near Eberndorf (*Dobrla vas)* east of Klagenfurt. He loved a peasant girl from a farm nicknamed (vulgo) Skrutel of Sankt Kanzian (Škocijan) no. 8. The nice maid was Barbara Jarz. The mother of family Jarz with that nickname could be related to Gaspar Skrutel and Maria's farm of Eberndorf no. 11 where their legal son Sebastian Skrutel was born on 19. 1. 1820 in Eberndorf no 5 vulgo Kanzian. The other family Skrutel had their kids born there on 24. 10. 1827 and on 22. 5. 1836. There were two illegitimate kids named Simon born in Eberndorf parish up to 1836. The illegitimate Ana Puschel's son Simon Puschel was born in Gösslssdorf no 15 of Eberndorf parish on 23. 10. 1829. On 22. 10. 1832 in Eberndorf Simon Puljer and Agnes Maiserl's daughter Maria gave illegitimate birth to Simon. Jarz family had no baptisms in Erberndorf parish of those times, but there was the similar Janzko family in Eberndorf no. 24.

On 14th March 1883, Jožef Stefan's first cousin named Simon Jarz married sixteen years younger already for six months pregnant very willing girl Anna Rigelnik on the farm Eberndorf no. 11. There Simon Jarz and Anna had three daughters and finally also a son Simon in 1883-1891.[2754] Simon Jarz probably helped in the farming in Eberndorf no. 11 and did his job all too good. It did not help much that there in Völkermarkt (Velikovec) District of Jaun (*Podjuna*) Valley the Jesuits used to have their main residence with the huge noviciate for the successful financing of their Klagenfurt college up to 1773. Mihael was even somewhat worse than his younger brother Aleš, as Mihael never bothered to marry his lover at all which was certainly not the behaviour which the Jesuits approved.

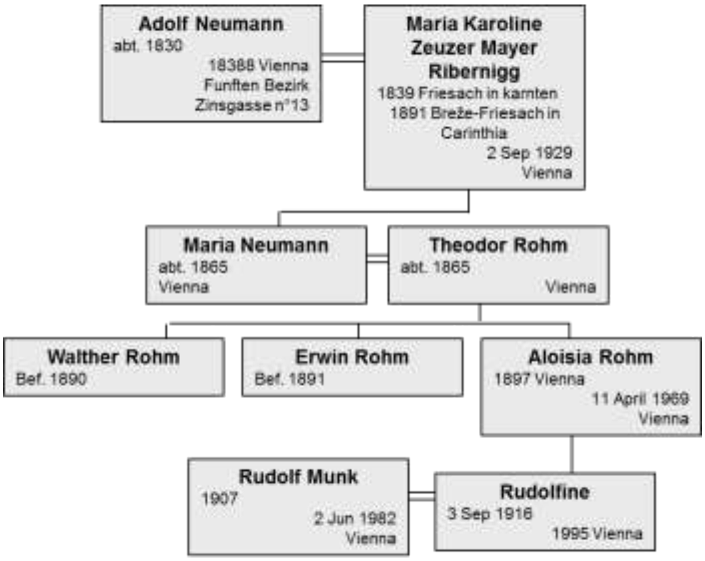

Figure 22-27: Descendants of Stefan's wife.

Figure 22-28: Marriage of J. Stefan's first cousin, Simon Jarz in 1883

The dreams of J. Stefan's mother that her boss could marry her were finally over for good. Did she like her Geiger boss anyway? Had Josip Geiger anything to do with Josip Stefan's birth at all? If yes, Josip Geiger was certainly able to pay for Jožef Stefan's studies, to give him a proper surname after arranging J. Stefan's marriage which was certainly condition sine qua non for his studies. Josip Geiger died just few weeks after Jožef Stefan, but in his later years after his mother and father died in 1865-1872, J. Stefan ceased to visit Carinthia until his own marriage which had allegedly something like reprise in Breže (Freisach) votive church of Carinthia in 1891. J. Stefan's bride was Maria (1830-1929) supposedly from Friesach in Carinthia (Kärnten), the widow of Adolf Neumann. She might have been related to

[2753] K20_016-1 Trauungsbuch II Klagenfurt St. Lorenz 2: 71; Geburtsbuch III K20_003-1 Klagenfurt St. Lorenz 3: 5.

Loschmidt's wife Caroline Mayr as Maria's maiden name was Zeuzer, Mayer, or Ribernigg which were the family names of all girls named Maria who were born in Breže on 1839 except for two girls named Maria who died very young.

Figure 22-29: Loschmidt's marriage in Votive-Church in 1887.

On 10 December 1887, Stefan's long-time roomie the sixty-six years old Josef Loschmidt (married his long-time lover and housekeeper unmarried (Ledig) Caroline Magdalena Barbara Mayr (1846 Bozen-13. 2. 1930) for the next eight years of their married happiness and Stefan followed his example four years later. In Vienna, Loschmidt's quarter of century younger wife Caroline hosted her nephew's wife or her niece Karoline Mayr (23. 2. 1885-13. 12. 1950) who was not baptized in Votivekirche. Loschmidt and Caroline decided to marry only after their son was on his way to be born to enable his future studies, but they did not think about their age as they were more than a century old altogether when the poor sick kid was born. Loschmidt's best man was a chemist Ludwig Barth von Barthenau (17. 1. 1839 Rovereto in Trentino-3. 8. 1890 Vienna) who served as a Dean of Viennese Faculty of Philosophy in 1885/86 and has a monument in arcaded court of faculty of philosophy erected in 1892. Ludwig Barth Ritter von Barthenau studied chemistry in Munich with Liebig (Dr. phil. 1860). He joined military missions in lost Sardinian war in 1859 in Academic Legion and in lost war against Prussians in 1866. Barth was a professor in Innsbruck in 1867 and moved to Vienna in 1876 as Professor of Chemistry at the University of Vienna where he taught until 1890. In 1876 he became a corresponding member, and an ordinary member of the Academy of Sciences (Math.-naturwiss. Class) in 1879. In 1880 Barth was a co-founder of the "Monatshefte für Chemie". Barth was a member of the Supreme Medical Council, promoted the Austrian Pharmacopoeia, discovered the resorcinol and successfully researched benzene derivatives as well as the action of potash fusion melt on organic substances. He was k. k. Hofrat and lead the executive committee of the Chemistry Laboratory. As an alpinist he explored the Stubai (Stubaier) Alps mountain group published in a monograph. In 1887, Barth lived in 9th Bezirk Wassergasse no. 9. The other Loschmidt's best man was Lawrenz Schons (Sohous, Sotious) k.k professor in pension from 2nd Bezirk Franzenbrukensreasse no. 24 who previously lectured in Viennese High School and had Bohemian ancestors according to his family name. J. Stefan was a good Loschmidt's friend, but not good enough for his best man.

Less than two months after their marriage their son Josef Karl Loschmidt was born. As he was not a strong child, he was baptized only after a month in Votive church. His godparent was Josefa Platider (Plakider) as shareholder (Winkschäfterin, Wintschäfterin) from Wassergasse no. 9 at Barth's 9th Bezirk. The midwife was Leopoldine Schima from Währing Hauptstrasse no. 17. J. Stefan was again not considered as a godfather.

The other Karoline Mayr lived as a widow of Sector Rath (Sector Counsellor) under the name Karoline Mayr-Miller in 3rd Bezirk in Rennweg no. 3. Sadly enough, Loschmidt and Caroline Mayr's only son Josef Karl Loschmidt (18. 2. 1888-23. 6. 1898) had a funeral on next day after he passed away.[2755] The poor son Josef Loschmidt had died soon after his father at the age of ten of Scarlach (scarlet) after his sickness in his family home in Gentzgasse no. 65. For his final days Josef Loschmidt was transferred to the children hospital in Kinderspitalgasse no 6 with a funeral ceremony performed in nearby Waehring (Währing) on 24. 6. 1898 (not on 27. 6.!). His baptism, his father's marriage or his father's funeral were not in that church three years earlier because the poor kid was eventually put in that church only because of convenience as the children's hospital he died in was near and the hospital usually used that church for funerals, while the family Loschmidt mostly used for their ceremonies some other Viennese church outside their domestic 18th Bezirk.

Caroline Mayr married Loschmidt died just few months before J. Stefan's widow Maria. Loschmidt

[2755] in 18 Waehring by Sterbebuch 03-18 page 57 (no funeral was noted in 18 Gersthof Sterbebuch 03-03 or 18 Poetzleinsdorf Sterbebuch 03-02; 1887 Votivkirche 9th Bezirk page 48 marriage note 136, 1887 Votivkirche 9th Bezirk has baptism listed at page 5 5 note 13; Adolph Lehmann's allgemeiner Wohnungs-Anzeiger 1885 p. 685.

once wrote his paradox on banknote in a pub for Boltzmann and Stefan. Until Loschmidt's marriage, Loschmidt and Stefan lived together in their official laboratory and classroom building at Türkenstrasse no. 3 in 9th Bezirk of Vienna called Alsergrund.[2756] In 1887, as a married man with a son, Loschmidt moved to the new location nearby in the same 9th Bezirk Alsergrund in Schwarzspanier-Strasse no 18, but Loschmidt's kid was not baptized in any of three churches in that Loschmidt's 9th Bezirk in or in his newly married wife's former 3rd Bezirk.[2757] For Boltzmann, Loschmidt was a type of scientist without a real touch with reality, but in that love-affair case Loschmidt proved Boltzmann's error. Stefan was certainly a little bit jealous upon the success of his long-time friend and collaborator, therefore he soon began to courtship the new housekeeper who replaced Loschmidt's pregnant wife after her previous husband died. The authorities were certainly clever to hire all the time the very best middle-aged housemaids for those funny clever bachelor physicists and Stefan was soon in the net.

Figure 22-30: The baptism of Loschmidt's only son in Votive-church in 1888.

Upon Stefan marriage, in October 1891 Loschmidt retired to his quiet family life in favour of the new boss of *Zweites Physikalisches Institut* Franz-Serafin Exner (1849 Vienna-1926 Vienna). Loschmidt lived in XVIII Bezirk Whn. (=Währing) at Johannesgasse no 5 in north-western Vienna as retired professor in the year 1892. He received an order of iron crown for his merits. In his final last years he suffered a lot in his last very modest flat in Lacknergasse of 18th Bezirk Währing where Boltzmann visited him and sarcastically declared that's the way how Habsburg pay their great man. In 1894, the street was named after Matthias von Lackner just few months before Loschmidt passed away there. Loschmidt's funeral was not in any of the churches of XVIII Bezirk Währing. Loschmidt's widow still lived in 18th Bezirk Währing but in Gentzgasse no. 68 (65) upon the death of her kid in 1898. In 1894 that street was renamed to Metternich's fellow politician known for his bisexuality Friedrich von Gentz (1764-1832). Before that time in 1892, Stefan lived in his official rooms in Türkenstrasse no. 3 as member of information trust for public curricula of religion and sciences (Mittglied der Normal-Aushangs-Emsn. EZ für Kultus und Wissenschaften, Offic, de l'instruc. Public).[2758]

Stefan's bride was a widow of comparatively important official Adolf Neumann. Adolf's relative Friedrich Neumann began to work for the developing local railways (Staatseisenbahn-Beamten) as the inspector of railways in Villach in 1883, the railway Ober inspector in Linz in 1884-1887 and finally in Bureau 4/e für den Wagen-Control (in 1888, transformed into Wagendienst in 1889 and after) of k.k. General Direktion der österreichische Staatsbahnen in Wien. Friedrich Neumann was still at work as Staatsbahndirektors in 1891 but no more when the other Ober inspector Victor Marek replaced him in 1892.[2759] Friedrich Neumann did not have a funeral in Viennese votive church as did J. Stefan less than two years later. In 1859 the Votivkirche was erected very close to Stefan's flat to commemorate the failed assassination attempt focused on emperor's brother, who met his firing squad in Mexico anyway.[2760]

Most source[2761]s noted Maria's husband Neumann as Adolf, while no Adolf Neumann appeared among the listed state or court employed inspectors of railways in the Habsburg empire high positions of those times. In fact, no Adolf Neumann was employed in Habsburg court or state jobs in 1858-1892 as Maria's husband Adolf Neumann from Friesach in Kärnten (Breže in Carinthia) probably worked for private Rothschild's railway company. In 1859, Adolf Neumann was not noted as engineer among the Viennese inhabitants. In 1860-1861, the engineer assistant Adolf Neumann lived in the Viennese Penzing Haupt Straße no. 93. In 1864, the engineer assistant Adolf Neumann lived in Bhschg. (Bischof Gasse Meidling 12th Bezirk) no. 197. In 1865, the engineer assistant to West Railway Adolf Neumann lived in the Viennese Rstd. (Rudolfstadt) no. 197. In 1867-1876, the engineer assistant to West Railway (bei Westbahn) Adolf Neumann lived in Rdlföh. (fifth district called Margareten) Schönbrunnerstrasse no. 19. In 1877-1881, Adolf Neumann was the Ober engineer der Wien Bahn (1877, 1878, 1880, 1881) and later Ober engineer der k.k. Dir. für St E Bahn Bettr. in 1882-1885. In 1877-1885 Adolf Neumann lived in Fünf. Bezik (fifth district called Margareten) Schönbrunnerstrasse no. 10, at least in 1881-1883 together with his son-in-law residing at the same address. Adolf Neumann was there no more in 1886 as he moved to a better flat. In 1886, the inspector der k.k. Gen. Dir. der (österr.) St. Bahnen (Österreichische Staat Bahnen, State Roads) Adolf Neumann lived in VII Bezirk Neubau in Zollergasse no. 6. In 1887-1888 he lived in 15th Bezirk (Fünfh.= Fünfhaus) Rudolfsheim-Fünfhaus Zinkgasse (Zinckgasse) no. 13. In the year 1889 he no more lived there and his widow Maria did not take over the flat. J. Stefan's stepdaughter Maria Neumann also did not take over that flat. Although many other Neumanns lived and died in 15th Bezirk, Adolf Neumann did not have his funeral ceremony in any of both churches of 15th Bezirk, Reindorf or Fünfhaus, in 1887-1889. Adolf Neumann's baptism, marriage or funeral was not noted in Friesach in Kärnten,[2762] and his funeral was not listed in Viennese votive church or in Viennese Catholic or Jewish cemeteries.

Adolf Neumann's daughter Maria Neumann married Theodor Rohm. Theodor Rohm was not noted as a person living in Vienna in 1876-1880. In 1881-1883, Theodor Rohm was an accountant (Buchhalter) of baron Rothschild's domains and lived in his father-in-law flat in 5th Bezirk in Viennese Schönbrunnerstrasse (Schönbrunner Straße) no 10 of 5th Bezirk Margareten just east of 4th Bezirk Wieden which contained Schönbrunner Straße up to no. 9. In 1884-1886 he kept the same job but left his father-in-law flat and lived in the Viennese VIII Bezirk in Piaristengasse no. 15. In 1889 Theodor Rohm advanced in Rothschild's networks to become a Cassa-Amt. der Bankhauses S. M. von Rothschild (Salomon Mayer von Rothschild, 9 September 1774 – 28 July 1855), in fact of his grandson Albert Salomon Anselm baron Rothschild (October 29, 1844 – February 11, 1911) who owned the Viennese Kreditanstalt (Creditanstalt) and the first Habsburg railway called Emperor Ferdinand Northern Railway (*Kaiser Ferdinands-Nordbahn*, KFNB). In the year 1889 Theodor Rohm lived in the Viennese VIII Bezirk in Piaristengasse no. 15, and he was a private Beamter (Official) in Viennese VIII Bezirk in Florianigasse no 44 on the north of his former apartment in the year 1892. In 1890-1892, Marie Neumann as the Bahn-Inspector's widow lived in Fifth Bezirk Margareten in Schönbrunnerstrasse no 5, which later became 4th Bezirk Wieden up to Schönbrunnerstrasse no 9. She was no more noted there in 1893 and later because she married J. Stefan in 1892.[2763] That could mean that Adolf Neumann's flat in 15th Rudolfsheim-Fünfhaus Bezirk Zinkgasse (Zinckgasse Fünfhaus) no. 13 belonged to his railway company, probably the North Rothschild's one, and his widow did not inherit it as she preferred to move nearby to the same fifth Bezirk near their old flat because she settled in Schönbrunnerstrasse no. 5.

What about J. Stefan's marriage? In 1875, Bismarck introduced civil common-law marriages in newly unified Germany, but that French revolutionary or British habit was not introduced in Austria before the Anschluss of 1. 8. 1938. There

Figure 22-32: J. Stefan's future wife Marie Neumann as the widow of the inspector Adolf Neumann on page 816 right 28th from the bottom living in Schonburgerstrasse 5 and waiting for J. Stefan as his housemaid in 1890 J. Stefan's was already courting that willing widow by then, although he should better wait a little bit.

was no real possibility for civil marriage for J. Stefan even if he wished to have one in Habsburg monarchy in 1891-1892. Anyway, J. Stefan's marriage was not noted in Breže,[2765] Klagenfurt or nearby, and not in major Viennese churches including the Votive church in Vienna where he had his funeral ceremony somewhat more than a year later, or in other churches in Stefan's domestic Viennese Bezirk. J. Stefan was not married in the Viennese churches of the district where he and his fiancé used to live.[2766]

After the marriage, the new Stefan couple still resided in Türkenstrasse no. 3. After Josef Stefan passed away, his widow had to move from that University flat and she went to live in the Piaristengasse no. 34 in 1894-1899. Her new flat was almost next door to the previous same street house of her daughter and son-in-law Theodor Rohm who lived there in 1897-1907. There the previous private official Theodor Rohm was noted as the chief of bureau of international Society for Electricity who now lived as private official in nearby 8th Bezirk Floriangasse no. 44 in 1892-1894, and in 8th Bezirk Lenaugasse no. 2 in 1897-1907. Previously the private official Theodor Rohm was noted there as the chief of bureau of international Society for Electricity (Bureauchef der Internationalen Elektrizitäts Gesellschaft, IEG) in 1905-1907, but no more in 1908-1909. Theodor Rohm was born in Neustadl in Bohemia in 1848/1849. He died on 10. 1. 1907 in Viennese 8th Bezirk Lenaugasse no. 2. His funeral ceremony

Figure 22-33: The funeral of the husband of J. Stefan's step-daughter Theodor Rohm in Maria Treu church in 1907.

was in nearby Maria Treu church of 8th Bezirk, north of Friars Minor Conventual monastery (Minoriten kloster). He was killed by the degeneration of his throat (Entartung des Rachens). He was buried in cemetery (Friedhof) Baumgartner on 12. 1. 1907. Theodor Rohm's father was a foreman master (Stürseher maister, Stürschermaister) in Bohemia in 1879. Theodor Rohm's younger brother Maximilian Eduard Rohm (* 30. 1. 1855 Neustadl (Náchod or Nové Město nad Metují) in Bohemia) was also the Viennese accountant (Buchhalter) in 5th Bezirk Margareten, at Grüngasse no. 25 just one block north of Theodor Rohm's Schönbrunnerstrasse. Therefore, the brothers in the same business get along very well, although Theodor Rohm was never a godfather to any of his nephews or nieces born in Viennese Grüngasse no 25 of 5th Bezirk in their domestic church St. Josef zu Margareten in 1881-1884. Maximilian Eduard Rohm got that flat in Grüngasse no 25 upon marriage and lived there with his father-in-law the master carpenter Ignaz Kreutz, his wife Maria Eva Siebert and their younger unmarried daughter Theresia Kreutz. Theodor Rohm got his first flat in Schönbrunnerstrasse no. 10 in fifth Bezirk in the same way upon his marriage as did his brother Maximilian Rohm. Theodor Rohm lived there with his father-in-law at least in 1881-1883, when his son Theodor Rohm (1883-27. 1. 1953) was born; Theodor Rohm junior died when he was 70 years old in the Viennese district of Hernals. They were all not far from J. Stefan's flat, that's why J. Stefan expected a great Christmas tree in 1892.

Theodor Rohm's boss was Miksa Déri (Max, 1854 Bács (Bač in Vojvodina-1938 Merano). The merchant Moritz Deutsch's son, Miksa Déri began his studies at the TU in Pest (Budapest) and continued from 1873 at the TH Vienna with his absolutorium in 1877. Until 1882 he worked on river regulation of the Danube and Tisa (Tisza) while he turned his attention more and more to electrical engineering. In 1878 in Budapest, Déri published the anthology of Faraday and Helmholtz's popular works. In 1882 Károly Zipernowsky, founder and head of the electrical engineering department of the Budapest company Ganz & Co., appointed Déri to his company. Among their joint inventions was a self-excited alternator (1883), in which the rotor was energized by rectified terminal voltage. The rectification was done by the rotor commutator mounted on the axis while a separate exciter machine was not necessary. The fact that the machine could be also used as a single-phase synchronous motor was very important in the "pre-rotation times" of the 1880s, because the distribution of alternating current was severely limited due to the lack of suitable motors. From 1883 on, Ottó Titusz Bláthy joined their efforts to develop step-down AC transformers while Tesla designed step-up AC transformers after all o them worked in Budapest in early 1880s which was a cradle of AC like it become the cradle o USA manufactured atomic om six decades later. The three Ganz geniuses patented their most important invention, the closed iron core transformer, in 1885. Other important inventions of Déri were the one- and two-phase Einankerumformer (1888, together with Zipernowsky), a compensated DC machine (1902), a single-phase repulsion motor and the Déri's motor (1904) with a fixed and a rotatable brush pair, in which the brush adjustment speed and direction of rotation could be changed. This engine was preferred in single phase networks and was used for passenger lifts. From 1883 in Vienna Déri was a representative of the Electrical Department of Ganz & Co. and Director of the International Electricity Society (IEG) in 1889-1896. The IEG was founded to finance power plants and their first power plant in Vienna was put in operation in 1890. In addition, he was a member of the board of the Austrian Union Electricity Company (Österreichischen Union-Elektrizitäts-Gesellschaft) and the Hungarian Electricity Company, as well as consultant to BBC, Stanley Electric and General Electric. Déri retired in 1923. He continued to work in the academic field. In 1908 he became a Hungarian court councilor, in 1910 he became a doctor of Technical Hochschule in Brno, and in 1913 he was appointed honorary member of the Electrotechnical Association in Vienna. Like

Tesla, he was born in later Yugoslavian areas whole he spent his last days in Tyrolean Merano.
The International Electricity Company (IEG) with J. Stefan's relative Rohm included was one of the three private electricity companies that received concessions for the construction of electricity plants in Vienna in the 1880s. After the concession was granted to it on March 27, 1887, the Wiener Elektrizitäts-Gesellschaft (WEG) entered direct competition with the Allgemeine Österreichische Elektrizitäts-Gesellschaft founded in 1889, and the Internationale Elektrizitäts-Gesellschaft. The IEG owned the steam-electric power station (Dampfzentrale 2) at Engerthstraße 199 (which was redeemed in 1908 by the city of Vienna during the municipalization of the power stations). It was built in 1890 according to Ganz & Co.'s transformer transmission system of Tesla's AC and expanded almost every year in line with the demand increase. The facility consisted of a machine shop, a parallel boiler house built directly next to it, a coal shed in the yard (above which were the workers' washing and dressing rooms and the dining rooms). Special precautions were necessary for the procurement of the required cooling water.

The success of J. Stefan's International Electricity Exhibition in Vienna (1883), which had already been preceded by exhibitions in Paris and Munich, aroused the need to use electrical energy for industry, commerce and traffic (electric motors) as well as lighting. Engineer G. Franz Fischer was the first in Vienna to apply for the concession for the construction and operation of an electrical central station and received it on 24 October 1885. Fischer transferred the concession in 1886 to the company Siemens & Halske in Vienna, because he did not have the necessary capital. He designed the lightning of Viennese streets by a contract with the municipality of Vienna. On 14 October 1887 this contract was completed, in September 1889 the central station in the city was put into operation. In 1891 the complex was transferred to the General Austrian Electricity Company (Allgemeine Österreichische Elektrizitäts-Gesellschaft), which was founded under the leadership of the Anglo-Austrian Bank to tackle a "Central Leopoldstadt" (2, Obere Donaustraße Nos. 23-27) due to the enormous interest. In 1918 the increase of connected customers demanded the design of additional steam power plant, later Umspann- and cable workshop and central warehouse of the municipal E-Werke. On April 21, 1893 a road contract with the municipality of Vienna valid for the entire urban area was completed. In 1887 a rival company, the Viennese Electricity (Wiener Elektrizitäts-Gesellschaft (WEG)) was founded. It was followed by the International Electricity Company (Internationale Elektrizitäts-Gesellschaft (IEG)). Their only difference was that the General Electricity Company had the right to use the extended urban area (19th district) and the other two companies remained limited to the old city and suburbs (Vorstädte). The Allgemeine Österreichische Elektrizitäts-Gesellschaft had the following facilities: Central Neubad of 1st Bezirk in Neubadgasse no. 6, commencement of operations September 14, 1889; the central at Leopoldstadt of 2nd Bezirk Upper Danube Street no. 23-27 built by Wilhelm Schimitzek (* 1847 Silesia; †1914 Vienna) which commencement its operations on December 10, 1892; as well as substations at 17th Bezirk Helblinggasse 7, and 19th Bezirk Billrothstraße 2.

In 1900-1911, J. Stefan's widow still lived 8/2nd Bezirk but in Fuhrmannsgasse no. 17 as Marie Stefan k.k. Hof-Rath- und Universität Professor's widow. In 1912-1914, Marie as J. Stefan's widow (Steffan, Stephan, Steppan) and her son-in-law Theodor Rohm were not noted in Vienna. In Vienna there was Marie Rohm in 8/1 Bezirk Lammgasse no. 9 in 1908-1915 and no more in 1916, while Rosa Rohm as milliners (Modisten) resided in 8/1 Bezirk Piaristengasse 36 in 1913-1916. Marie Rohm was not noted as Theodor's widow as she probably appeared in Vienna as the independent inhabitant only after Theodor left (i.e. passed away) in nearby flat of their same 8th Bezirk. During her last years in 1915-1929 J. Stefan's widow lived in south part of 13th Bezirk/10 Hietzing (Speising) of Vienna in Gallgasse no. 17 near 12th Bezirk Meidling and 23th Bezirk Liesing as Marie Stefan Hofrath's Widow while none of her relatives with their family name Rohm were noted in Vienna in 1915. As Marie Stefan was very old, she probably did not die in her home, but certainly had a Christian funeral before the Anschluss. She was buried next to her husband J. Stefan in the Viennese Zentral Friedhof with her age stated as 90 years as a probably approximation, but no Viennese church

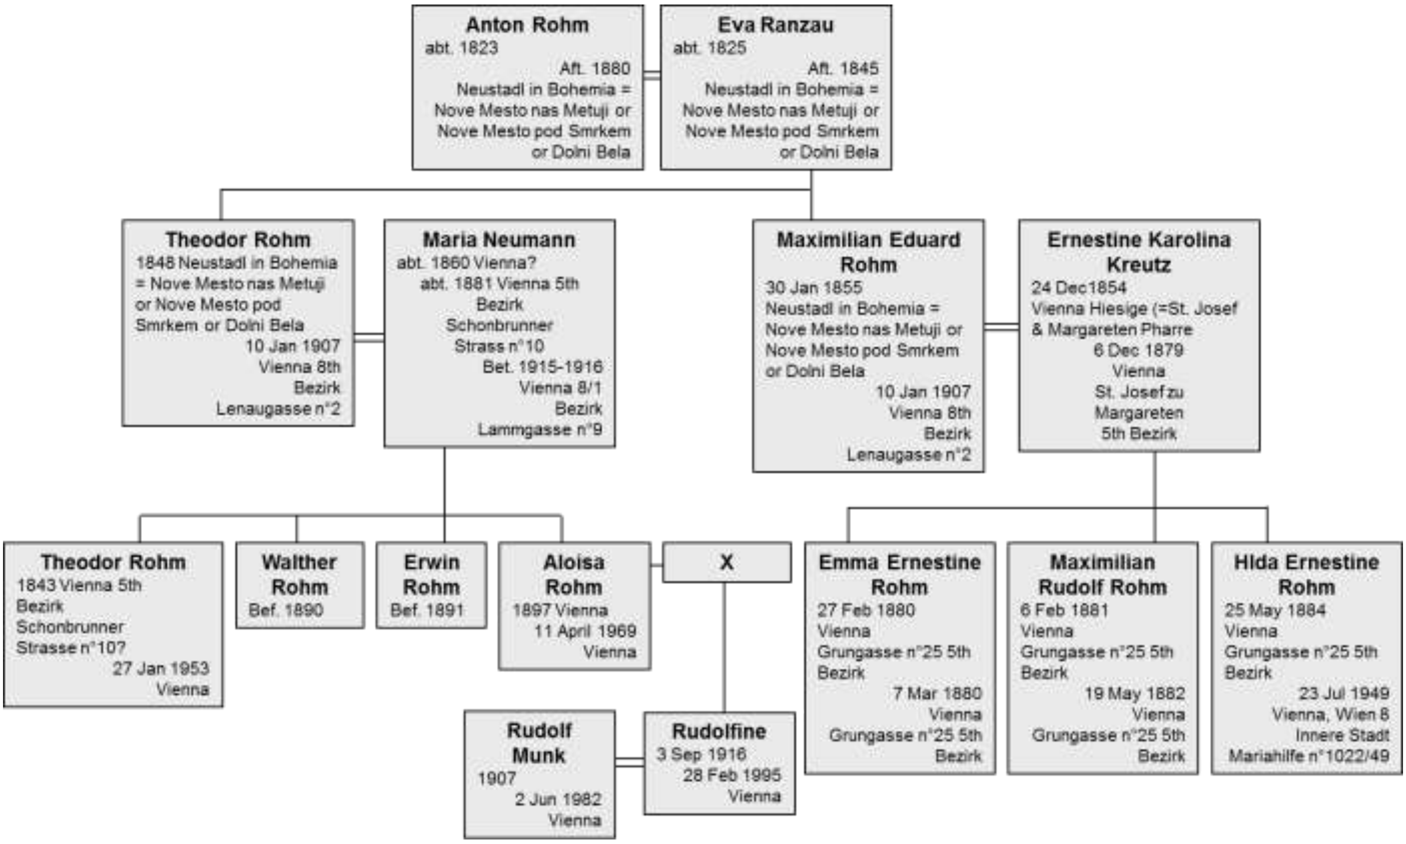

Figure 22-34: Theodor Rohm's family tree.

noted her funeral ceremony.[2767] The genealogical researches of J. Stefan are not finished because his marriage notes are still not found in Vienna or in major Carinthia churches.

It doesn't sound that any of J. Stefan's colleague physicists were his marriage best man resembling Boltzmann who picked up his collaborator Toepler as his marriage witness in Graz while Loschmidt did the similar later in Vienna. J. Stefan's best friend was the Viennese city engineer Eduard Lukesch (Emil Luksch) in whose house J. Stefan suffered his final stroke in Viennese Razumovski street (Rasumofskygasse) no. 8 on 18. 12. 1892. That site is northwest from Stefan's residence lab on the other side of the 1st Bezirk Innerestadt. Eduard Lukesch from 3rd Bezirk Landstraße in Rasumofskygasse no. 8 was Ober Engineer der Stadtbauamtes (City Construction Office) in retirement which was noted as pension abbreviated by (P.).[2768]

Jožef Stefan had good relationships with engineering groups, especially with the guys who were working in electrical engineering. Stefan's best friend and his wedding best man at J. Stefan's marriage with Maria Karoline, Emil Lukesch Eduard Lukež), was also an engineer probably in some private Viennese firm, maybe he even worked for Rothchild who employed J. Stefan's stepson. A guy named Emil Luksch worked as the Leiter des Bagatell-Ger. in Handels-Sachen of Rath-Sekretäre in k.k. Handelsgericht of Prague in 1889 and 1893.[2769] The once humiliated Carinthia

[2769] Leader of the minor commercial matters of Council Secretaries in k.k. commercial court Hof- und Staats-native J. Stefan returned to his home areas to show how successful he became, but he got his deadly flu combined with pneumonia right away as he eat, drunk and breathed better but missed any sleep with his fatal fiancé… J. Stefan's heritage passed to the family Jandl of St. Ruprecht in Klagenfurt, less probably bei Völkermarkt (Št. Rupert pri Velikovcu) no 1 or 9 or more unlikely from St. Ruprecht bei Villach (Beljak). Alois Jandl from Pokersdorf married Theresia the daughter of Anna Startinik married Blasnik from the Carinthia parish St. Thomas by Zeiselberg and moved to St Rupert by Klagenfurt no. 32 nicknamed Timenitz. Because all Maria and Anna Startinik's older brothers and sister died in infancy, and probably Maria and Anna Startinik's younger brother Simon Startinigg (* 11th January 1820 Rossenegg no. 2 in parish Ebenthal) and sister Katherine Startniek (Starinik) did not produce much offspring, the family of Jandl in St. Rupert of Klagenfurt were the closest J. Stefan's relatives left. Jandl of St. Rupert of Klagenfurt are mostly physicians and politicians today.

Figure 22-35: Funeral of J. Stefan's grandfather Joannes Stephan as the third one noted in 1810.

It was a Vormarch time of Metternich's industrialization which transformed old-fashion occupants into impoverished proletariat including J. Stefan's family members of carpenters, flour-dealers, tailors, tobacco fabric workers and housemaids. Just some gunsmiths kept their prosperous businesses around Borovlje as they worked out small editions of precise good-looking shotguns for wealthy hunters. With March revolution of 1848 the American immigrant settlers' dreams joined the chaos which buried old ways of life. The sexual freedom in suburbs was amazing while the clever guys were inventing all kinds of industrial tools but no distinct urgently needed contraception at all also because of official Catholic doctrines. The church of St. Egidus was full of illegitimate kids who did not trouble much their own networks, while the monastic high schools still cared a lot about married life, probably even too much.

J. Stefan's father Aleš Stefan prospered a little bit. Therefore, he leased from his boss entrepreneur (Großnigbauer) Franz Puntschart a small store to sell flour and bread on Obere Burggasse no. 372. The site was in Stadt No. 372, on the former monastery of Ursulines (ehemaligen Ursulinenkloster), in the former Palais Ursenbeck today Burggasse no. 15 in Klagenfurt south of St. Egidus church. In St. Egidus Aleš finally married his good old sympathy Maria to enable the studies of their alleged natural son in the Benedictine Grammar school of Klagenfurt. As the family later lived together, it was probably not just a marriage of convenience needed for J. Stefan's high school studies although it sounds somewhat strange to marry the girl and design a joint household nine years after you fathered her son. Aleš (Alex) Stefan was mostly just selling his stuff and he himself was not involved in milling or baking business.

The sexual freedom in suburbs was amazing while the clever guys were inventing all kinds of industrial tools but no distinct urgently needed sexual preservatives at all. The church of St. Egidus was full of illegitimate kids who did not care much in their own networks, while the monastic high schools still cared a lot, probably even too much.

J. Stefan's father Aleš Stefan prospered a little bit. Therefore, he leased from his boss entrepreneur (Großnigbauer) Franz Puntschart a small store to sell flour and bread on Obere Burggasse no. 372. The site was in Stadt No. 372, on the former monastery of Ursulines (ehemaligen

Handbuch… Wien 1889: p. 690; 1893 p. 591; Karl Josef Westritschnig, 2012.

Ursulinenkloster), in the former Palais Ursenbeck today Burggasse no. 15 in Klagenfurt south of St. Egidus church. In St. Egidus Aleš finally married his good old sympathy Maria to enable the studies of their alleged natural son in the Benedictine Grammar school of Klagenfurt. As the family later lived together, it was probably not just a marriage of convenience needed for J. Stefan's high school studies although it sounds somewhat strange to marry the girl on joint household nine years after you fathered her son. Aleš (Alex) Stefan was mostly just selling the stuff and he himself was not involved in milling or baking business.

Alexius (Aleš) Stefan has denied the entry of his name in the baptismal book in the first place. The ecclesiastical attribution of paternity was not written at the first place. An official acknowledgment of the paternity of Alexius Stefan by the church took place only immediately before the accession of his son to the Benedictine Gymnasium: "In front of well known and signed witnessing respected named persons, Alexius Stephan has made himself known in our presence as the father of the child created with Maria Startinik, and explicitly demanded to be registered as such in the baptism book. The Expository St. Lorenzen in Klagenfurt on 3rd of October 1845. Simon Heber was an Expositor [Pastor] and Simon Tomantschger (Tomačker) was witness". Simon Tomantschger (Tomačker) was otherwise not known as the friend of Aleš or Maria's family.

Jožef Stefan seriously thought about joining the Benedictine Order where such Habsburgian scientists like Robida or Ányos Jedlik prospered. After his final examination (Matura) he dropped the idea of entering the any further education in Benedictine Order as he preferred the Viennese university. Probably J. Stefan liked girls too much to become a monk. He was influenced by some Benedictines at the Gymnasium as he daily walked the oldest Klagenfurt Allee leading from the Völkermarkter Vorstadt Höhe "Kumpfgasse" no. 43 over the railroad crossing into the Fortschnigg Allee. A ten-minute walk brings you to the junction with Lindenallee on Ebenthalerstrasse, which leads to the Baroque-style castle Ebenthal. The avenue was built from Ebenthal to Klagenfurt in the years 1706 to 1710. The teachers of the Normal Hauptschule of a high school recognized the skills of the young boy and supported his high school attendance. The parents married and so paved the way for the smooth higher education at grammar school for the young Jožef Stefan. At that time, it was not possible for an illegitimate child to attend the Benedictine gymnasium. The Benedictine monks from St. Paul in Lavanttal have contracted to teach at the Klagenfurt Gymnasium since 1807. The Benedictine Fathers' task was to form their pupils' religious morals. The Prefect had to supervise this, with the respective district captains being responsible for it. The Benedictine Fathers taught in Klagenfurt Gymnasium after the dissolution of the Jesuit Gymnasium-Lyceum in 1773. In the period from 1807 to 1871 the Benedictine Fathers officially supervised that job.

Figure 22-36: Baptism of J. Stefan's father in 1805.

In the circle of the extended family of Josef Geiger, the bright boy Josef (Jožef) experienced his happy childhood together with the neighboring peasant children. The little Josef have been a favorite of all on the farm. The local chronicler, the director of city archive and librarian of Klagenfurt City hall (Magistrate) Carl Lebmacher (1876 Kirschentheuer in Rosental-1943 Klagenfurt) from Klagenfurt wrote in an article on the 100th birthday of Jožef Stefan: "In the circle of the numerous Geiger's family, the bright little boy, who at that time bore the surname of his mother, grew up diligently in the economy and [...] remained there until the age of nine, while he was the darling of all".[2770]

At the time when he attended the normal Hauptschule in Klagenfurt, the boy Josef was increasingly burdened by his illegitimate birth. The kid still used the surname of his mother Startinik. When Josef was nine years old, his parents financially afforded to start a joint household in the

[2770] Carl Lebmacher & editor Josef Höck, *Klagenfurt in alter Zeit: Historische Bilder aus dem Alltag in Kärnten*, Klagenfurt: Verlag des Geschichtsvereines für Kärnten, 1993.

Upper Burggasse in Klagenfurt. The boy literally bloomed through the marriage of his parents. His high school studies became possible! His way to school took only a few minutes by the Große Schulhausgasse in today's October 10th street. The parents supported their son according to their possibilities, especially later when Josef used to be a student of mathematics and physics at the University of Vienna.

Figure 22-37: Baptism of J. Stefan’s mother in 1814.

The little boy Josef spent a lot of time in the surrounding fields and meadows of the rural "Franzl" - estate. During this time, his first interest in nature probably awakened, while his mother was engaged in the field work with a little help of her kid. The young boy began to work in agriculture himself. He learned all about the monotonous peasant work from personal experience. The southern St. Peter is located on the Ebenthaler - Allee and increasingly become an important suburb of the city of Klagenfurt. An orientation of this area towards the trivial school and pilgrimage church Maria Hilf in Ebenthal took place until the second half of the 19th century. The pilgrimage church in Ebenthal became an Exposit (Expositur) of the old Provost parish (Propsteipfarre) of Gurnitz. The parish - Expositur of Gurnitz with the church of Ebenthal, also includes the "Großnighof" in Limmersach with fourteen people living there. The "Franzlhof" on the eastern edge of the Katastralgemeinde St. Ruprecht accommodated those fourteen persons. The farmer Josef Geiger had a large family, whereby the servants with their children were also counted. The immense factory expansion in Limmersach brought a huge increase in the number of pupils at the elementary school in Ebenthal. The lower classed of organized Trivialschule in Ebenthal accommodated 64 students attending the first class and 80 students in the second class. In the restrictive and censored Metternich’s Vormärz, on the eve of the bourgeois-liberal revolution of 1848, the provincial town Klagenfurt administratively performed its inappropriately low status of a county seat. The Klagenfurt district consisted of 75 tax districts with a total of 532 cadastral districts.

Jožef Stefan's parents were of educationally disadvantaged rural origin. In the first half of the 19th century, the degree of literacy in rural areas was still low. A poor curriculum for their trivial education lessons often took place in the vicarages. The teaching at primary schools left much to be desired. It took the whole of the 19th century until the "epochal" compulsory education increasingly prevailed in the agricultural sector. The liberal State Elementary School Law (Reichsvolksschulgesetz) brought a decisive improvement for the education of the people in 1869, when it was already too late for then university professor J. Stefan. The "parish schools" finally transformed into modernized secularized curricula. Buildings for the higher-organized elementary schools in rural areas were created for the predominantly peasant population. The increasing influence of the Catholic - conservative politics after the liberal phase brought the Reichsvolksschulgesetz - novella for relief of country children’s school attendance, whereby their compulsory school time was reduced. In the provincial capitals and in larger cities, public schools emerged as higher secondary schools. That school attendance relief worked far into the 20th century. The public schools were intended in large cities mainly for the students planning to join their handicraft and the trade. The farmer’s sons of larger peasant farms often frequented the public schools in the city, usually with the help of their relatives and acquaintances who provided their food and accommodation during their school time. These bourgeois educational institutions were increasingly becoming feeder schools for the middle technical and commercial education system. The emerging vocational secondary schools were increasingly becoming a competitor to the high schools. The strong attendance of the grammar school was somewhat discouraged by the increasingly important vocational schools. Their similar real tuition and linguistic education was gaining more and more importance in the Gymnasium. In addition to the "humanistic" Gymnasium, the equally 8-year long studies at the Realgymnasium were established in dying Habsburg monarchy in 1908. In the first half of the

19th century, less than half of the school attendants in the country visited schools, with increasing tendency at their lower education organized in the one- and two-class trivial school. For the rural population, the elementary school in the country was usually still a compulsory school in the rectory. The usual compulsory school nearest to the birthplace of the boy Josef (Jožef) was then the trivial school in Ebenthal. The normal Hauptschule was increasingly developing into a feeder school for the Gymnasium. By attending this upscale compulsory school, Josef (Jožef) made his first steps towards his higher education at the Gymnasium and at a university. In the normal Hauptschule in Klagenfurt, the young Josef Startinik-Stefan seriously contacted the German language networks for his first time because his mother tongue was Slovenian. Up to Josef's age of nine his mother was a single parent of the young boy.

For Josef Startinik-Stefan, the Normal Secondary School was a basis for the humanistic Gymnasium of the Benedictines in Klagenfurt. After their marriage, the boy's parents best supported their son according to their possibilities. The talented and interested son was thereby enabled to progress at his educational and professional level. The finally officialised relationship of his parents provided a positive stimulus to the boy Josef. The illegitimate life circumstances in primary school were not rosy for the student Josef, not just because of the humiliating jokes of his classmates but also because of the standpoints of his teachers. The illegitimate son Josef Startinik had until the age of nine a big problem. The parents were not married, and they lived separately. The distance between the two parents' homes was minimal even on foot. The aspiring and interested boy thought that his matriculation access to the grammar school of the Benedictines in Klagenfurt was hardly possible. An official recognition of paternity was still missing, despite of a marriage of Josef's parents that took place in the city's main parish church of St. Egidus in Klagenfurt. This fact enabled various interpretations. The marriage of the parents, the enormous improvement of the private and professional living conditions and the relocation to Klagenfurt also enabled an educational and social ascent of Josef Startinik-Stefan. The young Josef (Jožef) used the better living and professional situation of his parents in Klagenfurt extremely well for his educational efforts. The interest in education and diligence of the illegitimate boy coming from the Franzlscheune were increasing. Jožef Stefan developed into an important physics researcher and academic teacher of the Habsburg monarchy in the second half of the 19th century. A corresponding bourgeois relationship structure was missing to the young man, because of his educationally disadvantaged and low social origin. Jožef Stefan's father Alexius left his native "Stefanhube" in Lanzendorf in the then important tax district of Sonnegg in the Jaun Valley (Jauntal=Podjuna). The large control tax district Sonnegg had altogether 29 areas noted as cadastral communities (Katastralgemeinden) by the Franziszeischen cadastre of 1829. The owners of a farmhouse, which could take the considerable differences in size, then belonged to the rural middle class. Stefan's mother, a daughter of the country carpenter Gregor Startinick, came from the parish of Glainach im Rosental (Rož). The craftsmen in the country belonged mostly to the disowned class without real estates properties. In the 19th century, the artisans based in the periphery belonged more to the lower rural population. The craftsmen in the country usually had less education and training than those in the city. Since the Middle Ages the educational levels in the guilds have been fixed in the ranks of apprentice, journeyman and master. The rural structures of craftsmen usually did not have these three levels of education. The craftsmen from agricultural areas did not belong to guilds, as they did in the cities. In general, these craftsmen had a rather low reputation in the country. The possession of land and realities had a greater social significance in the country. His mother at the farm, and later also his father in town, created for the boy Josef a modest albeit still and limited possibilities of a suitable framework, which allowed a higher education for the young Josef. The ambitious and education-hungry adolescents were expected to get their higher education at the Gymnasium at the Benedictines in Klagenfurt. The guys from four-year compulsory school could enter the upper secondary school, which formed a good basis for a high school education. The musically, technically and mathematically gifted adolescent Josef entered the Gymnasium in Klagenfurt at his age of ten. His first education boosted immediately after the liberal-bourgeois revolution advanced through the Stadion's imposed March Constitution in 1849-1851. The higher schools and secondary schools were reorganized and thus also modernized. The Gymnasium had eight classes-years with the four-year lower and four-year upper grades, which remained still the basic structure today. The normal secondary schools were developing into important feeder schools of the "higher" grammar schools. Before the revolution of 1848, the grammar schools together with the Lyceums were still seen as "scholarly schools", therefore preparing guys for their studies at universities.

Did Geiger provide some help for Josef (Jožef)? Later in 20th century Geiger guy was not very happy with J. Stefan's memorial plate put in front of his house. It was probably hard for Geiger to confess that the poor kid was far the best of them all, with his bosses also included. The brand-new bride Maria and the product of her past love J. Stefan moved to Josef's father new home at least upon his matriculating in Grammar school. The kid Josef had to carry heavy sacks and bags full of flour which forever pushed his right shoulder somewhat higher above his left one. J. Stefan also praised beans a lot because they were a rare specialty in his juvenile Klagenfurt home.[2771]

Later, the family of J. Stefan moved to the neighboring Klagenfurt Stadt no. 370 which provided some more luxury for a small family of three members which had no ambition of multiplying for the time being. Aleš (Alexius) Stefan's son Josef worked diligently during the school-free time in the flour and bread business, as he carried those heavy flour sacks. At the beginning of the 19th century, there were eight mills on the Glan river in what is today a part of a city Klagenfurt. At that time, the flour mills were an important trade situated on the banks of rivers. No other equivalent energy suppliers were at hand except the less advantageous windmills with steam engines just slowly penetrating. The wheels of water mills on Glan river became the basis of Stefan's later brilliant hydrodynamic analogies. The Glan River has a low flow velocity in Limmersach in area of the Großnigmühle which stimulated J. Stefan's hydrodynamic interests. As a result, the Glan river in this area was very slow and swampy, therefore it was regulated accordingly by Franz Puntschart Junior in 1868. The "Großnighof in Limersach (Limmersach, Limarče)" in the Katastralgemeinde St. Peter - Ebenthal was owned by the large-scale farmer and miller Franz Puntschart. He owned his farms (Grundparzellen) mainly in the cadaster municipality (Katastralgemeinden) of St. Peter - Ebenthal, also in St. Ruprecht, in St. Martin and in Radsberg. In the Katastralgemeinde St. Peter - Ebenthal are the villages Harbach with the castle Harbach by Klagenfurt- Ölgemälde owned by Markus Pernhart (1824-1981), Ladinach (Ladine), Limersach (Limmersach, Limarče) and Rosenegg. Aleš (Alexius) Stefan worked as a miller's assistant at the "Großnighof", where a long-standing large flour mill already milled south-east of the town of Limmersach (Limarče). Jožef Stefan's father lived at the Großhighof in Limersach (Limmersach, Limarče). The Großnighof is only about one kilometer away from the birthplace of Jožef Stefan, which is located on the Ebenthaler Lindenallee.

In Limmersach the [property] owner and miller was Franz Georg Puntschart. His son, born in 1816, had the same name. He took over the local mill as early as 1837, soon after J. Stefan's birth. After traveling through Bohemia and Germany, Franz Georg Puntschart (1816–1872) began with the production of compressed yeast in 1840 and the mill became an 'art mill' in 1853. In 1868 he built a new plant and regulated the Glan river. The area was once owned by Viktring Abbey. Already the old Urbar as a list of the manorial taxes noted a mill on the Glan river in its narration of document.

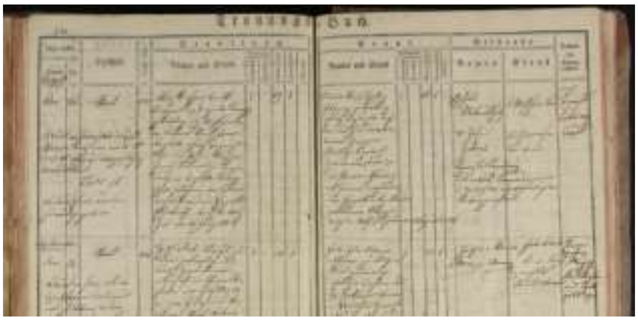

Figure 22-38: Marriage of J. Stefan's parents in 1844.

The technology of "pressed yeast production" in "Limersach (Limmersach, Limarče)" becomes more and more obsolete over time. Soon after Jožef Stefan passed away, the owners of the factory facilities Franz Puntschart & Söhne sold these objects to the Jewish industrial magnate Sigmund Fischl (Siegmund Fischel, * 1847 Myslkovice (Miskowitz) in Tabor district of south Bohemia; † 1905 Prague) from the industrialized country of Bohemia on January 26, 1894. The

[2771] Čermelj 1976 10-11.

funny old times of the small family businesses gave place to the big factories.

For one reason or another, only on 25 August 1844 J. Stefan's parents were married in the church of St. Egidus in Klagenfurt while they lived at Stadt no. 372. The illiterate marriage witnesses were Johann Urbantschitsch (Urbančič) as a colleague of Aleš Stefan in flour merchant business (Mehlhandler) and Johann Haberl as Büchsenmacher (gunsmith) from Ferlach where many branches of J. Stefan's mother's side originated. There was also noteabout "Franz Sal district solicited signer named for incentives crosses of illiterates (Franz Sal Kreis (=Salkreis) Erz als erbeten (=erbethen): Namensfertiger in Zungen des ein einhändigen Kreuzz Inzensen)". The celebrant of the marriage ceremony was the priest cooperator Franzsel Lehrbeng. The happy bride was noted without her old job as Maria Startijek born in Glainach by the already deceased Catholic master carpenter and his still living widow (zu Glainach Gebürtig, ehelich Erzeugten Tochter der schon Verstorbenes Gregor Startijek gewes: Zimmerman Meister im der Pfarre Gleinach und seiner nach lebendige Ehrgattin Apolonia geborenen Olippin beide Katholisch. Geborenen um 3 August 1814). J. Stefan's maternal grandfather was therefore buried long ago, but his maternal grandmother still lived. J. Stefan's father was noted as flour merchant in the city (in Diensten Staat Pfarrers Bezirke). Aleš (Alex) was a legitimate son of his deceased farming father and still living Catholic widow (ehrlich Erzeugten Sohn des Johann Stephan Gmons: Bauern zu Lanzendorf in Bezirke Souniggschen Inlichen, und Seiner noch lieb und en Ehrengattin Wittibe(th). Beide Katholich. Geboren am 16 July 1805). J. Stefan's paternal grandmother also still lived, and the polite J. Stefan became the favourite of his both grandmothers.

A year after that great marriage, J. Stefan was legalized in the Catholic church of St. Egidus at Pfarrhofgasse 4 in Klagenfurt on 3rd October 1845. It was high time because boy could have huge problems in Benedictine Grammar school of Klagenfurt as the illegitimate child.

J. Stefan finished his three-years Normal school in Klagenfurt as the illegitimate child, but he was already legitimized few days after he began his Grammar school studies under the schoolmaster the medicine doctor Johann Burger who also served as Matija Ahacel's descendant on the chair of Natural history and agriculture in 1845/46. J. Stefan loved Natural History and collected the botanical names in Slovenian language which amazed his teacher Janežič.

Why did J. Stefan's parents wait so long, at least nine years from their supposed love affair until their official marriage? The exposit priest Mathäus Tschuden (Mathias Čuden, Oskudek) certainly wrote father's name long after the baptism of J. Stefan and priest or his replacement later noted the fact of marriage and legitimization below with nearly the same ink. Much later with a plain pencil the data of J. Stefan's death were added on the right corner of the note.

J. Stefan's Slovenian Klagenfurt quickly became the cradle of Slovenian nationalism. Through the nationalism, languages were increasingly occupied by political ideology. The language-oriented nationalism becomes increasingly meaningful after the liberal revolution of 1848. The mother of Jožef Stefan came from Rosental (Rož) and there she spoke a corresponding Slovenian dialect. The father of Jožef Stefan came from Jauntal (Podjuna) and thus used the most common kind of local Slovenian dialect. In the Klagenfurt area the Rosentaler (Rož) variant of Slovenian dialect was spoken.

The Zedinjena Slovenia (United Slovenia) movement was formulated by the chaplain of Klagenfurt Cathedral the Carinthia native Matija Majar (1809 Wittenig (Vitenče) in Zilja (Ziljska Dolina, Gail valley)-1892 Prague) on 17 March 1848. Majar studied in Klagenfurt Lyceum under the prevailing influence of Anton Martin Slomšek who served as the spiritual director of seminarians at Klagenfurt from 1829 until 1838.

The Pan-Slavic priest Majar decisively influenced Stefan's romantic national feelings while the Viennese professor Fran Miklošič was much more coldblooded scientist like Kopitar before Miklošič.[2772] In autumn of 1848 by the order of minister, Anton Janežič (1828-1869) began to teach Slovenian language in Klagenfurt Grammar school, although without any salary. Next year in 1849/50 Janežič's Slovenian Language lectures in three classes for Slovenians were obligatory and

[2772] Čermelj 1976 34.

two classes were launched for Germans. The Slovenian student J. Stefan was among the best already in his first Slovenian language class which joined the students of 2nd, 3rd and 4th grades. There were a lot of problems with textbooks needed for Slovenian language lectures for higher grades. The officially declared Slovenian students were in minority, but in Stefan final 8th Matura class there were as much as eight Slovenes of altogether nineteen students in 1852/53. Still lower proportion of Slovenian students studied in Klagenfurt real school although the Slovenians had at least 1/3 of inhabitants in the area, but many preferred not to declare themselves as the Slovenians anymore because of their forced Germanization. Andreas Einspieler (Anfrej, 1812-1888) from Suetschach in Rosental (Sveče in Rož) attended the Gymnasium and the Lyceum in Klagenfurt. Einspieler was ordained a priest and taught catechism with religion at the Klagenfurt Gymnasium of the Benedictines. He studied for a teaching degree at the University of Vienna. Andrej Einspieler taught Slovene at secondary schools. Einspieler advocated a brotherly treatment of the Carinthia-based German and Slovenian "tongues". In the revolutionary period of 1848 Einspieler became an advocate of the equal rights of the Slovene language in the school, in the court and in the administration. Stefan published his writings in Einspieler's journal Šolski Prijatel (School Friend).

The versatile and diligent student Josef Startinik-Stefan was admitted to the Normal-Hauptschule which was a higher elementary school. The Normal-Hauptschule developed as a basis for the educational advancement focused through the Benedictine Gymnasium in Klagenfurt. The footpath of the boy to the normal Hauptschule in the small school lane of today's Kaufmanngasse was about 3.5 kilometers long. The way to school leads from J. Startinik-Stefan's place of residence in the south of the village of St. Peter of today Ebentalerstraße on the former Linden tree avenue through the Völkermarkter suburb to the corresponding gate, through the Burggasse to the normal secondary school in the small school lane. The parents had a low educational status as most had in rural areas of that era. The father and mother of boy Josef did neither know how to read nor to write. The parents best promoted the talents and interests of the young kid according to their possibilities. The good relationship between the son and his parents was still maintained when Jožef Stefan was already a successful researcher and outstanding professor of physics at the University of Vienna. Stefan become a modest and withdrawn person and a university teacher. He usually visited his parents in Klagenfurt for two months during the summer holidays. This was akind of thanking of the son to his gracious parents who financially supported their son according to their modest possibilities not only as a high school student but also as a student in Vienna. The general state scholarships were introduced in Austria only in the 1960s.

One year before entering the Klagenfurt Gymnasium, Jožef Stefan was fortunate in his personal circumstances. In 1844, his parents married, and a year later, his father recognized his paternity in the parish of St. Egidus just before J. Stefan entered the grammar school. The mother Maria moved from the Franzlkeusche in the south of the village of St. Peter to the city of Klagenfurt. The father Aleš was already working in the leased flour and bread shop in the Upper Burggasse. The long service in "Limersach (Limmersach, Limarče)" brought to the miller mate Aleš some luck by the gratitude of farmer and mill owner Franz Puntschart. Alexius (Aleš) Stefan took over the leased flour and bread business from the big farmer Puntschart. The miller's assistant Alexius Stefan leased the flour and bread shop in Burggasse in Klagenfurt from his employer. Alexius Stefan used to be a departing farmer's son of the "Stefanhube in Lanzendorf" in the cadastral town of Grabelsdorf, the large control district Sonnegg in Jauntal (Podjuna). The lease of the flour and bread shop in the Upper Burggasse in Klagenfurt meant a socially and financially better position for the family of Stefan which now lived together. In the initial premises of the Ursuline Monastery, a family of three now lived under one roof. The son Josef was spared of his previous long walk from the place of residence in southern St. Peter on the Ebenthaler Allee to the normal secondary school in Klagenfurt. J. Stefan's birthplace was a servant building on the farm of Joseph Geiger. The birthplace of Jožef Stefan is located on the eastern edge of the large area Katastralgemeinde St. Ruprecht. Due to his new place of residence in the upper Burggasse, the high school of the Benedictines in the large school lane was only a few minutes away from the new Josef's home in Burggasse. The marriage of the parents

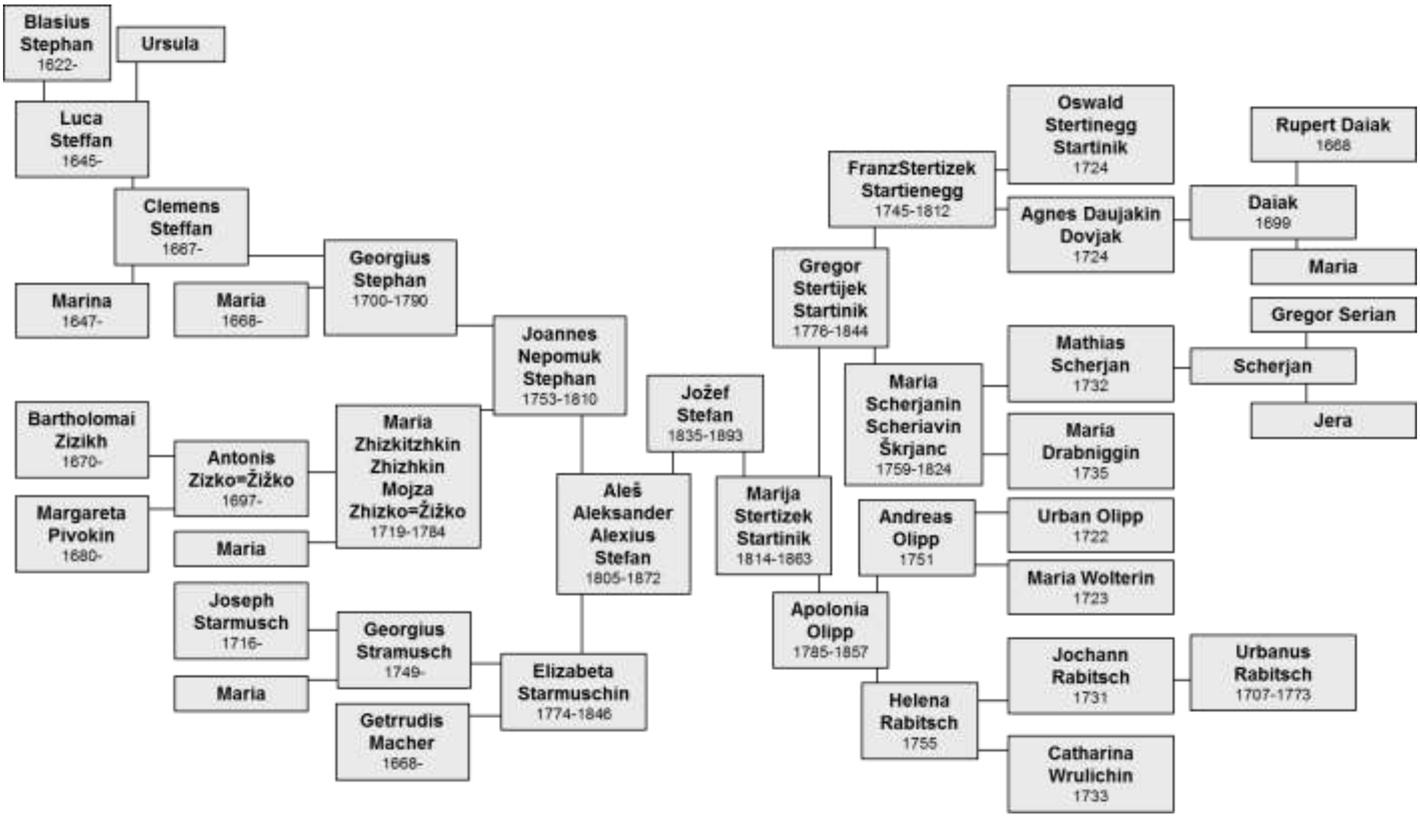

Figure 22-39: Stefan's ancestors on all branches

Figure 22-40: Funeral of J. Stefan's mother in 1863.

made it easier for Jožef Stefan to enter the Gymnasium under the direction of the Benedictines. The financial situation of the parents and the local situation due to the move to Klagenfurt have an extremely positive effect on Jožef Stefan in every respect. This may be one reason for Jožef Stefan's very kind and good personal relationship with his parents. Jožef Stefan was extremely grateful that the family's living conditions have developed so positively for him. He always visited his parents during the summer holidays in their lifetimes. He visited them even when he was already a recognized scholar and researcher at the University of the Imperial City of Vienna. Jožef Stefan's mother Maria Stefan died of apoplexy at the age of 48 in her home at Klagenfurt Stadt 370 as a wife of towns flour merchant on October 23, 1863. She was buried two days later at St. Egidus by the city priest Max Wallner.[2773] Just before she passed away in 1863 Stefan was appointed Full Professor of Mathematical Physics at the University of Vienna. Jožef Stefan's father Alexius Stefan lived until December 8, 1872. A decade after his mother, J. Stefan's father died 67 years old in his home of Klagenfurt Stadt 370 as the city flour merchant. He died of pneumonia noted as Lung infection (Lungenentzündung). He was buried two days after he passed away at St. Egidus church.[2774] J. Stefan's parents were illiterate, but he tried to teach his mother probably to enable her to read his letters which he frequently mailed to her from Vienna.

In Klagenfurt J. Stefan joined the local Slovenian male singing choir as the first singer of professor Robida's choir and later singed with his fellow Slovenian students in Vienna. The versatile Stefan was also dedicated to music and choral singing. In his 8th Class of the Gymnasium Stefan was a first

[2773] Schlagfluss, noted by K15_072-1, page 141, Sterbebuch XV.

[2774] Sterbebuch XVI; K15_073-1, page 255.

singer of the Klagenfurt singer choir. He became a student member and choirmaster of the "Slovenian Choral Society" in Vienna. J. Stefan coedited their Viennese local journal Slavia and joined the society *Mormonia*.[2775] Stefan also wrote in southern Bavarian dialect which is the German Carinthia dialect. Stefan later gave his entire unpublished literary material to the folk song composer Thomas Koschat (1845-1914) from Viktring (Vetrinj) near Klagenfurt who worked and lived in Vienna. Almost a century later, Viktring (Vetrinj) became the evil destiny for Nazi collaborators who tried in vain to surrender to the Anglo-American allies.

Stefan learned a lot of languages including Czech, Russian, Croatian, French and English. He loved to return from Vienna to his holidays into Carinthia home to his loving parents and he liked to hike around to Ferlach (Borovlje), Rosental (Rož), Rutarch (Rute), Bodental (Poden), Judenburg, Alps, Hüttenberg (Getemberg), Knappenberg, Lölling, Wolfsberg (Volšperk) and Völkermark (Velikovec) with his fellow Carinthia native Viennese and Graz students Gratzer, Gobanz, Martinz, Schücktanz and Karl von Jaeger (Jäger, 1936 Carinthia-1920 Graz) who studied law, politics and philosophy in Graz for his Ph.D. in 1861 and served in different ministerial administrations after 1869. Stefan also lectured for his fellow student privately on Leidenfrost's effect in 1857 and on diffusion and on Dulong-Petit's law in 1858.[2776] Dulong-Petit's law became one of the major focuses of Stefan-Boltzmann statistical kinetic atomism designed against Simon Šubic's opposition.

Figure 22-41: Funeral of J. Stefan's father in 1872.

The only Stefan school trouble has escalated in the first semester of his 6th grade in winter 1850 of 1850/51 school year. He was noted in catalogue as the guy "unavailable for good-natured reminders".[2777] The professor who made that trouble was not noted but he might be the professor of physics Robida whose Slovenian and other publications Stefan never mentioned even in his private diary where he praised Vertovec and other Slovenian writers.

The Benedictine Johann Chrysostomus Sepper taught mathematics in J. Stefan's class by Močnik's textbooks.[2778] Močnik became in many ways Stefan's model: both knew fairy well that there is no way to the top Habsburgian positions for Slovenian nationalists which forced Stefan to learn his life lessons very well and to abandon his early ambitions in Slovenian poetry.

In 1850/51, Robida taught physics and chemistry by Baumgartner's textbook in Stefan's sixth grade without any ideas about Stefan's future chair of physics at the University of Vienna and his leading roles at the Academy of Sciences in Vienna. Probably they had an argument in the winter of 1850. Robida was angry enough to have his frustration noted in the official reports and Stefan never forgot that humiliation. In his final class, Stefan attended his religious instructions 2 hours per week in winter semester and 2 hours per week in summer semester. He had 6/5 hours of Latin language a week, 4/5 hours of Greek language a week, German language 3/3 hours a week, Slovenian language 2/0 hours a week, history and geography 2/3 hours a week, mathematics 3/0 hours a week, natural history 4/1 hours a week, physics 0/3 hours per week and philosophical propaedeutic 0/2 hours a week. Stefan listened to his lecturers 26/24 hours per week in his final Grammar school year which was somewhat less than the students enjoy nowadays.

At the end of his 7th "Gymnasialclasse" Jožef Stefan received as his first prize, the physics textbook authored by Wilhelm Eisenlohr (1799-1872). Eisenlohr was an important professor of physics and mathematics at the Karlsruhe Polytechnic Institute which was an emerging higher technical education category in the 19th century named and designed by Parisian model. In this textbook of physics Eisenlohr also published his significant research results in the field of optics.

Figure 22-42: Baptism of J. Stefan's paternal grandmother Elisabeth in 1774.

After the Maturitätsprüfung, the high school professors awarded Stefan the complete dictionary of the mythology of all peoples of Karl May's (*1942= model professor of physics transformed into populariser of sciences Carl Gottfried Wilhelm Vollmer (Pseudonyms W. F. A. Zimmermann by his wife's maiden name, W. C. A. Zimmermann, C. Morvell, * 1797/98 Torún (Thorn) in north central Poland; † 1864 Stuttgart or Berlin). It was published with the editor Heinrich Kern's preface on 1091 pages with 415 concluding illustrations in Stuttgart in 1851. Stefan's teachers added the note: "To the high school graduate Jožef Stefan as a memory of his studies at k. k. Gymnasium in Klagenfurt from the faculty. Johann Burger Director, Klagenfurt, the 21st of September 1853." Vollmer visited Austria and Bohemia in 1827 and Stefan's teachers certainly wished to promulgate Stefan's passions for long distance travels by such readings, but Stefan disliked such traveling anyway.

22.2.4 Provincial Genius in Metropolis

Stefan soon recognized Vienna as the final place of his life ambitions. An unhealthy city full of Viennese movements in contrast to his domestic mountains, but those movements were necessary for the promotion of atomic movements on Stefan's Parnassus. Stefan was a poor country boy and his hard labour, talent and obedience were his only tools for a distinguished job.

During his High School studies Stefan used Experimentalphysik of August Kunzek who became Stefan's teacher at university as Lehrkanzel-Vorstand für Physik from 1850 to 1865. Stefan proved to be more papal than the popes of Viennese atomistic kinetics ether, Cauchy's protegee Ettingshausen and Ettingshausen's son-in-law Wilhelm Josef Grailich (1829 Bratislava-13. 9. 1859 Vienna). Grailich was a son of the professor of philology and mastered eight languages after his juvenile journeys through Hungary and Trieste. In 1857, he married the daughter of his boss Caroline Ettingshausen (1835-1913). In that year 1857 Stefan began to study the oscillations of waterdrops which Johann Gottlob Leidenfrost (* 1715; † 1794) discovered in 1756[2779] Almost two decades later, on 10. 4. 1875 August Toepler (* 1836; † 1912) lectured on them while focusing capillarity for Styrian Natural history society in Graz. Toepler strongly lighted the effect with the inflamed quartz of Scottish engineer Thomas Drummond (Drumond, * 1797; † 1840). Toepler (Töpler) used the system of mirrors to project the pictures for the great amusements of attenders. Toepler shew the curved surfaces of water or mercury with the apparatus developed for those occasions by Louis Jules Dubosq (* 1817; † 1886). Toepler also used the shattered limestone of a new type for a good illumination of experiments in the classroom with Oxyhydrogen gas.[2780]

Figure 22-43: Marriage of J. Stefan's paternal grandparents in 1792.

22.2.5 Koller Enabled for Stefan's Academic Success

Stefan's senior Viennese collaborator Grailich soon intervened in the very middle of Stefan's native Slovenian milieu. The Czech German Mitteis presented an interesting purchase of his physical cabinet of the gymnasium in Ljubljana to the Carniolan Museum Society. Mitteis popularized his physical cabinet, which was also

[2779] Ivan Šubic 1902 83.
[2780] Toepler, 1875, L–LX.

the purpose of later (primary) school exhibitions. On 11 October 1851 he was appointed as teacher of mathematics and physics and he began to teach at the Viennese Theresian Academy. Between 1862-1865 Mitteis was a member of the city council of the Ljubljana municipality. He was also a member of the Philharmonic Society and the Museum Society, and for thirteen years (1853-1866) he taught physics and occasionally mathematics in Ljubljana. At that time, members of the Philharmonic Society were arguing about Slovene or German singing. During this time, Mitteis dealt with meteorology and seismology. He investigated electromagnetic phenomena and their history. In 1856, he presented four lectures on electricity in front of the Carniolan Museum Society, among which three focused the historical data.

During his stay in Ljubljana, Mitteis actively participated in most meetings of the Museum Society. In 1856, he devoted his lectures to the history of electricity, which he published in the same year in the Yearly of the Ljubljana Gymnasium. Even in later lectures, Mitteis dealt with electricity, but his approach was no longer so distinctly historical, certainly under the influence of Grailich's critics. In 1858 Mitteis lectured on earthquakes and published on them in 1858 and 1862 in the Reports of the Museum Society. Two thirds of his lectures in front of the Museum Society were illustrated by experiments between 1856 and 1859. That is why the museum itself had to have some physical apparatius, although Mitteis brought most of the supplies from his physics cabinet of the Ljubljana Gymnasium. Lectures at the museum were often one of the first presentations of his new physical equipment purchased in gymnasium. All important and interesting instruments which he acquired in 1858/59 for the Gymnasium Physical Cabinet were presented to the Museum Society in the same year. He was a gifted experimenter, and among the members of the Museum Society he had enough educated listeners who were interested in his work.

On May 2, 1856, Mitteis had a lecture on the history of lightning in front of the Carniola Museum Society. He explained to listeners that, at southwestern border of Carniola in today's northern Italy, Franklin's points and conducting wires were used as lightning rods hundred years ago. This was proved by Mitteis with the content of the letter which G.F. Bianchini sent to Parisian academy on 16 December 1758. Mitteis found the data about those events in Lyceum library of Ljubljana.

Figure 22-44: Funeral of J. Stefan's paternal grandmother Elisabeth in 1846 which he attended as eleven years old recently legitimized kid.

Bianchini carried out experiments in the Devin castle of Carniola near Udine (Videm). At first, he used a military halberd. Otherwise, the observation of the lightning in the town of Devin already had a nice tradition, since it was already described by the monk P. Imperati in 1602.

Mitteis' lecture aroused considerable attention, as his listeners were also highly educated people, including a member of the museum society the director of lower real school in Ljubljana Mihael Peternel, a former student and assistant to professor J. K. Kersnik who was the first professor of chemistry in Ljubljana. In a paper delivered after Mitteis lecture, Peternel explained few additional facts about the connection between electrical phenomena in lightning and meteorology.

In 1856, Mitteis' interest in the history of electricity quickly aroused with the discovery of rich material on these issues in the Lyceum Library. The modern NUK keeps under the reference code 7078 two Bianchini's letters mailed to the Parisian Academy and printed in Venice in 1754. The first of these describes dr. Giovanni Fortunato Bianchini's atmospheric electricity in the town of Devin in western Carniola. These letters are also found in Kalister's and Čop's List of Lyceum Books from 1826-1832. However, the census does not contain a letter cited by Mitteis dated on 16 December 1758. Nevertheless, it is very probable that Mitteis also found that document in the Lyceum Library of Ljubljana renamed into Academic library, although it is no longer there today.

From here, we can rightly conclude that Mitteis also wrote his paper (1856) about the Nollet-Franklin dispute after a detailed study of the subject matter of that subject. A large part of these writings came to the Lyceum Library by the purchase of books from the legacy of Žiga Zois between 1809-1815. From the inventory of the Zois' Library at the time of his death, it is evident that Zois acquired mostly French books that advocated Nollet's ideas and criticized Franklin. Among these works are the books of Nollet himself and the Parisian French translation of Priestley which favored Nollet.

Grailich congratulated Mitteis for his picking up the interesting stuff related to Franklin-Nollet's quarrels, but Grailich stated that a guy must be careful while discussing the history of physics. Grailich between the lines missed Mitteis' taking sides in Franklin-Nollet's quarrel. Mitteis behaved like the neutral historian of physics while Grailich, who was more powerful in his Viennese networks, declared that the history had to serve a modern politics in physics. Stefan was silent just like during Grailich's critiques of Robida, but Stefan certainly previously discussed both problems with Grailich in their labs to make Stefan even more papal as he liked to declare later to his naughty students' invitations: "You see, we the physicists, we do not dance".

22.2.6 Stefan's Collaborator Grailich against Robida and Mitteis' Electromagnetism

On 17. 1. 1850, the Viennese institute for physics was established in the time of the first uses of cathode-ray tubes. Its first head became the mining councillor Doppler. He was a professor at the Viennese Polytechnic, together with the former Ljubljana mathematician Karl Schulz von Strassnitzki. Doppler became famous in Prague in 1842 by exploring the changing frequency of the emitted light of stars due to their movement in a vacuum. Doppler's claim was ok, but his astronomical examples were false which soon ruined his Viennese prestige in favour of Ettingshausen's variant of Doppler's kinetic atomistic while onlythe dissident Mach's group continued with Doppler's Prague research of waves. Almost all the other Habsburgian erudite opted for Stefan's atomic kinetics.

Figure 22-45: Stefan and his collaborators with experimental tools near their old lab in Erdbergstraße in 1873-1876 (Stefan Archive Wien 106_I_3988 Mitglieder des Physikalischen Instituts in der Erdbergstraße 1873-1876).

The director of the Physics Institute, Doppler was appointed as a full professor at the University of Vienna. His work began at the Institute on April 1st, 1850, at the premises of today's Academy of Sciences. Until 1875, the Erdberg Institute was at Erdbergstrasse No. 15, in the third Viennese district (Bezirk) Landstraβe. In 1875 Stefan moved the Institute to its more suitable location Türkenstrasse no. 3 in IX Stadtbezirk of Vienna called Alsergrund. It seems that something unhealthy was there at Erdberg, maybe connected with mercury in barometers, thermometers and vacuum pumps or other experimental apparatus, as Grailich died extremely young, Doppler hardly reached his fiftieth year, Stefan died before he was sixty, his student Boltzmann hanged himself at sixty-two, Baumgartner was soon unable to teach because of his neck disease in 1833, while Ettingshausen (* 1796; † 1878) went gravely ill in his early sixties although he lived to be eighty-two.

In the spring of 1852 after Doppler's forced dismissal-disease, the management of the Institute was taken over by Ettingshausen, the former professor of engineering in the Viennese Polytechnic. The court councilor Ettingshausen had an unusually many private docents compared to the universities in Germany. The state did not interfere with his attitude to postgraduates; he directed his docents into his own research, of course, primarily dedicated to confirming the assumptions about the atomic structure of matter. He bought vacuum tubes very early. He noticed that the color of the vacuum in the tubes was affected by the spectrum of the gas contained. In the narrower parts of the vacuum tube a disconnected illumination was observed, and in the wider parts of the tube there were nice layers. He therefore commissioned his assistant of Physics Institute Edmund Reitlinger (1830 Pest-1882) and the elevé in Physics Institute Stefan's few months younger colleague Luka Žerjav to investigate the spectra in vacuum tubes depending on the type of gas filling and the thickness of the vacuum tube.[2781] They relied on the physician turned spectroscopist expert François Auguste Morren's (1804 Bordeaux-1870 Marseille) letter sent from Marseilles to Cauchy's Jesuitical protegee François Napoleon Marie Moigno (* 1804; † 1884). Reitlinger began his studies in Heidelberg and Gottingen with Wilhelm Eduard Weber (1804-1891) who soon proved to be the grave enemy of Ettingshausen-Maxwell-Helmholtz's mainstream. Already on 24. 4. 1856 J. Stefan studied the works of W. Weber and Gauss a lot and even Boltzmann noted W. Weber,[2782] but Weber's electromagnetism was probably too close to Robida's undulatory theory for later Stefan's taste. Stefan even tried to study Cauchy's ideas very early and Stefan used books he was awarded with for his excellent marks in Grammar School.

Reitlinger received his doctorate by the institute of Ettingshausen in 1858, and in the following year, together with Stefan, he became an assistant professor at the Institute. For many years Reitlinger edited the supplement *Natur- und Völkerkunde* of *Neuen Freien Presse* where many Jewish correspondents wrote including the feuilleton of the father of Zionism Theodor Herzl. Reitlinger wrote an extensive biography of Josef Ressel in 1863, authored the history of Telegraphy in S. Šubic's sense in 1866, and published another extensive biography of Kepler in 1868. In 1866, Reitlinger became the professor of Viennese Polytechnic together with former Ljubljana professor J. Finger and Victor Pierre who researched fluorescence in 1866. In 1874, Reitlinger dedicated his anthology of his popular history of science articles *Freie blicke: Populär wissenschaftliche Aufsätze* to the Berliner climatologist Heinrich Wilhelm Dove (1803-1879). Later in 1905 Boltzmann also published an anthology of his popular scientific publications.

Figure 22-46: The title-page of Stefan's application for habilitation at the University of Vienna was submitted in September-October 1858 (Documents, September 3, 1858).

Luka Žerjav's publication of 1862 was a kind of his graduate thesis as he left Ettingshausen's institute soon afterwards while Stefan became the associate professor in 1863. In 1863-1878, Luka Žerjav (Lucas Zerjau, Sherjou * 1836 Bloke or Češnjice in Carniola) served under the deputy director the former Ljubljana professor Heinrich Mitteis as the prefect of Theresianum academy in Vienna. Then he prematurely retired and still lived in 1880. Luka's relative could have been Anton Žerjau who served in finance department of Sisak in Croatia in 1866.[2783]

Stefan served for one semester as "Zögling (elevé)" at the Viennese Physics Institute, where he showed "extraordinary talent". Between August 8, 1858,

[2781] Reitlinger, Žerjav, 1862, 352–361.
[2782] Ivan Šubic 1902, 72, 76.

[2783] *Hof- und Staats-Handbuch des Kaiserthumes Österreich* 1866, p. 648; 1868, p. 257; Gemmell-Flischbach, Montesole, 1880, p. 153.

and September 24, 1858, Stefan's Habilitation was conducted for his job of a private assistant professor of mathematical physics, but he still had to lecture in nearby high school to earn for living as he joked that everybody wanted to work with him while nobody wanted to eat with him. Like Helmholtz earlier, Stefan was first supported by the Viennese professors of medicine who were not happy with the liberal lectures of physics for the students of medicine in the class of E. Mach and Mach's successor Reitlinger. Stefan received the decisive support from the Viennese professors of medicine and physiology in their last great attack into physics' networks. Those physicians who finally decided to eat with Stefan after they've heard him lecturing were Helmholtz's (1821-1894) collaborators the naturalist Ernst Wilhelm Ritter von Brücke (1819 Berlin-1892 Vienna) appointed in Viennese university as professor of physiology and microscopical anatomy in 1849, and Carl Friedrich Wilhelm Ludwig (1816 Witzenhausen 20 km south of Gottingen-1895 Leipzig) who taught in Marburg where he joined the liberal spring of nation networks as the editor of *Neuen Verfassungsfreundes*. In 1855 Ludwig became the full professor of physiology and zoology in Viennese Josephinum school for military surgeons (Medizinisch-Chirurgische Militärakademie) and taught there until 1865. Ludwig and Stefan both had their surnames spelled like Christian names which sounded funny and contributed to their mutual friendship. Ludwig and Brücke were both from Germany and not from Habsburgian lands which made them more cosmopolite and less vulnerable for nationalistic feelings against Slavic folks of Stefan's sort. On his side, Stefan was willing to put aside his own Slovenian emotions in exchange for a great academic career.

Brücke's archenemy was the Viennese professor the supporter of romantic physiological vitalism Josef Hyrtl (1810 Eisenstadt (Železno) in Burgerland-1894 Viennese suburb) who suffered total loses of his personal belongings during the Viennese spring of nation in the course of March 1848 revolution and opposed Epicurus or Lucretius' materialistic atomism. In October 1857, Ludwig heard Stefan's talk at the Viennese academy entitled Observations on the Absorption of Gases and enabled Stefan to use Ludwig's lab while Ludwig also supported his Marburg student Adolf Fick's (1829 Kassel-1901 Blankenberge in Flemish Belgium) research of diffusion.[2784] Stefan was still unable to conduct his experiments according to his own ideas in Ludwig's lab, but it was a great step forward for a young provincial guy like Stefan whose Carinthia German dialect never allowed him to become a real Viennese freak.

With such support of the liberal Viennese professors of medicine, Stefan just could not fail on his way to the top. In 1860, Stefan became a corresponding member of the Imperial Academy of Sciences in Vienna because Brücke lobbied for him. After Grailich suddenly passed away, Stefan got his own five minutes. Brücke recommended Stefan to the counselor in the ministry for Education and Religion the Benedictine Marian Koller who personally attended the lecture in Stefan's classroom.[2785] As a native Carniolan, Koller had some special sympathies for Stefan's Slovenian origins. Koller worked together with Johann Kleemann, later baron Eduard Tomaschek, the counsellor Johann von Fontana and the cryptogamist Ludwig Samuel Joseph David Alexander baron Hohenbühel Heufler zu Rasen und Perdonegg (1817-1885) under the Section chief the writer later baron Adolph knight Kriegs (1819 Vienna-1884 Vienna) in 1866. In 1802–1811, Koller studied in Ljubljana with Kersnik. Koller studied higher mathematics in Vienna afterwards until he became a private tutor in Steinbach near Benedictine abbey Kremsmünster in 1814-1816. Koller lectured on physics and Natural history and headed the astronomical observatory in Kremsmünster Benedictine monastery after 1824. In 1848 he became a member of Viennese academy and got a Leopold's cross in 1859.[2786]

Between 20th January 1862 and 9th March 1863, the authorities run a process of Stefan's appointment as a full-time professor of higher mathematics and physics at the University of Vienna while he also became the co-director of the Physics Institute receiving his annual salary of 1680 guldens with an additional 157 guldens and

50 kr.[2787] The appointment of Stefan was already a secretary of state's introduction to Stefan's later replacement of the sick Ettingshausen.[2788]

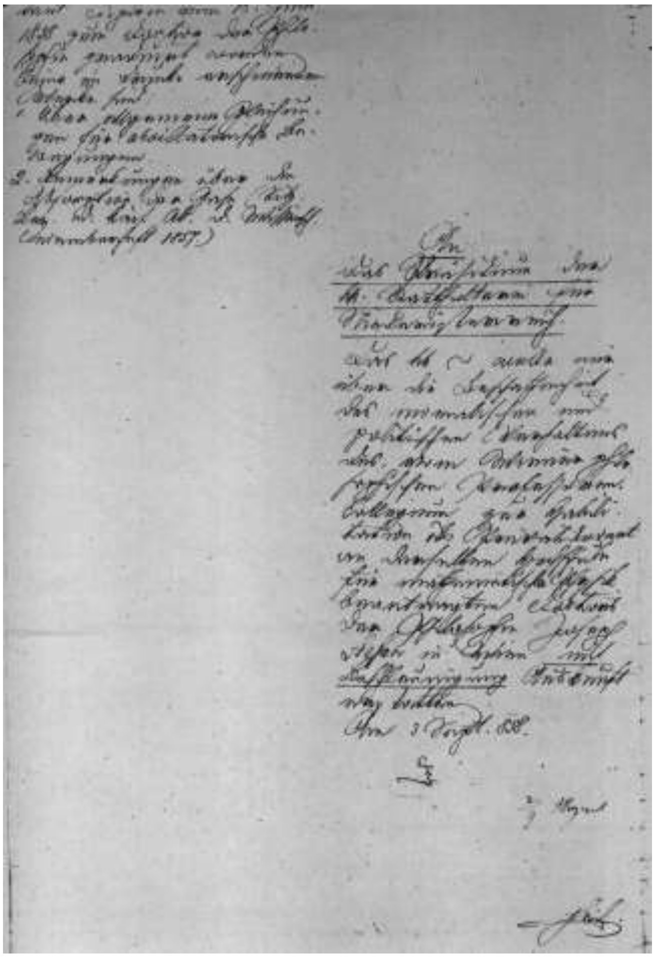

Figure 22-47: The second page of Stefan's application for habilitation issued on 3 September 1858. In the left upper corner, he listed his proposed paper on fluctuations, which was later published in Ann.Phys., and his work on the absorption of gases, on which he lectured at the Viennese Academy on 10 December 1857. He published that stuff in following year in the academic bulletin on 9. 12. 1858.

On 20 December 1862, on the supposedly given recommendation of the Emperor the liberal prime minister (Ministerpräsiden) newly appointed honorary member of Viennese academy Anton Ritter von Schmerling (1805 Lichtental by Vienna-1893 Vienna) listed fourteen Stefan's published works, one of which was just a continuation of the previous work. Three of the afore mentioned basic works have not yet been mentioned in Slovene literature,[2789] perhaps because Stefan there mostly discussed pure mathematics which soon ceased to be his main topics although it still attracted his best student Boltzmann. Stefan has published two of those previously unknown works in the then leading German mathematical Schlömilich's magazine, where they also printed papers about physics. Later, only the titles of Stefan's subsequent works were republished in Schlömilich's magazine.

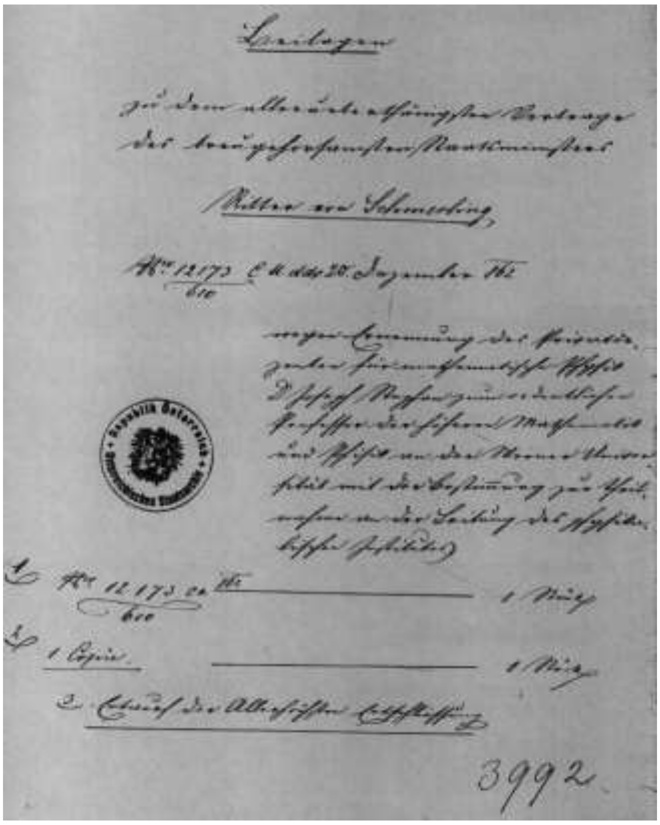

Figure 22-48: The cover letter of 20. 12. 1862, in which the Minister Schmerling recommended J. Stefan to the Emperor (Documents, 20. 12. 1862).

On 27th April 1865, Stefan was the first recipient of the prize of the wealthy Jewish banker Ignaz Isak Leopold Lieben (* 28 February 1805 Prague; † 12 March 1862 Vienna) in the amount of 900 Gulden. J. Stefan loved the opportunities to send some of his earnings to his bellowed mother back home, but she already passed away year and a half earlier to transform J. Stefan into a cosmopolite expatriate shaped by imperial wishes like Močnik. Until J. Stefan's domestic marriage, he spent both of his decades without singing of Slovenian songs of Carinthia. The Prague-Viennese Jewish

community which brought up W. Pauli, Stefan Zweig and Sigmund Freud was on its way~~s~~ up. J. Stefan got his Jewish Lieben's prize, but he did not welcome many Jewish guys in his Viennese Institute of physics as Stefan was far from E. Mach-Pauli Viennese Pro-Semitic circles in the times when the Viennese politics began to divide between the Jewish-infiltrated socialists and the future Nazis. The Jewish genius of physics and chemistry just began to emerge in USA with Helmholtz's doctoral student Albert Michelson (1852 Strzelno-1931 Pasadena) and in Prussia before Einstein with Helmholtz's Berliner students like the native of the free Hanseatic city of Hamburg with the greatest concentration of Jews in Germany Heinrich Rudolf Hertz (1857 Hamburg-1895 Bonn) or the Prussian Fritz Haber (1868 Wroclaw-1934 Basel) followed by Planck's Berliner assistants Max Abraham (1875 Gdansk-1822 Munich) and Lise Meitner (1878 Vienna-1968 Cambridge) who got her Ph.D. among the last in Boltzmann's class. The Prussians declared their full civil right to Jews in 1812 which was formalized in Habsburg empire only in 1867 long after many Jews joined the Habsburg empire with annexation of Galicia in 1772. The Jesuits used to be deeply hostile to the religious Jews, but the converts like Paul Guldin in Graz were very welcome. Stefan couldn't hire much more Jews in Vienna of his days even if he wished because physics was just becoming the goal of Jews and females in Stefan's days Vienna. The Slovenian areas were even slower before the first Jewish physicists of Ljubljana Ivan Kuščer (1918 Vienna-2000 Ljubljana) whose mother from Viennese Kautsky Austro-Marxist painting family was personal friend of Rosa Luxemburg, or the Russian-Jewish physician-chemist Evgen Kansky (1887 Warsaw-1977) and his son chemist-vacuum researcher Evgen Kansky (1926-1987). Stefan formally tried to stay out of daily politics, but nobody ever really succeeded in anything like that in this world.

Between 9. 6. 1866 and 10. 10. 1866 the procedure for retirement of Ettingshausen with an annual pension of 4000 florins was completed.[2790] The career of J. Stefan profited from his abandoning of early poetic Slovenian nationalism for his unquestionable loyalty to Habsburg comparable to Jewish Viennese loyalty which was challenged by the Anti-Semitic Catholic Viennese mayor Karl Lueger (1844-1910) only after J. Stefan's death. The minister Schmerling proposed and suggested that Stefan should take over Ettingshausen's senior physics chair and become the sole director of the Physics Institute and a professor at the University, with an annual income of 3500 guilders including the opportunity to have his flat in the building of Institute of physics. The appointment was signed by Franc Josef with a somewhat lower annual income in his imperial residence in Upper Austrian Bad Ischl on 1/10/1866. Ettingshausen entrusted his students to his disciple Stefan, because they were of the same opinion on the importance of atomism, kinetic theory, and vacuum experiments for further development of the physical sciences.

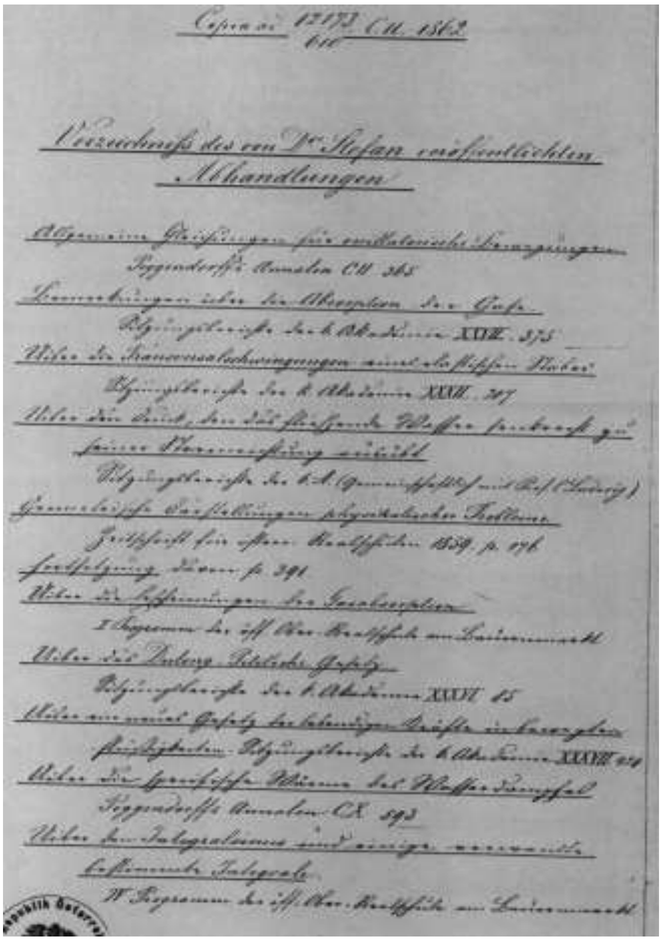

Figure 22-49: The first part of Schmerling's 20th December 1862 listing of fourteen Stefan's published works, one of which was only the continuation of the previous publication (Documents, 20. 12. 1862).

By order of 7 April 1873, Franc Josef I elevated Stefan to the first payment class-grade. His annual salary was increased from 3000 to 3500 florins according to the proposal of the Minister for the

[2790] Stefan Archive Wien 106_I_3988 Papers, 20 September 1866, pp. 11-12.

Education and Worship the liberal Karl Edler von Stremayr (* 1823 Graz; † 1904). For unmarried, modest Stefan, this was a great salary, it was quite a paycheck.

Zur Einsicht:

Figure 22-51: Emperor Franc Josef I in Vienna approved the appointment of Jožef Stefan as a professor of mathematical physics at the University of Vienna (Documents, 26. 1. 1863). Three years later between 9 June 1866 and 10 October 1866, Ettingshausen retired with the annual pension of 4000 fl.

In 1878, Ettingshausen died; his former student Stefan published his obituary for the Viennese Academy. On 27 October 1878, Stremayr's secretary of state of Educational and Religious Affairs (School and Worship) proposed Stefan and a professor of mineralogy and petrography Tschermak for the new court councilors. In his letter, the secretary of state Stremayr described their merits and life paths. Stremayr gave Stefan full credit for the Habsburg-Austrian mathematical-physical research comparable to the English, French and German scholars. Among Stefan's achievements he listed: taking over the secretarial work of the mathematical-science class of the Viennese Academy after the deceased professor of chemistry Kristelli, the rectorate at the university in the school year 1876/77, the leadership of the Habsburg-Austrian commission for teaching at the exhibition in Paris and membership in the Grammar school (gymnasium) examination commission. Stefan was also the Commissioner for Physics and Physical Textbook Consultant at the department of state.[2791] The third Parisian World's Fair, called an Exposition Universelle in French, was held from 1 May through to 10 November 1878. Among the many inventions on display was Alexander Graham Bell's telephone. Electric arc lighting had been installed all along the Avenue de l'Opera and the Place de l'Opera. In June, a switch was thrown, and the area was lit by electric Yablochkov's arc lamps, powered by Zénobe Gramme's dynamos. Thomas Edison had on display a megaphone and phonograph. International juries judged the various exhibits, awarding medals of gold, silver and bronze. In 1867 or more probably in 1878 Stefan obviously participated in that Parisian spectacle which might have been one of his rare journeys abroad. The second Parisian exposition with Carniolan Agricultural company participating with cereals was in 1867, the third under general commissioner navigational-construction engineer Jean-Baptiste Krantz (1817–1899 Paris) in 1878. In 1878 Austrian delegation was headed by emperor's son Rudolph. The director of Trieste school Vlacovich presented his physics lectures and many Ljubljana erudite also participated. Stefan's Parisian Habsburgian commission for secondary school teaching was officially headed by his Viennese university classmate Alexander Anton Bauer (Sandor, 1836 Altenburg (Mosonmagyaróvár)-1931 Vienna) who taught general chemistry at Viennese Polytechnic and organized the first chair of electrotechnics as the rector of Polytechnic in 1882/83 in connection with Stefan's technical leadership of the Viennese electrical exhibition of 1883.

The secretary of state Stremayr described Stefan and Tschermak as good and reliable in political and moral terms and respected among colleagues.

[2791] Stefan Archive Wien 106_I_3988 Papers, 27 October 1878, pp. 4-5.

Franc Josef signed the order appointing those two new court councilors in his imperial residence in Gödöllő in Budapest metropolitan areas on November 1, 1878. Tschermak was otherwise Stefan's opponent. He criticized Stefan’s (1858) extension of the Dulong-Petit’s law approximately valid for solids all the way to gases, which Tschermak’s opinion was also shared by S. Šubic. In 1893, Tschermak even suggested Mach as Stefan's successor at the University of Vienna and opposed Boltzmann's candidature for Stefan’s chair.[2792]

With this appointment, Stefan's career reached a peak. In the 1860-s and 1870-s, he was also an adviser to the secretary of state for the Strengthening and graduating of the Quality of Scientific Works and for granting scholarship for higher studies of physics, including even the scholarships for the study abroad.[2793] He thus directed the entire physical research in the monarchy and followed his teacher Ettingshausen in the research of atomism by using the evolving vacuum techniques.

22.2.7 Stefan Exploration of Kinetic Theory and Atoms

In the beginning of Stefan's scientific pathway, the director of the Polytechnic in Karlsruhe Ferdinand Redtenbacher (* 1809; † 1863) published the theory of smallest ultimate material elementary nuclei with envelopes made from the ether in 1852 and 1857. Redtenbacher’s theory was based on Regnault's experiments and on the model of vibrations in solids and gained a great initial support in Habsburg monarchy thanks to the key position of Ferdinand Redtenbacher’s influential cousins in the Viennese academy.

In Germany, a more contemporary theory was simultaneously published. It was designed by Krönig, director of the real school and editor of the *Fortschritte der Physik* in Berlin in 1856, and by Clausius, a professor at the University of Zurich in 1857. Their kinetic theory was based on the translation of molecules in gases and did not explicitly adhere to any model of atoms, ether or vacuum. Therefore, Redtenbacher generalized his vision based on solids to a general approach for all substances while his opponents Krönig and Clausius extrapolated their vision of gases to the other aggregate states. The key question on which the merger of both theories was broken was the behavior of the substance at low pressure in vacuum experiments. Just as the development of mathematics has always been propelled by the (Indian) ideas about the infinitely small quantities of Zenon's paradox of motion, Newton's infinitesimal calculus, and Cantor's paradoxes of groups, modern physics has advanced and progressed primarily through vacuum experiments, which were therefore equally focused on the infinitely small quantities, in their cases on the infinitely small densities and pressures. While answering the puzzling question of vacuum, of course, even great philosophical theories have failed, such as Descartes’ and Aristotle’s ideas.

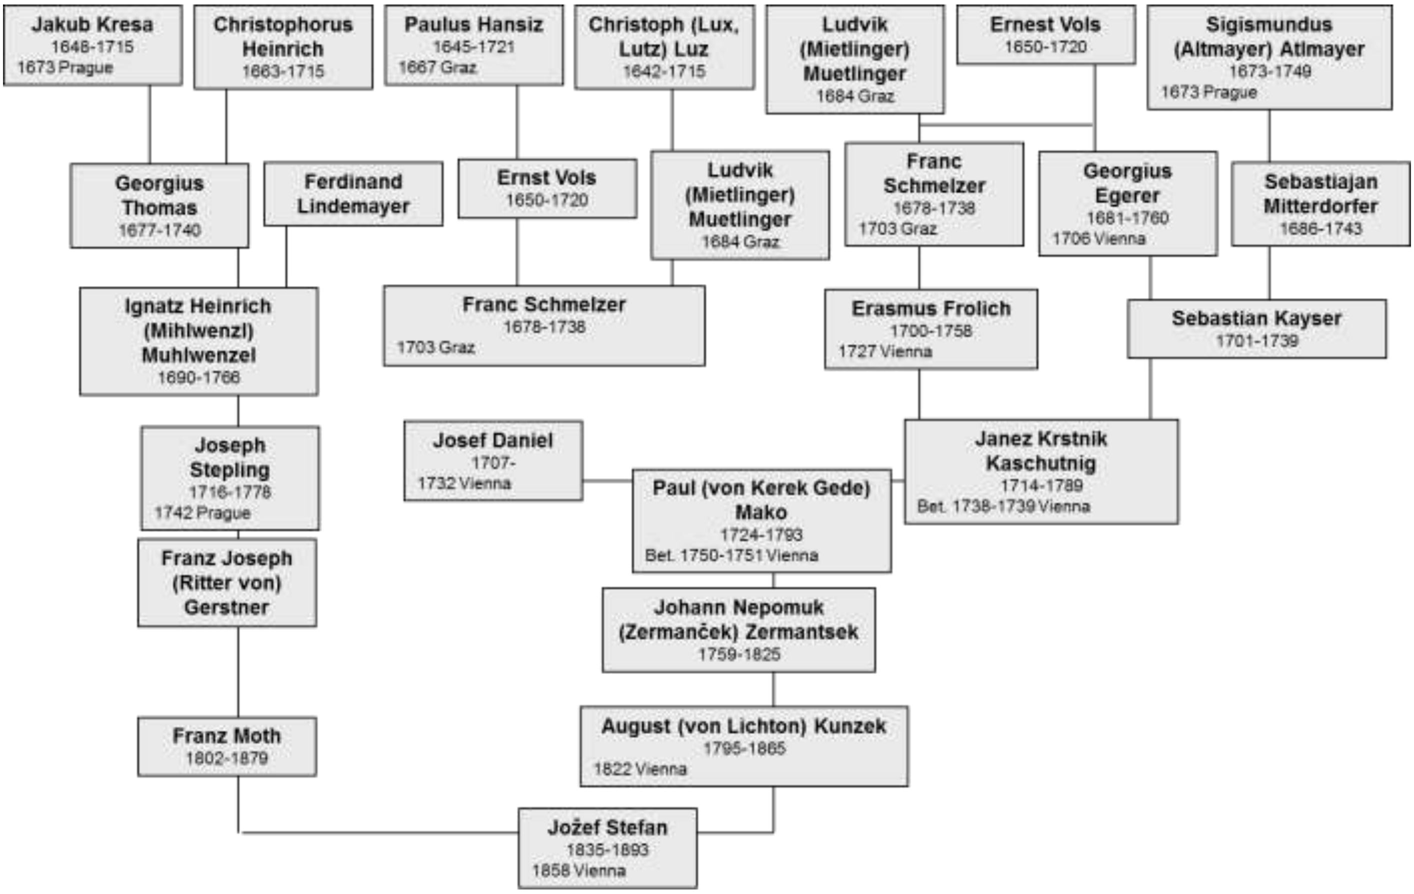

Figure 22-55: Stefan's academic descendants and ancestors by the Viennese Moth and Kunzek's branches.

When Stefan began his research work in the 1860-s, the kinetic theory of gases with the theory of vacuum went into problems that originated from differences in the methods of Clausius and Maxwell, and from lacking of adequate measurements of transport coefficients.

Stefan was a proponent of kinetic theory; nevertheless, in 1872, he chose the model of an atom close to F. Redtenbacher's Dynamides which probably gained some support of F. Redtenbacher's Viennese based relatives. While Clausius generalized the gas model and the translation of molecules for all thermal phenomena, Redtenbacher in a similar but opposite way expanded his own use of the model of vibrations of molecules in solids. Between those alternatives of solids and gases, Stefan chose the intermediate path focused on use of the liquid model as suitable for all forms of heat. Stefan's alternative was also acceptable for the proponents of Clausius' kinetic theory of gases because Thomas Andrews' data and later Van der Waals's researches proved that the phase transitions between liquids and gases were much smoother than the transition into crystalline solids. Stefan chose the established theory of hydrodynamics as the base his research, although Stefan very early as a student dismissed hydrostatics as boring,[2794] probably because it was so convincing without much researching alternatives left. The idea was very clever because the 18th century industrialized hydrodynamics used for high society entertainments and parks was the most advanced and finished theory inside physics except for the geometrical optics. Stefan's expansion and spread of heat was considered and treated as a special branch of hydrodynamics. Analytical mechanics has been supplemented by the thermal spread of matter and internal friction.[2795] So, we can have Stefan's research of thermal phenomena as the continuation of the Fourier research of transfer of heat published in its final form in 1822.
Stefan used the measurements of hydrodynamic in blood capillaries of the Parisian physician Jean Leonard Marie Poiseuille. Poiseuille's reducing of internal friction in the capillaries at a rising temperature questioned and doubted Maxwell's model of elastic balls which was announced in

[2794] Ivan Šubic 1902, 75.
[2795] Pourprix, Locqueneux,1988, 96.

1859. According to Maxwell, the internal friction should increase with rising temperature.[2796] Stefan treated the spread of heat and the diffusion of gases as the hydrodynamic phenomena[2797] in contrast to Graham who took a diffusion of gases for a chemical phenomenon. Stefan did not even accept Maxwell's "ad hoc" model of molecules with a force proportional to fifth potency of the distance. Maxwell's model provided the acceptable diffusion coefficient proportional to the temperature.[2798] However, Maxwell's model did not allow the determination of the internal properties of gas. That is why Stefan published his dynamic model of gas[2799] in which the radius of the molecule decreases with some power of the (absolute) temperature. In Stefan's model, the radius of faster molecules diminished due to increased possibilities of interpenetrations during their mutual collisions. The repulsive force is then proportional to the velocity, just as French Navier argued and claimed as early as in 1826.[2800]

Stefan thought within the sphere of force model, without explicitly declaring the molecules to be like solid bodies. The repulsive force between molecules must operate at greater distances, so that it can affect viscosity.

After 1872, Stefan with his hydrodynamic analogy mainly avoided and ignored the assumptions about the properties and characteristics of molecules and vacuum between them.[2801] Later he no longer published papers on "real" characteristics of atoms, since the critics of E. Mach and Ostwald's energeticists made Stefan afraid. He left a direct controversy to his former student Boltzmann who was a bull designed to fight down the matador Ostwald but not before Stefan passed away. Between 1873 and 1876, Boltzmann and Stefan were in daily contact as the colleagues at the University of Vienna. Their talks were described by Boltzmann in a letter to his later wife of the half Slovenian genus named Jetti on 23 March 1876.[2802]

A similar hydrodynamic model was used by researchers of electricity who assumed that ether and electricity are the same. Their negative electricity would then be the lack of ether, and the potential difference would than indicate the overplus of the ether. Among these researchers, besides the fans of Franklin's one-fluid electrical theory, were the Italian Jesuit and astronomer Secchi, the Swedish native Edlung (1871), Tesla, and Habsburgian Ukrainian Puluj (1880) known for his studies and experiments in vacuum at the Stefan's Institute of physics as he joined his decade older fellow Stefan already at the Exposition Universelle in Paris in 1878. Puluj collaborated with Nikola Tesla in A. Kundt's Strasbourg lab, resembled Tesla with his religious studies in his Orthodox' networks and worked in Mach's German part of Prague university.

22.2.8 The Radiation Law of Stefan

In 1878, Stefan read the "thirty-one-year-old" paper of the New York professor of chemistry and physiology Draper on the influence of electricity on capillaries, where the problem of the exponential increase in the density of the irradiated energy stream flow with temperature was not solved.[2803] Stefan decided to solve the puzzle by himself in probably the best research choice he ever made.

On March 20, 1879 Stefan submitted to the Viennese Academy a paper on radiation. The handwritten summary of the paper was four pages long in A4 format. He wrote the whole paper in his manuscript on 61 pages and printed it on 38 pages.

Half of the paper included its first part about the experimental attempts of Dulong and Petit and the shortcomings of their law "of the geometric increase of the amount of heat in the areas of red-hot grill while the temperatures are rising in the arithmetic sequence". Stefan's fourth-power equation was more in line with the experiments of French school inspector Fréderic Hervé de la Provostay and his friend the professor at Sorbonne Paul Quentin Desains (* 1817; † 1885) at low temperatures. Stefan's equation supposedly had an advantage in theoretical terms[2804] which Boltzmann proved few years later.

[2803] Draper, 1846, Rosenberger, 1890, 448; Sitar, 1993, 82.
[2804] Stefan, 1879, 2, 20; Strnad, 1985, 75.

Dulong-Petit's law was already 62 years old upon Stefan's research. In the meantime, new measurements were made, especially regarding the temperature of the Sun. The theoretical complaints were even more substantive, since in Dulong's time it was not known that thermal conductivity was independent of the density of gas.[2805] This was the most striking finding of Maxwell's kinetic theory of gases, which he described in a letter to Stokes in 1859 and published in the following year.

With Maxwell's theory, Stefan realized that Dulong and Petit really got rid of convection in their measurement of thermal radiation, but they did not exclude the transfer of heat with translations through conductors.[2806] At the time of Dulong and Petit's measurements, folks doubted whether the air was even able to translate the heat. The problem had been solved only by Stefan and his colleagues at their Viennese institute of physics with their measurements of the thermal conductivity of gases in the 1870-s. In the measurements with his newly invented dia-thermometer Stefan used the best achievements of then available vacuum technique.

According to the British results, Stefan already knew that there is also the third possibility of spread of heat, namely the one which involved the infrared radiations. Therefore, in his second part of the paper, Stefan determined the size of the thermal radiation in absolute units. He compared Desperetz' experiments with the experiments of Joseph Prudent Frédéric Herve de la Provostay from Parisian college Louis-Le-Grand and Desains from Sorbonne. All of them offered considerably lower results with their values of the thermal radiation.

In the third part of his paper, Stefan discussed the experiments of Draper and Ericsson. The paper began with a report on Wüllner's textbook adaptation of Tyndall's experiments, which should be especially well-compliant with Stefan's law as a great confirmation. So far, that half-page had been an essential part of Stefan's paper.[2807] However, Stefan did not even mention Wüllner and Tyndall in Stefan's handwritten summary of his work. Even in his published article, their measurement seemed less important than the measurements of Draper and Ericsson, with which Stefan addressed the third chapter of his paper. It is highly probable that Stefan learned about Wüllner's publication of Tyndall's results after Stefan wrote his manuscript and before his final publication, therefore Stefan added that data to his work, but more as the minor proof as Tyndall evidently did not provide any kind of very exact measurements. In later development of knowhow Tyndall influential enthusiastic reading of Stefan's law became decisive because Tyndall was probably happy to see his own contributions there although everybody knew that they were not any kind of exact science.

In the fourth part of his paper, Stefan determined the temperature of the Sun. He used the measurements of the Frenchman Claude Servait Matthias Pouillet, and above all mostly the experiments of Charles Soret, a professor at Geneva (Genf). So, Stefan as the first one offered a meaningful useful sensible value for the temperature of the Sun as 5580^{o}C. Charles Soret (1854, Geneva-1904) was the son of Jacques-Louis Soret, professor of physical medicine at University of Geneva. Charles graduated in Geneva and continued studies in mathematics at the Sorbonne. Soon, he was offered a place in the Department of crystallography and mineralogy at the University of Geneva where he published his first discussion on thermo-diffusion based on the experiments with solutions of NaCl and KNO_3 in pipes with heated or cooled ends in 1879. He noticed higher concentrations at the cooler end of the pipe. His experiments confirmed the results of Stefan's mentor-supporter Carl Friedrich Wilhelm Ludwig (1816-1895) published 20 years earlier) of which Soret probably did not know. Soret connection with Ludwig might have been the main reason for Stefan's enthusiastic use of Soret's results.

In contrast to Boltzmann Stefan was quite superficial in his citing and sloppy in quoting. Thus, in the paper of 1879, more than ten researchers were mentioned with no accurate references. Stefan quote of Draper and Ericson's work was incomplete; according to modern criteria, unfortunately, only Stefan's description of the work of Dulong and Petit from 1817 is a correct valuable citation. In Stefan's time that kind of quoting was no major flow as all researcher knew each other and understood well all the points

[2805] Stefan, summary 1879, 2.
[2806] Stefan, 1879, 2.
[2807] Stefan, 1879, 31; Čermelj, 1976; Strnad, 1985; Stefan, 1879, 421, 422, 393.

they were talking about, while in the next generations of Boltzmann the number of researchers involved increased so much that the exact citations became notorious, especially after the quotations became the critical point for the valuation and substantial financial state support of the researcher-author in question.

22.2.9 Stefan's Law among his Contemporaries

On 1 July 1876, Bartoli of the University of Bologna announced that thermal radiation in a vacuum radiometer opposed the second law of thermodynamics with Bartoli's supposedly contrary evidences which was a potentially fatal blow to all Boltzmann's networks. His ideas emerged from his research of vacuum in a radiometer, which Crookes had shown three years earlier before the Royal Society in London. Unlike Crookes, Bartoli was immediately confident and convinced that the radiometer did not measure the absolute vacuum[2808] because Bartoli relied on myriads of his Florentine academic ancestors' research of vacuum including Torricelli.

The Florentine native Bartoli studied physics and mathematics in Pisa until 1874. In 1876 he became an assistant at the University of Bologna and a physicist in Arezzo, in 1878 in Sasari, in 1879 at the Technical Institute in Florence, in 1886 at the University of Catania, and at the University of Pavia in 1893 when Pavia of Bošković and Volta was no longer ruled by Boltzmann's Habsburgians. He has published seventy-nine papers in the leading Italian newspaper *Il Nuovo Cimento* in Pisa. He focused every effort to his study of electric and thermal phenomena. Bartoli's theory of the pressure of light was like Maxwell's and enabled the first measurements. Lebedev published his experiments on the foundations of Bartoli's suppositions in Moscow in August 1901; the Russian Lebedev used G. Kahlbaum's Berlin vacuum pump and he measured the pressure with McLeod's manometer.

Thus, the experimental research of the vacuum began to influence directly the research before the publication of Stefan's law. In 1883, Bartoli's idea was supported by Henry Turner Eddy (1844-1921), a professor of mathematics and astronomy at Cincinnati University who studied in Yale, Paris and Berlin. Boltzmann criticized his peer Eddy. Like Stefan, Boltzmann read about Bartoli's research only in Eddy's work after Stefan gave Boltzmann the English vocabulary to learn enough to study Maxwell's works. The associate professor at Leipzig E. Wiedemann later edited the central physical magazine *Ann.Phys*. with his father G. H. Wiedeman in Leipzig and had a much better overview of Italian publications; so, he read Bartoli's work among the first Germans.

Boltzmann dealt with Bartoli's work in 1884, just before Boltzmann's theoretical derivation of Stefan's law.[2809] Even Stefan probably did not know Bartoli's reflections on vacuum in a radiometer from 1876 until Bartoli's ideas were publicly supported by Eddy. Therefore in scientific networks geographically nearby Pavia was much more distant from Vienna than the faraway USA, which became even more true in following century where the USA ownership of scientific and other media became so prominent that only the more democratic web provided some slight chances to others to challenge USA monopoly of media. That is why Bartoli's radiation studies did not decisively influence Stefan's path to the radiation law in 1879.

Naturally, like all other physicists of his era, Stefan was very interested in vacuum experiments in a radiometer. Stefan had several close contacts with Italian researchers, especially with his former colleague at the Viennese Physical Institute Blaserna, who was the presidents of the Roman Academy dei Lincei since 1904.

From 11 August 1883 to 3 November 1883 the electrotechnical exhibition in Vienna could have influenced Boltzmann's interest in radiation theory. On 25. 10. 1883 Stefan as a scientific leader of the exhibition met with the Honorary Chairman of the Technical-Scientific Commission William Thomson, the later Lord Kelvin. Together with William Siemens they were solemnly accepted by the English embassy in Vienna. William Siemens as a German-born British industrialist even lectured on the radiation inside vacuum in Vienna.[2810] Unfortunately, Siemens did not mention Stefan's law, although he knew our hero Stefan well. From such a short resentment on radiations in vacuum we will never know all

Sl. 8. Certifikat žarnice Laue-Fox.

Figure 22-58: In 1884, Stefan signed certificate for a Lane-Fox English vacuum bulb with glowing charcoal in the shape of a horseshoe at a Viennese exhibition.

Siemens' whereabouts and ideas about Stefan's law, since Siemens suddenly died in London only fifteen days after the end of Viennese exhibition.
Just four years after Edison's invention Stefan presented the facts of Edison's vacuum lamp to the Viennese mayor Eduard Uhl (1813-1892) with his municipal representatives included and even the Habsburg Crown Prince Rudolf was there soon after the birth of his only legitimate daughter Elisabeth on 2 September 1883.[2811] Rudolf sadly passed away five years later with his other lover. Stefan explored the light bulb as an example of his own theory of radiation. At the same time, he inherited the tendency towards useful application of knowhow of his teacher Ettingshausen and emphasized the advantages of the lighting bulb against other sources of light. Wächter and Puluj as the members of Viennese physics institute and Stefan's co-workers also showed their own designs of vacuum bulbs at the Viennese exhibition under Stefan's leadership. Puluj had already taken over his new chair in Prague, but he kept his vivid contact with the Viennese researchers of vacuum. Stefan has been evaluating the capacities of bulbs during several years following the Viennese exhibition. He has been expecting that the very experiments with radiation in vacuum bulbs will help to recognize his theory of radiation; the modern experiments fully justified his hopes.[2812]
The Viennese exhibition and subsequent important papers published about vacuum bulbs have greatly contributed to the popularity of Stefan's radiation law. By conducting the exhibition, Stefan became authority for the manufacturers, producers and users of the lamps, thereby Stefan paved the success of his own law. Nevertheless, during the first five years Stefan's equation was supported mainly by physicists writing in German language.[2813]

23 Major Industrial Uses of Vacuum Technologies for Roentgen

23.1 Roentgen Rays for Electronic

Stefan probably met Edison during the Viennese exhibition of 1883 or later. Edison's fans and his antagonist Americans had a huge politically colored quarrels about the possible scientific values of light bulb research while nobody doubted that J. Stefan's part of it was scientific. Because Stefan was academic person and Edison just wanted to be one. Their cathode ray tubes soon wrote another page of history. At the turn of the 19th century, the fifty-year-old Röntgen discovered mysterious X rays. The novelty was immediately put into use, especially in medicine and in military affairs. With a little help of X-rays many new facts were discovered in a few years. Their nature was explained only by the next generation of researchers in quantum mechanics.

23.2 Röntgen's Research on the Detection of Rays

Figure 23-1: Wilhelm Conrad Röntgen(* 1845; † 1923)

Röntgen was a lively high school student and had fingers in teenage caricature of professor at the Technical School in Utrecht (Figure 23-1).

The alleged artist was immediately excluded from school and could not complete his graduation; so, he studied at the Polytechnic in Zurich between 1865 and 1868, much like Einstein and his wife later because the Matura was not required for matriculation in Zurich. Roentgen learned most of his physical subjects at Zeuner's class, and in the second year he attended technical physics courses at the University of Zurich in the class of Clausius, who had just recently established a modern kinetic theory of heat and gases. In addition to Zeuner's lectures on mechanical heat theory, Röntgen also listened to Clausius's optional lectures on the same substance where Röntgen was deeply influenced by Clausuis' abstract clarity and accuracy. In 1868, young Kundt was elected as Clausuis' successor. After Röntgen's dissertation on gases in 1869, Kundt pushed the mechanic engineer Röntgen into physics.

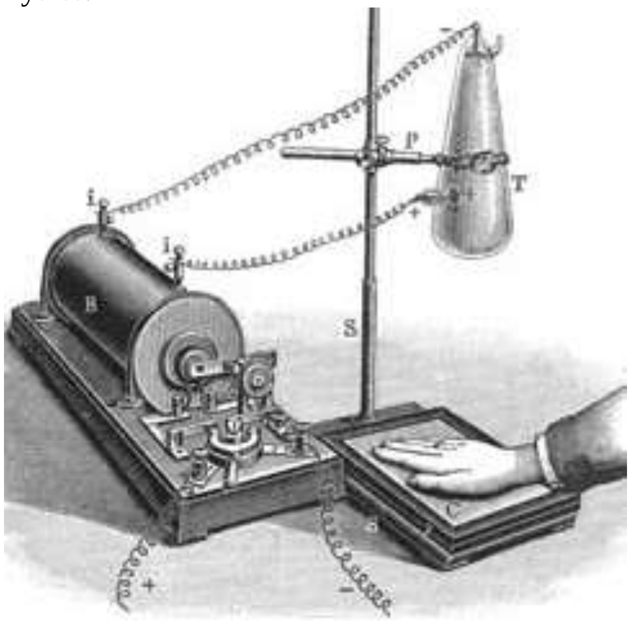

Figure 23-2: An experimental device to record the first X-ray of the human hand.[2814]

23.3 Discovery

On 7. 5. 1895, Lenard from Bonn fulfilled Röntgen's demand and sent to him an ordered tube made by the glassblower trained in Geissler's Bonn headquarters Louis Müller-Unkel~~'s~~ (1853-1938). Louis headed his Institut zur Anfertigung chemischer, physikalischer und meteorologischer Glasprācisions-Instrumente in Braunschweig. His

[2814] Heinrich Oscar Günther Ellinger (1857 Copenhagen-1947), Naturen og dens Kræfter. Populær Fysik. Copenhagen: Frem, 1897–1898.

glass cathode ray tube had an anti-cathode of 0.005 mm thick aluminium, which radiated the "cathode rays". Later it turned out that lightweight aluminium was the worst choice for experiments with X-rays. On 28 December 1890, Röntgen listed three different vacuum tubes, with which those new rays could be observed. We have different testimonies, colored with different interests regarding Lenard's priority about the device which Röntgen used for his discovery on 8 November 1895.[2815]

Figure 23-3: The X-ray image of a left hand with a wedding ring of his colleague Alberto von Koelliker (1817-1905), taken by Röntgen on 9. 3. 1896.

Figure 23-4: Manuscript and Cover page of the First Röntgen Discussion on the New

Röntgen used a large Ruhmkorff induction device of Ferdinand Ernecke's (1832-1914) Berliner firm. The tube was covered with a thin, screw-fitting cardboard. In the darkened room, even from the distance of 2 m, Röntgen noticed a fluorescence on a paper screen painted with barium platinocyanide, which he placed near the tube. Photographs were initially used to confirm the observed fluorescence. Already in 1895, Röntgen photographed, among other things, the bones of his wife's hand with a ring and a non-homogeneity in a piece of metal, which opened up a wide area of application next year (Figures 23-2 and 23-3).

In 1896, Röntgen published experiments in which he replaced the cardboard with a galvanized sheet metal box that had a window made of lead (Figure 23-4). He used a 3 cm thick and 45 cm long brass tube of 1 cm wide window, covered with aluminium sheet.[2816]

23.4 Disputes on the Nature of X-Rays

Along with copies of his first discovery on December 28, 1895, Röntgen also sent X-ray photographs to established researchers worldwide. The use of the photos supported the feelings that the new rays were waves because most of photography recoded visible light. Röntgen found that the new rays are not the same as cathode rays, since the electric charges do not affect them. Also, they are not UV light, because they do not diffract, they are incorrectly reflected, they cannot be polarized, and their absorption depends on the density of materials.[2817]

Boltzmann commented on Röntgen's discovery on 15 January 1896 and 22 September 1899; Kelvin added his ideas on 12 February 1896 and, together with other Britons, initially supported Röntgen's theory of the longitudinal waves of the ether. However, on February 25, 1896, he changed his mind as most of Brits did. At the lecture on 10 June 1896 J.J. Thomson gave priority to X-rays as transversal waves with shorter wavelength compared to UV light.[2818]

In Prague, Puluj[2819] also rejected Röntgen's unfounded hypothesis of longitudinal rays. But

[2819] Puluj, 1896, 238.

only the Englishman Barkla excluded any longitudinal possibility with proves of polarization of X-rays in 1904 and picked up the Nobel Prize in Physics thirteen years later. In January 1896 in his laboratory Puluj shot many X-ray photographs for doctors and surgeons. Even patients from a relatively remote Cologne arrived to get their X-ray photography in Puluj's lab.
Lenard considered that Röntgen described the very rapid cathode rays that Lenard himself had discovered before him. Together with other German physicists, he opposed the British theories of cathode rays as particles or electrons.

Besides the basic contradiction, there were also different theories of new rays. The Englishman WH Bragg in Australia and the Serbian Tesla in the US considered X-rays to be small particles that could spew out electrons from atoms on August 1, 1896 and August 29, 1896. On 23 January 1896, Schuster from Manchester announced that, that "cathode ray" emits X-rays from solids. Similarly, on March 26, 1896 Stokes and Wiechert argued that the braking of electrons produces very short pulses of X-rays.[2820] Stokes' idea that "each charged molecule creates such a pulse as it runs along the wall" was a compromise between the particles and waves adopted by most British physicists in the first decade of the 20th century.[2821] Stokes's pulse theory resembled Descartes's light as the pressure in a transparent medium as a compromise between emission theory of corpuscles and the undulatory theory of waves of light in a way that disputed ideas repeats themselves in history.

BIOGRAPHY: Philipp Lenard from Bratislava studied under supervision of the professor Helmholtz and received his doctorate at Bunsen's class in Heidelberg. As an assistant he served his five years older superior Jew Hertz in Bonn and after his death he published Hertz's collected works with mechanics included and led the Bonn Physics Institute. He then became professor in Breslau (today's Wroclaw), in 1895/96 in Aachen, between 1896 and 1898 in Heidelberg, between 1898 and 1908 in Kiel, and again in Heidelberg in 1910/1911. In 1905 he received the Nobel Prize. He sadly published a textbook "Deutsche Physik" with Nazi positions against Jews.[2822]

23.5 Experimental Determination of the Nature of X-Rays

After 1899, Röntgen as a professor of experimental physics in Munich reorganized the Institute of Theoretical Physics which was losing its importance after Professor Boltzmann's departure. In 1905, Röntgen arranged the appointment of the new professor Sommerfeld, who studied the theory of X-rays as a supporter of Stokes and Wiechert's theory. Four years later the private assistant Laue was employed.

In 1912 in the Hofgarten coffee shop in central Munich Laue defended the possibility of diffraction of X-rays on the crystal at a daily meeting of local physicists. Many doubted Laue's idea. Sommerfeld and Röntgen did not believe that the crystal could act as a diffraction grid because of its thermal motion. The assistant Friedrich set up an experiment in the laboratory half-secretly. He used a crystal of copper (II) sulfate (blue vitriol), which was not lacking in the laboratory. He put the crystal on the path of X-rays, and he installed a photographic plate perpendicular to the crystal, which would allow the detection of X-rays scattered at a right angle after a long irradiation. The rays did not appear because he placed the crystal too close to the source of the rays, just like in his time Röntgen did.

In the same room, P. Knipping was preparing a doctorate; in two or three weeks, he was expected to leave the laboratory. He set up a photographic plate behind the crystal, which brought success. The short report was published in April, and Sommerfeld presented the joint work of Laue, W. Friedrich and Knipping to the Munich Academy on June 8, 1912 (Figure 23-5).[2823]

Munich remained the center of X-ray research physics for a decade and a half.[2824] In the summer of 1912, W. H. Bragg tried to adjust the Munich experiment to his theory of X-rays imagined as corpuscles. His son Lawrence corrected Laue's analysis of the experiment in November 1912. Under the influence of his father's theory and Stokes's pulse theory, Lawrence assumed that X-rays were particles accompanied by waves. The

23.6 Notes on Röntgen's Discovery in Habsburg Areas and in Slovenian Countries

23.6.1 On Röntgen's Invention in the German Language of Triestino Mosetig (Mozetič)

The development of new science in Hallerstein's and Vega's time enabled subsequent Carniolan explorers to quickly accept new facts and ideas. It is therefore not surprising that in Ljubljana they wrote about X-rays immediately after Röntgen's discovery. The news was first reported in German language newspapers, especially in Laibacher Zeitung (LZg), only later in the journal Slovenec. For this reason, for the first time in historiography, we started a study on German written scientific discussions in Ljubljana. For many readers, it will be a great surprise to remember that Slovenian capital was a bilingual city a century ago. Early popular reports and writings about X-rays had an additional charm.

Röntgen's invention has quickly found use outside of physics. On the first day of the new year of 1896, the Viennese professor of physics Franz Exner received the paper of his former classmate Röntgen. He informed his co-worker, a Prague professor of physics Lecher, the son of the editor of the Die Viennese Neue Freie Presse, where they published the news already in the Sunday issue on 5 January 1896. Franz's brother, the physiologist Sigmund Exner, published his report in a Viennese medical newspaper on 16 January 1896.[2826]

On 12 January 1896, Röntgen was invited to Berlin by the emperor Wilhelm II. The emperor observed many experiments and personally decorated Röntgen's chest with the Prussian order of crown of the second order. Of course, Röntgen was a man who had not succeeded in Matura exam in his time and the gates of all Dutch, German and Austrian universities had been closed tightly to prevent his studies. However, that old youthful scandal was already forgotten, and Röntgen donated to his Emperor twenty-five personally arranged photographs, as the Berliner Localanzeiger accurately reported. Only a few days later, on 15. 1. 1896, the news was published in the LZg, with detailed descriptions of the famous Röntgen without Matura and his Berlin Emperor.

Only one-week after the Viennese, the residents of the town of Ljubljana read about the uses of X-rays in medicine. On 23 January 1896 LZg wrote about two operations of professor Mosetich of Slovenian genus, indeed Albert Johann Mosetig knight Moorhof (Mosetich, Mozetič, 1838 Trieste-1907 in Danube by Vienna) private docent for surgery superior (primarius) of General Hospital. Albert Johann Mosetig knight Moorhof finished his Grammar school in Trieste and studied in Vienna with Brücke and Josef Hyrtl to achieve his PhD in medicine and surgery in the class of his fellow Triestino Johann baron Dumreicher (* 1815

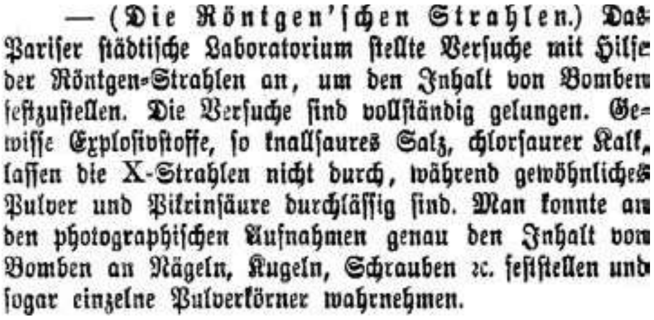
[2825] Madey, 1984, 54.

[2826] Wien.Klin.Wschr. (Glasser, 1959, 177, 185).

Trieste; † 1880 castle Janušovec northwest of Zagreb near Slovenian border). The general chief physician of the Teutonic Order Mosetig used X-rays to record the position of the projectile in the body and the broken leg of a beautiful young lady. It is interesting to note that even today Slovenians have the leading vacuum technology researchers from the family Mozetič.

— (Röntgen und die Chirurgie.) Im Posener photographischen Verein wurden diesertage, wie gemeldet wird, mittelst der Röntgen'schen Strahlen eine Kugel, die seit vierzehn Jahren in der Hand eines Mannes saß, sowie Schrottkörner, die ein Knabe seit Jahresfrist in der Hand hatte, photographiert.

Figure 23-6: Hand surgery after X-ray imaging2827

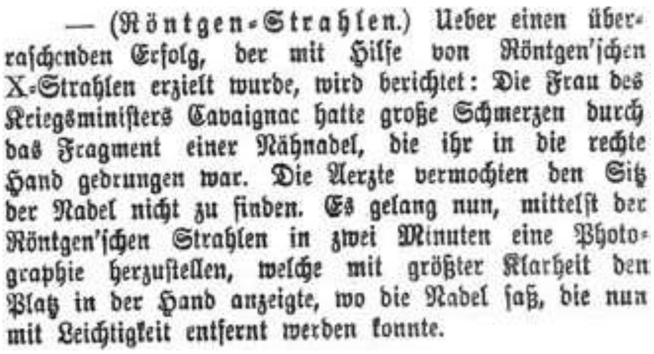


— (Die Röntgen'schen Strahlen.) Das Pariser städtische Laboratorium stellte Versuche mit Hilfe der Röntgen-Strahlen an, um den Inhalt von Bomben festzustellen. Die Versuche sind vollständig gelungen. Gewisse Explosivstoffe, so knallsaures Salz, chlorsaurer Kalk, lassen die X-Strahlen nicht durch, während gewöhnliches Pulver und Pikrinsäure durchlässig sind. Man konnte an den photographischen Aufnahmen genau den Inhalt von Bomben an Nägeln, Kugeln, Schrauben &c. feststellen und sogar einzelne Pulverkörner wahrnehmen.

Figure 23-7: The Parisian X-rays photo of the inside of the bomb[2828]

On 27 January 1896, the residents of Ljubljana published Lenard's report from Budapest. Lenard's Nazi career was still awaiting in the future, but at that time he disparagingly described Röntgen's discovery as the accidental success of his lucky rival in an area that he himself mastered to perfection. He tested the permeability of new rays through paper, wood and human hands. At the end of the month, the residents of Ljubljana summarized the Viennese Neue Freie Presse report from the Viennese clinic. Reusser successfully diagnosed kidney stones by his X-rays photographs. The next day, LZg reported X-ray bombardment for the search for a missile, which the man had in his hand for fourteen years (Figure 23-6). On February 2, 1896, a lecture was delivered by Franz Ernst Neumann's Königsberg (Kalinigrad) student now professor of physics Jean Pernet (Johannes, 1845 Bern-1902 Zürich) from the Viennese Polytechnic. Four days earlier, he had two hundred and fifty listeners on international days of clinical doctors. He hit the headlines after his experimental X-ray images of a boy's hand. Röntgen was then on a scientific visit to Zurich and sent Pernet the telegrams with heartfelt greetings as Pernet was his former professor of ETH experimental physics where he gave Einstein the lowest possible mark because Einstein was a rare guest in his lab.

The Army also quickly accepted Röntgen's discovery as did physicians themselves. On February 7, 1896, Röntgen's rays were used to check the quality of alloys in pipes and spheres. A month later, the inhabitants of Ljubljana read about the contents of the bomb, which was roentgenized out in a Parisian laboratory (Figure 23-7). They did not mention Curie's spouses, who were married for half a year and participated in the experiments as a leading expert in Parisian metropolitan area. On March 27, 1896, an idle was roentgenized in the right hand of Blanche Mojon (1854-1931), a spouse of the Parisian antisemitic War Minister Godefroy Cavaignac (1853-1905) in a matter of two minutes and the surgeons immediately saved the pain of a famous lady (Figure 23-8). This was the time of the first sewing machines and many careless housewives did not use the right security measures. Boltzmann personally made a sewing machine for his wife, the blue-haired Jetti of half Slovenian descent. Naturally, Jetti was smarter than the minister's lady and avoided harmlessly the supposed damage or injuries.



— (Röntgen-Strahlen.) Ueber einen überraschenden Erfolg, der mit Hilfe von Röntgen'schen X-Strahlen erzielt wurde, wird berichtet: Die Frau des Kriegsministers Cavaignac hatte große Schmerzen durch das Fragment einer Nähnadel, die ihr in die rechte Hand gedrungen war. Die Aerzte vermochten den Sitz der Nadel nicht zu finden. Es gelang nun, mittelst der Röntgen'schen Strahlen in zwei Minuten eine Photographie herzustellen, welche mit größter Klarheit den Platz in der Hand anzeigte, wo die Nadel saß, die nun mit Leichtigkeit entfernt werden konnte.

Figure 23-8: X-ray filming of a needle in the hand of the French minister's spouse[2829]

[2827] *LZg*. 1. 2. 1896. Tagesneuigkeiten. Röntgen und die Chirurgie. no. 26: 197.
[2828] *LZg*. 7. 3. 1896. Tagesneuigkeiten. Die Röntgen'schen Strahlen. no. 56: 433.
[2829] *LZg*. 27. 3. 1896. Tagesneuigkeiten. Röntgen-Strahlen. no. 71: 561.

On 18 February 1896, the LZg reported on the operational removal of needles strapped into the foot and arm of the careless Britons. On February 3, 1896, the inhabitants of Ljubljana summarized the report of the Munich Medicinische Wochenschrift on Hans Buchner's (1850-1902) experiments destroying the bacteria with X-rays. Especially infuriated typhus bacteria had already been successfully suppressed. Thus, the Ljubljana reader of the German language daily learned extremely quickly about all the circumstances of the new discoveries, which justified the subsequent exploration of X-ray in Ljubljana. The discoveries were presented to the German language readers of Ljubljana journal very quickly, only slightly later after the events.

The X-rays were so popular that there was almost no great delay before their descriptions in the imperial city and in the white provincial Ljubljana. In March 1896, the inhabitants of Ljubljana began to publish news about X-rays in Slovenian language magazines.

The opinions of the most important physicist Ludwig Boltzmann determined all other approaches to X-rays in the monarchy and, of course, in Ljubljana. Boltzmann was the best pupil of Slovenian Stefan, and even Boltzmann’s bride was half Slovenian. The Carniolan professors of physics discussed all the novelties associated with Röntgen's discovery in due time. Among the writers was Boltzmann's former associate from the University Graz S. Šubic and Boltzmann's student Čadež from Carniolan grammar school; they were especially distinguished. The Čadež’s family of Kranj has remained faithful to the X-ray even today.

23.6.2 *Slovenian Language Reports on X-rays*

Two and a half months after the first publication, X-rays were also described in the Slovenian language. On March 1 and in March 15, 1896, the Ljubljana journal Home and the World (Dom in Svet) published Šubic's first papers on a new discovery with two photographs of J Stefan’s student Josef Maria Eder (1855 Krems-1944 Kitzbühel in Tirol), the chair for photochemistry and scientific photography at the Viennese University of Technology. In a series of experiments in 1896, Eder and his father-in-law Eduard Valenta (1857-1937) managed to drastically improve the newly discovered effect of X-rays on light-sensitive substances within a few days (Figure 23-9). Šubic sent to Ljubljana the beautiful X-rays photos, produced by his colleague at the Graz University Czermak, but they were not published.

Človeško telo — prozorno.

(Spisal dr. Simon Šubic.)

Bilo je na Dunaju prvi mesec po Röntgenovi najdbi nove svetlobe, ko se je sešlo več strokovnjakov v delalnici prof. dr. Ederja, voditelja fotografske šole. Učenjaki so se pogovarjali o prevažni odkritvi prodirajoče sile Röntgenovih žarkov.

Pred možmi je stala draga zapletena priprava, sestavljena iz fizikalnih, električnih in fotografskih priprav. V zatemnjeni sobi je stal

In trudil se je prof. dr. Eder in trudil, in poskušali so še mnogi posnemalci in veščaki, a večinoma brez pravega uspeha. In zakaj je bilo vse prizadevanje zastonj? Zakaj bi ne mogli s prostimi očmi drugi ogledovati tega, kar je iznajdnik zagledal s svojimi očmi?

Preiskovanje tega vzroka je privědlo do spoznanja, da senco stvari, obsijane od katodnih žarkov, sprejme sicer fotografska ploščica, prosto

Fotografovanje nevidnih stvarij.

(Spisal prof. dr. Simon Šubic.)

„Kaj, ali se norčuješ?“ Tako vzkliknejo, mislim, ogledovalci, katerim pokažem sliko koščene roke, pa pravim, da je to roka živega človeka. Saj to ni živa roka, porekó, to so kosti nekdanjega človeka. Čudno me gledate, kaj ne, kako da se ne sramujem tako debele laži? Ostrmeli gledate novo fotografijo; sami ne veste, ali bi se čudili bolj mojemu vkusu, da toliko

tedaj bi fotografovanje ne pokazalo njegovega zunanjega obraza, ki smo ga vajeni, temveč slika bi kazala notranjega človeka, katerega pa v vsakdanjem življenju zakriva radovednim očem mesena odeja in polt — odkril bi se pred našimi očmi gotovo njegov kosteni koš, morebiti pa tudi njegov drob, če bi ne zazrli celó njegovih pluč, jeter in srca.

Röntgenova luč in človeško telo.

(Spisal prof. dr. Simon Šubic.)

Med tistim časom, ko je v Monakovem trajal zbor bijologov (životoslovcev), je bilo mnogo dotičnega orodja na ogled razstavljenega v dvoranah fizikalnega zavoda ondašnje univerze. Najzanimivejše je bilo na tej razstavi „Berolinsko električno društvo“

in najzaneslivejše slike na svetlikajočih se zaslonih in na fotografskih tablicah. Njegova nova ustrojitev fotografuje na širših ploščah osebe, ki stojé dalje od aparata kakor doslej, zakaj Röntgenova svetloba lije s širokim tokom iz Zehnderjeve cevi. Na ta način je

Figure 23-9: Excerpts from the articles of Simone Šubic, published in the period of 1896-1898 in the magazine Dom in svet.

The Slovenian ancestors read about this new discovery a century ago: "This property inspired Röntgen with the idea that the rays of this light do not have the same waves as the ordinary light, i.e. transversal vibration or oscillation in and out perpendicular to direction of light, but it extends by oscillating alongside its direction by longitudinal swinging, that is, back and forth, as the physicist observes in the sound waves."[2830] The former priest of Selce by Škofja Loka now Ljubljana cathedral canon Mihael Wurner’s high schools student Ivan Sušnik (* 1854 Škofja Loka; † 1942 Ljubljana) supplemented his Poljane neighbor: "Professor Röntgen was dealing with equal experiments. He wrapped the mentioned Hittorf or Crookes tube into a thick, blackened paper completely opaque for the strongest light. A second paper curtain was placed next to the tube,

[2830] Šubic, 1896, 186–187, 188.

which was coated with a luminous substance. When a strong induced electric current was introduced through Hittorf's tube, then the mentioned curtain was brightly lit even if that glassy tube was carefully wrapped with opaque paper..."[2831]

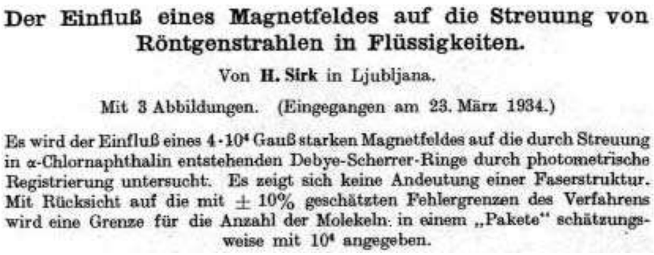
Röntgen and his discovery were admired in Slovenian secondary schools. In 1906/1907, the Curator Inwinkl updated his collection in the Cabinet of physics of the Gymnasium Koper with two X-ray tubes. He supplemented them with the third one next year, which also provided a screen from ZnS and preparations for photographing.[2832] Under the direction of physicist Senekovič, the Ljubljana gymnasium even more closely followed by new discoveries.

In 1897, during the year of "discovery" of the electron, Stefan's student Ivan Šubic published the first Slovenian book on electricity with an emphasis on electrical engineering, as well as the discovery of new rays. He was a pioneer in technical educations at Slovene countries. He described the experiments with Geissler's tubes and gave a quick reference to X-rays.[2833] More space was devoted to the X-ray by a Ljubljana substitute (suplent) teacher, later Peterlin's professor of physics Fran Čadež: "How this light is exposed to the outside, firstly the doctor (sic!) Röntgen examined in 1895. In a completely dark room, during his experiment, his tube was covered by a completely opaque cloth. Suddenly he observed that all the glass and porcelain vessels in his room began to lighten. Where did the light came from? Soon he was convinced that these rays were coming out of that part of his pipe covered with clothe that was greenish due to the impact of cathode rays..."[2834]

23.6.3 *Sirk's X-Ray Experiments in Ljubljana*

The Slovenian reader was kept up to date with Röntgen's achievements. Close cooperation between Viennese and Manchester researchers enabled the Slovenian researchers' understandings of Rutherford's discoveries.

Professor Sirk of Ljubljana was one of the most important researchers of X-rays and radioactivity in the Habsburg Monarchy. He was of Slovenian own genus, but he never become fluent in Slovenian language. He completed his reputation in Ljubljana as one of the most important X-ray researchers in the monarchy. On March 23, 1934, he published a study of the magnetic effects of scattering of X-rays in a liquid that brought the name of the University of Ljubljana into the very top of science (Figure 23-10). He continued the work of Parisian M. de Broglie, the older brother of Nobel laureate Louis, who lectured at the Collège de France until the end of the Second World War. In 1913 Maurice first studied the influence of steel and magnetite on X-rays.



Der Einfluß eines Magnetfeldes auf die Streuung von Röntgenstrahlen in Flüssigkeiten.

Von **H. Sirk** in Ljubljana.

wähnten oberen Grenze erscheint nur möglich, wenn es gelingen sollte, stärkere Magnetfelder anzuwenden und die zentralen Asymmetrien in den abgebeugten Debye-Scherrer-Kegeln genauer zu untersuchen, als es die Photometrierung photographischer Aufnahmen gestattet.

Die lichtelektrischen Registrierungen der Filme wurden mit dem Zeissschen Registrierphotometer der graphischen Lehr- und Versuchsanstalt in Wien ausgeführt. Es ist mir eine angenehme Pflicht, der Leitung der genannten Anstalt, insbesondere Herrn Fachvorstand Prof. Krumpel für die freundliche Überlassung des Apparates und Herrn Dr. A. Stiegler für seine Hilfe bei Ausführung der Registrierungen aufrichtig zu danken.

Bei Ausführung der Versuche wurde ich von meinem Assistenten, Herrn Peterlin, auf das Wirksamste unterstützt, wofür ich ihm hier meinen Dank ausspreche.

Ljubljana, Physikalisches Institut der Universität.

Figure 23-12: Sirk thanked his assistant Peterlin[2837]

Sirk was assisted by Peterlin at the Ljubljana Institute. They measured multi-atomic large molecules, which soon became Peterlin’s basic research field.[2838] Since 1930, the X-ray tube of the most famous Hamburger producer C. H. F. Müller was used at the Ljubljana Physics Institute (Figure 23-11).[2839] At the end of his paper Sirk warmly thanked his assistant Peterlin (Figure 23-12),[2840] who soon independently published a lot in the same leading Berlin magazine. Peterlin later took over the Physical Institute, which after the war worked within the Academy and grew into the Physical Institute, today's IJS. Peterlin's early interest in X-rays paved the way to his initiatives for introducing accelerators to the new Ljubljana Physical Institute a decade and half later.

23.6.4 Conclusion

Ljubljana residents read their domestically published news about X-rays without major delays. This is not surprising, and it only proves the capability of Carniolan people and its diverse inhabitants who chased the wind of knowledge from the Italian, German, Hungarian and Slavic sources to use the best among them. Of course, the Slovenian researchers had to wait for the development of university laboratories after the First World War. Sirk's work was the beginning of a long series of triumphs today associated with the IJS. The success of X-ray research was crowned by the start of PIXE surveys at the IJS almost immediately after the Swedish discovery in the 1970s. Experts from the IJS have been involved in research with the PIXE method practically from the very beginning on the initiative of prof. dr. Bogdan Povh and dr. Peter Kump. The blossoming of PIXE was based on the development of semiconductor X-ray detectors. At that time, they already achieved high enough energy resolution, so that it was possible to distinguish between characteristic X-rays belonging to individual elements. On the other hand, at that time, the accelerators developed for research in nuclear physics began to be abandoned, as the center of mainstream research shifted to higher energies. Accelerated energy ions of several MeV are precisely the appropriate tool for the ionization of internal atomic shells; so, PIXE researchers took them over from nuclear physicists at the IJS.[2841]

24 Major Scientific Uses of Vacuum Technologies: Electrons

24.1 Thomson's Research of Negative and Positive Rays

24.1.1 "Cathode rays"

X-rays might have been the outcome of continental obsessions with waves (of seas), while the Brits encircled by seas followed their own preferred particles trapped in their inherited linguistics which uses the same word for lightweight and for the lighting. We'll present a wider range of J.J. Thomson's vacuum research, his major and lesser successes. We will show that the "discovery" of the electron was only one of his many breaking successes.

24.1.1.1 Thomson's Career Path

Joseph John Thomson (Figure 24-1) was born into a bookshop family in Cheetham, a northern suburb of Manchester. He attended Owens College in Manchester, where Stewart taught him physics, after he tutored the Scotsman Tait and the German Schuster before Thomson.[2842] Manchester was already an important center of physics and of Engels' personal observations of deprived working class published a dozen years before the birth of Engels' Manchester neighbour J.J. Thomson.

After his Manchester beginnings, Thomson continued his studies under supervision of the professor Stokes at the Trinity College in Cambridge between 1876 and 1880. During this time Maxwell was already boss of the Cavendish Laboratory. Thomson never met Maxwell in the lab, but he listened to his lecture about the phone in the senate house in 1879. Thomson won the honour of second wrangler behind later glorified English physicist Larmor, who was also a professor in Cambridge since 1903. In 1881, Thomson was elected to the College of St. Trinity, with which he remained connected all his life. The following year, he received the Adams Prize for exploring the vortices in ideal fluid, and later became interested in similar vortexes needed for his models of the atom. At that time, he published some inaccurate electrical charge measurements. After short work in Cavendish under Rayleigh's leadership, when JJ Thomson excelled primarily by his theoretical researches, he relatively surprised the community when he was elected as the Cambridge professor and the third director of Cavendish's labs after Maxwell and Rayleigh in 1884. He retained the position for 28 years. J.J. Thomson's early experimenting might not be that clumsy as W. Pauli's or Peterlin's.

Figure 24-1: J. J. Thomson (* 1856; † 1940).

During 1905 and 1918 he was a professor at the RI, and after 1919, he was the head of the College of St. Trinity. He became a fellow of the RS in 1884 and its president between 1916 and 1920. In 1906 he received the Nobel Prize for the study of the "passage of electricity through gases", and he was knighted in 1908. During the First World War, he was a technical adviser to the government. He was buried in the Westminster Chapel near Newton, like his student Rutherford after him.

24.1.1.2 Thomson's Predecessors

The idea of the existence of an elemental electric charge or "electrical atom" was already described by American Benjamin Franklin in the 18th century: "The electrical substance consists of very small particles, as it can penetrate even into the densest substance with such freedom and ease that it does not feel greater resistance." Similar ideas were also published by the Italian Mossotti, the

[2842] Fox, Guagnini, 1999, 120.

Englishman Davy, the German Weber in 1871 and others. Faraday supported the assumption of an elementary electric charge by his discovery of quantitative electrolysis laws.[2843] Franklin's friend Bošković also described all sorts of small particles as the most of people believed that every substance consists of smaller ones after the discovery of microscopes.

From 1872 to 1878 **Eugen Goldstein** of Gleiwitz, today's Gliwice in Polish Silesia, researched at the University of Berlin at Helmholtz's class, and then he worked in astrophysics at the Berlin Observatory in Potsdam until 1890. In 1876 he coined the term "cathode ray", and five years later he received a doctorate in Berlin. Until 1896 he worked at the Physics and Technology Institute and then at the Higher Technical School in Berlin until his retirement in 1927.

There was much less consensus on the nature of "cathode rays". In 1876 the name was invented in Berlin by Goldstein, when his point cathode was replaced by a plate from which the rays flew in a rectangular direction. In 1869 Hittorf assumed that the "cathode rays" were waves like light which wave nature was almost not doubted any more after Fresnel and Young's research, although some Brits like Brewster still relied on Newtonian approach. However, two years later, Varley described the "cathode ray" as a small charge of particles: "This experiment, according to the author's opinion, shows that the arc is composed of charged particles of matter, which electricity break in all directions out of the negative electrode..."[2844]

As a telegraph engineer, **Cromwell Fleetwood Varley** advised W. Thomson, later Lord Kelvin, how to lay the telegraph cable in the deepness of Atlantic between 1856 and 1866. In 1870 he was half-retired when the British government nationalized private telegraph companies. So, he suddenly had enough time to explore the "cathode rays". Like Crookes, he dealt with spiritism, which in those Victorian times somehow stimulated particles over waves in Newtonian spirit.

[2843] Millikan, 1963, 15.
[2844] Vjalcev, 1981, 41; Dahl, 1997, 61.

So, both assumptions about the nature of cathode rays appeared almost simultaneously, and for almost three decades they initiated antagonism which was in many ways nationally and linguistically determined with the English language users preferring particles because of the similarity of English language terms lightweight and solar light. In 1888, in addition to the Slavic

Figure 24-2: The first page of Perrin's manuscript of the dissertation Rayons cathodiques et Rayons de Rœntgen in 1897[2845]

guys Šubic in Graz and Puluj in Prague,[2846] the wave theory of cathode rays was defended mainly in the Helmholtz's Berliner Circle including Goldstein and E. Wiederman in 1880, and H. Hertz in 1883-1892. With Perrin's experiments (1895), the corpuscular theory of mostly British researchers prevailed (Figure 22-4). It attracted Varely (1871), Crookes (1878-1879), the Fulda Grammar school professor and deputy rector retired in 1882 Wilhelm Gies (1813 Neustadt by Magdeburg in Hessen-1891) in 1885, and Schuster

[2845] Célébration du centenaire de la naisance de Jean Perrin, Presses Universitaires de France, Paris 1971, 13.
[2846] Puluj, 1889, 305.

(1882, 1884).[2847] Helmholtz himself, as the leading scientist with lot of international connections occasionally switched his supports from one group to another.[2848]

Jean Baptiste Perrin of Lille studied at the École Normale Supérieure and in 1897 he received a doctorate with a dissertation on cathode rays and X-rays. He then studied at the University of Paris Institute and was appointed Professor of Physical Chemistry in 1910. Between 1908 and 1913, he experimented to support Einstein and Smoluchowski's theory of Brownian motion. Prior to the First World War, he also visited Rutherford's Laboratory in Manchester. In 1926 he received the Nobel Prize in Physics "for his efforts to explore the structure of the substance and, above all, to discover the sedimentation equilibrium." As an active Anti-Fascist, he had to move to the US in 1938, where he supported Charles de Gaulle's struggle. He died in New York.[2849]

In 1882, Helmholtz's most important student, H. Hertz, found that "cathode rays" resembled the light. In his early experiments he seemingly proved that the electric field does not affect them.[2850] Later, it turned out that he did not notice the deflection because he placed his metal capacitor with a distance between the plates of 2 cm and a voltage of 22 V or 500 V outside his tube. This caused the reverse electrical current and overshadowed the effect of the field.[2851] In addition, he used the excess pressure in the discharge vessel. Because of the incorrect explanation of his experiments Hertz and many other German researchers for over a decade mistakenly believed that "cathode rays" were related to electricity only by their genesis, like light is related to an electric bulb which was popularized in Edison's version in those times.[2852] The electricity tend to produce light, but no identity among them was adequately promoted before Maxwell's work published in 1873.

Heinrich Rudolf Hertz was the oldest son of a lawyer, a later senator of the Jewish genus in Hamburg. Hertz was a part of huge wave of secular Jews who suddenly got their equal rights in central Europe and quickly proved their excellences like Karl Marx. After his graduation in 1875, Hertz first studied engineering in Munich for two years and, in the meantime, served a military term in new German state army for a year. Then he changed his mind and continued his studies of mathematics and natural science in Munich. In 1879 he completed two semesters at Kirchhoff's class in Heidelberg and in Berlin, where he studied at the Helmholtz's Institute. On 5 February 1880, he completed his magna cum laude study with a theoretical research of the rotation of metal balls in a magnetic field. During his research in Helmholtz's group in the following years, he was heavily influenced by seven-year-older Goldstein. In 1883, Hertz became an assistant professor at the University of Kiel. On the Helmholtz's recommendation, in the winter of 1884, Hertz succeeded Braun as a full-time professor of experimental physics at the Technical College in Karlsruhe, where he researched a photoelectricity and first detected electromagnetic waves with a transmitting dipole resonator and a receiver consisting of a loop antenna and spark gap. In 1889, he took over the Department of Physics after the death of Clausius in Bonn. Hertz died of cancer after prolonged illness infected because he carelessly used Clausius's room which previously served as a hospital. In the year before his death, Hertz wrote a book on the principles of mechanics (1904) in the Neo-Kantian spirit without the concept of force, unfortunately, without much influences on later researchers.

When the deflection of "cathode rays" in the magnetic field was finally proved beyond doubt, it was explained by deformation of "ether". Their spreading exclusively in the rectangular direction relative to the surface of their source was attributed to the special useful features of the formation of "cathode rays" associated with electricity. In 1880, Goldstein even proved that the spread of cathode rays was taking place in different directions. However, in 1906 J. J. Thomson showed that cathode rays deviate from their perpendicular directions to the surface of the source only after the

emission, under the influence of an electric field, or due to scattering.[2853]

For the advocates of the corpuscular model of cathode rays, their linear propagation was the fundamental problem although it looked very natural. In 1891 and 1892, Hertz additionally found that cathode rays could penetrate a thin layer of gold, silver, aluminium and various alloys, which could not be attributed to the then known types of particles.

In 1880, Tait and after him Goldstein argued that Crookes's supposed molecules at high velocities in cathode rays would have to change the wavelength of radiation due to the Doppler effect. However, no changes were observed in their measurements.[2854] The astronomers later observed similar phenomenon on celestial bodies as a redshift.

24.1.1.3 Thomson's Contemporaries

J.J. Thomson and his senior colleague from their students' days in Manchester Schuster simultaneously began exploring discharges in gases in 1883/84. However, Schuster wished to resolve that problem as a spectroscopy chemist and J. J. Thomson researched the same problems as a mathematical physicist. In 1884 and 1887 they were successively appointed new leaders of the most important British physical laboratories in Cambridge and in Manchester. Schuster was influenced by both English and German scientific traditions. He advocated the existence of a particle of electricity to put Faraday's electrolysis in agreement with Maxwell's theory of electromagnetism. He referred to Helmholtz's ideas summarized by Stoney: "Electricity is also some kind of fine matter, made up of the smallest atoms - electrons".[2855] However, he did not follow Maxwell's advocates, but rather preferred the model of his friend, chemist and astronomer Lockyer, who discovered the yellow line of helium in the spectrum of the Sun in 1869. According to Lockyer, the complicated dissociation of molecules in gases causes the complexity of their spectra. Schuster wanted to prove that every particle of gas caries the same amount of electricity that would allow the applications of Faraday's electrolysis laws in the gases.[2856] The concept of charge of electron as the smallest amount of electricity was born, although it was not yet connected with any named particle.

Unlike J. J. Thomson, Schuster was not interested in the size of the electricity particles and the nature of the "cathode ray". The contradictions between the researchers were partly the result of the old contradictions between the dual-fluid (Schuster) and the one-fluid (Thomson) model of electricity.

In 1884, Schuster continued Hittorf's experiments with the "cathode ray" deflection in the field. In such ancestor of the cyclotron, the radius of curvature of the particle's track was determined by its e/m ratio.

Six years later Schuster measured the ratio e/m of "cathode rays" and got a result between 1000 and 1,000,000 "electromagnetic units" per 10,000 As/kg. For hydrogen ions, this ratio was 10,000, both in gas and in the electrolyte. For Schuster exactly the highest measured value, i.e. 1,000,000, did not seem real because it requires a passage of a "particle" through a cathode-ray tube without a collision. By doing so, he eliminated his own correct measurement and, with it, a quick discovery of the "electron". Schuster erroneously expected an e/m ratio in gases of similar sizes than in electrolysis. Schuster's gas-carriers were unfortunately expected to be the ions which was, of course, a general misconception before J. J. Thomson's paper of 1897. The ions are at least few thousand times heavier than the electrons which were about to be "discovered". In addition, Schuster was not searching for the "electron" or the nature of "cathode rays," but he focused on the validity of Faraday's electrolysis laws; he did not compete with Thomson's discovery, and in 1895 he finally stopped exploring discharges in gases altogether.[2857]

24.1.1.4 Discovery: Measurement of e/m ratio for "Cathode Ray"

J. J. Thomson also initially argued that the laws of electrolysis are valid in gases, as the liquids and gases supposedly translated electricity in the same way. However, in 1891/92 he had to abandon that

[2853] Anderson, 1968, 36–37, 39.
[2854] Frisch, 1972, 55; Laue, 1969, 310–311; Anderson, 1968, 36, 39, 48–49.

idea. Only upon the very long sparks in the cathode-ray tube during the electrolysis of water vapor the substances are deposited on the same electrodes as in the electrolysis of water.

At the end of the 19th century, Thomson supported Crookes's ideas from 1874 about the cathode rays as the basic particles of the atom. However, as early as 1894, Thomson and other contemporaries saw ions of gases in their cathode rays.[2858] Only Lenard's measurements from 1893 showed that "cathode rays" have an average free path in the air of about 1 mm, which is about 10,000 times longer than molecules. The result convicted Thomson that he was dealing with much smaller particles than the lightest atom, which of course did not please everyone. In those times the researchers still knew some classical Greek language where any talk about divisible atoms sounded just like nonsense, resembling the funny concepts of vacuum in Latin language. To believe in vacuum and in particles smaller than atoms, the European people had to forget their eventual education in classical languages.

Thomson and the young Perrin (1895) had the deflection of cathode ray in the electric and magnetic fields for their essential characteristic, for their decisive experiment. The cathode rays were declared for long-sought electrons precisely because of their electric charge, whose ratio to the mass Thomson measured in 1897. The measurement was in perfect harmony with the English tradition, where Crookes immediately declared the "discovery" of electrons to confirm their own vision of the fourth aggregate state of the substances.[2859]

Thomson regarded and treated the penetration power of cathode rays in the substance as their less important feature. He suggested that the cathode rays in the substance cause secondary X-rays, which then penetrate further. In contrast to Crookes, Schuster and other English researchers, Thomson was not interested in the form of illumination in the Geissler tube nor in the analogy between chemical reactions in electrolysis and reactions in the vacuum cathode ray tube.[2860] Those puzzles belonged to the first generation of researchers of cathode ray tube invented in the time of Thomson's birth.

In 1894, Thomson measured the rays β (cathode rays), which were accelerated at a speed of 200 km/s; but later he refused his own results as inaccurate.[2861] Three years later he was able to measure the deflection of the rays β (cathode rays) in the electric field because he used better vacuum pumps than the late Hertz did; although did not have the best vacuum equipment and tools for degassing in Cavendish labs even after the First World War they.[2862] A similar success was achieved at the same time by Goldstein.

Thomson used Töpler's pump and Crookes's method for the removal of vapours of mercury with phosphorus or copper. In March 1897, he deflected electrons (cathode rays) with a transverse magnetic field, and then compensated the deflection by an electrostatic field of a flat capacitor with aluminium plates. He sent his rays through air, hydrogen or CO_2 at a low pressure 5 cm away into the electric and magnetic fields. The distance to the screen was an additional 1.1 meters. He obtained m/e ratio 10^{-7} "electromagnetic units" of 10^{-11} As/kg. His result was more than a thousand times smaller than the results obtained for hydrogen ion in electrolysis and depended on the nature of the gas, the type of cathode, the rate of light and the pressure in the cathode ray tube. In his experiments Thomson changed iron, platinum and aluminium electrodes. He did not record his measurement errors as it was not a necessity by that time, but today his experimental error is estimated at 14%.[2863]

Thomson presented his discovery in the RI lecture on 30 April 1897, and the following month he published it in leading English magazines. His quickly arranged publications prevented any possible independent discovery in other laboratories. The results reminded him of Prout's assumption. However, Thomson's substances were not hydrogen atoms, but a much smaller structure nicknamed "corpuscle". He wrote the claims that resemble Crookes's ideas because they both worked in similar networks: "From this point of view, in the cathode rays, we have the substance in

2858 Vjalcev, 1981, 49.

a new state, in which the division of matter goes much further than in ordinary gas: the state of that (cathode ray) matter obtained from various sources such as hydrogen, oxygen, is of a single species. This substance is a substance from which all chemical elements are built. The mass of the substance obtained by dissociation on the cathode is so small that almost excludes any possibility of direct chemical research of its properties. If the used coil would let it work day and night all year, it would, in my calculations, produce only about 3 trillionth part of a gram of this substance."[2864] Evidently, Thomson still considered that he is researching a special kind of chemical element, in fact a small ion. He changed his mind very soon as there was no place for his corpuscle in Mendeleev's table of chemical elements.

Thomson described the atom as a set of small particles; among which Bošković force of variable direction works, which he defended even later.[2865] He additionally proposed a different atom, according to Regnault's Parisian student Alfred Marshall Mayer, a professor at the Stevens Institute of Technology in Hoboken NJ in USA. In 1878, Mayer described an experiment with magnets geometrically arranged to float of the water, balanced with an external magnetic field and interacting with each other. However, FitzGerald, the pioneer of television Campbell-Swinton and most British researchers "rejected too much alchemy" involved in the supposition of Thomson; Rutherford's jokes put up with alchemy a few years later.[2866] In fact, alchemy was no more a taboo which crippled alchemy from centuries including its Newtonian era.

Thomson used a different method for determining his e/m ratio by measuring the heat produced by the cathode rays on the wall of cathode ray tube.[2867] Most physicists did not believe in Thomson's discovery of particles smaller than the atom, although he referred to a year-long measurement of the ratio e/m of the Dutch spectroscopist Zeeman, Lorentz's assistant in Leyden. Zeeman continued the very last Faraday's experiment conducted on 12. 3. 1862, in which he tried to influence the yellow line of sodium with a magnetic field. Faraday was convinced that a successful measurement could be done, while Larmor doubted it. Zeeman certainly thought that it would be worth pursuing where his famous predecessor finished his researches. Certainly, Zeeman was able to obtain much better equipment including the famous Rowland's high quality ~~of~~ the diffraction gratings with much higher resolution than the Faraday's spectroscope on prism, a better vacuum pump, and a stronger magnet. Zeeman, due to the wrongly defined axis of the λ/4-plate, published the result for a positive charge instead of a negative one. His debut was published in March 1897 in Phil. Mag., one volume before Thomson's "discovery." Lorentz's theory supported the results of his assistant therefore they shared the Nobel Prize in Physics in 1902.[2868]

Pieter Zeeman was born in a small village of Zonnemaire on the island of Schowen, in the province of Zeeland, in the Netherlands, in the family of a Protestant pastor. His High School Gymnasium paper was good enough to be published in the journal Nature. His teachers were mostly Lorentz and Kamerlingh-Onnes at Leyden University. In 1892, he studied one semester at Kohlrauch's lab in Strasbourg, and in 1894 he returned to Leyden as a private assistant professor (docent). In January 1897 he became a lecturer at the University of Amsterdam and remained there until his retirement in 1935. In 1908 he succeeded van der Waals as a professor and director of the Physics Institute in Amsterdam.

Thomson first realized that he was breaking atoms in his experiments. In good old English Newtonian and Crookes' traditions he declared the cathode rays as corpuscular matter, which he considered as particles in Newtonian classical mechanics.[2869] The assumption was completely different from the theory of "ether." Like Hertz (1888), Einstein (1905), and others, Thomson preferred to emphasize the connection of his discoveries with Maxwell's theory while he tried to diminish the differences in their description of the structure of the "ether" and of the electricity.[2870] Tesla might

have thought that ether and electricity are nearly the same, but Thomson or Einstein preferred different opinions.

Thomson showed that radiation and translation in gases cannot be explained by the waves themselves. Thomson's "corpuscles" finally got the name which Stoney coined: "In the electrolysis of each chemical compound we can separate in all cases the same quantity of electricity... The charge of that size is bound in every chemical atom ... These charges, which we will call 'electrons', cannot be separated from the atom; they do not show if the atoms are chemically bound". In 1897, FitzGerald and Lorentz introduced the term electron in physics.[2871] Wiechert supported Lenard's expression of the "quantum" of elemental negative charge; however, Planck's application of the term quantum was used in a different sense soon enough.[2872]

Stoney was thinking about the atomic structure of electricity already in his lecture before the British Association for the Advancement of Science (BAAS) in 1874, which he published only seven years later.[2873] Based on Faraday's electrolysis experiments, he approximately determined the charge. Faraday thought about the atomic structure of electricity and he was followed by Crookes. J. J. Thomson opposed Larmor's and FitzGerald's theory of electrons in several discussions, including in his criticism of Australian Sutherland. He considered that there was no evidence of the existence of a charge outside the substance. He preferred the assumption of "corpuscles" as the structured building blocks of the atom, although it was also impossible to prove the partition of the atom. He did not treat the "corpuscle" an independent particle, but as an interaction between ether and matter. Therefore, Thomson first used the term "electron" only in 1937, much later than his students Towsend (1915), Langevin (1904) and others. Even his opponent Villard accepted electron earlier, as Villard used the term at the Parisian Academy after 1908.

On the other hand, Thomson might have wanted to avoid confusion; unlike his younger colleagues, he remembered well that Stoney used the term electron as a unit of charge of both signs and not for the material particle.[2874] The vocabularies were shaped by the gaps between generations, while their terms were by no means unimportant.

The mysterious “cathode rays” soon got no less puzzling siblings. In 1899, Lenard and Thomson measured approximately the same e/m ratio obtained for "cathode rays" also in other circumstances including the particles in the photoelectric effect, and in the "Edison effect" of the thermal electron emission from glowing metallic surfaces. Becquerel received the same result for rays β from radium a few months later.[2875] As with all major discoveries, Thomson was fully established only with the print of the book and the influence of his students outside his home country, especially in Paris.[2876] Nobody is a prophet in his homeland.

24.1.1.5 Thomson's Successors

Wiechert developed an etheric version of Helmholtz's atoms in Königsberg (today's Kaliningrad) in 1894. Two years later, together with Theodor Des Coudres, they measured the speed of cathode rays. On 7 January 1897, Wiechert announced that cathode rays had a 200 to 2,000 times greater e/m than hydrogen ions, and thus envisaged an independent particle. However, Wiechert was only a beginner in the study of "cathode rays" and in addition he published his measurements at the local journal in Königsberg, just like much more successful Röntgen did in Würzburg in 1895. In 1897 and 1898, other Germans and British, especially Thomson, Schuster and Wien, published measurements of high-speed "cathode rays".[2877]

Simultaneously with Thomson, Kaufmann[2878] compared the e/m ratio in similar experiments in Berlin on 21 May 1897. He did not claim to be discovering a "new corpuscle," since such a claim in the German environment would have been even sharply rejected because of the dominant influence of the positivist Mach, whose parents lived in

Lower Carniola (Dolenjska).[2879] At that time Mach excited the supporters of the atoms with the provocative question: "Have you seen them?"[2880]

The German **Walter Kaufmann** studied in Berlin and graduated in Munich. Between 1896 and 1898 he was an assistant at the University and at the Physical Institute in Berlin. Between 1897 and 1899, he additionally worked as a librarian of the German Physical Society in Berlin. In 1899 he went to the University of Göttingen, where Des Coudres also studied the effect of the magnetic field on "cathode ray". In 1903, Kaufmann switched to Bonn University, where he also assembled the first high-vacuum rotary pump before Gaede. Due to the excellent knowledge of vacuum technology, he had some advantages over Cavendish lab researchers. Between 1908 and 1935 he taught in Königsberg, but he did not research "cathode rays" anymore.

Similarly, Mach's contemporary Mendeleev in his dissertation of 1857 described atomism only as a useful explanation in contrast to the theory of waves or to Copernican theory. An entirely different point was the English position, illustrated by Rutherford's exclamation answering Eddington's statement after dinner at Athenaeum club of London. The Quaker Eddington noted that the electrons may be just conceived concepts and do not really exist. The tall New Zeeland native rose up in all his great length and shouted: "Not exist, not exist - why I can see the little beggars there in front of me as plainly as I can see that spoon?!"[2881] The discovery of the electron was largely due to the national characteristics of the research environments, since British physicists performed much more extensive measurements of electric charges, while the Germans published much more theories about them.[2882]

In 1901 Kaufmann proved that the apparent (electromagnetic) part of the masses of Becquerel's fast electrons from radioactive substances is increasing with their velocities. Abraham supported that result with calculations in his first hypothesis about the structure of an electron imagined as a solid sphere with evenly distributed charges. For some time, Kaufmann's results were used against the theory of relativity, and then they were corrected by more accurate measurements.

On 1 April 1889, **Johann Emil Wiechert** became assistant professor of mathematical physics at the University of Königsberg. With his later celebrity student Sommerfeld, who was promoted in mathematical physics in 1891, they designed their harmonic oscillator. In 1897, Wiechert went to the University of Göttingen and Sommerfeld went to the nearby Clausthal-Zellenfeld, where they continued their cooperation. In the following years, the Jewish Herman Minkowski’s son-in-low Wiechert was involved in geophysics.

Max Abraham from Danzig (today's Gdansk) graduated from the University of Berlin in 1897 and worked there as Planck's assistant. Between 1900 and 1909 he was a professor in Göttingen. Until World War I and afterwards he taught in Milan, then in Stuttgart and Aachen.

Paul Ulrich Villard from Lyon started studying at the École Normale Supérieure in 1881, where he decided for physics three years later. He taught at various Lyceums outside of Paris, most recently in Montpellier. He then came to the Chemistry Laboratory of Henry Jules Debay at the École Normale Supérieure as a freelance researcher. Between 1906 and 1908, he published the theory of the northern light (Aurora Borealis), and then he became a member of the Parisian Academy on 21 December 1908.

In 1897, Villard[2883] abandoned the research of physical chemistry and began to study the "cathode rays". Unlike J. J. Thomson, the electrical charges of cathode rays were of less importance for Villard, while he mostly studied their chemical characteristics. The following year he described cathode rays as hydrogen ions because he wanted to avoid the "unnecessary" introduction of a new type of particles. The idea contradicted both the

[2883] Lelong, 1997, 92, 121.

British "corpuscles" and the German "waves" with the electron included. So, the Frenchman Villard was left alone.

During 1899 and 1900, Villard discovered the rays γ, which were initially named after him. He described his claims at the first International Congress of Physicists in Paris between 6 and 11 August 1900, at the reception of the Parisian Academy of Sciences on December 19, 1904 and especially in Abraham's and Langevin's Proceedings of 1905, where two thirds of the discussions were written by JJ Thomson and his disciples. Villard did not have the support of younger Parisian researchers who published in Le Radium after 1905 and joined the Journal de physique after 1918. Villard abandoned his theory only between 1906 and 1908, when he was already recognized as the most important French researcher of "cathode rays".[2884]

The Galway native Irishman **John Sealey Edward Towsend** graduated from the University of Dublin in 1890. Between 1896 and 1900, he and Rutherford were the first intern researchers at J. Thomson’s labs in Cavendish, when they officially introduced that status there. Towsend was a better mathematician than Rutherford and was chosen for a Wykeham professor of physics at Oxford and the head of the Electric Laboratory in 1900. In 1941, just few months after he was knighted, he lost his job because he refused to cooperate with the army by teaching the serviceman in Oxford in the wrong time of Anti-Nazi euphoria.

Towsend was the first to describe the ionization of gas in collisions. In 1897 and 1898, together with graduate student Harold Albert Wilson in Cavendish, he measured the total charge of "cathode rays" by weighing drops of water along their track in C. T. Wilson's cloud chamber (foggy cell). He estimated $1 \cdot 10^{-19}$ As and $0.9 \cdot 10^{-19}$ As for positive ions. At the same time, J. J. Thomson determined the charge of the ions obtained after the radiation of the X-rays. In 1898 he gained slightly higher values, $2.2 \cdot 10^{-19}$ As, and later $1.1 \cdot 10^{-19}$ As in 1901.

Robert Andrews Millikan was born in Illinois in a Protestant priest's family. In the college of his small town, physics was taught primarily during the teaching of the ancient Greek language. He enrolled at Columbia University as the sole listener oriented towards physics. In the meantime, he studied for a year at Michelson’s class in Chicago. After his PhD at Columbia University, he traveled to Europe to listen to the lectures of Planck, Nernst and Poincaré with the help of the Serb Pupin of Columbia University. A year later Pupin invited Millikan to become his assistant with a telegram. In 1910, Millikan became a professor in Chicago and held the position for eleven years. After two decades of lecturing and writing of textbooks he began with experimenting. In 1915, he was elected as new fellow of NAS and then became a scientific adviser to Western Electrics (WE). During the war he led the National Research Council. From 1921 to 1945, he headed the new Caltech with his extraordinary talents for the organization. Between the two wars he studied cosmic rays amidst of a sharp exchange of views with American A. H. Compton. In 1923 and 1927 they received the Nobel Prize in Physics one after another anyway.

In 1900 Towsend[2885] proved that the ionization of gas separates elementary charges of the same size as the ions proved to have in electrolysis.[2886] It was only around 1910 that he discovered that he measured the electrons. In his experiments, he used much higher pressures compared to the experiments of James Franck and Gustav L. Hertz in Berlin in 1914, who were measured according to the advice of the director Warburg at the Physical-Technical Institute. Towsend thus missed an important discovery. On the other hand, both Franck and Hertz were on the wrong track, as they accepted Lenard's incorrect explanation of the photoelectricity from 1902. As late as in 1916, Franck and Hertz refused to confirm Bohr’s theory even if Bohr supported their measurements with his calculations. The mistakes were caused by their lack of time due to their additional military responsibilities in WW1. Towsend never recognized the accuracy of the measurements of

Franc and Hertz, although they received the Nobel Prize for Physics in 1925.

The research centers gradually but slowly moved to the United States while the study of electrons was no exception. Edison's friend Rowland proved that the free charge in the moving conductor produces the same effects as the motion of the charges in a stationary conductor. Maxwell was especially impressed with their measurements as they turned their experimental problem upside down like Copernicans, Torricelli's pressure of air, radiometer researchers or Salcher in his collaborations with Mach.

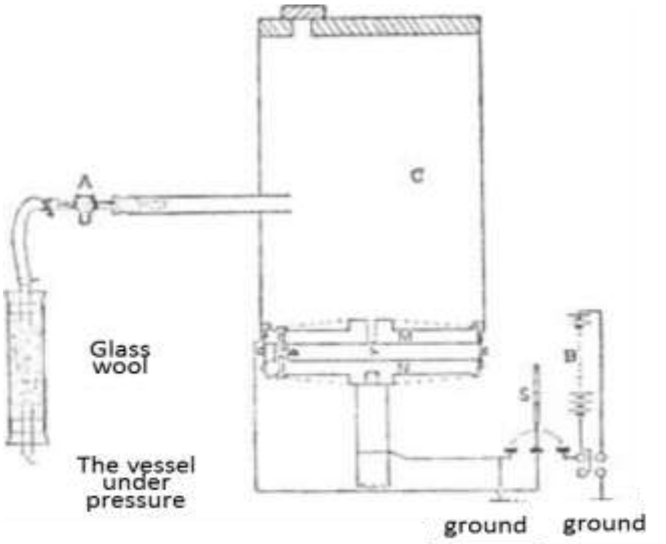

Figure 24-3: Millikan's measuring device[2887]

In 1906 in Chicago Millikan repeated Erich Regener's (1881 Wilczak in Poland-1955 Stuttgart) Berliner visual counting of scintillations as well as Wilson and Thomson experiments carried out in Cavendish to determine the magnitude of the charge in 1902. Millikan made up a stronger source to provide up to 10 kV needed for his "dropping process". Millikan placed his copper plate of radius 22 cm at the distance of 15 mm into a vessel whose variable pressure he measured with a manometer. Between his 10 kV voltage panels, Millikan ionized the air with X-rays. He was blowing a drop of oil that evaporated slower than water and watched through the telescope. The mass of droplets was determined by the rate of drop (Figure 24-3). Dr. Fletcher accidentally noticed that he could keep on floating individual droplets for a very long time with the electric force of the condenser. Thus, he was able to accurately measure their charge, which was always a multiple of the basic charge of $1.55 \cdot 10^{-19}$ As. He quickly dialed Millikan and then they measured for six weeks. Originally, they copied the experiments from Cavendish by counting and weighing condensed droplets, but the Americans soon turned into balancing them. They began to measure the rate of deflection only after it became constant. After passing the droplet over a certain point, they turned the direction of the electric field and found the speed of the ascending of the drop. They measured and determined the charge and mass of droplets.

In Edison's style, they published their data even in daily press and received a lot of attention. The famous little clever guy Steinmetz visited Millikan's laboratory and only then began to believe in the existence of electrons.

The Mormon **Harvey Fletcher** studied at the University of Chicago. After a brief collaboration, Millikan proposed the measuring of the electron charge for Fletcher's doctoral dissertation. His share of Millikan's measurements was published only after his death.[2888] Fletcher received his doctorate in 1911. He researched at Bell Labs between 1925 and 1952 and then taught at the Columbia and Brigham Young universities.

In August 1909, Rutherford at the BAAS meeting in Winnipeg, Canada, argued that "it has not yet been possible to detect an individual electron according to its electrical or optical effects, thus directly counting them, as they did with α-particles." On August 31, 1909, Millikan reported on successful measurements at the same meeting. On September 30, 1909, Millikan's paper was published, but only with the signing of Millikan, who won his Nobel Prize in Physics in 1923. In 1913, Millikan and Fletcher measured the basic charge of $1.591 \cdot 10^{-19}$ As.[2889] Fletcher was obviously somewhat neglected in Millikan's race to become the father of electron instead of J.J. Thomson, and Millikan might also perform some cooking of his data to make them more convicting also against the Jew Felix Ehrenhaft's supposed smaller units of electrical charges.

Most of the differences in terms of modern value of the unit of elehummel publictrical charge are caused by the inaccurate measurement of air viscosity in Millikan’s times. However, Millikan measured 175 drops, including 107 after 13 February 1912, when he made the first published measurements. Nevertheless, he published only 58 measurements, since others did not fit well enough with theorywhile Millikan criticized Viennese Ehrenhaft, who had a much better measuring device available as a professor of the University of Vienna since 1912. Ehrenhaft received his doctorate at F. S. Exner’s class. In 1901, as an assistant to Viktor Edler von Lange in Vienna, he measured the charge of metal particles estimated as $1.53 \cdot 10^{-19}$ As. Independently of Millikan, he developed a process for measuring the basic charge of his drops. However, he claimed to also measure sub-electronic charges smaller than the electronic one. While Millikan was a convinced atomist, Ehrenhaft defended the continuity of matter and never accepted Millikan's measurements of the falling droplets. However, at the Solvay Congress in 1911 Friderich Hasenhörl reported that Ehrenhaft's assistant the Jew Karl Przibram also accepted Millikan's results. At the same congress, Einstein reported on the measurements of his assistant at the German University of Prague, Edmund Weiss, who gave new evidence against Ehrenhaft's theory. Thus, Ehrenhaft retained only the support of some of his pupils, such as Lecher, F. Zerher, and the Protestant of Jewish origin David Kurt Konstantinowsky (* 1892 Vienna). After relocating to the United States, he had major problems in physical circles.[2890]

Later, it turned out that Millikan's device was not useful for drops with a charge of more than 30 base charges. Nevertheless, Millikan's measurement was at least 16 times more accurate than the previous ones. He only committed a mistake of about 0.5%, which he even did not publish as he wasn't obliged to do so in his times. His measurements were quickly repeated in other laboratories.

24.1.1.6 Significant Contributions to the »Discovery« of Electrons

In the last decade of the 19th century, over seventy discussions, directly related to the discovery of "electron", were published mostly in 1894 and even more in 1897 (Table 24-1). The contemporaries attributed the discovery to various persons (Table 24-2).[2891]

The discovery of the electron was a long-standing process, which, due to simplicity, is mostly attributed to Thomson. Thomson did not publish the most accurate experiments, but he unambiguously explained the results full of Victorian English pride as his own discovery of a new particle. Millikan added his own Yankee style to become a beloved father of MIT.

24.1.2 Thomson's Study of "Positive" Rays (1906-1914)

After the discovery of a "corpuscle" with a negative charge, Thomson wanted to detect a "positive" electricity. Therefore, at the beginning of the 20th century, he began to explore "positive"

rays. Despite some successes, the project did not bring such high-profile results as the older cathode ray research.

In 1886, Goldstein discovered "canal rays," which later proved to be a stream of positive ions. In the early years of the 20th century, the initiative was taken over by the French in the search for rays, but their contribution was very infamous. At first, they strongly supported the N-rays, which were “discovered” by Blondlot at the University of Nancy in 1903. However, by 1906, it turned out to be a mistake. In March 1906, J. Becquerel, son of Nobel Laureus Henri, published a surprising discovery of positive electrons, which in the following years also proved to be an experimental error.[2892]

In the years before the First World War, Thomson explored "canal rays". More than two decades after Goldstein's discovery, they were still a kind of enigma. It was not known much about them besides that they were positively charged and that their e/m ratio was comparable to that of hydrogen. Only in 1928 the student of Thomson's Cambridge Paul Dirac published a valuable theory of positive electron later named positron.

24.1.3 Search for the Atomic Composition

In his first research of discharges, JJ Thomson supported W. Thomson's vortex model of atom in 1882 and in 1884. A few months before H. Nagaoka, J.J. Thomson published a model of atom with an evenly distributed charge of both types in his Silliman lectures at the University of Yale, USA.[2893] The following year he described groups of electrons in the atom, which induce the periodicity of chemical elements. His atom consisted of thousands of rotating particles that radiate and destabilize the atom. The idea was explained only by the connections between the ionized molecules.
Thomson did not declare a mass of his carriers of positive electricity in 1905. The holders are supposed to bind together particles in the atom by analogy with the hydrodynamics of the fluid ether in the "Faraday tubes". He thus composed a model of a ball of uniform positive energy, with small separate particles moving inside. Although he had to abandon such a model in 1906, he still thought of Faraday's forces. His models of atoms were

most likely designed by the concepts of "corpuscles" he himself discovered.
In 1906, measurements of the scattering of light and X-rays and the absorption of β-rays in gases showed that the number of "corpuscles" in the atom is of order of magnitude of its mass number. The positive electrics could no longer be described without mass of its carriers, which should have even been much larger than the mass of electrons. That is why Thomson abandoned the use of Faraday's forces and the assumption of a completely electromagnetic mass of positive rays which he adopted at the beginning of the century.[2894]

24.1.4 *Measurement of e/m Ratios of "Positive Rays"*

In 1904, Fitzpatrick, a former demonstrator in Cavendish, and then president of the Queen's College, donated to the Cavendish Laboratory a device for liquefying of air. In that time, they used Sprengel's or Töpler's pump. In 1905, the inventive Gaede pump was very expensive, so there were only three or four of them in Cavendish in 1913.[2895] The vacuum was improved with charcoal cooled in the liquid air, which was added to the cathode-ray tube. The process was first introduced by Dewar and was even better than Gaede's rotary pump for a short while after pumping. Later, when charcoal absorbed all the gas it could, it no longer helped to maintain the vacuum. J. J. Thomson and Aston had only a very small hole in their vacuum flask connected to the discharge vessel by narrow capillary. Therefore, they were able to use the absorbing abilities of charcoal even for an hour and more.

Considering the success in measuring the e/m ration of his corpuscle, Thomson decided for similar measurements of positive "canal" rays in 1905. He deflected them into a parabolic orbit by the electric and magnetic fields. The results were heavily dependent on the pressure. At a pressure of 0.026 mbar, he observed almost flat luminous lines on the screen made of willemite.[2896] The lines of negative particles were symmetrical but pale. Due to straight lines, Thomson assumed that the "canal" rays had a constant velocity, but the variable e/m ratio with a maximum value which was the same as that of a hydrogen ion. Just as a decade earlier he assumed that atoms consist of "corpuscles", this time Thomson claimed that hydrogen ions are the basic building blocks of all atoms, following the famous Prout's ideas. At lower pressures down to 0.0039 mbar, the negative lines disappeared, and the positive lines were split into the curves. Because of the different e/m ratios, Thomson felt that the charge of the particles was changing, rather than their mass. A similar assumption was published by Helmholtz's student, an alleged East Prussian farmer W. Wien in 1898 and 1902. Thomson changed the pressure and type of gas in the measurements, but he always got the same line with the e/m ratio of 10,000 and 5000 (Figure 24-4).

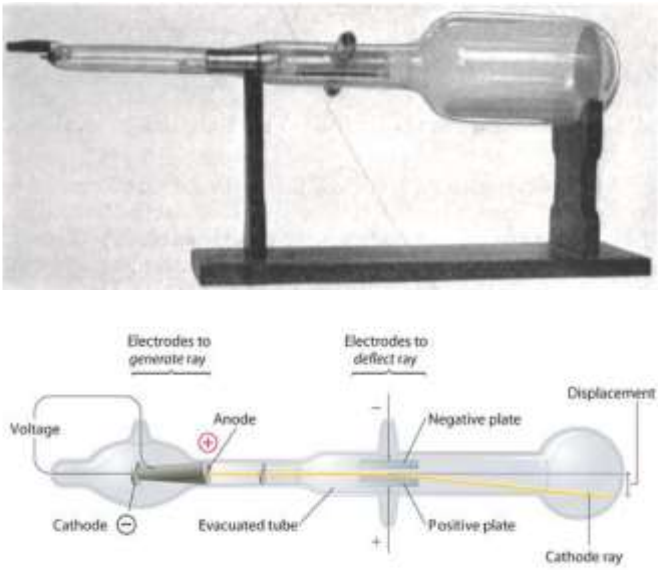

Figure 24-4: Thomson's cathode ray tube from 1907 used for his observation of positive rays on the luminescence screen from willemite. The vacuum was improved with an out growth full of charcoal cooled in liquified air

In 1908, Thomson announced that positive rays were neutralized at least during a fraction of the time measured, which he tried to explain with a pair of heterogeneous charges. In March 1909, Thomson bought for his lab Wehrstens' inductor "Mercedes", which supplied up to 20 kV of accelerating voltage, much more than Wimshurst's inductor, which was predominantly used as a supply of the multi-colored Geissler tubes in the late Victorian era.[2897] Unfortunately, the results did not change, as the speed of positive rays was the

[2896] Zn_2SiO_4
[2897] Bowers, 1998, 115.

same in all gases, regardless of the acceleration voltage.

Francis William Aston was the son of a wealthy metal dealer in Birmingham. He studied chemistry at the University of Birmingham and worked there between 1903 and 1908. He laboured for three years in a brewery, where he became interested in discharges.[2898] Like in Joule's case, beer again proved its beneficial influences on English physics. At the beginning of 1910 Aston became Thomson's research assistant. In 1913 he was selected for Maxwell's scholarship in Cavendish to develop his own research direction. In 1907, Thomson described the action of the mass spectrograph for the separation of the ions of various isotopes, already announced by Crookes in 1886. In 1912, the experiment first demonstrated the existence of isotopes of neon. The first mass spectrograph was compiled by Aston in 1919, and in the same year he proved the existence of chlorine and mercury isotopes.[2899] In 1922 he received the Nobel Prize in chemistry for his invention of spectrograph and research of isotopes. In 1925 and 1937 he improved the performance of the spectrograph. He discovered a mass defect, and he measured numerous isotopes in 1927. In 1931 he discovered the isotope ^{238}U.

After Aston's arrival, they began to measure more precisely in Cavendish labs. In September 1910, they increased the volume of the central part of the cathode ray tube to 2 l and cooled the charcoal in the liquid air to enable the measurements at lower pressures. In 1910, the basic experimental problem was a sufficiently high pressure needed for the discharge, and at the same time a sufficiently high vacuum in the vessel for deflection of charged particles. Therefore, they separated the discharge space from the electromagnetic deflection vessel by Lenard's method designed in 1895, which was already used for X-ray detection. Lenard's "window" began to be used in England in 1897, and only a year later in Germany, since Lenard interrupted experiments between 1896 and 1897 during his editing of the works of the deceased Lenard's boss, the Jew Hertz, long before Lenard developed his Anti-Semitic stances. Although Lenard's experiments were highly valued in England, the Brits immediately rejected his model of transmitting mechanical impulses in the ether and his assumption of the substance "Urstoff", the same for all atoms.[2900] The British physicists clearly disliked the German philosophical impacts even of they praised their accurate measurements.

In the beginning of 1910, Thomson used his old model of atom to treat the scattering of β-rays in matter, and two years later he reused it in his description of ionization. In the autumn of 1910, instead of the luminescent screen, he began to photograph "positive rays". Initially, the show lasted a few hours, then 3 minutes or less. With a tough heart he had to admit that in the older measurements he did not detect heavier ions because of the insensitivity of his luminescence screen from the willemite (Fig. 24-5).

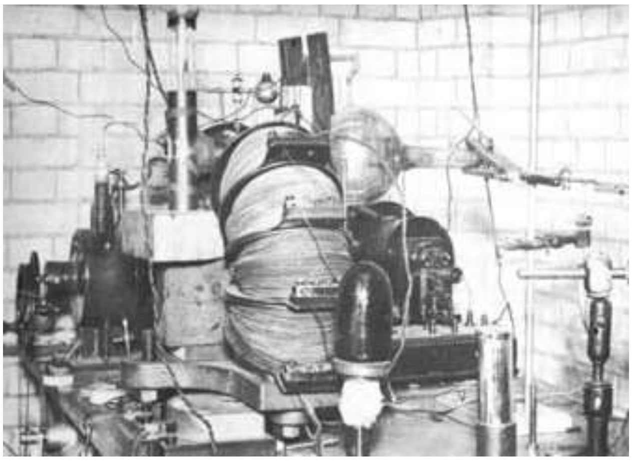

Figure 24-5: Thomson's measuring device from the period after 1910 which he used to photograph "positive rays". It included a large discharge vessel, a charcoal container cooled in the liquified air, and a large electromagnet.[2901]

After 1898, Thomson imagined ionization as result of a collision of the rapid cathode ray with the molecule from which it breaks out a new cathode ray. However, he did not know for sure whether the whole ion was splitting off from the molecule, as he believed in 1907 and he presumably confirmed with his measurements in 1910. Perhaps only the emission of the electrons and the ionization occurred?

In 1911 observations in the improved Wilson's cloud chamber (foggy cell) convinced Thomson that most ions in the gas formed after a collision

between ions and molecules. In 1912, he used Faraday's cylinder designed in 1843 for one of Thomson's few quantitative measurements, but soon he returned to qualitative measurements with photographic plates.

By 1910, Thomson still thought that the unit of positive electricity was a hydrogen ion. In 1912, this idea was finally abandoned, as the precise Aston proved that his early results were the result of the pollution of the measuring apparatus with hydrogen, although the gas could not be detected spectroscopically. Research on "positive rays" was no longer an answer to the question of the nature of electricity. Therefore, Thomson abandoned it and returned to study the composition of atoms and light.[2902] Already at the 2nd Solvay Conference in the summer of 1913, he described the quantum emission and absorption of radiation with his new atomic model. At the center of the atom, he imagined positive charges with most of the electrons, surrounded by rare weakly bound valence electrons. Until 1921 he probably thought that the mass of the atom consisted of α-particles, while hydrogen atoms were added only to the nucleuses with the odd mass numbers.[2903]

24.2 Spread of Thomson's Ideas

24.2.1 Nobel Laureates among Thomson Co-workers and Rutherford

Soon after the end of the First World War, Thomson left the heading of Cavendish laboratories to his former pupil Rutherford. He retained only a modest laboratory for exploring the positive rays in Cavendish and the honorable position as the head of the College of St. Trinity. He left a magnificent job behind him. Seven of his assistants received the Nobel Prizes, and twenty-seven of them were elected FRS. For some time, Thomson's students taught at most physics departments in Britain and in many other English-Speaking countries (Table 24-3).[2904] The success of Thomson's followers could be compared only with similar gains of Bošković's and Stefan-Boltzmann's fans in Habsburg monarchy or with the fame of later Bohr's Copenhagen interpreters of quantum mechanics. Among all those heroes, J.J. Thomson might be the best example of the able ambitious theorist who headed the prosperous experimental lab.

Even a "sun has its spots" and even JJ Thomson did not correctly evaluate the talent of Niels Bohr when he was a young postdoc doctor in Cavendish. In autumn of 1911 he proposed to Bohr an experiment with "canal" rays, but Bohr did not overjoy, because he would prefer some calculations. During this time, most experimental devices in Cavendish had to be made by themselves, including blowing glass, which was not Bohr's favorite. Later, Rutherford befriended Bohr much more because of Bohr's soccer performances.

Nonetheless, Thomson's theory of atom had a major impact on Rutherford's nuclear model in the winter of 1910/11.[2905] After the First World War, Thomson slowly began to lose contact with new discoveries. During the war, the flow of German and French newspapers in Cambridge was interrupted, and after the war, Thomson did not renew their subscriptions for one or another reason. Since German physicists at that time were as important as the later American ones, Thomson remained outside of the ideas of new generations of physicists.[2906]

Basically, Thomson accepted criticisms of his colleagues during interviews in the laboratory. His opinion was always ready to change under the pressure of arguments. Thus, on August 7, 1887, he was horrified to report to his friend and colleague Threlfall about suggestions that the girls should attend university lectures. Less than half a year later, on January 2, 1890, he married his student Rose Elisabeth Paget. Similarly, Boltzmann was also affected a decade earlier with his Jetty. Never say never! Millikan did not support feminization of USA science later in 1936, but he was already married by then.

24.2.2 Echoes of Thomson's Research in Slovenia

Before the end of the 19th century it was not possible to obtain a valid answer on the nature of electricity in the Slovenian language: "What is

[2902] Falconer, 1988, 265–267.
[2903] Falconer, 1988, 271–308.
[2904] Filonovič, 1990, 152–153; Thomson, 1967, 172 .
[2905] Dahl, 1997, 338.
[2906] Thomson, 1967, 155.

electricity? ... We must acknowledge that we do not know the answer to the question we put at the beginning of this paragraph. We have come to one of those limits, which we cannot exceed. I will not say that the scholars do not know incredibly cleverly to clarify the different electrical displays. But on the last cause of these depicting effects, we cannot say anything final with all the erudition of the world..."[2907]

JJ Thomson's model of an atom full of electrons had advocates in Slovenian lands just before World War I: "Recent research has brought many almost unexpected novelties about the composition of the atomic substance. Above all, it turned out that matter does not fill the entire atomic space, and that we must think of an atom composed of a large set of very fine body particles. These many thousand times smaller and lighter particles than atoms are called electrons. The lightest hydrogen atom has over 2000 electrons inside it; the other atoms certainly have even more of those. As the atoms in the body are constantly moving and shaking, electrons similarly circulate in a small space of atoms with a high velocity..."[2908] Certainly, Thomson's own ideas which later did not prove to be totally accurate.
Before the First World War, secondary school students in Slovenia were taught about electrons and positive rays:[2909]

"The electron is the smallest electrified material particle that is significantly different from the material atom ... There are also rays that fall on the cathode in the cathode ray tube space; if the cathode is porous, the rays run through it and they form on the other side the so-called canal rays. The magnet deflects them in the opposite sense as the cathode rays, but not with the same strength. Therefore, they are also positive electrons; their speed is smaller, their mass is larger than the mass of negative electrons."

A decade later, Slovenian ancestors read: "... the atoms of electricity which are separated from the ordinary matter. Thomson has named them corpuscles, and today we widely use the name 'electron' given to them by Stoney. Crookes' theory became the beginning of a very fruitful electronic theory."[2910]

Jožef Reisner, a graduate student at the Faculty of Arts in Vienna, served his one-year military term. From 1895/96 he received Knafelj's scholarship. Between 1899 and 1900 he was substitute (suplent) teacher in Celje and then until 1904 in the 8th district of Vienna, where he published the discussion "Determination of some definite integrals from definite equations" in German language in the school reports in 1904. Until 1905, he taught at Real school in Idrija and then at the Grammar School in Novo Mesto. In 1908/1909 he took one-year leave to write a textbook. By the orders of the Ministry in June and July 1910, he moved from Novo mesto to the 1st classical gymnasium in Ljubljana. He retired in Ljubljana in 1921, after lecturing on physics at the Faculty of Medicine during his final year. During the First World War, he was mobilized. Between 1921 and 1923 he was a Member of Parliament. Despite his retirement, he was director of the Technical High School in Ljubljana between 1923 and 1938.

25 Major Industrial Uses of Vacuum Technologies - Electron Microscope

25.1 Electron Microscopy

The English linguistic favouring light particles enabled J.J. Thomson's successes. The continental Europeans far enough from the waves of seas loved waves in their theories much more than islandic Brits, while *qi*-mediated interplay of yin and yang and Vedanta's interconnecting subject and object provided the basis for quantum synthesis of particles and waves. The continental European wave analogy between electron beam and light simultaneously led to important discoveries in physics and electrical engineering. An electron microscope uses a magnetic field instead of lenses and a jet of electrons instead of visible light. Let's look at the development of experimental electron beam focusing technique.

25.2 Optical Microscope

25.2.1 Early Users

The microscope for light was first used a few years after a telescope at the beginning of the 17th century in the Netherlands or at Galileo's networks in Padua.[2911] The people first wished to observe the seemingly invisibly small object far away, but soon also turned their attention to the invisibly small object nearby.

The microscopes were used early in Slovenia areas. On November 1, 1705, the Carniolan Provincial Assembly appointed 200 gold-denarius of the annual salary for a professor of mathematics and bought the necessary "mathematical instruments", including the optical devices. On 17 September 1755, a solar microscope and a smaller and larger hand microscope with a sphere were purchased for new Higher studies lab in Ljubljana. The solar microscope with natural light appeared in the 1730s as a tube with a condenser on one side and a simple screw-barrel microscope of James Wilson (c.1665–1730 London) designed in 1702 by Dutchman Nicolas Hartsoeker's ideas as a projection lens on the other side. Before 1811, in Ljubljana, they acquired a composite microscope and laterna magica, as they then called a microscope-projector with a concave mirror and two large lenses.[2912]

25.2.2 Jena: Optical Microscope Capability

In 1873, Abbe published the theory of the microscope as a professor at Jena University and a collaborator of Zeiss Optical Company.[2913] He showed that we cannot observe distances smaller than half of the wavelength of the light used. With visible light, the limit of resolution is 1/4 micrometres designed in the era of European limits of Carnot's efficiency, absolute zero temperature, relativistic maximum velocity and uncertainty principle mirroring Daoist limits of language and thought. Abbe's ideas about improving the resolution of the microscope by reducing the wavelength of the light used are particularly interesting today: "... There is nothing stopping us from going even further in this direction and imagining microscopic observation with the help of rays lying as far as the boundary of the visible spectrum in the UV region. Although this obtained image is not directly observable, it can be made visible through fluorescent materials..."[2914]

Abbe was thinking about UV light because X-rays and the electrons have not yet been detected. Nevertheless, it seems as if Abbe had predicted an electron microscope half a century in advance. The limit of resolution of microscope, however, became distracting when, at the turn of the century, the focus of physical exploration was shifted to the atoms and its particles. Even today, the frequently used term "submicroscopic" illustrates the problems of the atomists at that time.

25.3 Experiments with the Emission of Electrons in the Electromagnetic Field

Abbe's times witnessed decades of researched "cathode rays". Most scientists did not question that they can be curved by an electric field. On 9

[2911] Gloede, 1986, 22–28.

[2912] Gurikov, 1983, 163–164; Kircher, 1664, book no. X.

[2913] Gurikov, 1983, 122, Gurikov, 1985, 39–42.

[2914] Gurikov, 1985, 51; Gloede, 1986, 166.

October 1868 in Münster, Hittorf focused his "cathode rays" with a rotationally symmetric field of a cylindrical magnet. A similar experiment was made by Hittorf's former professor Plücker shortly before his death in Bonn, but Plücker did not publish it anymore.[2915]

Hittorf was experimenting at pressures of 0.25 to 0.125 mm Hg. He used an electro-magnetised iron cylinder with a diameter of 10 cm and a height of 50 cm attached to the 10 cm long iron join. At the ends of the cylinder he put amalgamated zinc plates with a diameter of 9 cm.[2916]

According to Hittorf, electricity in gases is translated in two ways: from a positive electrode resembling metals and electrolytes, and by discharge from the negative electrode. Under different conditions, the ratio was measured between those two modes of translation. He described the "cathode ray" as a very light "conductor" of the electrical current. The ends of "conductor" are attached to the electrodes while between the electrodes we can bend the rays with magnetic forces. Under the influence of a strong magnet, "rays" move along a curve with two to three full turns along the length of two feet. The divergent rays move after spiraling. The direction of the motion of the "cathode rays" is followed by observing the fluorescence that occurs when the rays sufficiently approach the glass wall of the vacuum tube. The best picture is seen when the cylinder of the vacuum tube is in the axis of armature of magnet.[2917]

Hittorf believed in the wave nature of "cathode rays". Therefore, he described their deflection in the magnetic field in analogy with the rotating of polarization plane of light in a magnetic field. Half a century before de Broglie he used an analogy between cathode ray and light.[2918]

Hittorf correctly predicted that experiments with the magnetic deflection of "cathode rays" in diluted gases eliminate from physics the very last electrical energy-related imponderable non-weighting substance. His work was supplemented in 1896 by Poincaré's pupil, the Norwegian Birkeland. Thus, the necessary knowledge for the development of electronics was prepared after the First World War.

25.4 The Beginnings of an Electron Microscope

The uses of established branch of physics in another developing branch helped J. Stefan's description of the diffusion process in terms of hydrodynamic laws applied in physiology. Hydrodynamics of blood became a model for heat transfer. The similar analogy between geometrical optics and other branches of physics has been repeatedly used in the century between the researches of Hamilton and Ruska. In 1826 and 1832, the geometrical optics became part of Irishman Hamilton's science. In 1834 and 1835 Hamilton expanded his idea of the characteristic function of the state from optics to mechanics. His achievements were only used in quantum mechanics.

The Frenchman de Broglie attributed wavelength to material particles in 1923. In this way he turned upside down Boltzmann's (1872) and Planck's (1900) idea of quantization of electromagnetic wave.

The "material waves" theory independently influenced experimental physics and electrotechnics. In the 1920s, the German physicist Brüche coined the term "electron optics".[2919]

25.4.1 Abbe's Successors in Jena Accomplish his Vision

On 18 October 1926 at the Physics Institute in Jena Busch published the equations for the motion of electrons in an axially symmetric magnetic and electric field by analogy with geometrical optics. He found that the focal point is a "cathode ray" current on the axis of symmetry passing through the entry point. He described the method for determining the distance between the electron source and the focal point of their jet with a mass and charge ratio (e/m) to a precision of one thousandth of a percent.[2920] On March 29, 1927, his Ph.D. student in University of Jena Fritz Wolf used that method.

[2915] Hittorf, 1869, 220–221; Ruska, 1990, 357.
[2916] Hittorf, 1869, 214.
[2917] Hittorf, 1869, 215–217, 219, 223.
[2918] Hittorf, 1869, 221; Vjalcev, 1981, 41, 47.

[2919] Gurikov, 1985, 54.
[2920] Busch, 1926, 993; Gloede, 1986, 170.

At the end of May 1927, Busch modified his idea in Braun's cathode ray tube, where a small deflection coil influenced the electron beam as a convex lens with the same focal length influences light. He described his electric field like the refractive index in optics. The idea was based on Schrödinger's wave-mechanical analogy between the beam of light and the particles with a mass, published in January 1926. To avoid sputtering, a sphere of 13 mm diameter was used for the cathode. Anode was a metal tube with a diameter of 25-30 mm and a length of 20-30 cm with a circular aperture of 8 mm diameter. On the fluorescent screen, more than 10% of his total electron flow drew an image with 0.3 mm diameter.[2921]

In 1927, Busch calculated the electron trajectories in the magnetic field. He found that the magnetic field of a short coil equally affects the electron beam, like a convex lens with a fixed focal length affect the light. The focal length of these "magnetic electronic lenses" can be continuously modified with the electrical current through the coil. Because of his lack of time, Busch did not make new experiments, but used his dozen years-old measurements from Göttingen. These did not fit well with theory, so he did not dare to announce the possibility of using an electron microscope.[2922] However, the great idea was there between the lines.

25.4.2 Electron Microscope in Berlin

At that time, a Berliner professor at the Faculty of Electrical Engineering and director of the Electronic Institute of Technical High School in Berlin-Charlottenburg Matthias founded a research group led by Knoll. Development of an effective electronic oscillograph for the measurement of high-speed electrical processes was their goal. The most important parameters that define the precision of the measurement in such an oscillograph on the "cathode ray" are the diameter and energy density of the electron beam. For a small bright spot, electrons from a divergent cathode ray tube must be focused on the fluorescent display of oscilloscope.

A student Ruska was included in the research group, as he just came to the University of Berlin after two years of electrical engineering studies in Munich where Sommerfeld also taught. In 1929, Ruska tried to verify Busch's theory of magnetic lenses. He investigated the sharpness and brightness of the freckle in the short-circuit electronic oscillograph. He got better results than Busch. However, he was not entirely pleased, as he, like Busch, used a coil with a very wide distribution of the field along the axis.

Ruska has published the first images of various magnification obtained by electron focusing. In 1930 in his diploma thesis, he focused a jet of electrons with electrostatic lenses. The choice was based on a mistake and turned out to be a disappointment. Therefore, he soon returned to magnetic lenses from his student times. After graduating in 1931, Ruska was considered happy that he could retain an unpaid doctorate post at the Institute for High Voltage in Berlin in the middle of severe economic crisis which brought Nazis to power.

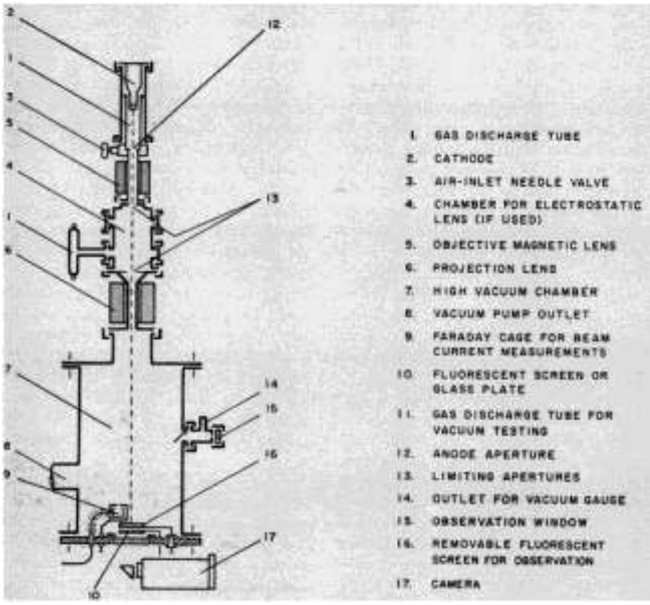

Figure 25-1: Sketches of the first Ruska's Electron a microscope with two magnetic lenses from 1931

Between 9 March and 7 April 1931, Ruska created the first electron microscope with a magnification of 3.6 to 4.8 hundred times (Figure 25-1). However, even the molybdenum or platinum grids quickly burned in the electron beam. Therefore, on 4 June 1931 Knoll avoided the term "electron microscope" in his professional lecture in Berlin.

2921 Busch, 1926, 993 and 1927, 583, 588, 592, 594.
2922 Ruska, 1986 357.

Many researchers (rightly) did not believe in the future of such a device. The shorter wavelength of the electrons increased the resolution, but at the same time increased the energy of the electrons that destroyed the observed sample.[2923] As usual in many problems of physics, the preferred circumstances tend to obstruct each other.

At the same time, other German physicists studied the electron microscope. E. Brüche and Helmut Johannson († 1982) obtained images with an electron microscope between 1931 and 1932, almost simultaneously with Ruska and Knoll.[2924] On 31 May 1931, Wiechert's student Rüdenberg patented basically the same Ruska's idea on behalf of Siemens-Schuckert-Werken in Berlin. Rüdenberg wished to observe small dangerous viruses which bothered his younger son. Due to the protests of Allgemeine Elektrizitätsgesellschaft, which had been conducting similar research since its founding in 1928, he has only patented his novelties in the US. He escaped to America from Hitler's Germany as one of those great Jews which Nazis lost.[2925]

Thus, several researchers in Berlin simultaneously approached the "discovery" of an electron microscope. Despite the economic crisis, the German industry has substantially supported basic research. In 1932, Knoll calculated from Abbe's equation that the electron microscope can distinguish the points separated by 0.22 nm, which was indeed only achieved forty years later. In April 1932, Knoll went to Telefunken of Berlin, where he worked on the development of television. At that time, Codelli also designed Telefunken's television technics.

Soon after Nazi's takeover, in November 1933, Ruska assembled an electron microscope with a 12,000-fold magnification. He published the first images with the new device few days after on 1. 12. 1933, when he left the university and got engaged in the industry. Together with his colleagues, he later received a special laboratory at Siemens with a specialized workshop for "serial" production. They also had a propagandist laboratory for guests, especially biologists and doctors, where visitors could observe viruses. During the Second World War from around 1939 to February 1945, they distributed about forty electron microscopes (Figure 25-2).[2926]

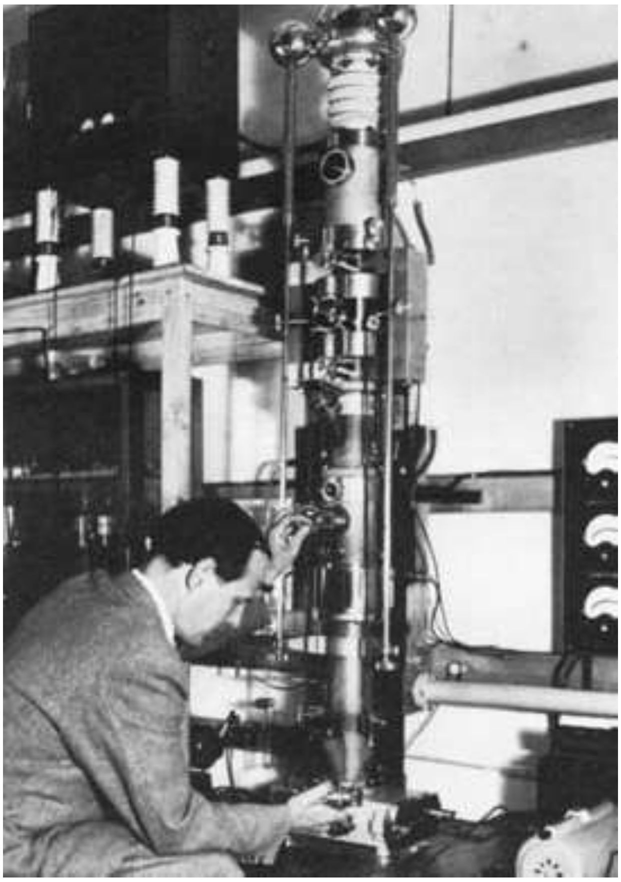

Figure 25-2: Manfred von Ardenne (1907-1997) measures with his universal linear electron microscope, which he first described at the end of 1937

25.5 "Parallel (Independent)" Discoveries in the Development of an Electron Microscope

The promising applicative technologies usually attract a lot of money from expecting businessfolks. In those privileged circumstances unplanned discoveries flourish. That fact is often used as the excuse for disastrous military projects involving unhuman researchers.

In case of electron microscopy, the unexpected inventions were especially numerous because it combined novel electronic technology with the most ancient geometrical optics basically developed already in the old Islamic Middle East.

25.6 The United States and England: the Refraction and Interference of Electrons

25.6.1 *European Mainland Love Waves Spread Overseas*

Ruska's idea of a wave aspects of "cathode rays" was vivid in Berlin already from the time of Helmholtz and Hertz. In the summer of 1931, the engineer Ruska first heard of de Broglie's "atomes couplés en onde", although the first publication was eight years old and de Broglie had already received the Nobel Prize in physics in 1929. The delay was due to the gap between Broglie's fundamental physics and Ruska's applicative engineering which prevented the guys from both fields to study each others' publications even if approaching combined Daoist dual nature of matter was in the air already during Ruska's studies in Sommerfeld's Munich.

On 10 September 1931 Ruska and Knoll did not mention de Broglie and GP Thomson in their analogy between the rays of light and the path of the massive particles with a mass in electron optics. Knoll only heard about de Broglie's work from Houtermans at the beginning of 1932. Ruska and Knoll quoted Davisson's and Germer's and Rupp's measurements of the diffraction of electrons after their reflection on crystals or on the artificial diffraction gratings, and when passing through a thin metal sheet.[2927]

Such "lack of information" is not unusual, as it was about research in sufficiently different branches of science: in practical electrical engineering and in theoretical physics. In addition, De Broglie's ideas were not easily endorsed even among theoretical physicists.

In July 1923, a professor of physics at Göttingen Franck encouraged his Jewish assistant later expert in theoretical biology Elsasser to analyze two types of experiments that could confirm de Broglie's equation. However, convincing experiments only succeeded in the USA later. As early as in 1921, Davisson in Western Electronics, the later Bell Telephone Laboratories, investigated the electron beam's reflection on a plate made from nickel in a vacuum. Together with Germer, he noticed by chance more pronounced amplifying after a reflection on a mono-crystal at the end of 1925.
In the summer of 1926, Davisson and Aberdeen professor G.P. Thomson attended a scientific meeting of the British Association in Oxford. There they got inspiration for new experiments. On 6 January 1927 in Western Electric of Manhattan in New York, Davisson and Germer observed an interference image of the scattering of slow electrons that fitted well with De Broglie's theory. This was one of the first major scientific discoveries made in an industrial laboratory. A month later G. P. Thomson independently confirmed de Broglie's theory. He observed the passage of fast electrons with a voltage of up to 30,000 eV through a gold leaf and obtained the interference pattern with rings.[2928]

Thus, applied electronics and theoretical physics, both the descendant of genus of cathode ray researchers from previous generations, found a common language in experiments at the birth of quantum mechanics. In 1937, Davisson and G. P. Thomson received the Nobel Prize in Physics for their study of the wave nature of electrons; three decades after G. P. Thomson's father J. J. Thomson, who was rewarded for measuring the particle properties of the electrons. But Thomsons, father and son, were allegedly not in furious disputes about the nature of the electrons.

25.6.2 *England: Electron Microscope and Holography*

The Hungarian engineer Gabor studied a high-frequency oscillograph in Berlin between 1924 and 1927 at the same faculty as the Knoll's group later worked. In 1927 Gabor worked at Siemens' laboratories. At the beginning of 1928, Gabor talked in a Berlin café with a fellow citizen from Budapest, Szilard, about the creation and use of an electron microscope.[2929] Soon, both Hungarian Budapest Jews Gabor and his two years elder Szilard left their ungrateful German fatherlands metamorphosed in Nazi-stan.

[2927] Knoll, Ruska, 1932, 661, 650; Gloede, 1986, 176–177.

[2928] Thomson, 1970, 158–160.

[2929] Knoll, Ruska, 1932 638, 642; Gurikov, 1985, 59; Gloede, 1986, 173.

In 1947, as a researcher at English subsidiary of the General Electric Company the Thomson-Houston Company in Rugby, Gabor experimented to increase the resolution of the electron microscope, which was theoretically 0.4 nm and practically only 1.2 nm (Figure 25-3). Due to incomplete optics, it was not possible to achieve resolution comparable to de Broglie's wavelength of fast electrons, which is 1/200 nm wide. Therefore, in addition to the amplitude, Gabor wanted to write a wave phase, filmed with a coherent jet of electrons. The idea was interesting enough to enable Gabor to experiment for the Metropolitan Vickers, which produced electron microscopes. On 15. 5. 1948 Gabor's first report indicated that the new reception could be used in electron microscopy. Gabor developed his holography electron microscopy with various colleagues during the next five years. Unfortunately, he had to abandon his "premature" efforts as electron microscopes needed another two decades to reach the theoretical limits of their resolution restricted only by spherical aberration. Improving resolution for a factor of two would only allow observation of atoms in such perfected microscopes, which Gabor predicted as a new possibility of "holographic electronic spectroscopy" in 1972.[2930]

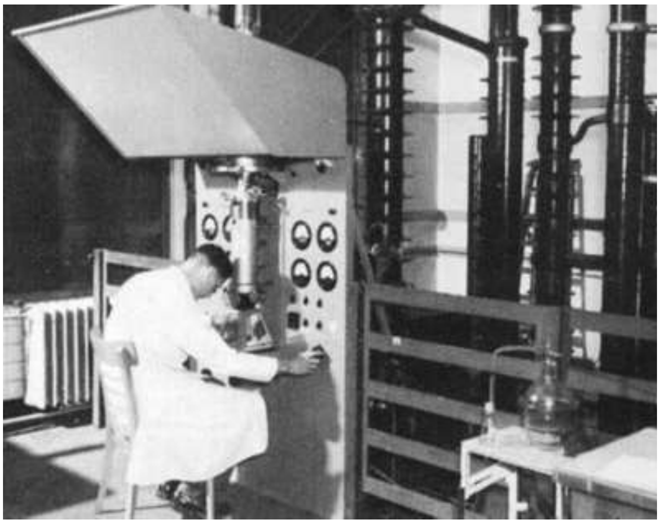

Figure 25-3: Philips' 400 kV electron microscope from 1947

After 1962, the invention of the laser enabled the use of Gabor's ideas in laser holograms. In 1971, Gabor received the Nobel Prize for his invention of holography.

25.7 Engineer Strojnik with the First Ljubljana Electronic Microscope

The dream of observing atoms has always been endorsed by both Ljubljana erudite and other scientists all over Europe. Vernon Ellis Cosslett (* 1908) has read Knoll and Ruska's discussions as a PhD student at the University of Bristol after graduating from Physical Chemistry in 1932. As a young researcher, he wished to observe biological samples through an electron microscope. During the war, he worked at Oxford, and in 1946 he came to the Oxfordian Cambridge competitors just before the English brought a seven-year-old Siemens electron microscope there as a kind of military refund. The American electron microscope RCA EMB has been used since 1942, so they quickly found themselves at home on their new German device.

Cosslett and colleagues soon developed Cambridge into the center of electron microscopy. In the summer 1956 they organized the first international conference "X-Ray Microscopy and Microanalysis". In 1960 they published the first transparent reviews book on X-ray microscopy.

Among the many students of Crosslett's work, the Slovenian Aleš Strojnik (* 1921 Ljubljana; † 6th November 1995, Arizona) was among the best. The Carniolans are everywhere where something important is going on. In the May issue of Physics Today, Alojz Paulin, one of the admirers of the Strojnik's successes, read the sad news of Strojnik's death. The death of Slovenian scientist happened in the former Wild West in the US, just where Karl May's (1842–1912) Winnetou and his men were going to eternal hunting grounds.

Already in Strojnik's cradle was a talent, since he was the son of a professor at Technic faculty in Ljubljana Romeo Fakin who changed his surname to Romeo Strojnik. In 1939 Aleš Strojnik graduated from the classical Grammar school (gymnasium). In the same year, he enrolled in the Department of Mechanical Engineering at the Technical Faculty of the University of King Aleksandar in Ljubljana. In 1941, he enrolled in the Department of Electrical Engineering, where he graduated during the war in 1944. He defended his doctorate in aerodynamics in 1953 under

[2930] Gabor, 1948, 778; Gabor, 1972, 302–303.

supervision of the professor Kuhelj. In 1955, Strojnik became alecturer-docent. He was promoted to the status of an assistant professor in 1960, and in 1969 he was a full-time professor at the Faculty of Electrical Engineering in Ljubljana. By his example the Faculty of Electrical Engineering has turned from the College of Thinkers and Philosophers to the faculty of technicians and inventors.

Aleš Strojnik was born in Ljubljana in the family of professor of mechanical engineering who changed his funny surname Fakin into more appropriate Strojnik. As a professor at the Faculty of Electrical Engineering in Ljubljana, he trained numerous domestic experts in electron microscopy. In 1969, Strojnik became a professor of physics and astronomy at State University of Arizona in Tucson, where he compiled a transversal linear microscope. He had already dealt with airplanes during the war as A. Kuhelj's assistant. Therefore, Strojnik successfully established himself in American networks of designers of planes. He did not stay only in vacuum technique, but he was mainly engaged with much more enthusiasm and even greater success in designing his aircrafts. His Slovenian knowledge was celebrated all over the Earth, and a bit above it. He compiled one hundred and fifty original plans for small planes, including an interesting model S-2A. He received numerous awards, including the Otto Lilienthal Prize named after the most famous German glider pilot of a heavier-than-air aircraft that is supported in flight by the dynamic reaction of the air against its lifting surfaces. In 1988 Strojnik got the Paul E. Tuntland (1922-1950) Memorial Award. He has published several books on light aircraft translated into many languages.

In Ljubljana, Strojnik made some decisive improvements. He introduced the first masters' degree postgraduate studies in Ljubljana, Yugoslavia and in Central Europe. In 1962, at the Faculty of Electrical Engineering of University of Ljubljana the students completed their first Masters' degrees of Science in Yugoslavia. They were educated in the field of electron optics and vacuum electronics. Later, the similar course of study was continued by Paulin in FERI in Maribor. In 1952, Strojnik received a five-month scholarship from the British Council for electron microscopy specialization at Cosslett's labs in Cambridge. At that time, there were no electron microscopes in Yugoslavia, since the price of that top device was about 30,000 US dollars. After Strojnik's return, the Faculty of Electrical Engineering of the Technical College of Ljubljana accepted the construction of an electron microscope in its work program in 1953.

Figure 25-4: The first Slovenian electron microscope, which was created fifty years ago according to the plans of prof. Aleš Strojnik.

The first electron microscope of domestic production with 50 kV and a resolution of 5-2.5 nm was put into operation in the spring of 1955 (Figure 25-4), and the LEM-2 microscope with 50 kV began to work at the Metallurgical Institute in Ljubljana in the spring of 1958. In an exceptional case, it reached a resolution of about 1.7 nm. Strojnik's group was the only one in Yugoslavia to develop an electronic microscope, if we excluded an unsuccessful experiment in Zagreb. During this time, only two microscopes of foreign manufacture were in Yugoslavia. In October 1954, the Material Research Laboratory at the Jožef Stefan Physics Institute received the electronic microscope of the firm Carl Zeiss. At the Ruđer Bošković Institute in

Zagreb, they focused mainly on biology. In 1958, besides LEM-2 at the Metallurgical Institute in Ljubljana, an electronic microscope was obtained at the University of Belgrade. In the 1970-s, there were about 2000 electronic microscopes around the world, with magnifications up to two million times. With them, it was already possible to observe individual large molecules in the cells, and there was no longer a "doubt that some atoms can be seen".[2931] The late Ernst Mach would certainly have been angry, but the atoms (indeed) finally become a reality.

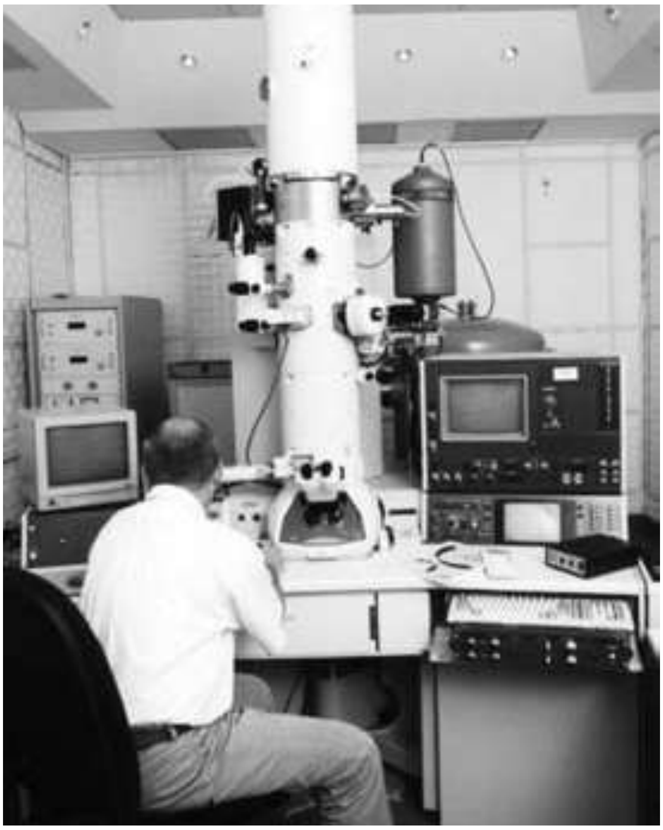

Figure 25-5: An analytical transmission electron microscope Jeol JEM-2010F at IJS

Strojnik educated numerous domestic experts in electron microscopy. Two rectors of the University of Ljubljana, several deans, university professors and other scientists came out of the Strojnik's school, among others Prof. dr. Navinšek. Today, of course, Strojnik's achievement contradicts the modern European doctoral studies without a master's degree.

Strojnik advanced the Slovenian technique. He built the first electron microscope in Yugoslavia, in the Balkans, in Central Europe with small resources.

The late Ernst Mach would surely have been angry with Strojnik if at that time could still visit his parents under Slovenian Gorjanci mountain range, but the atoms become a reality.

Cosslett's school soon began to collect fruits. In 1982, former team member of viruses and DNA pioneer Rosalind Franklin, the Jewish Aaron Klug from the Laboratory of Molecular Biology at the Medical Research Center in Cambridge received the Nobel Prize in Chemistry for the development of a crystallographic electron microscope.

In 1986, Ruska received the Nobel Prize for his "invention" of an electron microscope. The German Gerd Binning and Swiss Heinrich Rohrer shared a prize with Ruska for their invention of the tunnelling linear microscope. Four years earlier, Aaron Klug from the Laboratory of Molecular Biology at the Medical Research Center in Cambridge received the Nobel Prize in chemistry for the development of a crystallographic electron microscope. The engineer Strojnik's achievements were not that high, but he was a great technician and a scientist inside the Slovenian networks.

Unfortunately, the politicians of that time closed Strojnik's way to the membership of SAZU Academy. For Slovenes' spirits and hearts, a philosophical line of merit was and still is much closer than any productive technical direction. We see this at every step. In 1928, Professor Marij Osana set up the first transmitter in the Balkans in Domžale. At the 50th anniversary of Slovenian TV broadcastings, Slovenians remembered all announcers and other faces from small TV screens; but they almost did not mention Osana, who made all that possible. In Slovenian encyclopaedias, most artists and writers are mentioned, while many technicians and businessmen are simply forgotten. This mentality separates Slovenians from their western and northern neighbors, where the scientists are in the first place, even before the imperial dynasties, inventors and businessmen.

[2931] Strojnik, 1955, 214.

26 Major Scientific Uses of Vacuum Technologies - Accelerators

26.1 Accelerators: from Ideas to First Performances

Almost a century ago, there was a tough competition in accelerating the protons to the energy needed to break the nucleus of the atom. We can have those events for the beginning of the golden age of high-energy physics. Rutherford used only a few ropes and waxes for his famous experiments, but so much more reason and imagination. Later, accelerators developed into one of the most demanding technologies in the world.

26.2 Pre-history

The art of production of accelerators was born from the older technology of high-voltage electrostatic devices and vacuum pumps. Hauksbee compiled the first ancestor of tools of these sorts in 1705 or a year later. He rotated his emptied round glass container around its axis. When he rubbed rotating bowl against the fur, he got enough voltage to notice the weak scarlet glow inside the bowl. The glow could have been caused by the electron fluorescence or, more likely, by the ionization of residual gas in incomplete vacuum.

In 1784, the Dutchman van Marum received more than half of meter long nice spark with a magnificent electrostatic machine, which was set up in a large hall at Teyler Museum in Haarlem in Holland. In 1897, JJ Thomson attributed cathode ray properties to electrons as the first one who realized that he was breaking atoms in his experiments.

In 1911 in Manchester, Rutherford published the results of scattering of α-particles by atoms. Six years later Rutherford succeeded in his first artificial change of the nucleus (Figure 26-1). The nitrogen was bombarded with 5 to 8 MeV α-particles from radium and thorium to get protons.[2932] In 1925, near the orbit of proton, he observed a short trace of isotope ^{17}O in the Wilson's cloud chamber.

After the First World War, X-ray researchers developed devices in which the particles reached 100 to 200 keV. Due to the problems of insulation and discharges, it was not possible to achieve higher energies comparable to the radiation energy of radioactive elements used by Rutherford. Overcoming these problems has become one of the main orientations of researchers. It was suggested that it would soon be possible to study systematically or break down the recently discovered nucleus of the atom in the high energy accelerators. Several US researchers have reported that they broke the nucleus successfully, among them Millikan, who considered that he and his student George Winchester extracted hydrogen atoms from aluminium and other metals with strong discharges in a vacuum in Chicago as early as in 1912. To continue such experiments, Millikan switched to Caltech in 1921, where he measured with a voltage of one million volts. In 1923, the Slovenians read: "The "Stone of the Wise Men" we found. We can arbitrarily fragment the atoms."[2933]

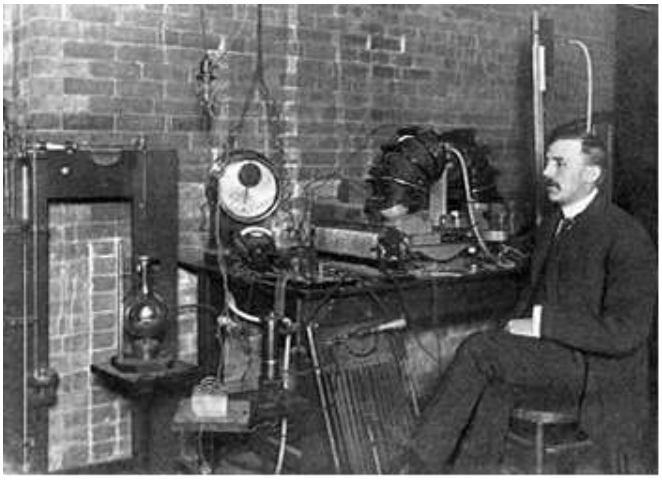

Figure 26-1: Rutherford with his tools[2934]

26.3 Who Will Break the First Nucleus?

Orlando Lawrence was a grandson of a Norwegian teacher who emigrated to Madison in Wisconsin. He was born in the small village of Canton, South Dakota, on 8 August 1901. He graduated from the University of South Dakota in 1922, and three

[2932] Livingston, Blewett, 1962, 4.

[2933] reprint: Čermelj, 1980, 111.

[2934] Campbell, 1998, 35.

years later he received his Ph.D. in Yale. In 1927 he worked at the University of California at Berkeley, where he remained in a pleasant university town until his death. One spring evening in 1929, he accidentally came across a discussion at the Archiv für Electrotechnik exerted from the doctorate of Norwegian Wideröe, who studied in Germany. Wideröe's criticism of Gaede's claim that the ultimate performances of vacuum pumps are limited was approved by Rogowski who invited Wideröe to his institute in Aachen in May 1926. Since 1932, Wideröe has worked with a branch of Swiss-based Brown-Boveri Company in Oslo, since 1946 in Baden in Switzerland, since 1952 at CERN and after 1959 at DESY in Hamburg. Lawrence did not look at Wideröe's writing in detail in the first place until his attention was drawn to his sketch of the measuring device. Then a Norwegian spark flourished among Scandinavian compatriots. The idea of the Swede Gustav Ising from 1924, which was used by Wideröe four years later, has gradually enabled betatron and resonant linear accelerator. It was not completely new invention. The president chairman of the MIT Compton compared that acceleration method compared a child on the swing. He knew that the swing could reach very high altitudes, although we periodically push it only by a small distance. According to the idea of Ising, speed should be increased linearly with energy. Wideröe succeeded in experimenting with resonant acceleration of sodium and potassium ions. Between three cylindrical electrodes he placed a 15 cm long gap. The oscillator has been adjusted to a frequency slightly above 1 MHz with differences of potentials of 20-50 kV. In such a linear accelerator he accelerated the ions to energies that corresponded to the doubled value of the selected voltage. He thus confirmed the possibility that with a low voltage we can increase the velocity by adding it at the correct resonant intervals.

Lawrence has long sought path to avoid high-frequency currents in his complicated device, in which he accelerated the projectiles to huge speeds in emptied containers. Wideröe's idea fell to fertile soil. In a few minutes, his fellow Norwegian Lawrence drew a camera and wrote equations. The next day he told his friend about the invention. He thought of circling an electrically charged missile in a very strong magnetic field. The first shot had a strong accelerator burst in the recipient in an empty space in the form of a pan, equipped with a lid. Lawrence then accelerated it with repeated electric shocks, causing the projectile to circulate in ever-wider circles at ever-higher speeds. Finally, the projectile hit the edge of the recipient and reached the reception space at the passage through the crack to bombard the atomic nuclei there. Lawrence set the magnetic field so that the projectile flew precisely at moment when the alternating current changed its direction and was ready to accept the next shock. High frequency fluctuations were used to increase the velocity of the projectile. He hoped that with the thousand times used thousands of volts he would achieve the same effect as if using one million volts at once. He used the same great idea of resonance as did Tesla for his tower two dozen years earlier. Except that Lawrence was a mainstream guy.

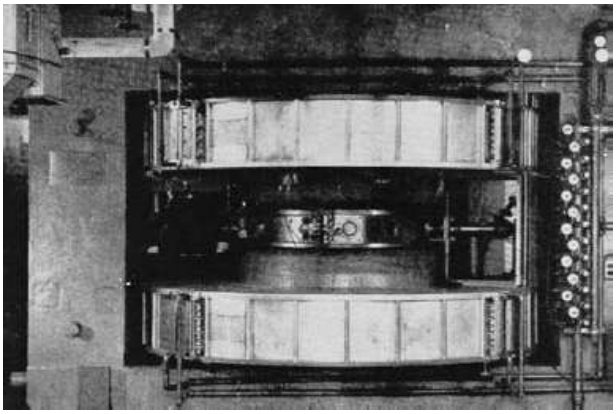

Figure 26-2: Lawrence's cyclotron for 16 MeV[2935]

In January 1930, Lawrence constructed the first resonance accelerator, later called cyclotron. Between the halves of the electromagnet, he placed an exhausted container of diameter 10 cm. He installed two isolated D-shaped electrodes connected to the high-frequency alternating current. Other parts of his device were made of glass, which was sealed with a wax. With the help of his another graduate student of Scandinavian genius Niels E. Edlefsen (1893 Cache, Utah-1971 Davis, Yolo, California), he got a resonance. In September 1930, at NAS in Berkeley he publicly reported for the first time on his cyclic magnetic resonance device and published a discussion in the journal Science together with Edlefsen. Lawrence's cyclotron used new discoveries about the electron, just like his contemporary electron microscope. Initially, it was aimed at exploring the structure of atoms like its later namesake nuclear magnetic resonance.

[2935] Livingston, Blewett, 1962, 133.

After his first model made of glass, Lawrence assembled another similar metal device with the help of his new PhD student Livingstone. With a 2000 V voltage, they were able to accelerate hydrogen ions to 80 keV energies. Livingston proved the utility of the principle of cyclotron resonance in his doctoral thesis on 14. 4. 1931.[2936]

In February 1932, Lawrence built a model worth US $ 1,000. It was 30.5 cm wide with a 1.2 MV acceleration voltage (Figure 26-2). In the summer of 1932, he was the first to break the lithium nucleus in the New World. The following year he was the sole US participant of the Solvay Conference, and in 1939 he received the Nobel Prize in Physics. The focus of mainstreams was gradually shifting across the big blue water nicknamed Atlantic.

In 1932, Chadwick discovered the neutron in Cavendish's laboratories, thereby increasing the number of elemental particles. But American of Scandinavian genus prospered the most, just like the Hungarian Martians a decade after them. Carl David Anderson was born to the Swedish parents in New York in 1905. On August 2, 1932, he spotted an electron moving opposite to the expected direction in the film shot at Wilson's cloud chamber in Millikan's laboratory at CalTech. In September 1932 he published the discovery of a particle, which P. A. M. Dirac had previously predicted as a positron. For their discoveries, Chadwick and Anderson received their Nobel Prizes in 1935 and 1936.

26.4 The English Won the Match

Lawrence and Livingston were the first to accelerate protons over 1 MeV; but they did not break the atomic nucleus as the first in the race. This happened in the Cavendish Laboratories to Cockcroft and his collaborator the Irishman Walton. Their boss the director Rutherford initially opposed expensive investment in accelerators at Cavendish's laboratories. He was drawn by the romance of the past generation, when it was possible to detect important physical phenomena with primitive tools. In 1927, in his speech before the RS, he already announced the devices with 300 and 900 kV, which will allow studies of the structures of the atomic nucleus. At the end of 1928, he ordered Cockcroft to start work on a high-voltage accelerator, where Walton joined him the following year. The first experiments were made in March 1930.

Over two years, Cockcroft and Walton rearranged the device to bomb the lithium nuclei with protons. At 125 kV, they already noticed a lot of strong scintillations. At 400 kV they spotted several hundreds of them every minute by the current of protons of a few mA. Due to sparking, they could only keep up to half a megawatt, with other sources up to 600 or even 700 kV. However, Rutherford advised the experiment. He believed in Gamow's theories (1928) and in ideas developed next year in 1929 by W.L. Bragg's Manchester student Ronald Wilfred Gurney (Wilfrid, 1898 Cheltenham in England-1953 New York) and later Manhattan project official almost turned McCarthyism's victim Edward Uhler Condon (1902 New Mexico-1974 Colorado). According to them 0.5 MeV or less would suffice for the breakdown of lighter nuclei, although other researchers predicted penetration into the nucleus only at voltages of about 1 MV.[2937]

Englishman **John Douglas Cockcroft** began working as an electrical engineer and after obtaining mathematical scholarship in Cambridge, he studied under Chadwick's leadership.[2938]

After the bombardment of lithium nuclei with protons, the Cavendish Laboratory produced particles with a maximum reach of about 8 cm. Thoseproved to be α-particles, which was confirmed by Wilson's cloud chamber images. The nucleus of the atom was broken, alchemy became a reality. On 20 April 1932, Rutherford reported on the successes of Cockcroft and Walton. The English got a game and showed that there is some important physics insight needed, not just the power of the costly tools used. They also found a mass defect of 0.018574 a. m. e., which corresponded to the predictions of Einstein's equation. Similar experiments were carried out with boron, fluorine and aluminium. The scintillations were also obtained during the experiments with beryllium and carbon, but not

2936 Livingston, Blewett, 1962, 134.

2937 Livingston, Blewett, 1962, 4.

2938 Brown, 1997, 74.

with oxygen and copper in the proton energy up to 4 keV.[2939] The similar transmutations of atoms were studied by Lawrence in 1935.

As a result, the Cockcroft-Walton's voltage multiplier could reach 750 kV. Later, the firm Philips in Eindhoven used their plans to install a device that reached 1.25 MV led in Cavendish Laboratory. It turned out that this is indeed the maximum that an accelerator of this type can achieve at normal pressure.[2940] Rutherford received the Nobel Prize in chemistry in 1908, and in 1951 Cockcroft and Walton shared the Nobel Prize in Physics for their success in the development of accelerators. Rutherford's prize was accompanied by his robust joke: "I have dealt with many different transformations with various periods of time, but the quickest that I have met was my own transformation in one moment from a physicist to a chemist!"

26.5 Accelerators Turn into "Big Science"

In 1936, Lawrence became director of Radiation Laboratory. William Brobeck was the first professional engineer to start his job at Lawrence's lab in 1938. He made every effort to change the previous technology of "thread and wax" into modern engineering practice. In the 1930s, Lawrence set up a 70 cm centric cyclotron giving some μA of deuteron currents with energy of 5 MeV or helium nuclei with energy of 10 MeV. The large electromagnetic pole had a diameter of 114 cm and was buried in the ground up to the height of the kitchen stove. The control room was 5 m higher, and the operator had an additional protective envelope. In 1939, Lawrence set up his 70 cm cyclotron in a larger 1.5 mł cyclotron, set for medical examination of cancer. The larger cyclotron weighted 220 tons and it gave a deuteron current of 10 mA with energies 16 MeV or a current of 1 mA of helium ions with energies of 32 MeV. In July 1941 Lawrence began building a 24-side structure in Berkeley. It was 30 meters high, 50 meters in diameter for the supposed more powerful cyclotron. The work continued after the attack on Pearl Harbor on December 7, while the military activities could also be expected which forced Lawrence to convert his old 37-inch cyclotron into a giant mass spectrometer needed for Manhattan bombers. Lawrence's 467 cm large synchrocyclotron was completed only after the war in 1949. It cost 1.8 million dollars and reached 340 or even 380 MeV. A multimillionaire banker and scientist Alfred Lee Loomis (1887 New York-1975 East Hampton New York) achieved the great merits by collecting the necessary money. To exceed the threshold energy of 100 MeV resulting from the increase in the mass of accelerated particles, they used the idea of Lawrence's Californian co-worker Edwin Mattison McMillan (1907-1991) and the Russian inventor of microtron Veksler from 1944 and 1945 for the synchronization of magnetic and electric fields. Thus, constant ion acceleration in the synchrocyclotron was achieved.[2941] In 1951, McMillan received half of the Nobel Prize in Chemistry for his discovery of transuranic elements.

26.6 Van de Graaff Generator

26.6.1 *Early Ideas*

In 1749, Franklin supposedly performed his dangerous experiments with lightning, even if some recent studies describe his work more like thought experiments. Less fortunate was the

Russian Academician Richman in 1753 in Petrograd.[2942] The Carniolans were not lagging much behind, as Ambschell described the lightning that hit the monastery church in 1782, 3 miles south of Ljubljana. The Carniolan Hallerstein participated in the first experiments with the ancestor of the electrophorus in Beijing (Peking) in the 1750s, and in 1833 Hummel published a paper about a simple electrophorus charged by friction.[2943]

26.6.2 *The Ljubljana Van de Graaff*

On 27. 11. 1954, a century after the departure of Hummel from Ljubljana to Graz, the electric part of Van de Graaff generator of Slovenian domestic production was used at the IJS in the laboratory of Edvard Cilenšek "for the construction and

maintenance of accelerators". The native scientists designed their own plans, constructed, assembled and tested individual parts, and therefore continued Hummel's efforts (Figure 26-4).

The whole build-up of the accelerator lasted just over four years from 1953 to 1957. They built a closed-type device that operated under a pressure of 10 bar of nitrogen. They could direct their elementary particles to the target by their range between 200 kV and 2.3 MV. For a high vacuum in the acceleration tube, a diffusion pump with a pumping velocity of 500 l/s was used. In May 1956, the beam was accelerated for the first time through a tube with a voltage of 2 MV at a pressure of 8 bar. In March 1961, the accelerator for 1.8 MeV was completed and since then it has been in almost constant operation (Figure 26-5).

In 1963, the structure of the levels in lighter elements was investigated by using the reaction (p, γ) with Van de Graaff. However, that device was already outdated for promising research in nuclear physics compared to betatron or neutron generator designed at Cavendish in 1930s.

26.7 Electron Accelerators

The first electron accelerator the "cathode ray tube" was used for the first time a century and a half ago. In the 20th century, the electrons were first accelerated with Van de Graaff devices, which could not exceed few MeV. The cyclotron was not useful because the mass of the accelerated electrons began to increase noticeably at a level of few 10 keV.

Therefore the American engineer Joseph Slepian (1891 Boston-1969) at Westinghouse and Wideröe did not achieve much success in accelerating electrons in the 1930s. In 1933 Steenbeck wrote the mathematical conditions for field stability in the accelerator at Siemens Röhrenwerk labs in Berlin just while Hitler ascended to his throne[2947] to enable Steenbeck's work for von Ardenne's part of Soviet nuclear bomb a dozen years later.

The American Kerst of the Illinois University constructed a betatron using the law of electromagnetic induction and reached 2.3 MeV for GE in 1940. He used Wideröe's idea of a "beam converter" from 1928 for his magnetic induction part of betatron. However, Wideröe did not yet know the rules needed to keep the electrons in orbit.[2948]

The Carniolans were fast in the game. In the summer of 1954, betatron was purchased at the IJS. In 1956 Darko Jamnik succeeded in achieving 20 MeV energy stabilization at 5 keV. Thus, Slovenian betatron in the range of energies of up to 30 MeV was the most accurate device in the world for the exploration of a nuclear photoelectric effect.

27 Vacuum for Entertainments - Television

27.1 Cathode Ray Tubes and other Vacuum Elements for Television

The developed telegraphy seemed to be able to transfer images to distances that go beyond physiological options. In 1843, Wheatstone's competitor the Scotsman Alexander Bain (1810-1877) described a system for transferring images, especially chemically colored portraits. The current between the electrodes applied on the image obtained information about the drawn image. Bain's telegraph with the corrections of the Viennese university mechanics designing working Baumgartner's magnets and Ettingshausen's photographic apparatuses Johann Michael Ekling (Eckling, * 1795 Vienna; † 1876 Vienna) was used in Austria since 1847, until the introduction of Morse telegraph.[2949]

In parallel, they developed other methods for chemical detection and electric transmission of the recorded data, including Frederick Collier Bakewell's (1800-1869 North London) Londoner telegraphic facsimile in 1847 commercialized only by the Florentine university professor priest Caselli with a little help of his Gran Duke Leopold II and Parisian emperor Napoleon III. The transfer of motion pictures became only relevant after Edison's invention of the cinema at the end of the century.

27.2 Naming of Television

The developed telegraphy seemed to be able to transfer images to distances that go beyond physiological options.

The term television was coined by the Russian Constantin Perskyi (Perski, Константин Дмитриевич Перский, 1854 Tver guvernorate-1906) by his paper read on First All-Russian Electrotechnical Congress (Перви Всероссий электротехнически съезд) in Petresburg in 1899 and repeated next year under the title The current state of the matter of the electrification at a distance (television; Современное состояние вопроса об электровидении на расстояние (телевизирование)) on the fourth International Congress of electricity, which was part of the Parisian exhibition in 1900. As the professor of electricity in Artillery academy (кадетски корпус), he was a member of the Institute of Technology in Petersburg, where Rosing and Zworykin later worked. The name was accepted when it was used by Hugo Gernsback (1884-1967), the publisher of the leading American radio news magazine Radio News, in the paper "Television and the Telephot", which was printed in the journal Modern Electrics in December 1909. Gernsback later founded Gernsback Inc., a publisher of Radio-Electronics magazine, renamed in Electronics Now in 1993.[2950]

In 1890, and especially 1903, and 1905 Walther Karl Eugen Stephan (Stephen) in 36th and 38th yearly of Real Grammar school in West Polish Drawsko Pomorskie (Dramburg) entitled his bipartite paper on total 60 illustrated pages "Konstruktion und Theorie eines elektrischen Fernsehers" resembling Nipkow's "Elektrisches Telescope". In 1891, the chemist photographer Raphael Eduard Liesegang (1869-1947) published the first German book about television "Beitrage zum elektrischen Fernsehen".

The Slovenes under the influence of the German term Fernsehen have long used the term "looking at a distance" or "far-sighted". The prevailing political influence of the German language in Yugoslavia ceased after WW1. When American electronics prevailed in the 1930s, the journal Illustrated Slovenian (Ilustrirani Slovenec) had already used the term television on Codelli and Slišković's page 150 of volume 6 no. 19 on 11 May 1930.

27.3 Sensors and Photocells

In the television, a light signal must be converted into an electric current, which was already transferable to large distance in the 19th century. A. E. Becquerel first observed that light causes electric current in some electrolytes in Paris in 1837 or 1839. Among other things, he discovered a photocurrent from illuminated selenium. In 1851,

2949 Šubic, 1875, 21.

2950 Fisher, 1996, 29, 45, 92.

Hittorf investigated the effect of heat on the electrical conductivity of selenium. Two decades later in 1873, Willoughby Smith's chief assistant at the English Telegraph Construction and Maintenance Company, Joseph May, accidentally discovered the dependence of light on the electrical conductivity of selenium during underwater cables testing along the southwest Irish coast in the island of Valentia. His experiment table was by the window, and so he could notice that the selenium conductivity increased when the sun was lit up. On February 2, 1873, the head of electrical engineering at the company, Willoughby Smith (1828-1891), wrote to Vice-President of the Society of Engineers, Latimer Clark (1822-1898), to report the phenomenon to the Annual Assembly on the following day. He described an increase in the conductivity of selenium bars by 15% to 100% at illumination as an annoying problem in experiments and did not even mention the discoverer May, who was just Smith's assistant anyway. A few days later, Smith met Edison, who visited London in May 1873. Smith subsequently developed the system of "visual telegraphy", while May investigated the transmission of the image by conductor. That newly recognized phenomenon was used by E. W. Siemens in the invention of the first selenium photocell, which he had, after two years of work, assembled in 1876. The initially undesired affect suddenly became very useful, just like the thin film metallic mirrors deposits in cathode ray tubes in those same times of happy accidental discoveries.

The news slowly penetrated in the USA. In Boston in 1875 or more probably in 1880, George R. Carey (1851 Malden, Massachusetts-1906) first described the television system with the projection of an object's image on a photo-sensitive surface of an insulator that was not selenium, but a silver compound. Sci. Am. reported about his work. In 1877, English professors former W. Thomson's assistants John Perry (1850 Garvagh in Londonderry-1920 London) and his Tokyo collaborator William E. Ayrton as the Chair of Natural Philosophy and Telegraphy department of the Imperial university reported in the Londoner Nature magazine on selenium cells and Faraday's discovery of the magnet effecting the polarization of light in an article entitled Lightning Conductors. In his patents on February 2-10, 1906, December 1, 1906 and 1908 as well as at Parisian demonstration in 1909, Georges-Pierre-Édouard Rignoux from Surgères in southwestern France with the help of the professor A. Fournier interconnected sixty-four selenium cells on the scanner contact plate for their téléphote.[2951]

On 27 August 1880 Bell and Charles Symner Tainter (1854-1940 San Diego) used selenium in their photophone. Soon Slovenians read about the discovery in the Slovene language: "If we speak in Bell's elastic mirror, and if the light returns from the mirror back then and into the glass tube, which has sooty in it, our speech is repeated in the sooty of the tube!"[2952] That was the beginning of Slovene telephony and the foundation of the modern exceptional popularity of mobile phones in the country on the sunny side of the Alps.

The photocell soon surpassed the possibilities of selenium. The photoelectric effect was discovered by Hertz in May 1887. He was exploring the resonance during the rapid oscillations in two Braun's modified coils, which he used as a vibrator and resonator. He noticed that the discharge of the Ruhmkorff induction coil triggered two completely simultaneous electric sparks in both coils. The first was the spark of the inductor's discharge and served to induce the primary oscillation. During experiments, Hertz accurately measured the maximum length of the second, weaker spark in the resonator, which was generated by the induced secondary oscillation. For better observation, Hertz shone the second sparkle with the box; he observed with a surprise that its length was significantly shortened. Moving the box showed that the barrier between the two sparks affects the length of the second spark even at a greater distance between the two sparks. UV light from the first spark caused the second spark, and the obstacle could have interrupted its effect.

Hertz was unable to explain his discovery with electrical charge of the obstruction, as the effect was observed both behind the barriers of conductors and behind the insulators, but not behind the metallic grid. He thought that the effect of shortwave UV light, which is absorbed by most solids, while he was also able to prove the effect of refraction and reflection of UV light. Hertz

measured in a rather wrapped circumstance, therefore, in its report, he carefully preferred to avoid the explanation of the photoelectric effect (Figure 27-1).[2953]

In 1889, Geitel and Elster got their photoelectric images at the Wolfenbüttel Gymnasium. They used photocathode made of potassium or sodium amalgam illuminated with visible light through anode in the form of a ring. They illuminated their cesium photocathode by UV light. The following year, they sealed their device a glass vacuum tube, thus obtaining the first modern photocell which Rosenthal first used for his "optical telegraphy".

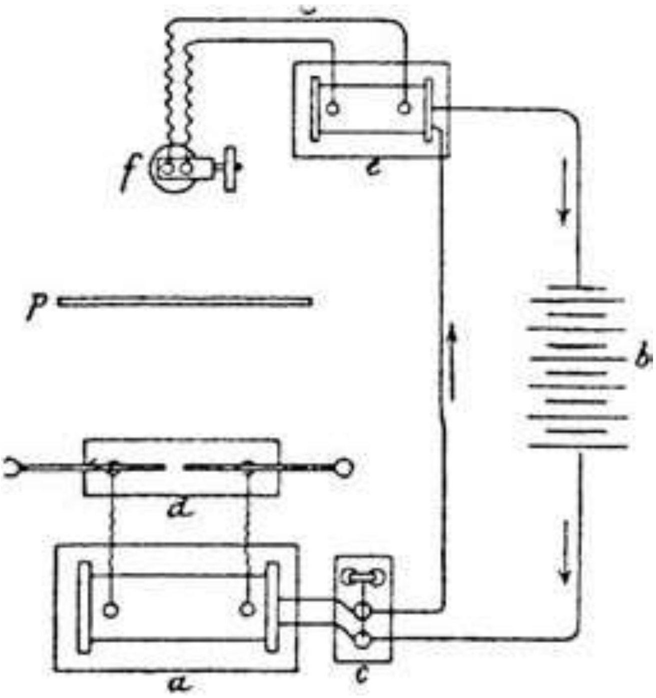

Figure 27-1: A schematic diagram of the device which Hertz used to discover his photoelectric effect[2954]

In March 1889, Hertz's assistant Lenard and the leading Heidelberg astronomer photographer Maximilian Wolf combined the idea of Hallwachs designed in 1888 for the emission of UV-light electrons and Nahrwold's study of the sputtering of metallic cathodes in a vacuum from 1887 and 1888. In the beginning, Lenard assumed that UV light emits particles with measurable mass.[2955] On 19 October 1899, as Hertz's successor in Bonn Lenard proved that light breaks out electrons in photoelectric effect. A photoelectric effect takes place even in the best vacuum, where other known phenomena of discharges are not possible anymore. At ordinary pressures, the breakout electrons stop in the surrounding gas.

Lenard measured the charge, which rays of UV light brought into motion in an empty space at various voltages between the electrodes.

He proved that the electrical forces themselves are not enough to overcome the work function (the electron binding energy) in the photoelectric effect.[2956] Lenard and J. J. Thomson measured approximately the same e/m ratio for "cathode rays," for particles ejected in the photoelectric effect and particles in the "Edison effect" of annealing metal surfaces.[2957] In this way they proved that in all cases they are dealing with the same kind of particles for which the name electron was gradually established. They repeated the same old Faraday's approach to show that all kinds of electricity are alike regardless of their origin.

In 1902, with his misinterpretation of the photoelectric effects Lenard impressed numerous German researchers, including Franck and Heinrich's nephew G. Hertz. Of course, Lenard was really very angry when Einstein published the correct theory three years later. No wonder that Lenard then wished to establish the German physics versus the Jewish physics.

27.4 The Amplifiers and Triode

Geitel, Elster and Guthrie (1873) investigated the thermionic emission, which was later named after Edison.[2958] Photometry has got a serious momentum barely with the Edison's inventions of the bulb. Like Crookes, Edison has occasionally been interested in "occult forces". In November 1874, he published his first experiments on the oscillations of various kinds of conductors. In 1875 he patented the discovery of the "ethereal force", which was supposed to cause a "revolution in telegraphy". The following year, the discovery was published in the press, immediately after the first US records of similar exploration of the "weak sparks" of German physicist Petrus Reiss in 1875. With his exploration of ether-based forces between

November 1875 and summer 1876, Edison supposedly invented a telegraph without wires.[2959] The problem about Edison's discovery was summarized by the Sci. Am., where Elihu Thomson and Edwin Houston claimed that Edison's discovery was an induction effect. In November 1878, Edison used a frog's leg as a galvanometer. However, most researchers criticized his assumption of an unexplored natural force resembling Reichenbach's "Od".[2960] Mihajlo Pupin later attributed a similar discovery to the older research of Joseph Henry, but between 1888 and 1889 Hertz explained it with electromagnetic waves.[2961] However, after the criticism of Edwin Houston and Elihu Thomson in a more scientific *Journal of the Franklin Institute* the 28 years old Edison put his discovery aside as he was also pressed by his senior business colleagues who requested Edison’s work on telephone patents. Later, Hertz in main points confirmed Edison’s ideas, but Edison was leaning on the disputed Reichenbach’s OD[2962] while unlike his opponents Edison was less inclined to follow the requirements of the scientific mainstreams. Of course, Edison was no less versed than his competitors and had one of the best equipped labs in his famous Menlo Park. His German assistant stated in the diary that Edison’s abandoned discovery soon became a base of wireless communication: therefore later, Edison regretted that he did not insist on the development of his discovery, whose cream was picked up by Hertz instead.[2963]

In 1880 and 1883 Edison set up an additional third insulated electrode during the study of the blackening of the bulbs between the electrodes. He discovered that the current flows through the vacuum from the third electrode to the filament, if the first electrode is positive and the other is negatively charged. The phenomenon became known as the 'Edison effect'.

In 1883 in a patent and in a lecture at an exhibition in Philadelphia, Edison described an "ethereal force", causing the charged plate to discharge near the incandescent bulb. The insulated platinum electrode was placed at the distance of 1.35 cm from the arc between the glowing filaments of the charcoal in the bulb. Edison used the galvanometer to measure the current between the platinum plate and one of the wires. He supposed that the charged particles of air or charcoal abandoned the carbon fiber thread in a straight line.[2964] The current changed the direction when Edison replaced the electrodes in the bulb and was more often (sic!) larger when the platinum plate was connected to a positive pole. The intensity of the current varied simultaneously with the glowing electrical current through the filament thread. After a while, the current between the platinum electrode and the positive electrode was weakened, and after cooling it was repeated with the previous intensity. He noticed the current through the glass of the light bulb towards the platinum electrode. However, Pupin later complained that the others discovered similar phenomenon before Edison.[2965]

Edison's consultant from London the last Maxwell’s Cambridge student Fleming explained "Edison phenomenon" with a thermo-electronic emission in 1890. As technical adviser of Marconi, Fleming invented a thermo-electron emission in the diode as the first thermionic vacuum tube, the precursor of today's radio vacuum tube (valve) in 1904."[2966] Even if Fleming occasionally cited Tesla as his role model, Fleming in fact served all Tesla’s antagonists in a row.

Richardson studied translation at low pressures under the influence of heated metals in Cavendish's laboratory of his teacher JJ Thomson between 1901 and 1903. The phenomenon is difficult, since it depends on level of ionization, temperature, nature of the remaining gas in a vacuum, "past" of a metal, also from its surface.

The conditions are simplified at higher temperatures when the translation depends only on negative particles extracted from the metal. Richardson investigated the temperature dependence of the current between heated metal and a metal electrode nearby. The size of the

current in equilibrium depends on the full number of particles that the surface extracted in the time unit.

At a pressure of 1/600 mm Hg, Richardson received surprisingly high currents up to 0.4 A between electrodes 2 mm away from each other at a voltage of 60 V. The heated platinum, charcoal or sodium electrodes transformed the vacuum into a superb electric conductor according to a thermodynamic equation that connects the current density with the surface of the cathode. Therefore Richardson rejected the possibility of ionizing gas molecules by collisions with heated metal.

According to the theory of German Drude and J.J. Thomson presented at the International Congress of Physicists in Paris in 1900, rapid free electrons were known to translate electricity into metals. Heating increases the average electron velocity. Therefore, several electrons escape from the surface in a process like evaporation, with which Richardson also explained Edison's "etheric force".[2967]

The thermo-emission should result in the escape of electrons with high kinetic energies while most of the early contemporaries searched for the consequences of chemical reactions due to residual gas. To avoid any doubt, both Langmuir and Richardson, who also studied in the United States at Princeton University between 1906 and 1913, measured in as high a vacuum as possible. Langmuir's tungsten experiments in 1913 definitively convinced the critics of Richardson. Richardson then returned to Londoner King's College. For his investigation of thermo-emission, he received the Nobel Prize in Physics for the year 1928.[2968]

In 1906, the Viennese Lieben used Wehnelt's discovery of slow "cathode rays" in his patent application in Germany and elsewhere. He moved the cathode ray with a magnet to change the resistance of the circuit. In the second patent in 1910, the description of his discovery was slightly changed, and in the third patent of the same year, he placed his grid with a low negative voltage to regulate the current in his cathode ray tube. Several German companies exploited Lieben's patent, which AEG developed into a usable amplifier in 1912.

Independently of Lieben, a freelancer entrepreneur Forest as a former engineer at Western Electric in Chicago, patented "audion" as a Fleming's diode with a grid in the United States in 1907. De Forest's triode was less sensitive to temperature changes than Lieben's, which contained a worse mercury vacuum for his supposed increased amplifying. In 1913 in the Telefunken, Alexander Meissner (Meißner, 1883 Vienna-1958 Berlin) used a triode with a positive feedback to prevent damping.

In the meantime, The Slovenian inventor Julius Nardin nearly invented the triode. Nardin studied physics at Šantel's class in Gorizia and graduated from Boltzmann's class in Vienna in 1904 just before Boltzmann went insane. In 1905, Šantel showed to Nardin a windbreaker with partly movable, resilient flexible blades according to the Ressel's idea. At that time, Nardin was an apprentice practitioner under Šantel's mentoring in Gorizia.

[2969] Vakuumist 16/1 (1996) 22.

Nardin taught at Real school in Idrija between 1905 and 1912. In 1913, with his friend René Zei from Gorizia he patented in Austria a stand-alone relay for telephones and telegraphs, especially useful for submarine cables (Figure 27-2). Attorney at law René Zei was a relative of the biologist Miroslav Zei (1914 Nabrežina by Trieste-2006) who later served as a university professor in Ljubljana together with Nardin.

They used Wehnelt's generator of slow electrons with a 400 V of voltage in the exhausted pipe with two (or more) equivalent, mutually isolated electrodes. They connected their anodes in the same circuit by winding up their ends outside the cathode ray tube in opposite directions around the iron core of primary coil of the transformer. A shorter anode with a constant current to prevent disturbing interferences could also be placed between the electrodes.
The did not heat their cathode directly, as we do today, but they grilled it with a special plate placed behind cathode in the cathode ray tube. They have placed an electromagnet between their electrodes for directing cathode rays and other (sic!) rays. Nardin twice mentioned "other rays" in addition to the cathode rays, to connect his patent discovery with "discoveries" of a whole series of dubious and less dubious new rays at the turn of the century.[2970] Caution is the mother of wisdom.

If the electrons fell symmetrically on both parts of the anode, they both got the same potential and the same current through both branches. The effect impact of both currents was balanced and eliminated on the wires wrapped in opposite direction around the coil. When more electrons fell on one of the anodes, so much less fell on the other, and the influence of their currents in the opposite windings of the coil was aggregated and therefore amplified.

While he tried to obtain a patent, Nardin found that his amplifier was four times stronger than Lieben's amplifier developed in the year 1906. The ionization of gases did not disturb his tool as it did Lieben's triode designed in 1910. Unfortunately, Nardin's device could not be tested because he did not have enough efficient vacuum pumps available. Zei and Nardin were not wealthy enough to buy a stronger pump, and therefore without better options they agreed to cooperate with the factory Telephon Apparat Fabrik of E. Zwietusch & Co. from Charlottenburg-Berlin, which joined Siemens and Halske during the First World War. The son of the Milwaukee brewer and mineral water seller Otto Zwietusch (* 1832 Germany), Eduard Otto Zwietusch (Edie, * 1866 Milwaukee-1931 Berlin), studied in Madison and Chicago. In 1888 he returned to the German areas of his ancestors with a great ingenuity to adapt USA patents to German soil especially for the needs of German post Office. As Codelli needed Telefunken to support his ideas, Nardin needed Zwietusch, but Nardin did not earn much by his invention, even though it was a good one.

From 1912 to 1920, Nardin taught at the Classical Gymnasium in Ljubljana with the later famous mathematician Ivo Lah among his students. To be able to exhaust his triode to a sufficiently low pressure, Nardin used his high Grammar school lab to design vacuum pump while using pressure of water drops and adhesion of mercury vapor as he previously learned in Šantel's lab. Unfortunately, the war nullified his agreement with his Viennese manufacturer and producer. That is why Nardin experimented with the electromagnetic deflection of the glowing gas arc between electrodes made from the carbon rod at ordinary pressure with no vacuum available.

On the eve of WW1 Nardin successfully patented his invention in Vienna, and Zei promoted the invention in other countries. Unfortunately, however, they forgot about the USA prestige, just like Codelli somewhat later. When the communications reopened again after the end of the First World War, it turned out that Nardin's invention was overtaken by the de Forest's invention of the triode and with its improvements designed by Langmuir for GE.[2971] The Americans took over the control of modern electronics and a good old Europe remained merely behind them.

Since 1922 Nardin has been a part-time professor of physics at the Faculty of Medicine in Ljubljana, where he founded the Physical Institute. Between

[2970] Goldstein's "channel rays", electrically neutral "magnetic rays" of Augusto Righi (1850-1920), "N rays" of Prosper-René Blondlot (1849-1930) and others.

[2971] Julij Nardin (1877-1959), René Zei, Relais für elektrische Ströme, Österreichische Patentschrift Nr. 66604, applied on 13. 8. 1912 with effect granted from 15. 6.1913, issued on 10. 9.1914, 1-2; Nardin, 1929, 44-48; Sitar, 1987, 193; Sitar, 1989, 167; Reich, 1983, 213.

1927 and 1928, he lectured on physics at the Faculty of Arts of the University of Ljubljana. At the Technical Engineering High School, he taught between 1920 and 1947 with a break during World War II.

27.5 Scanners

In 1880 the journal Scientific American stated that we must use at least 10,000 circuits for the accurate transfer of thirteen square centimeters of image. For this reason, Bakewell already used the principle of image scanning that the Portuguese Adriano De Paiva (1847-1907), a professor of physics at a polytechnic academy in Porto, first submitted for the use in television in 1878. Before the introduction of the Braun's cathode ray tube, the (microscopic) analysis of the image was used in a spiral-shaped plate, which the German physicist Nipkow patented in his "Elektrisches Telescope" on January 8, 1884. The Habsburgians Jan Szczepanik (* 1872 Ukraine or Poland, † 1926 Tarnów in Poland) and his sponsor the trader Ludwig Kleinberg patented a telescope with vibrating mirrors in 1897, and similar mechanical devices also promised a lot.

The German physicist **Paul Nipkow** studied natural sciences and mathematics in Lauenburg in Pomerania to became interested in photography in 1883. For the German patent of his "electric telescope" no. 30105 he received only 25 marks on February 8, 1884. He used Faraday's effect on the selenium cell. In 1885, Professor Dietrich von Engelhardt of noble Baltic-Germanic family reported on Nipkow's discovery in Stuttgart in front of the Association of German Engineers. Nipkow soon abandoned the television research and joined the German Railway Signaling Department in 1886.

Paul Nipkow (* 1860; † 1940)[2972]

After the war, Nipkow retired while his patent became the foundation of new television systems. On 11 May 1928, at a senior age, he watched the exhibition in Berlin. Nobody knew him among visitors, because he had lived in modest conditions for almost half of a century. He raised a lot of attention with his letter to the magazine Fernsehen, and soon he was glorified as a German pioneer of television.

In the meantime, the electronic analysis of the image, which later prevailed, was already developed as the competitor of mechanical scanning. In 1935, the Berlin TV station was renamed "Paul Nipkow Fernsehen, Berlin", because under the Nazis, the German Nipkow became the only acknowledged inventor of television.[2973]

27.6 Cathode Ray Tubes's Electronics

27.6.1 Braun

Karl Ferdinand Braun was born in Fulda in an official family who moved from northern Bad Hersfeld seven years earlier (Figure 27-3). His father was a Protestant, and so he taught his son. Braun's mother was of the Catholic religion, which prevailed in Fulda. The famous Jesuit vacuum researcher Kircher was born 30 km to the northeast in the city of Geisa.

Braun began studying at the Magdeburg University, but soon moved to a more promising Berlin, where he was supported by his 17 years older associate professor Quincke. Among 263 students Braun was one of four who could experiment in the renowned Magnus' Laboratory. On March 2, 1872, few months after Berlin

[2972] Fisher, 1996, 236.

[2973] Fisher, 1996, 19.

became the capital of the newly established German empire, he defended his doctorate in acoustics, while he selected the leading expert Helmholtz as his examiner, just like Hertz did eight years later. During the next two years he was Quincke's assistant in Würzburg, where they replaced Kundt and Kundt's helper Röntgen. The assistant Braun increased his small incomes by publishing satirical poems in the Munich newspaper under the pseudonym Fatty. He retained the artistic vein in older years by drawing watercolors. In Würzburg he continued Stefan's (1865) research on amplifying in semiconductor crystals, and on November 23, 1874 Braun described his "detector", an indispensable rectifier prior to the invention of triodes. A similar hot-wire microphone has been improved by Forbes. The device was later at the eve of WW1 used by Harold DeForest Arnold and his employee after 1913 Irving B. Crandall (* 1890 Chattanooga Tennessee); † 1927) at Western Electric Company labs at New York, transformed into Bell Telephone Laboratories Inc. 1925.[2974]

Figure 27-3: Karl Ferdinand Braun (* 1850; † 1918)

Braun solved his money problems for good in September 1874. He became an assistant lecturer and then a professor at the Grammar School St. Thomas in Leipzig. Between December 1877 and 1878, he continued Hittorf's (1869) study of the cathode sputtering and electrical conductivity of gases in Geissler's cathode ray tube at the University of Marburg. In 1880 he succeeded Röntgen as associate professor of theoretical physics at the University of Strasbourg, where he experimented in the Kundt's Physics Laboratory together with the guests like Tesla and Tesla's friend Puluj. In September 1883, as a full professor at the Technical University of Karlsruhe, Braun visited an international electrical exhibition in Vienna, whose scientific head was Stefan. Two years later he visited Stefan again Vienna, when Braun and his architect visited the leading European physical institutes to gain experience needed for building Braun's new Physical Institute in Tübingen. Later, Braun's research path met several times with Stefan, for example, when Braun published measurements of the radiation of a square centimetre of glowing porcelain plate compared to platinum and metal oxides in 1887. He did not mention Stefan's law of 1879 in his discussion, although both quoted the measurements of Irishman Tyndall from 1864.

In March 1895, Braun took over the former Kundt's position as director of the Physics Institute in Strasbourg. In 1897, Braun's exploration of the specificity of the translation of electricity in gases[2975] led to his discovery of the cathode ray tube. Immediately after Roentgen's discovery, Braun joined X-ray research. Unlike other experts, Braun decided to use the cathode-ray tube to "observe the events in an electrical circuit". He started work in the summer of 1896 and commissioned several types of cathode-ray tubes at the firm of Franz Müller (Beckenbauer, 1838-1906) and Franz Müller (1859-1921) who became Geissler's associates in 1874 as well as his successors in Bonn with the firm Dr. H. Geissler, Nachfolger Franz Müller. There they trained their cousin Louis Müller-Unkel (1853 Schmalenbuche (now part of Neuhaus am Rennweg)-1938 Rudolstadt in Thüringen) who moved his manufacture to Braunschweig in 1888/89 to produce photocells for Julius Elster and Hans Geitel and soon also glow discharge tubes for Heinrich Hertz, Philipp Lenard, and Röntgen. In the winter of 1896/97, they brought to Braun's Strasbourg a "half-meter long (glass) tube with a conical end" in which the mica screen was covered

[2974] Beyer, 1999, 178.

[2975] Braun, 1896, 688, 691–692.

with luminescent paint. In Bonn F. Müller precisely designed it with millimetre accuracy according to Braun's plan: "... The glass wall should be as uniform as possible and without cramping, with a phosphorescence screen through which glass and mica we could see the fluorescence spot of the cathode rays."

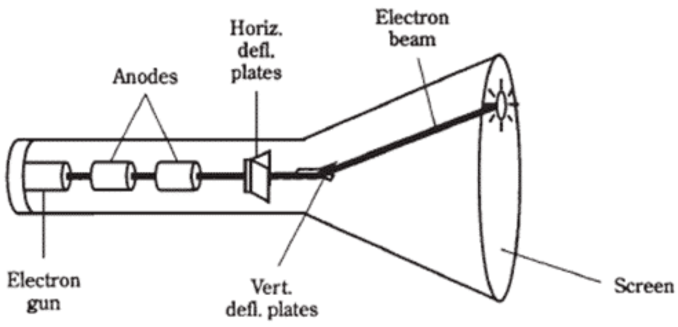

Figure 27-4: Braun's cathode ray tube scheme[2976]

They placed the cathode ray tube on their working table, connected it to electricity and started the vacuum pump. After the high-frequency generator was connected, a luminous display at the end of the tube showed a slight glare. In the second experiment, a better vacuum was achieved by pumping, so that the stain could be observed on the screen. Braun approached the tube coil and connected the alternating current. The stain turned into a oscillating line. He watched the oscillation on a rotating mirror, indicating a two-dimensional image. Professor Braun rose, addressed his assistantship, and asked them to "meet personally" with the alternating current of the Strasbourg Generation Station (Figure 27-4).

The discovery was published on February 15, 1897, at the 25th anniversary of Braun's doctorate. Braun accelerated the electrons from a cold aluminium cathode by Töpler's influential machine with twenty plates. They passed the anode to fly through an aluminium aperture of 3 mm wide. Near the opening, Braun placed a small electromagnet with its axis perpendicular to the tube axis. When the current flowed through the electromagnet, the recording point moved around the screen. In addition to the sinusoidal record of the alternating current of the electric power station in Strasbourg, he also observed the Lissajous curves and the phase shift in polarization. Additionally, he measured the rate of spread of the magnetic disturbance through the iron.[2977]

Braun followed the research of Bavarians down south. Graetz' neighbor in Munich Polytechnic, Beetz, used thin films to investigate magnetic phenomena. The son of the controversial famous Jewish historian Heinrich Graetz (1817 Książ Wielkopolski south east of Poznan-1891 Munich), the associate professor of Munich university Leo Graetz, confirmed Stefan's law in 1880. At the University of Munich Graetz discovered the rectifying (directional) effect of the aluminium electrode, covered with a thin layer of oxide, and showed the possibility of using it in cathode ray tube.[2978] On April 25th, 1897 Graetz discovered that the aluminium cathode, covered with a thin layer of oxide, acts as a rectifier without moving parts, which converts alternating current into DC. Two months later Karol Franciszek Pollak (November 15, 1859 Sanok in southeastern then Habsburg Poland–1928 Bielsko-Biała in southern Poland) announced that he had already used the same phenomenon at his battery factory in Frankfurt on Main.[2979]

On 14 April 1898 Braun continued Pollak's and Graetz's research by measuring the emitted light of the aluminium electrode in the electrolyte. On March 29, 1898, Braun supplemented his cathode ray tube with an additional iron rod in the glass tube on the screen. He compared the cathode rays with a "conductor" attached to the cathode. With the magnet he curved the other end of his "conductor" while considering the high velocity of electrons and their frictional interactions with gas particles in the cathode ray tube.[2980] Geissler's toy used as low-pressure glow discharge tube was finally transformed in highly commercially successful Braun's cathode ray tube for radar and television displays of a next century. Forty years passed in between to enable the growth of a funny toy into the great industrialized instruments in the hands of the new generation of researchers. Another decade passed from Braun's cathode ray tube to Forest's amplification vacuum tube (valve, electronic tube) as the first electronic amplifier which dominated electronic for a half of century.

[2976] Braun, 1897.

[2977] Braun, 1897, 552–553.

[2978] Graetz, 1902, 1100–1110.

[2979] Graetz, 1897, 326–327.

[2980] Braun, 1898, 368, 370–371.

Braun's discovery did not pass without conflicted struggles for priority. Albert Hess, the head of the electrochemical department of former Edison's collaborator Johann Sigmund Schuckert (1846 Nuremberg-1895 Wiesbaden) of Nuremberg, claimed in Annalen der Physik in 1898 the he himself described and the president of Parisian academy Marie Alfred Cornu (1841-1902) demonstrated a similar cathode-ray tube in French, American and other journals already in 1894. In 1898, Hess announced the construction of his popular form of cathode-ray tube.

Braun and colleagues gave lectures about the new device in weeks after discovery. Braun's assistant Zenneck embarrassed the engineers at a generator station in Strasbourg when he showed during the lecture that the frequency of their alternating current ranged from 48 to 52 Hz. They felt that they claimed that their customers should be satisfied because they even supplied them with a current above the commanded frequency of 50 Hz at no extra cost. Between July and October 1897, Braun introduced his invention to Toronto at a meeting of the British Society for the Advancement of Science. The demonstration experiment was not particularly successful, but Braun brought his cathode ray tube to America, where it penetrated virtually every house in the next century. Braun visited his successor, Hertz, in Karlsruhe, but initially he was not interested in Hertz's new electromagnetic waves and a photoelectron.

In the following months, Braun changed his mind about Hertz's discoveries, but only after returning from America he began to work on radiotelegraphy on the initiative of a group of entrepreneurs from Strasbourg. Together they founded Telebraun, which merged with Siemens and Halske in December 1900. For many years, Braun's company has been in dispute with Slaby's and Arco's Berlin-based AEG company until, on the orders of the Emperor, on 27 May 1903, they merged into Telefunken. Thus, they were able to compete with Marconian British company, as they had a monopoly on German radio. Arco, in contrast to Slaby, became a great Braun's (and Codelli's) friend. Braun even arranged Arco's honorary doctorate at the University of Strasbourg. For success in the development of the radio, Braun shared the Nobel Prize in Physics with Marconi in 1909.[2981]

Braun was primarily an experimental physicist and regretted his lack of mathematical knowledge in a joke.[2982] The students and friends liked ridiculing Braun's calculation inaccuracies. Braun's student and later co-worker Zenneck described how Professor Braun during the lecture rounded his result of the "2 × 25" multiplication to "2 × 30" and wrote 60 as a product, adding, "because previously we used 2 × 30 instead of 2 × 25, the real score will be close to 50." As a professor in Strasbourg, Braun accepted Alsace for his homeland and in February 1905 even rejected the most distinguished chair in Berlin offered by the Minister of Education after his lecture in honor of the Emperor's Birthday. The nationalism was foreign to him, and he was among the rare German professors who refused to sign under the chauvinist "Manifest 93" with Roentgen, Nerst, Wilhelm Wien, Planck, Ostwald upon the beginning of the First World War on October 4, 1914. Nevertheless, on December 17, 1914, Braun decided together with Zenneck to make a secret journey with a Norwegian ship to New York, where he was supposed to defend his company's interests against Marconi's demands. Returning to Europe was not successful because of the English blockade. Thus, he remained in the United States in the care of his son, Conrad, who had been working in New York Bank since 1912. After the United States entered the war, Zenneck was interned as an enemy spy; Braun did not have such huge problems but even he had no chance of scientific research as he was not allowed to leave Brooklyn. On 20 June 1917, Braun received the honorary doctoral title of the Technical University of Vienna, the only one of that kind during his famous life. A few months before the end of the war, he died in New York. He highly assessed the possibilities of the cathode ray tube for scientific research, although initially it was slow due to the low mobility of its ions.[2983]

27.6.2 Zenneck

Braun's assistant Zenneck improved the cathode ray tube by using an additional aperture in the neck for better focusing. He designed a method of deflection in the horizontal direction, so that it was

[2981] Hess, 1898, 622; Siemens, 1957, 1: 204–205, 185.
[2982] Jungnickel, McCormmach, 1986, 2: 346.
[2983] Braun, 1897, 553.

no longer necessary to observe the fluctuation of the current on the rotating mirror. On September 26, 1899, $CaDO_4$ cathodoluminescence was more easily photographed than green CaS, especially in low discharges, when the luminescent point travels quickly across the screen. $CaWO_4$ was recommended for use in X-ray photography, and in 1925 Zworykin patented it as a blue luminophore for color television. In 1904, Zenneck photographed the oscillograph of the dampening oscillation with the help of Braun's cathode ray tube used as oscilloscope.

Zenneck was the son of a minister from Swabia. At first, he intended to become a high school teacher of mathematics and science. After a Ph.D. in zoology, he had already studied in London and only came to Braun's laboratory in Tubingen as twenty-five years old expert. Braun offered him an assistant post in Strasbourg, but Zenneck nearly "escaped" two weeks later as an assistant to a zoology teacher in Tübingen. At that time, there were few students of natural sciences, but most of them preferred to teach secondary school pupils with a better salary than to wait for a free chair at their unpaid assistant posts.

In the school year 1901/1902, Zenneck was the first to lecture at the German university on electromagnetic fluctuations. In the summer of 1905, Zenneck became an associate professor at Danzig (now Gdansk), and shortly thereafter Braun arranged his regular full professorship at the Technical University of Braunschweig. In 1913 he moved to the Technical University of Munich. In 1933, he became the head of curators of the German Museum's administration in Munich, where he placed copies of Braun's original devices which were nearly lost in the US and the original Magdeburg hemispheres later examined there by the DVTS president Janez Kovač.

27.6.3 Other German Researchers: Wehnelt and Rogowski

The German Arthur Wehnelt was born in Brazil where his father worked as shipbuilding engineer, co-founder and co-owner of the Brazilian Lloyd. They returned to Hamburg while Arthur Wehnelt was still a baby, but the early Brazilian racial mixture still influenced his electrodynamic concepts. In Charlottenburg by Berlin, Arthur Wehnelt first studied engineering, then physics. In 1898, he received his doctorate in Erlangen in Bavaria. In 1903, as an associate professor there, he accidentally discovered more radiation from parts of the cathode damaged by the ointment used to seal the valves of cathode ray tubes. He assumed that the dirty areas contained metal oxides, so he was looking for the best among them. He chose barium oxide, which we use today. He got the electron beam already at the acceleration voltage of a few hundred volts in a cathode ray tube with a very thin glowing cathode of platinum, covered with a few millimeters wide metal oxide stain. He did not use the voltage above 1000 V, as it caused a strong sputtering of platinum. The slow electrons were easily controlled by electric or magnetic fields. The electrons heavily ionized gas, therefore the best possible vacuum was desired. Wehnelt’s current of electrons was continuous, and their velocity was subject to change within wide limits.[2984]

In 1903, Wehnelt and König placed diffraction electrostatic panels in Braun’s cathode ray tube, which they demonstrated at a gathering of German naturalists and doctors in Cologne in 1908. In the years 1904 and 1905, Wehnelt used a cylinder with a slit that he placed around the cathode to control the electron flow. In 1908, he became a full professor, and in 1926 he became director of the Physical Institute in Berlin. Wehnelt's cylinder was first used for X-rays, and the son of Triestino trader Victor Josef Karl Engelhardt (* 1866 Vienna; † 1944 Berlin) after his studies in Higher real school of Trieste and Polytechnic of Vienna rearranged it for Braun's cathode ray tube for his paper published in Physikalische Zeitschrift in 1923.

The professor at Technical College of Aachen, Walter Rogowski, was a leading expert for Braun's cathode ray tube for a long time, especially when they started to use Wehnelt’s oxide cathode. In 1925 in Aachen, Rogowski developed an oscilloscope with a phosphorescent layer of ZnS. He accelerated the electrons with 25000 V from a glowing cathode in a rectangular direction towards anode. Between the anode and the fluorescent display, he set a narrow aperture. In the older C. Samson’s model, the aperture was too close to the cathode. Therefore, the 5 mm diameter record on the screen was too dark and unusable for high

[2984] Wehnelt, 1905, 732–733.

frequencies.[2985] On the Rogowski screen, the beam plotted a curve that could be observed, measured or photographed. The first useful model was made for AEG, while an electron microscope was additionally built up during the development.[2986]

27.6.4 The "Mechanical" Television Development Period

Dieckmann, Rosing and Campbell-Swinton's use of the cathode-ray tube did not immediately affect the development of television at the beginning of the 20th century. The speed of reflection, the sharpness of the record, the lifetime of the device and the quality of the scanning beam focus were too low before Busch's electron optics was used. Therefore, Braun did not support the use of his tube in television that was for him something like telepathy. As the businessman-inventor Braun was clearly far from any kind of Victorian spiritism which even deteriorated his early acquaintance with Tesla in Kundt's lab in Strasbourg.

27.6.5 Television among Russians

Rosing was a descendant of Dutch apothecary whom Peter the Great invited to Petersburg general land hospital, and sent as courtier to Kyakhta near the Mongolian border south of the lake Bajkal. Rosing has built up more than hundred and twenty different television schemes and systems in total. In 1907, he set up an electronic television system with a Braun's cathode ray tube on the receiving side patented at home, in the United States, Germany, and England. At the University of Petersburg, he modulated the jet of electrons with a photocell signal and deflected it with magnets. His recording device was still mechanical. To scan the downloaded image, he used two mutually perpendicular mirror drums that he spun around the common axis. The slow selenium photoinduction cells were replaced by faster photocells from alkali metals but Rosing was still unable to amplify the weak flows of the order of 0.1 pA.

He exhibited his system in St. Petersburg in 1910[2987] and showed the receiving of simple geometric shapes in the following year. He continued his television research until 1931, when he was sentenced to three years in the Kotlas Archangelsk, during the Stalinist purges; there was a cold death waiting for the poor inventor (Figure 27-5).[2988]

Figure 27-5: Photo of Boris L'vovich Rosing (* 1869; † 1933)[2989]

In Leningrad (today St. Petersburg), Grabovski, the engineer later professor of electrotechnics in Saratov university Viktor Ivanovič Popov (Виктор Иванович Попов, 1895-1965) and Saratov exact science teacher Nikolai G. Piskunov (Николай Георгиевич Пискунов, 1886-1941?) filed a patent for "radiotelephot (radiotelefot, радиотелефот)", the first practical, purely electronic television. Among them only the comparatively wealthy Piskunov had previously visited other European countries and mastered several foreign languages to get more information about the progress of electronics in the west. They started experiments in the laboratory of industrial technics in Saratov in July 1925. In their system, under the influence of light the photocathode emitted electrons that were rejected by a grid in its vicinity.

[2985] Busch, 1927, 583, 591.
[2986] Siemens, 1957, 2: 192–193.
[2987] Kleinert, 1993, 71; Zworykin, Ramberg, Flory, 1958, 12, 9
[2988] Fisher, 1996, 263.
[2989] Fisher, 1996, 236.

The electrons as "rays" from thermo-cathode passed through the grid and collided with photocathode. There they collided with oppositely oriented photoelectrons, which more weakened the thermo-cathode rays as more of them gathered at a given point in the photocathode.

Thus, an electronic beam was modulated, which then transmitted information about the illumination of the object. In the next three months, they experimented at the Leningrad Vacuum Institute. They spent only 1,500 Rubles, despite relatively complicated experiments. Unfortunately, the commission in Leningrad initially did not support the use of their device.

The son of the exiled Ukrainian revolutionary poet Pavlo Hrabovsky, Boris Grabovski, returned to Tashkent through Saratov and continued his research with Rosing's help while Popov and Piskunov resumed their lecturing in Saratov on Volga river southeast of Moscow. On 28 July 1928, the commission acknowledged the usefulness of the "telephoto" patented by Grabovski and his laboratory assistant military officer Ivan F. Beljanski (Иван Филиппович Белянский, 1907-1979). They downloaded seven pictures per second to a screen placed 6-7 m away in another room. The screen had a diameter 5-6 cm with 200 to 300 lines. They changed their original idea by applying the photosensitive layer onto the impermeable silver base. The image projection and electronic rays were now on the same side of the photosensitive layer, like in later iconoscope of Rosnig's student helper Zworykin in USA in 1923 and in 1933.[2990] As White army official wealthy Parisian student Zworykin certainly did not collaborate with Red Army officers like Beljanski.

27.6.6 Television in the UK

The Edinburgh born engineer Campbell Swinton was director of industrial companies in London, where he was mainly concerned with the installation of electric lighting (Figure 27-6). After Röntgen's discovery, with the mediation of Lord Kelvin, Campbell Swinton published research of the cathode ray tube with the RS between 1896 and 1899. On 27 February 1897, he confirmed that X-rays originated from the area of green luminescence of the cathode ray tube and investigated the cathodoluminescence of charcoal. Two years later, he measured the cathodoluminescence of rare earths, while he described the cathode coloring with a radioactive radium that reduced the current required for the discharge of Wehnelt's cathode ray tube on 22 June 1906.

Figure 27-6: Photo of Campbell Swinton (* 1863; † 1930)[2991]

Campbell Swinton did not yet know about the photoelectric effect phenomenon suitable for the transmitter of such a high speed and amplification. In 1908 he responded to a discussion in Nature about the French television system of President of the French Society of Aerial Navigation graduate of the Ecole Polytechnique Jules Alexis Marie Armengaud (1842-1921) and Cambridge graduate Shelford Bidwell FRS (1848–1909 Weybridge in greater London) with a proposal to use the cathode ray tube. On November 7, 1911, for the Röntgen Society in England, whose chairman he was, Campbell Swinton described the screen of a transmitter from small cubes of ruthenium as a stand-alone photocell in a emptied vessel with a photochemical sodium steam.[2992] Until 1926, in his

own laboratory in London, Campbell Swinton successfully tested such mosaic photo-elements.

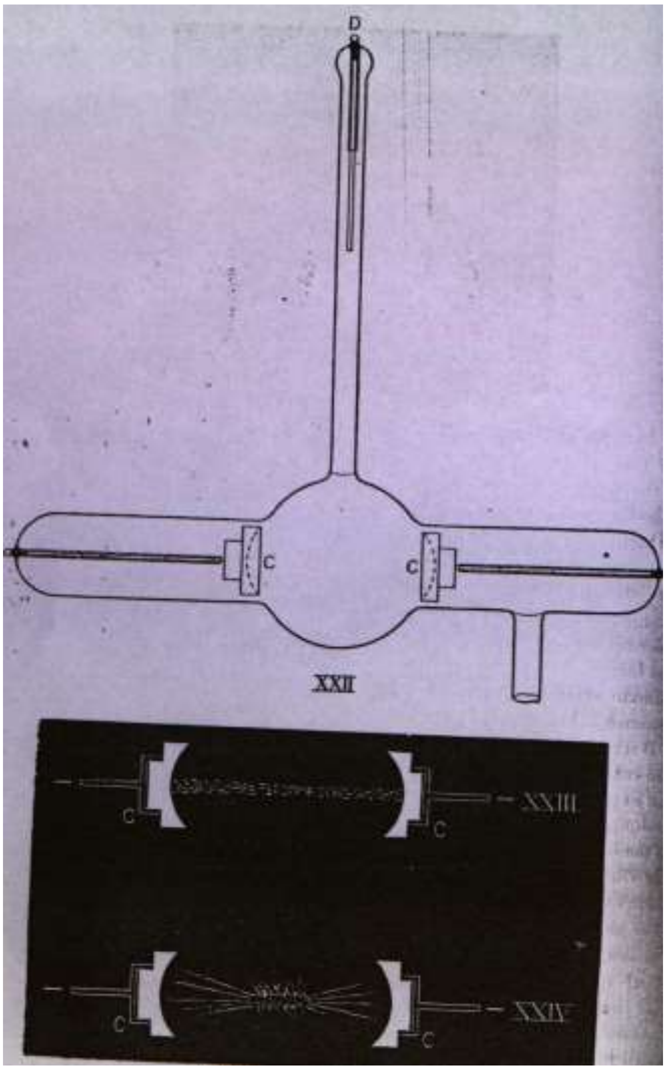

Figure 27-7: Swinton's cathode-ray tube with concave charcoal cathodes (Swinton, Alan Archibald. March 1, 1897. Some Experiments with Cathode Rays, Proc.Roy.Soc.London. 61: 94)

In September 1921, at a BAAS lecture, the visionary Campbell Swinton described the reception of radio signals from the Eiffel Tower in his London laboratory. On 6 December 1913 Braun published the results of similar measurements in Strasbourg. On 26 March 1924, Campbell-Swinton reported to the RS about the possibilities of wired and wireless television. Instead of a plurality of conductors that transmit individual elements of the mosaic of illuminated images, modeled on light-sensitive nerves in the eye, he designed only three wires and the grounding. His transmitter and receiver were Crookes' cathode ray tubes with perforated anode.

At a voltage of 100 kV, the fluorescent screen should illuminate every tenth of a second to suit the human vision.

Campbell-Swinton's television has never worked. His ideas were established only in the next decade, since big companies were not interested in them at first. Other researchers in the various countries have developed six other models of picture-making cathode ray tube models for television until November 1925.[2993]

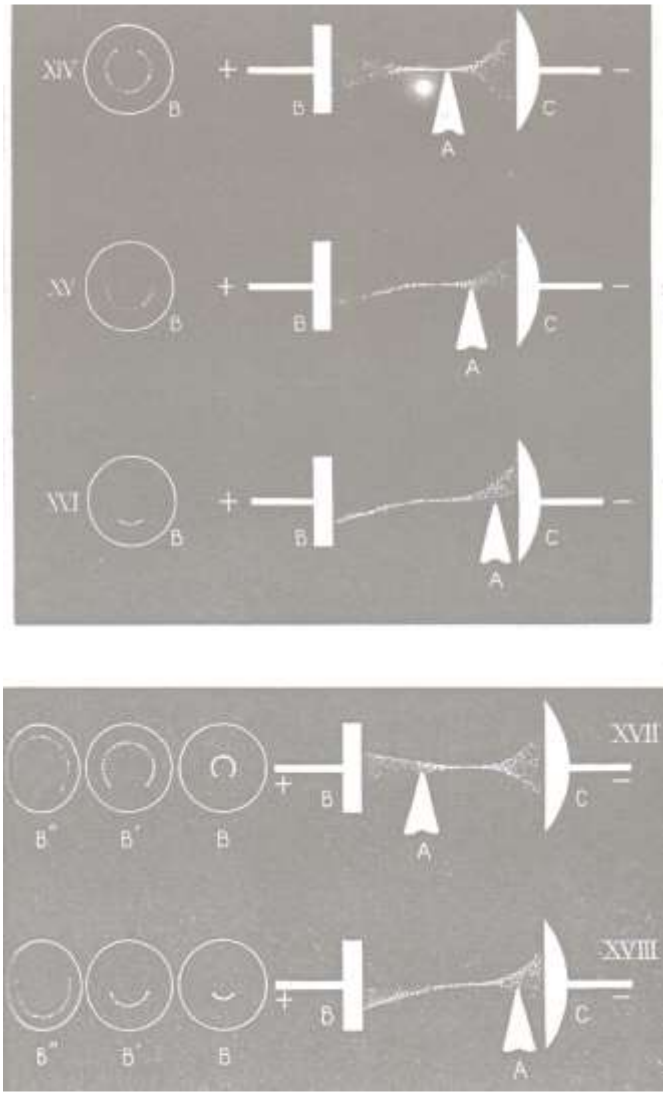

Figure 27-8: Swinton's experiments on the luminescence screen of a cathode electron tube (Swinton, Alan Archibald Campbell. March 1, 1897. Some Experiments with Cathode Rays, Proc.Roy.Soc.London. 61: 89)

The Scotsman Baird founded the first company dedicated exclusive to television named Television Limited. Until the decision of the British

.

[2993] Barancev, Urvalov, 1986, 131.

Commission on 13 February 1937 he successfully competed with the electronic television of Marconi's company EMI. Despite of the small material support received, he publicly demonstrated his television using Nipkow plate of frequency 8.3 Hz and colloidal self-manufactured cells for scanning the reflected light in April 1925. The sensor had to be thousands times more sensitive than older appliances, which broadcasted only the shadows of transmitted light. The letter "H" was clearly visible on the receiver, but it was harder to transmit picture of a hand or face on which it was possible to notice the movement of the mouth.[2994]

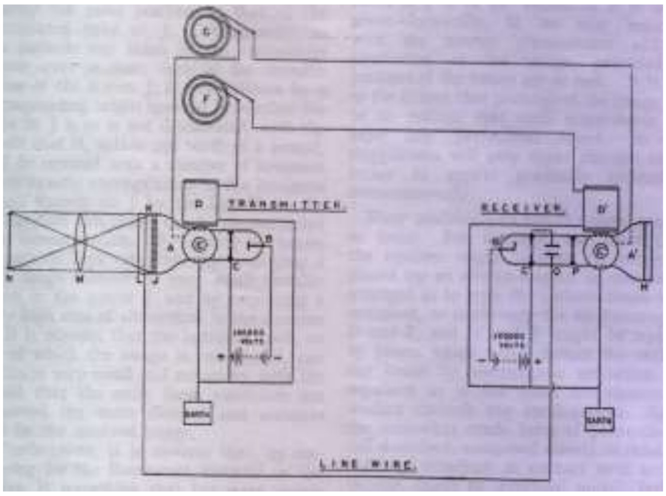

Figure 27-9: Swinton’s television system with cathode ray tube designed in 1911 (Swinton, Alan Archibald Campbell April 9, 1924. The Possibilities of Television, Wireless Word and Radio Review. 54)

Within a few months, Baird managed to solve the problem of wire transfer and even the wireless, which he showed to the forty members of the RI on 27 January 1926. Campbell Swinton looked at Baird's invention and reported in his London club about his "conversion". However, in July 1928, he changed his mind and criticized Baird's work in sharp letter sent to the Times as he preferred electronics to any other designs.

In 1927, Baird received a British patent for stereoscopic wired or wireless transmission of images or motion. Around the rotating Nipkow's disc he put one or two spiral lenses and photocells on each other so that each one covered only one area of the image or only one color. The light was filtered, and then he projected the colors into one in the receiver. The operation of his device was demonstrated in London on June 3, 1928.[2995]

Figure 27-10: A photograph of Baird in front of his favorite television system (Fisher, 1996, 236-237)

On February 8, 1928, Baird sent his first wireless image across the Atlantic with 45 m waves without intermediate transducers. On 18 July 1929, at Telefunken in Berlin Carl Schapira (1879 Gdansk-1957 New York) received two television models of Baird and his director, Captain Oliver George Hutchinson (1891 Belfast-1944). The devices cost 90 or 12 marks; they downloaded 12.5 images with 30 lines per second at 9000 Hz. Baird was sending images over the telephone cable inside the house and recognizing the seated person with no details. Schapira felt that the Telefunken's device with forty-eight mirrors better transmitted the moving images, just like Guericke thought that he was better than Boyle and vice versa almost three centuries earlier. In 1933 Nazis outed the Jew Shapira who flied to Madrid and New York where he became US citizen under the assumed name Carlos Soria as a notable art collector.

Baird replaced Nipkow disc by a drum with thirty mirrors, which the BBC used in its first public television show of horse races from Derby on June 1931 and on 29 April 1932. On 2 August 1932, the BBC began broadcasting a television program for eight months, and on November 2, 1936 the first regular television shows appeared in London.[2996]

27.6.7 Television in Germany

Braun's assistants Dieckmann and Glage patented Braun’s cathode ray tube for transferring letters and drawings without moving parts in the receiver in Strasbourg on September 12, 1906. They scanned images of metal models by twenty contact brushes, which replaced the apertures in the Nipkow–disc. The brushes were connected to a sawtooth voltage generator in the horizontal deflection coils of the cathode ray tube and with the contact brushes on the moving wires of the potentiometer that emitted current to the coils for the vertical deflection.

By contact with the conductive point on the metal model, the brushes of Nipkow plate produced a current through the electromagnet. They used the electromagnet to deviate a jet of electrons in the oscilloscope. So, the jet missed the opening on its way. Conductive parts of the model were therefore darkly reflected on the bright base of the oscilloscope screen. The entire turn of the Nipkow~~'s~~ disc lasted 0.1 s, so the light-emitter on the screen could follow the movement and rotation of the model. The screen could be photographed, which they emphasized twice in their patent file as the important and modern idea. Although Dieckmann's apparatus was more like a fax than a television, with its receiver it improved electronic recording of the image (Figure 27-12).[2997]

Patent did not delight their teacher, as you might expect. Braun was angry because his invention was used for such purposes. According to Dieckmann's record forty-two years later, "looking at the distance was not at all a respectable field of research at that time - it was something like it was once perpetuum mobile". Braun died prematurely before he could change his mind.

Figure 27-12: Photograph of Max Dieckmann (* 1882; † 1960)[2998]

Dieckmann finished the Grammar School St. Thomas in Leipzig where Braun once taught. In 1906 he became Braun's assistant in Strasbourg, and in the following year he defended his dissertation. In March 1914, as a private assistant in Munich, he collaborated with Braun and Count Zeppelin with his experiments in radiotelegraphy and aeronautics. He devoted to those problems all his career. During the First World War, he investigated the possibilities for a television connection between the crew of plane and their assistance on the ground. In 1925, at the exhibition of traffic and transport in Munich, he showed his

[2998] Fisher, 1996, 236.

television system with a cathode-ray tube. The device might not work, as his patent application failed. With the help of his assistant Rudolf Hell (1901-2002 Kiel) he described a similar recording tube, which Farnsworth patented in the US a year later.[2999] During the war years, Dieckmann was the director of the German Research Institute for Telecommunications near Munich.

Gustav Glage was the son of a lower railway official and he defended his PhD in Braun’s class in Strasburg. In 1908 he became Braun's assistant. He received his doctorate by researching the resonant inductor with the support of Telefunken, and then became a gymnasium professor.

At the Physical Institute of the College of Dresden in May 1925, Dember discovered an increase in emission by simultaneously exciting photolayers with electrons and photons. For his investigation of the dependence of the additional photocurrents on aluminium from the intensity of light at a constant flow of cathode rays, he used a diffusion pump from the Kaiser Wilhelm Institute in Berlin. The photoelectric effects increased due to cathode rays, and the long-wavelength threshold (red) of photoelectron emission shifted towards longer waves.

Dember's experiments confirmed Lenard's theory, according to which the average energy of incident cathode rays is smaller than the work function (the electron binding energy) of the material and is therefore not enough for the emission of electrons from the substrate. So, the electrons remain in the metal in their excited state and the light of lesser energy can then eject them from their metal.[3000]

In 1931, Dember found that the illumination of copper oxides with strongly absorbing light produces a difference in potentials in the direction of the propagation of rays. The following year, such a phenomenon was observed in diamond and ZnS, and later in other semiconductors. In 1935, Frenkel showed that such a potential difference occurred in unevenly illuminated cases due to differences in coefficients of diffusion of electrons and holes. The faster charge carriers overtake the slower ones, and between the illuminated surface and the inside there is a difference in potential. If the speeds of the electrons and holes are the same and they have equal lifetimes (relaxation times), then the effect of Dember disappears. In practice, it is covered by much larger changes in the contact difference of potentials caused by unbalanced carriers near the electrodes.

In the summer of 1919, Mihály publicly demonstrated his television system "telehor" in Budapest. He was born in Gödöllő near Budapest in the family of a doctor. After a real gymnasium, he studied at the Technical College of Budapest. He became acquainted with the problems of television during the war when he worked at Telefonfabrik in Budapest. In 1923, he published the first book, entirely dedicated to television. The following year he went to Berlin and from 1927 he developed television for German State Post while Edouard Bélin researched in Paris for the Austrian state radio company RAVAG.

Figure 27-13: Photo of Dénes von Mihály (* 1894; † 1953)[3001]

The co-worker and assistant of the Physics Institute in Leipzig, Karolus, improved the photocell. He used the effect of Scotsman Kerr to modulate light in a television set. On June 21, 1924, he received a German patent for scanning with two Nipkow plates with 48 holes. Behind them he put Elster-Geitel’s alkaline photocell.[3002]

On 11 May 1928, in addition to Telefunken Television, produced by Karolus and Schröter, Mihály's 30-channel television was also presented at the Berlin Radio Show. In one second, it

[3002] Siemens, 1957, 100.

changed 10 images sized 4 cm × 4 cm. Mihály used a tungsten filament arc light and a 30-hole Nipkow plate made of pertinax hard paper (Figure 27-13). In March 1929, state post office in Berlin had a television picture with 900 points, but soundless.

The Allgemeiner Deutscher Fernsehverein was founded on September 13, 1929 and began to issue Fernsehen magazine in August of the following year in Berlin. Apart from Codelli and Mihály, most of the other authors of the new magazine defended the advantages of electronic television with the cathode-ray tube because of its more promising synchronization and in number of points in the picture. Most of the discussions in Fernsehen were published by von Ardenne, who, in his own laboratory in Berlin developed a cathode-ray tube in the form of a modern electronic rifle parallel to Zworykin in the late 1920s. Ardenne advocated the use of ultra-short waves in television. In 1931 he described the indirect warming of the cathode to prevent the scattering or sputtering of cathode material in the cathode-ray tube which could cover the vital parts of the tool. At the Berlin Radio Show together with the Jew Siegmund Loewe (1885-1962), Ardenne first publicly demonstrated purely electronic television. His system overshadowed the designs of Mihály and Baird (Figure 27-14).[3003]

Figure 27-14: Photo of John L. Baird (left) (* 1888; † 1946) visiting von Ardenne's laboratory[3004]

Von Ardenne used Zworykin's suggestion issued on 29/12/1923 about the cathode ray tubes as a scroll engine with a moving point of the record. He depicted on the cathode-ray tube the scanned model of uniform intensity, whose image he wanted to transfer. The leaked or reflected light was collected by a photocell. The effect was proportional to the permeability or repulsiveness of the scanned point and generated a signal for the image. If the light was emitting longer than the transition time of each element of the image, the scanned point was stretched to the line, and accordingly lowered the horizontal resolution. The original scanners with a mobile data point in the cathode-ray tube were not practically usable until effective photomultipliers with low inertia and high sensitivity began to use.[3005]

The basic problem of television with a cathode-ray tube was the sharpness and brightness of the point of the record, and the simultaneous control of the light and the distribution of points in the cathode ray tubes. Von Ardenne used Wehnelt's low-voltage cathode ray tubes according to Schröter's "half-image" method.[3006]

Manfred von Ardenne was born in Hamburg in the family of an army officer. In 1925 and 1926, he studied physics, chemistry and mathematics at the University of Berlin. He was wealthy enough to be able to organize work in his own laboratory, which received orders from the big industry and from Hitler's postal minister. In addition to income from numerous inventions, especially related to the cathode ray tubes, he also had a contract with Siemens & Halske. In 1936, he prepared a television broadcast of the Berlin Olympic Games, and on December 25, 1937, he published an explanation of the operation of a linear electronic microscope. A year later he used a jet of electrons as a working tool. In the years 1939 and 1940, he dealt with the electromagnetic separation of the ^{235}U needed for Heisenberg’s atomic bomb. After the war, he spent a decade in the Soviet Union, where he was no less successful than under the Nazi government. In 1955, he returned to the post of director of the Dresden Scientific Research Institute.[3007]

[3007] Gloede, 1986, 178, 196, 199.

Among von Ardenne's associates at the Heinrich-Hertz-Institut für Schwingungsforschung in Berlin was Vladimir Šlebinger from Ljubljana, ason of the literary historian the academician Janko, and the brother of geologist Ciril. After graduating in Ljubljana in 1925, he studied electrical engineering in Prague and graduated in 1929. With the recommendation of the University of Prague, he received a research assignment for the training for the use of cathode ray tubes for television at the Hertz Institute. Between 1930 and 1933, he studied there with the founders of the Institute and its director between 1927 and 1936, Wagner, and his co-worker, prof. dr. Gustav Engelbert Leithäuser. On June 30, 1933, Leithäuser projected the adopted 90-line mechanical scanned image of the dimensions 18 cm × 21.5 cm in the lecture room of the Institute.

The image only took 30 and later 90 lines instead of today's 625. The Cathode ray tube was arranged at the Hertz Institute for light modulation and the reception, which took place in Berlin in 1930 during the World Energy Conference. In 1932, Šlebinger received a patent for the synchronization of the image in the receiver and for the light modulation of the cathode ray. The following year, he withdrew from Germany in fear of Nazism to join his parents in Ljubljana. He was without any full-time employment for four years and, therefore, he assisted the Trieste native Osana at the Department of Electrical Engineering at the Technical Faculty in Ljubljana until 1935. After 1928, Osana was involved in television technology and used Nipkow disc for his first experiments on the basics of television. Šlebinger went for some time to Belgrade as technical director of Philips, who planned to build a radio equipment factory there. In the meantime, in 1939 he promoted in Prague with the thesis "Exploitation of the waterpower and the Danube waterway in Djerdap". After years of work at the hydroelectric power plants in Yugoslavia, he left as a UN expert in Abidjan in 1968. After returning, he taught at the Faculty of Electrical Engineering in Ljubljana, as he always wanted.[3008]

On March 22, 1935, a television program was broadcasted in Berlin while changing 25 images with 180 rows per second. On 19 August 1935, the UKV television system was burnt on the third day of the 12th radio show in Berlin, which was then repaired within 30 hours. The broadcasting from the day of the Nazi party in Nuremberg in 1936 could not be carried out because there was not yet an adequate cable. In the same year, the summer Olympic Games from Berlin were broadcast with Telefunken's iconoscope and Farnsworth's camera. On August 11, 1939, a boxing event was broadcasted and on 26 November 1939, a football game between Italy and Germany.

27.6.8 Mechanical Television in the US

Jenkins began to research television in 1894. Only a few months after Baird, on March 21, 1925, he developed a wireless mechanical television with a transmission of shadow contours over several kilometers. In 1926 he patented "remote cinema"[3009] and two years later he started with his first television shows near Washington. Like the Carniolan Codelli, Jenkins also did not have enough financial support for a successful transition to an increasingly promising electronic TV.

At the same time, Herbert E. Ives of Bell Labs applied for a patent for television in natural colors with improved scanning. He used Nipkow–plate with photocells that covered the individual parts of the spectrum. Light fell on the rotating mirror through the holes in the panel. In the receiver, the current transmitted a record to the photocells connected to the individual parts of the plate plant by the conductor. The mechanism of rotation was such that the panel made a little more or little less turns than the commutator, thus achieving a change in the order of the links between the photocell and the modulator in the successive scan of the object.

Bell Labs offered the best mechanical television at that time.[3010] The development went to two directions: a "video phone", which would feature a visible image of the interlocutor and wireless television that would offer the picture with the sound of the radio. The advertising of products by radio and the press has become so profitable before the economic crisis of the 1930s to channel television into wireless development. The "video phone" featuring a visible image of the interlocutor was never profitable despite of good technology

backing because there were always a lot of people who wanted to talk without being seen.

27.6.9 Electronic Television in USA

Campbell-Swinton's ideas of purely electronic television flourished the most in the US. The USA researchers also faced the problem of moving the image to a long distance with a lower density of population than in Europe.

In 1921, the production of Braun's cathode ray tube in the United States was initiated by physicists Hendrik J. Van der Bijl of New York and Johnson from Gothenburg in Sweden, who has been studying at the University of North Dakota since 1910. In 1914 Johnson graduated and became an American. He received his doctorate in Yale in 1917. Between 1917 and 1925 he worked with Western Electric Co. and studied oscillographs with low-voltage cathode-ray tubes patented in the US. He then worked in Bell Telephone Laboratories, Inc., Mapelwood New Jersey, and finally at Laboratories Thomas Alva Edison Inc. In addition to cathode-ray electronics and noise, Johnson investigated the ionization of gases, the supersonic velocity in liquids and the secondary emission.
Bijl published his experimental research on the motion of slow electrons and ions in dense media before the First World War in leading German journals. At the end of the war, he studied the theory of thermionic cathode ray tube in the US and published a book in 1920.
The Electronic Television prevailed after Zworykin's success. At first, he worked for Westinghouse, where they were not enthusiastic about the modulation of electron beam intensities in television with an axially symmetric grid, reported by Zworykin on December 29, 1923; he therefore had obtained Patent No. 2141059 in the United States only on December 20, 1938. In 1925, as a Russian citizen in the service of Westinghouse, he supplemented the patent twice. The Cathode ray tube was reprocessed with a plate of 33 layers of different substances that replaced the fluorescent screen. On a plate made of aluminium or otherwise good conductor, he first put an insulator layer made of Al_2O_3 or MgO. A thin layer of photochemical potassium hydride was followed, which made it gray until it was thicker at higher thicknesses. He quickly dropped hydrogen on it to give it a light blue color compound that had not yet turned purple.

Each pot of potassium hydride acted as a photocell. The mosaic screen for green, blue, and red was placed between the lenses.

From 1910 to 1912, **Vladimir Zworykin** studied at the Institute of Technology in Petrograd . In Rosing's laboratory, he realized the advantages of the electronic system compares to the mechanical. After graduating, he studied under supervision of the professor Langevin at the Collège de France in Paris. During the First World War, the theoretical physicist Langevin also dealt with radio-telegraphy and cathode-ray electronics. Rosing's Petersburg student and Paul Langevin Parisian student Zworykin did similar work in the Russian army and participated in the Petersburg branch of the Russian Marconi Company military electronic. At the end of the First World War, he went to the US as the emissary of White Army of Kolchak (Колча́к).

Vladimir Zworykin (* 1888; † 1982)[3011]

On each sphere of potassium hydride, they were indeed a translation between spheres and the grid. The potassium hydride electrons did not come on the screen due to an intermediate insulator, so that the current ran only between the screen and the grid. They were modulated according to the generated current, amplified by triode and transmitted over the antenna.

[3011] Fisher, 1996, 236.

Zworykin used an alternating current of 16 Hz frequency, and the images were changed twice faster, at 32 per second. The screens were made of compounds that were sensitive to different kind of colors, e.g. cesium chloride for red.[3012]

Figure 27-15: Photo of David Sarnoff (* 1891; † 1971)[3013]

On 18 November 1927 and in the following year, they made the first television shows in the United States.[3014] In November 1928, Westinghouse sent Zworykin to a visit to electrical laboratories in France, where the Bélin in Parisian Laboratory showed him the possibility of electrostatic focusing of electrons in a sufficiently good vacuum, which later replaced magnetic focusing. In 1928 or in early January 1929, Zworykin visited his two years younger Belarusian Jew Sarnoff at the Radio Corporation of America (RCA) in New York and described his idea of electronic television.

Sarnoff led the development of radio in the US and became president of the RCA on 3 January 1930 (Figure 27-15). From his conversation with Zworykin a Russian bond was born between the entrepreneur and the inventor, which enabled the dominance of electronic television in the coming years.[3015] Did they communicate in Russian or in English language?

[3012] Zworykin, 1927, 1, 3, 5.
[3013] Fisher, 1996, 236.
[3014] Swift, 1950, 61.
[3015] Fisher, 1966, 114, 167, 174, 199, 360.

On 16 November 1929, at a meeting of I. R. E. in Rochester, New York, Zworykin reported on a kinescope patented in the United States under no. 2109245 on February 22, 1938. RCA already had a functioning television system and the necessary financial resources available. However, the financial collapse in October 1929 delayed the marketing of already completed technology.

In 1930, Zworykin became the head of an electronic laboratory at RCA, which developed in 1919 from a branch of Marcon's company in the United States. Zworykin was served as the Honorary Vice-President of RCA in 1954. His early rival was Ernst Frederick Werner Alexanderson, born in 1878 in Uppsala. Alexanderson promoted his mechanical television. Zworykin challenged his ideas and displaced him at Sarnoff's networks while Sarnoff was leading the development at RCA.[3016] Certainly, the ex-Russians made a better deal among themselves than with their traditional Swedish rivals. On November 13, 1931, Zworykin developed an iconoscope and for it a US Pat. 2021907 on 26 November 1935. The first iconoscope was not capable of more than 240 lines, but it first found a practical use. The image was transferred to a mosaic of mutually insulated silver balls that fluoresced the added cesium. The balls were at the same time photocathodes and capacitor plates. The other side of the mica substrate was covered with a metal electrode, which was at the same time the second plate of the condenser.

Each element of the image had its photocell (condenser), so that the density of the mosaic was about 100,000 cm^2. Lighting of the photocell depended on the light of the corresponding element. The photocurrent has charged the capacitor. During the rotation of the electron beam, which was used by the iconoscope as a commutator, the capacitors discharged one after another through the resistor. The voltage drops at the resistance corresponded to the luminous intensity of the individual elements of the image. The signals were then amplified and modulated by a carrier wave. The idea was developed in 1931 by RCA with a cost of $ 4 million and replaced with mechanical television after 1934.

[3016] Fisher, 1996, 236.

Philo Taylor Farnsworth of the Mormon family in Utah spent his youth on the farm without contact with radio devices and only heard about electricity when he was fourteen years old. He finished high school in Ragby, Idaho, and then studied for two years at Brigham Young University in Provence, Utah.

In 1926, his ideas on electronic television were supported by Crocker Research Laboratories of San Francisco, which became Farnsworth Television and Radio Corporation in 1938. Apart from television, his ideas also influenced the development of radar and nuclear reactors. Later he drank too much and died forgotten by the world of science in Salt Lake City.

Philo Taylor Farnsworth (* 1906; † 1971)[3017]

In the image analyzer, the transferred image was projected onto a photocathode. Zworykin deflected the stream of photoelectrons from the cathode with rectangular magnetic fields by passing electrons from the various openings in the sequence along the scanned line to generate an image signal.

Farnsworth improved Dieckmann's German patent analyzer in San Francisco. He added a longitudinal magnetic field to focus parallel to the axis, to achieve a sharp electronic image in the plane of the aperture. His ideas were drawn from the popular papers of Russian Rosing, who therefore influenced the main USA rivals Farnsworth and Zworykin. In 1931, Farnsworth scanned 200,000 elements of the image of three people in the size of 4 × 2.75 inches with alternating sawtooth voltage with frequency of 12 Hz and 4800 Hz. His transmitter was Braun's cold-cathode ray tube in high vacuum and a small photocathode on silver-plated glass. Only a small part of the photocathode was not shaded from the gas discharge. The anode parallel to the photocathode were from a thin layer of tungsten or nickel. The protection was a thin layer of platinum on the inside of the tube. In the photocell plane was a fluorescent screen. The electrons were accelerated with a voltage of about 500 V and deflected with a transverse magnetic field.

By an alternating sawtooth voltage with frequency of 3000 Hz and 15 Hz, it scanned 200 lines with 15 frames per second. The receiver was "oscillite", like Zworykin's, with two mutually perpendicular coils. The anode tube was at the center of the electrons flew from the transmitter or the fiber. He gave a better picture than a mechanical television from Bell Labs. At the end of 1931, Farnsworth's television was sold at 50 pounds, and the adapter for an additional 20 pounds. The customers were able to look forward to TV shows of 1000 hours, while the cost of restoring a deteriorated receiver was 2-3 pounds.[3018]

On 22 July 1935, Farnsworth was given priority in the invention of the television system after years of his conflict with RCA.[3019] Farnsworth's image analyzer has long competed with Zworykin's system until the patents were granted to Zworykin on December 20, 1938.

In the next thirty years nobody could not get rid of the effect of gas ionization due to the low vacuum in the cathode ray tube. Therefore, they used special "loops" for ions to prevent destructive dispersion with the oxide of the coated cathode due to the positive ions formed in the electron beam. Until the aluminium screen was added to the cathode ray tubes, the fastest negative ions repeatedly burned the center of the phosphor screen.

[3017] Fisher, 1996, 136.

[3018] Dinsdale, 1931, 286–288.
[3019] Fisher, 1966, 236.

The undesirable effect of the secondary emission was eliminated by the physicists Harley Ambrose Iams and Albert Rose at Zworykin's Laboratory at RCA in Princeton in 1939. They used a slow switching beam that falls everywhere perpendicular to the mosaic in the recording tube, called the orthicon. In January 1946, with the collaboration of Paul Kessler Weimer and Harold Bell Law, RCA developed another 100 to 1000 times more sensitive image orthicon. The super orthicon came into use in 1947, and the smaller vidicon was designed in 1950.[3020]

The oldest of those researchers named Iams was born in 1905 and graduated from Stanford in 1928. Between 1927 and 1929 he worked at Westinghouse, later from 1931 to 1933 at RCA. Between 1933 and 1942 he was a design engineer at Harrison, and then until 1947 he was in Princeton as Einstein's neighbor.

Rose was born in 1910 in New York. After three years of assisting at Cornell University, after a doctorate in 1935, he was employed by RCA. He stayed there until 1975 and during that time he published fifty patents related to the television. One-year younger Law from Iowa received his doctorate in 1941. Between 1939 and 1941 he was an assistant at the State University of Ohio, where received his Ph.D. Weimer was in Indiana in 1914. From 1936 to 1937, Weimer was an assistant in Kansas, and between 1939 and 1942 he returned to the Ohio State University, from where he moved to RCA in 1942, RCA therefore brought together most of the American researchers of television. Ross, Weimer and Law received the prize "Television Broadcasters" in 1946. Rose also received the Liebman's Prize while Law got the Zworykin Prize in 1955.

27.6.10 Color TV

In 1880 Maurice Leblanc published a study on the problem of a television with a prism that divided the seven colors among the amplifying selenium cells. It was a naïve performance that solved the problem solely on a quantitative level for the desired features of the television system.

A Russian inventor Alexander Appolonovich Polumordvinov of Kazan asked for the patenting of a color television system with rotating Nipkow plates and concentric cylinders with slits covered with red, green and blue filters; his Russian patent was grated in December 1899. However, he had not yet had the technology available to enable such a system to function. On 12 June 1902, the German Bronk patented a mirror drum, a selenium cell and a Geissler tube filter with color filters.

On 27 June 1929 in the Bell Labs Ives demonstrated a color television for the first time in the United States. The receiver for electronic color TV was patented by Austrian J. Nagler in 1935, and in 1936 his system was developed by Baird in a color television with 120 lines scanned with Nipkow-plates in red, green and blue colors.

On 12. 7. 1938 the German Werner Flechsig patented the idea of a "shadow mask", which in electronic color television allows impact of a jet of electrons at different angles, only the excitement of luminophore of one of the three available colors. In the same year, Hans Pressler discussed his television in natural colors and, together with von Ardenne, solved the issue of the required frequency bands.[3021]

Peter Goldmark, born in 1906 in Hungary, designed a color television already while studying in Vienna. After a doctorate in physics in 1931, he tried in vain dio some experiments with Baird in London, and then moved to the United States in September 1933. He published his color television system in the British Journal, and he was employed by Columbia Broadcasting Company (CBS) in New York on the New Year day in 1936. He invented a mechanical rotary filter, while otherwise he used Farnsworth's television system. On August 28, 1940 and on September 4, 1940, Goldmark demonstrated the operation of color television. On 25 June 1951, CBS began broadcasting a color TV program, which, however, had little audience because of the opposition of Sarnoff at RCA.[3022]

In September 1949, RCA organized several groups for researching the color image electronics, comparable to the black and white version of

[3020] Zworykin, Ramberg, Flory, 1958, 18–19; Ustinov, Borisov, 1989, 121–123.

[3021] Leblanc, 1880, 477; Fisher, 1996, 299–301; Goebel, 1974, 853–856.

[3022] Fisher, 1996, 302–304, 320.

television. After his doctorate in 1942, Herold was employed at the RCA Laboratories in Princeton, New Jersey, where he organized and managed all Sarnoff projects. In 1949 at the RCA, Law drafted a prototype of a kinescope which could get a picture somewhat larger than 100 cm^2. In March 1950 RCA publicly demonstrated the operation of the prototype of cathode ray tubes with a shadow mask that was first produced in the following year. In 1952, the project was compiled by the Americans Lawrence, Luis Walter Alvarez and McMilan. Lawrence won the Nobel Prize for Physics in 1939, Alvarez in 1968, and McMilan got his Nobel prize for Chemistry in 1951.

The television's development accelerated the development of electronics. After the jump in the late 1940s, the growth in electronics production was also five times higher than the average growths in the US industry in the next decade. The total amount of sales doubled between 1950 and 1960. Table 27-1 is an overview of major events in the developments of television.

Table 27-1: The First Century of Television (time, world events, Slovenian Contributions)

1817 - Berzelius discovers selenium
1837 - Becquerel discovers photocurrent on selenium illumination
1843 - Bain's picture telegraph
1845 - Faraday discovers the rotation of a polarization plane of light in a magnetic field
1847 - Bakewell copper telegraph
1851 Hittorf investigates the conductivity of selenium
1858 - Plücker discovers the deflection of cathode rays in the magnetic field
1863 - Caselli first transferred the images from Paris to Lyon
1869 -Hittorf investigated the luminous phenomena in the Geissler tube
1881 - Ayrton and Perry used the Faraday discovery of 1845
1883 - Edison patents the thermionic emission
1884 - Nipkow's plate
1887 - Hertz discovers the photoelectric effect
1890 - Fleming explains Edison the discovery of the thermionic emission
1893 - Elster and Geitel's photocells
1897 - Braun published the first discussion on cathode ray tube
1904 - Wehnelt low-voltage cathode ray tube
1906 - De Forest's triode
12 September 1906 - German patent: Dieckmann and Glage use cathode ray ruby for the broadcasting of the letters and images
1907 - Rosenthal used photocell in his optical telegraphy
1907 - Rosnig's Television in St. Petersburg
1908, 1911 - Campbell-Swinton Television in England
1910 - Lieben's Triode 1912 Nardin's relé

27.6.11 Television in Slovenia

The Bosnian Croat Josip Slišković (1901 Mostar-1984 Vienna) worked as an engineer for the firm Kapsch & Sons in Vienna. He finished his Grammar school in Mostar and studied at Viennese Technical high school. He was the first to show television in Austria for his own production of shadows He scanned his pictures with a Nipkow's plate and photocell. He lectured about his inventions in Ljubljana and other major cities of the monarchy.[3023] The first one introduced radio on European railways with his "autodyne" device, reported by the Ljubljana-based Slovene. In December 1949 he was the first in Austria to introduce a transistor.

27.6.12 Codelli's Television

Parallel to Nardin's (* 1877) work at the Ljubljana university and Slišković's (*1901) novelties, the other inventors, especially Nardin's two and half year senior Codelli, developed their networks in Ljubljana. Codelli was aware of Slišković's merits and well enough to write few page long notes about "our compatriot Slišković" among his papers.

Anton III baron Codelli von Fahnenfeld (22. 3. 1875 Naples; † 26. 4. 1954 Porto Ronco near Ascona) was born in Naples in Italy to a Carniolan noble family of Italian descent just because his poor father had to put his anchor there to regain health. Anton Codelli's mother was from the family of baron Taufferer who also produced the leading Carniolan jacobine. The authors of Nardin's and other inventors connected with the University of Ljubljana, made Ljubljana the important site of the early age of television development. Among them was the owner of the Ljubljana quart Kodeljevo baron Anton Codelli, who was born in Naples in the Italian family based in Carniola.

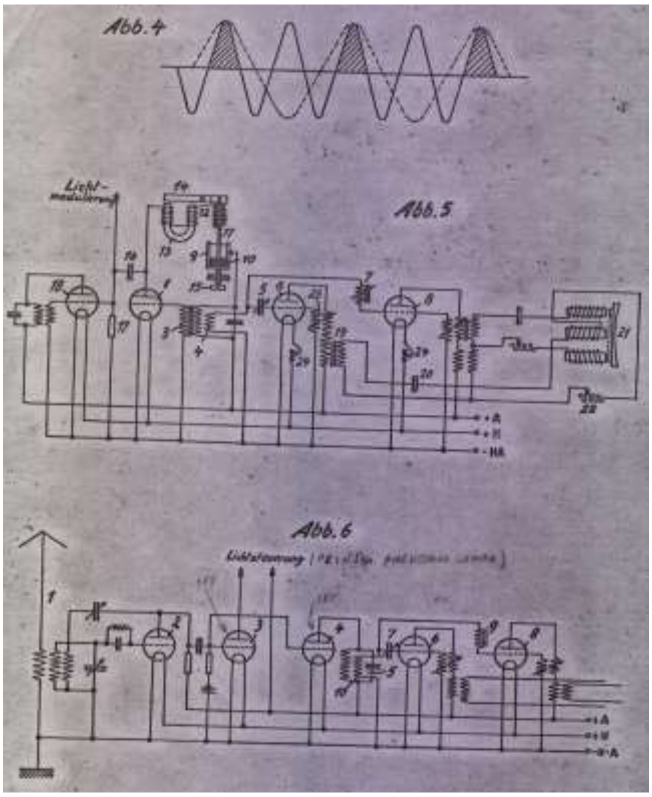

Figure 27-17: Illustrations 4-6 as an appendix to the German Codelli's text, also referring to the 80-page long Codelli's typescript, probably mailed to USA (Codelli, SI_AS 791, box 19)

After his schoolings in Ljubljana, Anton III baron Codelli graduated at the elite Theresian Academy of Nobility in Vienna in 1894. He followed the

[3023] Codelli, box 19.

example of the deceased father and entered the Austrian Navy; but he left the uniform soon and studied law in Vienna for some time in 1897. In 1898 he patented his first invention, an electric lighter for motor vehicles, and later he designed a heating and cooling appliance for motorists on long journeys. He did not acquire vocal academic titles, however, he could, as a nobleman, devote himself entirely to technical inventions.

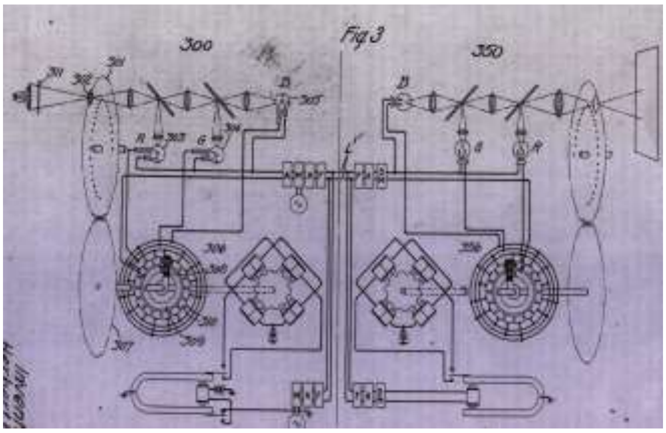

Figure 27-18: Ives' Color Scanner from his patent kept in Codelli's domestic Archive (Ives, 1929, Figure 3)

In 1906, he completed a six-month technical training course at Telefunken in Berlin. From 1907 he worked with his six years senior friend the pacifist Georg Wilhelm Alexander Hans count Arco (1869 Gorzyce, Groß Gorschütz-1940), who was born in the now Polish Upper Silesia. Arco and Codelli did not merely socialize their technical inventor stars of the nobility, but they also shared the way of life of the high nobility in the era of the erosion of its size. After completing the Humanistic Gymnasium in Breslau (today's Wrocław), Arco studied mathematics and physics in Berlin at Helmholtz's class for two semesters. He worked for some time as an active officer, then studied mechanics with Slaby and Alois Riedler (1850 Graz-1936) in Berlin between 1893 and 1898. Arco received his doctorate in Strasbourg and served as an assistant for wireless telegraphy of Adolf Carl Heinrich Slaby (1849-1913) between 1896 and 1898. Slaby served as a professor of electrical engineering at the Technical College in Charlottenburg of Berlin. Following the merger of AEG of Slaby and Arco with the Braun-Siemens Group in the Gesellschaft für Drahtlose Telegraphie mbH (Telefunken), Arco became technical director of the new company in 1903. Siemens had some previous fights with the new German empire, but both sides decide to settle it down for more profits. Arco retired in 1930 and died in Berlin ten years later.

On 12 January 1908, Codelli described the scanning of a television image with the mirror of the Wehnelt's cylinder by using selenium cells. Codelli asked Telefunken for support. The technical Director of Telefunken Count Arco consulted with colleague J. Schoemlich. On 28 January 1908 Arco answered that selenium was not enough sensitive for light to be used for that performance. The selenium could not follow the rapid changes of light luminosity and does not give a sharp picture. It was necessary to find something faster while the use of Braun's cathode-ray tube did not seem to be as obvious choice to him as it seems to us today.[3024]

Codelli informed Telefunken via Arco about possibilities for penetration of Berlin capacitors instead of Austrian Svetics's ones sold than on the Habsburg market especially for the navy. Codelli agreed to cooperate with the branch of Siemens & Halske in Vienna, which was closely associated with Telefunken.[3025] On April 23, 1908, Arco sent to Codelli the latest Loewe's invention of photo amplifier (enhancement) and Schoemlich's simultaneous reading and photographing system, which was able to read and photograph at the same time. Codelli thanked Arco for his photographic aids in favor of their close long-standing cooperation. Codelli developed the television system after returning from Africa. Codelli continued his research on television on Arco's incentive on 14 December 1927. He collaborated with Schröter, director of the research department of Telefunken in Berlin between 1920 and 1947. The experienced Schröter experimented with cathode "rays" in discharge tube before the First World War. In the first professional paper published in the new Fernsehen magazine, Schröter submitted the description of use of a cathode ray tubes filled with argon at a pressure of a hundred or thousand mbar for both reception and

scanning of the image.[3026] In the same volume of Fernsehen magazine, Codelli described his television system without a cathode-ray tubes.

On 27 September 1930, Schröter applied for a patent designed for the reproduction of "half-sized" images with the successive alternation of barrels and odd rows recognized as his invention in Germany on March 23, 1933. Together with Knoll, he investigated the transmission of electronic images in the Telefunken Television Laboratory in Berlin and published several books and encyclopaedias on television.

On 18 May 1928 in Germany, Codelli patented the reproduction of images along the spiral. On 22 June 1928, he concluded negotiations with Telefunken's agents represented by Schapiro and Schröter. Telefunken has redeemed and bought out 60% of shares of the rights to Codelli's television system for the whole white world except for the USA. Until then, Telefunken owned only Karolus' television system, which Telefunken intended to supplement with Codelli's inventions.[3027]

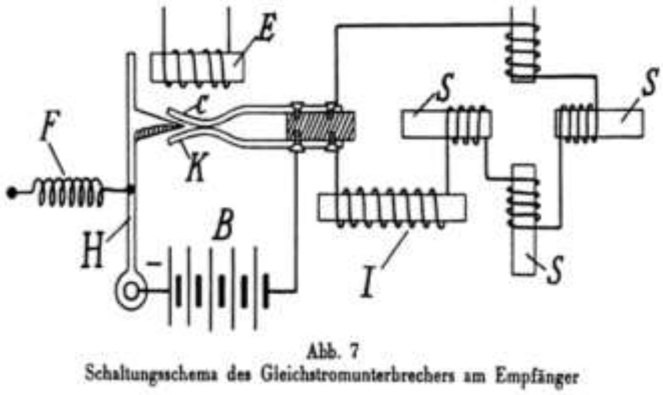

Figure 27-21: Seventh sketch of a direct current receiver from Codelli's publication (Codelli. 1930. Ein neues Fernseh-System. Fernsehen. 1 / item no. 3, p. 107–114, here p. 113)

On 14 November 1928, Codelli sent to Schröter a description of his TV with John Kerr's (1824 Androssan in Scotland-1907) cell used in a same way as in the Karolus' system. With Codelli's help, they made the prototype device in Berlin in six months. On June 22, 1929, the director Dr. Karel Schapiro at Telefunken issued a laboratory certificate for production of a prototype television according to Codelli's patent for Telefunken, for which 25,300 marks were granted and approved, of which 13,000 marks were given for Codelli's

[3026] Schröter, 1930, 4; Schröter, 1930, 246.
[3027] NUK, Manuscript department, reference code: Ms 1397, III (155).

compensation and for the reimbursement of his travel expenses from Ljubljana to Berlin. The final used price of the device became almost twice as high because of additional parts, while Codelli had at least temporarily all luck in front of him.[3028]

On 17 January 1930, Codelli described a scan with a Nipkow's plate with two spiral holes in a total of 25 coils. For them, Schröter's photocells were installed, which worked alternately. The device was carrying and transmitted 12.5 images with 2500 elements per second. The streams of photocells were strengthened by the De Forest's Audion, produced at Telefunken. In place of Nipkow's panels, a L. Weiller's mirror wheel was also provided for use. as it was designed for the first time in 1889.[3029]

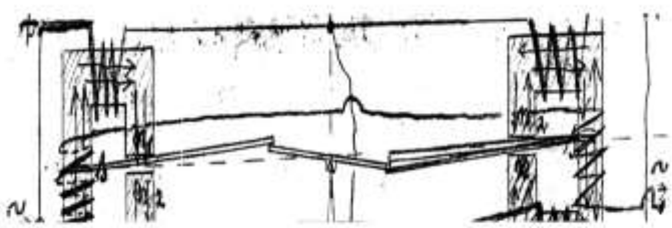

Figure 27-22: Sketch of the television system from Codelli's letter to Schröter on 14 November 1928 (Archives of the Republic of Slovenia, SI_AS 791 Manor archives, Turn by Ljubljanica, box 19)

In the case of spiral scanning, a small difference in the staged phase at the outer edge was known in the center of the image, while the normal scanning of the phase difference itself was eliminated. Therefore, the damping and frequency of their own fluctuations and oscillation of the mirror on the receiving and transmitting sides of Codelli's system were exactly the same, which was practically unfeasible for the technology.[3030]

Recording of an image with a mechanical scanner with detectable persistence caused loss and damage to the image. Only the recording-shooting along a spiral in the Codelli's system can accurately transmit images in a mechanical television. Therefore, the damping and the frequency of their own oscillation of the mirror on the receiving and transmitting sides of the Codelli's system were the same, which was not practical issue for then available technology. The recording of an image with a mechanical scanner with detectable persistence caused loss and damage to the image.[3031]

In 1928 and 1931, Codelli patented his stereoscopic electric "far-sighted" vision in all major European centers and in Canada, but he did not succeed in the United States. On 10 November 1933, the chairman-President of the Ljubljana section of the Association of Engineers and Architects, Milan Šuklje, considered that Codelli's lawyer Abrahamson made a mistake when he missed the deadline for the application and payment of the request-requirement for an American patent on January 23, 1931. Due to the incorrect filling and irregular application on 25 June 1927 and on 29 December 1930, under no. 60718, Codelli's patent in the USA was rejected on 18 August 1932. In 1928 and 1931, Codelli patented his stereoscopic electric "far-sighted" in all major European centers and in Canada, but he failed in the URnited States. Nevertheless, the company of Tesla's patron the multimillionaire J. Pierpont Morgan named Shortwave and TV Corporation asked Codelli's Washington lawyer Emil Bönnelyck for information on Codelli's patent on 11 October 1932, but later, on 20 January 1933, J. Pierpont Morgan refused to buy it.[3032] Tesla's "friend" J.P. Morgan senior was already dead at that time, so that his son with the same name replaced him.

The competitors were harsh and Codelli also had to show teeth sometimes. Among Slovenians on the Slovenian soil Codelli was the first to use the cathode ray tube electronically in television only in cooperation with the Ljubljana electrician and radio technician Franci Bar (* 2. 12. 1901 St. Anton by Trieste-24. 11. 1988 Ljubljana). After the Italians took over Trieste, Franci Bar and his family moved to Ljubljana where his father opened a store on Cankarjevo nabrežje on the banks of Ljubljanica River in 1919. In 1931, Franci Bar took over the store with the help of his wife and brother. They were selling stamps, radios, gramophones, typewriters and photo-apparats and

they loved to repair them. Franci Bar became the fascinated radio-amateur and photographer. He especially excelled as the best cave photographer of his times and as a very active member of the Society for the research of Caves in Ljubljana which was reorganized after the publications of Pavel Kunaver in 1924. Besides Franci Bar, the other active members were Valter Bohinec, Srečko Brodar, Marjan Bukovec, Ivan Dolar, Jovan Hadži, Ljudevit Kuščer, his son Ivan Kuščer, Roman Kenk, Ivan Michler, Hubert Pehani, Ljubo Podpac, Egon Pretner, Ivan Rakovec… The leading biologist Jovan Hadži (1884 Timisoara-1972 Ljubljana) spoke Slovenian language with a strange Serbian accent, but he was a great expert. Franci Bar from the practical side and Albin Belar from the academic side were certainly the best collaborators which Anton Codelli could find in Ljubljana between the Wars. Certainly, the baron Codelli was a high society for all those other Ljubljana guys, but those old class social rules slowly collapsed under the pressures of modern networks. Codelli family members still mostly married the nobles, but he also had sympathies elsewhere and certainly avoided class rules in his research of the electromagnetic designs. Codelli did not specially like Yugoslavia as his son Karl Anton Codelli was shot death while he was trespassing the railway track near their family home which happened to be also near the military stronghold in Ljubljana in 1921. On 14 March 1930, Codelli announced in his response to a month-old Schröter's letter that the TV equipment from Berlin should be delivered to Franci Bar's store address on Mestni trg (City Market) no. 5/I in Ljubljana.[3033]

Schröter exhibited a mechanical system in Berlin on 11. 5. 1928 and he advocated the use of a cathode-ray tube in August 1930. On 27 September 1930, Schroter filled a patent for the reproduction of images by sequentially changing even and odd rows, which was recognized ang granted in Germany on March 23, 1933. Together with Knoll, he studied the transmission of electronic images in Telefunken Television laboratory in Berlin. He published several books and encyclopaedias on Television, which Codelli used. On June 18, 1928 Codelli patented his invention in Germany, and then elsewhere including his homeland Yugoslavia. Thus, at the same time Schröter and Codelli both adopted and approached the "American" version of electronic television, which soon prevailed.

27.6.13 Codelli's Cathode Ray Tubes

Codelli as the first used the invention of the cathode-ray tube in television in Ljubljana. In his legacy kept in ARS there are numerous copies of foreign patents, from which he appeared to be well-versed in electrotechnics. He knew that the electronics without the cathode ray tubes dogged his success in the United States. That is why both Codelli and Schröter began to use cathode-ray tubes in the late 1920s for their television, which best suited the Russian Zworykin in the United States RCA form. Codelli used Braun's cathode ray tubes which resembled Farnsworth's designs with photocathode. Codelli and arranged his basic idea of recording and receiving the image along the spiral so that the picture had denser elements in the middle than on the edges. Farnsworth was of course the main Zworykin rival and Codelli's choice was well thought out. Of course, Codelli would need money to make a prototype after the Telefunken gave him funds for the mechanical version of the device in 1929. He developed a television device with a single line – but one that formed a continuous spiral on the screen. Codelli based his ingenious design on his understanding of the human eye as he knew that objects seen in peripheral vision don't need to be as sharp as those in the center. His television system, whose image was sharpest in the middle, worked well, and he was soon able to transmit images of his third wife married in 1923, Ilona von Drasche-Lazar de Thorda (Ily Lázár, * 4 May 1904 Budapest). The success did not help much as the couple divorced few years later in 1935 and their son Anton (Sikst) Sixtus Rudolf Codelli von Codellisberg, Sterngreif and Fahnenfeld (* 21 November 1923) joined the Nazis whom his father hated.

The new setters of former Land of Native Americans began to dictate their criteria to their European ancestors. The former Land of Indians' guys began to dictate its electronic criteria worldwide. Codelli patented the television while Codelli knew little about the Russian-American alliances in RCA, which soon brought television to our homes.

[3033] Grabnar, 1977, 112; Codelli, AS, box 19; NUK, 134; (Boštjan Kiauta, 2015. Spomini na mladostno "entomologiziranje" v Ljubljani med drugo svetovno vojno in neposredno po njej (1941-1953). *Erjavecia* no 30: 31.

After returning from Africa, Codelli re-joined Telefunken again, but in the first years he did not get contact news from abroad. In Germany, he patented the reproduction of images along the spiral. With Codelli's help, they made the device in Berlin in six months. Codelli patented his stereoscopic electric "distant vision" in all major European centers and in Canada, but not in the US. As the first one in Slovenia he started using a cathode-ray tube in television. To gain his support in the USA, besides mechanical scanning and mobile optical devices, Codelli described the purely electronic TV with no moving mechanical parts as his third option.

In an electronic version, Codelli retained the basic idea of recording and receiving an image along a spiral with denser elements in the middle than at the edges. To gain a foothold in the US, Codelli described, in addition to mechanical scanning and mobile optical devices, the third option on 80 pages. He filled 61 patent claims for a fully electronic television without movable mechanical parts. He used Farnsworth's design including Braun cathode ray tube with photocathode. Codelli reproduced the image with a strong Braun's cathode ray tube shaped as a funnel with a punctured anode and a slightly convex fluorescence display. The cathode in the form of a concave mirror had a focal point in the middle of the screen. The recording tube was a glass receptacle, divided by a glass pan into two emptied spaces, of which the other was Braun's warmed cathode ray tube.[3034]

His cathode ray tube had two cathodes for electron emission and one anode. Codelli has already used the term electron[3035] for cathode rays, although he had repeatedly written about the cathode ray deflection in his typewriting.[3036] In one place, he explicitly described the transmitter from the long Geissler's cathode ray tube on the same page with a diffused reflector made of glass.[3037]

In the electronic version of his television, Codelli also retained the basic idea of recording and receiving the image along the spiral so that the image had denser set of elements in the middle of the screen than on the edges. The idea was based on the physiology of the eye, and among the first it was used by A. Ekström in his Swedish patent no. 32220 of 24 January 1910 bought by Bell labs and bettered by the chief of physics research and cosmic rays as well as X-rays in Parisian Louis de Broglie labs Alexandre Dauvillier (1892 Saint-Lubin-des-Joncherets-1979 Bagnères-de-Bigorre) in 1926. The similar design was developed by the Scottish expert Alexander McLean Nicholson in patent no. 1470696 in New York in USA on 7 December 1917 and 16 October 1923. As leader in the development of piezoelectric crystals and vacuum tube oscillators in television and radio for the Bell labs in 1917-1923, American Telephone and Telegraph Company and the Western Electric Company Nicholson used Braun's cathode ray tube electronic device for his receiver, in which a stream of electrons on a fluorescence screen drew a picture of Archimedes spiral. The MIT graduate Transmission and Development Engineer of ATT Otto Bernard Blackwell (1884-1970) from Plandome northeast of Queen in New York city and J. Herman from New York as assigners to American telephone and telegraph company applied for US patent for similar spiral scanning Method and Apparatus for Television on May 7, 1925. Their patent no 1,624,918 was granted on 19 April 1927. Blackwell was later vice president of Bell labs and assistant vice president of American telephone and telegraph company.

The engineer with his University diploma Paul Kirchhoff from Frankfurt on Main filed his version on 6 September 1925 bettered with his elemental scanning area oscillated rapidly in direction transverse to main scanning direction for a German patent filled on 7 October 1930 and granted five years later. After their prolonged negotiations due to the Telefunken's opposition, Kirchhoff finally refused to compete with Codelli and Telefunken in Berlin on 14 August 1936. The Jewish Berliner university professor of physics Arthur Korn's (1870 Wroclaw-1945, Jersey City, New Jersey) reedition of the former Eilhard Wiedemann's assistant Bruno Glatzel's (1878 Berlin-1914 by Verdun) manual published in 1931 cited French patent no. 570825 of September 14, 1923, February 21, 1923, February 7, 1924 for scanning a spiral with Braun's cathode ray tube electronic device.[3038]

Competitors were harsh and Codelli also had to show muscles sometimes. Unfortunately, the key to success was waiting beyond the Atlantic. That's why he wrote to the Americans in somewhat modernized following narration:[3039]

"I installed two photocells with anodes connected through resistors to the openings in the screen. Each of the cathodes was connected to the grids in the other two tubes. The glowing cathodes were interconnected with the flow of the current, which is then further amplified. This is then through the resistance (pictured on Codelli's figure as point no. 12) led to the next stage of amplification. During one oscillation of the circuit the photocurrent passes from the coil and the condenser through one and then through the second cathode ray tube.

The circuit is tuned to a frequency equal to the product between the number of pixel points and the number of broadcasts per second up to 0.18 MHz. The receiver was tuned in such a way that the amplifier (de Forest's audion) produced a continuous stream of currents with the frequency of the image elements, which are through a condenser converted to alternating current of the same frequency on the grids of two cathode ray tubes.

The anode current of the cathode ray tube runs a current through a circuit tuned to the frequency of the current of resonance oscillation of the elements of two images with a large amplitude. This high-voltage alternating current is used as an anode current in the second cathode ray tube (presented in Codelli's illustration with a point no 10).

In this circuit (presented in Codelli's illustration with a point no 11), the frequency is twice as low as in the previous circuit 8. Circuit 11 is in a known manner in the feedback relationship to the grid current of the cathode ray tube 10 via the transformer 12. Because of this feedback every other positive pulse current of the alternating current of the anode is damped due to the negative charge of the grid.

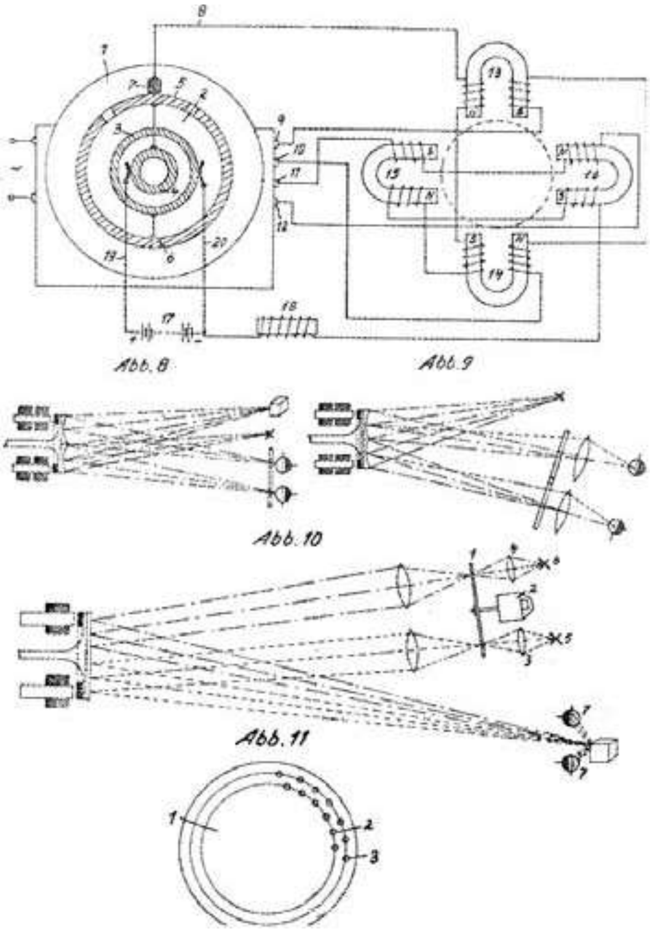

Figure 27-23: Figure 27-23: Figures 7-11 as an attachment to the Codelli's typescript written in German language. Except for figure 10, those illustrations partly also correspond to now lost illustrations of 80 pages long Codelli's English language typescript, whose copy was probably sent to the United States (source: … circuit 11 with the half-frequency (Codelli's USA patent application, Figure 4)

Since the negative phases of the alternating current cannot be transmitted through the cathode ray tube, only the currents resonant with the oscillating circuit 11 with the half-frequency (Codelli's Fig. 4) remain. The current in the oscillator 11 is connected to the grid network current of cathode ray tubes 15 and 16 via the transformer 13 and 14 so that at the same time one of the two grids in the cathode ray tube (15 or 16) receives a negative voltage and the other receives a positive voltage relative to the corresponding cathode. When one (15) of the gas-discharge lamp (17) is intended for the image on the left eye, connected to the row, another second picture frame for the image on the left eye is connected. Both cathode ray tubes with their grids are positioned parallel to the anode current of the tube 6, whose grid is regulating the

[3039] Codelli, AS, box 19. The numbers in brackets indicate the pages of Codelli's typescript. The illustrations noted in typescript did not survive the naughty greedy customers of the archive.

power of the current and thus the degree of illumination of the gas-discharge cathode ray tube in connection with the illumination of each element of both images, while the cathode ray tubes 15 and 16 operating in the phase delay, split the picture elements to the left and right eye.

In front of the gas-discharge cathode ray tubes are perforated diaphragms in the form of equilateral triangles. With the concave mirror 21 of the receiver, we project two real pictures of the apertures in the diaphragm onto the surface where they are intercepted and can be observed with a conventional stereoscopic apparatus. Two images can be observed with the appropriate synchronous motion of the transmitting mirror and receiving mirror. The transmitter projects two real–images while moving across its corresponding devices on the screen so that all parts of the screen can reflect their rays on the photocell. In this way, both images of the diaphragm on the receiver, whose light intensity is controlled in the same way, move in the same way, so that two images appear.

During the oscillating period of the alternating current the direction of circulation changes, and instead of the circle we get an ellipse which becomes more steeper, with greater current changes in the unit of time. The diagram for the moving mirror is described as follows: the triode generator and the oscillating circuit tuned to the natural frequency of the mirror is generated in a known way using an alternating reverse link current. With the transformer 4, the alternating current voltage is transferred to the grid of the cathode ray tube 6 through the variable capacitor 5, and on the other side to the cathode ray tube 8 via the variable damping coil 7, while the phases of the two alternative currents are relocated. The anode current of the cathode ray tube 1 is transmitted over the circuit breaker, which interrupts the current after a few cycles of the circuit 2. This can then damped due to natural attenuation. After many such oscillations, the anode circle can be closed again by interrupting the anode current, which is then repeated. The interrupter consists of an iron container filled with mercury in which the iron rod with its spiral winding keeps a frequency of the circuit in resonance with the number of images broadcasted per second. The conductor connects the spiral spring with the winding of electromagnet.

The level of mercury in the container can be raised or lowered. Variable jets of anode current in the cathode ray tube 1 due to the variable current 2 are transferred to the grid of the transmission cathode ray tube via the capacitor 16 and the clutch of resistor 17 as long as the interrupter (circuit breaker) holds the closed circuit. This grid affects the modulation of the transmitted wave over the amplified current from the photocell. So long as the anode current of the cathode ray tube 1 is interrupted, it affects only the transmitting electrode 18 just with a slight modulation, and during this time, the damping circuits 2 continue to control the cathode ray tube 6 and 8.

As soon as the anode voltage is connected to the cathode ray tube, the alternating currents shifted from of their phases, put the transmitting mirror into a raising spiral oscillation to the maximum values that, due to the large natural damping of mirror, are soon reached.

During this time, the transmitting electrode has the same frequency as emitted by the modulated waves. The anode current of the tube generator 1 is then interrupted. The spiral has a logarithmic shape.

In the receiver, 6 modulated waves emitted from the transmitter during the cascading spiral of the oscillating mirror and modulated with the oscillation frequency of the mirror are received by the antenna 1 and translated in a known way to the amplifier (audion).

The resulting low frequency pulses are then translated in a known way to the grid of the cathode ray tube 3 and to the grid of the cathode ray tube 4. The anode current of the cathode ray tube 3 is used to operate the gas-discharge lamp (according to Codelli’s USA patent application, Figure 4).

In the anode current of the cathode ray tube 4, we put the resonant circuit 5, which is tuned to the frequency of the oscillation of transmitting mirror. Through the transformer 10, the alternating voltage of the oscillator 5 is transmitted through the grids of cathode ray tubes 6 and 8: through the first by the condenser, and through the other by the self-induction, as previously described.

The synchronized mirror movement is formed automatically with the correct adjustment of the oscillator current. By the generation of the current to the coil of the transmitting mirror, as well as the receiving mirror, they influence the grids of cathode ray tubes which are simultaneously controlled by the emitted current pulses.

The synchronization of currents can also be obtained by using the transmitter and the receiver alternating flux currents from the magnets on the mirror generated through the frequency reduction according to the previously described methods. An electromagnet can also be used instead of a permanent magnet.

We can use the Nipkow plate with two spirals of holes for which two photocells or gas-discharge lamps are installed, each for their spiral, where they alternate. We can also use Weiller's mirror drum.[3040] We also obtain two real images of the object for stereoscopic transmission, which is influenced by two concave mirrors around the mirror carrier (Codelli's USA patent application, Figure 8). Weiller's mirror drum therefore also replaces the circular setting of the concave mirrors.

The transmission of the stereoscopic film can also be used to control the light rays. In the case of stereoscopic broadcasting of objects, the illumination is insufficient. However, we can also use controlled normal light that falls by two different angles.

The diffusely reflected light then falls on a few nearby cells (Codelli's USA patent application, Figure 10). The sources of light are positioned in such a way that the light can only go through a certain series of openings.

Codelli also used similar combination of parts for his receiver. Therefore, Codelli claimed that he invented:

1. A method for stereoscopic television, where the transmitter, in turn, transmits image elements that are divided into their elements and are distributed to images suiting the left and right eye.

2. The method according to claim 1, wherein the transmitter is illuminated from the two sides at a slightly different angle from where the image is projected onto a stationary display. This has in its middle two small openings and photocells behind them, which are activated sequentially.

3. The openings on the receiver have the form of an equilateral triangle.

4. Two real images are copied by two hollow mirrors, placed with a side in front of a working distributor.

5. Controlling the light rays, determined by the falling of light on the moving distribution mirror through two slides or films above two photocells, which are activated sequentially.

6. Modification of a method 5 with a single source of light.

7. Two successively lighting up sources of illuminations are diffusely reflected by the object, so that one or more photocells are consecutively visible to one or the other eye.

8. On the receiver are the real images of two successively activated light sources projected through a moving dispensing (distributing) mirror through a stereoscope.

9. Change of point 8, where each lens is equipped with a cathode ray tube and a control hole at the distance of its focal point.

10. Device for sequential activation of photocells in the transmitter or of sources of light in the receiver. Two parallelly connected photocells or two sources of light are characteristic. The electrodes are placed in series. An alternating voltage is applied on them so that only one cathode ray tube transmits current in one phase, while in the second phase only the second cathode ray tube transmits the current.

11. An alternate activation of the photocells in the transmitter, characterized by two openings on the screen in the transmitter or opposite to the light source on the receiver movable diaphragms to cover one of the openings for such an space of time as is necessary for the transmitting of image element and opening a second aperture to

[3040] According to Codelli wrongly noted as Weller's wheel, in fact described by the French worker Lazare Weiller in 1888 in the publication about "phoroscopus« (Swift, 1950, 49; Fisher, 1996, 85).

transmit the beams towards the second element of the images through said pierced plates.

12. A device for synchronizing the distribution of individual image elements for the left and right eye so that the pulses passing through the transmitter and constituting the picture element of the receiver produce fluctuations in the electric resonant circuit tuned to the number of elements of the image per second or its half.

13. Method of carrying out the described synchronization for individual image elements.

14. A method for reducing the frequency defined by the high-frequency alternating anode current through a triode by which the pulsating low-natural frequency circuit is connected in the series so that in a known way it affects the grid by means of a feedback link. Thus, only the impulses that are suitable for generating low frequency oscillations in the circuit can pass through the cathode ray tube.

15. A device capable of varying frequency.

16. Magnetic system with few magnets which are surrounding the mirror so that they change the amplitude of the alternating current (in the case of permanent magnets) or they are changing the amplitude of the DC current, if we use electromagnets.

17. Rotating magnets exhibit their greatest attraction of the iron frames of the mirror only during certain periods of alternating current.

27.6.14 Problems with Politicians

Up to 1933, Codelli's patent applications failed in the US, and then the Nazi nationalists took over the control of the German state, which was criticized by careless Codelli. Unfortunately, Codelli lost the German support, therefore he couldn't compete against the television of the American RCA anymore. Codelli's opposition to the Nazi regime in Germany caused the interruption of his cooperation with Telefunken. Without the Telefunken, however, the amiable baron of Ljubljana could not rival the emerging television industry in the US, although he sold out a large part of his estate on Kodeljevo. Codelli sold most of the property of his Kodeljevo home, but the Americans picked up best of the invention of television anyway. In this, he was most comforted by the fact that television was not his only hobby: he owned the first (and second) car on Slovenian soil, paid for the first live action African film to be shot with a dreamy German star in Africa and he even replaced three noble women as his wives. After the war, his castle Turn along the Ljubljanica River was nationalized, while the well-informed Codelli folded up his tents to settle down in Switzerland before the end of the war. We do not know yet whether he was watching television there, which, unfortunately, (yet) did not follow his spiral innovations.

Codelli's opposition to the Nazi regime in Germany caused the suspension of Codelli's co-operation with Telefunken. In 1930, the pacifist Arco retired and died in 1940, so, Codelli failed to get much German support without his friend Arco. Without Telefunken's support, Codelli was not able to deal with the emerging television industry in the US, although he sold out a large part of his property at Kodeljevo in Ljubljana.

The only true early Slovenian TV breakthrough was achieved by the Ljubljana baron Anton Codelli, who already used the term electron instead of a cathode rays, although he repeatedly wrote about the cathode ray deflection in his US Patent application. He explicitly described a transmitter designed from a long Geissler tube placed on the same surface with a diffused reflector made of glass. The Ljubljana vacuum research was therefore born at least on Kodeljevo, if we ignore the school labs attempts of Codelli's predecessors. In Codelli's and his father's military base in Pula bravely served a doctor and high naval officer Jožef Potočnik (1841 Upper Razbor by Slovenji Gradec-1894 Pula), who fought at Vis under Tegetthoff's command and became a general. He was the father of the inventor of the geostationary satellite the engineering captain Herman Potočnik - Noordung (1892 Pula - 1929). The naval officer Karl Jožef Baron Codelli (1846-1878 Pula) also served in Pula. After his graduation his son, a navy officer, an inventor of the television Anton Baron Codelli (1875-1954) from Kodeljevo worked there in Pula from 1894 until 1897. Although Idrija and Ljubljana professor Nardin patented a lot in the direction of Tesla's ideas, the Ljubljana Baron Anton Codelli is the only one among Slovenian inventors at least remotely comparable to Tesla.

Alongside Tesla's 170 patents, Codelli also filled many patents, although he did not have enough experience in the US. Codelli was almost two decades younger than Tesla during the rapid development of electrical engineering, when the new inventions were catching each other. Codelli studied cathode ray tubes primarily as a device for establishing his model of spiral television image broadcasting on the US market; Codelli devoted less attention to Tesla's innovations. Since they were moving in the same electrotechnical environment, Tesla and Codelli had many common friends and acquaintances. Tesla corresponded with Adolf Slaby in 1901 and 1903. As a professor of electrical engineering at the Technical College in Charlottenburg, Slaby used German translation of Tesla's work as the basis for high-frequency techniques. Slaby also taught George Count Arco. Arco soon corresponded with Tesla himself. At the same time, Arco became a friend and major Codelli's associate in the Berlin based Telefunken. Thus, Codelli was at least indirectly associated with Tesla, which, according to his inventive approach, worked and invented very much like Codelli. Of course, Codelli was the son of a rich man, but he wasted his Kodeljevo property on the altar of science.

Codelli's main invention was television. He constructed it so that the image flows spirally. His density of the picture elements (pixel) with their resolution in the center is greater, since the lower density at the edges does not disturb the observer. Codelli therefore also became the expert physiologist of the vision which might affect his frequent marriages. His patent was purchased by Telefunken, which enabled Codelli's journeys to Berlin. When Hitler came to power, Codelli was not too much fascinated and after the year his connections with Telefunken broke up. Otherwise, he patented across Europe and Canada. But when he wanted to obtain patent in the USA, he failed.

Tesla's USA fan was a wealthy man, J. P. Morgan, who otherwise supported Tesla until he realized that it would not be possible to extract any money from Tesla's wireless. The other Morgan, Avigdor M. Vic Morgan of Belmont Massachusetts, however, initially supported Codelli. Codelli's patent was also modernized, but in the USA Codelli had a competitor, the Russian Zworykin, who had stronger patents in USA. This television did not bring Codelli any money, but he also had the first car, he also created terrible losses, and sold one piece by piece of his Kodeljevo property in Ljubljana. From Togo, he brought with him a black man, who was maltreated while he walked around Ljubljana because the locals thought he was painted with a shoe polish. However, the Negro responded by saying that the local Ljubljana people were uncultured bush folks.

27.6.15 Other Codelli's Inventions

The father of inventor Codelli married his cousin baroness Taufferer, after whom Anton could inherit his technical abilities. Taufferers were an important Carniolan family, which gave more prominent officials, officers and priests, among the latter two writers of Slovenian pious books. They were lower Roman-German nobles, in the 16th century also patricians in Augsburg. In the second half of the 16th century they came to Carniola.

Taufferers gave a powerful stamp on Ljubljana's education and science. The ancestor of Codelli's mother, Baron Maximilian Taufferer, assisted the Ljubljana teacher of mathematics Stainer in exams at the College of Ljubljana. In his library, he had numerous works on mathematical science. He was the elder brother of Cistercian Janez Vajkard later Pater Aleksander, who became the Kostanjevica Abbey and Gorizia Archi-deacon, and was also a member of the Dizma brotherhood of Carniolan nobles. Alexander studied the last year of philosophy in Ljubljana and wrote his exam lectures about general and special physics. In general physics he described the siphon and other water pumping devices. In his paragraph about lightning he narrated about the storms as they happened in Vienna and Ljubljana. He advocated the theory of mercury vapor above the tower in the barometer, although he acknowledged the weight of the air. In special physics he described and draw the systems of Ptolemy, Copernicus and Jesuit Riccioli in the discussion of the Universe. Resembling Kelallur Nilakantha Somayaji (Comatiri, 1444-1544) of the Kerala school or Tycho Brahe, Riccioli imagined somewhat modified the rotation of three planets, Mercury, Venus and Mars around the Sun, while the orbits of the Sun, Saturn, Jupiter, and fixed Stars were centred on the Earth. Unlike Kelallur Nilakantha Somayaji and after him Tycho Brahe, Riccioli retained the Ptolemaic rotation of Saturn and Jupiter around the Earth.

Maksimilijan Taufferer was the owner of the new castle in Peščenik. His bookplates are found in books that later became part of the Lyceum library in Ljubljana. He was the son of Mark Anton Taufferer. The first of his twelve children Inocenc Taufferer became professor of physics at the University of Ljubljana. Inocenc was interested in vacuum experiments, and in September he reprinted Mairan's book about the causes of the mercury fluctuation in the barometer with his own examination thesis included. Five years later he published a German Computing manual. Inocenc's nephew was an officer, a revolutionary and a revolutionary Janez Siegfried Herbert Taufferer. Since he joined the hostile French army, the Habsburgians sentenced him to death by Maria Theresian Criminal Code in Vienna for his alleged insult of the Emperor and the high treason. His influential relatives could not afford to help him in those wartime times.

Codelli used to be a pioneer of film industry. During the World War I Baron Codelli was in Togo and he set up a telegraph for the Germans and financed the first live action African film by the scenario of his mother. His mother was from the genus Taufferer, a baroness from Višnja gora, and his father was a mayor for some time; otherwise the Codelli family originated as Zois and Valvasor from the Bergamo areas. When Žiga Zois' father came to Carniola, he served as Codelli's assistant. Anton Codelli did not study much. He went to the elite noble academy in Vienna, and then did some electrical engineering courses. He also had strong international ties, including those with Tesla, at least indirectly, as they had common friends. He did not exactly correspond with him. Compared to Tesla, Codelli was also 18 years younger.

At the beginning of 1910, Codelli, in financial distress, accepted Telefunken's offer and began building a large radio transmitting station in the then German colony of Togo, in Africa. There, he covered the cost with 46,000 marks and was directly involved in the shooting of 3000 m frames of one of the first African films "Lost Daughter *Weiße Göttin der Wangora* (*The White Goddess of the Wangora*)" in 1913. It was the first live action film shot in Africa, and the main actress was Codelli's sympathy, the beautiful Meg Gehrts (1891-1966). Meg was Schomburgk's wife from 1922 until 1925. Fine crafty inventor Codelli was, on the other hand, married to a Czech baroness, and he was secretly admiring the brilliant German actress. They recorded their film in the idyllic virgin forests until the World War I was over. The successful radio station had to be put down and destroyed with dynamite by Codelli and the French troops of Togo, while Codelli returned from prison only ten years after his journey to Africa. He brought with him a rich collection of African products which later enriched the Ljubljana Ethnographic Museum.

Miha Čelar's film was recorded on the 70th anniversary of Codelli's death. His African adventures were described. Miha showed how he tried to adapt to the requirements of the American market with the electronic version of his television system and briefly summarized the other Codelli's inventions. In 2017, Miha Čelar produced a documentary and played film about a film project of the baron Anton Codelli. Together with filmmaker and adventurer Hans Schomburgk (1880-1967) Codelli filmed in Togo in 1914 the first live-action film in Africa, which possibly inspired James Rice Burroughs's Tarzan. In the company of three Codelli's female and male descendants and the actor Primož Bezjak, Čelar traced the fate of Codelli's film, brought the remaining artefacts from Togo and Berlin to Ljubljana and used the Green Screen technology to bring to life 15 live-action scenes based on 600 Codelli's museum photographs. A. Codelli's old granddaughter was surprised how the young actor Primož Bezjak could feature as A. Codelli whom his granddaughter remembered only as an old man, but it happened to be just another misunderstanding. Miha Čelar stated that the fact that A. Codelli's great granddaughter was just abandoned by her fiancé mirrors the fact that they are the members of the rotten capitalist folks, but he was wrong, as they were just the members of the elite, just like the film stars loved to marry as much times as possible.

Codelli entered the world of film and television just when it became a novelty recognized and named in America. In these years after the first war, Codelli naturally created new inventions, and due to poor communications, he lagged somewhat behind by the development in the United States. In many respects, the American television has largely developed thanks to Russian fugitives escaped from the Leninist regime, just as the American

nuclear industry was later invaded by fugitives escaped from Hitler's Nazis, and USA again got many useful immigrants after the humiliated destruction of Soviet Union in 1990s.
Codelli has grown with a new era of electrical engineering. He got Karl Benz's car in Vienna and scared the poor folks of Ljubljana with his speedy journeys. Soon, he got tired of the dust of the Carniolan roads, and along with the driver drove to Nice, for the effort he gave a gold coin to the driver. Unfortunately, he gambled away all the savings and a car on top on his loss, so, the baron had to leave only in his trousers, and the driver had to lend him his hard-earned gold coin so that they could take the train home. Of course, Codelli soon bought a new stronger Gottlieb Daimler's car. In 1903 in Nice in France he patented small heating and cooling apparatus, while preparing for a long journey. In a special container, the food was first frozen and then heated to the desired temperature before use. Of course, he could not advise users how to wisely save their money which he spent in Nice.

In 1906, Codelli developed a rotary explosive engine, the predecessor of a half-century later engine of the Nazis' fan Felix Wankel (1902 Lahr-1988 Heidelberg) designed after Codelli passed away. With improvements to the car, Codelli paved the way for inventors of modern car drives, among them Andrej Detela of the Jožef Stefan Institute.

The aeronaut Kraškovič soon enough welcomed his descendants among Slovenes. Among the most expensive physical devices at the gymnasium in Koper, in 1867, a rubber balloon was purchased with a pipe made of brass, which was probably intended for exploring gases. They bought it for 58 florins or 4.5 DM. In 1904/05, Maks Samec the Younger (* June 27, 1881; † June 1, 1964) began to fly with balloons for research purposes as well. On 24th of May 1908, at 11:55, he rose to the double balloon, which was administered by Ludwig's son dr. Arthur Boltzmann (* 1881; † 1952). The fellow Samec checked how the luminosity was increasing with height. In 1910, Codelli designed an airship which was a kilometer long, 100 meters in diameter. The imposing balloon was designed for the transport of 20 000 passengers at 160 km/h. Its volume of 1.25 million m^3 would be eleven times smaller than a balloon with a radius of 240 m. The lift would exceed the weight of a steel frame of less than a millimeter thick if Codelli exhausted the air from its ship to achieve the vacuum. During the exploration of balloon flights, the Ljubljana baron Codelli was able to identify the advantages of their size and on five typewritten pages he designed a huge steel balloon Dreadnought under the direction of Ober lieutenant Wallach in 1910.

In 1910, Codelli made a radio receiver for receiving accurate time signals. He donated the device to ~~a~~ professor at a higher school in Ljubljana Belar, who had his own seismic observatory in the basement of the real school on Vegova Street, a later electrical engineering secondary school.

Codelli did not like the Nazis who closed his door to Telefunken. Unfortunately, without a big backing company, he could not claim his inventions on the US market.

The Slovenes are justifiably proud of Codelli's contribution to modern technology. On important anniversaries, they are preparing numerous celebrations to draw attention to Codelli's achievements in vacuum technology, early television and automotive. An interesting picture of Codelli's early television might resurface anytime soon by pointing out that Codelli's scanning along the spiral is also interesting for the modern industry.

Codelli's opposition to the militaristic Nazi regime in Germany likely caused the interruption of his cooperation with Telefunken. After the Second World War Codelli's Turn by Ljubljanica river manor was nationalized. Codelli cautiously retreated to Switzerland before the end of the war. He knew very well where the trouble was and went to Switzerland in time to find his last rest. On 26 April 1954 he died in Port Roncas (Porto Ronco) near Ascona, where he was also buried.

In December 1995, a memorial plaque was unveiled at former A. Codelli's Manor-Castle in Kodeljevo part of Ljubljana. Codelli's achievements have been celebrated. The car enthusiasts provided a memorial plaque in front of his former castle. A memorial plaque was put at his former Manor Castle on Kodeljevo, which presents to the passers-by all about the first motorist in that part of Europe.

27.6.16 Slovenian Television before and After World War II

Codelli's spiral scan was never used on a larger scale and may still be waiting for its innovator. The development of television technique was booming after the Second World War. The Slovenians were well prepared for it. In 1937, a simple experiment with television was made in the first natural science circle in Slovenia at the 1st National Real Grammar School in Ljubljana. Eighth grade students Drago Leskovšek and the descendant of local noble family R. Švajgar made a cathode ray vacuum tube from the Erlenmeyer flask about 30 cm in length. On the bottom they applied ZnO. In the workshop of Arnold Zupančič, they brought electrodes into a container and to some extent sucked out the air without reaching a particularly high vacuum. During their demonstration, they used the Nipkow’s disc of their own production and received a lot of approval from the audience, among which were the later leading Slovenian scientists including Ivan Kuščer (Figure 27-24).

Figure 27-24: Invitation to Rasto Švajgar’s lecture on television in 1937.

The development of television technique after the Second World War Slovenia, also in Yugoslavia, was connected with the activity of the Institute (later Industries) for electric wires in Ljubljana, which was officially established in the beginning of 1948. Initially, it was run by German experts, and among others, by my friend Albin Wedam, the organizational and technical director of the TV-lab since the summer of 1949 or 1950. When Wedam authored his very last book in my cooperation he was facing his death very bravely while he narrated: “If they did not save François Mitterrand with the same type of cancer I have, they will not save me either. In the meanwhile, I think that there is error in your part of our book where you published Marconi’s noble title of marquis with capital letter which therefore sound like it was his Christian name!” The pedantic scientist until his very end!

Wedam and his collaborators bought a super-orthicon from RCA and introduced the 625-line system of the German Swiss former ETH student Walter Gerber (* 1902 Bern; † 1986) invented in 1950, otherwise also designed in the Soviet Union. At the exhibition in the TVD Partizan hall on Tabor in Ljubljana Wedam and his assistants improvised a small TV studio with a super orthicon as the only recording camera in 1953. During the international exhibition of electronics in Ljubljana, Slovenian television program began to be broadcasted from the transmitter at the Economic Exhibition Center (Gospodarsko Razstavišče) and at Ljubljana castle in August 1956.

28 Major Industrial Uses of Vacuum Technologies - Ion Implantation

28.1 Rutherford's Discovery of Ion Implantation for Transistor

28.1.1 Introduction

The ion implantation belongs to plasma technologies. It enables the controlled installation of impurities in the substrate by electrically accelerating the selected ions. With the acceleration voltage from a few kilovolts to several hundred kilovolts, we change the energy of the implantation and the depth of the implantation. The current in the form of pulses determines the given charge and with it the number of implanted ions (the dose). The doses extend up to 10^{16} cm^{-2} s^{-1} and can be controlled during the procedure.

The essential components of the implanter are the ion source, the mass separator and the deflection mechanism with the target. The ion implantation takes precedence over diffusion processes because it does not pollute the environment, it is useful at a substantially lower substrate temperature (from 20°C to 200°C), and the mass separator allows implantation of the ions of a single element.

Besides the high costs, the defects in the process is undesirable radiant damage, which alters the electrical properties of the substrate and can be partially eliminated by subsequent heating to high temperatures by thermal annealing. Doping in deeper depths is less successful than in thin films below the surface. During implantation and afterwards, the doped ions penetrate deeper than expected due to diffusion and other phenomena.[3041]

Ion implantation enabled the development of semiconductor technology in which the micrometer distances from the 1960s were sharply reduced in the new millennium. Although new surface doping technologies are also being developed to compensate for individual stages of semiconductor processing, ion implantation still has a future. Today, it is also used outside the industry of integrated circuits, where the total financial share of plasma technologies in the production of integrated circuits is about 30%.

The development of ion implantation is particularly interesting, since it has witnessed unusually long delay from its "invention" until the first technological use four decades later. That delay in the 20th century is comparable only to the Einstein theory of stimulated radiation from 1916 and 1917, which also waited four decades for the first masers and lasers. However, Einstein published only a theory and not a useful invention like Rutherford did with his ion implantation. Certainly, Tesla's coil is waiting for its greater technological uses besides vacuum system leak detectors already for 130 years.

28.1.2 Rutherford's Era

During almost nine years before his premature death Maxwell was employed as the first professor of experimental physics and director of Cavendish laboratories of the University of Cambridge. His successors John Rayleigh, JJ Thomson and Rutherford developed those laboratories into the most important center of particle-dynamic tradition.

Helmholtz, like Kelvin and many others of their over-proud generation, promoted the funny thought that the main physical discoveries are already completed. So, they expected just more precise experimental results from their younger physicists of new generations. Such funny idea may have occurred in Helmholtz's age of vanity, but it was soon totally out of tune, because the new X-rays, radioactivity and quantum theory emerged immediately on their ways to hitherto unknown. The oversimplification of Helmholtz and Kelvin provoked the reaction of new rebel generation of Kiwi British immigrant Rutherford, as it always happens in such cases.

As a leading experimental researcher of dynamics of particles, Rutherford in Cavendish laboratories again played Galilean role of Damocles sword, or of Occam's razor. His opinion was decisive for quarrels between theorists on the eve of a new revolution in physics. Rutherford's times were clearly different, so there was no talk about the process of Galileo as it sadly happened in 1633:

[3041] Ryssel, Ruge, 1986, 1–2; Dresselhaus, Kalish, 1992, 31.

there was no church strong enough to make it happen. Almost three centuries after Galileo's misfortune the tall Kiwi native Rutherford was even promoted to the rank of first Baron of Nelson.

Galileo demonstrated his modernized attempts for innovations by experimenting mainly because he run out of any decisive logical arguments against peripatetic Aristotelians, but in Rutherford's times the experimental evidence was considered just as good or even better than theory. Rutherford, of course, mostly carried out real experiments and not the thought experiments of Galileo's, Bohr's or Einstein's preferences.

The supposed uselessness of their own theories described by famous mathematician Godfrey Harold Hardy and others in Rutherford's Cambridge was their great pride. Similarly, on the eve of Nazis' takeover in 1933, Hardy's five years younger Cambridge colleague Rutherford ensured everybody that nuclear energy will never be ready for any release; this was one of his rare scientific misleads, as Fermi showed nine years later when Rutherford was no longer in this world to object.

28.1.3 Electrified Particles in Solid Matter: "Cathode Rays" of Helmholtz Pupils

The Germans published the first studies of the transfer of charged particles through a solid substance. In 1882, Goldstein in Berlin proved that the "cathode rays" are diffusely reflected ~~back~~ during their passage through a lightly thin layer of metal. Nine years later, Hertz in Bonn continued to explore the scattering of "cathode rays". He noticed that the metal was more penetrable for "cathode rays" than for the light. The "cathode ray" could have penetrated a thin layer of metal, which previously known rays could not. He covered a part of the plate made of glass enriched with uranium compounds with a thin layer of gold while he covered the other part with a mica. He placed the glass plate in the cathode ray tube so that the side coated with gold was facing the cathode was. He observed luminescence on a part of the glass covered with gold, but not on other past covered with a mica. Two or three layers of golden leaves did not prevent the luminescence. The cathode rays also penetrated through the leaves of silver, aluminium, lead alloys with gold, silver, zinc or copper. The layers of copper, silver or platinum, sputtered in a vacuum after discharge also did not stop the cathode rays.[3042]

After Hertz's death, his assistant Lenard continued his measurements of the reach and scattering of "cathode rays" in solid substances. Lenard used 2.65 mm thick aluminium sheets and studied gold, silver, copper, paper, glass and mica. For all measurements, the absorption of "cathode rays" was approximately proportional to the density of the substance. In 1898, Lenard passed the cathode rays through an aluminium window with a thickness of 3 mm and a diameter of 1.8 mm at a pressure of 30 mPa, thus observing the penetration of charged particles through a solid.[3043]

During the experiments with "cathode rays" outside the "Lenard's" cathode ray tube, after passing through thin metal sheets, many important phenomena were discovered within a few years, among them X-rays in 1895 and soon afterwards an electron was proclaimed after experimenting with the similar tools. By the middle of the 20th century, the researchers were mainly interested in the properties of missiles while they cared much less about the changes caused by their flight or by their implantation in the target. The exception was Lenard himself; his exploring of the target, and not just missiles, may have been one of the reasons why the "cream" of discoveries of X-rays, electrons and photons was picked up by others, although Lenard was considered the most important connoisseur of "cathode rays."

28.1.4 Montreal and Paris: Ion Implantation Follows Absorption of α-rays (1905-1906)

The development of physics at the transition to the 20th century was marked by thoughts about the composition of the atom and the discovery of various rays and particles. Among numerous novelties, Rutherford chose rays α for his research path at the end of the 19th century. He published about them 50 out of total of his 130 most important works between 1895 and 1914.[3044] In 1905 and 1906 in Montreal, he studied the reduction of the rate of light passing through the

[3042] Hertz, 1895, 355; Frisch, 1972, 55; Laue, 1969, 310–311; Anderson, 1968, 48–49.
[3043] Lenard, 1905, 369, 378, 386, 391, 558–559 .
[3044] Vjalcev, 1981, 218–219.

substance. After 1909, he proved in Manchester that the α particles are helium ions. Between 1909 and 1914, he experimented to confirm the model of the atom with a small "center charge", which he called "the nucleus" a year or two after his discovery. Rutherford's description of the absorption of α-rays was opposed by Becquerel and by J.J. Thomson's model of atom. Both opponents were awarded the Nobel Prize in Physics, and Rutherford received his Nobel Prize in Chemistry.

The "discovery" of ion implantation occurred during a dispute between researchers in Paris and Montreal about the nature of the α-rays. In 1898, Rutherford observed the absorption of rays from uranium in aluminium sheets of various thicknesses in his first independent investigations after arriving in Montreal. He found that absorption dropped significantly at thicknesses of several hundredths of a millimeter and then again at thicknesses of a few inches. He therefore assumed that he observed the rays of two species. Immediately after the new year, he announced that he was dealing with the rays α and with the rays β. The later should be like X-rays, while the first resembled their secondary, softer radiation. The assumption of the wave nature of radioactive rays was perhaps unusual in view of the strong tradition of particle defenders in Cavendish.

In March 1899 in Paris, Becquerel accepted Rutherford's observation; but Rutherford's explanations only reigned for a year until the Curie spouses separated both types of radiation from a stronger polonium with a magnet. Until 1902/1903 most researchers were convinced that the β-rays were electrons. In 1900, they announced that the rays α did not spread after the transition through metal, which in the following years sparked a lively discussion between Parisian and Montreal erudite. The Curie couple, together with Becquerel, separated both types of rays by deflection in magnetic field, and Rutherford distinguished among them by their different absorption in the metallic sheets. The approaches of the Parisian literati and Kiwi-English-Canadian researchers in predominantly French Montreal were again directly opposite. They repeated a couple of years older antagonism when J. J. Thomson "discovered" the nature of "cathode rays" with their deflection in the magnetic field which Villard in Paris considered as a secondary property while Villard himself mostly explored their chemical effects.[3045]

Rutherford's friend, former J. J. Thomson's student Bragg of the University of Adelaide in Australia, entered the world of experimental research in 1904 with the theory of absorption of α-rays and the description of their ionization in the air. In Bragg's letter of 31 August 1904, Rutherford read for the first time a description of an "open" atom with a lot of empty space.[3046] Thus, Bragg encouraged Rutherford's research of the penetration of the rays α and the nuclear model of the atom.

Ernest Rutherford was born in New Zealand in a family of collier and his wife a former teacher. As a 11-year-old boy, he learned science from book Outlines of Physics of Stewart whose chair in Manchester he took over a quarter of a century later. Rutherford studied at Canterbury University, founded in Christchurch in 1873. After the master's degree in 1893, he was not particularly successful as a secondary school teacher. He made up a detector to catch radio waves at distance of 3 km, which was at that time a record achievement. His experiments opened the way to his research fellowship of the Royal Commission for the Exhibition of 1851, which was first offered to a year older Rutherford's colleague chemist James The Scotsman Maclaurin (1864 Unst the northernmost of the Shetland islands in Scotland-1939 Wellington) of Auckland University College who declined it for family reasons, in fact because he wished to retain his position in Auckland. Thus, in 1895, Rutherford went to Cambridge, where they only then begin to award research degrees like universities in Berlin, Glasgow and elsewhere. On his way he stopped to see Bragg in Australia. Rutherford became the first research assistant to J. J. Thomson. Thomson correctly assessed the high potential of his new colleague and already in 1896 invited him to participate in the BAAS meeting on the translation of electricity in gases. Thomson and Rutherford were very different. Thomson studied the β-rays with the greatest successes, while Rutherford studied the α-rays[3047] for nearly four decades. Both had a very personal relationship with their investigated "corpuscles", which was preserved

[3045] Lelong,, 1997, 102.
[3046] Rutherford, 1906, 135, 143; Danin, 1983, 40.

in many funny stories. However, colleagues preferred to see that Thomson did not use laboratory equipment. His clumsiness was already quite legendary, almost comparable to that of Pauli, who was reportedly destroying experiments at the distance from several meters.[3048] Rutherford was a skillful man. Later as head of the laboratory, visited researchers several times a day and has reprimanded them for inefficiency and slowness. He had twice briefly met a plumber whom Rutherford mistakenly took for one of his "boys". The plumber was upset and refused to finish his work.[3049]

Ernest Rutherford (* 1871; † 1937)

In September 1898 and June 1907, Rutherford went to Canada as a professor of McGill University of Montreal and head of a laboratory there, which was financially supported by Sir William Christopher Macdonald's (1831-1917 Montreal) tobacco industry founded in 1858. In 1899 Rutherford discovered a new element radiumto study its rays β and α. For radioactive noble gases, he used the term "emanation" from Robert Boyle's vocabulary because he did not know whether he was dealing with gases, steams, or particles. In 1905 he became Fellow of the RS. By 1919, he taught at the University of Victoria in Manchester, which developed from Owens College, established in 1846. Physics was once taught there by Dalton and Joule, who was Dalton's student from 1835 to April 1837. From 1870 until his death Stewart lectured there along with the famous spectroscopist Henry Roscoe and Schuster. Reynolds taught technic in Manchester there between 1868 and 1905. The college developed a physical laboratory in 1900 and became an independent university three years later.[3050]

In 1908, Rutherford received the Nobel Prize in Chemistry for his exploration of radioactivity, which began to undermine the ancient idea of the indivisibility of atoms. In a party after the Nobel Prize-winning lecture, Rutherford declared that "I had already dealt with many different conversions with different periods, but among all the fastest is my own instant conversion from physicist to chemist." On the news about the Nobel Prize, his mother, one of the first female teachers in New Zealand, congratulated him in her letter and expressed her hope that he would come home to help dig potatoes anyway. She therefore quickly forgot that her son had shown her "the last potato that he dug" years ago when she told him about his receipt of a research fellowship of the Royal Commission for the Exhibition of 1851 during their work in the garden.[3051]

In 1914, Rutherford discovered the proton and he was knighted. In 1917 he studied ultrasound for the needs of the army, along with his former colleague in Cavendish Langevin whose previous student was a later inventor of the television Zworykin at Collège de France. In 1919, Rutherford succeeded Thomson as the head of Cavendish. In 1925, he became president of the RI, and in 1931 he was named Lord Nelson after a town in New Zealand where he attended secondary school. Rutherford's book Radioactivity repeatedly received new chapters after the first printing of 1904 and influenced a whole generation of experimental physicists. Neary a dozen Rutherford's pupils and colleagues received their Nobel Prizes, among them many foreigners including Germans, Russians and the inhabitants of the Habsburg Monarchy.

In July 1905, Rutherford published measurements of the decrease in the rate of rays α during their passage through the substance (Figure 28-1). When their initial velocity on their way through the aluminium leaves dropped to around 60%, they could no longer influence the photo plate or ionize

the gas. The results supported Bragg's theory of absorption and the conclusion that "radium emits four types of rays α with different penetrating powers"; they were subsequently explained by the fine structure of the spectrum of rays α, or by the radiation of the ^{226}Ra daughter nuclide of the radioactive decay chain.[3052]

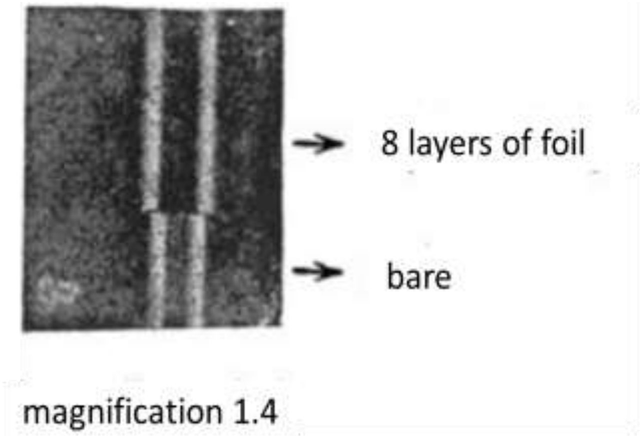

Figure 28-1: Rutherford's photo of α-particles taken in a vacuum, after half of them reached the photo plate through eight aluminium leaves, while the other half felt there on that same photo plate without intermediate obstacles.[3053]

Rutherford's results contradicted the research of H. Becquerel, who measured the magnetic deflections of α rays at a normal pressure recorded on the photographic plate in 1903. He found that the twice stronger field does not move the traces of rays α in the photo. Becquerel therefore claimed that the source is homogeneous and radiates only the α rays of the same velocities. The radius of deflection was increasing with distance from the source. H. Becquerel explained that fact with the assumption that the mass of rays α increases with the distance due to the "added particles from the air." Similar ideas were published at the turn of the century by Curie, Crookes, Kelvin and Perrin,[3054] but from a modern point of view they sound quite unusual which enabled Rutherford to effectively reject them. Probably, Becquerel had in mind a kind of cosmical radiation which was researched in more details only by Victor Franz Hess's (1883 Waldstein castle in Styrian Peggau-1964 Mount Vernon suburb of New York) balloons in 1911-1913.

Antoine Henri Becquerel was the son of the president of the Parisian Academy as the third generation of the famous family of physicists and chemists. In 1874 he completed the Polytechnic of Paris. He was appointed a lecturer there two years later, and he became a professor in 1895. In 1892, he succeeded his father's job at Muséum d'Histoire Naturelle in Paris, along with excellent preparations of uranium compounds stained in glass, which were waiting for their researcher. On March 1, 1896, he discovered the rays, which many, including J. J. Thomson, called "Becquerel's rays". At first, Becquerel thought he was observing luminescence in the X-ray range, supported by Thomson's research in 1896. In January 1899 Rutherford declared them as new types of rays α and β.[3055] Becquerel's discovery was later called radioactivity, and in 1903 he received the Nobel Prize in Physics together with the Curie spouses. In 1900 he measured the e/m ratio of the β rays and found that it is the same as in the three-year-old Thomson's measurements of "cathode rays". On 16 November 1908 he became the permanent secretary of the Parisian Academy. On 11. 9. 1905, H. Becquerel repeated Rutherford's measurements of absorption of rays after their transition through the aluminium sheets. In contrast to Rutherford, he has measured at atmospheric pressure and not in a vacuum and he included a magnetic field. Like Rutherford, he used barriers from aluminium leaves down to a thickness of 0.034 mm, in a distance of a few millimeters from the photographic plate. Photographs of the α-rays after passing through the aluminium sheets could not be distinguished separated from others to which the rays approached only through the air. Therefore, he considered that Rutherford noticed the absorption of rays due to the specificity of the radium which he used. Becquerel easily afforded this sort of critique because of course he had much better radium and its salts in his disposal. Rutherford only used radium from 1 mg sample of his pure $RaCl_2$, which the Parisian Societé Centrale des Produits Chimiques donated to him. Becquerel again rejected Bragg's and Rutherford's theory of the absorption of α-rays in matter. The Parisian Becquerel like Nollet a century and a half before him refused the strange ideas from the wild new worlds of America, Australia and New Zealand under the pens of Franklin, Bragg and

[3052] Rutherford, 1906, 11: 166, 171; Rutherford, 1906, 12: 141.

[3055] Feffer, 1989, 18–20.

Rutherford, but ultimately failed. Becquerel thought that all rays had the same velocity that does not change when they penetrate through the substance, while the mass of the rays α "increases in some way while traveling through the air."[3056] The conservation of the mass was put into question, which was at the same time solved by Einstein with his theory of relativity, but only for much faster particles. It was a turning-point full of fascinating novelties when the impossible theories became probable, and the unusual experiments were decisive.

On 15. 11. 1905 Rutherford again reported from Montreal about his bombarding of the aluminium leaf with the α-particles. Of course, he did not dare to challenge the measurements of his more famous Parisian colleague and Nobel laureate. Therefore, he preferred to acknowledge their validity and explained the results boldly in favor of his and Bragg's theory. He used the aluminium sheets of a thickness of 3.1 μm and a constant magnetic field, which he periodically turned. By adding aluminium sheets, he increased the distance between the lines on the half of the photographic plate and the lines on the other half of the panel, which the rays reached without obstacles. With thirteen aluminium sheets, he reduced the beam speed to 62% and disabled their record on the photo plate.

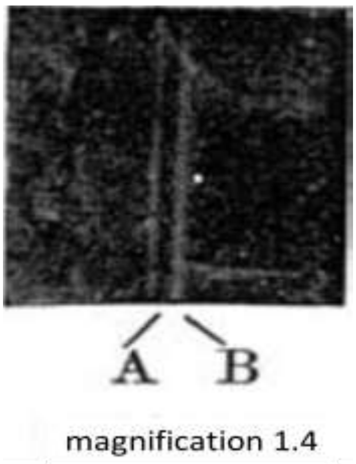

Figure 28-2: Rutherford's α rays from pure RaCl2 on a 4 cm distant photo plate in a vacuum.[3057] He used a weak magnetic field to deflect the β rays, but that field did not deflect α rays.

In next series of his measurements, Rutherford used a measuring device like Becquerel's. He split his photo plate into two halves with a mica screen. He covered one half with eight aluminium sheets. A higher diffraction of the rays α after passage through the aluminium sheet was clearly visible in the photograph, although Rutherford had some problems in excessive acceleration voltages due to the sputtering of the black layer from the copper conductor, which slightly reduced the beam velocity.

Rutherford recorded the α-rays of pure $RaCl_2$ at a 4 cm distant photo plate in a vacuum. He used a weak magnetic field that deflected the rays β, but not the rays α (Figure 28-2). His magnetic field did not change by more than 0.5% during the experiment. After passing through the aluminium sheets, the rays recorded themselves on the photo with 1.9 times wider lines that rays flying through the vacuum. The broadening of the lines already supported Rutherford's greatest ideas of repulsion from a large "center charge" of atoms. The result of the experiment was supported by the description of the rays α as particles with the same e/m ratios but travelling by different speeds, which enabled their separation in the magnetic field. The measurements were, of course, disturbed by the accompanying β and γ rays with their own contribution to the blackening of the photographic plate. Rutherford explained Becquerel's observations with his and Bragg's theory of absorption. After the passage through the aluminium barrier, only the fastest rays, which are most deflected in the magnetic field, should come to the photographic plate. The same rays were deflected the most without passing through the aluminium barrier. The lines on both halves of the photographic plate, separated by the mica screen, were therefore matched. The finding was valid both in the flight through air and when passing through the vacuum to the other half of the plate. Due to the reduced speed, the inner edge of the trace on photographic plate was moved outwardly. With wide Becquerel's beam, it was hard to notice the shift. Additionally, it was blurred by the scattering of rays on air molecules because Becquerel did not measure in a vacuum. The bearded Parisian Becquerel lost his first game defeated by the Kiwi mustached Rutherford coming out from nowhere of the Oceanian new world.

[3056] Rutherford, 1906, 168–169.
[3057] Rutherford, 1906, fig. 2 of plate IV printed after page 192.

To investigate Becquerel's claim that the radius of curvature of paths of α rays increases with distance from the source, Rutherford additionally measured it at normal pressure (Figure 28-3). After 40 minutes of illumination of the photographic plate, the metal barrier was moved to the other half of the panel and they exhausted the measuring vessel. On the same photo, the trace of rays after passing through a vacuum was plotted with two narrower lines. After the same long flight through the air, the lines were more deflected and wider. A slight shift between the two groups of lines occurred due to the random movement of the plate during the shifting of metal obstacles in the middle of the experiment, probably one of the participants made a careless mistake. At the end of his paper, Rutherford announced similar measurements of scattering on solid substances, which indeed followed.

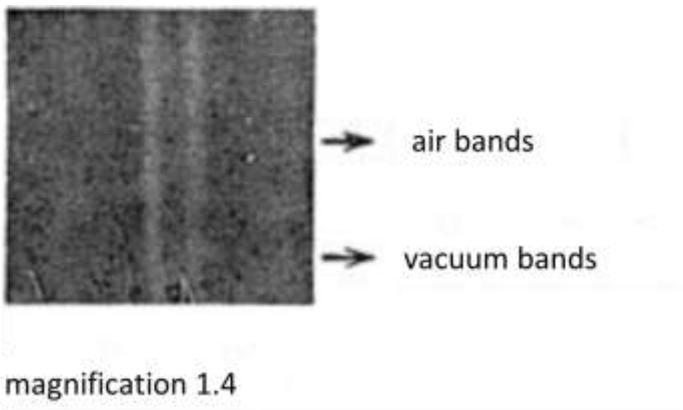

Figure 28-3: Rutherford's photos of α rays at normal pressure in a homogeneous magnetic field. Half of the photographic plate catches the rays after passing through the eight aluminium leaves, while the other half, separated by a mica screen, takes the rays that approach the plate without intermediate obstacles.[3058]

The result contradicted Becquerel's claim about the reduction of the e/m ratio with a distance from the source. This, according to Rutherford, was the result of Becquerel's incorrect assumption about the homogeneity of the α-rays. The radius of curvature of the α-beam at the outer edge of the photographic trace has been rising with distance from the source because only the rays with higher initial velocities approached larger distances. On the inner edge, the opposite was true, since the speed of the fastest rays falls with the distance from the source. The rise in the radius of curvature on the outer edge prevails over the reduction in the radius of curvature at the inner edge of the image. Therefore, the radius of curvature increases, as Becquerel correctly observed.[3059]

His disputes against Becquerel forced Rutherford's high-vacuum measurements that avoided the side effects of the substance. If he had a poorer radioactive pattern than Parisian rivals, he could at least put it in a better vacuum of a container. In the following months, he supplemented his evidence of a constant e/m ratio of α-rays. For rays β, such ratio was measured nearly thirty years earlier by Thomson and after him by Becquerel. Rutherford measured the ratio between the momentum and the electric charge, and between the kinetic energy and the electric charge of α-ray after their passing through a vacuum towards a mica screen. When an aluminium sheet was added to the mice, it absorbed almost twice as much. In all measurements, Rutherford received roughly the same e/m ratio. Although the results seemed too high, he proved with them that he was always observing the same particles. Rutherford's finding of the same e/m ratio for all rays α was the introduction in three years later subsequent proof of their identity with helium ions. Rutherford wished to obtain his own particle like his mentor J.J. Thomson obtained his corpuscle alias electron few years earlier. Becquerel preferred one sole type of radiations which he discovered, but Rutherford was not willing to abandon his hardly received toys although his particles later proved to be "only" the ions of helium and not something completely new as he hoped in secret. Without the kiwi Rutherford's premature death, his WW2 features as Manhattan project boss might have been interesting as he opposed the military uses of airplanes but worked on military detections of enemy's submarines in WW1 anyway.

On 14/06/1906 in Montreal Rutherford reported on the burning of aluminium leaf with α-rays. He also described the radium conductor in the triangular groove of the bronze cylinder, attached to the base plate (Figure 28-4). On one side of the roller he fixed the vertical stick. Two mobile stands were connected through a notch in the middle. The lower one had a slit, and the upper one had a small photographic plate. The distance between the stands could be changed by screws. The gauge was

[3058] Rutherford, January-June 1906, fig. 3 of plate IV printed after page 192.

[3059] Rutherford, 1906, 170–176.

surrounded by a bronze-top closed cylinder whose lower side was connected to the edge of the wheel inserted in the base plate. He sealed his wheel with the ointment used for drills, so that the container could be quickly discharged with Fleuss' pump.

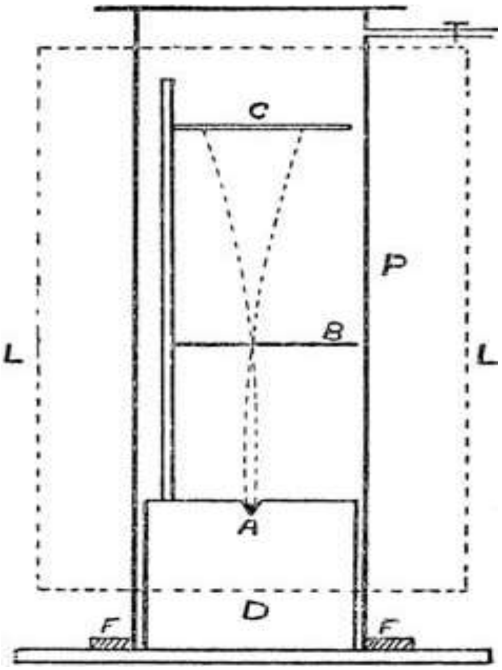

Figure 28-4: Rutherford's measuring device, compiled in Canada in 1906[3060]

Thus, he avoided the flattering of his bronze container when sealing it against the bronze plate and saved time and work, which was very important in experiments with the magnetic beam deflection of α- rays from the radium. He put it all together in a wooden frame between the pole of a large electromagnet with a field parallel to the rays which was practically identical along the path of rays. The area between the radium as the source and the photographic plate was divided into two halves by vertical plates of mica. The first was uncovered or covered with a screen that absorbed as many α-rays as 3.5 cm of air. The other was covered with a different number of aluminium sheets. Thus, on the photographic plate, he obtained two groups of lines with centers, spaced apart for the dual deflection of the ray α of the rectangle due to the influence of the magnetic field. The distance between the deflected lines was inversely proportional to the speed of the rays after passing through the obstacle (Figure 28-5).[3061]

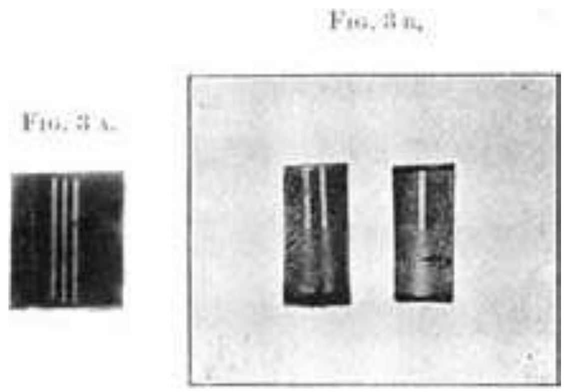

Figure 28-5: Rutherford's α-beam after passing through the mite from 1906[3062]

Rutherford made over hundred photographs showing the effect of the electric and magnetic fields on the α-rays. Initially, photos were observed through a microscope, but that kind of work severely tired the eyes of researchers. That's why Rutherford and his helpers preferred to project a 20 to 40-fold enlarged image on the screen with a lamp resembling their Chinese predecessors' watching pinhole image through their camera obscura two millennia and a half earlier. Rutherford used aluminium leaves that stopped as many α rays as about 5 mm wide layer of air. The distances between the radioactive source and the slit and between the slit and the photo plate were 2 cm, while in their other experiments they shortened them to 0.5 cm and 1.5 cm. In a row, they changed their obstacles that consisted of up to fourteen aluminium sheets. If two more layers of more permeable "Dutch" metals[3063] were added to them, they completely absorbed α rays, just like 7.06 cm of air according to Bragg's exponential law.[3064]

At the beginning of the 20th century, absorption of α-rays in matter was studied mainly in Cavendish, Manchester and Vienna. In 1909, T. S. Taylor of Sloane labs in Yale University measured that the absorption of α-rays in different substances more changes with their speed at greater beam velocity and the greater atomic mass of the substance. He compared the absorption coefficients in hydrogen, aluminium, lead, gold and tin with air. Later in 1912 T. S. Taylor researched on Physics Buildings in Urbana Illinois and collaborated with Marsden in 1913 while Rutherford's golf partner Geoffrey Ingram Taylor (1886 London-1975 Cambridge)

collaborated in Cavendish where in 1910 JJ. Thomson investigated the absorption of α-rays in thin films, and two years later the ionization of matter along the track of the charged particle was studied. Bragg's model of the absorption of α rays in the air was supported by Geiger's measurements of polonium α rays, as well as by Taylor, Francis Lee Friedman (1918 New York-1963 Boston) and Boltzmann's son-in-law L. Flamm in Vienna.[3065]

28.1.5 Rutherford in Manchester: Implanter and Identification of α -rays with He^{++} (1908-1909)

To supplement his small amount of radium of the Parisian Societé Centrale des Produits Chimique, Rutherford later used about 400 mg of radioactive material derived from uranium, which he loaned from the Viennese Academy in January 1908. Similarly, the people of Vienna previously supplied several tons of Czech uranium ore to the Curie spouses in Paris. In fair exchange of those times, the Viennese got some western photographs for studies in their labs.

In August 1908, in addition to photographs Rutherford in his laboratory used an improved spinthariscope,[3066] which Crookes described for the first time on 19 March 1903. Through the microscope they observed the scintillations of the α rays induced on the luminescent ZnS after their passage through the substance. Geiger and Rutherford compiled a particle counter of α particles, which, after subsequent improvements, was named Geiger-Müller. As early as 1893, the Scotsman C. T. Wilson began to develop a cloud chamber named after him which he rearranged to observe the α rays in Cavendish in 1911. Initially they used Töpler's pump, supplemented with graphite in the liquid air. Later, they acquired few Gaede's rotary mercury pumps, but it was difficult to get hold of them because many users in the lab were waiting in the row to get some pumping. Thus, Lenard in Heidelberg had better vacuum pumps than they could afford in Manchester prior to the First World War.[3067]

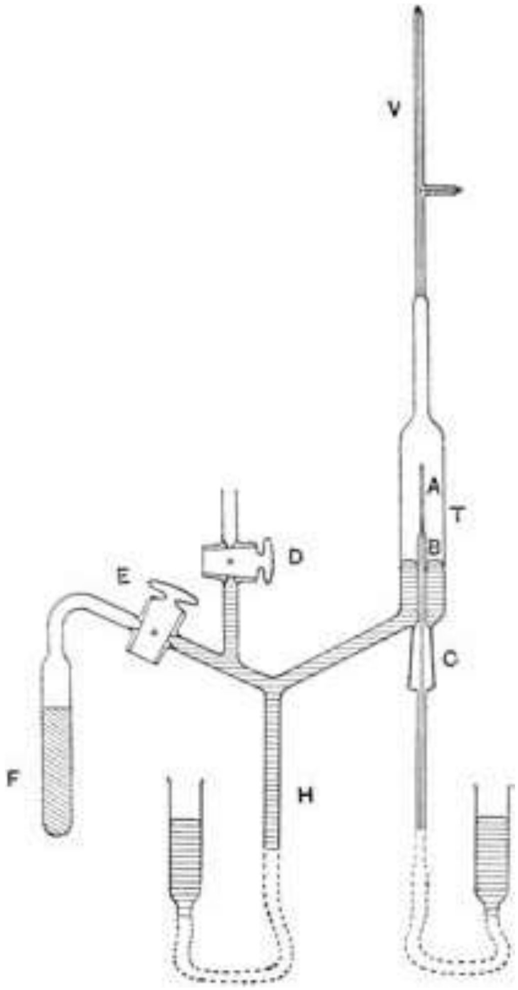

Figure 28-6: The first device for ion implantation according to Rutherford's and Royds' designs[3068]

Rutherford's first ion implantation device was no more complicated than a small glass tube with radioactive radon emitting αrays (Figure 28-6). On 13 November 1908, he described it together with Royds, who, as Geiger, learned all about spectroscopy in Manchester with Rutherford's predecessor, Schuster. They explored the nature of the α-rays in an experiment that Rutherford conceived already in Canada. About 140 mg of radium was cleaned and compressed with a mercury column in a thin glass tube, about a half centimeter long. The German glassblower Otto Baumbach (1882 Niederwilligen in Thuringia-1966 Alkrington, UK) was able to produce glass containers with even thickness of less than 0.01 mm, which was strong enough to withstand mercury pressure. At the same time, it had enough thin walls to stop only as many α-rays as a 2 cm thick layer of air. Thus, most rays escaped from the container towards the luminescent ZnS screen, but at first only up to the distance of 3 cm. After an

[3065] Geiger, 1910, 505.

[3068] Rutherford, 1909, Royds, 282.

hour, luminescence was observed at the distance of 5 cm, since α rays were at a higher speed, while those with lower velocities were mostly emitted within their half-life of 3 minutes. The glass receptacle touched the inner walls of a glass cylinder of 7.5 cm long with a diameter of 1.5 cm, emptied by the pump. They improved their vacuum by a tube full of charcoal cooled in the liquid air. After their flight through the thin wall of the inner glass container the α rays stopped in the walls of the outer glass vessel or on the surface of mercury.

If the α rays were ions of helium, they would gradually diffuse from glass and mercury back into the vacuum. They pushed the gases ensembled above the column of mercury into a vacuumed vessel and examined them there by a spectroscope. After two days, they noticed a characteristic yellow line of helium, after four days the additional green line appeared, and after six days, they observed all the main lines of the helium spectrum. Geiger helped some of those Rutherford and Royds' experiments.[3069]

Rutherford's evidence of the identity of helium ions and α-rays has greatly increased his reputation, because he was supported by Dewar and other older British researchers because the matching between experiments and Rutherford's theoretical predictions is almost wonderful, which confirms the correctness of the theory of radioactive changes for which onset and development he has already done so much. "[3070]

28.1.6 Ruherford's "Center Charge" of Atoms and Scattering of α-rays on Metals (1909-1914)

Rutherford had already seen in Montreal that reflection produces diffuse images of α rays after passing through thin metal sheets. Even at his earliest studies of the scattering of the α rays, he assumed that "some of the α rays in passing through the mica have been deflected from their course through an angle of about (2°). It is possible that some were deflected through a considerably greater angle: but, if so, their photographic action was too weak to detect on the plate... change of direction of 2° in the direction of motion of some of the α particles in passing through thickness of mica (0.003 cm.) would require over that distance an average transverse electric field of about 100 million volts per cm. Such a result brings out clearly the fact that the atoms of matter must be the seat of very intense electrical forces – a deduction in harmony with the electronic theory of matter."[3071] That claim was the outline of the subsequent Rutherford nuclear theory of atoms.

Already in May 1909 in Phil. Mag. Rutherford announced that he "knows what the atoms looked like".[3072] Many researchers, including Lebedev in 22. 1. 1887, Bragg, Nagaoka and Stoney, discussed the nuclear model before Rutherford. Many suggestions followed the discovery of the "electron": JJ Thomson and Larmor (1896), Perrin (1901) with subsequent additions of his compatriot H. Becquerel, Kelvin (1902), Lenard (1903) after half of a century older Dynamides, in the same year again JJ Thomson, and Stark (1907) who already used the idea of quanta. The popularity of the new model with empty space in bulk of the atom[3073] was increasing due to the prevailing experiments with vacuum devices, the similarities with solar system and then authoritarian states circulating around their nuclear leaders.

In the spring of 1909 according to Rutherford's instructions, Marsden and Geiger observed a reflection of one of about 8,000 bombarding α rays from Ra-C'[3074] when passing through a thin layer of platinum. On a gold leaf with thickness of 4 μm, which absorbed as much α rays as the 1.6 mm of air, on average, one of 20,000 α rays was deflected by more than the right angle. They also measured the percentage of reflected rays on the sheets of metals like lead, tin, silver, copper, iron and aluminium. The 20 Mg $RaBr_2$ tube was pumped out to a few mbar and closed with a mica window that absorbed only as many α rays as did 1 cm of air. The deflections greater than 90° were observed with the microscope as scintillations on the ZnS-screen. Except for lead, they confirmed Bragg's theory, according to which absorption on the atom is proportional to the square root of its mass. Thea measured the reflections on various numbers of thin golden sheets with reflectivity equal to 0.4 mm of air. They proved that they were not dealing

with a surface effect but with a bulk-related phenomenon.[3075]

James Arnold Crowther was professor of physics at Reading University southeast of Oxford between 1924 and 1946. From 1936 he was a secretary Physical Institute in London, and from 1946 he was its Vice-President.

The New Zealander born in England **Ernest Marsden** studied in Manchester until 1914. He then returned to New Zealand, where he was a professor in Wellington until 1922, and then worked in the Department of Scientific and Industrial Research until 1954, after 1947 as the president of the New Zealand RS.[3076]

Geiger reported to Rutherford about an unexpected discovery. Half an hour later, Rutherford announced his colleagues at Sunday lunch ~~for~~ the discovery of a "nuclear charge" in the atom. He bombastically described the result at one of his last lectures before his death "It was as if you fired a 15-inch shell (*38-cm bullet*) at a piece of silk paper and it came back and hit you." This was yet another of Rutherford's speeches which made history. In fact, he has been supporting the nuclear model for many years, but he has not been able to effectively prove it with experiments until then. On March 7, 1911, he described it to the Manchester Literary and Philosophical Society, where Dalton reported on the study of masses of "indivisible" atoms a century earlier.[3077] Naturally, Dalton turned over in his grave several times, as Rutherford's powerful voice was announcing a new era where the ancient uncuttable atoms were suddenly cut up. The people were subjected to statistics like atoms even of they retained their private individual complex structures.

In his discussion of the dispersion of α rays and β rays, Rutherford did his best to provide some theoretical computations, although he was not known as a mathematician. He wished to disprove those claims. Next month, the discussion with "Rutherford's equation" was sent to Phil. Mag. He showed that atoms contain the center of a strong electric field. He first considered Thomson's theory of scattering of charged particles on a thin layer of "pudding-atom", in which the mass and charges of both signs were evenly distributed.

Figure 28-7: A page from Rutherford's laboratory logbook, where he sketched the composition of the atom[3078]

Crowther and Marsden experimental measurements of the scattering of rays on the aluminium supported Thomson's model in 1910. Marsden measured on slightly thicker layers. Crowther estimated that the number of electrons was approximately three times greater than the atomic number. From Geiger's and Marsden's measurements of the scattering of the α rays on alloys of platinum and gold it followed that these atoms have at the center about 100 basic charges, almost identical to their atomic mass. Rutherford considered that the same general laws govern the transmission of a beam of α-rays or β-rays through the substance which indicate that the atom has a central charge about the same as its atomic mass allegedly centered at a central point, at least for atoms more massive than aluminium. (Figure 28-7) He has not yet dared to determine the type of charge in the center of the atom. He referred to the

similarity of his assumptions with the "Saturn's" atom of Japanese Nagaoka, published at the Physico-Mathematical Society in Tokyo on December 5, 1903, few weeks before the outbreak of Russo-Japanese war. On 11 March 1911, WH Bragg informed Rutherford about Nagaoka , and nine days later Rutherford already wrote about it to Nagaoka.[3079] Japan entered the world of science as a superpower, and the kiwi Rutherford recognized the Japanese as one of the first.

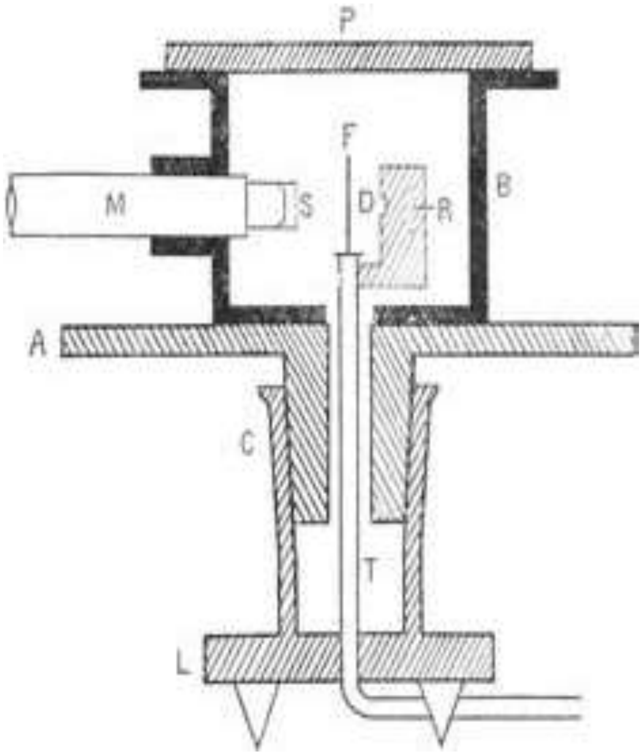

Figure 28-8: Geiger and Marsden's measuring equipment in 1913[3080]

John William Nicholson (* 1 November 1881, Darlington; † 3. 10. 1955) was a physicist, astrophysicist and mathematician. He was chairman of the X-ray Society, vice president of the London Physical Society, the secretary of British Mathematical Association in 1910-1920 and its president in 1920-1930.

Rutherford's colleagues and their experiments did not initially come to terms with the idea of the "center charge" of the atom, most of all not in J.J. Thomson's Cavendish Laboratory.[3081] Rutherford attended the 1st Solvay Congress in Brussels at the end of October 1911, but nobody was interested in the nuclear model there. In 1912 Nicholson tried to describe it with quantum mechanics. In August, Bohr joined Rutherford's laboratory, where he even helped with the measurements. Bohr's model of atom no longer only described radioactivity;[3082] he established himself with a new generation of researchers and encouraged the development of quantum mechanics.

In 1912 C. G. Darwin supplemented Rutherford's scattering theory. He thus endorsed the predictions of his grandfather, CR Darwin, of the billions of years of development of species that Rutherford's theory of radioactivity had just explained.

Thomas D. Royds, like Rutherford (1895), Barkla (1899) and Chadwick (1913), received a research fellowship of the Royal Commission for the Exhibition of 1851, to enable his studies of physics in Manchester at Schuster and Rutherford's labs. On the initiative of Queen Victoria's husband, this most dignified scholarship for graduates of provincial universities in the amount of 150 pounds sterling was given out of a part of the income of the world exhibition in London in 1851. During the WW2, the solar physicist Royds led the observatory in Istanbul while lecturing even in Turkish language.

Next year, Geiger and Marsden continued the measurements by varying the angle of incidence and the speed of the rays (Figure 28-8). They first published the results at the Viennese Academy of Sciences, most of all to express their gratitude for the loaned radium. They used the same source as Rutherford and Royds did four years earlier. The radium was closed into lead to decrease the influence of β-rays. They measured on gold and silver sheets whose absorption was equal to 4.5 mm or 3 mm of air, while their vacuum was improved with graphite cooled in the liquid air. The scattering on thin sheets was proportional to their thickness. They also measured tin, copper, aluminium and charcoal in paraffin wax. The scattering on a 21 μm thick golden sheet at the

distance of 1 cm from the source has confirmed Rutherford's prediction. The "central charges" covered about half of the atomic mass of the substance[3083] which proved to be good guess after later discoveries of neutrons.

In 1913 at the 2nd Solvay Congress Rutherford had already demonstrated the advantages of his description of the atom in his paper scheduled after Thomson's report. The following year he estimated the size of nucleus to be less than 1.7 fm, which was even slightly below then relevant estimate of the size of the electron. He approached the later concept of binding energy or mass defect.[3084]

In 1906, **Hans Wilhelm Geiger** from Neustadt an der-Weinstrasse finished his studies with associate professor Wehnelt in Erlangen. Then he worked with Rutherford for seven years. In 1911, he published a relationship between half-life and energy of α rays. In 1912 he began to run his own laboratory at Physikalisch-Technische Reichsenstalt in Berlin, which was created by Helmholtz and Werner Siemens. In 1925, Geiger proved that energy and motion were maintained at Compton's scattering phenomenon. Between 1925 and 1929 he was a professor at the University of Kiel, until 1936 he taught in Tübingen and then at the Technical University of Berlin.

Upon his return to Manchester, he began to scatter the α rays on lighter nucleuses. Due to the military obligations of national-level collaborators during the First World War, his only help was a laboratory assistant William Kay (1879–1961), who, prior to his arrival in Manchester, had assembled most of the Dewar high pressure appliances in the RI. William Kay had been Chief Steward of the Manchester physics laboratory from 1908 until his retirement in 1946. In December 1917 nitrogen tests led to the first planned nuclear reaction. This was the last Rutherford discovery before going to Cavendish where he retired from ion implantation and began researching the structure of the nucleus.[3085]

28.1.7 Bohr in Manchester and Copenhagen: the Theory of Ion Implantation

In August 1912 and July 1915 Bohr linked the results of Rutherford's laboratorial measurements to a convincing theory where the absorption of α rays in the heaviest elements was determined by the number of electrons in their atoms and with their characteristic frequency. The average absorption of fast particles was supplemented two years later by his investigating of the loss of velocity of individual particles. Bohr noted only the influence of electrons but ignored the nuclei of atoms in his estimation of the decrease in speed or energy loss per unit of the path. The slowing of α rays and other ions in heavier elements was roughly described by the idea that the heavier elements have, along with external electrons with their own natural frequencies in the visible range, also the electrons bind by higher energy with their own natural frequencies in the X-ray range.

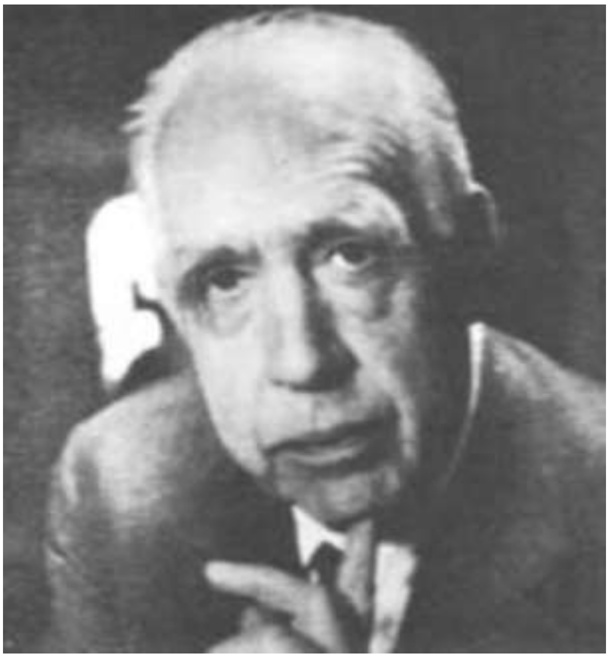
Thomson's theory predicted the correct results, considering secondary ionizations caused by electrons ejected out of atoms. Bohr's work was supplemented by more realistic theories by Rutherford's occasional associates Bethe and Swiss Bloch from the University of Leipzig, later director of CERN. In 1952 Bloch received half of the Nobel Prize in physics for his discovery of nuclear magnetic resonance, and Bethe earned his award two decades later by exploring nuclear reactions in stars.[3086]

After C. Christiansen, Martin Knudsen became the professor physics in Copenhagen in 1912. Therefore, in July 1912 Bohr was left only as a private docent at his Alma Mater. In the autumn of 1914, he took over Darwin's "Schuster" lectures of mathematical physics at Rutherford's Manchester until he got a post of a professor in Copenhagen in the summer of 1916. In the following decades, he developed the most influential physical "school" of his time, which developed the modern quantum mechanics during the World War I which left the Denmark happily neutral. In 1918 he described the principle of correspondence, with which classical mechanics connected with the emerging quantum theory. In 1922, Bohr received the Nobel Prize in physics for exploring the structure of atoms and

[3086] Bohr, 1970, 1: 83, 216, 245–246; Ryssel, Ruge, 1986, 5.

resulting radiation. After the German occupation of Denmark, he fled to England and then to the United States where he decisively helped the production of an atomic bomb. After the war, he returned to Copenhagen as a famous physicist. He was comparable only to Einstein, whom he often opposed in physics, especially for the notion of principle of complementarity developed as Bohr's reaction to Heisenberg's uncertainty principle in February-March 1927, which Bohr publicly described for the first time at the International Physical Congress in the town of Como on the centenary of the death of Alessandro Volta on 16 September 1927.

The son of Jewish mother **Niels Hendrik David Bohr** was born in Copenhagen. He studied physics there, got a master's degree in 1909 and took a doctorate on 13 May 1911. After his PhD, the scholarship enabled his studies at Thomson's Cambridge. Bohr met Rutherford for the first time in October 1911 at an annual dinner in Cavendish, but only a few weeks later he befriended him during Bohr's visit to his father's friend in Manchester.[3087] Since Thomson did not show much interest in the descriptions of atoms that opposed his own, Bohr preferred to go to Manchester in mid-March 1912. There Bohr as theoretician accompanied by the experimental physicist Rutherford created an effective circle of advocates of the nuclear model of the atom. Rutherford's laboratory was constantly checking Bohr's ideas, and Bohr theoretically supported Rutherford's model of atom. Their relationship was spiced up with a lot of humor. Rutherford did not respect the theoreticians. At the end of a Heisenberg's colloquia at Cambridge, Rutherford declared: "We are all much obliged for your exposition of a lot of interesting nonsense, which is most suggestive." Therefore, people were wondering why Rutherford had a totally different attitude to Bohr's theory. An excited athlete and the fan of soccer, Rutherford, came up with the answer: "Bohr - he is completely different, he is a footballer."[3088] Nevertheless, Rutherford disliked uncertainty even in Bohr's interpretations. Bohr delivered first prestigious Memorial Lectures of A.W. The Scotsman, Phillips Professor of physics and mathematics at St David's College, Lampeter in Central Wales. Bohr narrated on the uncertainty principle in Cavendish on April 28-May 2, 1930. Rutherford could not remain without a note: "You know, Bohr, your conclusions seems to me to be as uncertain as the premises upon which they are built."[3089]



Niels Bohr (* 185; † 1962)[3090]

Despite significant achievements, ion bombardment for a long time remained a specially adapted experiment to prove the nuclear model of the atom, and after 1917 to trigger nuclear reactions. Initially, nobody investigated any applicability of the procedure in other fields. They considered it only as laboratory specificity, like half a century before that happened to cathode ray tube and sputtering. Basically, the forces which stopped the ions in matter were investigated while the opinions of Bohr and his Danish counterparts prevailed. In 1948 Bohr described the basics of the transition of ions through the substance. He published a special law on the exchange of energy along the path of the ions and evaluated the gradual reduction in the charge of ions. At the beginning of the transition of ions through the substance, the collisions with electrons are dominant. In the end of the transition of ions through the substance, when the ions are slowing down and mostly losing their charge, the collisions with nucleuses prevail. The equation illustrated the effect of the charge of ion and its velocity on the

number of electrons that the ion captures during its penetration through the substance. Bohr's namesake Dr. Niels Ove Lassen (1914 Hammel-2008) continued Copenhagen investigations with measurements of energy loss of particles formed after the fission of nuclei along their path through argon and other gases. Later, the Danes Jens Lindhard and Morten Scharff (1926 Tibirke 60 kilometres north of Copenhagen-1961 Copenhagen) developed the foundations for understanding the stopping of high and low energy ions while penetrating the substance. Their collaborator Hans E. Schiøtt helped them describe the energy range of ion implantation using real interactions between nucleuses and electrons, which were no longer regarded as free particles. According to the initials of the authors, the theory was named LSS. With precise measurements of ion reach in matter of John A. Davies (1927-2016) of Chalk River Nuclear Labs in collaboration with Aarhus University in Denmark and other followers of Rutherford's work in Canada, the ion implantation techniques developed more rapidly than sputtering of thin films.[3091] The longtime delay in its industrial applications enabled the already prepared mature theory of ion implantations ready for use in techniques, just like the Goddess Athens birth from the forehead of Zeus.

28.1.8 Rutherford's Research Affects the Networks of Slovenians

The physicist Fran Čadež of Carniola, a former Boltzmann's Viennese student, reported on the research of ionized particles in the matter in the Slovene language: "Alfa-rays ... at a small distance of 6-8 cm from the radium already quietly stop in the air. They did not make their short paths unsuccessful. All the air molecules they encountered along their path were split immediately into atoms or ions. A single α-particle disperses in its path over 100,000 molecules into ions. How much greater the influence of all the α-particles must be!"

The Slovenian reader was convinced in the equivalence of helium and α rays, already a year before Rutherford's finally recognized proof, although still somewhat in relation to the obsolete JJ Thomson's assumption of the structure of the atom: "We already asked the question about what are those clusters of electrons that leave individual radium atoms at a speed of 10,000 kilometers per second. We were already discussing these clusters at our notes on α-rays described as positive electric atoms, which are only twice heavier than hydrogen. The chemistry teaches that this weight is unique to atoms of the gas helium. It is then considered that α-rays consist of helium atoms and that there is so much of them accumulated near the radium to enable our investigation. Indeed, it has already been proven in several ways that there is always some helium around the radium..." And later: "Rutherford tested the α-rays' passage through various substances and came to the following view of the composition of atoms: each atom represents a complex, planetary system with central nucleus. It attracts other smallest parts and combines them into the whole atom in the smallest space to rotate around the nucleus as the planet around the sun. Space: macro-cosmos! And by applying electron theory, Rutherford put it that these smallest parts of the atoms are nothing else than electrons - those are the smallest atoms of electricity. Thus, the matter of all bodies is electrically formed: the matter consists of atoms which consist of electrons."

The Slovenian ancestors could read the explanation of new experiments, which later proved inaccurate: "In the most recent times, even a fourth type of rays was discovered as they constantly radiate from the radium. They consist of atoms that fully match α-particles, they differ only in that they are not positively electric as α-particles, but negative. What are their effects, the future will clear up."[3092] The subsequent studies did not confirm the existence of such particles, possibly related to "Goldstein's rays", Righi's electrically neutral "magnetic rays" or Blondlot's "N-rays."[3093]

The Slovenian reader thus followed Rutherford's achievements. In his native language, he could be convinced of the benefits of the nuclear model of the atom: "Rutherford concluded that the helium atom should be the carrier of this positive electricity, and T. Royds confirmed this assumption spectroscopically. α rays are helium atoms, each bearing two elementary quantities...

[3091] Bohr, 1971, 2: 446, 454, 469; Ryssel, Ruge, 1986, 7; Dresselhaus, Kalish, 1992, 35.

[3092] Derganc, 1917, 103; Čadež, 1908, 39, 33, 35.

[3093] Carazza, Kragh, 1990, 12.

Positive electrons cannot be classified in the surface of such a large sphere, but must be concentrated in the minimal space in the so-called atomic nucleus, which is very small, certainly less than 10^{-12} cm, almost 10^{-16} cm in size... The electrons are not enclosed in a positive electric sphere but circulate around a positive nucleus like the planets around the sun." The discoveries, of course, aroused excitement: "What alchemy could not do, radiochemistry is capable today."[3094]

The close cooperation between Viennese and Manchester researchers enabled Slovenian erudite to supplement Rutherford's discoveries. Later Ljubljana professor Sirk was one of the most important researchers of radioactivity in the Habsburgian monarchy. At the Physical Institute in Graz, Sirk also continued Rutherford's research of the radioactivity of thorium. In 1913, Sirk started working at the Viennese Institute for Radium Studies, which, under Stefan Meyer's leadership, worked closely related to Rutherford's laboratory in Manchester between 1910 and 1920. Thus, in 1910 as the Uppsala postgraduate in Vienna, Hans Petterson (Pettersson, 1888–1966) observed the thermal phenomena caused by the β and γ-radiation of the radium. He researched the equilibrium of the ionization flow in parallel with similar research in Manchester. After his transition to the newly established Institute for the Study of the radioactivity in Vienna, on 13 March 1913 Sirk published a discussion on the pressure drop of the pulsating glow discharge under the influence of a transversal magnetic field. He continued the exploration and research of Goldstein (1881), who was the only one dealing with the transfer of particles of gas at glow pulsating discharge, albeit with too few precision devices needed for useful measured data.[3095] In the theoretical part of his discussion, Sirk showed that the average mean free path in the gas is much smaller than the size of the vacuum vessel, which has already been proved by Puluj according to Stefan's theory in contrast to Crookes (1879) and Stokes' opinions.[3096]
During the summer of 1923 and December 1927, there was a sharp exchange of views between Cavendish and Viennese researchers on the measurements of artificial nuclear fission and Rutherford's atomic model. In June 1924 in Vienna, the Swede Hans Petterson (Pettersson) and Gerhard Kirch sent to Rutherford a discussion on their bombarding of charcoal and aluminium with α rays. The results were published two months later at a gathering of German naturalists and doctors in Innsbruck and in Vienna under the title *Über die Reflexion von α-Teilchen an Atomkernen* in 1925. In May and December 1927, Petterson and Chadwick in vain tried to settle down the disputes with the people researching in Vienna by comparing their experimental techniques of their highly personally experiences of counting of scintillations as no instrument was invented for that job as far. The situation resembled Galileo's three centuries earlier experiments using the experienced singers of repeated rhythmical Italian songs as an aid for the measurements of times of accelerated motions when no accurate clocks were available. Pettersson later mostly researched oceanography while Kirch focused his work on geomechanics.

Rutherford worked all the time in collaborations with Viennese physicists. Rutherford sent to Vienna his discussion on the thermal effects of α rays, together with his demonstrator and assistant at the University of Manchester, Robinson. They sent their results to the Viennese Academy in July 1912, which the Viennese published after half of a year. It was only between 1927 and 1933 that Rutherford arranged a payment for the radium rented in 1908, and thus saved the Viennese Institute for the Study of Radium of the severe material shortages. Rutherford's Hungarian associate the Jewish Catholic Hevesy, along with the Jewish Protestant Frederic Paneth (Fritz, 1887 Vienna-1958 Mainz), experimented in Vienna in early 1913. In 1916, Natanson's student the Jewish Pole Stanislaw Loria (1883 Warsaw-1958 London) researched at the Viennese Institute of Radium Studies with experiments like Sirk's. He later worked at Rutherford's labs in Manchester.[3097]

28.1.9 Conclusion

The first uses of ion implantation were associated with various descriptions of the properties of the α radiation at Rutherford and H. Becquerel's networks. Soon the distribution of mass and charge

[3094] Čadež, 1908, 31, 37; Čermelj, 1980, 97, 148, 110.

inside the atom became an apple of dispute, while Rutherford's former teacher, Thomson, turned into Rutherford's main enemy. Thir antagonism illustrated their generation gap and had a significant impact on the early development of quantum mechanics. Four decades after the discovery, ion implantation remained primarily a tool for investigating of the incident and fired particles, but fewer literati researched the targets. They investigated the properties of α rays and radioactive products, and not the changes in the bombarded targets. Thin targets were mostly made of metals, while the development of ion implantation was later mainly associated with semiconductors. Before the Second World War, ion implantation was not used in industry, in complete contradiction with modern developments, when research has shifted from missiles to targets whose properties were changed by implantation. And the last became the first, just like in the Bible.

28.2 Discovery and Development of Transistor

28.2.1 Introduction

In 1998, the transistor met Abraham as it turned fifty. We do not know why Abraham's famous birthday is put right in the fifties, but it's nice to remember interesting stories. Perhaps no discovery in physics has ever so rapidly affected human life as did a transistor. That's why its discoverers were awarded the Nobel Prize in 1956, the first one granted for an engineering device after the fifty years of waiting. The transistor was not the result of a planned experiment but emerged from a broad program of co-investigating scientists. In addition to physicists, experts in electronics, physical chemistry and metallurgy were also involved in the discovery.

28.2.2 The Discovery of Silicon and Germanium

Gay-Lussac and Tenar researched their first silicon in 1811. Its elementary nature was proven dozen years later by the Swede Berzelius, who obtained it from silicon fluoride. On 17 February 1869 Mendeleyev classified silicon into his periodic system. Beside it, he also envisioned "eka-silicon". Its properties were announced at a meeting of the Russian Physical Society on December 3, 1870. Mendeleyev tried to extract a new element from titanium and zirconium compounds between early December 1870 and mid-December 1871. He reported to German chemist Erlenmeyer during his survey. A similar element was considered by the Englishman Newlands in his periodic table of 1864, but he did not have a real echo. In 1886, "Eka-silicon" was discovered by professor of technical chemistry at the Royal Academy in Freiburg in Saxony, Winkler. He obtained it by analyzing the argyrodite mineral, which was found in a mine near Freiburg by Ludwig Julius Weisbach, a professor of mineralogy at the same Freiburg Academy. In February 1886, that new element named germanium was reported to the German Chemical Society and the discovery supported Mendeleyev's predictions and notifications.

28.2.3 Early Semiconductor Research

The semiconductors caught Faraday's attention on April 15, 1833. Contrary to the conductivity of metals such as described Davy in 1821, the Ag_2S conductivity increased with increasing temperature: If a 1 cm thick piece of Ag_2S (sulfuret) is placed on the surface of the platinum between the poles of the voltaic battery with twenty pairs of plates 10 cm wide, the galvanometer needle will only be slightly deflected in its circuit due to the small conductivity of Ag_2S. When we press with fingers the platinum to the sulfide, the conductivity will increase due to heating. With the heat of the lamp under the sulfide, the conductivity increases rapidly, but finally the galvanometer jumps into the permanent position and Ag_2S starts translating just like metal. After the lamp is moved away, the phenomena are followed in the opposite order... Except for the hot Ag_2S, I do not know any other substances that could be compared with the metals in the translation of low-voltage electricity, but when they cool down they lose this ability, while metals, on the contrary, are gaining it. We will probably find many more of these substances when we search for them..." In December 1838, Faraday fulfilled his forecast and continued the measurements on other semiconductors, especially on lead fluoride. Today we know that Faraday erroneously represented the translation of electricity in all substances in the same way; he distinguished only the magnitude of the conductivity of individual substances, while Faraday's mechanisms of translation seemed to be unitary.[3098]

28.2.4 *Stefan-Braun's Discovery of a Potential Barrier in a Crystal Diodes (Detectors)*

In 1865 the Slovenian Stefan discovered strong thermoelectric voltages between the karst pyrites and the Lead (II) oxide PbO in its tetragonal crystal structure (litharge). In a short preliminary notice on the course of his research, he described the combinations of some sulfur ores with an unusually higher thermoelectric voltages compared to the combinations of pure metals. He presented thermocouples that greatly outperformed the Sb-Bi thermocouple. He measured fourteen different pairs of substances with Daniel's galvanic battery, while some measurements with copper were already performed by Bunsen. In 1857 and 1865, the Jewish assistant working for Stefan and Stefan's mentor physiologist Karl Ludwig as technician in the Physical Institute of the Medical School Siegfried Samuel Marcus (1831 Malchin in northern Germany-1898 Vienna) described his constructions of thermocouple. The design endorsed by the Parisian Academy, and his work was subsequently continued by E. Becquerel with measurements of CuS between 300°C and 400°C with Daniel's battery. Marcus also first used petrol to propel a vehicle in the simple handcart of 1864. In 1865 just before Stefan's report Marcus published his paper Ueber eine neue Thermosäule at the journal of Viennese academy.[3099]

Stefan's research of translation in semiconductors was just a prelude to his much more famous main topics focussed on translation through gases crowned with his measurements with diathermometer for the development of vacuum insulation in 1870s. Karl Ferdinand Braun followed the same path as his research of translation in semiconductors in 1870s became just another prelude to his much more famous cathode ray tube of 1890s. The research of solids was not of primary concern in the era after the spring of nation of 1848 when even the kinetic theory itself relied on gaseous examples. No matter how industry might have needed the more profound research of solid state material and its uses, academic research of those times could not prosper much in solid state topics while everybody was interested in gases even if Stefan loved to use for them his hydrodynamic analogies. The main topic of condensed matter physics called solid state physics as the basis of material science emerged as a separate field of solid-state physics only in the 1940s with the establishment of the Division of Solid State Physics (DSSP) within the American Physical Society. In the times of Stefan and Braun the researches of solid states were only sporadic until the great attention was focused of liquefaction and solidification of "permanent" gases and the phase transitions involved.

Almost ten years passed until Karl Ferdinand Braun continued Stefan's measurements with a discovery of the potential barrier which directs the translation in semiconductor crystals. Braun discovered rectification in metal–sulfide semiconductor contacts. He began his measurements as Quincke's assistant in Würzburg, since he published the first discussion on 23 November 1874, only two months after moving to the Grammar School St. Thomas in Leipzig, where he used crystals from a Grammar School (gymnasium) collection. Braun measured the contact between a silver conductor and a semiconductor crystal. He was aware that such an experiment with at least one small electrode was the most suitable for observation. The first of six Braun's publications on electrical conductivity of semiconductors in Ann. Phys. showed the limited value of Ohm's law, which he tried to complement with the constant and the factor depending on the square of the electric current. In the measurements, he used eight Grove's elements. He quoted Hittorf's measurements and extensive Herwig's study of the conductivity of iron and steel, but he probably did not know Stefan's work.[3100]

Without any persuasive theory, the research of 24-year-old Braun did not get any good reputation. His experimental technique was so demanding that the French mineralogist Henri Dufet announced after unsuccessful experiments on pyrite that Braun had made a mistake. WG Adams and RE Day in England, and EW Siemens in Germany, when

[3100] Braun, 1874, 561, 562.

researching the influences impacts of light on electrical properties of selenium also faced difficulties in obtaining unequivocal, reproducible results.

In 1875 Braun presented his discovery in front of a Naturalists Association in Leipzig, where among his listeners were a former Magnus' student, professor of Physical Chemistry GH Wiedemann, and Wilhelm Hankel as a professor of physics and researcher of electrical properties of crystals. At the end of the lecture, Braun successfully demonstrated the deviation from Ohm's law at the measurement of brown manganese, which was not sulfide, and PbS. The deflection of the galvanometer depended on the direction of the current. He explained that Dufet did not get the expected results because he used a contact of the same size. One contact should be formed in a thin tip, which Braun did not emphasize enough in his first discourse in 1874. Instead of general theory, Braun offered only clever guesses. He assumed that a thin surface layer would direct the electric current to a point electrode. The current remained the same if it ran across the crystal to a single electrode or a pair of electrodes. If the phenomenon concerned the total volume of the crystal, the current should be half as low as the experiment with two electrodes.

Braun pointed out that the rectifying also occurs when the current flows only for 1/500 s. That was too little for the warming, which, according to E. W. Siemens, would have caused Braun's results. Thus, Braun attributed to the discovery of two fundamental properties of a later transistor, in which the changes occur in a superficial layer at a high speed.[3101]

In his last discussion about the semiconductors in 1878, Braun used a plate of dimension 8 mm × 35 mm × 20 mm from psilomelane (hard black manganese oxide).[3102] For contact, he made a metal clamp which he strongly tightened to the psilomelane plate that he insulated with paper. Only a peak of a clamp made of platinum 3 mm long and 2 mm thick with its semicircular tip was touching the minerals.

The platinum is softer than psilomelane, so, when Braun tightening it, it caused a stain measuring 1/3 mm^2, which Braun observed under a microscope. The stain could not be scratched away with paper or smooth steel but could be removed only together with neighboring fragments of psilomelane. The pressure of the ambient air did not influence the measurement, and the electrolytic effects did not cause change in resistance. Hittorf studied Ag_2S likewise. Obviously, that Braun's stain had some similarities with stains obtained by sputtering.

Braun searched for the analogy between translations in semiconductors and translations in gases, which was also dependent on the direction of flow under certain conditions. Because the gases were still the main topics of research of physics of those times, every aspect of physics had to be comparted to the phenomena in gases to make it a part of mainstream. Braun measured the resistance to the current e with a differential galvanometer on a plate with five contact screws. The resistance in psilomelane was different in opposite directions, like that of the Geissler tubes with funnel valves. Three quarters of a century later Shockley shared the same Braun's opinion while Barden view was the opposite.

Braun also measured the dependence of the distribution of fluxes from the magnetic force at his psilomelane. He wondered if resistance was a property of a current of charges or could it possibly be a property of molecules of matter? Does the variable induction current through the substance change at the same time the resistance compared to its value of at a constant flow, or the discharge method have no effect? Braun tried to confirm the second claim.

Maxwell's assistant at Cavendish Laboratories in Cambridge Schuster measured the contacts between his purified and then then oxidized copper conductors and sulphides. His English results deeply resembled Braun's German claims[3103] on behalf of French ideas. The dissymmetry (asymmetry) was slowly penetrating into physics and related fields from crystal optics of Malus, Haüy and Biot. In 1820 and 1827 Sir John Frederick William Herschel (1792-1871) offered dissymmetry as the explanation of Biot's optical experiments while Louis Pasteur offered to Biot his chiral molecules of recrystallised salt of tartaric acid with two kinds of small crystals that were mirror images of each other in 1848.

As Herschel and Hanoverian dynasty before him, their fellow compatriot German Schuster also proved to be a blessing for Brits. The German **Arthur Schuster** was born in Frankfurt on Main in a rich Jewish family which was dealing with textiles. When Frankfurt was annexed to Prussia in 1879, the family moved together with their companies to Manchester where Engels also concentrated his business. The physics became passion of Arthur Schuster after his reading of spectral analysis textbook of Henry Roscoe who, together with Stewart, later taught at the University of Manchester. In 1872, Stewart highly estimated Schuster's research of the nitrogen spectrum. Roscoe enabled Schuster's doctoral studies at Kirchhoff and Bunsen's Heidelberg, where Schuster e completed his Ph.D. in 1873. In the summer of 1874 in Göttingen, he assisted Weber's testing Ohm's law for AC currents of high frequency known as "unilateral" conductivity by which current can flow in one direction only. Schuster also worked for some time with Helmholtz in Berlin, where his peer Goldstein then studied discharges in the cathode ray tubes. Schuster discovered the "Schuster phenomenon", where the electrical current from the rotating magnet constantly increases the average deflection of the pointer of the galvanometer. Therefore, he announced that the resistance of the wire diminishes by stronger currents at a meeting of the British Association in Belfast in 1874. Maxwell was interested in Schuster's claim, because he did not have a strong theoretical justification for Ohm's law, which was challenged by Schuster's experiments. However, in the spring of 1876, the Cavendish Laboratory found that the "Schuster phenomenon" was only the result of uneven magnetization in the magnet and in the coil. In 1875, Schuster received English citizenship. In October 1877 he started working in Cavendish and in 1884 he was the main competitor of J. J. Thomson for managing Cavendish. In 1881, he became a professor of applied mathematics at the University of Manchester, and in 1887, after Stewart's death, he took over Langworthy's Department of Experimental Physics where he selected Rutherford as his successor twenty years later.[3104] The choice proved to be a good one.

28.2.5 Semiconductor Research before World War II

In 1874 Braun's discovery of crystalline diode began the research of contact potential barriers in which germanium had not yet been used.[3105] As much as thirty years later, contacts of metals and crystals for "detectors" of radio signals were utilized. These early-radio crystal amplifiers were in use even in the 1950s.[3106]

From 1880 to 1884, **Jagadish Chandra Bose** studied in Cambridge with the new director of Cavendish laboratories Rayleigh. From 1885, Bose was a professor in Calcutta, where he investigated the detectors and lectured about them for RI with Rayleigh's recommendations. Bose's mercury detector, reported by Rayleigh in front of the RS on March 6, 1899, was used by Marconi to receive the first transatlantic radio signal on 12 December 1901.

At the dawn of the new century, the India native Bose invented and patented the first crystal detector in the United States (Figure 28-9).[3107] In 1906, the crystal detector was patented by H. H. C. Dunwoody and G. W. Pickard, and independently by the Berlin Telefunken. The metal axis or crystal was attached to the crystals of carborundum (Silicon carbide, SiC), galenite, pyrite, etc. On 5 October 1910 in the US Benjamin Franklin Miessner (1890 Indiana-1976 Miami) patented Braun's electrode with a conductor as a "detector for radio".[3108]
The basics facts about transistors were known at a time when researchers from Shockley's group at Bell Labs were still the teenagers. After the First World War, triodes and other cathode-ray tubes pushed out crystalline detectors of the market. During many decades, the kingdom of cathode ray tubes so sharply embraced all the mainstreams, that any competitive solid-state research looked like a heresy while the semiconductors secretly prepared their comeback. Only a handful of brave researchers were still studied the semiconductors outside mainstream, including the Russian noble without formal academic education Oleg

Vladimirovič Losev (Оле́г Влади́мирович Ло́сев, Lossev, Lossew, 1903 Tver-1942 Leningrad), who built a zincite oscillator between 1919 and 1923 as the precursor of a later tunnel diode. The Habsburgian Jew Lilienfeld was a professor of physics at the University of Leipzig between 1910 and 1926; he published a study on field electron emission in vacuum in 1920. He continued his research of vacuum cathode ray tube with his studies of solid matter. After emigrating to the United States, he was director of research at Ergon Research Laboratory in Malden, Maryland. Between 8 October 1926 and 1932, he filed and obtained three patents for the basics of a transistor with a field effect (metal - oxide - semiconductor, MOSFET).[3109] He suggested using CuS, but it is not known that he ever designed a functioning transistor amplifier. In 1935, he became a citizen of the United States.

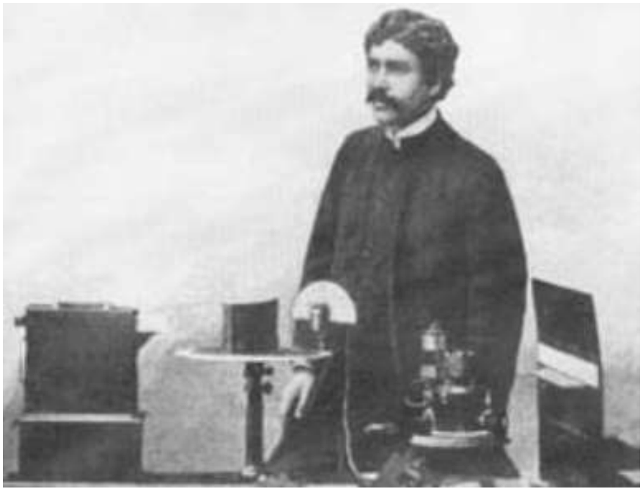

Figure 28-9: Bose with a first patent of a semiconductor device in the world on 30. 9. 1901[3110]

In 1935 the German Oskar Heil (1908 Langwieden in western Germany-1994, San Mateo, California) in Britain filed a patent describing the operation of the MOSFET using modern theory of electrons and holes (gaps) developed by A. H. Wilson in Cambridge in 1931. Heil described both the n-type and the p-type in the tellurium, iodine, Cu_2O, and V_2O_5. Heil in fact produced the precursor to the modern FET, while C. Zener designed diode named by him. In 1935 Heil and his wife a promising young Russian physicist Agnesa Arsenjewa (Агнесса Николаевна Арсеньева, 1901–1991) in their pioneering German paper developed the concept of the velocity-modulated tube, in which a beam of electrons could generate with reasonable efficiency radio waves of considerably higher frequency and power than with conventional vacuum tubes/thermionic valves. "Heil tube" became the first practical microwave generator.

Around 1935, electric switches of valves with copper or selenium oxides were developed; they were named "Westector" in the USA, while in Germany they called them "Sirutor". As Lilienfeld's and Heil's research was largely forgotten during the war, their discoveries were merely complemented by the p-n junctions for field-effect transistor (FET) and the minority carrier injection in Bell Labs between 1947 and 1952 (Figure 28-10).[3111]

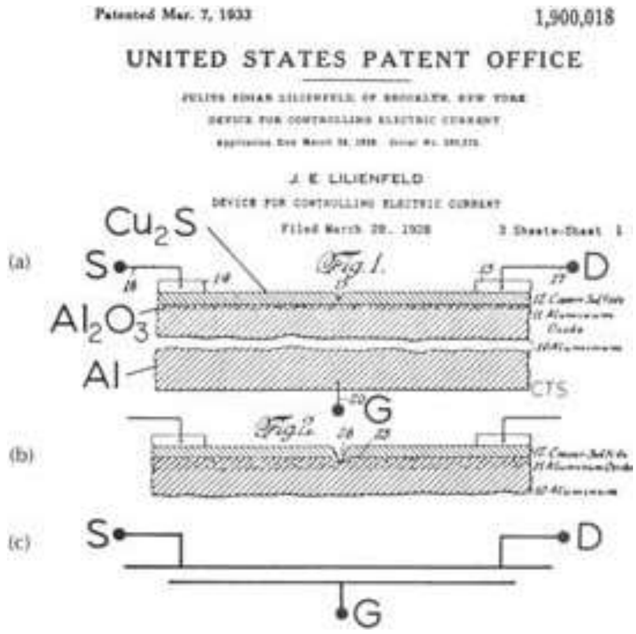

Figure 28-10: Lilienfeld's patent with the MOSFET Structure in 1933[3112]

It turned out that the specificity of the semiconductors in the illumination and in the rectifiers are surface appearances, while the photoconductivity and the negative temperature coefficient of resistance are related to the volume. At the end of the 1920s, semi-conductivity was found to depend both on the number of charge carriers in the volume unit and on their mobility, determined by the ratio between the speed of carriers in the electric field and the strength of that field. In the following years, the measurements of Hall effect have shown that the values of both

[3112] Sah, 1988, 1282.

quantities in semiconductors differ greatly from metals. The density or the number of charge carriers in the metal is not nearly constant only at the transition from one metal to the other at their contact, but also in the case of temperature changes. The density of charge carriers is different in semiconductor, and for several orders of magnitude smaller than in metals.

The solid-state researchers had to wait until the military development of radar stimulated again the exploration of crystal diodes with the transition to higher frequencies where the cathode ray tubes were not usable. Around 1938, stable detector was assembled by depositing a metal nail on the germanium crystal plate. H. Wilson explained many properties of a semiconductor with quantum mechanics behavior of electrons in solids with discrete energy bands in Cambridge in 1931. Already in 1917 in Phil. Mag. Frenkel from the University of Petrograd qualitatively explained the existence of an electrical double-layer (closure),[3113] which in the subsequent Bardeen's version had received strong experimental support. In 1932, Frenkel described a metal-semiconductor with a quantum-mechanical tunneling.

Edwin Hilbert Hall discovered the phenomenon called with his name in the United States in 1879. Between 1881 and 1921, he taught at the Harvard University.

The Swiss German **Walter Schottky** studied under supervision of the professor Sommerfeld. Between 1916 and 1919, and after 1927, he researched with Siemens & Halske.

In 1927, the son of Norwegian migrant American engineer Lars Olai Grondahl (1880 Hendrum, Minnesota-1968) in Westinghouse's Union Switch and Signal Company in Pittsburgh tested his plates of Cu_2O at higher temperatures around 1000°C. They were excellent conductors of the electrical current in one direction, while they had a high resistance in the opposite direction. Thus, it was possible to obtain DC current from the alternating current while Grondahl became famous enough to teach at University of Washington in Seattle and then at the Carnegie Institute of Technology.

The first photocell with copper-Cu_2O insulating layer was patented by Grondahl's collaborator assistant director of Union Switch and Signal Company Paul Harold Geiger (1896 Paris, Michigan-1954) on 14 November 1926.[3114] The device was improved by Schottky and Emil Duhme after his Gottingen PhD at the Siemens & Halske Laboratory and independently of them F. Haber's PhD student tat Berliner university Bruno Albert Lange (* 1903 Berlin; † 1969 Berlin) at 6th German Physics Days in Kaliningrad from 4th to 7th September 1930. Schottky described the operation of the submicroscopic thin layer between the surfaces of copper and Cu_2O.[3115] Despite the discovery of Braun, the phenomenon was called "Schottky's effect."

According to Bardeen, Schottky could have detected a transistor by examining in detail the behavior of the n-type semiconductor gap near the contact.[3116] Of course, then he would have taken over Bardeen's first Nobel Prize. Schottky's similar theory of the obstruction of a thickness of about 1 μm at the boundary between a semiconductor and a metal was also published by Bristol professor Mott, and by Ukrainian Jew Ioffe's student the Jewish editor of Boltzmann's, Einstein's and Smoluchowski's works Boris Davidov (Davydov, Борис Иосифович Давыдов (1908 Petersburg-1963 Moskva) in Ioffe's Physico-Technical Institute in Leningrad in the Soviet Union before the Second World War. In 1977, Mott shared Nobel prize in physics with D. Haldane's teacher Philip W. Anderson and John H. van Vleck.

28.2.6 Junction (Point Contact) Transistors

Point-contact contact semiconductor diodes were indispensable during the war for their uses in radars and other electronic devices. In 1940 in Bell Labs Russell Shoemaker Ohl (1898 Pennsylvania-1987 California) asked chemists and metallurgists for a more homogeneous material that would have more stable properties than silicon. They obtained much purer materials than they ever, and even

[3113] Trigg, 1978, 175.

[3116] Holonyak, 1992, 38, 37

controlled the type of their defects and impurities. Their conductivity was caused by smaller amounts of these impurities, which Ohl divided into n- and p-types.[3117]

On 29 December 1939, Shockley wrote down what the future "transistor" is supposed to be. On 29 February 1940, his idea was improved with a description of the later MOSFET (Figure 28-11). After the war,[3118] he became head of the group of researchers of germanium and silicon at Bell Labs. It was easier to work with elementary substances, and the technology for them was already developed, although copper oxides and ZnO were much more used in those times.

Figure 28-11: Shockley's transistor sketches with Brattain's signature on 29 February 1940.[3119]

Besides technological, they also tackled the theoretical problems. According to Schottky, the barrier closing layer consists of a spatially charged region of a semiconductor of thickness from 10^{-6} cm to 10^{-4} cm and an induced charge on the surface of the metal. The spatially distributed charge raises electrostatic potential energy on the surface of a semiconductor. The electrons are exhausted from the area with spatial charge, which can enables high resistance of the layer.

If the potential of a semiconductor is negative with respect to metal, the energy levels in the semiconductor are raised and electrons can easily pass through higher potential in the metal. This is a translation direction. On the other hand, in a positive semiconductor, the levels are reduced, which raises the level of barrier, so that the electron pass harder from the semiconductor to the metal. This is the closing direction.

For the first time, Ioffe's student **Igor Evgenevich Tamm** described localized states called Tamm's Levels in Physik. Zeits. Sowietunion (1932) 1: 733. He was followed by Shockley's paper in Phys. Rev. (1939) 56: 317.[3120] In 1958, Tamm was awarded the Nobel Prize for the study of electromagnetic waves emitted by particles during their rapid motions in matter.

According to Schottky, the equilibrium height of the potential obstacle and the degree of orientation depend on the output of the metal.[3121] He wrongly predicted the difference between the contacts of the n- and p-type in silicon, and he was not able to explain the results of Shockley and Bell labs pioneer of solar cells Gerald L. Pearson (1905 Oregon-1987 California).[3122] Other research supported Schottky's assumptions, among them H. Schweickert's measurements of the interdependence between resistance of selenium rectifiers and output in metal at the physics institute of Erlangen university, later Siemens' employee.[3123] Under the guidance of Joseph Adam Becker (Joe, * 1897 Saar land; † 1961), Brattain and John N. Shive found a good correlation between the degree of rectifying tendency directing and the output of metal contacts evaporated on copper oxide and on n- and p-type silicon in Bell Labs in 1940.

Shive got results resembling Schweickert's exploring of the contacts between various metals that were evaporated on selenium. Ioffe (Joffe) attempted to reject Schottky and Davidov's theories in Leningrad as Ioffe was a friend of Bardeen. Unfortunately, the Schottky barrier problem remains unresolved today.[3124]

Due to discrepancy with experiments, Shockley group member, Bardeen, explored in detail the nature of the contact between metal and a semiconductor on February 13, 1947. He was

[3117] Trigg, 1978, 177, 178; Kramer, 1997, 1205.

[3123] Bardeen, 1947, 718.
[3124] Bardeen, 1947, 718; Ioffe (Joffe), 1983, 222–22.3

interested in the influence of electronic states at the surface of the semiconductor on the equilibrium value of the potential obstacle and the surprising absence of the influence of the metal in contact. However, he still lacked experimental confirmation of the existence of electronic surface states, which Shockley used in his one-dimensional model in 1939. Bardeen assumed that the electrons on the surface of the semiconductor come into balance after each electrical contact; for balance it is necessary to exchange the electrostatic potential between the interior of the semiconductor and its surface. The events within the semiconductor do not depend on contact with the metal, which explained the results of W. E. Meyerhof's measurement of the relation between the contact potential differences and rectification. An analysis of the effect on the surface of the metal and the semiconductor during the switching showed that the surface charge only slightly changes the output of the metal, and much more of the semiconductor. The localized states (Tamm levels), having energies distributed in the "forbidden" range between the filled band and the conduction band, may exist at the surface of a semi-conductor. A condition of no net charge on the surface atoms may correspond to a partial filling of these states. If the density of surface levels is sufficiently high, there will be an appreciable double layer at the free surface of a semi-conductor formed from a net charge from electrons in surface states and a space charge of opposite sign, like that at a rectifying junction, extending into the semi-conductor. This double layer tends to make the work function independent of the height of the Fermi level in the interior (which in turn depends on impurity content). The work function (the minimum energy needed to remove an electron from a solid) in n-type silicon is for about 0.25 eV different from the work function of the p-type, which is much less than the energy gap of about 1.1 eV. If contact is made with a metal, the difference in work function between metal and semi-conductor is compensated by surface states charge, rather than by a space charge as is ordinarily assumed, so that the space charge layer is independent of the metal. The characteristics of rectification are then independent of the metal. Contrary to Shockley and Shive's focus on space charge, Bardeen had surface states charge as basic for the rectification. For Bardeen, the contact surface was of primary concern, while Shockley and Shive focused their research on bulk space behind it.

Bardeen was aware of the shortcomings of his model describing close contact between the metal and the semiconductor, which prevents the separate treatment of different work function in both contacted materials. In addition to his presentation, he processed in detail the example of a uniform Schottky barrier. He described the following barriers made up of double layers:[3125]

1) The one-atomic layer on the surface of the metal
2) The one-atomic layer on the surface of the semiconductor
3) The surface charge on metals and semiconductors with the thickness of few atomic layers
4) The surface charge layer, with the thickness of few atomic layers, and the spatial charge, which extends from 10^{-6} cm to 10^{-4} cm deep into the semiconductor.

Bardeen's amplifying (reinforcement) in the shutter layers can be estimated in various useful ways:

a) For a surface density level above 10^{13} cm^{-2}, the double-layer closure (4) is independent of metal and it is the same as on the free surface of a semiconductor. The rectifying (steering) capability will then be largely independent of the output of the metal. The difference in the contact potentials is compensated by the closure layer (3).

b) For a surface density of less than 10^{13} cm^{-2}, the double-layer closure (3) will be small and will be (4) approximately determined by the difference in the output section.

c) On the close contact between the metal and the semiconductor we cannot distinguish between the double-layer closures (1), (2) and (3). Even if the spread of surface levels of the metal is small compared to the energy gap, that finding will still be valid.

d) With large surface levels spreading, surface charge cannot be described based on measurements of potential difference at the point of contact.

Brattain and Shockley supported Bardeen's theory with experiments. Among the surface properties they considered the photoelectric effect, which

[3125] Bardeen, 1947, 717, 719, 720, 724–726.

changes the contact potential during the illumination. Immediately after their letter, Brattain described a double sealing layer on the surface of a semiconductor. At room temperature, the system should achieve a balance in a matter of seconds.

The next stage of the survey was to measure potential changes on the surface of silicon or germanium at different temperatures. The experiment was inhibited by condensation of water vapor on the cold surface of the semiconductor, therefore they soaked their system in a non-conducting liquid. They measured the contact voltages and found changes in photovoltaics during irrigation. Brattain warned colleague the chemist Robert Bernard Gibney (* 1911 Wilmington, DE) that water and some of the used liquids were not good dielectrics, but electrolytes. Therefore, it was assumed that the potential is changing between the surface of the semiconductor and the comparative electrode.

Those results were introduced to the entire research group at Bell Labs. A few days later in the morning, Bardeen came to Brattain's cabinet and described a device that could get the desired rectifications. Brattain set up an experiment in a laboratory where the metal fitting was covered with a thin layer of wax and affixed to p-type silicon. The surface was so treated that a transition to the n-type was formed. The contact was wetted with a drop of water and the electrode was placed. The point of contact was isolated from the water with a layer of wax. As expected, they discovered that the potential between water and silicon changes the current that flows over the metal point into silicon.[3126]

This discovery of the amplifier has enabled the advancement of electronics in the next half century. Once it has long been known that the raising temperature of the semiconductor increases the number of electrons and holes (gaps), and the illumination multiplies the number of charge carriers, Bardeen and Brattain used the electric current to change the distribution of the media by injecting the holes (gaps) that were minority charge carriers. The positive metal electrode (emitter) in contact with the surface of the semiconductor of the n-type (base) has caused the electrical current of holes (gaps) into it.

In the meantime, in the middle of December 1947, Bardeen communicated to his wife with a typical silent voice while she was preparing dinner: "We've discovered something today."[3127] In the kitchen, it smelled slightly for the Nobel Prize, the first of the two earned by Bardeen. His fiancé was full of understanding and began to pour soup...
Bardeen proposed a similar experiment on germanium n-type, which would give an even better result. After discussion with Bardeen, Brattain's group compiled an electronic device with an emitter, a collector and a broad low-resistance contact on a germanium base that could be used as an amplifier, an oscillator, and more, instead of vacuum cathode ray tubes.

The name transistor is derived from "Transfer resistor". **John Robinson Pierce** coined the term after he joined Bell Labs together with Shockley. As an engineer, he mainly studied vacuum tubes for microwave devices, but he also knew the essence of semiconductor research of his colleagues. Before 28 March 1948 while they searched for a suitable name for a new device in analogy with similar resistors, thermistors and varistors, proposals on the Brattain's initiative were made as the "transmitter... trans-resistor ... transistor". And the later prevailed.

The comeback of semiconductors was a fact! It could be funny to see eventual comeback of cathode ray tubes somewhere in the future as they were never entirely abandoned for TV screens, better gramophones and the like, resembling the sailboats beaten by steamers whose gravediggers were motored ships, steam engines beaten by internal combustion for locomotives and elsewhere, gas-lamps beaten by electrical bulbs, balloons beaten by planes, carriages beaten by cars, optical telegraph beaten by electrical telegraphy, telephones nearly beaten by cellphones and likewise.

To enable transistors' victories over cathode ray tubes, Brattain's boys made two junction points of contacts on the surface, separated by distance between 0.25 mm and 0.05 mm. Two diodes were thus placed so close together that the events in one

[3126] Trigg, 1978, 183, 185–186.

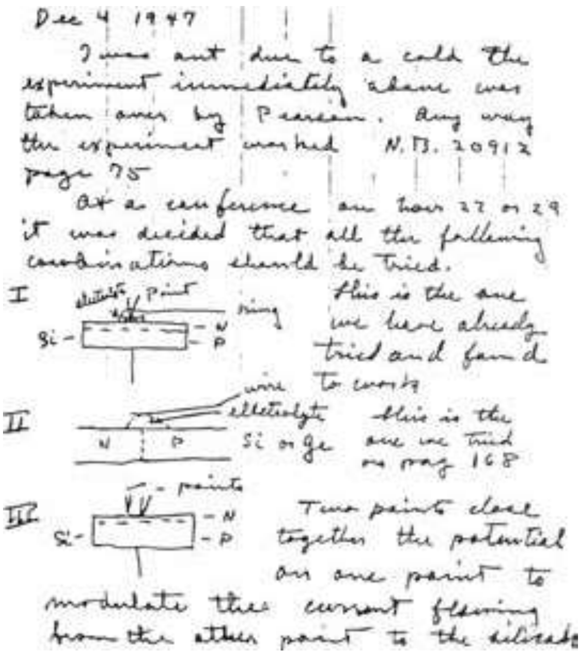
[3127] Kramer (1997, 1205) dated the invention on 16. 12. 1947, just like Holonyak, 1992 39; Bondyopadhyay, 1998, 63.

of them affected its neighbor. A triangular layer was cut from the polystyrene with a small narrow and straight end while they attached a thin gold leaf to it. Brattain cut a sheet of paper through a pole to the height of the triangle and attached it to the germanium. A part of the golden leaf was used as an emitter and the other part as a collector. The junction point contacts were made of tungsten also from phosphor bronze.

When they approached the junction ~~point~~ contacts to each other and pressed the DC voltage, they received mutual influences that enabled the amplification of alternating current signals. A small positive voltage on the emitter caused the electrical current of several milliamps. A sufficiently high voltage was applied on the collector to obtain a collector current of the same or larger order of magnitude from the emitter current. The collector voltage had such a sign that it attracted the holes from the emitter, so that a large part of the emitters flowed towards the collector. The collector inhibited the flow of electrons into a semiconductor, but the current of the holes (gaps) at the contact junction point was only a bit hindered. If they then changed the emitter current with the signal voltage, they received corresponding changes in the collector current. The electrical current from the emitter to the collector could change the normal flow from the base to the collector so that the change in the collector current was greater than the change in the emitter current.

Bardeen and Brattain investigated the nature of the additional conductivity of the transistor by measuring the potential near the contact at the level of the surface of the thick germanium base n-type, which was prepared in the same way as for use in high-voltage rectifiers. In the tests, the surface was first grinded and etched milled and finally oxidized in an air at 500°C for one hour. In the other tests, the upper surface was additionally anodically oxidized in the glycol borate solution, then they grinded and etched it in the ordinary manner. The rinsed oxide did not directly affect the results. Later, they discovered that surfaces could be prepared in other ways.

The change in conductivity with the changing current indicated that in addition to the ohmic conductivity, there is a different component of the additional conductivity, which is increasing with the increasing current. It was attributed to the increasing concentration of carriers (holes and electrons) near the point with increasing current. It has been presumed that the conductive layer of the p-type may be due to the excess of impurities in the receiver near the surface or due to the closure layer in a spatial charge adequate for the raising of saturated band near the Fermi level.



Dec 4 1947
I was out due to a cold the experiment immediately above was taken over by Pearson. Any way the experiment worked N.B. 20912 page 75
At a conference on Nov 27 or 29 it was decided that all the following combinations should be tried.
I — This is the one we have already tried and found to work
II — This is the one we tried on page 168
III — Two points close together the potential on one point to modulate the current flowing from the other point to the silicon

Figure 28-12: Laboratory notes of demonstration of sound reinforcement with a transistor with bipolar junction (points of the contacts) on December 24, 1947

Seymour Benzer (1921 Brooklyn-2007 Pasadena) of Purdue University published the measurements of the temperature dependence of the germanium amplifier immediately after the war on 31 December 1945. He confirmed the alleged conductivity of the p-type on the surface but soon switched into molecular biology under Schrödinger’s influences.

On December 24 1947 he received a hundredth-fold amplification in all spectrum of frequencies of sound (Figure 28-12).[3128] On 17 June 1948, Bardeen and Brattain patented their invention. Eight days later, they described the discovery in two letters, published in July 1948. The findings were supplemented by the simultaneously sent measurements of their chief Shockley and Pearson from Bell Labs. They used a 1 cm x 2 cm capacitor from gold and a semiconductor, which was loaded

[3128] Trigg, 1978, 187, 188.

on the opposite side of the silicon plate, 0.06 mm thick. To measure the changes in conductivity, a current was flowing between two additional gold electrodes, charged at two ends of the semiconductor. The measurements on germanium were comparable to the results obtained by the older measurements of Brattain and Shockley's silicon in the previous year.[3129]

28.2.7 FET Transistors

Shockley was the head of a research group in which Bardeen and Brattain discovered a bipolar junction transistor (with points contact) after a series of experiments (Fig. 28-13). The discovery, however, was based on Shockley's idea, but he was not directly involved in experiments. This was surely annoying, and in the following months, he closely followed the research of his colleagues, more than it is usually in groups of creative scientists. He felt that the Nobel Prize could slip away from his pockets. With all his might, he threw himself into researching a field-effect transistor, whose version called JFET[3130] he developed until 23 January 1948, thirty-eight days after the discovery of Bardeen and Brattain. The invention was patented on June 26, 1948 and September 24, 1948 (Figure 28-14).[3131] Shockley wanted to have a bulk effect involved and he did it, while Bardeen wanted the changed junction in the first place and he designed his transistor in his ways.

The operation of the new Shockley's transistor version was easier to follow with the theory, its noise was lower, and it could have used more power. Therefore, it soon displaced the bipolar junction transistor (with dot contact points). Soon after the Bell Labs, the junction transistor was produced in a similar form, but with different mechanical details by GE's research laboratory, followed by RCA, Raytheon and Sylvania in 1949.[3132]

The theory of the transistor brought a new challenge to the physicists. The operation of the vacuum cathode ray tube was already part of the standard knowledge of an electrician in the mid-1950s, while the motion of particles in the solid state was a significant novelty. Anyway, the processes in the solid state are more complex. The properties of the cathode ray tube depend only on the geometry and on the outer boundary conditions, while the properties of the solids also affected the transistor. In the cathode ray tube, we are dealing only with the motion of electrons in an electric field, but in the semiconductor, besides the electrons, there are quasiparticle electrons holes as the kind of gaps. Therefore, it is understandable that early researchers of the transistor initially differently explained phenomena involved in it. At least partly, the discovery of the industrially usable transistor preceded its full theory.

Figure 28-13: Shockley, Brattain and Bardeen at Bell Labs in 1947 upon receiving the Nobel Prize in 1956 or at the 25th anniversary of the invention of Transistor in 1972[3133]

Bardeen attributed the success of the experiments with electrolyte to the presence of a modified semiconductor layer on the surface that limited the electron flow. However, such an explanation became doubtful when they began to produce good transistors with a surface produced by leveling a high counter voltage, provided that the collector contact was made electrically.

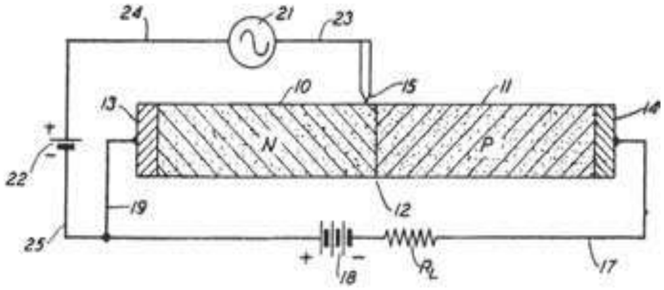

Figure 28-14: Shockley Transistor Pattern from Patent Filed on September 24, 1948[3134]

William Bradford Shockley was born in London in the family of a wealthy American mining engineer. He graduated at Caltech in 1932 and received his doctorate at MIT in 1936 with Slater, who founded quantum mechanics together with Bohr in the mid-1920s. In 1936, Shockley came to Bell Labs. There he hoped to work with Davisson, who received the Nobel Prize in Physics for the study of interference of reflected electrons on a crystal in the following year. During the war, Shockley was involved in applied research, and after the war, he became the head of a new research department of solid state. He also included Bardeen, whom he met in the Cambridge in mid-1930s. In 1955, Shockley became the Director of the Arms Development Research Group at the US Department of Defense and founded his own transistor company. In 1963, he became a professor of engineering at Stanford University.

In contrast to Bardeen, Shockley (23 January 1948) and Shive independently of him assumed that the modified surface layer had no important decisive role to play. They considered the transistor rectification as primarily bulk and not surface phenomenon. In February 1948, Shive proved his assumption with an experiment. The emitter and collector junctions (points) were switched on opposite sides of the 0.01 mm thin layer of germanium and thus produced a transistor effect comparable to the transistors of Bardeen and Brattain. In 1839, a century before the regulation of conductivity with a transistor effect, E. Becquerel first observed that light is causing electrical current in some electrolytes, since the illumination increases the conductivity of the semiconductor.

The changed theory reflected the different conditions in which Shockley's transistor operated. Unlike Bardeen-Brattain's, where the rectifying emerges at contact between the metal conductor and the germanium, in Shockley's pnp-transistor the rectification occurred inside the crystal of germanium.

The current ran primarily due to diffusion, rather than because of the electric field. In a simplified model, Shockley assumed that:

1) donors and acceptors were completely ionized, which holds good for germanium at room temperature,
2) the density of minority charge carriers is much lower than the density of majority charge carriers in each area,
3) the total recombination ratio in each region linearly depends on the irregularity of the density of the minority charge carriers according to its value in thermal equilibrium,
4) the spatial charge is not important except in the pn-contacts itself.

The behavior of his semiconductor device seemed like the vacuum cathode ray tube to Shockley. The analogy was nearly the same for Braun half of a century earlier.

The area of the emitter should correspond to the cathodes of the cathode ray tube, the base area around the grid conductors and the collector area was like the anodes. A transistor with a grounded emitter region and a signal facing the base operated as a triode with grounded cathode.
Both the transistor and the cathode ray tube are controlled by the interaction between two forms of currents of electrons. In the cathode ray tube, the grid voltage determines the flow of electrons from the cathode to the anode. In the transistor, the electrical current of holes in the base changes the voltage between the base and the emitter and regulates the flow of electrons through the base layer.

The analogy between transistors and cathode ray tubes was very human approach as both fulfilled the same industrial needs. People always prefer such analogies, like Edison who copied his own design of the bulb by gas lightning. But, in both cases the analogy is just in the appearance because the principles of physics involved are quite different in the case of earlier technology

[3134] Shockley,1988, 34.

compared to its newly designed replacement. But Bardeen did not support any analogy with a vacuum tube from his very beginning. It is precisely because of this that he introduced the emitter, collector and base fluxes as the terms still used today.

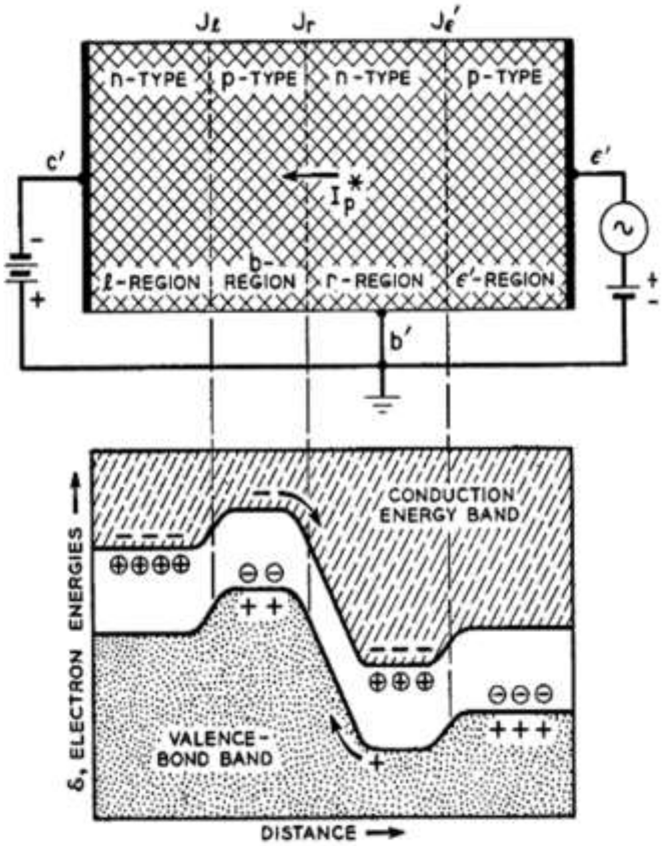

Figure 28-15: A pnpn-transistor from Shockley's 1951 paper[3135]

Shockley research group used a monocrystalline germanium with a p-type layer interposed between two n-type areas. The transistor worked evenly on the surfaces of pn-contacts. The size of its active surface could have changed greatly, which was not possible with point-contact Bardeen-Brattain's point-contact transistor. Thus, Shockley could increase output without increasing current. One of the greater npn transistors he presented in June and July 1950 had a contact surface of 30 mm^2, a base of thickness about 0.7 mm and gave 2.0 W of undeformed power at the output. Even in smaller devices with a contact surface of about 1 mm^2, all the characteristics of the Bardeen-Brattain's point-contact transistor were improved by several orders of magnitude (Figure 28-15).[3136]

The News of Radio

Two New Shows on CBS Will Replace 'Radio Theatre' During the Summer

Two new shows are announced by CBS to serve as summer replacements for the hour-long "Radio Theatre" on Monday evenings. The first, to be heard at 9:30 P. M., will be "Mr. Tutt," based on the stories of the late Arthur Train. Willard Wright will have the title role and Arnold Perl will do the adaptations. It will make its debut next week.

The second, to open on July 12, will be "Our Miss Brooks," with Eve Arden playing the role of a school teacher who encounters a variety of adventures. It will be written by Al Lewis and Lee Loeb, with Larry Berns serving as director. "Our Miss Brooks" will be offered at 9 P. M. Mondays.

A situation comedy with musical overtones, headlined by Mel Torme, has been selected as the replacement for the Dinah Shore-Harry James program at 9 P. M. Tuesdays over NBC, starting next week. The supporting company will include Janet Waldo and John Brown. Harmon Alexander and Ben Perry will do the script. Frank Danzig will be the producer and Ben Elliott, the musical director.

Station WFUV, Fordham University's frequency modulation outlet, will observe the completion of its first year of operation today. Throughout the day there will be special programs to mark the occasion and a number of personages on local commercial stations will participate, including John McCaffrey, Eileen O'Connell, Pat Barnes, Mary Small, Alma Dettinger and Arlene Francis.

At 8:05 P. M. there will be a critical discussion of present-day radio, the members of the panel including the Rev. Robert I. Gannon, president of Fordham; Morris Novik, John Garrison and F. W. Carlington.

"On Your Mark," a new audience-participation item, will be added to WOR's schedule next Monday. It will be heard at 2:30 P. M. each weekday afternoon.

Beginning tomorrow, "Waltz Time" will be heard for a full hour for three successive Friday evenings at 9 o'clock over NBC.

A memorial tribute to Col. David Marcus, who died in action while commanding the Israeli forces on the Jerusalem front, will be presented at 10:30 this evening over WMCA. Gov. Thomas E. Dewey and Mayor O'Dwyer will be among the speakers to be heard by means of transcriptions.

Station WNEW will transmit reports on traffic conditions on the major highways in the metropolitan area for those who plan to spend the holiday week-end out of town. On Friday, the reports will be heard on the hour at frequent intervals between 4 and 11 P. M. The same schedule also will be followed on Sunday and Monday afternoons and evenings.

"The Better Half," which is to go under commercial sponsorship on Sept. 16 over the Mutual network, will take to the air as a sustainer on Aug. 19.

A device called a transistor, which has several applications in radio where a vacuum tube ordinarily is employed, was demonstrated for the first time yesterday at Bell Telephone Laboratories, 463 West Street, where it was invented.

The device was demonstrated in a radio receiver, which contained none of the conventional tubes. It also was shown in a telephone system and in a television unit controlled by a receiver on a lower floor. In each case the transistor was employed as an amplifier, although it is claimed that it also can be used as an oscillator in that it will create and send radio waves.

In the shape of a small metal cylinder about a half-inch long, the transistor contains no vacuum, grid, plate or glass envelope to keep the air away. Its action is

Figure 28-16: A copy of the New York Times article with the first transistor reference.

On July 1, 1948, the New York Times reported the discovery of a transistor among radio news (Figure 28-16). A few months later, Bell Labs published more detailed physical principles and electrical properties of the device.

In 1948 in Bell Labs Gordon Kidd Teal (1907 Dallas-2003 Dallas) and John B. Little developed the technology of growth of large germanium mono-crystals, in which the interior could detect and recognize the charge carriers inserted after the contact with the metal. In April 1950, Shockley, Morgan Sparks and Teal grew a crystal that had a thin layer of p-type on the n-type material. Only then the production of npn and pnp transistors started to provide nowadays indispensable parts of each microchip. In 1949 and 1954, Shockley patented devices for implanting ions into semiconductors. After Ohl's implantation of helium ions into semiconductors in 1952, Shockley and others continued the study of solid-state bombarding of ions began in the efforts of Rutherford, Royds and Bohr in 1909. But there was one important change: the new generation of researchers this time directly worked for the needs of the industry.[3137] They even worked at better paid posts in the industrial labs and not anymore in the academic university posts. The huge Manhattan project changed everything, especially in the USA. The times changed, and the great money needed for experimental research was available only in industrial networks.

28.2.8 Priority Problem

The invention of the transistor was the result of the collective work of Bell Labs (Figure 28-17). The US Navy initially embraced the priority of their own researchers, but their effort was soon abandoned. The problem of priority further eased Bardeen's characteristic that the he acknowledged even the small merit of his predecessors. On June 6, 1948, he thanked Shockley for "... the initiative and running of a research program that led to the discovery ..." In December 1950, Bill Shockley wrote a dedication in his new book: "John Bardeen, who made such a book needed." In the foreword, Bardeen and Brattain were quoted as inventors of a transistor. However, Bardeen's and Shockley's admirers were nevertheless discussing the priorities that are still unresolved today. Some researchers believe that Bardeen had already known the concept of injecting minor carrier in the transistor on 17 December 1947, and that Shockley only embraced it more than a month later. Bardeen and Shockley's joint research path separated when they left Bell Labs one after another in the first half of the 1950s and continued their careers in such diverse directions as research of superconductors at the university and the commercialization of transistors in the San Francisco Bay area. They were no longer involved in any joint research after their Nobel Prize in 1956, so Bardeen even avoided writing an obituary to his former chief, Shockley, in August 1989.[3138] From 1951 to 1975 Bardeen taught at the University of Illinois at Urbana–Champaign and later became professor emeritus there. Bardeen's longtime golf partner at the Champaign Country Club in Illinois once asked him: "Say John, you know I've been meaning to ask you. Just what is it you do for living?" If anything, anyway.

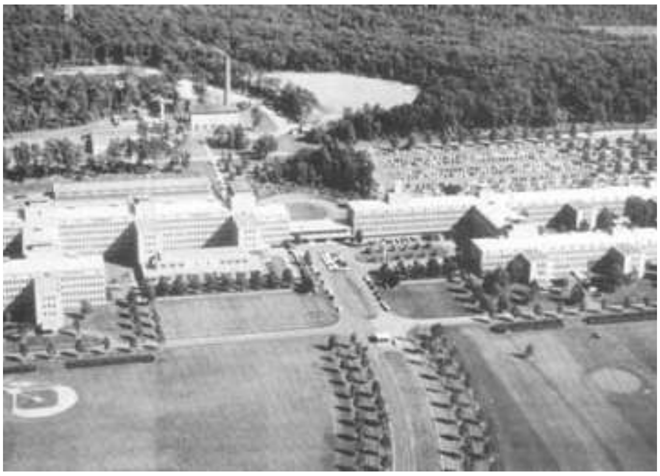

Figure 28-17: Bell Labs in Murray Hill, New Jersey in 1950[3139]

28.2.9 "Silicon Valley" and Research of Scientists in Industrial Laboratories

In September 1955, Shockley left Bell Labs and personally began commercializing his inventions of a transistor. He followed the example of Edison's three-fourths of a century older case of the production of incandescent bulbs in Menlo Park. Shockley set up transistor laboratories in his native Palo Alto, California, and headed them until August 1963. This led directly to the emergence of the silicon transistor industry in my native San Francisco Bay Area, later fortunately nicknamed as the Silicon Valley.

The center of development has moved from the eastern to the western coast of the US, where the most important researchers of the transistor were at home.

The industry, which grew from the invention of the transistor, promises a lot. The computers were their very best chance, as the transistor elements largely solved the problem of overheating, slowness and, basically, the oversize of the first computers with tubes which began to assemble just before the invention of the transistor. The modern computers

[3137] Yarling, 2000, 1746.
[3138] Holonyak, 1992, 39. Bondyopadhyay published his opposite opinion (1998, 196, 207).
[3139] Ehrenreich, 1995, 33.

and semiconductor switches were born almost simultaneously, quickly married in their early ages, and absolutely ruled the world ever since, unchallenged except for the futuristic quantum computers.

The great race began. The Raytheon of Vannevar Bush and his friends was one of thirty-five companies which learned FET technology Transistors at the Bell Labs symposium in April 1952. In March 1953, Raytheon produced 1000 germanium transistors per month at a price of $ 9 per piece. By 1957, the Raytheon controlled the market, but then stayed behind in the development of technology. In the mid-1950s, when the transistor according to Shockley's idea was still largely an "improved cathode ray tube", the production of transistors still yielded twenty times less income than the production of cathode ray tubes. The profits of both industries have become comparable only in the early 1960s, when the US government, following the success of Russia's Sputnik on September 4, 1957, began generously promoting the miniaturization of transistors in fear of technological lag.

The role of scientist Shockley in the production of transistors was the fruit of the half of a century of the coexistence of academically educated scientists and industry in highly developed Western societies which culminated in Manhattan project. The successful operation of industrial scientists began with the chemist educated at Yale university Charles Benjamin Dudley (1842 Oxford, New York-1909 Pennsylvania), who organized a laboratory for the testing of materials with thirty chemists at Pennsylvania Railroad from 1875 to 1905. The scientists have been particularly successful in developing of bulbs, as the physicists Edward Leamington Nichols (1854-1937 West Palm Beach) and Upton have greatest credit for Edison's success. Similar tasks were performed by John Stone (1869 Virginia-1943 San Diego) who grew up in Cairo and George Campbell in Bell's telephone systems, where after his studies in Vienna, Berlin, Leipzig and Gottingen the professor of physics William White Jacques (1855 Haverhill, Massachusetts-1932) of MIT researched as an expert at the department for electricity and patents in 1880-1897. Between 1885 and 1911 they had Hammond V. Hayes borrowed from MIT, and from April 1911 onwards there was a special research team in Bell labs led by Edwin Colpitts (1872-1949).

So, Bell Labs already had a rich scientific tradition upon Shockley's arrival. Scientists no longer relied for a single industry survey, as academically trained researchers rather became permanent developers in specific laboratories. The novelty was first introduced by the chemical company Bayer, where the chemist Duisberg, who has received his Ph.D. in Jena,[3140] has been studying new colors since 1884. In 1889, they decided to include him in a new major scientific laboratory, which opened in August 1891, and the Patent Office was added to it six years later. New developments in Bayer began to promote modern science-industry relationships, which were soon adopted by British chemical companies and the electrical engineering industry.

The American companies were particularly influenced by the experimental electrochemical laboratory, which was set up by GE in the spring of 1900, after Steinmetz's long-term efforts. Since 1890, Steinmetz has been researching in GE's calculating department and has been aware of the progress in Europe. Nevertheless, Steinmetz failed to separate the laboratory from the factory completely, as his lab had to provide the marketspace for his factory.

28.2.10 Application of Ion Implantation in the Semiconductor Industry

The ion implantation is a seemingly tough process, but with full electronic control, it enables embedding specific ions into the desired parts of the substrate. The already made procedure was welcomed into the new-born semiconductor industry.

At the same time, at the beginning of development of ion implantation in the laboratories, many accelerators and separators were available, which due to their low energy capacities were no longer used seriously in nuclear physics. In many aspects, the rapid growth of ion implantation was a child of Manhattan project. The rapid growth of the extremely optimistic Gordon Earle Moore's Law was an inevitable consequence of matching happy circumstances. In course of three decades, ion implantation has become a mature form of

[3140] Fox, Guagnini, 1999, 255; Schopman, 1988, 142.

technology, and today its use in the semiconductor industry is expanding elsewhere.

28.2.11 Transistor and the Beginnings of the Use of Ion Implantation in Semiconductors

The single vacuum process used in the production of the first transistors and integrated circuits was the chemical vapor deposition of aluminium and gold contact layers from a hot vanadium conductor. In the following years, more reports have been published about the bombarding of semiconductors with ions, but nobody had compiled any working devices.[3141]

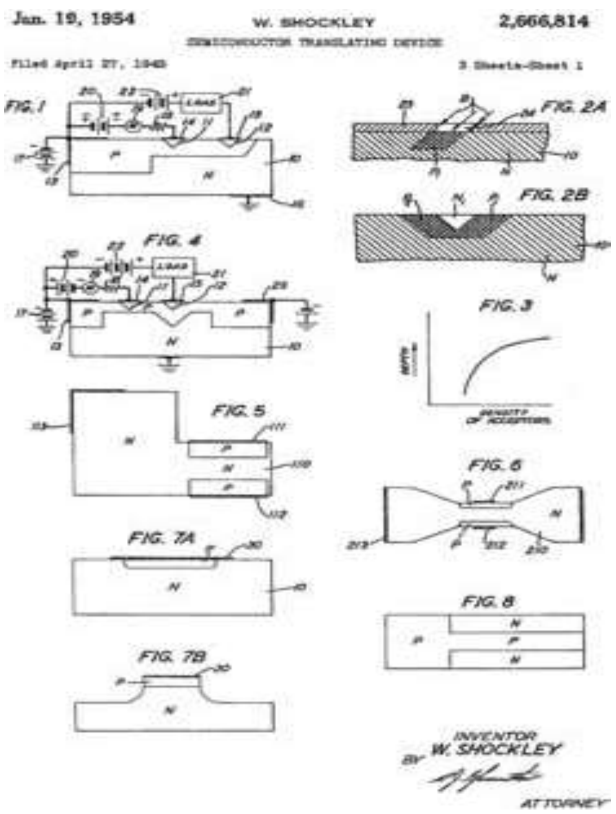

Figure 28-18: Shockley's idea for the manufacture of a pn-contact with ionic bombardment in U.S. Pat. 2666814, endorsed on 19. 1. 1954.[3142]

On 27 April 1949, Shockley filed a patent for a semiconductor translation device. He described the production of the pn-contact of a separate JFET-transistor using ion implantation. He suggested bombarding of a semiconductor with deuterons and α rays (Figure 28-18).[3143]

On 31 January 1950 Ohl submitted the first patent for the bombardment by oxygen, hydrogen, nitrogen, helium, argon, CO, and even $CHCl_3$ in the production of semiconductor devices. The first one described all the basic features of ion implantation. Unfortunately, he incorrectly believed that the impurity ions entered the surface layer of the crystal and changed the number of charge carriers and with it the electrical characteristics of the substance. The mistake misled the research of many people.[3144] Five years later, Bell Labs first used implantation of He+ in the point-contact semiconductor diodes of junction. This improved the properties of the reverse (feedback, return) current, which was modified by the He^+ bombardment.[3145]

On 28 October 1954, Shockley at Bell Labs filed a patent for the "formation of semiconductor devices with ionic bombardment". He described the basics of ion implantation equipment in the production of the JFET transistor.[3146] Although he gave only the foundation of the procedure, he also submitted the data about the ion separation before implantation and electrical and mechanical scanning. He additionally introduced the concept of the ion implantation area and identified the damage to crystalline silicon due to ion bombardment.

Shockley's patent implied the birth of successful ion implantation, which was not specifically patented since it was widely known. He was particularly interested in the invention of heating the semiconductor up to 400°C after implantation, which was necessary for removing the damage caused by the ion bombardment and for the electrical excitation of the implanted dopant. Such successes, independent of the ion implantation equipment itself, remained a characteristic of its development later.

Otherwise from Ohl who considered only surface changes, Shockley considered that the energy of

[3144] Ohl, 1952, 104; Fair, 1998, 112.
[3145] Yarling, 2000, 1746.
[3146] Shockley, American patent no. 2787564, 2. 4. 1957, granted -accepted on 12. 4. 1958; Sah, 1988, 1285, 1288, 1321; Bondyopadhyay, 1998, 199.

incident ions also determined the depth of implanted doped impurities. Thus, Ohl described the essence of ion implantation as the possibility of inserting impurities into the desired location in the semiconductor. The east coasters were not defeated easily by Silicon Valley as James W. Moyer at GE in Schenectady, New York had filed similar patent four months before Shockley. However, Moyer's patent was only validated 15 months after Shockley's patent when the use of beams of ions had already become domesticized in the manufacture of pn junctions and transistors.

In 1955, W.D. Cussins from the former Rutherford's Cambridge reported the first semiconductor doping by implantation. He doped a dozen different dopant elements into germanium. The following year Ohl got the first patent for the basics of ion implantation.[3147] Later he patented the first solar cell.

28.2.12 Integrated Circuits

During the first decade after the invention of the transistor, pn-contacts were made by diffusion of doping elements. In parallel, semiconductor researchers thought of an integrated circuit because the possibilities for miniaturization were at hand and the needs of the space industry were enormous. On 25 April 1956, Shockley filed a patent for a "semiconductor mobile register" after leaving Bell Labs. This was the beginning of the development of monolithic integrated circuits (Figure 28-20).[3148]

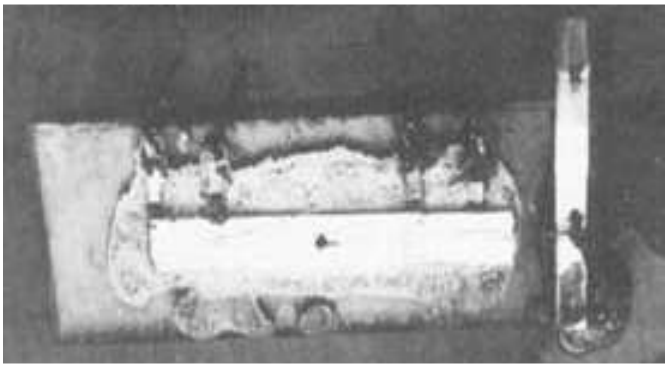

Figure 28-19: First Kilby Integrated Circuit for Texas Instruments (TI)[3149]

Kilby successfully invented the integrated circuit in July 1958. He placed the resistors, capacitors and diodes made of germanium on a common basis. Next month, Kilby compiled a simplified version of the circuit, and he showed the operation of the first simple microchip on September 2, 1958. On 6 February 1959 he filed a patent called "Miniaturized Electronic Circuits" for depositing an Aluminium layer on a layer of SiO_2. He knew that his invention would be important for electronics, but he could not think about the extent to which reduced prices of transistors would accelerate its development. His semiconductor microchip (microarray of integrated circuit) was a bit cumbersome and expensive to produce (Figure 28-19).[3150]

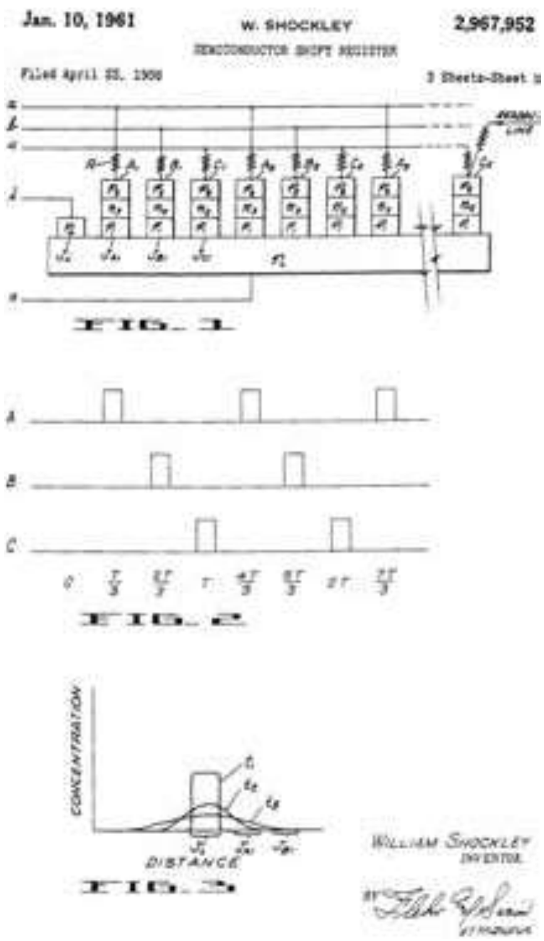

Figure 28-20: Shockley Patent for a "Semiconductor Moving Register" filed on 25 April 1956[3151]

Figure 28-21: Photo of the Fairchild Semiconductor building in Palo Alto, California, with a memorial plaque dedicated to Noyce's invention[3152]

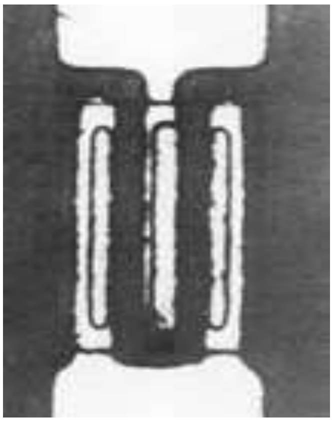

Figure 28-22: Microphotography of the first planar transistor according to Hoerni's invention at Fairchild[3153]

That was a time of Soviet success with the Sputnik on September 4, 1957, when the US government invested enormous resources in miniaturization. Therefore, it is not surprising that the idea for a different version of the integrated circuit was independently developed by physicist Noyce in January 1959.

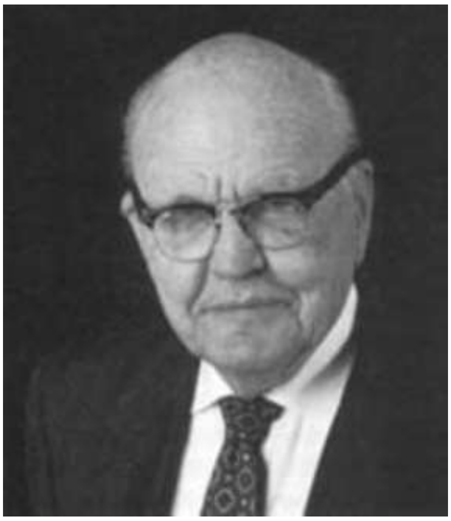
A week after Sputnik, Noyce and eight other researchers of different disciplines left Shockley's semiconductor laboratories after a year and a half. They founded Fairchild, just a mile away with the support of Fairchild Camera and Instrument Corporation. The original aim of Fairchild was the development, manufacture and sale of double-diffused silicon transistors without the use of ion implantation. After a few months, the first success occurred when the theoretical physicist Hoerni invented the process of making a planar transistor to avoid impurities. However, those ideas were not immediately used.

Jack StClair Kilby of Missouri spent his childhood in neighboring Kansas. Already in his youth, he helped his father who was an electrical engineer. In 1941 he began his studies at the University of Illinois. He graduated only after the war and achieved his master's degree as electronics engineer in Wisconsin in 1950. In 1947 he began to develop electronic devices in the Semiconductor Department of the Globe Union Inc. Centralab in Milwaukee. He became acquainted with transistors pn by the lectures at Bell Labs. In May 1958, he joined the TI. Since 1952, TI Semiconductor Laboratory has been led by G. K. Teal, who came from Bell Labs, where he was involved in the development of the technology of large crystals of germanium in 1948. Between 1965 and 14 April 1971, Kilby developed the first pocket computer. In November 1970, he became an independent inventor. Among other things, he was researching solar cells. Between 1978 and 1984 he was a professor of electrical engineering at A & M University in Texas. In 1982, he was placed in the "honor room" alongside Edison and other American inventors, whom Noyce also joined in the following year. In 1989, both researchers received the first NAE Charles Stark Draper Prize for Engineering that was equivalent to the Nobel Prize for inventors. Kilby received half of the Nobel Prize in Physics for his "share of the invention of integrated circuits". The other half of the prize was shared by Zhores Ivanovič Alferov (Жоре́с Ива́нович Алфёров, 1930 Vitebsk- 2019 Saint Petersburg) of the Petersburg Institute of Physics and Technology and Professor Herbert Krömer (Kroemer, * 1928 Weimar) from the University of California, Santa Barbara, for "the development of semiconductor heterostructures used in high-speed and optical electronics." They developed the semiconductor superlattice

idea, first published by the Japanese Leo Esaki (江崎 玲於奈, Reona, * 1925 Osaka) and the Chinese Raphael Tsu (* 1931 Shanghai) for USA IBM in 1970. Krömer was the first to use heterostructures in crystalline transistors and crystalline lasers, and Alferov compiled the first laser with GaAs-heterostructure. In the mid-1950s Krömer tried to increase the speed of transistor devices, and in the last decade of the

[3152] Moore, 1998, 55.
[3153] Moore, 1998, 58.

twentieth century heterostructures became a key component of solid state electronics without which there would be no modern CDs.



Jack StClair Kilby (* 1923; † 2005)[3154]

Noyce was the only one in Fairchild who had experience with semiconductor research, mostly with germanium, before their research at Shockley's company. At the initiative of the Patent Office, he organized the meeting of the leading technical researchers as Fairchild research and development director (Figure 28-21). He explained to them how Hoerni's idea could be used to produce complete circuits, and not just individual components by printing a plate using lithography.[3155] On July 30, 1959, Noyce filed a patent for a "semiconductor device and rectifier" describing a planar integrated circuit and using Hoerni's ideas. The circuits have been replaced by the implantation of aluminium. In August 1959 Fairchild announced to the public that they would begin to produce transistors according to Hoerni's new planar procedure. The group led by the member of Hoerni, Moore and Noyce's traitorous eight betraying Shockley the physicist Jay T. Last (* 1929 Pennsylvania) made the first planar integrated circuit at Fairchild the same year (Figures 28-22 and 28-23).[3156]

Production started next year. In May 1961, President John F. Kennedy announced the Apollo program. At the end of the year, they introduced the first four integrated circuits Micrologic™, which consisted of five basic logic functions. Those were mainly bought by the army. The computer that Apollo took to the moon had some parts from the Micrologic family of circuits.[3157]

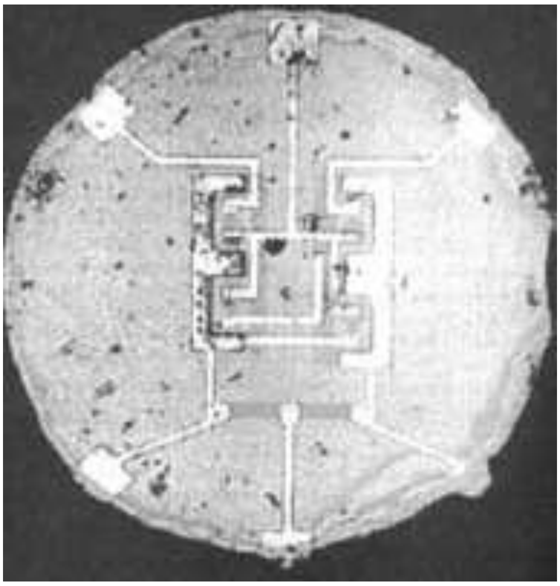


Figure 28-23: Microphotographs of the first planar integrated circuit, which were developed by Noyce's invention at Fairchild[3158]

However, there was no way without a dispute on priorities. Noyce received a patent before Hoerni and Kilby and was initially proclaimed as the inventor. However, the longstanding dispute between Fairchild and TI ended with an agreement in 1966, so Noyce and Kilby shared a priority in the invention of the integrated circuit.[3159]

In June 1960, the Korean Dawon Kahng (1931 Seoul-1992 New Jersey) and the Egyptian Mohamed Mohamed Atalla (محمد محمد عطالله,; 1924 Bur Saʽīd (Port Said)–2009 California) of Bell Labs published a description of the MOS transistor that realized the ideas of the transistor invention of 1947. In 1964, RCA first used MOS technology to produce integrated circuits.[3160]

Despite of the obvious success of integrated circuits, due to some doubts few types of "molecular electronics" were parallelly developed for at least five years, for example, in the US Air

Robert N. Noyce was the son of a Protestant priest from Iowa. Bardeen's classmate from the University Grant, Oscar Gale (1903-1998), was Noyce's professor of physics at Grinnell College in Iowa. Gale impressed him with physics and mathematics, introduced him to transistors, and saved Noyce from punishment after Noyce stole a pig from a mayor's farm. Noyce received his doctorate in 1953 at the MIT and joined Philco Corporation in Philadelphia to develop transistors. In January 1956, after Shockley's invitation, he was employed in semiconductor laboratories in Palo Alto. As usual in the Silicon Valley, Noyce often took part in setting up new businesses. In September 1957 he co-founded Fairchild, in July 1968 Intel, and finally Sematech.

Robert N. Noyce (* 1927; † 1990)[3161]

Force and in Bell Labs. In the Bell Labs, they established an ion implantation group only in the mid-1960s, a decade after Shockley's patent, after researchers of ion implantation stimulated the search for new applications of outdated accelerators and mass separators that were replaced by nuclear physicists by their devices with higher energy performance. Thus, research equipment for ion implantation has already been available in Chalk River Nuclear Laboratories, Oak Ridge National Laboratories, AERE Harwell at Oxfordshire UK and elsewhere. However, accelerators with high energies of the MeV range and small currents were not particularly suitable for ion implantation, and initially they directed research to ordinary temperatures, at most up to a few hundred degrees Celsius, where no real possibility of a new method of doping has been shown yet.[3162]

The Chinese **Chin-Tang Sah** arrived in the United States in 1949 and in 1953 he listened to Bardeen's lectures on transistors at the University of Illinois in Urbana. Sah collaborated with Noyce in Shockley's Transistor Laboratory and in Fairchild since 1959. Sah led a physics department with sixty-four to sixty-five associates and developed a large part of the first generation of silicon integrated circuits until 1964. In 1962/63, Bardeen intervened to enable Sah's chair of electrical engineering and physics at the University of Illinois at Urbana–Champaign.[3163]

In 1960, a small Danish company for the accelerators called Danfysik produced the first industrial implant for a Canadian state-owned research company in Ontario. The 70 keV model was called "Scandinavian". Soon, pioneering research into ion implantation at the University of Copenhagen shortly after Bohr's death enabled the Danish industry to succeed globally. Investment in fundamental science paid off relatively fast.

Almost no progress was made in the field of ion implantation from 1956 to 1961. In 1961 at Knolls Atomic Power Laboratory of GE in Schenectady, Frank M. Rourke and colleagues described ionic doping of silicon with elements of groups III or V. The concentration of the atoms 10^{18} cm^{-3} in the layer near the surface of the silicon target was obtained. Rourke's work encouraged the research by Swedes Torsten Alväger and Niels J. Hansen, who reported about the first use of semiconductor doping implants in industry in 1962. They implanted 10 kV phosphor ions in silicon crystal of p-type doped with boron, with a resistivity of 9000 $\Omega \cdot$ cm, by an electromagnetic isotope separator at Argonne in US. They got a junction few ten nanometers beneath the surface. After their bombardment, the product was heated to 600°C to get rid of radiation damage, but some phosphorus

[3163] Sah, 1988, 1326.

was diffused into silicon. Their detector of α particles with a 25 mm^2 plate was comparable to devices made by a diffusion process.

In 1947, Van de Graaff of MIT, his assistant John G. Trump, and the head of the British delegation at MIT Denis M. Robinson set up a High Voltage Engineering Company (HVEC) for production of implants. Trump first described the use of ion implantation for the treatment of cancer. HVEC researchers later set up new businesses, among them Ion Physics Corporation (IPC) for space research. In 1965, HVEC manufactured the first implant for the industry.

Around 1967, the users of ion implantation equipment had to solve the problem of optimum pumping and to choose the best installation of the pumping device at the source, the beam or the target. The implantation planners were mainly high-voltage experts and had only to learn about vacuum technology. In 1971, they founded Extrion, the first long-term successful importer. Later, the company was renamed Varian SEA and is still dominant in the market today. In addition to it, KEV, Ortec and Accelerators, Inc. were engaged in ion implantation in the United States in 1971, while in England Linott Inc. excelled and later joined Applied Materials.[3164]

28.2.13 Ion Implantation at Higher Temperatures

On the 1967 conference in Aarhus (Århus) in Denmark, Kenneth E. Manchester (Ken, 1925 Winona, Minnesota-2014) of Sprague Electric Co., North Adams, Mass. and colleagues reported on the first bipolar transistor, made exclusively with electron and ion jets. The new advanced technology was already called "ion implantation" in the title of their discussion (Figure 28-24).[3165] The prosperous baby was born long ago, but its godparents somehow delayed its baptism for decades.

At the same conference W.J. King from the Illinois based firm Institute of Printed Circuits (IPC) established in 1957 announced the possibility of predicting the depth of implanted contacts and the use of higher temperatures that just opened the right possibilities of ion implantation. King's proposals conflicted the opinion of most participants. Nevertheless, King’s opinion was welcomed since King was no newcomer after he observed three years earlier the implantation of phosphorus and other elements of V- and III groups with accelerating energies of 1 MeV in solar cells. His research followed a year older Alväger and Hanson’s implantation of phosphorus ions in silicon for production of nuclear radiation detectors, while King already used the term "ion implantation."

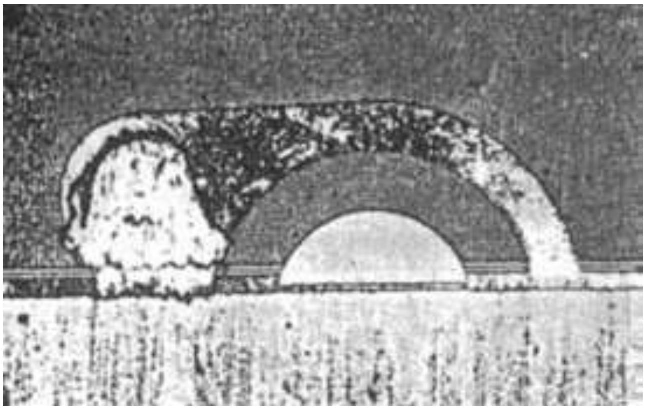

Figure 28-24: The first bipolar transistor produced by the ion implantation technique by Manchester’s group in 1965[3166]

King's group used Van de Graaff’s generator to accelerate spectroscopically pure ions of ^{11}B and ^{31}P with the voltages between 80 keV and 400 keV. By currents 1 μA to 10 μA they obtained n- and p-type layers in semiconductor substances of group IV, especially in silicon. The high voltages reduced sputtering so that they made their contacts at the usable depth without the "channeling" process along the selected crystal surfaces. In the first half of the 1960s, IPCs produced solar cells with their surfaces of 2 cm^2, radiation detectors 1.25 cm in diameter, spectrometers, magnetic spectrographs, unipolar (FET) and bipolar transistors. The diodes were also tested with the production of the n-type layer after the implantation of the ^{31}P in the diamond. King’s process provided a good control of the density of implanted ions between 10^{14} cm^{-3} and 10^{20} cm^{-3} in a repeatable manner. The ions of high energies were implanted through the passive protective layer of SiO_2.

Since the temperatures used were below the diffusion temperatures, different devices or elements could be produced in one piece without any interaction events, including the npn and pnp transistors. This prevented the diffusion of unwanted impurities. The temperature of the substrate was controlled between -195°C and +800°C. At ion concentrations up to 10^{18} cm^{-3} all the ions were used for substitution, and at a hundred times higher concentration, the number of useful ions fell to 50%. The concentration was calculated according to the LSS theory of Lindhard, Scharff and Schiøtt. The difference between theory and measurements was below 10%. For most distributions and resistances of the silicon target, only the highest implanting energy determined the depth of contact.[3169]

King's initiative enabled the invention of self-aligned MOSFET-gates. In the comparatively short dozen months period different able groups of researchers in the Netherlands and the US succeeded in their production. They've got the same results while solving various problems. On June 1, 1964, H.A. Klasens' group at Philips patented and in the same year published an improved procedure for production of a thin-film transistor. The gates for automatic control of the source and outflow area were used for the first time. Two years later, Tics Siebalt (Ties Siebolt) Te Velde invented the use of the transistor gate as an anti-ion barrier in the same company Philips' US headquarters (Figure 28-25). He used the damage caused by the bombardment with ions of argon, oxygen or nitrogen ions to make a transistor in a semiconductor substrate made of sulfides or selenides of cadmium or zinc. Like in the case of sputtering, the apparent damage appeared to be benevolent as the foundation of new stage of useful devices.

At the same time, on May 1, 1966, Hans G. Dill tested polycrystalline silicon with a melting point at 1410°C for its use in high-temperature gates at Howard Hughes's (1905-1976) Aircraft Company Newport Beach in California. On 26 October 1966, he filed a patent describing the process of making self- aligned gates (Figure 28-26). The next day, his colleague, Robert W. Bower (* 1936 Santa Monica), filed a similar patent with aluminium gates made at low temperatures. R.E. Kerwin, D.L. Klein and John C. Sarace filed a patent with Bell Labs on 27 March 1967, which was technically

[3169] Wegmann, 1981, 5; Yarling, Johnson, Keenan, Larson, 1991, 57; Fair, 1998, 111, 115, 117–118.

equivalent to half a year older Dill's work. The San Francisco resident Boyd G. Watkins of Santa Clara General Micro-Electronics (GME) patented his invention more than a year before others, but not without errors.

The priority was attributed to Bell Labs in 1974, but various companies developed different technologies. Due to disagreement in the choice of technology, the group of engineers with Noyce and Gordon E. Moore included left Fairchild and founded Intel for the development of products based on silicon gates technology. Intel has developed the first microprocessor.[3170]

28.2.14 Ion Implantation as a Mature Form of Technology

In parallel with the US, ion implantation was developed in the Soviet Union; they presented their achievements in a more popular form only after the fall of the Berlin Wall in October 1991, and triggered a great surprise; the research of ancient uses of silica in Chinese porcelain and Egyptian or Phoenician glass will provide more surprises even if the ancient silicon might be mostly the unwanted impurity of pig iron and steal productions.

Already in 1952, Ioffe's student Mikhail Mikhailovich Bredov (1916 Smela Station by Kiev-1976 Leningrad) noticed the changes in the conductivity of the p-type germanium after he bombarded it with Li^+ in the Physicochemical Institute in Leningrad. In 1961, in the Laboratory for ionic bombardment of the Institute of Atomic Energy of Kurčatov, the formed Ardenne's collaborators Viktor M. Gusev (Виктор Михайлович Гусев, 1919—1978) and Marija I. Guseva (Мария Ильинична Гусева, 1925 Нежин (Nizhyn) in northern Ukraine)-2017) got pn-contact with good amplification properties after the bombarding of silicon with the ions of elements from groups III and V of the periodic table. Five years later, the technology of ion implantation was used for the first time in the Soviet Union for the mass production of switching pin diodes and bipolar transistors. The advantages of ion implantation in the production of solar cells were announced by the Gusev's group even before King's publications in the United States.[3171]
The involved amounts of implanted ions were initially determined optically. In 1973, IBM tested them for the first time with an automatic layer resistance tester.[3172] Today, we determine the amounts of implanted ions by measuring electrically doped atoms or by evaluating target damage.[3173]

In 1967, in French Grenoble, the first conference was dedicated to the use of ion implantation in the semiconductor industry. In 1970 they released the first book entirely dedicated to ion implantation.[3174] Since then, the international conferences on these technologies regularly follow one another. The Exitron DF-4 designed in Varian's production in 1975 became the most common implant in the world two years later. With these achievements, ion implantation has become a mature form of technology developed in semiconductors. As always happens in sciences, the symposia and monographs made ion implantation a kind of a independent field of research and applications.

In the following decades, the ion implantation began to be used in other fields, especially in the metallurgy for the development of new alloys, to better understand the role of impurities in metals, to change the temperature of the phase transition of superconductors and the chemical and mechanical properties of metal surfaces. To avoid the problems of sputtering molecules from surfaces and limited concentration of implanted matter with ions, we prefer bombarding of already sputtered thin films. Thus, two vacuum technologies have been complemented, although they were developed independently until then. Certainly, they were enough close to each other that some experts were familiar with both.

The ion implantation has several advantages because it does not require increased target temperatures, allows continuous modification of the composition, does not form oxides and other barriers between thin films as other method do, allows higher reaction rates and lower temperatures than conventional metallurgical processes.[3175] With the possibility of precisely dosing any of the sufficiently low ion concentration in thin films, the implantation of ions

Table 28-1: The most important steps achieved during the first century of ion implantations

Year	Researcher	Place	Field of research or discovery
1891–1895	Hertz, Lenard	Bonn	Penetrability of "Cathode rays" through solid-state barriers
1904	Bragg, Kleeman	Adelaide	zone of air ionized by flight of α rays
1905–1906	Rutherford, Becquerel	Montreal, Paris	first ion implantation in research of the penetration of α rays
1908–1909	Rutherford, Royds	Manchester	published description of the first implanter in the discussion on the helium nature of the α rays
1911–1914	Rutherford and colleagues	Manchester	bombarding of solid matter with ions, discovery of the atomic nucleus
1913, 1915	Bohr	Manchester	theory of the interaction of charged particles with electrons and nuclei in targets
1948	Bohr	Copenhagen	theory of reduction of charges of charged particles during their penetration of matter
1952	Ohl	New Jersey	patent for the first use of implantation in semiconductors, confirmed in 1956
1954	Shockley	New Jersey	patent for overheating with description of ion implantation, confirmed in 1958
1958–1960	Kilby, Hoerni, Noyce	Dallas, California	patents for planar transistors and integrated circuits, granted between 1961 and 1964
1962	King and S.J. Solomon	Massachusetts	use the term "ion implantation", the creation of special research groups
1963	Lindhard, Scharff, Schiøtt	Copenhagen	LSS theory of the ion implantation energy field
1967	Fairchild	California	first use of ion implantation in a planar integrated circuit
1970	Mayer, Eriksson, Davies	New York	the first monograph on ion implantation
1971	Extrion company	California	Establishment of the first long-term successful company of suppliers of implants
1975–1978	Extrion company	California	DF-4 becomes the most widely used implanter

has the worthwhile future among modern nanotechnologies.

28.2.15 Conclusion

The development of ion implantation began as a laboratory specificity that Rutherford and Bohr used for measurements in support of their nuclear model of the atom. They were initially interested just in the properties of bombardment particles while the ion implantation was needed just to determine their whereabouts. The attendant phenomena in the targets were not particularly attentive during next four decades, but the experimental tools and the accompanying theory was three at hand, ready for use.

With the miniaturization of transistors for space research, the need for the use of precisely such, seemingly simple, cumbersome techniques had been demonstrated, which determines the depth of ion input to the substrate and the density with the accelerating voltage. In a few years, the newly developed technology got its name, excited the special research groups, specialized conferences, monographs, and even the prevailing implanter model emerged son enough. In this way, ion implantation as an internal enhanced technology has opened the wide possibilities for use outside the boundaries of the semiconductor industry for which it was initially developed (Table 28-1).

The rapidly accelerated development of ion implantation has caused some of the annoying side effects that might have been avoided with wider knowledge of the history of related technologies. An interesting parallel is clearly seen between ion implantation and an electron microscope. Both technologies used narrow jets in 1935 and thirty years later, which caused shading, reflection, dispersion and contamination. After ten years, in both technologies they opted for broader jets in 1945 and 1975. Why didn't the researchers of ion implantation learn from the experience of older researchers of the electron microscope early enough?[3176] Of course, this is merely an assessment of the "general after the battle".

There was certainly a generation long gap between them which prevented the same researchers to be active in both pursuits. Anyway, broader knowledge of the history of sciences closely related to their own field of vacuum technologies could save them a lot of efforts, but in that case they would not be able to pose as inventors, but only as the borrowers of old technologies for new fields. Most of the people prefer glory of invention and like to hide their borrowing form other parties, especially from the older almost forgotten ones. The borrowing is especially annoying for industrial scientists and their patents, because their originality is all that matters. Bardeen as a guy who loved to reference on his predecessors was more like an exception from the rule perish or publish (your seemingly original research).

28.3 Spread of Transistors to Europe

During his visit to the United States in 1911, the son of Karl Marx's first cousin the Jew Anton Frederik Philips (* 1874) was impressed by Langmuir's successful use of scientific achievements to consolidate his position on the market. He decided to follow the example of GE; therefore, he founded the Natuurkundig Laboratorium (Nat. Lab.) as a Scientific Research Department with a special status at Philips. In the beginning of 1914, the department was taken over by Holst. He completed his doctorate at Leyden labs of Kamerlingh-Onnes, who was then awarded the Nobel Prize for helium condensation. Under Holst's leadership, Philips researchers successfully investigated the use of semiconductors between the two wars.

During the World War II, Philips did not perform surveys that enabled Bell Labs to master the technology of purifying and doping of germanium and silicon for use in radar. The German occupation put Philips in isolation, so that the American technology of germanium became acquainted for Philips only after the war, when H.B.G. Casimir and Henne Rinia's replacement at the post of director of the Nat. Lab. Evert Johannes Willem Verweij brought few grams of germanium by his first visit to the USA. In that way, despite of their similar names, the Germans delayed the Germanium use in Philips.

In 1949, Johannes Jacobus Asuerus Ploos van Amstel and Adrianus van Wieringen already produced polycrystalline germanium diodes with a new method, paying great attention to the purity of the material and the degree of doping. During the following six years, research has grown into a new plant that was set up in Nijmegen.

The concentration of US companies has hampered European marketing of transistors. In 1948, F. H. Stieltjes was responsible for initiating the research of transistors at Philips. After four years he was already running a group of ten researchers who developed Bell Labs point-contact transistor connections and transferred it to the Philips' development laboratory after the Bell Symposium in April 1952. Among the Philips' European competitors, the symposium was attended by the German companies Telefunken and Siemens & Halske. Collaboration was enabled by the Main Agreement of 1947, which was extended on 31 March 1952. Philips Nat. Lab. had not yet mastered the transistor technology and therefore needed the help of Bell and RCA.

At the Bell Symposium they demonstrated various methods for production of germanium crystals, but in Nijmegen they preferred to use the RCA alloys. Philips was in the hurry to prevent any initiative taken over by other companies that previously did not participate in the production of cathode ray tubes. Among such were, for example, US and Geophysical Services, later renamed Texas Instruments, where Teal from the Bell Labs took over the research facilities.

[3176] Ruska, 1986, 359; Wegmann, 1981, 2.

By the end of 1954, Philips had mastered the new technology that affected the whole company. First, they followed the American discovery, and then then Nat. Lab. established its own way to produce a transistor by the alloy-diffusion in solids POB (Pushed-Out-Base) which sold very well. In 1957, thirty-five researchers in Nat. Lab. have been studying semiconductors and the additional twenty other Philips' researchers were doing the same abroad. Philips has become a leading European semiconductor research company, despite its strong competitors. The American companies have established their branches in Europe, and many military orders enabled rapid development.

The Dutch universities, however, were not particularly interested in semiconductors despite frequent collaboration with Philips. That's why Philips was in a very disadvantageous position compared to Bell Labs. Although many Philips experts, along with Holst himself, occasionally lectured at the universities, Philips had to train most their semiconductors experts in their own Philips company. The situation improved in 1952 when Gerhart Wolfgang Rathenau (1911 Charlottenburg-1989 Waalre) left Philips and became the first professor of solid-state physics in the Netherlands at the University of Amsterdam.[3177]

In the mid-1990s, Philips sold more semiconductor devices than other European companies but globally still stayed behind nine US and Japanese competitors.

28.4 Development of Transistors in Slovenian Country

The first successful transistors appeared in April 1950. However, semiconductors did not quickly penetrate to less developed countries like Slovenia. Thus, A. Wedam did not yet discuss semiconductors and transistors in his book of 1955, while in his three-year-older book, the famous Bela Krajina physicist Adlešič already promised them good future:
"... that the transistor was born as the competitor of cathode ray tube to whom in many respects, it would sooner or later succumb."[3178]

In 1958, Lončar from the Faculty of Electrical Engineering in Zagreb published a discussion of semiconductors with his own experiments. With this, he opened the door to other researchers. So, the graduated engineer Zdravko Bendeković from the RIZ-Factory of Semiconductors (Tvornica Poluprovodnika) manufactured the first domestic silicon transistor when only SGS produced them in Europe in Milan. Nevertheless, in the late 1960s, domestic Yugoslavian researchers had less experience with transistors than with cathode ray tubes. The transistor devices were more expensive, so the integrated circuits still lacked in Yugoslavia.

In Yugoslavia, the Iskra and RR in Niš soon began to manufacture transistors, so they were already on sale in 1962. At the beginning of the 1960s, in the Semiconductor Department of the Institute of Electrical Transmissions (Elektrozveze) as the part of the concern Iskra (Spark), they developed their own germanium diodes and transistors. The technology was later transferred to Iskra Semiconductors in Trbovlje, where they switched to silicon diodes and planar technology as the basis for integrated circuits. However, the development did not go further from the domestic experiments, as it did not pay off to compete with the countries with a much larger market.

In the 1970s, the Laboratory for Microelectronics of the Faculty of Electrical Engineering used Varian-Extrion's cold cathode implant. The test circuit was made by engineer of chemistry Andrej Belič who patented some inventions together with his neighbour in Californian Sunnyvale by Santa Clara (Silicon Valley) Danilo D. Lasič (1952-2000) in the USA for their Liposome Technology, Inc. in Californian Menlo Park. Belič's ions were accelerated from 20 keV to 200 keV at 75 μA for boron and 250 μA for phosphorus and arsenic. The stream of ions was directed at an angle of 7^o. Prior to the implantation of MOS transistors with channel p, the device was pumped to 0.03 mPa, and during work even down to 2 mPa. The concentration of the ions in dependence on the depth was determined by the sheet resistance of the implanted layer and by the threshold voltage of the MOS transistors with the channel p. After implantation, the product was tempered at 900°C.

The modern plasma technologies are used at the Faculty of Electrical Engineering in Ljubljana. In oxygen plasma, the photopolymer is removed by

[3177] Schopman, 1988, 162, 168–170.
[3178] Adlešič, 1952, 454–455, 468–469.

photo-lithographic procedures. SF_6-plasma with additives is used for the selective etching of silicon nitride, oxide and polycrystalline silicon. Similar procedures are also used for micro-processing of silicon. Plasma procedures are also used for PECVD-layers[3179] of silicon oxide and nitrides. The conductivity of metals (aluminium, titanium, gold, etc.) in argon plasma is used to produce conductive connections on elements.

Gordon E. Moore from my own native San Francisco studied at Berkeley and received his doctorate at Caltech in 1954. Shortly after its founding, he joined Shockley's transistor laboratories in 1956. In 1957, he founded Fairchild, where he became director of development two years later. In 1968, together with Noyce, he left Fairchild and co-founded Intel for the development and production of LSI (Large Scale Integrated Products). Intel began manufacturing semiconductor memories, and it sold most semiconductor devices among all companies in the world in the mid-1990s.

Gordon E. Moore (* 1929)[3180]

28.5 Future of Transistors

The search for semiconductors has been intertwined throughout the various branches of science. In the period of decades of dominance of the cathode ray tubes, the semiconductors were mainly studied by metallurgists and physicists. After the invention of the transistor, the physicochemical properties of the materials used became interesting. At that time, the price became the dominant factor, so that physicists and technicians determined developmental orientations with the definitions of the required properties of the product. Finally, circuit designers took the lead in the production of integrated circuits. Changes in the transistor industry took place so rapidly that many experts could not follow them.

In 1965, the director of research and development for semiconductors Fairchild, the physical chemist Moore, attributed to transistor manufacturers doubling of the number of integrated components at the same time intervals. The claim is still valid: if the current eighteen months doubling period is maintained, we will have a transistor with a dimension of 10 nm in 2020.[3181]

Moore expected that the production of transistors in integrated circuit (chip) will exceed the number of printed letters in books. This will make the new way of communication a serious substitute of half a millennium older Gutenberg's invention. Certainly, he did not consider the possibilities of quantum computers.

29 Industrial Uses of Vacuum Technologies: Crooke's Vision Materialized in Ether Full of Plasma

29.1 Early History of Research of Plasma

29.1.1 Introduction

In the spirit of the ancient Greeks, the world seemed to be made up of four (types) of matter: earth, water, air and fire. If they had aggregate states in mind, their opinion is like today's. It was Prometheus who gave fire to people and he was punished for this shame.

Over the next millennia, fire was useful and of course interesting. However, only in the second half of the 19th century, the European researchers mastered higher temperatures at high and low pressures. The exploration of high pressures was especially developed in the former Habsburg monarchy, where Natterer reached pressures of 3000-4000 bar since 1844 and successfully sold his own devices. However, plasma physics, which at the end of the 2nd millennium celebrated only the seventieth anniversary of its name, did not evolve from exploration of high pressures, but from the study of the discharge of low-pressure gases in cathode-ray tubes.

29.1.2 A Weak Plasma in a Flame

29.1.2.1 Faraday's Experiments with Flame

The research of flame became especially popular with Faraday's Christmas Lectures for Youth: "... none of these rival the brilliancy and beauty of flame. What diamond can shine like flame? It owes its lustre at night-time to the very flame shining upon it. The flame shines in darkness, but the light which the diamond has is as nothing until the flame shine upon it, when it is brilliant again..."

Faraday observed the stratification of the flame projected by sunlight as a shade on white paper.[3182] In 1818 he published a physical discussion "about the flying flame" of various gases in the tube, which has prompted many further researches. In 1845, Faraday began to explore the "magnetic properties of gases". His discoveries were later supplemented by Plücker. Diamagnetism of the flame was discovered by a genuine university professor of physics in Genoa and corresponding member of the Academy of Sciences of Turin, a Piarist monk Michele Alberto Bancalari who previously taught mathematics and physics in the Nazzareno college for three years. He has ascertained diamagnetism of the flame placed between the poles of an electromagnet, where it is rejected by the axial line as soon as the magnetic field is established. Bancalari Avogadro and Hermann Kopp's specific caloric of the atom of a compound body is expressed by the sum of the specific heats of the simple atoms which form the compound atom. Bancalari's repulsion forces diminished inversely by the cubes of the distances.

Zantedeschi, a professor of physics and mathematics at Lyceum of St. Catherine in then Habsburgian Venice and a member of the Institute there published his continuations of Bancalari's research of diamagnetism. Besides Daniel's battery with ten elements with a diameter of 18 cm, he used a weak magnet that only lifted cargoes by a force of 480 N. For

this, Zantedeschi ordered in Turin a stronger cylindrical electromagnet with a 33.5 cm long iron core and a thickness of 1.5 cm, wrapped with copper conductors 33 m in length. He placed the poles of his magnet at the distance of 2.7 cm. The flame of the candle, of the oil lamp or the spiral lamp was adjusted so that the tip was four times narrower than the center. He proved that the flame directly reflects the magnet and not by an air vortex. However, Zantedeschi linked his diamagnetism of the flame to Kepler's theory of the magnetic Sun that attracts the planets; the editor of the German translation of Zantedeschi's papers, Poggendorff, made a great deal of doubt about that kind of metaphysics.

Zantedeschi sent a copy of his discussion to Arago of Parisian Royal Academy (AR) and to Faraday in London, because he knew all about Faraday's research of diamagnetism. In December 1847, Faraday added his own experiments to Zantedeschi's data and the editor Richard Taylor

[3182] Faraday, 1950, 9, 10, 18.

(1781-1858) published both in Phil. Mag. He used a much stronger electromagnet with a cylindrical iron core of 117 cm long, 9.5 cm in diameter and the distance of 15.2 cm. The copper coil was 1326 m long with a 4.3 mm radius of conductor. He proved that the magnet affects all types of flames. He found that the warmed air and flames were more diamagnetic than cold ones, and therefore the heated air was separated from the colder air in their flow toward the pole of the magnet.

Faraday rejected Zantedeschi's complaint that Faraday supposedly attributed the magnetic properties to solids and liquids, not to gases. Bancalari's discovery convinced Faraday of the temperature dependence of diamagnetism, which he initially ascribed only in the case of gases, but not in solids and liquids. He made many comparisons between the diamagnetism of various gases depending on the temperature.[3183] Thus, Faraday upgraded Zantedeschi's description of oxygen as one of the most diamagnetic gases.[3184]

Faraday proved that diamagnetism occurs "primarily due to the warm state of the gaseous part of the flame". After three years of recovering his health, Faraday continued his research of diamagnetism of gases at normal temperatures with the measurements in the atmosphere.

The research of flames also attracted young Braun. Between December 1877 and 1878, Braun upgraded Hittorff's (1869) study of the cathode sputtering and unipolar electrical conductivity of gases in Geissler cathode ray tube at the University of Marburg.

With measurements of "unipolarity" as the greater conductivity of flame in one direction, Braun continued the works of Herwig (1877), Hoppe, Hittorf (1869) and E. Becquerel. Braun assumed that the electric current does not move the parts of flames themselves, but the translation of electric current in flames takes place in the same way as in the liquid.[3185] Braun's flame alias plasma therefore resembled Stefan's hydrodynamic analogies.

29.1.2.2 Exploration of Weakly (Partially) Ionized Plasma of Flame at Viennese Physical Institute

A professor and assistant curator of the Mineralogical Cabinet in Vienna Grailich investigated the flames together with Edmund Weiss from Jesenik in Bohemian Silesian Sudetenland, the later director of the observatory and university professor in Vienna. They found that non-periodic sounds during burning occur when the volume changes by the penetration of hot oxygen and the flame products from the combustible tube into warmed air.[3186] They accepted Faraday's theory of flame, like Zoch did later in Erlangen. Zoch assumed that the flame is disappearing in higher positions and breaking the new flames. He discussed Grailich's study of changes in flame volumes, performed experiments with cigarette smoke, and concluded that all phenomena of fire were accompanied by sounds due to the rise of temperature.

Johann Zoch studied physics at the Viennese Polytechnic and at University of Erlangen in Beetz's class. Beetz taught at Erlangen between 1858 and 1868. Later, Beetz used thin films for the investigation of magnetic phenomena at Munich Polytechnic.[3187] In 1876-1877 the Bishop Strossmayer employed Zoch as a lecturer at the grammar school in Osijek in Slavonia. After the occupation of Bosnia and Herzegovina he became a provisional director of the new Sarajevo real grammar school in 1879. In 1882 he returned to Osijek for seven years. In 1889 he became a secondary school director in Bjelovar then served as a director of the Real Grammar school in the Croatian Petrinja until his retirement in 1908. In 1869 he published the first Slovakian textbook of secondary school physics, developed scientific terminology, encyclopedias and Croatian meteorology in Petrinja in 1891. As the director in Petrina he published among the first in Slavic languages a paper about Tesla's Electricity Transmission System in Sarajevo in 1895.

On July 14, 1859 the assistant at the Physics Institute in Vienna, later head of the Academy in

[3186] Grailich, Weiss, 1858, 271.
[3187] Rosenberger, 1890, 745; Jungnickel, McCormmach, 1986, 1: 204, 224; Höflechner, 1994, 2: 139.

Rome Blaserna and his students E. Mach and Julius Peterin studied induction. Later in summer 1860 Blasena of Regnault's Parisian lab and Reitlinger of Vienna investigated the bright (glittering) figures in the water with its insulation between metals and isolators resembling the middle between Lichtenberg's figures and metallic phenomena. They relied on data of A. de la Rive's *Traité d'électricité* (*Treatise on Electricity in Theory and Practice*, 1856) and Riess. Soon afterwards on April 11, 1861, Reitlinger and his student (eleve) Luka Žerjav performed similar investigations of flame, anode sputtering and Lichtenberg's figures discovered in 1777. Reitlinger confirmed Faraday's findings about the distances for (minimal) breakdown voltage, the shape of the Lichtenberg's figures of branching electric discharges appearing on the surface or in the interior of insulating materials, and the relationship between the figures obtained in positive and negative electricity. He measured four very different gases, which allowed general conclusions.[3188]

On 10 July 1862 in Viennese physics institute, the assistant Reitlinger and his new student (eleve) Franz Kraus reorganized Brande's experiment with the flame between isolated spheres, which were connected to the electrical device by conductors.[3189] In the following year, Stefan replaced Ettingshausen as an assistant director of the Viennese Institute, and thus directly supervised early plasma researchers. By funny coincidence the leading modern Slovenian researcher of plasma Matjaž Panjan works at Jožef Stefan Institute.

Faraday in London and Magnus in Berlin researched Brande's discovery as Faraday joined RI simultaneously with Brande in 1813 and eventually became his successor in the chair of chemistry. Reitlinger and Kraus used a capacitor instead of Brande's balls and proved unequal discharging at both electrodes. The flames of alcohol and oils were attracted to the negative electrode, and the flame of sulphur, phenol and SO_2 inclined to the positive electrode. The results of their experiments were consistent with the predictions of Clausius's theory of electrolysis.[3190]

29.1.3 The Fourth Physical State

Physics and chemists of those days increasingly focused their research to the diluted gases. They better understood unusually high-temperature plasma in the Sun only after successful experiments with low-pressure cathode ray tubes' discharges. The term "discharge" is still used today, although with it, besides the abrupt spark, we also describe permanent electric currents through gas.

At the beginning of his scientific work in the lecture "On Radiation Matter" twenty-four years old Faraday first narrated about a special substance to the City Philosophical Society in 1816: "…If we now conceive a change as far beyond vaporisation as that is above fluidity, and then also consider the proportional increased extent of alteration as the changes rise, we shall perhaps, if we can form any conception at all, not fall far short of radiant matter; and as in the last conversion many qualities were lost, so here also many more would disappear..."

Faraday developed those ideas soon, but they had to wait for their more challenging proponent like Crookes. Six decades later Crookes referred to Faraday when he described radiation as the fourth aggregate state of the substance: "So distinct are these phenomena from anything which occurs in air or gas at ordinary tension, that we are led to assume that we are here brought face to face with matter in a fourth state or condition, a condition as far removed from the state of gas as a gas is from a liquid (in which its properties are so far removed from those of a gas as this is from a liquid)."[3191]

The reference to Faraday has further enhanced the popularity of Crookes' ideas in Britain. Unfortunately, Crookes died prematurely to recognize the realization of his assumptions about the fourth aggregate state in modern plasma physics. Certainly, Crookes' daring proposals and his widely known spiritism got a great opposition among the Germans.

29.2 Modern Plasma

29.2.1 What Shines in the Sun?

At the time of the first Crookes papers on the fourth aggregate state, on the 20th of March 1879, Stefan calculated the acceptable temperature of the Sun as 5586°C (Figure 29-1).[3192] During the following four decades, people searched for fuel which gives the sun so much energy without exhausting its supply.

In 1854, Helmholtz used gravity as the source of the Solar energy. He calculated the course of the solar shrinkage due to the loss of energy, but he computed too low age of the Earth. Similarly, W. Thomson thermodynamically determined his much lower age of the Earth compared to the age needed by geologists for their studies of the fossil remains.

Later, on May 20, 1904, Kelvin reluctantly listened to the professor of McGill University in Montreal Rutherford's Bakerian lecture on newly discovered radioactivity as the source of the internal energy of celestial bodies. Rutherford had in mind fission, not fusion, when he said that: "... the existence of a radium in the Sun in the ratio of four parts per million per million covers by itself the present irradiated heat. The discovery of radioactive elements, which, at the time of its disintegration, liberate enormous amounts of energy, thus increases the possible life limit on this planet and allows the time that geologists and biologists require for evolution."[3193] Of course, Rutherford hoped to tell this openly just because Kelvin first nodded and afterwards got a little nap. Unfortunately, his conclusion suddenly waked up Kelvin. The frightened Rutherford immediately added the observation that Kelvin's theory of the cooling of the Earth is perfectly correct, and the discovery of radioactivity just supplements it in some cases.

Rutherford's similar conjectures about the processes with which the Sun is shining were read four years later in the Slovene language. The text mentioned the helium, while it contained much more reminiscences of the modern description of the fusion of nuclei in stars: "We can ask ourselves, why the heat from the sun, apparently never runs out ... There is a huge amount of helium gas in the sun. It is very probable that this helium was formed from radioactive substances, which are also found in great quantities at the sun. If this opinion is right, it is not difficult for us to explain why the solar output is unchangeable. When helium is formed from radioactive substances, so much heat is developed to maintain solar heat at its same level..."[3194]

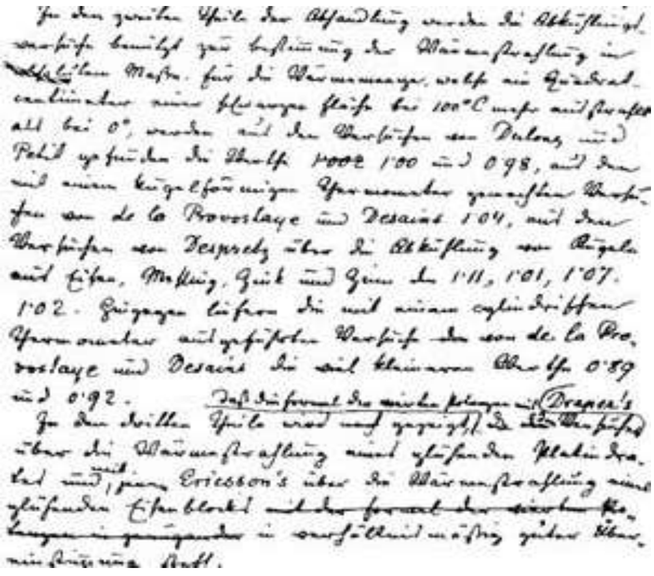

Figure 29-1: Facsimile of Stefan's manuscript of his calculations of temperature of the Sun at a session of the Viennese Academy on 20 March 1979.[3195]

In 1920 and 1925 in Cavendish's mass spectrometry laboratory, Aston found that the helium has 0.8 % less mass than four protons. The chemist Harkens of the University of Chicago called the difference "binding energy". The director of the Cambridge University Observatory, the Quaker Eddington, attributed the energy of stars to the fusion of hydrogen atoms into the heavier elements.

In 1928 in Gottingen, the German Houtermans and the Russian theorist Gamow wrote the discussion of the collapse of α particles involving a tunnel effect. Houtermans thought that an inverted process is possible, in which the nucleus absorbs the α particle and then decays. However, such a fusion was not feasible by the energy available in the laboratories of the time. While studying in Gottingen the young British physicist, Robert d'Escourt Atkinson (1898 Rhayader in Wales-1982

[3192] Stefan, 1879, 36–37.
[3193] Wilson, 1987, 220.
[3194] Čadež, 1908, 46.
[3195] AVA MinCU 282 ex 1879, 4.

Indiana) focused on Eddington's determination of the temperature inside the stars[3196] where energy was not lacking.

In March 1929, Houtermans and Atkinson wrote their paper titled "How to Cook Helium Nucleuses in a Potential Pot", but the disgruntled mainstream editors changed the title to "The Question about the Possibility of Synthesizing Elements in the Stars."

After his article on nuclear reactions as a source of energy of stars, Houtermans walked under the starry sky with a pleasant bride, his later wife. "Do they not shine beautifully?" she gently whispered to him. He shrugged and said, "From yesterday, I know why they shine." Charlotte subsequently married and divorced her star Houtermans twice instead of her other candidate even wealthier millionaire Oppenheimer with Pauli always as their best man, but Pauli was famous for ruining all experiments at a distance…

Friedrich Georg Houtermans ("Fizzl", 1903; † 1966) from Zappot by Danzig (today's Sopot by Gdansk) grew up in Vienna, where his mother Elza, a half-Jewish woman, received the first doctorate in chemistry awarded to a female. In 1921 Friedrich Georg Houtermans began studying physics in Gottingen. However, due to lack of money, his studies had to be interrupted and he supported himself as a tourist guide in Rome. In 1927 in Gottingen he completed the dissertation on resonant fluorescence in mercury with James Frank, who shared his Nobel Prize with G. L. Hertz in the previous year and later joined the Manhattan project. In 1929, Houtermans assisted Wilhelm Westphal and later Hertz at the Technical College in Berlin. For Hertz, Houtermans developed an electron microscope, which was at that time under construction by several research groups in Germany. In August 1930, during a Physics Conference in Odessa, Pauli was a best man at the first and later again to third marriage of Houtermans and Charlotte Rieffenstahl (1899 Bielefeld, Germany-1993 Northfield, Minnesota), who received their doctorates in physics at Gottingen together with Oppenheimer. In 1932, Houtermans was habilitated at the university, but due to his Jewish origins and as a member of the German Communist Party, he left Germany to work in a laboratory of electrical and musical equipment store near London in the summer of 1933. In December 1934 he went to the Physics and Engineering Institute in Kharkov, where he researched with Landau. Houtermans worked in an experimental laboratory for nuclear physics but he was arrested on 1 December 1937 as a German intelligence spy, much like the Jew Landau half a year later. Landau's exam with their theoretical minimums were legendary Peterlin's models; Landau suffered from political intrigues like Peterlin and even harder because Landau was not willing to leave Soviet Union, while Peterlin never got his strong backer Kapitsa like Landau did. Like Peterlin or Plemelj, Landau was unable to produce his own textbook without Evgeny Mikhailovich Lifshitz (Lifšic), but Landau's car accident was the disgrace like Kuhelj's, the accident that almost no one of their scientific capacity ever suffered. On 25 April 1940, the foolish Russians handed Houtermans over to the Gestapo. Von Laue saved Houtermans from their claws. In 1941 Houtermans was able to join the private laboratory of von Ardenne in Lichterfelde near Berlin, where he studied the theory of the chain reaction for the state post office. Before the end of the war, he moved to the 2nd Physics Institute in Gottingen, and in 1952 he became a professor at the University of Bern. He died in Switzerland in 1966.

Friedrich Georg Houtermans (* 1903; † 1966)[3197]

[3196] Eddington, 1928, 18, 149, 364, 368, 392, 394.

[3197] Khriplovich, 1992, 30.

But Houtermans and Atkinson had almost no experimental results available. They knew that at higher temperatures at the core of the Sun, hydrogen atoms could come nearer to their electrons. The high pressure in the Sun would then compress the atoms into a mixture of protons, eight times thicker than lead. They calculated that fusion of hydrogen would generate enough heat of the Sun. But they did not know whether a mixture of protons in the conditions of the Sun would in fact sustain a thermonuclear reaction.

Later the folks found that Houtermans and Atkinson incorrectly determined the cross-section for capture in the nucleus and the likelihood of radioactive decay. However, the errors mutually annihilated each other to enable the sound results. Houtermans description of the nuclear reaction gave Cockroft the idea to build a proton accelerator. In 1932, Cockroft completed it along with six years younger Ernest Walton at the Cavendish Laboratory and later joined the Manhattan project.

Figure 29-2: Hans Bethe (lower row, first from right) with Richard Feynman (* 1918; † 1988) at a meeting in Rochester in January 1952

In 1938, at the University of Cornell, Bethe already had experimental researches of nuclear reactions available, since in the early 1930s fusion reactions were in the focus of research on high-energy physics. He calculated how fast the protons must chain reaction fuse with each other to keep the hot stuff inside the Sun.

In the years 1938 and 1939, Bethe and Teller's PhD student Charles Critchfield (1910 Ohio-1994 Los Alamos) found that the thermonuclear reaction in the universe was carried out in two ways: in hydrogen (proton-proton) or in the carbon cycle. The later was independently discovered in Berlin by the German Heisenberg's collaborator Karl baron Weizsäcker (1912-2007).[3198] The hydrogen cycle strongly resembled the quantitative proposals of a wide variety of researchers, including M. Curie in 1912 and independently Perrin, Eddington and the Swedish initiator of global warming ideas Arrhenius in 1923.[3199]

The German **Hans Albrecht Bethe** was born in Strasbourg, where his father co-operated with Braun at university (Figure 29-2). He studied physics at Sommerfeld's class in Munich in 1928. He continued his research work with Rutherford in Cambridge, and with Fermi in Rome. At the beginning of the pressures of Nazi authorities in 1933, Bethe's professional route at the universities in Munich and Tübingen was interrupted because of his Jewish mother and he left for England. In 1935 he went to the University of Cornell in the United States, where he became a professor of physics two years later. In 1940, Debye came to Cornell as a professor of chemistry. Bethe was the head of the technical department for production of the atomic bomb in Los Alamos. In the last year of the war, under Bethe's leadership, his year and a half younger friend the naturalized American Edward Teller studied a hydrogen bomb.

In 1949, Bethe patented an invention associated with a hydrogen bomb.[3200] After the war in Geneva, he participated in negotiations with the Soviet Union for controllable nuclear testing.
Bethe's pioneering work evoked enthusiasm and vigorous debate, as it turned out that the giant stars could not radiate with today's brightness for billions of years. Since they were not yet aware of the passage of the star to a state of lower intensity, in 1948 Spitzer assumed that star giants had to arise relatively late from the dust in the spiral constellations (galaxies).[3201]

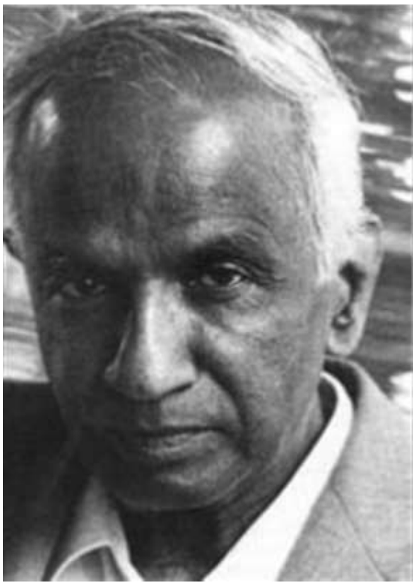
Subrahmanyan Chandrasekhar of Lahore graduated from the University of Madras at the age of twenty. During the long summer journey of 1930, he calculated his theory of white dwarfs while traveling to England, where he studied under supervision of the professor Dirac in Cambridge and received his Ph.D. in 1933. He disputed with Eddington over the reality of black holes and the upper limit for the mass of white dwarfs. Although Eddington's sharp criticism at the meeting of the Royal Astronomical Society in January 1935 almost destroyed Chandrasekhar's career, he remained an admirer of Eddington's work. Eddington for himself did not feel guilty as he supposed that if the famous Eddington mentioned virtually unknown Chandrasekhar was good for Chandrasekhar even if Eddington criticized Chandrasekhar. Subrahmanyan Chandrasekhar’s second cousin Sivaramakrishna Chandrasekhar (1930-2004) discovered discotic liquid crystals in 1977.



Subrahmanyan Chandrasekhar (* 1910; † 1995)

Since Ralph Howard Fowler (1889-1944), Rutherford's only son-in-law and Dirac's professor at Cambridge, explained high-pressures inside the stars with a model of gas of nucleuses and electrons. His research was continued by Chandrasekhar, a Dirac student at Cambridge. In 1931, Chandrasekhar announced that white dwarfs, discovered by Adams in 1915 and studied by Eddington, consisted of a highly compressed substance, the plasma. After the war, Chandrasekhar, as a professor in Chicago, continued to solve astrophysical problems together with Fermi.[3202]

1937, Chandrasekhar worked at the University of Chicago. In 1944 he became a professor, and in 1953 he became a naturalized American. In 1983, he shared the Nobel Prize in Physics with William Alfred Fowler (Pittsburgh-1995 Pasadena), a professor at Caltech. Since 1947, Fowler has simulated thermonuclear reactions in the laboratory, as they should take place in the stars. In doing so, he was helped by the rich experience of investigating elementary particles in accelerators. When in 1953 five years younger English astronomer Fred Hoyle visited Fowler’s Caltech Institute, they began a long research of the synthesis of chemical atoms in stars and additionally in supernovae in 1980. Subrahmanyan Chandrasekhar explored liquid crystals at Raman Research Institute in Bangalore. He died in Chicago. Subrahmanyan Chandrasekhar’s article is noted among the nicest one ever written in science and Podgornik also loved it as one of the best he ever read.

29.2.2 Langmuir's Study of Fluctuations in a Plasma

The research of plasma gradually moved form academic institutions into the industrial labs. In the middle of 1920s, Langmuir focused the hydrogen gas stream to a heated tungsten filament tube to dissolve hydrogen molecules atoms. When the hydrogen stream was distracted to the hot parts of the experimental device, the atoms reunited in the molecules while the heat of recombination raised the temperature to near 6000°C, just like the surface of the Sun.

The most important properties of the plasma were measured with the voltage between the walls of the vessel and Langmuir’s thin probe made of from a high melting metal such as tungsten or molybdenum. An adequate tiny probe could not perceptibly change the distribution of plasma tension. In arc discharges in mercury vapors with his heated cathode at room temperature he detected many possibilities for accelerating primary electrons up to speed above the potential difference in the cathode ray tubes. Other electrons had lower

[3202] Spitzer, 1956, 12–14.

speeds, so on average, energy was just the right one.

Numerous explanations of the phenomenon did not fully fit. A natural assumption was made that electrical arcs caused scattering, with the influence of rapidly changing electric fields on electrons, as well as with voltage changes on electrodes. In 1923 and 1924, Langmuir’s collaborator at the research laboratory of the General Electric Company at Schenectady A. F. Dittmer discovered a particularly pronounced anomaly in a thin layer a few millimeters away from the fiber using Langmuir's technique. To explain Langmuir's discovery of unusually strong scattering in the arc, Dittmer first announced strong internal fluctuations. The oscillatory period were comparable to 10^{-8} s with the continuous transition of primary 50 kV electron energies from the thread to the areas of maximum scatterings, but he was unable to detect them.

Even before the printout of Dittmer’s discussion Kamerlingh Onnes’ PhD student Frans Michel Penning (1894-1953 Utrecht) in Eindhoven Philips’ labs published observations of controlled oscillations of frequencies of radio waves in low-pressure arc discharges in mercury vapours under the same conditions as those that led to the electron scattering, which convincingly confirmed the correlation between the observed strong scattering and radiation.[3203]

In addition to surprisingly strong scattering, they observed two other specificities of glow discharges in gases, associated with plasma fluctuations. The first of these was the "angular" scattering of the primary jet near the cathode at the arc. It was most convincingly examined by Karl George Emeleus (1901–1989) and his students from the Queen's University of Belfast with simplified Langmuir probes after 1941. Emeleus was a former Appleton’s PhD student and Dirac’s fellow member of Kapitsa’s Cambridge club. Emeleus and his assistants described several times the connection between the angular scatterings of the primary jet and the existence of primary oscillations in discharges. They used tungsten cathode in mercury at low pressure and anode in the form of a coaxial cylinder. A sufficiently small movable probe that was not detectably changing the distribution of plasma tension was placed between the electrodes. At a voltage of 15 V to 100 V and an electrical current from a few milliamps to 100 mA, fluctuations with wavelengths of about 10 cm were almost always detected at very different frequencies and amplitudes (Figure 29-3).

Figure 29-3: A simple probe for detecting plasma fluctuations3204

Another special kind of feature is sometimes nicknamed Langmuir's paradox which Langmuir described in 1925 and D. Gabor named a decade later. They detected the anomalous short relaxation length of the cathode beam and the existence of a Maxwellian electron energy distribution function in the positive column of a DC arc discharge at low gas pressure. The electrons of an electrical discharge in a gas contradict theoretical indications with their same velocity distribution as the molecules of a gas. Maxwell's distribution of electron energies is maintained at discharge in gas very close to the insulated wall. The measurement surprised the researchers, since on the negative charge of the wall only high-energy electrons from the gas are collected, and therefore they detract Maxwell's distribution of electrons nearby. Far from the wall, Maxwell's distribution is restored due to the energy transfer of collisions between electrons and other charged of neutral particles. In any case, the average free paths of energy transfer were known to be larger for several orders of magnitude than the very small distances needed to restore the equilibrium distribution of discharges.

29.2.3 *Naming of Plasma*

A century ago, Crookes' idea of the fourth aggregate state passed to Langmuir, who named it "Plasma" and described the fluctuations in it. Langmuir studied the neon lamp and measured the parameters of the low temperature plasma in the diluted gas with the probe.

In the spring of 1928 during his exploration of arc discharges in mercury at low pressure at room temperature, Langmuir asked his colleague at GE

[3203] Tonks, Langmuir, 1929, 195; Lafferty, 1998, 319–320.

[3204] Gabor, 1951, 209.

for advice: "Look, Tonks, I'm looking for a name. For these glow discharges, the area is in the immediate vicinity of the electrode wall as the "border layer", which is fine. But how do we call the main part of the discharge? Conductivity is large there, so you cannot get a voltage difference as with a boundary layer that collects the entire charge. We have a complete neutralization of spatial charges there. I do not want to make up the name, but I need to describe this type of space separately from the boundary layer. What do you suggest?" Langmuir, of course, exaggerated the tension and neutralization of spatial charges, but Tonks took the time to think. Unfortunately, he was too slow, because Langmuir came to him the next day and proclaimed, "I know how we will name it! We will call it 'plasma.'"

The paper with the new term was sent to print on June 21, 1928 (Figure 29-4). Crookes dreams come true after his German critics have all died and even Crookes himself passed away nine years ago.

$$\delta n = n\partial\xi/\partial x \qquad (1)$$

Originally the net charge was zero, so after the displacement Poisson's equation gives

[4] Langmuir, Proc. Nat. Acad. Sci. 14, 627 (1926).

[5] The word "plasma" will be used to designate that portion of an arc-type discharge in which the densities of ions and electrons are high but substantially equal. It embraces the whole space not occupied by "sheaths." See Footnote 4.

Figure 29-4: The first mention of the term "plasma" and electronic fluctuations in Langmuir and Tonks's discussions on 20 November 1928[3205]

Thirty-nine years later Tonks remembered that Langmuir mentioned blood in his choice. He chose the name in contrast to the name of the "border layer" along the wall to describe a wide spectrum of phenomena of motion in electrolytes, flames and the Heaviside layer in the atmosphere. The choice of the name was not influenced by the characteristics of unstable oscillating plasma, nor by twisting motion in living cells, nor by the similarity with the protoplasm. At that time, they knew much about gases and much less about blood plasma than today. Tonks and Langmuir used the name of the plasma for that part of the arc-type discharge, where the density of the ions and electrons is high, but essentially the same without much differences among them. Plasma comprises all the space not occupied by the "boundary layers (sheaths)".[3206] Partially ionized gas is called plasma when Debye's length is small in comparison to other distances.[3207]

Langmuir was extremely successful in inventing new names. Among other things, in 1914, he helped to establish the "-tron" suffix, which is still held by a wide range of electronic devices. He had very useful ideas, and above all important links to put them into circulation. The other guy who loved to invent newly coined terms in physics was Clausius, although Clausius relied on the ancient Greek language and his suggestions were not always accepted as Maxwell, Tait and other Brits made fun of several of them.

In 1911, Langmuir acquired one-atom hydrogen and described the metal welding in hydrogen flame. In 1913 he published the law of thermionic emission which is still named after him. In 1916 he constructed a pressure gauge and a high-vacuum pump. Three years later he presented his model of atoms based on the older Bohr's ideas. He has also become known by the Langmuir and M. Sah's equations that connect the surface ionization to the surface temperature of the metal, its output, and the ionization potential of atoms. Together with his rival Berkeley suicidal professor Gilbert Newton Lewis, Langmuir set up a theory of chemical valences. In 1916 Langmuir published the equation of isomerism of single-molecular adsorption. Langmuir also helped inventor Westinghouse's AC contractor William Stanley (1858 Brooklin-1916) to solve his problems of heat transfer in the metallic thermos, which helped his invention of a 25% more efficient vacuum bulb.

In 1932, Langmuir was awarded the Nobel Prize in Chemistry as the first American industrial scientist for his investigation of monomolecular surface thin films. In the same year in 1932, Coolidge succeeded Whitney as director of GE's laboratory, and Langmuir became director and later the adviser. Among GE's advisers were the other Nobel Prize winners: Hans Bethe of Cornell, Ernest Lawrence of Berkeley and Eugene Wigner of Princeton who later joined the Manhattan project.

[3206] Tonks, Langmuir, 1929, 196.

[3207] Spitzer, 1956, 17.

In 1903, **Irving Langmuir** from New York became a metallurgical engineer at the University of Columbia. Three years later, he received his Ph.D. in Göttingen under supervision of the professor of Electrochemistry Nernst, a former Boltzmann's student. Nernst was not a useful consultant, and Langmuir got much more help from the former Plücker pupil, the mathematician Klein, who also taught at the University of Göttingen between 1886 and 1910. After several years of chemistry teaching, Langmuir listened to a classmate's advice and began research work at the GE Research Laboratory in Schenectady, New York, where Edison moved his research facilities in 1886. At the beginning of December 1900, the Laboratory was set up in a barn near Steinmetz's house. Steinmetz set up the former chemistry instructor at MIT, Whitney, for the first director of research at GE with one assistant. Whitney studied in Leipzig and then taught at MIT.[3208] Langmuir wrote to his mother: "While I am in Schenectady, I will look for a really goody job at the university." This "while" was extended to nearly half a century of Langmuir's GE research. Times changed as research was not necessary coupled with teachings anymore because modern science produces money of its own.

Irving Langmuir (* 1881; † 1957)[3209]

By the end of the Second World War GE labs more closely resembled Edison's time than Einstein's era. GE's researchers were dealing exclusively with electricity, where they had strong patents. They worked in small groups according to the method that was baptized in Cambridge as the "classic tradition of cords and seal wax". Langmuir, with his colleague the learned chemist-meteorologist Vincent Schaefer (1906 Schenectady-1993 Schenectady) and the first female physicist in industrial laboratory the same-sex Boston marriage households practitioner Catharine Burr Blodgett (1898 Schenectady, New York -1979 Schenectady, New York), discovered single-molecular thin films of liquid on the liquid during the search for a better lubricant for bearings. They are called Langmuir-Blodgett's layers.

In 1939, Langmuir was impressed by Hahn's discovery of a nuclear chain reaction, so that Kenneth Hay Kingdon (1894 Montego Bay in Jamaica-1982 Schenectady) and the chief plant steward Howard C. Pollock began exploring GE's uranium in 1940, which at the end of the war turned into the core research group. In 1947, Langmuir, Pollock and Franck R. Elder first detected synchronic radiation on the 70 MeV synchrotron.

In 1945, the GE had 630 staff including 160 scientists and engineers. About half of them previously studied physics, 30% chemistry, 15% metallurgy and 5% mechanics. Soon after Whitney, Coolidge retired in 1946. At the end of 1948 they were followed by Dushman and Albert W. Hull. In 1950, Langmuir joined them. At that time, there were already 1000 people working in the laboratory who were able to set up a new building in Electric's Knolls Atomic Power Laboratory, near Schenectady, New York. New generations of researchers and market competition then already demanded the implementation of major projects at GE.

Irving Langmuir considered that he had avoided the possibility of fluctuations in plasma during his experiments.[3210] Following Dittmer's 1926 paper, Langmuir together with Tonks, investigated the fluctuations of very high frequencies, in 1928 and in February 1929. They published a simple theory of plasma-electron oscillations in an ionized gas with a single mechanism for clarifying both the

[3208] Bowers, 1998, 145.
[3209] Redhead, 1994, 79.
[3210] Gabor, 1951, 210.

special nice features of electric discharge in gases: "angular" scattering and Langmuir paradox. The famous J. J. Thomson by his personal letters helped them to find some of the theoretical solutions. The new theory was based on completely uniform, macroscopically neutral plasma at zero temperature. After every small displacement of the electrons from an approximately neutral equilibrium Coulomb force restores the balance. There are harmonic oscillations with a characteristic frequency called by Langmuir’s name, although they were first described in Lorentz’s electron theory in 1909. However, Lorentz considered transverse waves, while Tonks and Langmuir described the longitudinal waves of a completely different nature. To emphasize the difference, Langmuir's waves were called electron-acoustic waves (sound type oscillations in Langmuir-Tonks notation of 1929), although the name is not quite appropriate. Initially Helmholtz, Roentgen, Hertz, and the eternal Tesla were trying to prove their own kind of longitudinal waves, but they never had much luck.

In addition to these waves, others are also possible in plasma. Among them acoustic and later hydromagnetic (Alfvén's) waves were detected in 1942.

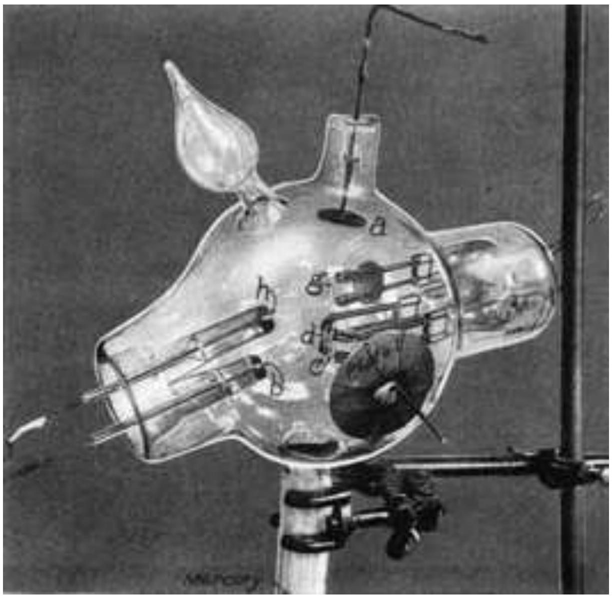

Figure 29-5: Langmuir and Tonk’s measuring apparatus, described on 20. 11. 1928[3211]

In 1929, Tonks and Langmuir noted two theoretically possible oscillations: the oscillations of electrons of 1000 MHz are too fast to be followed by the heavy ions. The oscillations of ions are so slow that they always leave the density of electrons at the equilibrium value corresponding to Boltzmann's law.

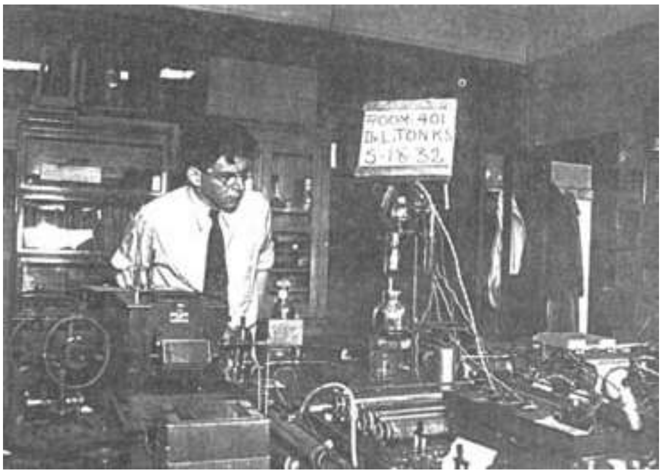

Figure 29-6: Lewi Tonks (* 1897; † 1971) in the laboratory[3212]

Lewi Tonks received his doctorate in 1923 at the Pupin’s University of Columbia, where he studied a generation after Langmuir (Figure 29-6). Three years after graduation Tonks started working at GE. In 1937, he named the "pinch"-effect, which Bennett discovered three years earlier as "magnetic self-focussing streams". The term pinch was jokingly used by Carl Hering (1860 Philadelphia-1926 Philadelphia) and his friend former Rowland’s assistant Edwin Fitch Northrup (1866 Syracuse-1940) in 1907.

In 1929, Tonks and Langmuir measured in two cathode ray tubes containing filamentary cathodes used as the sources of electrons. The collectors were placed in such a way that they received a part of the direct stream of primary electrons from the filament. Off to one side they put an anode that maintained the discharge. In the first tube, two tungsten filaments were supported near the middle of the 18 cm spherical bulb by long leads (conductors) covered with glass. . Their exposed portions were about 1.1 cm long and parallel at distance of 0.5 cm from each other. 4.2 cm away they put a round collector, a circular disc plate with a diameter of 1.1 cm backed by mica. Their second

[3211] Tonks, Langmuir, 1929, 202.

[3212] Stroke, 1994, 724.

cathode ray tube was the same, although it had three vertical tungsten filaments and not just two (Figure 29-5). With ZnO-Te-detector and galvanometer, they detected oscillation frequencies (fluctuations) with the frequencies of plasma-electron oscillations.[3213]

In the next volume of Phys. Rev. Tonks and Langmuir also studied the boundary layer formed at contact of the plasma with a solid surface without any magnetic field.

They used different assumptions about the potential difference between the plasma and the wall; the thickness of the boundary layer was roughly given by Debye's length (Debye and Eric Hückel's (1896 Berlin-1980 Marburg) distance calculated at ETH in Langmuir's narration), which is like the reciprocal value of the ionized fluid's absorption coefficient for electric forces.[3214]

29.2.4 "Pinch"- Effect

The great global economic crisis brought together in plasma physics the research of astronomers (later called astrophysicists), geophysics and fans of discharges in diluted gases. For Langmuir's definition of plasma, there was still an essential electric field, which caused heating and ionization. Later, plasma became a synonym for partially ionized gas.[3215]

Langmuir's heirs studied the unusual behavior of plasma in a magnetic field, and in the next decades they developed a new branch of science called magnetohydrodynamics. Physics of plasma has already quickly given its sense in the efforts to explore space and to simulate cosmic conditions in local laboratories. The basic problem was not the ignition of plasma, but its retention in a limited space. As with the electron microscope in the early 1930s or later with the unworkable fusion power plants, plasma researchers decided to prefer to keep the plasma with the electromagnetic fields far enough away from the walls of the container, as they did not believe that any material could withstand such higher temperatures. That was the same problem which still bothers the inventors of fusion reactors whose success is always a decade ahead. Rutherford's student Mark Oliphant (1901 Adelaide-2000 Canberra) designed his Cavendish lab nuclear fusion of hydrogen isotopes in 1932, a half of dozen years before the escaped Jewess Lise Meitner and her Berliner ex-colleagues described nuclear fission. Still, the fission bombing of Japanese happened a half of dozen years before Pacific nuclear fusions while the controlled fusion reactor is among the longest delayed technological applications of theory along with Tesla's tower and coil despite Matjaž Panjan's optimism.

On February 15, 1932, at Thomas Corwin Mendenhall's (1841-1924) Laboratory of Physics at Ohio State University physicist Bennett assumed that the breakdown in cold-emission (field discharge) was caused by small streams of quick positive ions from the anode, which strike the cathode along the electron current. Bennett's important term breakdown designated the modification in the not entirely outgassed cathode which causes the current to change suddenly in its order of magnitude without any change in the "measured field".

If the current of ions is less than 10^{-2} A, they eliminate all emitting points by their collisions. The stronger currents, on the contrary, cause damage on the surface of the cathode and thus create new emission surfaces. The positive ions formed from residual gas or at the anode by the electron stream would at least partly follow the stream back to the emitting point. This bombardment of the emitting point by positive ions, if their current is not too concentrated, would eliminate the emitting point, perhaps by pounding it down. The breakdown in cold emission, at pressures of 10 mm or less, is due to a stream of positive ions with high velocity, which is produced by an initially small electron current striking the target of the emission (cathode). Elimination of cold emission from high voltage tubes, by using electrodes which were not outgassed, depends on preventing the positive ions leaving the target from hitting the cathode with high velocities. Bennett could not explain that phenomenon, therefore, in next months he used his new million-volt tube applied to centimetre surfaces at short distances from the anode to produce measurable emission. In the case of high voltage tubes, the longer distances and the higher voltages, he formed self-focussing streams.

[3213] Tonks, Langmuir, 1929, 203–210.
[3214] Tonks, Langmuir, 1929, 201, 876–922; Spitzer, 1956, 17–18.
[3215] Alfvén, 1963, 134–135.

On January 13, 1933 published only in June 1934, he described a "pinch" effect discovered at his State University of Ohio when he investigated the causes of cold-emission breakdown and regulation of plasma with magnetic fields:

"Streams of fast electrons which can accumulate positive ions in sufficient quantity to have a linear density of positives about equal to the linear density of electrons, along the stream, become magnetically self-focussing when the current exceeds a value which can be calculated from the initial stream conditions…" Self-focusing particles approach the axis in an ever-increasing part of the electron stream... This type of process can be continued into infinity if magnetic self-focusing is obtained in each part of the stream, which is long compared to its own diameter ...

The described process is probably only short-lived of the order of 10^{-4} s or 10^{-5} s. Later streams cease to be self-focusing since the transverse energy of the electrons along the sharp edges of the craters of the cathode becomes too large or too close to the cathode, or the density of matter increases so that we can no longer ignore the collisions (Figure 29-7).

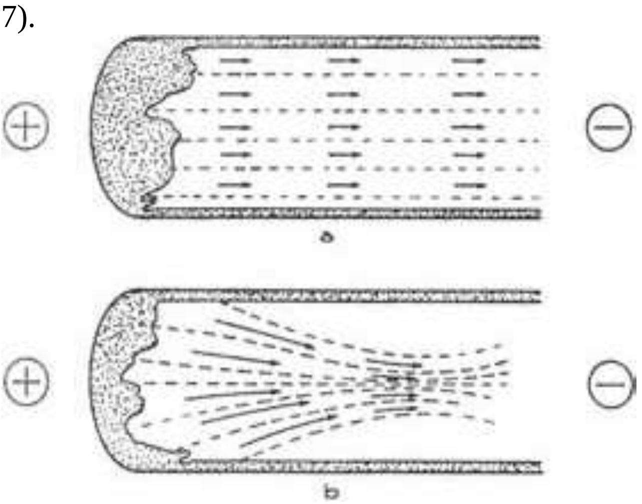

Figure 29-7: The scheme of "pinch-effect"[3216]

The researchers before Bennett studied the focussing effect of residual gas on slow low voltage electrons because the ions have much smaller velocities than the electrons freed by ionization of the residual gas. Nobody studied focusing effect on electron streams due to the magnetic attraction between the parts of electron stream, which becomes important at high voltages.

Willard Harrison Bennett of Findlay graduated from the University of Wisconsin in 1926. Between 1928 and 1930 he worked at Caltech, and then at the University of Ohio until 1938. Between 1946 and 1950 he researched at the National Bureau of Standards. Academic jobs followed: from 1951 to 1961, he lectured at the University of Arkansas, and then at the University of North Carolina where he met Peterlin although their fields of research were not the same. He developed the principle of a tandem Van de Graaf accelerator.

Bennett has proven that breakdowns by cold emission are not caused by structural defects in the surface of the cathode, but rather by the circumstances in the flow of plasma. He concluded his description of breakdown in cold emission in June 1934:

1) The breakdown was much more abrupt when the electrodes are not outgassed than when they are outgassed.

2) The fineness of the polish on the surface of the cathode does not affect the value of the field intensity at which breakdown occurs" but only affects the fields at which the first small currents pass (surface impurities are not the cause of breakdown).

3) Without outgassed electrodes, after breakdown has occurred, if a field intensity a little less than the field at which breakdown occurred is applied to the cathode, large sudden surges of current pass through the tube, similarin every observable respect to the surge of current which accompanied the original breakdown, but the frequency of occurrence of these surges decreases with time.

4) We can prevent the breakdown or at least greatly diminished by outgassing (both) electrodes or by increasing the resistance in series with the source of potential to a value which will limit the maximum value to which the current can rise, to the order of 10^{-3} or less.

5) Before the breakdown, the current is very erratic, rising abruptly, and dropping sometimes abruptly, and sometimes gradually; these erratic fluctuations while the current is small occur at

[3216] Gamow, 1961, 132.

values of field much higher than the values of the field for the same order of magnitude of current after breakdown; but once the value of the current has increased to more than the order of 10^{-2} amperes, the resistance of the tube decreases and the surface of the cathode becomes permanently altered to give much higher order currents at a given field than before.

6) During the breakdown, Bennett noticed small flashes of light both at the anode and at the cathode

He could not explain his discoveries with the older ideas of tearing up impurities or pieces of metal bodily from the cathode with the field. It more resembled the idea of magnetically self-focusing streams.

Bennett's charged particles form an electric current which can induce their own magnetic field. This then pinches the plasma together and forces individual ions to collide with each other. The more powerful and more frequent the collisions, the "hotter" the plasma is, the greater is the likelihood of fusion of nuclei.

29.2.5 The Kinetics of Plasma

The Americans were good, but the Soviets were no worse. In 1936 and 1946, Lev Davidovich Landau (Davidovič) and Anatoly Alexandrovich Vlasov (Анатóлий Алексáндрович Влáсов, 1908 Balashov-1975 Moscow) in 1938 studied the plasma kinetics. Landau lifted away Langmuir and Tonks' limits set on a zero temperature. It has been shown that Langmuir frequency[3217] is not the only frequency of vibration of pressure, but only the lower limit of vibration frequencies associated with the smallest damping of the diffusion type. The spectrum of vibrations is regulated by a dispersion law that connects the frequency with the wave number of the disorder. For the upper limit of the frequency spectrum, Landau equated the wavelength of the oscillations with Debye's length, defined as early as 1912. Landau first explained that there were no collisions in the diluted plasma, but there was a damping of the waves. The plasma electrons move chaotically at different speeds. Some electrons move together with plasma waves, as they have such a velocity that they remain all the time in the front of the waves. Thus, they are always under the influence of the same electric field, and therefore everyone equally accelerates and stops. For decades, this "dampening of Landau" was practically useless; in hot plasma, there were not enough high-speed electrons that would generate enough current in terms of the power input. The change occurred in 1978 after theoretical plasma research in TOKAMAK at MIT, so today with the damping of Landau we additionally heat plasma in the regulation of thermonuclear reactions. It was the same old story of the invention waiting for its users with the only except of Tesla's coil and tower which are still on the waiting list a century after their invention.

29.2.6 Magnetohydrodynamics

In 1822, Ampère investigated the movement of the conductive liquid, i.e. mercury in a magnetic field. He tested the "electric mill" that turned the magnetic needle on the surface of mercury. However, because of the low conductivity of mercury, hydromagnetic phenomena were weak and they have not been observed during previous centuries.[3218]

In his investigations of transport phenomena in liquids Stefan used equations of the hydrodynamics of a continuous substance on the problems of kinetic theory of gases. In this way, in 1886, he avoided determining the force between molecules, since he did not know with certainty its dependence on distance. Half a century later, the completed mathematics of classical hydrodynamics again helped the physicist in their problems; Alfvén explained a series of phenomena in cosmic plasma with the equations of magnetohydrodynamics in 1942. He published his basic assumptions with the idea of "frozen" magnetic field in plasma and described magnetohydrodynamic waves, a new wave of motion of a conductive medium in a magnetic field. Alfvén's magnetohydrodynamic waves enabled comeback of waves temporarily beaten by Einstein's photons and Heisenberg's matrix quantum theoretical opposing of Schrödinger wave equitation. After the success of magnetohydrodynamic waves, many similarities followed including solitons, phasons and the like.[3219]

[3217] Tonks, Langmuir, 1929, 198.

[3218] Faraday, 1952, 810–811; Alfvén, 1963, 106–107.

[3219] T. G. Cowling used the term Magnetohydrodinamics, which Spitzer endorsed at the same time (1956, vi) .

Hannes Olof Gösta Alfvén described the simplest behavior of plasma, as his classic Boltzmann transport theory from the end of the 19th century was retrieved from the closets. Then valid theory of conduction was developed only for partially ionized gas; so, they were only approximately valid for completely ionized gas of charged particles in plasma.
After the end of the Second World War, Spitzer returned to Yale and continued his research of interstellar material from the period before the war. Even after he joined the University Observatory in Princeton, the development of a deeper theory seemed reluctant, with no useful experimental results. In 1948, during Alfvén's visit to the USA, Spitzer became acquainted with the foundations of magnetohydrodynamics, which he developed in the following years. In 1950, he and his colleagues calculated the thermal and electrical conductivity of completely ionized gas. They discussed the influence of the individual electrons on the velocity distribution and described it as a diffusion in the velocity space. Three years later, they published a more detailed theory of astrophysics.[3220]

Spitzer early figured out the importance of determining the thermal and electrical "Spitzer" conductivity and mechanical transport coefficients in a fully ionized gas. His pioneering research on plasma physics was crowned by a monograph on the physics of completely ionized gases. As always, the monograph declared that the focused branch of science became a mature recognizable fellow of other branches.

The American Rosenbluth and his co-workers from the Radiation Laboratory of the University of California at Berkeley used Chandrasekhar's idea of 1943 to develop Boltzmann's transport equation for the description of collisions of two bodies with an isotropic distribution function in space and in velocity-space. They numerically solved the simple conservative axisymmetric Fokker-Planck's equation for Newton's force, which is inversely proportional to the square of the distance; Chandrasekhar and Spitzer's approaches were presented as the special kind of cases. As early as on 31 August 1956 they were among the first to propose the use of a computer, which immediately gave their theory a promising gift of modernity.

Hannes Olof Gösta Alfvén from Norrköping, Sweden, studied in Uppsala. Between 1937 and 1940 he worked at the Nobel Institute of Physics in Stockholm, and then he taught at the university there. As a Scandinavian, he was destined to clarify the northern light (Aurora Borealis). He continued the research of Norwegians Carl Störmer (1874-1957) and his assistant Kristian Birkeland (1867-1917) from the late 19th and early 20th centuries. Alfvén connected northern lights with "cathode rays" following the example of Arago's description of Davy's arc-lamp of 1820. In 1939 Alfvén developed the theory of magnetic storm and of the northern lights, which was based on the idea of "frozen" magnetic fields in plasma. In semi-neutral Nazi-influenced Sweden Alfvén was able to make his research heaven without noticing the hell on the Earth during WW2. In 1943, he developed a planetary cosmogony with an early sun piglet, which caused ionization in galactic gas while traveling through a galactic nebula. The ions were supposed to move around the spirals circling the magnetic field of the Sun, and later they become thicker to form the planets. Thus, Alfvén designed a new science called cosmic electrodynamics, which, however, took many years for recognition, so that he had to publish his papers in obscure magazines at first. In 1970, he received a half of the Nobel Prize in Physics.

Hannes Olof Gösta Alfvén (* 1908; † 1995)[3221]

Their procedure could be carried out sufficiently correctly in the low-pressure plasma limit, where the mean free path is long compared to Debye's

[3220] Spitzer, 1997, 409; 1997, 434–443.

[3221] Casimir (anonymous notice), Europhysics news, July-August 2000.

length. In other words, the potential energy between the particles is much lower than the product between the Boltzmann constant and the temperature. Extension to the limit of strong interactions required more complicated statistical mechanics.

Lyman Spitzer from Toledo, Ohio, studied at Yale University in Edinburgh, Illinois. After graduating from Yale, he studied in Eddington's class of the college of St. John's in Cambridge between 1935 and 1936. Spitzer admired Eddington, even though he was disappointed with personal contact with him, just like Chandrasekhar used to be.[3222] Between 1936 and 1938 Spitzer completed his doctorate at Russell's class in Princeton, and then taught at Harvard, Yale and Columbia universities. In 1947 he succeeded Russell as a professor of astronomy and director of the Princeton Observatory, which he led for a quarter of a century until 1979. In 1985, he received the Crafoord Prize of the Swedish Royal Academy of Sciences, which is at the level of the Nobel Prize for those areas not covered by Nobel. Spitzer~~'s~~ researched ~~in~~ four major areas: interstellar matter, stellar dynamics, astronomy, and plasma physics, which he studied up to 1966.

Lyman Spitzer (right) with the American astronomer and Princeton University director Henry Norris Russell (* 1877; † 1957) who demonstrated spectroscopically that the Sun is mostly made up of hydrogen in 1929[3223]

Teller picked up Rosenbluth to help Teller's H-Bomb projects. Following the International Plasma Physics Seminar from 5 to 31 October 1964, Marshall Nicholas Rosenbluth (1927 Albany, New York-2003 San Diego, California) led a plasma physics program at the International Center for Theoretical Physics in Trieste, thus affecting the Slovenians across the Italian border. In 2002, he received the third prestigious Alfvén's Award for outstanding contributions to plasma physics from the European Physical Society.

29.2.7 Continuing Langmuir's Research Into Plasma Fluctuations

The fluctuations in plasma did not allow much practical use other than the "plasma oscillator" described by the expert in sputtering Gottfried Karl Wehner (Fred, 1910 Bärenwalde 100 km southeast of Dresden-1996 Gauting 20 km southeast of Munich) at Wilbur Wright Air Force Field in Dayton, Ohio in 1950. Wehner began his studies of plasma as PhD student of Winfried Otto Schumann at Technical University of Munich and they both joined Wright-Patterson Air Force Base in Ohio by secret USA at Operation Paperclip. Otherwise, the study of the occurrence of fluctuations in plasma has a great scientific significance.

In 1952, Gabor calculated the rate of energy exchange between individual electrons and the entire spectrum of oscillations of plasma in the discharge, assuming an equipartition of energy between the various modes of plasma fluctuation. With too little energy transfer, he could not describe the phenomena that led to the concept of plasma fluctuations being introduced. It turned out that the modified theory explained much less than the original Langmuir's theory. The aged GE's counselor Langmuir was not yet a scrapheap as a godfather of plasma.

So, Gabor returned to the original assumption of the existence of strong coherent, almost uniform frequency fluctuations within the discharge. Gabor's first doctoral student at Londoner Imperial college the son of escaped Jewish jeweller sir Eric Albert Ash (* 1928 Berlin) and Gabor's later PhD student E.D. Dracott assisted him at Imperial college to verify his assumption by sending a special electron beam through the discharge to the fluorescence display in 1955. They found that there are surprisingly high fluctuations in the plasma amplitude in the positive ion layer, which separates

[3222] Spitzer, 1997, 3, 505.
[3223] Stroke, 723.

the plasma from the isolated wall. Such fluctuations are not in the plasma itself; therefore, they considered the influence of the plasma boundary and the boundary layer on plasma fluctuations, with which Bohm and one of his first graduate students at Princeton Eugene P. Gross (1926 New York-1991 Boston) supplemented the older Vlasov's assumptions in Princeton in 1949.[3224]

One of Bohm's and Gross's predictions was that oscillations were caused by electrons sent through a homogeneous plasma. Their assumptions were supported by experiments of Harrison J. Merrill (1913 Preston, Idaho-2008 Reston, VA) and Pupin's graduate student Harold Worthington Webb (1884-1974) of Columbia university published a decade earlier. With improved technique, they localized plasma fluctuations and established the relationship between oscillation and strong scattering, which didn't succeed in Langmuir and Tonks's lab in 1929.

The results of Merill and Webb were analyzed by Richard Quintin Twiss (1920 Simla in North India-2005) in 1951. However, the agreement between experiments and theory was not indisputable, since in Merrill's and Webb's measurements the electron beams came into plasma through conus shaped sleeve formed by ions.

To overcome the doubts, Duncan H. Looney and Rumford's biographer Sanborn C. Brown (1913 Beirut-1981 Henniker, N.H.) experimented without their tube-shaped covering at MIT lab of electronics between 1952 and 1954. They did not detect the fluctuations in plasma seemingly predicted by Bohm and Gross. Hence, the dispersion laws were systematically analyzed and interpreted. In 1958 J. E. Drumond and Marshall Nicholas Rosenbluth's collaborator at General Atomic Division of General Dynamics Corporation, John Jay Hopkins Laboratory for Pure and Applied Science in San Diego David B. Chang showed that Bohm's and Gross's law of scattering predicts more amplifying than fluctuations. The same conclusions were already noted by Pierce with different methods. Looney and Brown probably did not notice any gain due to losses in their measuring system.

In a similar experiment, the Soviet researcher of plasma accelerators R. A. Demirkanov obtained a strong interaction between the modulated jet and plasma. A rare UFO researcher Peter Andrew Sturrock (* 1924 Stifford in Essex) showed that the diameter of the electron beam in the experiment of Looney and Brown was much smaller than the wavelength in plasma, and it did not fulfill with the condition of Bohm and Gross on an infinitely narrow jet. The theory of dispersion of waves and plasma was published by GJ Budker in 1956 at CERN (Fig. 29-8).

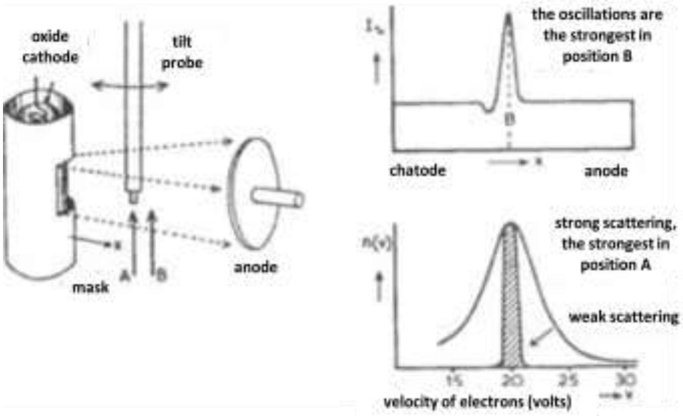

Figure 29-8: Merill and Webb's experiments with localization of plasma fluctuation in 1939[3225]

The basic problem of plasma physics was the interaction of individual electrons with others in the ionized gas. In 1951 and 1952, Bohm and his PhD student David Pines (1924 Kansas City-2018 Urbana) studied plasma fluctuations. The other main problem of plasma research was the "escaping" electrons in thermonuclear devices. Rapid electrons interact strongly with plasma and cause high frequency instability, amplification, or oscillation.

Another, equally important problem is the interaction of plasma fluctuations with electromagnetic field. Plasma fluctuations should explain the irregularities associated with the behavior of electrons in arc discharges. The existence of these fluctuations was supported by the discovery of radio waves of approximately relevant frequencies emitted by the arc discharges. However, the theory of oscillation has shown that these waves are longitudinal and do not radiate.

[3224] Gabor, 1951, 216.

[3225] Gabor, 1951, 210.

Tonks and Langmuir also predicted transverse waves in plasma, but these methods of propagation did not affect other plasma fluctuations. Therefore, it was necessary to consider the influence of edges or non-homogeneity, which combine both types of waves. Such theories were developed by N. G. Denisov at his PhD in Gorkovsky University (Горьковский университет, today Lobachevsky State University of Nizhny Novgorod) in 1954, by Spitzer doctoral student at Princeton George B. Field (* 1929 Providence, Rhode Island) in 1956 and by the collaborator of the Jewish atheistic Nobel laureate Vitaly Lazarevich Ginzburg named Vladimir Vasiljevič in 1956. Another important way of coupling the energies of plasma fluctuations with a radiation field allows the formation of a static magnetic field in plasma.

Sin-Itiro Tomonaga of Tokyo studied in Kyoto and completed his studies at Heisenberg's class in the University of Leipzig between 1937 and 1939. Their collaboration was a part of the militarization of both their countries on the eve of WW2. In 1946, Sin-Itiro Tomonaga developed a mathematical description of the interactions between photons and electrons, and he independently developed the theoretical foundations of quantum electrodynamics by 1948. Similar ideas were separately developed by Richard Feynman and Julian Schwinger (1918-1994) in the United States, therefore, Sin-Itiro Tomonaga shared the Nobel Prize in Physics with them in 1965. In 1950, Tomonaga considered fermions as quantum of sound.

Sin-Itiro Tomonaga (* 1906; † 1979)[3226]

Plasma physics initially considered the exchange of energies between an individual electron and the collective motion of many particles. The same happened to its related quantum physics of plasma.

In 1934, Bloch expanded his research of power of stopping the charged particles by quantifying the excited states of Fermi gas. He did not describe the particles with the holes and excited states, but as states of fluctuations of gas resembling the sound.

In 1949 Bohm in his theory of superconductivity assumed that the fluctuations of plasma in a metal are not easily disturbed with the external forces of perturbation. The prediction was proved by Sin-Itiro Tomonaga of the Tokyo University in 1950 and 1958. After 1954, they began to differentiate between the collective and individual excitations of particles that the fast electrons cause in metals. They measured eigen-energies and intensities in dependence on the angle of scattering of the incident electrons, the impurity in the target and the temperature.

Like the classical physics, the quantum plasma physics has also a problem of the interaction of plasma fluctuations with electromagnetic fields, which was investigated by Heisenberg's postdoc student Richard Alan Ferrell (1926 Santa Ana-2005) at Naval Ordnance Laboratory in the United States in 1958 and 1959.

29.2.8 Nuclear Fusion

As most of the discoveries in physics of the 20th century, the plasma physics have also developed from the study of discharges in dilute gases. Soon it interfered with the substance in space and became particularly interesting for astrophysics, which until then was not explicitly interested in cathode ray tubes research. Thus, the discoveries of plasma physics touch upon the very foundations of the knowledge of the world which surrounds us.

The plasma makes 99% of all substances in stars and between them, while on Earth it is rare. The firing and spark at normal pressures were well understood only in the middle of the 20th century. The translation of electricity through diluted gases, which appears in the high parts of the atmosphere as a northern glow, began to be intensively

[3226] Schweber, Treiman, Phys. Today (December 1994) 59.

explored in the second half of the 19th century.[3227] From the same time there are also the first explanations of meteors, another example of the appearance of plasma in the upper layers of the atmosphere. The Polar Aurora Borealis also attracted interest among Slovenes, although it was more rarely seen in their latitudes, for example, on 24 and 25 October 1870 and on 14 February 1892, when it was described by Josip Torbar (1871) and Simon Šubic.

The magnetohydrodynamics, or, better, magnetofluidodynamics deals with the motion of conducting liquids in magnetic fields, thus combining electrodynamics and hydrodynamics. The astrophysicists had been involved in magnetohydrodynamics since the beginnings of physics of radiofrequency plasma. They studied the "hydrodynamics of Sun" and the source of the magnetic fields of the Earth and the Sun. The treatment of currents through the Earth's core has evolved into the study of the motion of an incompressible conductive field, which has become the fundamental problem of magnetohydrodynamics. Practically, it is used primarily in "magnetic self-focusing systems", the basis of the operation of fusion reactors. Physics of plasma has emerged as a special branch of science later than other branches of science. The delay has brought some advantages, since it is precisely from the research of plasma and fusion that we expect the solution of the energy crisis due to the supposed exhaustion of fossil fuels mostly stored outside westerner domains. The rise in the price of coal and other imported fossil fuels has directed the British and many other replacements of the thermal power stations with nuclear plants.

The fusion would, of course, have priority over fission nuclear power stations, because its fuel deuterium as is very cheap. By using nuclear fusion reactors, plasma physics promises a solution to the energy crisis and at the same time reduces the pollution of the environment.

The artificial Sun of fusion is almost naturally inherent to humans. In the early 1970s, following Natan Aronovich Yavlinsky's (Javlinsky, Yavlinskii, Натан Аронович Явлинский, 1912 Kharkov-1962) and Ksenia Aleksandrovna Razumova's (Ксения Александровна Разумова, Xenia Razumova, * 1931) success at the TOKAMAK T-3 in the Soviet Union, it seemed that controlled fusion of nucleuses was ahead. Surveys were designed by TOKAMAK for individual households... However, decades later, it seems that the solution is not so close because its final designs are always supposed to appear a dozen years ahead.

Majority of plasma surveys were devoted to the control of the fusion energy, which is supposed to be used as an inexhaustible energy source. This problem has attracted most of the magnetic fusion investigations between 1945 and 1958 as well as later the research of Inertial confinement fusion using lasers.[3228]

We developed two basic types of thermonuclear reactors. In the first, whose oldest representative is TOKAMAK, we need external energy only to trigger a thermonuclear reaction. For the second type, α particles produce too little energy to maintain the reaction, so we must supply energy from the outside.

29.2.9 Magnetic Traps and Stellarators

In 1952, Leontovich's Moscow helper Vitaly Dmitrievich Shafranov (Виталий Дмитриевич Шафранов, 1929 small village Morvinovo 100 km east of Moscow-2014 Moscow), and the Jewish relative of Julius Robert Oppenheimer Martin David Kruskal (1925 New York-2006 Princeton) at Plasma Physics Laboratory in Princeton independently from each other found the conditions for stabilization of plasma with a magnetic field. They researched during the collusions of the Cold War. The experiments in the Soviet Union were conducted under the direction of Tamm's PhD student Igor Nikolaevich Golovin (1913 Moscow-1997 Moscow) and Natan Aronovich Yavlinsky. The Jew Gersh Itskovich Budker (Герш Ицкович Будкер, Andrey Mikhailovich, 1918 Murafa in Ukraine-1977 Akademgorodok) suggested that a "tape" of plasma be inserted into another external magnetic field directed along the axis. The interaction of this field with the plasma flow results in a force in the direction of the plasma thread. If we correctly choose the size of the average field, this force can compensate for the effect of ballooning.

[3227] Penning, 1957, 1.

[3228] Stroke, 742.

The nonstationary aspects of plasma had forced researchers to find other ways to hold plasma using magnetic fields. In 1952, Budker in the Soviet Union and independently of him Herb York and Dick Post in Livermore in USA, produced a trap in which the long-term plasma retention was used by the reflection of charged particles from the field with increased induction of the magnetic field. A simple trap was in the shape of a bottle with two necks. Induction of the magnetic field is higher in the throats than in the middle of the bottle trap, where bottle was used by USA terminology and trap in Soviet slang. This increased induction consists of a magnetic plug preventing the plasma from escaping from the trap. That is why Budker called his construction of a trap with "magnetic stoppers" "probkotron". In the United States, the same kind of trajectory was called a "magnetic mirror system."

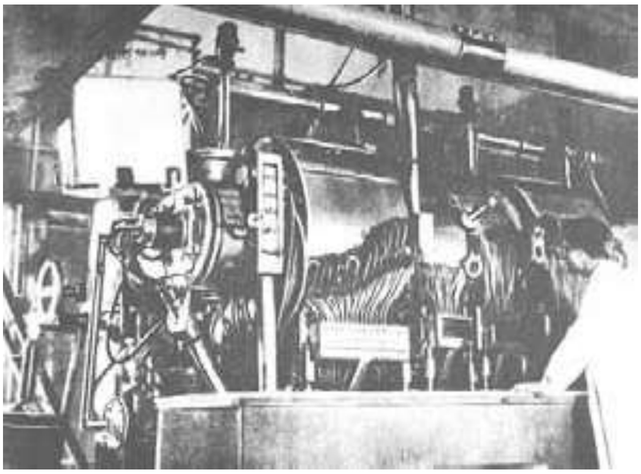

Figure 29-9: Photo of Ioffe's "PR-1"[3229]

In 1953, Budker assumed that the mass of particles was changing during the passage through the trap, which was experimentally detected by the device "OGRA"[3230] in the Soviet Union and by the Oak Ridge Direct Current Experiment "DCX" in Tennessee.

OGRA was built at the Kurčatov Institute for Atomic Energy in 1958. It had a vacuum vessel of 1.4 m in diameter and 12 m in length. The magnetic field in the middle of the trap reached up to 0.5 T and at the ends up to 0.8 T. In such large devices, a vacuum of 10^{-9} mbar could already be achieved.

Another much smaller trap "PR-1" operated under the guidance of M.S. Ioffe at the same Kurčatov institute (Figure 29-9). The diameter of the vacuumed vessel with a pressure of down to $0.8 \cdot 10^{-7}$ mbar was 0.5 m, and the distance between the magnetic stoppers was about 1 m. In the middle of the room there was a magnetic field of 0.2 T density and in the stoppers, there could be even 3.4 T. Even before the attempts at "PR-2", in 1957 B.B. Kadomtsov in the Soviet Union and Marshall Nicholas Rosenbluth (1927-2003 San Diego) with Conrad Lee Longmire (1921-2010 Santa Barbara) of Los Alamos in the US were predicted that plasma not only runs away through the stops in the traps of the magnetic field of, but also transversally through the magnetic field (Figure 29-10).[3231]

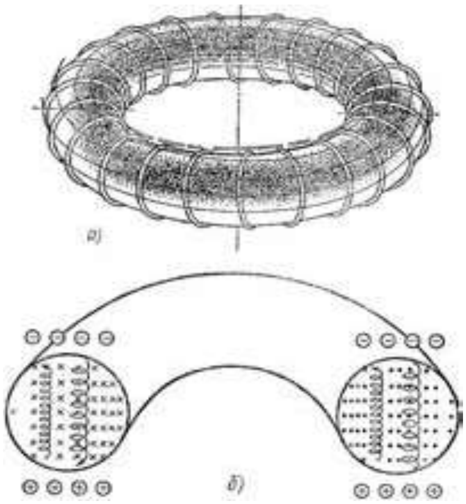

Figure 29-10: Sketches of magnetic traps [3232]

In March 1951 the Argentinian President Peron, the husband of beautiful Evita of Madonna's movie, announced that his researchers successfully carried out a controlled thermonuclear reaction. The news made Spitzer reflect deeply, while he just went to his family skiing. He was thinking during his long waiting lines on the ski lift and, after returning to Princeton, he designed a stellarator.[3233] The Atomic Energy Commission immediately paid a year of his theoretical studies of a stellarator to obtain energy from thermonuclear reactions using deuterium or 2 deuterium and tritium.

After theoretical research, experiments were started under the leadership of James Van Allen (1914-2006) at the University of Iowa, who first

[3229] Arcimovič, 1964, 336.
[3230] "Odin Gramm Nejtronov v Sutki", gram of neutrons per day was just enough for thermonuclear reaction.
[3231] Arcimovič, 1964, 251, 330, 340–342, 391
[3232] Voronov, 1985, 67.
[3233] Star knot.

submitted a simple model A with a glass vacuum container of diameter 5 cm. Van Allen later became famous for his radiation belts. The model B followed with the vacuum tank of same size where Van Allen reduced the diameter of the plasma to 2.5 cm and the magnetic field to 5 T. With ultrahigh vacuum he reduced the flow of impurities from the walls and obtained good agreement with the predictions of magnetohydrodynamics. It seemed that success was just near ahead. That's why they started to make up four times bigger model "C", which should follow the model "D" in the form of a usable reactor.

Unfortunately, more detailed experiments showed that the plasma confinement time in the "B" model was unexpectedly short, of order of only 10^{-4} s. Therefore, the Atomic Energy Commission stopped the program after the "C" model. Since the work was already underway, experiments were started anyway in May 1961. They achieved one order of magnitude higher plasma confinement time.

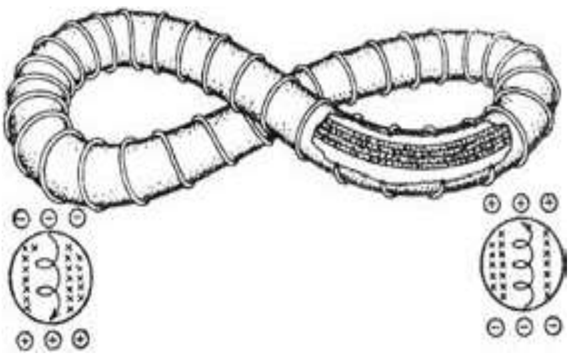

Figure 29-11:Sketch of stellarator [3234]

In stellarators, the problems in toroidal magnetic fields were removed with a magnetic retention design in the form of a "8"-shaped plasma (Fig. 29-11). The magnetic forces from a thin magnetic coil, wrapped around a vacuum vessel shaped as number 8, directed hydrogen ions into the vessel. An unusual vessel was designed at Princeton University to prevent energy losses by hydrogen-ions' colliding with the wall. The charged pick particle moved in one loop in the clockwise direction and in the opposite direction in the other loop. The particle deviation from their preferred orbits was luckily nullified.

In 1954, at the University of California, then leader of the production of American hydrogen bombs Teller noted that that form of stellarator is not resistant to the excitation of plasma along the helical line. The problem was later resolved by Spitzer, who led a plasma physics laboratory in Princeton from 1953 to 1966, initially under the secret name "Matterhorn Project" to make a joke on earlier Manhattan project.[3235]
Since no vessel can keep something as hot as plasma, it had to be kept in a limited space with magnetic fields in a "magnetic bottle". Of course, the plasma should not escape from the bottle, as it would cool down on the walls of the vessel and thus lower its temperature needed for fusion.

At the end of the 1950s, the United States guys reached around 10 million degrees. Similar attempts have been made in the Soviet Union, Great Britain, Sweden, Germany, Japan and elsewhere. As pioneers of the new field of research the Brits used their particularly large devices. Initially, deuterium was preferred as the reaction substance, and later tritium which posed greater radiation problems. When using pure deuterium, where two-thirds of the energy is carried by the charged particles, it seemed possible to turn all the energy of particles straight into electricity. Like the piston in the steam engine, we can imagine a moving plasma that operates against a magnetic field, and an electric current that takes away energy.

In the mixture of deuterium and tritium, most of the energy is taken by neutrons. The liquid lid barrier can be used to absorb neutrons and to change their energy into heat; and the decay of lithium produces useful tritium atoms at the same time. The fusion energy of the nuclei is then used to heat outside the plasma, which is then used again to produce even more energy.
In 1952, the Soviet Union guys found that at certain conditions strong "pinch" in the diluted deuterium characteristically source strong radiation neutrons and X-rays.

Bennett's "pinch"-effect has become a constant topic of astrophysics and geophysics research, and in the second half of the 20th century" also of fusion which was not easily to controlled or stabilized. In 1950, the Soviet Union and the USA proposed the use of Bennett's discovery of

[3234] Voronov, 1985, 68.

[3235] Spitzer, 1997, 445.

magnetic thermal insulation of plasma for controlled thermonuclear fusion of nuclei.

Between 1950 and 1951, the "pinch"-effect of deuterium was researched on the state level in the Soviet Union, the United States and the United Kingdom. In the US, the project Sherwood named after friar Tuck (in fact James Leslie Tuck) and Robin Hood's residence has been set up to develop a controlled output of fusion power. In 1951, the research began with little support, but the project was given as much as $ 40 million a year until 1959.

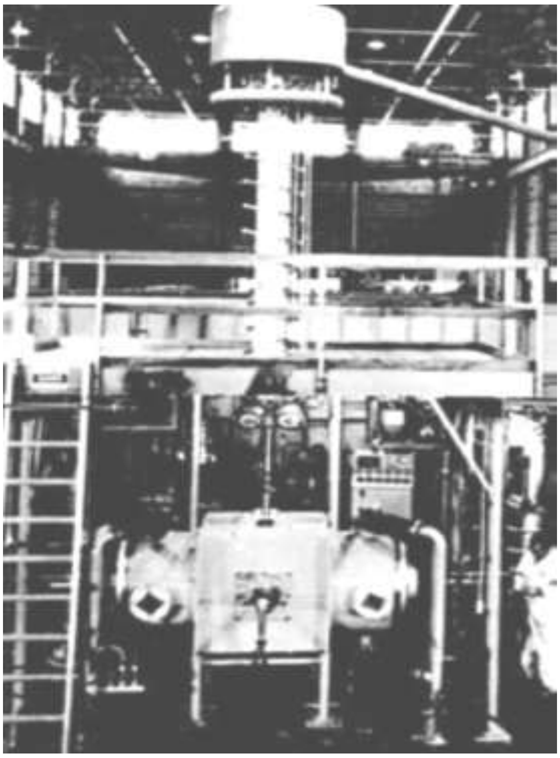

Figure 29-12: Photo of the fusion research facility in Oak Ridge[3236]

A whole series of experimental devices for exploring the "pinch"-effect were put in a scientific laboratory in Los Alamos. James Leslie Tuck (1910 Manchester-1980) Gamow jokily baptized "Perhapsatron" a funny device built in 1952. In it, the hydrogen ions circulated in a cathode ray tube shaped like a donut, and the electric current pulled them together into a narrow column inside the tube. Plasma was limited only by the magnetic field generated by the plasma current itself, which did not enable the desired stability. In lab of Laurence Livermore University 44 miles east of San Francisco in California, they chose different way of solving fusion problems, called "magnetic mirrors". Instead of space in the form of a donut, they used a straight tube; hydrogen plasma was trapped by strong magnetic fields and "repelled" back from the end of the tube to the inside. In the National Laboratory at Oak Ridge, fusion was undertaken by launching the deuterium molecules down into the reaction vessel. They were ionized there with an electric arc and then influenced by magnetic fields (Figure 29-12).

29.2.10 TOKAMAK[3237]

The structure of the magnetic field in TOKAMAK (Figure 29-13) resembles the stellarator; only we so not get rotation of the magnetic field lines with the outer wrapper of the helix, but with the flow that flows along the plasma. Closed magnetic surfaces are alike in both devices.

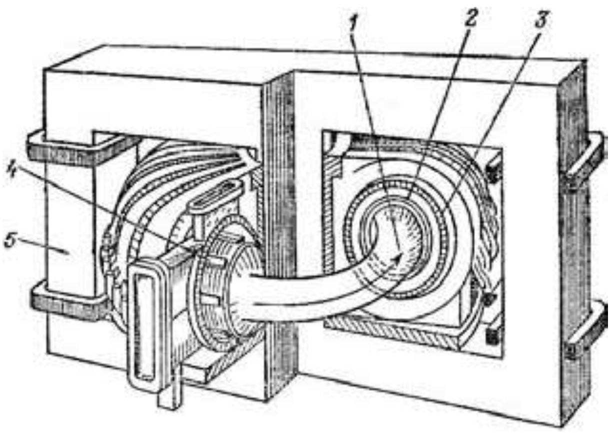

Figure 29-13: TOKAMAK[3238]

TOKAMAK is the simplest and best-studied design for limited controlled plasma, since only the simplest toroidal field, plasma and current are required. The first TOKAMAK was developed by Lev Andreievich Artsimovich's (Arcimovich, Arcimovič, Лев Андреевич Арцимович, 1909 Moscow-1973 Moscow) group at the Kurchatov (Kurčatov) Institute of Atomic Energy (Национáльный исслéдовательский центр «Курчáтовский инститýт» previously Институт атомной энергии (ИАЭ) имени Йгорьа Васúльевича Курчáтова) in the Soviet Union in 1956. They reached temperatures of 15 million degrees.[3239]

[3236] Lapp, 1960, 170.

[3237] In Russian language: "Toroidal'naja KAmera s MAgnitnymi Katuškami".

[3238] Voronov, 1985, 87.

[3239] Tarasov, 1985, 164.

Initially, they used the term "Toroid in the magnetic field (TMR)" for TOKAMAK. In 1958, T-1 was assembled with the stainless kind of steel container, but only reached a few thousand degrees and did not exceed the potential barrier. In practice, the same T-1 and T-2 had a 125 cm diameter vacuum container at a maximum magnetic field strength of 0.8 MA/m.[3240]

After the numerous monographs by leading researchers,[3241] plasma physics has become a recognized research area on both sides of the "iron curtain." Another distinguished field of physics.

The antagonist of the biologist Lysenko (Трофи́м Дени́сович Лысе́нко, Трохим Денисович Лисенко, 1898-1976), **Lev Andreevich Arcimovich** (Arcimovič) from Moscow studied in Minsk where his parents escaped during the revolution. Between 1930 and 1944 he studied at the Leningrad Physical-Technical Institute of the National Academy of the Soviet Union, and then at the Kurčatov Institute of Atomic Energy. In 1936 he and his colleagues demonstrated the preservation of the impulse in the annihilation of positron and electron. From 1951 he led the research of thermonuclear synthesis in the Soviet Union. In the following year, together with Leontovich (Leontovič) from Moscow and colleagues, he discovered neutron radiation in a high-temperature plasma. In 1955, Geneva hosted the first international conference on the peaceful use of atomic energy, which did not yet discuss fusion. In 1956, after the February speech of Nikita Khrushchev against Stalinism at the 20th Congress of the Communist Party of the Soviet Union, Kurchatov lectured on fundamental thermonuclear research at the Harwell Atomic Center in England near Harwell in Oxfordshire, thus revealing the secret curtain of the mystery. Two years later, the exchange of experience continued at the 2nd International Conference on the Peaceful Uses of Atomic Energy under the auspices of the UN in Geneva, where Spitzer first publicly presented his stellarator. In 1961, the researchers met in Salzburg at the 1st International Conference on Plasma Physics and Controlled Nuclear Fusion.

In the early 1950s, Nikolai Vasiljevič Filippov's (Николай Васильевич Филиппов, 1921 Moscow-1998 Moscow) invention ~~a~~ remained one of the real variants of the solution of the thermonuclear problem, but Filippov died after a winter ski trip along the Moskva River. When it became clear that one of the main paths of energy loss in these discharges was associated with the exclusion of admixtures, the academician Arcimovich presented a replacement of the wall of the discharge vessel with copper. He assumed that high thermal conductivity of the copper would reduce the surface heating by contact with the plasma and diminish the flow of admixtures into plasma. For safety purposes, the side wall of the room was electrically connected to the cathode. When the high-voltage pulse was applied on the anode, the discharge illuminated the room. The researchers were surprised at the extraordinary phenomenon, since the change in the sidewall material produced huge increase in the number of output neutrons. Unlike conventional discharges, the neutron pulse in this system began to retain stability. V. Filippov found the source of neutrons in a very small area on an axis between anode and a cathode of about 1 cm in diameter by lead-collimator with a small aperture and with an internal neutron counter. It seemed that, during the release of such composite charges, under the pressure of the magnetic field plasma is directed from all sides to the center of the system.

At the point of symmetry, the "streams" of plasmas collide and form a surface thickening from which neutrons emerge. This area, and with it the whole contained system was called a "dense plasma focus (DPF)". The plasma flow was indeed collected along the axis like the light beams were collected at the focal point of the lens.

In 1965 at the 2nd International Conference on Plasma Physics and Controlled Fusion of nucleuses in England, Bohm described the relationship between the time of existence, the temperature and the magnetic field size in plasma, which caused the pessimism about the operation of the thermonuclear reactor because Bohm predicted the decreasing of the time of existence of plasma by increasing its temperature. Ksenia Aleksandrovna Razumova's Tokamaks seemingly proved Bohm's error.

In 1961 the T-3 was designed in the Soviet Union with a toroidal container of diameter 200 cm,

[3240] Arcimovič, 1964, 211.

[3241] Spitzer (1956, 2: 1962), T. G. Cowling (1957), Chandrasekhar (1960), Alfvén (1950, 2: 1963), Arcimovič (1961, 2:1964).

where they started experiments in the summer of 1962. A smaller "plasma diameter" 40 cm was achieved with two vacuum pumps at a pressure of 4 x 10^{-8} mbar at a maximum magnetic field strength of 3 MA/m. In 1968, the first quasi-stationary thermonuclear reaction was obtained and at the 3rd International Conference on Plasma Physics and Controlled Fusion of Nuclei in Novosibirsk, the guests were told that the Soviets were able to exceed the radiation barrier, under which almost all the energy inputs were emitted by was a elimination of impurities. The TOKAMAK T-3 was expected to reach ten million degrees, almost ten times as high as in the best stellerators. The Americans did not want to believe this at first, so they started a discussion on the methods of measuring the temperature and other properties of plasmas at the conference and tried to find a mistake in the measurements of their Soviet counterparts. In the following year, the English themselves measured the temperature in T-3 and gained even higher value. That's why the US stopped developing stellarators, which seemed like a blind alley.

The largest USA stellarator model C was transformed into spherical Tokamak (ST). They removed the screw coil and inserted a larger vacuum container.[3242] In 1970 the experiments began and were reported next year at an international conference on plasma physics and controlled fusion of nuclei in Madison. At MIT, TOKAMAK was set up, which was somewhat smaller than the Soviet T-3, but it had almost three times stronger magnetic field of 9 Tesla. The T-3 model, according to the type of modernization called T-3a and T-4, operated until 1978.

The more recent successes of stellarators in the Soviet Union, where they first set it up at the Physics Institute PN Lebedev at the Academy of Sciences in 1962, caused their re-establishment, since at that time they had around 20 TOKAMAKS and no stellarators. That's why the Princeton Large Torus TOKAMAK PLT, which reached 60 million degrees, was transformed into a stellarator. In the middle of 1983, the National Research Laboratory in Oak Ridge received $ 15 million for a stellarator.

In 1982 in TOKAMAK T-10 in the Soviet Union ions in the axis of the filament, heated by jets of fast atoms, already reached "energy lifetime" of 0.1 s and a temperature of 80 million degrees.

In the next generation of TOKAMAKS, the T-15 in the Soviet Union, the TFTR in the United States,[3243] JET in the European Union and JT in Japan achieved plasma parameters close to those required for thermonuclear reactor.

In 1957 the Englishmen John David Lawson (1923 Coverntry-2008) proved that the product of the density plasma ions and the confinement time exceeding $3 \cdot 10^{20}$ s/m^3 is needed to maintain a thermonuclear reaction after the end of external warming.

In 1994, the Tokamak Fusion Test Reactor (TFTR) in Princeton had already come close to Lawson's criterion for the product between the density of ionized nuclei and confinement time, which, according to today's calculations, should exceed $2 \cdot 10^{20}$ s/m^3. They reached temperatures of up to $4 \cdot 10^8$ K, but not in the same experiment. TFTR began operating at the end of 1982, but later the Princeton Plasma Laboratory went into crisis, while reducing former 1800 employee to only 800 in 1984.

Later it turned out that the price of the test reactor would exceed the possible budgets of individual countries. Therefore, in 1985 Michael Gorbachev submitted to Ronald Reagan the proposal for the joint production of TOKAMAK. Based on this agreement, researchers from the European Community (with Switzerland), Japan, Russia and the United States meet at intervals in Garching north of Munich in Germany in 1987. In April 1988, they decided to build a TOKAMAK ITER[3244] jointly at French Provence.[3245] The toroid plasma should be about 5 m wide, 10 m long and the diameter around the toroidal center line should be about 50 m. The concept for ITER was completed in 1990.

At that time, Japan began to build their stellarator type device with a smaller radius of the vacuum vessel. Their design was much smaller than ITER, but it enables more direct comparison with TOKAMAKs.

29.2.11 Laser Method

The nuclear fusion can be controlled by a pulse method without the use of magnetic retention of plasma. The compacted density of deuterium and tritium with a diameter of about a millimeter diameter can be heated in a very short time, in which it cannot yet decompose. This creates a very high pressure, which enables more intense heat exchange between electrons and protons. We use well-focused, strong laser radiation, which must simultaneously heat the compression all sides during the time of the order of the nanosecond. The method shows some technical and structural problems, for example, how to use profitably the obtained energy of neutrons (Figure 29-14).[3246]

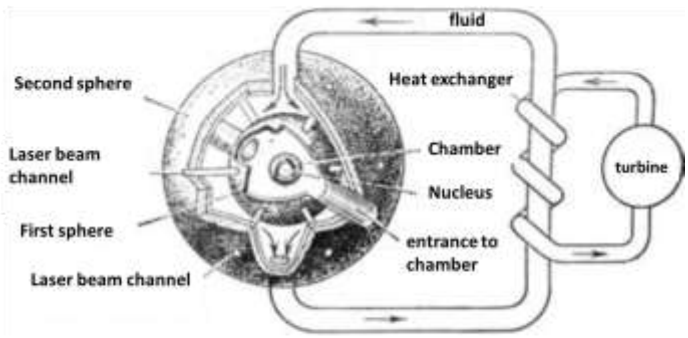

Figure 29-14: Sketch of a laser thermonuclear reactor project[3247]

The first laser thermonuclear fusion was achieved in the laboratory of Basov at the Kalmar (Кальмар) plant at Physical Institute P. N. Lebedev at the Soviet Academy of Sciences in 1968. In 1964, Basov received half of the Nobel Prize in Physics for Quantum Electronics Research, which led to the invention of lasers and masers. In 1995 in the laboratory of the University of Lawrence Livermore in California, they produced the most powerful (10^{15} W) laser needed for the research of fusion.

29.2.12 Uninterrupted Plasma Heating: Continuous Laser Method

In the Laboratory for physics problems in Moscow led by former Ioffe's student and Rutherford's collaborator Kapitsa and his collaborators developed the continuously heated plasma method in 1969.[3248]

Unlike TOKAMAK and laser methods, Kapitsa's group randomly found a method for obtaining "flaming" plasma. As early as 1950, they produced a powerful high frequency continuously working generator called "Nigotron" (нигoтрон) named by his summer house at Nikolina Gora (Николина Гора) west of Moscow. In one of the models, the wave was passed through a ball of silica filled with helium at a pressure of 133 mbar. In the sharp borders, the sphere radiated for few seconds, and in one place it melted.

In 1955, they published a hypothesis that even the mysterious ball lightings in storm clouds appear after ordinary thunder because of the high pressure's fluctuations that deliver the energy to glitter the sphere. In March 1958, the plasma parameters with a spherical resonator filled with helium at normal pressure began to be measured. They received a freely falling charge of the oval shape formed in the region of the maximum electric field and slowly moving along the circle and coinciding with the lines of force.

The most interesting was plasma radiation in hydrogen or deuterium. For small power discharges, it had no strictly defined limits, and the lights were diffused. By greater power the luminosity enlarged, the diameter of the discharge increased, and a strictly separated core shaped as a thread formed in the interior.

In the initial experiments, the discharge was triggered with a power of up to 15 kW at a pressure of 5 bar. The greater the pressure, the more stable the discharge was, and the more pronounced the shape of the plasma core. The study of the plasma conductivity including the active and passive spectral diagnostics found that the electrons at the center of the discharge have a very high temperature of several million degrees. At the boundary of plasma, a large temperature gradient was created, which can only be achieved by a well-temperature insulated layer. Initially, such kind of gradient aroused doubts until they found a physical explanation for it. At the boundary of "burning" plasma, a double electric layer must be formed, from which the electrons are reflected without loss of energy. Similarly happens

[3246] Kapitsa, 1981, 118.
[3247] Voronov, 1985, 155.
[3248] Kapitsa, 1981, 19.

when the plasma is surrounded by a layer of dielectric, such as glass or porcelain. Due to the double electrical layer on the surface of the dielectric, even at higher pressure the temperature of electrons might be more than 10,000 degrees, without perceptible heating of the walls of the container. The model of such thermal plasma insulation was first described by Langmuir. The electrons in the collision with dielectrics penetrate deeper than the more cumbersome ions. The volume charge density of the electrons therefore reached deeper than the surface charge of the ions, and reverses the electric field of the double layer, so that the fast electrons are elastically repelled from it.

In the 1970s, the microwave diagnostic method was greatly improved, so that they could measure the distribution of the density along the radius of the filament and its dependence on the magnetic field and pressure in a plasma with an accuracy of 5%. The conditions that led to the stabilization of plasma were also explained. They increased the power brought to the filamentation for several times and raised the electron temperature to 50 million degrees. This would allow fusion of deuterium with tritium without the addition of a plasma heating with magneto-acoustic oscillation if it was possible to provide a temperature equilibrium between ion and electron gas. This would greatly simplify the construction of the thermonuclear reactor.

Although the construction of Kapitsa's reactor for continuous plasma heating was very simple, Kapitsa doubted whether it could be used for controlled fusion of nucleuses. The convection processes of heat exchange cannot be assessed by theory, and therefore Kapitsa had to investigate it experimentally at the end of the 1970s.

Maxwell first described the possibility of air convection around the radiometer due to internal stresses caused by temperature gradients near the blades of mill. Shortly before Maxwell's death, his research of Crookes' radiometer showed that the internal tensions are proportional to the viscosity square and the outflow of the temperature gradient.[3249] Viscosity is proportional to the mean free path, which is close to 10^{-4} mm for ordinary gases at ordinary pressures. For small temperature gradients, the internal tension is unmeasurably small.

In the case of plasma, the average free path extends to a centimeter, and the gradient temperature is large. That is why the internal tension in plasma by Maxwell's equation could be ten times larger than in the gas, and it can cause convection current and turbulence in plasma. The magnetic field can affect the nature of this phenomenon. Unfortunately, the additional action of the electric field completely disables even a rough estimation of the power of the convection necessary for efficient heating of the ions. Similarly, we can mask the possible increase in the critical plasma size of the reactor by increasing the dimensions of the reactor without proper gains of energy. The latter, of course, would call into question the economy of the construction of a reactor of this kind.[3250]

29.2.13 *Future Research of Plasma and of Plasma Technologies*

In the ideal limit without scattering, plasma is completely frozen in the field of magnetic forces. The real plasma is usually turbulent and complex, so that the research of its behaviour has become one of the key contributors to the development of nonlinear physics.

The years of troubles have prompted researchers to make a joking remark that the solution of the problems of the fusion reactor opens a new challenge to the newcomers in this field with ever more expensive solutions as a moving target that is constantly running away. The solution to the problem of fusion should be "always 20 years later". However, there is no doubt that a 1 GW capacity fusion reactor can be built, although many problems remain open. The basics of plasma physics in TOKAMAK are well known, but much research is still focused on understanding the detailed nature of microturbulences that cause anomalous transmission of energy and fuel. The fundamental problems of the Earth's dynamics and the influence of magnetic fields on cosmological development remain open. During the research of fusion, new unplanned plasma technologies were emerging. The successes are mostly the results of the "Edison mode" of experiments and errors

[3249] Maxwell, 1879, 231.

[3250] Kapitsa, 1981, 127–128.

which really brings success, but only at highest costs.

A detailed understanding of the possibility of predicting turbulence and the behavior of fusion of plasma are important challenges of modern physics. The plasma becomes more and more important in the technology of welding, cutting, cleaning, and applying thin films of 2.5-5 μm thickness, sterilization, etc. The most important and most profitable is the use of plasma for etching, which was used for the first time in the production of integrated circuit (chip) in the late 1970s and became indispensable for production of VLSI.[3251] In 1990, the global plasma-processed industry generated revenues of around US $ 1 billion.

Figure 29-15: Plasma etching devices[3252]

The advantage of plasma processes enables anisotropic removal of semiconductor, insulator or metal material. In plasma etching with reactive ions, rapidly erecting with fast ions is complemented by chemically-reactive interactions. Therefore, the etching is performed in the direction perpendicular to the surface. The procedure allows fast enough even etching of furrows in silicon with a thickness of 0.2 μm and a depth of 4 μm, which cannot be carried out by liquid etching or other modern methods (Fig. 29-15).

Plasma is used in accelerators; with plasma spatially charged waves we produce very strong electric fields moving at a phase velocity close to the light. Thus, plasma is indispensable in all industries where the greatest amount of money circulates in the space research, accelerators, fusion, and computers.

29.2.14 Conclusion

Now we can observe our space environment with X-rays and γ - radiations that are mostly emitted by plasma forms. Traditionally, our knowledge of the universe came from the observation of the visible octave, later supplemented by radio frequencies and some views into the infrared. The space age allowed us to observe beyond the 'visible universe' also the 'universe of plasma' ... The relationship between visible and plasma universe is like the relationship between the visible and the X-ray image of a human... Like our visual image informs us about the surface of the celestial bodies, we are studying the plasma to learn about the structure of the space between the planets and, by extrapolation, of how the Solar System was once formed from small particles of plasma... The transition from 'visible universe' to 'plasma universe' is in some respects like the transition from geocentric to heliocentric cosmology 400 years ago. The latter is mostly attributed to Copernicus, but Galileo's use of the telescope may have been more important since it gave a lot of new material for observation. In fact, for 2000 years before Copernicus, Aristarchus of Samos submitted a heliocentric system, but he could not prove it without a telescope like the pharaoh Akhenaten (Echnaton, † 1334/35 BC), Han Yu Xi (虞喜, fl. 307-345), the Arabic Alpetragius (Abū Ishāq Nūr al-Dīn al-Bitrūyī, † 1205), the Persian Nasir al-Din Tusi (1201-1274) and the Kerala school predecessor of Tycho Keḷallur Nilakantha Somayaji (1444-1544). Similarly, the use of spacecrafts gives us a wealth of newly induced information calling for a new model of space.[3253]

29.3 Slovenian Plasma: Sirk's Plasma and the Beginning of Physics at the University of Ljubljana

Boltzmann's transport equations were the basis of plasma research; Boltzmann himself did not actively cooperate there, except as a mentor of research of cathode rays with a huge electromagnet at the Viennese Physics Institute. Boltzmann's teacher was Slovenian, his wife too, and he also had many Slovenian PhD students. On 18 March 1906, Boltzmann advised the dissertation of Johann Radakovits (Radakovič, * 1877 Celje). Johann measured the conductivity of ionized air at various pressures as "not quite without scientific interest". J. Radakovits described the history of research of the properties of warmed air and, basically, outlined Nahrwold's work.[3254] J. Radakovits taught at German communal Grammar school in Ostrava (Ostau) in Moravian Silesia in 1910/11. The other Boltzmann's student the Croatian Michael Radakovits (Radaković, 1866 Graz-1934 Graz) taught mathematics and physics at the university of Czernowitz (Černovice) as the member of commission for high school professora in 1911 while he corresponded greatly with Slovenian mathematician Plemelj. Michael Radakovits's chair of physics in Graz was taken over by Schrödinger while one of Michael's sons belonged to the Viennese Mach's circle.

In 1880 in Graz the priest Ivan Svetina (1851 Breznica in the municipality of Žirovnica-1936 Žirovnica) defended his dissertation Natural sciences and philosophy: their mutual relationship and the limits of the knowledge that can be achieved through both (Naturwissenschaften und Philosophie: ihr gegenseitiges Verhältnis und die Grenzen der durch beide erreichbaren Erkenntnisse) with his advisors Boltzmann and neo-Kantian Alois Adolf Riehl (Aloys, * 1844 Riehlhof by Bolzano (Bozen); † 1924 Neubabelsberg by Potsdam). In 1885 in Graz another priest Frančišek Lampe (*1859 Zadlog between Idrija and Ajdovščina; † 1900 Ljubljana) defended his dissertation causality: a contribution to the theory of knowledge with the advisers Boltzmann and the philosopher-psychologist Alexius Meinong Ritter von Handschuchsheim (1853 Lvov-1920 Graz). Boltzmann's Slovenian Styrian PhD students include Josef Hoffmann's (* 1854 Ptuj) dissertation about geometry in its dependence on the masses contained in space (Die Geometrie in ihrer Abhängigkeit von den Massverhältnissen des Raumes) in 1881. Boltzmann and Albert Ettingshausen advised Thomas Romich's (Tomaž Romih, * December 8, 1853 Maria Dobje by Planina between Sevnica and Šentjur southeast of Celje-1935 Novo mesto) and Ignac Fajdiga's (1850 Šentvid by Stična-1929 Kranj) Experimental Untersuchung über die Fernwirkung dielektrischer Körper and then

[3254] Nahrwold, 1888, 107–121; Höflechner, 1994, 1: 238.

Romich and Nowak's Experimental investigation of dielectric bodies regarding their dielectric aftereffects and Experimental investigation of the long-range effect of dielectric bodies (Experimental untersuchung dielektrischer Körper in Bezug auf ihre dielektrische Nachwirkung and Experimental untersuchung über die Fernwirkung dielektrischer Körper) in 1874. After his rigorous exam Romih finally defended his additional PhD at Graz philosophical faculty in 1889 just before Boltzmann left for Munich. Next year in 1890 in Prague Romih published the first Slovenian inventory of physical appliances, with images, prices and instructions on how to use them as designed by the factory of physical instruments and metrical models of E. Mach Prague students in 1867/68-1871 Dr. František Houdek (1847–1917) and Josef Hervert (1846–1883). Romih became a headmaster of Krško municipal boys' school in 1900. Fajdiga taught physics and mathematics in grammar schools in Graz, Trieste, Novo Mesto, Ljubljana and Kranj and published about plasmatic atmospheric electricity and lighting rods by studies of J. Elster, H. Geitel and E. Mach in Novo mesto in 1896. Boltzmann's work in Graz was continued by the first important Slovenian explorer of oscillating discharges and plasma was Hugo Victor Carl Sirk, born on 11 March 1881 in Graz. He studied physics at Pfaundler's class in Graz because Czermak was an associate professor of experimental physics at the University of Graz only until 30 March 1898. He left before the beginning of Sirk's studies. The theoretical physics was taught by Wassmuth, who, after a twice unsuccessful candidacy, finally moved to Graz from Prague in 1893. He brought from Prague Puluj and Gintel's interest in cathode rays. Wassmuth was also assisted by Streinz, who was at the same time a professor at the Technical College in Graz from 1892. At the Department of Theoretical Physics of the University of Graz the assistant professor was Hausmaninger and associate professor was S. Šubic, who was retired in the middle of Sirk's studies in September 1902.

Sirk researched molecular size of soluble starch (Über die Molekulargröße löslicher Stärke) for his doctorate advised by the chemists Hugo Schrötter in 1904 and worked in the following years at the Graz Physical Institute. It was well equipped for investigation of discharges in gases, since soon after Roentgen's detection, Roentgen photographs were taken both by Pfaundler and Czermak in Graz labs.[3255]

As early as 21 January 1896, at the session of the Viennese Academy, Pfaundler had published his own X-ray photo of a needle in the palm of his hand for the needs of surgery with illumination of 15-20 minutes, eight days after Boltzmann's report.[3256]

Simultaneously with his research work, Sirk taught at the Viennese university, so that he was prepared for his lecturing in Ljubljana. Even before the establishment of the University of Ljubljana in 1919, at the initiative of the engineer Milan Šuklje, Sirk began his lectures at the temporary higher education course for students who intended to study the technique. Lectures lasted from March to November 1919 with two semesters of study of techniques. Rihard Zupančič taught mathematics to the students there.

Rubinowitcz became the first full professor of theoretical physics at the Faculty of Arts of the University of Ljubljana on July 24, 1920, but on 23 February 1922 he left for Technical University of Lvov.

Kušar from Reteče near Škofja Loka lectured on the Theoretical Physics at the Faculty of Philosophy. At the lower gymnasium in Kranj and at higher gymnasium in Ljubljana he received Jožef Anton Schiffrer von Schiferstein's (Šifrer, 1677 Kranj-1756) scholarship for talented students. During his studies at the Viennese Faculty of Philosophy, he received much higher Knafelj's scholarship from 1892/93. Just after Kušar's matriculation, J. Stefan died, and Boltzmann taught physics. In 1896, Kušar finished his studies of mathematics and physics and received his doctorate in 1897 with a dissertation in the field of mathematics: "Third and fourth level congruences". As Sirk, Kušar also did not work out any physics for his PhD, which was a great handicap for their later chairs of physics in Ljubljana. In 1898, he completed his graduation teaching exam, whereby he was able to teach mathematics and physics at secondary schools. He taught in Kranj, Koper and Ljubljana. He was in professional training in Berlin in 1903 and in Paris in 1902, 1928, and 1937. In 1919, he briefly helped

[3255] Šubic, 1896, 187.
[3256] Glasser, 1959, 186.

to organize the education at the Ministry of the Arts and the Worship in Belgrade.

From December 1919, at the Technical Faculty, he conducted an experimental physics course as a "part-time teacher", took care of the Physical Institute, equipped a laboratory and led a library. On September 1, 1924, Kušar became an associate professor of experimental physics at the Faculty of Engineering. A complimentary expert opinion was written for him by the mathematician and the second rector of the University of Ljubljana, prof. Zupančič. Due to eye problems, Kušar was on sick leave several times and was retired on 31 October 1932. Lectures from experimental physics were in the rooms of real gymnasium until the spring of 1925, when the faculty of engineering received a high ground floor in the east wing of the main university building for its physical and mathematical institute. It worked there for another twenty year.

Due to Kušar's illness, Nardin from the technical high school delivered a part-time lecture on the physics for the Faculty of Engineering in 1927. Between April 1928 and 1934, he was replaced by the Viennese private assistant Sirk who became a contractual full-time professor of experimental physics at the Faculty of Engineering. The professors Plemelj and Zupančič were against his election, but they were voted out. Despite of Slovenian origin, Sirk only partly mastered Slovene language, and he was accused of being a German, in fact a Jew by all his mother's wholesale industrialist ancestors from Bohemia, Budapest and Vienna. Hugo Sirk's grandfather Mathia was born at the neighbourhood of Trebnje just like the famous Boltzmann's student I. Klemenčič. In 1860s Mathia worked as the chief guard in Šoštanj, the native city of his wife, just like the grandfather of Tobias Gruber did in Vienna. After his retirement Mathia's family moved to Radetsky Strasse 2 by Jakominiplatz in Graz near the new Joanneum Regional and Technical College established in 1864 with a diploma examination and specialist training needed for his son. Hugo Sirk's Slovenian father Victor H. Sirk (* 1845) used to be technical officer machinist of 3rd class promoted on 1st November 1870, of 2nd class between 1st November 1874 and 1878 at the Habsburgian Navy, as well as a teacher of mechanics and mechanical engineering at the machine school (Maschinenschulen zu Pola, Strojnička učiona, Scuola di macchine) in Pula with one year course for engineering sub-officers and three grade course for 14-16 years old freshman. At marine corps in Pula he collaborated with the inventor's father Karl baron Codelli who served as first lieutenant at battleships of the line in from 1st May 1869 until his death in 1878 and with Noordung's father Dr. Jožef Potočnik who became frigate physician on 1st November 1869 and served as physician at (Codelli's?) ship of the line in 1878-1879 and as marine staff physician in 1893-1894. The inventor Anton Codelli served as a line ship sea aspirant from 1st October 1894 and as sea cadette from 1 March 1896 to 1897. Therefore, the military marine corps in Pula used to be the cradle of Slovenian technicians.

In 1875 Victor H. Sirk published a monography on marine engines steam boilers and marine steam navigation and researched in London n July 17, 1878. After his marriage with a wealthy Jewess he left Pula and settled in Grazer Jacomini Gasse (later downtown square and district) near his parents as engineer and inspector of steam boilers. On July 2, 1890 in Ljubljana in order to develop a reliable and trained machine and boiler attendants he held a specialist course to which a total of 34 participants had registered, as did in previous years. Therefore, Hugo Sirk knew Ljubljana well even before he got his chair there, but his Slovenian grandfather Mathia died before Hugo was dozen years old which deprived Hugo of opportunities to learn Slovenian language better in rapidly Germanized downtown Graz. On July 29, 1915, few months after he received his habilitation (venia legendi) in Vienna in 1914. Hugo Sirk resigned from the Catholic Church in Rossau in Vienna, which might be another reason for Plemelj's anger even if Zupančič did the same to enable his orthodox remarriage. Hugo Sirk taught Peterlin and his year older classmate Miroslav Adlešič. Adlešič and Josip Potokar graduated in physics in Ljubljana in 1930 as the only students before the Second World War.

Peterlin, Anton Moljk, Ivan Kuščer who had the Viennese Jewish mother like Sirk, and others graduated from mathematics. In 1930, Peterlin and Kuhelj became assistants at the Technical Faculty, where Peterlin lectured experimental physics since 1933. Peterlin became Sirk's assistant and retained the post after Sirk's appointment as assistant professor at the University of Vienna in 1934. The

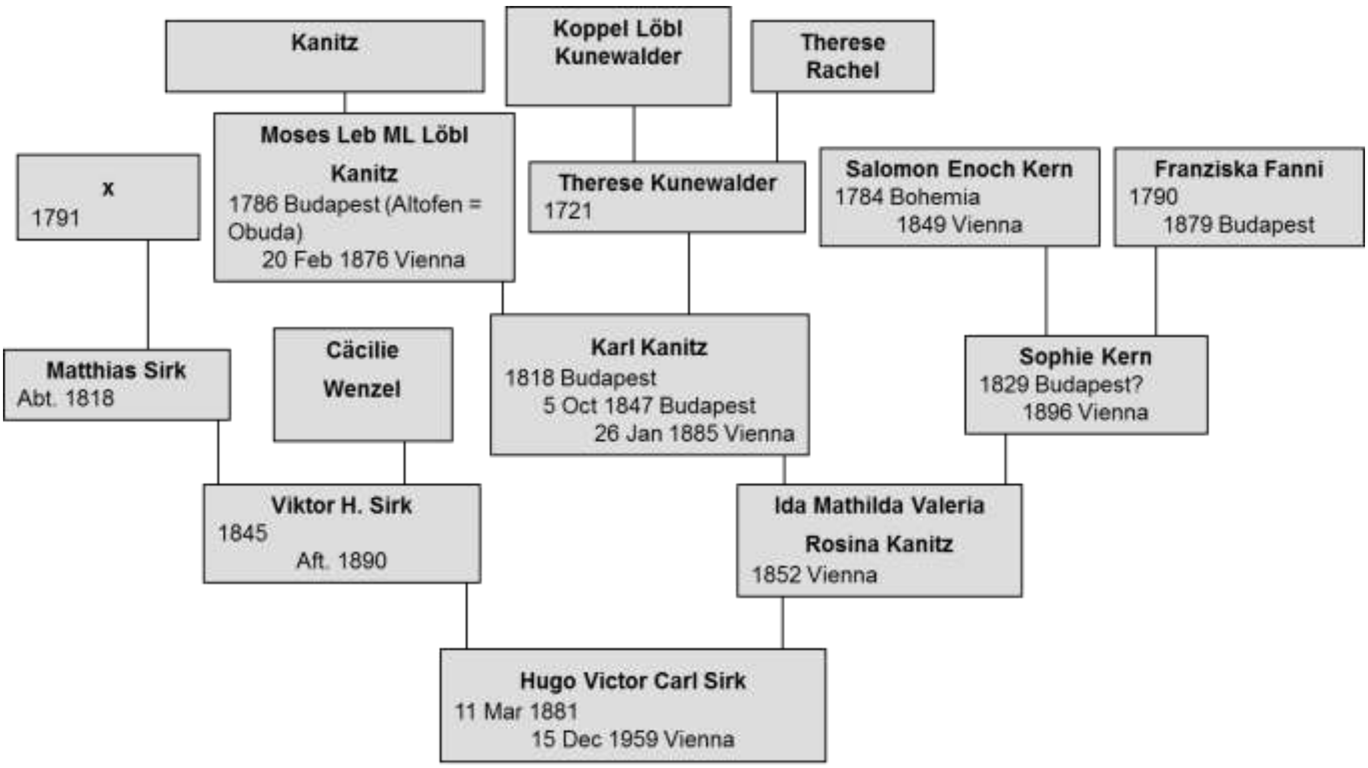

Figure 29-19: Geneological ancestors of Sirk

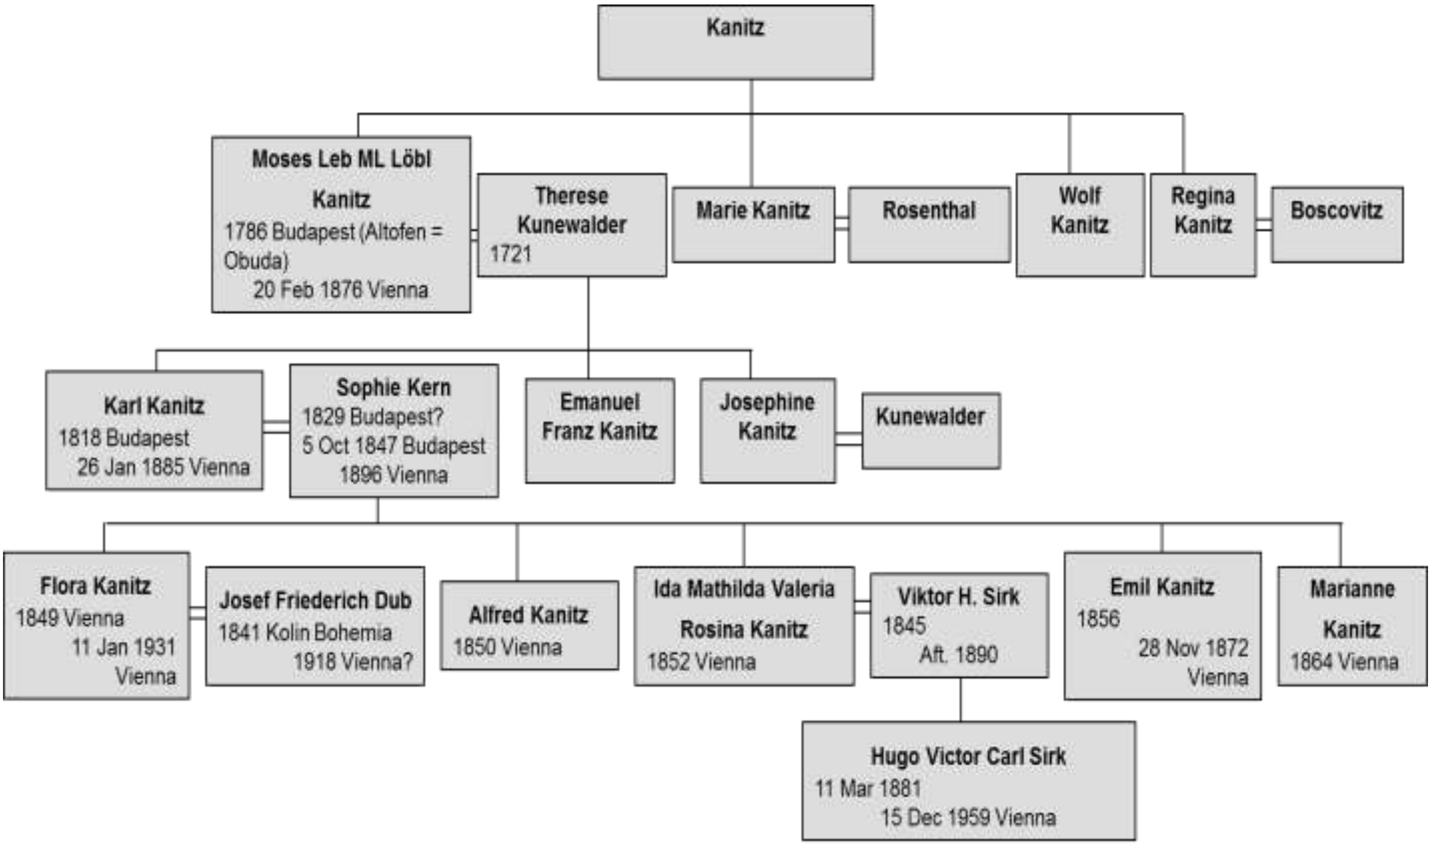

Figure 29-20: Geneological ancestors of Sirk by Jarni line

students attended lectures on physics at the Faculty of Engineering at Kuhelj's class.

In 1930 and 1931, the authorities in Ljubljana tried in vain to employ a full professor of theoretical physics at the Faculty of Arts in Ljubljana. They wished to persuade the son of Andrija the Croat Stjepan Mohorovičić (1890-1980) to take over the post which was somewhat risky as Stjepan Mohorovičić disliked Einstein just as Kušar did before him. Stjepan Mohorovičić also had political troubles and therefore never left high school teachings although he predicted positronium in Astronomische Nachrichten in 1934. His prediction was experimentally verified in 1951.

In 1938, Kuhelj was elected as an associate professor and for some time he replaced Peterlin's Physics lessons. After returning from study leave in Germany, Peterlin was elected as assistant professor in 1939, and in the same year he moved from the Faculty of Technical Sciences to the Faculty of Philosophy. In 1939, he was appointed as the honorary lecturer in experimental physics at the Faculty of Philosophy.

Dr Rihard Klemen was an assistant professor for agricultural chemistry and chemistry of ferments at the Faculty of Engineering. In the following year 1940, Moljk became an assistant at the Physics Institute, while Peterlin was a lecturer in physics at the Faculty of Engineering. The head of the Physical Institute was often the mathematician Zupančič until he left for Austria in 1945.[3257]

At the Faculty of Medicine, J. Reisner gave a lecture in physics in 1920/21. The following year, he was replaced by Nardin, who taught at the Faculty of Medicine as a full professor and founded the Physical Institute.

Sirk was promoted to the rank of the associate professor in Nazis' Vienna in 1940 despite of being a Jew as the Jewish descent is granted by female lines. His mother's wealthy Kantz family of Budapest-Viennese bankers and wholesale sellers of sewing needles (Diamond-eyed, drill-eyed) probably helped him. The following year he published a textbook for natural science studies of mathematicians with numerous examples related to

[3257] Suhadolc, 2000, 148, 183.

Van der Waals', Maxwell's, and other equations of physics. In the cover of his textbook Sirk specifically pointed out his former Ljubljana chair.[3258] He was not in any deep dispute with the fascist regime, which forced Schrödinger to leave the University of Graz in 1938. Sirk published first-class research at his late age[3259] and became very active translator in Esperanto language. Sirk wrote many scientific articles in the Esperanto language and translated a lot from German language to Esperanto language including the work of the Austrian socialist party member Viennese professor of physics Hans Thirring (1888-1976). Thirring was the head of the Institute of Theoretical Physics in Vienna. The socialist and pacifist Thirring lost his job after Anschluss in 1938, and after the war he became the Dean of the Faculty of Philosophy in Vienna and the socialist member of federal council. Thirring corresponded with Einstein in 1917, and he was a friend of Sigmund Freud. Sirk also wrote about Humanism of the Jewish initiator of Esperanto Ludwik Lejzer Zamenhof (Ludwik Łazarz Zamenhof, 1859-1917) and about the history of Esperanto language. After the reorganization of the International Congress Summer University Groet of North Holland in 1948 he regularly conducted his physical themes at the conferences until his death. He was retired in 1952 and died in Vienna on December 15, 1959.

30 Industrial Uses of Vacuum Technologies: IJS &IEVT&Haldane

30.1 Peterlin's Contribution to the Development of Vacuum Techniques

30.1.1 Introduction

Many Peterlin's Ph.D. candidates advanced Slovenian vacuum technology. The merits of all Peterlin graduates are even greater. What kind of Sirk's and Rubinowitcz's teachings enabled Peterlin's success even if he was basically a theoretical physicist? The Ljubljana authorities were unable to keep Sirk and Rubinowitcz for long similarly as they were not able to keep Frischlin three and a half centuries earlier. The natives Plemelj, R. Zupančič, J. Plečnik, Milan Vidmar and Samec established their faculties while physics lacked such Slovenian heroes also because of J. Stefan's premature death.

30.1.2 Samec's Spectral Analysis

Peterlin's relatives and his ancestors were important Slovene physicists, mathematicians and chemists. His wife's grandfather Maks Samec became a doctor in Kamnik after studying in Graz. Samec's discussions show a wide range of his insights into current professional literature. In Samec's discussion of spectral analysis, we find even many interesting physics thoughts that he learned at the University of Graz at Ernst Mach and S. Šubic's lectures.

In the introduction to Spectral Analysis, Samec first described some history of optics. He linked Newton's optical experiments from the years 1676-1704 with modern conceptions. Samec did not even mention that at the beginning of the 19th century Newton's corpuscular theory was replaced by the wave theory of light. With this simplification, Samec described the continuous development of optics leading to the discovery and the use of spectral analysis in the most recent times. Samec's summary of the results of the spectral analysis in the Slovene language was published only a decade after its beginnings in Germany, when Kirchhoff and Bunsen enabled a real breakthrough in chemistry by the discovery of caesium and rubidium as the new elements between 1859-1860. The third element (thallium) was added by eastern French expert Claude Auguste Lamy and the famous London vacuum technology innovator Crookes in 1861.

Samec was interested in John Tyndall's vacuum experiments: "Tyndall proved that so heavily rarefied matter could reflect the sunlight. He put in an airless glass tube 1/100 gran (0.0082 grams), of a practically unobservable allyl iodide steam, and in the dark before the tube he provided the electric sparks. The entire tube looked like filled with a dense, blue-reddish fog. In the light, however, the tube looked like completely empty."[3260]

[3282] Kokole (1969, 56) noted Blinc's supervisor Hadži, which he was only on operational level, while on the official Faculty level Peterlin was noted as a mentor (Information of Tanja Peterlin-Neumaier 12 January 2007). According to data of FNT and on Cobiss platform, it was supposedly a typescript dissertation typed in the year 1958. As a supervisor Peterlin was noted, but in the time pf promotion he was already abroad. In the time Blinc's and Poberaj's defence (24 February 1959) Peterlin was back in Ljubljana for a while. He left Ljubljana just before Blinc's promotion. Poberaj's had his promotion on International Women's Day 8 March 1959. Later Peterlin was again in Ljubljana from early August until the middle October 1959, so he could attend the defence of a dissertation of Bibijana Dobovišek Čujec on 24 September 1959.

3289 Bibijana Dobovišek Čujec graduated in 1950. Peterlin did not bring his supervising of Bibijana Dobovišek Čujec's PhD to its successful end according to report of his daughter Tanja Peterlin-Neumaier and Strnad (2006). But Kokole (1969, 60) did not note any limitations of Peterlin's supervising. Bibijana Dobovišek Čujec supervised many PhD candidates abroad as narrated by Mitja Rosina in October 2007.

Samec used a somewhat dubious mechanical description of the ether, which in physics of those days covered many of the features of today's vacuum: "The thinner the ether is, the more of its oscillations are needed to excite the (human) retina."

Samec also noted an interesting similarity between ether and air, as well as between the eye and the ear. Descriptions of the ether like Samec were not unusual in the Habsburg Monarchy at that time, although individual criticism of ether at the writings of Graz professor Simon Šubic (1862) and his friend, the teacher of Nikola Tesla Martin Sekulić also gained some attention. Samec's note appeared in 1874:[3290] "Physicists of the recent times claim that there is no ether, but that what has been called ether is just plain gas (air) that fills up, certainly very rarefied, all the world's spaces."

Figure 30-2: Samec's vacuum tubes with hydrogen, solitre and carbon dioxide (Samec, 1871, 267)

Of course, Samec was also aware of the significance of the vacuum in experiments:[3291] "... If, then, we observe spark through the spectroscope, we do not see only the spectra of metal, but also the spectrum of each individual component of the air; we see, for example, the spectrum of hydrogen, oxygen, nitrogen. If, however, we want to get a pure spectrum, this is the spectrum of the metal itself only, we must make this experiment in the vacuum space."

Samec's discussion also included quotes of very modern papers, such as the publications which appeared in 1868 under the pens of Ångström or Zöllner. According to the short delay of Samec's writing about the German language publications of researchers, he certainly read German professional literature, most probably Poggendorff's Annalen der Physik und Chemie.

In 1876, Samec published on brain with some Darwinist echoes.[3292] He translated the Somatology of Jan Nepomuk Woldrich (1834-1906 Prague), but his publisher Slovenska Matica doubted about the successful print and sales because of Samec's lack of knowledge of pedagogical conditions as he never lectured in schools. Thus, the translation was completed by the Gorizian professor Fran Erjavec, who published it under his name.[3293] Samec often used Russian literature in his writings, especially in Črtica (Note) on the impact of the climate in 1871. Samec even translated Turgenev's novel Dim (Smoke) in Slovene language.[3294]

Samec had advanced views: he opposed the use of corsets in the women's wardrobe, and in his garden, he set up a gym for his children. He visited the 3rd International Electrical Exhibition in Vienna, which was led by Jožef Stefan on the technical and scientific basis from 11 August 1883 onwards.[3295] In Kamniška Bistrica he was the mayor (1880-1886) and since 1883 a regional representative of the districts of Radovljica, Tržič and Kamnik. He wanted to build a dam and a power plant for the needs of Kamnik; unfortunately, the project was abandoned because of his premature death. His son, the chemist Maks, later became the honorable citizen of Kamnik. Both are buried in Kamnik.

30.1.3 Samec Junior in Chemistry

The son of Maks Samec, Maks Samec the younger (* June 27, 1881; † June 1, 1964), studied chemistry in Vienna at a time when he could still hear the lectures of the famous Boltzmann. Already as a twenty-year-old he published a fifty-pages long discussion on meteorology and air transparency in various weather conditions for the Viennese Academy in 1905. In the end he thanked the court councilor Hans Pernter for his help. The

younger Samec participated in the formation of the Colloid Society in 1922, which awarded him a half a decade later. He published a lot in Kolloidzeitschrift, which wasprinted in Dresden since 1906 with Ostwald as coeditor after 1907.

Maks Samec the younger was a rector of the University of Ljubljana between 1935-1937.[3296] On the 16th May 1940, he was elected a regular member of the Academy of Sciences and Arts, and on 6 June 1940 the President announced his election. On 16 December 1940, Samec typed on the sheet of half-A4 format to renounce his membership in the academy, as professor Plemelj's "cooperation was effectively hindered by his presence" at meetings of the mathematical-natural class. On 1 January 1941, the President of SAZU (SASA) accepted the resignation of Samec, and on February 1, 1941, the manager of SAZU (SASA) also did the same. On 6 December 1949, Samec as administrator of the Chemical Institute in Ljubljana was accepted again as a regular member of the Slovenian Academy of Sciences in the mathematical, technical, and physical sciences class.[3297]

In the summer of 1945 Maks Samec was deprived of his full professorship in Ljubljana for the alleged violation of cultural silence, since he published his findings in German scientific journals during the war. Samec's co-author Peterlin did not suffer from such an absurd measure. Samec's opponent was a professor of inorganic chemistry in Ljubljana. Samec could no longer work in the laboratory, which he himself founded in 1919 in the basement of the real school on Vegova street, but Samec could only work in the emergency laboratories of the building of today's NUK. As a student, Boris Kidrič knew Samec's work in the field of starch and colloids; so, he protected him, so Samec continued to receive a salary despite the loss of his profession. However, Samec was certainly punished just a little bit, because Samec was still able to research in another facility which Kidrič established for his old professor Samec. Much worse happened to Samec's co-worker Salvislav Jenčič (1891-1968), who was retired without the right to a pension. Salvislav was the brother of the first Samec's wife Maria (Mira) Jenčič, who died shortly after the birth of her daughter. The noble Jenčič family were from Kočevje, later from Nova vas in Dolenjska. Samec second German wife was much sharper and she was expelled from Yugoslavia as a Viennese woman, but Kidrič's order somewhat solved Samec's problems because his wife occasionally maltreated him.[3298]

On 1 October 1946, Samec became the administrator of the Chemical Institute at SASA in Ljubljana, which originally existed only on paper. On 6 December 2006, for the first time, Samec's prizes for successful chemistry students in Slovenia were awarded.

In 1938, Maks Samec the younger received the Laura R. Leonard Award from Kolloidgesellschaft, which was founded in 1922. On 27 September 1938 he received a memorial medal of University of Nancy. He also received August Wilhelm von Hofmann's award of the German Chemical Society on 4 May 1940, the prize of Arbeitsgemeinschafts-Getreideforschunf (AGF) established at Detmold in 1946, additional doctoral degree from the University of Vienna and several French awards, among them L'Ordre du Mérite pour la Recherche et l'Invention (Grand Officier). On 31 December 1949, he received the Federal Planning Commission Prize, and the Prešeren Prize for the year 1950.

Maks Samec, the elder married the daughter of Jožef Rode from Rodice no. 9, where the Cardinal Franc Rode was born later. Theresa Rode and Maks Samec had three children whose descendants became important musicians and scientists. Samec's granddaughter, the mathematician Leopoldina (Oli) Leskovic, married the physicist Peterlin, son of Anton Peterlin from Šiška and Zofija Pučnik from Kranj. Maks Samec the younger was uncle of the wife of Anton Peterlin the physicist. From the end of the 1940s onward, Samec Jr. and Peterlin led the two most important physical and chemical institutes in Ljubljana.

30.1.4 Peterlin's Experiments and Lectures on Vacuum Techniques: Slovenian Vacuum Technique at the Time of Peterlin and Supek

30.1.4.1 Youth and Kinship

Anton Peterlin was the most important modern physicist in Ljubljana. His role would certainly be comparable in many ways to the success of the mathematics of Plemelj if Peterlin could avoid so much trouble in his ascent to power, which Plemelj happily avoided.

The father Anton Peterlin studied under supervision of the professor Jožef Stefan in Vienna, and at the end of his studies of philosophy study he received a prestigious Knafelj's Scholarship with a free flat in Knafelj's Viennese House in 1888/89. He became a Grammar School (gymnasium) professor of physics and mathematics in Kranj, and then at the Poljane Grammar School (gymnasium) in Ljubljana. He processed the arithmetic textbook of Blaž Matek for lower schools according to the new curriculum, while, the Gorizia gymnasium professor Jakob Zupančič reorganized Matek's books for secondary schools in 1910.[3299] Blaž Matek (* 5. 2. 1855 Gornji Grad ob Dreti (Upper castle by Dreta River); † 29. 1. 1910 Maribor) published his arithmetic and geometry textbooks for lower Grammar School (gymnasium) between 1896 and 1898, but due to his premature death, he could not completely organize all his works.

Peterlin was born in the family of professor of physics Anton Peterlin of Ljubljana – Šiška and Zofije Pučnik from the important family of tailors in Kranj. Her father occasionally had seven employees. Grandfather on his father's side was a traveling dealer with flour from Gameljne.

The physicist Anton Peterlin the younger had older stepsister Sonja born Guzelj married Remec at Lancovo in Radovljica and he also had a younger sister Marja Peterlin married Lapajne who worked in the accounting office for IJS in Ljubljana. After Anton Peterlin the elder died, his widow Zofia took care of all three children as a primary school teacher. Because her pay was often insufficient, she helped herself with a renting rooms to students, and occasionally even by selling her furniture and jewels.

30.1.4.2 Studies

Anton Peterlin the younger was not satisfied with his gymnasium professors of physics Fran Čadež, therefore Anton Peterlin later criticized Čadež's relatives. So, Anton Peterlin was assisted by a university professor of biology, Pavel Grošelj, who received a philosophical doctorate in 1906 and passed his qualification exam for secondary school teachers with natural sciences as main subject, mathematics and physics as secondary subjects in 1908. In 1910, Grošelj passed his additional exam with physics as the main subject.

Anton Peterlin the younger also used the help of his uncle, dr. Simon Dolar, professor of mathematics, physics and philosophy at the gymnasium in Kranj. Anton Peterlin the younger disliked his high school professor of physics Čadež, but he was greatly assisted by his uncle dr. Simon Dolar who married Zofia's younger sister Mihaela (Hela) Pučnik. Their son Daro Dolar (* 1921; † 2006) became a professor of physical chemistry at the University of Ljubljana; he was the first cousin of Anton Peterlin the younger and participated in public lectures on radioactivity in Ljubljana.[3300] In 1957, Daro Dolar earned his doctorate in chemistry in the class of Ljubo Knop, who received his doctorate from the Technical Sciences at Maks Samec's class in 1933.[3301] In 1965, Daro's colleague Karel Južnič earned a Doctorate in Chemistry. K. Južnič lived in Mirje in Ljubljana with his wife Danica, son Andrej and two daughters; one of them was a physician. However, K. Južnič died relatively young while his skin was severely damaged by radiation as IJS did not have a proper security against radioactivity developed in that times yet.

In 1926, Anton Peterlin first enrolled in the mechanical engineering of the University of Ljubljana, but Rihard Zupančič addressed him before the end of the first semester. Rihard advised

[3301] Kokole, 1969, 63, 75.

him to enroll in studies of pure mathematics at the Faculty of Philosophy.

Peterlin again did not have much better lecturers at the university, so he liked to listen to Plemelj's mathematical and Vidmar's electrotechnical lectures. Peterlin listened to Vidmar's lectures on electricity, but Peterlin admired very good pedagogue and the educator Zupančič.[3302]

Even before the end of mathematical studies, Peterlin became Sirk's assistant lecturer in physics in the fourth year of Peterlin's studies and Peterlin kept that post in 1929-1931. Sirk was not very versed in mathematics, which students felt boldly, because almost all of them had mathematics for their main subject and they judged the math by Plemelj's merits. Sirk lectured mainly on electricity, while Sirk discussed everything else in his course of physics during a few weeks. Peterlin helped him set up an introductory lecture for all students of technique and philosophy.

In his third semester, Peterlin became an assistant for the descriptive geometry of the engineer Milan Fakin and kept his duty for three years in 1927-1929. Milan Fakin took over the lectures of the engineer Ciril Juvan who taught in 1922-1926. Therefore, Fakin taught only for one year before he recruited Peterlin. On 19. 12. 1924 Fakin and his brother Romeo officially changed their family name to Strojnik as the term Fakin have a disrespectful meaning in Slovene slang of Ljubljana.

Julius Nardin was a good experimenter with vacuum devices, while as a lecturer he was not among the best; so, Peterlin attended only one of his lectures. After April 1928, Peterlin listened to Hugo Sirk's lectures, although they were mathematically defective and mainly dedicated to electricity.

On Sirk's recommendation, Peterlin visited for one month Franz Halla (1884 Vienna-1971 Dörfl in Lower Austria) at the Institute of Physical Chemistry of the Viennese Technical College where Peterlin learned X-ray diffraction techniques of measuring scattering X-rays at wide angles and for the first time used top-modern vacuum technology. Prior to the end of his mathematics studies, Peterlin became Sirk's assistant lecturer in Peterlin's fourth year.

On 16 June 1930 Anton Peterlin graduated in mathematics from the Faculty of Arts in Ljubljana with greatest success under supervision of the professor Plemelj. In the same year, Peterlin and Anton Kuhelj became assistants at the Technical Faculty. In 1930/31, Anton Peterlin taught physics in the eighth grade at the 1st Women's Gymnasium (Lyceum), and in 1931/32 he taught at the Ursuline (Uršulinke) gymnasium of Ljubljana which proved that he must have been a devoted Catholic at least in those times which might provoke some antagonism with Sirk and later with Kuščer.

After graduation, Peterlin measured in Sirk's lab the scattering of X-rays in liquids completely without success, as he could have previously calculated that the effect would be too weak for the measurements. That was one of the reasons why Peterlin had so much doubts in Sirk's mathematical abilities, but that mistake could also be partly Peterlin's fault because Peterlin was not a great expert in experimenting, unlike, for example Peterlin's antagonist Moljk.

Peterlin became Sirk's assistant in 1933. In 1934, Sirk published a paper on X-rays in a magnetic field. Peterlin assisted in Sirk's measurements, for which Sirk thanked him at the end of the article. Peterlin also retained the assistant position after Sirk's appointment as assistant professor of the University of Vienna in 1934/35, after Sirk failed to extend his Ljubljana contract and returned to Vienna. The assistant professor of mechanics Kuhelj took over the lectures on physics at the Faculty of Technology in Ljubljana. In the school year 1935/36 Kuhelj lectured on physics in Ljubljana, while Peterlin began to teach experimental physics in the autumn of 1936. For six or seven years Peterlin was the only lecturer in experimental physics in Ljubljana. As an assistant he organized a physical practicum and conducted student experiments for almost ten years.[3303]

From February to May 1936, Peterlin was measuring the scattering of X-ray beams on liquid tetrachloride-carbon in the lab of professor Dragoljub Jovanović (1891–1970) in Belgrade. For eight years Dragoljub K. Jovanović worked at the Marie Curie Institute in Paris, like his student P.

[3302] Bartol, 1961, 106.

[3303] Bartol, 1961, 108.

Savić after him, but Dragoljub Jovanović did not love communists so much as Savić and Jovanović became a kind of dissident. Professor Jovanović founded the Institute of Radiology at the Medical Faculty in Beograd in 1927, where he was the head of the institute until 1964. He taught physics to medical students from 1932 to 1966. He also taught physics for the students of veterinary, pharmacy and dentistry. From 1945, Professor Jovanović taught physics at the Department of Physics at the Faculty of Natural Sciences and Mathematics, where he was the Head of the Department and the manager of the physics institute. In addition to all this, the professor Jovanović also had time for his scientific research, and he processed the latest developments in the field of modern physics.

Unfortunately for Peterlin, physics in Belgrade was poorly equipped, but Peterlin at last became domestic in the metropolis of Beograd which proved to be very useful for Peterlin's later politics. The Beograd guys were more oriented towards Parisians just like Polish literati, while the Zagreb guys preferred Germany for their politics and science. Compared to Beograd, in Zagreb they had at least experimental and theoretical physics, but Peterlin did not want to study for his doctorate in Zagreb as Peterlin had much higher international goals. Peterlin wrote a paper about the scatterings of X-rays in liquids and the arrangement of molecules in the liquid, which the Ljubljana German R. Zupančič corrected for him. Peterlin's work was accepted for publication in Physikalische Zeitschrift and published in the first months of 1936. This was so exciting that Zupančič wrote to Peterlin that he had send a request for Peterlin's scholarship in Germany for 1937/38, which was again very successful.

On 1 November 1937, Peterlin went to Germany with his scholarship and received a university study leave by the University Council on June 10, 1938 for the period from 1 December 1937 to 1 June 1938 and from 1 November 1938 to 28 February 1939. In 1938 and 1939 Peterlin worked at the Max Planck Institute of Physics at the Berlin Humboldt University and in May 1938 he wrote a dissertation on the hydrodynamic and optical properties of solutions of large molecules.[3304] On 22 June he passed the exams. On November 20, 1938, he was promoted to the status of doctor of natural science with a professor of physics of molecules H.A. Stuart.

Peterlin wished to have a supervisor Peter Debye, who received his Nobel Prize in chemistry for the research of dipole moments two years earlier and has been running the Physics Institute in Berlin for the last three years. Debye was among the first to study polymers, but Debye did not take Peterlin as his doctoral student because Debye and Stuart thought that the twenty-nine years old Peterlin was too old for the job and Peterlin just got one year available for his doctoral studies. Debye left Peterlin to Stuart, who was in Debye's office upon Peterlin's visit. Peterlin was probably humiliated a little bit, but there was no help available. In fact, he developed the excellent relations with Stuart very soon.

Peterlin stayed in Germany for a year with intervals after visiting his Slovenian home already as a full-time employee with a doctorate. He returned from Berlin to Ljubljana at the end of March 1939. In April 1939 and later with the decree of the Council of Ministry of Education signed on May 21, 1939, Peterlin was appointed as assistant professor of physics at the Technical Faculty after he returned to Ljubljana. He was confirmed at a council meeting on 23 June 1939. On 12. 3. 1940 Peterlin became assistant professor at the Faculty of philosophy while Zupančič was able to maintain leadership in both departments of mathematics and physics at the Philosophical faculty as well as at the Faculty of Technical Sciences. In 1939, Dr. Rihard Klemen as an assistant professor at the Faculty of Philosophy was set up for a freelance lecturer in experimental physics at the philosophical faculty. Next year on 25. 1. 1940 Moljk became an assistant at the Institute-Department of Physics on the proposal by R. Zupančič, because the Vrhnika native Moljk was stationed in Ljubljana and therefore the library under his leadership will be open in the summer, while Moljk was also a part-time lecturer in physics at the Faculty of Technology.[3305]

On 4 May 1940, Peterlin was elected an honorary physics lecturer at the Faculty of Engineering. At that time, Peterlin gave Moljk a theme for the doctoral dissertation from a current-flow double refraction (streaming birefringence) but Moljk never finished it even though Peterlin assumed

[3304] Bartol, 1961, 106-107.

[3305] Peterlin's personal map (archive of IJS in Podgorica).

most of Moljk's teaching duties. Later, Dr. Čopič was awarded his PhD in 1955. Čopič took over the similar Moljk's dissertation under the title "The Effect of Solvent on Optical Anisotropy of Velocities". Moljk had his hands trained to make them useful for experimental work, while Peterlin did not have that talent although Peterlin was not that bad as W. Pauli.

By the end of April 1939, Peterlin was dealing with spectroscopic measurements with the son-in-law of his doctoral advisor Friedrich Paschen, the professor Hermann Schuler (Schüler, * 1894 Posen; † 1964 Göttingen) in Kaiser Wilhelm Institute in Dahlem southwest of Berlin under Debye's directorship of the physics section. Schüler was a head of spectroscopy section and published fundamental research to determine the nuclear momentum of thallium and the isotope shift in the thallium spectrum which Wolfgang Pauli previously studied.[3306]

During the holidays from August 1939 until the beginning of the autumn semester, Stuart wrote a book called *Doppelbrechung* in Dresden, which was published only in 1943. In 1939, Peterlin published a discussion on the Determination of the size and axial ratio of ellipsoidal rigid particles from the data of internal friction at their dilute suspensions. He included seven graphs, which were illustrated by different models; he then compared them with real solutions.

That work was followed by a series of papers which Peterlin and Stuart prepared in Berlin in December 1938, and the last one appeared after Peterlin returned to Ljubljana, and Stuart went to the Physical Institute of the Technical College in Dresden. They published the papers in Geiger's Zeitschrift für Physik in 1939, and later Peterlin briefly wrote about them for the Collection of the Natural History Society in Ljubljana.

In 1938 and 1939, René Lucas noticed that castor (Ricinus) oil and linseed oil became bipolar if a sufficiently strong ultrasound wave was passed through them. The droplet behaves as a single crystal with the direction of the optical axis parallel to the direction of the wave propagation. Peterlin and Stuart assumed that a dynamic double refraction was due to deformation in linear flow. They proceeded from the theory of C.V. Raman and K.S. Krishnan (1928) but did not provide a good explanation for the nonlinear turbulent flow. Better results were predicted by the double refraction model as consequence of the kinematic arrangement of molecules in the field of a flowing liquid, which clearly explains the acoustic double refraction. The molecule of the liquid was described as a rotating ellipsoid.

Peterlin and Stuart improved Lucas's equation by focusing relaxation; molecules cannot follow the rapidly changing direction of force and are increasingly left unregulated. Acoustic double refraction is low in benzene, but it is larger in oleic acid. The writers also expected useful measurements for Ricinus and linseed oil. They used Sadron's axis orientation theories based on the nitrocellulose measurements. Stuart even photographed the arrangement of molecules in the solution in 1939.

30.1.4.3 Textbook

On 1. 9. 1939, the WW2 broke out which soon affected Peterlin's German ties. Both Supek and Peterlin were involved in their Ph.D. researches in Leipzig and Berlin with highly controversial pro-Nazi figures of Heisenberg and Debye. While Supek actively supported Partisans and opposed nuclear program, the Catholic Peterlin was more pragmatic. In 1971 Supek supported Croatian spring nicknamed Maspok, while Peterlin was unable to support the similar Stane Kavčič's plans in Slovenia as Peterlin already previously left for USA. Supek criticized F. Tuđman's post-communism mishmash, while Peterlin preferred to stay out of trouble, and to mind his own business in his physics managements.

In 1940, the professor Peterlin published a physics textbook for his students which was technically equipped by Peterlin's employees the Bulgarian absolvents of mining engineering studies Alexander Barliev and Georgi Kotov. The textbook had been mimeographed in 170 copies, but it was impossible to get any copy shortly after

[3306] Just before Peterlin's arrival, Schüler published with H. Gollnow. Über die Verteilung der Rotationszustände bei einem Elementarprozeβ der Molekülbildung (keine Boltzmann-Verteilung) und die Änderung der relativen Übergangswahrscheinlichkeit, *Zeitschrift für Physik A Hadrons and Nuclei*, 1938, 432-432 the war. The individual copies were beautifully bound.[3307]

In his textbook, Peterlin divided classical physics in four parts: mechanics, heat, electricity (with magnetism) and optics. Peterlin did not write additional chapters, as was usual in high school textbooks where they loved to describe astronomy, atoms, and meteorology. Peterlin's textbook was typed only a year before Sirk's Book of Physics for Naturalists and Chemists. However, Peterlin's textbook was never printed similarly as Plemelj avoided publishing his textbooks for a long time. Peterlin missed the time or courage for publishing, although into his typescript textbook he manually introduced the additions and corrections over the years. In any case, all subsequent Slovene physical textbooks were derived from Peterlin's typescript.

Peterlin wrote the text from edge to edge and furnished it with numerous mathematical and experimental sketches. He composed 344 pages of A4 format in 56 chapters with additional three unnumbered pages full of improved images from the text. Modern physics, later physics II, was only introduced in the last four chapters of electricity (42. Glow discharge (257); 43. Electron beams from glowing metals (267); 44. X-ray (272) and 45. Radioactivity (275-280). Peterlin's modern physics also spread through his penultimate chapters about light entitled (54). Light spectrum (328) and 55. Quantum effects of light (pages 332-336).

In the case of discharges in gas, he scanned and pictured vacuum tubes in detail: "If we lower the pressure in a cathode ray tube with two electrodes (cathode and anode), at the pressure of a few centimeters of mercury and a few 100 V voltage we get bright, bluish red tape through the tube that becomes even wider with the falling pressure."[3308] "Vacuum 10^{-5} to 10^{-6} torr (practically we can barely achieve any better vacuum) is a perfect isolator because it is missing the flow carriers, and we can translate the flow in it if we insert artificial carriers (by electrons and glowing cathodes)«.[3309]

The X-rays were then and later the basic Peterlin experimental tool, and therefore he described them in detail: "In addition to medical applications, X-rays are used in the technique of so-called rough investigation of the material. In this case, we are investigating to trace the inhomogeneity, cracks, air bubbles, slag inserts or other contaminants in castings, to investigate welded seams and heavily loaded parts of the structure. In this way, it is easy to test light metals (aluminium, magnesium, etc.) while up to a thickness of several cm we also research data for iron, copper, etc. But we only have success in thinner pieces (sheets of metals)..."[3310] His X-ray chapter section was intended to supplement the description of their diffraction and interferences of beams-rays of electrons.[3311]

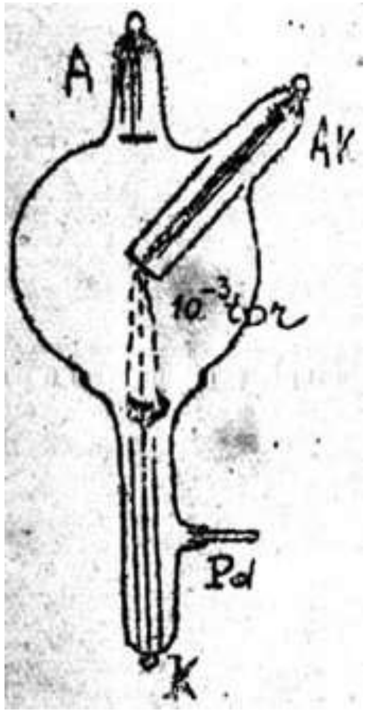

Figure 30-3: The vacuum cathode ray tube in first Slovenian university textbook of physics (Peterlin, 1940, p. 261 and Appendix 1).

Peterlin noted Einstein's relativity theory only by the way with the equation describing conversions of mass into energy at the end of the chapter on radioactivity. "Especially large energies are found in so-called height rays, whose origins are not yet known. Near the surface of the earth this beam consists from very solid beams of rays γ, beams-rays of positrons, electrons and mesons. The maximum energies measured in these rays reach a value of $2 \cdot 10^{11}$ eV, which is the energy contained

in the mass of the heaviest atomic nucleus ($m{\cdot}c^2$)."[3312] The Styrian Victor Hess received his Nobel prize in physics for his research of those cosmic rays, but he and his Jewish wife left for USA in 1938 which gravely diminished the support of his work among Peterlin's German teachers. By later notes in his domestic copy of his textbook, Peterlin intended to insert a chapter on the physics of the atomic nucleus there.

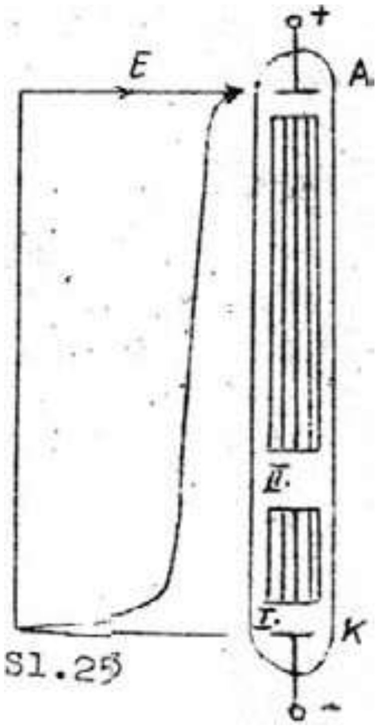

Figure 30-4: The X-ray cathode ray tube in first Slovenian university textbook of physics (Peterlin, 1940, 272).

Somewhat more, but again without mentioning the Jew Einstein, Peterlin wrote about the special theory of relativity in the subsection of the Doppler effect:

"Observations have shown that the Doppler effect depends only on the relative motion of the light and the observer, but it is absolutely unimportant fact who moves for example in the cases of moving sources of light observed on channel rays, or in the cases of moving observer in the cases of observation of astronomical objects and moving Earth. - This difference between observation and the above classic thinking (about idle ether) has culminated in the relativity theory which requires us to apply to the moving systems of the so-called Lorentz transformation obtained from the requirement that the light velocity in all equally and linearly moving systems is the same. From this assumption we arrive at the conclusion that the length and the time (the four-dimensional space)[3313] change in the moving system." Later, Peterlin described a special theory of relativity in one of the first issues of the Ljubljana based Journal of Mathematics and Physics in 1951 when Einstein ceased to be a German persona non grata. He just felt that the students needed Einstein and not any more the ether. Peterlin's early aversion to Einstein's novelties might have been influenced by Kušar and especially R. Zupančič's critique of Einstein, and certainly also developed through Peterlin's experiences in Berlin where Einstein's data were slowly becoming a hostile part of Jewish non-Arian physics.

In the case of spectrum of light Peterlin continued to describe the ideas of grandfather of his future wife, Maks Samec the elder, who published about spectrum of light in 1871. Of course, Peterlin already introduced an elementary quantum of action, although he did not mention Planck by name.[3314] Peterlin specifically described the "band" spectra of molecules, but he did not mention his later major research field, the macromolecules. For this field of research, Peterlin definitively decided a few years later. In terms of quantum effects, Peterlin described in detail the fluorescence, phosphorescence, and photoelectric effects based on Einstein's law. Peterlin did not mention Stefan's radiation law which Peterlin later promoted by naming his institute by Stefan.

30.1.4.4 Occupation

In February 1941 Peterlin married mathematics teacher Leopoldina (Oli) Leskovic, whom he also met during student days and during their joint teaching at the Women's Real Gymnasium (Lyceum) and at the Ursuline Gymnasium. At the end of the war, she taught Bibiana Dobovišek, later married to Čujec, who studied under supervision of her husband Peterlin after the war, and then worked in the department of Darko Jamnik at the IJS.

In April 1941, Peterlin was briefly recruited to the army in the surroundings of Cerknica, but the front quickly collapsed and Peterlin continued with lectures under the Italian occupation in Ljubljana.

3312 Peterlin, 1940, 280.

3313 Peterlin, 1940, 284.

3314 Peterlin, 1940, 330.

In May 1942, the Italians searched for Peterlin's assistant Škerlak (Schkerlack) because of Škerlak's illegal distribution of forbidden resistance partisan news; because they did not find Škerlak they jailed Peterlin for two weeks.

In May 1941, Peterlin was already a member of the illegal domestic matrix committee of the OF (Liberation Front) at the University of Ljubljana, where he transferred action orders-papers to his co-workers of the Faculty of Philosophy and the Faculty of Engineering. The Main OF Board of the University of Ljubljana was first headed by prof. dr. Franc Šturm (Sturm, * 1881 Donja Košana; † March 31, 1944), the head of the Department of Romance Languages and Literatures, a representative of cultural workers at the founding meeting of the OF, a member of the Communist Party of Yugoslavia, and the Dean of the Faculty of Arts until the domestic Nazis took his life. He was replaced by another Littoral native, the founder of Slovenian comparative literature prof. dr. Anton Ocvirk (* 1907 Žaga by Bovec; † 1980).

In 1943, Senate of the University elected Peterlin as associate professor, but the Italian authorities did not confirm the election. The Italians did not have any special reason to dislike Peterlin except that he certainly was a Slovenian patriot. On 9 July 1943, Peterlin was re-elected as an honorary lecturer at the Faculty of Technical Engineering.

Upon disembarkation in Normandy, he was detained-arrested by Home Guard militia (Domobranci) in May 1944. On 7. 7. 1944 he was detained at the police station and released; on that day, he received a paid study leave until 30 September 1944, which was extended until 31 December 1944 on 12 September 1944. After his wife's intervention based on Stuart's letters with invitations to continue his scientific work, Peterlin was interned in Dresden during his academic study leave. There, with professor Stuart, Peterlin decided to study the big molecules with which he successfully dealt during next four decades. Peterlin worked in Dresden for three months again under supervision of the professor Stuart; this time he has already deliberately decided to explore large molecules, which he has successfully dealt with since then.

Until 1947, Peterlin, together with Stuart, published three of his ten papers, mostly in Zeitschrift für Physik. Together with Stuart, he also shared a book on artificial birefringence in crystals. Peterlin did not experience the Allied forces' bombing of Dresden in February 1945, as he had previously travelled to Slovenia to spend Christmas holidays with his family. His return was delayed for a long time and thus he avoided that catastrophe.[3315] He worked in a knitting factory of a Volksdeutscher female owner in Radovljica near his half-sister's house; he never had so much leisure time in his life as in those Radovljica afternoons according to his own testimony. Of course, the Gestapo in Bled controlled Peterlin's work in Radovljica. On December 29, 1944, Peterlin thanked SASA Secretary Fran Ramovš (1890 Ljubljana-1952) from Ljubljana who assisted Peterlin and his wife in the last half of the year when his wife was pregnant with their first child. Peterlin wrote to him because he felt "much better to sit at home and not show around town". Peterlin again thanked Ramovš for his confirmation of his service at the University in a relatively courageous even somewhat revolutionary letter: "Highly respected Mr. Professor! ... It is very good for me, because now after a long time I can work again, that I must say that the emigration from Ljubljana was a blessing. After the war, all forces will have to be focussed that we will also create the conditions for scientific work in science in the University of Ljubljana, and I refer specifically to your help, since you already have so much experience in this regard."[3316]

30.1.4.5 Professor Peterlin Organizes the IJS Using Vacuum Techniques

During the war, most of the equipment of the Physics Institute of Ljubljana disappeared or was destroyed. Immediately after the liberation, Peterlin and the assistant professor Anton Moljk began searching for material from the abandoned German military warehouses for their Physical Institute. They found only radar devices with cathode ray tubes. They used them for the voltmeters and amperemeters, which they had not

[3315] Plenec, 2003, 6, Message of Tanja Peterlin Neumaier 2006.

previously owned. All new apparatus in a physical practicum consisted of that material.[3317]

On 1 June 1945, Peterlin from his posts at the Physics Institute and the Faculty of Arts proposed to the Ministry of Education in Ljubljana to send Moljk to study in the Soviet Union, England or the USA. In this, he particularly emphasized Moljk's wartime captivity in Italian prisons between April 7, 1941 and November 1, 1941, and Moljk's detention in Gonars concentration camp from March 7, 1942 to 11. 3. 1943, where Osredkar was also jailed from May 1942, although Osredkar later ceased to support Moljk. Moljk was sent abroad as a second scholar from the Physics Institute of Ljubljana. Moljk was in Basel in the summer of 1949, and he later transferred to Paris. In 1953 Moljk went to Glasgow for two years;[3318] Moljk covered the cost of his first year of specialization with his IJS scholarship, and during his second he used a scholarship from the University of Glasgow. In 1953, Kuščer was also nearby for five months in Birmingham studying the half-life and spectrum of short-lived isotopes with a British Council scholarship. Ivan Franjo Havliček (1906 Moravska Ostrava-1971 Novi Vinodolski) was sent to Switzerland in 1951. Havliček matriculated in Zagreb University but graduated and got his Ph.D. at Eidgenössische Technische Hochschule (ETH) in Zürich in 1932. In February 1944, I.F. Havliček became the assistant professor of physics and sub-chief of institute of physic of Technical faculty of Zagreb where his father Jaroslav Havliček (1879 Garešnica southeast of Zagreb-1950 Zagreb) also taught. In 1946, F. I. Havliček participated in the Cambridge conference on the physics of atonic nucleuses. F. I. Havliček's lectures in Zagreb were mathematically too advanced and there he did not show enough experiments, therefore the students mutinied against him. In 1950-1963 Havliček worked for Peterlin's institute as the head of four labs for concentration of isotopes, reactor technics, electronic (electrostatic) generators and optics.[3319]

On 5 July 1945 Peterlin sharply protested in furry against the mechanics of his physical institute Josip Dermota. For twelve years, that man supposedly came to work late, he was even stealing the material, especially during the relocation; so Peterlin demanded his firing.[3320] It was a disastrous move, but Peterlin's daughter later stated that Pertelin was "a socially feeling guy" despite of that humiliating affair with Josip Dermota who obviously did not show enough respect for Peterlin's absolute authority. Peterlin was an authoritative guy who did not tolerate any opposition, but folks like Dermota and Moljk loved to make secret jokes about Peterlin's awful experimentations and similar handy abilities. There was also a huge problem with Anton Peterlin's relative the career officer Ernest Peterlin (1903 Ljubljana-20 March 1946) who was executed as a leading Slovenian Home Guard Quisling although the Nazis put him in Dachau for his ties with West in opposition to Leon Rupnik's (1880-1946) unchallenged Pro-German stance. In bloody finale Ernest Peterlin and his collaborator-antagonist Rupnik received just the similar kind of commies' bullet.

On 25 July 1945 Peterlin was re-appointed as a lecturer assistant professor at the Faculty of Arts, with the decree of the Ministry of Education in Ljubljana. On 27 July 1945, at a session of the University administration, he proposed a plan for a physical institute. On 25 August 1945 and on 7 September 1945, he was appointed as associate professor with a decree valued back to 1 July 1945.

At the end of August 1945, Peterlin, together with Moljk and Kuhelj, headed for Milan with Kidrič's three million liras in three suitcases for the purchase of vacuum research equipment. The volume of money put in the hundred lira banknotes was quite hilarious and, of course, very noticeable. This was the money of the government derived from the differences of exchange rates, and the president of the Slovenian government, Boris Kidrič, gave it to the Physics Institute after the mediation of his father, the professor France Kidrič, the president of the Slovenian Academy of Sciences and Arts and a full professor of Slavic studies since 1920. In Vienna France Kidrič met a staff member of gas distribution company Jelica Krušič and married her in Vienna in 1911. The relatives of Krušič were at home in Celje, from where they visited F. Kidrič during the First World War. France Kidrič's father-in-law and mother-in-law remained in Vienna, and the occupying powers

of Nazis moved F. Kidrič from the refugee prison to Viennese internment in 1944/45.

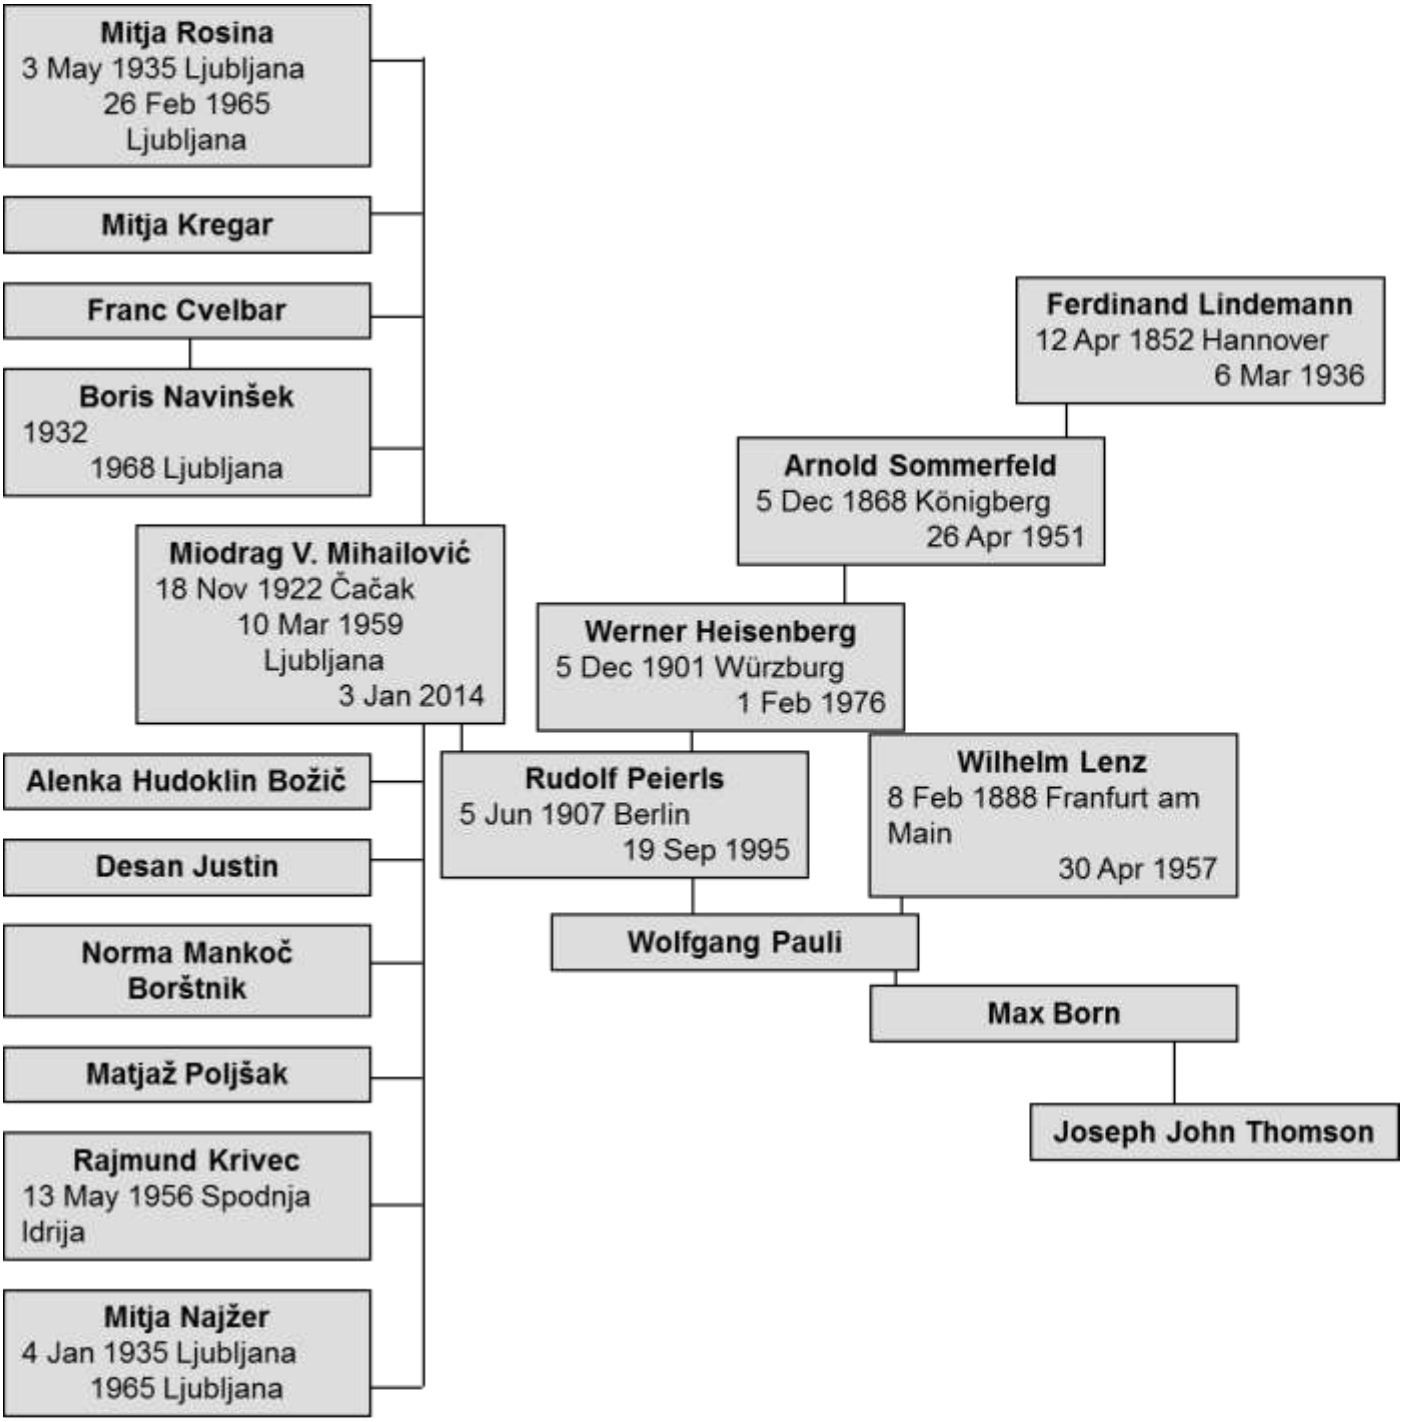

Figure 30-5: Academic descendants and ancestors of Miodrag V. Mihailović according to his Birmingham postdoc

Three university professors from Ljubljana, all of them named Anton, expected information from the party cell member in Trieste with instructions for their further journey. Unfortunately, the guy did not show up. Then they travelled by bus from Trieste to Milan without knowing that the Italians had started the routine checks of passengers in Vicenza on the previous day. The suitcases with money were taken away from them in Vicenza, where they were detained for some time in military prisons barracks on September 1, 1945. Only half a million liras were later returned to Yugoslavia by the Italian bank. The money in the boxes of three guys named Anton seemed to be damaged, so the Italian authorities suspected it originated from the recently robbed burned Italian bank. As the native of Trieste areas Kuhelj spoke a good Italian language, but those skills did not help much.

In the prison Moljk supposedly shew "a severe vanity and a great misbehaviour", but Peterlin nevertheless proposed him later to a post of scientific associate of the SAZU.[3321] In November 1945, Peterlin and his companions were transferred to the refugee camp and then to the British military prison in Padua. They were only released on 21 December 1945 after the intervention of the University (17 November 1945) and mostly by the help of British parliamentarians visiting Slovenia. Boris Kidrič, after this breakthrough, said somewhat witty that science can be explored even without money, and Peterlin named his unsuccessful group as "three university awkward guys".

On November 22, 1948, Kidrič announced to Peterlin the Italian remittance for half a million liras, and Peterlin promised to deliver a list of necessary literature and tools for the Physical Institute. On December 22, 1948, Kidrič described his intervention about half a million of the lost three million liras in the Banco d'Italia in Vicenza. The money was available to the Physical Institute of the University of Ljubljana, which became part of SAZU in 1946. The total amount is supposed to be spent on the purchase of the "instrumentation for neutron apparatus" after the settlement with the Yugoslav Embassy in Rome.

Peterlin's half a million liras was deposited in Vicenza after Kidrič's mediation succeeded in getting money back with the help of Yugoslav consulate in Milan in 1952. Peterlin personally travelled to Vicenza by the train, this time much more carefully, and spent money on purchasing devices for the Physical Institute. Moljk, Kuhelj and Peterlin signed the authorization to raise money on 9 May 1950. On 6 June 1952, the Vicenza Bank confirmed its willingness to pay. On 2 October 1952, Antonije Filipić explained in writing to Peterlin how to purchase devices for the Physical Institute, which he will buy with this money. Antonije Filipić got his Ph.D. with the thesis La Jugoslavia Economica at Università Commerciale Luigi Bocconi in Milano in July 1921.

On 8 October 1952, Peterlin wrote to vice-consul Vojko Santrać in Milan about his fears because he was already once imprisoned for several months in Italy with the same money involved.[3322] On November 24, 1952, the engineer Evgen Černigoj (* 1908 Cesta by Vipavski Križ) from the Milan Consulate explained to Peterlin how to ride trains to Vicenza and how to raise money there. Evgen Černigoj studied in Ljubljana in difficult conditions to graduate as an electrical engineer. Due to the economic crisis, he was unable to get a job and was only employed as an assistant to the Laboratory for Materials Research at the Technical Faculty in Ljubljana in 1938. Because of his activity against the Fascist Italian occupier, he was arrested in 1942. After the war, he carried out various tasks of economic and administrative character. Thus, he was also a councilor at Yugoslavian commercial attaché in Milan, and a member of Yugoslavian reparation commission with Ivo Lah's calculations involved which enabled Evgen Černigoj to give a good insiders' advices to Peterlin who was just one single day Evgen Černigoj's younger. During this time, Evgen Černigoj worked at the Institute of Electrical Engineering in the laboratory for the development of electronic components for a while. Later in 1953 he took over the post of director of the barely emerging Vacuum Laboratory at the Faculty of Electrical Engineering and remained there until his retirement in 1971. Under his leadership, the laboratory became a powerful research and development center in which the Yugoslavian vacuum technology has its strong scientific support, while at the same time IEVT has created a reputation in the foreign circles. Evgen Černigoj participated in vacuum congresses. At the 6th vacuum congress, 13th Bulletin-anthology of the Congress was dedicated to Evgen Černigoj for his organizational work.

On 11. 12. 1945 the University Senate of education proposed Peterlin for a full professor of theoretical physics at the Faculty of Arts of the University of Ljubljana and he was promoted on 5 January 1946. In 1945, he had a Slovene assistant who was native from the now Italian state neighbourhood. The assistant suffered a fatal accident down the stairs of the University.[3323]

In 1946 Peterlin was appointed as an extraordinary and in 1948/49 as a regular member of the SAZU.

[3321] Annex to Peterlin's letter mailed to Kraigher on 30. 9.1960, page 3a (material of the Peterlin family, kept by Tanja Peterlin-Neumaier).

[3322] ARS, SI_AS 1961, Box 1, Folder 3.

[3323] Ivan Vidav, letter ro Tanja Peterlin-Neumaier, 10. 7. 2006 (GDP).

At that time the disputes with the Cominform (Informbiro) were settled and with them the scientific situation in Yugoslavia significantly improved. At the end of the year, the uncle of Peterlin's wife Maks Samec became a regular member of the SAZU in the same class for mathematical, technical and physical sciences as Peterlin. From 1946 to 1948 Peterlin was the Dean (1946/47) and the Vice-Dean (1947/48) of the Faculty of Arts in Ljubljana.

On 10 January 1948, Peterlin signed a "justification for the necessity of establishing an astronomy institute at the Faculty of Philosophy of the University of Ljubljana", which enabled the employment of Dominiko. On 14 September 1966, Dominko among the first visited the astronomical observatory in Bucharest.[3324]

On 145 November 1948, Peterlin was able to attend a scientific conference about the Large molecules in solution (Les grosses molécules en solution) in Paris in honor of the recently deceased Langevin and Perrin. The invitation was supported by one of the editors of J. Chimie physique, a polymers physicist Charles Sadron from Strasbourg.[3325] Peterlin met him shortly before the war in July 1939.

At the beginning of December 1948, Boris Kidrič instructed Peterlin to collect data on nuclear energy. In February 1949, at a meeting with Kidrič in Belgrade, Peterlin undertook organizing a nuclear institute in Ljubljana, whose main task was to construct a reactor. In planning, he came into conflict with the leading physicist in Belgrade, Pavle Savić. In 1932, Savić graduated in Physical Chemistry in Belgrade and measured the radiation under supervision of the professor Jovanović. From 1934 until the war he worked with Irena Curie and Frederic Joliot to prepare the discovery of the fission of the nucleus in Paris where Tito occasionally used Savić's flat. Irene and Joliot followed their leftist ideas. During WW2 Savić was in the partisans' unit as the head of the highly confidential cryptography department of Tito's headquarters and vice president of the Executive Board of AVNOJ.[3326] In 1945, Savić became professor of physical chemistry in Belgrade, in 1946 a member of the Academy, and from 1971-1981 its president. As the former head of the Confidential Tito's Headquarters, he was trying to direct the development of physics in Yugoslavia. He wished to produce a nuclear bomb as director of the Vinča Institute. After Kidrič's death Peterlin was somehow hiding his seemingly unpromising research of macromolecules from Savić during his visits combined with hunting in Slovenian forests where he disliked macromolecular polyvinyl plastic bags. Savić represented nuclear physics as the sole goal. Thus, only physicist M. Čopič and chemist G. Mohorič with their research of the double refraction in flow (streaming birefringence) or the synthesis of polyhedrons were awarded their Ph.D. from Peterlin's basic field. Later, Peterlin sent Čopič to the training in the United States to be able to dedicate himself to the reactors.

Peterlin's best association with politicians in Belgrade was Tito's secretary general between 1953-1958, the lawyer dr. Jože Vilfan,[3327] Peterlin's juvenile friend and Carniolan student of Peterlin's uncle. Vilfan was the son of the Trieste lawyer and politician Josip Vilfan (* August 30, 1878 Trieste; † March 8, 1955 Belgrade), and he attended the grammar school in Kranj in 1919-1926. Vilfan's mother was the native of Kranj, so she came on a summer vacation in Kranj. Vilfan and Peterlin's mothers were familiar from their juvenile days; so, both boys met each other, they played together and walked by the Sava river.

In 1929-1932 Vilfan studied law in Ljubljana. He got his degree in 1932 and promotion next year, so they shared time with Peterlin during their student years. Of course, their scientific interests were completely different. They often discussed Serbian temperaments and Peterlin once stated that Serbians often make impossibly higher goals for themselves to gain, which the stable small narrowminded Slovenians do not.

The former student of chemistry, Boris Kidrič, knew the capabilities of his four-year-older

[3327] Peterlin's letter to Joža Wilfan (Vilfan, * 6. 7. 1908 Trieste (Trst)) mailed from Detroit to Beograd 23. 7. 1955, which was not mailed as he wrote another letter instead of that one (GDP; SBL, 4: 469).

Peterlin and allowed him to continue with the research of large molecules within the framework of the Physics Institute. The institute was named Jožef Stefan after Peterlin's proposal. Peterlin headed it for a whole decade until 1959. The coincidence was that he died 158 years after Jožef Stefan's birthday (1835-1993). Peterlin learned experimental approaches from Sirk. Although he initially followed him in quantum mechanical experiments, Peterlin was among the first to discover greatest potential for the investigation of solid matter and new materials. He thus focused on the research of macromolecules (common plastics and synthetic fibers) and was, after the Second World War, by far the most renowned Slovenian physicist. Thus, at the time of the establishment of a nuclear institute in Ljubljana, there was no other choice, and Peterlin became the director with wide powers, although his research field was far from a nuclear bomb. The decision was correct, as Peterlin showed an extraordinary gift to the organization and quickly developed an extremely effective scientific institute on the Western models.

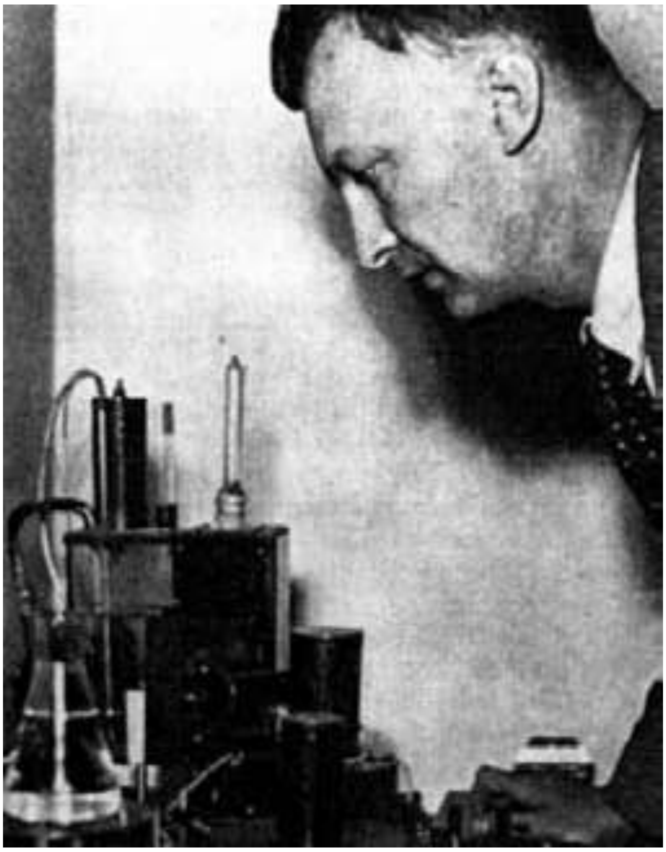

Figure 30-6: Peterlin experimented in the 1950s

Physical Institute premises were initially at the SAZU. Between and in 1949-1953 they built a new building at the intersection of Jamova and the Jadranska streets. The workers in the construction of the Institute were mainly prisoners, among them the relative of Gottschee forester Anton Prelesnik the physicist Anton (Tone) Prelesnik who was imprisoned for his careless political talk. In July 1955, he worked as a practitioner in Havliček's Laboratory. In 1959 he graduated in Kuščer’s class, and in 1960 he published in the same topics a report on NMR research in Rochelle salt in *J.Chem.Phys*, together with Blinc.

30.1.4.6 Macromolecules

On Prešeren's day in 1953, the new Physical Institute was ceremoniously opened, which since then was named after Jožef Stefan. Two months after the ceremony Peterlin's mighty patron Boris Kidrič died. In that time on 7 February 1953, just one day before the opening of new IJS buildings, Peterlin published his calculation of the persistent length of the DNA molecule and its elastic constants, which he sent from Ljubljana to a leading magazine Nature on 5 June 1952. He used Bunce's measurements of the scattering of light in DNA solutions done for her doctorate with Doty at Harvard, Cambridge, Mass. In 1953, two months after Peterlin’s announcement, Watson and Crick published the discovery of a double-ended DNA in the same magazine, and Peterlin's calculation again became interesting forty years later.

Peterlin presented his findings for the first time at the International Macromolecular Colloquium in Strasbourg between 9 June and 12 June 1952 in relation to the measurements of the light scattering of Mrs. Barbara H. Bunce married to McGill and Ernest Peter Geiduschek (* 1928 Vienna), that is, immediately after Peterlin sent them to Nature. Already in 1951, Havliček in Nature reported on the determination of the wave surface for known spherical aberrations, while Moljk reported in the prestigious Phil.Mag. in volume 36.

On 5 August 1952 Peterlin sent his report from Strasbourg and published it in Doty's Journal of Polymer Science in April 1953. At the same colloquium, Doty presented his measurements of scattering, which, of course, encouraged Peterlin to make new announcements, as he improved his calculations during the following decade. As a graduate student Doty joined the Manhattan project to become an associate professor of chemistry at Harvard between 1950-1956, then a professor. Between 1967-1970 he was a head of the

Department of Biochemistry and Molecular Biology, and Edward Mallinckrodt (1878 Saint Louis-1967) professor of biochemistry since 1968. In 1973 he founded Robert and Renée Belfer Center for Science and International Affairs at Harvard as its first director. Shortly after her doctorate, Bunce was employed at the Oberlin College chemistry department south of Cleveland. With Doty's measurements, Peterlin studied the scattering of light in protein solutions in the second part of his discussion on the Physics of High Polymers. The epoch-making monograph on macromolecules was edited by Stuart in 1953. Peterlin contributed four chapters, among them the longest on the Artificial Double refraction together with Stuart.

In chapter twelve, Stuart and Peterlin determined the characteristic constants of submicroscopic particles from the measurements of artificial double refraction and internal friction; the connection between the internal friction and the measurable properties of the substance was like the one developed in the previous century by S. Šubic's criticism of Clausius and Boltzmann. In the case of a double refraction in flow (streaming birefringence) Peterlin re-introduced the model of a free torus. He compared it with the results of experiments. The artificial double refraction was divided into electrical (Kerr's), magnetic (Aimé Cotton-Henri Mouton's) and dynamic or current or acoustic double refraction of flow (streaming birefringence, Maxwell's).

In chapter 6, Peterlin described the scatterings of light in mixtures and solutions of macromolecules (simple and repeated scattering). Stjepan Jakšeković performed similar measurements on seawater already in his Zagreb dissertation in 1932, while several measurements were published by Marin Katalinić (1887 Trogir-1959 Skopje) at Zagreb University physics institute and P.J. Jurišić of the Physiology Institute of Medical faculty of Zagreb in 1935-1938. Peterlin also quoted the early work of Lars Onsager on the viscosity of the suspension of several spheres published in 1936.[3328]

In the meanwhile, the foundations for both faculty buildings in the Jadranska street next to Peterlin's institute have long been waiting for the start of construction. In 1960 they built the building of the Faculty of Physics at the Adriatic (Jadranska) street no. 19, while the anticipated building of mathematics was waiting for its foundations as the Computer Center; the planned intermediate pavilion never saw a white day.[3329]

In 1955 for nearly eight months from mid-May to the end of December Peterlin was "guest professor" on study leave under supervision of the former collaborator at University of Paris from 1933 to 1937 the Jewish professor Wilfried Heller (1903 Bad-Durkheim-1982 Huntington Woods suburb of Detroit) from the Chemistry Department of the Wayne State University in Detroit, precisely at the time when the writer of these lines was born somewhere to the west in San Francisco. Peterlin led the work of the IJS with numerous letters from the USA. His wife wanted to visit him, but she wrote in her visa application that she was a member of the SZDL, which, as a civil servant, she must have been. The request was not granted to her during then presidency of Eisenhower and vice-presidency of Nixon.[3330] Peterlin was a guest lecturer at the Department of Chemistry at the Wayne State University in Detroit, with the participation of the head of the project, Professor Wilfried Heller, and visiting professor from the University of Osaka and Tanaka Masayuki Nakagaki (1929 Fukuoka Perfecture-2008 Kyoto). 31 syllables poet Masayuki Nakagaki worked in USA with Wilfred Heller of Wayne Stater University in 1955-1957 and in 1968-1969. Peterlin was engaged with the same problem at the meeting of the American Physical Society in Philadelphia on 16 March 1957.

Based on Debye's (1931) model of the molecule as a free-dipping torus, they tried to explain the results of experiments with the angular distribution of unpolarized light. The symmetry of the ellipsoid was found in the end section of the macromolecule, the ratio of the axes increasing with the segment size. They determined the mean square of the distance between the ends and its alteration with the size of the segment used, that is, the statistical form of the macromolecule and its variation with the flow. They designed a model for scattering light on a curved macromolecule consisting of supposedly isotropic parts like pearls in a necklace. For small deformations, the

[3330] Message of Tanja Peterlin Neumaier, message on December 6,. 2006.

computation was easy, but for large deformations it was necessary to perform numerical integration, the results of which were presented in eight graphs using the Wayne State University computers. On October 25, 1956, Čopič and Peterlin published their invention of a double capillary viscosity meter together with a photograph in the Bulletin Scientifique of the Academic Council of Yugoslavia, which Peterlin edited since 1953. In October 1958, Peterlin reported on shortrange and longrange interactions at Linear macromolecules based on scattering of light and X-rays. Günther Kratky’s (1919 Faak am See near Villach (Beljak)-1984 Graz) and his Viennese teacher Otto Porod’s (1949) Austrian worm model still seemed better than others, but Peterlin again warned that the distribution was not Gauss's, and thus has some of the advantages over the older Hermann Staudinger’s statistical dumbbell-model handles designed by ETH student turned Basel professor Werner Kuhn (* 1899 Maur am Greifensee; † 1963 Basel) and his talented doctoral student Hans Kuhn (* 1919 Berne; † 2012) in 1943. Hans conducted his postdoc with Linus Pauling and N. Bohr.

In 1959, Peterlin published his Determination of the Size of Molecules by their lighting data in booklet at the prestigious Pergamon Press, together with a sketch of a measuring device drawn up at the IJS. In 1959, Peterlin re-studied the electro-distribution of macromolecules. After Debye's promising discovery in 1954 it was used for the dissertations of Poberaj (1955) and Ribarič on 16 March 1959.

During an intensive study of macromolecules, Peterlin was forced to study reactor physics and accelerators as well. At the IJS Betatron Seminar, the lecturer once reported on the electron path through a rather dense system of dipole and quadrupole magnets. At the end of the seminar, Peterlin stated that the results were wrong because they did not coincide in the first approximation with the path of analogous light rays through prisms and lenses. On 28 October 1953, Supek announced to Peterlin the Zagreb lectures by the head of the cyclotron group of the French Atomic Energy Commission P. Debraine. The French cyclotron had the most successful performance in Europe at that time. On 3 November 1953, Peterlin reminded Supek that a year ago Barbarić and his colleagues had removed all the support for Samec’s Chemical Institute as well as for M. Vidmar's Electrotechnics Institute, which were established by Kidrič, although both should prepare practically utilization of nuclear energy. Supek, unlike his colleague from Zagreb institute the electro engineer Marcel Lažanski, did not attend a conference in Geneva, where Livingston from the Brookhaven National Laboratory and CERN Director Huib J. Bakker of the Amsterdam Institute of Atomic and Molecular Physics questioned Supek in person. Bakker was even a bit angry because Supek recalled Lažanski from Geneva where Marcel Lažanski held permanent post from 1965.

In 1952, Livingston together with the great-grandson of Emil Heinrich du Bois-Reymond the Jewish Ernest Courant (*1920 Göttingen) and independently of the two years earlier efforts of Nicholas Constantine Christofilos (Νικόλαος Χριστοφίλου, 1916 Boston-1972), published the idea of strong focusing as the basis for the work of all subsequent powerful accelerators. After the first model of the glass, Lawrence, with the help of his student Livingston, assembled a second cyclotron from the metal. With a 2000 V voltage, it could accelerate hydrogen ions to 80 keV energies. In his doctoral thesis Livingston proved the utility of the principle of cyclotron resonance on 14. 4. 1931. Lawrence and Livingston were the first to accelerate protons over 1 MeV; but they did not break the nucleus of the atom before Cockcroft and Walton success in the British Cavendish Laboratory.

In the summer of 1959, Livingston, as director of the 6 GeV accelerator in Cambridge which was used by the researchers of Harvard and MIT, visited the IJS to talk~~a~~ about further Dekleva's specialization in the USA. However, the new director of the IJS, Lucijan Šinkovec nicknamed "a valve" by the local bicycles’ fans changed his mind overnight and called Dekleva home. Ranković demanded Lucijan’s construction of the Ljubljana reactor.

On 7 November 1953, Supek wrote to Peterlin that he would support the independent Samec’s Chemical Institute, although in Zagreb all such studies were united in the Ruđer Bošković Institute. At the same time, he asked for Peterlin's help on the question of the Zagreb 16 MeV cyclotron, which, according to some rumors, Pavle Savić and Stevan Dedijer would like to have in

Vinča produced by Philips for a million dollars, which would be a "heavy attack" on Zagreb, where, after the approval of Kidrič in 1950, they have built such a device together with the factory "Rade Končar" with only 10% of the foreign currency funds under the leadership of Supek as the youngest member of the JAZU. Tito personally pushed the button commissioning Supek and Lažanski's Zagreb cyclotron on October 25, 1962.

On 20 November 1953, Peterlin congratulated Supek for Supek's new book, "The project of cyclotron 16 MeV". In fact, Vinča got a cascade generator. On 7 December 1953, Peterlin wrote to Supek to inform him that Pierre Debraine from Faculté des sciences de Paris could speak in Ljubljana on 11 December or 12 December 1953, if he travels from Zagreb by train; but if he uses airline, it would not be rational to organize the matter because of the excessive costs. In fact, Debraine lectured in Ljubljana on Wednesday, December 11, 1953 at 10:00 am, and two hours later, they celebrated Plemelj's 80th anniversary, as Peterlin reported to Dedijer on November 20, 1953. Two years later, a writer of these lines was born. Peterlin suggested to Supek to meet on the train for their joint trip to Belgrade to overcome the issues that will be discussed with Svetozar Vukmanović – Tempo (* 1912 Podgora in Montenegro; † 2000) in Belgrade, especially on the Administration of Mines, probably the mines of uranium ores. On 27 January 1953, Dedijer invited Peterlin to come to lecture in Vinča several times in 1953. On 26 February 1953, Peterlin wrote to Dedijer about the opening of the IJS as he described in Ljubljana newspapers and in the journal Borba. He praised the return of a great connoisseur of the reactor problems Dragiša M. Ivanović, who later published some philosophical books, and with the Marxist concept of self-motion came into serious conflict with Kuščer in the mid-1970s. During the first post-war years Ivanović was Savić's assistant and opponent of the mainstream quantum and relativity theory from Marxist standpoints. Peterlin also mentioned recent arguments at a meeting in Belgrade as unproductive attempts of uneducated guys to prove the facts, while they are all too little aware of the realities of reactors. On Dedijer's complained about the lack of a report about Peterlin's trip to the United States, Peterlin assured him that, at the request of his hosts, he was only dealing with macromolecules. He disliked the affairs of Mirjan Gruden (1910 Ljubljana-2001). After his diploma in Ljubljana in 1937 and his studies in California in USA, Gruden first worked with the IJS, and then suddenly Gruden was supposedly unfairly hired in Vinča. Nor did Peterlin approve Ranković's handling the precise extremely costly measurements of uranium content in the Idrija ores that are not accessible to Slovenes. He also mentioned the CERN proton synchrotron leader O. Dahl's offer of assistance in the production of heavy water. On 2 April 1953, Peterlin asked Dedijer to send the professor Pieter Frits Abraham Klinkenberg (1915 Amsterdam-2005) from Zeeman's Laboratories in Amsterdam, who will be in Vinča for three weeks. Peterlin wished to have Klinkenberg in Ljubljana to present to the selected experts the theory of the shell as a model of nucleus for one day on 8 April 1953. At that time, Dedijer's deputy Ž. Petrović was also visiting Ljubljana.

On 2 March 1953, Carlo Salvetti and Aldo Pontrer of the Istituto Nazionale di Fisica Nucleare at University of Milan announced that they could not visit Ljubljana and Belgrade. On February 25, 1953, Heisenberg wrote to Dedijer that he would like to come to Belgrade and Zagreb after the conference in Geneva at the end of May. Heisenberg visited the IJS in 1955, when Črt Zupančič came to pick him up Zagreb with a driver in the official vehicle.

On 27 April 1953, Peterlin asked Dedijer upon the visit of Charles A. Berthelot from Bureau Central de Mesures Nucléaires (Euratom) in Geel in Belgium who just arrived in Belgrade. Peterlin wished to host Berthelot in Ljubljana for 4-5 days and for the same number of lectures on co-determination coincidence measurements. Peterlin wrote to Savić about the visit of the only French participant at Fermi's Chicago reactors and at Manhattan USA based project the Jewish father of French atomic bomb in 1960 Bertrand Goldschmidt (1912 Paris-2002 Paris), while Peterlin also asked for details about the work in Vinča.

Peterlin prepared a report for Physikalische Blätter and Physics Today along with a description of the IJS and the Supek's Report of the Ruđer Bošković Institute. On 12 May 1953, Dedijer complained to Peterlin that two or three months ago, when the ministry of interior and Vinča collaborator Bojan

Zaletel (* 1920 Postojna; † 1981 Kranjska Gora) wrote about Stefan and the Physics Institute, Osredkar tried to obtain Zaletel for work in Ljubljana as Zaletel was on his way to specialisations in Paris in 1953. Dedijer did not feel right and mentioned "the procedure one year and a half ago, when another guy named Moljk asked to work at our Institute (Vinča), and when we responded in writing to Moljk, which you (Peterlin) can get that copy whenever you want. Dedijer welcomed Moljk's proposal on condition that Moljk's boss Peterlin is informed of it." Dedijer therefore proposed a kind of fair-play in hiring the experts in both institutes.

Dedijer regularly wrote Osredkar's surname Osretkar, according to Vuk Stefanović Karađić's principle "write as you speak." Peterlin did not even try to exaggerate too much about Zaletel in his letter dated May 18, 1953, but he wrote, "when you mention that Moljk's offered himself to Vinča, I must tell you that I have only learned about this from your letter, because he never said to me about that. Your position was completely correct in his case." Certainly, Peterlin had too little politics skills to see how Dedijer checked the terrain: the docent Moljk was often in Belgrade as a delegate at atomic energy meetings, and the Belgrade-based folks had already chosen him for Peterlin's replacement, even though Moljk would wait another five years to fulfil his secret wish supposedly with a lithe help of his friend Tito's dentist. In fact, Peterlin and Dedijer will be very soon forced to escape abroad.

On 11 June 1953, Moljk together with Lieutenant Colonel Gajić (later major-general of air forces Pavao Gajić (* 1923), Kosta and Osredkar attended a meeting on nuclear energy, as well as an inter-institutional meeting in Zagreb on 6/1/1953 and in Ljubljana on 9 February 1953, 7. 5. 1953, and 8. 5. 1953 together with Peterlin, Havliček, Jamnik and Osredkar. By 25. 4. 1953 they determined that the reactor needed 7 tons of heavy water and 2 tons of uranium ore, like the the first French atomic reactor Zoé (EL-1) built at the Fort de Châtillon in Fontenay-aux-Roses suburb of Paris in 1947. On August 24, 1953, Peterlin reported to Dedijer about his visit to Niels Bohr's fourth son, the physicist Aage Bohr, who would take another student to work in Copenhagen besides Črt Zupančič in December 1952-1954.

On September 1, 1953, they sent from Ljubljana the IJS Reports to Dedijer. On 11 September 1953, Peterlin reported to Dedijer about the conference on accelerators in Zagreb with Alfvén, Gogard and Odd Dahl of the Carnegie Institution in Washington. Due to the changed situation after the construction of the Zagreb cyclotron and due to lack of foreign currency, the conference was later cancelled and only Debraine was invited.

On 20 November 1953, Peterlin wrote to Stevan Dedijer about dr. Otto Kofoed-Hansen (1921-1990), Bohr's co-worker, who will be the guest of the Dedijer Institute for the examination of the structure of matter for two weeks in Belgrade, and could arrive to Ljubljana on December 17, 1953, after his lecture in Zagreb on the previous day. On 26 November 1953, Peterlin sent Dedijer the book Secrets of the Atom of the writers Osredkar, Čopič and Kosta.

On 4 December 1953, Peterlin reported to Dedijer about Matteucci from the University of Maine, who gave lectures in Ljubljana on European mass spectrometers, while Albert Jan Staverman (1912 Bussum-1993) from The Hague applied physics TNO Institute for Plastics lectured on relaxation phenomena and plastic masses. In the spring of 1954, Peterlin announced a possible visit by Sadron and Per Claeson, the successor to Göte Swedberg at the institute in Uppsala. A week ago, Dekleva returned from work on mass spectroscopy in Mainz and could come to Belgrade in December 1953. For the Swede Harry Brynielsson (1914 Stockholm-1995 Vaxholm), Peterlin considered that he might hide some special methods from other researchers.

The state Defence Secretary carpenter turned general Ivan Gošnjak (1909 Ogulin-1980 Beograd) submitted to Peterlin the Rules on Nuclear and Chemical Weapons, and Moljk responded in writing to him, including on the notes on explosion of the bomb and on the irregularity of radiation for the telephone network. The JNA provided a list of experiments in nuclear physics that would be of interest to the army.

On 27 November 1953, the annual reports were published with papers of Havliček, Kosta, Moljk, Peterlin (double refraction at flow (streaming birefringence), scattering of light on the particles of the PVC sample) and Kosta. Pičman was gone, and Perman was at the army as soldier.

Peterlin traveled by boat in both directions, since the Yugoslavian firm Putnik had badly arranged the reservation for him, so he had to buy the his tickets from his own pocket. Otherwise, ZKNE granted him $ 390 for his trip to the US and an additional $ 100 for his way to Detroit. In September 1955 Peterlin met with the great advocate of the peaceful use of nuclear energy Walker Lee Cisler (1897 Marietta, Ohio-1994), the president and CEO of Detroit-Edison Co. which Fermi founded in cooperation with other companies in 1963. Cisler contributed money, so Peterlin could extend his stay in Detroit for two months. From 12 December to 16 December 1955, Peterlin attended the Nuclear Science and Engineering Congress in Cleveland. On 30 April 1955, Beograd educated electronic engineer Slobodan Nakićenović (1916-1996 Vienna) wrote to Peterlin a letter which Peterlin received on July 5, 1955 and wrote back immediately. Nakićenović reported problems of interregnum in the IJS; it is necessary to appoint a director and administration as soon as possible. On 5 July 1955, Peterlin replied to Nakićenović from Detroit that only now, after six years of work at the organization, the IJS discovers something new, since so far it has published years old achievements only. During this time, Havliček ceased to be a member of the IJS Governing Board.

On 14 May 1755, Peterlin recommended Nakićenović to send Osredkar to study in the United States while eventually replacing Havliček. So, Savić will be satisfied as the Croatian Havliček was not Savić's best friend. During Peterlin's stay in the US on 16 May 1955, at a meeting of the Scientific Council of the IJS, a new statute was adopted with only three bodies: The Administrative Director, the Scientific Council under Peterlin's Presidency and the Council, later the Board of Governors. This was a real turning point, since Peterlin, Supek and Savić, as heads of scientific councils, did not have any real power, but Peterlin because of his fame nevertheless retained informal power. During the change, Peterlin stayed in the USA almost without an accommodation in IJS. IJS was left without a legitimate basis, as Nakićenović delayed the appointment of Peterlin and the IJS Governing Board. A lawyer named Karol Kajfež became the administrative director. Kajfež therefore left his service for railways.

Osredkar together with the secretary Greta Novak came to the Institute from SUZUP under the director Sokol leader and Osredkar's fellow radio Kričač activist Ivan (Miloš) Brelih (Mihael, Mitja, 1916 Trebnje-2002 Ljubljana); Osredkar no longer had any administrative function in the IJS since Peterlin has dismissed him as his assistant. Prior to his return to the city of Ljubljana the electro engineer Brelih worked with ZKNE in Belgrade, where he was replaced by the engineer Barbarić who published the book *Nuklearna energija i njena primena* in Beograd in 1961.[3331]

On 18 May 1955, ZKNE postponed the appointment of Peterlin as administrator and the Managing Board of the IJS; Peterlin was thus "de facto put deprived of his job, and IJS was put out of the law", as Peterlin complained to Ranković in a somewhat broken Serbian language on June 17, 1955. The discrimination of the IJS was due to the proposal of Savić, which Peterlin emphasized at the same time in the letter to Nakićenović, as Savić believed that during Peterlin's departure to the United States they should penalize both Peterlin and the IJS.
On 21 November 1955 Peterlin wrote to Nakićenović from Detroit about his lectures in the USA and his understanding of Savić's antipathies to Havliček, who is also as good expert in reactor technology as Milorad Ristić later director of Vinča) or anyone else in Vinča, so it is not nice that Savić is pushing Havliček out from the IJS. Peterlin could even be a bit witty: "I am extremely pleased that with my stay in America I missed numerous conferences on programs that have always been distinguished for their hectivity like budget deals."

By 23 December 1955 after returning from the United States by boat Peterlin planned to visit Marjan Senegačnik (1928-2002) in Paris where Senegačnik defended his Ph.D. entitled A Study on the Isotope Effects in the Reduction of Carbon Dioxide by Zinc (*Etude des effets isotopiques dans la réduction du gaz carbonique par le zinc*) in University of Paris in 1957. Peterlin also wished to visit Moljk in Glasgow and others, then he wanted to afford some skiing, so in mid-January he would be in office again. Peterlin emphasized that

[3331] GDP.

researchers of the IJS will find enough domestic uranium for all needs of Ljubljana, which soon turned out to be doubtful. During Peterlin's absence, Kosta and Dekleva attended the First International Conference on Peaceful Uses of Nuclear Energy in Geneva on 8. 8. 1955-20. 8. 1955. There, Kosta asked for a possible visit to the IJS Workers at Harwell. The answer was not completely negative, but the Brits suggested that people should be first send to Oxford, Liverpool and Birmingham.

The heads of IJS laboratories wrote reports for June 1955, which Peterlin's sister Marja Lapajne then sent to Peterlin in the United States. Among them was Edvard Cilenšel.–He worked at the IJS from 1950 until his departure to Iskra in 1965, described in the report to Peterlin for June 1955 the work of the vacuum laboratory A1. On the electrostatic accelerator, the leakage of all vacuum elements with McLeod was measured, and a rectifier for the Penning's Vacuum-Meter[3332] was placed on the panel of the radiofrequency ion source. They developed a power supply for the Leybold ionization triode Telefunken IM 5, in part, they had the prototype ionization triodes IM 5 and 5 Penning's vacuum gauges with the M19[3333] connector cone. In a report for July 1955, Cilenšek complained about the liquid air imported from Ruše, because 15 liters of poorly insulated vessels were sometimes emptied because of the evaporation on their way to the IJS. At home, a 60 l/s diffusion pump was built, and a slightly worse Edwards' pump and Knudsen's vacuum gauge was used.[3334] In September 1955, in Cilenšek's networks, the flow protection was designed and tested to stop the diffusion pump from burning in the event of a power failure and to produce an ionization triode. In October, the maximum suction speed of 300 l/s of the diffusion pump with a receiver of a volume 500 l was measured for the Institute Elektrozveze. It was achieved at 1200 W using klofen in a vacuum of 10^{-4} mm Hg.[3335] Klofen was later mostly used in the pharmacy. Peter Zazula built a vacuum calibration device in a laboratory for mass spectroscopy led by Janez Dekleva,[3336] and at the beginning of October 1955, he worked with engineer Alojz Paulin.[3337]

On June 28, 1955, Peterlin wrote from Detroit a letter that arrived at the IJS on July 8, 1955.[3338] He proposed that they sent one of the new chemists or physicists to a nuclear engineering course at the University of New York. Until then, that branch was developed only by Zagreb Czech F.I. Havliček. Now Peterlin wished in his place above all Osredkar, and he was a little angry because Osredkar has postponed his departure to New York for personal benefits. Havliček's work consistently challenged disputes with researchers in Vinča. On 6 July 1955, Osredkar wrote to Peterlin that he refused to go to New York University because of his family, which was too often separated from him because of his previous work, as Peterlin's sister Marja reported to Peterlin's American address with funny remarks about the harsh Osredkar nervousness in those days.

When the issue of daily subscriptions was settled on 29. 7. 1955, Osredkar announced that he would go to New York. On August 23, 1955 Peterlin wrote a recommendation for him. Osredkar went to Belgrade to meet Secretary General Slobodan Nakićenović and his assistant the Dalmatian Ljuba Barbarić. Osredkar joined the Professor Richard Montgomery Stephenson (* 1917) at the College of Engineering of New York University in the USA with a $ 273 grant per month, which was half as much as the usual sum. Their joint publication was a research of low-power, high-thermal-flux experimental nuclear reactor.[3339]

Osredkar went to Belgrade to Secretary General of the ZKNE (Federal Nuclear Energy Commission) Slobodan Nakićenović and then to New York, so that Kajfež could have moved to his room on September 26, 1955. After a long reflection, Osredkar realized that he would need a doctorate for further work, so he would move to the US for two years, where his son the physicist Radko Osredkar also went to school. In fact, Milan Osredkar stayed in the United States only until December 1956.

[3339] *Osredkar, Stephenson, 1957,*: 210-214.

Peterlin often wrote to Kajfež and other associates from the USA. On 20 September 1955 he visited the University of Chicago.[3340] There he examined the Institute for Nuclear Studies, which is "a huge thing for three Ljubljana, have a 450 MeV synchrotron for protons, a 100 MeV betatron, 3 cathode ray tube electronics, mass spectrometers and all other devices. I only saw an insignificant piece of the whole huge apparatus. The next day, at noon, dr. William A. Chupka (1923 Pittston-2007) drove me to Argonne, 40 km away, where unfortunately I only had very little time to see only the mass spectrometry and the school of reactor engineering."[3341] A few months later Peterlin sent Čopič to the Argonne National Laboratory in Chicago. On February 14, 1956, Pičman went to Copenhagen for a one-year study of nuclear theoretical physics at Bohr's networks, where, prior to him, Črt Zupančič worked on Van de Graaff accelerator since December 1952. Lovro Pičman (* 1929 Ljubljana) always kept a great respect to Bohr, Teller and other Manhattan fellows as he told the author of this lines.

Peterlin went to Israel for fifteen days, of which he spent five days in Turkey. On June 29, 1956, Jamnik was given a visa to travel to the Netherlands, Switzerland, Germany and Austria. On July 12, 1956, the IJS imported equipment with money from Hungarian reparations.

On 15 September 1956, a passport was raised on the Swedish consulate for the journey of Uči and her fiancée Milan Osredkar. On 16 September 1956, the IJS reported to the Federal Nuclear Energy Commission about travels abroad after 1 July 1956. On 3 August 1956 and 4 August 1956, Peterlin purchased the ultracentrifuge for the separation of isotopes or polymers at high peripheral speeds.

The senior referent Osredkar has been studying reactor physics in New York since September 1955 under supervision of the professor Stephenson. Janez's sister, the assistant Alenka Dekleva (1929 Ljubljana; † 1995), later married Likar, attended the electron microscopy congress in Stockholm on September 18, 1956 and visited Saclay University in Paris. Alenka research at Marinković's lab between 1954-1960, and after Peterlin's departure and difficulties in studying macromolecules, she took over the professorship at the Faculty of Medicine in Ljubljana.

Jamnik was in Amsterdam at a conference on nuclear reactions in July for 10 days. Čopič was in the United States at the School of Reactor Physics. In December 1956, Senegačnik worked on isotropic effects in Saclay in Paris. The IJS fleet was already complete for success, including a 10-year-old Ford, which Peterlin used as a former Kidrič's gift. The car was driven by Vinko Ravnikar, who, after Peterlin's departure from the IJS, had to find another job.

On 15 November 1956, IJS sent engineer Janez Kristan for one-year study in the USA after Kristan graduated in Vinko Kramaršič's class in Ljubljana in 1952. Kristan worked at the IJS, especially in Podgorica nuclear reactor between 1953-1977, and then went to the national health inspectorate. Čopič was in the United States in the middle of his affairs with countess' plane from 3 July 1956 to 30 September 1956. On 13 and 14 January 1956, the IJS representatives met with scientists. The JNA has decided to use the services of the existing three Yugoslav nuclear energy-dedicated institutes and will not build their own JNA nuclear institute. On 9 October 1956, Peterlin wrote to Nakićenović about Knop's proposal for the gradual abandonment of the heavy water department, which only became a financial burden since importation became possible. Savić agreed with the proposal. As the secretary of the newly-established CK ZKJ at the IJS, biochemist Zagreb PhD student Drago Lebez (1922 Borovnica-2015) already published in the final report for the year 1956 two pages of glorifying of IJS importance on November 29th, 1956. It was a part of his speech at the celebration at the institute. It was followed by 30 pages of Peterlin's report, half the page of D. Sušnik's library report, which at that time had 4536 books and 105 magazines, etc. Knop was still working at the heavy water department, while Havliček decided to concentrate uranium on the decision of the IJS Council of 4 February 1956. With this decision, they stopped the development of the ion source with heated cathode for the neutron generator and systematic measurements of the neutron spectrum Ra-Be source and neutron diffusion calculations within the homogeneous reactor program.

[3340] GDP.
[3341] Peterlin's letter to his wife 24. 9. 1955 (GDP).

The IJS Council commissioned work on uranium concentration by the distillation method, E.W. Becker of Marburg-Carl Gustaf Patrik de Laval nozzles and diffusion membranes. They developed the technique of enrichment uranium measurements at distillation using an ionization cell. The liquid UF_6 was produced until 1 April 1956, and then again from October 1956 onwards. On 12 June 1956, Havliček presented the expected separation effect at the lecture and published in Reports 24/25. 9. 1956. Work with mass up to half a kilogram of UF_6 was possible, while only 50-60 g for fractional distillation had previously been used. They had Becker-Laval nozzle, but the IJS did not have enough sensitive measurement devices. The microtron of Paulin was nearly completed; the vacuum chamber and microwave elements were designed from the output of magnetron to the accelerator resonator of the pulse generator.

Marinković's co-workers in the material testing laboratory were using Carl Zeiss' electron microscope, purchased at the Laboratory for Investigating Material of the IJS in October 1954. They examined ten domestic and three foreign PVC samples. The molecular masses of polymers were determined. Alenka Dekleva studied erythrocytes for her research of virus cultures at Marinković's lab. With an electron microscope they also filmed for external subscribers from Geological Institute's samples of chalk from the lakes and eighty zinc oxide samples from Cinkarna Celje. Soon, Boris Navinšek joined the electron microscopy section in 1957. In Marinković group, the scattering of X-rays was also studied.

On 5 March 1956, Peterlin lectured about his scientific and pedagogical work in the Ljubljana club of Scientific and Cultural Workers in Ljubljana, and he talked about the IJS for the Radio Slovenia on the day of the republic on 29 November 1956. On 21 October 1956, Peterlin wrote about Science in Sweden for Human Rights (Ljudska pravica) journal of Ljubljana.

Between 10 and 26 October 1956, the IJS organized a second course of radioactivity with lectures of Č. Zupančič, Kosta, Lebez, the mathematician Anton Vakselj's (* 1899; † 1987) son Marko Vakselj (1932—2017) and others, but without Kuščer or Moljk. The third course followed from 19. 11. 1956 to 28. 11. 1956.

On 10. 1. 1957, Peterlin wrote to Nakićenović an angry letter. Nakićenović told him by telephone that ZKNE did not oppose Peterlin's departure to Moscow at the invitation of the academy of science there. However, the Nuclear Energy Commission argued that macromolecules do not fall within its scope. Of course, Peterlin was very angry because his macromolecules' research was at Hamletian position to be or not to be. In 1956 he got the IJS task to study Teflon as the fluorocarbon macromolecules. In 1955, Vinča wanted to work with Teflon, but the IJS experts were more experienced with both macromolecules and fluorine. Thus, the IJS received these highly macromolecular orders according to the budget for the years 1955 and 1956. In a conversation with Savić after returning from Israel, Peterlin got the feeling that Savić had to explore many impacts of the radiation on the macromolecules which they were dealing with at Harwell. Therefore, Peterlin sarcastically asked the Commission for "an authentic explanation of where macromolecules are starting and whether Teflon and polyelectrolytes are involved, i.e., are the ion exchangers under the notion of macromolecule or not." It was clearly a joke because Peterlin knew much more about the macromolecules compared to the folks he was asking about them.

On 22 January 1957, Dr. Bahittin Baysal (1922 Kırşehir-2017) from the Department of Physical Chemistry Fen of the Faculty of the University of Ankara visited the IJS. Peterlin organized his visit during his journey to Israel and Turkey. Peterlin, as a member of ZKNE, attended conferences in Egypt and Greece in 1957, and he joined the conferences in India in 1958.

On 12. 3. 1955, Peterlin dismissed Moljk from the IJS based on Moljk's letter with validity on 28 February 1955. That conflict was a basis of the later Moljk's revenge. Nevertheless, on 13 November 1956, with the validity date of 1 January 1956, Moljk concluded a part-time contract with the IJS as a leader and organizer group (laboratory) for N-3 nuclear spectroscopy. In July, August and September 1957 and in 1958, Moljk did not receive salaries due to his work in England and Scotland.

Moljk began as a physicist before the war after graduating from mathematics, just like Kuščer and Peterlin. Moljk received his doctorate in 1956 in

Peterlin's class when Kuščer and Dominko were also in the exam committee. The topic of Moljk's 209-page dissertation, mostly done at the Glasgow University Institute, was Beta spectroscopy in the range of smaller energies. The defense was on the first floor of an old university in a room that has a balcony facing the Revolution (Congress) Square. Dominko did not ask questions, but Kuščer asked the question about thermal efficiency. Peterlin asked three questions, but the candidate Moljk could not answer the third on the spectrum of beta rays. Peterlin then mentioned that this area is not exactly Moljk's favorite.

All the audience expected that Moljk failed his exam as Molk's performance was very bad. There was a longer interruption due to the meeting of the commission, and then the rapporteur dr. Ivan Vidav came to inform that candidate Moljk successfully passed the doctoral examination. Later, the students were murmuring that Moljk had a high connection, although he was not in the communist party, as everybody felt that Moljk did not pass his exam adequately. Moljk's promotion was followed in the presence of the entire examining committee only one week after the defence, while other doctoral candidates waited several months or even a year for their promotions.

Unlike Plemelj, Peterlin soon got influential opponents in his own house, as he did not have the right support at the university for the development of his institute. He joined the UDBA but not the communist party which proved to be fatal as he was nor famous enough to play Heisenberg's WW2 quiet oppositions. At the beginning of 1959, the new institute had 300 employees. In the third year, Peterlin lectured on electromagnetic field with relativity theory and optics for the seventeenth year, and for the fourth yeas students he explained quantum and nuclear theory (1943-1959). After his departure, the lecture of the electromagnetic field was taken over by Blinc.

30.1.4.7 Replacement

At the end of the year 1957 the Institute Vinča near Beograd got from Soviet Union the first two Yugoslav heterogeneous nuclear reactors working with natural or enriched uranium and heavy water. In addition to this, Kidrič's successor the minister Vukmanović-Tempo, besides the experimental reactor received from the Soviets' major target nuclear reactor designed for China, which produced annually one or even two kilos of plutonium. Tempo got the experimental reactor, which was provided for usual Soviet European satellite states, but also the bigger one made for China.[3342]

The ZKNE gathered to approve Tempo's deal and Supek was certainly heavily against it. The ZKNE met to formally confirm Tempo's purchase several years after Tempo's brother met his last hour in Slovenia as a quisling on the run.

Despite of the threats and the anger of Beograd politicians, Supek with Peterlin's help organized the meeting of IJS, Zagreb Institute Ruđer Bošković, and Institute Boris Kidrič of Vinča as three centers financed by ZKNE. At the meeting, they recommended that the government withdraw from work on the nuclear power plant, which Supek subsequently established as a conclusion fit for all non-aligned countries in Accra (Ghana). Even Savić agreed with the conclusions of the meeting in Ljubljana, which was an exceptional turning point in Savić's chairing in Vinča. In Ljubljana meeting there was also a secretary of the ZKNE who happened to be the unfinished student of technique. Of course, he did not confirm the conclusions of the meeting while after the meeting he threatened Supek with consequences. Savić's support of the results of Ljubljana meeting probably worsened his position in Vinča.

Supek later described the event in his dramatized fiction work. The Minster of defense Gošnjak secretly told Supek that even army has no interest for a Yugoslavian nuclear bomb but Kardelj wanted it. Supek and Peterlin usually planned their joint Beograd budged strategy during their journey on the train. Ivan Supek's brother Rudi was also a distinguished literati and Tito guarded their Zagreb oppositional headquarters form total damages as a secret Croatian nationalist.

The politician soon made a revenge. Peterlin, Supek, and Savić were dismissed after the disastrous accident at Vinča on October 15, 1958 with six workers injured. Peterlin, Supek and Savić's dismissal occurred after the accident in Vinča in Beograd suburb on 15 October 1958, which hit six workers just after Tito's huge

[3342] Peterlin, Fizika 1957, 11; Pravdić, 1994, 34.

celebration festival by putting Vinča reactor in operation half of a year earlier on 17. 5. 1958.

The reactor under the chief of project and leader of the group Dragoslav D. Popović (1926 Skopje-2013) had no work permit as the security was far from being adequate. Dragoslav Popović was dismissed immediately after the accident and lectured in the Electrotechnical faculty of Beograd after 1959. His main collaborators in Vinča were the engineer Nenad M. Raišić, Stevan M. Takač with diploma in engineering physics and Hranislav Marković also with diploma in engineering physics. S. Dedijer's replacement in 1954 Vojko Pavičić as the director IBK was also fired after the accident in Vinča in 1958.

Savič noted that Dragoslav Popović's inexperienced student, in their desires for quick measurements, maybe pulled out the control rods from a small learning reactor, as the student was compelled to collect data for his diploma thesis as Savić narrated, or the rods were removed most of the time anyway as Hajduković remembered.

The students worked in Vinča for three months before the disaster. The entrance was strictly controlled as the legend tells that you were forced even to give the number of your shoes to the doorkeeper, but the reactor was not controlled and even the alarm devices were disabled not to disturb the employees. During the accident the radiation was so heavy that the Geiger counters were "damped (suffocated)" and stopped to react. In Savić's version, the young postgraduate student wanted to get the experimental results as quickly as possible and pulled out the control sticks of the little school reactor, where he worked on his dissertation. The radiation was so great that the Geiger counters were overflowed, and they didn't count at all.

The student got aware of the danger only after he smelled the ozone produced at the air by radiation; he released the rods at their proper places quickly, but he already got the mortal amount of radiation. The excellent student with Matura from (Titovo) Užice Života Vranić was aware of the danger only when he smelled the ozone that was generated by radiation in the air; he dropped the rods back into the reactor and bravely stopped the reactor to prevent further damages, but he had already received too much radiation. By Hajduković's narration Roksanda Dangubić (Rosa) stopped the reaction with her hand by putting cadmium rods into the reactor as no automatic worked.

The engineers were in the meeting but soon one of them entered and ordered all folks out of the building while Hajduković told everybody in Vinča by phone about the disaster.

After their huge radiation doses, six people were immediately taken to Paris for treatment, but the student of physics Života Vranić (Žika, 1934 Mojsinje by Čačak-1958 Paris) died.

The student Roksanda Dangubić (Rosa) who few years later became a mother of healthy daughter despite her unpromising family name, the student Radojko Maksić (* 28th October 1933 Popova by Jastrepac in Serbia), Draško Grujić, Stjepo Hajduković (Stijepo) who posthumously published his accusation report Svedok događaja in Bilten Instituta za nuklearne nauke Vinča no 4/97, in 1997 against P. Savić's comment published in the Beograd based leading journal NIN no 1838 on 23. 3. 1986. They and their less radiated senior Živorad Bogojević recovered in the Parisian hands of Georges Mathé (9 July 1922 – 15 October 2010) by the first ever bone marrow transplants. The graduate works of dying Života Vranić and Radojko Maksić was noted as finished during their six months of Parisian treatment, while Roksanda Dangubić (Rosa), Draško Grujić, and Stjepo (Stjepko) Hajduković had to finish their work for diplomas with their newly advanced fellowships.

Most of the victims of the accident and even their children continued to work in nuclear physics after their recovery while Hajduković especially excelled in radiation related medical studies in Vinča Institute renamed to Boris Kidrič and in Federal bureau of measures and precious metals in Belgrade in Yugoslavia. Dr. Maksić worked under Ranković in state department of nuclear energy ZKNE for next forty decades including the elaborating of Krško nuclear power plant. Maksić survived all the others in 2015, while besides him only Roksanda Dangubić (Rosa) was still alive in 2011.

The big boss Leka Ranković personally told Nakićenović to keep strict confidence. Nakićenović told Hajduković to pass to other victims to be silent about the accident for at last next three decades. Although dr. Pavle Savić was not directly guilty, Peterlin nevertheless blamed him.

It was the first major after-war publicly acknowledged nuclear accident. The Director Dr. Pavle Savić was not directly involved at the disaster, but Peterlin eventually put forward his responsibility.[3343] Savić was former Curie's collaborator, Tito's host during Tito's visits in Paris and Tito's code-maker during WW2. Savić also published few nice cosmological books.

A month after the accident, on 21 November 1958, at 8:30, the humiliating disaster was discussed by Ranković's Federal Nuclear Energy Commission. A month later, on November 21, 1958 at 8:30 Ranković's Federal Commission for Nuclear Energy discussed the accident and the commission member Nakićenović mailed the meeting protocol to Kraigher at Ljubljana as "top secret". Nakićenović reported strictly confidential to Boris Kraigher (Janez, 1914 Sveta Trojica in Slovenske gorice; † 1967 Sremska) the dropout student of civil engineering in Ljubljana in 1932 and 1934 and now Chairman of the Executive Council of the People's Assembly of Slovenia. The leading politicians and scientists like Tempo, Savić, the minister of defense Gošnjak, Milentije Popović (1913 Crna Trava in Serbia-1971) who graduated at Beograd technical faculty and Milan Radulović were also present. In point 2, they discussed the accident at the "zero" reactor in Vinča and concluded that the workers should remain on treatment in Paris, and the Yugoslav Commission with Barbarić and Lebez should consider the consequences among their members. Savić submitted the conclusions of the meeting of the CK ZKJ Vinča, but Ranković opposed his reading, since such a small committee would not have enough power to solve the sensitive problem. Savić put at the limelight the protocol of the meeting of CK ZKJ of Vinča, but Ranković did not allow him to read it, because he thought that such a small group of the communist was unable to handle such a delicate problem. He preferred to change the subject and discussed the relations between the leading scientists and the president of the IJS scientific board (Peterlin) suggesting that Kraigher will make a full report for Federal Commission for Nuclear Energy soon. Ranković was more inclined to change the topic to the relations between leading staff and the President of the Scientific Council of the IJS, on which Kraigher will soon inform the Federal Nuclear Energy Commission.

The disaster at Vinča may have somewhat postponed Ranković's action to replace Peterlin, as it was a shameful severe blow to the ability of Yugoslav experts to build A-bomb. In any case, Ranković saw in Peterlin (and Supek) the obstacles on the way to the A-bomb and did not allow his victims to escape. The Vinča disaster postponed the dismissal of in the decade after hisPeterlin and others. Few days after the disaster in Vinča, Kraigher forced Peterlin to resign.[3344] All three directors of the nuclear institutes were replaced by obedient managers of the ZKNE, who were supposed to introduce discipline: Zagreb got Tomo Bosanac (1918 Bjelovar-2003 Zagreb), and Vinča got the engineer Vojislav Babić who headed Vinča in 1959-1961. All three directors of Nuclear Institutes were replaced by the obedient managers of ZKNE, to force the discipline. The new directors of the institutes should be engineers: in Vinča the Secretary of the Scientific Council of Serbia engineer Vojislav Babić, in Ruđer Bošković they got the engineer Tomo Bosanac, and they also agreed with the Kraigher's changes in the IJS.

Ranković proposed that the number of members of the Federal Nuclear Energy Commission should be reduced from 25 to 9 or 11, while in addition to officials two or three scientists would be more effective because of those changes: this was, of course, the exclusion of Peterlin and Supek, although Supek was installed by Tito and was not easily removed.

The collapse of the A-bomb project with huge investments slowly contributed to Ranković's fall. As President of the Scientific Council in Vinča, Savić was appointed as the President of the Council of the Institute. In reformed the federal bureaucracy, Savić no longer represented real power in Vinča, Rudjer Bošković Institute in Zagreb, or the IJS. Savić later lectured at the chair of Physical Chemistry of the Natural Science-mathematical Faculty and never put his foot at Vinča again after his second mandate as the director in Vinča.[3345] Savić continued to work at

[3343] Peterlin's letter to Kraigher, August 6, 1960 (GDP); Zupančič, 2000, 80.

[3344] Zupančič, 2007, 13.

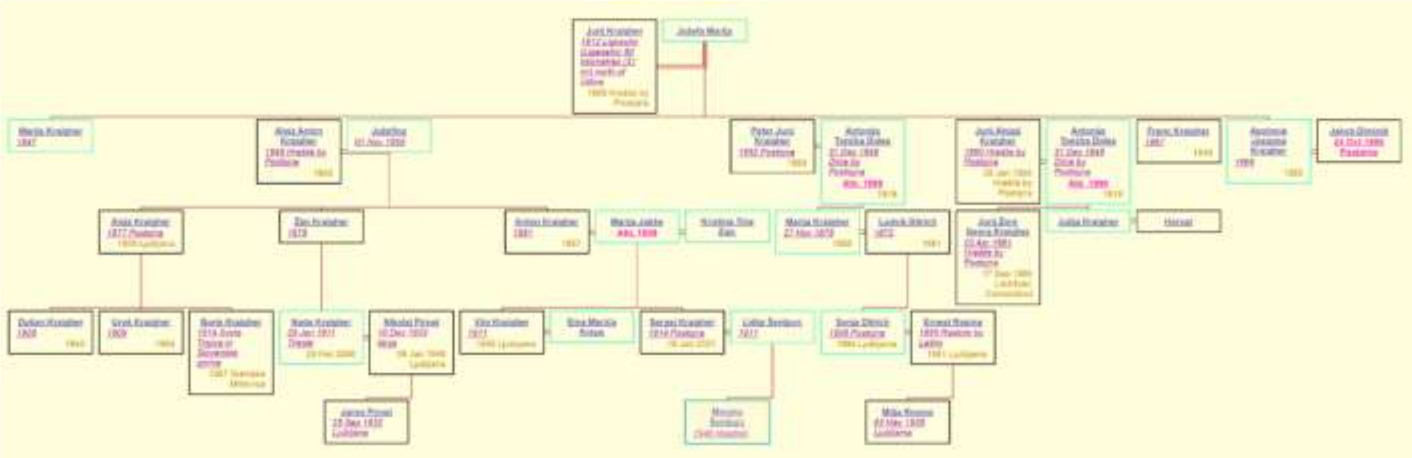

Figure 30-7: Ancestors of the IJS boss Boris Kraigher

the Department of Physical Chemistry at the Faculty of Natural Sciences and Mathematics.

In the winter of early 1959, Savić had to resign in Vinča, while Peterlin's friend Ivan Supek left the leading position at the Rudjer Bošković Institute in Zagreb, and Peterlin did the same at the IJS. Supek later returned to his position, Savić no longer headed Vinča, and Peterlin was replaced by Moljk. So, after the meeting of the IJS Council on January 8, 1959, when Kraigher was present, Peterlin was forced to confirm the resignation from his duties of the president of the Scientific Council with the date of validity 31. 12. 1958. He remained only an university professor.

Peterlin summoned a speech in which he wanted to propose Moljk to his successor. But for those circumstances, he did not have a written speech, as he noted at his draft. Moljk was not only Peterlin's successor, but, even more surprisingly, the successor to Savić as the president of the expert council of the ZKNE. He was in this position in 1967, when he published a discussion with his colleagues in Belgrade on the future work on nuclear energy, especially on reactors. Supek remained a member of ZKNE (SAKNE), since Ranković could not withdraw Supek from there without Tito's consent; there to some extent Supek succeeded in opposing the construction of a Yugoslav reactor based on the example of Chernobyl, especially with Milentije Popović, Avdo Humo and Gošnjak, who whispered to Supek during the pause of the meeting "the army has no interest in the A-bomb". Supek was also a member of the CERN Council and addressed the company "Rade Končar" that produced a large magnet for the accelerator in Geneva.

However, Ranković's ZKNE later removed Yugoslavians from CERN, certainly in fear of the Western influences. In November 1958, Peterlin was compelled to apply for dismissal, he was forced to ask for replacement. His replacement was dated December 30, 1958, and Nakićenović signed it with Ranković's approval.[3346] Nakićenović signed Peterlin's resignation with Ranković's authorization.

On 3 December 1958, Nakićenović reported to Ranković that Peterlin is currently in Belgrade at the session meeting of the Scientific Council-Board of the FNRJ, and in the next two days he will apply from Ljubljana for a specialization abroad, during which he will no longer be president of the IJS Scientific Council. Peterlin left the post of the president of the Scientific Board of IJS. Nakićenović proposed Moljk, who was active in the DMFA since 1952, and Šinkovec, who worked with the partisans only since 1943, and for the reserve Nakićenović had even more faithful Pečnikar. On November 4, 1958 Peterlin really asked ZKNE for the stipend for his work abroad. He planned to work for four months at Mathematical Institute of Munich and at the Polymer Institute of Mainz. Next, Peterlin wished to research during eight months at Wayne University in Detroit, where he had already agreed on a visit to solve the diffusion equation of the motion of polymers molecules in the laminar flow

[3346] GDP; personal note of Tanja Peterlin-Neumaier, February 2, 2007.

at the Institute of Computer Calculations. used to be at Wayne University of Detroit already at 1955. Peterlin wished to arrange his future work to solve the diffusion equitation of polymer molecule moving at laminar flow. Of course, he was particularly interested in the amount of the scholarship, indicating that in 1951 Emil Theodor Kocher (1841 Bern-1917) Institute at Medical faculty of University in Bern paid him 1200 Swiss Francs per month for a salary of a university professor, and Mirjan Gruden, a university professor, received $ 600 per month from Vinča institute for his work in the US.

Kolman Hodoščček was responsible for security at the IJS, but the political characteristics of Čopič issued on 24 January 1953 and notes on other workers were signed by the director K. Kajfež together with Tomaž Vos, who relatively illegible signed himself. Hodoščček, together with a mechanical engineer Ciril Pisanski, Moljk, Kuščer and others belonged to the new leadership of the IJS, photographed in 1959 in a group including Ranković. Pisanski worked at the IJS, and immediately assumed the leadership position between 1959 and 1969. He graduated in 1953 with the work "To create an additional mechanism for sharpening the pointed arrows with a universal cutter grinding machine for Reinecker type URF 7a gear wheels, the maximum diameter of the gearing 3000 mm" on 52 pages. He occasionally wrote about the mechanical problems of teethed machines for another half a decade. At the IJS, he focused entirely on researching reactors and received his doctorate in 1963 with the dissertation Structural and technological problems related to the safety of the Magnox nuclear power plants on 30 pages. As a member of the elite, he was also an important hunting association official and a court special engineer which helped a lot the whereabouts of his son Tomaž Pisanski.

In the new Scientific Council after Peterlin's removal, the physicists were Kladnik, Kuščer and Č. Zupančič, and among the outer members, the captain of the battleship Stevo Žutić. The members appointed to the Management Board were among others Č. Zupančič, Osredkar, Kosta, Kuščer, Moljk, Pečnikar, Lebez, dr. Janez Milčinski as the forensic medicine expert, and head of the semiconductors laboratory at the Institute for electro-connections the engineer Matija Seliger (21. 1. 1925 Vrhnika). Seliger participated in the NOV since 1942, and he became a member of the KPJ in 1944. However, he was expelled because of the failure at battlefield action. In 1953 he graduated and was trained abroad. He was again accepted in the ZKJ in 1955. Matija Seliger was a father of the physicist Janez Seliger (* 1949).

In the decade after his dismissal, in journal Proteus Peterlin reported on genetics of Zalokar who found space in the USA instead of his natural Slovenian home which Peterlin regretted as his own destiny. Zalokar got his Ph.D. in Laboratoire de zoologie et anatomie comparée with a thesis Contribution à l'étude de la régénération du cristallin chez le triton printed in Geneva in the middle of the war in 1944. Marko Zalokar (July 14, 1918 Ljubljana-September 4, 2012 Seattle, WA.) published several articles under Peterlin's editorship in Proteus from 1936 to 1947. Zalokar and brothers Ivan Kuščer and Dušan Kuščer (1920-2012) researched undersea flora and fauna in Rača 75 km southeast of Rijeka south of Senj south of Sveti Juraj (Jurjevo) under Velebit which Peterlin praised. Peterlin was never fully aware that Ivan Kuščer was Peterlin's chief antagonist in Ljubljana as both loved to write in their good Slovenian language, both loved the mountaineering and admired all sorts of natural phenomena. Therefore, Peterlin always considered Moljk as his devil destiny.

Zalokar's first love was the botany but in USA he turned to genetics which later produced CRISPR/Cas genome editing in 2012 and enabled the myriads of Chinese human genes editing in 2018. After WW2 Hadži invited Zalokar to Ljubljana university, but Zalokar declined from personal reasons certainly involved in politics.

Zalokar worked at Department of Zoology, University of Washington, Seattle, Washington USA in 1953-1955, and at National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Bethesda, Maryland, USA in 1955, where later R. Podgornik researched.

In 1959, Zalokar worked in for Yale University at New Haven, Connecticut. In 1968-1969 he was in Pasadena in California, and in 1976-1984 in Centre de Génétique Moléculaire de C.N.R.S., 91190 Gif sur Yvette, France, in 1984 also in Station zoologique of Université P. et M. Curie, Paris VI.

Peterlin praised the penetrating Kidrič, as well as Osredkar and Stephenson, who was supposed to recalculate the operation of the Oak Ridge reactor. Peterlin especially emphasized the "poorly grounded Yugoslav speculation for the A-bomb" that wasted a fortune and even more for fantastic nuclear technology and mining. He did not specifically mention Ranković, but Peterlin sarcastically explained that with the escape of Slovenian brains in the United States, where the folks soon forget Slovenian language, there is nothing new in domestic fields. "The hungry crow is feeding the satiated one".

Although Pavle Savić was not directly guilty,[3347] he was accused as the president of the scientific council in Vinča, because the post of president of the institute's council after the reforms was no longer a real power in Vinča, at the Rudjer Bošković Institute in Zagreb or at the IJS. In 1959 Savić had to resign, while at the same time Peterlin's friend Ivan Supek at the Rudjer Bošković Institute in Zagreb, and Peterlin at the IJS also resigned. However, Peterlin's friend Supek and his opponent Savić soon returned to their posts, while Peterlin was only a university professor after 8 January 1959.

Unaware of those deep Slovenian mishmashes, Stephenson visited Ljubljana at least twice including his visits to the IJS. On July 31, 1971, Moljk denied the allegations published by Peterlin in the previous issues of the same newspaper on July 17, 1971 of the journal Delo in Sobotna Priloga as part of a series of interviews of the poet-journalist Dušan Željeznov (1927 Ljubljana-1995) with the creators of the Yugoslav atomic era at the dawn of the Croatian Maspok. At the same time, Moljk complained that someone (Peterlin) had crossed out Moljk's name with a shower from the preface to Peterlin's book of radioactivity. Moljk stated that in June 1958 Kraigher, as President of the Executive Council of Slovenia and an official (Chairman of the Board of Directors), called Moljk at the IJS and told him that a five-member delegation from the IJS visited him and asked Kraigher to replace the management of Peterlin. The delegation or commission was established at the end of 1957, but its composition under the leadership of Osredkar was changing. Moljk claimed that he did not know the names of all five, although he knew them all too well from other sources. Since the fall of 1953 with smaller intervals, Moljk has been measuring beta spectroscopy at the Physics Institute of Glasgow University and returned to the Yugoslavia during the holidays in 1958. In December 1958, Kraigher called Moljk again and told him that, in view of Peterlin's request, Moljk would have to replace Peterlin, but Molk must provide Peterlin with smooth work with the macromolecules at the IJS. Moljk hesitated about his new functions in the IJS, as he wanted to continue his measurements in Glasgow, and he was also preparing a book on the measurement of low radioactivity entitled The Low Radioactivity Measurements for the London Butterworths publishing house, for which the University had already given him a summer vacation in 1959. On 15. 12. 1958, Moljk indeed wrote to Kraigher that he had too much work at the university, while Kuščer just sent out the first part of their joint textbook, and Moljk was preparing two more papers about his measurements in Glasgow. Moljk considered that the new president of the Scientific Council of the IJS would have a better position if he had not been in the same game with Peterlin before, as was the case with Šinkovec.

On 10 February 1959, based on his talk with the new IJS director Šinkovec, Peterlin proposed his part-time job in measuring nuclear magnetic resonance on organic crystals in IJS. The work should cover the temperature effects and different radiation effects on NMR spectra of those substances. At his typescript Peterlin stated that he could describe the details later, his work can be further explained. After January 1, 1959 he should work eighteen hours per week, that is, three hours per day.

Under Peterlin's writing the other hand, probably Šinkovec's, wrote: »Demand the details, data: How many people« Peterlin didn't request any extra budget for that year.[3348] There it turned out that Peterlin intended to employ Blinc, Adrijan Levstik (* 1939 Brežice), Krašovec, the lady Marjana Oblak, Marinković and Peter Venturini in his working group. As for the funds, Peterlin considered that "this year he needs no money" because he did not plan too buy new tools. He allocated his works at the rooms 117 and 110 at the IJS. On March 5, 1959, Peterlin signed the contract

[3347] Peterlin, letter to Kraigher signed on 6. 8. 1960, appendix, page 4a (GDP).

[3348] Peterlin's personal map, Archive IJS at Podgorica.

with IJS for his work with NMR of organic crystals for the analysis of spectrum dependency on temperature and nuclear radiations. The plan was not put into action as Peterlin slowly decided to move abroad.[3349]

Dr. Franc Krašovec worked at the IJS between 1953 and 1968, then worked with LEK of Sandoz corporation. Igor Levstek published an article in 1960 with Peterlin. In 1960 and 1961, he published NMR research with Blinc. Apparently, Peterlin had enough young people willing to explore the NMR, but his star at the IJS was orbiting into Moljk's shadow. Blinc was eventually to clever and well informed to put his scientific destiny on Peterlin's disposal in Ljubljana in those times of Peterlin's disgrace.

Peterlin went abroad after the 5th of March 1959, when he concluded a one-year contract for the honorary research of organic crystals with nuclear magnetic resonance with the new director of the IJS, Lucijan Šinkovec. On 20 March 1959 Peterlin's proposal was adopted by the Vice-Dean of the Ljubljana Faculty of Natural Sciences Dušan Hadži, based on a meeting of the Management Board on 11 March 1959, permitting Peterlin's part-time employment at the IJS with a basic salary of 59,800 dinars, in addition to 29,800 dinars paid for his position of full professor and the adds of the Institute 6,200 dinars per month. On 5 March 1959, Peterlin signed a one-year contract with the new director of the IJS Lucijan Šinkovec for the honorary research of organic crystals with nuclear magnetic resonance. The Inner Carniolan engineer Lucijan Šinkovec from the poor official family was forced to earn his bread during his secondary and high schooling by his additional teaching classmates and drawing. His father Jože was killed in the First World War, while the parents of his mother of Frančiška Mayer lived in Hungary. In this sense, there were suspicious Šinkovec's statements about Cominform (Informbiro) quarrels of 1948, which would be uninteresting for average job, but not for a position of director, as a Škofja Loka resident Stane Bernik from the People's Committee of Kranj wrote in Šinkovec's characteristic for the IS of Slovenia.

In 1935, Šinkovec graduated from the Faculty of Electrical Engineering in Ljubljana, and in 1935/36 he served as a military officer at the Reserve Officers' College in Sarajevo. From 1936 to 1945 he worked in Zagreb as a Siemens representative. In 1937, he was sent to a five-month specialization in Berlin, therefore in Nazi headquarters. In April 1941 Šinkovec was captured as a soldier at Zenica and Šinkovec was detained to the camp in Osnabrück until 1942. He did not participate in the NOV and only decided to enter the ZK after the war. On 13 November 1945, he was admitted to the ZKJ based on his merits in protecting his company's assets against German confiscations during the war. Between 1945 and 1946, Šinkovec was the representative of Rade Končar in Zagreb. In 1946/47 Šinkovec was a delegate at the Yugoslav military delegation in Budapest (Jugoslovenska vojna delegacija u Budimpešti). In 1947 and 1948 he was Director of the Iskra Telecommunications Industry in Kranj, which was too low for him. In 1949 he was the Chief Director of the Federal Department of Electrical Engineering, where folks unsuccessfully proposed to exclude Šinkovec from the ZKJ for financial irregularities in October 1949. According to Croatian sources, Šinkovec was a typical representative of the old Siemens clique as the CEO of the Federal Directorate of Electrical Industry. Šinkovec even offensively offended the republican delegations, such as the Slovenian ones. In Iskra, they remembered Šinkovec as a good organizer, but among workers Šinkovec was rated as autocrat. He traveled abroad with Dr. Milan Lilek from Silvo Hrast's Iskra, which Bernik did not consider good for Šinkovec.

After the collapse of the Ljubljana (Yugoslav) nuclear project, Lucijan Šinkovec's (* 2. 6. 1914 Laze by Logatec; † 1966 Ethiopia) resigned from IJS on 15. 5. 1963 and went to similar work in Africa, but there he was hit by a car in Ethiopia in 1966.

On March 5, 1959 Peterlin concluded a contract with the IJS to work on NMR organic crystals by studying the dependence of spectra on temperature and nuclear radiation. He should not be paid during the planned collective leave and during Peterlin's stay abroad so Peterlin probably did not get much money at all. The anticipated receipts were even considerably lower than those designed by Hadži's command a few days later. Šinkovec offered only a basic salary of 34,800 dinars, a positional salary of 15,000 dinars and a special institute allowance of slightly over 8,000 dinars per month. Since

[3349] Peterlin, 1981, autobiography.

Peterlin was supposed to be at the IJS only three hours out of the obliged seven working hours a day during the six working days of the week when the Saturday was still a working day, only 3/7 of these amounts belonged to him, that is, 14,900 dinars, 6,400 dinars and 3,400 dinars respectably.

The realization did not happen, because after some Moljk's direct scandalous shouting, for which Peterlin appealed in writing to the director of Šinkovec, Peterlin slowly decided to work abroad. According to Peterlin, Kraigher have removed him to some extent even against Ranković's instructions. The cards were later turned back; B. Kraigher harshly criticized Ranković at the 4th plenary session of Brioni on 1st July 1966, after Maček criticized Ranković's attacks against Kardelj who cooperated with Soviet pre-war agents including Kardelj, Josip Kopinič (1911 Radoviči by Metlika-1997 Ljubljana), Vladimir Bakarić and the prime minister Petar Stambolić (1912-2007). They arranged the wiretapping affair against Ranković, comparable to Obama wiretapping of Trump in 2016. Kraigher was still angry because Ranković opposed Kraigher's deadly Dachau processes in 1945. Stane Kavčič was even worser in Brioni as everybody knew that Stane used to be in love with future Ranković's Slovenian wife earlier during the WW2, just like the Montenegrin UDBA general Jovo Kapičić (Kapa, 1919 Gaeta-2013 Beograd) used to love Tito's unmarried wife Davorjanka Paunović.

Ranković's most acute political error was that he began to wear the same type of bright hat as Tito! With that hat affair, everybody knew that Ranković looked forward for Tito's heritage while Jovanka and Kardelj nursed the same ambitions.

After the dismissal from the post of President of the Scientific Council of the IJS, Peterlin went abroad despite the contract with IJS. He first visited Stuart at the Institute of Physical Chemistry at the University of Mainz. On 9 March 1959, he left Ljubljana and researched the thermodynamic stability of individual polymer crystals with Stuart's assistant Erhard Wolfgang Fischer (* 16. 2. 1929 Wiederau south of Leipzig; † 2011). By the NMR they investigated the crystals of polyethylene, which Peterlin was already researched to in Ljubljana. In 1957 in Mainz independently from Hungarian Jewish immigrant Bristol PhD student Andrew Keller in the UK, and P.H. Till of Research Division, Polychemicals Department, E. I. du Pont de Nemours & Company, Wilmington, Delaware in USA, Fischer discovered that crystals of polyethylene contained folded (wrinkled) molecular chains. The discovery has completely changed the situation and has become the new major branch of polymer physics. Just before the WW2 Gilbert Newton Lewis's PhD student-discoverer of hydrogen bounding Maurice Loyal Huggins (1897 Berkeley-1981 California) was the first to adequately determine the viscosity of large molecules, the existence of which some scientists rejected. Some scientists still doubted even their existence.[3350] With the professor Günter Victor Schulz (1905 Łódź-1999), head of the Institute of Physical Chemistry at the University of Mainz, Peterlin completed his paper Determining the size of molecules from rheological measurements (Calculations of the molecular length from rheology data) on July 13, 1959. There he devoted special attention to the additional problems caused by the molecular diversification and branching.[3351] He reported on similar research in Basel at the Second International Expert Meeting on Laboratory Technique, Measurement Technique and Automation in Chemistry from 15 to 20 October 1962.[3352]

Between 1955-1957, Peterlin was serving as president of the board of directors and the president of the council at the IJS before Kajfež replaced him in the position of director. While serving as president of the board of directors, Peterlin was also the president of the council at the IJS. In 1957, he was replaced by Boris Kraigher as chairman of the board of directors and in 1958the post was taken over by the Republican Secretary for Industry and Craft the engineer of metallurgy Viktor Kotnik (* 1910 Zgornji Jakobski Dol; † 1991 Ljubljana) who vetoed the erasing of J. Stefan's name of the Institute on 12 June 1959. Thus, Kraigher was delegated by politicians to regulate relations with the IJS; he could not keep Peterlin from fall, and Kraigher was "no fan of Peterlin".[3353] On 13 December 1959, Peterlin wrote to Kraigher from Cambridge University in Boston and thanked him for helping to obtain the ZKNE scholarship. Peterlin "perfectly anchored" in

Cambridge, although he must "because of some partial calculation depart for Philadelphia." Of course, he told Kraigher that he wanted to stay abroad for a year longer, where everybody is trying to make his work as smooth as possible, while at home Moljk "tries to make my life as hard and unbearable as possible, to dismiss my secretary (sister Marja Lapajne), to destroy the group which I led, and prevent us from perfecting our device. For a year now, it lies a laminated magnet wrapped in a paper that cost only $ 10,000 and was ordered in my time, without the hope that it would ever be used for scientific research for which it was purchased because they refuse to buy additional parts, because it would be used by me and the people who have cooperated with me so far. An institute analogue calculator is offered to other folks in Ljubljana; unfortunately, there are no interested parties outside of the institute to prove that the idea with it was one of my nonsense, so Kuščer uses that computer at his classroom ..."

Peterlin figured that his successors did not prove their capabilities in six months of their IJS leadership as they wasted the efforts of past ten years of their complaints against Peterlin mailed to the Beograd government.

Peterlin announced to Kraigher his departure to Detroit in March 1960; there he calculated a diffusion problem with his results from Mainz on a powerful computer. He gave Kraigher plenty of technical detail, which Kraigher could not understand. To some extent, Peterlin tried to justify his state scholarship with these details, but on the other hand he showed his strength with knowledge.

After six months spent in Mainz, Peterlin was in Ljubljana since June 1959. On 11 September 1959, the University of Ljubljana granted Peterlin an extended leave for eight months. During a visit to Harvard in Boston (December 1959-March 1960), Peterlin received a tempting invitation to run the Physics Institute of the University of Munich. While working at Wayne State University in Detroit from March to June 1960, Peterlin received a professor's degree at a local university. He could not decide for a long time about living Slovenia. The decision fell only on July 19, 1960 after the arrival of his wife and son in Villach:[3354] on September 1, 1960, he took over the leadership of the Physics Institute of the Technical University of Munich until 1961.

Boris Kraigher informed Peterlin that the problems on the IJS continue under the new leadership. Kraigher suffered from Ranković's criticism of Kraigher's firing Peterlin. Therefore, Kraigher wished to arrange Peterlin's personal visit to which the newspapers would report; so, he would conceal from the public that Peterlin immediately got a higher position in Munich after being forced out of Ljubljana. The insane people of Ljubljana were, of course, crying out that German physics was no longer what it was, with the Bavarian Munich included. Such newspaper report indeed appeared.

On 26 November 1959, Peterlin wrote the last of his papers at the IJS where with his colleagues he published his first NMR study. According to Stuart's (1958) measurements of rubber full of doubts in the crystallinity of polymeric solids,[3355] Peterlin and co-authors for their measured material selected polyethylene and proved irreversible crystallization. Peterlin used NMR to research the re-crystallization of polyethylene.[3356] It was discussed in Pirkmajer's graduation thesis at a time when Peterlin was already in Munich. The chemist Marinković prepared monocrystalline samples, dr. Blinc did the math, and Miss M. Pregelj took over the measurements.

In the spring of 1961, Kraigher invited Vidav, Kuščer and Dominko to his office, and ordered them to try to attract Peterlin back to Slovenia. Dominko visited Peterlin in Munich in April 1961. Dominko tried to persuade him to return to Slovenia. Fourteen-year-old Boris Matija Peterlin loaned his room to Dominko during his visit, while Boris Matija Peterlin himself slept with his old mother. Since Dominko could not offer him anything tangible, Peterlin preferred to stay abroad, although, according to Osredkar, he could never get used to the emigration completely. He just dreamed Slovenian Alps and Moljk's revenge.[3357]

In 1961, Peterlin went to the US and continued with successful research and organization there. In

the meantime, he particularly enjoyed lecturing in Slovenia, especially at the IJS, but only after the new Director Osredkar renewed contact with him in 1963. Peterlin particularly enjoyed lectures in Slovenia, especially at the IJS after Moljk's departure in 1963. Osredkar as the new director of the IJS introduced an efficient order again. Peterlin’s lectures in IJS were well attended until once Peterlin had to live the auditorium in hurry with the scaring whisper “Ah my God”.

The Americans, of course, hurried to put Peterlin on the leading position of the new institute in North Carolina because they knew all about Peterlin's successes in the organization of the IJS. The Americans, of course, were eager to take Peterlin to the leading position of the new institute in North Carolina. As director of lab at Camille Dreyfus in Durham, North Carolina. Peterlin studied macromolecules of plastic in a situation that could only be dreamed about at home.

In 1961-1973 in North Carolina, he studied macromolecules with the help of chemist developer of polymer synthesizers Anton E. Schindler (* 1921) of Research Triangle Park Institute in North Carolina, head of the research laboratory of Celanese Corporation of America, New York Robert Thexton Armstrong (1909-1992) and other physicists who worked mostly in the laboratory for a year or two. The Laboratory was founded a few years after the death of pioneers of artificial fibers, chemicals and plastics, the Dreyfus brothers. Dreyfus succeeded in synthesizing acetate fibers so that they could be set up by Celanese Corporation.

After compulsory retirement at the age of 65, he worked at the National Standards Bureau (NBS)~~,in~~ in Washington DC between 1973 and 1984, after 1975 as Assistant Director of the Polymers Department. In Slovenia, he collaborated primarily with Robert Blinc’s group focused on NMR. After the second retirement, Peterlin studied in his office at the NBS until his second hip fracture in December 1991. In mid-September 1978, the American Chemical Society published Peterlin’s biography with a report on his scientific work in a special book. Peterlin delivered the copy to SASA and thanked the president Milčinski for his birthday cards.[3358]

Until then, in the lobby of the NBS, in those times called NIST in Washington DC (Gaithersburg), they hung a large oil portrait of Peterlin, which was brought elsewhere after 1991. Peterlin was certainly successful boss, but not the beloved one. After compulsory retirement at the age of 65, Peterlin’s great several meters high oil picture in Camille Dreyfus in Durham was immediately removed as his high profiled autocratic leadership was never extremely popular among his collaborators as Podgornik noticed.

30.1.4.8 Pedagogical and Populatisation Efforts

In 1955, after Gosar’s graduate thesis, Peterlin used the nuclear magnetic resonance which later became the main tool of Peterlin’s student Blinc. Many Peterlin’s graduates, even those who did not accomplish doctorates later excelled in physics. In 1962, Milavc and Bezić published a discussion on the total absorption of gamma rays together with D. Jamnik, Kernel and others. In 1975, at the first symposium on applied physics in Škofja Loka Milavc, Marjan Hribar, Moljk, Jože Trontelj’s and others presented work and results of physicists in Slovenia.

As a professor, Peterlin had a special tactic of questioning. He jumped with his questions from field to field until he thought he had found a candidate's weak point. There he stopped and tried to drill as deeply as possible. This approach enabled Črt Zupančič to take advantage as Črt deliberately pretended to be unsure in the topics he prepared the best for his exam. Črt Zupančič had some previous acquaintance with those funny kinds of questioning as Črt Zupančič’s Grammar School teacher of Latin languages Rudolf Južnič also used to post very quick questions in his class while jumping from one student to another which forced everybody to be prepared for each lesson. Later, Črt Zupančič confessed to Peterlin about his misbehaviour on exam, but Peterlin’s was then already Črt Zupančič’s colleague; so, he was not very upset at all.

[3358] Peterlin's typescript letter addressed to J. Milčinski on 30. 9. 1978 on quarter of page of A4 format (Archive SAZU, courtesy of Drago Samec).

Peterlin has published over 350 papers. After the initial interest in scattering X-ray light in liquids, he described the plastic deformation of crystalline polymers and transport properties, thermodynamics, crystallization, morphology, nuclear and electron magnetic resonance in polymeric solids. In between, as the IJS director Peterlin introduced nuclear physics in Slovenia.

After the WW2, Peterlin also edited the Proteus magazine for two years. Peterlin later edited Macromolecular Reviews and co-edited many other magazines. In Proteus Peterlin relatively sharply criticized the article of Beograd meteorologist Fran's son Marijan Čadež, although in 1942 Marijan Čadež with the dissertation of the influence of turbulence on the formation and development of inversions and on the development of zero-degree isotherms received his doctorate at the class of Anton Melik, Oscar Reya and then assistant professor Peterlin.[3359]. The leading Beograd meteorologist Marijan Čadež formally led the meteorological studies in Ljubljana in 1961 and 1962 which was far from Peterlin's wishes.

In 1968, Peterlin became an honorary member of the IJS, in 1983 he received the Kidrič Prize for Lifetime Work, and in 1988 he was awarded the Honorary Doctorate at the University of Ljubljana. In 1988 at Osredkar's initiative a statue of Peterlin was placed in front of the Jožef Stefan Institute just a few months before Peterlin's eightieth birthday. In 1992, Peterlin returned to Ljubljana as a retired person, but died after a few months. On the 50th anniversary of the IJS, Osredkar and colleagues published a monograph on the IJS, which was largely devoted to praiseworthy memories about Peterlin.

30.1.4.9 Thin Films at IJS in the Shadow of Nuclear Physics

30.1.4.9.1 *Introduction*

The research of thin films on the IJS developed within the Yugoslav nuclear program. Ranković's efforts for a Yugoslav atomic bomb lasted for two decades (1947-1966). The interior Minister Ranković as vice president of the ZIS (1955) and vice-president of the state (1963-1966) as the second man in the country searched for Yugoslav nuclear raw materials, educated personnel and to prepare reactors. Even though the main center of Savić's Vinča was in Belgrade, they spent a large part of the funds for the IJS under Peterlin's and later under Čopič's and Osredkar's leadership. Peterlin was hoping for the American Oppenheimer's role to develop the Ljubljana Physics Institute in the shadow of the bomb. The new materials and accelerators were closest to Peterlin. From the rich table of nuclear research, income was also pouring out for the various directions of research at the Physics Institute. According to the original Peterlin's scheme, which has been preserved in many versions up to date, Peterlin primarily advanced various forms of research of (solid) matter: on the one hand, Marinković's laboratory for analyzing materials with X-ray and electron microscope of Carl Zeiss acquired in October 1954 and, on the other side the rapidly evolving Dekleva and Cilenšek's mass spectroscopy with accelerators.

30.1.4.9.2 *Investigation of Matter in the Shadow of Atomic Mushroom*

Velibor Marinković, together with Ljubo Knop, produced heavy water with electrolysis and thermo-diffusion until autumn 1956. It turned out that efforts of this kind were merely a waste of time and money, as imports of nuclear raw materials and reactor technology were already released during Peterlin's roaming in the US before the First International Conference on the Peaceful Uses of Nuclear Energy in Geneva on 8. 8.-20. 8. 1955, attended by Kosta and Dekleva from the IJS. The countries without adequate technical possibilities for their own production of nuclear raw materials, especially enriched uranium and heavy water, have since been able to get them on the free market, and indeed even with American gifts. According to Peterlin's report at the first session of the IJS Committee under Kraigher's leadership, this situation changed,[3360] which probably also undermined the service of Czech Zagreb's Havliček at the IJS. Peterlin began sending people to trainings in the US.

On 9 October 1956, Peterlin wrote to Nakićenović about Knop's proposal for the gradual abandonment of the heavy water department, which only became a financial burden since importation became possible. Savić agreed with the proposal, although he was often unsupportive to Peterlin's ideas. Since then, Marinković has been able to devote entirely to the study of substances and surfaces. In 1956, he examined ten domestic and three foreign PVC samples. Molecular masses of polymers were determined, and for the new ones they used better preparatory procedures for carbon filling and plastic impressions with polyester in a vacuum. Alenka Dekleva studied erythrocytes forher investigation of virus cultures; she researched with Marinković between 1954-1960, and then, due to the ever more difficult acquisition of funds for the study of macromolecules after Peterlin's departure, she took over the professorship at the Faculty of Medicine in Ljubljana. They also offered their electron microscope for external users, since they were almost free of competitors until the spring of 1955, Aleš Strojnik assembled an electron microscope with 50 kV and a resolution of 5-2.5 nm at the Faculty of Electrical Engineering at the Technical College in Ljubljana. In 1956, Marinković's group examined a sample from the lake through anelectron microscope for the Geological Institute, while eighty zinc oxide samples were collected for Cinkarna Celje. In 1957 Boris Navinšek joined Marinković's laboratory for electron microscopy. Marinković's group also studied the scattering of X-rays on crystals in the form of dust according to Debye's (1916) method, which Peterlin knew well from the time of his Berlin studies.

30.1.4.9.3 Accelerators and Thin Films in the Shadow of the (Yugo)Slovenian A-bomb

Excellent experts in electronics and vacuumists were the foundation of Peterlin's Institute, among them Dekleva and Cilenšek, who in the Slovenian context became the true heir to the American Nobel laureate Lawrence, his assistants Livingston and Van de Graaff. On 2 January 1950 and on 3 October 1950, Peterlin exceptionally wrote his manuscript and did not typewrite a report to minister Boris Kidrič[3361] about the construction of the largest neutron generator. He reported on basic measurements of nuclear sections for

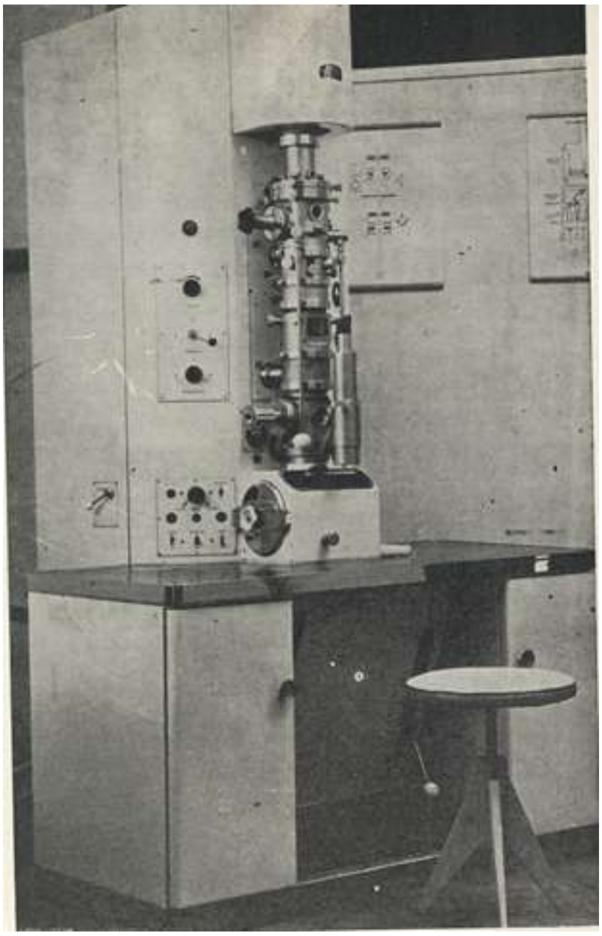

Figure 30-8: Electron microscope in Marinković's Laboratory IJS

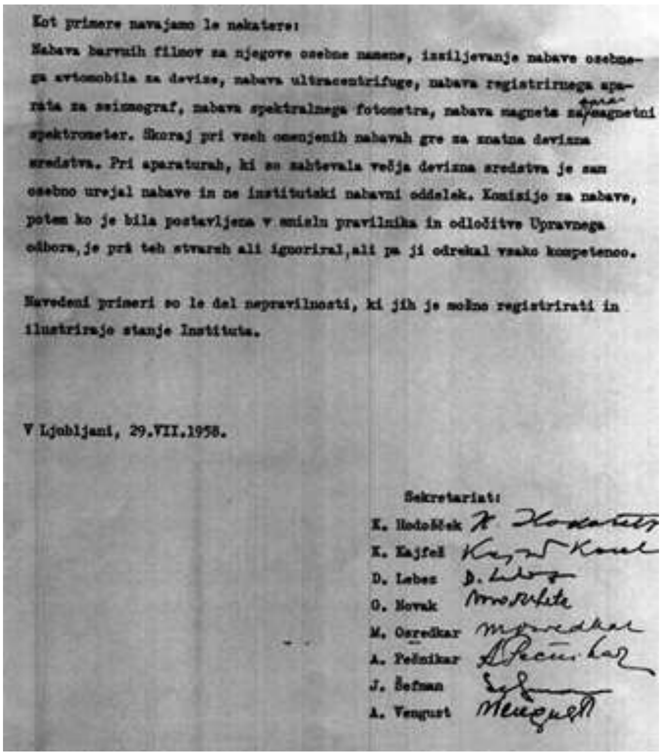
uranium copper planning. In another letter he said that he did not want to buy a 1 MeV generator. He planned the purchase of an electrostatic Van de Graaff generator for $ 200,000. It was first designed in 1931 as an improvement of the electrophorus electrostatic generator with the idea of a transformer to increase the tension by the old Guericke's ideas promoted in 1671. The charging of the electrostatic generator with a conveyor belt was first described by Righi in Bologna in 1890. He rearranged an older W. Thomson idea of a generator on charged drops of water. On 27 November 1954, at the IJS, in the laboratory of Edvard Cilenšek "for the construction and maintenance of accelerators", the electric part of Van de Graaff generator of domestic production began to be used after long-term design, construction, assembly and testing of individual parts in 1953-1957. IJS Van de Graaff of a closed type under pressure of 10 bar of nitrogen could direct elementary particles to the target in the range between 200 kV and 2.3 MV. A high vacuum in the acceleration cathode ray tube was used with a diffusion pump with a pumping speed of 500 l/s. In

[3361] ARS, SI_AS 1961, box 1, map 1.

May 1956, their beam was accelerated for the first time through a tube with a voltage of 2 MV at a pressure of 8 bar. After Peterlin's departure, in March 1961, an accelerator of 1.8 MeV was completed.



Kot primere navajamo le nekatere:

Nabava barvnih filmov za njegove osebne namene, izsiljevanje nabave osebnega avtomobila za devize, nabava ultracentrifuge, nabava registrirnega aparata za seizmograf, nabava spektralnega fotometra, nabava magneta za magnetni spektrometer. Skoraj pri vseh omenjenih nabavah gre za znatna devizna sredstva. Pri aparaturah, ki so zahtevala večja devizna sredstva je sam osebno urejal nabave in ne institutski nabavni oddelek. Komisijo za nabave, potem ko je bila postavljena v smislu pravilnika in odločitve Upravnega odbora, je pri teh stvareh ali ignoriral, ali pa ji odrekal vsako kompetenco.

Navedeni primeri so le del nepravilnosti, ki jih je možno registrirati in ilustrirajo stanje Instituta.

V Ljubljani, 29.VII.1958.

Figure 30-9: "Analysis of the Secretariat of the OCC ZKJ on the situation at the Institute" reported to Boris Kraigher in the middle of the summer heat on 29. 7.1958 (ARS, Government of the Republic of Slovenia, 1945-1992, AS 223, box 701 (thanks to Aleš Gabrič for help)).

Due to the interest of the head of the spectroscopic laboratory Dekleva for the microtron, Peterlin invited two engineers who built their own microtron. It was intended for research in medicine instead of betatron, although its use was questionable due to the low energy. The engineers completed a month of their training in Sweden, and the microtron was to be displayed at the Economic Exhibition Center at the exhibition of electronics as a great device in 1957. Although this was not the case, and the Scientific Council decided that the IJS would not attend the exhibitions.

Of course, the microtron produced much less noise and was therefore more suitable for public exhibitions than the Van de Graaff accelerator, which caused a rather unpleasant noise by sparking. One engineer was Požar, the other was Alojz Paulin, who started working in J. Dekleva's laboratory in October 1955, and in 1948/49 became Peterlin's student demonstrator at the Physics Institute. Paulin was assisted by student of mechanic engineering Mihael Svetlin and Franc Požar, who worked at the IJS between 1956-1963 to finish his master's degree work entitled Interaction between electron beam and electromagnetic fields in resonators in 1962, and then went to the Netherlands. Paulin worked for two and a half years on a 3-cm microcontroller micro-throne with a tolerance of 1: 10^8 until he was banned from further research and had to obtain a special permission to test the device in the afternoon in his spare time. The problem was particularly interesting to Paulin, although he had some problems with his own slow blood clotting because of poor radiation control in IJS. After seven years of service, Paulin went to develop accelerators together with Požar for Desy (Deutsches Elektronen-Synchrotron) in Hamburg in 1962/63, and then went to Debye's former student Paul Scherrer's (1890-1969 Zurich) Institute in Zurich. Požar remained abroad while Paulin returned and then lectured at FERI in Maribor.[3362]

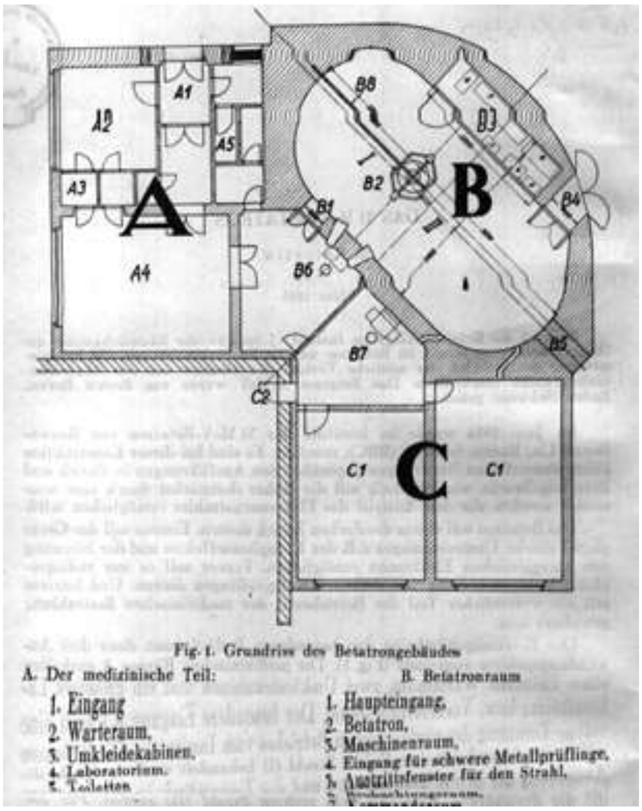

Figure 30-10: Betatron at the IJS (Peterlin, 1955. Das 31 MeV Betatron, 34)

[3362] Dekleva, 2000, 203; Alojz Paulin, personal message on 6. 2. 2007.

Besides the increasingly outdated Van de Graaff, the betatron and the neutron generator, Peterlin and Dekleva were also interested in other American accelerators. In 1952, Livingston together with Ernest D. Courant and independently of the two years older efforts, published the idea of strong focusing as the basis for the work of all subsequent powerful accelerators. After the first model made of glass, Lawrence, with the help of his student Livingston, assembled a second cyclotron from the metal. With a 2000 V voltage, it could accelerate hydrogen ions to 80 keV energies. Livingston proved in his doctoral thesis the utility of the principle of cyclotron resonance on 14. 4. 1931.[3363] Lawrence and Livingston were the first to accelerate protons over 1 MeV; but they did not break the nucleus of the atom before Cockcroft and Walton success in the British Cavendish Laboratory.

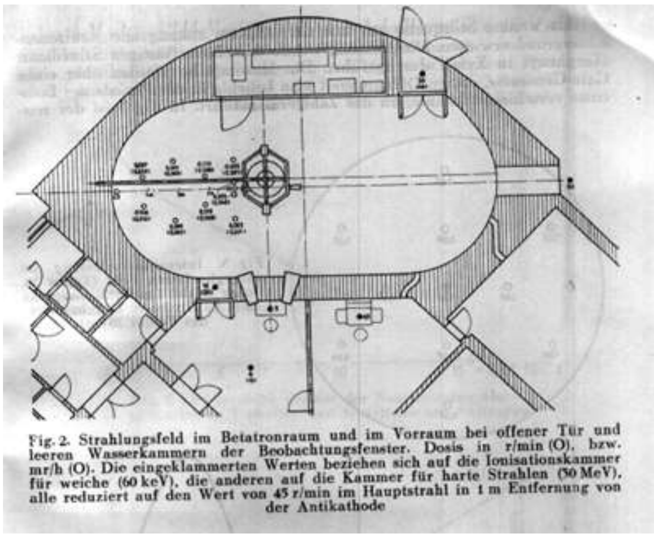

Figure 30-11: The drawing of the machine space of betatron at IJS (Peterlin, 1955. Das 31 MeV Betatron, 35)

Upon his eight-month visit to the United States, Peterlin was well acquainted with the situation in the following year. Lawrence passed away and the upcoming Livingston star. Peterlin decided to send one of his major colleagues, Dekleva, to Livingston's lab. On 20 October 1957, Kajfež wrote to Dekleva in the US that his wife Nina must have already told him how the IJS had granted him a year of unpaid leave in the United States, where she would join him. However, Kajfež asked Dekleva to send the promised reports to the IJS. Upon the fall of Peterlin, Dekleva returned to the IJS, and then again returned to M.S. Livingston's USA. In December 1959 he was again in the IJS. As the head of the previous Cilenšek's Accelerator and Electrophysical Department, Dekleva trained the Van de Graaff accelerator guys for the work in nuclear physics. His associate engineer Anton Brinšek maintained the betatron, and two pulsed neutron generators were assembled for reactor physics in 1961. A magnetic mass spectrometer for the chemical department and omegathrone mass spectrometer have also been constructed as useful tool for detecting vacuum leakage up to $1.33 \cdot 10^{-9}$ mbar $\cdot$ s^{-1}.[3364]

In the summer of 1959, Livingston, as director of the 6 GeV accelerator in Cambridge which was used by the researchers of Harvard and MIT, visited the IJS to talk about further Dekleva's specialization in the USA. However, the new director of the IJS, Lucijan Šinkovec nicknamed "a valve" after Ranković's pressure for the construction of the Ljubljana reactor changed his mind overnight and called Dekleva back home.

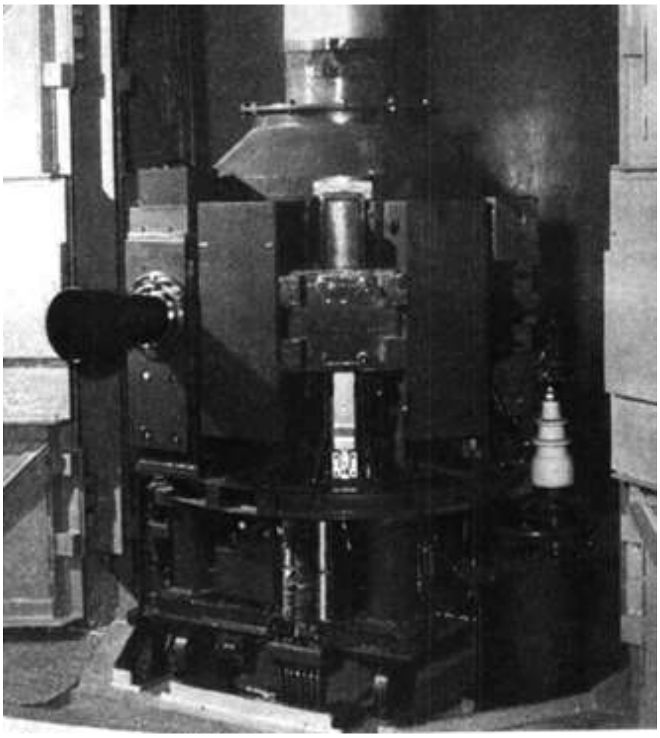

Figure 30-12: Photography of betatron at IJS (Peterlin, 1955 Das 31 MeV Betatron, 38)

In December 1959, Dekleva was again at the IJS. As the head of the Cilenšek's Accelerator and Electrophysical Department, he was trained on the Van de Graaff generator for the work of nuclear

[3363] Livingston, Blewett, 1962, 134.

[3364] ARS, SI_AS 1961, box 11, map 25.

physicists. His associate engineer Anton Brinšek maintained the betatron, and in 1961 two pulsed neutron generators were assembled for reactor physics. They developed a magnetic mass spectrometer for the chemical department and omegathron mass spectrometer for detection of vacuum leakage up to $1.33 \cdot 10^{-9}$ mbar · l · s^{-1}. In August 1963, Cilenšek began to lecture at the Split Faculty of Electrical Engineering, Mechanical Engineering and Shipbuilding, and later at the Faculty of Mechanical Engineering in Ljubljana.[3365]

Figure 30-13: Kuhelj's letter "For Help" from the Italian prison where three Antons from the University of Ljubljana suffered after their failed acquisition of a neutron generator (GDP).

Unlike the Soviet block favoured by people from the Vinča Institute, the Peterlin's Ljubljana and Supek's Zagreb Physical Institutes were directed mainly to the West. In 1946, the delegation of the Slovenian Academy of Sciences and Arts together with President F. Kidrič visited the Soviet Union,[3366] but later Peterlin's collaboration was limited to the Polish people. On 14th May 1957, at the ZKNE meeting in Supek's absence, the agreement with Poland on the peaceful uses of nuclear energy was confirmed. On 5 November 1957, Barbarić informed the IJS that they would sent to Ljubljana practice Lech Borowski and the other Poles according to an agreement approved by ZKNE. However, Kajfež was very angry because, despite the announcement of the Poles, they did not show up at Ljubljana in time. After this exchange, Cilenšek departed for a month in Warsaw in November and December 1957, and Osredkar went there for three weeks.[3367] Later, Navinšek visited the Warsaw Physics Department to complete his knowledge of Strojnik's electron microscopy by accurate processes of measurement of the grid constants of thin films by the electron diffraction.[3368]

FIZIKALNI INŠTITUT
672

Figure 30-14: Invitation dated 23 May 1952 to an extraordinary meeting of the class for mathematical, physical and technical sciences of the SAZU dated 24 May 1952, led by deputy secretary Peterlin where they successfully renamed the Physics Institute in the IJS. Peterlin headed the meeting instead of the absent secretary Milan Vidmar, Josip's brother. Peterlin successfully proposed renaming of the Physics Institute in the IJS with a typical conclusion of SF - SN! (Death to Fascism - Freedom to the People) (ARS, AS, box 1, map 1; ARS, AS, box 2, map 5).

3365 Dekleva, 2000, 202-205; Osredkar, 2000, 319.

3366 Message of Aleš Gabrič on 31. 1. 2007.

3367 ARS, SI_AS 1961, box 11, map 25.

3368 Navinšek, 2000, 160; Panjan, 2002, 43.

After Navinšek's return, the electro-technicians "of weak currents" at the IJS were no longer exercised only at the Cilenšek, Dekleva or Bremšak's departments for accelerators, mass spectroscopy or electronics, but also in the department for the research of materials of the chemist Marinković (r-9). Everything started at the renewed Ljubljana Physics Institute with a neutron generator, which the three Antons (Kuhelj, Moljk, Peterlin) tried to acquire in Vincenza immediately after the war with a lot of money in their bags. When Kidrič only allowed the acquisition later, attempts were by no means limited to A-bombing and reactor efforts. From the neutron generator, which was in the bad and in the good period the base of the first decade of the development of the Ljubljana Physical Institute, the electro-technician Navinšek used a beam of radio-frequency source for the first measurements of the sputtering coefficients after his return from Hamburg in 1961. In preparing the Yugoslav nuclear program, IJS has constantly developed advanced vacuum technology. Mostly the successful methods for ionic etching of radioactive materials with an argon ion beam have proved successful. The surface of ceramic samples of UO_2 and reactor graphite could be etched or prepared for analysis of its surface microstructure only with argon energy ions of several keV. Thus, ion bombarding became one of the fundamental technologies of reactor physics, even before the construction of the TRIGA reactor in Podgorica. What Peterlin conceived as the co-operation of researchers of macromolecules with industry, in fact, immediately after his departure from Ljubljana began to occur primarily with Slovenian thin-layer technologies. During the Manhattan project of manufacturing atomic bombs during the Second World War, Lawrence's postdoc the physicist-musician John Graham Backus (1911-1988 Los Angeles) of Radiation Laboratory, University of California in Berkeley and his colleagues developed ionization meters with the cold cathode, and in 1943/44 invented a vacuum meter in the vacuum system with a mass spectrometer. Likewise, the Slovenian physics also recovered from the shadows of the bomb. With only one "slight" difference: the Americans really made the bomb, while the Yugoslav bombers were deposed at the Brioni Plenum together with Ranković.

After the collapse or bankruptcy of the Yugoslav bombing program with Ranković's retirement, after

in umetnosti,
dir.dr.L.Baebler,
Ljubljana.

Priloženo Vam pošiljam dva izvoda zapisnika zadnje seje razreda za matematične, fizikalne in tehnične vede z dne 24.5.1952 s prošnjo, da pošljete zapisnik vsem članom razreda.

S.F. - S.N!

Figure 30-15: Peterlin's accompanying record to Kuhelj's notes of the extraordinary meeting of the class for mathematical, physical and technical sciences of the SAZU on 24. 5. 1952, sent to SAZU administration director lawyer the alpinist Nordic skiing fan Lev Baebler (1912 Žiri-1976) five days later concluded by the usual motto "Death to Fascism - Freedom to the People". Lev Baebler was the nephew of the chemist Balthasar Baebler (Baldi, 1880-1936) who was the father of the Bolshevik revolutionary Aleš Bebler (1907-1981) and the grandfather of the expert of defence studies Anton Bebler (* 1937). (SBL, 4: 1038; ARS, SI_AS, box 1, map 1; ARS, SI_AS 1961/18/5, box 2, map 5).

1975 it became interesting to study the formation of blistering in the (homogeneous) reactor core and the intense erosion of the first inner wall of the reactor vessel, for which it was difficult to find enough resistant materials in fusion (thermonuclear) reactors, as before the same problem bothered the physics of the homogeneous physical reactors, promoted by Peterlin's Group. Ion bombardment of solids and the production of thin metal layers gained its fundamental importance shortly after Velibor Marinković's section for electron microscopy was joined by Boris Navinšek in 1957.[3369] Marinković graduated in chemistry, received his Ph.D. on December 29, 1965, and promoted on February 25, 1966 with Samec's former doctoral student Branko Brčić.[3370] Jože Gasperič (1968) was among Marinković's doctoral candidates, while Navinšek obtained his diploma, a master's degree and a doctorate (after a one-year study in Liverpool) with Aleš Strojnik at the Faculty of Electrical Engineering. At the Faculty of Electrical Engineering few years before Navinšek Cilenšek and Dekleva also studied. In any case, the study of thin films requested a group

\- 2 -

že preosjšnje število službenih let izgledalo kot degradacija. Zato predlaga, da se vsi trije nastavijo kot znanstveni sodelavci in sicer ing. Rajko Kavčič in ing. Karel Andrejč v VII. skupini, ing. Boris Lavrenčič pa v VI. skupini. Svoj predlog utemeljuje z dosedanjim znanstvenim in strokovnim delom, kot je razvidno iz njihovih življenjepisov.

Dalje predlaga za znanstvenega sodelavca v VII. skupini ing. Mirota Dermelja in utemelji svoj predlog s posebnim poročilom o njegovem dosedanjem strokovnem in znanstvenem delu.

M.Samec predlaga, da se nastavi kot asistent v Kemijskem institutu ing. Majdič Aleksander, ki je bil doslej v enakem položaju v institutu za fužinarstvo TVŠ. Sprejeto.

4\. A.Peterlin predlaga nastavitev tov. Rudija Petkovška v Fizikalnem institutu kot laboranta v IX. plačilnem razredu (Din 11.5oo) od 1.VI-1952. Dalje od 1.VI.1952. honorarje za ing. Battestina Din 5.ooo.- in za D. Sušnikovo in 1.5oo.- mesečno. Sprejeto.

5\. Peterlin predlaga, da se Fizikalni institut SAZU odslej imenuje Fizikalni institut Jožefa Stefana. Sprejeto.

6\. Peterlin poroča o zadnji seji predsedstva, ki se je je udeležil namesto odsotnega tajnika Vidmarja. Iz zapisnika prejšnje seje predsedstva je ugotovil, da se je Terminološka ko-misija pri Institutu za slovenski jezik SAZU razšla. Namesto nje se ustanovijo posebne terminološke komisije oziroma odbori pri posameznih razredih. Pri 3. razredu se ustanovi Komisija za matematično, fizikalno, kemijsko in tehniško terminologijo. Tajnik razreda naj poišče stik s to komisijo in naj poroča o njenem sestavu, delu in programu.

Krediti za tiskanje akademijskih publikacij so tako skrčeni, od predlaganih 17 na 14 milijonov, tako da je mogla iti v tisk samo ena rasprava razreda. Predsedstvo se bo potrudilo, da dobi še nadaljnje kredite za tisk. Prednost imajo rasprave pred deli.

Triglavska tiskarna je dobila nove matrice. Razred prosi za odtis teh novih znakov. V kolikor bi kljub novi nabavi ostala še potreba po novih znakih za matematični tisk, prosi razred, da se te potrebe upoštevajo pri novih naročilih.

Seja zaključena ob 14 uri.

Zapisnikar: Dr.ing.A.Kuhelj

Za Tajnika: Dr.A.Peterlin

of various experts including chemists, physicists and electro-technicians.

30.1.4.10 New Materials and Vacuum Techniques for a Homogeneous Reactor

The fundamental problem of Peterlin's homogeneous reactor was to prevent the corrosion of the reactor vessel withstanding extremely high pressures, which at the same time should pass through enough neutrons. The titanium, zirconium, or ruthenium had the first two advantages, but they absorbed too many neutrons. That is why Peterlin conceived two walls of the vessel, one of which had the appropriate chemical characteristics and the other provided desired nuclear properties. Of course, the volume of the reactor was proportional to the maximum of the usable electrons, so it was necessary to use heavy water instead of plain water. Peterlin listed twelve advantages of a homogeneous reactor, including safety, and only one disadvantage associated with spontaneous bubble blistering. Peterlin's idea of two walls was not particularly successful after a similar problem was raised in fusion reactors. For this reason, the Navy's Solid-State Ion bombarding team was included in the group of M. Kaminsky (Kaminski) within the Argonne National Laboratory in Chicago under the research entitled "Study of erosion and capture of light ions in the surface of first-surface materials". For research, the IJS built a low-energy accelerometer with double magnetic ion beam focusing needed to investigate the AISI 316 L, Inconel 600 and 625 steel which were then used in chambers of all (experimental) reactors for nuclear fusion.[3371] Thus, Peterlin's Ljubljana thoughts designed in 1950s remained important for decades afterwards. His computations of the preventions against corrosion of the reactor vessel influenced his calculation of the persistent length of the DNA molecule including its elastic constants which he sent from Ljubljana to the Nature magazine on June 5, 1952; it became extremely interesting only in the times of Peterlin's death.

30.1.4.11 Conclusion

Kraigher and Ranković's dealing with Peterlin's heritage went through two phases. They first replaced him with physicists from a neighboring building on the Jadranska street no. 19, who extremely clumsily took
over the power at the IJS with the help of reactor operators. This was only a maneuver that was intended to conceal the actual takeover of power by the ZKJ, which took over the director's chair, the chairman of the Expert Committee and the Scientific Council of the IJS after the new year of 1963.

Peterlin marked the beginning of modern physics in Ljubljana in the best possible usable way. The "gift" that was arranged for him at his meeting with Abraham was perhaps not the most pleasant one, but Peterlin in the US opened the new world horizons as no other Slovenian scientist before him.

30.2 Vacuum for Modern Slovenes

*30.2.1 Vacuum at the Time of Director Osredkar and Vacuum Techniques in the Nuclear Magnetic Resonance of Robert Blinc (*1933; †2011)*

30.2.1.1 Introduction

Tesla was a gifted inventor without a real talent for making money while his younger contemporary

[3371] Navinšek, 2000, 162.

Milan Osredkar (* 19th October 1919 Ljubljana; † 2003) was completely different; he was perhaps the best among Slovene physicists of the recent past, who has a top knowledge of nuclear technologies with the capability of their practical moneymaking realization in Slovenia. He was able to gather around him the capable talented experts, who upgraded Peterlin's justification of the Jožef Stefan Institute (IJS) in a way that still binds Slovenians to this day.

30.2.1.2 Osredkar and Peterlin

From 1931 to 1938 Osredkar was attending the first national real gymnasium in Ljubljana. Between 1938 and 1941 he studied electrical engineering. By the end of 1940, he completed the first part of the preparatory exams and at the same time he regularly studied at the Academy of Music. In the summer of 1941, he interrupted his studies for cooperation with the Radio Kričač of OF. A few weeks after the end of Kričač's broadcasts, in May 1942 the Italians captured Osredkar and sent him to Gonars after two weeks in prison; there he met the physicist Anton Moljk, who, after the war in Ljubljana, began the vacuum measuring techniques of nuclear radiation.

Dragi tov. Osredkar!

Na predvčerajšnji seji znanstvenega sveta, ki bo sedaj postal upravni odbor, smo se prav razgovarjali o reaktorski tehniki in se pri tem odločili, da pošljemo enega fizika in enega kemika v Ameriko na 10-mesečni kurs o Nuclear Engineering. Soglasni smo bili v tem, da pridete kot fizik najprej Vi v poštev, ker ste se že vse čas bavili s to problematiko pri svojem referatu o perspektivah atomske energije.

Seveda bi bilo potrebno, da se pred svojim odhodom v Ameriko (verjetno v jeseni) temeljito seznanite z osnovnimi matematično-fizikalnimi problemi tega vprašanja, ker zahteva Amerika (gre tu za New York University, s katero smo v tem vprašanju že v stiku), da pošljemo res "outstanding students".

Za kemika bo še Kosta izbiral med dvema kandidatoma, ki sta se javila na institutu in ki bosta prav tako morala še v Ljubljani skozi kurz jedrske in reaktorske fizike.

Upam, da Vam bo ta ponudba ustrezala, ker se boste tu lahko ukvarjali z najbolj aktualnimi problemi instituta in spravili tako to nekoliko šepajočo vejo naše dejavnosti na zeleno vejico, ker postaja vsak dan bolj potrebno.

Prosim, da o svoji odločitvi takoj obvestite ing. Kosto, ki bo sedaj vodil vse posle namesto mene.

Na včerajšnji seji znanstvenega sveta smo v glavnem sprejeli pravilnik, ki se naslanja predvsem na zagrebškega. Izgleda, da bo v sedanji obliki institut lahko dobro funkcioniral, ker bo samo eno telo, v katerem bodo pa predstavniki vseh laboratorijev.

Iskreno Vas pozdravlja

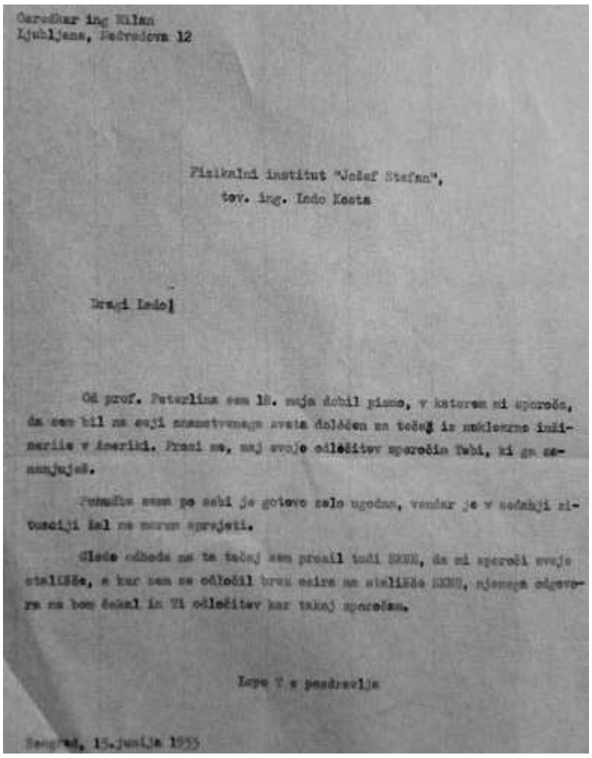
Figure 30-34: Peterlin offers to Osredkar the American engineering studies of American Reactor Engineering in his letter mailed from the USA on May 17, 1955 (Author's archive).

The capitulation of Italy enabled Osredkar to join the Partisans. After liberation, he remained in the Yugoslav National Army as a major UDBA. From 1946 to April 1948 he worked in Austria. Immediately after the war and again at the time of the Cominform (Informbiro) quarrels, Osredkar rescued from the prison the father of the Slovenian nuclear reactors Milan Čopič, when Čopič did not find himself in the promising position among various orthodox opinions on Stalin's person while returning from his studies in the Soviet Union.

In the autumn of 1948, Osredkar became the commander of the SUZUP (Service for the Protection of the Constitutional Order) in Ljubljana, and in 1952 he transferred to the later IJS as Peterlin's assistant administrator of the Institute.

At the beginning of his work in 1950, he began his studies again, this time in technical physics, which in Ljubljana of that time offered the best insight into the new achievements of vacuum techniques. On February 10, 1954 he graduated in Peterlin's class at the Department of Physics inside the Department of Chemistry of Technical Faculty of the University of Ljubljana. For his diploma Osredkar measured the strengths, time and spatial distribution of gamma radiation in the betatron vacuum with the counter of Cherenkov. Pavel Alekseevich Cherenkov (* 1904; † 1990) won a third part of the Nobel Prize three years after Osredkar's graduation, although Cherenkov saw the blue shine already in glass-bottled water exposed to radioactive radiation during his work with Sergei Vavilov in 1934. Cherenkov studied that remarkable phenomenon for six years.

The year before Osredkar's diploma, Darko Jamnik, the professor of the writer of this book, took the leadership of the beta-throne at the Institute. The institute was named after Jožef Stefan on Prešeren's day in 1953. After short practical training in Switzerland, Jamnik participated in the installation of Brown-Boveri betatron, which he bought in the summer of 1954 for the Jožef Stefan Institute. Osredkar knew how to perform his measurements at home; he helped to ensure that Jamnik succeeded in achieving the stabilization of the betatron at 5 keV for 20 MeV energy in 1956. Thus, a betatron at the IJS in the range of energies of up to 30 MeV became the most accurate device for investigating the nuclear photoelectricity on a global scale with the help of Osredkar's diploma work. The work at Betatron was the first rewarding Osredkar's intervention in modern vacuum technique, which was then followed throughout his life. Sure, Osredkar was not beloved among all vacuum researchers.



Osredkar ing Milan
Ljubljana, Nedvedova 12

Fizikalni institut "Jožef Stefan",
tov. ing. Lado Kosta

Dragi Lado!

Od prof. Peterlina sem 18. maja dobil pismo, v katerem mi sporoča, da sem bil na seji znanstvenega sveta določen za tečaj iz nuklearne inženerije v Ameriki. Prosi me, naj svojo odločitev sporočim Tebi, ki ga zamenjuješ.

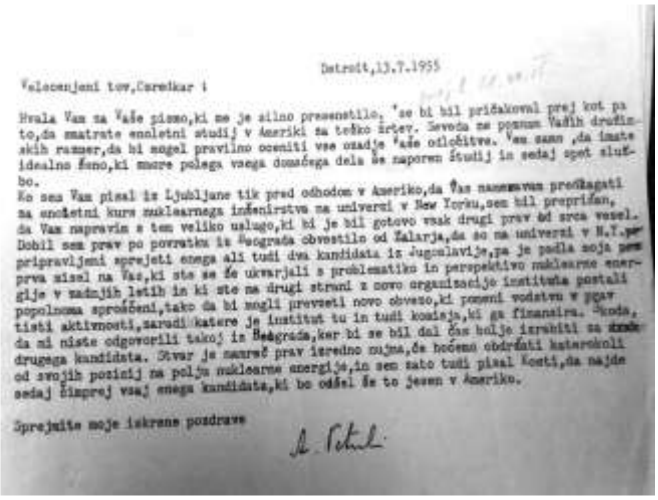
Ponudba sama po sebi je gotovo zelo ugodna, vendar je v sedanji situaciji žal ne morem sprejeti.

Glede odhoda na ta tečaj sem prosil tudi SKNE, da mi sporoči svoje stališče, a ker sem se odločil brez ozira na stališče SKNE, njenega odgovora ne bom čakal in Ti odločitev kar takoj sporočam.

Lepe T e pozdravlja

Beograd, 15.junija 1955

Figure 30-35: Osredkar writes to Lado Kosta about his disappointment, because Peterlin neglected him at the assignments of functions at the Jožef Stefan Institute. As a comforting reward Peterlin offered to Osredkar a ten-month reactor technology study in New York (Archives of Južnič).



Detroit,13.7.1955

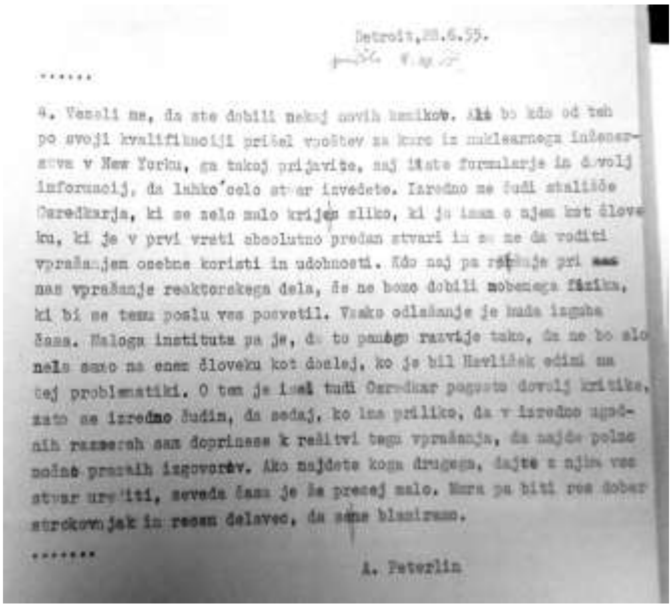
Velecenjeni tov.Osredkar !

Hvala Vam za Vaše pismo,ki me je silno presenetilo. Vse bi bil pričakoval prej kot pa to,da smatrate enoletni studij v Ameriki za težko žrtev. Seveda ne poznam Vaših družinskih razmer,da bi mogel pravilno oceniti vse ozadje Vaše odločitve. Vem samo ,da imate idealno ženo,ki more poleg vsega domačega dela še naporen študij in sedaj spet službo.
Ko sem Vam pisal iz Ljubljane tik pred odhodom v Ameriko,da Vas nameravam predlagati za enoletni kurs nuklearnega inženirstva na univerzi v New Yorku,sem bil prepričan, da Vam napravim s tem veliko uslugo,ki bi je bil gotovo vsak drugi prav od srca vesel. Dobil sem prav po povratku iz Beograda obvestilo od Žalarja,da so na univerzi v N.Y. pripravljeni sprejeti enega ali tudi dva kandidata iz Jugoslavije,pa je padla moja prva misel na Vas,ki ste se že ukvarjali s problematiko in perspektivo nuklearne energije v zadnjih letih in ki ste na drugi strani z novo organizacijo instituta postali popolnoma sproščeni,tako da bi mogli prevzeti novo obvezo,ki pomeni vodstvo v prav tisti aktivnosti,zaradi katere je institut tu in tudi komisija,ki ga financira. Škoda, da mi niste odgovorili takoj iz Beograda,ker bi se bil dal čas bolje izrabiti za drugega kandidata. Stvar je namreč prav izredno nujna,če hočemo obdržati katerokoli od svojih pozicij na polju nuklearne energije,in sem zato tudi pisal Kosti,da najde sedaj čimprej vsaj enega kandidata,ki bo odšel še to jesen v Ameriko.

Sprejmite moje iskrene pozdrave

A. Peterlin

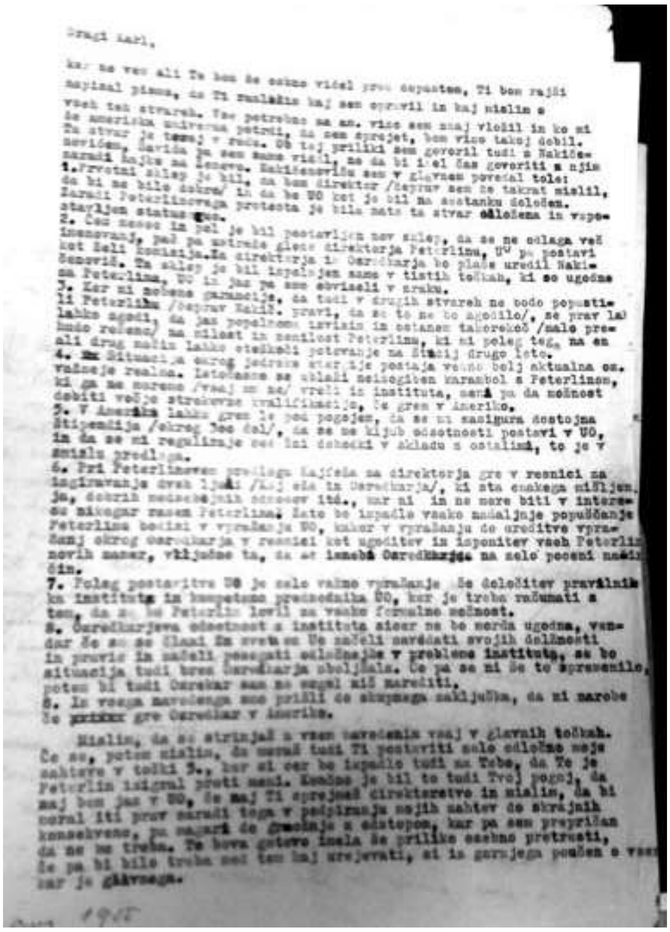
Figure 30-36: Peterlin writes to Osredkar with a surprise because of Osredkar's rejection of the offer for American studies (Archive Južnič).



Detroit,28.6.55.

A. Peterlin

Figure 30-37: Osredkar apologizes to Peterlin for any inconvenience and accepts the offer for his studies in New York (Archive Južnič).



Dragi Karl,

Figure 30-38: In 1955 Osredkar reports to Lado Kosta (* 11 February 1921 the Strniščе by Ptuj refugee camp; † 1986) about his disagreements with Anton Peterlin (Archive of Južnič).

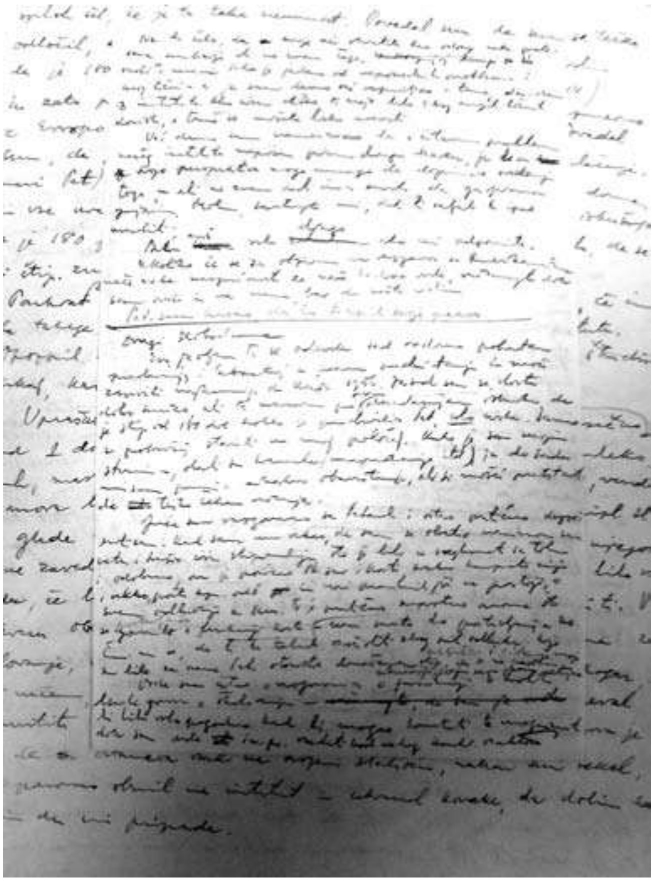


Figure 30-39: From the United States Osredkar reports to Peterlin about his US talks on November 5, 1955 (Archive Južnič).

On 1 January 1955, Osredkar started working at the IJS after the termination of his job at the SUZUP. His bride Uči Fajgelj (* 31st August 1927 Kred by Kobarid) was a graduate at the Faculty of Chemistry in 1955 and gained the title of engineer. In September 1955, after Peterlin's mediation, Osredkar traveled to the Department of Nuclear Engineering at the University of New York. There he became acquainted with modern vacuum and nuclear technology and got the prestigious title Master of Nuclear Engineering in 1956.

At his Inside-out Reactor study Osredkar looked at the specific distribution of the internal reflector and absorbers to increase thermal flux compared to that of ordinary nuclear reactors at the time. In December 1956 he reported on his research at a meeting in Boston; he published the paper in the prestigious Journal of Nuclear Energy along with his American supervisor and soon also his friend Richard (Dick) Stephenson. In the period 1956-1958, they published three papers, and Osredkar himself also published independently. Osredkar then calculated the relationship between flux and power in real reactors, which he intended to set up in Yugoslavia. On 22 February 1957, Peterlin and Moljk proposed Osredkar as a scientific assistant to the IJS, where he was chief of the reactor group between 1956 and 1958; with his American insights and knowledge of modern vacuum techniques, Osredkar replaced the previously unique professor of nuclear physics in Ljubljana Franjo I. Havliček (* 3. 12. 1906 Moravska Ostrava). After returning from a prolonged two-year stay in the United States and a shorter visit to the Swiss Vacuum and Nuclear Capabilities Osredkar got his Ph.D. at Peterlin's class. Osredkar's 211-page long dissertation, dated August 4, 1958, was titled The Research of the Possibilities for Increasing the Thermal Flux in the Moderator Cavity Reactor as a continuation of his American research, adapted for the possibilities of vacuum nuclear technology in the domestic Ljubljana circumstances. Osredkar defended his doctorate about five months after Anton Moljk as one of the last of Peterlin's students in the Jožef Stefan Institute. After the defence, Peterlin sceptically asked Osredkar what could be the use of that type of reactor as none of them expected that the Americans and Soviets will soon really build it. Milan Osredkar was promoted on June 27, 1959,[3372] when he and his family already moved to Vienna. Immediately after submitting and defending the dissertation, Osredkar again went to neighbouring Austria. Between September 1958 and 1961, under the command of the ZKNE (Federal Nuclear Energy Commission), he worked in the Viennese IAEA Reactor Department. He thus diplomatically avoided complications around Peterlin's humiliations in Ljubljana, likewise as a year older Ivan Kuščer (* 17 June 1918 Vienna-† 2000).

30.2.1.3 Returning of Osredkar to the Rudder of the Jožef Stefan Institute

At the Faculty of Mining, Metallurgy and Chemical Technology Osredkar has been teaching the subject Encyclopaedia of Nuclear Engineering and Nuclear Materials since 1961, after applying from Vienna as the only candidate on 8 February 1960. On 8 September 1962, he was elected as Associate Professor in Ljubljana; he completed his work on the nuclear power plant and projected and submitted it to the Viennese International Atomic Energy Agency.

3372 Kokole, 1969, 61.

From 1 January 1963 to 8 April 1975, Osredkar was the Director and Scientific Adviser of the IJS; he proved to be an extremely imaginative and effective negotiator with foreign partners with an enviable knowledge of English and German language.

In 1963, as the new director of the IJS, Osredkar immediately renewed contacts with Peterlin, who then extensively lectured in Slovenia, and especially at the IJS. Osredkar's management of the IJS enabled the breakthrough in the development of the Ljubljana-based thin-films protective layers. Precisely upon Osredkar's takeover of the director's chair, prof. dr. Boris Navinšek began to develop first simple "table" device for ion bombarding and ion etching. In the next half of the century, thin-layer vacuum technology became the pride of the applied science of the IJS, which is in many ways Osredkar's merit in the time before Navinšek recruited his successor, Peter Panjan.

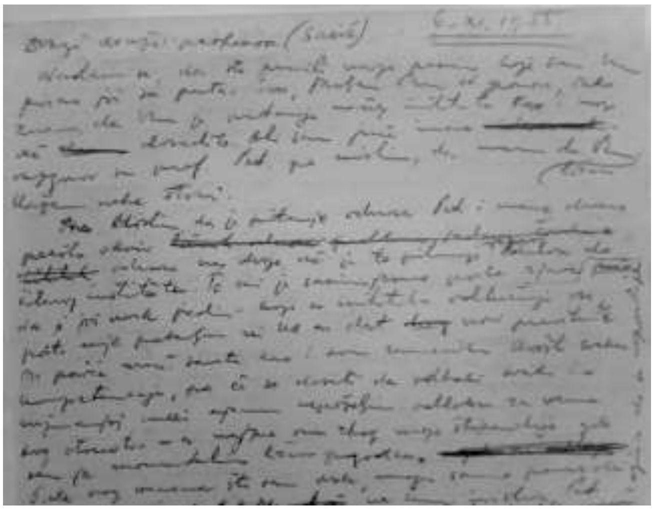

Figure 30-40: Osredkar writes from New York to the director of Belgrade-based Reactor Center in Vinča named after Boris Kidrič. The director Pavle Savić (* 1909; † 1994) worked with the couple Joliot-Curie during his Paris research on the effects of neutrons of heavy elements. Savić was nominated for the Nobel Prize at the side of Irène Joliot-Curie, and during the war he was distinguished as the Tito's Code manager. Among the Slovenes, he was not overly popular, especially after the first fatal accident, which was he indirectly caused as a chief in Vinča.

After Osredkar's return from the Viennese IAEA, he revived work for the Slovenian nuclear reactor. The land near Gradaščica river opposite the IJS was occupied in the meantime, so they discussed the nearby location of the existing buildings of the Faculty of Mathematics and Physics. Later the location at Podgorica prevailed as the most reliable static building land.[3373]

On 8 July 1959, ZKNE commanded an examination of the needs for the installation of a new reactor immediately after Peterlin's resignation. The IJS has appointed a special commission with Moljk, Šinkovec, Bremšak, Kosta, Kladnik, Lebez and Kuščer. They studied the necessary circumstances for the installation of the reactor. In March, April and May 1960 an overview of possible locations was carried out by a technical group composed of S. Zupan, engineer later head of Triga reactor Zdravko Gabrovšek, engineer Natan Bernot (1931 Ljubljana-2018) and B. Sotošek after comparing them to similar locations elsewhere in the world. In that time in Vienna Osredkar learned how to upgrade Slovenian capabilities with modern vacuum techniques.

N.Y. - USA

Dragi tov. Osredkar!

Hvala Vam za Vaše pismo. Prav posebno me veseli Vaše delo skupaj s Stephensonom, ker bo pri tem najbrže prišlo do ene zelo lepe publikacije, ki Vas bo lepo afirmirala v strokovnem svetu.

Kar se tiče Vaših potovanj se mi zdijo zelo utemeljena in kar pošljite čimprej podrobnejši predračun stroškov. Zelo škoda bi bilo, če se Vam ne bi posrečila praksa, ker se pri teh največ nauči prav tistega praktičnega dela, katerega predavanja in študij na univerzi ne morejo dati.

Za danes kar končam, ker sem v strašni časovni stiski in Vas lepo pozdravljam

Figure 30-41: On 26 June 1956, Peterlin recommended to Osredkar many journeys to the United States in favor of the international implementation of the Slovenian Physics.

After lengthy negotiations through Osredkar's IAEA, the Americans donated to the IJS fuel for

[3373] Search for location for reactor (Archive IJS in Podgorica, box 326, map 578); Osredkar, 2000, 38–39; Dimic, 2000, 237.

the reactor in Podgorica; they even planned to shift the entire JS into Podgorica, which was left only on paper,[3374] sadly or maybe fortunately.

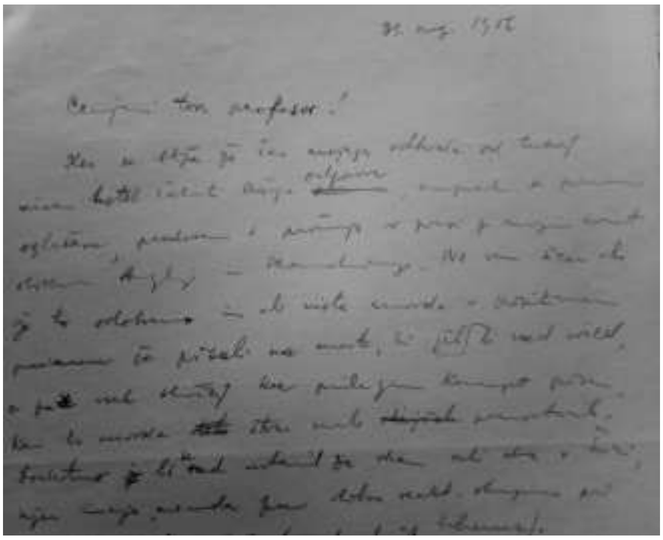

Figure 30-42: Osredkar writes to Peterlin just before his return from New York on August 31, 1956.

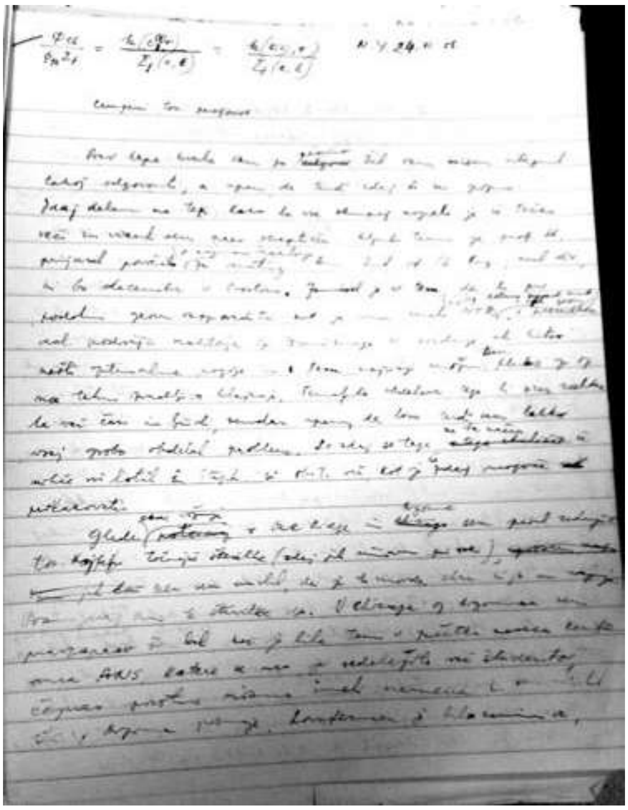

Figure 30-43: Osredkar reports to Peterlin from America on June 24, 1956. The top of the draft letter was decorated with equations describing the flow in the nuclear reactor.

The construction of the Triga (Training, Research, Isotope, General Atomic) reactor in Podgorica started in May 1963, only a few months after Osredkar's takeover of the IJS leadership. At the end of Osredkar's mandate at the IJS, the foundation stone for the Nuclear Power Plant Krško (NEK) was laid on December 1, 1974, and construction work began in February 1975. Immediately afterwards, Osredkar completed his 12-year management of the IJS as a new member of the SRS Executive Council; there he took care that the Krško NEK was granted permission for regular operation in January 1984. Westinghouse donated NEK facilities parted among Slovenia and Croatia including Tesla's native Lika, maybe as a kind of compensation for Tesla's favors.

On 9 June 1967 the old Zagreb physicist Ivan Supek endorsed Osredkar's candidature. Supek was the only professor of the Experimental Physics and Reactors available for the University of Ljubljana. As Heisenberg's pre-war doctoral student Supek was proud of the fact that Osredkar asked for his opinion; Supek certainly did not explicitly support the research of nuclear technologies in fear of atomic bombs, but Supek nevertheless obviously highly appreciated Osredkar.

30.2.1.4 Vacuum Techniques for Nuclear Magnetic Resonance of Robert Blinc

On September 26, 2011, the academician Robert Blinc died several years after his mother passed away in a slight accident when Blinc drove his car into the fields near the Brnik airport. Blinc was certainly one of the most important Slovenian physicists of his time. I made my own first steps in the world of science under his supervising, so it is right to give him a short memorandum on this occasion. It seems that Professor Blinc in Slovenia was able to combine the novelties of experimental vacuum technique with an ingenious theoretical insight into the secrets of solid matter spiced up by the artificial use of scientific discoveries in the industry. Therefore, his work can certainly be an example to us.

Robert Blinc was born on 31 October 1933 as the nephew of chemist dr. Marta Blinc (1904-2000). Robert was a grandnephew of the wholesale merchant Robert Kollman (1872-1932) and the great grandson of the glassman Franz Kollman (1839-1908) from Begunje. The unmarried

3374 Osredkar, 2000, 30; note of the deceased dr. Matjaž Ravnik on 10. 1. 2007; Ravnik & Južnič, 2010, 185.

philanthrope Robert Kollman, among other things, owned the former Gruber's villa Podrožnik, which the older inhabitants of Ljubljana had long known as Kollman's castle. In 2015, the state officials put the memorial plate of Kollman there.

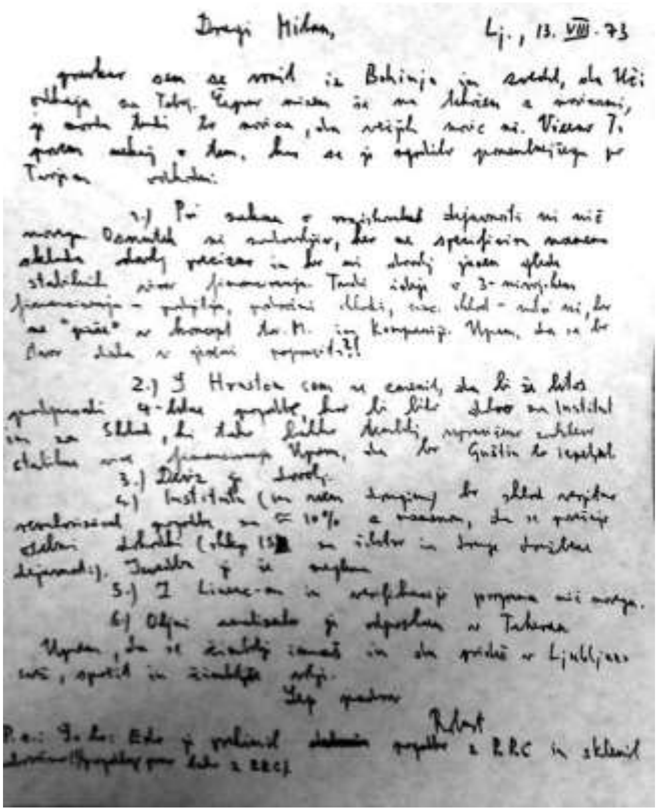
In gymnasium, the driver in nice official suit was always waiting for Robert Blinc to drive him home while his classmate Lado Rupnik (* 1934) sometimes got a lift. In Blinc's class were Jurij Kunaver (* 1933) the son of their professor of geography Pavel Kunaver, the future sociologist of migrations and great defender of classical studies Peter Klinar, later practitioner in Havliček's lab Anton Prelesnik, Stefan Slak and the future priest Alojzij Oražem. After his graduation with Matura at the classical gymnasium in Ljubljana, Blinc graduated in Anton Peterlin's class with the work Infrared spectra and the shape of the potential function of the hydrogen bond KH_2PO_4 and KD_2PO_4 in the non-ferroelectric and ferroelectric phase in 1957.

In the following year, Blinc prepared a doctoral dissertation on the Tunnel effect of protons in ferroelectrics with short hydrogen bonds on the eighty pages with graphical representations. In the head of the thesis Peterlin was noted. Peterlin may have participated in the defense on February 25, 1959, but Peterlin was certainly not present at the promotion on March 10, 1959, since he went to Mainz on 9. 3. 1959. Thus, final mentor of Blinc's work was Dušan Hadži, with whom Blinc submitted a report on "Hydrogen bonding studies" to the Slovenian Researchers' Society in 1957.

In 1957, Blinc published two papers in the IJS Reports, together with Jože Pahor and Edo Pirkmajer. In 1958, Blinc began publishing abroad, initially along with his aunt Marta Blinc or Hadži, but soon also alone as well. Already in 1958, Blinc published a brief report on hydrogen bonds in the leading Nature magazine in London, which greatly contributed to the international prestige of Slovenian researchers. The phase transitions soon became the basic direction of Blinc's research therefore ~~it is~~ precisely his early collaboration with the leading Slovenian chemists and an insight into the progress of the then vacuum technic ~~which~~ paved his way to outstanding discoveries.

Already before 1959, the physicists Ivan Zupančič (1930 Ljubljana-1999 Ljubljana), Blinc and colleagues at the IJS built the first device for NMR in the former Yugoslavia, which was an exceptional achievement. Their success was also reported at the Bologna congress in the same year.

In 1960, the first son of Robert Blinc was born, who became the Doctor of medicine. The son Aleš was nice and when I met him for the first time in his father's office in IJS, he started to talk to me in English language. Aleš Blinc began his medicinal success by NMR studies of his fathers' lab to become the head of vascular diseases in UKC of Ljubljana and a businessman owner of the famous pub Maček in Ljubljana.



Dragi Milan, Lj., 13. VIII. 73

Robert

Figure 30-44: Robert Blinc's letter dated in Ljubljana on 13 August 1973, sent to IJS Director Milan Osredkar.

Blinc went on to postdoctoral training at MIT, where he became acquainted with the technique of magnetic pulse resonance. The tunnel model of ferroelectrics with hydrogen bonds explained the electrical properties of ferroelectrics and their changes when hydrogen is replaced by deuterium. In 1960 Robert Blinc became a docent, in 1965 he became an assistant professor and he was a full professor in 1969. On 17 October 1964, Blinc was elected chairman of the expert committee of the IJS according to Čopič's proposal. There Robert

Blinc chaired a total of sixteen meetings until 1 September 1965. [3375]

Blinc reported to Osredkar on events at the Jožef Stefan Institute, mostly on the agreement with Iskra electrical engineer Silvo Hrast (* 1921 Trieste-1999). Blinc noted the signing of a four-year contract between the IJS and the Fund of Boris Kidrič of Slovenia whose president was Hrast for eleven years. The contract was carried out by the director of Litostroj the mechanical engineering Božidar Guštin (* 1912; † 1984) the member of the Federal Nuclear Energy Commission in 1957. Hrast was a member and for a time also a president of the Kraigher's Steering Committee of the IJS in 1957. Hrast was even the technical director of Vinča institute from 1. 2. 1950 to 28. 2. 1952.

Under the sixth point, Blinc reported on the oil analyzer dispatched to Teheran. It was the NMR-analyzer of the oil and moisture content of grains of the agricultural crops, especially in the sunflowers. In the annotation Blinc reported on contracts signed by physicist dr. Edo Pirkmajer (* 1932) as the Secretary General of the Research Society of Slovenia and later Secretary of State (1996-2001), concluded with the Republican Computation Center (RRC). At first, RRC operated in the IJS frame in 1968 according to Južnič's Archive. The studies of phase transitions and liquid crystals were supported by new methods of microscopy and photography at the beginning of the 19th century. In the mid-20th century, the new discoveries demanded new methods of research. These were found mainly in the NMR, which was invented immediately after the Second World War and even included in Moljk's dissertation in 1956.

Already Stern and Rabi investigated the magnetic fields of nuclei in streams of atoms or gas molecules. Bloch developed a method for determining the magnetic field of nucleuses in liquids and solids at Stanford University. A slightly different method was discovered by Purcell at MIT in 1946, so the researcher shared the Nobel Prize for NMR development in 1952. In 1960, special serial publications devoted to NMR were also launched, among English-written mainly Advances and Magnetic Resonance in New York in 1965 and NMR Basic Principles and Progress in Berlin in 1969. Soon after, periodicals and journals focused on NMR apeared, mostly Journal of Magnetic Resonance in New York in 1969 and Nuclear Magnetic Resonance Spectrometry Abstracts in London in 1971. With those journals, NMR became a separate field of research for half of a century, just like the ion implantation somewhat earlier.

The American **Edward Mills Purcell** was born in Illinois in 1912 and died in 1997. He graduated from Purdue University in 1933. After completing his studies in Germany, in 1938 he received his doctorate at Harvard, where he became a professor in 1948. Between 1940 and 1946 he studied at the MIT Laboratory for radiation. He also studied the spectroscopy of radio waves in astronomy. The Swiss born Jewish American Felix Bloch was born in Zurich in 1905, where he graduated as an engineer. He then went to Leipzig, where he became the very first Heisenberg's doctoral student in 1928 and received his first professorial post four years later. However, in the following year he left as he was afraid of Hitler's power. In 1934, he settled in the United States and taught at Stanford University, where he became a professor in 1936. Between 1942 and 1945 he worked at the Los Alamos Laboratory. In 1954 and 1955 he was the first general director of CERN. He died in 1983 in Zurich.

At the same time, with the introduction of the first magazines focused on NMR, the use of high-resolution NMR for the study of phase transitions at the IJS began when Blinc from the United States brought the first liquid crystals in the early 1960s. In Ljubljana even Doane learned about newly advanced approaches, and he was employed at the State University of Kent in 1965. That same year, the Ljubljana Blinc's Group got its second Kidrič Prize for researching liquid crystals.

In 1966, an international congress for magnetic resonances AMPERE was organized in Ljubljana, which was attended by leading scientists all over the world. International connections were strengthened, since Blinc also collaborated with then Harvard PhD student of electromagnetic fields

[3375] Archive Of Republic Slovenia (ARS), SI_AS 1961 box 71, map 722; ARS, SI_AS 1961 box 72, map 723; Osredkar, Polenec, 2000, 314.

on the structure of liquid crystals. Robert Bruce Meyer (* 1943 Saint Louis) at ETH in Zurich. In 1986, they discovered polymerically distributed liquid crystals in which NMR proved particularly useful for studying the dynamics of molecules and phase transitions, although without distinguishing between thermotropic and lyotropic liquid crystals.[3376]In 1974, Blinc and Boštjan Žekš published a remarkable monograph on ferroelectrics and antiferroelectric. The following year, the other R.J. Meyer and W.L. McMillan of Department of Physics and Materials Research Laboratory, University of Illinois in Urbana published the theory of the average field for smectic liquid crystals. In 1974 at Harvard Robert B. Meyer announced the possibility of ferroelectric liquid crystals which he during his Parisian sabbatical synthesized as DOBAMBC ferroelectric with the help of L. Liébert, L. Strzelecki and P. Keller at Université Paris-Sud, Physique des Solides Orsay in the next year 1975.

Robert B. Meyer received his master's degree and doctorate in 1970 at Harvard University. Later, at sabbatical he led a research team at ETH and at the South Parisian University[3377] and became a professor of physics at Brandeis University, Waltham, Ma. USA.

In 1980, Noel Anthony Clark (* 1940 Cleveland) at the university of Colorado and Sven Torbjörn Lagerwall (* 1934) of Swedish college Chalmers discovered the technological significance of fast electro-optical switches from ferroelectric liquid crystals. Many studies followed in 1989 after the discovery of antiferroelectric and intermediate ferroelectric phases of liquid crystals of of Tokyo Institute of Technology graduate student A. Deeberam L. Chandani Perera from the Department of Chemistry in University of Peradeniya of Sri Lanka and her associates. By 1990, two hundred and fifty ferroelectrics were discovered, including fifty liquid crystals since 1984.

In 2000, Blinc's Ljubljana group focused their research on ferroelectrics and antiferroelectric exclusively favouring liquid crystals, thus rounding of three decades of their previous research. The use of NMRs has enabled a very accurate monitoring of changes in the magnetic fields of molecules, especially water, with continuous and discontinuous changes in the structure of the substance. Blinc’s department F5 was particularly successful in the study of disordered ferroelectric and antiferroelectric crystals, especially incommensurable systems in 1980s. Their solitons were discovered in the IJS and they proved the existence of phasic excitations. In the case of an incommensurable phase transition, a change in the size of the base cell can be observed at a longer temperature range, which occurs at a temperature point at ordinary transition.

The incommensurability extends the phase transition from narrow point to wide temperature range, even up to 111°C at Rb_2ZnCl_4.[3378] Stretching the phase transition gives a sense of the existence of a special intermediate state, like that of liquid crystals. An experiment with a stretched phase transition is like a microscope view. It reveals details to the variable structure of the observed object, which is not detected in ordinary passages at the temperature point. Similarly, a microscope reveals the components invisible to the naked eye. The telescope suddenly showed details at the surface of the moon to the fascinated Galileo, which were barely perceptible until then. Likewise, two centuries ago, Volta’s discovery enabled the prolonged times for observations of electrical phenomena that occurred in the older experiments with the discharges of the Leiden bottle only in the instant. There might be a possibility that no phase transition ~~n~~ever took place at the sharp constant temperature point as there is always some interval involved which makes incommensurable extension of the phase transition a general natural phenomenon like Faraday’s diamagnetism. Such idea profoundly changes the present concept of point-like thermodynamic systems phase transitions at constant unchangeable temperatures just like the telescope transformed point-like stars into measurable objects. Even the linguistics might change from melting point to melting range, which could be as huge innovation as the Copernican motions of the Earth as it is already in use for industrial and educational purposes especially in compounds where the practical *melting (boiling) range* is defined as the

[3377] Lagerwall, 1999, 1–5, 405; Blinc, Žekš, 1974, 150; Čepič, 1998, 14; Muševič, Blinc, Žekš, 2000, XI, 1.

[3378] Južnič, 1980, 29; Blinc, Žumer, Rutar, Seliger, Južnič, 1980, 610.

interval of temperatures from the *point* at which the crystals first begin to liquefy to the *point* at which the entire sample is liquid. The changed approach might even affect the phase transitions of non-thermodynamic systems, where temperature is not a parameter. Any experimental proof of the phase transition at ordinary temperature involving the incommensurable extension of that point into observable interval would be welcomed as it makes experiments cheaper without any liquid helium needed for cooling. The industrial application of relatively stable incommensurable phase at broad higher temperature interval could emerge considering its strange peculiarities and funny fact that Thomas Kuhn used the same term incommensurability.

The discoverer of the Solitons, Scott **Russell** (* 1808; † 1882), studied at universities in Edinburgh, Glasgow and Saint Andrews. In 1832/33 he received natural science lectures at the University of Edinburgh after the death of John Leslie (* 1766: † 1832) who used to be one of the most prominent advocates of Bošković's physics. Later, the Union Canal Company explored steamboat navigation along the canal between Edinburgh and Glasgow. In 1838 Russell first noticed the soliton there, which he described six years later. The phenomenon was called a "wave of translation". He also noticed that after the meeting-collision the solitons switched over each other without any special changes, which, when rediscovered 130 years later, delighted the researchers. However, in his time of dominance of wave theory, Russell could not see the similarity between the soliton and the particle while particles gained momentum in Britain only few decades later. He later used his observations in the construction of ships.

The Scotsman Russell's discovery was not widely noticed on the European continent. It was criticized by Russell's British compatriots the astronomer George Biddel Eary (* 1801; † 1892) and the leading British hydrodynamic expert George Gabriel Stokes (* 1819; † 1903) who did not believe in the existence of a soliton. Although Descartes's vortex theory in the 19th century, despite Newton's criticism, developed strongly in works of Ampère, Faraday, Maxwell, and Helmholtz, it was necessary to wait until the systematic theory of nonlinear fluctuations and waves. Only then the theory of solitons in a vacuum developed in the second half of the 20th century.

Upon returning from his two-year stay in India at the thin films department of the University of Sri Venkateswara, Tirupati, and at the Indian Institute of Science in Bangalore, the professor dr. Jože Gasperič was employed in Blinc's department in 1987/88. Blinc used the skills of his several months older classmate from a classical gymnasium in Ljubljana, professor dr. Jože Gasperič, the leading Slovenian expert in vacuum technology.[3379] Thus, the advancement of modern vacuum techniques in the solid matter research section gained momentum, and as a collaborator of Blinc's laboratories, Gasperič became exceptionally well established as the organizer of the DVTS activity.

30.2.1.5 Conclusions

Osredkar built his career as a partisan. He had been decorated in 1941 mainly for technical and project work for the radio Kričač. On 25 April 1946, he received a medal for his meritorious deed for the nation. On December 20, 1951 he got the decoration for courage and the decoration of fraternity and unity, in 1965 he was awarded a medal of the work with the flag, and by the order of the president on 16 November 1967 he received the following year the order of fraternity and unity with a golden wreath for the introduction of the radio transmitter Kričač.[3380] In 2001, he somewhat postponed the celebrations of his eightieth birthday with the receipt of the golden honorary sign of the freedom of the Republic of Slovenia. His staying in the US and Austria was of key importance for the Osredkar's cosmopolitan scientific path, closely linked with the introduction of modern vacuum techniques to the IJS.

Blinc, was a descendant of one of the richest families in Ljubljana, but Robert Blinc was able to adapt to the Partisan authorities with the Osredkar included. Blinc was the dean of FNT and head of the Research Society of Slovenia, longtime vice president of the SAZU (October 1980 - May 6, 1999) and in December 2007 the winner of the golden mark of the IJS for outstanding merits in the establishment, development and operation of

[3379] Jenko, 1997, 30: Pregelj, Zalar, 2002, 27
[3380] M. Osredkar's personal map (Archive IJS in Podgorica).

Jožef Stefan International Postgraduate School. On November 24, 2008, he received the Zois Prize for the year 2008 for lifetime work in the field of solid matter physics. The academician Robert Blinc raised his entire generation of influential scientists in his famous F5 section at the Jožef Stefan Institute. He had an exceptional gift for international cooperation: many foreigners who were visiting F5 could praise the extremely modern laboratory equipment, compiled according to the latest achievements of vacuum technology. On the other hand, they admired the fuel economy in F5, which was merely indicated by a small beauty error: the electric lights were always lit. Professor Blinc wandered through the F5 laboratories every morning and participated in a traditional tea party. His walk among colleagues was very like Ernest Rutherford's behavior at Cavendish's laboratories. Both were able to show to all colleagues that they were interested in their work, but at the same time they expected the soonest results and publications. Naturally, Rutherford liked to exaggerate, because in such a large laboratory he no longer knew all his subordinates. So, one afternoon, a nervous plumber broke into Rutherford's secretary's rooms and demanded the termination of the contract by which he was supposed to repair the water supply system in Cavendish labs. The surprised secretary asked him: "What's up?" The plumber-man refused to finish his job: "You know, during my morning work, I was struck by a high-pitched man who jelled on me few times why I didn't finish my measurement and when will I publish my results!"

We once warned the cleaner from the South Yugoslavian areas named Bosiljka that she must get her wristwatch away during cleaning around a strong NMR magnet in section F5, because otherwise her watch might be magnetized and therefore would not show the right time in the future. When we met her the next day we chattered, did she act according to our instructions? She proudly assured us: "Of course, I kept my watch in my pocket when I was cleaning around the magnet!"

In F5 Blinc also employed the expert for EPR and liquid crystals Marjeta Šentjurc (* 1940 Hrastnik), the daughter of leading communists Lidija Šentjurc (* 1911) and Boris Kraigher's first cousin Sergej Kraigher. That was one of the ways for Blinc's success to avoid the sufferings of his aunt Majda and Robert's grandmother after WW2. Blinc taught me how to find the references in the literature and how to cite them, and even showed me full packet of his refused papers so I learned that even he is not successful all the time. He was always taking and forgetting his pencils during his rides in F5 lab which put his own smell everywhere.

I enjoyed everyday tea parties at 10 o'clock where we talked mostly about sailing and the sailors' knots in F5. Once Blinc accompanied the Russian professor there and introduced me as an expert on Russian incommensurability studies because I just found the fundamental new book about that in DZS library in Ljubljana. I was so proud that I was hardly able to answer the question of the Russian even if I learned Russian well recently in Minsk. Once me, Blinc and another Russian professor were standing on the stairs of the university physics department and the worldwide leading expert for computer simulation of chemical structures Milan Hodošček run upstairs nearby barefoot with a slight short salute. The Russian looked at Milan's barefoot legs all the way upstairs and then declared deeply astonished: "With us at Lomonosov (university) that would not be possible (у нас на Ломоносове это невозможно)." Me and Blinc just smiled because we knew that Milan is a great guy.

Vinko Rutar was among the best Blinc's collaborators and loved to wear the white laboratory suit just as Blinc did, while the others avoided that habit. Later Vinko became the Director of Quality of energy absorption Systems, Inc. in Chicago. Blinc was always wondering how Vinko knows so much about laws until Blinc find out: "I see, your wife studied law!"

Blinc also lectured in general theory of relativity for us students of the last class before graduating, although he usually entered his classroom unprepared. Once during the break, he stopped me with a big book in my hand. When he discovered that it was Robert Merton's sociology of science book, he was not entirely happy, but anyway started to narrate how he was in West Coast of USA at Berkeley during the students' revolts in late 1960s. Blinc loved to talk about his many travels especially to Brazil where he weighted himself and measured out that he gained so many kilos. His friends then told him that the weighting there gave some extra heaviness because of the big nearby mountain full of iron ore.

When the Brazilians returned their visit to Ljubljana, Blinc offered them the machine for counting the votes in polls. The Brazilians smiled and refused as they say that their political system was just like the Yugoslavian system and there is no urgent need to count the votes as the winner is known in advance anyway.

30.2.2 Honorable Professor Janez Strnad

30.2.2.1 Introduction

Blinc's university classmate Janez Strnad, despite their joint research efforts at the IJS, went to the completely different unconnected ways of research. Robert was often a foreign critic of Strnad’s way for absolute devotion to the teaching only. I agreed with Robert on that point.

30.2.2.2 Study and Research Work

Janez Strnad (1934 Ljubljana-2015) was among the best students of Anton Kuhelj (* 11 November 1902 Opčine in Municipality of Trieste; † 31 July 1980, Ljubljana); the legend says that A. Kuhelj’s classes of mechanics did not even get anywhere if Strnad was not in the first benches of Kuhelj’s lecture room.

Strnad graduated in 1957 under supervision of Professor Anton Peterlin. His graduate thesis (diploma) was the continuation of the diploma of another important writer of Slovene physical textbooks, Rudolf Kladnik (* 1933; † 1996). While Kladnik prepared for Peterlin a diploma on reactor physics with a work "Double-core conversion of reactor systems with a homogeneous nucleus," Strnad continued a year later with a similar work "Double-bulk approximation in neutron diffraction in a reflector."

In the same year when Strnad and Robert Blinc (* 1933; † 2011) graduated under supervision of the professor Peterlin, the physicist Jože Pahor also graduated, but he later researched in other fields. The following year, Peterlin has awarded a diploma to another prospective physicist, the future professor of physics Franc Cvelbar (* 1932). Cvelbar focused on the Transformation of a Neutron Generator and Calibration of Neutron Crops. Nuclear physics was, for the most part, the only true path of Slovene physicists, although Peterlin and Blinc were both swimming against the stream into the solid matter physics.

Strnad received his doctorate on June 29, 1963/ 18 February 1964[3381] under supervision of the professor Bogdan Povh (* 20. 8. 1932, Belgrade) and under supervision of the associate professor at the Institute of Theoretical Physics of the Faculty of Science, Zagreb, Gajo Alaga (* 1924; † 1988); Marko Vakselj (* 1932) did the same.[3382] Strnad and Vakselj completed their doctorates after Osredkar took over the management of the IJS and contacted A. Peterlin in the US. Alaga was a student of Peterlin's friend Ivan Supek. After Peterlin's sudden departure, it was necessary for some time to look for supervisors for doctorates outside Slovenia, mainly in Zagreb.

Strnad measured the paramagnetic resonance on the IJS. He studied neutron diffusion, especially the theory of relativity and nuclear physics. He was trained in Heidelberg, where his supervisor B. Povh became a full professor on 8 December 1955. Later, Strnad frequently visited Giessen to research all about the teaching of physics and its history.

30.2.2.3 Teaching and History of Physics

For the purposes of his physical lectures, Strnad began to develop the history of physics, in which he focused primarily on the best Slovenian physicists, such as Jožef Stefan[3383] or Anton Peterlin.[3384] He helped a great deal in the dissertation on Graz professor of physics Simon Šubic. A large part of Strnad's several thousand published works goes back to the history of physics. The basic problem that interested Strnad and many others from his generation was the genesis of modern physics, which in the basic lines ended in the time of Strnad's birth but became the

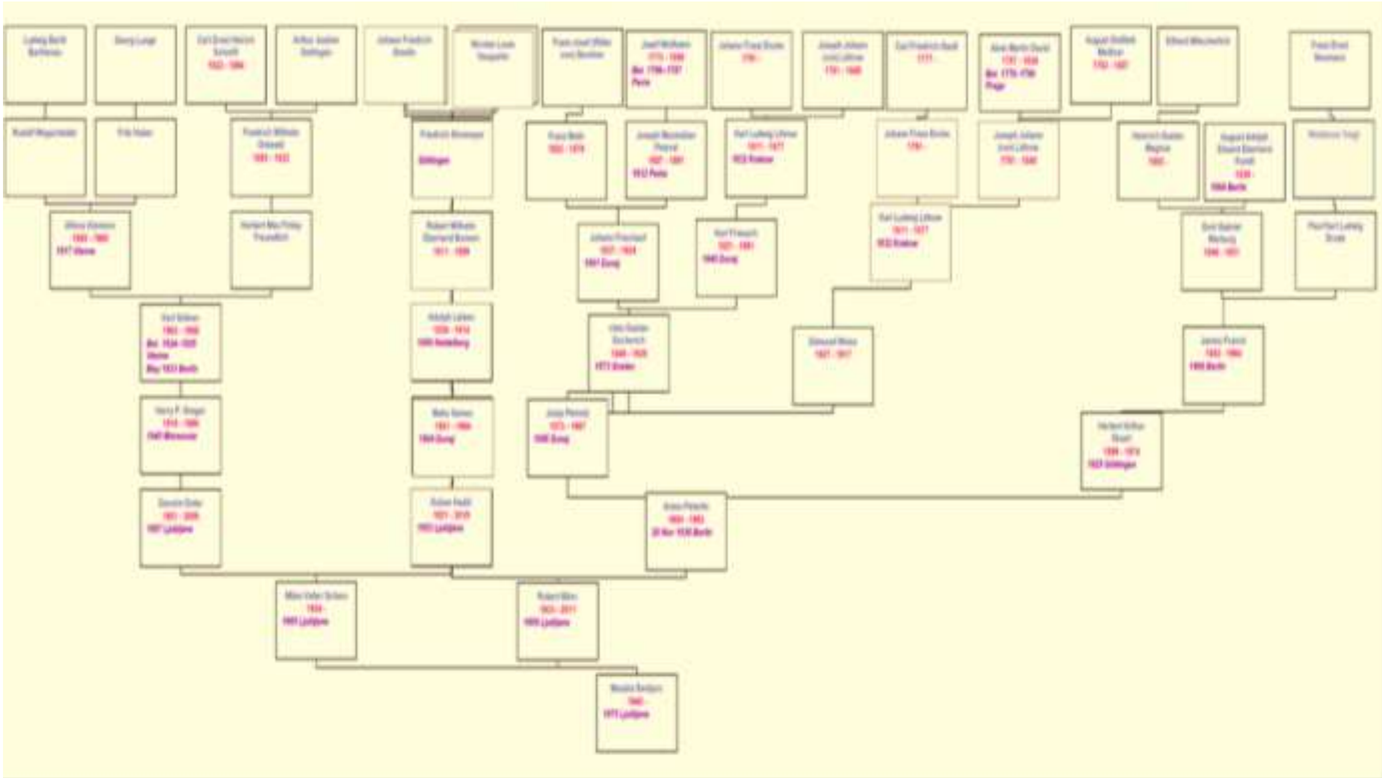

Figure 30-45: Academic ancestors of researcher of liquid crystals Marjeta Šentjurc including the Viennese expert of gas analysis, nitrochemistry and glow light electrolysis Alfonz Klemenc from Spodnja Šiška

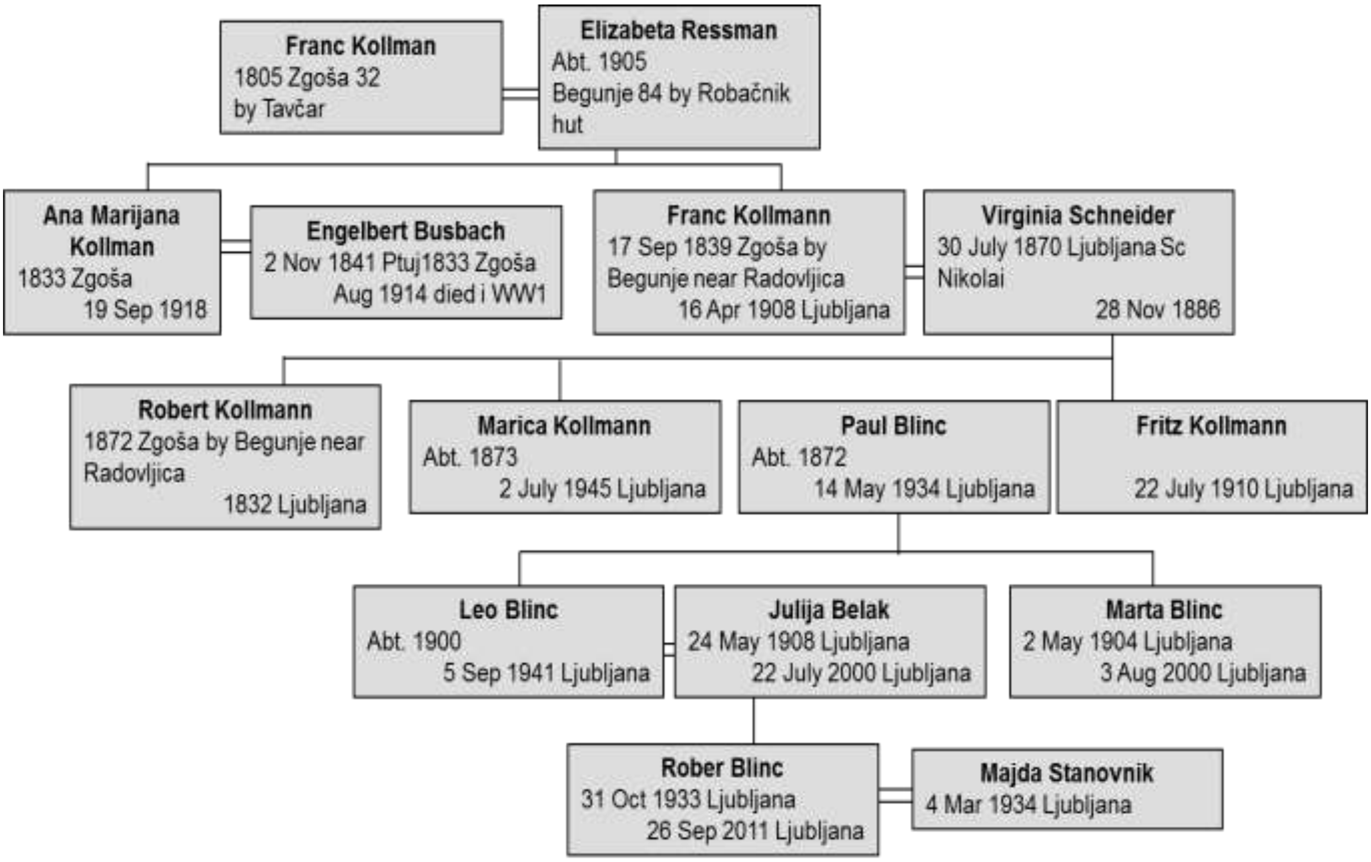

Figure 30-46: Blinc's family tree

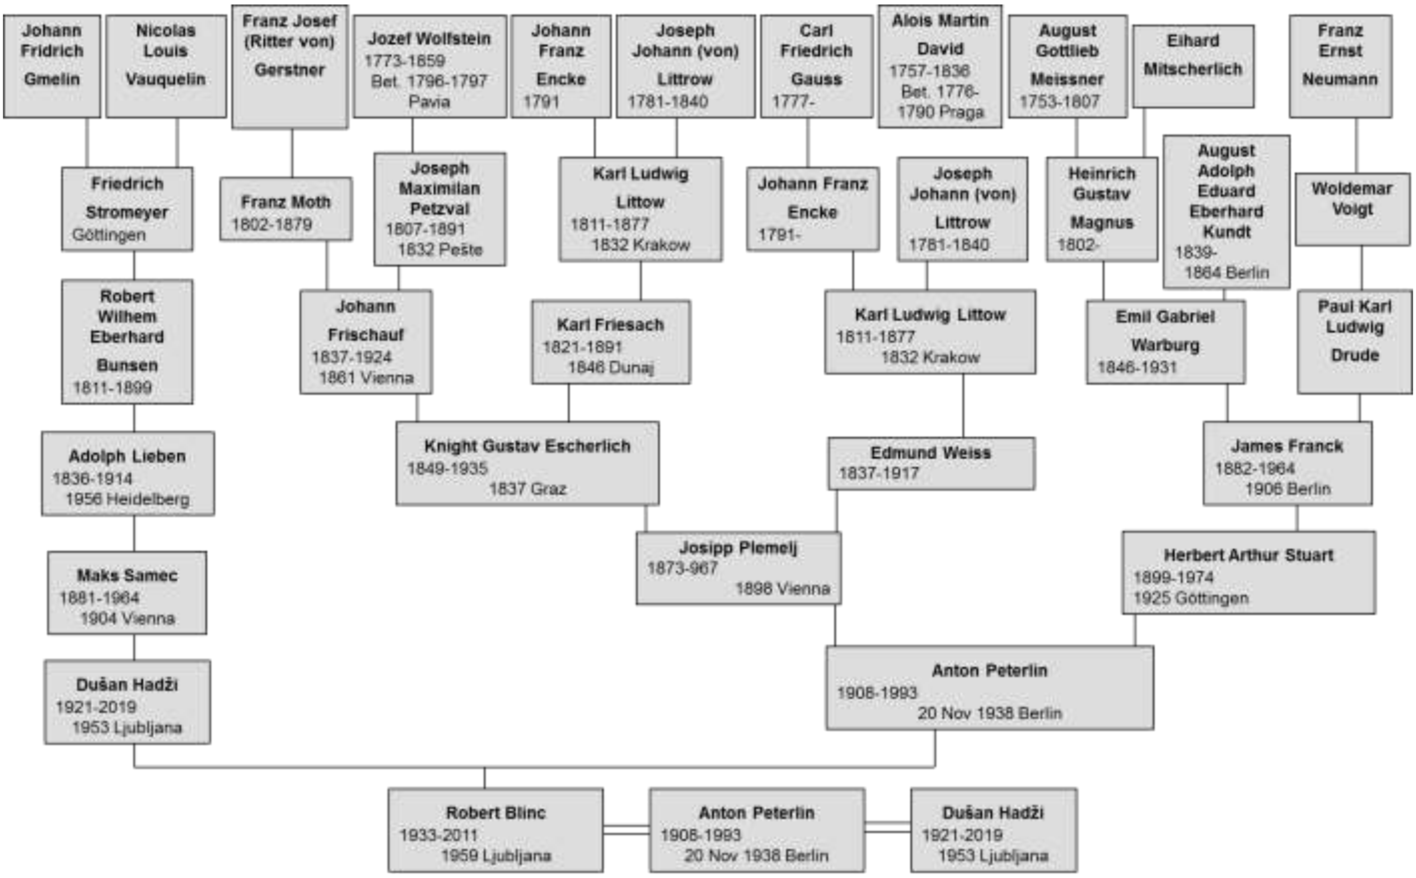

Figure 30-47: Blinc's academic ancestors

mainstream only after 1945 Japanese bombings. He correctly perceived the decisive importance of the rapid development of vacuum measuring techniques, especially Stefan's and other devices used for measuring the "black body" radiation in the decades before the First World War. He realized that top vacuum techniques had been the main incentive to develop often unusual achievements of the Copenhagen School of N. Bohr.

The professor Strnad described and drawn early vacuum experiments of Torricelli and Pascal.[3385] He was interested in the vacuum techniques of Ernst Rutherford's associates in Manchester, including Hans Geiger and Ernest Marsden.[3386] Among the rare experimental physicists in his opus, Professor Strnad studied in greater detail the work of American Leon Lederman (* 1920 New York; † 2018), who already in 1950 measured that many pions of the Synchrocyclotron of the Columbia University leave the vacuum container of the accelerator. Because of the magnetic field they then rotate outside the vacuum along the accelerator.[3387]

Ivan Kuščer was always the main Strnad's supporter after Peterlin's departure; in his humorous manner, Kuščer was jealous at the extraordinary speed of Strnad's publication, which Kuščer himself could not master. Kuščer and Strnad successfully used Slovene physical terminology in their textbooks, and often also interfered with the field of vacuum techniques. They liked to join the students for mountain trips to Kofce and elsewhere, where we listened carefully to their first-class sharp-eyed teasers, which were often difficult to follow.

30.2.2.4 Conclusion

In his final works, Strnad produced many wirelessly broadcasted shows on eminent physicists and posthumously published a little booklet on Doppler, his best unique inventive case study, the nicest he ever made.

[3385] Strnad, 1996, 100–101.
[3386] Strnad, 1996, 294–296.
[3387] Strnad, 1995, 145.

The honorable professor Janez Strnad is the iceberg of Slovenian history of physics. He also indicated many ways in the development of the use of vacuum measuring devices, especially for experiments that led to quantum mechanics.

30.2.3 The Valley of the Upper Kolpa for Slovenian Vacuum Researchers Once and Today

Strnad and Blinc were the teachers of us all. Numerous Slovenian and Croatian researchers of vacuum with their homes near Upper Kolpa river joined the 22nd meeting of Slovenian-Croatian vacuumists in Upper Kolpa valley of Osilnica in 2015. Among them Upper Kolpa experts are Janez Kovač (from Srobotnik), the first author of the Slovene post-war textbook about physics Franc Kvaternik (* 1919, Osilnica; † 1981), Matjaž Panjan and his uncle Peter Panjan (from Sodevci); their achievements were described by their neighbor from Fara by Kolpa river. An interesting fact of their success is explained by the extraordinary technical heritage of the inhabitants of the Upper Kolpa, which dates far back to the medieval mill used until 1651 for the processing of Carniolan iron ore by Count Petar Zrinski in Čabar. They exported the products through Bakar port. Andreas Kouach (Kovač, smith) was working there in 1672. As his surname indicates he was certainly something like a master blacksmith in Čabar areas.[3388] Aleksander Vilhar (* 16 February 1814, Mountain (Planina) no. 74 by Rakek, 1868) and Wilhelm Vilhar were immigrants from the Slovene side in the 19th century. They were brothers of the famous poet and F. Levstik's friend Miroslav Vilhar (Wilicher, * 1818, Upper Mountain (Planina) no. 74; † 1871). At the Milan Summit (Vrh) between Čabar and Prezid they designed one of the first Croatian steam turbines worked using vacuum techniques in 1847/48. Aleksander's grandfather Dušan Vilhar, a friend of the Rijeka patriot Frano Supil, made a steam saw based on updated vacuum techniques in nearby Gerovo; the physicist Franc Kvaternik was growing up somewhat westwards by the Čabranka and Kolpa riverbanks at Osilnica where, of course, he learned all about that saw very well.

The work of Vilhar family in the Gorski Kotar and the Maribor period (1878-1879) of the Military Krajina native Nikola Tesla were the first Croatian-Slovenian collaborations of vacuum techniques experts. Their 22nd meeting of Slovenian-Croatian vacuumists continues with their tradition. Tesla's transfer of the vacuum technique ~~of~~ from Karlovac (Rakovac) of Zagreb academician Martin Sekulić to Maribor finished infamously, although the urgently growing Maribor environment of those days had certainly affected Tesla's visions. Tesla coil and transformer, especially in the giant version at the Wardenclyffe tower, has increased Sekulić's Rakovac by Karlovac school-based laboratory models through Tesla's Maribor dreams about a free electric energy and similar necessities for everyone.

30.2.4 Duncan Haldane's Eight Part of Slovenian Nobel Prize

Duncan Haldane won the first eighth part of Nobel Prize for Slovenian physicists with his works related to Thin Film Research. The half Slovenian Duncan Haldane's topological research of electromagnetic properties of thin films are presently in focus. His approach might have some connections with his Slovenian heritage as he predicted the quantum computers' future.

The third try brings luck, they say. The third try has a charm. The Slovenian countries contributed to the three Nobel Prize winners: to the ancient Ljubljana born Fritz Pregl's prize for chemistry, to a part of the Nobel Peace Prize of Lučka Kafež-Bogataj, and recently, finally, to the quarter of the Nobel Prize of Duncan Haldane for physics and there is also Peter Handke who first spoke in Slovenian language during his Nobel prize ceremony. Each of these rewards is different, each covers different area. What did smart Duncan for such an honor?

Duncan's mother studied medicine in Vienna in 1942. There was not much help provided by her father Joseph Renko, brothers Franc (d. 1982), Pepi and Anton Renko (d. 1968) and sisters Alojzija Markič (Markitz, d. 1962) and Theresa Scheiber (d. 1998) or an uncle from Begunje in Upper Carniola Janez Renko with his daughter Jera Renko (* 14. 3. 1907) from Srednja vas (Central village) with the then valid number 2 between Begunje and Tržič. The old Slovenian proverb stated: When you go to Vienna, you leave your

[3388] Andreas Kouach at the settlement of Czabar (Burić, 1983, 182).

stomach outside (because it's so expensive in Vienna). More help was provided by Ljudmila's wealthy grandfather the trader in Carinthia Čikov (Tschithekoff) and from her mother Alojzija from Borovlje who married in 1906.
The Borovlje based forearms manufacturing supported Ljudmila's decision for profession of treating wounds. The lost Slovenian Carinthian plebiscite was among the reasons why the nationally aware Slovenian Ljudmila wished her son's name to be Dušan, the name of the greatest Serbian ruler of all times. With another son named John Stuart Haldane (6. 12. 1957-21. 8. 2000)Ljudmila did not have so many Slovenian second thoughts.

The teenager Duncan liked to go to Borovlje, where he learned German language as well as Slovenian language in the Inn Renko-Stiegler that still operates today on the main market No. 3.[3389]

30.2.4.1 Doctors for Thin Films

In Klagenfurt the young doctor Ljudmila helped the local wounded partisans together with her Scottish counterpart Frederick Paterson Haldane (24.5. 1912-15. 9. 1983) as a first-class basis for Duncan's London birth; Frederick was still married to Heulwen Morgan, who has given birth to their daughter Ana Haldane married Nuki (26. 6. 1936-2001) and to their son. Of course, in Klagenfurt Frederick was temporarily fascinated by the local Partisans, and even much more with the nice Carinthia native Ljudmila.

Duncan was a relative of celebrated Marxist Geneticist named John Burdon Sanderson Haldane (1892-1964). In 1924 he became famous after publication of his novel *Daedalus* with the first description of the birth of a man from a test tube as the ancestor of A. Huxley's Brave New world printed eight years later. The Slovenian thinkers used John Haldane as a role model with his research. He distinguished French theory of probability developed from gambling games, as opposed to English version of the same developed from insurance and the problematic O. Heaviside's Genesis of Leibniz's operational calculus developed for Maxwellian Electrical engineering in 1893. John was of course much more than just a mere special guy; that's why in his last years the British archipelago became too tight for him and he preferred to move under the Himalaya.[3390]

John's heritage and a native medical family guided Duncan's fate when he decided between the early developed of string theory and the solid state physics of thin films; he soon realized that the chemical-medical experiments of his parents are not his own innate love. He opted for his research of the solid state of thin two-dimensional layers or one-dimensional chains of small-scale magnetic atoms under the supervising of just awarded Nobel prize winner the atheist Philip Warren Anderson (* 1923) rather than for then most popular one-dimensional strings.

Duncan's eternal inspiration was Anderson. Just like the other J.H. van Vleck's PhD student Thomas Kuhn, Anderson also deeply understood philosophy of learning with his interpretation of phenomena "more is different" of broken symmetry of emergence structures that develop properties completely foreign to their own ingredients, such as thermites' mounds or Duncan's thin films. Not "more is better" of modern consumer society, but "more is different".

In 1977 Duncan's Cambridge Professor of physics Anderson earned his Nobel Prize in physics together with his teacher Van Vleck for their exploration of electromagnetic and unordered systems that soon enabled electronic switches and memory cells of computers. In the following year Duncan in his PhD thesis expanded Anderson model to the rare-earth elements with mixed valences.[3391]

After his initial research of rare-earth elements which for most of his readers seemed too strange to be correct, Duncan began to explore Tomonaga-Luttinger's liquids used to describe the behavior of electrons in carbon nanotubes, or of any fermions in different quantum chains-threads. The model of Fermi liquids is apparently not usable for single-dimensional tubes; therefore, the son of Jewish

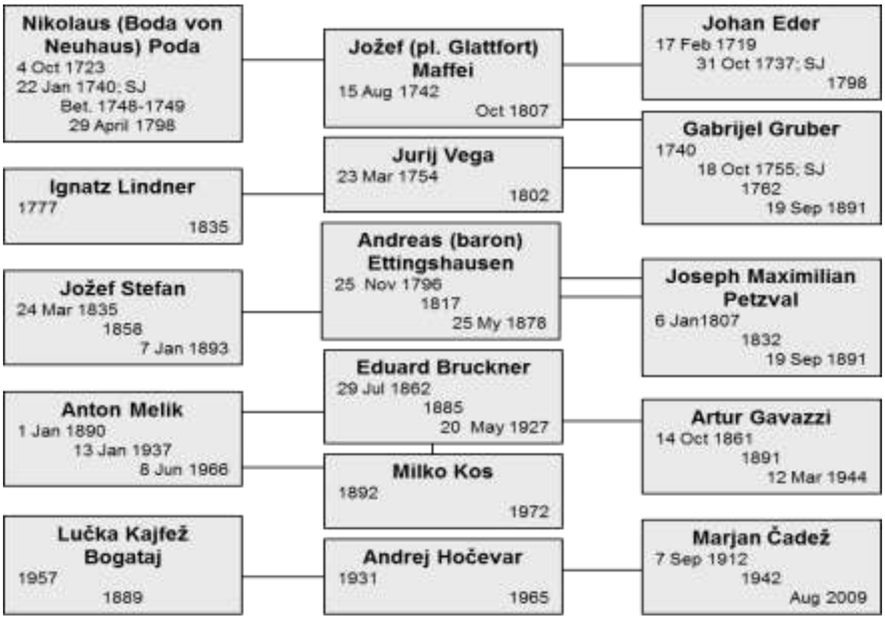

Figure 30-48: Academic ancestors of the first Slovenian winner of Nobel prize related to global warming Lučka Kajfež Bogataj all the way to Gruber and Vega

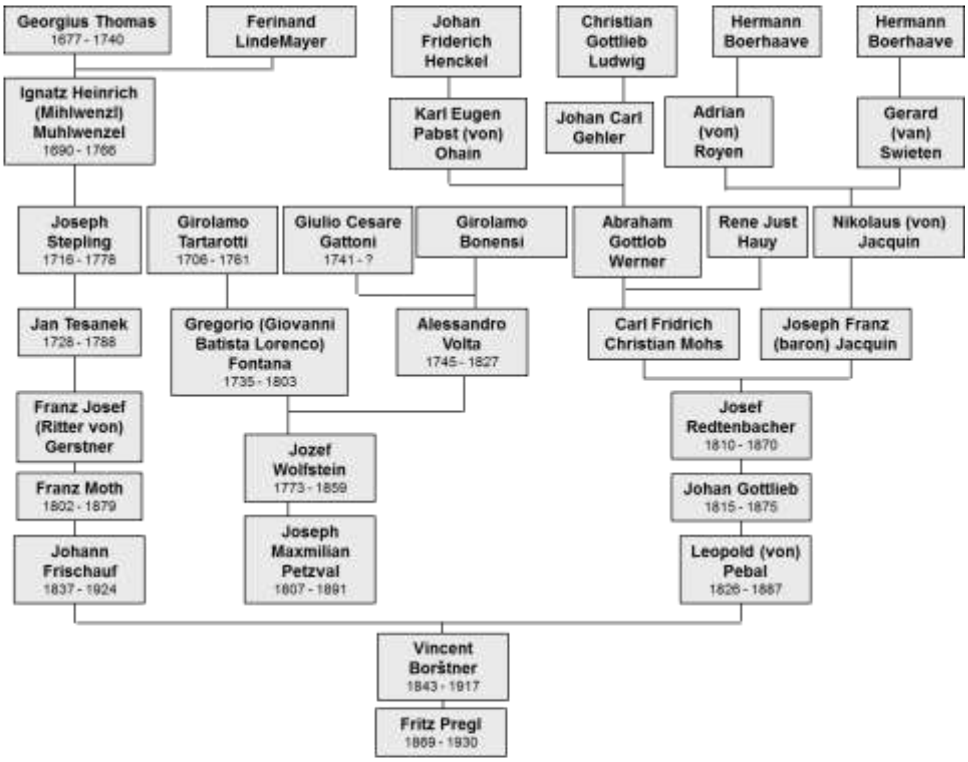

Figure 30-49: Pregl's academic ancestors according to his Ljubljana Professor Borštner, who also taught Pregl's junior Classmate Josip Plemelj (1873-1967). The family name Haldane was originally spelled Halfdane in the sense of a half-Dane due to the Danish Scandinavian Vikings, whose descendants settled in the Glasgow area before the millennium. Half-Dane would be the wrong mark today, because Haldane is half Slovenian. Duncan Haldane was in fact supposed to be Dušan by the original imagination of his mother, the Carinthian Slovene physician, Ljudmila Renko (Mila translated as People's pleasure, 24. 12.1919 Borovlje (Ferlach)-August 2016). Of course, her Scottish relatives pressed a little on the thirty-two-year-old mother and her small Slovene London oasis quickly surrendered. Duncan was very happy after that, because he avoided the jokes of fellow students with his better Londoner environment friendly name.

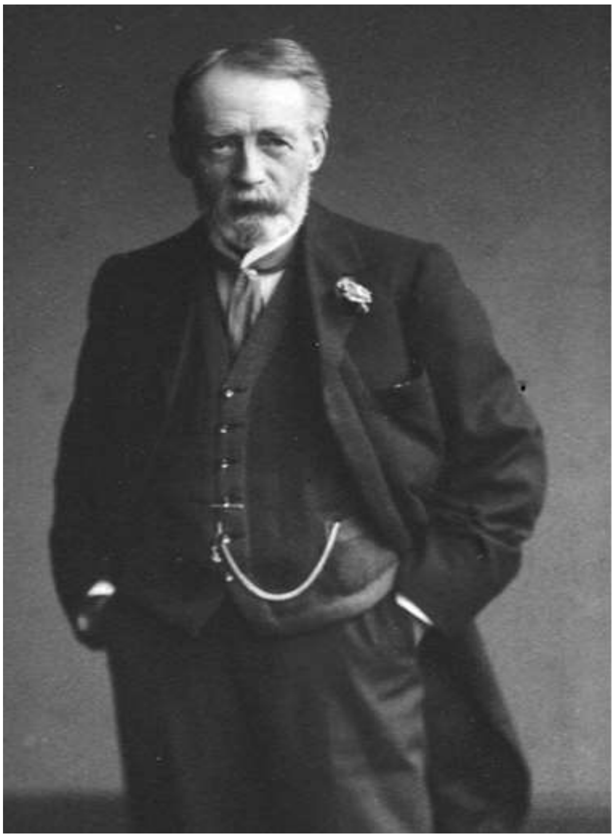

Figure 30-50: Duncan's grandfather Thomas Frederick Haldane (1839 Kran High Church Paisley Renfrew-1916 Paisley, Renfrewshire 10 km west of Glasgow near the airport) along with his younger brother Roberto (* 1841) headed the enterprise for drying of salts and chemical products as a good base for his offspring physicians and physics.

immigrants Joaquin Mazdak Luttinger (Quin, 1923 New York-1997) from Columbia University of New York described the low energy excitations of one-dimensional electron gas with bosons in 1963. He certificated the »plasmon« of David Bohm (1952) as wave-oscillation of the density of charge in the plasma of a gas of free electrons. Despite of Einstein's support, the left-winger David Bohm had

to live Princeton for Brazil, while his plasmons remained mainly at the Princeton anyway. In Fermi gas the plasmon behaves similarly to the photon in electromagnetic wave. Bohm's plasmon was created during the flooding of ideas focused on new quasiparticles which revitalized the old observations of solitons of John Scott Russell (1834), as well as new quasiparticles phasons in quasicrystals onboarded at phase transitions in incommensurable solids. The similar elementary particles had lost momentum of their prestige in nuclear physics; therefore, they were soon replaced by quarks from the imaginative book of the Irish Trieste immigrant James Joyce, while the quasiparticles established themselves relatively a lot deeper into their much more hospitable physics of solid state.

Figure 30-51: Duncan's great-grandmother Euphemia Bell (b. 1851) married Haldane at her wedding day on 6. 7. 1876 in Glasgow; Duncan, like his supervisor Anderson, worked for some time in the Bell labs of his distant cousin, American inventor of the phone.

The surface quasiparticles of plasmas enabled the further insight into the interaction between the light and the surface for welcome industrial influences of semiconductors and metals. The topology of plasmons has become a first-class tool for the interpretations of the unusual phenomena of superconductivity and magnetism of thin films with which researchers have increased the massive uses of thin films in the industry. The scattering characteristic of plasma thin films of the professor of Jožef Stefan, the Ježica by Ljubljana native Karl Robida (1857-1858), have found their theory in the research of their Carinthia countryman Duncan Haldane a century afterwards. So far Robida's and related experiments with thin films guided theoretical search, while Duncan's theories go the opposite way and give advice to appropriate measurements which bring profit, even if in 1988

Duncan did not advise~~d~~ any experimental verification of his ideas until it was achieved with new low temperature aids for the detection of fermions (electrons) developed in the welfare of the thin layer industry a quarter-century later.[3392]
After three decades of exploring one-dimensional chains of small magnetic atoms, Duncan was finally able to get into an additional dimension of two-dimensional thin films of his comprehensive Carinthia-based spiritual ancestor, Stefan's professor Karl Robida. In June 2011 Duncan embarked on other areas of research of plasmons in the fractional quantum Hall effect (FQHE), discovered in 1980 by German Klaus von Klitzing (* 1943) in electrons flowing unusually tidy while limited in thin films between two semiconductors near absolute temperature zero. The conductivity of electrons steeply grows up in the proportions of integers with the reinforcement of magnetic fields irrespective of the purity of the measured substance. That phenomenon is obviously a topological feature, just like the number of holes in the object.

With Thouless' FQHE Topology, Duncan went from one-dimensional system to a two-dimensional system of electrons. Duncan spread the original model of plasma of Stanford critic of global warming ecosystems Robert Betts Laughlin (* 1950) to the hierarchy of characteristic states of condensed quasiparticles. So, Duncan as a very especially stubborn son of a Slovenian mother with his second dimension of thin films returned to his once refused unpublished thinking developed during his post-doctoral study in Grenoble in 1981/82. A decade old discovery of superconductivity of the thin films of Haldane's British fellows Michael Costerlitz and David Thouless helped a lot, therefore they shared theor Nobel prize. Haldane first completed topology of unidimensional small chains of magnetic atoms resembling the former Ampѐre's vortexes.

Duncan ascribed to the even chains of such magnetic atoms the topological features of half-spins at both ends of the chain, but not to the odd chains. Those spins are in fact common properties of chains that can enable decoding of information in the future quantum computers[3393] at escalating speed and miniaturization, which is undoubtedly still waiting for us.

Duncan's topological insulators do not translate electricity in their internal parts but only through their thin-layer two-dimensional surface in their own kind of skin-effect that with much higher voltages fascinated Nikola Tesla's charismatic public appearances a century earlier.
Duncan's thin films maintain the same topological properties during their deformations, until we break them up. The topological Gordian knots resemble the ancient Alexander's knot or Descartes' vortexes: they are easy to follow, but hard to destroy, because they are protected by their own dynamics of preserved symmetry necessary to maintain the T symmetry (*Time Reversal Symmetry*).

There are no topological differences between most of the balls according to Duncan's speech at the Stockholm Nobel Prize banquet; the games with perforated balls and other similar accessories in the form of a popular bagel would be very interesting, such as, for example, the Sinjska Alka (Alka of Sinj) of Dalmatian Adriatic shore competitions from the 18th century or new American eight times pierced wiffle balls, perforated boomerang, or frisbees.

In the 1970-s the senior researchers still assumed that the two-dimensional ordered symmetrical structures of the thin films could not be persistent due to thermal fluctuations. Without order, the phase transitions between the individual phases cannot appear. Those erroneous doubts repeated the similar distrust in Laue's crystalline diffraction grid for X-rays because of its thermal motion six decades earlier. The hidden thermal fluctuations ultimately proved to be much more ordered than their initial designers Stefan-Boltzmann-Maxwell believed during early era of massive workers' motions in growing cities because those same workers steadily transformed form nameless objects into modern individuals.

It turned out that also for thin two-dimensional layers we have a persistent arranged topology. The phase transitions of two-dimensional thin films between states with different topologies (KT transitions of Michael Kosterlitis and David Thouless) show equally similar non-continuity of individual parameters as they are known at other phase transitions between aggregate states, but no symmetry breaking occurs.

The parameters of phase transitions are becoming increasingly unusual by developing of the research of thin films, even if the system of non-continuous transition from one state to another is always the same. Duncan's phase shift involves a non-continuous change of topologies of two-dimensional thin films. The low temperature superconductivity of thin films disappears during the topological phase transition at higher temperatures. The ancient (Descartes') swirls are adhering to solid pairs at low temperatures, but after the KT phase transition at elevated temperatures, however, those vortices abandon their pairs and fly separately. Already Descartes has proposed his simple model of a space full of vortices swirling in mutually opposite directions. Newtonians found all swirls completely unsympathetic, which, for some time banished them from Duncan Haldane's British archipelago, while Euler, Ampère, Cauchy, Gauss, Robida or Stefan's disciple Ljubljana-Maribor professor Luka Lavtar never abandoned those nice vortices.

30.2.4.2 Nobel Laureate in Bled

Between 26th and 30th April 2000 Duncan of Princeton was an invited Lecturer at the Bled Conference *Open Problems and Strongly Correlated Electron Systems*, headed by Peter Prelovšek (* 1949), Ramšak, Igor Sega and Janez Bonta (* 1960). Duncan lectured on the quantum Hall effect. He announced the phase shift of the first order of pairs of electrons and another non-associated phase with lines of compressed anisotropic Smectic Phase. Lines are one-dimensional arrangement of the density of charge in the high temperature superconductors, which were a little earlier discovered and confirmed in 1986, while their most quoted but incomplete theory was proposed by Duncan's supervisor Anderson in the next year.
Duncan proved that the observed lines are not related to superconductivity, because they belong to a special phase. In addition, among the thirty lecturers was also Vinko Zlatić (* 1974) from the Zagreb Institute Rudjer Bošković.[3394]
In Bled, Duncan told Peter Prelovšek about his mother's Carinthian Slovenian heritages. Duncan also narrated to Žlatić about her Partisan pursuits that could have deprived her of Austrian citizenship immediately upon her relocation to London. Of course, Duncan's work does not belong to an extremely eloquent or understandable readings but he combines his brilliant physics with extremely deep theoretical considerations.

30.2.4.3 Conclusion

The topology of the Seven bridges of Kaliningrad (Königsberg) and the polyhedral formula were designed by Leonhard Euler in 1736 and 1750. Euler's four years younger contemporary Bošković in the course of his visits in Ljubljana in 1750s and in 1760s researched dimensionless substances which he used to builds his three-dimensional substances with some difficulties. In 1832 and 1835 the Ljubljana Professor Leopold Karl Schulz Edler Strassnitzki has supplemented Euler's polyhedral formula by significant evidence, while in the following two years Augustin-Louis Cauchy added his own bettering in Gorizia. In 1847, Gauss' student and Weber's replacement as the Göttingen professor Johann Benedict Listing (1808 Frankfurt-1882 Göttingen) coined the term topology, while in 1870-s the slightly unbalanced Georg Cantor developed his theory of sets needed for the topologies. In 1895 Einstein's competitor Henri Poincaré, advances his topology in his *Analysis Situs*. In those days, of course, Duncan has not yet been even planed by his ancestors and even Nobel has not started delivering his fancy prizes. Anyway, all was ready for Duncan's performance except for the fact that physicists are delayed in their using of the imaginative novelties of mathematicians. In Duncan's case, the delay was a century long.

In the meantime, the scholars had to make sure that the small invisible particles really influenced the big ones: it was not just the particles of physicists and chemists, but even more the ones of living species, since Pasteur initially has convinced no one that a small bacterium can kill a big man or a horse; the people still feel like in Hippocratic's

[3394] Haldane, 2001, 203-213; Anderson, !!!5 1987. 1196-1198.

times. They preferred to see the environment as the cause factor of diseases of humans', dogs' and potatoes' (1845-1846) which Pasteur didn't particularly love. Barely a quarter of century of Pasteur's experiments with selective manual separating of one type of substance from other convinced our ancestors in microbes which the officious Pasteur found everywhere, even during his lunch.[3395]

Two-dimensional thin films and one-dimensional chains of small magnetic atoms of similar former Ampère's vortices already attracted the student Duncan Haldane much more than one-dimensional strings of fundamental quantum-mechanical research of uniform field theory. Instead of astrophysics, Duncan started with his solid substances, as he felt that the theory of strings somewhat damaged physics of post-Manhattan bombers because the whole generation of strings' fans in some way remained a torso. Two-dimensionality obviously offers more than one-dimensionality which soon also affected Duncan's Nobel pocket. His staying on solid soil of solid-state physics solids payed much better than buzzing on the strings of the foundations of physics. Undoubtedly, it is Noble to be Nobel's chosen one, but it is also the opportunity for Slovenians to supplement Duncan's Slovenian Nobel Prizes with the other seven eights.
The strangeness of a thin layer in Duncan's predictions was particularly typical of Nobel Prizes in 2016, as it has finally been touched by contemporary music, which has been a cradle of first-class literature for half a century, especially with Bob Dylan and his Stockholm deputy Patti Smith. Finally, the Swedish Academy acknowledged the new media that the Duncan's quantum computers continue to accelerate.

30.2.5 Merits of Modern Slovenian Experts Connected with DVTS, IEVT, IMT and IJS

30.2.5.1 Introduction

The Slovenian research of sciences related to vacuum has an eminent tradition. Prince Johann Weikhard Auersperg was nearly the only person whom Otto Guericke mentioned in his book about the pioneering vacuum experiments. Guericke reported that Auersperg's doubts forced him to modify and approve his tools. Auersperg just became prince and worked as the informal prime minister of the Viennese Emperor. He was born in castle Žužemberk of the present days Slovenia and died in his amazing baroque palace of Ljubljana where he collected many vacuum-related curiosities and the best private European library of his era where no vacuum-related item was missing. He collaborated with leading Jesuits vacuum researchers of his times including Gaspar Schott who pioneered the announcement of the Guericke's vacuum equipment. Schott's teacher Athanasius Kircher witnessed the early barometer experiments in Rome, dedicated to Auersperg a part of his book Oedipus, and donated many books to the Auersperg's library of Ljubljana. Later Auersperg became too mighty and the new Emperor forced him to live Vienna for Ljubljana where Auersperg began to spread his knowledge through his high society circle which included leading local Jesuit literati and Valvasor. Soon after his death the public higher studies were established in Ljubljana and Gorizia to match the already existing ones in Vienna, Prague, Olomouc, Graz, Trnava, Košice, Klagenfurt, and Zagreb of the same Jesuit Province. The Jesuit professors frequently rotated between those colleges and spread their knowledge initially based on Kircher and Schott's ideas of vacuum. A century after Guericke-Auersperg's Regensburg experiments a physics laboratory was established in Ljubljana Jesuit College under the leadership of the grandson of Auersperg's customs officer baron Erberg. In next decades the Ljubljana Jesuits shared their laboratory equipment with similar laboratories along the province to provide the relevant knowledge to their students who build up the modern Slovenian Vacuum Techniques. The 17th century Auerspergs were la crème de la crème and were not guilty for prince Alfred and Agatha Auersperg Nazism in 1930s and 1940's and also were not connected with the fact that prince Auersperg sold his Gottschee property to Italian-Fiume company at the best price to expropriate-resettle Gottscheers who trusted him in vain.

[3395] Dubos, Rene J. 1950. *Louis Pasteur Free Lance of Science*. Boston: Little, Brown and Company, 242-243, 248, 259, 265-266.

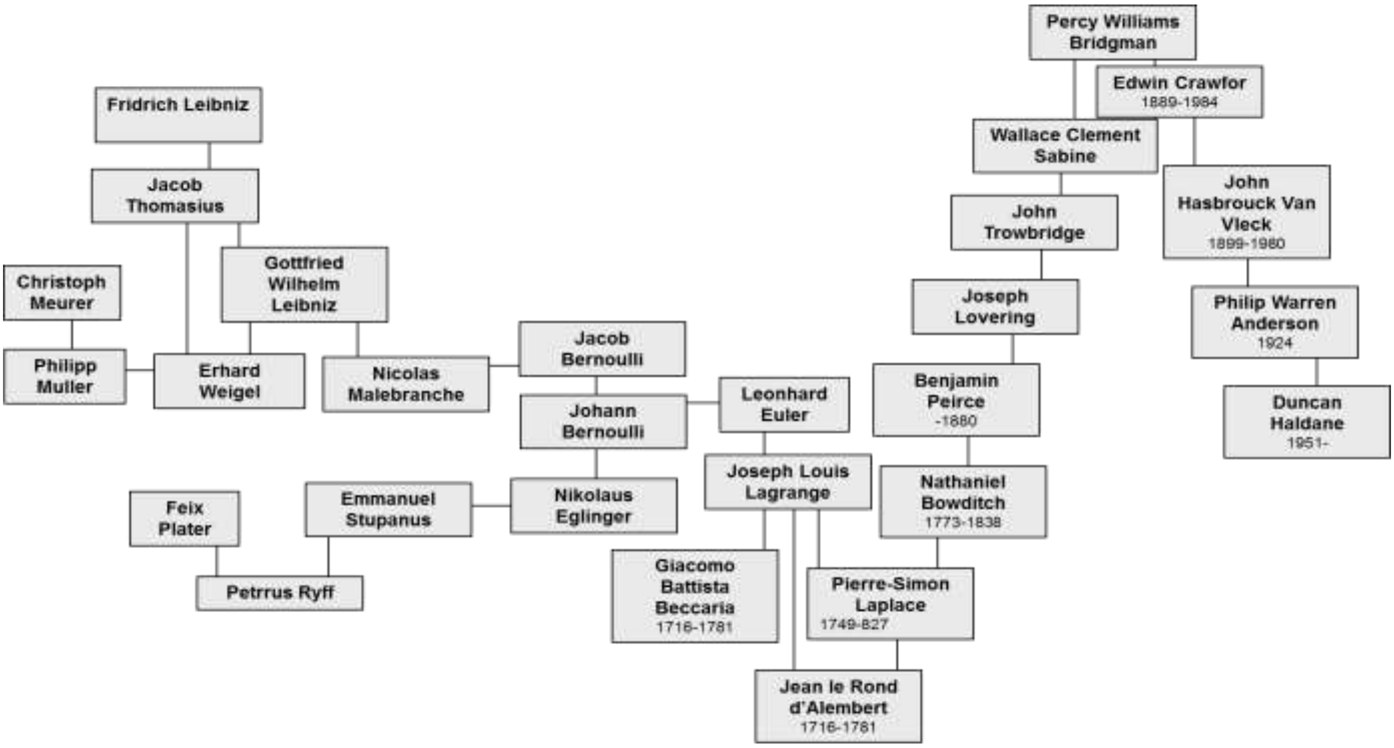

Figure 30-52: Duncan's academic ancestors in the history of electricity research including Bošković's friend Turin professor Piarist Giacomo Battista Beccaria. Duncan's Academic Ancestors down to the famous Leibniz, who founded the magazine Acta Eruditorum where Valvasor published about his Ljubljana thin walled sculptures

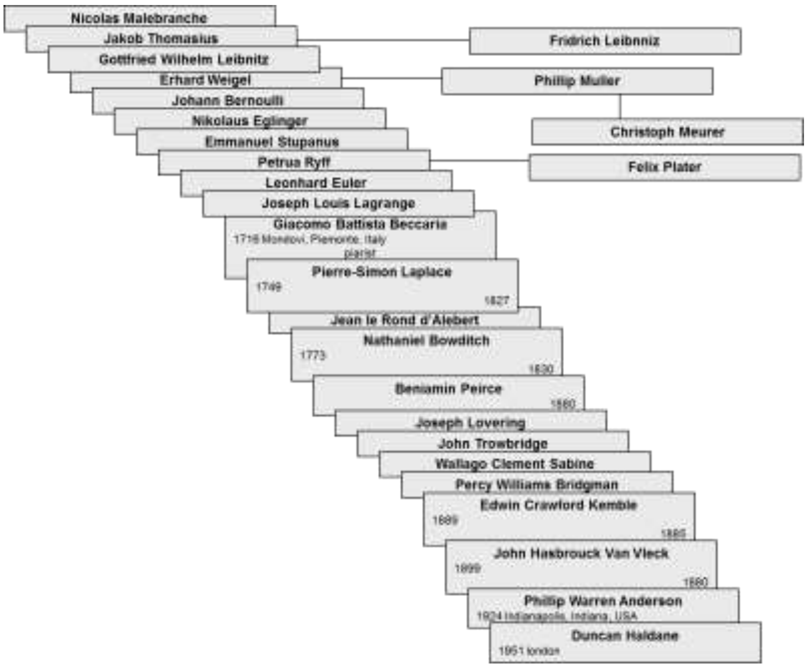

Figure 30-53: Duncan's academic ancestors selected according to their doctoral supervisings. The first professors of physics at today's elite American Harvard University were self-taught. Therefore, we had to attribute Laplace as an academic ancestor to Bowditch and the friend of his son Benjamin Peirce because of their translation of Laplace's works. Among Laplace's academic ancestors was also Lagrange because of Laplace's original publications in the Lagrange's Torino Gazette. Bowditch was grateful for his education to the local pirates. In the 1770s they robbed a ship on its way from Ireland to England during the Revolution and found onboard the library of Irish separatist phlogiston gas researcher Richard Kirwan (1733-1812). A century later, Americans no longer had to plunder European books, but rather brain drained their writers by the promise of their thicker wallet among Americans.

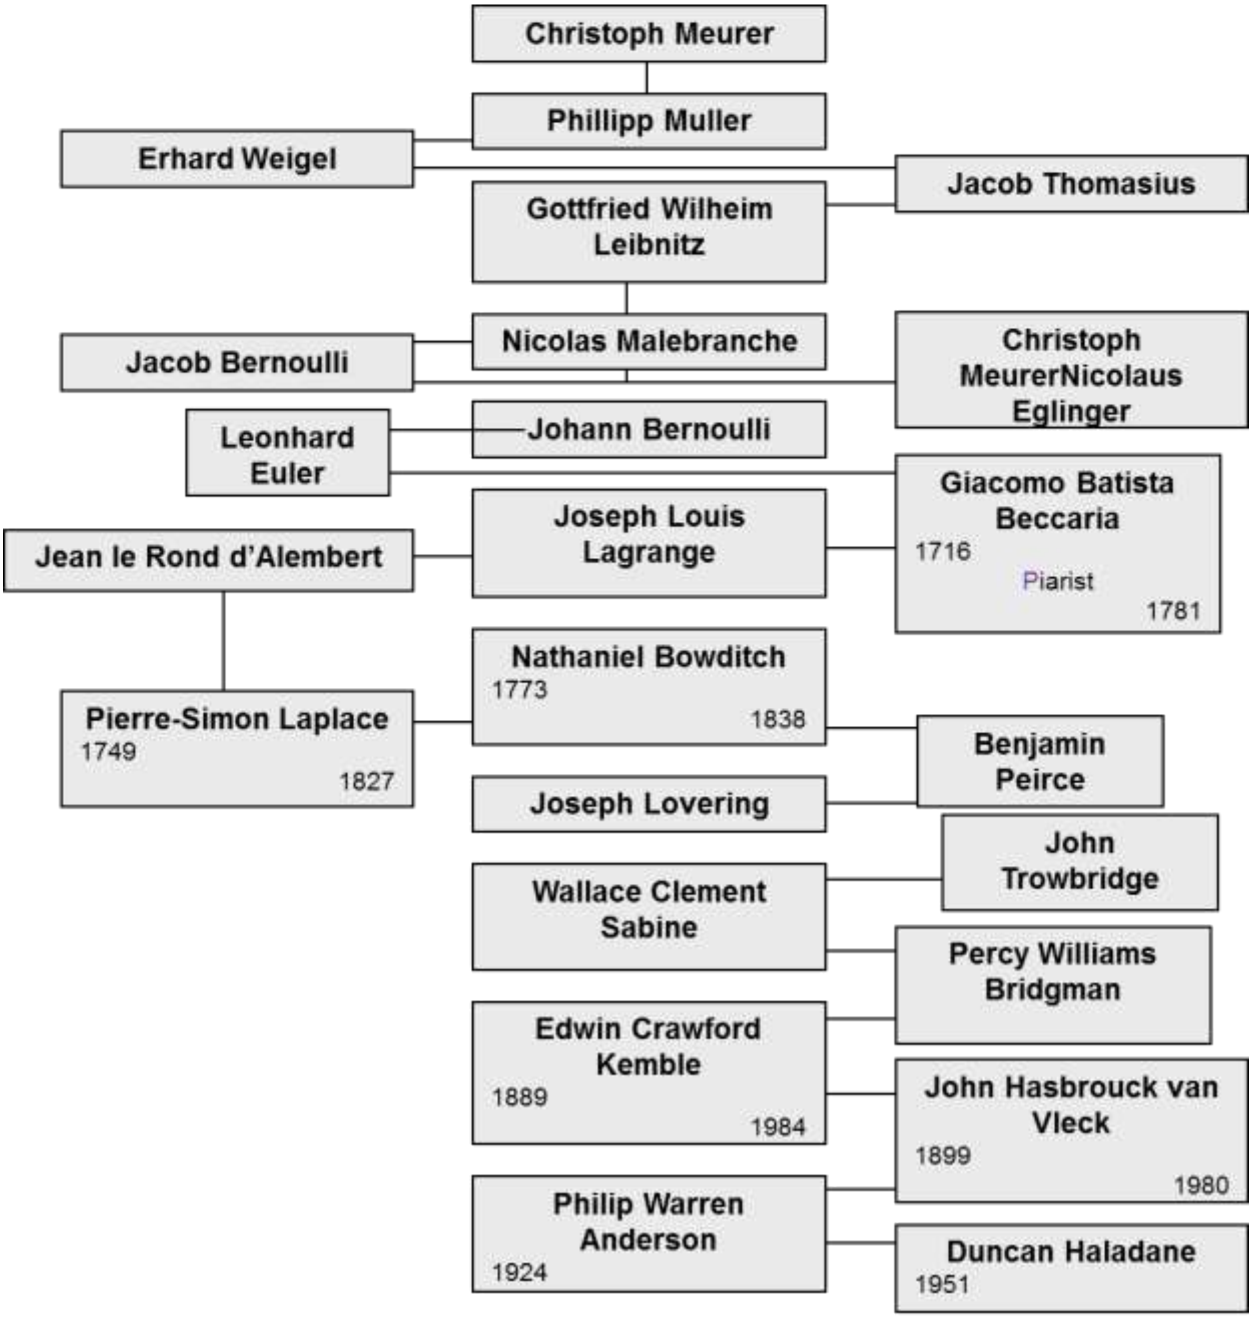

Figure 30-54: Duncan's academic ancestors from another point of view.

30.2.5.2 Institute for Electronics and Vacuum Technique (IEVT)

Auersperg's descendants in Ljubljana vacuum research especially flourished with Dušan Lasič and Evgen Kansky (1926-1987). Dušan Lasič (1908 Gorica-1980 Vrsar) graduated in 1933 in Electrotechnical section of Ljubljana Technical faculty in 1933. He joined partisans and headed the broadcasting radio in Stare Žage of Lower Carniola and worked for Ljubljana radio Kričač during WW2. In 1949 he established the institute for electronic of Ljubljana EF which under his leadership (1949-1966) developed into Vacuum laboratory on Aškerčeva 9 in Ljubljana in 1950 to give birth to IEVT named in 1970s. As a leading researcher of cathode ray tubes, he was the first president of Yugoslavian center-committee for vacuum technique (JCVT) from 23rd October 1960 to 1962 when he was replaced by Kansky. Among his collaborators in IEVT was his wife Vida Jelka (1920 Zagorje ob Savi-1997 Ljubljana) who also worked for radio Kričač of Ljubljana during WW2. She graduated from the Faculty of Electrical

Engineering, and after graduation led the experimental production of electronic elements in the field of vacuum technologies at the Institute of Electronics and Vacuum Engineering in Ljubljana. Dušan Lasič was a great Alpinist and passed his passion to his IEVT collaborators including Jože Gasperič. Dušan Lasič's son the pioneer in the development of liposomes in medicine Danilo D. Lasič (Dan, Laki, 1952-2000) world-renowned authority on liposomes, passed away at his Newark Californian home on October 14, 2000 at the age of 48 as a leader of his own firm Liposome Consultations in Newark. He did not witness the new biotech millennia he helped to build as heart attack carried him away in front of his home TV while dreaming about his new farm in Nebraska. Dan did not bother much for his insurances which forced his Californian collaborators the Greek Stelios Tzannis of Inhale Therapeutic Systems Inc. (today Nectar Therapeutic in San Francisco) from San Carlos (now resident of Newark) and Jeffry G Weers from Inhale Therapeutic Systems Inc. in San Carlos (now resident of New Mexico) to collect funds for education of his daughter the translator and even IJS discussed the possibility to cover the cost of his last medical treatments. Dan was born in Ljubljana on August 7, 1952. He graduated from the University of Ljubljana in 1975 with a degree in Physical Chemistry. He received his M.S. in 1977 at the same University and his Ph.D. degree with his research of the lyotropic liquid crystals in 1979 at Blinc's Solid State Physics department at the J. Stefan Institute in Ljubljana. There he collaborated with a writer of this lines always encouragingly asking about the time I had to wait to get the results of my experiments and cheering when I told him about the short time needed. He then undertook postdoctoral studies with Dr Charles Tanford at Duke University, and Dr Helmut Hauser at ETH Zurich from 1982 to 1984. In 1984, he returned as a research fellow at the B. Kidrič chemistry institute and J. Stefan Institute, where he remained until 1986. In 1986, he became visiting professor at the Department of Physics at the University of Waterloo in Canada, and in spring 1988, he continued his research at Clarkson University in New York. In September 1988, Dan left east coast for west coast to join the Liposome Technology Inc. (LTI), now the Alza Corporation in Menlo Park, CA, as a senior scientist and widely collaborated with Rudi Podgornik. While he searched for new feasibility of molecule modulations, he led studies designed to provide a theoretical understanding of long circulating (stealth) liposomes discovered in 1961 as entities having at least one lipid bilayer. His academic research on the thermodynamics and mechanism of vesicle formation was an excellent preparation for his active participation in the development of 'stealth' liposomes at LTI(Lymphoid tissue-inducer cell). He also developed the first formulations for preclinical studies and actively contributed to the scale-up of a 'stealth' liposome laden with the anticancer agent doxorubicin. This formulation later became the first US Food and Drug Administration (FDA)-approved liposome formulation in 1995. He began research on interaction of cationic liposomes with DNA, and the use of these complexes in gene delivery and gene therapy. In March 1994, Dan joined Megabios Corporation Burlingame, CA (later Valentis, Inc. at Burlingame), where he continued his research on cationic liposomes, DNA lipid complexation and associated scaleup issues. Shortly after leaving Megabios, as the US citizen he formed his own consulting company, Liposome Consultations Newark, CA. in October 1996. Over his last four years, he worked in various ways with the Drug Product Research department at Roche Bioscience Palo Alto, CA. Dan published more than 160 refereed papers in prestigious journals, including Science, Nature and Proceedings of the National Academy of Sciences (PNAS), while giving numerous invited lectures. Furthermore, he authored or edited seven books on liposomes and drug delivery, including: Liposomes: From Physics to Applications Elsevier, 1993, Liposomes in Gene Delivery CRC Press, 1997, Stealth Liposomes CRC Press, 1995, and a four-book series, Nonmedical Application of Liposomes CRC Press, 1996. His best-known papers are those that deal with thermodynamics and the mechanism of vesicle formation, the origin of biological environments stability of spherical vesicle liposome, their gene delivery related to viruses, and the applications of drug-laden liposomes. He postulated the first model of liposome vesicle formation widely known as the 'Lasic model'. Dan has been the co-inventor on several patents on the application of liposomes for the delivery of doxorubicin and other anticancer drugs. He received numerous citations and mentions in the 'Who's Who in the World', 'Who's Who in the West', 'Who's Who in Science and Engineering' and 'Men of Achievement'. He served on the

Editorial Board of several journals including the Journal of Liposome Research and Current Opinion in Colloid and Interface Science, where he was also a section editor.

Dan's success was enabled by his awesome Ljubljana predecessors. Evgen Kansky junior was a son of medicinal-chemist of Jewish genus Evgen Kansky (1887 Warsaw–1977) and a chemistry expert mother Ana Mayer Kansky (Anka, 1895 castle Lože by Vipava–1962). After she completed the first (female) PhD in Ljubljana in the chemistry class of Maks Samec and his assistant Marius Rebek (Marij, 1889 Barkovlje (Barcola) suburb of Trieste-1982) in June-July 1920, Ana Mayer married Evgen Kansky next year. She taught at Secondary Technical School in Ljubljana after WW2 where the teachers from IEVT lectured about the vacuum techniques to the students of final 4th class of electrotechnical department in 1961 and 1962. By the recommendation of the Bohemian president Tomáš Masaryk her husband Evgen Kansky senior moved to Ljubljana, where he taught chemistry and physiology at the newly founded medical school. He and his wife founded a chemical company in Podgrad by Zalog by Ljubljana in 1922 to produce ether and its compounds which made Ana the very first Slovenian female user of sophisticated vacuum techniques. Her husband was president of the International Society of High Vacuum Chemistry.

In summer 1950 Dušan Lasič (1908 Gorica-1980 Vrsar) invited Evgen Kansky junior and France Lah to the Institute of the weak currents of the Ljubljana Electrotechnical faculty which later developed into institute for Electronic and automatization and then to its heir IEVT. Evgen Kansky junior graduated in 1951 and received his PhD in 1961 at FNT of Ljubljana. Evgen Kansky junior was a professor of chemistry and thin-films analysis in vacuums at the University of Ljubljana's Faculty of Natural Science and Technology. In 1990 Peter Panjan edited for DVTS Kansky's textbook Nastajanje in rast vakuumskih tankih plasti (Vacuum thin film formation and growth) as Kansky's great posthumous heritage.[3396]

The research of vacuum related tools in Slovenia was further advanced by Paulin, Andrej Pregelj, Gasperič, Zalar, Šetina, Mozetič, Nemanič, Kovač, Monika and Bojan Jenko. The professor Alojz Paulin (Pavlin, * 1930 Podbrezje in Franckova house) is the oldest Slovenian Vacuum researcher today. He has mainly developed accelerators, and today as the pensioner lives in his native areas of Tržič. Among his PhD students was also Janez Kovač whose ancestors were at home from Srobotnik in Kostel where his mother organized the building of the local bell tower in 1990s. After graduating at Kočevje Grammar school Janez Kovač graduated in physics of nuclear quadrupole resonance in J. Seliger's class (1990) and studied electrical characteristics of Schottky's structures for his PhD in Paulin's class in 2000. Kovač was trained in Bazovica (Basovizza) Elettra-Sincrotrone near Trieste in Italy andlater joined IEVT which subsequently became the part of IJS. Until 2020 Kovač was a president of DVTS and then the general editor of journal Vakuumist.

In 1979 Andrej Pregelj graduated with the work Technological utility of blacksmith rolling at the Faculty of Mechanical Engineering in the class of Karl Kuzman (* 1941 Vitanje northeast of Celje halfway to Žreče). In 1994 Andrej Pregelj crowned his education with master's degree focused on Compact microwave tube: design proposal for measuring HF properties of superconducting materials in Paulin's Maribor class as an able experimentalist lastly working for the lighting protection in Iskra. His wife is the granddaughter of the chief J. Plečnik's liberal competitor architect Ivan Vurnik and the leading Slovenian physicist Slobodan Žumer (Daša, * 1945) is Andrej's brother-in-law. Andrej Pregelj became the heading figure in Ljubljana gymnastic society Sokol as its president in 2007-2015 where he regretted that his organization never got back its nationalized real estates in Bežigrad unlike it's happier Sokol branches in Zagreb and Bohemia who received back their property lost after WW2. After the suppression of his IEVT firm Pregelj got his new job in Iskra lightning rods production. Soon afterwards he retired to his house in Mirje by Roman Walls in downtown Ljubljana where he disliked frequent sitting behind the computer but loved to write and research about the local history of vacuum techniques and the Slovenian Sokol. Pregelj is among rare nice persons who managed his friendly relation with Paulin and Gasperič in the same time as Paulin stated that Pregelj's

[3396] http://www.dvts.si/arhiv/1984/1984_2/1984_2_1_100dpi.pdf retrieved on March 3, 2020 masters' thesis is more valuable than most of the PhDs.

Prof. Dr. Miran Mozetič received his B. Sc. Degree of Physics from the Faculty of Natural Sciences and Technology, University of Ljubljana, Slovenia in 1988. In 1992 he received the M. Sc. Degree from the Technical Faculty, University of Maribor, Slovenia, and in 1997 the Ph. D. Degree in electronic vacuum technology with his research of hydrogen plasma interaction with solids surfaces at Paulin's class of the Faculty of Electro-technique, Computer Sciences and Informatics, University of Maribor. In 1993 he attended courses on Application of synchrotron radiation techniques at International centre for theoretical physics in Trieste, Italy. He joined Jožef Stefan Institute in 2003 and since 2009 he is the Head of Department F4 (Department of Surface Engineering) developed from the former DVTS as the leader of a research group of surface engineering. His research interests include interaction of nonequilibrium plasma with organic and composite materials, fusion oriented research on plasma surface interaction from his PhD, plasma nanoscience and plasma techniques for biomedical application. His R&D activities are related to plasma science and development of plasma systems for industrial applications. His bibliography includes about 30 patents granted by different offices and 300 scientific papers with H-index of 37. He was a president of DVTS before Janez Kovač took over.

Vinko Nemanič of Bela Krajina origins graduated from the class of M. Kregar in 1981 and started his research optoelectronic for special cathode ray tubes in IEVT in the group of E. Kansky. He received his master's degree in the class of A. Paulin in Maribor in 1991. He received his PhD with a research of vacuum thermic insulation at the class of Alois Poredoš and Peter Novak in 1997.

30.2.5.3 Jozef Stefan Institute (IJS)

Kansky's colleagues excelled by their research of the thin films including Boris Navinšek, Peter Panjan, J. Dolinšek and Miha Čekada. The basic research of thin films is engaged in the section for thin films and surfaces of the Jožef Stefan Institute (IJS), notably in cooperation with the Balzers company. In the first half of 1960s professor Dr. Boris Navinšek produced the first simple "desktop" device for ion bombarding and Ion etching while his results of the 1965 were reported in the American Magazine and in 1964 in the editions of IJS. He received his PhD in the year 1968 and further graduated in the class of director Osredkar with the research of the surface effects and radiation etching caused with low energy ion bombarding in solid and thin-film targets. As a kind of prophet, he promoted his early idea of the advantages of streamed sputtered protective layers, which he presented with his collaborator Viktor Kraševec at consultation on the new methods of surface protection of NATO's Advanced Study Institute on Science and Technology of Surface Coating at Imperial College of University of London in April 1972 with their anthology published in edition of Brian N. Chapman and the keen Jazz pianist Imperial College chair Joseph Chapman Anderson (Andy, 1922–2001) two years later. Navinšek's group assembled its own ion bombarding device and while their sputtering tool Sputron was purchased at Balzers in 1978. In their home workshops they produced a cylindrical sputtering device with titanium cathodes for the application of hard-coated tools.

At the end of 1970-s after large investments and many researches the Balzers has penetrated to the promising market with hard protective coatings. In 1983 the Balzers began to develop its special research and production centres on all continents to provide Balzers's leading place in the world. The Balzers supported the participation of the Ljubljana Group, which protected domestic thin-layer technology with the patent and the brand JOSTiN in the twenty-three countries of Europe in 1983. On 18. 12. 1985 they opened the centre for hard coatings in Domžale. There for industrial needs they covered tools by protective coatings with an evaporation apparatus Balzers BAI730 including all the required tools for the TiN coatings whose purchase financially supported the Slovenian firm SMELT.

After the discovery of high temperature superconductivity in 1986, research of thin films from modified $YBa_2Cu_3O_{7x}$ (YBCO) based on Sapphire (Al_2O_3) and MgO also started at the IJS. The products are used for precise magnetic field meters. The basis of MgO is particularly useful because there we can achieve a critical temperature above the boiling point of N_2 at the temperature 77 K.

The quasi-crystalline coatings soon became one of their best tools. The professor Navinšek retired in 2002 while for next leaders of the department of his thin films at the Jožef Stefan Institute, he successfully employed Peter Panjan and Miha Čekada. Peter graduated in 1980 at F. Cvelbar's class and received his PhD at the Ljubljana Faculty of Metallurgy in the field of materials, the same as later did Dr. Čekada, who took over the leadership of their department in 2012. In 2004 together with J. Dolinšek he took over the advantages of high hardness quasi-crystalline covers and began to produce the extremely solid covers among the first in the world. Under the then liberal government with Gregor Golobič (* 1964 Novo Mesto) as Minister for Science and Higher Education of Slovenia between November 2008 and June 2011 with the motto: "Znanje Žanje" meaning that the "knowhow gets the harvest" P. Panjan's department purchased many new tools in their new headquarters in the basement of IJS.

30.2.5.4 Institute of Metals and Technology (IMT)

Most of Ljubljana vacuum research and educational facilities were always located in Vič area southwest of Roman Town Walls of Mirje including IJS, EF, IEVT, and IMT. Janez Šetina heads the Pressure Metrology Laboratory Institute of Metals and Technology (IMT, Institute of Metals and Technology) with expertise in Instrumentation Engineering. His senior Monika Jenko of the Department of Physics and Chemistry of Materials of IMT completed her PhD in Material Science at the University of Ljubljana. For eleven years she was the director and initiator at the Institute of Metals and Technologies (IMT) and later joined the Jožef Stefan International Postgraduate School with Advanced Metallic Materials in the framework of the Nanoscience and Nanotechnology study program with an expertise in the field of Material Science, Applied Surface Science, Surface Engineering, Nanoscience and Biocompatible Materials

30.2.6 The First Slovenian Female Vacuum Researchers

30.2.6.1 Introduction

Monika Jenko certainly belongs to the best users of vacuum technology, while she has valuable predecessors and descendants. The brave empress Barbara of Celje opened our story of new materials and vacuum technologies. Many important men followed her pioneering calls through the centuries. Almost half of millennia passed with the research at least officially almost entirely belonging to wealthy white man's business. Suddenly it happened and their monopoly ways were broken with academically trained woman, non-whites and sometimes even the children of poor families. The Slovenes have always been deeply aware of the achievements of women scientists. We have explored that development from the first books of female physicists available in areas inhabited with Slovenians up to first Slovenians female vacuum researchers, who studied before 1963.

30.2.6.2 Writers about Vacuum Techniques and First Female Students of Physics

Already in 1678, the new Ljubljana bookstore of Janez Kersnik Mayr offered to the erudite of Ljubljana mathematical and astronomical works of Maria Kunic married von Love (Kunitz, Cunitz, † 1664). Among 2566 Mayor's titles, her book was the only one written by a woman's hand. Not far from the Slovene national territory, the first lady of mathematics Maria Gaetana Agnesi (* 1718; † 1799) took over the chair of mathematics and science at the University of Bologna in 1750. Five years later, the Trieste professor of mathematics, Franjo Orlando, had already acquired her book on analysis for his instructions of the future sea captains and skippers. F. Orlando taught many Slovenians; so, Slovenian ancestors have long known that mathematical and physical sciences are not entirely male occupations.

Among the first books on solid state and crystals was the work of Elizabeth Fulham, the wife of dr. Thomas Fulham. In her high English society, she discussed with the most important scientists of her age, especially with Joseph Priestley. Her thinking about phlogiston was very interesting for Lavoisier in Paris. Unfortunately, Lavoisier lost his head a few months before the publication of Elizabeth's book, which contained even the beginnings of the subsequent discovery of catalysis.

Slovenian vacuumists began to establish themselves a century ago, when women began to enroll at the universities of the late 19th century. They were another new type of students, which until then had no almost no official academic duties among Europeans. Just before the First World War, the image of the lecture rooms suddenly changed dramatically.

Among the first female vacuum researchers, the Jewess Phoebe Sarah Marx (Marks, 1854 Portsea-1923 Bexhill-on-Sea) has excelled in England. After her marriage she was known as Hertha Ayrton. Hertha's father was a Polish Jewish immigrant who led a small jewelry store in England. She studied mathematics at Cambridge, but in her time, it was impossible for a female to graduate from a university; she received only a certificate in 1880. She therefore had to pass additional exams and graduated from the London University. Soon after graduation, she changed her name from Phoebe to Hertha. In the autumn 1884 she attended lectures at the laboratory of Kelvin's student the professor William Edward Ayrton (1847 London-1908 London), whom she married next year. In 1895, she started publishing on hissing and resistance of electric arc experiments in the Electrician magazine, which she summarized in the book in 1902. In 1899 she became the first member of the prestigious Institution of Electrical Engineers. T*here, she was the first woman to* lecture on the electric arc lightings. She later addressed to the Royal Society in London. The event aroused many echoes even in the press outside of professional circles.

After her husband's death, Hertha set up a laboratory in her home, and the Royal Society of London awarded her with Hughes' golden medal for her exploring of the arc discharges. From 1905 to 1910, she developed the standardized carbon electrodes for the Navy. During the First World War, she invented a defense against German poisonous gases, but the army refused to accept it.

In the Habsburg monarchy, the girls occasionally received permits for listening to university lectures, but there was no chance for the regular enrollment. For regular studies, a graduation course had to be carried out, and the girls' official academic door was still completely closed in the 19th century. The first girl could regularly enroll at the Faculty of Philosophy at the University of Vienna in 1897, at the Viennese Medical School in 1900, at the University of Heidelberg in April 1900, at the University of Graz in 1897/98 and 1901 and at the University of Innsbruck in 1904. However, especially in Habsburg Monarchy, the number of female students remained small, while only in imperial Vienna it reached 5%. Wassmuth's physics assistant focused on point contact diodes Angelika Szekely de Doba (Maria Josefa Székely, * 1891 Olomouc; † 1979 Graz) was the first female to habilitate at the Graz University in Natural Sciences and the second among all girls promoted at University of Graz just before Christmas in 1917.

30.2.6.3 The First Slovenian Physicist Maria Wirgler

Maria Wirgler (* 1879; † 1874) was the first academically educated Slovenian woman in physics and in science in general. In 1905/06, after she graduated in Graz, she taught mathematics, physics and natural science at the first Slovene City School of Girls' School in Ljubljana and taught until the school became Lyceum in 1909/10.

The first Slovenian woman with a doctorate in natural science or mathematics was Carinthia native Ángela Piskernik (* 1886; † 1967). On 28. 10. 1914 she graduated in Vienna. She taught physics in Novo mesto and Ljubljana. Although Knafelj's scholarship on 6 November 1678 was established without an explicit restriction on male sex, no girl was given Knafelj's scholarship before the First World War. The first Knafelj's scholarships at the University of Vienna were awarded to Amalija Šimec (1893 Tržič-1960 Ljubljana) in 1915/16 at the Faculty of Medicine, to the countess Victoria de Mestri at the Faculty of Arts, and in 1918 to Hedwig Ebner at the Faculty of Arts (Philosophy).

After Maria Wirgler retired, Dr. Marta Blinc and dr. Dora Kokalj, taught chemistry and mathematics at the Women's Real Gymnasium as guardians of the chemical cabinet. Like Wirgler, Marta graduated in chemistry, mathematics and physics, and she also occasionally taught physics. She was the aunt of Robert Blinc. Marta has published a series of scientific works in the field of chemistry and microbiology. She was the first president of the Union of Microbiologists of Yugoslavia, and she received the Prešeren Prize and many other awards.

Fulhame, An Essay on Combustion with a View to a New Art of Dying and Painting, wherein the Phlogistic and Antiphlogistic Hypotheses are proved Erroneous, J.Cooper, London, 1794. Translation: Versuche über die Wiederherstellung der Metalle durch Wasserstoffgas, Phosphor, Schwefel, Schwefellber, geschewfeltes Wasserstoffgas, gephosphortes Wasserstoffgas, Kohle, Licht und Säuren, Gottingen: Dieterich, 1798)

30.2.6.4 Barometers of Serafina Dežman in Ljubljana

Serafina contributed greatly to the development of Slovenian physics and meteorology among the first Ljubljana women. After the death of her brother Karl Dežman († 11. 3. 1889), she continued to measure the weather conditions in Ljubljana and thus complemented the first long-term continuous collection of measurements in Slovenian capital. She measured from 11. 3. 1889 until June 1895, almost until her death in 1896, therefore, she did it alone during six long years and with the help of Kajs in while her brother was absent as Viennese MP in 1861–1863. Like her brother she never marred while she literally devoted most of her work to measurements of weather conditions.

Dežman was interested in meteorology even before he took over the observatory. In 1856 in the museum's Reports, he published Zeilinger's measurements accomplished at Prečna ulica of Ljubljana in 1855. In February 1857 Serafina and Karl Dežman took over meteorological measurements of the second-order observatory in Prečna ulica (former Ljubljana downtown no. 212) from the Ljubljana telegraph officer, Josef Zeilinger (Zeillinger, * 1815) married to Theresa (* 1824) who have birth to his two sons. Overall, Dežman family measured for four decades. During the frequent absences of her brother, Serafina repeatedly replaced him and was very well advanced in using thermometers, vacuum barometers, precipitation gauges and other experimental equipment. She was one of the first Ljubljana experimental physicists and meteorologists, a specialist in vacuum barometers. Dežman used mainly three measuring devices for daily measurements at 6, 14 and 22 'clock. He inherited them from J. Zeilinger who used them already in 1855:[3397]

- barometer in the Heinrich Kappeller's container, acquired from ETH in Zurich, calibrated at the Viennese Central Institute of Meteorology and Geo-magnetism. In 1856 and 1857, the director Gintl performed control measurements at the Ljubljana Railway Station at the height of 950 feet.

[3397] K. Dežman, Meteorologische Beobachtung zu Laibach im Jahre 1865. Jahresheft Krain. Museum (Ljubljana) (1856) 11.

- August's psychometer which was mounted once on the north side of the Zeilinger's observatory. In 1825 and 1828 the high school professor Ernst Ferdinand August (* 1795; † 1870) designed the device based on a proposal suggested by Leslie. August became director of a real gymnasium in Cologne in 1827.

- ombrometer as an instrument for measuring rainfall with a measuring tube of Kappeller. The vessel for catching atmospheric sediments was installed on the roof of the Ljubljana school.

Dežman computed the vapor pressure according to the August's tables adapted to 0^{o} Réaumur. Until 1854, only temperature and pressure were measured in Ljubljana, while humidity was not yet measured.[3398] On 21 October 1881, Dežman received a thermometer from Vienna, a precipitation gauge, which was crossed out at his delivery note, and a snow gauge.

Serafina carefully kept all publications on meteorology at her home. In addition to her and her brother's own announcements in the Laibacher Zeitung, she also saved the Carniolan newspaper report on the unusual red snow of 1846, on the earthquake in Carniola in 1873 and the world exhibition in Vienna in 1873,[3399] where they founded the International Meteorological Organization IMO with twenty countries under the first President Christoph Heinrich Diederick Buys-Ballot (* 1817; † 1890) from Utrecht. Their meeting gave an initiative to explore a relative humidity meter that would be more accurate than the psychrometer.[3400] Dežman reported particularly on the bloody red snow for the Viennese Academy. The son of Ribnica manor owner Karel Dragotin Rudež (* 1833 Ribnica; † 21 January 1885 Gracarjev Turn) sent those "Snowflakes" to Dežman's Provincial Museum of Ljubljana. There, Dežman examined them under the microscope and discovered their opalescence. In the sediment, the colorful particles were between 2 μm and 20 μm long.

Figure 30-56: The very first Ljubljana user of vacuum experimental tools Serafina Dežman (Serafine, 29. 9. 1822 Idrija-1896 Ljubljana Prečna ulica no. 6) painted by her niece Julija Pauer's (* Ljubljana) husband Ladislav von Benesch (1845 Slavkov-1922 Vienna) in 1880 (National Museum, Ljubljana). Really a nice lady in her late fifties! Julija's brother Karl Pauer (* 1847 Ljubljana), his wife Ana (* 1850 Šentjernej) and their three children lived with Seraphina at Prečna ulica 6 at 295 m height above sea level across the Ljubljanica river from Lyceum (now central market) in 1890. In 1869, Serafina lived with her year and a half older brother at the suburb of St. Peter no. 108 in Ljubljana. Karl and Serafina also lived for a while at Figovec farm with some pigs to maintain in downtown Ljubljana where Serafina stayed below her brother at the ground floor

Between 12 June 1850 and 30 June 1851 Zeilinger in Ljubljana wrote the numbers obtained in his meteorological measurements into the tables which he personally constructed. Serafina and Karel Dežman already entered the numbers obtained in their meteorological measurements in Ljubljana in the official forms of the double A3 format, which were dispatched from Vienna among the observers at the Habsburgian monarchy.[3401] Until 1888, the completed forms were signed by Karl as "Deschmann" and in the following years his sister signed as "S. Deschmann", maybe also to hide her gender as L. Meitner used to do much later. At the

[3401] AS, Private Archive Karel Dežman, fasc. 854, box 15.

head of the tables, the measuring devices were mentioned, especially the Kappeller's barometer. They measured at the seventh and ninth hour of the morning. In the spreadsheet, they recorded the measured pressures and temperatures, while the number of windy days, precipitation and lightning were added separately in the form provided for them on the right side of the bottom of spreadsheet.

Their results were immediately published in short records of the Laibacher Zeitung. On 28 January 1857, they published the entire A3 page of their measurements. The upper part of the long half-length side was filled with measurements of moisture, temperature in the degrees Réaumur, and rainfall rates for individual months in 1856. In the lower part of their page printed in newspaper, they published one paragraph about the characteristics of the weather for each month of the previous year. They announced similar but shorter reports at the beginning of the new year. At the same time, their equal measurements were published in the Bulletin of the Museum Society with additional details for the years 1856 and 1857.[3402] The people of Ljubljana were therefore well aware of the weather around them which used to be the topic of their debates as ridiculed by the local poet Franc Prešeren and also very popular in modern global warming era.

On 13 December 1860, Dežman published data on the pressure, temperature and other characteristics of the weather on the day of publication and added the forecast for the next day, like we read in modern newspapers today. He repeated his forecasts on 11. 1. 1869 and later.[3403]

Serafina has already used European weather maps with isobars for the period from 1 January 1888 to 31 December 1888. As internationally aware expert, she also used the map designed for USA with isotherms painted in colors on 16 October 1872. In the year of her death (1896) she used a whole map of snowfall measured throughout the world. She also collected measurements of other meteorologists.[3404] Thus, Serafina's legacy is a true history of the Carniolan and even world meteorology of the second half of the 19th century.

A female one. Her brother Karl Dežman published the paper Das Klima and Krain without the authorship mark in the book of the doctor Friedrich Keesbacher (1831-1901), printed in Ljubljana in 1883. Dežman was then 62 years old. Thus, we have that discussion rightly for the crown of his and Serafina's 26-year-long management of the Meteorological Observatory of 2nd order in Ljubljana. Dežman used only his and Serafina's measurements from 1872-1881. The limitation on this ten-year cycle is somewhat surprising, since both Zeilinger and later Dežman have already measured all tabulated quantities since at least 1857, except the number of days of lightning and thunder in individual months and humidity in percentage. They also used the same observatory station at Prečna ulica (Crossing street) in Ljubljana. In his early measurements Dežman did not note the precipitation fallen during in the wettest rainy day of the month as the maximum of humidity. For cloudiness, however, he did not calculate the average value, but only counted the number of cloudy days per month.

Even more difficult was the fact that the measurements were recorded in the Parisian Ligne (Pariser Mass) and in the degrees of Réaumur until the 1860s. Until 1854, only temperature and pressure were measured in Ljubljana, while humidity was not measured. The Act on the Metric Measurement System was adopted in Austria-Hungary on 23. 7. 1871 with the mandatory use after 1. 1. 1875 as Habsburgian monarchy joined the Metre Convention (Convention du Mètre) signed by representatives of seventeen nations in Paris on 20 May 1875. That treaty created the International Bureau of Weights and Measures (BIPM), an intergovernmental organization under the authority of the General Conference on Weights and Measures (CGPM) where Avčin excelled on Tesla's behalf almost a century later.

Dežman also checked dr. K. Jelinek's analysis of changes in average annual temperatures for Ljubljana and Novo Mesto (Rudolfswerth) after five daily cycles. Ettingshausen's Viennese student Karl Jelinek (1822 Brno-1876 Vienna) analysed 14.9 years for Ljubljana and 9.9 years for Novo mesto. However, Dežman did not write down what period he was discussing. Later, Jelinek analysed those measurements that were sent to him by the

Table 30-3: Dežman's recapitulations of his, Serafina's and J. Zeilenger's measurements noted in the years 1857 and 1858 (K. Dežman, Naturwissenschafte in Krain, Jahresheft Krain, 1858, pp. 3-6, 12-15)

Quantity	**Frequency of measurements**	**Unit**
Temperature	Monthly average at 6h, 14h and 22h, the highest and lowest temperatures in each month	Réaumur degrees
Pressure	Equal	Parisian line reduced to 0^{o} Réaumur
Vapor pressure	Equal	Equal
Precipitation (fog, rain, snow, storm)	Number of days with precipitation in the month, the amount of precipitation is summed by months	Parisian lines
Clouds	Number of cloudy days in a month	
Wind direction	By months	

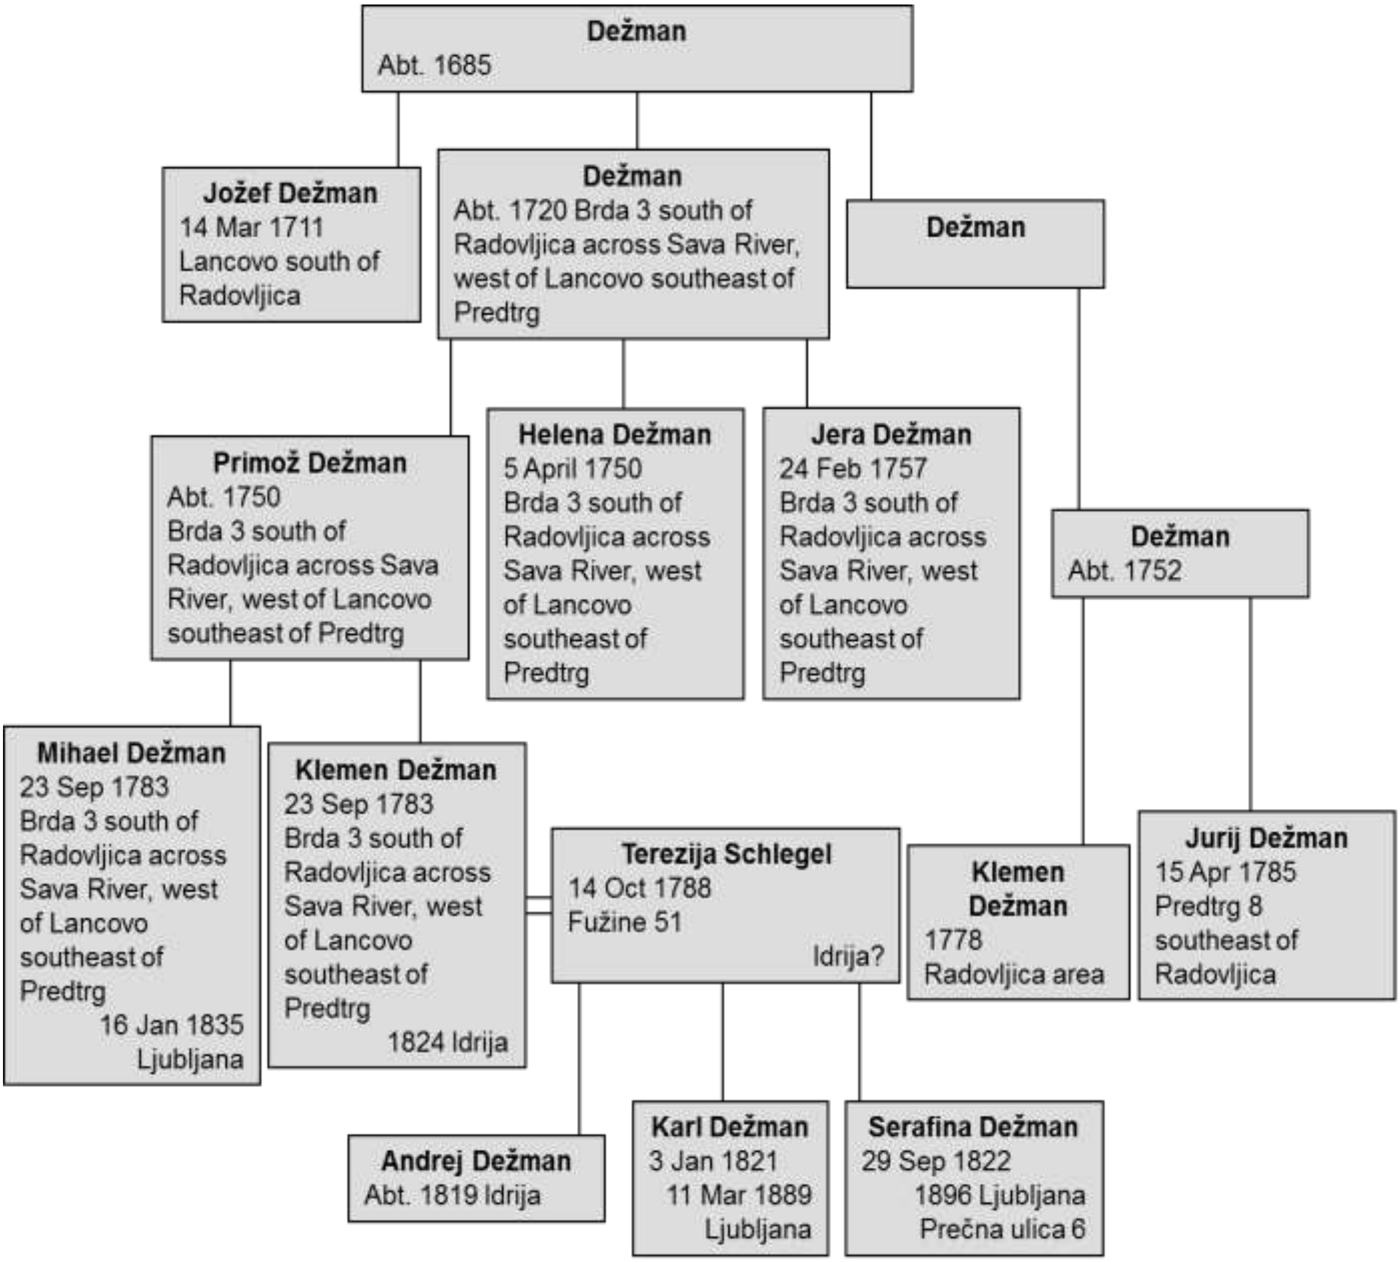

Figure 30-57: Ancestors of Serafina and Karl Dežman

Table 30-4: Dežmans' analyzing of his own meteorological measurement

Quantity	Unit	Average value	Sum	Maximum	Minimum	Number of days	Direction
Temperature	Degrees	+		+	+		
Pressure	mm Hg	+		+	+		
Vapor pressure	mm Hg	+					
Humidity	%	+			+		
Cloudiness	1:10	+					
Precipitation	mm		+	+		+	
Lightnings						+	
Wind	Number of days						+

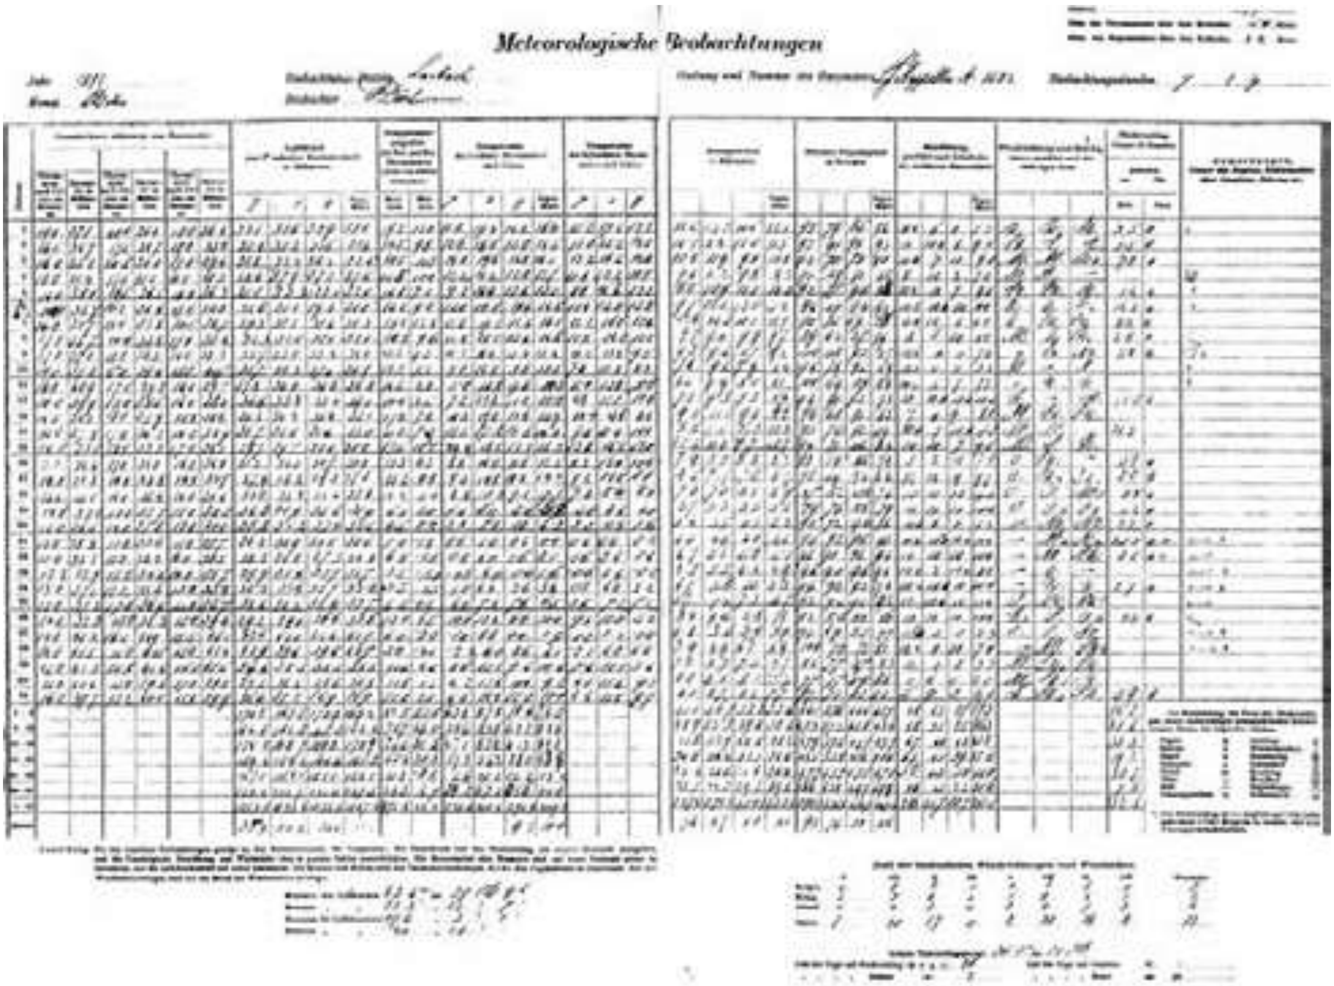

Figure 30-58: Meteorological measurements by Serafinae Dežman in October 1892 (AS, Private Archive Karel Dežman, Fasc. 854, box 17).

Figure 30-59: Serafina Dežman's meteorological measurements in October 1892 (AS, Private Archive Karel Dežman, fasc., 854, box 17). Serafina Dežman is one of the first successful physicists in Ljubljana, specially trained to measure pressures in barometric vacuum tubes. Filip Fröhlich (1826 Metlika-1869 Ljubljana) painted Karl Dežman on a portrait kept by Fröhlich's daughter in Ljubljana.

Ljubljana observers. Dežman and the novice observer, the Franciscan father Bernard Vovk, measured between 1858-1885, and sent their data to Vienna between 1862-1876, where Karl Kreil (1798–1862 Vienna) and after his death K. Jelinek were the directors of the Viennese Central Institute for Meteorology and Geomagnetism (Centralanstalt für Meteorologie und Erdmagnetismus).

Dežman compared the average temperature and precipitation with the measured data in other major cities of the Austrian half of the monarchy. Beyond the analysis of the obtained numbers for Ljubljana, he tried to explain special distinguished local features, inter alia, with the influence of the Ljubljana moor on the change in temperature.[3405] Most notably, Dežman analysed temperature measurements on 2.5 pages while analysing the other seven measured quantities on a total of four pages of his discussion. Certainly, he used the precious help of his sister Serafina.

Dežman analysed the tabulated numerical values of the measurements, and not the graphs of annual changes in pressure and temperature, as Mitteis did in 1854. Dežman also did not mention Mitteis' 29-year-older paper about the same problems in his discussion. He also avoided to mention M. Wurner's analysis of the weather conditions in Jesenice, printed in 1872. Thus, for a more complete analysis of the Carniolan meteorological conditions, it was necessary to wait for another two decades. It was not until 1902 that Ferdinand Siedl (1856-1942), a professor at a higher real School in Gorizia, analysed temperature, humidity, cloudiness and precipitation measurements in Carniola in his 650-page book. Seidl studied the basics of meteorology with his Slovenian teachers. He attended a gymnasium in Novo mesto between 1863 and 1874, where Francis Bernand Vovk (Vouk) taught him physics in lower and upper gymnasium and mathematics in grades 7 and 8. Vovk led the meteorological observatory in Novo mesto between 1858-1885. Between 1874-1880 Siedl studied Natural history, physics and mathematics, at the University of Graz, where Simon Šubic lectured on meteorology.

30.2.6.5 Snegulka Detoni

The inner Carniolan (Notranjka) Snegulka Detoni later married Moljk (De Toni, 1921 Begunje by Cerknica-2016 Ljubljana) became the first assistant to professor dr. Anton Peterlin in 1944. She was born in a very affluent family a few kilometers north of Cerknica in a relatively remote Menišija of the village Dobec pri Krajnčih by Begunje near the birthplace of Ivo Lah. She even excelled herself in glider sailplane sports in Bloke with her exam for a pilot included.

Snegulka's grandfather Vincenc de Toni (1851 Trelli near Paularo (Paulâr) in Friuli-1907 Begunje no. 24, later no. 39) migrated because he was dissatisfied with Italy of Risorgimento. He married the local Slovenian maid Frančiška (* 1859) and bought the farm of Cenc in Begunje. He became a prosperous innkeeper, trader, and butcher. He learned some Slovenian language and enjoyed the silent hunting with his eldest son and third child Toni de Toni (Anton, * 1884 Cerknica), Snegulka's father. Vincenc's next to youngest son Vincenc de Toni (* 1899) died in the war on

[3405] Dežman 1858 3-6; Dežman 1883 12-15, 19-21, 23; Mitteis, 1854, 7; Miroslav Kurelac, 1981, 86.

partisan side which enabled Snegulka's relative prosperity under communists.

Snegulka graduated from the Chemical Institute of the Faculty of Technology immediately before World War II. She completed her diploma work with Peterlin and graduated in 1944 as the first Peterlin's graduate student. She listened to mathematics at the Plemelj's class, and Physics at Peterlin's class, while she passed several exams. She might have been one of the reasons for the quarrels between Peterlin and Moljk, because the big ideas of Slovenian ideological quarrels always have in their fundament just two reasons: wine and females.

In the autumn 1945 she started her first job at the Bacteriological Institute of the Medical Faculty. At the invitation of Peterlin, she worked at the Department of Physics of the Faculty of Engineering since 1946. As the only assistant, she conducted exercises for all students of the Technical College, where she taught electrical engineers, machine engineers, miners, metallurgists, builders and surveyors: in total, about 250 listeners each semester. She also conducted exercises for students of the Faculty of Natural Sciences and Mathematics, where she taught physics, mathematics, chemistry, geology and meteorology to about eighty students each semester. For all those students she also prepared a written part of the exams in physics. She helped with experiments in physics classes.

She designed camera of Joseph Boussinesq's and Gabriel Lippmann's student turned professor of physics at the Catholic University of Angers (Université Catholique de l'Ouest) Maurice Marie Alfred Couette (1858 Tours-1943, Angers) for measuring the double refraction of flow (current, streaming birefringence) like Čopič. Her tool was supposed to be produced at the Mechanical Engineering Department of the Faculty of Engineering. However, their manufacturing was too slow. Nevertheless, she managed to prepare the measurements that Peterlin and Samec evaluated theoretically on September 1, 1944, when Peterlin was already in Dresden. They published their joint paper in the journal KolloidZeitschrift where Samec was always the closest collaborator, and Peterlin also published there his papers after the war; both Peterlin and Samec were members of the Kolloid-Gesellschaft which W. Ostwald established in Leipzig in 1922. Their publication was later used as a pretext for Samec's penalization because of his alleged break of cultural silence ordered by OF, while Peterlin and Snegulka were not punished at all.
Snegulka used two Paul Glan-Silvanus Philipps Thomson prisms designed in 1880/81 for a polarizer and an analyzer. Possibly because of the lack of other chemicals, the extracts from potatoes were measured.
In 1954, Snegulka joined the Department of Structural Chemistry, where she completed her Ph.D. in the class of chemist academician Dušan Hadži with a hundred pages long dissertation on the structure of surfactants whose ultraviolet spectra and formulas she studied in 1956.

She was interested in the hydrogen bond research at Samec's Chemical Institute. In June 1957, an international symposium on hydrogen bonds was held in Ljubljana, where Snegulka participated in the organizational committee. The symposium was also attended by Professor Linus Pauling, the Nobel Prize winner in Chemistry in 1954 and the Nobel prize winner for Peace in 1963. Pauling offered Snegulka one-year scholarship to work in his department at Caltech in Californian Pasadena starting on 1 August 1957. This was a great honor and happiness. Unfortunately, Snegulka did not receive a Yugoslav visa for USA, although Professor Pauling was waiting for her for four years. Unable to reach USA, Snegulka went to Copenhagen university in 1958, like Črt Zupančič. Snegulka used the fellowship of Danish government. She researched the chemical compounds with microwave and infrared spectroscopy in the group of the former anti-Nazi resistance firefighter Børge Bak (1912-22 February 1990). In Denmark, she lectured twice on hydrogen bonding. At the same time she published three papers, together under supervision of the professor Bak and colleagues.

In 1960, Snegulka replaced prof. Hadži, who went for one year to America. She conducted the exercises about his thematic and participated in the experimental work with ferroelectrics with a group of professors Blinc at the Jožef Stefan Institute. In 1961 Snegulka together with prof. Blinc and colleagues received the Kidrič Prize for research of ferroelectrics with hydrogen bonds. She studied infrared and Raman spectra of organic molecules with S-O, Se-O, P-O and C-N bonds and organic acids with strong and weak OH bonds and published important results. Since 1976 she lectured on infrared and Raman's in chemistry and technology to for postgraduate students of spectroscopy and X-ray analysis of polymers. At four international symposiums and congresses, she presented papers on hydrogen bonding. She has published a total of forty-seven papers in cooperation with professor Blinc's and professor Hadži's teams, or alone. She even participated with her works in two books published abroad. In 1979 she was habilitated in Ljubljana, and in 1980 she was elected an extraordinary professor. In the mid-1980s she published high-profile research on vibration spectra in collaboration with academicians dr. Hadži and dr. Ljubo Golič, a native from eastern Slovenia. Snegulka's work was so important that some of her achievements are still cited today.[3406]

The Detoni (De Toni) family was extremely rich, which was not the best recommendation in Slovenia of those times. The Inner Carniola was not the favorite of communists anyway. The communist connections of her uncle might have been an obstacle for Snegulka's USA visa.

In her advanced years Snegulka also collected the data for her family history. Snegulka lived during her last years in the home of the elderly citizens in Bokalce near Ljubljana like Vidav, but the clever Vidav survived there much longer. The legend tells that Snegulka kept the piece of Chicago nuclear reactor which Fermi personally gave to her as a present.

30.2.6.6 Bibiana Čujec Dobovišek, Nuclear Reaction and Religion

The development of the modern physics of small and fast took place in parallel with the establishment of a new University of Ljubljana, which finally offered many opportunities to the Slovenian physicists of both genders. Emilija Mlakar, married Branz, was the first woman to graduate from mathematics at the University of Ljubljana. She completed her studies in the pedagogical field of mathematics in 1928 as the thirteenth Ljubljana graduate,[3407] and she lectured at the classical gymnasium in Ljubljana. Among the physicists of Ljubljana, Bibiana Dobovišek (* 25 December 1926 Ljubljana) was born in the family of machine technician and clerk. Like Marija Wirgler and Ángela Piskernik, she also finished elementary school and high school at Ljubljana Ursulines' classes upon the end of the war.

Table 30-5: The first dozen women who finished their studies of physics and meteorology in Ljubljana until 1963

Name and surname	Date of diploma (supervisor)	Date of doctorate (supervisor)
Bibiana Dobovišek Čujec	1950 (A. Peterlin)	1959
Danila Nemec (Meteorology)	1954	
Marija Robavs (Meteorology)	1954	
Milena Bevc (Meteorology)	1958	
Jelena (Alenka) Hudoklin Božič	1958 (Pedagogical)	1968 (M.V. Mihailović)
Cvetka Bartol (Pedagogical)	1958	
Alenka Kmecl (Meteorology)	1960	
Danica Burg Hanžel	1960 (A. Moljk)	1973 (A. Moljk)
Petra Beniger	1962 (I. Kuščer)	
Helena Velikonja	1962 (A. Hočevar)	
Ana Rudolf	1962 (R. Blinc)	
Marija Simonič (Pedagogical)	1963	

After the German occupation, she studied under supervision of the professor Plemelj, Vidav and Peterlin from the autumn of 1945 onwards. From her personal inclination, she also listened to the first year of lectures on ancient Greek philosophy. After graduating in 1950, Bibiana worked for four years at the SASA Physics Institute, and then in its

[3406] Notes of dr. Veronika Kralj Iglič on 16. 5. 2005 and 8. 10. 2005.

[3407] D. Krstić, Mileva & Albert Einstein ljubezen in skupno delo. Didakta, Radovljica 2002, p. 100.

successor, the Nuclear Institute, today's Jožef Stefan Institute, from 1955 to 1966. She began by analyzing nuclear emulsions on photographic plates of the professor Sten von Fresen (1907 Uppsala-1996) of Lund University in Sweden which Fresen exposed out to cosmic rays at a height of 30 km, and then donated them to Ljubljana researchers. By measuring the ionization and the travelled distance, Bibiana calculated the mass of the meson K (kaon) newly detected in Manchester in 1947.

Bibiana studied photonuclear reactions on the new betatron of Darko Jamnik, which was purchased in 1954. It used to be the most accurate device for exploring a nuclear photoelectric effect in the energy range up to 30 MeV. That's why Bibiana's measurements were particularly pleasing. Jamnik graduated a year after Bibiana in the pedagogical direction of the studies of physics in Ljubljana, and they both received their doctorates in the same year after having completed all their studies in Ljubljana in 1955.

Bibiana first measured the reaction of carbon and oxygen nuclei in the emulsion, where the traces of alpha particles give characteristic three-pointed stars or four-pointed stars. These enable the determination of the energy of the photon that triggered the reaction, while giving a good insight into the course of the reaction. An interesting question was the "giant" resonance, which usually occurs at energies of around 20 MeV. It was not clear whether a collective excitation of the nucleus is involved, or the photon reacts with a nucleon, raises it to a higher energy level from which the photon can then emerge out of the nucleus or became absorbed back into the nucleus. Based on the shell model it has been shown that photon reacts with the single proton.

In 1959, Bibiana's study led her to the dissertation titled Photo-nuclear reactions with a special focus on Wilkinson's model, written in 204 pages. The dissertation was accepted in 1958, but she as the candidate had to make the oral exam (rigoroz). She completed it with the commission composed of Peterlin, Kuščer, and Črtomir Zupančič on 2 September 1959 as the date of her doctor's degree. The defense followed on September 24, and the promotion took place on November 24, 1959.

Maurice Hugh Frederick Wilkins (* 15 December 1916; † 2004), like Rutherford before him, arrived from New Zeeland to become the successful British physicist. As a former communist at the University of California in Berkeley, he developed isotope separation for the atomic bomb, which disappointed him and directed him to the research of DNA. In 1962, he received a part of the Nobel Prize in Medicine and Physiology for his contribution to the discovery of DNA together with the Jewish phage group member Salvador Luria's (1912–1991) doctoral student James Watson (* 1928) who tempered his racist views only after LGBT girl Lori Lightfoot became one of many African American mayors of his native Chicago. Of course, the prize for the research of DNA should be earned by the agnostic Jewish physicist Rosalind Franklin, who, unfortunately, did not manage to get to the recognition because of her female disadvantage. By her X-ray diffraction pictures she discovered the full structure of the virus in 1955. Dr. Hadži invited Franklin to Slovenia several times, in 1952/53, and she enjoyed their Alpine tours including Bled, Triglav Lakes Valley and Triglav itself in May 1952.

Bibiana then proceeded to study photo-nuclear reactions of beryllium applied to nuclear emulsions. The transfer of a slightly bound neutron into ^{9}Be was carried out with an extremely high probability. She found out various reactions and determined the energy of photons that she triggered. She measured the spectra of protons emanating from the nuclei of silicon, phosphorus, and sulphur radiated at the betatron.

After her wedding, Bibiana took over her husband's surname Čujec and later gave birth to her three daughters and a son. Following the reorganization of the Institute IJS in 1960, she applied for the position of assistant and assistant professor in the physical department, but she wasn't successful. Therefore, in 1961, with the recommendation of Črt Zupančič, she went on to postdoctoral training in Pittsburgh. There she studied the nuclear structure with experiments on the cyclotron of the controversial theorist of cancer risk from low level radiation the professor Bernard Leonard Cohen (1924 Pittsburgh - 2012), which accelerated deuterons to 15 MeV. She measured the reactions (d, ^{3}He) and (d, p) on different nucleus. To the other side of the sea she was followed by her husband and children.

In 1963/64 she moved with her family to nearby Canada. She lectured at Alberta University in Edmonton and measured the stripping reaction (d, n) with 5.5 MeV Van de Graaff accelerator. In the following year she went to Laval University in Quebec, where an accelerator of the same type was installed in 1963 and later expanded to 7.2 MeV. She stayed in Quebec until her retirement in 1993. She quickly mastered the French language and first detected deuterons through a magnetic spectrometer in nuclear emulsions. She studied nuclear spectroscopy during her measurements of nuclear reactions with deuterons. For more detailed study of nuclear levels (determination of spin, nature of electromagnetic transitions and lifetime levels), a more demanding technique was required.

In 1966, she was elected an extraordinary professor, and she became a full professor in 1970. Quick successes were her match. She also began to research astrophysics with the study of heavier nuclei. She spent the first two sabbatical years at the California Institute of Technology's Kellogg Radiation Laboratory in Pasadena, investigating nuclear reactions in the stars in 1971/72 and 1978/79. She spent her last sabbatical year in the CERN of Geneva in 1985/86, where the professor Bogdan Povh of Heidelberg accepted to participate in her measurement of collisions between protons and antiprotons. Today, Bibiana's daughter of the same name follows her as she chose cardiology for her profession. Bibiana's youngest daughter Ana Marija Čujec studied physics by mother's footsteps.

After the seventy scientific papers Bibiana Čujec the elder described for her Slovene readers her Catholic view of the world of physics in an interesting Slovene book in the year of physics in 2005. The preface to her successful book was written by an important Slovenian experimental physicist dr. Franc Cvelbar, also a devoted Catholic. She described the development of science with her physics included from ancient Greeks to modern times. She showed how much quantum mechanics had changed our view of the world with the principle of indeterminacy. Thus, despite her long absence, Bibiana was by no means alienated from the Slovenian people. On the contrary.

30.2.6.7 Danica Burg-Hanžel's Research of Materials with Mösbauer Spectroscopy

Dr. Danica Burg Hanžel studied at the Ptuj Grammar School in Ljubljana and graduated in March 1960 as the first Slovenian female physics engineer, the first graduate female Slovenian physicist outside the pedagogical direction and a 50th Slovenian graduate in "pure" physics. She had six classmates including Ančka Rudolf and the daughter of writer Narte Velikonja (1891-1945), Helena Klara Velikonja (1936-1991). Both those classmates graduated in 1962: Ančka researched paramagnetic matter with nuclear magnetic resonance under supervision of dr. Blinc, and Helena measured tensile strengths of glass welds with metals under supervision of dr. A. Hočevar. Ančka later joined Iskra Elektrooptika in Stegne, and Alenka lectured at the Secondary Technical School in Ljubljana until her premature death. Danica was employed at the IJS and initially participated primarily under supervision of her supervisor, dr. Anton Moljk.

Two years before her diploma, the Munich native Rudolf Ludwig Mössbauer (* 1929) during the work for his dissertation discovered the resonant and recoil-free absorption of gamma rays in solid matter. He received a Nobel Prize while he continued his research at MIT in 1961. His discovery ultimately demolished the barrier between nuclear physics and physics of solid state,[3408] and thus, at the experimental level, new vacuum techniques combined basic quantum research with useful studies of new materials. The promising novelty was particularly intriguing to Danica. Already before her doctorate under the supervision of dr. Moljk in 1973, she developed her domestic Mössbauer spectrometer for the research of magnetic properties, phase transitions and the electronic structure of iron-containing materials. With the new method she cooperated with several IJS laboratories and with German and French researchers. She has published over a hundred works. Therefore she received the prestigious Boris Kidrič Foundation Award in 1978.

[3408] Note of Master of sciences Djordj Krstić (* 1936 Novi Sad; † 2014 Kranj) on 16. 5. 2005 and dr. Danica Burg-Hanžel on 15. 9. 2005.

30.2.6.8 Conclusion

Vacuum technology has directed the development of modern physics in the last century. They were developed in parallel with the entry of the first academically qualified female and non-white physicists into research. It is therefore not surprising that the first Slovenian female physicists were particularly active in introducing vacuum experimental techniques into science.

30.2.7 Nanotubes

30.2.7.1 Introduction

Every great discovery hides its small prehistory. It is the same with the first inorganic nanotubes that were assembled in Ljubljana two decades ago. Like nanotubes, which they grew for twenty-two days in the Laboratories of the Jožef Stefan Solid State Department, the knowledge needed for their invention have been accumulated in Carniola for two centuries. The story begins with Hacquet's pioneering microscopy of crystalline structures at the end of 1776 at the premises of today's Ljubljana market in Vodnikov trg, from where the lyceum was removed after the earthquake.

30.2.7.2 Crystalline Tubes of Professor Hacqut's Hard Rime in Ljubljana

Naturalist Hacquet studied hard rimes on his window in Ljubljana Gornji Trg above Hercules' fountain in former Jesuitical apothecary. Later, he recognized similar forms at the University of Lviv (Lvov, Lemberg) in apparently inanimate ice-frost flowers.[3409] The hard rimes tracery on Hacquet's frosted window used to be one of the bravest moments of Hacquet's research. He watched the flowers from his study room a year and a half after coming from Ljubljana to the University of Lviv. They were mounted on his 60 cm wide double window looking north-north-east.

Hacquet argued that many observations of ice have not yet convincingly explained its various crystalline forms. Among the predominant hexagonal (six angular) forms, he observed prisms and pyramids with four or six faces through his microscope. In Linnaeus's way they were sorted by the shapes of the basic surfaces of their crystals. The arranged structures were intertwined with stacks of broken pillars and hollow tubes.[3410] These tubes were extremely small for Hacquet's time, although thousands of times wider than modern nanotubes. Times change and with them the perception and observation of the smallest distances.

Figure 30-60: Hacquet's sketch of ice flowers in hard rime (Hacquet, 1790, fig. A, Tab I).

Hacquet rejected the possibility that salts of bases formed in plants could have an impact on the formation of ice in his hard rimes. In the new year of 1789, he was warming up in his workroom, while the outside was a wet weather accompanied by the northern wind at a temperature of -19°C to -24°C (-15.5°R to -19°R). With a 4 mm thick barometer, full of Idrija mercury, he measured a pressure of 0.94 bar. He noted lengths in the elbows (hoods) measuring 114.3 cm. He wrote his smaller distances in inches (cols, "). The 26.33 mm long (today just 25.4 mm) inch contained 12 lines ('"). He recorded the temperature in the degrees of Frenchman René Antoine Ferchault de Réaumur (* 1683; † 1757), like most of the then researchers; among them Gregor Schöttl and Hacquet in their meteorological measurements published in 1776 in Ljubljana, Gabriel Gruber a decade later, and even Dežman a century after them.

[3409] Hacquet, 1790, 27.

[3410] Hassenfratz, 1789, 34, Hacquet, 1790, 20.

Hacquet has outlined the forms of ice flowers in hard rime from his window. He carefully observed the formation of long needles from crystals of ice. He compared them with sketches of the mathematician Giovanni Francesco Melchior Castillon (* 1708; † 1791), rector of the University of Utrecht, who became the member of mathematical class of the Berlin Academy in 1751. In February, the needle ice frost flowers on the Hacquet window changed considerably. On the sides they developed symmetrical hard rime resembling living beings of a similar shape. Likewise, modern researchers describe their observations of the growth of nanotubes.

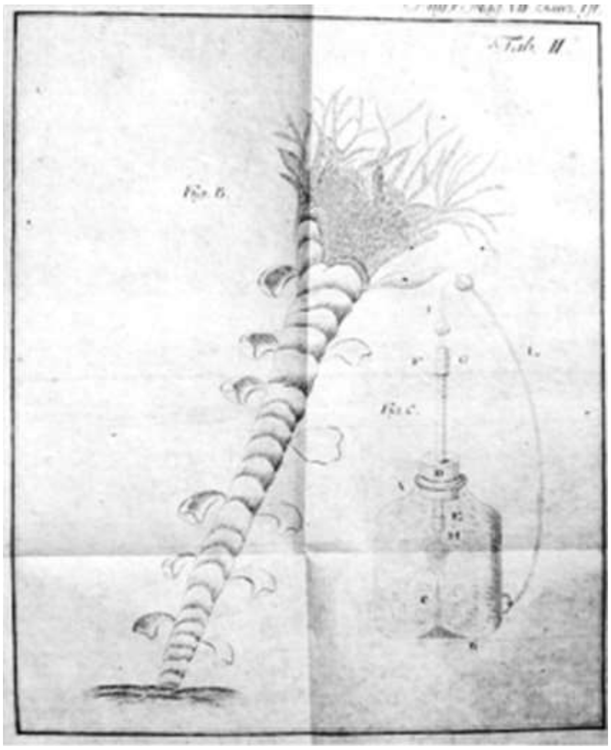

Figure 30-61: Hacquet's sketches branched in a tube of joined ice flowers in hard rime on his window (Hacquet, 1790, fig. B, Tab II).

On the upper edge of an ice flower, Hacquet spotted an open hose with its rings resembling the spring. Many pores inside his iced flower reminded him of the perforated marine polyps. On 7 June 1676 similar forms were observed in Altdorf on grains of hail.[3411]

At his frosted flowers Hacquet recognized all three kingdoms of nature: animals, plants and crystals as intermediate films like viruses, liquid crystals or aperiodic order of Islamic and African ornaments-architecture chaos quasicrystals borrowed by Fibonacci were mostly not discussed among westerners of those times . The branched ice reminded him of the trees. Similar ideas have been developed by Dr. Friedrich Casimir Medicus (* 1736; † 1809) two decades earlier. He was an important advocate of vitalism, since he first used the concept of life force in 1775. In 1764 he became a garrison doctor in Mannheim and a member of the Academy of Sciences of the city. Four years later, he described the structure of hard coal (anthracite) comparable to Hacquet's icy frost flowers.

Hacquet used the explorations of the icy flowers of hard rime of Johann Gottlieb Gleditsch (* 1714; † 1786), the count Georges Louise Leclerc de Buffon (* 1707; † 1788), the Calvinist doctor Jean F. Reynier (* 1730) from Lausanne near Lake Geneva as the father of the physicist-pharmacist researcher of similar crystals Jean Louis Antoine Reynier (1762 Lausanne-1824 Lausanne) and the Napoleonic general Jean Louis Ebénézer Reynier (1771 Lausanne-1814) who both joined Napoleonic Egyptian expedition. The Hamburg native Johann Heinrich Müller (* 1671; † 1731) also provided such data as the professor of mathematics and physics at Altdorf University. Hacquet's friend Andreas Sigismund Marggraf (Margraff, * 1709; † 1782) systematized an ice flower of hard rime into the "kingdom of rocks with plant forms". In 1738, the king Friderik Wilhelm I (* 1688; † 1740) named Marggraf a Berliner academician. After sixteen years he was promoted to the head of the academic chemical laboratory and finally he became the director of the physical class of the academy in Berlin in 1760. In 1747, he used the microscope to develop a method for obtaining sugar from sugar beet. This was probably the first chemical identification with a microscope,[3412] which soon became the basic tool of Hacquet's research.

Hacquet wrote about the hard rime to Johann Heinrich Voigt (* 1751; † 1823). Voigt published Hacquet's letter and supplemented it with his own observations. In 1774, Voigt began to teach in gymnasiums in Gotha, where he published the astronomical part of the court calendar. Between 1786 and 1799 he took over the editing of the Journal of novelties about Physics and Natural

[3411] Hacquet, 1790, 25.

[3412] Tišler, 2003, 73.

Sciences (Magazin für das Neueste aus der Physik und Naturgeschichte together with Georg Christoph Lichtenberg's elder brother Ludwig Christian Lichtenberg (* 1737; † 1812 Gotha). In 1789, Voigt received a PhD from philosophy at the University of Jena, where he took over the department of mathematics, and he also took over the chair of physics for thirteen years. After 1797, he published twelve papers about the latest research on nature in the journal printed in Jena. He wrote papers about mathematics, fire, air, electricity, magnetism, optics, comets and the history of the calendar. Among his friends were Hacquet and his enemies the brothers Gabriel and Tobias Gruber; so, he published and evaluated their works.

Hacquet read interesting descriptions of hard rimes ice flowers in French magazines. On 13 July 1788, his attention was drawn to St. Mauritz, three French miles east of Paris. The grains of conical shapes with diameters of 79 mm and lengths of 6.6 mm were made up of octahedrons and pyramid crystals. Horace Bénédict de Saussure (1740-1799), a professor of philosophy, studied ice flowers on the window of his office at the Geneva Academy, where he lectured from 1762 to 1784. In the meantime, he studied alpine glaciers. In 1787, he first climbed to the top of Mont Blanc and therefore followed Hacquet, who climbed on the top of Triglav on 8 August 1779. We do not know if both famous mountaineers met at one of the Alpine peaks; in any case, Hacquet measured with the Saussure barometers on his Lyceum in Ljubljana. Saussure invented a special hygrometer on the hair that he put under the bell. The air quality was determined by the nitric oxide eudiometer, which they had for the equally important instrument as the thermometer or barometer during those times. His son Nicolas Théodore de Saussure (1767-1845) explained the work of photosynthesis discovered in 1779 in Vienna by Hacquet's "teacher and friend", the Dutchman Jan Ingenhousz (1730-1799), just before Jan returned to London.

30.2.7.3 Molybdenum and Tungsten in Ljubljana

In Hacquet's time, the name molybdenum barely began to be used for special metal. In nature, molybdenum is rare in its pure form, so it was not distinguished from graphite and similar minerals two hundred years ago. According to Scheel's advice, Peter Jacob Hjelm (* 1746; † 1813) used a procedure like Gahn's isolation of manganese from its oxide in Stockholm in 1781. Johann Gottlieb Gahn (1745-1818) was the assessor of mines at Fahlun in 1770, and chemist for the Swedish Board of Mines called Bergskollegium from 1773 to 1817. As a practical miner Gahn did not publish his scientific findings himself, but freely communicated them to the professor in Uppsala Tobern Bergman's (1735 Katrineberg-1784 Medevi) and his protegee Scheele, which also benefited Hjelm in the times when the military fame of Swedish king fighter Gustav Adolf was over for good, but the Swedish metallurgy with their very pure iron ore was still in its summit. Thus, Hjelm succeeded in isolating the previously unknown metal, molybdenum, as its discoverer Hjelm's fellow Swede Karl Wilhelm Scheele (* 1742; † 1786) happily wrote to Hjelm on 16 November 1781. Of course, the first molybdenum was not particularly pure, until Berzelius separated a better one later.[3413]

Shortly after Hjelm's success, the Spaniard Don Fausto d'Elhuyar (1755; † 1833) discovered tungsten in 1783. The new metals molybdenum and tungsten were soon acquired for the Ljubljana Lyceum collection, so that professor Kersnik listed them in his cabinet as early as in 1811.

30.2.7.4 Crystal Symmetry of the Ljubljana Professor Schulz von Strassnitzki

Schulz von Strassnitzki was the most important professor of mathematics in Ljubljana until the twentieth century. Shortly before his arrival in Ljubljana, he published a book about a rectangular triangle and three-sided pyramids as an introduction to his crystallographic studies in Vienna in 1827. He devoted his work to Andreas Joseph baron Stifft like Neumann before him, and in his discussion, (he referred mostly to Lagrange's analytical solutions to the problems of the three sided pyramid (tetrahedron, 1783). At his first twenty-eight pages, Schulz first presented the historical background of studying triangles from Thales to Euler.[3414] In the second part devoted to the three sided pyramid (tetrahedron), Schulz

[3413] Diogenov, 1960, 169.
[3414] Schulz, 1827, 5.

Karol (Leopold) Schulz Edler von Strassnitzki was a professor of mathematics in Ljubljana between 1827 and 1834. During his service in Ljubljana, Schulz published five books and even more important scientific discussions on crystallography and mathematics; after leaving Ljubljana, despite his premature death he published another eleven books. His best students in Ljubljana were

Franc Močnik and Mihael Peternel. Before the reform, Schulz taught seven hours of mathematics a week in German language according to Appeltauer's textbook of theoretical mathematics, which was also used elsewhere in the monarchy, including at universities in Schulz's native Galicia and Olomouc, where Schulz's pupil Močnik later taught. Schulz's father Anton was the first district commissioner of the Galician countries, while his mother Carolina died when he was an eight-year-old boy. Together with brother Joseph, they went to Vienna, where their paternal grandfather Leopold Ludwig took care of them. He served as a professor of political sciences, a political writer, district chief and a counsellor of the guberniya. Unfortunately, the grandfather died after a long illness two years after he took over the care foe his young grandsons; he certainly left a great impression on them. Karl Schulz finished high school as the best in his class. In the last year, he told his teacher that he would like to become a mathematician and a teacher according to his grandfather's example. In those days at Viennese three-year philosophy faculty, they had a college of mathematics and astronomy with professors Ettingshausen, Littrow, former Ljubljana professor dr. Josef Jenko and the philosopher Leopold Rembold dismissed for his alleged atheism in 1825, like Bolzano before him. Among Schultz's high school colleagues-classmates was a later professor, ministerial councilor, philosopher and reformer of schools dr. Franz Exner (1802-1853) and poet J. B. Seidl. Rembold's students F. Exner later taught Josef Loschmidt at the Prague High School. In 1891, Loschmidt's successor in the management of the Viennese Physical Institute was~~,~~ the son of F. Exner the crystallographer Franz Serafin Exner (1849-1926).[3415]

[3415] Stiller, 1989, 48, 67.

referred to the August Leopold Crelle's (1780–1855) Berliner collection of mathematical expressions and observations published in 1821.[3416] Considering his previous findings about triangle, Schulz calculated the equations for the center of gravity of the pyramid for the sphere circumscribing the pyramid and for the coordinates of the center of gravity of the pyramid.[3417] Schulz's booklet was an expanded reprint of two papers that he simultaneously published in Baumgartner's and Ettingshausen's Viennese magazine.

Schulz was, of course, the best in mathematics among almost three hundred classmates. On 22 March 1823, Jožef Jenko from Kranj organized an annual disputation, where Schulz successfully defended several mathematical theses. At first, Jenko taught mathematics at the Ljubljana Central Schools, but he suffered from unhappy love with a girl who preferred Jenko's wealthy student. So, he resigned in favor of Kersnik and went to the University of Graz on June 14, 1810. After the death of Franz Jeschowsky on 29 April 1814, he took over the lectures of mathematics, and on 24 November 1814 he lectured the technology at Joaneum. On December 13, 1819, with Ž. Zois's recommendations, Jenko went to Viennese University[3418] where he became best friend of Jernej Kopitar who eventually passed away in Jenko's house.

Schulz learned the history in the class of professor and librarian Martin Johann Wikosch (1754 Uherský Brod (Ungarisch Brod) in Moravia-1826 Vienna). By the decree of the Provincial Government no. 691 of 17. 1. 1823, Schulz received a mathematical scholarship of 300 florins, and at the same time he became an adjunct under supervision of the professors Baumgartner, Jenko and Ettingshausen under act no. 43.605 issued on 13 September 1824. On 9 November 1824, Schulz became a mathematician and physicist, while his brother Josef received his doctorate of jurisprudence and became a financial adviser.

In 1827, Karl Schulz received a simultaneous offer from the Lyceums in Ljubljana and in Salzburg.

[3416] Schulz, 1827, pp. 31-100, mostly on p. 52.
[3417] Schulz, 1827, 100.
[3418] Krones, 1886, 137, 290. During his Ljubljana employments, Jenko used to borrow books from Zois' library (Svoljšak, Vidmar, 2019, 33).

However, the authorities rather invited the assistant Adam Burg to the chair in Salzburg, and Schulz came to Ljubljana on 13 June 1827. Professor Jenko almost certainly described him that small town by the Ljubljanica riverbanks. During his first three years Schulz was a Ljubljana adjunct and substitute (suplent) teacher, and later he taught as a professor.[3419] Littrow confirmed Schulz's curriculum and highly praised him; Schulz's lectures were approved by the highest decree on 24 January 1829. Schulz's mathematical lectures in Ljubljana were highly evaluated by his pupil, later school supervisor Močnik, in his letter dated 28 October 1853. The naughty students especially liked Schulz's jokes during lectures. In the summer months Schulz invited students even to domestic celebrations. In 1830, a professor of sciences Schulz married Antonia's daughter Sophia Selinger (Sofie Seeliger, Zeillinger, Zeilinger, Seliger) in Ljubljana. Their eldest son Johann Nepomuk Paul Friedrich (* 6. 7. 1831 Ljubljana) became secretary of state in the Ministry of Agriculture, their younger son Franz Leopold (* 1835) was a sectional adviser at the interior ministry (Ministerialsekretar) and married governorate counsellor Johann's and Kristine von Canal's daughter Natalie baroness Grimbschitz (* 1845) in Ljubljana with his brother Johann as his best man on 1 May 1871. Karl Schulz's third son Friderik was an engineer at the Western Railway. Despite a relatively short stay in white in Ljubljana, Schulz von Strassnitzki completely adapted to Slovenian local circumstances and even became a member of the Carniolan Agricultural Society. He resided in Ljubljana in Poljane (Polan) no. 23.

Like Močnik's teachings, Schulz's lectures praised by the then Governor of Illyria, Josef Camilo baron Schmidburg (1779 Graz-1846 Vienna) according to act no. 3958 in his letter to the study court commission on 11 August 1832. Schulz extraordinary lectured at the two-year higher mathematics course and at the one-year course of popular astronomy in Ljubljana between 1829-1834. The astronomy was among the optional subjects at the Ljubljana semi-university according to the syllabus of 1824. In addition to numerous students from all classes, Schulz's lectures of astronomy were attended by many citizens, elderly people, women, girls, and even the poet France Prešeren (1800-1848) who wrote his funny poem about star-observers.

Figure 30-62: Ljubljana crystallographer, mathematician and astronomer Schulz von Strassnitzki (Huber, Karl, 1879. Schulz von Strassnitzki, Ein Lehrerleben aus österreichs Sturm-und-Drang Zeit, Wien and Leipzig: Julius Klinkhardt (NUK-36951))

Schulz' predecessor from the areas of the modern Slovenia might have been Tartini. At Schulz' times shortly before his death Giuseppe Tartini of Piran wrote a manuscript about Plato's circles connected the music intervals. He discussed five Plato's regular polyhedrons with a special concern about the pentagon.[3420] Shortly before his death in the manuscript describing Plato's circles, the Piran native Giuseppe Tartini tied up his music with four regular polyhedrons, among them mainly with Plato's pentagon. He considered three Plato principles: the nature of the whole, the nature of diversity and substance. Although Schulz was a liberal guy and opponent of Cauchy's politics, they complement their research. Researching the regular polyhedrons also opened a new science for Schulz, the crystallography. In 1835 Schulz participated as a lecturer in Ljubljana in one of the leading

[3419] Schematismus Laibacher Gouvernenments Königreichen Illyrie für das Jahr 1834, page 155.

[3420] G. Tartini, *Scienza Platonica fondata nel Cerchio*, Cedam-Casa Editrice Dott. Antonio Milani, Padua, **1977**, 1, 8, 11, 70, 94, 161, 277, 279, 309, 385, 399, 439, 443.

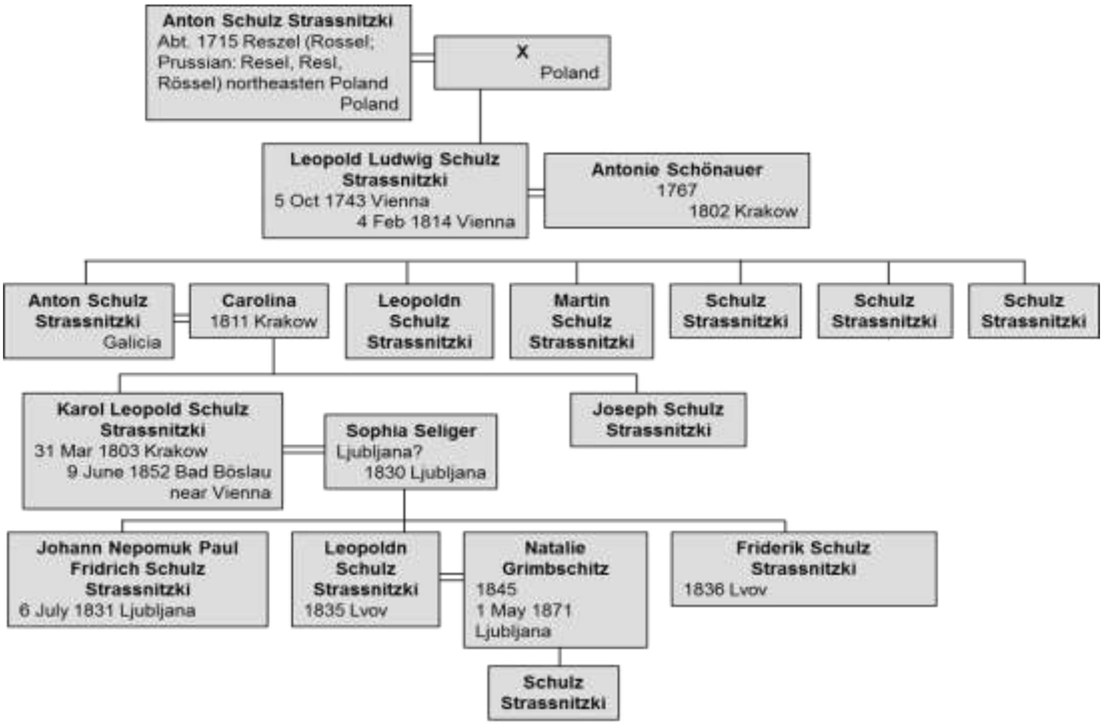

Figure 30-63: Ancestors of Ljubljana professor Schulz Strassnitzky

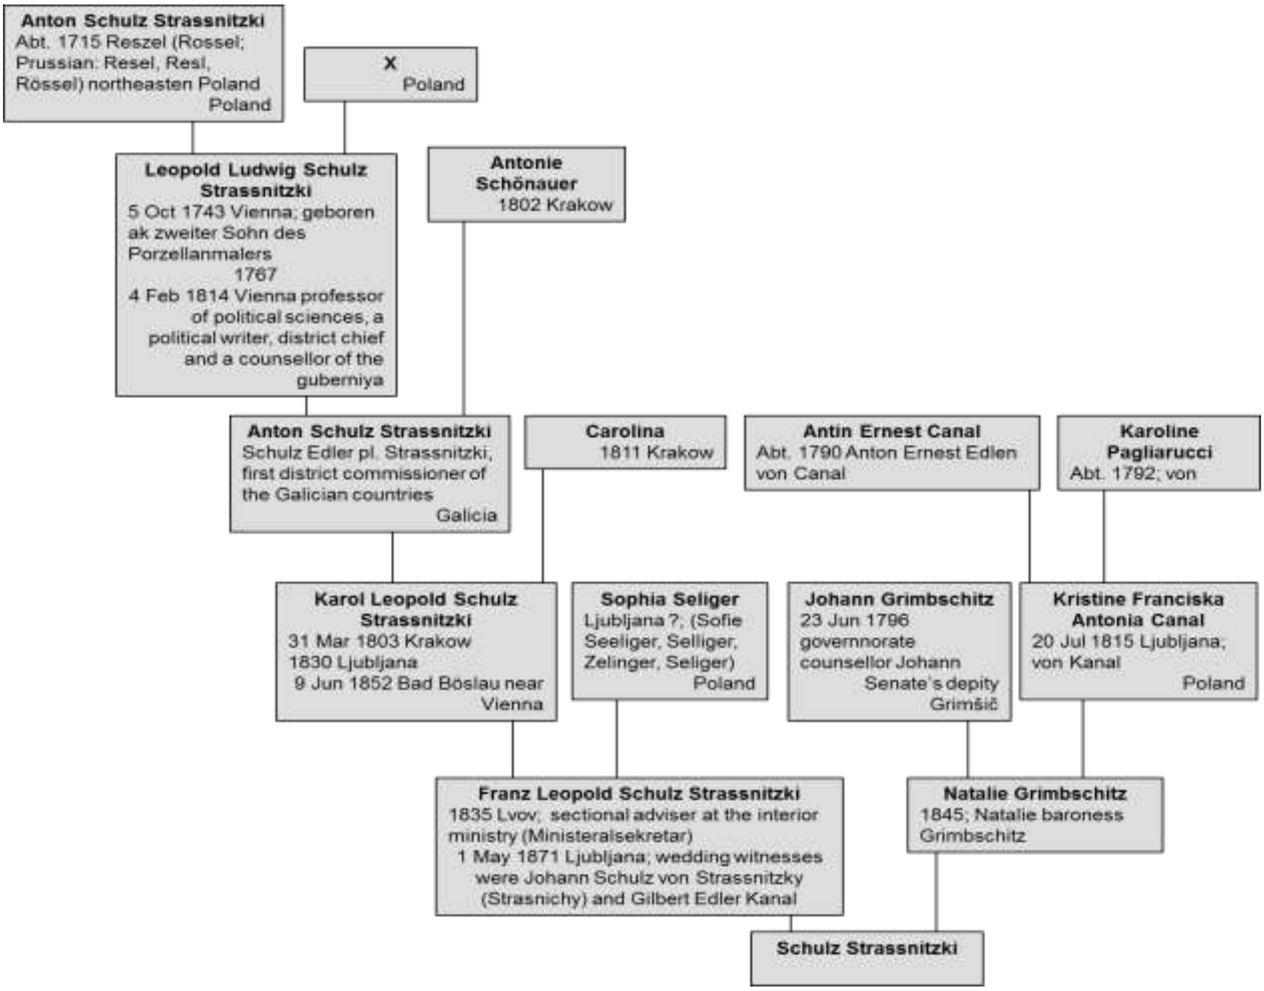

Figure 30-64: Ancestors of Schulz Strassnitzki and his son married in Ljubljana

mathematical journals' discussion of the exceptions to Euler's theorem about polyhedron. The operative part of theorem was discovered by Descartes and was described by Leibniz afterwards. However, in 1750 and 1752, Euler explained it in modern form:[3421]

The number of angles of polyhedron + number of sides = number of its edges + 2

The impeccable evidence of a general proof was posted only by the young Cauchy in the year 1811/12. The survey was based on Plato's five regular polyhedral bodies to which the clever Kepler added two other non-convex dodecahedrons in 1619. In 1809, Poinsot adjoined a further pair, great dodecahedron and great icosahedron. In 1811/12 Cauchy proved that it is possible to correct both Poinsot's solids as they are stellated forms of the dodecahedron and icosahedron. In September 1832 in Ljubljana Schulz demonstrated that Euler's theorem applies to all geometrically simple bodies. He noted the description which physician and professor of mineralogy Johann Friedrich Christian Hessel (1796-1872) extended to more complex bodies of compound (double) crystals for which Euler's theorem is not valid. Finally, Schulz derived Euler's theorem from the more general Cauchy's ideas. Schulz' paper was the crown of multilevel debates about the Eulerian disposition in Crelle's Berliner magazine, which began with the anonymous publication Remark about a polyhedron (Bemerkung über ein Polyeder) in the year 1828. Cauchy and Legendre complemented Euler rule regarding the number of edges. In 1828, Dr. Hessel from Marburg described more polyhedral whose properties are not consistent with the Euler rule. Hessel has relied on Haüy's crystallographic research, published in German translation "Zwölfrautenflächers aus dem Würfel; treppenartige Kochs alztrichter usw". In 1830, Hessel in his article published in Johann Samuel Traugott Gehler's (1751 Görlitz-1795 Leipzig) Physics Dictionary (*Gehler's Physikalische Wörterbuch*) and in his books printed next year in Latin translation in Marburg and republished in German language Leipzig with Haüy's acquaintance Leopold Gmelin's (1788-1853) additions derived from the Haüy's dynamic tradition of crystallographers. The German practitioner Hessel was far from Cauchy's more theoretical French background, while Cauchy's fan Bravais developed similar ideas independently in structurally theoretical tradition in 1849.

Beiträge zur Discussion des Eulerschen Lehrsatzes von Polyëdern in Beziehung auf die neulich bemerkten Ausnahmen desselben.

Figure 30-65: The introductory page of Schulz's Ljubljana discussion on polyhedrons (Schulz von Strassnitzki, Karol. 1835. Beitrage zur Discussion des Eulerschen Lehrsatzes von Polyëdern und Bezichung auf die neulich bemerkten Ausnahmen desselben. Journal for Reine und Angewandte Mathematik (Berlin, ed. AL Crelle) 14/1: 83).

According to his criticism of Hessel, Schulz was also directed against Bošković's dynamic atom, just like Bravais. Certainly, Schulz' work in Ljubljana was the beginning of mathematical crystallography there and in all Habsburg monarchy after Leopold Gmelin flied to Joseph Franz von Jacquin's Viennese University headquarters in March 1811 when Karol Leopold Schulz Strassnitzki was still a kid. The new geometrical crystallography soon found its foundation in Galois' group theory, but the conservative Cauchy during the life of Galois may not have supported Galois due to Galois' extreme political positions in Paris during the July revolution.

[3421] Euler, letter mailed to Goldbach in the year 1750; Euler, 1758, 109-140; Cantor, 1901, 3: 556.

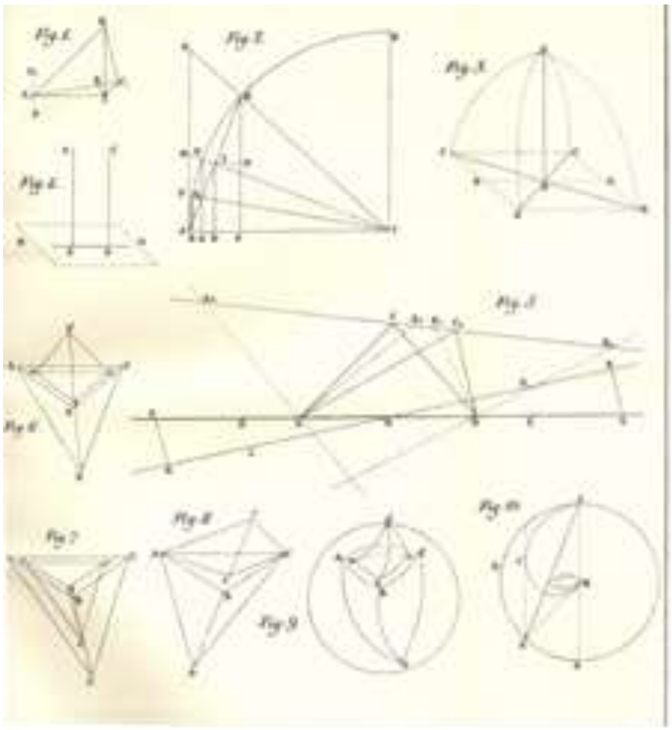

Figure 30-66: Images from Schulz's Ljubljana discussion on Polyhedrons (Schulz von Strassnitzki, Karol, 1835. Beitrage zur Discussion of Eulerschen Lehrsatzes von Polyëdern und Bezichung auf die neulich bemerkten Ausnahmen desselben. Journal for Reine und Angewandte Mathematik (Berlin, ed. Crelle) 14/1: 381 (Table I, Figures 6-9).)

In September 1832 Schulz proved that Euler's theorem holds for all geometrically simple bodies. He replied to Hessel's description of moved or extended complex structures for which Euler's theorem did not apply.[3422] Finally, Schulz derived Euler's theorem from the more general Cauchy's theorem.[3423] Schulz's discussion was the crown of multiannual polemics about crystallography and polyhedral in the Crelle's Berliner journal where Gauss, NH Abel and CGJ Jacobi also published. Schulz and Hessel continued the early exploration of the crystal symmetries of Haüy[3424] started in Paris in 1784.

In 1809 William Hyde Wollaston and after him Romé de l'Isle invented a contact optical goniometer. It used reflection to accurately determine the angles in the crystal.[3425] With that tool, the science of crystallography was born because there is no real science without new tools, journals, textbooks, and meetings on its behalf. The researchers have identified the correlation between the surfaces and the chemical composition of the crystal. In 1845, in the labs of Ljubljana Lyceum, Kersnik listed two Baumgartner hand goniometers for reflection; they acquired the first for a price of 33 florins 60 kreuzers. The goniometer was completed by the Welsh William Hallowes Miller (* 1801; † 1880 Cambridge) in 1874, while the descendant of Geneva watchmakers of the dynasty of local horologist family Bobinet added a binocular to it for more detailed observations of the smallest crystals.

In 1849, Breithaupt's theory of paragenesis limited Haüy's excessive claim that every chemical substance develops only one crystal structure. In 1852 Breithaupt's theory was supported by CS Weiss and Berzelius' PhD student Gustav in the direction of the systematic classification of minerals based only on chemistry and crystallography. Haüy's connection of crystallography with geometry stimulated the Parisian professor of physics Bravais[3426] who described the mathematically precise arrangement of crystal molecules. In 1850 Bravais proved that only fourteen different crystal networks were possible. Bravais was a naval officer, botanist, mineralogist, researcher and more. His papers were presented by Cauchy to the Parisian Academy. One of the most important crystallographers of the next generation, the Russian Evgraf Stepanovich von Fedorov, was also an officer. In 1891 Fedorov's later friend of the Jewish genus Arthur Moritz Schoenflies (* 17. 4. 1853 Landsberg (Gorzów) in western Poland; † 1928) under the influence of Felix Klein independently published similar Fedorov's theory of 230 groups based on Galois's premises. Fedorov also explored the growth of crystals.

Ernest-François Mallard (1833-1894 Paris) developed the theory of modern crystallography in 1874. He relied on Bravais' data. Leonhard Sohncke (1842-1897 Munich) presented the theory in his dissertation with sixty-five correct crystalline space groups to explain the degree of symmetry in 1879. Bravais's arguments about the exact arrangement of crystalline molecules were advantageously used to study the scattering of X-

rays on crystals in the 20th century. Of course, it took several decades before practical crystallographers accepted Galois' mathematical theory of groups as the basis of their much more practical science. Certainly, the effort paid out.

Schulz's interest in crystallography in the Carniolan capital was by no means a coincidence. Carniolans followed the development of the research of new materials in the Habsburg Monarchy, where, among other things, Josef Jacob (Jacobs) and Franz Köller (Koeller) acquired the tungsten steel in Reichraming in the district of Steyr-Land in the Upper Austria in 1855, tested it at the Viennese Polytechnic Institute in 1856, and patented their process in France in 1855 and in Vienna on March 10th, 1858. The former student of Viennese Polytechnic, head of Zois's iron works in Bohinj the technical director of the Carniolan industrial company (KID) knight Lambert Pantz (* 18 August 1835 Tržič; † 3 February 1895 Fieberbrunn in Tyrol) as the first in the world produced 37% ferromanganese in the Javornik blast furnace as first-class surprise in the world of technology. Scheele discovered the manganese in 1774 while the Carniola natives discovered a rich manganese ore a hundred years later in 1872 at Begunjščica river. Pantz's city of Jesenice was recognized with an honor of the invention of the first ferromanganese process, while the Javornik ferromanganese received a gold medal at the Viennese World Exposition in 1873 as the best and richest. It received an award in the form of a diploma at the international exhibition in Philadelphia on the centenary of the United States on September 27, 1876.[3427] Lambert Pantz's success was not accidental because already his father worked as Sava suburb of Jesenice ironworks administrator (Verwalter) together with Viktor Ruard (1814 Stara Sava by Jesenice-1886 Stara Sava) in 1843. In 1836 Viktor married Ana Atzl, the daughter of the manager of the manor in Tržič Josef Atzl (1780–1873) and Theresia Atzl who were godparents of Lambert Pantz's brother Johann Emil Pantz in Jesenice on 16 March 1828. In 1825-1829 Lambert Pantz's uncle Ignaz Vitus Engelbert von Pantz was the director of Prince of Auersperg ironworks in Dvor (Hof) in Carniola where Ignaz Vitus Engelbert Pantz's son Eduard knight Pantz trained as a practice in 1825. The collaborations among predominantly Slovenian Inner Austrian metallurgists was vivid. Those traditions survived by Tržič areas native A. Paulin and the son of his classmate Matjaž Ravnik. The use of manganese, molybdenum and tungsten in Carniola lasted for two centuries, although initially those metals aroused interest only because of the high melting point. Few decades ago, molybdenum was finally used to greater extent in the steel industry.

30.2.7.5 Molybdenium and Tungsten in Early Vacuum Technique

Because of the high boiling point, molybdenum and tungsten quickly used in vacuum techniques. Langmuir developed a method for exploring discharge in gases with a thin charged probe made from refractory metals with high melting points such as tungsten or molybdenum. An adequate tiny probe did not perceptibly change the distribution of tensions in plasma.

The later mayor of Zagreb Franjo Hanaman (* 1878 Denovac in the county of Županja; † 1941) together with dr. Aleksandar Just patented tungsten lamps in Germany in April 1903. They were much more economical than carbon filaments, but unfortunately quite fragile. The production began in 1909 and soon showed the advantages of tungsten compared to the Osram.

Initially many researchers did not believe in the future of Ruska's electron microscope where smaller wavelength of electrons increased the resolution of the device, but at the same time it increased the energy of the electrons that destroyed the observed sample and molybdenum grids. The prospects seemed to be helpless. Today, molybdenum is widely used mainly in the form of MoS_2 for desulphurisation of petroleum, lubricants, solar cells, photocopiers and batteries.

30.2.7.6 Ljubljana Nanotubes

Dr. Velibor Marinković has been researching the layered crystals of molybdenum dichalcogenides and other transition metals in the IJS Laboratory for electron microscopy over three decades including his dissertation in 1965, and his discoveries were supplemented by his helper Maja Remškar. She investigated inorganic nanotubes, which she synthesized for the first time at the Jožef Stefan Institute with the technical assistance of Zora Škraba two decades ago.

[3427] Lačen Benedičič, 1999, 76-77.

Sumio Iijima (* 2. 5. 1939) studied in Tokyo and Sendai. Between 1970 and 1982 he studied crystalline substances with high-resolution electron microscopes at the State University of Arizona, and in 1979 he visited Cambridge University. Upon his return to his native island, he worked with a Japanese research development company until 1987, then at the NEC in Tskubi near Tokyo, which he has been coordinating with his lectures at Meijo University since 1999. After publishing the discovery of nanotube on November 7, 1991, he needed a dozen years to market his invention used in laptop computers, lightweight tennis equipment and computer components.)

Due to the great attention focused on carbon nanotubes, inorganic nanotubes from MoS_2 an WS_2 were somehow squeezed away, although Reshef Tenne from Weizman's institute in Israel discovered carbon-like "tubes like needles" in 1992, only a few months after Iijima.

Dr. Maja Remškar prepared the tubes differently than Tenne. For the first time, MoS_2 crystals were observed at the Jožef Stefan Institute in 1995 and they immediately detected their special useful features. They found that the diffraction image at the ends of the needles of MoS_2 differs from the image from the central parts of the nanotube. The diameter of needles was only a few micrometers but they were permeable to the old Philips 300 digestive electron microscope at 100 keV at her disposal. The diffraction image did not change during rotation of the needles of the MoS_2 around their axis, which testified to the enviable symmetry of unusual hollow tubes. The new discovery appeared on the Ljubljana horizon, although Slovenian researchers were initially unaware of the achievements of Tenne. This gave them a lot of advantage, since the nanotube in Ljubljana would

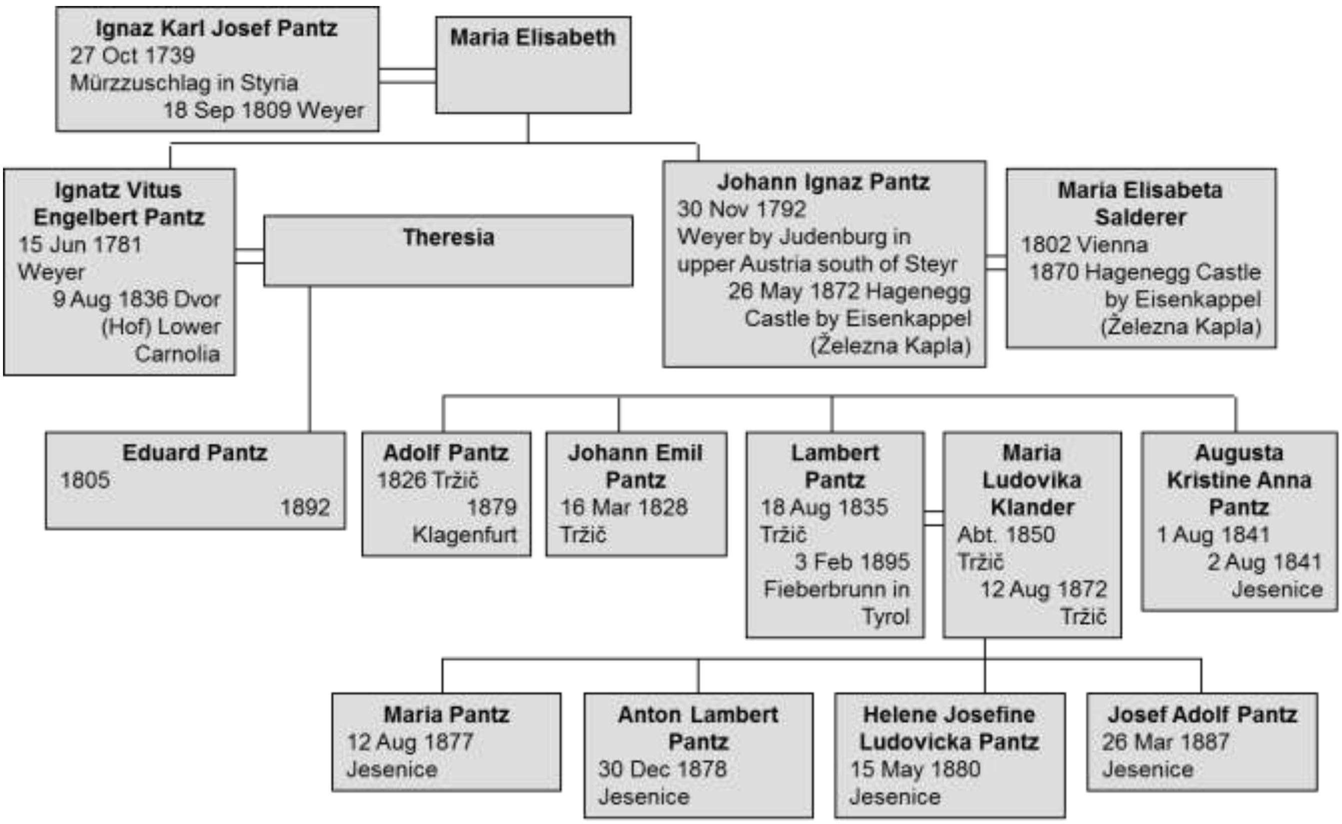

Figure 30-67: Family of Upper Carniola inventor Lambert Pantz

not have been synthesized in a way that they did it if they were aware of Israelis' anticipation. The Ljubljana nanotubes were significantly larger than Tenne's, as they had up to 20 μm diameter and were several mm long.

Dr. Maja Remškar just started her post-doctoral research at the Federal Polytechnic in Lausanne. There she had excellent electron microscopy facilities in the spirit of the microscopic tradition of Hacquet's contemporary Reynier. The professor

Francis Levy enabled her to continue researching inorganic nanotubes. Levy was not only aware of the great possibilities of a new discovery, but he also knew how to stimulate a young researchers by constantly supporting them. The Swiss academic circles have always been extremely hospitable to Slavic scientists like Einstein's first wife. Every year since then, Maja has been able to afford some carefully planned weeks of research in Lausanne, where on first-class devices, they examine their domestically developed ideas and check them in cooperation with their Swiss counterparts.

The Ljubljana process offered a more complete crystal structure than Israelis' achievements with a better understanding of the structural properties of new nanomaterials. In May 2001 she received the Zois Prize for her contribution to new nanotubes published in Science magazine. She wrote the only Slovenian contribution in the prestigious encyclopaedia of nanoscience and nanotechnology, published by the international publishing house Marcel Dekker, Inc. Slovenia has been recognized on the world map of the achievements of modern nanotechnologies.

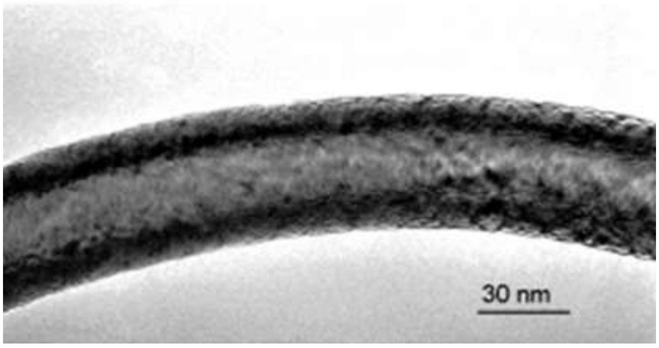

Figure 30-68: High-voltage cracking errors and peeling of the thin layer of the nanotube surface due to additional pressure upon bending (photo: Maja Remškar).

MoS_2 and WS_2 nanotubes were synthesized by Maja and colleagues in a conventional chemical transport reaction as commonly used for the growth of dihalogen layered crystals. They added the precious metals to sulfur, molybdenum or tungsten in a ratio of 0.5 % for the synthesis of the starting material before the beginning of the transport reaction. The reaction run for twenty-two days at a temperature of 1060 K in the emptied silicon vessel exhausted to a vacuum of a hundred Pa. The temperature gradient of 5.6 K / cm in a well-isolated ampoule was relatively small and probably didn't detectably affect the growth of nanotubes.

The inorganic tubes do not withstand high pressures, but with the interlocking of their fibers they strongly resist the forces of stretching. The pipes have an extremely high surface-to-weight ratio, as well as the ratio of volume and weight. Both promise a useful use in the industry. Unfortunately, we are not yet able to measure the two relations exactly: they are in fact non-standard in themselves, but the problem of measurement is further complicated by the extremely small dimensions of the samples. We need to deal with individual molecules, but the direct measurements of the properties of the molecule are not so far anymore as the fulfilment of dreams of the previous centuries.

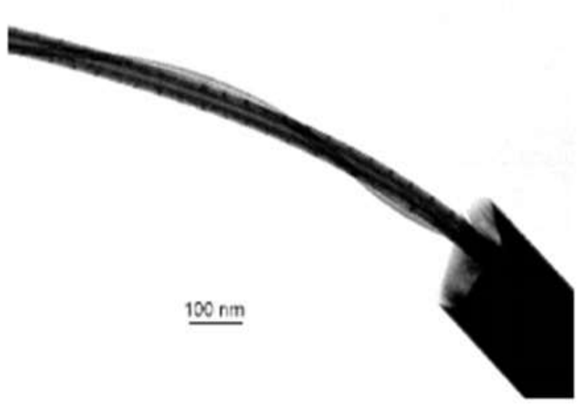

Figure 30-69: The first inorganic nanotubes in Ljubljana: a pair of WS2 nanotubes grow from the inside of the micro-tube. A narrow tube with a diameter of 18 nm is wound sufficiently evenly around a thicker tube of diameter 40 nm. The mating of both tubes can be explained by the formation of intermediate surfaces between the crystalline nets of the two tubes. Contact between pipes is possible only at points where the arrangement and orientation of the walls are in accordance with the P63 / mmc spatial group (photo: Maja Remškar).

MoS_2 seems to be more promising than the similar WS_2 for Ljubljana researchers. The distance between the centers of approximately equally thick MoS_2 tube is 0.96 nm and is thus comparable to the smallest carbon nanotubes. The nanotubes grow in bundles with typical diameters of half micrometers, and in the length of several dozen micrometers under the influence of the C_{60} catalyst. Catalysis is a complicated phenomenon in these tight conditions, and we do not yet have the right model for it. Naturally, the choices increase, since nowadays we know many inorganic substances that form nanotubes.

Reshef Tenne (* 1944 kibbutz Usha in the western Galilee) was born in Israel, precisely during the final defeat of the Holocaust practitioners. After the tragic apartheid occupation of crusaded Palestine in June 1967 he received a diploma (1969), a master's degree and a doctorate at the Jewish University in Jerusalem combining physics and chemistry studies. After three years of study in Switzerland, he was employed at the Weizmann Institute in Rehvot, Israel, where he became a full professor in 1995. In the summer of 1991, he attended Tokyo University and there he listened to a lecture of five-year-older Iijima on the new discovery of carbon nanotubes. Reshef immediately observed the specialty of carbon, which behaved similarly in nanotubes or nanoparticles. Upon returning home, he consulted with colleagues and after a few months already reported on the first successes with inorganic nanotubes. Initially he by no means thought of sales and industrial uses of his inventions in the Japanese way, because he was especially impressed in the extraordinary properties of nanotubes whose properties already perceptibly aligned with smallest changes in diameter and screw resistance of the tubes. Their property is comparable with other popular materials today, for example with changes of colours of liquid crystals with the smallest increase in temperature, or with changes in crystalline structures and commercially available materials at phase transitions stretched to a wide temperature range. Soon Rashef discovered the benefits of his inorganic tubes compared to Iijima's use of them in higher temperatures, pressures and loads. Nevertheless, today carbon nanotubes still have great advantages on the market: first come first served.)

The growth of Ljubljana nanotubes resembles Hacquet's hard rime flowers; only the distances are thousand times smaller. Instead of Hacquet's microscope, Maja Remškar, of course, had to use a high-resolution transmission microscope. MoS_2 nanotube walls are built from a single layer of MoS_2.[3428] Thus, the first single nanoparticle of the inorganic compound was formed in Ljubljana and with it the first molecular crystal was made from nanotubes.

The sum of the flexibility energy per individual primitive cell of the crystal is higher in nanotubes than in larger micro-cells, where the elastic energy is distributed over a larger number of molecules. The accumulation of a layer of molecules in nanotubes of diameter down to 200 nm is different from that of ten and more thicker tubes. While micro-cells grow individually, nanotubes often form ropes and several dozens of them grow together up to a few millimeters in length. In nanotubes, individual specimen fuse while the forest of the tube grows with individual tubes-trees separated by very small angles. The instability of the growth of thin films of MoS_2 molecules in flat-shaped crystals under normal conditions for nanotubes, at the same time, allows ~~for~~ growth in extremely long hollow structures, which would surely delight even the old Hacquet. Of course, Hacquet could not distinguish nanotubes through his microscope.

Adding gold or silver to the mixture prevents chirality, which is otherwise shown by nanotubes from pure MoS_2. The walls of the tube consist of coaxial cylinders. Precious metals do not bind to the apertures of nanotubes where there is no room for atoms of precious metal, since the distance between the layers of the MoS_2 molecules is reduced due to greater internal pressure. The growth of the layer from a layer of molecules prevails. The precious metals are unevenly distributed in layers because they are practically absent at the nanoparticles.

Of course, Maja's discoveries are less prominent than Israelis' achievements, which have much higher financial support. Nevertheless, more and more modern researchers are researching the mechanical, physical and catalytic characteristics of inorganic MoS_2 tubes. At the Jožef Stefan Institute, nanotubes are still studied by dr. Dragan Mihailović.

The Israelis have already published the first theoretical calculations with powerful computers; experimental work has indicated new dimensions

[3428] Panjan, 2001, 15; Remškar et all, 2001.

with helpful guidance.[3429] Apparently, in inorganic nanostructures the growth of new compounds is stable only in cylindrical geometry. The concept of the crystal developed in Hacquet's age is changing rapidly today as we study new symmetries of the quasicrystals, viruses and nanotubes that Hacquet's contemporaries did not expect. Indeed, the description of the regular shapes of the crystals was already initially somewhat forced, as liquid crystals and other forms were discovered in parallel, while they were never consistent with the systematic classification of "ordinary" crystals. Nonetheless, the description of the ideal Schulz's and his contemporaries' crystalline network has been retained until today, when it is obviously that we need a change. It seems that there are no ideal correct structures in nature, just as they are not in relationships between people. The recent official change describes the crystals mainly in relation to their behavior under X-rays.[3430] The regular shapes of rigid systems of previous centuries changed in modern world where even the gender and race ceased to obey its onetime dualities.

The new influence of geometry on the concept of stability in chemistry reminiscent ~~of~~ the reversal that explorations of geometric symmetries ~~which~~ had sparked in the physics of high speeds and great distances during Einstein's "wonderful" year. Among the important properties of the chemical compound, modern transient microscopes gradually include a geometric symmetry, which was not imagined during the former underperforming resolution. The more powerful devices opened up new dimensions of knowledge, resembling the happening in the more notorious, more expensive and ever-more powerful particle accelerators.

The nanoscience is already a well-established concept, but not inorganic nanotubes as its part. This will flower after the researchers of inorganic nanotubes will publish their own focused conferences, the specialized experimental tools, and monograph. Three fertile decades after the discovery, the time is ripe for the good textbook, as it will help the newcomers at the first steps in a promising new scientific field.

30.2.7.7 Conclusion

Inventions in science are the result of sudden surprise called discovery. However, there is no discovery without a solid prior work. The fertile research is always based on the shoulders of many scientists, who substantiate and facilitate the invention with their contributions for centuries. Due to the lack of money and the excess of local traditional quarrels, the large discoveries in small Slovenia are rare. The nanotubes are not large by themselves; therefore, they may be right goal for researchers from small Slovenia.

31 Industrial Uses of Vacuum Technologies - Luminescence

31.1 History of Research of Luminescent Materials

The research of luminescence might not belong to the proper vacuum technologies, but both have their strong correlations. "Phosphorus is called the body whose light is like the light of the moon and is often even weaker. They do not leave a stronger impression in the eye in which they collect, nor they cause sensible heat, nor they significantly increase the temperature of the surrounding bodies." Thus, luminophores and the phosphorus elements, which he commonly referred to as phosphorus, were described by a long-time professor of physics in Ljubljana Ambschell two hundred years ago.[3431] Today, we describe luminescence with the difference between its high energy absorbed and the lower energy of the photons emitted. The distinction between definitions is the product of centuries of research, discoveries, and errors that have enabled many uses of luminophores, without which one cannot imagine the modern lights, computer and television world of Ching Wan Tang's organic light-emitting diodes (OLED) developed for Eastman Kodak.

31.2 Research of Luminescence before the Discovery of Ultraviolet Lights

As in most other history of knowhow, the westerners learned most about the luminescence from Africans, Asians, Oceanians and Native Americans to appropriate their wisdom into European business. We will learn a lot about Westerners' success while the real colourful inventors must be described later. The shine of matter in the dark has attracted attention already in Antiquity. The indigenous peoples of Indonesia used bioluminescent fungi as flashlights in their forests. The Daoist Record of the Ten Sea Islands (Ten Continents in World Ocean, Ten islands in the inner seas, Hai Nei Shih Chou Chi, 十州記, Hainei shizhou ji, 海內十洲記) in a fourth or fifth-century BCE China detailed nautical adventures including fiery sparks when the water is stirred, later attributed to the Han court jester Dongfang Shuo (東方朔, c. 160 BCE – c. 93 BCE). The bioluminescence of mushrooms and fish was already known to Aristotle, and Pliny the elder also described the phosphorescence of rocks.[3432] All the way to Osamu Shimomura's (1928, Kyoto-2018, Nagasaki) Nobel Prize in Chemistry 2008 for his research of the maritime jellyfish Aequorea victoria Green Fluorescent Protein (GFP) inspired by the Japanese WW2 experiences including his teenaged spotting of Bohr's bombing of his native Nagasaki. The bioluminescence was and still is far-eastern domain despite of Princeton university and Eastman Kodak involvements.

31.2.1 First European Description of Fluorescence

The Native Americans might have influenced early modern European luminescence even more than Far Easterners. The ancient Maya polished jadeite appears luminescent and glassy. Their *Eysenhardtia polystachya* (blue wood (Palo azul), *Mexican kidneywood*) was always widely used in folk medicine as an anti-rheumatic, analgesic medication, blood depurative, antitussive, antispasmodic, anti-diabetic, febrifuge, anti-inflammatory, herbal remedy for several illnesses on the renal tract, especially as a diuretic and antimicrobial agent for treatment of kidney and bladder infections. In 1565 the Spanish physician Monardes first told Europeans about fluorescence of that small Mexican tree Eysenhardtia polystachya which Aztecs cooked for the beneficial effects of tea prepared from its wood. The "lignum nephriticum" was derived from its water solutions known in various forms in ancient India tall tree narra (Pterocarpus indicus) while it was particularly common in Mexico nicknamed "New Spain". The other "lapis nephriticum (λίθος νεφριτικός; νεφρός λίθος)" which means 'kidney stone', is nephrite $Ca_2(Mg, Fe)_5Si_8O_{22}(OH)_2$ as one of two different mineral species called jade. For one reason or another, the

---

[3431] Ambschell, 1792, 4: 279, 280; Ambschell, 1807, Dissertatio secunda de lumine, 133.

[3432] Emil Wilde (1793-1859), professor of mathematics and physics in Berlin Grammar school, *Geschichte der Optik vom Ursprunge dieser Wissenschaft bis auf die gegenwärtige Zeit, Rücker & Püchler*, Berlin 1843, II part, 384-385.

water solutions of the wood and the mineral are both believed to be a cure for the troubles with kidneys stones in folk medicine, probably because of the remote awareness of the equally luminescent phosphorus contained in urine. In the same book, Monardes also published the first description of the tobacco that the Native Americans showed to Spaniards.[3433]

The Ljubljana copy of posthumous Dutch edition of Monardes' book was bind to his other medical work printed in the year 1582 and to five works of other contemporaries. In 1626, the book was owned by the Viennese doctor ~~of~~ Conrad Widder, probably related to Widdeke or Widdersheim. Later, the book was moved to Ljubljana Augustinians' library and after Josef II suppressed the Augustinians in Ljubljana it was catalogued in the Lyceum library in Ljubljana around 1800. Certainly, the folks of Ljubljana were cured from their kidney stones by Augustinian readers of Monardes' book in no time.

Monardes' data were soon supplemented by his fellow Mesoamerican intruders. Bernardino de Sahagún (born Bernardino de Rivera (Ribera, Ribeira), c. 1499 Sahagún-1590) as a Salamanca educated Franciscan friar learned Aztec Nahuatl language to research their plants and habits for his bilingual Spanish-Nahuatl manuscript General History of the Things of New Spain (Historia General de las Cosas de Nueva España) best preserved in its Florentine Codex. Next the university of Alcala graduate Francisco Hernandez (1514 La Puebla de Montalbán, Toledo-1587 Madrid) worked closely with Aztec artists and physicians in central Mexico for his Nova plantarum et mineralium mexicanorum historia partly published by Galileo and his patron Cesi. All was prepared for Bologna stone as the first among early modern imported European optical curiosities predeceasing the Bolognese Jesuitical diffractions and Danish birefringence.

31.2.2 The First European Artificial Luminophore: "Bologna Stone"

The dissolved natural stones and wood luminophores made their European front pages only after their local alchemists were able to copy their effects, the same as happened after the discovery of radioactivity three centuries later. The shoemaker with alchemistic ambition Vincenzio Cascariolo (Casciriolo, Casciarolo, 1571 Bologna-1624 Bologna) obtained the first European artificial luminophore by his alchemical experiments in Bologna between 1602 and 1604. He mixed his grounded barite $BaSO_4$ dug up by Monte Paderno above Bologna and powdered charcoal. At night he noticed that the cooled mixture emits purple-blue light.

Galileo was among the first to learn about the novelty at the nearby University of Padua. Upon his demonstration of telescope to the Pope and Roman erudite, Galileo gave the piece of stone to his peripatetic friend Lagalla in 1611. The shine of the "Bologna stone", also called "lapis solaris", put at the limelight the doctor Giulio Cesare Lagalla (La Galla, 1571 Padula by Salerno-1624 Rome) from the Roman College later called Sapienza, who first published the discovery. In retention of light in luminophore, Lagalla saw the proof that light does not have weight, since the weight of the stone does not change during luminescence. He thus opposed the claims of Galileo and criticized Galileo's description of the lunar observation through the telescope in the same booklet.[3434] Galileo was angry, but he did not publicly respond.

Lagalla (1612), Fortunio Liceti (1640), Kircher (1641), Schott (1656), as well as the 18th-century researchers Dufay (1735), Scheele (1771) and Herbert (1773) assumed that luminophore absorbs light as a sponge. The curator of Aldrovandi's collections the Bolognese mathematician-astrologer-physician Ovidio Montalbani (1601 Bologna-1671 Bologna) from the illustrious Bolognese family in 1634, Leméry (1698), de Mairan (1717), the changeable Dufay again in 1726, Zanotti (1748), Volta (1776) and de Saussure (1792) assumed that it was a type of burning.[3435]

Montalbani's elder colleague professor of Philosophy at the University of Bologna Fortunio Liceti (1577 Rapallo-1657 Padua) described the "pietra lucifera di Bologna (*Litheosphorus, sive De lapide Bononiensi lucem in se conceptam*)" in 1640. He believed that unilluminated side of the

[3433] Monardes, De simplicicus medicamentis 1574, 50-52, 21.

[3434] Mlađenović, 1985, 177.

[3435] Edmund Newton Harvey, A history of luminescence. From the Earliest Times Until 1900, The American Philosophical Society, Philadelphia 1957, 362.

moon shined with brighter light due to phosphorescence, like the "Bologna stone". Therefore he criticized the correct Galilean description of lunar ash light, the reflection of the sunlight from Earth, published already by Leonardo da Vinci (1452-1519). Liceti was one of the most important thinkers of his time. Among other things, he also wrote to Gassendi about the atoms. That is why Galileo could not overlook his criticism, as he initially intended. In the spring of 1640, a former Galileo's pupil Prince Leopoldo Medici (1617-1675) wrote from Florence to Arcetri to persuade Galileo to answer "Liceti's light-hearted arguments". In his last scientific work produced before his death Galileo criticized Liceti in "Lettera al Principe Leopoldo di Toscana". He labeled Liceti's great knowledge as a mere gathering of unrelated facts, and he rejected the analogy between the Moon and the "Bologna stone" as unfounded. Certainly, Galileo and Liceti befriended already during their joint teaching in Padua, therefore Galileo's criticism was relatively friendly. Later, on 19 June 1657, the prince Leopoldo chaired the first European experimental physics group called Academia del Cimento.[3436] Liceti's idea of the phosphorescence of unexposed celestial bodies was used by Puluj in his description of Venus centuries later.[3437]

Lagalla, Montalbani, Paduan and Bologna professor Liceti were not the Jesuits. Finally, the Roman Jesuits joined the luminescent Bolognese debate which was reserved for alchemists and physicians up to date. Kircher completed his description of "Bologna stone" six years after Liceti with his own observations of luminescence of animals, fish and stones. He noticed that "the light emanating from the stone is not constant, because it faded with time like a magnet. The power of the simplest shining "fireplaces" is suppressed by the elimination... The light is within the shadow, and it is stored in the shiny body. In contrast to the prevailing opinion of the educated philosophers, (Bologna) stone drags light on itself like oil attracts fire and magnet attracts iron. Light in such a stone has the properties of heaven and fire to shine in darkness, like the Moon itself. In some stones light ignite the atomic particles which are trying to get rid of that light in one way or another."[3438]

CAPVT VIII.

[illegible]

Figure 31-1: Figure: Kircher's page of Ars Magna with description of Liceti's work.

Kircher's work had a profound influence on contemporaries, especially in Jesuitical schools. In the Jesuit college in Ljubljana it was obtained already in 1697 as a gift of the prince Auersperg. During the fire on 28 June 1774, it was borrowed, since it was not listed among the books that were saved from burning on March 1, 1775. Galileo criticized and ridiculed Kircher's approach to science in his letter to Torricelli. Kircher used to mix astronomical records of music or astrolabe clock with medicine against the bite of the tarantula related to the dance tarantella at the same page of his book. The Aristotelian Kircher was widely read as a great Jesuitical information mailbox but officially mocked as the modernized European sciences preferred focusing on single simplified topics. Galilean, Boyle's, and Huygens's criticism alienated later scientists from Kircher's physical investigations,[3439] until modern revival of studies of Kircher in the USA.

Kircher is often referred as the discoverer of fluorescence in solutions, as he wrote that the solution "is transparent in the light, and in the shadow the dark parts become reddish and

magically change according to the color of the environment ... To the best of my knowledge, I am the first to notice this chameleonic property of (luminophore)". The local procurator of society of Jesuits Francisco de Florencia (1619/20 Florida Espanola-1695 Mexico) sent the "Lignum nephriticum" solution to Kircher by a vessel sailing from Mexico so that Kircher and his fellow Jesuits could show the phenomena to the rulers. Newton and others later corrected Kircher's description.[3440] The clever Jesuits cashed their ability to perform missionary and scientific works in the areas unreachable to the other European mortals of those times.

31.2.3 *Chemical Element Detection: Phosphorus*

The Italian monopoly of European luminescent debates was over when the different German alchemistic approach entered the stages especially in Saxony desperately ruined during the Thirty Years War. The junior army officer of Thirty Years War turned unsuccessful Hamburg dealer Hennig Brandt (also Brand, around 1630 Hamburg-1710 Hamburg) extracted phosphorus

[3440] Harvey, 1957, 392-393; Boyle, *Opera varia* Genevae 1680, 81.

from several tons of urine obtained from the Hanoverian military barracks between the years 1669 and 1675. For 200 thalers he disclosed the discovery to his friend, the doctor of medicine and court councilor of Prince elector of Mainz and Saxony, Johann Daniel Krafft (Kraft, Crafft, 1624 Werheim-1697 Amsterdam). In the same year, Leibniz's friend-collaborator Krafft informed Boyle of the discovery after the ceremony when Newton was named professor of physics at Cambridge. The other Leibniz's friend Papin was also there assisting Boyle in the same era more as an engineer and not so much as the alchemist. According to other sources, Boyle discovered the item himself by Krafft's directions. On 17 May 1677, the Lutheran Krafft gave a lecture on phosphorus at the Royal Society in London. Boyle was in the audience and Boyle soon announced that "the cold light of the Bologna stone" needs air while it is quenched by ammonia and alcohol, among other things. He also studied the flickering of animals and "lignum nephriticum". The company of the former Boyle's assistant of German genus Ambros Godfrey Hanckwitz (1660 Köthen (Cöthen, Anhalt)-1741 London) successfully produced and sold phosphorus in England and elsewhere in Europe during half of a century. Hanckwitz skillfully advertised his products, became rich and even the baron, while his descendants were less lucky.

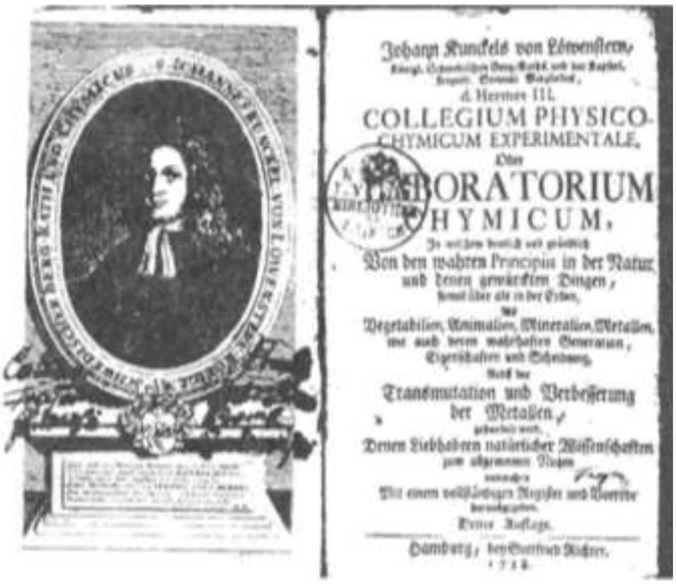

Figure 31-3: Figure: Kunckel portraited by the title page of his book with the signature of previous owner the Idrija pharmacist E. Freyer in a copy today kept in NUK.

The son of alchemist at the court of Holstein prince Kunckel rediscovered the phosphorus at a time when he was a lecturer at the University of Wittenberg in 1676. Other sources report that he learned secrets from Krafft, or from Brandt. Kunckel also became famous with his ruby glass.[3441]

In the spring of 1677, Krafft organized a public presentation of phosphorus at the court of Johann Friedrich (1625-1679) in Hanover, where Leibniz also listened as newly appointed ducal privy councillor and librarian. In 1710, with his authority, Leibniz helped recognition of Brandt's discovery of phosphorus in Saxony.

Figure 31-4: The title page of Kunckel's notes about chemistry published in 1721 with his phosphorus described in fourth part of the copy of Idrija pharmacist E. Freyer, today kept in NUK.

Leibniz closely followed the whereabout of the economist-alchemist Johann Joahim Becher. Becher studied the properties of phosphorus as a chemistry professor at the University of Mainz together with his friend the doctor of electoral prince in Mainz Georg Caspar Kirchmaier (1635-1700 Wittenberg), who also reported on Kunckel's

[3441] Under Kunckel's portrait on the cover of his book on experimental chemistry from 1738 there is a propriety entry of Ernest (Ernst) Freyer, born in Žatec of Bohemia, a pharmacist in Idrija. His knowledge of the botany was also appreciated by Janez Anton Scopoli (1723-1788), who was a medical doctor in Idrija between 1754 and 1770. The botanist Henrik Freyer (1802-1866), Ernest's grandson, was the curator of the Regional Museum in Ljubljana between 1832 and 1853. E. Freyer's signature shows that Kuckel's discussions on chemistry from 1721 with the description of phosphorus in part IV was also once his property research. As the professor of Wittenberg university Kirchmaier also published his student's university exam disputation *De vacuo et loco, pro loco* to claim that the total vacuum is not possible in 1660. On twenty-two pages he noted Hero, Bacon de Verulam, Democritus, Jan Baptist van Helmont, Valeriano Magni, Guericke from Magdeburg 50 km west of Wittenberg, G. Schott in Würzburg 300 km northwest from Wittenberg, Cartesians, the Jesuit Arriaga, Sennert and many others except Torricelli and Boyle. Kirchmaier probably retained some peripatetic doubts about vacuum.

Lemery reported how the Saxon official Christian Adolph Balduin (* 1632 Döbeln southwest of Leipzig; † 1682 Grossenhain west of Leipzig) treated luminescence during his search for the alchemistic philosopher stone. At first Balduin kept his production secret, but the clever Johannes Kunckel coaxed it from him and made a profit from the public demonstration, as he did a little later with the phosphorus designed by Hennig Brand. In 1675, Balduin discovered that the residue of the distillation of the crushed chalk solution in saltpeter (nitric) acid is lit in a dark like "Bologna stone". The shimmering flickering rapidly waned outdoors, and much longer lasted in a hermetically sealed glass tube. Balduin lived for a while in Regensburg and as the member of Academy of Sciences Leopoldina had a lot of opportunity to learn all about sealing techniques of his quarter of century older fellow Saxon official Guericke. Balduin described his method of production in a difficult hardly understandable alchemical language. His second artificial luminophore $CaNO_3$, probably with some sulfur added, was sent to the Royal Society of London with a cover letter in 1676. The preparation of Balduin's "phosphorus hermeticus" was improved by Placidus Heinrich.[3442] Later studies have shown that phosphorus surrounded by air is shining due to slow oxidation of vapor without photoluminescence involved. Similar chemiluminescence as in phosphorus is furthermore observed in many other substances, and the phenomenon is also the foundation of all bioluminescence.[3443]

Friedrich Hoffmann (1660-1742), professor of medicine in Halle, discovered the luminescence of the gypsum $CaSO_4$ in 1700, but did not describe his preparation process in more detail. In the meanwhile, the Chinese, Mesoamerican, North Italian, Roman, Saxonian and imperial Prague alchemistic research of (artificial) luminescence entered Boyle's and Newton's England. The weaver's son John Canton (1718-1772 London) as the assistant teacher at a private school in London calcinated oyster-shell (as calcium carbonate) with sulfur to get impure CaS in 1768. That yellow light luminophore is still called by Canton's name. A similar substance was already known to the Chinese[3444] as described in the vinaya (jièlǜ 戒律, kairitsu 戒律) related text of master Buddhist monk chemist-microbiologist Lu Tsan-ning's (919-1001 AD) Sung Biographies of Eminent Monks (Sung Kao-seng chuan) finished in 988. The Chinese gradually influenced all European research including Barbara of Celje. The joyful fans of Roman mysteries of Bacchus widely used J. Canton's luminescent compound of lime and sulfur in 300 BC.

Soon the luminescent phosphorus got its rivals while Liebig's chemistry developed into profitable discipline. After his return from Moscow economical institute to Frankfurt on Oder and Berlin, the opponent of vital force theories of chemicals like phosphorus or potassium Johann Friedrich John (* 1782 Anklam; † 1847 Berlin) noticed phosphorescence of strontium sulfide in his textbook published in 1817.

31.2.4 Investigation of Luminescence after the Discovery of Phosphorus

The luminescence was researched in parallel with other optical phenomena. Nevertheless, because of its alchemistic background it did not affect the development of optics so much as the diffraction or the double refraction (birefringence), first described by the professor Erasmus Bartholin (1625-1698) in 1669 in Copenhagen. In the same year his elder brother Thomas (1616-1680), professor of anatomy in Copenhagen, published the 2nd edition of his bioluminescence research of the animals first issued in 1647.

The electroluminescence has prompted a lot of attention in the pioneering era of electrostatics. In 1768, the weaver's son Canton investigated the

[3442] Wilde, 1843, 390.
[3443] Harvey, 1957, 448-.
[3444] Teple, 1991, 171.

excitation of luminescence by discharging[3445] resembling a century later research of another textile businessman's son Crookes. The prior in Rillé and Anjon, the member of AR Abbé Jean Picard (1620-1682) studied electroluminescence in an empty glass vessel in 1675. His device was called the "electric egg". He also described the triboluminescence of mercury in a barometer,[3446] which was additionally examined by Hauksbee in 1709 and influenced Newtonian experiments with colours. The research was continued by Swiss Johann Bernoulli (1667-1748) and his son Daniel Bernoulli, until the Berliner physician and academic Christian Friedrich Ludolf (1707-1763) preferred the explanations with electric charges as his barometer first attracted and later repelled the nearby paper in 1744/45. The era of luminous phenomena of electrical discharges in rarefied gases was born to broadly affect next three centuries, literally born out of nothing.

The European part of our story began in Bologna. The first artificial luminophore earned the name "Bologna" both by the inventor and by researchers who published their findings in the Bolognese Academic Bulletin in 1731. The Bolognese Jesuitical student Domenico Gusmano Galeazzi (Galeati, 1686 Bologna-1775 Bologna) learned his science under the influence of professor of physics at Bologna Giacomo (Jacopo) Bartolomeo Beccari who published his research of phosphorus in 1768 to influence his Ljubljana fans. On 11 April 1771 Beccari's letter about his phosphor sent to J. Canton was read at the Royal Society of London. In 1714 Galeazzi met Louis Lémery, Malebranche and Réaumur in Paris. In 1716 Galeazzi was appointed professor of philosophy at Bologna and kept that post for forty years. He began as substitute lecturer in experimental physics; in 1734, when Beccari transferred to the chair of chemistry, Galeazzi succeeded him as professor of physics. In 1731, his first published work in physics dealt with the construction of mercury thermometers as he found that phosphorescence is weakened in vacuum, but its duration does not change. Galeazzi further published in his Bolognese Commentarii de Bononiensi Scientiarum et Artium Instituto about the thermometers of Amontons' drafting ("De thermometris Amontonianis conficiendis) in 1746.

[3445] Wilde, 1843, 392.

[3446] Wilde, 1843, 392, 406; Bowers, 1998, 112.

Galeazzi's boss, the professor of Logic, Philosophy and Physics at the University and President of the Academy of Bologna Francesco Maria Zanotti (1692-1777) described the characteristics of the "Bologna stone" in 1718. He endorsed the wave hypothesis because the stone always illuminated in its characteristic color, regardless of the color of the illumination.

Galeazzi and his role model Giacomo Bartholomeo Beccari (Jacopo, 1682 Bologna-1766 Bologna) used to be Jesuitical students. Beccari also published with the Bolognese Academy. In 1758 he corresponded with his 34-years younger Piarist Giovanni Battista Beccaria, Bošković's friend and supporter of Franklin's theory of electricity.[3447] Jacopo Bartholomeo Beccari distinguished natural and artificial "phosphorus" and among them noted the luminophores as well as elementary phosphorus, just like Ambschell later. Beccari described the colors of various luminophores and found that there were no metals among them, but they included the many useful types of salt.[3448] In

[3447] Dell'elettricismo. Lettere di Giambattista Beccaria De CC. The Piarist Giovanni Battista Beccaria (Beccheria, 1716-1781), professor of rhetoric and philosophy in Rome and Palermo, taught experimental physics at the University of Turin since 1748. He wrote a letter to Jesuits' student Iacopo (Giacomo Bartholomeo) Beccaria (Beccari, 1682-1766), doctor and professor of chemistry at the Institute of Sciences in Bologna (*Accademia delle Scienze dell'Istituto di Bologna*), also a fellow of the RS and of the Bologna Academy of Sciences, who was Galvani's teacher. The book is kept in the library of the Italian gymnasium in Koper with the bookplate of the local Piarists. Considering the later controversy between Galvani and Volta, it is interesting that Piarists were teachers of them both

[3448] Reprint: Viri Clarissimi Iacobi Beccariae Comentarii duo, de Phosphoris Naturalibus et Artificialibus, ex Actis Bononiensibus Excerpti, Graecii, Typis Haeredvm Widmanstadii, Anno Domini 1768, 12, 19. His work was republished by the Jesuits G. Schöttl in Ljubljana and by Gottlieb Leopold Biwald (1731-1805), an influential advocate of Bošković's theory, who in the sixties also lectured on the Ljubljana lyceum. In 1798 the book was enumerated in the library of Jožef Klasanc Erberg (1771-1843) in Dol, and until 1803, Wilde enrolled it in the Lyceum contrast to Zanotti, Jacopo Bartholomeo Beccari, after an experiment of 1770, considered that the "Bologna stone" was shining blue under the blue kind of glass but shined red under red glass, while he later doubted the accuracy of his own measurements. In 1772, Priestley nevertheless cited him in support of Newtonian corpuscular theory of light, which greatly hurt Seebeck who preferred Goethe's waves.[3449]

Figure 31-5: Figure: The title page of Giacomo Bartholomeo Beccari's book about phosphorus reprinted by Biwald in Graz and by G. Schöttl student in Ljubljana, catalogued in Erberg's library on 1788, in Lyceum library of Ljubljana on 1803 and in Franciscan Ljubljana library.

In 1746 the Swiss Leonhard Euler (1707-1783), a professor of mathematics at the University of Berlin, explained luminescence with fluctuations at luminophores' own body triggered by absorbed light. His wave theory was contradicted by Bošković, according to whom the particle of light should be absorbed in the body at the distance from the material point's centre of forces where the attraction prevails. Due to the internal heat motion, the same particle should be later radiated at a lower oscillation rate (frequency) at the distance from the centre of forces at which the repulsive force is predominant. Bošković explained the delay in phosphorescence like his other contemporaries: "After reflections along the many-sided and diverse paths within the opaque bodies, the light at least partially reaches the surface particles and then radiates. From this emerges the light of many accessible phosphorescence bodies, which is hidden from the sun in darkness and later shines for a few seconds. The number of seconds of its delay allows us to guess about the length of the path between its many movements, inside and outside the bodies..."[3450]

31.2.5 Echoes of Luminescence Exploration in Ljubljana

Among fifty-four experimental devices acquired for teaching physics and mathematics in Ljubljana was probably also a "Bologna stone", although the term "vitra Bononiensia" was used instead of the usual "lapis" on 17. 9. 1755. However, it might have also been a Bologna bottle (Bolognese phial, philosophical vial) of great external strength, often used in physics demonstrations and magic tricks, created by heating a glass bottle and then rapidly cooling the outside whilst slowly cooling the inside. This causes external compression and internal tension such that even a scratch on the inside could shatter the bottle as noted in the publication of the Royal Society in 1740s after its discovery in Bologna.

The short Napoleonic occupation stimulated additional fans of luminescence in Ljubljana. In Kersnik's census of 1811, we find both barite and phosphorus.[3451]

[3451] Kersnik, 1811.

The oldest published luminescence records in Ljubljana were included in Lyceum examination theses about the heat and light of professor of physics G. Schöttl in 1772. The theses were based on Newtonian science in Boerhaave's interpretations. At his 26th thesis Schöttl asked students about luminescence: "What is the difference between annealing, heat and light? What is pyrophore (substance that ignites spontaneously by contacting air)? What is phosphorus? What are the characteristics of artificial and natural phosphorus? Is the light of phosphorus the very light of the Sun hidden within the body of luminophore until it is excited by the sunshine, or does the absorbed light in luminophore lead to the movement of its radiated light?"[3452]

Figure 31-6: The title page and 26th exam theses about luminescence in G. Schöttl's class in Ljubljana on 1772.

After Schöttl passed away, the chair of physics on the Lyceum of Ljubljana was taken over by Ambschell as another important advocate of Bošković's physics.[3453] In Ambschell's examination theses there are no questions about luminescence, but he described it in his textbooks of physics, which, after the dissolution of the Ljubljana lyceum, he published as a professor of physics and mechanics at the Viennese University.

Ambschell distinguished "phosphors" that only glow in contact with the air and others, "which do not need to contact any air, and emerge in an empty space, so that they have to get their light from the Sun, or they shine because of their elevated temperature. Bologna phosphorus is shining in the air and in an empty space..."[3454]

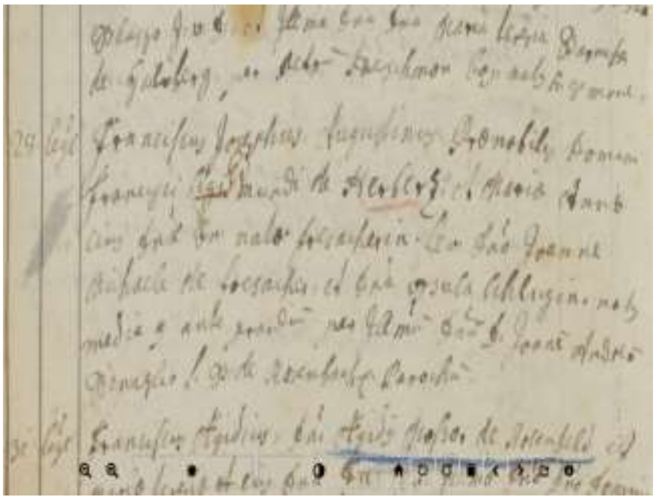

Figure 31-7: The birth certification of Joseph Herbert noted at St Egidius church in Klagenfurt on 28 August 1725

He observed the luminescence through the prism in a darkened room with an opening designed for illumination. He described short-term electroluminescence discharged in the air[3455] and in a vacuum of barometric tube.[3456] Concerning the phosphorescence of diamonds, "in subsequent experiments, it would be worthwhile to know more about the diamond components and about the forces that combine them."[3457] In fact, already two decades earlier in 1772 Lavoisier concentrated the rays of the sun by lens on a diamond in an oxygen atmosphere to produce carbon dioxide as a proof that diamond is composed of carbon.

[3452] Pyrophors are substances that spontaneously burns in the air, but usually with this word they meant a fireburst (Harvey, 1957, 448.

[3453] Ambschel, 1807, Dissertatio prima, 62, fig.1.
[3454] Ambschel, 1792, 284.
[3455] Ambschel, 1792, 285.
[3456] Ambschel, 1792, 290-292.
[3457] Ambschel, 1792, 285, 290.

From 1771 to 1773, Ambschell studied physics and mathematics in Vienna with a professor of experimental physics and Canon of St. Stephen Carinthia native Jesuit Josef Edler von Herbert (Joseph Herverth, Hervert, Herwerth, Baptized in Klagenfurt St. Egid on 26 August 1725 Klagenfurt-18 March 1794 Linz or parish Wels-St. Stephan 20 km southwest of Linz in bishopric Linz), one of the most important researchers of luminescence. The physicist Joseph Herbert was a grandson of a grandson of Eduard Herbert, a member of the well-known Welsh-English family of the Herbert counts von Pembroke and Montgomery, who left his fatherland at the time of Cromwell's Protectorate. As a prosecuted British Catholic he was attached to the house of Stuart under Charles I. He first turned to France and from there because of the Huguenot unrest to German Münster, where his son Herrmann Herbert as a poor emigrant lived at Rüden in Westphalia 30 km north of Cologne. The wars raged under Louis XIV and the controversial bishop of Münster Bernhard von Ghellen (Gallen, Christoph Bernhard baron Galen, 1606 Drensteinfurt-1678) damaged the countries between the Rhine and the Weser. Herrmann's son Johann studied medicine in South Germany to gain his doctorate in pharmaceutical sciences Innsbruck. As doctor he became a protomedicus at Klagenfurt in Carinthia. On March 19, 1692 he married there the nice widow Rosina Barbara von Khleß, a sister of a provost of Teinach (Teinach, Tinje) 10 km east of Klagenfurt, who took care of Johann's offspring after the pest murdered Johann in Villach (Beljak). Soon after the completion of his philosophical studies Johann's son Franz Edmund was raised to the inherited knighthood by the emperor Karl VI on September 21, 1715. The physicist Joseph Herbert was a son of Franz Edmund von Herbert and grandson of the physician Johann Herbert who immigrated to Carinthia from Paderborn in eastern North Rhine-Westphalia 100 km southwest of Hanover in the direction of Bonn. The younger brother of physicist Joseph Herbert, (Johann) Michael visited Holland and England of his ancestors to study the production process of lead and gain deeper insights. In 1761 he used Dutch process to establish the first Austrian fabric of white lead (Bleiweiss) in Ehrental by Klagenfurt with exports allover Europe. Johann Michael Herbert heated the lead in iron cauldrons, scooped out in liquid form with pans and poured onto cold iron plates to form thin lead sheets. These were then cut into narrow strips, rolled up and placed in glazed jugs filled with vinegar for fermentation, which in turn were placed in pits filled with manure. Herbert first used Styrian wine for the vinegar preparation, then a heavy wine from Veneto. Herbert was one of the founders of the Carinthian Agricultural Society on October 1, 1764, which progressed the local agriculture. In 1763 the entrepreneur from Klagenfurt, later employer of Jožef Stefan's parents, bought a paper mill in St. Veit an der Glan, because he needed blue wrapping paper to wrap his white lead in sale for painters. In that year he sent his printed offers to dealers and pharmacists for the first time. In 1765, those increasing demand encouraged Johann Michael Herbert to relocate his production facility and to build a two-story factory building nearer to the downtown Klagenfurt (at the beginning of today's Radetzkystraße), to which he added another wing in 1766. He replaced the pots by large brick chambers into which he poured water vapor, carbonic acid and acetic acid. Michael's older brother Joseph taught physics at Viennese university from 1758 and Michael father-in-law excelled as a Viennese wholesale merchant, therefore the empress Maria Theresa, her husband as wel as sons Josef and Leopold paid a visit to Michael's manufacture on July 12, 1765. Two years later he became a baron (Johann) Michael by Maria Theresa's diploma dated February 28, 1767 »in consideration of his old noble knightly family, and of his sixteen years of faithful service. His productions enabled his elder brother Joseph Herbert to become the very first notable Semi-Slovenian researcher of bioluminescence as Klagenfurt (Celovec) and Tainach (Tinje) were still predominantly Slovenian in those times while the British noble emigrants steadily mixed with the locals. Joseph Herbert noticed that the Bologna phosphorus was shining after heating to the temperature of the boiling oil, and therefore he thought that it contained its own light, whose substantial nature resembled later Lavoisier's caloric. He did not have the luminescence for burning, but described it with a mushroom model, like before him Lagala (La Galla), Liceti and Kircher. In 1773 while his Jesuitical society was being suppressed, Herbert entitled his last paragraph Fire in form of light as freed from phosphorous substances, and the flames (Ignis forma luminis liberatur in phosphoris, et flamma). It was an effective end of his Discourse concerning the fire, its triple state embraced as an elastic fluid, and heat effects, with the vibrated movement of its light separated from the bodies, when it is finally captured or brought forth from the absorbing body. Herbert cited Beccaria, Kunckel, Bolognese stone and phosphorus, Balduin's phosphorous Saxon topaz (in fact triboluminescent citrine as quartz much lighter than topaz, which is hydroxyl fluorosilicate of aluminium), and pyrophore of W. Homberg who used to be a Parisian associate of Nicolas's son Louis Lemery (Lémery, 1677-1743).

Herbert experienced very often, repeatedly and clearly that the air accessed the radiations of the existing phosphor's light. He therefore thought that the phosphor holds on the matter (of light) from the air, which is the elastic fluid material, to which the light is ensnared. It is initially more attracted and later radiates as much in vacuo or in the air while its matter is fully saturated with light emitted by rotting timber. As already shining by its worms and taints, it releases the things that went through it when it was exposed to the light. While during the day they are quiet and stifled, they begin to move in the time of the onset of the night, while increasing immediately. Upon cutting of the light emission for a long time from the mold of each body, it liberates the same equal light day and night. All the above is confined to the air, to be held by the matter alone, to which the light, ensnared as is to say, is not equal to transpiration of this emission by the body in the whole, or of its insides. The nature of putrefaction promotes the abilities which in the daytime and at peace have no such living power. Indeed, those fires radiate such curios light, which opens its passages by breaking out. It has no other effect on vapors of the radiating material accessed by the air, which held it entangled before leaving off[3458]. Herbert did not provide any pictures of luminescence in his otherwise nicely illustrated book. He described fire and light as the same material substance that is absorbed in luminophore resembling a sponge:

"Fire is liberated in the form of light from the flame". Herbert argued that the light emitted from the luminophore always had different observed colors than absorbed, but did not describe the difference in their intensity, which prevents the human eye's perceiving some weak luminescence.[3459]

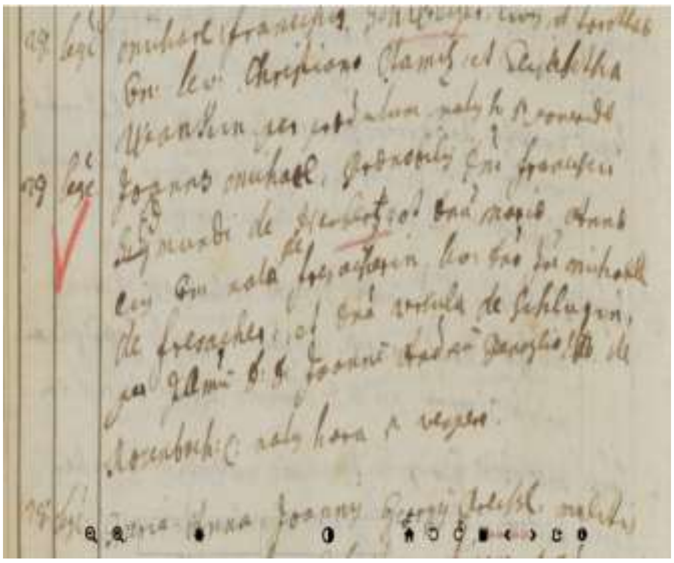

Figure 31-8: The birth certification of Johan Michael Herbert noted at St Egidius church in Klagenfurt on 28 September 1726

Ambschell stayed in contact with his professor Herbert later, and in 1778 he published a German translation of Herbert's Latin booklet about the compressibility of water, which he often quoted in his works.[3460] The Florentine academy del Cimento declared water as incompressible, but a century later J. Canton with the help of his friend Henry Cavendish's father vice-president of RS Charles lord Cavendish (1704-1783) proved compressed water under the column of mercury in 1762 and

[3458] Quo experimento frequentissime repetito, multo iam apertius patuit, aeris, et huius recentis, accessum ad liberandam phosphori lucem requisitum exstitisse; rebar igitur, me tenere rem, aerem que id fluidum elasticum esse, quod ad materiam, cui lux irretita est, magis attractum, hanc suo accessu liberet, atque hinc tantum esse, cur in vacuo, cur in aere, iam huiuscemodi materia saturato, non luceant phosphori, non ligna putrida. Lucentes iam vermes, infectaque, quae ad manum erant perlustrans, quum animaduertissem, horum lumen, quum interdiu quiescunt, restingui, prouit noctis ingruentis tempore se mouere incipiunt, pastumque concedunt, ita augeri continuo; in putrescentibus vero iisdem insectis lucis emissionem diu, noctuque aequalem esse, rebar, lucis liberationem eodem, ac supra, modo ab aere haberi, fed materiam folum, cui lux irretita est, non aequaliter perspirare, huius emissionem aut corporis totius, aut intestino putrefactionis motu promoueri, interdiu in viuentibus et quiescentibus nullam esse. Facto ab his ad ignes fatuos, ad lucem, quando que apertis ex cryptis erumpentem, transitu, neque hic deprehendi aliud, quam, quod vapores, materia luminis foeti (foetus), ad aeris accessum, quam irretitam ante tenuere, lucem dimittant (Herbert, 1773, 164-165.)

1764. His work resembled J. Herbert's and Ambschell's experiments. By his own and his brother's British connections J. Herbert learned about J. Canton research of compressibility and luminescence. Ambschell cited Herbert as his professor in the description of luminophore even thirty years later.[3461]

31.3 Research of Luminescence in Germany after the Discovery of Ultraviolet Light

The British-French colonial acquaintances with eastern invisibles strangely affected their romantic neighbours publishing in German and Latin languages with J. Herbert included. Few months after Hanover born musician of Jewish descent W. Herschel's determination of infrared light west of London, the apothecary and physicist member of the Munich Academy Johann Wilhelm Ritter (1776 Zamienice in Silesian southwestern Poland-1810) experimentally proved the ultraviolet light in Jena in 1801. His invisible rays just beyond the violet end of the spectrum even more effectively darkened silver chloride-soaked paper inside romantic Naturphilosophie of his friends Goethe, A. Humboldt, Hans Christian Oersted (1777-1851) or Schelling. Like Oersted later in 1819, Ri: tter searched for *Naturphilosophie* polarities in the several "forces" of nature, and for the relation between them inside Chinese yin-yang dichotomy adapted for German experimental business mind. A half-century of research later showed that the ultraviolet light is Maxwellian radiation of higher frequencies. It is invisible for humans, but it can lead to visible luminescence. Stokes then wrote that luminescence "gives physicist eyes to the observation of invisible light". In 1810, Goethe described colors in the fluorescent "lignum nephriticum" by his more artistic than physical approach. At the end of the book, he praised the experiments of his Baltic friend Seebeck performed in Jena since 1806. Seebeck is now more famous for his discovery of thermoelectricity in 1821.

Seebeck, with "special joy", confirmed Zanotti's assumption that each type of "Bologna stone" emits the light of a characteristic color, regardless of the color of the excited light.[3462]

According to Seebeck, the blue and violet color are an "exciting force" because they cause the phosphorescence to be as bright and powerful as white light. On the contrary, red and yellow light has the "depression power", as the luminescent substance, which would otherwise illuminate for several minutes, will lose its light after a few

[3461] Ambschel, 1807, 135.

[3462] Goethe, 1810, 710.

seconds of irradiation. He echoed the Chinese terminology where red is masculine yang while violet is more feminine yin to provide one of the first reports on stimulated emissions. Seebeck and his collaborator Goethe disliked Newtonian conclusion that white light consists of spectral colors.[3463] Hegel's friend and Oersted's scientific companion Seebeck joined *Jenaer Romantikerkreis* of natural philosophers like Schelling, the biologist Lorenz Oken (1 August 1779 – 11 August 1851), leaders of romanticism in Jena the brothers Schlegel, electrochemistry expert Ritter, and many other outstanding personalities. The *Romantische Naturphilosophie* shaped Ritter, Seebeck and Oersted's scientific pursuits in progressive way even if it later dogged German erudite with its funny profound ideas coquetting with August Wilhelm Schlegel's (1767 Hanover-1845 Bonn) Indology of newly translated Bhagavad Gita published in 1823.

Figure 31-12: George Stokes (* 1819; † 1903)

The Benedictine monk Placidus Heinrich (born Joseph Heinrich, 1758 Schierling by Regensburg-1825 Regensburg) from the Abbey St. Emmeram in Regensburg observed phosphorescence through a small aperture in a dark room, like Jacopo Bartholomeo Beccari and Ambschell. In 1791-1798 Placidus Heinrich taught physics, astronomy and meteorology at the university of Ingolstadt. In 1808, Placidus Heinrich's and the early Lavoisier's fan Heinrich Friedrich Link's (1767 Hildesheim in Lower Saxony-1851 Berlin) work was awarded with 500 roubles prize and printed in Petersburg based on the award of Petersburg academy announced four years earlier. Heinrich divided the luminophores into five species as their phosphorescence arose from:

1. sunlight
2. combustion
3. it occurs on its own in plants and animals
4. pressure, cutting or friction
5. chemical reaction

Placidus Heinrich found description of the phosphorescence as a slow burning inappropriate because the most phosphorescence belongs to non-flammable substances. Later indeed, with the slow burning, only the light of the element of phosphorus was properly described, but not the real luminophores. Nevertheless, light is emitted during the phosphorescence while the oxygen is bound, but during the absorption of light the oxygen was supposedly released. That confused influences of oxygen mirrored Lavoisier's exaggerated claims about the roles of his beloved oxygen (acid maker) in all acids which was only slowly refuted by Davy's HCl and Liebig's almost final replacement of oxygen by hydrogen as acid maker. The development of European knowhow was never enough to change now deeply misleading oxygen's name, as names are always more persistent than truths in natural sciences including the divisible atoms and raising of immovable Copernican sun. Due to the change in color in phosphorescence, Heinrich rejected the explanation by repeated reflection of light in matter which Bošković and many others preferred earlier. Heinrich explained the phosphorescence after heating by the decomposition of the substance that releases Newton's material particles of light which T. Young tried to refute earlier, Goethe doubted in 1810 and Fresnel dismissed for almost a century soon after Napoleonic downfall. Therefore, Heinrich's optical Newtonianism was still in German mainstream during the peak of Napoleonic regime in 1809. On the other hand, Heinrich described the oscillation of the ether by analogy with the oscillation of the retina of the eye while absorbing the physiological colors. In 1809, due to this contradiction, the patriotic Parisian Institute did not award the 3000-franc award announced in 1808 to Placidus Heinrich's phosphorescence research praised in St. Petersburg, but to the lesser-minded French studies of Jean-Philibert Dessaignes (1762 Le Puy-en-Velay-1832 Vendôme in central France), director of the

[3463] Nielsen, 1991, 143, 144-145.

boarding school in Vendome 150 km southwest of Paris.[3464] In those times Placidus Heinrich was still a Benedictine monk because his monastery was not dissolved by Napoleonic armies in 1808 but only after 1810 which also affected the choices in Napoleonic Paris where the monks were still not universally welcomed despite of the concordat between Napoleon and the Pope signed in 1801. Even Dessaignes used to be the Oratorian monk, but the French revolutionaries dissolved his monastery despite of Dessaignes and other Oratorian support of the revolution, just like they later secularized Placidus Heinrich. The contestants advocated a completely different theory of light in the luminophore. Placidus Heinrich believed that the acidic fraction in luminophore causes light, while Dessaignes attributed a similar role to water. Few years younger graduate of the Parisian École Polytechnique Theodor von Grotthuss (1785 Leipzig-1822 Gedučiai in Lithuania) and Brewster unsuccessfully participated in that Parisian prize competition. Grotthuss in his triboluminescence research attributed the central basic role to electricity, after he proposed the first basically correct theory of electrolysis in 1806.

According to Placidus Heinrich, any color of absorbed light does not cause phosphorescence, for example, in diamond which was already popular in India for six millennia but gained European fans mostly after its great British advertising in 19th century. Riess continued Placidus Heinrich's experiments with diamond. In 1845 Riess confirmed the assumption of the English painter Benjamin Wilson (1721 Leeds-1788) of 1775, as well as the ideas of Germans Ritter (1805) and Seebeck (1806) that the blue light of greater refractive index (frequency) produces much more phosphorescence than red part of the sunlight.[3465] Later, Riess severely polemicized about the nature of light in the cathode ray tube with Reitlinger from the Viennese Polytechnic who continued Plücker's and Hittorf's work.

[3464] Wilde, 1843, 386, 406-407. Ten years later the dominance of Newton's corpuscular optics would no longer be so pronounced, as at that time Parisian academics had already rewarded Fresnel's wave theory of light, which later became the foundation of Stokes' work as the basis for a better theory of luminescence.

[3465] Riess, 1845, 335.

31.4 Exploration of Solutions of Fluorescent Materials in England: the Stokes Law

Goethe as a famous writer entered the field of optics as an artistic antagonist of Newtonian theory of colors. Goethe described the fluorescence of aniline as follows: "A solution of wild chestnut in water gains the blue color of the sky in the shortest time when we observe a glossy bottle on a dark background. When we place it against the light, we see the most beautiful yellow (color)".[3466] In the mid-19th century, the erudite mostly studied fluorescence of fluorite; therefore Stokes even used the term fluorite to name the phenomenon.

In 1851, the English born John William Draper, a professor of chemistry at the University of New York, wrote about the fluorite irradiated by light of electrical sparks:

1. the volume of luminophore does not change,

2. the structure of the luminophore does not change,

3. the luminophores' surface changes as the mercury vapor condensation changes at the irradiated points,

4. In addition to the light, luminophore also undoubtedly radiates heat,

5. Isolated luminophore does not indicate electrical charging,

6. just a small amount of light is emitted during the luminescence,

7. the luminescent fluorite shines stronger, the cooler it was when irradiated.[3467]

In 1833, Brewster described a bloody red trace with a lens-directed beam in an otherwise green chlorophyll solution. A similar phenomenon was also observed in the fluorite solution. The English astronomer Sir John Frederick William Herschel did not know Brewster's work, since he was currently engaged in astronomical works and in his

[3466] Goethe, 1810; Theodor Hoh, Zur Geschichte der Fluorescenz, Ann.Phys. 131 (1867) 659.
[3467] Rosenberger, 1890, 472-473.

wife's botanical measurements in South Africa. In 1833 slavery was formally abolished in the middle of warfare Mfecane (Difaqane, Lifaqane) raging between 1815 and about 1840. In suburb of Cape Town Charles Robert Darwin (1809-1882) visited Herschel during his return trip onboard a ship Beagle to discuss natural selection on 15th June 1836 even if great promotor of revival of British science Herschel later rejected mystery of mysteries of evolutional Darwinism as the greatest British idea of Victorian times. Herschel was probably influenced by his wife who was a daughter of a Presbyterian minister, but he also resisted acceptance of the law of conservation of energy somewhat later by the sensible Indic philosophical argument that not all forms of energy were yet known and therefore the sum over them may be incomplete or testable. In 1845, Herschel observed the dark blue color of the illuminated surface of the transparent solution of American Quechua quinine sulphate in sulfuric acid at the spot where the light enters. The dispersion on the prism showed that its blue surface did not contain the red spectrum. He did not detect any polarization at his solution put between crossed tourmalines. The linearly polarized light from dichroic tourmaline might not have been his best choice because its dichroic effect is strongly wavelength dependent and the crystal appears coloured.

Herschel wrongly claimed that the "dispersive reflected" light can no longer turn blue the surface of the other solution. His false conclusion resembled Newtonian rightful claim that colours dispersed by prism cannot be dispersed again. By using a light of greater intensity or a less concentrated solution, Herschel would notice the blue light also in its interior.

In 1846, Brewster concentrated the light in a glass with a fluorescent solution by his strong focusing lens. He described the "internal dispersion" that was supposedly caused by the alleged double refraction (birefringence) at the crystals inside the solution. His special case was Herschel's "dispersive reflection". Luminescence inside the fluorite was already known before.[3468]

They needed the authority of W. Thomson's friend Stokes, the youngest son of the Irish priest, to resolve the dispute. Stokes studied at Cambridge, where he stayed for fifty-four years until his death. He also retained the Lucas Chair of Mathematics, where Newton once taught. Between 1854 and 1890, as the secretary and then the President of the RS, Stokes strongly influenced the development of British physics in the Victorian era.

In May 1852, Stokes lectured at the RS in London on the investigation of luminescence by two new methods: the luminescence of the filtered light was observed through a complementary filter, or illuminated by luminophore with the colors split into the spectrum, so that one could observe the difference between the absorbed and radiated light at any wavelength. "It was certainly a curious sight to see the tube instantaneously light up when plunged into the invisible rays; it was literally, "the darkness became visible"".[3469] Similar visible darkness appeared earlier in Fresnel's illuminated interference point in the shadow behind the obstacle needed to convince Poisson's Parisian doubts.

Stokes was aware of the significance of his discovery, and with his authority he also introduced a new name for it: "I am inclined to coin a term and call it fluorescence from fluorite (fluorspar, mineral form of calcium fluoride, CaF_2) as the analogous term opalescence is derived from the name of a mineral." The new name did not depend on the supposed radiation flow in Brewster's or Herschel's theory.[3470] The results are summarized in "Stokes' law": the refractive ability (frequency) of fluorescent light is always less than the refractive ability of the light that caused it.

Stokes was awarded the Rumford Medal for his research. On June 27, 1856, he wrote to Herschel

[3469] Harvey, 1957, 398.

[3470] Harvey, 1957, 397; Pisko, 1861, 21.

about his funny analogies between the waves of the ocean and rays that produce fluorescence. His ships were analogous to particles of matter, and the impact of ships on waves were analogous to absorbing the incident rays, which always comes along with fluorescence. The waves that travel away from the ship were like fluorescent light. Stokes assumed that the force is in a simple ratio with the distance of the substance from the equilibrium position. It depends on the composition of the ether and the distance between the molecules of the substance. The oscillation amplitude is infinitely small in comparison with the size of the molecules. The period of oscillation of the molecules is different from the period of oscillation of the particles of the ether, and the frequency of fluorescence is reduced by decreasing the amplitude.[3471] A great praise of wave theories for Victorian ships' Rule the Waves Britannia!

At first, Stokes based his arguments on his theory of ether. Considering the cause of internal dispersion, he at once discarded all supposition of reflection and refraction of the vibrations of the luminiferous ether amongst the ultimate molecules of bodies as it seemed quite contrary to dynamic principles to suppose that any such causes should be adequate to produce vibrations of one period from the vibrations of another (frequency). Later, Stokes changed his opinion without giving up his law. However, in 1885 in Aberdeen he was not able to draw the right boundaries between fluorescence and phosphorescence.[3472]

Jožef Stefan soon challenged some Stokes' claims with his own measurements of polarisation. The analytical chemist James Alfred Wanklyn FRS translated Stefan's paper for abbreviated publication in *Phil.Mag*. The professor of chemistry at the London Institution from 1863 Wanklyn is mostly remembered today for his "ammonia method" of determining water quality. His translation was not published in Intelligence and Miscellaneous Articles of *Phil.Mag*. as were most of other Stefan's articles, but in main part of magazine.[3473] There Stefan supported Cauchy's law while criticizing Jean-Baptiste Biot's law, also because Augustin-Louis Cauchy used to be a friend of Stefan's supervisors Ettingshausen and Koller. In his footnotes to the translated Stefan's paper, George Gabriel Stokes, signed as G.G.S.,[3474] stated that Stefan made an error by omitting his arbitrary constant after integration and by obtaining negative constant in dispersion formula, which indicated that Biot's law is still maintained in Stefan's experiments. Besides Brewster, Stokes was the greatest British expert in optics of those days and probably the initiator of that translation, while Stokes himself supposedly lacked sufficient knowledge of German language to translate himself. Stokes' criticism might have contributed to Stefan's abandonments of further research in optics after 1866, except for his two papers[3475] which were not translated in *Phil.Mag*. where W. Thomson worked as an associate editor after July-December 1871. Stokes was close to Thomson who later befriended Stefan during the Viennese Electrical exposition in October 1883. Stokes' criticism may have had even some political motives as Cauchy used to be the most Catholic conservative of all top scientists, while his Parisian antagonist Biot remained the last valuable supporter of Newtonian corpuscular theory of light and furthermore Biot disliked aether. Cauchy widely travelled with the exiled French court, but mostly through Catholic states including Gorizia and Prague.

31.4.1 Discussions on the Validity of Stokes' Law

Besides Stefan, many other researchers discussed Stokes's claims in German language. In 1853, Anders Jonas Ångström (Angstrom, * 1814; † 1874 Uppsala) came to the opposite conclusion by experiments resembling Stokes's data. According to him, the atoms of the ether should even oscillate one octave higher and fluorescent light would therefore have a higher frequency than absorbed.[3476]

[3476] Anders Jonas Ängstrom (1814-1874), professor of physics and astronomy at the University of Uppsala, Optische untersuchungen, Ann.Phys. 94 (1855) 164; Sekulić, 1871, 80; Kayser, 1908, IV, 866. Paragraph about fluorescence on pp. 839-1214 was authored by Heinrich Konen.

As the best in his 7th grade J. Stefan received the textbook of Wilhelm Eisenlohr (1799-1872) who studied the fluorescence in Geissler's tube and examined Helmholtz's color combination of fluorescence light in analogy with sound. He described fluorescence as an interference of blue-violet and ultraviolet light.[3477]

In 1859 and 1866 in now Polish Szczecin, Emsmann studied the experiments of "negative fluorescence" in which refractive ability (index, frequency) is expected to increase. In 1861 he compared fluorescence with hysteresis of iron. The irradiation could cause the motion of atoms in the body with a special "coercive force", which maintains the orderly arrangement of atoms. This coercive force is supposed to be strong in phosphorescent bodies and weak in fluorescence.[3478]

In 1864, the Hungarian Jew Károly Akin (C.K., 1830 Buda-1895 Rijeka (Fiume)) put fluorite on the air in his academical lab in Pest, where it radiated visible light for another one to two minutes after irradiation with thermal rays (infrared in modernized slang). In the same year, John Tyndall (1820-1893) independently noticed the "negative fluorescence" in the focus of his concave mirror, on which only infrared light had fallen. Akin called that phenomenon calescence in analogy with fluorescence, while Tyndall coined the other term caloriscence.[3479] As always in science, the battle between the different proposed terminology was an echo and companion of the battle among ideas themselves. As the professor in Pest, Aikin was a neighbor of S. Šubic and Tesla’s teacher M. Sekulić. On March 18, 1868, Aikin was elected a correspondent of the Hungarian Academy of Sciences. In 1872, he was a candidate for the parliament in Lipótváros part of Pest joined next year into Budapest. He failed on the elections but continued to publish political pamphlets alongside with fundamental physics. After 1872 in Vienna he invented the postcard but could not provide adequate financial resources to realize the idea which the Belgians introduced in 1882. In his fatal autumn Aikin killed himself in then Hungarian port Rijeka.

Eugen von Lommel (1837-1899) studied in Munich and habilitated at Polytechnics in Zurich. Between 1868-1886 he was a professor at the University of Erlangen and in 1872 he married there Luise Friederike Caroline Hegel (1853-1924) the granddaughter of the famous philosopher Hegel (1770-1831). He organized a new physical institute at Munich University. In 1893, he published an exceptionally successful experimental textbook, the 26th edition of which was published twenty-seven years later. From 1890 to 1894, Lommel attracted his friend Boltzmann from Graz to accept the chair of the professor of theoretical physics in Munich. After Lommel's death, his chair in Munich was occupied by Röntgen.[3480]

The native of Bornheim’s merry red-light district of Frankfurt J.C. Bohn learned a lot as the Parisian Regnault’s assistant in 1855. In 1867 in Bavarian Aschaffenburg Bohn announced that an increase in refractive index (frequency) of "negative fluorescence" occurs due to a rise in temperature rather than as a direct effect of absorbed infrared light. So, there would be no "negative fluorescence" and exceptions to Stokes' law. Akin criticized Bohn’s arguments and at the same time proudly quoted Tyndall's claim that "the concept of the transformation of heat rays into light rays clearly belongs to Akin according to his first publication" which was also read by Charles Darwin. The Irishman Tyndall was always very fair to German language publications. Today, Akin and Tyndall seem to have justly proved that the infrared rays can sufficiently heat the body to radiate in the visible area, which does not concern luminescence.[3481]

[3477] Johann Conrad Bohn (1831-1897), professor of mathematics in central forester school of Aschaffenburg, Ueber negative Fluorescenz und Phosphorescenz, Ann.Phys. 130 (1867) 390.

[3478] August Hugo Emsmann (1810-1889), professor of physics of real school in Szczecin (Stettin), Positive und negative Fluorescenz. Phosphorescenz und Fluorescenz, Ann.Phys. 190/12/114 (1861) pp. 651-657, here p. 654; Bohn, 1867, 386; Lommel, Ueber Fluorescenz, Ann.Phys. 143 (1871) 40; Rosenberger, 1890, 474-475.

[3479] In 1865 Bohn assigned them a priority in the discovery to trigger a dispute between Emsmann (Prioritätsansprüche in Betreff der negativen Fluorescenz oder Calorescenz oder Calcescenz, Ann.Phys. 129 (1866) 352) and C.K.Akin from the physics cabinet of academy of science in Pest (Erwiderung auf eine Notiz des Hrn.Emsmann, Ann.Phys. 131 (1867) 561).

[3481] C. K. Akin, Ueber Calcescenz und Fluorescenz, Ann.Phys. 131 (1867) 556; Harvey, 1957, 399-400.

The following year J.C. Bohn announced that fluorescence depends on the nature of the bodies and the color of the absorbed light. The intensity of absorbed light does not affect fluorescence but affects the radiations of the heated body. Bohn described the fluorescence as "irregular refraction with a change of frequency".[3482] It was certainly a good try to link it with better known phenomena of light.

In 1871, the native of then Bavarian Edenkoben winegrowing aras near French border Lommel developed Eisenlohr's ideas to contradict Stokes' theory of fluorescence, according to which the frequency of the emanated light can increase because of resonance between the absorbed light and the body's own oscillation. In 1875 and 1876 in Bavarian Erlangen, he wrote that "every dark band of the absorption spectrum corresponds to the bright band of the fluorescence spectrum in the solution ... so, we can place a generally valid claim that the body fluorescents with the help of those rays that it absorbed ... The phosphorescence is an effect of absorbed light like a fluorescence". Lommel’s unification was in the mainstream of earlier Faraday’s unifications of all kinds of electricity and appeared simultaneously with Maxwellian unifications. Marriage into Hegel’s family helped Lommel’s success. His PhD student J. Stark graduated with his optical studies in Munich in 1897 but later somewhat ashamed himself in Nazis’ headquarters.

Magnus’ Berliner and Jamin’s Parisian student the Swiss Hagenbach-Bischoff did not accept Lommel's assumptions and supported the general validity of the Stokes’ Law.[3483] His alleged "negative fluorescence" was supposedly associated with impurities and the incompleteness of the incident light. In 1878, Lommel described the absorption of light as a friction like the interaction between the molecules of the ether and the substance. Due to the lack of knowledge of the properties of the supposed ether, many researchers were not yet able to decide between Stokes and Eisenlohr-Lommel's theory.[3484] The choice was certainly also nationally motivated while new unified German state gradually challenged other older European powers by militaristic aggressions and by preferring wave interpretations of newly discovered rays. There was always a linguistic controversy: Johann Wilhelm Ritter called ultraviolet light "oxidizing rays" to distinguish them from "heat rays". The simpler term "chemical rays" was adopted soon afterwards, and remained popularity throughout the 19th century, although John William Draper named them "tithonic rays" by husband of Aurora Tithonus gained the immortality but not eternal youth with allusion to the visible effect of UV rays on photographic paper fading over time. The terms "chemical rays" and "heat rays" were eventually gradually abandoned dropped in favor of ultraviolet and infrared radiation. The luminescence and photography remained the principal tool of detection until Charles Thomson Rees Wilson's (1869–1959) Scottish cloud chamber perfected for radioactivity in 1911. Photomultipliers kind of vacuum tubes based on the photoelectric effect and the secondary emission were developed for RCA together with TV after 1934. Avalanche photodiode (APD) as a highly sensitive semiconductor photodiode can be regarded as the semiconductor analogue of photomultipliers invented by Japanese engineer Jun-ichi Nishizawa (西澤 潤一, Jun'ichi, 1926 Sendai-2018 Sendai) in 1952. Only after 1960s operational liquid-crystal displays as the fourth phase of matter different from Crookes’ fourth visions surpassed cathode ray tube luminescent displays, also in their total sales in early 3rd millennia.

31.4.2 The Modern Theory of Stokes's Law

Einstein provided a handy explanation of Stokes’ law with its possible exceptions when he awarded it the first place among three examples of his use of photons in quantum theory in 1905.[3485] Nowadays, the "negative fluorescence" is described by the anti-Stokes lines and we consider Lommel’s correction of the Stokes law, according to which the maximum of the luminescence spectrum is shifted to lower frequencies with respect to the maximum absorbed spectrum. In 1887, it was found that the sulfides are not

luminophores in the pure state but must contain a small amount of activating metal. J. Stark's antisemitic buddy P. Lenard first described the distribution of ion activators in T. Sidot's blende and other crystals hosts in 1890. The ion activators are surrounded by host ions to form luminescent centers where the excitation and radiation process take place. These centers should not be too close together, so only the trace of the activator should be inserted into the host for the highest efficiency of the luminophore. In 1917 and 1918 Lenard announced that each group of lines in the luminophores spectrum would cause a different luminescence center. Twenty years later, Lise Meitner and Otto Hahn Berliner PhD student Nikolaus Riehl (1901 Saint Petersburg-1990 Munich) from the Auergesellschaft in Berlin criticized Lenard's presumptions and, together with afterwar Osram GmbH researcher Michael Schön (1903 Weisbaden-1960 Munich), developed the foundations of the modern quantum mechanical model of crystal luminophores in Zeitschrift für Physik in November 1939.[3486] Certainly, the Jewish Meitner and Riehl could not be any great Lenard's fans even of they liked his physics, which they did not. Already then in the context of the German Atomic Energy Program Riehl was responsible for work on the purification of uranium since September 1939. After WW2 Riehl witched sides and spent a whole decade at Soviet bomb project as a son of Jewish-Russian mother and then taught technical physics at Technical University of Munich.

On 18 June 1903, in Kiel Lenard published the equation for the intensity of cathodoluminescence in dependence on the number and velocity of accelerated electrons. In the same year in once Lommel's Friedrich-Alexander University Erlangen-Nuremberg, Wehnelt noticed that the equation does not give acceptable predictions for low acceleration stresses, as Lenard measured as much as 10^{-7} times smaller density of electrons compared to Wehnelt's data.[3487] In the years 1938 and 1939, Eugene Wigner's Princeton PhD student Frederick Seitz (1911 San Francisco-2008) at General Electric labs and the editor of his paper at Philosophical Magazine Nevill Francis Mott at Bristol developed an electronic configuration diagram to understand Stokes' law.

Several generations of Parisian family **Becquerel** as well as Wiedemann from Germany successfully researched on physics chemistry. The later professor of physics at the Conservatory of Measures and Weights E. Becquerel, son of the president of the Parisian Academy Antoine Charles (1788-1878), was already famous in 1839 with his description of the electric current that light causes in some electrolytes. In the same year in 1839, together with his father and professor at the Parisian University Jean Baptiste Biot (1774-1862) E. Becquerel published a study of the transition of the light of spark through a colored screen. Biot was opponent of Fresnel optics, researcher of polarization, and winner of Rumford Medal in 1840. Such supporters helped then only nineteen years old E. Becquerel to bring the luminescence research to a higher experimental level within the next thirty years without deepening into the theory that he avoided with the polite but neutral phrase "the disturbance of the molecular equilibrium".

Becquerel acknowledged Stokes' law. Becquerel and Lommel did not distinguish between fluorescence and phosphorescence, like Stokes, who was looking for different mechanisms of disintegration for both, but Stokes was unable to distinguish those convincingly in his lecture at Aberdeen in 1885. E. Becquerel, on the contrary, did not accept Stokes' expression of fluorescence at all, since for Becquerel it does not characterize a special kind of phenomenon. In 1892 E. Wiedemann affirmed E. Becquerel's ideas with the conclusion that by changing the temperature itself, the phosphorescence can be changed continuously in fluorescence. Previously in 1888, E. Wiedemann mistakenly assumed that fluorescence is characteristic of liquids, while the phosphorescence happens in solids. Such an opinion prevailed two decades later because almost no phosphorescence was observed in liquids apart from Dewar's description of liquid oxygen phosphorescence in 1894. In 1925, with the improved phosphorus at Nikolaj Ernestovič Bauman Moscow State Technical University (BMSTU, Московский государственный технический университет им. Н. Э. Баумана) S.I. Vavilov observed an unconstrained transition

[3486] Lea Županc Mežnar, Luminiscenčne snovi (I part 4, Vakuumist 16/3 (1996) 14-15.
[3487] Kayser, 1908, IV, 700-701; Diploma engineer Felix Fritz, Leuchtfarben, Geschichte, Herstellung, Eigenschaften und Anwendung, Berlin 1940, 117, 121.

of fluorescence into phosphorescence in solids and very dense liquid solutions, and thus refused Stokes' efforts. He announced that phosphorescence is "forbidden" and therefore a slower transition from excited state into the ground state.[3488] In modern books, we often read also E. Becquerel's claim that fluorescence and phosphorescence are the same appearance of different duration.

31.5 Exploration of the Phosphorescence of Solid Matter in France - E. Becquerel's Phosphoroscope

Like Placidus Heinrich, E. Becquerel also distinguished five causes of phosphorescence:

1. ordinary raising of temperature, often already below the red glow,
2. mechanical effects,
3. electricity (in cathode ray tubes),
4. spontaneous phosphorescence in animals and plants,
5. sunlight.

He attributed special rules to his last, most common type of phosphorescence:

1. violet and ultraviolet rays are most effective,
2. luminophores differ in the width and spectrum of their spectra,
3. the color of phosphorescence is characteristic of luminophore and does not depend on the color of absorbed light,
4. absorbed ultraviolet light causes phosphorescence of lower refractive index (lower frequency),
5. if we put luminophore in the dark, the phosphorescence will be weakened, and it will increase with the increased temperature,
6. an increase in temperature during radiation by sunlight reduces subsequent phosphorescence,
7. if the spectrum of light falls on paper coated with calcium sulfide, the number of spectral lines increases, as Herschel found in 1842.

In 1857 in simultaneous publications in Annales de chimie et de physique, Il Nuovo Cimento and Philosophical magazine, E. Becquerel described the first version of his phosphor-scope, which consisted of two panels with openings for incident light and for observation. He could rotate the panels around their common axis. The openings were not the opposite, but rather displaced. He placed the plates in a darkened drum. Inside the intermediate space between the plates in the direction of the boundary of the two openings, he put the luminophore. When rotating the lever, the plate turned around through the toothed wheels so that the delay of the phosphorescence can be measured up to 1/2000 s after irradiation with the sunlight. That ingenious method of detecting small intervals resembled Coulomb's magnetic measurements by torsional balance equipped with a mirror in their same Parisian milieu almost a century earlier. Becquerel's phosphor-scope was perfected by E. Wiedemann, but even he could not measure the retardations of fluorescence.[3489] With mechanical phosphor-scope it was possible to measure the duration of phosphorescence only down to 10^{-5} s. Today shorter times are measured with modern photoelectric methods.

Becquerel performed the first qualitative measurements with his phosphor-scope. Already in 1859, he announced that phosphorescence consists of very narrow bands or lines of discontinuous spectrum. His precise measurements of the luminescence spectra enabled many discoveries.[3490]

In 1860 he discovered that the intensity of phosphorescence is decreasing exponentially with time. After his death, his son Henri continued his measurements in 1891 and 1892, while the descendant of another family of physicists E.

(Biography: Eilhardt Ernst Gustav Wiedemann (1852-1928) was a son of a professor of physics chemistry in Leipzig Gustav Heinrich (1826-1899). After 1879 he helped his father in editing the leading German journal Ann.Phys. in Leipzig. His mother Clara Louise was born in 1827 as daughter of the famous chemist Eilhard Mitscherlich (1794-1863). She translated Tyndall's books about physics and about alpine tours in Alps. Therefore, E. Wiedemann like Becquerel, researched luminescence inside his extended family traditions. He served as a professor of physics in the Universities of Leipzig and Erlangen).

[3490] Kayser, 1908, IV, 647-648.

Wiedemann published slightly different parallel results in Germany as Parisian antagonists. The significance of the discovery was only discovered when H. Becquerel measured radioactivity, which was subjected to the same rule during his investigation of the phosphorescence of potassium uranium sulfate in 1896. Later researchers advocated more complicated laws of decay, as various luminescence lines appeared with different half-lives.[3491]

In 1888, E. Wiedemann introduced the name luminescence for all "light phenomena not exclusively caused by the rise of temperature", which was already the established definition of phosphorescence.[3492]

31.6 Cathodoluminescence

31.6.1 Discovery

The cathodoluminescence was discovered during exploration of discharges in dilute gases. Sir Humphry Davy (1778-1829) reported about the green phosphorescence of glass in 1822. More detailed research was carried out in the next generation, in conjunction with E. Becquerel's measurements in solids and Stokes' measurements in solutions. In 1858 and 1859, the Englishman Gassiot, Frenchman E. Becquerel and German Plücker independently described the greenish fluorescence of glass in the cathode ray tube. In 1839 E. Becquerel studied the effect of an electric spark on fluorite on which just few electrons fell due to poor vacuum. In 1859, he used a discharged container with sealed conductors and external electrodes. He measured at the pressure of a thousandth part of bar of sulfide of calcium, silfide of bromine or platin-cyanide. He noticed that the fluorescence near the cathode is stronger than in other parts of the tube, and even the color of the fluorescence was different near the cathode and the anode compared to other parts of the tube. Like in phosphor-scope, a greenish shine of glass was also observed in his cathode ray tubes. At first, he thought that this was a subjective perception, but later wrote that blue fluorescence appeared on the lead glass, as Gassiot published independently in 1858. Plücker described the phenomenon as "magnetic light" which could be moved with a magnet. Gassiot wrote that he observed green fluorescence only in the English potassium flint glass, while blue fluorescence was observed on lead glass nicknamed crystal.[3493]

Dewar investigated the effect of heat, which aroused brief luminescence for short space of time. He mentioned Geissler, who first noticed the luminescence in exhausted vessel, where the gas remains bright for about 5 seconds after discharge. E. Becquerel and others attributed the occurrence to the residual traces of oxygen in a vacuum and the like. Geissler died on January 24, 1879, so he may have watched fluorescence in the cathode ray tube before Hittorf, though he detected it in gas and not on glass.[3494]

Hittorf described luminescence in a cathode-ray tube:[3495] "... Slightly radiant rays fly over the distance of one foot inside a tube. The side of the glass that stops them fluoresces with bright green-yellow light and loses some transparency ... If we increase the number of voltaic cells, we get along with the described green fluorescence light in the form of a wider or narrower ring around the end of the cathode." And also:[3496] "... (the spiral of pulsating discharges in the cathode ray tube) lie on the cone coat with its a peak opposite to the pole. We clearly distinguish two to three full turns (spirals).

When (rays) encounter a glass wall, they cause vigorous fluorescence ... Nice scene is shown to the eyes when we rotate (the spiral) by slowly shrinking the rheostat." Certainly, some artistic proudness was involved there almost a century before interesting physics of Manhattan bombers.

Hittorf found in his discovery the key to the secrets of luminescence:[3497] "Anyone who will satisfactorily explain the layering observed at those experiments (with discharges in cathode ray tubes) will explain the most important aspects of

phosphorescence". And additionally:[3498] "In optics, we distinguish two ways of secreting the light from the bodies: the first comes ... due to the increase in temperature in glowing. The low-temperature phosphorescence does not happen alone, but with the involvement of other sources of energy."

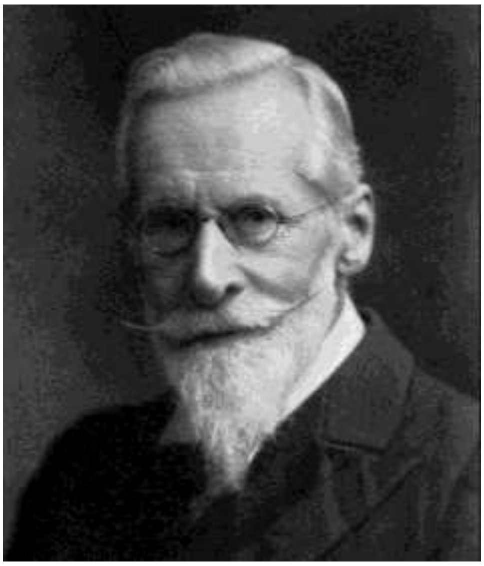

Figure 31-13: Figure: Crookes

In 1879, at the lecture at BAAS in Sheffield, Crookes described the cathode ray phosphorescence without knowing Hittorf's measurements published only five years later: "... The diamond is a ruby stone with the most prominent phosphorescence. We placed a collection of rubies in the form of pebbles in the cathode ray tube, and when the inductive current arose, rubies lighted up in a beautiful red (color) as if it were glowing." In 1881, E. Becquerel rightly demanded his own priority preceding Crookes' research of cathodoluminescence, although Becquerel himself thought he was observing the absorption of rays of light and not the cathode rays.[3499]

In the 1880s and 1890s, Crookes used "spectral camera" of his own design to study Fraunhofer's cathodoluminescence lines of "rare earths", which he mistakenly took for non-elementary. The son of a wealthy family of cognac producers from the French province bearing his own name Paul Émile Lecoq de Boisbaudran (1838-1912) supported the opposite opinion. He had his own laboratory at the age of twenty. In the ore of zinc from the Pyrenees, Lecoq discovered a gallium on August 27, 1875, which he named by the Latinized name of his French homeland as well as by the Latin translation of his surname Lecoq. Later, he learned that he was dealing with an eka-aluminium, described by Mendeleyev at a meeting of the Russian physicochemical society on 3 December 1870. Between 1879 and 1886, during the spectroscopic exploration of cathodoluminescence, Lecoq identified lines of previously unknown elements of rare earths (lanthanides): samarium, gadolinium, and dysprosium. In 1886 Lecoq and E. Becquerel published in parallel their investigations of luminescence in discharges at dilute gases.[3500]

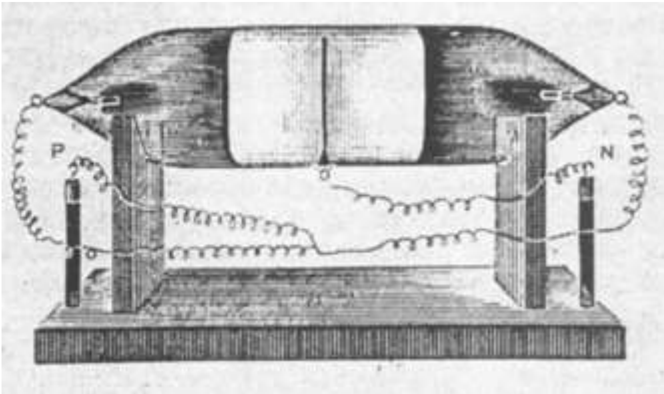

Figure 31-14: Figure: Crookes's apparatus.

The later pioneer of television research Campbell Swinton continued those researches of the rare earth's cathodoluminescence. After Röntgen's discovery, with the mediation of Lord Kelvin, Royal Society published Campbell Swinton's research of the cathode-ray tube between 1896 and 1899. On 27 February 1897, he confirmed that X-rays originated from the area of green luminescence of the cathode ray tube and he investigated the cathodoluminescence of charcoal.

Two years later the changing pressure and the type of gas in his cathode ray tube showed that in the case of cathodoluminescence of rare earth we obtain different luminescent colors than by heating with a Bunsen's burner. In some rare earths including thorium Campbell Swinton observed cathodoluminescence, but not in others like cerium, although they are equally bright when heated to the same temperature. The phenomenon is called Cando-luminescence. It used to be an important topics before the introduction of electric

[3498] Hittorf, 1884, 131.

[3500] Kayser, 1908, 693, 795.

lighting with most artificial light of those days produced by fuel combustion, but in 1950s it was more relevant to explain it with to selective thermal radiation than with the luminescence. The Cando-luminescence is not always simply due to selective thermal emission, but the mechanisms vary depending on the materials involved and method of heating.

In his later reflections on the television set, Campbell Swinton was aware of the need for a "sensitive fluorescent display."[3501] His Scottish visions certainly became true.

At the end of the century, the first approaches to modern theory were published during the exploration of cathodoluminescence. On 26 June 1894, Goldstein published measurements of the fluorescence of chloride of alkali metals evaporated on a smoothed plate 14 cm away from the cathode inside cathode ray tube. He assumed that "particles (bodies) are removed from their normal position or from their motion by strong external vibrations after irradiation... It appears that particles are transferred to a different position through phosphorescence without chemical changes. Those states are mostly rather labile, so the particles eventually return to their basic or less labile condition."[3502] Goldstein's note strongly resembles the excited states of the atom described few years later in quantum mechanics. Certainly, the designers of quantum novelties read Goldstein’s data in their student years…

31.6.2 Radioluminescence

On 28 December 1895 Röntgen described his observation of the X-ray fluorescence on the paper screen in a cathode ray tube beam coated with barium platinocyanide BaPt $(CN)_3$, which he received from Lenard. In January of the following year, many believed that Röntgen produced a new fluorescence research. On May 2, 1896, Mihajlo Pupin (1858-1935) photographed a luminescence screen in the United States on which X-ray reflected the image of an hand shot through, a welcome topic for the former wild west. This greatly reduced the exposure time required for direct photographing of X-rays. Only two months after Röntgen’s discovery, T. A. Edison has already been researching X-rays in hundred and fifty different cathode ray tubes. He examined many substances while he changed electrodes and the gases left in the vacuum to measure the permeability of various substances for the rays. Thus, he could greatly lower the price of Crookes' cathode ray tube. He tested nearly 1,300 substances to get the best luminescence for X-rays, even if he slightly exaggerated his sensational merits to amaze the publics. On 13 March 1896, he decided to use calcium tungstate (Scheelite) for his fluoroscope and five days later he published a report in the journal Electrical Engineer. He found that the X-rays do not cause fluorescence in relatively dense substances fluorescent that they used until then, but also in rarer ones like ammonium salicylate. Although he obtained good pictures and did not patent his discoveries, the physicians preferred to use more permanent photographs instead of less handy temporarily visible luminescence. Edison's reflections on the nature of X-rays were not accepted, but his experiments later enabled the fluorescent lamp.[3503]

The son of the late president of the Parisian Academy, H. Becquerel, "has come to the idea of seeing whether the characteristic of radiated rays is intimately associated with phosphorescence since the first time he learned about the discovery of the X-ray of Professor Röntgen." The idea was also adopted by other Parisian academics who reported on the research of various phosphorescent materials at their meetings. Jules Henri Poincaré (1854-1912) suggested on January 20, 1896: "Would you research if all bodies in which the fluorescence is strong enough do not emit, besides the visible light rays, also Röntgen’s X-rays, regardless of the cause of their fluorescence ... It's not very likely, but it's possible and very easy to verify". Together with H. Becquerel they wondered whether X-rays were not radiated together with ordinary luminescence. As the glass of X-ray tube showed green luminescence like crystal uranium, Poincaré advised H. Becquerel to investigate the photoluminescence of potassium

[3501] Stokes, 1888, 116-117; Wilson, 1987, 194; Campbell Swinton, On the Luminosity of the Rare Earths when heated in Vacuo by means of Cathode Rays, Proc.Roy. Soc.London 65 (27. 4. 1899) 119; Campbell Swinton, Distant Electric Vision, Nature, 18. 6. 1908, 151; Harvey, 957, 377.

[3502] Eugen Goldstein (1850-1930) from Berlin, Ueber die Einwirkung von Kathodenstrahlen auf einige Salze, Ann.Phys. 54 (1895) 372, 373, 378, 380.

[3503] Isreael, 1998, 309-310, 387; Fritz, 1940, 94; Harvey, 1957, 416-417.

uranium sulphate on 24 February 1896. Jules Henri Poincaré was a brother-in-law of conservative historian of sciences Emile Boutroux and a first cousin of even more conservative French anti-German prime minister Raymond Poincaré (1860-1934) who might have prevented Nazis' wars. Therefore, Jules Henri Poincaré's opinion was obligatory even if he rejected G. Cantor's transfinite numbers and Indic actual infinite and wasn't a great fan of logics. As early as 1872, H. Becquerel's father measured that uranium salts luminescence 0.001 s after illumination. For a dozen years, excellent preparations of uranium compounds, sealed in glass, have been waiting for a researcher at the Parisian Muséum. On 1 January 1896, H. Becquerel wrote with his real or slightly staged surprise: "Observations suggest that this unusual phenomenon cannot be attributed to the radiation of light in phosphorescence since that radiation would have to become so weak that it almost certainly couldn't be detected after 0.01 s".[3504] The discovery was called radioactivity, and for it H. Becquerel received the Nobel Prize in Physics in 1903.

On March 19, 1903, Crookes described an experiment in which the grain of radium salts was placed at the end of a metal thread at the distance of about 0.5 mm from the screen of Sidot's blende. While observing through the magnifying glass, he noticed "the real rain of bright spots that appears and disappears and give the screen the appearance of the sky with its stars." Because thin-walled obstacles prevented scintillation, he correctly concluded that they were caused by alpha rays baptized by Rutherford and Villard four years earlier. Crookes called his device a spinthariscope.[3505]
In 1910 in Rutherford's laboratory in Manchester, Marsden proved that the active centres producing scintillations had the size of the molecules and therefore do not show the lightings caused by any mechanical split of small crystals with rays α.[3506] Together with Geiger, they bombarded the zinc blende (ZnS) with alpha particles and watched tiny scintillations in the improved Crookes' device through a microscope. With unexpected scintillations of the reflected α-rays, luminescence enabled the discovery of a solid atomic nucleus, it helped the discoveries of the X-rays, radioactivity, electron and Braun's cathode ray tube between 1895 and 1897. The modern physics was based on luminescence observations, as Stokes prophetically predicted. Later, it turned out that the northern lights are also due to the radioluminescence of charged particles, which the Sun shines in the high layers of the Earth's atmosphere.

31.6.3 Cathodoluminescence in Braun's Cathode Ray Tube and Television Displays

In 1878 as a professor in Marburg Braun continued with Hittorf's studies of electrical conductivity of gases. He was also interested in X-ray luminescence. In 1897, he placed a screen of mosaic coated with a phosphorescence paint on the axis of the enlarged part of the cathode ray tube, and first observed the variable flow of "cathode rays".[3507]

Initially, they used the luminophore CaS at Braun's Physical Institute in Strasbourg. On 26 September 1899 Braun's assistant Zenneck announced that cathodoluminescence of $CaWO_4$ is easier to photograph compared to the green CaS, especially during weak discharges, when the luminescent point travels quickly across the screen. He also recommended it for use in X-ray photography, and Zworykin patented it as a blue luminophore for color television in 1925.[3508]

Codelli, as the first in Slovenian areas, described a "fluorescence display in an image-processing cathode ray tubes" in his television design with a cathode-ray tube for the US market. He assumed that the "reception of the image" can also be used to "separate spaces filled with diluted gases that fluorescent in different colors..."[3509]

Figure 31-15: Ferdinand Braun (* 1850; † 1918).

With Röntgen's discovery, the production of luminescence screens increased significantly, including $BaPt(CN)_4$ and many others. In 1931 Telefunken patented the use of a blue luminescence screen of zinc sulfide with copper or manganese admixtures, which exceeded the luminosity of tungsten compounds two to three times. In the same year, Telefunken patented a more useful blend of zinc sulfide admixed with zinc cadmium sulfide. In 1931, the willemite was also used for television screens at the labs of RCA. Since 1931, after successful Zworykin's interview, Humboldt Walter Leverenz has been working in RCA as one of the leading modern researchers in the use of crystalline luminophores in cathode ray tube. Humboldt Walter Leverenz was born in Chicago in 1909. After graduating from Stanford in 1930, he specialized his education at Münster where the expert spectroscopist enemy of Nazis Heinrich Konen's (1874 Cologne-1948) used to work earlier. In 1954 Leverenz received the Franklin's Award and became the director of the physic-chemical laboratory at RCA.[3510]

31.6.4 A Description of the First Luminophores Used for Television Displays

The smelting and extraction of impure zinc by reducing calamine with wool and other organic substances was accomplished in India in the 13th century and later in China which is the greatest modern producer of zinc. The large deposits by the Lake Titicaca were and are still used. Only in the middle of the 18th century, German researchers assumed that natural ZnS could be a luminophore. The first artificial synthesis of zinc blende (sphalerite) was described by the Frenchmen Henri Étienne Sainte-Claire Deville and Troost in 1861. Its yellow luminescence was described only by the young chemistry preparer-assistant (préparateur) at Lycée Charlemagne in Paris the Frenchman Theodor Sidot, who heated the porcelain tube with zinc oxide in the atmosphere of sulfuric acid in 1866 to attract Becquerel's attentions. The zinc sulfide with copper admixtures (ZnS: Cu) crystallized on cooled parts of the tube, which, under the name "Sidot's blende", became the basis of many important industrial luminophores, and later television displays but it did not prevent Sidot's injury in war against Bismarck's Prussians in 1870. In 1893 Nikola Tesla described strong phosphorescence of zinc sulfide with addition of few ppm of suitable activator.

In 1868 the later founder and first president of Bern photographic society Aimé Forster (1843 Beringen in Switzerland-1926 Bern) published the detailed instructions for the synthesis of many luminophores, including the blue "Balmain's luminous paint", which was established on the market as the first widely known luminescent paint in 1870. In June 1907, that same professor of astronomy and physics and director of the Physical institute Observatory in Bern Aimé Forster returned Einstein's relativity paper delivered as a proposal for Einstein's post at Bern University with the comment "I can't understand a word of what you have written there.“ He proved that the expert in luminescence need not to be an expert in relativity which might also apply to Tesla's criticism of Einstein. Balmain was former teacher at the University college of London transformed into a manufacturing chemist at Greenbank Alkali Works St. Helen in Lancashire of inventors Henry F. Ihlee & William L. Horne of London. Edward Turner's (1798-1837) Londoner

[3510] Fritz, 1940, 99, 196, 201, 203.

student William Henry Balmain (* 1817 in then British now German Helgoland North Sea island spa; † 1880 Ventnor at English isle of Wright) patented the procedure for production of his colour in England with a patent no. 4,152, dated November 7, 1877, and founded a company that began selling it at the price of 110 German marks per pound. For binding, he used pure gelatine without water. When the price was lowered to acceptable 4.5 marks, demand for luminescence increased significantly. In 1886, the French inventor of the first commercially viable process for the manufacture of synthetic gemstones Auguste Victor Louis Verneuil (1856 Dunkirk-1913) found that in Balmain's paint the essentially calcium sulfide had admixtures of metals, especially bismuth. Balmain's paint is basically the same as the older Balduin's "phosphorus hermeticus" and Canton's oyster shells[3511] therefore it connects a great ancient Chinese knowhow with modern technology.

In 1906 at City College of New York, Charles Baskeville (1870 Deerbrook, Mississippi-1922 New York) found that the manganese-doped (manganese-activated) willemite Zn_2SiO_4 is a fluorescent phosphor material with green to yellow emission. He discovered its sensitivity to X-rays and rays form radioactive sources in 1904. Instead of manganese in artificial production we now also use rare earths, for example, iridium.[3512]

31.7 Bioluminescence and Chemoluminescence
